Preface

Acknowledgments

Unit I. Introduction to Pharmacology

Introduction

1. Drug Development and Ethical Considerations

- Core Ethical Principles
- Objectives and Phases of Pharmaceutical Research
- American Nurses Association Code of Ethics
- Drug Standards and Legislation
- Nurse Practice Acts
- Canadian Drug Regulation
- Initiatives to Combat Drug Counterfeiting
- Drug Names
- Over-the-Counter Drugs
- Drug Resources
- Critical Thinking Case Study

2. Pharmacokinetics, Pharmacodynamics, and Pharmacogenetics

- Pharmacokinetics
- Pharmacodynamics
- Pharmacogenetics
- Drug Interactions
- Drug-Nutrient Interactions
- Drug-Laboratory Interactions
- Drug-Induced Photosensitivity
- Critical Thinking Case Study

3. Cultural Considerations

- Ethnomedicine
- Ethnopharmacology
- Pharmacogenetics
- Transcultural Nursing
- The Giger and Davidhizar Transcultural Assessment Model
- Critical Thinking Case Study

4. Complementary and Alternative Therapies

- Dietary Supplement Health and Education Act Of 1994
- Current Good Manufacturing Practices
- Commonly Used Herbal Remedies
- Potential Hazards of Herbs
- Tips for Consumers and Health Care Providers
- Herbal Resources
- Critical Thinking Case Study

5. Pediatric Considerations

- Pharmacokinetics
- Pharmacodynamics
- Nursing Implications
- Considerations for the Adolescent Patient
- Nursing Process: Family-Centered Collaborative Care
- Critical Thinking Case Study

6. Geriatric Considerations

- Physiologic Changes
- Pharmacokinetics
- Pharmacodynamics
- Nursing Implications: Older Adult Drug Dosing and Monitoring
- Health Teaching with the Older Adult
- Critical Thinking Case Study

7. Drugs in Substance Use Disorder

Substance Use Disorder

Special Needs of Patients with Substance Use Disorder

The Nurse with Substance Use Disorder

Critical Thinking Case Study

Unit II. Pharmacotherapy and Drug Administration

Introduction

8. The Nursing Process and Patient-Centered Care

Nursing Process: Patient-Centered Collaborative Care

Critical Thinking Case Study

9. Safety and Quality

“Five-Plus-Five” Rights of Medication Administration

Nurses’ Rights when Administering Medication

Culture of Safety

Safety Risks with Medication Administration

High-Alert Medications

Look-Alike and Sound-Alike Drug Names

Other Factors in the Prevention of Medication Errors

Resources for Preventing Errors in Medication Administration

Pregnancy Categories and Subsections

Guidelines for Medication Administration

Critical Thinking Case Study

10. Drug Administration

Self-Administration of Medication

Forms and Routes of Drug Administration

Nursing Implications for Administration of Parenteral Medications

Developmental Needs of Pediatric Patients

Technological Advances

Critical Thinking Case Study

11. Drug Calculations

Overview

Section 11A. Systems of Measurement With Conversion Factors

Section 11B. Calculation Methods—Enteral and Parenteral Drug Dosages

Section 11C. Calculating Dosages—Drugs That Require Reconstitution

Section 11D. Calculation Methods—Insulin Dosages

Section 11E. Calculation Methods—Intravenous Flow Rates

Unit III. Maintenance of Homeostasis

Introduction

12. Fluid Volume and Electrolytes

- Homeostasis
- Fluid Replacement
- Electrolytes
- Critical Thinking Case Study

13. Vitamin and Mineral Replacement

- Vitamins
- Minerals
- Critical Thinking Case Study

14. Nutritional Support

- Different Types of Nutritional Support
- Critical Thinking Case Study

Unit IV. Autonomic Nervous System Drugs

Introduction

- Sympathetic Nervous System
- Parasympathetic Nervous System

15. Adrenergic Agonists and Antagonists

- Adrenergic Agonists
- Central-Acting Alpha Agonists
- Adrenergic Antagonists (Adrenergic Blockers)
- Critical Thinking Case Study

16. Cholinergic Agonists and Antagonists

- Cholinergic Agonists
- Cholinergic Antagonists
- Critical Thinking Case Study

Unit V. Central and Peripheral Nervous System Drugs

Introduction

17. Stimulants

- Pathophysiology
- Amphetamines

Anorexiants and Analeptics
Critical Thinking Case Study

18. Depressants
Types and Stages of Sleep
Nonpharmacologic Methods
Sedative-Hypnotics
Anesthetics
Critical Thinking Case Study

19. Antiseizure Drugs
International Classification of Seizures
Antiseizure Drugs
Critical Thinking Case Study

20. Drugs for Parkinson's Disease and Alzheimer Disease
Parkinson's Disease
Alzheimer Disease
Critical Thinking Case Study

21. Drugs for Neuromuscular Disorders and Muscle Spasms
Myasthenia Gravis
Multiple Sclerosis
Skeletal Muscle Relaxants
Critical Thinking Case Study

Unit VI. Mental and Behavioral Health Drugs

Introduction

22. Antipsychotics and Anxiolytics
Psychosis
Antipsychotic Agents
Anxiolytics
Critical Thinking Case Study

23. Antidepressants and Mood Stabilizers
Depression
Antidepressant Agents
Mood Stabilizers
Critical Thinking Case Study

Unit VII. Pain and Inflammation Management Drugs

Introduction

24. Antiinflammatories

Pathophysiology

Antiinflammatory Agents

Nonsteroidal Antiinflammatory Drugs

Corticosteroids

Disease-Modifying Antirheumatic Drugs

Antigout Drugs

Critical Thinking Case Study

25. Analgesics

Pathophysiology

Nonopioid Analgesics

Opioid Analgesics

Adjuvant Therapy

Treatment for Opioid-Addicted Individuals

Opioid Agonist-Antagonists

Opioid Antagonists

Headaches: Migraine and Cluster

Critical Thinking Case Study

Unit VIII. Antimicrobial Drugs

Introduction

26. Antibacterials

Pathophysiology

Antibacterial Drugs

Section 26A. Penicillins and Cephalosporins

Section 26B. Macrolides, Oxazolidinones, Lincosamides, Glycopeptides, Ketolides, Tetracyclines, and Glycylcyclines

Section 26C. Aminoglycosides, Fluoroquinolones, and Lipopeptides

Section 26D. Sulfonamides and Nitroimidazoles

27. Antituberculars, Antifungals, and Antivirals

Tuberculosis

Antitubercular Drugs

Special Populations

Fungus

Antifungal Drugs

Viruses

Non-HIV Antivirals

Critical Thinking Case Study

28. Antimalarials, Anthelmintics, and Peptides

Antimalarial Drugs

Anthelmintic Drugs

Peptides

Critical Thinking Case Study

Unit IX. Immunologic Drugs

Introduction

Immune System Structure

Immune System Function

29. HIV- and AIDS-Related Drugs

HIV Infection: Pathophysiology

HIV Life Cycle

HIV Transmission

Laboratory Testing

Classification

Indications for Antiretroviral Therapy

Antiretroviral Drugs

Immune Reconstitution Inflammatory Syndrome

The Nurse's Role in Antiretroviral Therapy

Opportunistic Infections

Antiretroviral Therapy in Pregnancy

Occupational HIV Exposure and Postexposure Prophylaxis

Critical Thinking Case Study

30. Transplant Drugs

Organ Transplantation

Promoting Adherence

Critical Thinking Case Study

31. Vaccines

Immunity

Vaccines

Vaccine-Preventable Diseases

Vaccination Recommendations

Immunization Before International Travel

Vaccine Safety: Reporting Diseases and Adverse Reactions

Varicella Vaccine

Future Developments in Vaccines

Critical Thinking Case Study

Unit X. Antineoplastics and Biologic Response Modifiers

Introduction

- The Cell Cycle
- Growth Rate
- Anticancer Therapy

32. Anticancer Drugs

- Genetic, Inflammatory, Infective, Environmental, and Dietary Influences
- Cell Cycle–Nonspecific and Cell Cycle–Specific Anticancer Drugs
- Cancer Chemotherapy
- Alkylating Drugs
- Antimetabolites
- Antitumor Antibiotics
- Plant Alkaloids
- Immunomodulators
- Targeted Therapies
- Liposomal Chemotherapy
- Hormones and Hormonal Agonists and Antagonists
- Biologic Response Modifiers
- Miscellaneous Chemotherapy Agents
- Critical Thinking Case Study

33. Targeted Therapies to Treat Cancer

- Pathophysiology
- Targeted Therapy Drugs
- Critical Thinking Case Study

34. Biologic Response Modifiers

- Interferons
- Colony-Stimulating Factors
- Interleukin 2
- Critical Thinking Case Study

Unit XI. Respiratory Drugs

Introduction

- Lung Compliance
- Control of Respiration
- Bronchial Smooth Muscle

35. Upper Respiratory Disorders

Common Cold, Acute Rhinitis, and Allergic Rhinitis
Sinusitis
Acute Pharyngitis
Critical Thinking Case Study

36. Lower Respiratory Disorders
Chronic Obstructive Pulmonary Disease
Sympathomimetics: Alpha- and Beta$_2$-Adrenergic Agonists
Anticholinergics
Methylxanthine (Xanthine) Derivatives
Leukotriene Receptor Antagonists and Synthesis Inhibitors
Glucocorticoids (Steroids)
Cromolyn
Drug Therapy for Asthma According to Severity
Drug Therapy for Asthma According to Age
Mucolytics
Antimicrobials
Critical Thinking Case Study

Unit XII. Cardiovascular Drugs

Introduction
Heart
Conduction of Electrical Impulses
Circulation
Blood

37. Cardiac Glycosides, Antianginals, and Antidysrhythmics
Cardiac Glycosides
Other Agents Used to Treat Heart Failure
Antianginal Drugs
Antidysrhythmic Drugs
Critical Thinking Case Study

38. Diuretics
Thiazides and Thiazide-Like Diuretics
Loop (High-Ceiling) Diuretics
Osmotic Diuretics
Carbonic Anhydrase Inhibitors
Potassium-Sparing Diuretics
Critical Thinking Case Study

39. Antihypertensives

Hypertension
Nonpharmacologic Control of Hypertension
Guidelines for Hypertension
Pharmacologic Control of Hypertension
Critical Thinking Case Study

40. Anticoagulants, Antiplatelets, and Thrombolytics
Pathophysiology: Thrombus Formation
Anticoagulants
Antiplatelet Drugs
Thrombolytics
Critical Thinking Case Study

41. Antihyperlipidemics and Drugs to Improve Peripheral Blood Flow
Lipoproteins
Apolipoproteins
Nonpharmacologic Methods of Cholesterol Reduction
Antihyperlipidemics
Drugs to Improve Peripheral Blood Flow
Critical Thinking Case Study

Unit XIII. Gastrointestinal Drugs

Introduction
Oral Cavity
Esophagus
Stomach
Small Intestine
Large Intestine
Drugs for Gastrointestinal Disorders

42. Gastrointestinal Tract Disorders
Vomiting
Emetics
Diarrhea
Constipation
Critical Thinking Case Study

43. Antiulcer Drugs
Predisposing Factors in Peptic Ulcer Disease
Nonpharmacologic Measures for Managing Peptic Ulcer and Gastroesophageal Reflux Disease
Antiulcer Drugs
Critical Thinking Case Study

Unit XIV. Eye, Ear, and Skin Drugs

Introduction

- Overview of the Eye
- Overview of the Ear
- Overview of the Skin

44. Eye and Ear Disorders

- Drugs for Disorders of the Eye
- Drugs for Disorders of the Ear
- Critical Thinking Case Study

45. Dermatologic Disorders

- Acne Vulgaris
- Psoriasis
- Verruca Vulgaris (Warts)
- Drug-Induced Dermatitis
- Contact Dermatitis
- Impetigo
- Hair Loss and Baldness
- Sunscreens
- Burns and Burn Preparations
- Critical Thinking Case Study

Unit XV. Endocrine Drugs

Introduction

- Pituitary Gland
- Anterior Pituitary Gland
- Thyroid-Stimulating Hormone
- Adrenocorticotropic Hormone
- Gonadotropic Hormones
- Growth Hormone
- Posterior Pituitary Gland
- Thyroid Gland
- Parathyroid Glands
- Adrenal Glands
- Pancreas
- Drugs For Endocrine Disorders

46. Pituitary, Thyroid, Parathyroid, and Adrenal Disorders

- Pituitary Gland

Thyroid Gland
Parathyroid Glands
Adrenal Glands
Critical Thinking Case Study

47. Antidiabetics
Diabetes Mellitus
Critical Thinking Case Study

Unit XVI. Renal and Urologic Drugs

Introduction

48. Urinary Disorders
Urinary Antiseptics/Antiinfectives and Antibiotics
Urinary Analgesics
Urinary Stimulants
Urinary Antispasmodics/Antimuscarinics/Anticholinergics
Critical Thinking Case Study

Unit XVII. Reproductive and Gender-Related Drugs

Introduction
Female Reproductive Processes
Male Reproductive Processes
Process of Fertilization

49. Pregnancy and Preterm Labor
Physiology of Pregnancy
Therapeutic Drugs and Use of Herbs in Pregnancy
Drugs That Decrease Uterine Muscle Contractility
Corticosteroid Therapy in Preterm Labor
Drugs for Gestational Hypertension
Critical Thinking Case Study

50. Labor, Delivery, and Postpartum
Drugs for Pain Control During Labor
Drugs that Enhance Uterine Muscle Contractility
Drugs Used During the Postpartum Period
Immunizations
Critical Thinking Case Study

51. Neonatal and Newborn

Drug Administered to Preterm Neonates
Drugs Administered to Full-Term, Healthy Neonates
Critical Thinking Case Study

52. Women's Reproductive Health
Combined Hormonal Contraceptives
Progestin Contraceptives
Other Methods of Contraception
Medical Abortion
Drugs Used to Treat Disorders in Women's Health
Drugs Used to Promote Fertility
Menopause
Critical Thinking Case Study

53. Men's Health and Reproductive Disorders
Drugs Related to Male Reproductive Disorders
Critical Thinking Case Study

54. Sexually Transmitted Infections
Sexually Transmitted Infections
Sexually Transmitted Pathogens
Critical Thinking Case Study

Unit XVIII. Emergency Drugs

Introduction

55. Adult and Pediatric Emergency Drugs
Oxygen as an Emergency Drug
Emergency Drugs for Cardiac Disorders
Emergency Drug for Intracranial Hypertension
Emergency Drugs for Poisoning
Emergency Drugs for Shock
Emergency Drugs for Hypertensive Crises and Pulmonary Edema
Critical Thinking Case Study

Appendix A. NANDA-I Definitions

Appendix B. Solution Compatibility Chart

Appendix C. Immunizations

Appendix D. Herb-Drug Interactions

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

Dedication

To Dr. Gerald DeLuca for his expert guidance; to Joyce LeFever Kee, who originated this book; to Evelyn R. Hayes for her efforts; and in memory of my parents, Otto and Pauline Schmidt.

Linda E. McCuistion

To Dr. Linda McCuistion, for her friendship and guidance, and to my daughters, Christina Boudreaux, Maria DiMaggio, and Katie Leboutillier for their constant love and encouragement.

Kathleen Vuljoin-DiMaggio

To my Lord and Savior for the gift of nursing and teaching, to Dr. Richard A. Winton for his love and support for many years, and in loving memory of my parents, Matthew and Mary Wagner.

Mary B. Winton

To Tracy L. Yeager, my husband, my rock, and support; and to my boys, Jacob and Joshua, for just being boys.

Jennifer J. Yeager

Meet the Authors

Linda E. McCuistion

Dr. Linda E. McCuistion received a Diploma of Nursing from the Lutheran Hospital School of

Nursing in Fort Wayne, Indiana; Bachelor of Science in Nursing from William Carey College in Hattiesburg, Mississippi; Masters in Nursing from Louisiana State University Medical Center, New Orleans; and PhD in Curriculum and Instruction from the University of New Orleans. She was licensed as an Advanced Practice Nurse in Louisiana and has many years of nursing experience that include acute care and home health nursing. For 20 years, Linda was a Nursing Professor at Our Lady of Holy Cross College in New Orleans, Louisiana. She received an Endowed Professorship Award in 2000 and 2003. Linda worked as a nursing professor at South University, Richmond, Virginia, for 3 years. Currently, Linda teaches NCLEX® review courses for Elsevier.

Linda has served as a past president, vice president, and faculty advisor of the Sigma Theta Tau International Honor Society in Nursing, Xi Psi chapter-at-large. She is a past associate editor of the *NODNA Times,* a New Orleans District Nurses Association newsletter. She has been a member of Phi Delta Kappa and the American Society of Hypertension.

Linda was coordinator for the Graduate Plus internship program, a preceptorship program for new nursing graduates in the state of Louisiana. She has served as a legal nurse consultant; a member of a medical review panel; advisory board member, consultant, and reviewer of a software preparation company focused on the state licensure examination; advisory board member for a school for surgical technicians; and consultant to a local hospital to improve the quality of nursing care and assist acute care facilities in preparation for accreditation.

Linda was chosen as a "Great One-Hundred Nurse" by the New Orleans District Nurses Association in 1993. She is also listed in the 2005/2006 edition of the Empire Who's Who Executive and Professional Registry.

Linda has given numerous lectures and presentations regionally and nationally on a variety of nursing topics. She has published articles in nursing journals and has authored many chapters in several nursing textbooks, including *Pharmacotherapeutics: Clinical Decision Making in Nursing* (1999), *Saunders Manual of Medical-Surgical Nursing: A Guide for Clinical Decision Making* (2002), and *Saunders Nursing Survival Guide: Pathophysiology* (2007). She is author and coauthor of many chapters and coeditor of *Saunders Nursing Survival Guide: Pharmacology* (2007).

Linda enjoys cruises and other travel. When at home, she enjoys family, friends, golf, crafts, playing bridge, and writing.

Kathleen Vuljoin-DiMaggio

Kathleen Vuljoin-DiMaggio received her Bachelor of Science in Nursing from Our Lady of Holy Cross College of New Orleans and her Master of Science in Nursing from Loyola University of New Orleans, with a focus on Healthcare Systems Management. She completed a preceptorship in palliative care at Ochsner Foundation Hospital through Loyola University. She received Level I designation from the National Hospice and Palliative Care Organization in hospice management and development. She is certified with the Louisiana Department of Health and Hospitals Developmental Disabilities as a Registered Nurse Instructor in medication administration. Kathleen has over 20 years of clinical nursing experience and over 9 years of baccalaureate nursing education. Her professional practice experience includes medical-surgical nursing, neurologic nursing, and home health and hospice nursing. She has experience in nursing management and has worked as director of nursing for a facility specializing in developmental disabilities. In addition, Kathleen has worked as director of nursing in home health and hospice care. She has worked in quality improvement, disease management, and case management.

Kathleen teaches medical-surgical nursing at both junior and senior levels. She teaches in Perspectives of Nursing, a senior launching course, and serves as coordinator of Professional Dimensions of Nursing. She is an academic nursing advisor and serves on the Curriculum Committee, Administrative Council Committee, and Diversity Committee.

Kathleen has served as a volunteer for Junior Achievement of New Orleans, has volunteered for a local hospice agency, and has served in the homeless ministry through her church.

Kathleen is a member of the American Nurses Association, Louisiana State Nurses Association, and Sigma Theta Tau International Honor Society of Nursing, and she is a member of the Alpha Sigma Nu Jesuit Honor Society.

Kathleen is a recipient of the 2011 and 2015 Endowed Professorship from Eminent Eye, Ear, Nose and Throat Hospital. She has received the Order of St. Louis Award through the Archdiocese of New Orleans and has also received the Florence Nightingale Society Award for Nursing.

Kathleen enjoys time with her friends, daughters, and grandchildren. She enjoys golfing, quilting, and cooking.

Dr. Mary B. Winton received her Associate Degree in Nursing from Tarleton State University in Stephenville, Texas, a member of the Texas A&M University System; her Bachelor and Master of Science in Nursing from the University of Texas at Arlington; and her PhD in Nursing from the University of Texas at Tyler. Additionally, she is board certified through the American Nurses Credentialing Center as an Acute Care Adult Nurse Practitioner. Mary has many years of hospital nursing experience that include critical care and nursing supervisor. Additionally, she was employed with a hospitalist group as an Acute Care Nurse Practitioner for many years. She is currently an Assistant Professor in the College of Health Sciences and Human Services, Department of Nursing, at Tarleton State University. Mary has experience in teaching graduate-level pharmacology and pathophysiology and nursing informatics and has vast experience teaching at all levels of the undergraduate nursing program, including nursing pathophysiology and pharmacology.

Mary has served as faculty advisor for the Student Nurses Association at Tarleton. She is a member of several organizations, including Sigma Theta Tau International Honor Society in Nursing, Tau Chi chapter; American Nurses Association/Texas Nurses Association; and Rural Nurse Organization. She is actively involved in various university, college, and departmental committees.

During her career as a nurse educator, Mary was the recipient of the Texas A&M Student Evaluation Teaching Excellence Award and the O.A. Grant Excellence in Teaching Award. She is involved in teaching English as a Second Language at her church of membership.

Mary's research interests include health disparity among minorities, especially among Korean immigrants; student learning outcomes; and the use of technology in classrooms. She has presented at several conferences and has published on the health care of Korean immigrants.

During her spare time, Mary enjoys spending time with her husband, daughters, and grandchildren. She also enjoys traveling, reading, crocheting, and snow skiing.

Jennifer J. Yeager

Dr. Jennifer J. Yeager graduated from the University of Portland, Oregon, in 1987 with her Bachelor of Science in Nursing degree; she attended the university on an Air Force ROTC nursing scholarship. Following graduation, she began her nursing career as an Air Force officer, assigned to Wilford Hall USAF Medical Center in San Antonio, Texas. The Air Force provided Jennifer with excellent experience as a transplant/nephrology nurse, and after 6 years of active duty she entered the civilian world as a transplant coordinator at Methodist Medical Center in Dallas, Texas. While there, Jennifer began her Master of Science in Nursing degree at the University of Texas at Arlington, and she completed her degree as an Adult/Gerontological Nurse Practitioner with

Educator Role in 1998. After completing ANCC certification in both specialty areas, she went to work in the Baylor Health Care System as a nurse practitioner in Long-term Care and Elder House Calls.

Jennifer moved to Stephenville, Texas, in 2007 and began teaching at Tarleton State University, where she is now Director of the Graduate Nursing Program and RN-BSN Liaison. Since then, she has taught nursing care of the older adult, pharmacology, and research to undergraduate students and RN-BSN students as well as teaching nursing theory, informatics, teaching methods and strategies, pharmacology, and assessment at the master's level. She completed her PhD in Nursing at the University of Texas at Tyler in fall 2013. The findings from her dissertation research were presented at the National Gerontological Nursing Association's annual convention in San Antonio, Texas, in 2014. Currently, she is project director on a research grant funded through the Texas Higher Education Coordinating Board, Nursing Innovation Grant Program, titled "Enhancing Simulation Realism and Building Lab and Simulation Capacity in a Rural BSN Program." Along with a coworker, Jennifer presented the findings from a previous simulation grant at the International Meeting on Simulation in Health Care in San Diego, California, in 2016.

Jennifer currently serves as President of the Tau Chi chapter of Sigma Theta Tau International and as Book Salon Chair for the Society for Simulation in Health Care. She has been involved with revising and reviewing Lehne's *Pharmacology for Nursing Care,* including online components and the study guide, since 2007. She revised chapters for the fifth edition of Meiner's *Gerontologic Nursing.*

To relax, Jennifer enjoys spending time with her family, including multiple dogs. She is a strong advocate for dog rescue organizations and is a member of Pets Are Worth Saving in Stephenville, Texas. Additionally, she enjoys reading, food, and watching television.

In Recognition

Joyce LeFever Kee taught a pharmacology course to student nurses for 10 years from 1980 to 1990 at the University of Delaware. At the time, there were very few pharmacology texts available and what was published was not appropriate for some BSN and ADN nursing programs. Daniel Ruth from W.B. Saunders approached Kee in 1990 to write a pharmacology book for nurses. With experience in teaching the subject, Kee developed the contents and format for a pharmacology text.

The chapter, Drug Action: Pharmaceutic, Pharmacokinetics, and Pharmacodynamics phases, became the first chapter. These drug phases appear both in the Prototype Drug Charts and within the contents in most of the current chapters. There are many drug tables Kee developed which have been updated by co-authors through the years. The important part that Kee established in the chapters were the five steps of the Nursing Process.

Dr. Evelyn R. Hayes joined Kee starting with the first edition. Hayes developed certain chapters and took the responsibility to work with contributors for the book such as the six chapters on Reproductive and Gender-Related Agents among others.

Linda McCuistion joined Kee and Hayes in 2005. McCuistion has updated many of Kee's chapters with new drugs and content.

Contributors

Christina DiMaggio Boudreaux, RN, BSN, IBCLC, Director of Nursing, Elba Medical Distributors, Metairie, Louisiana

Wanda Wagner, MSN, CNS, RN, Assistant Professor, School of Nursing, University of Holy Cross, New Orleans, Louisiana

Preface

The ninth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* is written for nursing students who can benefit from presentation of the principles of pharmacology in a straightforward, student-friendly manner. It focuses on need-to-know content and helps students learn to administer drugs safely and eliminate medication errors through extensive practice of dosage calculations and evidence-based application of the nursing process.

Organization

Pharmacology: A Patient-Centered Nursing Process Approach is organized into 18 units and 55 chapters. **Unit I** is an introduction to pharmacology and includes thoroughly updated chapters on drug action, the drug approval process, cultural and pharmacogenetic considerations, drug interactions, over-the-counter drugs, drugs for substance use disorder, complementary and alternative therapies, lifespan issues, patient collaboration in community settings, and the role of the nurse in drug research.

Unit II focuses on patient care and safety, with completely revised and updated chapters on the nursing process in patient-centered pharmacotherapy, safety and quality in pharmacotherapy, and medication administration. **Unit II** features an introduction to the Quality and Safety Education for Nurses (QSEN) initiative, with special emphasis on patient-centered care and on the QSEN competencies of safety and quality. **Unit II** also features a comprehensive review of drug dosage calculations for adults and children and is a unique strength of this book. This unit, tabbed for quick reference, consists of five sections: Systems of Measurement with Conversion Factors, Calculation Methods: Enteral and Parenteral Drug Dosages, Calculation Methods: Drugs That Require Reconstitution, Calculation Methods: Insulin Dosages, and Calculation Methods: Intravenous Flow Rates. Five methods of dosage calculation are presented, with color coding for easy identification: basic formula, ratio and proportion/fractional equation, dimensional analysis, body weight, and body surface area. Integral to the sections on dosage calculations are clinical practice problems that feature actual drug labels in full color, which provides extensive practice in real-world dosage calculations. With this wide array of practice problems in a variety of health care settings, this unit eliminates the need to purchase a separate dosage calculations book.

Unit III addresses nutrition, fluids, and electrolytes with separate chapters that cover vitamin and mineral replacement, fluid and electrolyte replacement, and nutritional support.

Units IV through XVIII make up the core of *Pharmacology: A Patient-Centered Nursing Process Approach* and covers the drug classifications that students must understand to practice effectively. Each drug family chapter includes a chapter outline, learning objectives, key terms, at least one prototype drug chart, a drug table, and an extensive nursing process section.

- The **prototype drug charts** are a unique tool that students can use to view the many facets of a prototype drug through the lens of the nursing process. Each prototype drug is one of the common drugs in its drug class. The charts include drug class, contraindications, dosage, drug-lab-food interactions, pharmacokinetics, pharmacodynamics, therapeutic effects/uses, side effects, and adverse reactions. With these charts, students can see how the steps of the nursing process correlate with these key aspects of drug information and therapy.
- The **drug tables** provide a quick reference to routes, dosages, uses, and key considerations for the most commonly prescribed medications for a given class. They list the drug's generic names, dosages, uses and considerations, pregnancy categories, and specific information on half-life and protein binding.
- The **nursing process sections** provide a convenient summary of patient assessments, potential nursing diagnoses, plan of care, and outcomes. These sections also include cultural content, nursing interventions, suggestions for patient teaching, and relevant herbal information.

Additional Features

Throughout this edition, we have retained, enhanced, and added a variety of features that teach students the fundamental principles of pharmacology and the role of the nurse in drug therapy:

- **NCLEX study questions** at the end of each chapter help prepare students for the NCLEX examination with its increasing emphasis on pharmacology; answers are listed upside down below the questions for quick feedback.
- **Patient safety boxes** include information on medication safety, complementary and alternative therapies, and more.
- **Key terms** include page numbers and are defined in the text to enhance this "built-in glossary" feature for students.
- **Critical thinking case studies** conclude most chapters. These clinical scenarios are followed by a series of questions that challenge students to carefully consider the scenario and apply their knowledge and analytical skills to respond to the situations.
- **Complementary and alternative therapies** appear throughout the text to provide students with a quick reference to information on popular herbs and their side effects, drug interactions, and more.
- **Anatomy and physiology** unit openers for all drug therapy chapters include illustrated overviews of normal anatomy and physiology. These introductions give students the foundation for understanding how drugs work in various body systems.
- **High-alert drugs** (denoted with the symbol) and **safety concerns** (denoted with the symbol) are identified within the text with distinctive icons that make it easy to find crucial information.

Teaching and Learning Resources

The ninth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* is the core of a complete teaching and learning package for nursing pharmacology. Additional components of this package include resources for students, resources for faculty members, and resources for both students and faculty.

For Students

A comprehensive *Study Guide,* available for purchase separately, provides thousands of study questions and answers, including clinically based situational practice problems, drug calculation problems and questions (many with actual drug labels), and case studies to help students master textbook content. Answers are provided at the end of the *Study Guide*.

A completely updated Evolve website (http://evolve.elsevier.com/McCuistion/pharmacology) provides additional resources for students, including the following:

- **Review questions for the NCLEX® Examination** organized by chapter
- **Downloadable key points** for content review on the go
- **Pharmacology animations** and **videos**
- **Unfolding case studies** with review questions

For Faculty Members

The updated faculty Evolve website (http://evolve.elsevier.com/McCuistion/pharmacology) includes all of the student resources mentioned previously plus the following instructor-only resources:

- ***TEACH for Nurses* lesson plans** focus on the most important content from each chapter and provide innovative strategies for student engagement and learning. The lesson plans include strategies for integrating nursing curriculum standards (QSEN, concept-based learning, and BSN essentials), links to all relevant student and instructor resources, and an original instructor-only case study in each chapter.
- **ExamView Test Bank** features more than 1000 NCLEX® Examination–format questions that include alternate-item questions as well as rationales and page references for each question.
- **PowerPoint Collection** features customizable slides with images, integrated audience response system questions, and new unfolding case studies with questions.

• **Image Collection** provides approximately 125 full-color images from the book.

This textbook may be supplemented with the drug content found on government agency websites, which supply the latest information regarding changes to drug brand names.

It is our hope that *Pharmacology: A Patient-Centered Nursing Process Approach* and its comprehensive ancillary package will serve as a dynamic resource for teaching students the basic principles of pharmacology and their vital role in drug therapy.

Acknowledgments

We wish to extend our sincere appreciation to the many professionals who assisted in the preparation of the ninth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* by reviewing chapters and offering suggestions.

We wish to especially thank Joyce LeFever Kee, who originated this pharmacology textbook, and her coauthor Evelyn R. Hayes, who worked tirelessly on many editions of this book.

We wish to thank the current contributors: Christina DiMaggio Boudreaux, Bettyrae Jordan, Linda Laskowski-Jones, Suzanne Riche, and Jared Robertson.

We wish to thank those who created and updated the previous established chapters: Margaret Barton-Burke, Joseph Boullata, Jacqueline Rosenjack Burchum, Katherine L. Byar, Michelle M. Byrne, Karen Carmody, Robin Webb Corbett, Sandy Elliott, Linda Goodwin, Janice Heinssen, Marilyn Herbert-Ashton, Judith W. Herrman, Kathleen J. Jones, Bettyrae Jordan, Robert J. Kizior, Paula R. Klemm, Anne E. Lara, Linda Laskowski-Jones, Ronald J. LeFever, Patricia S. Lincoln, Patricia O'Brien, Laura K. Williford Owens, Byron Peters, Lisa Ann Plowfield, Larry D. Purnell, Nancy C. Sharts-Hopko, Jane Purnell Taylor, Donald L. Taylor, Lynette M. Wachholz, Marcia Welsh, Gail Wilkes, and M. Linda Workman.

Of course, we are deeply indebted to the many patients and students we have had throughout our many years of professional nursing practice. From them we have learned many fine points about the role of therapeutic pharmacology in nursing practice.

Our deepest appreciation goes to pharmaceutical companies for use of their drug labels. Pharmaceutical companies that extended their courtesy to this book include the following:

- Abbott Laboratories
- AstraZeneca Pharmaceuticals
- Aventis
- Bayer Corporation
- Bristol-Myers Squibb (including Apothecon Laboratories and Mead Johnson Pharmaceuticals)
- DuPont/Merck Pharmaceuticals
- Eli Lilly and Company
- Elkins-Sinn, Inc.
- Glaxo-Wellcome
- Marion Merrell Dow, Inc.
- McNeill Laboratory, Inc.
- Merck and Co., Inc.
- Parke-Davis Co.
- Pfizer Inc.
- Rhone-Poulenc Rorer
- SmithKline Beecham Pharmaceutical
- Wyeth-Ayerst Laboratories

Thanks to Becton, Dickinson and Company for the syringe displays. Thanks to CareFusion Corporation for the photos of the infusion pumps.

Our sincere thanks to Elsevier, especially Jamie Blum and Sonya Seigafuse, Content Strategists; Tina Kaemmerer, Senior Content Development Specialist; Tracey Schriefer, Senior Project Manager–Book Production; and Charlene Ketchum, Freelance Content Development Specialist, for their suggestions and assistance.

UNIT I
Introduction to Pharmacology

OUTLINE

Introduction
1. Drug Development and Ethical Considerations
2. Pharmacokinetics, Pharmacodynamics, and Pharmacogenetics
3. Cultural Considerations
4. Complementary and Alternative Therapies
5. Pediatric Considerations
6. Geriatric Considerations
7. Drugs in Substance Use Disorder

Introduction

When administering drug therapy, it is important that nurses have an understanding of the drug development process and their responsibilities related to drug development and ethical research practices. These topics are discussed in Chapter 1, Drug Development and Ethical Considerations.

Assessing a patient's response to drug therapy is an ongoing nursing responsibility. To adequately assess, plan, intervene, and evaluate drug effects, the nurse must have knowledge of the pharmacokinetic and pharmacodynamic phases of drug action as well as current advances in pharmacogenetics, which are described in Chapter 2, Pharmacokinetics, Pharmacodynamics, and Pharmacogenetics.

Chapter 3, Cultural Considerations, helps the nurse understand and respond to unique cultural factors that may influence adherence to drug therapy for a particular patient. Factors such as heritage, communication styles, family organization, spirituality and religion, health beliefs and practices, and traditional medicine are discussed.

Chapter 4, Complementary and Alternative Therapies, explores herbal supplements that are available over the counter. It covers the most commonly used herbs and discusses their indications, potential hazards, and tips for safe and effective use.

Chapter 5, Pediatric Considerations, and Chapter 6, Geriatric Considerations, cover pharmacokinetic and pharmacodynamic effects specific to these age groups. They also discuss the special attention required when administering drugs to these age groups.

Whereas most drugs are used safely and within prescribed guidelines, it is possible for all drugs to be misused. Drugs that are misused cause serious and complex social and health issues with negative consequences for both the individual and society. This is the topic of Chapter 7, Drugs in Substance Use Disorder.

Drug Development and Ethical Considerations

OUTLINE

Core Ethical Principles
- Respect for Persons
- Beneficence
- Justice

Objectives and Phases of Pharmaceutical Research
- Preclinical Trials
- Human Clinical Experimentation
- Clinical Research Study Design

American Nurses Association Code of Ethics
- The Nurse's Role in Clinical Research
- Nursing Process: Patient-Centered Collaborative Care—Clinical Research

Drug Standards and Legislation
- Drug Standards
- Federal Legislation

Nurse Practice Acts
Canadian Drug Regulation
Initiatives to Combat Drug Counterfeiting
Drug Names
Over-the-Counter Drugs
Drug Resources
Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Identify the three core ethical principles.
- Relate the core ethical principles that govern informed consent and risk-benefit ratio.
- Discuss the 2015 American Nurses Association Code of Ethics and its nine provisions.
- Describe the objectives of each phase of human clinical experimentation.
- Discuss federal legislation acts related to U.S. Food and Drug Administration drug approvals.
- Explain the Canadian schedules for drugs sold in Canada.
- Describe the function of state nurse practice acts.
- Differentiate between chemical, generic, and brand names of drugs.
- Define "over the counter" as it relates to drugs.
- Identify three useful drug reference resources.

Approval of new drugs by the **U.S. Food and Drug Administration (FDA)** has been steady since the early 2000s, reaching an all-time high in 2014 with the approval of 44 new drugs. To facilitate this increase, in 2004 the FDA established its **Critical Path Initiative**, a national strategy "to drive innovation in the scientific processes through which medical products are developed, evaluated, and manufactured." One focus of this initiative is on "improving the prevention, diagnosis, and treatment of rare and neglected disorders." Initiative successes include developing biomarkers and other scientific tools, streamlining clinical trials, and ensuring product safety.

The process of drug discovery and manufacturing takes 10 to 12 years, with a cost of more than $1 billion for each drug. Out of every 5000 to 10,000 compounds that begin preclinical testing, only one makes it through the FDA approval process. The steps of the process are shown in Fig. 1.1. Drug research and development is a complex process that is of particular interest and importance to professional nursing practice.

This chapter is devoted to a description of basic ethical principles that govern drug development and the nurse's role in this process.

Core Ethical Principles

Three core ethical principles are relevant to research involving human subjects: **respect for persons**, beneficence, and justice. Derived from the Belmont Report, the World Medical Association Declaration of Helsinki set out ethical principles for medical research that involves human subjects. These ethical principles are integral to the issues of informed consent and risk-benefit ratio in such research.

Respect for Persons

Patients should be treated as independent persons who are capable of making decisions in their own best interests. Patients with diminished decision-making capacity are entitled to protection. When making health care decisions, patients should be made aware of alternatives available to them as well as the consequences that stem from those alternatives. The patient's choice should be honored whenever possible. It is imperative that nurses recognize when patients are not capable of making decisions in their own best interest and are therefore entitled to protection. The nurse can assist with the determination of decision-making capacity through frequent assessment of the patient's cognitive status.

Autonomy is an integral component of respect for persons. **Autonomy** is the right to self-determination. In health care settings, health care personnel must respect the patient's right to make decisions in their own best interest, even if the decision is not what the health care personnel want or think is best for the patient. Generally, patients can refuse any and all treatments (right of autonomy) except when the decision poses a threat to others—such as with tuberculosis, when taking medications is legally mandated. Autonomy is as relevant to the conduct of research as it is in health care decision making; Patients have the right to refuse to participate in a research study and may withdraw from studies at any time without penalty.

Informed Consent

Informed consent has its roots in the 1947 Nuremberg Code. The two most relevant aspects of the Code are the right to be informed and that participation is voluntary, without coercion. If coercion is suspected, the nurse is obligated to report this suspicion promptly. Informed consent has dimensions beyond protection of the individual patient's choice:

- It is a mutual sharing of information, a process of communication.
- It expresses respect for the person.
- It gains the patient's active involvement in their care.
- It respects the patient's right to self-determination.

It is the role of the health care provider, *not* the nurse, to explain the study and what is expected of the patient to the patient and to respond to questions from the patient. While giving written consent, the patient must be alert and able to comprehend; consent forms should be written at or below the eighth-grade reading level, and words should be kept to fewer than three syllables.

Nurses are patient advocates. In collaboration with the health care provider and the pharmacist, the nurse must be knowledgeable about all aspects of a drug study—including all inclusion and exclusion criteria for participants (Box 1.1), study protocol, and study-related documentation—in order to promote participant safety and quality study results.

Fig. 1.2 shows a sample of an informed consent form for a clinical drug trial, and Box 1.2 shows an informed consent checklist.

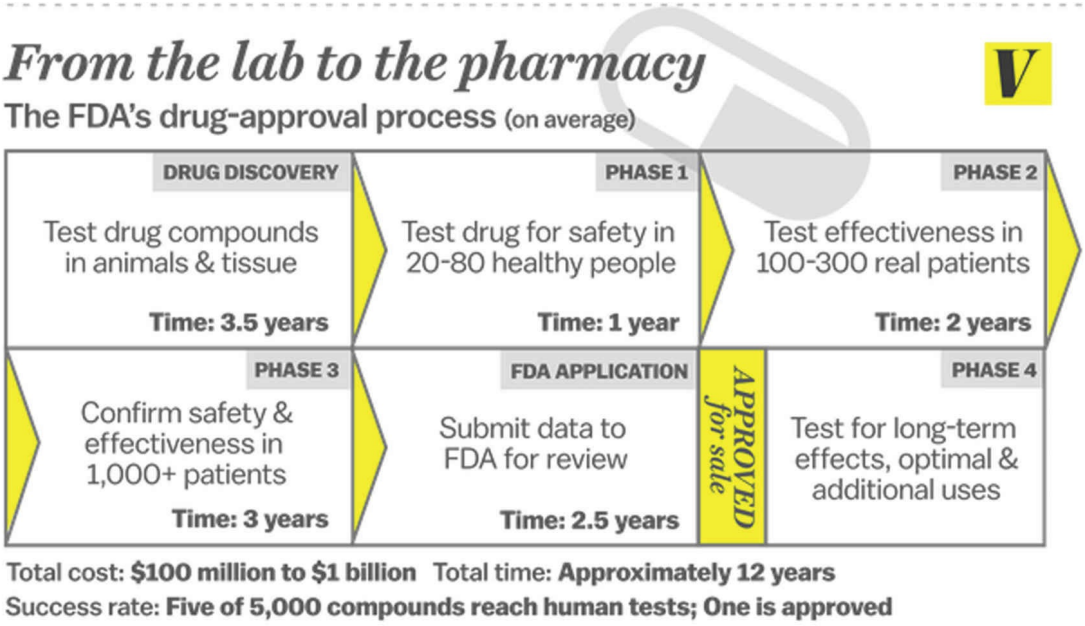

FIG. 1.1 The Drug Approval Process.

FDA, Food and Drug Administration. From Belluz, J. (2015). This new bill would add $9 billion for medical research. Here are 5 reasons critics are terrified. *VOX Science & Health.* Retrieved from http://www.vox.com/2015/7/14/8961923/21st-century-cures-act

BOX 1.1 Sample Inclusion and Exclusion Criteria

Inclusion

- Persons between the ages of 18 and 65
- Persons weighing between 50 and 100 kg
- Persons on a stable dose (i.e., no dose change in the previous 3 months) of cardiac medications (e.g., anticoagulants, angiotensin-converting enzyme inhibitors [ACEIs], angiotensin II–receptor blockers [ARBs], beta blockers, and diuretics)
- Persons adhering to a no-added-salt diet

Exclusion

- Women who are pregnant or nursing
- Women of childbearing age who do not use oral contraceptives
- Persons with symptomatic cardiac disease, hepatic dysfunction, chronic kidney disease, neurologic disorders, or musculoskeletal disorders
- Persons with clinically significant abnormal laboratory values (chemistry and hematology)

Beneficence

Beneficence is the duty to protect research subjects from harm. It involves assessing potential risks and possible benefits and ensuring the benefits are greater than the risk.

Risk-Benefit Ratio

The **risk-benefit ratio** is one of the most complex problems faced by the researcher. All possible consequences of a clinical study must be analyzed and balanced against the inherent risks and the anticipated benefits. Physical, psychological, and social risks must be identified and weighed against the benefits. A requirement of the Department of Health and Human Services (DHHS) is that institutional review boards (IRBs) determine that risks to subjects be reasonable in relation to the anticipated benefits, if any, for subjects. No matter how noble the intentions, the calculation of risks and benefits by the researcher cannot be totally accurate or comprehensive.

Justice

Justice requires that the selection of research subjects be fair. Research must be conducted so that the distribution of benefits and burdens is equitable (i.e., research subjects reflect all social classes and racial and ethnic groups).

Objectives and Phases of Pharmaceutical Research

The FDA requires clinical research to follow the **Good Clinical Practice (GCP) Consolidated Guideline**, an international ethical and scientific quality standard for designing, conducting, monitoring, auditing, recording, analyzing, and reporting clinical research. It is the foundation of clinical trials that involve human subjects. Additional guidance and information sheets are available from the FDA on multiple topics related to clinical research.

Preclinical Trials

Prior to the implementation of clinical research, the FDA requires preclinical trials to determine a drug's toxic and pharmacologic effects through in vitro and in vivo animal testing in the laboratory. Through these trials, drug developers are able to determine **genotoxicity**, the ability of a compound to damage genetic information in a cell, in addition to drug absorption, distribution, metabolism, and excretion.

Human Clinical Experimentation

Historically, drug research was done only with Caucasian males, causing uncertainty as to the validity of research results for people of other ethnicities and for women and children. In 1993, Congress passed the National Institutes of Health (NIH) Revitalization Act, which helped to establish guidelines to include women and minorities in clinical research. Additionally, the Best Pharmaceuticals for Children Act (BPCA) of 2002 and the Pediatric Research Equity Act (PREA) of 2003 encourage pharmaceutical companies to study their drugs in children.

Clinical experimentation in drug research and development encompasses four phases, each with its own objectives (see Fig. 1.1). A multidisciplinary team approach that includes nurses, physicians, pharmacologists, statisticians, and research associates is required to ensure safety and quality in all phases of clinical research. A brief description of each phase follows.

Phase I: Researchers test a new drug or treatment in a small group of people for the first time to evaluate its safety, determine a safe dosage range, and identify side effects.

Phase II: The drug or treatment is given to a larger group of people to see if it is effective and to further evaluate its safety.

Phase III: The drug or treatment is given to large groups of people to confirm its effectiveness, monitor side effects, compare it to commonly used treatments, and collect information that will allow the drug or treatment to be used safely.

Phase IV: Studies are done after the drug or treatment has been marketed to gather information on the drug's effects in various populations and to assess any side effects associated with long-term use.

Pharmaceutical companies are eager to bring new drugs to market. To reduce delays in the FDA approval process, in 1992 congress passed the Prescription Drug User Fee Act, which provided the FDA with funds to expedite the review process. As a result, the average drug approval time has decreased from 30 months to 12.

Clinical Research Study Design

An appropriate experimental design is important to answer questions about drug safety and efficacy. Studies are designed to determine the effect of the **independent variable** (treatment, such as with a drug) on the **dependent variable** (outcome, such as clinical effect). Intervening (extraneous) variables are factors that may interfere with study results, and these may include age, sex, weight, disease state, diet, and the subject's social environment. It is important to control for as many of the intervening variables as possible to increase study validity.

Sample Informed Consent Form for Randomized Clinical Trial of a Drug

Title of study: Comparison of a new drug [A] with an existing drug [B] used in treatment of disease X

Principal investigator: Dr. ABC

Institute: Department of Pediatrics, Aga Khan University

Introduction:

I am Dr. [SAK] from Department of Pediatrics, the Aga Khan University and doing a research on treatment of disease [X, for example malaria]. There is a new drug [A] which is being recommended for its treatment. I want to see if the new drug [A] is as good as or better than the commonly used drug [B] for the treatment of disease [malaria]. Since you are a patient of (or suffering from) disease [malaria], I would like to invite you to join this research study.

Background information

Disease X (Malaria) is a common disease in Pakistan, Asia and Africa, caused by a germ (parasite) spread by mosquito. It causes high grade fever. Some patients may have complications and even die. The commonly used drugs are losing their effectiveness and germs are getting resistant to it. A new drug known as [A] is supposed to be effective in treatment of disease (malaria) but there is not enough evidence that it is as good as other drugs used for treatment of disease (malaria).

Purpose of this research study

The purpose of study is to find out if the new drug is as good as or better than other drugs used for treatment of malaria in our population and; also to see if germs are not resistant to it.

Procedures

In this study, all patients aged 15 to 50 years of age, presenting at the clinic with fever for less than one week duration and having no other diagnosis will be registered and screened for malaria. For diagnosis of disease (malaria), one ml of blood will be taken from the patients and checked for presence of germs (malarial parasite). Those patients having positive test for the disease (malaria), will be included in the study. They will be divided randomly in to two groups by a computer draw. One group will get the new drug (A) and the other group will get the commonly used drug (B). Neither the doctor nor the patient will know which drug he/she is getting for treatment of his/her disease. A record will be kept for the duration of fever and other symptoms including any other side effect. Other necessary treatment will also be provided if needed.

Possible risks or benefits

No significant side effects have been reported for this new drug (A). However, some patients may feel nausea or may have vomiting. Drawing of blood may cause some discomfort or blue discoloration at the site of bleeding. Lowering of white blood cells and platelet is a common feature of the disease.

There is no direct financial or other benefit for the participant of the study. However, all the investigations will be done free of cost to the patients and; the drugs (A) or (B) will be provided free. Treatment of any side effect will also be provided free of cost. Sponsor of the study will bear the cost of drugs, investigations and treatment of side effects related to the study drugs.

Right of refusal to participate and withdrawal

You are free to choose to participate in the study. You may refuse to participate without any loss of benefit which you are otherwise entitled to. You child will receive the same standard care and treatment which is considered best for him irrespective of your decision to participate in the study. You may also withdraw any time from the study without any adverse effect on management of your child or any loss of benefit which you are otherwise entitled to. You may also refuse to answer some or all the questions if you don't feel comfortable with those questions.

Confidentiality

The information provided by you will remain confidential. Nobody except principal investigator will have an access to it. Your name and identity will also not be disclosed at any time. However the data may be seen by Ethical review committee and may be published in journal and elsewhere without giving your name or disclosing your identity.

Available Sources of Information

If you have any further questions you may contact Principal Investigator (Dr. SAK), department of pediatrics at Aga Khan University on following phone number 486xxxx

1. AUTHORIZATION

I have read and understand this consent form, and I volunteer to participate in this research study. I understand that I will receive a copy of this form. I voluntarily choose to participate, but I understand that my consent does not take away any legal rights in the case of negligence or other legal fault of anyone who is involved in this study. I further understand that nothing in this consent form is intended to replace any applicable Federal, state, or local laws.

Participant's Name (Printed or Typed):
Date:

Participant's Signature or thumb impression:
Date:

Principal Investigator's Signature:
Date:

Signature of Person Obtaining Consent:
Date:

FIG. 1.2 Sample Informed Consent for a Clinical Trial of a Drug.

From Sample Informed Consent for a Randomized Clinical Trial of a Drug. (n.d.) Aga Khan University. Retrieved from http://www.aku.edu/research/urc/ethicalreviewcommittee/sampleconsentforms/Pages/sampleconsentforms.aspx

BOX 1.2 Informed Consent Checklist: Basic Elements

- A statement that the study involves research
- An explanation of the purposes of the research
- The expected duration of the subject's participation
- A description of the procedures to be followed
- Identification of any experimental procedures
- A description of any reasonably foreseeable risks or discomforts to the subject
- A description of any benefits to the subject or to others that may reasonably be expected from the research
- A disclosure of appropriate alternative procedures or courses of treatment, if any, that might be advantageous to the subject
- A statement describing the extent, if any, to which confidentiality of records identifying the subject will be maintained
- For research that involves more than minimal risk, an explanation as to whether any compensation will be paid and whether any medical treatments are available if injury occurs, and if so, what the treatments consist of or where further information may be obtained
- **Research, Rights or Injury**: An explanation of whom to contact for answers to pertinent questions about the research and research subjects' rights and whom to contact in the event of a research-related injury to the subject
- A statement that participation is voluntary, refusal to participate will involve no penalty or loss of benefits to which the subject is otherwise entitled, and the subject may discontinue participation at any time without penalty or loss of benefits to which the subject is otherwise entitled

From Office for Human Research Protections (OHRP). (2014). U.S. Department of Health & Human Services. Retrieved from http://www.hhs.gov/ohrp/policy/consentckls.html

The *experimental group* in drug trials is the group that receives the drug being tested. The *control group* in drug trials may receive no drug; a different drug; a **placebo** (pharmacologically inert substance); or the same drug with a different dose, route, or frequency of administration.

American Nurses Association Code of Ethics

The **American Nurses Association (ANA) Code of Ethics** "was developed as a guide for carrying out nursing responsibilities in a manner consistent with quality in nursing care and the ethical obligations of the profession." It was first adopted in 1950 and most recently was revised with interpretive statements in 2015. The ANA Code of Ethics is founded on the principles first identified by Florence Nightingale, who believed that a nurse's ethical duty was first and foremost to care for the patient. It contains nine provisions (Box 1.3). The 2015 update addresses advances in nursing leadership, social policy and global health, and the challenges nurses face related to social media, electronic health records, and the nurse's expanded role in clinical research.

The Nurse's Role in Clinical Research

Nurses are at the forefront of clinical research. Regardless of the setting (inpatient or outpatient), nurses are likely to encounter patients who are eligible to participate, considering participation, or actively participating in clinical research. As such, nurses are responsible for both the safety of the patient and the integrity of the research protocol.

Nursing Process: Patient-Centered Collaborative Care

Clinical Research

Assessment

- Identify patients who are eligible to participate in or who are participating in clinical research.
- Assess response to the study agent and identify adverse events (an unfavorable or unintended sign, symptom, or disease that was not present at the time of study enrollment and is associated with the treatment or procedure).

Planning

- Have a process in place to identify persons who are eligible to participate in a clinical research or to identify participants actively participating in clinical research studies.
- Have a process in place to facilitate education and informed consent of eligible study participants.
- Plan educational programming for staff who provide direct care to study participants.
- Plan participant care to ensure integrity and compliance with study protocol.

Nursing Interventions

- Support the process of informed consent in a culturally competent manner.
  - Provide an interpreter when necessary.
  - Provide enough time for the person to read the consent and ask questions.
  - Serve as a witness to informed consent.
- After reviewing the study protocol, administer study agent(s).
- Accurately document all participant care, assessment findings, and study agent administration.
- Accurately and safely collect biospecimens.
- Act as advocate, educator, and collaborator in the research process.
  - Ensure safe care.
  - Ensure integrity of study data.
  - Communicate clearly.

Evaluation

- Determine if the potential participant understands what it means to participate in the study by asking open-ended questions.
- Monitor response to the study agent or other interventions.
- Determine whether participants understand how to take their study agents, what to do if they miss a dose, how to store the study agent, and when to call their health care provider.

Drug Standards and Legislation

Drug Standards

The set of drug standards used in the United States is the United States Pharmacopeia (USP). The *United States Pharmacopeia and the National Formulary* (USP-NF), the authoritative source for drug standards (dosage, forms, drug substances, excipients, biologics, compounded preparations, and dietary supplements), is published annually. Experts in nursing, pharmaceutics, pharmacology, chemistry, and microbiology all contribute. Drugs included in the USP-NF have met high standards for therapeutic use, patient safety, quality, purity, strength, packaging safety, and dosage form. Drugs that meet these standards have the initials "USP" following their official name, denoting global recognition of high quality.

The *International Pharmacopeia,* first published in 1951 by the World Health Organization (WHO), provides a basis for standards in strength and composition of drugs for use throughout the world. The book is published in English, Spanish, and French.

BOX 1.3 Provisions of the American Nurses Association Code of Ethics

Provision 1

The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.

Provision 2

The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population.

Provision 3

The nurse promotes, advocates for, and protects the rights, health, and safety of the patient.

Provision 4

The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.

Provision 5

The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.

Provision 6

The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.

Provision 7

The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.

Provision 8

The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.

Provision 9

The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice

into nursing and health policy.

From American Nurses Association. (2015). Code of ethics for nurses with interpretive statements. Retrieved from http://nursingworld.org/DocumentVault/Ethics_1/Code-of-Ethics-for-Nurses.html

Federal Legislation

Federal legislation attempts to protect the public from drugs that are impure, toxic, ineffective, or not tested before public sale. The primary purpose of the legislation is to ensure safety. America's first law to regulate drugs was the Food and Drug Act of 1906, which prohibited the sale of misbranded and adulterated drugs but did not address drug effectiveness and safety.

1912: The Sherley Amendment

This act prohibited false therapeutic claims on drug labels. It came about as a result of Mrs. Winslow's Soothing Syrup, a product advertised to treat teething and colic, which contained morphine and led to the death of many infants. Under the Sherley Amendment, the government had to prove intent to defraud before a drug could be removed from the market.

1914: The Harrison Narcotic Act

This act required prescriptions for drugs that exceeded set narcotic limits. It also mandated increased record keeping by physicians and pharmacists.

1938: The Federal Food, Drug, and Cosmetic Act

The Federal Food, Drug, and Cosmetic Act of 1938 empowered the FDA to ensure a drug was safe prior to marketing. It is the FDA's responsibility to ensure that all drugs are tested for harmful effects; it also required that drugs be labeled with accurate information and have detailed literature in the drug packaging that explains adverse effects. The FDA can prevent the marketing of any drug it judges to be incompletely tested or dangerous. Only drugs considered safe by the FDA are approved for marketing.

1951: Durham-Humphrey Amendment

The Durham-Humphrey Amendment distinguished between drugs that could be sold with or without prescription by a licensed health care provider.

1962: Kefauver-Harris Amendment to the 1938 Act

The Kefauver-Harris Amendment resulted from the widely publicized thalidomide tragedy of the 1950s in which European patients who took the sedative-hypnotic thalidomide during the first trimester of pregnancy gave birth to infants with extreme limb deformities. The Kefauver-Harris amendment tightened controls on drug safety, especially experimental drugs, and required that adverse reactions and contraindications must be labeled and included in the literature. The amendment also included provisions for the evaluation of testing methods used by manufacturers, the process for withdrawal of approved drugs when safety and effectiveness were in doubt, and the establishment of effectiveness of new drugs before marketing.

1965: Drug Abuse Control Amendments

Enacted in 1965, the Drug Abuse Control Amendments attempted to control the abuse of depressants, stimulants, and hallucinogens.

1970: The Comprehensive Drug Abuse Prevention and Control Act

In 1970, Congress passed the Comprehensive Drug Abuse Prevention and Control Act. This act, designed to remedy the escalating problem of drug abuse, included several provisions: (1) promotion of drug education and research into the prevention and treatment of drug dependence; (2) strengthening of enforcement authority; (3) establishment of treatment and rehabilitation facilities; and (4) designation of schedules, or categories, for controlled substances according to abuse liability.

Based on their abuse potential and acceptable medical use practices, **controlled substances** are categorized into five schedules, which are listed in Table 1.1. Schedule I drugs are not approved for

medical use and have high abuse potential; schedule II through V drugs have acceptable medical use and decreasing potential for abuse leading to psychological and/or physiologic dependence.

Nurses are key to creating a culture of safety and accountability related to controlled substances. As such, nurses must:

- Verify orders prior to drug administration.
- Account for all controlled drugs.
- Maintain a controlled-substance log that ensures all required information is documented accurately.
- Document all discarded or wasted medication; wastage must be witnessed by another nurse.
- Ensure timely documentation in the patient record following drug administration, including patient response to drug administration.
- Keep all controlled drugs in a locked storage area; keep narcotics under double lock. Be certain that only authorized persons have access to the keys, including keys for patient-controlled analgesia and epidural pumps. Medication may also be administered via an automated dispensing cabinet, with bioidentical identifiers used for access.
- The ANA recognizes the significant threat to patient safety and liability to health care organizations caused by nurse drug diversion and recommends that all states have a peer-to-peer assistance program for addicted nurses. Reporting is mandatory if suspected or known diversion occurs.

1983: The Orphan Drug Act

The Orphan Drug Act was designed to promote the development and manufacture of drugs used in the treatment of rare diseases (orphan drugs). The act's three primary incentives are (1) federal funding of grants and contracts to perform clinical trials of orphan products; (2) a 50% tax credit for costs of clinical testing; and (3) exclusive rights to market the drug for 7 years from the marketing approval date.

1994: Dietary Supplement Health and Education Act

This act established labeling requirements for dietary supplements and authorized the FDA to promote safe manufacturing practices. It classified dietary supplements as food.

1996: Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act (HIPAA) of 1996 protects health insurance coverage for workers who change or lose their jobs and sets the standard for the privacy of individually identifiable health information. The act provides patients more control over their health information, including boundaries on the use and release of health records.

1997: The Food and Drug Administration Modernization Act

The five provisions in this act are (1) review and use of new drugs is accelerated; (2) drugs can be tested in children before marketing; (3) clinical trial data are necessary for experimental drug use for serious or life-threatening health conditions; (4) drug companies are required to give information on off-label (non–FDA-approved) use of drugs and their costs; and (5) drug companies that plan to discontinue drugs must inform health professionals and patients at least 6 months before stopping drug production.

TABLE 1.1

Schedule Categories of Controlled Substances

Schedule	Examples	Description
I	Some examples of substances listed in Schedule I are heroin, lysergic acid diethylamide (LSD), *Cannabis*, peyote, methaqualone, and methylenedioxymethamphetamine (MDMA)	Substances in this schedule have no currently accepted medical use in the United States, a lack of accepted safety for use under medical supervision, and a high potential for abuse.
II	Examples of Schedule II narcotics include hydromorphone (Dilaudid), methadone (Dolophine), meperidine (Demerol), oxycodone (OxyContin, Percocet), and fentanyl (Sublimaze, Duragesic). Other Schedule II narcotics include morphine, opium, codeine, and hydrocodone. Examples of Schedule IIN stimulants include amphetamine (Dexedrine, Adderall), methamphetamine (Desoxyn), and methylphenidate (Ritalin). Other Schedule II substances include amobarbital, glutethimide, and pentobarbital.	Substances in this schedule have a high potential for abuse that may lead to severe psychological or physical dependence.
III	Examples of Schedule III narcotics include products containing not more than 15 mg of hydrocodone per dosage unit (acetaminophen with hydrocodone) or 90 mg of codeine per dosage unit (acetaminophen with codeine), and buprenorphine and naloxone. Examples of Schedule IIIN nonnarcotics include benzphetamine, phendimetrazine, ketamine, and anabolic steroids such as Depo-Testosterone.	Substances in this schedule have a potential for abuse less than substances in Schedules I or II, and abuse may lead to moderate or low physical dependence or high psychological dependence.
IV	Examples of Schedule IV substances include alprazolam, carisoprodol, clonazepam, clorazepate,	Substances in this schedule have a low potential for abuse relative to

	diazepam, lorazepam, midazolam, temazepam, and triazolam.	substances in Schedule III.
V	Examples of Schedule V substances include cough preparations containing not more than 200 mg of codeine per 100 mL or per 100 g (guaifenesin with codeine, promethazine with codeine), and ezogabine.	Substances in this schedule have a low potential for abuse relative to substances listed in Schedule IV and consist primarily of preparations containing limited quantities of certain narcotics.

From Controlled substance schedules. (n.d.). U.S. Department of Justice, Drug Enforcement Administration, Office of Diversion Control. Retrieved from http://www.deadiversion.usdoj.gov/schedules/#define

2002: Best Pharmaceuticals for Children Act

The BPCA gives manufacturers a 6-month extension of patents to evaluate drugs on the market for their safety and efficacy in children.

2003: Pediatric Research Equity Act

This act authorizes the FDA to require that drug manufacturers test certain drugs and biologic products for their safety and effectiveness in children, noting that "children are not small adults." Additionally, studies that involve children must be conducted with the same drug and in the same disease process as adults.

2007: Food and Drug Administration Amendments Act

This act allows the FDA to do more comprehensive reviews of potential new drugs, mandates postmarketing safety studies, and affects the distribution of drugs found to be not as safe as premarket studies indicated.

2010: Patient Protection and Affordable Care Act

This act was signed into law in 2010 and became effective January 1, 2014. Essential provisions of the reform include (1) quality, affordable health care for all Americans; (2) improved quality and efficiency of health care; (3) prevention of chronic disease and improved public health; (4) improved access to innovative medical therapies; and (5) community living services and supports.

2012: Food and Drug Administration Safety and Innovation Act (FDASIA)

This act was signed into law on July 9, 2012. It strengthens the FDA's ability to safeguard and advance public health by:

- Collecting fees from industry to fund reviews of drugs with the "breakthrough therapy" designation, medical devices, generic drugs, and biosimilar biologic products
- Expediting development of innovative, safe, and effective products
- Increasing stakeholder engagement in FDA processes
- Enhancing the safety of the global drug supply chain

Nurse Practice Acts

All states and territories have rules and regulations in place to provide guidance and govern nursing practice, which includes drug administration by nurses. Generally, nurses cannot prescribe or administer drugs without a health care provider's order. Practicing nurses should be knowledgeable about the nurse practice act in the state where they are licensed. (Information can be found through the National Council of State Boards of Nursing at www.ncsbn.org.) Nurses are responsible for knowing their state's law and administrative code. Nurses who administer a drug without a licensed health care provider's order are in violation of the Nurse Practice Act and can have their licenses revoked.

In a civil court, the nurse can be prosecuted for giving the wrong drug or dosage, omitting a drug dose, or giving the drug by the wrong route.

Canadian Drug Regulation

In Canada, prior to approval and becoming available to patients, drugs must be reviewed for safety, efficacy, and quality by the Health Products and Food Branch (HPFB) of Health Canada. Health Canada is a federal department tasked with the mission of improving the quality of life of all Canadians. (Further information can be found at www.hc-sc.gc.ca).

In 1996, the Canadian government passed the Controlled Drugs and Substances Act. This act broke controlled drugs and substances into eight schedules and two classes of precursors (Table 1.2). In 2012, the Safe Streets and Communities Act was passed in Canada, which reclassified amphetamines—including methylenedioxyamphetamine (MDA) and methylenedioxymethamphetamine (MDMA)—and also flunitrazepam and gamma hydroxybutyrate (GHB) from Schedule III to Schedule I drugs. This change imposed stiffer penalties for dealers and those in possession.

Initiatives to Combat Drug Counterfeiting

Distribution of counterfeit drugs is a worldwide problem; it is estimated that more than 10% of all drugs available are counterfeit. Counterfeit drugs may contain the incorrect ingredients, insufficient amounts of active ingredients, or no active ingredients. Additionally, they may contain impurities and contaminants or may be distributed in fake packaging.

The most common drugs counterfeited are those used to treat erectile dysfunction, high cholesterol, hypertension, infections, cancer, and HIV/AIDS. The high cost of drugs, combined with the need for prescription drugs to treat chronic diseases—as well as the desire by consumers to misuse drugs (e.g., steroid-containing drugs for body building)—generate a constant demand easily filled by criminals via rogue Internet drug sites. The FDA and consumer groups are working on strategies to combat this problem, including tougher oversight of distributors, a rapid alert system, and better-informed consumers.

The role of the nurse is critical in consumer education. The nurse must advise patients to report any differences in taste or appearance of a drug or in its packaging. Patients should be alert to slight variations in packaging or labeling (e.g., color, package seal), note any unexpected side effects, and buy drugs from reputable sources. Reputable online pharmacies carry the designation of Verified Internet Pharmacy Practice Site (VIPPS; a list of VIPPS-verified pharmacies can be found at www.nabp.net) and display an approval seal. If any suspicion of counterfeit arises, the patient, family, or nurse should contact the FDA at www.fda.gov/Safety/MedWatch/HowToReport.

TABLE 1.2

Canadian Controlled Drugs and Substances Schedule

Schedule	Examples	Description
I	Codeine, hydrocodone, oxycodone, coca, cocaine, levomethorphan, ketamine, sufentanil, methamphetamine, amphetamine, gamma hydroxybutyrate (GHB)	Opium poppy, coca leaves, phenylpiperidines, phenazepines, amidones, methadols, phenalkoxams, thiambutenes, moramides, morphinans, benzazocines, ampromides, benzimidazoles, phencyclidine, fentanyls, tilidine, methamphetamine, amphetamine, flunitrazepam, and GHB and its derivatives, alkaloids, and salts
II	*Cannabis*, nabilone, tetrahydrocannabinol	*Cannabis*, its derivatives, and similar synthetic preparations
III	Thirty-three compounds including methylphenidate, lysergic acid diethylamide (LSD), psilocybin, and mescaline	
IV	Twenty-six parent compounds including chlorphentermine, butorphanol, nalbuphine, meprobamate, and zolpidem	Barbiturates, thiobarbiturates, benzodiazepines, and their salts and derivatives; anabolic steroids and their derivatives
V		Propylhexedine and any of its salts
VI	Class A includes 23 compounds such as ephedrine, ergotamine, and pseudoephedrine. Class B includes six compounds such as acetone and sulfuric acid.	Part 1 – Class A precursors Part 2 – Class B precursors Part 3 – Preparations and mixtures
VII		*Cannabis* resin 3 kg *Cannabis* 3 kg
VIII		*Cannabis* resin 1 g *Cannabis* 30 g

For more detailed information, please see the Canadian Legal Information Institute at http://www.canlii.org/.

Drug Names

Drugs have several names. The **chemical name** describes the drug's chemical structure. The **generic name** is the official, *nonproprietary* name for the drug; this name is not owned by any drug company and is universally accepted. Nearly 80% of all prescription drugs in the United States are ordered by generic name. The **brand (trade) name**, also known as the *proprietary* name, is chosen by the drug company and is usually a registered trademark. Drug companies market a compound using its brand name. For example, Lunesta is the (proprietary) brand name of a drug whose generic name is eszopiclone.

Throughout this text, only generic names for each drug will be used because many brand names may exist for a single generic name—for example, the generic drug ibuprofen carries the brand names Advil, Medipren, Motrin, and Nuprin. Generic names are given in lowercase letters, whereas brand names always begin with a capital letter. An example of a generic and brand-name drug listing is *furosemide (Lasix).*

Generic drugs must be approved by the FDA before they can be marketed. If the generic drug is found to be *bioequivalent* to the brand-name drug, the generic drug is considered *therapeutically equivalent* and is given an "A" rating. If there is less than a 20% variance in drug absorption, distribution, metabolism, and excretion, a generic drug is considered *equivalent* to the brand-name drug.

A list of FDA-approved drug products can be found at www.accessdata.fda.gov/scripts/cder/drugsatfda. The FDA also publishes a list of approved generic drugs that are bioequivalent to brand-name drugs. Generic drugs have the same active ingredients as brand-name drugs but are usually less expensive because manufacturers do not have to do extensive testing; these drugs were clinically tested for safety and efficacy by the pharmaceutical company that first formulated the drug. However, all drugs have varying inert fillers, binders, and excipients used to shape tablets and control how fast or slow the drug is released in the body, and these factors may result in variations in drug bioavailability.

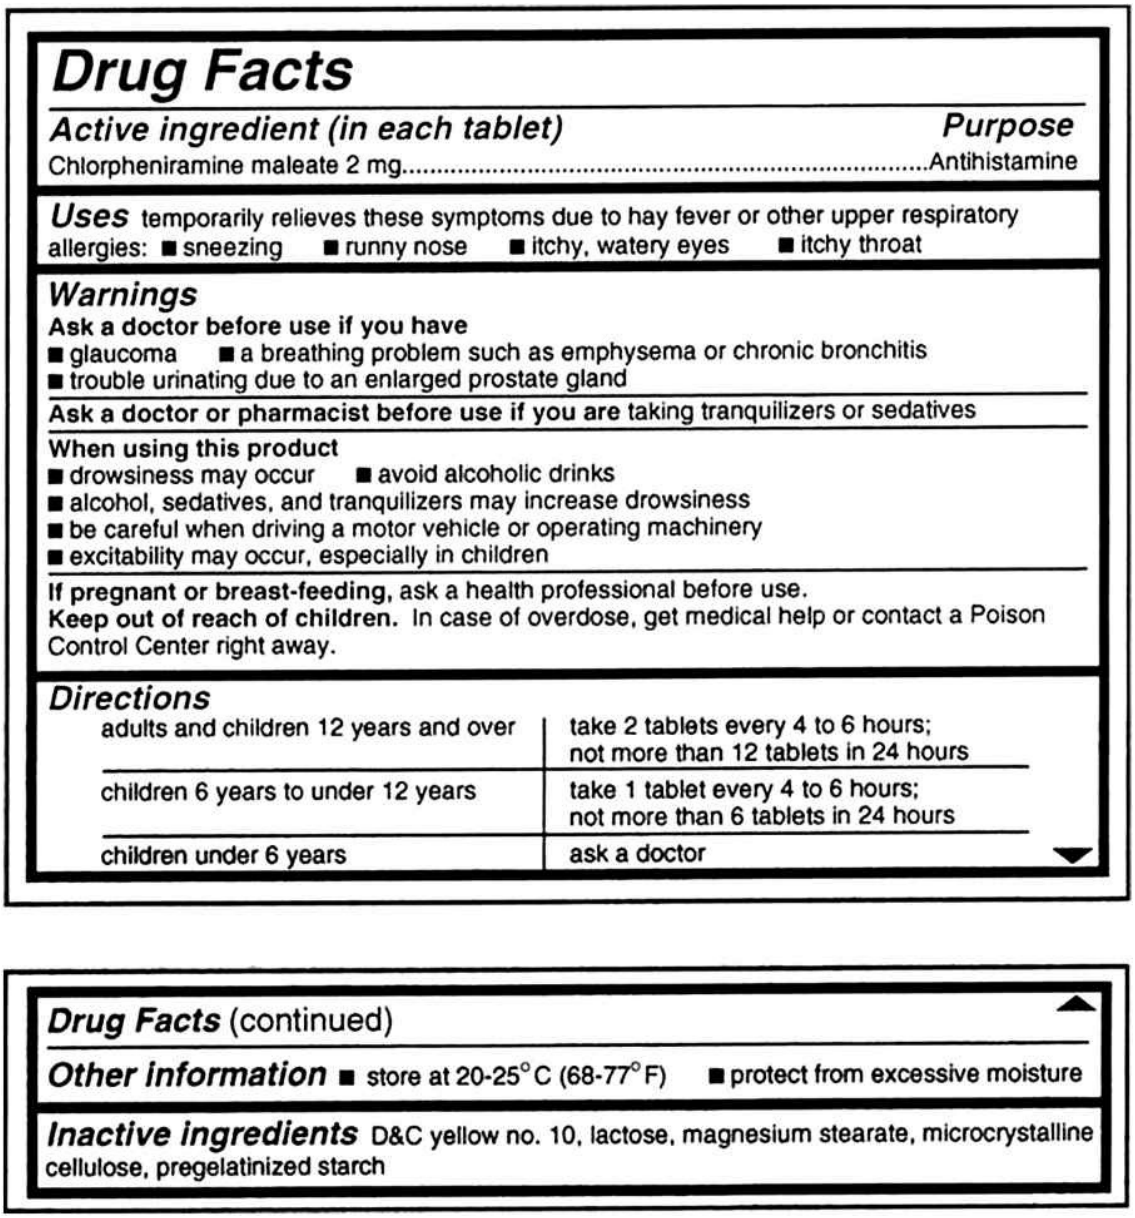
Health care providers and patients must exercise care when choosing generic drugs because of possible variations in their action or in the patient's response to them. In order to maintain stable drug levels, patients should be cautioned *not* to change generic drug manufacturers; this is particularly true when patients are prescribed phenytoin or warfarin. Nurses should check with the health care provider or the pharmacist when generic drugs are prescribed. Health care providers must note on prescriptions whether the pharmacist may substitute the generic drug when the brand name is prescribed.

Over-the-Counter Drugs

Although all drugs carry risk, **over-the-counter (OTC)** drugs have been found to be safe and appropriate for use without the direct supervision of a health care provider. They are available for purchase without a prescription in many retail locations. Other OTC drugs (e.g., pseudoephedrine, emergency contraception) are available with some restrictions and must be kept behind the pharmacy counter; prior to dispensing, patient age and identify are verified, and education is provided.

More than $23 billion is spent annually on OTC drugs, which include vitamin supplements, cold remedies, analgesics, antacids, laxatives, antihistamines, sleep aids, nasal sprays, weight-control drugs, drugs for dermatitis and fungal infections, fluoride toothpaste, corn and callus removal products, and herbal products. Information related to OTC drugs available on the market can be found at http://www.drugs.com/otc.

In 2002, the FDA standardized OTC labeling to provide consumers with better information and to describe the benefits and risks associated with taking OTC drugs. It is an important nursing responsibility to ensure that patients are able to read and understand OTC labels. All OTC drugs must have labels that provide the following information in this specific order (Fig. 1.3).



- The product's active ingredients, including the amount in each dosage unit
- The purpose of the product
- The uses (indications) for the product
- Specific warnings, including when the product should not be used under any circumstances, substances or activities to avoid, side effects that could occur, and when it is appropriate to consult with a doctor or pharmacist
- Dosage instructions that include when, how, and how often to take the product
- The product's inactive ingredients and important information to help consumers avoid ingredients that may cause an allergic reaction

Nurses must be aware of OTC drugs and the implications of their use. OTC drugs provide both advantages and potential serious complications for the consumer. The nurse needs to emphasize that many of these drugs are potent and can cause moderate to severe side effects, especially when taken with other drugs. Additionally, many OTC drugs contain the same active ingredients, potentially leading to overdose. Self-diagnosis and self-prescribing OTC drugs may mask the seriousness of clinical conditions. See Box 1.4 for nursing considerations related to OTC drugs.

Interactions between prescription drugs and OTC drugs are potentially dangerous. Many individuals routinely reach for aspirin, acetaminophen, and ibuprofen to relieve discomfort or pain without being aware of these interactions. For example, ibuprofen can increase fluid retention, which can worsen heart failure; use of ibuprofen on a daily basis may decrease the effectiveness of antihypertensive drugs. Ibuprofen has also been linked with cardiovascular events, such as myocardial infarction and stroke; this risk increases with long-term use.

Some OTC drugs, such as cough medicine, are a combination product of two to four drugs. It is conceivable that there could be a drug-drug interaction with a cough medicine and one of the drugs prescribed by the patient's health care provider.

Patients with asthma should be aware that aspirin can trigger an acute asthma episode. Patients may be allergic to aspirin, or aspirin may act as a deregulator of leukotrienes. Aspirin is also not recommended for children with influenza symptoms or chickenpox because it has been associated with Reye syndrome. Patients with kidney disease should avoid aspirin, acetaminophen, and ibuprofen because these can further decrease kidney function, especially with long-term use. Also, patients taking moderate to high doses of aspirin, ibuprofen, or naproxen concurrently with an oral anticoagulant may be at increased risk for bleeding.

Drug Facts

Active ingredient (in each tablet) — **Purpose**

Chlorpheniramine maleate 2 mg ..... Antihistamine

Uses temporarily relieves these symptoms due to hay fever or other upper respiratory allergies: ■ sneezing ■ runny nose ■ itchy, watery eyes ■ itchy throat

Warnings

Ask a doctor before use if you have

■ glaucoma ■ a breathing problem such as emphysema or chronic bronchitis
■ trouble urinating due to an enlarged prostate gland

Ask a doctor or pharmacist before use if you are taking tranquilizers or sedatives

When using this product

■ drowsiness may occur ■ avoid alcoholic drinks
■ alcohol, sedatives, and tranquilizers may increase drowsiness
■ be careful when driving a motor vehicle or operating machinery
■ excitability may occur, especially in children

If pregnant or breast-feeding, ask a health professional before use.
Keep out of reach of children. In case of overdose, get medical help or contact a Poison Control Center right away.

Directions

adults and children 12 years and over	take 2 tablets every 4 to 6 hours; not more than 12 tablets in 24 hours
children 6 years to under 12 years	take 1 tablet every 4 to 6 hours; not more than 6 tablets in 24 hours
children under 6 years	ask a doctor

Drug Facts (continued)

Other information ■ store at 20-25°C (68-77°F) ■ protect from excessive moisture

Inactive ingredients D&C yellow no. 10, lactose, magnesium stearate, microcrystalline cellulose, pregelatinized starch

FIG. 1.3 Sample Over-the-Counter Drug Label.

From U.S. Food and Drug Administration. (2014). The current over-the-counter medicine label: Take a look. U.S. Food and Drug Administration. Retrieved from http://www.fda.gov/drugs/emergencypreparedness/bioterrorismanddrugpreparedness/ucm133411.htm

BOX 1.4 Nursing Considerations Related to Over-the-Counter Drugs

Nurses should advise patients of the following when over-the-counter (OTC) drugs are considered:

- Always read the instructions on the label.
- Do not take OTC medicines in higher dosages or for a longer time than the label states.
- If you do not get well, stop treating yourself and talk with a health care professional.
- Side effects from OTCs are relatively uncommon, but it is your job to know what side effects might result from the medicines you are taking.
- Because every person is different, your response to the medicine may be different than another person's response.
- OTC medicines often interact with other medicines, and with food or alcohol, or they might have an effect on other health problems you may have.
- If you do not understand the label, check with the pharmacist.

- Do not take medicine if the package does not have a label on it.
- Throw away medicines that have expired (are older than the date on the package).
- Do not use medicine that belongs to a friend.
- Buy products that treat only the symptoms you have.
- If cost is an issue, generic OTC products may be cheaper than brand name items.
- Avoid buying these products online, outside of well-known Internet insurance company sites, because many OTC preparations sold through the Internet are counterfeit products. These may not be what you ordered and may be dangerous.

Parents should know the following special information about using OTCs for children:

- Parents should never guess about the amount of medicine to give a child. Half an adult dose may be too much or not enough to be effective. This is very true of medicines such as acetaminophen (Tylenol) or ibuprofen (Advil), in which repeated overdoses may lead to poisoning of the child, liver destruction, or coma.
- If the label says to take 2 teaspoons and the dosing cup is marked with ounces only, get another measuring device. Don't try to guess about how much should be given.
- Always follow the age limits listed. If the label says the product should not be given to a child younger than 2 years, do not give it.
- Always use the child-resistant cap, and relock the cap after use.
- Throw away old, discolored, or expired medicine or medicine that has lost its label instructions.
- Do not give medicine containing alcohol to children.

From Edmunds MW: *Introduction to Clinical Pharmacology*, ed 8, St. Louis, 2016, Mosby.

The previous examples are not all inclusive. Caution is advised before using any OTC preparation, including antacids, decongestants, and laxatives. Patients should check with their health care providers and read drug labels before taking OTC medications so they are aware of possible contraindications and adverse reactions.

The acronym *SAFER* is a mnemonic for the instructions that the FDA recommends before taking any medicine: **s**peak up, **a**sk questions, **f**ind the facts, **e**valuate your choices, and **r**ead labels.

Drug Resources

Many drug references are available, including nursing texts that identify related nursing implications and areas for health teaching. Some recommended resources follow.

American Hospital Formulary Service (AHFS) Drug Information is published by the American Society of Health-System Pharmacists in Bethesda, Maryland. It provides accurate and complete drug information for both the health care provider and the consumer on nearly all prescription drugs marketed in the United States. This text contains drugs listed according to therapeutic drug classification. The information given for each drug includes chemistry and stability, pharmacologic actions, pharmacokinetics, uses, cautions, contraindications, acute toxicity, drug interactions, dosage and administration, and preparations.

This reference is updated yearly with monthly supplements that provide information on new drugs such as dosage forms and strengths, uses, and cautions. The text is unbiased. Drug information from the AHFS is available online or in print format.

United States Pharmacopeia—Drug Information (USP-DI) is available in most hospitals and pharmacies either online or in print format. It provides drug information for the health care provider, including pharmacology, precautions to consider, side effects and adverse effects, patient consultation, general dosing information, and dosage forms. The USP-DI also contains patient information presented in a way that is easily understood. The topics include administration of drugs, drug effects, indications, adverse reactions, dosage guidelines, and what to do for missed doses.

The *Medical Letter* on drugs and therapeutics is a nonprofit publication for physicians, nurse practitioners, and other health professionals. Each biweekly issue provides reviews of new FDA-approved drugs and comparisons of drugs available for common diseases.

Prescriber's Letter is a newsletter published monthly by the Therapeutic Research Center in Stockton, California. It provides concise updates and advice concerning new FDA-approved drugs, various uses of older drugs, and FDA warnings.

MedlinePlus is a service of the U.S. National Library of Medicine. Available at www.nlm.nih.gov/medlineplus/druginformation.html, it offers extensive information on prescribed drugs, as well as herbs and supplements, indexed by generic and brand names.

A good source for OTC drug information is *The Handbook of Nonprescription Drugs,* published by the American Pharmacists Association in Washington, DC. This resource is available online and in text. The Internet can be another great resource, but only if credible websites are used.

Critical Thinking Case Study

Miguel, a 53-year-old Hispanic male, is seen by his health care provider for chronic pain in his knees. He states the pain is a dull, constant ache in both knees that happens in the evenings after he's been working as a cashier all day.

1. It is important for the nurse to gather what information about Miguel's medications?
2. Miguel has taken ibuprofen for an extended period of time to control his pain. What risk does this over-the-counter (OTC) drug pose for him?
3. What patient education should the nurse provide Miguel concerning OTC drugs?
4. Miguel is advised by his health care provider to stop taking ibuprofen and begin taking acetaminophen. Prior to leaving the office, he asks the nurse how he will be able to remember the possible side effects of this drug. The nurse tells him he can read the label on his bottle. What is the standardized order of information on OTC drug labels?

Nclex Study Questions

1. The nurse in the clinical research setting is knowledgeable about ethical principles and protection of human subjects. What principle is demonstrated by ensuring the patient's right to self-determination?
   a. Beneficence
   b. Respect for persons
   c. Justice
   d. Informed consent
2. The research nurse is meeting with a patient and determines, based on the assessment, that the patient meets inclusion criteria for clinical research. The patient agrees to participate in the clinical trial. The nurse advises the patient that which member of the health care team has the responsibility to explain the study and respond to questions?
   a. Registered nurse
   b. Pharmacist
   c. Research associate
   d. Health care provider
3. The clinical research nurse knows that only a small proportion of drugs survive the research and development process. An appreciation of the process and associated costs grows when the nurse is aware that approximately one in how many potential drugs is approved by the U.S. Food and Drug Administration?
   a. 100
   b. 1000
   c. 10,000
   d. 100,000
4. The nurse is interviewing a patient in a Phase I clinical trial. Which patient statement indicates an understanding of this trial phase?
   a. I am doing this to be sure this drug is safe.
   b. I am doing this to be sure this drug is effective.
   c. I hope this drug is better than the current treatment.
   d. I can be part of demonstrating a cure.
5. The foundation of clinical trials, Good Clinical Practice, is a helpful resource for nurses. The nurse is correct in choosing Good Clinical Practice as a reference for standards in which areas? (Select all that apply.)
   a. Design
   b. Monitoring and auditing
   c. Analyses
   d. Reporting
   e. Outcomes evaluation
6. The nurse researcher reviews the proposed informed consent form for a future clinical trial. The nurse expects to find which in the document? (Select all that apply.)
   a. Description of benefits and risks
   b. Identification of related drugs, treatments, and techniques
   c. Description of outcomes
   d. Statement of compensation for participants, if any
   e. Description of serious risks
7. The nurse knows that the patient should be informed about the risks and benefits related to clinical research. What ethical principle does this describe?

a. Respect for persons

b. Justice

c. Beneficence

d. Informed consent

8. The nurse is reviewing a patient's list of medications and notes that several have the highest abuse potential. According to U.S. standards, the highest potential for abuse of drugs with accepted medical uses is found in drugs included in which schedule?

a. II

b. III

c. IV

d. V

9. The nurse is reviewing the drug-approval process in the United States and learns that the Food and Drug Administration Modernization Act of 1997 contains which provisions? (Select all that apply.)

a. Review of new drugs is accelerated.

b. Drug companies must provide information on off-label use of drugs.

c. Privacy of individually identifiable health information must be protected.

d. Drug companies must offer advanced notice of plans to discontinue drugs.

e. Drug labels must describe side effects and adverse effects.

10. The patient has questions about counterfeit drugs. Which factors alert the patient or nurse that a drug is counterfeit or adulterated? (Select all that apply.)

a. Variations in packaging

b. Unexpected side effects

c. Different taste

d. Different chemical components

e. Different odor

11. The nurse knows the importance of administering the right medication to the patient and that drugs have many names. It is therefore most important that drugs be ordered by which name?

a. Generic

b. Brand

c. Trade

d. Chemical

12. What provisions from the Controlled Substances Act of 1970 were designed to remedy drug abuse?

a. The act established treatment and rehabilitation facilities.

b. The act tightened controls on experimental drugs.

c. The act required clinical trial data on drugs.

d. The act required drug companies to give information on off-label use of drugs.

Answers: 1, b; 2, d; 3, c; 4, a; 5, a, b, c, d; 6, a, b, d, e; 7, c; 8, a; 9, a, b, d; 10, a, b, c; 11, a; 12, a.

Pharmacokinetics, Pharmacodynamics, and Pharmacogenetics

OUTLINE

Pharmacokinetics
- Drug Absorption
- Drug Distribution
- Drug Metabolism
- Drug Excretion

Pharmacodynamics
- Dose-Response Relationship
- Onset, Peak, and Duration of Action
- Therapeutic Drug Monitoring
- Receptor Theory
- Agonists and Antagonists
- Nonspecific and Nonselective Drug Effects
- Mechanisms of Drug Action
- Side Effects, Adverse Drug Reactions, and Drug Toxicity

Pharmacogenetics
- Biologic Variations
- Tolerance and Tachyphylaxis
- Placebo Effect

Drug Interactions
- Pharmacokinetic Interactions
- Pharmacodynamic Interactions

Drug-Nutrient Interactions

Drug-Laboratory Interactions

Drug-Induced Photosensitivity
- Nursing Process: Patient-Centered Collaborative Care—Pharmacokinetic, Pharmacodynamic, and Pharmacogenetic Considerations

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Differentiate the three phases of drug action.
- Describe the four processes of pharmacokinetics.
- Identify the four receptor families.
- Describe the influence of protein binding on drug bioavailability.
- Check drugs for half-life, percentage of protein binding, therapeutic index, and side effects in a drug reference book.

- Anticipate potential unique responses to drugs based on biologic variations.
- Differentiate the four types of drug interactions.
- Explain the three mechanisms involved with drug-drug interactions.
- Describe the effects of drug-nutrient interactions.
- Explain the meaning of drug-induced photosensitivity.
- Describe the nursing implications of pharmacokinetics and pharmacodynamics.

tolerance, p. 23
trough drug level, p. 20

http://evolve.elsevier.com/McCuistion/pharmacology
Once a drug is administered, it goes through two phases, the pharmacokinetic phase and the pharmacodynamic phase. The *pharmacokinetic phase,* or what the body does to the drug, describes the movement of the drug through the body. It is composed of four processes: (1) absorption, (2) distribution, (3) metabolism (biotransformation), and (4) excretion (elimination). The *pharmacodynamic phase,* or what the drug does to the body, involves receptor binding, postreceptor effects, and chemical reactions. A biologic or physiologic response results from the pharmacodynamic phase.

Pharmacokinetics

Pharmacokinetics is the process of drug movement throughout the body that is necessary to achieve drug action. The four processes are absorption, distribution, metabolism (or biotransformation), and excretion (or elimination).

Drug Absorption

Drug **absorption** is the movement of the drug into the bloodstream after administration. Approximately 80% of drugs are taken by mouth (enteral). For the body to utilize drugs taken by mouth, a drug in solid form (e.g., tablet or capsule) must disintegrate into small particles and combine with a liquid to form a solution, a process known as *dissolution* (drugs in liquid form are already in solution), in order to be absorbed from the gastrointestinal (GI) tract into the bloodstream. Unlike drugs taken by mouth, parenteral drugs such as eyedrops, eardrops, nasal sprays, respiratory inhalants, transdermal drugs, and sublingual drugs do not pass through the GI tract.

Tablets are not 100% drug. Fillers and inert substances—such as simple syrup, vegetable gums, aromatic powder, honey, and various elixirs—called excipients are used in drug preparation to allow the drug to take on a particular size and shape and to enhance drug dissolution. Some excipients, such as the ions potassium (K+) in penicillin potassium and sodium (Na+) in penicillin sodium, increase the absorbability of the drug. Penicillin is poorly absorbed by the GI tract because of gastric acid. However, by adding potassium or sodium salts, penicillin can be absorbed.

Disintegration is the breakdown of an oral drug into smaller particles. The rate of dissolution is the time it takes the drug to disintegrate and dissolve to become available for the body to absorb it. Drugs in liquid form are more rapidly available for GI absorption than are solids. Generally, drugs are both disintegrated and absorbed faster in acidic fluids with a pH of 1 or 2 rather than in alkaline fluids (those with a pH greater than 7). Both the very young and older adults have less gastric acidity, therefore drug absorption is generally slower for those drugs absorbed primarily in the stomach.

Enteric-coated (EC) drugs resist disintegration in the gastric acid of the stomach, so disintegration does not occur until the drug reaches the alkaline environment of the small intestine. EC tablets can remain in the stomach for a long time, therefore their effect may be delayed in onset. EC tablets or capsules and sustained-release (beaded) capsules should not be crushed because crushing alters the place and time of absorption of the drug. Food in the GI tract may interfere with the dissolution of certain drugs. Some drugs irritate the gastric mucosa, so fluids or food may be necessary to dilute the drug concentration and provide protection.

Most oral drugs enter the bloodstream following absorption across the mucosal lining of the small intestine. The epithelial lining of the small intestine is covered with villi, fingerlike protrusions that increase the surface area available for absorption. Absorption is reduced if the villi are decreased in number because of disease, drug effect, or the removal of some or all of the small intestine.

Absorption across the mucosal lining of the small intestine occurs through passive transport, active transport, or pinocytosis. **Passive transport** occurs through two processes, diffusion and facilitated diffusion. In **diffusion** drugs move across the cell membrane from an area of higher concentration to one of lower concentration. **Facilitated diffusion** relies on a carrier protein to move the drug from an area of higher concentration to an area of lower concentration. Passive transport does not require energy to move drugs across the membrane. **Active transport** requires a carrier, such as an enzyme or protein, to move the drug against a concentration gradient. Energy is required for active absorption (Fig. 2.1). **Pinocytosis** is a process by which cells carry a drug across their membrane by engulfing the drug particles in a vesicle.

The mucous membrane that lines the GI tract is composed of lipids (fat) and protein such that lipid-soluble drugs are able to pass rapidly through the mucous membrane. Water-soluble drugs need a carrier, either an enzyme or a protein, to pass through the mucous membrane. Large particles are able to pass through the mucous membrane if they are nonionized (have no positive or negative charge). Drugs that are lipid soluble and nonionized are absorbed faster than water-soluble and ionized drugs.

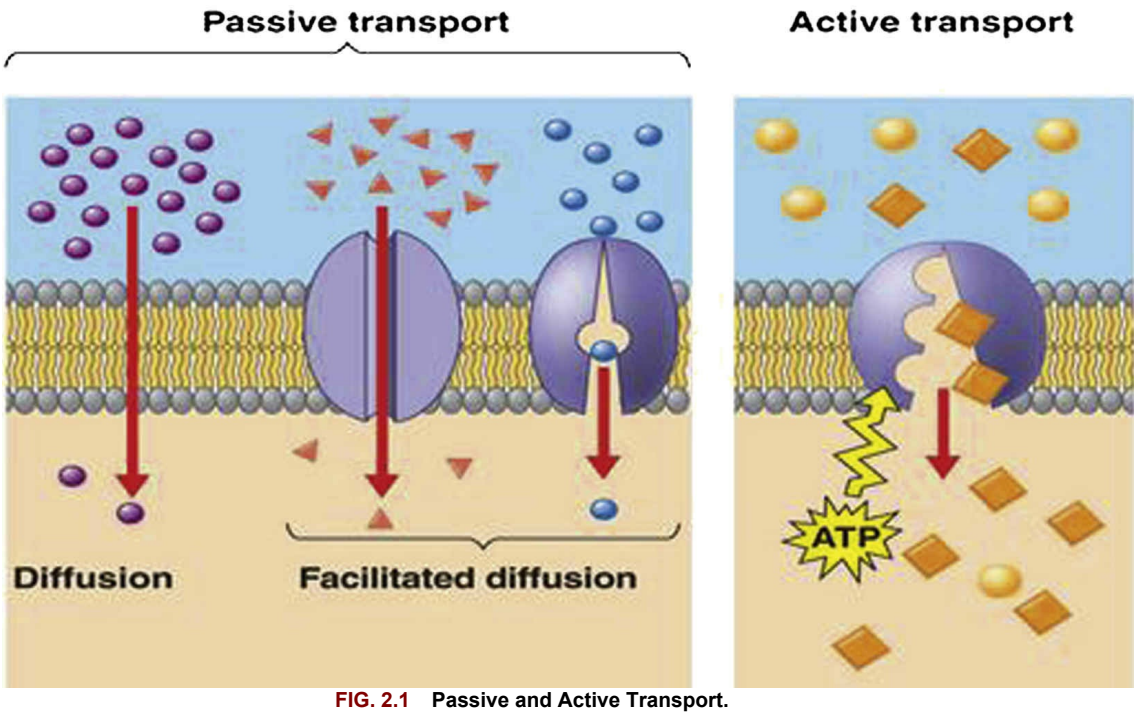

FIG. 2.1 Passive and Active Transport.
ATP, Adenosine triphosphate. Copyright 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings.

Blood flow, pain, stress, hunger, fasting, food, and pH affect drug absorption. Poor circulation to the stomach as a result of shock, vasoconstrictor drugs, or disease hampers absorption. Pain, stress, and foods that are solid, hot, or high in fat can slow gastric emptying time, so drugs remain in the stomach longer. Exercise can decrease gastric blood flow by shunting blood flow to peripheral muscles, thereby decreasing blood circulation to the GI tract.

Drugs given intramuscularly are absorbed faster in muscles that have increased blood flow (e.g., deltoid) than in those that do not (e.g., gluteus maximus). Subcutaneous tissue has decreased blood flow when compared with muscle, so absorption is slower when drugs are given subcutaneously. However, drugs that are given subcutaneously have a more rapid and predictable rate of absorption than those given by mouth.

Drugs given rectally are absorbed slower than drugs administered by the oral route. Absorption is slower because the surface area in the rectum is smaller than the stomach, and it has no villi. Additionally, the composition of the suppository base (e.g., fatty bases or water-soluble bases) affects drug absorption.

Following absorption of oral drugs from the GI tract, they pass from the intestinal lumen to the liver via the portal vein. In the liver, some drugs are metabolized to an inactive form and are excreted, thus reducing the amount of active drug available to exert a pharmacologic effect. This is referred to as the **first-pass effect** or *first-pass metabolism*. Most oral drugs are affected to some degree by first-pass metabolism. Lidocaine and some nitroglycerines, for example, are not given orally because they have extensive first-pass metabolism, and most of the drug is inactivated.

Bioavailability refers to the percentage of administered drug available for activity. For orally administered drugs, bioavailability is affected by absorption and first-pass metabolism. The bioavailability of oral drugs is always less than 100% and varies based on the rate of first-pass metabolism (i.e., the bioavailability of rosuvastatin is 20%, whereas the bioavailability of digoxin ranges from 70% to 85%). The bioavailability of intravenous (IV) drugs is 100%.

Factors that alter bioavailability include the (1) drug form, such as tablet, capsule, sustained-release beads, liquid, transdermal patch, suppository, or inhalation; (2) route of administration (e.g., enteral, topical, or parenteral); (3) gastric mucosa and motility; (4) administration with food and other drugs; and (5) changes in liver metabolism caused by liver dysfunction or inadequate hepatic blood flow. A decrease in liver function or a decrease in hepatic blood flow can increase the bioavailability of a drug, but only if the drug is metabolized by the liver. Less drug is destroyed by hepatic metabolism in the presence of a liver disorder.

Drug Distribution

Distribution is the movement of the drug from the circulation to body tissues. Drug distribution is influenced by the rate of blood flow to the tissue, the drug's affinity to the tissue, and **protein binding** (Fig. 2.2).

Protein Binding

As drugs are distributed in the plasma, many bind with plasma proteins (albumin, lipoproteins, and alpha-1-acid-glycoprotein [AGP]). Acidic drugs such as aspirin and methotrexate and neutral drugs such as nortriptyline bind with albumin or lipoproteins; however, basic drugs (morphine, amantadine) bind to AGP. Drugs that are more than 90% bound to protein are known as *highly protein-bound drugs* (e.g., warfarin, glyburide, sertraline, furosemide, and diazepam); drugs that are less than 10% bound to protein are *weakly protein-bound drugs* (e.g., gentamycin, metformin, metoprolol, and lisinopril). The portion of the drug bound to protein is inactive because it is not available to interact with tissue receptors and therefore is unable to exert a pharmacologic effect. The portion that remains unbound is free, active drug. **Free drugs** are able to exit blood vessels and reach their site of action, causing a pharmacologic response.

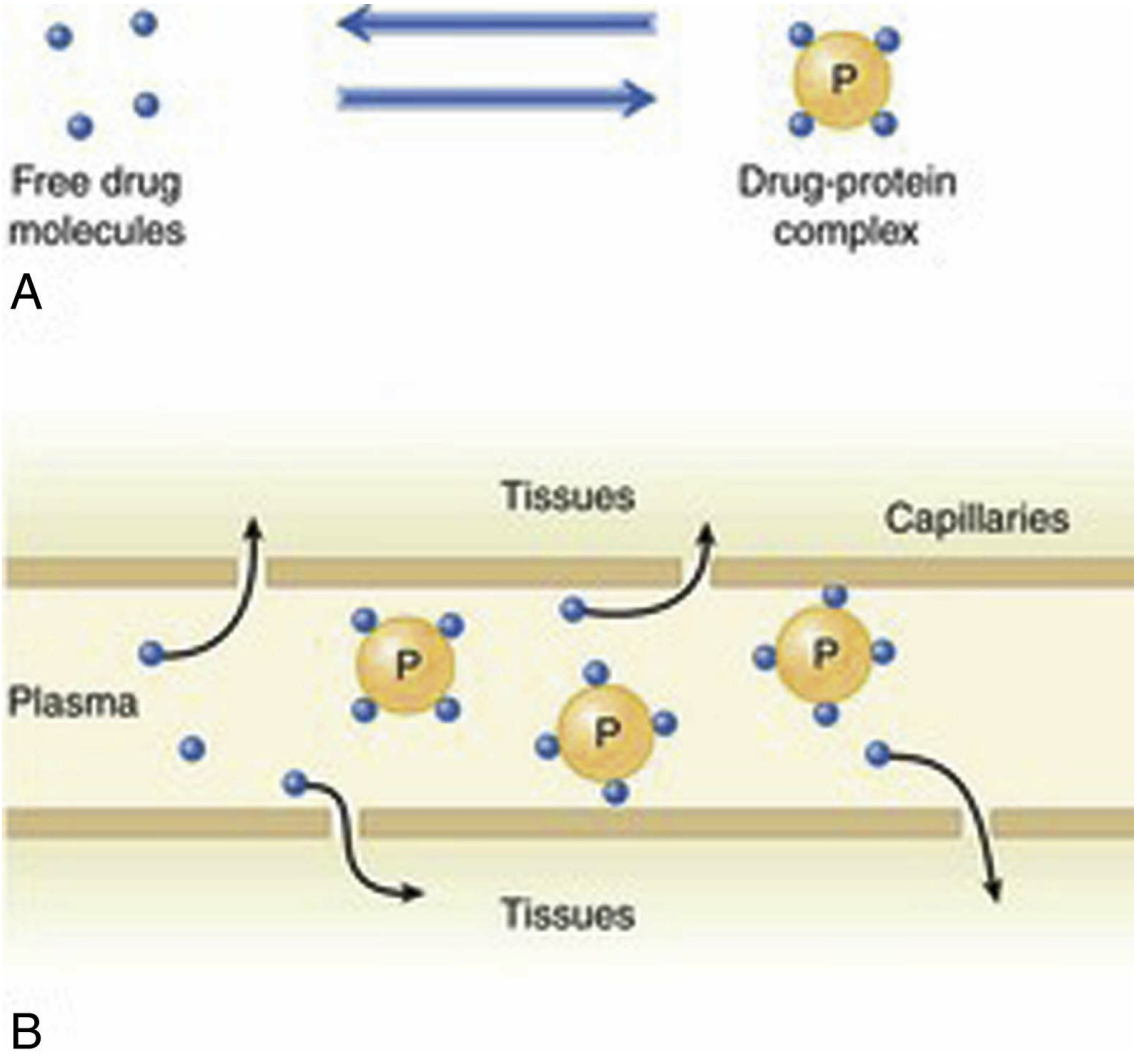

FIG. 2.2 Protein Binding.
P, Protein. From *Pharmacokinetics—objectives* (chap. 4). Retrieved January 1, 2016, from https://quizlet.com/21147360/pharmacology-4-pharmacokinetics-objectives-flash-cards/

When two highly protein-bound drugs are administered together, they compete for protein-binding sites, leading to an increase in free drug being released into the circulation. For example, if warfarin (99% protein bound) and furosemide (95% protein bound) were administered together, warfarin—the more highly bound drug—could displace furosemide from its binding site. In this situation, it is possible for drug accumulation to occur and for toxicity to result. Another factor that may alter protein binding is low plasma protein levels, which potentially decrease the number of available binding sites and can lead to an increase in the amount of free drug available, resulting in drug accumulation and toxicity. Patients with liver or kidney disease and those who are malnourished may have significantly lower serum albumin levels. Additionally, older adults are more likely to have hypoalbuminemia, particularly if they have multiple chronic illnesses. With these factors in mind, it is important for nurses to understand the concept of protein binding and check their patient's protein and albumin levels when administering drugs.

Blood vessels in the brain have a special endothelial lining where the cells are pressed tightly together (*tight junctions*); this lining is referred to as the **blood-brain barrier (BBB)**. The BBB protects the brain from foreign substances, which includes about 98% of the drugs on the market. Some drugs that are highly lipid soluble and of low molecular weight (e.g., benzodiazepines) are able to cross the BBB through diffusion, and others cross via transport proteins. Water-soluble drugs (e.g., atenolol and penicillin) and drugs that are not bound to transport proteins (free drugs) are not able to cross the BBB, which makes it difficult for these drugs to reach the brain (Fig. 2.3).

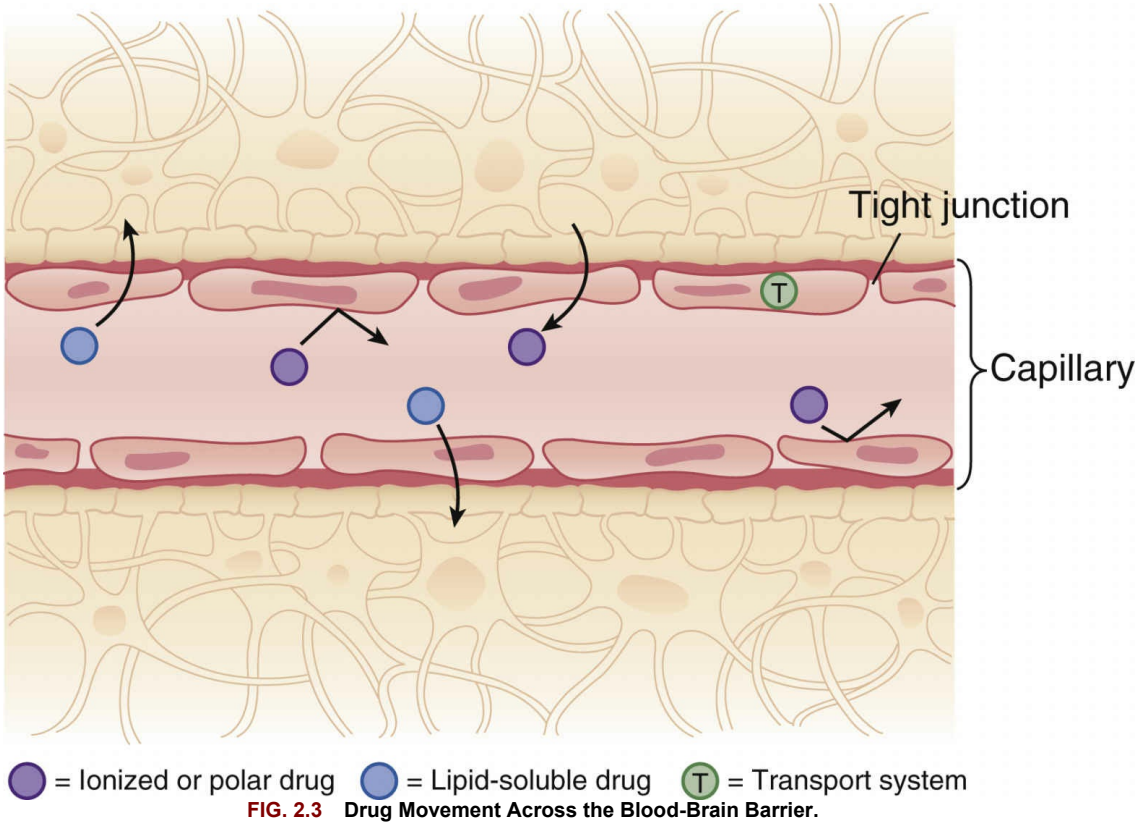

FIG. 2.3 **Drug Movement Across the Blood-Brain Barrier.**

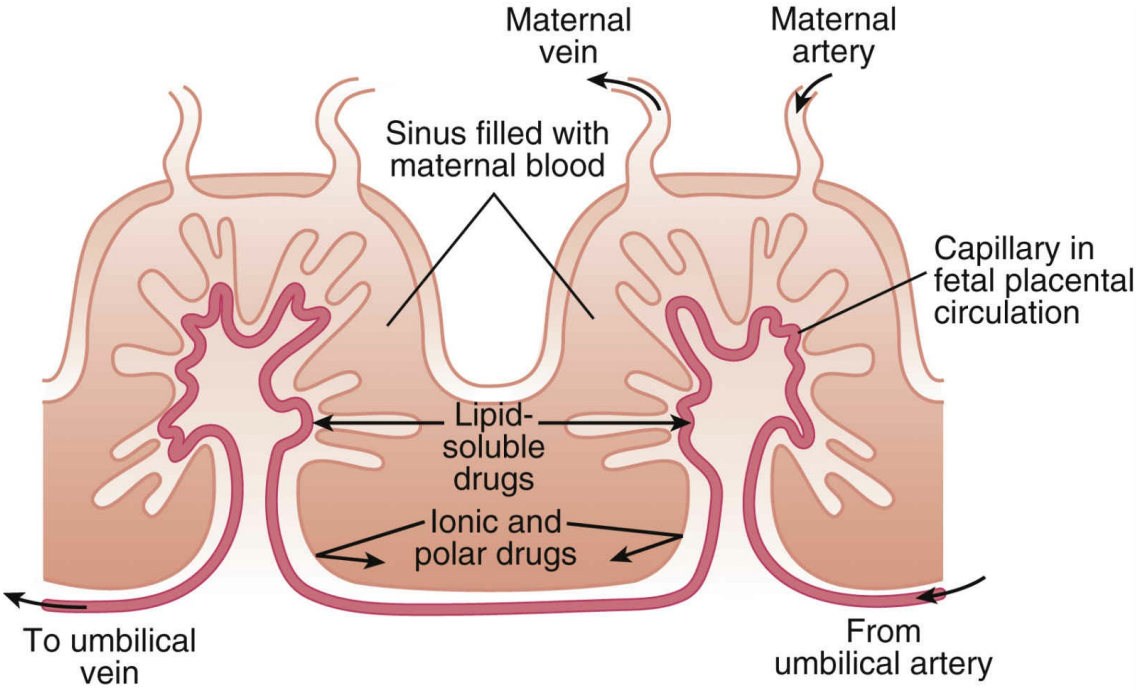

FIG. 2.4 **Drug Crossing the Placenta.**

During pregnancy, drugs can cross the placenta much as they do across other membranes, and this affects both the fetus and the mother (Fig. 2.4). Drugs taken during the first trimester can lead to spontaneous abortion. During the second trimester, drugs can lead to spontaneous abortion, teratogenesis, or other subtler defects. During the third trimester, drugs may alter fetal growth and development. The risk-benefit ratio should be considered before any drugs are given during

pregnancy. During breastfeeding, drugs can pass into breast milk, which can affect the nursing infant. Nurses must teach women who breastfeed to consult their health care provider prior to taking any drug—whether over the counter (OTC) or prescribed—or any herb or supplement.

Drug Metabolism

Metabolism, or **biotransformation**, is the process by which the body chemically changes drugs into a form that can be excreted. The liver is the primary site of metabolism. Liver enzymes—collectively referred to as the *cytochrome P450 system*, or the *P450 system,* of drug-metabolizing enzymes—convert drugs to metabolites. A large percentage of drugs are lipid soluble, thus the liver metabolizes the lipid-soluble drug substance to a water-soluble substance for renal excretion. However, some drugs are transformed into active metabolites, causing an increased pharmacologic response. Liver diseases such as cirrhosis and hepatitis alter drug metabolism by inhibiting the drug-metabolizing enzymes in the liver. When the drug metabolism rate is decreased, excess drug accumulation can occur and can lead to toxicity.

The drug **half-life** ($t½$) is the time it takes for the amount of drug in the body to be reduced by half. The amount of drug administered, the amount of drug remaining in the body from previous doses, metabolism, and elimination affect the half-life of a drug. For example, with liver or kidney dysfunction, the half-life of the drug is prolonged, and less drug is metabolized and eliminated.

A drug goes through several half-lives before complete elimination occurs, and drug half-life is used to determine dosing interval. This is best understood with an example: Ibuprofen has a half-life of about 2 hours. If a person takes 200 mg, in 2 hours, 50% of the drug will be gone, leaving 100 mg. Two hours later, another 50% of the drug will be gone, this time leaving 50 mg; in another 2 hours, 50% more will be gone, so only 25 mg will remain. This process continues such that 10 hours after 200 mg of ibuprofen has been taken, if no additional doses are administered, 6.25 mg of the drug remains.

By knowing the half-life, the time it takes for a drug to reach a **steady state** (plateau drug level) can be determined. A steady state occurs when the amount of drug being administered is the same as the amount of drug being eliminated; a steady state of drug concentration is necessary to achieve optimal therapeutic benefit. This takes about four half-lives, if the size of all doses is the same. For example, digoxin—which has a half-life of 36 hours with normal renal function—takes approximately 6 days to reach a steady state concentration.

Loading Dose

However, in the case of drugs with long half-lives, it may not be acceptable to wait for a steady state to be achieved. Take, for example, the case of a person with seizures receiving phenytoin. The half-life of phenytoin is approximately 22 hours; if all doses of the drug were the same, steady state would not be achieved for about 3½ days. By giving a large initial dose, known as a **loading dose**, that is significantly higher than maintenance dosing, therapeutic effects can be obtained while a steady state is reached.

Drug Excretion

The main route of drug **excretion**, elimination of drugs from the body, is through the kidneys. Drugs are also excreted through bile, the lungs, saliva, sweat, and breast milk. The kidneys filter free drugs (in healthy kidneys, drugs bound to protein are not filtered), water-soluble drugs, and drugs that are unchanged. The lungs eliminate volatile drug substances, and products metabolize to carbon dioxide (CO_2) and water (H_2O).

The urine pH influences drug excretion. Normal urine pH varies from 4.6 to 8.0. Acidic urine promotes elimination of weak base drugs, and alkaline urine promotes elimination of weak acid drugs. Salicylic acid (aspirin), a weak acid, is excreted rapidly in alkaline urine. Treatment of salicylate toxicity includes IV administration of sodium bicarbonate to increase urine pH to 8.0 or higher (alkaline); maintaining alkaline urine promotes the excretion of salicylate at 18 times the normal rate.

Prerenal, intrarenal, and postrenal conditions affect drug excretion. Prerenal conditions, such as dehydration or hemorrhage, reduce blood flow to the kidney and result in decreased glomerular filtration. Intrarenal conditions, such as glomerulonephritis and chronic kidney disease (CKD),

affect glomerular filtration and tubular secretion and reabsorption. Postrenal conditions that obstruct urine flow—such as prostatic hypertrophy, stones, and neurogenic bladder—adversely affect glomerular filtration. With any of these situations, drug accumulation may occur, resulting in adverse drug reactions.

Common tests used to determine renal function include creatinine and blood urea nitrogen (BUN). Creatinine is a metabolic by-product of muscle that is excreted by the kidneys; urea nitrogen is the metabolic breakdown product of protein metabolism. Based on National Kidney Foundation recommendations, the estimated glomerular filtration rate (eGFR) is now calculated as part of routine comprehensive metabolic panels (CMPs) and basic metabolic panels (BMPs). The eGFR is calculated using the person's creatinine level, age, body size, and gender. Decreased eGFR is expected in older adult and female patients because of their decreased muscle mass. It is important for nurses to know their patient's kidney function to ensure correct drug dosage.

Pharmacodynamics

Pharmacodynamics is the study of the effects of drugs on the body. Drugs act within the body to mimic the actions of the body's own chemical messengers. Drug response can cause a primary or secondary physiologic effect or both. A drug's primary effect is the desirable response, and the secondary effect may be desirable or undesirable. An example of a drug with a primary and secondary effect is diphenhydramine, an antihistamine. The primary effect of diphenhydramine is to treat the symptoms of allergy; the secondary effect is a central nervous system (CNS) depression that causes drowsiness. The secondary effect is undesirable when the patient drives a car, but at bedtime it could be desirable because it causes mild sedation.

Dose-Response Relationship

The **dose-response relationship** is the body's physiologic response to changes in drug concentration at the site of action. Two concepts further describe this relationship. **Potency** refers to the amount of drug needed to elicit a specific physiologic response to a drug. A drug with high potency, such as fentanyl, produces significant therapeutic responses at low concentrations; a drug with low potency, such as codeine, produces minimal therapeutic responses at low concentrations. The point at which increasing a drug's dosage no longer increases the desired therapeutic response is referred to as **maximal efficacy** (Fig. 2.5).

Closely related to dose-response and efficacy is the **therapeutic index (TI)**, which describes the relationship between the *therapeutic dose* of a drug (ED_{50}) and the *toxic dose* of a drug (TD_{50}). ED_{50} is the dose of a drug that produces a therapeutic response in 50% of the population; TD_{50} is the dose of a drug that produces a toxic response in 50% of the population. The therapeutic index is the difference between these two points (Fig. 2.6). If the ED_{50} and TD_{50} are close, the drug is said to have a narrow therapeutic index. Drugs with a narrow therapeutic index—such as warfarin, digoxin, and phenytoin—require close monitoring to ensure patient safety.

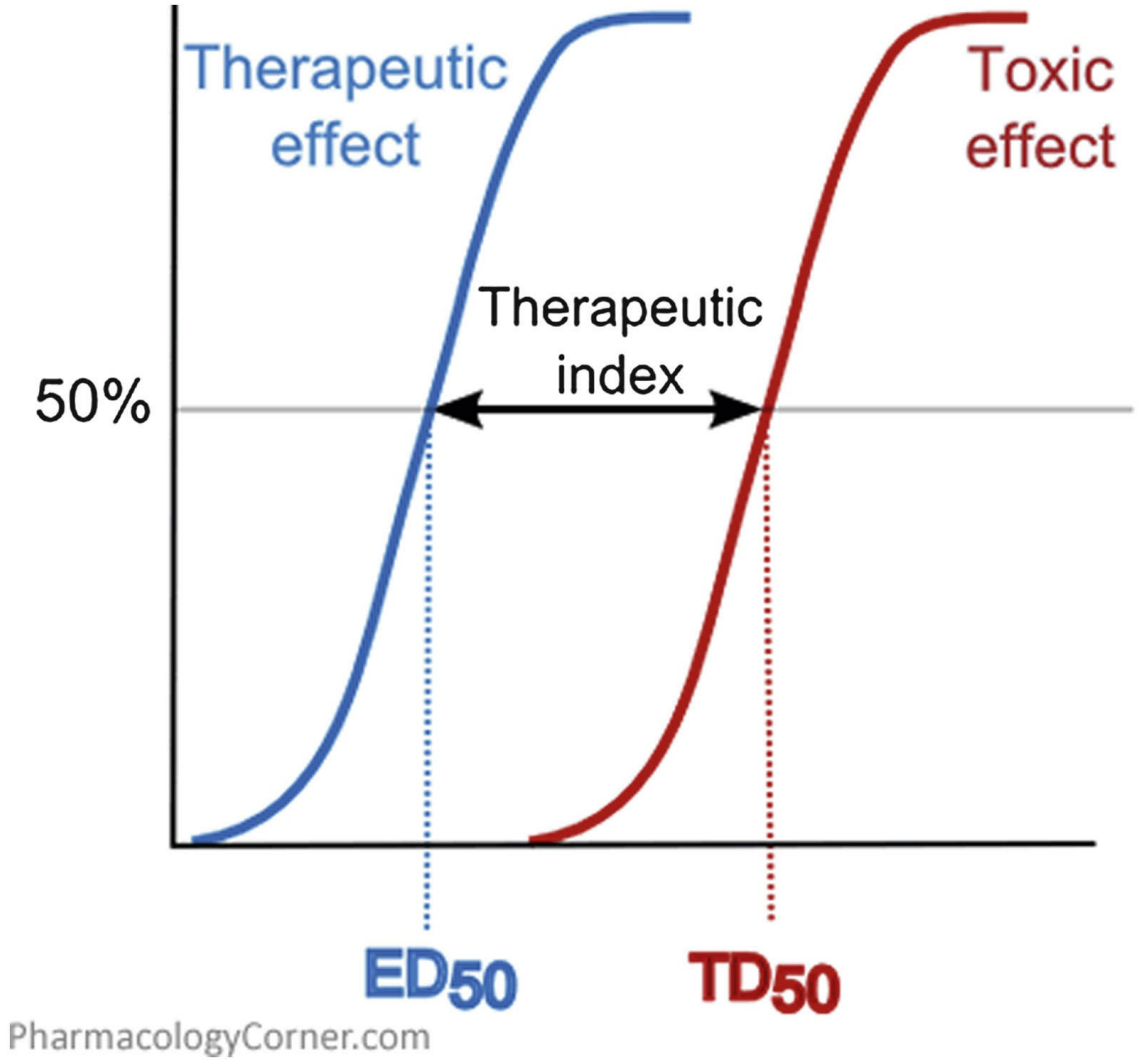

FIG. 2.6 The Therapeutic Index.
The therapeutic index is the ratio between the toxic dose of a drug and the therapeutic dose of a drug. From Guzman, F. (n.d.). *Pharmacology corner.* Retrieved on January 1, 2016, from http://pharmacologycorner.com/therapeutic-index/.

Onset, Peak, and Duration of Action

Other important aspects of pharmacodynamics to understand include a drug's onset, peak, and duration of action. **Onset** is the time it takes for a drug to reach the minimum effective concentration (MEC) after administration. A drug's **peak** occurs when it reaches its highest concentration in the blood. **Duration of action** is the length of time the drug exerts a therapeutic effect. Fig. 2.7 illustrates the areas in which onset, peak, and duration of action occur.

It is necessary to understand this information in relation to drug administration. Some drugs produce effects in minutes, but others may take hours or days. If the drug plasma concentration decreases below the MEC, adequate drug dosing is not achieved; too high of a drug concentration can result in toxicity.

Therapeutic Drug Monitoring

Once steady state has been achieved, drug concentration can be determined by measuring peak and trough drug levels. Peak and trough levels are requested for drugs that have a narrow therapeutic index and are considered toxic.

The **peak drug level** is the highest plasma concentration of drug at a specific time, and it

indicates the rate of drug absorption. If the peak is too low, effective concentration has not been reached. If the drug is given orally, the peak time is usually 2 to 3 hours after drug administration. If the drug is given intravenously, the peak time is usually 30 to 60 minutes after the infusion is complete. If the drug is given intramuscularly, the peak time is usually 2 to 4 hours after injection. If a peak drug level is ordered, a blood sample should be drawn at the appropriate peak time based on the route of administration.

Most drugs only require trough concentration levels to be drawn (the exception is aminoglycoside antibiotics, which require both peak and trough levels). The **trough drug level** is the lowest plasma concentration of a drug, and it measures the rate at which the drug is eliminated. Trough levels are drawn just prior to the next dose of drug regardless of route of administration.

Receptor Theory

Drugs act by binding to receptors. Binding of the drug may activate a receptor, producing a response, or it may inactivate a receptor, blocking a response. The activity of many drugs is determined by the ability of the drug to bind to a specific receptor. The better the drug fits at the receptor site, the more active the drug is. Drug-receptor interactions are similar to the fit of the right key in a lock. Fig. 2.8 illustrates a drug binding to a receptor.

Most **receptors**, which are protein in nature, are found on cell surface membranes or within the cell itself. Drug-binding sites are primarily on proteins, glycoproteins, proteolipids, and enzymes. The four receptor families (Fig. 2.9) include (1) cell membrane–embedded enzymes, (2) ligand-gated ion channels, (3) G protein–coupled receptor systems, and (4) transcription factors. The **ligand-binding domain** is the site on the receptor at which drugs bind.

- *Cell membrane–embedded enzymes.* The ligand-binding domain for drug binding is on the cell surface. The drug activates the enzyme inside the cell, and a response is initiated.
- *Ligand-gated ion channels.* The channel crosses the cell membrane. When the channel opens, ions flow into and out of the cells. This primarily affects sodium and calcium ions.
- *G protein–coupled receptor systems.* The three components to this receptor response are (1) the receptor, (2) the G protein that binds with guanosine triphosphate (GTP), and (3) the effector, which is either an enzyme or an ion channel. The system works as follows:

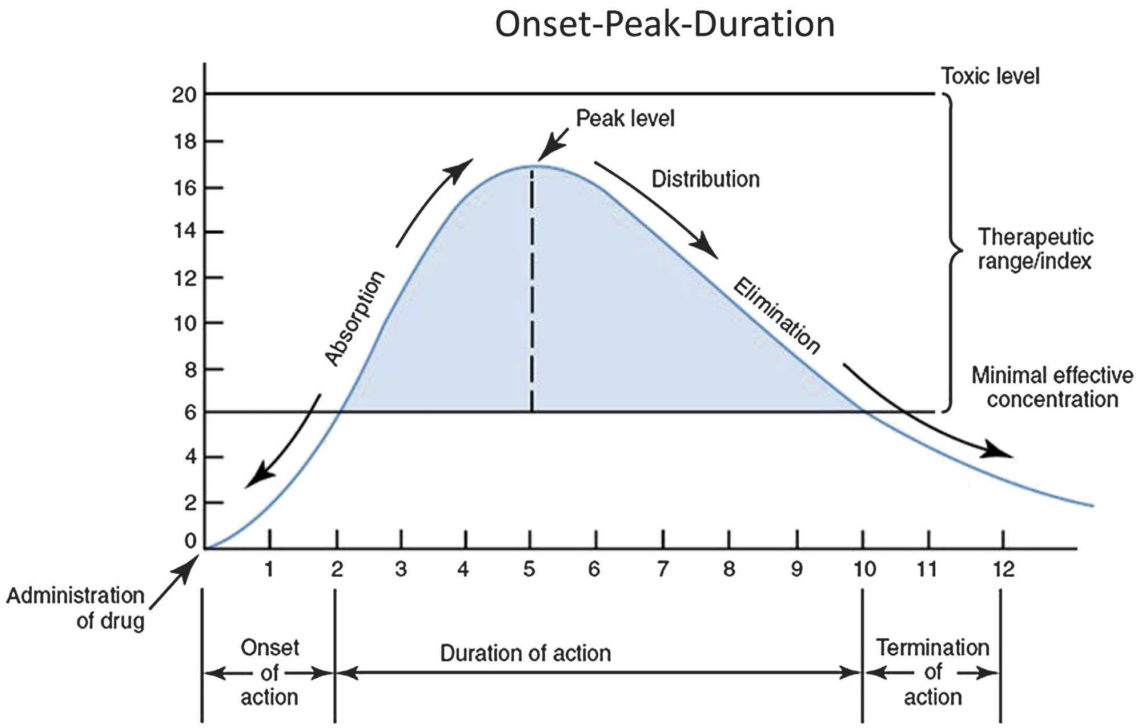

FIG. 2.7 Onset, Peak, and Duration of Action.

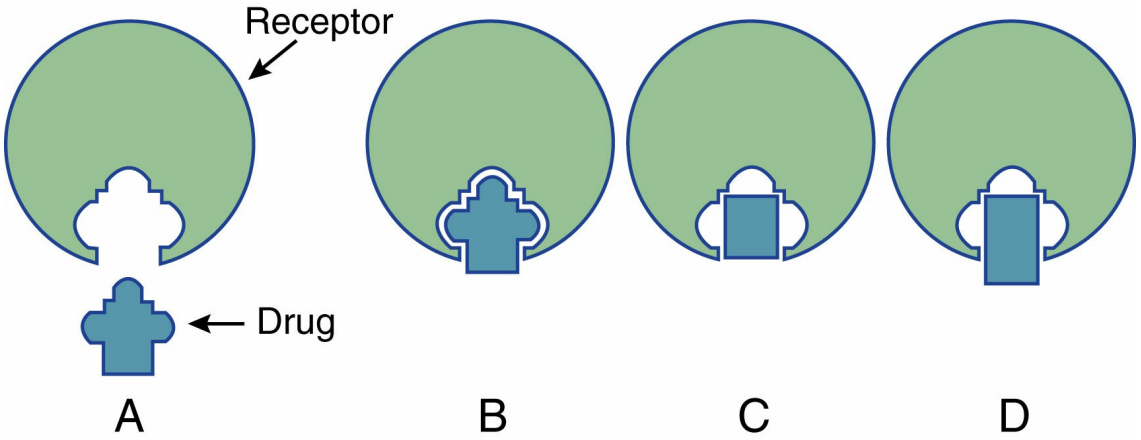

FIG. 2.8 A, Drugs act by forming chemical bonds with specific receptor sites, similar to a key and lock. B, The better the fit, the better the response. Drugs with complete attachment and response are called *agonists*. C, Drugs that attach but do not elicit a response are called antagonists. D, Drugs that attach and elicit a small response but also block other responses are called partial agonists. From Clayton, B. D. & Willihnganz, M. J. (2017). *Basic pharmacology for nurses* (17th ed). St. Louis: Elsevier.

drug $\xrightarrow{\text{activates}}$ receptors $\xrightarrow{\text{activates}}$ G protein $\xrightarrow{\text{activates}}$ effect

- *Transcription factors.* Found in the cell nucleus on DNA, not on the surface. Activation of receptors through transcription factors regulates protein synthesis and is prolonged. With the first three receptor groups, activation of the receptors is rapid.

Agonists and Antagonists

Drugs that activate receptors and produce a desired response are called **agonists**. Drugs that prevent receptor activation and block a response are called **antagonists**. Blocking receptor activation either increases or decreases cellular action, depending on the endogenous action of the chemical messenger that is blocked.

Nonspecific and Nonselective Drug Effects

Many agonists and antagonists lack specific and selective effects. Receptors produce a variety of physiologic responses, depending on where the receptor is located. Cholinergic receptors are located in the bladder, heart, blood vessels, stomach, bronchi, and eyes. A drug that stimulates or blocks the cholinergic receptors affects all anatomic sites. Drugs that affect multiple receptor sites are considered **nonspecific**. For example, bethanechol may be prescribed for postoperative urinary retention to increase bladder contraction. This drug stimulates cholinergic receptors located in the bladder, and urination occurs by strengthening bladder contraction. However, because bethanechol is nonspecific, other cholinergic sites are also affected: the heart rate decreases, blood pressure decreases, gastric acid secretion increases, the bronchioles constrict, and the pupils of the eye constrict (Fig. 2.10). These other effects may be either desirable or harmful.

Some drugs affect multiple receptors, and these are considered **nonselective** drugs. For example, epinephrine, which is used for treatment of anaphylaxis or severe asthma exacerbations, acts on the alpha$_1$, beta$_1$, and beta$_2$ receptors (Fig. 2.11), affecting multiple body systems.

Mechanisms of Drug Action

Mechanisms of drug action include (1) stimulation, (2) depression, (3) irritation, (4) replacement, (5) cytotoxic action, (6) antimicrobial action, and (7) modification of immune status. A drug that stimulates enhances intrinsic activity (e.g., adrenergic drugs that increase heart rate, sweating, and respiratory rate during fight-or-flight response). Depressant drugs decrease neural activity and bodily functions (e.g., barbiturates and opiates). Drugs that irritate have a noxious effect, such as astringents. Replacement drugs such as insulins, thyroid drugs, and hormones replace essential body compounds. Cytotoxic drugs selectively kill invading parasites or cancers. Antimicrobial drugs prevent, inhibit, or kill infectious organisms. Drugs that modify immune status modify, enhance, or depress the immune system (e.g., interferons and methotrexate).

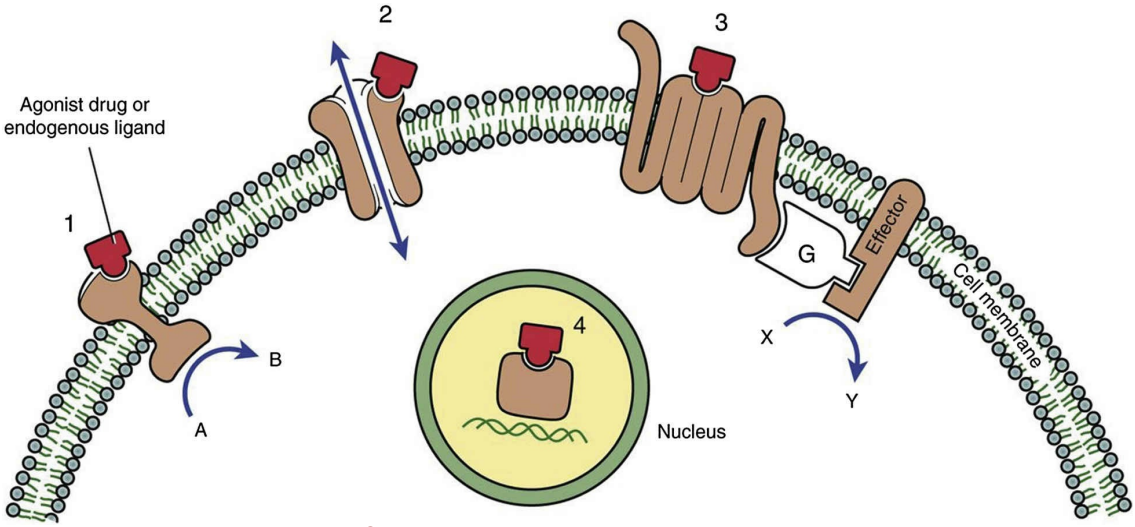

FIG. 2.9 The Four Receptor Families.
The four receptor families are (1) cell membrane–embedded enzymes, (2) ligand-gated ion channels, (3) G protein–coupled receptor systems, and (4) transcription factors. From Burchum, J. & Rosenthal, L. (2016). *Lehne's pharmacology for nursing care* (9th ed). St. Louis: Elsevier.

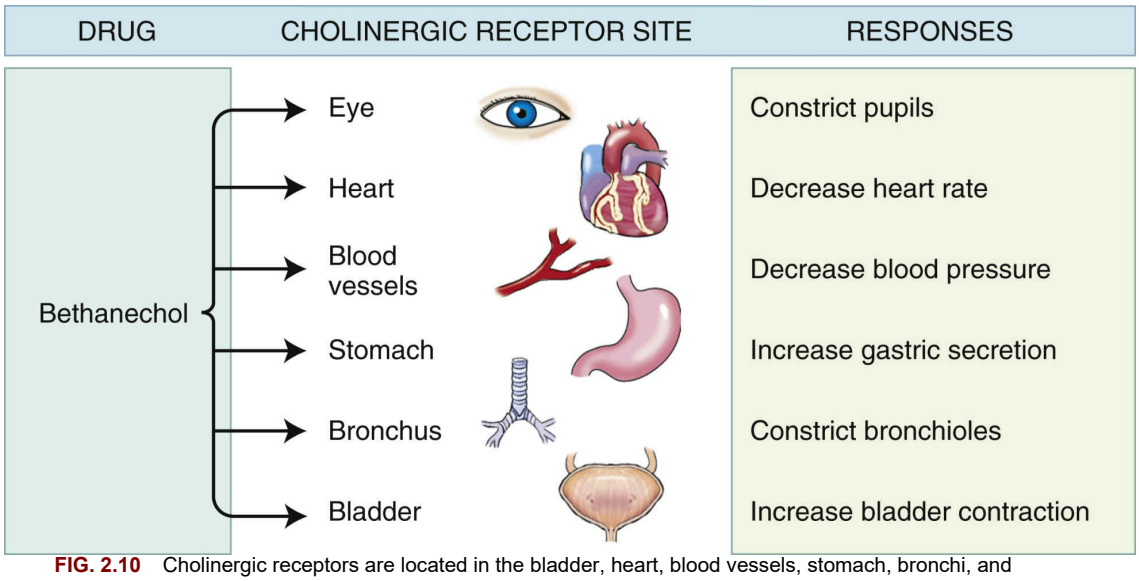

FIG. 2.10 Cholinergic receptors are located in the bladder, heart, blood vessels, stomach, bronchi, and eyes.

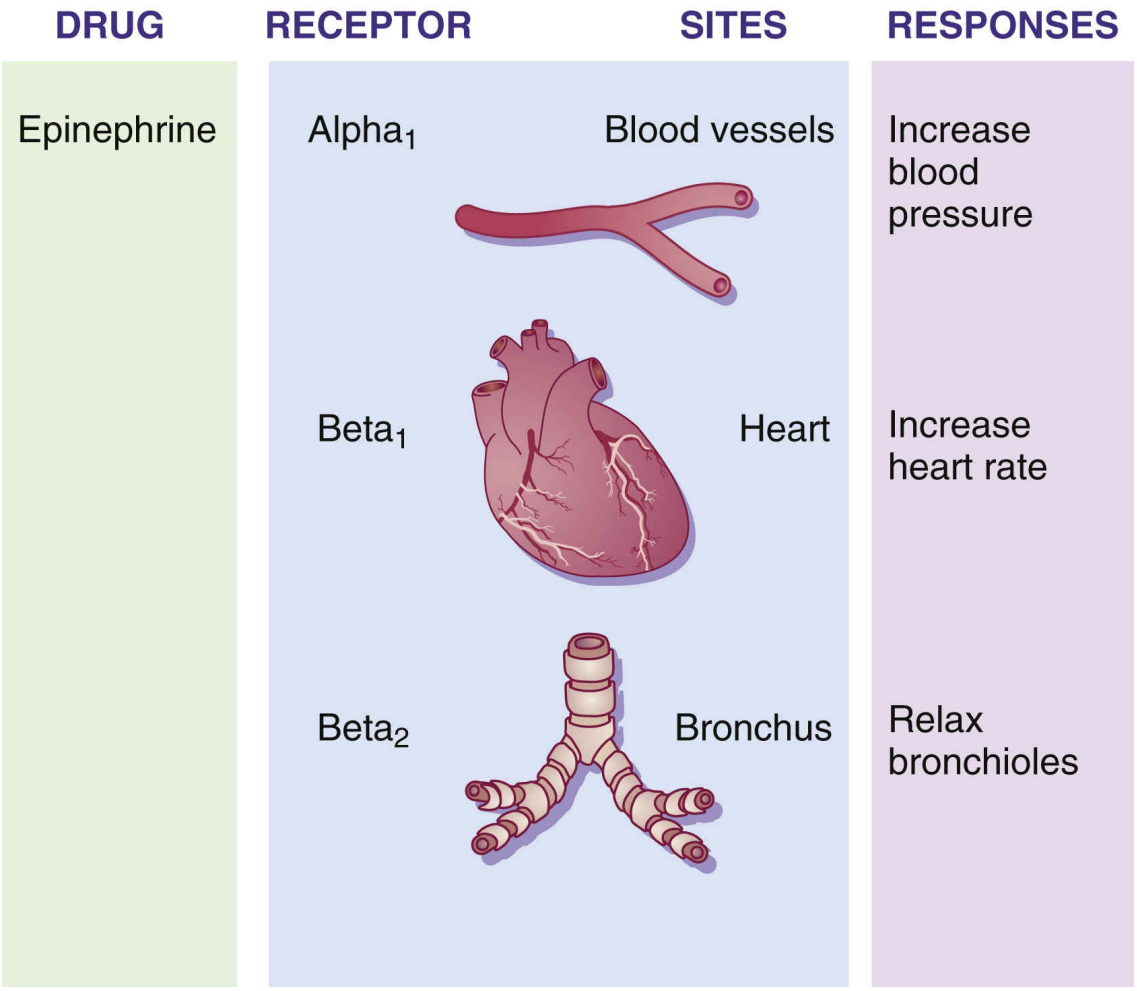

FIG. 2.11 Epinephrine affects three different receptors: alpha$_1$, beta$_1$, and beta$_2$.

Side Effects, Adverse Drug Reactions, and Drug Toxicity

Side effects are secondary effects of drug therapy. All drugs have side effects. Even with correct drug dosage, side effects occur that can be predictable and range from inconvenient to severe or life threatening. In some instances, the side effects may be desirable (e.g., using diphenhydramine at bedtime, when its side effect of drowsiness is beneficial). Chronic illness, age, weight, gender, and ethnicity all play a part in drug side effects.

It is important to know that the occurrence of side effects is one of the primary reasons patients stop taking their prescribed medications. An important role of the nurse includes teaching patients about a drug's side effects and encouraging them to report side effects. Many can be managed with dosage adjustments, changing to a different drug in the same class, or implementing other interventions.

Adverse drug reactions (ADRs) are unintentional, unexpected reactions to drug therapy that occur at normal drug dosages. The reactions may be mild to severe and include anaphylaxis (cardiovascular collapse). Adverse drug reactions are always undesirable and must be reported and documented because they represent variances from planned therapy.

Drug toxicity occurs when drug levels exceed the therapeutic range; toxicity may occur secondary to overdose (intentional or unintentional) or drug accumulation. Factors that influence drug toxicity include disease, genetics, and age.

Pharmacogenetics

Pharmacogenetics refers to the study of genetic factors that influence an individual's response to a specific drug. Genetic factors can alter drug metabolism, resulting in either enhanced or diminished drug response. Nurses must integrate knowledge of pharmacogenetics into their practice in order to identify patients at increased risk for adverse drug reactions, and they must effectively monitor patients for therapeutic drug responses and prevent complications to drug therapy.

Biologic Variations

Through the work of the *Human Genome Project,* an international collaborative research program, the field of pharmacogenomics is rapidly expanding. In the United States, the project is managed by the National Human Genome Research Institute, which is part of the National Institutes of Health (NIH). **Pharmacogenomics** refers to the study of how genetics play a role in a person's response to drugs (absorption, distribution, metabolism, and excretion). Through the use of pharmacogenomics, the goal is to develop *precision medicine*, which uses the person's genetic makeup to determine appropriate drug therapy, thereby improving patient outcomes and safety (Table 2.1).

In 2005, IBM and the National Geographic Society launched the *Genographic Project.* Since then, the Project has performed DNA testing on populations all over the world. Findings reveal that human beings are 99.9% genetically identical; this implies that there are not multiple races but multiple genotypes (an individual's genetic identity).

TABLE 2.1

Terminology Used in Pharmacogenetics

Term	Definition
Genome	Complete genetic material present in a cell
Genotype	The complete genetic constitution of an individual as determined by the specific combination and location of the genes on the chromosomes
Pharmacogenetics	Study of the effect genetic factors have on response to certain drugs.
Pharmacogenomics	A larger scale study of how variations in the human genome affect the response to medications
Phenocopy	An environmentally induced, nonhereditary variation in an organism, closely resembling a genetically determined trait
Phenotype	The observable physical or biochemical characteristics of an organism as determined by both genetic makeup and environmental influences
Polymorphism	The occurrence of different forms, stages, or types in individuals independent of sexual variations

Certain classifications of medications have different effects in individuals with specific genetic markers. For example, 10% of Caucasians have no CYP2D6 enzyme activity (identified as poor metabolizers), the enzyme responsible for metabolizing drugs in a variety of therapeutic categories, such as antidepressants, antipsychotics, and beta blockers. A lack of this enzyme becomes important, for example, when a patient who is a poor metabolizer is prescribed codeine. The CYP2D6 enzyme is necessary to convert codeine to the active metabolite, morphine. Individuals lacking this enzyme will have little to no pain relief when prescribed codeine. Conversely, 30% of Ethiopians are ultrarapid metabolizers, individuals who could experience severe, toxic consequences from taking codeine.

Researchers conducting clinical trials for development of new drugs are now required to obtain genetic testing of the participants in the study. The U.S. Food and Drug Administration (FDA) includes pharmacogenomics information in package inserts of more than 150 drugs. The information relates to "dosage guidance, possible side effects or differences in effectiveness for people with certain genomic variations."

Issues to be resolved before widespread genetic testing can occur include cost-benefit ratio and ethical considerations. Genetic testing is expensive and is generally not covered by third-party payers. Genetic information can affect employment, insurability, and family relationships.

Tolerance and Tachyphylaxis

Tolerance refers to a decreased responsiveness to a drug over the course of therapy; an individual with drug tolerance requires a higher dosage of drug to achieve the same therapeutic response. In contrast, **tachyphylaxis** refers to an acute, rapid decrease in response to a drug; it may occur after the first dose or after several doses. Tachyphylaxis has been demonstrated with drugs such as centrally acting analgesics, nitroglycerine, and ranitidine, to name a few. To provide safe and effective care, nurses must be aware of these potential reasons a patient may fail to respond

therapeutically to drug administration.

Placebo Effect

Placebo effect is a drug response not attributed to the chemical properties of the drug. The response can be positive or negative and may be influenced by the beliefs, attitudes, and expectations of the patient. Although the placebo effect is psychological in origin, the response can be physiologic, resulting in changes in heart rate, blood pressure, and pain sensation.

Drug Interactions

Seventy percent of Americans are taking one or more prescription drugs. Drug therapy is complex because of the great number of drugs available. Drug-drug, drug-nutrient (e.g., food, supplements, alcohol), drug-disease, and drug-laboratory interactions (when a drug interferes with laboratory testing) are an increasing problem. Because of the possibility of numerous interactions, the nurse must be knowledgeable about drug interactions and must closely monitor patient response to drug therapy. Thorough and timely communication among members of the health team is essential. Patients at high risk for interactions include those who have chronic health conditions, take multiple medications, see more than one health care provider, and use multiple pharmacies. Older adults are at especially high risk for drug interactions because 20% of older adults take five or more medications. Multiple drug-interaction checker websites are available on the Internet for both health care personnel and consumer use, such as Drugs.com at www.drugs.com/drug_interactions.html or *Web*MD at www.webmd.com/interaction-checker.

A **drug interaction** is defined as an altered or modified action or effect of a drug as a result of interaction with one or multiple drugs. It should not be confused with drug incompatibility or an adverse drug reaction, an undesirable drug effect that ranges from mild untoward effects to severe toxic effects that include hypersensitivity reaction and anaphylaxis. Drug incompatibility is a chemical or physical reaction that occurs among two or more drugs in vitro. In other words, the reaction occurs between two or more drugs within a syringe, IV bag, or other artificial environment outside of the body.

Drug interactions can be divided into two categories, pharmacokinetic and pharmacodynamic interactions.

Pharmacokinetic Interactions

Pharmacokinetic interactions are changes that occur in the absorption, distribution, metabolism, and excretion of one or more drugs.

Absorption

When a person takes two drugs at the same time, the rate of absorption of one or both drugs can change. A drug can block, decrease, or increase the absorption of another drug. It can do this in one of three ways: (1) by increasing or decreasing gastric emptying time, (2) by changing the gastric pH, or (3) by forming drug complexes.

Drugs that increase the speed of gastric emptying, such as laxatives, may cause an increase in gastric and intestinal motility and a decrease in drug absorption. Most drugs are absorbed primarily in the small intestine; exceptions include barbiturates, salicylates, and theophylline, which undergo gastric absorption. Opioids and anticholinergic drugs such as atropine decrease gastric emptying time and GI motility, causing an increase in absorption rate. For drugs that undergo gastric absorption, the amount or extent of absorption increases the longer the drug remains in the stomach.

When the gastric pH is decreased, a weakly acidic drug such as aspirin is less ionized and is more rapidly absorbed. Drugs that increase the gastric pH decrease absorption of weak-acid drugs. Antacids such as magnesium hydroxide and aluminum hydroxide raise the gastric pH and block or slow absorption. Some drugs may react chemically. For example, tetracycline and the heavy-metal ions calcium, magnesium, aluminum, and iron found in antacids or iron supplements may lead to the formation of a drug complex and thus prevent the absorption of tetracycline. This phenomenon may also be observed when products that contain calcium, magnesium, or iron are ingested with fluoroquinolone antibiotics such as ciprofloxacin. Consequently, dairy products, multivitamins, and antacids should be avoided 1 hour before and 2 hours after tetracycline or ciprofloxacin administration. The nonabsorbable, cholesterol-lowering drug cholestyramine binds with multiple drugs and fat-soluble vitamins (e.g., vitamin K) in the GI tract, resulting in reduced absorption. Vitamin supplementation may be necessary when cholestyramine is prescribed.

At times, the formation of drug complexes is desired; for example, in the case of acute iron poisoning. In this situation, the chelating agent deferoxamine is administered; it binds to the excess iron in the blood so it can be excreted from the body via the kidneys.

GI bacteria account for 70% of the body's microbes. They play a major role in the absorption of drugs and nutrients and in the metabolism of bilirubin, bile acids, cholesterol, and steroid hormones as well as the synthesis of vitamins B and K. GI bacteria help to maintain homeostasis and factor into the overall health and immune status of an individual. Alteration of bacteria normally found in the GI tract (caused by patient genotype, antibiotic treatment, diet, and environment) can affect drug pharmacokinetics. Orally administered drugs can be metabolized by intestinal microbial enzymes, resulting in toxic compounds or reduced drug absorption, which leads to decreased therapeutic response. For example, administration of antibiotics can alter the synthesis of vitamin K, interfering with therapeutic blood levels of the anticoagulant warfarin.

Metabolism

Many drug interactions of metabolism occur with the induction or inhibition of the hepatic microsomal system. A drug can increase the metabolism of another drug by stimulating liver enzymes. These enzymes produce a cascade effect in drug function. Drugs that promote induction of enzymes are called *enzyme inducers.* Some drugs—such as phenobarbital, carbamazepine, and rifampin—are enzyme inducers. Phenobarbital increases the metabolism of most antipsychotics and methylxanthine; phenobarbital, carbamazepine, and rifampin increase the metabolism of warfarin. Increased metabolism promotes drug elimination and decreases plasma concentration of the drug; the result is a decrease in therapeutic drug action. Care must be taken when enzyme inducers are discontinued because less drug is eliminated by hepatic metabolism, and toxicity can result.

Some drugs are enzyme inhibitors. The antiulcer drug cimetidine is an enzyme inhibitor that decreases metabolism of certain drugs (e.g., theophylline, warfarin, phenytoin) and causes an increase in the plasma concentration of these drugs. To avoid toxicity, dosage of these drugs must be reduced. If cimetidine or any enzyme drug inhibitor is discontinued, the dosage of other drugs affected by its administration should be adjusted, and blood levels should be closely monitored.

The use of tobacco and alcohol may have variable effects on drug metabolism. Polycyclic aromatic hydrocarbons found in cigarette smoke induce production of the specific family of enzymes responsible for theophylline metabolism. Chronic cigarette smoking leads to an increase in hepatic enzyme activity and can increase theophylline clearance. Asthmatics who smoke and take theophylline to manage their disease may require an increase in theophylline dosage. With chronic alcohol use, hepatic enzyme activities are increased; with acute alcohol use, metabolism is inhibited.

Natural or herbal products can also impact drug metabolism. St. John's wort, an OTC herbal product used to manage symptoms of depression, induces the metabolism of certain drugs (e.g., warfarin, digoxin, and theophylline). This action potentially decreases the effectiveness of these medications, possibly necessitating a dose increase to sustain efficacy. Flavonoids, a group of naturally occurring compounds found in the juice and pulp of citrus fruits, are potent inhibitors of the metabolism of certain drugs (e.g., carbamazepine, calcium channel blockers, and drugs for erectile dysfunction). Patients who are stabilized on therapeutic doses of these drugs may subject themselves to adverse effects from greater-than-expected drug levels if they eat or drink grapefruit products concurrently with the drug. Table 2.2 describes the effects of drug enzyme inducers and inhibitors.

Excretion

Most drugs are filtered through the glomeruli and are excreted in the urine. With some drugs, excretion occurs in the bile, which passes into the intestinal tract. Drugs can increase or decrease renal excretion and can have an effect on the excretion of other drugs. Drugs that decrease cardiac output decrease blood flow to the kidneys; decreased blood flow results in decreased glomerular filtration rate, which can decrease or delay drug excretion.

Diuretics promote water and sodium excretion from the renal tubules. Furosemide acts on the loop of Henle, and hydrochlorothiazide acts on the distal tubules. Both diuretics decrease reabsorption of water, sodium, and potassium. The renal loss of potassium can result in *hypokalemia,* which can alter the action of some drugs; for example, it can enhance the action of digoxin and can lead to toxicity.

TABLE 2.2

Drugs: Enzyme Inducers and Enzyme Inhibitors

Drug Category	Drug Effect
Drug enzyme inducer	Onset and termination of drug effect is slow, approximately 1 week.
	Drug dosage may need to be increased with use of drug inducer.
	Drug dosage should be adjusted after termination of drug inducer.
	Monitor serum drug levels, especially if the drug has a narrow therapeutic drug range.
Drug enzyme inhibitor	Onset of drug effect usually occurs rapidly.
	Half-life ($t_{1/2}$) of the second drug may be increased, causing a prolonged drug effect.
	Interaction may occur related to the dosage prescribed.
	Disease entities affect drug dosing.
	Monitor serum drug levels, especially if the drug has a narrow therapeutic range.

Two or more drugs that undergo the same route of excretion may compete with one another for elimination from the body. Probenecid, a drug for gout, decreases penicillin excretion by inhibiting the secretion of penicillin in the renal tubules of the kidneys. In some cases, this effect may be desirable to increase or maintain the plasma concentration of penicillin—which has a short half-life—for a prolonged period of time.

Changing urine pH affects drug excretion. The antacid sodium bicarbonate causes the urine to be alkaline. Alkaline urine promotes the excretion of drugs that are weak acids (e.g., aspirin, barbiturates). Drugs that acidify the urine, such as ascorbic acid, promote the excretion of drugs that are weak bases (e.g., amphetamine).

With decreased renal or hepatic function, there is usually an increase in free drug concentration. It is essential to closely monitor these patients for drug toxicity when they take multiple drugs. Checking serum drug levels, a practice known as **therapeutic drug monitoring (TDM)**, is especially important for drugs that have a narrow therapeutic range and are highly protein bound. Digoxin and phenytoin are two drugs that require TDM.

Pharmacodynamic Interactions

Pharmacodynamic interactions are those that result in additive, synergistic, or antagonistic drug effects.

Additive Drug Effects

When two drugs are administered in combination, and the response is increased beyond what either could produce alone, the drug interaction is called an **additive effect**; it is the sum of the effects of the two drugs. Additive effects can be desirable or undesirable. For example, a desirable additive drug effect occurs when a diuretic and a beta blocker are administered for the treatment of hypertension. In combination, these two drugs use different mechanisms to have a more pronounced blood pressure–lowering effect. As another example, aspirin and codeine are two analgesics that work by different mechanisms but can be given together for increased pain relief.

An example of an undesirable additive effect is that from two vasodilators, hydralazine prescribed for hypertension and nitroglycerin prescribed for angina. The result could be a severe hypotensive response. Another example is the interaction of aspirin and alcohol. Aspirin is directly irritating to the stomach; it causes platelet dysfunction, and it inhibits prostaglandin-mediated mucus production of the gastric mucosa that protects the underlying tissues of the stomach. Alcohol disrupts the gastric mucosal barrier and suppresses platelet production. Both aspirin and alcohol can prolong bleeding time and, when taken together, may result in gastric bleeding.

Synergistic Drug Effects and Potentiation

When two or more drugs are given together, one drug can have a **synergistic effect** on another. In other words, the clinical effect of the two drugs given together is substantially greater than that of either drug alone. An example of this is the use of two cytotoxic drugs to reduce individual drug

dosing, thereby decreasing side effects. An example of an undesirable effect occurs when alcohol and a sedative-hypnotic drug such as diazepam are combined. The resultant effect of this example is increased CNS depression.

Some antibiotics have an enzyme inhibitor added to the drug to potentiate the therapeutic effect. Examples are ampicillin with sulbactam and amoxicillin with clavulanate, in which sulbactam and clavulanate potassium are bacterial enzyme inhibitors. Ampicillin and amoxicillin can be given without these inhibitors; however, the desired therapeutic effect may not occur because of the bacterial beta-lactamase, which inactivates the drugs and causes bacterial resistance. The combination of the antibiotic with either sulbactam or clavulanate inhibits bacterial enzyme activity and enhances the effect, or broadens the spectrum of activity, of the antibacterial agent.

Antagonistic Drug Effects

When drugs with **antagonistic effects** are administered together, one drug reduces or blocks the effect of the other. In some situations, antagonistic effects are desirable. In morphine sulfate overdose, naloxone is given as an antagonist to block the narcotic effects of morphine sulfate. This is a beneficial drug interaction of an antagonist. Likewise, in the case of heparin overdose, protamine sulfate is administered to block the effects of heparin.

The most common symptoms of drug-drug interactions include nausea, heartburn, headache, and lightheadedness. Patients should contact their pharmacist or health care provider if they experience any unusual reaction. The most feared interactions are those that result in a dramatic drop in blood pressure or cause a rapid or irregular heart rate. Also of concern are drug interactions that produce toxins capable of damaging vital organs such as the heart or liver. Fortunately, most interactions are not severe or life threatening. Patients should be aware that prescription drugs, OTC drugs, and herbal products can interact with each other. It is a myth that interactions occur only with prescription medications. Severe adverse reactions are highlighted with a boxed warning in the product literature.

Drug-Nutrient Interactions

Food may increase, decrease, or delay the body's pharmacokinetic response to drugs. A classic drug-food interaction occurs when a monoamine oxidase inhibitor (MAOI) antidepressant (e.g., phenelzine) is taken with tyramine-rich foods such as cheese, wine, organ meats, beer, yogurt, sour cream, or bananas. Tyramine is a potent vasoconstrictor, and when taken in conjunction with an MAOI, the result could be a hypertensive crisis. These foods must be avoided when taking MAOIs.

Grapefruit alters the metabolism of many drugs through inhibition of the CYP450-3A4 drug-metabolizing enzyme. This is important because the CYP3A4 substrate is involved in metabolism of roughly 50% of the drugs on the market; grapefruit is known to effect more than 44 drugs, inhibiting metabolism and potentially causing serious adverse drug reactions.

Nutritional deficiencies such as protein-energy malnutrition (PEM) may alter pharmacokinetic processes and drug responses, resulting in toxicity. There are two forms of PEM, kwashiorkor and marasmus. Persons with either form of PEM may have altered pharmacokinetics, such as decreased drug absorption and decreased protein binding, altered volume of distribution and biotransformation, and decreased drug elimination. Because of the risk for toxicity, persons with PEM require careful monitoring and possible changes in drug dosing.

Drug-Laboratory Interactions

Drugs often interfere with clinical laboratory testing by cross-reaction with antibodies, interference with enzyme reactions, or alteration of chemical reactions. Drug-laboratory interactions may lead to misinterpretation or invalidation of test results, resulting in additional health care costs associated with unnecessary repeat laboratory testing or additional testing. Drug-laboratory interactions may also lead to missed or erroneous clinical diagnosis. Health care personnel and consumers can find information related to drug-laboratory interactions on several websites on the Internet, such as RxList at http://www.rxlist.com/script/main/hp.asp.

Drug-Induced Photosensitivity

A drug-induced **photosensitivity** reaction is a skin reaction caused by exposure to sunlight. It is caused most often by the interaction of a drug and exposure to ultraviolet A (UVA) light, which can cause cellular damage; however, ultraviolet B (UVB) light may also contribute to drug-induced photosensitivity reactions.

The two types of photosensitivity reactions are photoallergic and phototoxic. A *photoallergic reaction* occurs when a drug (e.g., sulfonamide) undergoes activation in the skin by ultraviolet light to a compound that is more allergenic than the parent compound. Because it takes time to develop antibodies, photoallergic reactions are a type of delayed hypersensitivity reaction. With a *phototoxic reaction,* a photosensitive drug undergoes photochemical reactions within the skin to cause damage. This type of reaction is not immune mediated. The onset of a phototoxic reaction with erythema can be rapid, occurring within 2 to 6 hours of sunlight exposure.

Both types of reactions are the result of light exposure, but they differ according to the wavelength of light and the photosensitive drug. A phototoxic reaction may be the result of the drug dose, whereas a photoallergic reaction is not and only requires previous exposure, or sensitization, to the offending agent. Examples of drugs that can induce photosensitivity are listed in Table 2.3.

Most photosensitive reactions can be avoided by using sunscreen with a sun protection factor (SPF) greater than 15; avoiding excessive sunlight, especially at the height of the daylight hours; and wearing protective clothing. Decreasing the drug dose may decrease the risk of photosensitivity if treatment is required. It may be necessary, however, to discontinue use of the offending drug.

TABLE 2.3

Examples of Drugs That Cause Drug-Induced Photosensitivity

Oral Drugs	
Antibiotics	Tetracyclines Fluoroquinolones (e.g., ciprofloxacin) Sulfonamides
Nonsteroidal antiinflammatory drugs (NSAIDs)	Ibuprofen Naproxen Ketoprofen Celecoxib
Diuretics	Furosemide Bumetanide Hydrochlorothiazide
Retinoids	Isotretinoin Acitretin
Hypoglycemics	Sulfonylureas (e.g., glipizide, glyburide)
Anticonvulsants	Phenothiazines (e.g., chlorpromazine, fluphenazine) Thioxanthenes (e.g., chlorprothixene)
Other drugs	Amiodarone Diltiazem Quinine Quinidine Hydroxychloroquine Enalapril Dapsone
Topical Agents	
Sunscreens	Benzophenones Para-aminobenzoic acid (PABA) Cinnamates Salicylates
Fragrances	Musk 6-Methylcoumarin
Miscellaneous	5-Fluorouracil (oral and topical) Coal tar

Nursing Process: Patient-Centered Collaborative Care

Pharmacokinetic, Pharmacodynamic, and Pharmacogenetic Considerations

Assessment

- Assess family patterns, economic issues, and cultural patterns that influence compliance with the medical regimen.
- Assess language spoken, literacy level, cognitive level, and use of glasses or other aids.
- Check peak levels and trough levels of drugs as appropriate.
- Detect possible interactions and cumulative or other adverse effects among prescribed medications, self-administered over-the-counter (OTC) products, culturally based home treatments, herbal remedies, and foods.
- Determine whether the patient participates in traditional health practices or complementary

and alternative medical practices.
- Determine renal function by checking for adequate urine output; the guideline is 30 mL/hr for adults.
- Determine the potential for drug interaction problems related to an increased or decreased absorption rate of drugs.
- Determine whether the patient smokes cigarettes.
- Identify all of the patient's current drugs, including prescription and OTC drugs, supplements, herbs, and teas.
- Inquire about the patient's preferences regarding touch, modesty, and personal space.
- Perform a physical exam to identify problems that may affect pharmacokinetics and pharmacodynamics.
- Review all literature provided by drug companies and pharmacies; be sure to check the protein-binding percentage of the drug and any need for therapeutic monitoring.
- Take a thorough patient history to identify factors that may affect drug pharmacokinetics and pharmacodynamics.

Nursing Diagnoses

- Anxiety related to health status, unmet needs, role function and status, heredity
- Deficient Knowledge related to information misinterpretations, unfamiliarity with information resources and cultural differences
- Ineffective Self–Health Management related to complexity of therapeutic regimen, economic difficulties, complexity of health care system and cultural differences
- Ineffective Health Maintenance related to deficient communication skills, insufficient resources, ineffective coping
- Ineffective Protection related to pharmaceutical agents and treatment-related side effects

Planning

- The patient will demonstrate behaviors that decrease the risk for injury.
- The patient will describe the rationale for the therapeutic regimen.
- The patient will discuss blocks to implementing a therapeutic regimen or related fears.
- Effective communication techniques will be utilized.
- The patient will follow a mutually agreed on health maintenance plan.
- The patient will be aware of drug interactions, will avoid drugs that may cause a severe reaction, and will know what to report immediately to the health care provider.
- The patient will effectively manage the therapeutic regimen.
- The patient will not take any OTC drugs without consultation with the health care provider.
- The patient's health care needs will be met within a culturally competent framework.
- The patient will express confidence in his or her personal ability to manage the health situation and remain in control of life.

Nursing Interventions

- Advise patients not to eat high-fat foods before ingesting an enteric-coated tablet; high-fat foods decrease the drug absorption rate.
- Allow patients adequate time with significant members of the social group.
- Anticipate unique responses to drugs based on social, cultural, and biologic influences.
- Consult a pharmacist about the use of a drug-interaction computer program.
- Consult with persons who are knowledgeable about both the patient's culture and mainstream culture.
- Contact the health care provider to assess the need for a drug dose adjustment if one has not been ordered after a drug enzyme inducer has been discontinued.
- If negative side effects of prescribed drugs are a problem, explain that many side effects can be controlled or eliminated.
- Include significant members of the social group in the planning and implementation of patient care.
- Monitor the therapeutic range of drugs that are more toxic or that have a narrow therapeutic range.
- Notify the health care provider of drugs ordered that have antagonistic or opposite effects, such as beta stimulants and beta blockers.

- Recognize drugs of the same category that might have an additive effect. The additive drug effect might be undesirable and could cause a severe physiologic response.
- Recognize the need for patients to exercise control in their environment.
- Reconcile all drugs at discharge and provide a list to the patient; ensure that accurate drug information is available to all health care personnel involved in patient care.
- Simplify therapy.
- Use appropriate persons as translators.
- Use therapeutic communication.

Patient Teaching

- Advise patients not to take OTC drugs with prescribed drugs without first notifying the health care provider.
- Encourage the patient to use one pharmacy.
- Include significant members of the social group, when appropriate, in the drug regimen.
- Remind patients to be cautious about taking herbal products, especially if taking OTC or prescription medications; advise that they check with their health care provider first.
- Use illustrations to explain the drug regimen.

 Cultural Considerations

- Assess for adverse effects that may result from pharmacogenomic variances.
- Incorporate traditional health practices with mainstream prescriptive therapies when appropriate.
- Facilitate adherence to mainstream prescriptive therapies within the patient's social and cultural contexts.
- Provide health information written in the patient's primary language. Medline, an online service of the National Institutes of Health, offers a variety of patient education materials in a number of languages online at www.nlm.nih.gov/medlineplus/languages/languages.html.

Evaluation

- Assess for signs and symptoms of drug side effects and toxicity.
- Evaluate physical, social, and psychological outcomes of prescriptive therapies.
- Evaluate the effectiveness of the drugs.
- Monitor for patient adherence to prescriptive therapies.

Critical Thinking Case Study

The nurse is caring for JM, a patient who was admitted to the hospital with severe migraines. JM has been taking warfarin, a highly protein-bound anticoagulant, for atrial fibrillation. After a thorough evaluation, the neurologist has ordered valproic acid, an antiseizure medication. Valproic acid is also highly protein bound.

1. What nursing diagnosis would be appropriate for this patient?
2. What information needs to be included in the interdisciplinary health/teaching plan for this patient?
3. During a teaching session, the patient shares that he plans to start taking over-the-counter products to boost his energy. What is the nurse's best response to the patient's comment? Explain your answer.

Nclex Study Questions

1. Which components of pharmacokinetics does the nurse need to understand before administering a drug? (Select all that apply.)
   a. Drugs with a smaller volume of drug distribution have a longer half-life.
   b. Oral drugs are dissolved through the process of pinocytosis.
   c. Patients with kidney disease may have fewer protein-binding sites and are at risk for drug toxicity.
   d. Rapid absorption decreases the bioavailability of the drug.
   e. When the drug metabolism rate is decreased, excess drug accumulation can occur, which can cause toxicity.
2. The nurse will question the health care provider if a drug with a half-life ($t½$) of more than 24 hours is ordered to be given more than how often?
   a. Once daily
   b. Every other day
   c. Twice weekly
   d. Once weekly
3. The nurse is explaining drug action to a nursing student. Which statement made by the nurse is correct?
   a. Water-soluble and ionized drugs are quickly absorbed.
   b. A drug not bound to protein is an active drug.
   c. Most receptors are found under the cell membrane.
   d. Toxic effects can result if the trough level is low.
4. A Native American patient is newly diagnosed with type 2 diabetes mellitus and is prescribed the antidiabetic drug metformin 500 mg per os with morning and evening meals. Which statement best indicates to the nurse that the patient will adhere to the therapeutic regimen?
   a. I will no longer put sugar on my cereal because that will help me be healthier.
   b. If I take this medicine, I will feel better soon and won't have to take it anymore.
   c. To reduce the possibility of damage to my body, I must take the medicine as scheduled.
   d. I have diabetes because of my ancestry, so there's not much I can do about it.
5. The nurse is aware that the rate of absorption can be changed by which actions? (Select all that apply.)
   a. Modifying gastric emptying time
   b. Changing gastric pH
   c. Decreasing inflammation
   d. Forming drug complexes
   e. Eating too slowly
6. The nurse is reviewing a patient's medications as part of patient teaching. The nurse is aware that which drug is least likely to cause photosensitivity?
   a. Penicillins
   b. Sulfonamides
   c. Sulfonylureas
   d. Thiazides
7. The nurse is meeting with a community group about medication safety. The nurse must emphasize that patients at high risk for drug interactions include which groups? (Select all that apply.)
   a. Older patients
   b. Patients with chronic health conditions

c. Patients taking three or more drugs

d. Patients dealing with only one pharmacy

e. Patients covered by Medicare or Medicaid

8. The nurse recognizes that when a patient takes a hepatic enzyme inducer, the dose of warfarin is usually modified in which way?

a. It is increased.

b. It is decreased.

c. It remains the same.

d. It is unpredictable.

9. The nurse is describing to a patient the synergistic effects of two of his medications. Which statement by the nurse is correct about synergistic drug effects?

a. Two drugs have antagonistic effects on each other.

b. The action of a drug is nullified by another drug.

c. One drug acts as an antidote to the side effects of another drug.

d. A greater effect is achieved when two drugs are combined.

10. A patient asks the nurse about drug interactions with over-the-counter preparations. What is the nurse's best response?

a. Discuss this with the health care provider.

b. There are not many interactions, so don't worry about it.

c. Read the labels carefully, and check with your health care provider.

d. Avoid over-the-counter preparations.

Answers: 1, c, e; 2, a; 3, b; 4 a; 5, a, b, d; 6, a; 7, a, b, c; 8, a; 9, d; 10, c.

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Recognize verbal and nonverbal communication practices of various social and cultural groups.
- Explain appropriate spatial configurations for patients when delivering nursing care.
- Discuss the importance of including significant members of the social group in the planning and implementation of patient care.
- Compare patients' perception of time based on cultural constructs.
- Describe patients' need to exercise control in their environment.
- Anticipate potential unique responses to drugs based on social, cultural, and biologic influences.
- Safeguard patients' rights to confidentiality during inclusion of significant others in the plan of care.

Ethnomedicine

Ethnomedicine, sometimes referred to as *folk medicine* or *traditional medicine,* is a focus within medical anthropology that examines the ways in which people in different cultures conceptualize health and illness. These cultural constructs dictate healing practices. In many non-Western cultures, there is the belief that illness is spiritually based rather than biologically based. In some cultures, illness is thought to be caused by spirit possession or by a loss of balance within the body. Healing techniques may be based on astrology, magic, rituals, and indigenous medicinal compounds.

Traditional **healers** play a role in health practices worldwide and can include priests, shamans, bone setters, herbalists, curanderos, and midwives. Some cultural groups perceive that certain practitioners have specialized knowledge and skills. Traditional practitioners usually have some practical understanding of human anatomy and physiology and of pharmaceutical substances. Rituals may be performed to seek the assistance of otherworldly forces such as deities or spirits. Every cultural group has its own traditions, superstitions, and belief systems. Throughout history, healing practices, religious ideology, and spirituality have been tightly intertwined.

Ethnopharmacology

Ethnopharmacology is a subdivision of ethnomedicine and focuses on the use of herbs, powders, teas, and animal products as healing remedies (Guest, 2016). These traditional health practices can have neutral, beneficial, or deleterious effects on a patient's health. The emergence of ethnopharmacology highlights the need for nurses to use research from the social sciences, as well as the biological and physical sciences, to provide holistic nursing care within a culturally competent context. **Culture** is based on learned beliefs and behaviors that are shared by a group of people. Symbols, artifacts, institutions, values, mores, and rules are the products of culture. Culture is not biologically inherited. There are certain universals that are biologically driven, such as the need to eat, but what is eaten and how it is eaten is culturally driven.

Pharmacogenetics

Pharmacogenetics refers to the study of all the different genes that determine drug behavior within the human body. Culturally competent care integrates pharmacogenetics with the social and cultural attributes of the patient, which helps to predict variations in drug responses.

Transcultural Nursing

The concept of transcultural nursing was formalized by Madeleine Leininger, a nurse anthropologist who founded the Transcultural Nursing Society in 1974. A challenge for nurses worldwide is the degree of cultural diversity owing to migration across the globe. To provide culturally competent care, it is imperative that nurses be sensitive to the beliefs and practices of immigrant and indigenous groups concerning health and illness. As part of the health history, it is important to determine all the pharmacotherapeutic agents the patient is using. Obtaining a thorough history is more difficult than it seems. Patients may not reveal pertinent information, assuming that such things as herbs and teas are natural substances and therefore are not drugs. They may also be reluctant to share this information with a conventional Western health care practitioner.

Varying degrees of **assimilation** occur within and among cultural groups, such as when a minority group changes its ways to blend in with the dominant cultural group. Adults who immigrate into a new region usually take longer to assimilate than children or adolescents. Minority groups often practice the life-ways of the dominant culture while maintaining their ethnic identity. This sets the stage for **complementary health therapies** that combine traditional and conventional Western health practices. However, it is essential that nurses not make generalizations about an individual's beliefs or behaviors based on membership in a certain cultural group.

Adding to the challenges faced by nurses in countries with a high degree of cultural diversity is the phenomenon of the dominant cultural group borrowing traditional health practices from less dominant groups, resulting in **alternative health therapies**. This often involves the use of a traditional therapy in place of a conventional therapy. Use of complementary and alternative health therapies is growing in the United States. A major impetus for this movement is the difficulty many patients experience when attempting to access conventional Western health care. This difficulty may stem from a lack of faith in the system, a lack of funds, or the lack of services in a particular geographic location. Conversely, individuals who have access to conventional Western health care may perceive that it is not personalized or effective. The vast amount of teas and herbs available in drug stores, health stores, and supermarkets and the increased use of acupuncture, acupressure, and therapeutic massage serve as evidence to this trend.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 3.1 Gender-Specific Herb Protocols

Women have traditionally sought substitutes for hormonal replacement therapy. More women are now using phytoestrogens like those found in flaxseed, licorice, black cohosh, and soybeans. Health care providers should ask patients about the use of these naturally occurring phytoestrogens because they are contraindicated in women with a history of or risk for hormonally mediated cancers and benign tumors.

The Giger and Davidhizar Transcultural Assessment Model

The Transcultural Assessment model, developed by Giger and Davidhizar in 1998, depicts the six cultural phenomena of (1) communication, (2) space, (3) social organization, (4) time, (5) environmental control, and (6) biologic variation. These cultural phenomena flow from a culturally unique individual (Fig. 3.1). This model has been frequently reviewed for relevancy and is clinically useful for nurses and other members of the health care team.

Communication

Communication occurs verbally and nonverbally. Nurses must be alert to different types of communication styles among patients to provide culturally competent care. A myriad languages are spoken in pluralistic societies. When the patient and the health care provider speak different languages, professional translators should be used whenever possible to safeguard a patient's confidentiality. If a professional translator is not available, it is important that the nurse select an alternative person carefully. For example, asking the teenage son of a patient with gynecologic health issues to translate may create an uncomfortable situation that is better avoided. Even with the use of a translator, nuances in languages are unique and may not lend themselves to accurate translation in another language. There can be miscommunication between the patient, the translator, and the nurse.

Vernacular English and Standard English

There can be miscommunication between speakers of the same language when there is a pervasive use of words and phrases that are popular in particular social or cultural groups. This is evidenced by multiple regional dialects within a population. The term *African-American Vernacular English* has been used to describe a style of English speaking used among some African Americans. This vernacular is thought to be a mixture of English and the West African languages spoken by slaves. More generally, vernacular English is any style of speaking that varies from standard English.

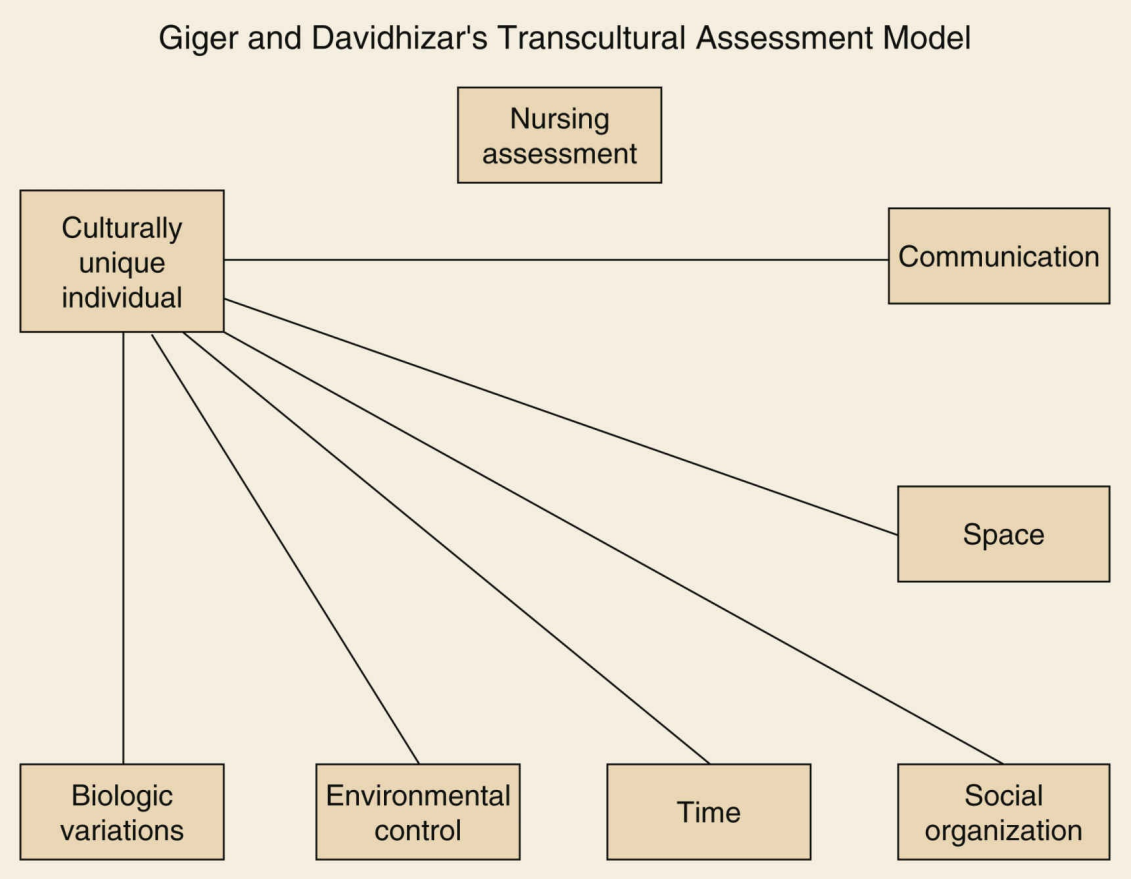

FIG. 3.1 The Giger and Davidhizar Transcultural Assessment Model.
From Newman Giger, J. (2016). *Transcultural nursing: assessment and intervention* (7th ed.). St Louis: Elsevier.

Greetings and Communication Styles

All cultures have prescribed norms for greeting and addressing others. Americans of European descent may be more informal when greeting and addressing others than descendants of non-European cultures. Nurses must keep in mind that patient-nurse interactions in health care settings are considered formal and that informal styles of communication should be used only after careful consideration.

A communication style that might hinder culturally competent nursing care can be found in some patients of Asian descent, who might speak in a soft tone of voice and avoid direct eye contact. This type of communication is intended to be respectful of the health care practitioner. The nurse who is unaware of this may miss cues that care is needed. Asian Americans and Native Americans may be comfortable with periods of silence, whereas persons of Latin American, African, Middle Eastern, or European descent may be uneasy during periods of silence. Being cognizant of these preferences will help the nurse provide a comfortable environment for the patient. Nurses should not confuse politeness with meaningful communication. Many patients will nod in agreement to statements made by the nurse even if the statements are not well understood.

Space

The amount of space around a person's body is an important psychological consideration. Americans often desire a great deal of personal space and value privacy. In other cultures, population density dictates limited personal space. Patients who are used to dense living quarters may feel insecure in a hospital room. It is important that the nurse have frequent contact with these patients and allow significant members of the social group to remain with the patient as much as possible.

A major challenge in caring for patients is the use of touch and the protection of modesty.

Although nurses must touch patients to administer care, all cultures have taboos regarding touch. There are added considerations when the patient is of a different gender than the nurse. This is a particularly sensitive issue for those within Muslim, Orthodox Jewish, Amish, and Roma groups. For example, a Muslim woman will likely prefer to be cared for by a female nurse rather than a male nurse. East Asians consider a pat on the head to be offensive due to the belief that the head is sacred. Nurses should consider inquiring about patients' preferences regarding touch before implementing nursing care. If possible, it may be best to have a family member of the same gender as the patient present during procedures. There may also be apparent paradoxes within cultures; for example, persons of Hispanic descent may value human contact but also value modesty.

Social Organization

Families are basic social units. The definition of *family* and the criteria for inclusion vary among individuals and among cultures. Americans of Western European descent are likely to have small, nuclear families, whereas other cultural groups living in the United States may have larger, extended families. Nurses are in a position to advocate for inclusion of the family in health care settings. Limiting the amount of time a patient can visit with members of the social group is a long-standing practice in American health care settings, but in some other countries, such as the Philippines, it is expected that family members will stay by the patient's bedside and participate in his or her care.

Time

Nurses and patients are likely to have different perceptions of time. Time moves slowly for a patient who is anxious or in pain but moves quickly for a nurse who has a demanding workload. The use of vague terms to denote time may also cause a disparity between nurses' and patients' perceptions of time. Words like *soon*, *about*, or *later* may have vastly different nuances among individuals and groups.

Adding to the complexity of time perception are the concepts of *linear* time and *circular* time. When time is perceived as linear, the present flows into the future and is irretrievably lost. Viewing time as linear is likely to prompt thinking such as "I must do this now." When time is perceived as circular, the present has more stability, and the need to do things at a particular moment has less urgency. Viewing time as circular is likely to prompt thinking such as, "I will have the opportunity to do this later." The cultural aspect of time perception has a profound effect on pharmacotherapeutic adherence, especially if dosing is more than once a day. All cultures have a concept of time as it is related to the past, present, and future. It is the *relative importance* placed on the past, present, and future that directs the use of time.

People of Western European descent are likely to exhibit future orientation. Future orientation promotes health practices perceived to prevent illness, such as adhering to a low-fat diet to prevent high cholesterol levels or wearing a condom during sex to prevent disease. Concern for the future also serves as motivation to take steps to control chronic illness, which is likely to lead to greater adherence to long-term pharmacotherapy. A possible explanation for this phenomenon is that people of Western European descent have historically experienced longevity and expect to have a long future ahead of them. Also to be considered is that their economic and social lives have revolved around calendars and clocks for centuries.

Non-European cultural groups such as those of African, Asian, Native American, Latin American, and Middle Eastern descent have exhibited less dependence on strict time schedules for economic and social activities. The perception of time for these groups may be rooted in agrarian cultures that use daily and seasonal rhythms of the earth and the sun to direct activities. This could result in emphasis being placed on the present. Measures to ease the discomfort of a current illness may take precedence over measures to promote long-term wellness or to treat a chronic illness. Patients with a present-oriented perception of time are more likely to discontinue conventional prescriptive therapies when they feel well. It must be noted, however, that agrarian cultures are shrinking and European-style economic practices are spreading, therefore the perception of time is changing among these groups.

Environmental Control

A major aspect of some cultures is the desire to enlist the assistance of nature to facilitate the needs of human beings. The concept of "nature" may include otherworldly forces or beings, such as deities and spirits.

Healers and spiritual advisors can be beneficial in health care settings; examples include the practice of clergy (e.g., ministers, priests, rabbis) visiting ill members of a congregation or the inclusion of a traditional healer in the plan of care.

The Indian Health Service is a federal agency within the U.S. Department of Health and Human Services that oversees the health care of approximately 2 million Native Americans who belong to federally recognized tribes. Similarly, the Canadian health care system has developed many initiatives to improve the health care of its indigenous peoples, known as the *First Nations*, *Inuit*, and *Metis*. In both systems, the use of traditional healers and spiritual guides is incorporated into conventional prescriptive therapies.

Biologic Variations

The *Genographic Project* was conducted by National Geographic scientists and performed DNA testing on populations all over the world. Findings reveal that human beings are 99.9% genetically identical. This implies that there are not multiple races but multiple genotypes that define an individual's genetic identity.

Through the work of the *Human Genome Project,* an international collaborative research program, the field of pharmacogenetics has rapidly expanded. In the United States, the project was managed by the National Human Genome Research Institute, which is part of the National Institutes of Health (NIH). A significant finding is the effect of the cytochrome P450 (CYP450) enzymes on drug response, drug-drug interactions, and adverse drug events.

To illustrate the significance of these findings in patient care settings, it is necessary to review additional terms used in the field of pharmacogenetics. **Genomes** are a complete set of chromosomes and make up a cell's DNA. **Polymorphisms** are DNA variants that occur within a specific population at a frequency greater than 1%. A *substrate* is a substance that binds to and is metabolized by one or more enzymes. Drugs are chemical substances and a type of substrate. The CYP450 enzyme system either induces or inhibits the action of substrates. Induction or inhibition of a substrate accounts for the variations in drug metabolism in individuals and groups.

Human migration around the world has been so vast over such a long period of time that most people have a variety of genetic markers. The study of pharmacogenetics can pave the way for pharmacotherapy that yields greater therapeutic benefits and causes fewer adverse reactions. The application of pharmacogenetics should be approached with caution. A person who is dark skinned and appears to be of African descent is likely to have some European genetic markers.

Certain classifications of medications have different effects in individuals whose genetic markers are predominantly characteristic of a certain biologic group. For example, in the United States, Caucasians are more likely than people of Asian or African heritage to have abnormally low levels of the CYP2D6 enzyme that metabolizes drugs belonging to a variety of therapeutic areas, such as antidepressants, antipsychotics, and beta blockers.

African Americans respond poorly to several classes of antihypertensive agents such as beta blockers and angiotensin-converting enzyme (ACE) inhibitors. Differences in skin structure and physiology can affect response to dermatologic and topically applied products. Clinical trials have demonstrated lower responses to interferon-alfa used in the treatment of hepatitis C among African Americans compared with other racial subgroups.

The U.S. Food and Drug Administration (FDA) has entered into an agreement with the manufacturers of drugs containing carbamazepine to include product labeling recommending that patients of Asian ancestry be genetically tested before treatment with this agent begins. There is a strong association between serious skin reactions and an inherited variant of the *H 1502LA-B* gene found in Asians. These intrinsic biologic factors must be considered, along with extrinsic factors such as diet and environmental and sociocultural issues, to prescribe effective therapies and provide holistic health care.

Researchers conducting clinical trials for development of new drugs are now required to obtain genetic testing of the participants in the study. Issues to be resolved concerning widespread genetic testing are the cost-benefit ratio and ethical considerations. Genetic testing is expensive and is generally not covered by third-party payers. Genetic information can affect employment, insurability, and family relationships. There is also the danger of genetic stereotyping.

Table 3.1 applies the Giger and Davidhizar Transcultural Assessment model to six broad cultural categories of people of European, African, Latin American, Native American, Asian, and Middle-Eastern descent. It is important to keep in mind that there is no generic prototype for any of these categories. Italian Americans are likely to have different customs than German Americans in spite of both groups being of European descent. There is often a perception in the United States that most Asians are Chinese and most Hispanics are Mexican, but in fact there is great variation among these broad groups regarding geography of origin, language, customs, and spiritual systems. Another misperception in the United States is that people of African descent are a homogenous group from one country, but Africa comprises 54 countries over a large geographic area. Language, customs, and spiritual systems vary extensively.

TABLE 3.1

Selected Cultural Groups and Components of the Giger and Davidhizar Transcultural Assessment Model*

Cultural Group	Communication Styles	Spatial Preferences	Social Organization	Perception of Time	Environmental Control	Biologic Variations
People of European descent	• Prefer direct eye contact • Use moderate to loud vocal volume • Use many words to describe symptoms • Uncomfortable with silence	• Prefer a large amount of personal space • Value privacy • Exhibit low to moderate amount of touching among group members	• Small, nuclear families • Extended family members often live a far distance away • Increasing number of single-parent families headed by a female • High degree of individualism	Future oriented	• Believe that healthy behaviors prevent or control illness • Believe in being united with a deity in the afterlife	Poor metabolizers of antidepressants, antipsychotics, cardiovascular agents, and isoniazid, which can lead to toxicity
People of African Descent	• Prefer direct eye contact • Use moderate to loud vocal volume • Uncomfortable with silence	• Comfortable with smaller personal spaces • Exhibit moderate amount of touching among group members	• Small, nuclear families in household but have large extended family networks • Increasing number of single parent families headed by a female • May include unrelated persons as family • Strong church affiliations	Present oriented	• Spiritually oriented • Important to include clergy in plan of care • Believe in being united with a deity in the afterlife	Diminished therapeutic effects from beta blockers, ACE inhibitors, and warfarin
People of Latin American descent	• May avoid direct eye contact with persons perceived to be in a position of authority • Uncomfortable with long periods of silence	• Comfortable with smaller personal spaces • Value touching • Like the physical presence of other people	• Extended, multigenerational family important • Godparents play important roles in an individual's life.	Present oriented	• Spiritually oriented • Use traditional healers and folk medicine • Believe in being united with a deity in the afterlife	There is great biologic diversity among Latin Americans, who can have European, Native American, and Asian biomarkers.
Table Continued						

Cultural Group	Communication Styles	Spatial Preferences	Social Organization	Perception of Time	Environmental Control	Biologic Variations
People of Native American descent	• Value silence • Sensitive to body language • Wish to keep tribal languages alive	• Value personal space • Engage in light touch	• Tribal affiliation valued • Traditional kinship patterns are valued.	Present oriented	• Spiritually oriented • Use traditional healers and folk medicine	Increased vasomotor response to alcohol
People of Asian descent	• Value silence • Sensitive to body language	• Comfortable with smaller personal spaces • Exhibit low amount of touching among group members	• Hierarchic social structure • Traditional kinship patterns are valued.	Present oriented	• Many religious systems; some are polytheistic and believe in reincarnation.	Diminished therapeutic effects of codeine; rapid metabolizers of isoniazid
People of Middle-Eastern descent	• Patient may appear quiet and docile while family members ask many questions about the diagnosis and plan of care.	• Comfortable with smaller personal spaces • Displays of public affection strongly discouraged • Gender separation in social settings	• Males are strong heads of household. • Extended family important • Sharing with others highly valued	Present oriented	• Spiritually oriented • Although the majority of Middle Easterners are of the Muslim faith, minority groups practice Christianity and Judaism. • Use traditional healers and folk medicine but consider Western health care institutions to be more prestigious • Believe in being united with a deity in the afterlife	Many genetic diseases such as thalassemia

* This table is limited in scope and does not necessarily reflect an individual's beliefs, behaviors, or biologic functioning.

Nursing Process: Patient-Centered Collaborative Care

Cultural and Pharmacogenetic Considerations

Assessment

- Assess the patient's ability to communicate using standard English.
- Determine if the patient participates in traditional health practices or uses complementary or alternative medical therapies.
- List the patient's use of pharmacotherapeutic agents, including prescription medications, over-the-counter (OTC) medications, herbs, teas, and ointments.
- Ascertain whether a patient's belief system includes a traditional faith healer, and if so, if the

presence of a healer would facilitate the patient's adherence to the prescriptive therapies.
- Inquire about the patient's preferences regarding touch, modesty, and personal space.
- Gauge the patient's perception of time.

Nursing Diagnoses

- Anxiety related to unfamiliarity with conventional Western health care practices
- Impaired Verbal Communication related to limited fluency in the English language
- Spiritual Distress, Risk for
- Ineffective Self–Health Management related to limited knowledge of health care resources

Planning

- The patient's health care needs will be met within a culturally competent framework.
- The patient will effectively manage self–health care.

Nursing Interventions

- Use appropriate translators when the patient's use of standard English is limited.
- Anticipate that therapeutic communication with the patient and significant others will require additional time with each encounter.
- Provide appropriate spatial configurations for the patient when delivering nursing care.
- Include significant members of the social group in the planning and implementation of patient care.
- Allow the patient adequate time with significant members of the social group.
- Recognize the need for the patient to exercise control of the environment.
- Anticipate unique responses to drugs based on social, cultural, and biologic influences.
- Consult with persons who are knowledgeable about the patient's culture.
- Incorporate traditional health practices with conventional prescriptive therapies when appropriate.
- Facilitate adherence to conventional prescriptive therapies within the patient's social and cultural contexts.

Patient Teaching

- Include significant members of the social group, when appropriate, while teaching about prescriptive therapies.
- Provide health information written in the patient's primary language. Medline, an online service of the National Institutes of Health, offers a variety of patient-education materials in a number of languages online at www.nlm.nih.gov/medlineplus/languages/languages.html.
- Use illustrations to explain prescriptive therapies.

Evaluation

- Monitor for patient adherence to prescriptive therapies.
- Evaluate physical, social, and psychological outcomes of prescriptive therapies.

Critical Thinking Case Study

NS is a 72-year-old woman who immigrated to the United States from Egypt 5 years ago. She is a widow, has five grown children, and follows Islamic doctrine. She lives with her oldest daughter, and a younger daughter and three sons live near her home. NS is currently hospitalized due to a recent cerebral vascular accident. She has left-sided paralysis. The attending physician tells the patient she should go to a rehabilitation unit for 3 weeks for physical therapy. The oldest daughter is present for the physician's visit. Both the patient and her daughter appear anxious but do not ask the physician any questions.

1. What cultural factors could explain the apparent anxiety?
2. Which nursing interventions would help decrease the anxiety?
3. How might the patient view the idea of physical therapy?
4. How can other members of the family be included in the plan of care?

NCLEX Study Questions

1. The nurse is performing a health assessment on a newly admitted patient of Asian descent. The patient looks at the floor whenever the nurse asks a question. Communication is enhanced when the nurse does which action?
   a. Frequently touches the patient
   b. Asks questions that require only "yes" or "no" answers
   c. Discontinues the health assessment
   d. Uses eye contact sparingly
2. The nurse has been measuring the blood pressure of an African-American patient every 4 hours for the past 3 days in a hospital setting. The blood pressure is consistently above 140/90. The patient has been adherent to the antihypertensive drug therapy while hospitalized. The nurse will initially perform which action?
   a. Determine if the patient has been given high sodium foods from visitors.
   b. Withhold the antihypertensive drug until the physician can be notified.
   c. Increase blood pressure measurements to every 2 hours.
   d. Place the patient on a restricted fluid intake.
3. A male nurse is caring for a young married woman who is an observant Muslim. It is important that the nurse initially perform which action?
   a. Delay any care that requires touching until a female nurse is available.
   b. Identify the patient's preference regarding touch.
   c. Touch the patient only when her spouse is present.
   d. Inform the patient that she must allow him to touch her.
4. A nurse is teaching a 16-year-old female patient about a newly prescribed medication. The patient is bilingual in Spanish and English. Which behavior best indicates the patient's understanding of the instructions?
   a. The patient frequently nods her head while listening to the nurse's instructions.
   b. The patient states that she understands the instructions.
   c. The patient repeats the nurse's instructions to her parents.
   d. The patient does not ask the nurse for clarification of the instructions.
5. A Native American patient is newly diagnosed with diabetes mellitus type 2 and is prescribed the antidiabetic drug metformin 500 mg per os with morning and evening meals. Which statement best indicates to the nurse that the patient will adhere to the pharmacotherapy?
   a. I will be healthier if I don't eat sugar anymore.
   b. When I feel better, I won't have to take this medicine.
   c. I must take the medicine as scheduled to prevent damage to my body.
   d. I have diabetes because of my ancestry, so there's not much I can do about it.

Answers: 1, d; 2, a; 3, b; 4, c; 5, c.

Complementary and Alternative Therapies

OUTLINE

Dietary Supplement Health and Education Act of 1994
Current Good Manufacturing Practices
Commonly Used Herbal Remedies
- *Astragalus (A. membranaceus* and *A. mongholicus)*
- Chamomile *(Matricaria recutita* and *Chamomilla recutita)*
- Cinnamon *(Cinnamomum zeylanicum* and *C. cassia)*
- Echinacea *(Echinacea purpurea)*
- Garlic *(Allium sativum)*
- Ginger *(Zingiber officinale)*
- Ginkgo *(Ginkgo biloba)*
- Ginseng *(Panax ginseng)*
- Hawthorn *(Crataegus laevigata* and *C. monogyna)*
- Licorice Root *(Glycyrrhiza glabra* and *G. uralensis)*
- Milk Thistle *(Silybum marianum)*
- Peppermint *(Mentha x piperita)*
- St. John's Wort *(Hypericum perforatum)*
- Turmeric *(Curcuma longa)*
- Valerian *(Valeriana officinalis)*

Potential Hazards of Herbs
Tips for Consumers and Health Care Providers
Herbal Resources
- Nursing Process: Patient-Centered Collaborative Care—Complementary and Alternative Therapies

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Discuss at least six important points associated with the use of complementary and alternative medicine.
- Compare at least six common herbs and their associated toxicity.
- Differentiate at least eight of the most common herbal therapies and the potential use for each.
- Describe the recommendations for labels on herbal products.
- Discuss the nursing implications, including patient teaching, related to herbal products.

KEY TERMS

Complementary and alternative medicine (CAM) is used by 40% of adults to either augment or replace traditional medical therapies. CAM practices include, but are not limited to, botanicals, nutritional products, and herbal supplements. It is critical for nurses to know about alternative medicine and to note its use in their assessment. CAM products can have both positive and negative effects, and they can interact with prescription and over-the-counter (OTC) medications. Nurses are in an excellent position to educate patients about these interactions.

Botanicals are additive substances that come from plants; an **herb** is "any plant that is used for culinary or medicinal purposes." Plants have been the source of old and new drugs for some time: foxglove is the source of digitalis, from snakeroot we get reserpine, willow bark is the source of aspirin, and Taxol comes from the Pacific yew tree, just to name a few. The therapeutic value of plants is the basis of **phytomedicine**. Research into the effects of CAM continues to grow.

Many Americans use botanical dietary supplements for therapeutic or preventive reasons, and herbal therapy has surged in popularity; marketing and media have fueled the demand, with advertisements and promotions on television, in magazines, and on the Internet. In the United States alone, sales have topped the $6 billion mark and are expected to continue to grow.

Few pharmacy schools in the United States offer courses in botanical remedies, but herbal therapy is being addressed in the professional literature with increasing frequency and seriousness. Health care providers and consumers are asking questions about herbal therapy's effectiveness, potential toxicity, and reactions with conventional medications. Consumers are right to question advertisements that imply that herbs will cure anything. Herbs can be useful, but they can also be ineffectual or even dangerous (Complementary and Alternative Therapies 4.1).

COMPLEMENTARY AND ALTERNATIVE THERAPIES 4.1 Patient Responsibility

To optimize the therapeutic regimen, the patient has the responsibility to (1) consult with the health care provider before taking any herbal preparation, (2) report all herbal preparations taken to all health care providers, (3) inform health care providers of any allergy or sensitivity to any herbal products, (4) use caution if pregnant or lactating, and (5) not take a greater dose than recommended.

In 1992 the U.S. Congress instructed the National Institutes of Health (NIH) to develop an Office of Alternative Medicine to support studies of alternative therapies. This office is now called the *National Center for Complementary and Integrative Health* (NCCIH), which lists current clinical trials with herbal products on their website (www.nccam.nih.gov/research/clinicaltrials). The Natural Standard research collaboration also reviews global literature on herbal studies. These studies are important because CAM cannot be patented, so their manufacturers generally cannot justify the expenses associated with safety and efficacy testing in an already booming conventional medicine economy.

This chapter describes selected aspects of herbal therapy, including (1) the Dietary Supplement Health and Education Act (DSHEA) of 1994, (2) varieties of herbal preparations, (3) the most commonly used herbs, (4) herbs used to treat selected common ailments, (5) potential hazards of herbs, (6) tips for consumers and health care providers, and (7) herbal resources.

Dietary Supplement Health and Education Act Of 1994

In 1994 the U.S. Congress enacted the **Dietary Supplement Health and Education Act (DSHEA)**, which defined dietary supplements as the following:

- Is intended to supplement the diet
- Contains one or more dietary ingredients (including vitamins, minerals, herbs or other botanicals, amino acids, and certain other substances) or their constituents
- Is intended to be taken by mouth, in forms such as tablet, capsule, powder, softgel, gelcap, or liquid
- Is labeled as being a dietary supplement

Although dietary supplements are regulated through the Food and Drug Administration (FDA), oversight is limited compared with prescription drugs (see http://www.fda.gov/Food/DietarySupplements/default.htm). Manufacturers are required to ensure that their products are safe and that the label information is truthful and not misleading; however, they are not required to demonstrate product safety before the product is sold. Packaging of all dietary supplements must bear the wording "This statement has not been evaluated by the U.S. Food and Drug Administration (FDA). This product is not intended to diagnose, treat, cure, or prevent any disease."

Additionally, all labels are required to have the following five components:

1. Name of the supplement
2. Amount of the supplement (net quantity)
3. Nutrition labeling
4. Ingredient list
5. Name and place of the manufacturer, packer, or distributor

Manufacturers of dietary supplements are allowed to make three types of claims: (1) health claims, (2) structure and function claims, and (3) nutrient content claims. To make these claims, manufacturers must have supporting data. The Federal Trade Commission (FTC) is responsible for regulating the truth in advertising related to dietary supplements. Herbal supplements can be marketed with suggested dosages. The physiologic effects of the product can be noted, but no claims can be made about preventing or curing specific conditions. For example, a product label cannot claim that the agent "prevents heart disease," but it can say that the agent "helps increase blood flow to the heart." Health maintenance claims (e.g., "maintains a healthy immune system") and claims for relief of minor symptoms related to life stages (e.g., "alleviates hot flashes") are acceptable because they do not relate to disease. Herbal products using a "may be beneficial" disclaimer, rather than claims of definite benefit, are appropriate legally. Dietary supplement manufacturers are still required to substantiate any claims they make. Consumers are reminded that premarket testing for safety and efficacy is not required, and manufacturing is not standardized.

Current Good Manufacturing Practices

The FDA proposed standards for marketing and labeling dietary supplements in 2003. Known as the **Current Good Manufacturing Practices (CGMPs)**, these standards are multifaceted and require that package labels give the quality and strength of all contents and that products be free of contaminants and impurities (Table 4.1). Manufacturing quality control procedures are part of the CGMPs.

Additionally, a *seal of approval* is awarded to products that meet criteria similar to that of the CGMPs by four organizations: the U.S. Pharmacopeial Convention (USP), ConsumerLab.com, National Products Association, and NSF International. The fee-based tests provide information on an herbal product's identity, potency, dissolution, purity, and labeling accuracy. However, the seal of approval is no indication of the product's safety or efficacy.

Commonly Used Herbal Remedies

Most herbal therapies are used to maintain or improve health. This section discusses the most commonly used herbs. The National Center for Complementary and Integrative Health (https://nccih.nih.gov/) is an excellent resource for information on herbal therapies not discussed here.

Astragalus (A. membranaceus and *A. mongholicus)*

Astragalus membranaceus and *Astragalus mongholicus* have been used as an adjunct to boost the immune system, such as for hepatitis and cancer, and to limit the effects of cold and flu symptoms. There is no strong evidence to support the use of *Astragalus* to support the immune system; however, preliminary evidence supports such benefits. *Astragalus* is considered safe, but little is known about its side effect profile because it is commonly used as adjunctive therapy. The herb may interact with drugs used to alter immune function, such as cyclosporine. Persons using CAM need to be aware that not all species of *Astragalus* are safe for human consumption; some species contain the neurotoxin swainsonine, others contain toxic levels of selenium.

TABLE 4.1

Definitions of Herbal Preparations

Preparation	Definition
Decoction	A tea made from boiling plant material—usually the bark, rhizomes, roots, or other woody parts—in water. May be used therapeutically. Natural dyes are often made this way.
Infusion	A tea made by pouring water over plant material (usually dried flowers, fruit, leaves, and other parts, although fresh plant material may also be used); the mixture is then allowed to steep. The water is usually boiling, but cold infusions are also an option. May be used therapeutically; hot tea is an excellent way to administer herbs.
Tincture	An extract of a plant made by soaking herbs in a dark place with a desired amount of either glycerine, alcohol, or vinegar for two to six weeks. The liquid is strained from the plant material and then may be used therapeutically.
Liniment	Extract of a plant added to either alcohol or vinegar and applied topically for therapeutic benefits.
Poultice	A therapeutic topical application of a soft moist mass of plant material (such as bruised fresh herbs), usually wrapped in a fine woven cloth.
Essential oils	Aromatic volatile oils extracted from the leaves, stems, flowers, and other parts of plants. Therapeutic use generally includes dilution of the highly concentrated oil.
Herb-infused oils	A process of extraction in which the volatile oils of a plant substance are obtained by soaking the plant in a carrier oil for approximately 2 weeks and then straining the oil. The resulting oil is used therapeutically and may contain the plant's aromatic characteristics.
Percolation	A process to extract the soluble constituents of a plant with the assistance of gravity. The material is moistened and evenly packed into a tall, slightly conical vessel; the liquid (menstruum) is then poured onto the material and allowed to steep for a certain length of time. A small opening is then made in the bottom, which allows the extract to slowly flow out of the vessel. The remaining plant material (the *marc*) may be discarded. Many tinctures and liquid extracts are prepared this way.

From American Botanical Council. (2013). *Terminology*. Retrieved from http://abc.herbalgram.org/site/PageServer?pagename=Terminology

Chamomile *(Matricaria recutita* and *Chamomilla recutita)*

Chamomile is used primarily to treat sleeplessness, anxiety, and stomach or intestinal ailments. Little research has been conducted on chamomile; however, early studies indicate some benefit in the use of chamomile for some skin conditions and oral ulcers secondary to chemotherapy or radiation treatment. Side effects include allergic reaction from mild skin reactions to anaphylaxis. Allergic reactions are more likely to occur in persons who are allergic to ragweed or other members of the daisy family.

Cinnamon *(Cinnamomum zeylanicum* and *C. cassia)*

Cinnamon has a long history of use as a treatment for bronchitis, gastrointestinal (GI) problems, anorexia, and diabetes. However, little evidence is available to support any of these claims. Although some people have allergic reactions to cinnamon, in general it is usually safe if taken in amounts of no more than 6 g a day for no longer than 6 weeks. Both species of cinnamon contain coumarin; however, cassia cinnamon contains much larger amounts and may decrease blood clotting.

Echinacea *(Echinacea purpurea)*

Echinacea is commonly used for colds, flu, and infections. It has also been used for skin problems, such as acne. It is thought to stimulate the immune system to fight infection. Research regarding the benefits of *Echinacea* as treatment for cold and flu symptoms is inconclusive. Few side effects are

reported by persons taking the herb, the most common being GI effects and allergic reactions, particularly in those who are allergic to ragweed.

Garlic *(Allium sativum)*

Garlic is reported to lower cholesterol, decrease blood pressure, and reduce heart disease. It has also been used to prevent cancer of the stomach and colon. Inconclusive evidence supports the use of this herb as a treatment for elevated cholesterol, hypertension, and heart disease; no evidence supports its use in the prevention of cancer. Garlic has few side effects but may cause heartburn and upset stomach; it has also been associated with body odor. Because it also reduces blood clotting, patients should be advised to notify their health care provider about taking garlic if they are having surgery or dental work. Patients should be cautioned not to take garlic if they have a bleeding disorder or if they are taking the drug saquinavir (a protease inhibitor used in the treatment of HIV). Garlic reduces the effectiveness of saquinavir.

Ginger *(Zingiber officinale)*

Ginger has been used to treat postoperative, pregnancy-related, and chemotherapy-related nausea as well as motion sickness and diarrhea. In addition, it may provide relief from pain, swelling, and stiffness of both osteoarthritis and rheumatoid arthritis. Available research suggests it is effective for the short-term treatment of nausea associated with pregnancy. Evidence is inconclusive concerning its use for motion sickness, as treatment of chemotherapy-induced or postoperative nausea, and in the treatment of arthritis. Side effects of ginger include gas, bloating, heartburn, and nausea.

Ginkgo *(Ginkgo biloba)*

Ginkgo has been used for thousands of years to treat ailments such as asthma, bronchitis, fatigue, and tinnitus. In more recent times, it has been used to improve memory, prevent Alzheimer disease and other dementias, decrease intermittent claudication, and as a treatment for sexual dysfunction and multiple sclerosis. In a study following older adult subjects for an average of 6 years, *Ginkgo* was shown to be ineffective in the prevention of Alzheimer and other dementias. Other studies have shown it to be ineffective in improving memory in older adults. There is conflicting evidence of the benefit of *Ginkgo* for treatment of intermittent claudication and tinnitus. Side effects include headache, nausea, GI upset, dizziness, and allergic reactions that include severe reactions leading to death. In patients taking blood thinners, *Ginkgo* has been shown to increase bleeding risk. Animal studies have shown that rats and mice given *Gingko* develop tumors; however, more research is needed to determine if this is true for humans.

Ginseng *(Panax ginseng)*

Ginseng has been said to boost the immune system, increase a person's sense of well-being, and increase stamina. It has also been used to treat erectile dysfunction, hepatitis C, and menopausal symptoms and to lower glucose and blood pressure. The active component in the herb is thought to be a chemical called *ginsenoside.* Some evidence supports the use of ginseng in the treatment of hypertension and as an immune system booster. Short-term use of the herb appears to be safe; however, long-term use is associated with side effects such as headaches, GI problems, and allergic reactions. There have also been reports of breast tenderness, menstrual irregularities, and high blood pressure, although it is not known if it is the herb causing these effects or other components. Diabetics should use caution when taking ginseng, especially if used in conjunction with other herbs or drugs, because hypoglycemia may result.

Hawthorn *(Crataegus laevigata* and *C. monogyna)*

Hawthorn has predominantly been used in the treatment of heart disease (e.g., heart failure and angina). It has also been used to treat digestive issues and kidney disease. Although some evidence supports its use in mild heart failure, study results are conflicting. Side effects of hawthorn include nausea, headache, and dizziness. Hawthorn may interact with multiple drugs, including those used

for erectile dysfunction (hypotension), nitrates (dizziness and lightheadedness), and antihypertensives (hypotension).

Licorice Root *(Glycyrrhiza glabra* and *G. uralensis)*

Licorice has been used to treat stomach ulcers, bronchitis, sore throat, and viral hepatitis. However, there is not enough research to show the benefit of licorice in the treatment of any condition. In large amounts, licorice can elevate blood pressure, cause salt and water retention, and lower potassium levels. When taken with diuretics, corticosteroids, or other medications that lower potassium, life-threatening hypokalemia may result. People with heart disease or hypertension and those who are pregnant (some data associate licorice with preterm labor) should not take licorice in large amounts.

Milk Thistle *(Silybum marianum)*

Milk thistle has been used widely to treat cirrhosis, chronic hepatitis, and gallbladder disorders. It has also seen use in the treatment of elevated cholesterol and insulin resistance in type 2 diabetes. Although laboratory study has indicated that milk thistle may promote the growth of liver cells and may fight oxidation and inhibit inflammation, two rigorous human studies found no benefit when compared with standard therapy and no change in viral activity or inflammation. Milk thistle may cause stomach upset, and in persons allergic to ragweed, milk thistle may trigger an allergic reaction. When combined with drugs for diabetes, milk thistle may lead to hypoglycemia. Nurses should caution diabetics using milk thistle to closely monitor their blood sugars and to watch for symptoms of hypoglycemia.

Peppermint *(Mentha x piperita)*

Peppermint has been used to treat a wide variety of ailments, from nausea, indigestion, and irritable bowel syndrome (IBS) to cold symptoms, headaches, and muscle and nerve pain. Some evidence supports the use of peppermint in the treatment of IBS and possibly the use of peppermint oil to relieve indigestion; however, no current evidence supports the use of peppermint to treat other ailments. Side effects include possible allergic reaction and heartburn.

St. John's Wort *(Hypericum perforatum)*

St. John's wort has been used extensively throughout history to treat mental disorders and nerve pain. It has also been used as a treatment for malaria, sleep disorders, and wounds. Current research indicates St. John's wort is no more effective than placebo as treatment for depression, whether mild, moderate, or severe. Patients must be informed that this herb is not effective in the treatment of depression, and that for adequate treatment to take place, they must see their health care provider. St. John's wort interacts with multiple drugs including antidepressants, which can lead to serotonin syndrome; birth control pills, cyclosporine, digoxin, indinavir, irinotecan, drugs for seizure control, and anticoagulants. Side effects include sensitivity to sunlight, anxiety, dry mouth, dizziness, GI problems, fatigue, headache, and sexual dysfunction.

Turmeric *(Curcuma longa)*

Turmeric has been used for heartburn, stomach ulcers, gallstones, inflammation, and cancer. However, little research has been conducted on the use of turmeric to treat health conditions. Preliminary research in the lab suggests that it may have antiinflammatory, anticancer, and antioxidant properties, but human studies have not been conducted to confirm such properties outside of the lab. Turmeric is generally safe, although high doses may cause nausea or diarrhea. Persons with gallbladder disease should avoid the herb because it may worsen their condition.

Valerian *(Valeriana officinalis)*

Valerian has seen wide use in the treatment of insomnia; it has also been used to treat anxiety, headaches, depression, irregular heartbeat, and tremors. Although early research indicates valerian

may be useful in the treatment of insomnia, there is not enough evidence to recommend the herb for this treatment. Multiple research studies are in progress, but no available evidence supports the use of valerian for any other medical condition at this time. Valerian is generally safe when used for short periods of time (4 to 6 weeks). Side effects include fatigue, headaches, dizziness, and stomach upset.

Potential Hazards of Herbs

Consumers and health care providers must be alert to potential hazards with herbal therapy; although herbs are natural substances, *natural* does not mean safe. Patients may not disclose use of herbal products to health care providers for a variety of reasons, including the sense that the health care provider is biased against or not knowledgeable about herbal products or the belief that these products are not considered medications. However, it is essential that health care providers obtain a complete listing of all of the herbal preparations the patient takes in all forms—teas, infusions, tinctures, tablets, and dried herbs—the reason they are taken, and their perceived effectiveness to ensure that they do not interfere with the use and actions of prescribed medications. This assessment should be updated regularly along with information on the patient's OTC and prescription drug use.

Health care providers must be alert for possible herb-drug interactions. For example, Asian ginseng induces the drug-metabolizing enzyme CYP3A; when taken in combination with other CYP3A substrates with a narrow therapeutic index, drug levels and therapeutic response should be monitored carefully. Goldenseal has a high potential for herb-drug interaction because it is a potent inhibitor of both CYP3A4 and CYP2D6. St. John's wort has significant documented interactions with cyclosporine, indinavir, oral contraceptives, warfarin, digoxin, and benzodiazepines, among other drugs; it is also a potent inducer of CYP-450 enzymes and intestinal p-glycoprotein.

Some herbal products can also directly affect laboratory test results. Two Chinese alternative therapies, Dan Shen and Chan Su, are known to interfere with tests to determine digoxin levels. It is *extremely important* that patients taking digoxin avoid these two products!

Not all compounds are safe via all routes. For example, comfrey has both internal and external preparations. Internal use is discouraged because hepatic damage may be fatal. For external use, comfrey is used as an ointment for relief of swelling associated with abrasions and sprains.

Many products have significance for patients facing surgery because they may interfere with the absorption, breakdown, and excretion of anesthetics, anticoagulants, and other surgery-related medications (Complementary and Alternative Therapies 4.2). The American Society of Anesthesiologists suggests patients discontinue herbal therapy beginning 2 to 3 weeks prior to surgery.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 4.2

Anticoagulants

The following commonly used herbal products have been reported to interfere with anticoagulants: bilberry, cat's claw, chamomile (German), Dong Quai, feverfew, garlic, ginseng, ginger, *Ginkgo,* and licorice.

Tips for Consumers and Health Care Providers

The following are guidelines for prudent use of herbs:

- Do not take herbs without talking to your health care provider first if you are taking any prescription drugs.
- Do not take herbal supplements if you are pregnant, attempting to become pregnant, or are nursing.
- Do not give herbs to infants or young children.
- Follow the label instructions!
- If you experience any side effects that concern you, stop taking the herb and contact your health care provider.
- *Natural* does not mean safe!
- Herbal supplements may contain many compounds, and all of the ingredients may not be known; what is on the label may not be what is in the bottle.

Herbal Resources

It is the responsibility of consumers to educate themselves about herbs before use and to purchase products only from reputable dealers. Determination of the purity and concentration of a particular product can be done only through assays, a costly process; thus most products have not had appropriate human toxicologic analysis. Many herbal resources are available on the Internet and from print sources, and the reader must evaluate each independently and decide whether the information is credible and appropriate.

Nursing Process: Patient-Centered Collaborative Care

Complementary and Alternative Therapies

In the provision of holistic nursing care, it is important that nurses understand both conventional drug therapy and complementary and alternative practices.

Assessment

- Assess for the influence of cultural beliefs, norms, and values in the patient's therapeutic regimen.
- Using culturally sensitive, nonjudgmental, and unbiased questioning, assess the following:
  - Which herbs are being used and how long ago were they started?
  - Why is the herb being used?
  - Who recommended the herb?
  - How often and how much of the herb is being taken?
- Assess use of other prescribed and over-the-counter (OTC) drugs and supplements, and include the reason for and duration of use.
- Assess for potential or actual side effects of any drug, herb, or supplement being used.
- Assess for potential or actual drug-drug, drug-herb, or drug-supplement interactions.
- Assess the patient's readiness to learn and literacy skill.

Nursing Diagnoses

- Deficient Knowledge related to treatment regimen
- Readiness for Enhanced Knowledge related to complementary and alternative therapies

Planning

- The patient and family will verbalize understanding of herbal therapy, prescription and OTC drugs, interaction between herbal therapy and prescription and OTC drugs, and strategies for optimal participation in the therapeutic regimen.

Nursing Interventions

- Engage patients in the care-planning process; provide information supportive of self-management and mutual goal setting; support patients and family choices.
- Consult a dietitian and other specialists as necessary.

Patient Teaching

- Use an individualized, culturally appropriate approach when discussing the therapeutic regimen.
- Use open-ended questions.
- Due to inconsistencies in manufacturing, advise patients to continue with the same brand of herbal therapy, and advise them to notify their health care provider if considering changing brands or preparations.
- Advise patients to first notify their health care provider before substituting any herbal product for a prescription or OTC medication.
- Encourage patients to read labels and heed the recommended information displayed on the label.
- Teach patients about foods that enhance or diminish the action of specific herbs.
- Advise patients about foods to avoid, if any, while taking herbs.

- Advise patients of potential side effects of herbal therapy.
- Counsel patients about symptoms that require prompt reporting to the health care provider.

Evaluation

- Evaluate perceived effectiveness of herbal remedies for alleviating symptoms.
- Evaluate adherence to the therapeutic regimen.
- Evaluate drug-herb interactions or side effects.
- Evaluate the patient's use of resources.

Critical Thinking Case Study

JR, a 55-year-old white male, is seen in follow-up after being diagnosed with type 2 diabetes. He was prescribed metformin 500 mg twice daily at his last visit. When talking to JR, he admits he never filled his prescription but took his neighbor's advice instead and began taking cinnamon. He states he Googled the spice and found that it is effective at lowering blood sugar. Upon further questioning, he states he just grabs a spoon from the drawer and uses his wife's baking cinnamon.

1. What additional information is needed prior to developing a mutually agreed upon plan of care?
2. What information should JR be given concerning the use of cinnamon to treat diabetes?

NCLEX Study Questions

1. What provisions of the Dietary Supplement Health and Education Act of 1994 are most important for the nurse to know related to patient health teaching? (Select all that apply.)
   a. Clarified marketing regulations
   b. Reclassified herbs as dietary supplements
   c. Stated that herbal products can be marketed with suggested dosages
   d. Required that package labels give quality and strength of all contents
   e. Stated that herbs can be used as drugs
2. The nurse discovers that a patient has recently decided to take four herbal preparations. Which action will the nurse take first?
   a. Discuss the cost of herbal products.
   b. Instruct the patient to inform the health care provider of all products taken.
   c. Instruct the patient to stop taking all herbal products immediately.
   d. Suggest that the patient taper off use of herbal products over the next 2 weeks.
3. Labeling of herbal products is important. Which is an appropriate claim for an herbal product?
   a. Prevents diabetes
   b. Helps increase blood flow to the extremities
   c. Cures Alzheimer disease
   d. Is safe for all
4. The nurse is reviewing a patient's current medications. Which herbal products interfere with the action of anticoagulants? (Select all that apply.)
   a. *Astragalus*
   b. Garlic
   c. Ginger
   d. Licorice root
   e. *Gingko*
5. A patient being seen at a cardiovascular clinic mentions he takes garlic, which is reported to decrease cholesterol, blood pressure, and heart disease. Which patient statement indicates a need for further teaching? (Select all that apply.)
   a. I can just take garlic for my heart problems.
   b. Garlic may provide some decrease in blood pressure.
   c. Garlic is very effective in preventing depression.
   d. Garlic will not cure impotence.

Answers: 1, a, b, c; 2, b; 3, b; 4, b, e; 5, a, c.

Pediatric Considerations

OUTLINE

Pharmacokinetics
- Absorption
- Distribution
- Metabolism
- Excretion

Pharmacodynamics
Nursing Implications
- Pediatric Drug Dosing and Monitoring
- Pediatric Drug Administration

Considerations for the Adolescent Patient
Nursing Process: Family-Centered Collaborative Care
- Nursing Process: Family-Centered Collaborative Care—Pediatrics

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Apply principles of pharmacokinetics and pharmacodynamics to pediatric drug administration.
- Differentiate components of pharmacology unique to pediatric patients.
- Synthesize knowledge about pediatric drug safety and administration with current or potential nursing practice.

A nurse who is providing care to children must make certain adaptations in assessment, treatment, and evaluation of nursing care because of the physiologic, psychological, and developmental differences inherent in the pediatric population. This is especially true in the science of pharmacology, in both the administration of drugs to children and evaluation of the therapeutic and adverse effects of a drug. This chapter addresses pediatric nursing adaptations and discusses the impact of a child's growth and development on many aspects of pharmacology:

pharmacokinetics, pharmacodynamics, dosing and monitoring, methods of drug administration, and nursing implications.

Pediatric pharmacology is limited to available research in the provision of dosing protocols, safe practices, key assessments, and important nursing implications. Most available information about drugs is derived from studies that use adult samples, small sample sizes, or samples with healthy children. Few studies have been conducted to determine the effectiveness of drugs in the pediatric population. Generalizing the results of studies using adult patients to pediatric populations may result in serious errors and ignores the impact of growth and development on pharmacology.

Patient Safety

Preventing Drug Administration Errors in Pediatric Pharmacology

- Owing to developmental factors and smaller body size, infants and young children may receive drug dosages much different from those of adults. Careful calculations, double-checking math, and checking with another registered nurse can prevent errors in drug administration.
- Ensure that families understand the units of measurement for a drug. Confusion may occur with the discussion of metric, household, and other measurement systems.
- For safety when administering injectable drugs to children, use the smallest syringe that ensures the most exact measurement of the drug.
- Use the correct drug and procedure to ensure safe dosing. Dilutions, different concentrations, and different solutions of a prescribed drug can complicate administration of appropriate pediatric dosages.
- Infants and children may not be able to confirm identity, allergies, or drugs. The nurse must be positive of such information before drug administration.
- Nurses must be vigilant for severe side effects or adverse reactions to drugs because information on pediatric drug response is limited.
- Regulatory agencies caution that drug administration errors are more common in pediatric patients, which warrants increased precautions in drug administration.

Research related to pediatric patients is limited because of several factors. Research risks and obtaining informed consent make it difficult to recruit a pediatric sample. Parents and guardians are reluctant to provide permission for children to participate in research studies because of the risk involved and the potentially invasive nature of data gathering. Pharmaceutical companies invest fewer resources in pediatric drug research because of the smaller market share afforded to pediatric drugs. However, many contend that lack of pediatric data reflects lack of due diligence, especially when drugs are administered to pediatric patients without supporting research data on which to base safe practices. As a result, less is known about the effects, uses, and dosages of pediatric drugs, and nurses must investigate pediatric drugs carefully to provide knowledgeable nursing care for children.

Closely aligned with the conflicts that affect pediatric pharmacologic research are those associated with drug labeling and dosing instructions. Because many drugs have not undergone the clinical trials required for federal approval, they have not been approved for pediatric use. Safe use for children may be guided by small studies or the judgment of the clinician and may be based on anecdotal evidence rather than scientific study. These conflicts have generated new legislation designed to protect pediatric patients and provide health care professionals with better information and resources.

Despite the permanent reauthorization of the Pediatric Research Equity Act (PREA) in 2012, which requires drug manufacturers to study pediatric drug use and offers incentives for pediatric pharmacology research, only half of all drugs carry federally approved indications for use in children. This means many drugs prescribed for children are being prescribed **off label**, which means the drug is being used for some purpose for which it has not been approved. Current research agendas reinforce the need for pediatric drug research and establishment of safe guidelines for pediatric drug dosing, administration, and evaluation.

Pharmacokinetics

Significant differences exist in drug pharmacokinetics for pediatric patients versus adults. These distinctions stem from differences in body composition and organ maturity and appear to be more pronounced in neonates and infants but less significant in school-age and adolescent children. **Pharmacokinetics** may be defined as the study of the time course of drug absorption, distribution, metabolism, and excretion.

Absorption

The degree and rate of drug absorption are based on factors such as age (Table 5.1), health status, weight, and route of administration. As children grow and develop, the absorption of drugs generally becomes more effective; therefore less developed absorption in neonates and infants must be considered in dosage and administration. In contrast, poor nutritional habits, changes in physical maturity, and hormonal differences during the adolescent years may cause slowing of drug absorption. Hydration status, presence of underlying disease, and gastrointestinal (GI) disorders in the child may be significant factors in the absorption of drugs.

TABLE 5.1

Pediatric Age Classification

Classification	Age
Term neonate	Birth at 38 or more weeks' gestation to 27 days
Infant/toddler	28 days to 23 months
Children	24 months to 11 years
Adolescent	12 years to 16 or 18 years (regional difference)

From U.S. Food and Drug Administration. (2014). *Pediatric exclusivity study age group* (C-DRG-00909). Retrieved from http://www.fda.gov/Drugs/DevelopmentApprovalProcess/FormsSubmissionRequirements/ElectronicSubmissions/DataStandardsMa

Drug absorption is initially influenced by the route of administration. For oral drugs, conditions in the stomach and intestine such as gastric acidity, gastric emptying, gastric motility, GI surface area, enzyme levels, and intestinal flora all mediate drug absorption. Lack of maturation of the GI tract is most pronounced in infancy, making the neonatal and infancy periods those most affected by changes in absorption physiology. Gastric pH is alkaline at birth; acid production begins in the neonatal period, and gastric acid secretion reaches adult levels around 2 to 3 years of age. A low pH, or acidic environment, favors acidic drug absorption, whereas a high pH, or alkaline environment, favors basic drug formulations; therefore differences in pH may hinder or enhance drug absorption. Gastric emptying and GI motility are unpredictable in neonates and infants; however, it approaches that of adults between 6 and 8 months of age. Gastric emptying is affected by feeding, and breast-fed infants have faster gastric emptying than formula-fed infants. Unpredictable GI motility may hinder or enhance absorption of oral drugs, depending on the usual site of chemical absorption.

Intestinal surface area in neonates does not reach that of adults until 20 weeks; prior to this, the reduced surface area leads to reduced drug absorption. Immature enzyme function may also affect drug absorption; neonates have inadequate production of bile salts and pancreatic enzymes, which leads to reduced absorption of lipid-soluble drugs. Intestinal microbial colonization begins in the first few hours after birth and is influenced by gestational age and whether the neonate is breast or formula fed; GI microbial colonization reaches adult levels in adolescence. All of these factors must be considered when assessing the effectiveness of drugs administered by the oral route.

For drugs administered via the subcutaneous (subcut) or intramuscular (IM) routes, absorption occurs at the tissue level. The level of peripheral perfusion and effectiveness of circulation affects drug absorption. Conditions that alter perfusion—dehydration, cold temperatures, and alterations in cardiac status—may impede absorption of drugs in the tissues. Intravenous (IV) drugs are administered directly into the bloodstream and are immediately absorbed and distributed.

The skin of infants and young children is thinner than that of adults; additionally, the ratio of body surface area to body mass of infants and children is proportionately higher than for adults such that many drugs are more readily absorbed in children, and toxicity may result.

Distribution

Drug distribution is affected by factors such as body fluid composition, body tissue composition, protein-binding capability, and effectiveness of various barriers to drug transport. In neonates and infants, the body is about 75% water, compared with 60% in adults. This increased body fluid proportion allows for a greater volume of fluid in which to distribute drugs, which results in a lower drug concentration. Until about age 2 years, the pediatric patient requires higher doses of water-soluble drugs to achieve therapeutic levels. Younger patients also have higher levels of extracellular fluids, which increases the tendency for children to become dehydrated and changes the distribution of water-soluble drugs. Compared with older children, neonates and infants have fat stores with an increased ratio of water to lipids, which alters the distribution of some lipid-soluble drugs. Close monitoring of drug levels (e.g., anti-epileptic drugs) can help ensure drug safety.

To varying degrees, drugs become bound to circulating plasma proteins in the body. Only drugs that are free, or unbound, are available to cross the cell membrane and exert their effect. Neonates and infants have decreased protein concentrations compared with adults, and they have fewer protein receptor sites with an affinity for drug binding in the first 12 months after birth; this results in higher levels of unbound drug and an increased risk of drug toxicity.

In neonates, high bilirubin levels may pose a health risk related to drug administration. Bilirubin molecules may bind with protein receptor sites, which makes the sites unavailable to drugs or displaces drugs from binding sites, allowing large amounts of drug to remain free and available for effect. When drugs are prescribed to neonates, dosages must be decreased and closely monitored to both avoid adverse effects and ensure therapeutic effectiveness.

Anatomic barriers to drug distribution, such as the blood-brain barrier (BBB), must be considered when drugs are administered to pediatric patients. This barrier in neonates is relatively immature and allows drugs to pass easily into central nervous system (CNS) tissue, thereby increasing the likelihood for toxicity. As a child matures, the BBB becomes more impervious to drugs, and drug dosages must be titrated accordingly.

Metabolism

The metabolism of drugs depends greatly on the maturation level of the pediatric patient and varies from child to child. Metabolism is carried out primarily in the liver, with the kidneys and lungs playing a small part in metabolism. Infants have reduced hepatic blood flow and drug-metabolizing enzymes; however, by the time they reach 1 year of age, hepatic blood flow has reached that of an adult. Whereas drug-metabolizing enzymes reach an adult level at around age 11, it is important to understand that the isoenzymes involved in the cytochrome P450 system—CYP1, CYP2, and CYP3 (Table 5.2)—develop at different rates and demonstrate individual variation. Drug prescribing should be based on therapeutic effect and drug concentration. Such differences in drug metabolism, as with other pharmacokinetic factors, reinforce the importance of the nurse evaluating therapeutic effects and monitoring the adverse effects of drugs.

Excretion

Renal excretion is the predominant means of drug elimination. The glomerular filtration rate (GFR) in term neonates is roughly 30% that of adults. During infancy, the GFR rises, and by 12 months, it reaches adult levels. Nurses must carefully monitor renal function, urine flow, and drug effectiveness to evaluate the impact of drug administration on patient status.

Pharmacodynamics

Pharmacodynamics refers to the mechanisms of action and effects of a drug on the body and includes the onset, peak, and duration of effect of a drug. It can also be described as the intensity and time course of therapeutic and adverse effects of drugs. The variables of pharmacokinetics—absorption, distribution, metabolism, and excretion—all affect the parameters of pharmacodynamics. These processes determine the time a drug begins to function, reaches its peak, and sustains its length of action. Variables such as organ function, developmental factors, and administration issues affect drug pharmacodynamics and drug half-life in pediatric patients (Table 5.3), and these have an impact on drug dosing.

Nursing Implications

Pediatric Drug Dosing and Monitoring

Because of the changes in pharmacokinetics and pharmacodynamics inherent in pediatric patients, a key nursing role is to monitor the patient for therapeutic effect and adverse reactions. The processes described earlier in the chapter may be measured using plasma or serum drug levels, which indicate the amount of drug in a patient's body. The therapeutic ranges established for many drug levels are based on adult studies; therefore close monitoring of serum drug levels can assist in establishing appropriate dosages, schedules, and routes of administration. Monitoring can also assist in indicating when the dose is subtherapeutic or becomes toxic. Serum blood levels are not available for all drugs, so patient clinical responses to drugs are especially important when monitoring drug effects.

The calculation of pediatric dosages is based in part on U.S. Food and Drug Administration (FDA) recommendations; as a result of the Best Pharmaceuticals for Children Act (BPCA) and PREA, pediatric dosing is now available for over 450 drugs. For those drugs without pediatric dosing schedules, dosing is based on approved protocols, research studies, and provider experience. Drugs for pediatric patients are ordered based on either the child's weight in kilograms (mg/kg) or body surface area (BSA; or mg/m^2). Body surface is based on a percentage of adult surface area (1.73 m^2). Dosing must also consider the individual child's status, including age, organ function, health, and route of administration.

TABLE 5.2

Isoenzyme Activity in the Pediatric Population Compared With Adults

Isoenzyme	Pediatric Activity	Drug Class	Examples
CYP1A2	↓ Until 2 y	Antidepressant Bronchodilator Diuretic	Duloxetine Theophylline Triamterene
CYP2C9	↓ Until 1-2 y	Anticoagulant Antidepressant Nonsteroidal antiinflammatory	Warfarin Phenytoin Diclofenac, ibuprofen, naproxen, tolbutamide
CYP2C19	↓ Until 10 y	Antidepressant Benzodiazepine Proton pump inhibitor	Citalopram, sertraline Diazepam Lansoprazole, omeprazole, pantoprazole
CYP2D6	↓ Until 12 y	Analgesic Antidepressant Antihistamine Antipsychotic Beta blocker	Codeine, tramadol amitriptyline, desipramine, doxepin, imipramine, fluoxetine, nortriptyline, paroxetine, venlafaxine Diphenhydramine Risperidone Labetalol, metoprolol
CYP3A4	↓ Until 2 y	Analgesic Antiepileptic Antifungal Antihistamine Antiretroviral Benzodiazepine	Alfentanil, fentanyl Carbamazepine Itraconazole, ketoconazole Loratadine Indinavir, lopinavir/ritonavir, saquinavir Alprazolam, midazolam
MAO A	↑ Until 2 y		
MAO B	≈		
***N*-methyltransferases** **UGTs**	≈		
	↓ Until 7-10 y	Analgesic	Morphine
		Antiepileptic Benzodiazepine	Lamotrigine Clonazepam, lorazepam
NAT2	↓ Until 1-4 y	Antihypertensive Antibacterial	Hydralazine Isoniazid

Pediatric Drug Administration

Developmental and cognitive differences must always be considered in pediatric drug administration. It is important for the nurse to differentiate the child's developmental age from chronologic age, because this difference has an impact on the child's response to drug administration. The pediatric patient's ability to understand the process, the reason for drug administration, and the need to cooperate with the procedure must always figure prominently in the nurse's plan of care. The child's temperament may influence understanding and level of cooperation. The concept of **family-centered care** is essential to ensuring safety during and after health care interventions, especially drug administration. Teaching is directed toward both family members or caregivers and patients, commensurate with the cognitive level of the child. When possible, family members or caregivers should be solicited to assist in drug administration. These significant persons in the child's life, individuals who see the child on a day-to-day basis, are usually in the best position to evaluate the effectiveness of a drug and observe for adverse reactions. Some adverse drug reactions in children, such as ringing in the ears and nausea, may be difficult to evaluate; those closest to the child may be in the best position to assess for these reactions. However, family members or caregivers may request not to participate in invasive procedures such as injections. This request should be respected, and family members or caregivers should be encouraged to provide comfort to the child after drugs are administered. Family members or caregivers should always be supported in their caring function so that the child feels safe and secure.

Pediatric patients must be assessed for the ability to understand the reason for the drug, the need for the drug despite unpleasant taste or method of administration, and the need to complete all doses and courses of the drug. When the family is taught about pediatric drug administration, education for the child at a developmentally appropriate level must also be included. Communication with the child and family members or caregivers must always consider level of knowledge, developmental age, cultural factors, and anxiety levels. The nurse should use optimal interpersonal skills to ensure the best outcome in drug administration to pediatric patients.

The primary concerns in drug administration to infants are maintaining safety and providing care while ensuring as much comfort as possible. Family members or caregivers must be able to practice and repeat the psychomotor skills associated with drug administration. The following are tips to enhance safe drug administration and facilitate comfort:

- Toddlers may react violently and negatively to drug administration. Simple explanations, a firm approach, and enlisting the imagination of a toddler through play may enhance success.
- Preschoolers are fairly cooperative and respond well to age-appropriate explanations. Allowing some level of choice and control may facilitate success with preschool children.
- School-age children, although often cooperative, may fear bodily injury and should be permitted even more control, involvement in the process, and information.
- Age-appropriate fears related to pain, changes in body image, and injury are prevalent among

older school-age and adolescent patients. The nurse should establish a positive rapport with the patient, develop the plan of care in collaboration with the patient, and ensure privacy in all aspects of drug administration.

Atraumatic care principles should be used when possible. Donna Wong's **Principle of Atraumatic Care** is "the philosophy of providing therapeutic care through the use of interventions that eliminate or minimize the psychologic and physical distress experienced by children and families." Atraumatic care is achieved by decreasing the separation of children from their family members or caregivers, identifying family and patient stressors, decreasing pain, and providing care within the framework of a collaborative partnership.

TABLE 5.4

Dosage Form Variability for Pediatric Age Groups

Neonates: 0-4 weeks	???
Infants: 1 month-2 years	Liquids—small volumes (syrups, solutions)
Children: 2-5 years	Liquids; effervescent tablets dispersed in liquids; sprinkles on food
Children: 6-11 years	Solids (chewable tablets, orally disintegrating tablets, oral films)
Adolescents: 12-18 years	Solids (typical adult dosage forms—tablets, capsules)

From Pinto, J. C. (n.d.). *Pediatric dosage development: Where are we?* [PowerPoint slides]. Retrieved from http://www.fda.gov/downloads/NewsEvents/MeetingsConferencesWorkshops/UCM415217.pdf

Most pediatric drugs are administered via the oral route (Table 5.4). This route is the least invasive and easiest to use and can be used by family members or caregivers. Topical, rectal, and parenteral routes are also used to deliver drugs to pediatric patients for whom the oral route is contraindicated. Because of tissue differences among children, the IV route is more predictable than other routes.

Most oral drugs administered to children under the age of 6 are given using an oral syringe. Oral syringes ensure more exact dosing and are relatively easy to use. Syringes may be marked to ensure correct dosages. The syringe is inserted into either side of the mouth and is pointed toward the buccal mucosa. Depositing the drug too close to the front of the mouth increases the likelihood that it will be spit out. Pointing the syringe directly toward the back of the mouth may increase the risk for gagging or choking. Infants may suck drugs from a bottle nipple into which the measured drug has been squirted from an oral syringe. Preschool and school-age children are usually able to inject oral drugs into their own mouths, enhancing their sense of control over what can be an anxiety-provoking situation.

Nurses may need to crush pills or dissolve the contents of capsules in fluid for administration to pediatric patients. The nurse should work closely with the pharmacist and in compliance with hospital policies to determine the advisability of crushing or dissolving a drug before administration; some drugs, particularly timed-release and enteric-coated drugs, should *not* be crushed or dissolved. Some drugs may be made more palatable by adding jam, yogurt, or honey (although infants younger than 1 year should not be given honey because of the risk of botulism). Small volumes (10 mL) should be used to dilute drugs so the patient is ensured the full dose. For children who require tube feeding, oral drugs can be administered via nasogastric, orogastric, or gastrostomy tubes, if the drugs can be crushed or dissolved prior to administration.

When drug injection or venipuncture is necessary, topical anesthetic protocols may be followed to reduce the pain associated with the procedure. Agents such as eutectic mixture of local anesthetics (EMLA), topical liposomal 4% lidocaine cream (LMX4), or a vapocoolant spray may be effective in reducing the pain and fear associated with invasive procedures, such as injection or venipuncture, in children.

Based on the cognitive level of the child, other nonpharmacologic methods of pain and anxiety control such as distraction, diversion, relaxation, and creative imagery can also be used to decrease the perception of pain. Injections should *never* be given to a sleeping child with the intent to surprise the child with a quick procedure. The child may subsequently experience a lack of trust and may be reluctant to sleep in the future.

IV infusion sites must be protected, especially in infants and toddlers, who do not understand the rationale or importance of maintaining the IV site. Commercial products are available to protect the IV site and maintain an intact IV infusion set. Stocking-like covers may hide the IV site from infants before they master the concept of object permanence. The patency of an IV site should be checked prior to each drug administration to avoid infiltration and extravasation. Any injection site on a preschooler should be covered with a bandage, preferably a decorated one, so that the child does

not fear "leakage" from the area. Selection of injection and IV sites is made based on developmental variables, site of preference, and access to administration sites. The ventrogluteal or vastus lateralis are preferred sites for pediatric IM injections. The length of the needle depends on the child's muscle mass, subcutaneous tissue, and the site of injection. Children may prefer subcutaneous injections in the leg or upper arm rather than in the abdomen. IV sites may be difficult to find in children. The amount of fatty tissue, hydration status of the child, and ability to isolate and immobilize veins are all mitigating factors.

When administering drugs to children, follow these basic principles: honesty, respect, age-appropriate teaching and explanations, attention to safety, atraumatic care, use of the least amount of restraint necessary (e.g., swaddling a neonate), providing positive reinforcement for age-appropriate cooperation, refraining from use of negative messages or behaviors, and upholding family-centered principles. These standards may be used throughout the pediatric life span and highlight the need for nursing interventions that are sensitive, individualized, and caring.

Considerations for the Adolescent Patient

Adolescent patients need individualized nursing care specific to their developmental stage. Age-oriented developmental considerations include physical changes, cognitive level and abilities, emotional factors, and impact of chronic illness.

Physically, adolescence is a highly diverse period of growth and development. Growth rates during these years may be affected by nutrition, factors within the environment, genetics and heredity, and gender. A group of adolescents of similar ages may manifest very different sizes, height-to-weight proportions, timing of secondary sex characteristics, and other indicators of physical maturity. These differences may warrant individualization of drug dosage based on weight or body surface area, even when the adolescent meets or exceeds the size of standard adults. For example, an adjustment may be required in the dosage of a lipid-soluble drug because of the changes in lean-to-fat body mass, especially in young adolescent males, that coincide with physical maturation. Hormonal changes and growth spurts may necessitate changes in drug dosages; many children with chronic illnesses require dosage adjustments in the early teen years as a result of these transitions. Sleep requirements and metabolic rates may greatly increase during the teen years, along with appetite and food consumption, which may affect the scheduling of and response to drugs. Although adolescents' physical appearance and organ structure and function resemble those of adults, their bodies continue to grow and change; this requires increased vigilance in monitoring therapeutic and toxic drug levels.

The cognitive level and abilities of adolescents may pose additional considerations. Cognitive theorists have posited that adolescents progress from concrete to abstract reasoning. Individuals who are still in the concrete operational stage may have difficulty comprehending how a drug exerts its effects on the body and the importance of meticulous dosing and administration. Adolescents may also have difficulty understanding such concepts as drug interactions, side effects, adverse reactions, and therapeutic levels. For example, the patient taking birth control pills may or may not be able to comprehend the reduced action of birth control pills caused by antibiotics taken during an acute infection and may fail to take extra precautions to prevent pregnancy.

An understanding of the adolescent brain and the ongoing development of social, reasoning, and decision-making skills can be used to guide nursing assessment and interventions with the pediatric patient. As adolescents learn to reason in an abstract manner, teaching may be based on more complex information. Potentially, adolescent perception of invulnerability and difficulty relating future consequences to current actions may dictate that the nurse adapt teaching to address specific adolescent thought processes. An adolescent who is told that an insulin injection schedule must be adhered to in order to avoid long-term complications may not understand the rationale for treatment if it is only substantiated by abstract, future-oriented risks. The same patient may find the relationship between using insulin to maintain normoglycemia and the ability to participate in sports more immediate and relevant. Allowing the adolescent to verbalize concerns about the drug and its regimen may offer opportunities for clarifying misconceptions and teaching new concepts.

Emotional development of the adolescent also occurs on an individual basis. The adolescent years are characterized by sensation seeking, risk taking, questioning, formation of identity, and increasing influences exerted by peer groups. To avoid potential drug interactions, the nurse should assess for high-risk behaviors that include use of alcohol, tobacco, and recreational drugs. Other issues, including sexual practices and stressful family and social situations, may affect the patient's response to drugs. Nurses must be respectful of the emotional needs of adolescence while attending to the mental health issues that may surface during these years. A comprehensive history must be solicited from adolescent patients to ensure appropriate drug administration. The nurse must also be conscious of the need to exercise care in offering confidentiality in the event that information needs to be divulged to other health care providers, family members, or caregivers to ensure patient safety.

As adolescents attain greater levels of independence from their parents, self-care behaviors increase. The nurse should assess the patient's abilities to self-administer drugs and monitor therapeutic and adverse reactions. Adolescents spend less time with family members and caregivers and may need increased instruction about their drug regimen and the key observations that are needed. Although adolescents frequently display "breaking away" behaviors in response to parental bonds, they often continue to use family members or caregiver drug habits as models for

their own drug behaviors.

For the pediatric patient with a chronic illness, issues may change during adolescence. Engaging peers in the plan of care for drug administration, allowing the adolescent to make safe choices and have flexibility within that plan, setting up mutual drug contracts, and permitting the patient to design their own adult-monitored drug regimen may facilitate adherence. The nurse can facilitate required adaptations and support both the patient and family members during these times.

Nursing Process: Family-Centered Collaborative Care

In working with pediatric patients, key developmental differences must be considered when administering and monitoring drugs. The nursing process provides the framework to guide nursing practice in administering drugs, planning and evaluating nursing care, providing patient and family teaching, and incorporating the family into all aspects of treatment.

Family and patient teaching is a key role for the nurse. Issues such as indications for the drug, the side effects, the dose, how to measure the dose, how to administer the dose, the therapeutic effect, adverse effects to monitor for, the duration, and the frequency are all important information needed by the family or caregiver. Specifics such as the need for refrigeration, the need to shake the medicine, the difference between household and prescriptive measurements, and other issues should be addressed to ensure patient safety. Adherence to the drug regimen is of paramount importance with children and families; providing written instructions or a drug calendar may facilitate this through concrete reminders.

Nurses should also be aware of the tendency for parents to treat infants and children with over-the-counter (OTC) analgesics. Parents may provide frequent analgesia to their children and may be largely unaware of the potential for misuse and overuse in the pediatric population. Additional concern has arisen regarding the inappropriate use of OTC cough and cold remedies with children. Deaths and significant illness have been attributed to lack of label recommendations, misuse of adult drugs, poor drug instructions, and overdose, which warrants rigid restrictions on the use of these drugs in the pediatric population.

Nursing Process: Family-Centered Collaborative Care

Pediatrics

Assessment

- Assess the context and meaning of illness.
- Assess developmental age, health status, nutritional status, and hydration status.
- Assess family member and caregiver health literacy level and the child's cognitive level.
- Assess family patterns, economic issues, and cultural patterns that influence adherence to a therapeutic regimen.
- Assess learning style.
- Assess readiness to learn.
- Assess the allergy history of the child and determine family allergy history.
- Identify all of the patient's drugs (prescriptions, over-the-counter [OTC], and herbal).
- Record the age, weight, and height of the child. Drug calculations are based on these three factors.

Nursing Diagnoses

- Knowledge, Deficient related to cognitive limitation or decreased health literacy, misinterpretation of available information or unfamiliarity with available resources, lack of interest in learning
- Health Maintenance, Ineffective related to cognitive limitations, insufficient resources, and unachieved developmental tasks
- Knowledge, Readiness for Enhanced
- Injury, Risk for

Planning

- Family members and caregivers, as well as the pediatric patient if appropriate, will recognize the need for drug administration.
- Family members and caregivers, as well as the pediatric patient if appropriate, will describe the rationale for drug therapy.
- Family members and caregivers, as well as the pediatric patient if appropriate, will incorporate the drug treatment regimen into their lifestyle.

- Family members and caregivers, as well as the pediatric patient if appropriate, will demonstrate safe drug administration practices.
- Family members and caregivers, as well as the pediatric patient if appropriate, will state with confidence their ability to manage the treatment regimen and remain in control of their life.
- The pediatric patient will remain free of drug-related injuries.

Nursing Interventions

- Assist the patient, family members, and caregivers with appropriate follow-up resources and support.
- Avoid the use of restraints.
- Engage the patient, family members, and caregivers as partners in the educational process.
- Follow all rights of safe drug administration.
- Help patients, their family members, and caregivers manage complex drug schedules.
- Reconcile the drug list at discharge, and provide the list to the patient, family members, and caregivers as appropriate.
- Support patient, family member, and caregiver priorities, preferences, and choices.
- Use at least two methods of patient identification.
- Use open-ended questions and encourage two-way communication.

Patient Teaching

- Consider the use of alternative settings for teaching the chronically ill pediatric patient, their family members, and caregivers.
- Provide a developmentally appropriate environment when addressing the health education needs of adolescents.
- Provide information to support self-efficacy, self-regulation, and self-management of the drug regimen.
- Use educational strategies that are interactive and engaging for younger children and toddlers.
- Use family-centered approaches when teaching children and adolescents.
- Use strategies to promote motivation and sustain learning.

Cultural Considerations

- Assess for cultural/ethnic self-care practices.
- Assess the influence of cultural beliefs and values on the knowledge base.
- Provide educational materials in the native language of patients, family members, and caregivers.

Evaluation

- Evaluate the child's physiologic and psychological response to the drug regimen.
- Evaluate the family member's knowledge about the drug, the dosage, the schedule for administration, and the side effects.
- Evaluate the therapeutic and adverse effects of the drug(s).

Critical Thinking Case Study

A 9-month-old infant weighing 20 pounds comes to the emergency department with a 3-day history of vomiting, fever greater than 102.5°F, and significant pain. Physical assessment reveals acute otitis media, for which the doctor prescribed amoxicillin 500 mg three times a day for 5 days and ibuprofen 2.5 mL every 6 hours.

1. Prior to administration of amoxicillin, what must the nurse assess for?
2. If the safe dose of amoxicillin for a child under the age of 2 is 80 mg/kg/day in divided doses, is the prescribed dose safe? How do you know?
3. How will you instruct the family member to safely administer the drugs?

NCLEX Study Questions

1. A 4-year-old patient is discharged on an oral liquid drug suspension of 4 mL per dose. Which device will the nurse recommend to ensure the highest level of accuracy in home administration of the drug?
   a. Measuring spoon
   b. Graduated medicine cup
   c. Household teaspoon
   d. Oral syringe
2. A child is ordered to receive naloxone intravenously STAT. The child's weight is 20 kg, and the recommended child's dosage is 0.01 mg/kg. Naloxone is available in a 400 mcg/mL solution. How much drug will the nurse plan to administer?
3. A child who weighs 88 pounds is ordered to receive 3 mg/kg of a drug. The drug is available in a 15 mg/mL elixir. How much drug will the patient receive?
4. The nurse understands the differences between drug excretion in children and that in adults. With this knowledge, what does the nurse consider when administering drugs to children?
   a. Most children need a higher dose of drug, so the nurse will contact the physician for an increase in the ordered dose.
   b. Children excrete drugs rapidly, so the nurse must assess carefully for therapeutic effects of the drug.
   c. The most important assessment is to evaluate for drug accumulation, because the excretion of drugs is slower in children.
   d. Excretion of most drugs is the same in children as in adults, but assessments are important to avoid side effects.
5. A parent is learning to administer drug to a school-age child. Which strategy will the nurse teach the parent to achieve cooperation in a child of this age?
   a. Enlisting physical restraint
   b. Establishing drug contracts
   c. Providing age-appropriate explanations
   d. Tolerating violent reactions
6. A nurse caring for a child with developmental delay prepares to teach the patient about prescribed drugs. Which actions are essential to ensure patient safety? (Select all that apply.)
   a. Assess the child's developmental age.
   b. Assess for side effects the same as those experienced by adults.
   c. Consider the actions and uses of the drug.
   d. Focus on the child's chronologic age.
   e. Involve the family in teaching sessions.
7. The Principle of Atraumatic Care includes (select all that apply):
   a. Pain management
   b. Collaborative care with family members
   c. Restraining infants to administer drugs
   d. Keeping the child apart from family members when administering drugs
8. Which of the following strategies are helpful when working with adolescent patients to promote adherence? (Select all that apply.)
   a. Allow flexibility in the treatment plan.
   b. Use future-oriented examples and consequences to support the need for drug therapy.
   c. Guarantee the adolescent patient privacy when obtaining history.
   d. Set up a mutually developed drug contract.

Answers: 1, d; 2, 0.5 mL; 3, 8 mL; 4, c; 5, c; 6, a, c, e; 7, a, b; 8, a, d.

Geriatric Considerations

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Explain how the physiologic changes associated with aging impact drug therapy.
- Describe two ways the Beers criteria can be used to improve the care of older adults.
- Discuss issues that affect older adults' adherence to therapeutic regimens.
- Describe nursing implications related to drug therapy in the older adult.

KEY TERMS

adherence, p. 55
adverse drug events (ADEs), p. 55
Beers Criteria for Potentially Inappropriate Medication Use in Older Adults, p. 54
older adult, p. 52
polypharmacy, p. 54

By 2033, persons over the age of 65 will outnumber those under the age of 18 in the United States. There are expected to be over 98 million older adults by the year 2060, with close to 20 million over the age of 85. These numbers are staggering, more so considering 92% of older adults have at least

one chronic illness, and over 75% of older adults have two chronic illnesses. Typically, persons with two or more chronic conditions take five or more prescription drugs.

Over half of all older adults use at least one over-the-counter (OTC) drug, and nearly three-quarters of older adults use at least one supplement to augment their prescription drugs; however, older adults are more likely to experience adverse reactions or drug interactions related to OTC drugs and supplements, many times resulting in hospitalization.

Administration of drugs in the **older adult** population requires special attention to age-related factors that influence drug absorption, distribution, metabolism, and excretion. Drug dosages are often adjusted according to the older adult's weight, laboratory results (e.g., liver enzymes and glomerular filtration), and comorbid health problems. Because of altered organ function in the older adult, the effects of drug therapy must be closely monitored to prevent adverse reactions and possible toxicity.

Drug toxicity may develop in the older adult for drug doses that are within the therapeutic range for the younger adult. These therapeutic drug ranges are usually safe for young and middle-aged adults but are not always within the safe range for older adults. It has been suggested that drugs for older adults should initially be prescribed at low dosages with a gradual increase in dosage based on therapeutic response; this practice is commonly stated as *start low and go slow*. This approach to drug prescribing reduces the chance of drug toxicity.

Common characteristics in older adults that increase the risk for problems with drug administration include lack of coordinated care, recent discharge from the hospital, self-treatment, multiple diagnoses, sensory and physical changes associated with aging, multiple health care providers, and cognitive impairment.

Physiologic Changes

Physiologic changes associated with aging can influence absorption, distribution, metabolism, and excretion of drugs as well as pharmacodynamic responses at receptors and target organs. These physiologic changes include the following:

- A reduction in total body water and lean body mass, resulting in increased body fat, which alters the volume of distribution of drugs.
- A reduction in kidney mass and lower kidney blood flow, leading to a reduced glomerular filtration rate (GFR) and reduced clearance of drugs excreted by the kidneys.
- A reduction in liver size and blood flow, resulting in reduced hepatic clearance of drugs.

A decline in the physiologic processes that maintain equilibrium in the older adult may mean a higher incidence of adverse effects. Examples of this include:

- Postural hypotension in response to drugs that reduce blood pressure
- Volume depletion and electrolyte imbalance in response to diuretics
- Excessive bleeding with anticoagulant and antiplatelet drugs
- Altered glycemic response to antidiabetic drugs
- Gastrointestinal (GI) irritation with nonsteroidal antiinflammatory drugs (NSAIDs)

Physiologic changes with aging affect the determination of risk versus benefit underlying drug choice, dose, and frequency.

Pharmacokinetics

Pharmacologic processes have not received adequate study in the older adult, therefore a thorough understanding of pharmacokinetics is necessary for the safe administration of drugs in this population.

Absorption

Adults experience several GI changes with aging that may influence drug absorption. These include a decrease in small-bowel surface area, slowed gastric emptying, reduced gastric blood flow, and a 5% to 10% decrease in gastric acid production. These changes are not always clinically relevant; however, calcium carbonate is affected by the decreased gastric acidity. Older adults should be prescribed calcium citrate, which requires a less acidic environment for dissolution. Other common problems that occur in older adults that can significantly influence drug absorption include swallowing difficulties, poor nutrition, and dependence on feeding tubes.

Distribution

Aging can significantly alter drug distribution. With aging, adults experience a decline in muscle mass and a 20% to 40% increase in fat. The increase in body fat means lipid-soluble drugs have a greater volume of distribution, increased drug storage, reduced elimination, and a prolonged period of action. Older adults have a 10% to 15% reduction in total body water, which affects water-soluble drugs, and a 10% reduction in albumin. Reduced albumin levels can result in decreased protein binding of drugs and increased free drug available to exert therapeutic effects, but it also increases the risk for drug toxicity.

Metabolism

Hepatic blood flow in the older adult may be decreased by 40%; aging also results in a 15% to 30% decrease in liver size and a reduction in cytochrome P450 (CYP450) enzyme activity that is responsible for the breakdown of drugs. Drug clearance by hepatic metabolism can be reduced by these age-related changes. A reduction in hepatic metabolism can decrease first-pass metabolism and can prolong drug half-life, resulting in increased drug levels and potential drug toxicity. Nurses must be aware of these metabolic changes and must monitor response to drug therapy to avoid adverse reactions.

To assess liver function, liver enzymes must be checked. Elevated levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) may indicate possible liver dysfunction. However, an older adult can have normal liver function test (LFT) results and still have impaired hepatic enzyme activity.

Excretion

Renal excretion of drugs decreases with age. Excretion is altered by age-related changes in kidney function, such as decreased renal size and volume, which differ for each individual. However, it is generally accepted that the GFR declines by 1 mL/min after the age of 40 (normal GFR is 100 to 125 mL/min). Despite a decline in kidney function, an individual's creatinine may remain normal as he or she ages due to a decline in muscle mass and activity. Changes in kidney function affect many drugs, leading to a prolonged half-life and elevated drug levels. Changes in kidney function require dosage adjustment, especially if the drug has a narrow therapeutic range.

GFR can be calculated using the Cockroft-Gault formula, which is the formula recommended by the U.S. Food and Drug Administration (FDA) and therefore used by pharmaceutical manufacturers when determining dosage adjustments:

$$C_{Cr} = [(140 - age) \times weight) / (72 \times S_{Cr}) \times 0.85 \ (\text{if female})$$

Abbreviations/Units: C_{Cr} (creatinine clearance) = mL/minute; Age = years; Weight = kg; S_{Cr} (serum creatinine) = mg/dL.

However, it can also be estimated by many calculators found on the Internet (www.globalrph.com/crcl.htm).

Nurses must have a general understanding of drug classifications that require dosage adjustment in patients with chronic kidney disease (CKD). The mnemonic *BANDD CAMP* (Table 6.1) may be helpful in remembering the drug classifications; however, nurses should not rely on their memory for drug administration. Package inserts, up-to-date drug reference books, and reputable websites (www.globalrph.com/index_renal.htm) maintain current dosing information.

Pharmacodynamics

Pharmacodynamic responses to drugs are altered with aging as a result of changes in the number of receptor sites, which affects the affinity of certain drugs. These changes are seen most clearly in the cardiovascular and central nervous systems.

TABLE 6.1

Drug Classes That Require Dosage Adjustment in Chronic Kidney Disease

	Drug Class	Adjust Dose	Avoid in Stages 4 and 5
B	Beta blockers	Acebutolol, atenolol, bisoprolol, nadolol, sotalol	Sotalol
A	ACEIs/ARBs	All ACEIs	Olmesartan
N	NSAIDs, opioids	Codeine, morphine, oxycodone, tramadol	All NSAIDs, meperidine
D	Diuretics	Potassium-sparing diuretics, thiazide diuretics	Potassium-sparing diuretics, thiazide diuretics
D	Diabetic medications	Gliclazide, acarbose, insulin, gliptins	Glyburide, metformin, exenatide
C	Cholesterol medications	Pravastatin, rosuvastatin, fibrates	—
A	Antimicrobials (dose reductions are often delayed for 24-48 h to allow for aggressive dosing and for the drug to reach steady state)	Antibiotics: Most antibiotics except cloxacillin, clindamycin, metronidazole, erythromycin, azithromycin Antifungals: Fluconazole, itraconazole Antivirals: Acyclovir, famciclovir, valacyclovir	Nitrofurantoin
M	Miscellaneous	Allopurinol, colchicine, digoxin, H_2RAs	New anticoagulants
P	Psychotropics	Lithium, gabapentin, pregabalin, topiramate, vigabatrin; bupropion, duloxetine, paroxetine, venlafaxine	—

ACEI, Angiotensin-converting enzyme inhibitor; *ARB,* angiotensin II-receptor blocker; *h,* hours; H_2RAs, histamine-2 receptor antagonists; *NSAID,* nonsteroidal antiinflammatory drug.

From Meyer, D., Damm, T., & Jensen, K. (2012). Drug dosage adjustments in chronic kidney disease: The pharmacist's role. Saskatchewan Drug Information Services College of Pharmacy and Nutrition, University of Saskatchewan. Retrieved from www.rxfiles.ca/rxfiles/uploads/documents/ltc/HCPs/CKD/SDIS.Renal_newsletter.pdf

Older adults experience a loss of sensitivity in adrenergic receptors, affecting both agonists and antagonists; this results in a reduced response to beta blockers and $beta_2$ agonists. Older adults also experience a blunting in compensatory reflexes leading to orthostatic hypotension and falls.

With age, there is a reduction in dopaminergic and cholinergic receptors, neurons, and available neural connections in the brain. There is reduced blood flow to the brain, and the blood-brain barrier also becomes more permeable. This puts the older adult at risk for central nervous system (CNS) drug side effects, which include dizziness, seizures, confusion, sedation, and extrapyramidal effects.

Nursing Implications: Older Adult Drug Dosing and Monitoring

Polypharmacy

Polypharmacy refers to the use of more medications than is medically necessary. There is little agreement on the actual number of drugs that constitutes polypharmacy, but researchers use five drugs because this number has been associated with increased incidence of adverse drug reactions, geriatric syndromes, and increased mortality.

Risk factors associated with polypharmacy include advanced age, female sex, multiple health care providers, use of herbal therapies and OTC drugs, multiple chronic diseases, and the number of hospitalizations and care transitions. Polypharmacy can cause an increase in geriatric syndromes (cognitive impairment, falls, decreased functional status, urinary incontinence, and poor nutrition) as well as an increased incidence of adverse drug reactions and poor adherence.

Pharmacotherapy in older adults is complex. In order to reduce the risk for and incidence of polypharmacy, nurses must be involved in the coordination of care for older adults. Older adults should be encouraged to use only one pharmacy and should give the pharmacist a list of all the drugs taken—prescribed, herbal, and OTC. A properly informed pharmacist will be able to conduct a clinical review of the patient's drugs to ensure the appropriateness of therapy. A pharmacist can also confirm patient understanding of individual therapy and can monitor responses to drug therapy. All of this is done to improve the overall quality of life of patients in their care.

Beers Criteria for Potentially Inappropriate Medication Use in Older Adults

The American Geriatrics Society **Beers Criteria for Potentially Inappropriate Medication Use in Older Adults** is a document developed by a consensus panel of 12 experts in geriatric care to aid health care providers in the safe prescription and administration of drugs to older adults (available free from http://onlinelibrary.wiley.com/doi/10.1111/jgs.13702/epdf). First developed in 1991, it has been revised four times, most recently in 2015. The 2015 Beers Criteria added new information on renal dosing of drugs and drug-drug interactions; as in previous editions, it continues to provide safety information based on best available evidence to use in decision making for drug therapy. Although the document provides information on drugs to avoid in older adults and drugs to use with caution, it is not designed for use in isolation. All drug therapy decisions should be made taking into consideration an individual's preferences, values, and needs. It is very important that the nurse advocate for the patient in these areas to ensure safety and promote adherence.

TABLE 6.2

Barriers to Effective Drug Use by Older Adults

Causes	Nursing Actions
Taking too many drugs at different times	Develop a chart indicating times to take drugs. Provide space to place a mark for each drug taken. Coordinate the drug regimen with activities of daily living (e.g., meals) and events. Use an organizer container (daily or weekly). Have the patient bring all drugs—including over-the-counter drugs and herbal, vitamin, and mineral supplements—to all health appointments.
Failure to understand the purpose or reason for a drug	Explain the purpose, drug action, and importance of the drug. Provide time for questions and reinforcement. Reinforce with written information.
Impaired memory	Encourage family members or friends to monitor the patient's drug regimen.
Decreased mobility and dexterity	Advise family members or friends to have drugs and water or other fluid accessible and to assist older adults as needed.
Visual and hearing disturbances	Suggest eye and ear examinations (glasses or hearing aids).
High cost of prescriptions	Contact the social services department of your institution and compassionate care programs as appropriate.
Childproof drug bottles	Suggest that the patient request nonchildproof bottle caps.
Side effects or adverse reactions from the drug	Educate the patient and family about side effects to report to the health care provider.

Adverse Drug Events

No drug is safe. Every year, over 775,000 emergency department (ED) visits occur due to adverse drug events (ADEs), and over 125,000 people are hospitalized due to ADEs. Older adults are twice

as likely as younger adults to visit the ED with adverse drug events and are seven times as likely to be hospitalized. Most visits and hospitalizations occur due to reactions to blood thinners, drugs used to treat diabetes and seizures, cardiac drugs, and drugs used for pain control.

According to the World Health Organization, ADEs are "unintended and undesired effects of a [drug] at the normal dose." There are five types of adverse drug events: (1) adverse drug reactions, (2) medication errors, (3) therapeutic failures, (4) adverse drug withdrawal events, and (5) overdoses. Older adults have multiple risk factors for ADEs, including frailty, multiple comorbidities, polypharmacy, and cognitive issues.

Adherence

Adherence to a drug regimen is a problem for all patient age groups, but it is especially troublesome in older adult patients. Older adults may fail to ask questions during interactions with health care providers, which leads to the drug regimen not being fully understood or precisely followed. Failure to adhere to a drug regimen can cause underdosing or overdosing that could be harmful to the patient's health. Table 6.2 lists barriers to effective drug use by older adults.

Failure to adhere to a drug regimen can lead to ADEs, resulting in hospital admission, readmission to health care institutions, and even death. Complex drug regimens may be difficult for older adults to follow. Education is the cornerstone of adherence, and this includes education of the patient, family, and formal and informal caregivers.

Working with older adult patients is an ongoing nursing responsibility. The nurse should plan strategies with the patient and family or friends to encourage adherence with prescribed regimens. Daily contact may be necessary at first. Simply ordering the drug does not mean that the patient is able to get the drug or take it correctly. Older adults should have their prescriptions filled at one pharmacy if possible so a relationship can be established with a pharmacist and drug interactions can be identified and monitored closely.

The Medicare Modernization Act of 2003 made it possible for older adults to obtain prescription drug coverage through Medicare, with initial enrollment beginning in 2006. Older adults who are eligible for Medicare Part A or Part B are eligible for the optional Medicare Prescription Drug Plan (Part D) or coverage through a Medicare Advantage Plan (Part C). Each of these plans has its own formulary, copay rate, and in-network pharmacies. No plan is perfect for every older adult; the nurse, as advocate, must be able to assist the older adult to find the plan that is right for him or her and to make the most of the policy.

However, not all older adults have insurance that includes prescription drug coverage, nor are they able to afford their drugs even with insurance. Nurses need to assess the patient's ability to obtain prescriptions prior to sending the patient home. Options for assistance are available, and the nurse can assist patients in navigating the system to obtain their drugs for free or at a reduced cost (see Partnership for Prescription Assistance at www.pparx.org and Extra Help at www.ssa.gov/medicare/prescriptionhelp).

Health care professionals—nurses, pharmacists, and health care providers—need to work collaboratively to enhance safety and adherence of older adult patients and to avoid errors and unwarranted concerns. Nurses are in a unique position to educate patients and to monitor the effectiveness of therapeutic regimens. A handout of tips for patients on talking with their pharmacist can be found at www.fda.gov/downloads/Drugs/ResourcesForYou/UCM163349.pdf.

Health Teaching with the Older Adult

Specific factors that enhance educational readiness and promote adherence in the older adult include the following:

- Ensure that the patient is wearing eyeglasses and has working hearing aids in place if needed. Check sensory aids to be sure they are clean and working.
- Speak in a tone of voice that the patient can hear; sit facing the patient, and limit distractions.
- Treat the patient with respect; never infantilize (also referred to as "elderspeak"); expect that the patient can learn.
- Use large print and dark type against a light background; use a font with serifs, or "feet and tails" (like this one), which makes letters close together easier to read.
- Review all drugs at each patient visit; ask the patient to bring all drugs to each appointment, and advise use of only one pharmacy.
- Advise the patient to complete the *vial of life* (medical information for emergency personnel to use in the provision of care; www.vialoflife.com) and keep it on the refrigerator door where safety personnel will know to look for it.
- Instruct the patient to keep a list of all drugs taken, bring it to all health appointments, and carry it when out of the house.
- Encourage a simple dosing schedule when possible.
- Suspect recently prescribed drug(s) if new confusion or disorientation occurs.
- Encourage the patient to report if a drug is not improving the condition for which it was prescribed.
- Consider use of memory aids such as pill organizers or planners, alarms, blinking lights, or prerecorded messages.

The National Institutes of Health (NIH) websites on aging are excellent resources for both health care providers and older adults and their families. The website for health care providers is www.nia.nih.gov; it has sections on health information, research, grants, training, news, and events. The website for older adults is www.nihseniorhealth.gov.

Nursing Process: Patient-Centered Collaborative Care

Geriatrics

Assessment

- Assess for allergies.
- Assess for sensory and cognitive barriers.
  - Assess the patient's use of eyeglasses, and check the date of the last eye examination.
  - Is the patient confused or disoriented? If so, is this state transitory?
- Assess laboratory test results, and follow up as appropriate.
  - Decreased kidney and liver function can increase the half-life of drugs.
- Assess weight and vital signs.
- Determine all drugs the patient takes, including illicit, prescription, and OTC drugs and supplements.
  - Assess patient adherence to the drug regimen.
  - Assess patient knowledge of the purpose of each drug, how it works, and its possible side effects.
- Discern whether the patient has difficulty opening drug containers and whether the patient is experiencing side effects or adverse reactions.
- Discern whether the patient lives alone, with or without social support, and if assistance is needed with drugs, including costs or the transportation to acquire them.
- Obtain a history of chronic conditions.

Nursing Diagnoses

- Health Maintenance, Ineffective related to lack of, or alteration in, communication skills (written, verbal, and nonverbal)

- Therapeutic Regimen Management, Ineffective related to the complexity of the regimen
- Knowledge, Deficient related to cognitive limitation, information misinterpretation, and lack of interest in learning
- Constipation, Risk for related to use of drugs (e.g., aluminum-containing antacids, anticholinergics, calcium channel blockers, diuretics, and opiates)

Planning

- The patient will collaborate with health care providers to develop a therapeutic regimen that is congruent with health goals and lifestyle.
- The patient will describe why the drug is needed, how the drug is administered, common adverse reactions, and drug interactions.
- The patient will identify measures to prevent constipation.
- The patient will list resources that can be used for more information or support.
- The patient will verbalize the ability to manage the therapeutic regimen.

Nursing Interventions

- Ascertain whether financial problems are preventing the patient from purchasing prescribed drugs. Assistance programs are available.
- Communicate with the pharmacist or health care provider when a drug dose is in question. Check drug references for recommended drug dosages for older adults.
- Establish a collaborative partnership with the patient in order to meet health-related goals.
- Monitor the patient's laboratory results to ensure that blood urea nitrogen (BUN), serum creatinine, estimated glomerular filtration rate (eGFR), and liver enzymes are within normal range and that drug levels are within the therapeutic range. Discuss findings with the health care provider.
- Observe the patient for adverse reactions when multiple drugs are being taken.
- Recognize a change in usual behavior or an increase in confusion. One of the first signs of drug toxicity is a change in mental status. Report changes to the health care provider.
- Remind the patient and family to tell the pharmacist about OTC preparations the patient is taking when picking up prescriptions.

Patient Teaching

General

- Advise patients and family to request a non–childproof cap from the pharmacy if the patient has arthritis in the hand joint or has difficulty opening childproof bottle caps. The patient may need to sign for this at the pharmacy, and safety of children or pets in the environment must be ensured.
- Advise patients to keep a record of their drugs and when they are to be taken. Consider offering them a sample log for recording information. This removes barriers, increases drug adherence, and avoids drug errors.
- Advise patients to use one pharmacy to fill prescriptions, and instruct them to inform the pharmacist of all illicit, prescription, and OTC drugs and supplements taken.
- Be available to answer patient questions. Be supportive of the older adult and the family. Discuss problems related to the drugs.
- Counsel patients not to share prescribed drugs with others or to take drugs prescribed for another person.
- Explain to patients and family the importance of adherence to the drug regimen. Emphasize the importance of taking drugs as prescribed.
- Review drugs with patients and family, including the reason the drug was prescribed, route of administration, frequency, common side effects, and when to notify the health care provider.

Cultural Considerations

- Do not assume that lack of eye contact means the patient is not listening or does not care; it might indicate respect. More traditional or older individuals in some cultures do not maintain eye contact.
- Provide additional time for verbal and written explanations to ensure all questions related to the drug regimen have been asked and answered. This will promote adherence.
- Recognize that language difficulties may interfere with older adults' understanding of the prescribed drug regimen if English is not their first language; provide educational material in

the patient's native language.

Evaluation

- Evaluate adherence to the drug regimen, and answer any questions the older adult may have.
- Evaluate therapeutic drug response, and ascertain side effects or adverse reactions.

Critical Thinking Case Study

A 78-year-old woman comes to the clinic for a new-patient examination. She reports that she smokes *Cannabis* several times a week and also takes alprazolam 0.5 mg three times per day, a combination tablet of metoprolol tartrate 50 mg/hydrochlorothiazide 25 mg daily, aspirin 81 mg daily; garlic soft-gels 1000 mg twice a day; and ibuprofen 400 mg four times a day.

1. Do any of these drugs appear on the 2015 American Geriatrics Society Beers Criteria for Potentially Inappropriate Medication Use in Older Adults? If so, what do the criteria say about them?
2. What interactions exist among the drugs and supplements this patient is taking?
3. What is the evidence for taking garlic to reduce cholesterol?

NCLEX Study Questions

1. A patient has nine drugs prescribed to take daily. Which are common reasons for nonadherence to the drug regimen in an older adult? (Select all that apply.)
   a. Taking multiple drugs at one time
   b. Impaired memory
   c. Decreased dexterity
   d. Increased mobility
   e. Increased visual acuity
2. The nurse is reviewing a patient's list of drugs. The nurse understands that the older adult's slower absorption of oral drugs is primarily because of which phenomenon?
   a. Decreased cardiac output
   b. Increased gastric emptying time
   c. Decreased gastric blood flow
   d. Increased gastric acid secretion
3. The older adult patient has questions about oral drug metabolism. Information on what subject is most important to include in this patient's teaching plan?
   a. First-pass effect
   b. Enzyme function
   c. Glomerular filtration rate
   d. Motility
4. An older patient has just started on hydrochlorothiazide and is advised by the health care provider to eat foods rich in potassium. What is the nurse's best recommendation of foods to consume?
   a. Cabbage and corn
   b. Bread and cheese
   c. Avocados and mushrooms
   d. Brown rice and fish
5. The nurse is developing teaching materials for an 82-year-old African-American man with macular degeneration, who is being discharged on two new drugs. Which strategies would be best to use to impart the information? (Select all that apply.)
   a. Limit distractions in the room when teaching.
   b. Wait until discharge to teach so information is fresh in the memory.
   c. Augment teaching with audio material.
   d. Use *Honey* and other terms of familiarity to promote trust.
   e. Use large, dark print on a light background for written material.
6. What changes with aging alter drug distribution? (Select all that apply.)
   a. An increase in muscle mass and a decrease in fat
   b. A decrease in muscle mass and an increase in fat
   c. A decrease in serum albumin levels
   d. An increase in total body water
   e. A decrease in kidney mass
7. What factors contribute to polypharmacy in the elderly? (Select all that apply.)
   a. Multiple health care providers
   b. Multiple chronic diseases
   c. Use of a single pharmacy
   d. Care coordination by a nurse

e. Few hospitalizations

8. What is the best measure for the nurse to use to determine a patient's kidney function?
   a. Creatinine clearance
   b. Estimated glomerular filtration rate
   c. Serum creatinine level
   d. Blood urea nitrogen level

Answers: 1, a, b, c; 2, c; 3, a; 4, c; 5, a, c, e; 6, b, c, e; 7, a, b; 8, b.

Drugs in Substance Use Disorder

OUTLINE

Substance Use Disorder

- Definition
- Neurobiology
- Types of Substance Use Disorders

Special Needs of Patients With Substance Use Disorder
- Surgical Patients
- Pain Management

The Nurse With Substance Use Disorder
- Contributing Factors
- Characteristics
- Management
- Nursing Process: Patient-Centered Collaborative Care—Tobacco Use Disorder

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Define substance use disorder and differentiate among mild, moderate, and severe cases.
- Describe the short- and long-term effects of drug use.
- Identify the physical and psychological assessment findings associated with drugs most commonly used.
- Explain the rationale for the use of drug-assisted treatments during toxicity, withdrawal, and maintenance of abstinence from commonly misused drugs.
- Prioritize appropriate nursing interventions to use during the treatment of patients with drug toxicity and withdrawal.
- Identify nursing interventions appropriate during the management of surgical experiences and pain in patients with substance use disorder.
- Describe the nurse's role in recognizing and promoting the treatment of nurses with substance use disorder.
- Implement the nursing process in the care of patients with substance use disorders.

Although most drugs are used safely and within prescribed guidelines, it is possible for all drugs to be misused. It has been reported that over 40 million Americans ages 12 and over use tobacco, alcohol, or illicit drugs. Drug use is a serious and complex social and health issue with negative consequences for both the individual and society that include family dysfunction, loss of employment, failure in school, domestic violence, and child abuse. The economic cost of drug use is staggering: $600 billion annually in costs related to lost productivity, health-related issues, and crime.

Substance Use Disorder

Context

Since 1975, the **Monitoring the Future project** has been tracking drug use in adolescents and young adults. Current data from the survey indicate that 26.4% of children have tried illicit drugs by the eighth grade, 40% by the tenth grade, and 51.8% by the twelfth grade. Tenth graders had tried alcohol (49.8%), *Cannabis* (28.8%), amphetamines (6.6%), and prescription and over-the-counter (OTC) drugs such as oxycodone or cough medicine (2.6% to 5.9%). Between 15% and 39% used more than one drug, known as **polydrug use**.

Many factors play into the decision to use drugs and whether an individual develops substance use disorder. Cognitive development at the time drugs are introduced plays a major role; adolescents are in a period of brain development where they are especially vulnerable to stress and risk-seeking behaviors. Other risk factors are also related to substance use disorder:

- *Family-related risk factors*: Between 16% and 29% of children who suffer neglect or abuse—physical, sexual, and emotional—have tried or use drugs.

TABLE 7.1

Substance Use Disorder Categories

Criteria	Subcomponents

• Mild substance use disorder (2-3 criteria required)
• Moderate substance use disorder (4-5 criteria required)
• Severe substance use disorder (6-7 criteria required)
	• The substance is often taken in larger amounts or over a longer period than was intended.
	• There is a persistent desire or unsuccessful effort to cut down on or control use of the substance.
	• A great deal of time is spent in activities necessary to obtain the substance, use the substance, or recover from its effects.
	• Craving, or a strong desire or urge to use the substance, is present.
	• Recurrent use of the substance results in a failure to fulfill major role obligations at work, school, or home.
	• Continued use of the substance occurs despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of its use.
	• Important social, occupational, or recreational activities are given up or reduced because of use of the substance.
	• Recurrent use of the substance occurs in situations in which it is physically hazardous.
	• Use of the substance is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance.
	• *Tolerance occurs, as defined by either of the following:
	  • A need for markedly increased amounts of the substance to achieve intoxication or desired effect
	  • A markedly diminished effect with continued use of the same amount of the substance
	• *Withdrawal occurs, as manifested by either of the following:
	  • The characteristic withdrawal syndrome for that substance is evident as specified in the DSM-5.
	  • The substance or a closely related substance is taken to relieve or avoid withdrawal symptoms.

* Does not apply when used appropriately under medical supervision.
DSM-5, Diagnostic and Statistical Manual of Mental Disorders, 5th edition.

From Horvath, A. T., Misra, K., Epner, A. K., & Cooper, G. M. (n.d.). The diagnostic criteria for substance use disorders (addiction). Retrieved from www.amhc.org/1408-addictions/article/48502-the-diagnostic-criteria-for-substance-use-disorders-addiction; and National Institute on Drug Abuse. (2014). The science of drug abuse and addiction: The basics. Retrieved May 16, 2016, from www.drugabuse.gov/publications/media-guide/science-drug-abuse-addiction-basics

- *Social risk factors*: Deviant peer relationships (i.e., the adolescent associates with abusers and uses drugs to feel accepted), peer pressure, popularity, and bullying have all been correlated to drug use. Gang affiliation is associated with higher drug use and delinquent behavior.
- *Individual risk factors*: Individuals with attention-deficit/hyperactivity disorder (ADHD) are three times as likely as the general population to use drugs such as nicotine, alcohol, and drugs other than *Cannabis*; depression is associated with alcohol use, particularly among young men.

It should be noted that positive family relationships are a protective factor that has been related to a decrease in drug use among adolescents.

Definition

According to the *Diagnostic and Statistical Manual of Mental Disorders* (5th edition [DSM-5]), **substance use disorder** occurs "when the recurrent use of alcohol and/or drugs causes clinically and functionally significant impairment, such as health problems, disability, and failure to meet major responsibilities at work, school, or home." Substance use disorder is categorized along a continuum from mild to severe, based on the number of diagnostic criteria met (Table 7.1). The terms *abuse* and *dependence* are no longer used due to the violence and stigma associated with the term *abuse* and the ambiguity associated with the term *dependence*; gambling is the only condition in the category of behavioral addiction (continued involvement in an activity despite the substantial harm it causes; Table 7.2). Excessive caffeine use is not considered a substance use disorder, even though there appears to be a withdrawal syndrome with cessation of use.

Neurobiology

Drugs that are misused typically increase the availability of dopamine and other neurotransmitters in the limbic system of the brain. This area contains the brain's **reward circuit**, a structure that regulates our ability to feel pleasure and other emotions, both positive and negative. The drugs interfere with the way neurons in the brain normally send, receive, and process information by mimicking the brain's own neurotransmitters; however, drugs do not copy neurotransmitters exactly, which results in faulty transmission or excessive stimulation. Most of the drugs facilitate an increase of dopamine in the system, leading to mood elevation or euphoria—factors that provide strong motivation to repeat the experience. Some drugs increase the availability of other neurotransmitters, such as serotonin and gamma-aminobutyric acid (GABA), but dopamine's effect on the reward system appears to be pivotal to substance use disorder.

Repeated use of drugs remodels the neural circuitry of the brain cells and reduces the responsiveness of receptors. This decreased responsiveness leads to **tolerance**, the need for a larger dose of a drug to obtain the original euphoria. Drug use results in levels of dopamine that do not naturally occur; tolerance also reduces the sense of pleasure from experiences that previously resulted in positive feelings, such as food, sex, or relationships. Without the drug, the individual may experience depression, anxiety, and/or irritability (Table 7.3; see also Table 7.2).

Current research is focused on **epigenetics**, the study of environmental influences on genetics. How a person responds to their social and cultural environment affects drug use. Altering environmental factors that increase the risk for drug use can discourage drug-seeking behavior. Studies have shown that drug use alters DNA proteins, those that affect both gene expression and function, and this influences drug-seeking behavior. Understanding these processes may lead to new treatments for substance use disorders.

TABLE 7.2

Terminology Related to Substance Use Disorder

Term	Definition
Abstinence	Refraining from drug use
Craving	Strong desire for a drug or for the intoxicating effects of that drug
Intoxication	A condition that results in disturbances in the level of consciousness, cognition, perception, judgment, affect or behavior, or other psychophysiological functions and responses
Stabilization	Acute treatment for substance use disorder involving supervision, observation, support, intensive education, and counseling that involves multidisciplinary treatment interventions
Tolerance	Requiring a significantly increased amount of a drug to achieve the desired effect
Withdrawal syndrome	A group of symptoms of varying severity that occur upon cessation or reduction of use of a drug that has been taken repeatedly, usually for a prolonged period and/or in high doses; may be accompanied by signs of physiological disturbance
Remission	None of the 11 criteria for substance use disorder for at least three months (early remission, 3 to 12 months; sustained remission, after 12 months)
Controlled environment	Environment where access to any drug is restricted (e.g., treatment center or halfway house)
Impaired control	Diminished ability of an individual to control his or her use of a drug in terms of onset, level, or termination
Social impairment	Recurrent drug use despite problems at work or school, interpersonal problems, or the cessation of social and recreational activities
Risky use	Recurrent drug use despite the difficulty it is causing (e.g., driving while intoxicated, liver damage)
Recovery	A process of change through which an individual improves health and wellness, lives a self-directed life, and strives to reach full potentials
Relapse	A return to drug use after a period of abstinence, often accompanied by reinstatement of substance use disorder

Types of Substance Use Disorders

Alcohol Use Disorder (AUD)

People drink for many reasons, including socializing, celebrating, and relaxing; people also drink to cope, because of low self-esteem and a need for approval, or because of peer pressure. Alcohol affects everyone differently, depending on the amount consumed, the frequency of consumption, age, health status, and family history. People of all ages drink, and 15% of all alcohol sales in the United States are to teens. Alcohol use is the underlying cause in 88,000 deaths per year. Additionally, the Centers for Disease Control and Prevention report that AUD may shorten a person's life by up to 30 years!

Alcohol use inhibits the effects of GABA, thereby reducing neurotransmission in the brain. Short-term effects of alcohol use include nausea, vomiting, headaches, slurred speech, impaired judgment, memory loss, hangovers, and blackouts. Box 7.1 discusses **alcohol toxicity**.

Long-term problems associated with heavy drinking include stomach ailments, heart problems,

cancer, brain damage, serious memory loss, immune system compromise, and liver cirrhosis. Persons with AUD increase their chances of dying from automobile accidents, homicide, and suicide. Spouses and children of persons with AUD may face family violence, and children may suffer physical and sexual abuse and neglect and may develop psychological problems. Women who drink during pregnancy run a serious risk of their fetus developing fetal alcohol spectrum disorder. To intervene promptly and avoid long-term problems associated with AUD, nurses should question all patients about their drinking habits with every encounter, using plain language, without bias (Fig. 7.1).

Treatment

AUD can be treated through a variety of options. However, very few people with the disorder seek care. Alcohol treatment centers offer inpatient-type care, where the person undergoes stabilization in a controlled environment that includes group therapy. Persons with AUD are provided the tools they need to become abstinent and go into remission. Outpatient treatment is also available. People with AUD who participate in outpatient therapy are given the tools to become abstinent and go into remission (Table 7.4).

Drug-assisted treatment

Several drugs have been approved by the U.S. Food and Drug Administration (FDA) to treat AUD. Disulfiram, acamprosate, and naltrexone are the most commonly used (Table 7.5). Disulfiram inhibits aldehyde dehydrogenase, the enzyme involved in metabolizing alcohol. It is best used in people who are newly abstinent. Disulfiram is administered in tablet form; dosage ranges from 125 to 500 mg daily. It is contraindicated in persons who are intoxicated and should not be taken within 12 hours of alcohol consumption (including use of mouthwash, cough medicine, or eating desserts that contain alcohol or eating foods cooked in alcohol). Side effects occur within 10 minutes of alcohol consumption and can last for over an hour. These side effects include nausea, headache, vomiting, chest pains, and difficulty breathing. Disulfiram keeps patients from drinking because of the unpleasant side effects that occur if alcohol is consumed while taking the drug. Patients who have recently been treated with metronidazole or paraldehyde should not take disulfiram because these same side effects will occur, as if they had been drinking. Because of the risk for drug toxicity, disulfiram should *never* be used in combination with eliglustat or ritonavir.

TABLE 7.3

Most Commonly Used Illicit Drugs

Drug	Street Name	Desired Effects by the User	Short-Term Effects	Long-Term Health Effects	Treatment
Inhalants are compounds that can be breathed in without smoking or using heat to vaporize them. Includes solvents, aerosols, and gases found in household products such as spray paints, markers, glues, and cleaning fluids; also nitrites (e.g., amyl nitrite), which are prescription medications for chest pain.	Poppers, snappers, whippets, laughing gas	Generally, people experience mild highs that last for a short time—normally on the order of minutes—so they tend to be taken repeatedly to extend the high.	Confusion; nausea; slurred speech; lack of coordination; euphoria; dizziness; drowsiness; disinhibition, lightheadedness, hallucinations, delusions; headaches	Liver and kidney damage; bone marrow damage; limb spasms due to nerve damage; brain damage from lack of oxygen that can cause problems with thinking, movement, vision, and hearing; sudden death due to heart failure (from sniffing butane, propane, and other chemicals in aerosols); death from asphyxiation or suffocation, convulsions or seizures, coma, or choking	There are no FDA-approved medications to treat inhalant addiction. More research is needed to find out if behavioral therapies can be used to treat inhalant addiction.
Ketamine is a dissociative drug used as an anesthetic in veterinary practice. Dissociative drugs are hallucinogens that cause the user to feel detached from reality. It is typically injected or snorted, but it can be smoked or taken in pill form.	Cat valium, K, Special K, Vitamin K	Ketamine produces an abrupt high that lasts for about an hour. Large doses of ketamine can result in what some describe as the "K-hole," which can include intense and unpleasant visual and auditory hallucinations coupled with marked de-realization and a frightening detachment from reality.	Problems with attention, learning, and memory; dreamlike states, hallucinations; sedation; confusion and problems speaking; loss of memory; problems moving to the point of being immobile; raised blood pressure; unconsciousness; slowed breathing that can lead to death	Ulcers and pain in the bladder; kidney problems; stomach pain; depression; poor memory	There are no FDA-approved medications to treat ketamine addiction. More research is needed to find out if behavioral therapies can be used.

Table Continued

Drug	Street Name	Desired Effects by the User	Short-Term Effects	Long-Term Health Effects	Treatment
Cocaine hydrochloride is a powerfully addictive stimulant drug made from the leaves of the coca plant. It is usually snorted, smoked, or injected.	Blow, Bump, C, Candy, Charlie, Coke, Crack, Flake, Rock, Snow, Toot	Users claim to feel euphoric or high when using crack; some paradoxical drawbacks exist to using crack for any length of time—the initial euphoria can quickly turn to feelings of depression and paranoia. People who experience drug-induced paranoia might imagine someone is following them or trying to get into their house or that others are trying to attack them.	Narrowed blood vessels; enlarged pupils; increased body temperature, heart rate, and blood pressure; headache; abdominal pain and nausea; euphoria; increased energy and alertness; insomnia, restlessness; anxiety; erratic and violent behavior, panic attacks, paranoia, psychosis; heart rhythm problems, heart attack, inflammation of the heart muscle, deterioration of the ability of the heart to contract, and aortic ruptures; stroke, seizure, coma	Loss of sense of smell, nosebleeds, nasal damage and trouble swallowing from snorting; infection and death of bowel tissue from decreased blood flow; poor nutrition and weight loss from decreased appetite Movement disorders, including Parkinson's disease, may also occur after many years of cocaine use. Smoking cocaine damages the lungs and can worsen asthma.	There are no FDA-approved medications to treat cocaine addiction. CBT, a community reinforcement approach, plus vouchers, contingency management, motivational incentives, the matrix model (an intensive, structured, 16-week outpatient treatment program), and 12-step therapy may facilitate recovery.
Methamphetamine is a central nervous system stimulant drug with high potential for addiction, easily made in small clandestine laboratories, with relatively inexpensive over-the-counter ingredients such as pseudoephedrine, a common ingredient in cold medicines. It is typically swallowed, snorted, smoked, or injected.	Crank, Chalk, Crystal, Fire, Glass, Go Fast, Ice, Meth, Speed ("Crystal meth" is methamphetamine in the form of a rocklike crystal.)	Methamphetamine is a wildly addictive and dangerous substance. Users can rapidly develop a dependency on its effects (increased wakefulness and physical activity). The illegal production and distribution of meth is one of the leading reasons for crime within some areas of the United States.	Decreased appetite; increased breathing, heart rate, blood pressure, temperature; irregular heartbeat	Anxiety, confusion, insomnia, mood problems, violent behavior, paranoia, hallucinations, delusions, weight loss, severe dental problems ("meth mouth"), intense itching leading to skin sores from scratching	There are no FDA-approved medications to treat methamphetamine addiction. CBT, contingency management, or motivational incentives along with matrix model 12-step therapy may facilitate recovery.

Table Continued

Drug	Street Name	Desired Effects by the User	Short-Term Effects	Long-Term Health Effects	Treatment
MDMA is an abbreviation for 3,4-methylenedioxymethamphetamine. It is a synthetic chemical with complex effects that mimic both methamphetamine stimulants and mescaline hallucinogens. It is typically swallowed or snorted.	Adam, Clarity, Ecstasy, Eve, Molly, Lover's Speed, Peace, Uppers, E, X, XTC, Scooby snacks, Roll, Beans	A perceived increase in energy levels and a euphoric state of being; distorted perception of time; higher pleasure from and desire for physical touch; increased levels of sexuality and sexual arousal; elevated alertness, increased energy and focus	Lowered inhibition, enhanced sensory perception; confusion, depression, sleep problems, anxiety; increased heart rate and blood pressure; muscle tension, teeth clenching; nausea; blurred vision; faintness; chills or sweating Taking more than one dose at a time or taking a series of pills over time to maintain the desired effects (*piggybacking*) can lead to overdose, which presents with high blood pressure, seizures, loss of consciousness, and a sharp rise in body temperature that leads to liver, kidney, or heart failure and death.	Long-lasting confusion, depression, problems with attention, memory, and sleep; increased anxiety, impulsiveness, aggression; loss of appetite; decreased libido	There are no FDA-approved medications to treat MDMA addiction. More research is needed to find out if behavioral therapies can be used; however, psychosocial and behavioral interventions and participation in a 12-step group or other support fellowship may be effective.
Synthetic cathinones (bath salts) are typically made from a synthetic version of an amphetamine-like stimulant in the cathinone class, α-PVP. Bath salts can be swallowed, snorted, or injected.	Bloom, Cloud Nine, Cosmic Blast, Flakka, Ivory Wave, Lunar Wave, Scarface, Vanilla Sky, White Lightning	Use results in a flood of dopamine in the brain leading to an intense feeling of euphoria.	Increased heart rate and blood pressure, euphoria, increased sociability and sex drive, paranoia, agitation, hallucinations, psychotic or violent behavior, nosebleeds, sweating, nausea and vomiting, insomnia, irritability, dizziness, depression, suicidal thoughts, panic attacks, reduced motor control, cloudy thinking	Breakdown of skeletal muscle tissue, kidney failure, death	There are no FDA-approved medications to treat addiction to synthetic cathinones. Behavioral therapy includes CBT, contingency management, and motivational incentives such as motivational enhancement therapy (MET) and behavioral treatments geared to teens.

Table Continued

Drug	Street Name	Desired Effects by the User	Short-Term Effects	Long-Term Health Effects	Treatment
Kratom comes from the leaves of a tropical deciduous tree, *Mitragyna speciosa*, that contains mitragynine, a psychoactive opioid. The leaves may be chewed, eaten (mixed in food or brewed as tea), or smoked.	Herbal Speedball, Biak-biak, Ketum, Kahuam, Ithang, Thom	Kratom is consumed for mood-lifting effects and pain relief and as an aphrodisiac	Sensitivity to sunburn, nausea, itching, sweating, dry mouth, constipation, increased urination, loss of appetite *Low doses:* Increased energy, sociability, alertness *High doses:* Sedation, euphoria, decreased pain	Anorexia, weight loss, insomnia, skin darkening, dry mouth, frequent urination, constipation; with long-term use at high doses, hallucination and paranoia	No clinical trials have been conducted on medications for kratom addiction. More research is needed to find out if behavioral therapies can be used.
Heroin is an opioid drug processed from morphine, a naturally occurring opiate extracted from the seedpod of certain varieties of poppy plants. It can be injected, smoked, or snorted.	Brown sugar, China White, Dope, H, Horse, Junk, Skag, Skunk, Smack, White Horse	Heroin binds to opioid receptors in the body, prompting a release of dopamine and creating intensely pleasurable feelings.	Euphoria, warm flushing of skin, dry mouth, heavy feeling in the hands and feet, clouded thinking, alternating wakeful and drowsy states, itching, nausea and vomiting, slowed breathing and heart rate	Collapsed veins, abscesses, infection of the lining and valves in the heart, constipation and stomach cramps, liver or kidney disease, pneumonia, and hypoxic brain injury	Medications approved to treat heroin addiction and aid withdrawal include methadone, buprenorphine, and naltrexone. Behavioral therapy includes contingency management, motivational incentives, and 12-step facilitation therapy.
Phencyclidine (PCP) is a dissociative drug that causes the user to feel detached from reality. It can be injected, snorted, swallowed, or smoked.	Angel Dust, Boat, Hog, Love Boat, Peace Pill	Produces visual and auditory distortions and perceptual changes that result in an individual feeling detached from themselves or the world around them; users may feel that their body is not their own.	Delusions, hallucinations, paranoia, problems thinking, a sense of distance from one's environment, anxiety *Low doses:* A slight increase in breathing rate, increased blood pressure and heart rate, shallow breathing, face redness and sweating, numbness of the hands or feet, problems with movement *High doses:* Lowered blood pressure, pulse rate, breathing rate; nausea and vomiting; blurred vision; flicking up and down of the eyes; drooling; loss of balance, dizziness; violence or suicidal thoughts; seizures, coma, death	Impaired memory, thinking, and decision-making abilities; speech problems; severe depression, suicidal thoughts; higher anxiety, paranoia, and isolation; extreme weight loss; "flashback" phenomena and continuous hallucinations and delusional thinking even when not using the substance	There are no FDA-approved medications to treat addiction to PCP. More research is needed to find out if behavioral therapies can be used to treat addiction to dissociative drugs.

Table Continued

Drug	Street Name	Desired Effects by the User	Short-Term Effects	Long-Term Health Effects	Treatment
Synthetic cannabinoids; may be smoked or swallowed	K2, Spice, Black Mamba, Bliss, Bombay Blue, Fake Weed, Fire, Genie, Moon Rocks, Skunk, Smacked, Yucatan, Zohai	Euphoric feelings, altered perception, feelings of relaxation	Increased heart rate, vomiting, agitation, confusion, hallucinations, anxiety, paranoia, increased blood pressure	Kidney failure and heart attacks; severe and lasting heart conditions, seizure activity in frequent users	There are no FDA-approved medications to treat synthetic cannabinoid addiction. More research is needed to find out if behavioral therapies can be used.
Rohypnol (flunitrazepam); an intermediate-acting benzodiazepine typically swallowed (as a pill or dissolved in a drink) or snorted	Circles, Date Rape Drug, Forget Pill, Forget-Me Pill, La Rocha, Lunch Money, Mexican Valium, Mind Eraser, Pingus, R2, Reynolds, Rib, Roach, Roach 2, Roaches, Roachies, Roapies, Rochas Dos, Roofies, Rope, Rophies, Row-Shay, Ruffies, Trip-and-Fall, Wolfies	Because of the strong amnesia produced by the drug, it has been used for it its ability to sedate and incapacitate unsuspecting rape victims when placed in their drinks. It has also been used illegally to lessen the depression caused by the use of stimulants, such as cocaine and methamphetamine, and by heroin and cocaine users to produce profound intoxication and boost the high of heroin.	Drowsiness, sedation, sleep; amnesia, blackout; decreased anxiety; muscle relaxation, impaired reaction time and motor coordination; impaired mental functioning and judgment; confusion; aggression; excitability; slurred speech; headache; slowed breathing and heart rate; in combination with alcohol, severe sedation, unconsciousness, and slowed heart rate and breathing can lead to death.	Unknown	There are no FDA-approved medications to treat addiction to flunitrazepam. More research is needed to find out if behavioral therapies can be used to treat addiction.
GHB (gamma-hydroxybutyrate) is a depressant approved for use in the treatment of narcolepsy. It is swallowed.	G, Georgia Home Boy, Goop, Grievous Bodily Harm, Liquid Ecstasy, Liquid X, Soap, Scoop	Euphoria, increased sex drive, and tranquility; has been used for sexual assault as victims become incapacitated due to the sedative effects and they are unable to resist. GHB may also induce amnesia in its victims.	Euphoria, drowsiness, decreased anxiety, confusion, memory loss, hallucinations, excited and aggressive behavior, nausea, vomiting, unconsciousness, slowed heart rate and breathing, lower body temperature *High doses:* Even without other illicit substances or alcohol, high doses may result in profound sedation, seizures, coma, severe respiratory depression, and death.	Unknown	Withdrawal may be treated with benzodiazepines. More research is needed to find out if behavioral therapies can be used to treat GHB addiction.
LSD (lysergic acid diethylamide) is a hallucinogen that is swallowed or absorbed through mouth tissues	Acid, Blotter, Blue Heaven, Cubes, Microdot, Yellow Sunshine	Users experience impaired depth and time perception and a distorted perception of the size and shape of objects, movements, color, sound, touch, and body image; sensations may seem to "cross over," giving the feeling of hearing colors or seeing sounds (synesthesia, also called "tripping").	Rapid emotional swings; distortion of a person's ability to recognize reality, think rationally, or communicate with others; raised blood pressure, heart rate, body temperature; insomnia; loss of appetite, dry mouth, sweating, numbness, weakness, tremors, dizziness, enlarged pupils	Frightening flashbacks (called *hallucinogen persisting perception disorder* [HPPD]); ongoing visual disturbances, disorganized thinking, paranoia, and mood swings	There are no FDA-approved medications to treat addiction to LSD. More research is needed to find out if behavioral therapies can be used to treat addiction.

α-PVP, Alpha-pyrrolidinopentiophenone; *CBT,* cognitive behavioral therapy; *FDA,* U.S. Food and Drug Administration.

BOX 7.1 Alcohol Toxicity

Alcohol toxicity is a life-threatening condition that can occur by drinking large amounts of alcohol over a short period of time. A standard drink contains 10 g of alcohol. This is equal to 10 ounces of beer with 5% alcohol, 3.25 ounces of wine with 12% alcohol, or 1 ounce of hard liquor with 40% alcohol (or 80 "proof"). Roughly 20% of alcohol is absorbed from the stomach, and the remainder is absorbed in the small intestine. Food intake slows absorption. Alcohol is metabolized in the liver and is excreted by the lungs and kidneys, and the average person can only metabolize 10 g of alcohol per hour.

Complications of alcohol toxicity include aspiration of vomitus, asphyxiation, severe dehydration, seizures, hypothermia, brain damage, and death. Treatment involves airway management and supplemental oxygenation, correction of hypoglycemia if present, supportive care, and intravenous (IV) hydration. If the person chronically uses alcohol, thiamine 100 mg may be administered intramuscularly to prevent neurologic damage. Patients with impaired hepatic function may require hemodialysis to remove alcohol from the blood; however, this invasive treatment is only used in persons whose condition is rapidly deteriorating.

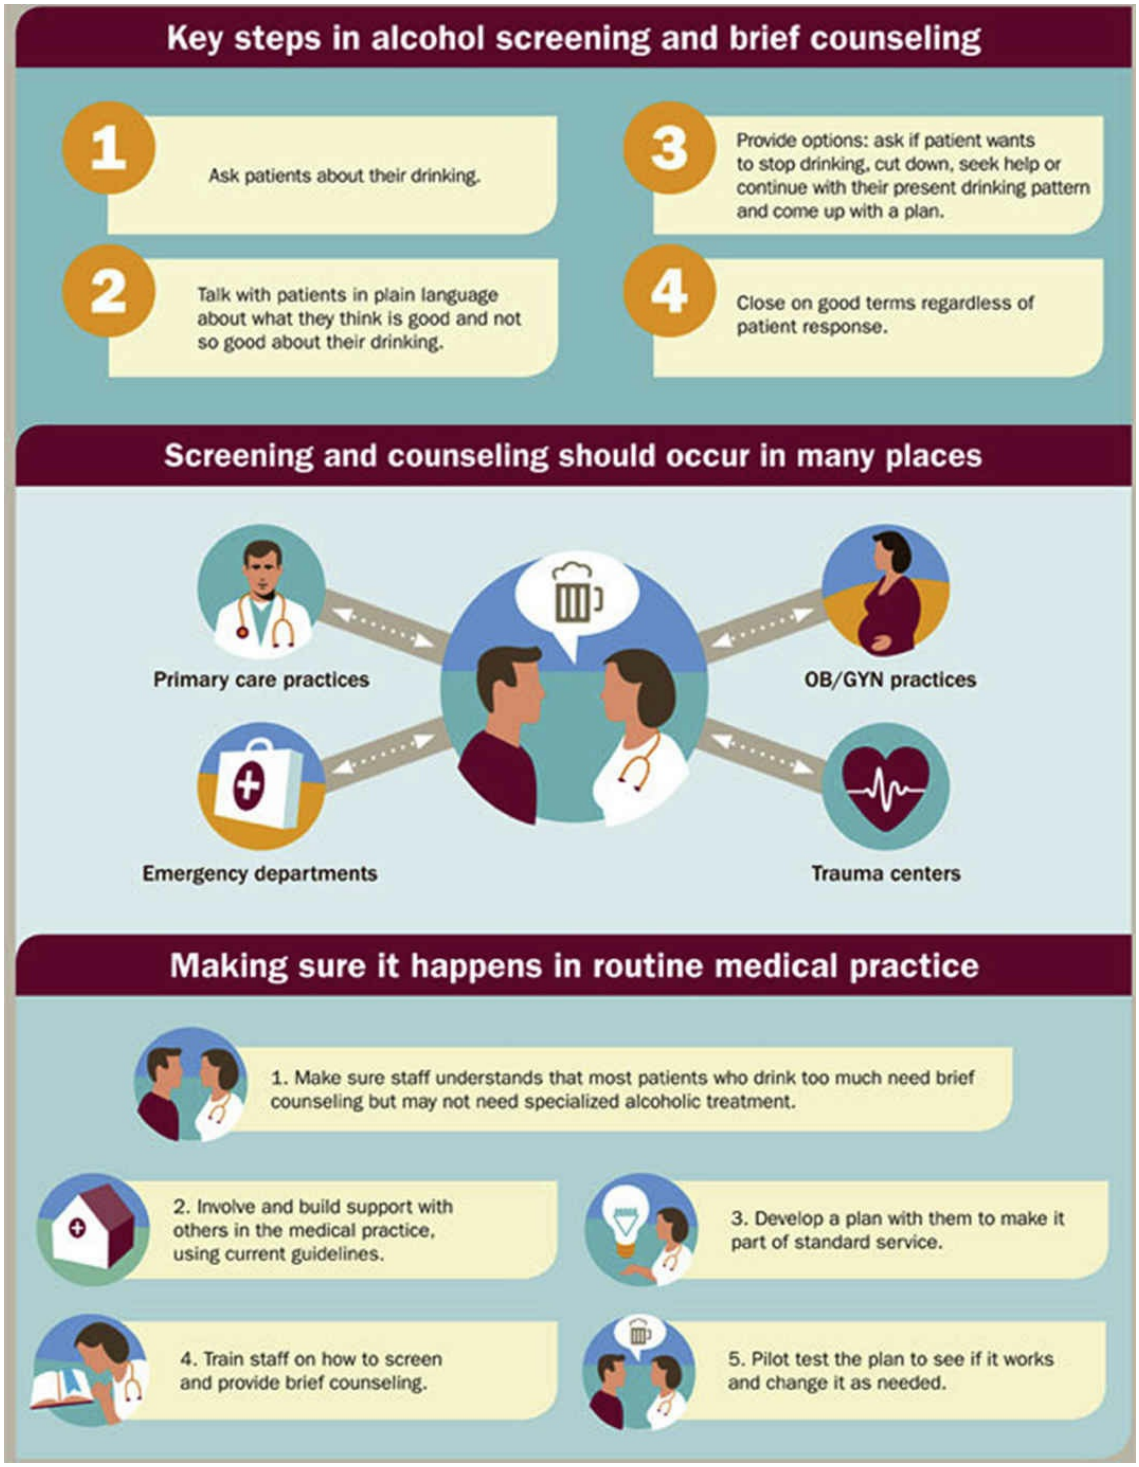

FIG. 7.1 Alcohol Screening and Brief Counseling.
From Centers of Disease Control and Prevention.

Other side effects of disulfiram include rash, drowsiness, impotence, acne, and a metallic aftertaste. Serious reactions include psychosis, hepatotoxicity, peripheral neuropathy, and optic neuritis. Patients taking disulfiram should have baseline liver function studies obtained; liver function studies should be repeated after 2 weeks of therapy. For disulfiram to be effective, persons with AUD also need to participate in behavior modification, psychotherapy, and counseling. Disulfiram was designated pregnancy category C, and whether it will harm the fetus is unknown; however, it is excreted into breast milk. Therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

TABLE 7.4

Nonpharmacological Therapy for Substance Use Disorders: Individual and Group Counseling

Therapy	Description
Cognitive behavioral therapy (CBT)	CBT teaches people to recognize and stop negative patterns of thinking and behavior and helps enhance self-control. For instance, therapy might help a person become aware of the stressors, situations, and feelings that lead to substance use so that the person can avoid them or act differently when they occur.
Contingency management	This approach is based on frequent monitoring of behavior and removal of rewards for drug use and was designed to provide incentives to reinforce positive behavior and help the person remain abstinent from drug use.
Motivational enhancement therapy (MET)	MET helps people with substance use disorders develop internally motivated changes and commit to specific plans to engage in treatment and seek recovery. It is often used early in the process to engage people in treatment.
Twelve-step facilitation therapy	Seeks to guide and support engagement in 12-step programs such as Alcoholics Anonymous or Narcotics Anonymous.

From Substance Abuse and Mental Health Services Administration. (2015). Treatments for substance use disorders. Retrieved June 3, 2016, from www.samhsa.gov/treatment/substance-use-disorders

Acamprosate is a GABA analogue thought to work in the brain to restore the balance between neuronal excitation and inhibition via GABA and glutamate. It should only be used in persons who are abstinent; however, acamprosate may be continued through a relapse. Usual dosing is 666 mg orally three times per day. Dosing is adjusted in kidney disease, and a serum creatinine level should be obtained at baseline. Persons with a creatinine clearance of 30 mL/min to 50 mL/min should only take 333 mg three times per day. Acamprosate is contraindicated in people with a creatinine clearance less than 30 mL/min. Common side effects include pain, loss of appetite, nausea, diarrhea, dizziness, anxiety, pruritus, depression, insomnia, xerostomia, and paresthesia. Patients should be assessed for suicide ideology prior to beginning treatment. This drug is used in conjunction with behavior modification and counseling. Naltrexone increases acamprosate levels. No dosage adjustment is needed, but patients should be monitored closely. Acamprosate was designated pregnancy category C; it is not known if it will harm the fetus or if it is excreted into breast milk. Therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

TABLE 7.5

Pharmacokinetics of Drug-Assisted Treatments

Drug Name	Absorption	Distribution	Metabolism	Excretion
Acamprosate	Peak plasma time: 3-8 h Bioavailability: 11%, decreased by food but not clinically important	Protein binding: Negligible	Not metabolized	In urine as unchanged drug Half-life: 20-33 h
Buprenorphine	Extensive first-pass effect if taken orally; 31% bioavailability (SL) Time to peak plasma varies from 40 min-3.5 h.	Highly lipophilic Highly protein bound (96%)	Extensive hepatic	In bile and feces, 70%; urine, 30% Half-life: SL, 37 h
Disulfiram	Absorbed from the GI tract (80%-90%), onset is 3-12 h after administration. Effects may persist up to 14 d after the last dose.	Highly lipophilic	Hepatic	In urine primarily but also in feces (5%-20% unchanged) and lungs
Methadone	Oral administration: Bioavailability ranges from 36%-100%, and peak plasma concentrations are achieved between 1 and 7.5 h.	Lipophilic; 85%-90% protein bound	Hepatic, into inactive metabolite	Renal and fecal Half-life is highly variable.
Naloxone	Onset: Administered IV, 2 min; subcut and IM, 5 min Duration of action is 30-60 min.	Plasma protein binding occurs but is relatively weak.	Hepatic	In urine Half-life is 1-1.5 h.
Naltrexone	96% absorbed from the GI tract; extensive first-pass metabolism; 5%-40% reaches the systemic circulation. Onset is 15-30 min; duration is 24 h and is dose dependent.	Protein bound: 21%-28%	Hepatic, into active metabolite	In urine
Varenicline	Well absorbed from the GI tract and unaffected by food Time to peak plasma: 3-4 h	Less than 20% protein binding	Minimal hepatic (<10%)	In urine, 92% unchanged Half-life: 24 h

d, Day; *GI,* gastrointestinal; *h,* hours; *IM,* intramuscular; *IV,* intravenous; *min,* minutes; *SL,* sublingual; *subcut,* subcutaneous.

Naltrexone is a competitive opioid antagonist with a high affinity for mu receptors. Oral forms absorbed through the gastrointestinal (GI) tract undergo up to 40% first-pass metabolism. Onset occurs in 15 to 30 minutes with peak occurring in 1 hour. Naltrexone is used in persons who are abstinent. If there is concern about comorbid opioid use disorder (OUD), a naloxone challenge test may be done prior to initiating treatment, in which a test dose of 25 mg is administered orally, and the patient is observed for an hour. If no withdrawal is observed, dosing may begin the following day at 50 mg per day for 12 weeks or less. Dosing using 380 mg intramuscularly (IM) once every 4 weeks can be used for maintenance therapy. Common side effects include insomnia, nausea, vomiting, anxiety, headache, abdominal pain, myalgia, arthralgia, rash, dizziness, fatigue, constipation, and increased creatine phosphokinase (CPK). Serious reactions include suicidality, depression, hepatotoxicity, and hypersensitivity reaction. Patients should be assessed for suicide ideology prior to beginning treatment. This drug should *not* be taken in conjunction with any drugs that bind to opioid receptors because withdrawal may be precipitated in persons with OUD.

Naltrexone was designated pregnancy category C; it is not known if it will harm the fetus, and it is excreted into breast milk. Therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

Cannabis Use Disorder

Cannabis is the most commonly used recreational drug in the United States. Over 4.2 million people ages 12 and over meet the criteria for *Cannabis* use disorder. *Cannabis* use disorder is more common among people in their late teens and early 20s. Users report feeling an alteration in their senses and an altered sense of time as well as changes in mood. *Cannabis* goes by many street names, including Marijuana, Blunt, Bud, Dope, Ganja, Grass, Green, Herb, Joint, Mary Jane, Pot, Reefer, Sinsemilla, Skunk, Smoke, Trees, and Weed; names for various forms of hashish include Boom, Gangster, Hash, and Hemp. *Cannabis* contains more than 60 related psychoactive chemicals known as *cannabinoids*; however, the most abundant of these is delta-9-tetrahydrocannabinol (THC).

When smoked, THC rapidly crosses the blood-brain barrier and binds to cannabinoid receptors in many areas of the brain, overwhelming the endocannabinoid system and making it difficult for the user to respond appropriately to incoming stimuli. The drug impairs short-term memory, learning, and ability to focus, and it can cause problems with balance and coordination. In addition, *Cannabis* increases heart rate and may cause hallucinations, anxiety, panic attacks, and psychosis in some people. When smoked, *Cannabis* may harm the lungs, and concurrent use of alcohol increases blood pressure in addition to heart rate and further slows mental processes and reaction times.

Long-term use of *Cannabis* is associated with chronic cough, frequent respiratory infections, and exposure to cancer-causing compounds because the smoke has many of the same irritating and lung-damaging properties as tobacco. Ingestion of the drug increases the heart rate for hours, increasing risk for heart attack and stroke. When repeated use begins in adolescence, there is an association with decreased motivation and decreased performance on memory-related tasks. The drug has also been linked to mental health problems and increased symptoms in persons with schizophrenia. Babies born to women who use *Cannabis* have behavioral issues and problems with attention, memory, and problem solving.

Many have supported the nationwide legalization of *Cannabis* to treat medical conditions; however, rigorous scientific evidence to show that the benefits of *Cannabis* outweigh its health risks is limited and does not support approval. Despite the current evidence, 24 states have legalized medical use of *Cannabis* to treat pain (e.g., cancer pain, headaches, glaucoma, and nerve pain), muscle spasms related to multiple sclerosis, chemotherapy-induced nausea and vomiting, anorexia and weight loss associated with HIV, seizure disorders, and Crohn disease. Four states—Alaska, Colorado, Oregon, and Washington—have legalized the recreational use of *Cannabis,* leading to sales upward of $2.7 billion.

Cognitive behavioral therapy (CBT), contingency management, and motivational enhancement therapy (MET) may be effective in the treatment of *Cannabis* use disorder; however, no medications are currently approved or indicated for this use.

Opioid Use Disorder

Opioids (e.g., oxycodone, hydrocodone, morphine, methadone, and fentanyl) are controlled substances legally prescribed to treat moderate to severe pain. These drugs interact with opioid receptors in the brain and nervous system to reduce pain. In addition to reducing pain, this receptor interaction floods the brain's reward system with dopamine, producing a sense of euphoria and tranquility.

Short-term effects of opioid use include drowsiness, mental confusion, nausea, constipation, and dose-dependent respiratory depression. When taken with alcohol, users may experience dangerous slowing of heart rate and breathing leading to coma or death. When taken with serotonergic drugs (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin-norepinephrine reuptake inhibitors [SNRIs], and antimigraine agents), serotonin syndrome may occur. Symptoms of serotonin syndrome include agitation, hallucinations, coma, tachycardia, hypertension, hyperthermia, and rigidity.

In addition to the oral route, when misused, opioids are smoked, snorted, or administered parenterally. Prescription opioids are also known by numerous street names, including Vikes, Cody, China White, Fizzies, M, Demmies, Blue Heavens, Juice, Smack, Hillbilly Heroin, and Roxy.

Nonmedical use of prescription opioid drugs has reached epidemic proportions; over 1.9 million

people in the United States meet criteria for OUD. Close to 19,000 people with OUD die each year secondary to overdose of prescription opioids. Over 50% of people who misuse prescription opioids obtain them from a friend or relative for free, and 22.1% obtain them from a doctor. With repeated use, tolerance to the euphoric effects of the drug increase, and users may not be able to obtain the drug from friends, relatives, or any doctor; this causes them to turn to the street for drugs. Some users switch from prescription drugs to cheaper and riskier substitutes, like heroin.

The FDA has toughened the safety warnings on opioids, including adding a boxed warning about the potentially lethal risks associated with misuse. The safety warning includes a caution regarding the use of opioids during pregnancy and the risk of neonatal opioid withdrawal syndrome (NOWS), which can be life threatening.

Contingency management therapy or 12-step facilitation therapy may be useful in treating prescription opioid addiction. Treatment approaches are tailored to each patient and are often combined with medication therapy.

Drug-Assisted Treatment

Naloxone (see Table 7.6) is the drug of choice in the treatment of respiratory depression associated with opioid overdose. Naloxone is a short-acting opioid antagonist that competitively attaches to opioid receptors in the central nervous system (CNS), thereby blocking activation by opioid drugs. In emergency situations, it is administered IV; however, it may also be administered IM or subcutaneously (subcut). In persons with suspected opioid use disorder, dosing begins at 0.1 to 0.2 mg every 2 to 3 minutes until the patient responds. Careful monitoring is required to prevent opioid withdrawal. Symptoms of withdrawal include nausea and vomiting, abdominal cramps, hyperthermia, hypertension, and restlessness.

Naltrexone is approved by the FDA to treat opioid use disorder. (See the previous discussion under alcohol use disorder.) Dosing begins at 50 mg daily after the patient has been opioid free for 7 to 10 days. It is also available in an injectable, extended-release form, with dosing at 380 mg each month. Once treated with naltrexone, patients may have reduced tolerance to opioids; if they relapse after a period of abstinence and resume opioid use at previous doses, they may experience life-threatening consequences, including respiratory arrest and circulatory collapse.

Since the 1950s, methadone has been prescribed to treat persons with OUD. When taken as prescribed and combined with counseling and behavioral therapies, administration of this long-acting opioid drug is safe and effective. Methadone has a boxed warning concerning the risk of cardiac and respiratory-related deaths due to QT prolongation and cardiac arrhythmias. Methadone used for stabilization and maintenance of persons with OUD may only be administered by programs certified by the Substance Abuse and Mental Health Services Administration (SAMHSA) and approved by state authority. Opioid treatment programs must follow federal guidelines and standards for medically monitored withdrawal and treatment.

Methadone works by changing the way a person's brain responds to pain; it is an opioid receptor agonist at the mu receptor and an antagonist at the *N*-methyl-D-aspartate (NMDA) receptor. Taken daily, it blocks the sense of euphoria and tranquility caused by opioid use and prevents opioid withdrawal and craving. Concurrent administration of rifampin, phenytoin, St. John's wort, phenobarbital, and carbamazepine can reduce serum methadone levels and precipitate withdrawal. Administration with zidovudine may lead to toxicity.

Initial dosing ranges from 15 mg to 30 mg, followed by 5 mg to 10 mg, adjusting the dose to suppress withdrawal and block the euphoric effects of opioids. Maximum dosage is 40 mg on the first day of stabilization. Maintenance therapy is based on patient assessment and ranges from 80 to 120 mg a day. Tapering methadone should only be done under medical supervision, with dose reductions of less than 10% every 14 days.

Common methadone side effects include lightheadedness, constipation, dizziness, sedation, nausea, and vomiting. Patients should be educated to prevent theft and misuse of methadone by friends, family, and others. Methadone was designated pregnancy category C; whether it will harm the fetus is unknown, but it is excreted into breast milk, therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

Buprenorphine is a long-acting, mixed narcotic agonist-antagonist. It binds to various opioid receptors in the brain, producing partial agonism at mu receptors and antagonism at kappa receptors, resulting in decreased withdrawal symptoms and cravings. Although it does produce

some euphoria, there is a ceiling effect: increasing the dose beyond a moderate level (8 to 16 mg) does not increase euphoria, therefore it has a low potential for misuse. To further deter people from misusing buprenorphine, naloxone is added. Because of the almost complete first-pass metabolism of naloxone, it has minimal pharmacologic activity when the drug is used appropriately as a sublingual tablet. However, if the tablet is crushed and injected, the effects of naloxone lead to opioid withdrawal.

This drug may be administered in qualified outpatient settings (e.g., office, health department, or correctional facility) after providers have received training. When taken as prescribed and used in combination with counseling and behavioral therapies, it is safe and effective. Initial dosing begins when the person with OUD has been opioid free for at least 12 hours and is beginning to experience withdrawal. Dosing starts at 2 to 8 mg sublingual (SL) for the first day, then it is raised to 8 to 16 mg SL for 1 to 2 days. Once the patient is stable and is not experiencing cravings or significant side effects, dosing is tailored to the individual; the maximum daily dose of buprenorphine is 44 mg.

Side effects of buprenorphine include nausea, vomiting, and constipation; muscle aches and cramps; and cravings, sedation, headache, depression, anxiety, and withdrawal symptoms. Buprenorphine was designated pregnancy category C; whether it will harm the fetus is unknown, but it is excreted into breast milk. Therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

Tobacco Use Disorder

In 2014, nearly 70 million Americans aged 12 and older used tobacco products. The largest group of users (35%) were those in the 18- to 25-year-old group, followed by adults aged 26 or older (25.8%). American Indians and Alaska Natives made up the largest group of users in 2014, followed by Caucasians and African Americans.

When smoked, nicotine is absorbed from the lungs into the pulmonary venous circulation. It then enters the arterial circulation and moves quickly to the brain. Once across the blood-brain barrier, nicotine stimulates the release of dopamine, norepinephrine, GABA, glutamate, and endorphins, resulting in stimulation and pleasure and a reduction in stress and anxiety. These sensations fuel the brain's reward circuit.

According to the Centers for Disease Control and Prevention (CDC), more than 480,000 deaths each year are caused by cigarette smoking. Short-term effects of tobacco use include increased blood pressure, breathing, and heart rate. Tobacco use does long-term damage to nearly every organ in the human body, often leading to a variety of cancers, respiratory disorders, heart disease, stroke, immune dysfunction, and type 2 diabetes. Women who smoke while pregnant may experience miscarriage, premature delivery, and stillbirth and may have infants of lower birthweight. Children born to women who used tobacco while pregnant may be born with learning and behavior problems. Persons with tobacco use disorder (TUD) have increased health care utilization and higher health care costs compared with nonusers, and they are frequently absent from work.

Since 2002, the number of persons with TUD in sustained remission has outnumbered those actively using nicotine; the CDC reported that 70% of smokers want to quit. Within 1 to 2 years of quitting, persons with TUD significantly reduce their risk for cancer, heart disease, stroke, and respiratory illness. Quitting is difficult. Persons attempting to quit experience irritability, anger, anxiousness, difficulty thinking, cravings, and increased hunger. Support is a very important part of the process and is often combined with pharmacologic measures.

Cognitive behavioral therapy (CBT) is a goal-directed and problem-focused therapy designed to help the person with TUD identify negative thought patterns and inaccurate beliefs to learn new ways of coping and develop new ways of thinking. It helps the person increase their self-confidence in the ability to quit. CBT helps people identify their triggers and learn to either avoid them or respond differently to them. It also helps with any ambivalence people may feel about quitting.

Self-help materials in the form of Internet-based aids or cell phone apps are available to assist the person with TUD. For example, the American Lung Association offers *Freedom From Smoking Online* (www.ffsonline.org/?referrer=http://www.lung.org/stop-smoking/join-freedom-from-smoking), which offers modules with lessons and activities that reinforce the person's commitment to quit. Phone apps are available as well. Some require a small fee, such as *Butt Out—Quit Smoking Forever*, which monitors progress and helps the person stay focused on the goal to quit by providing motivational pictures and messages. Other apps are free, such as *Get Rich or Die Smoking*, which shows the person how much money they are saving each day by not smoking. It also monitors their

health progress and shows what the person could buy with the money they have saved, and it rewards the app user with trophies.

Telephone-based resources link persons with TUD with counselors trained to assist the caller in developing an individualized plan to quit smoking. Telephone-based counseling is easy to use because it does not require the person to drive or find child care in order to attend a meeting in person; additionally, it is available nights and weekends.

Combining a nonpharmacologic support measure with drug-assisted treatment is the most effective means to quit smoking.

Drug-Assisted Treatment

Nicotine replacement drugs—sold as a gum, patch, spray, inhaler, or lozenge—mimic the nicotine effects of tobacco by binding to nicotine receptors in the CNS. They are used to relieve the withdrawal symptoms associated with smoking cessation and provide some of the stimulation and stress-relief effects the user gained from smoking (see Table 7.6). Those who choose to use nicotine-replacement gums, sprays, inhalers, or lozenges dose themselves when they feel the urge to smoke; those who use the patch have a sustained nicotine level throughout the day (see Nursing Process: Patient-Centered Collaborative Care—Tobacco Use Disorder). Side effects include hypertension, tachycardia, dizziness, insomnia, irritability, anorexia, dyspepsia, nausea, vomiting, hiccups, and cough. In 2013 the FDA relaxed warnings about patients who relapse while using nicotine-replacement products; it was determined there are no significant safety concerns. Designated pregnancy category D, nicotine has been shown to cause adverse fetal outcomes in animals; however, nicotine replacement is believed to be safer during pregnancy than smoking. Nicotine is excreted into breast milk and may increase infant heart rate, therefore a decision should be made to discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

Bupropion, an antidepressant drug, increases levels of dopamine and norepinephrine in the brain, mimicking the effects of nicotine. It also has some neuronal nicotinic receptor–blocking activity, reducing reinforcement from the brain's reward circuit. When used for smoking cessation, the dosage is 150 mg/day for 7 to 12 weeks. When starting the drug, smokers continue to smoke for the first week but have a stop date set for the second week. If patients have not quit smoking by week seven, providers may add a nicotine-replacement drug. Bupropion should not be used by those who have seizures or eating disorders. Additionally, it should not be taken within 14 days of taking a monoamine oxidase inhibitor (MAOI). Bupropion should not be stopped suddenly, rather the patient should be weaned off the drug to avoid withdrawal symptoms. The drug can cause a false-positive drug screen; when providing urine for a drug screen, laboratory personnel should be told of bupropion use. Bupropion was designated pregnancy category C; whether it will harm the fetus is unknown, but it is excreted into breast milk, therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

Varenicline is a partial alpha-4–beta-2 nicotinic receptor agonist that stimulates dopamine activity in the brain but not to the extent of nicotine, thereby reducing cravings and withdrawal. Dosing begins 1 week before an identified quit date at 0.5 mg daily for 3 days, then 0.5 mg are taken twice daily for 4 days, then maintenance therapy begins at 1 mg twice daily for 11 weeks. Dosage is adjusted for patients with a creatinine clearance (CrCl) less than 30 mL/min (maximum dosage, 0.5 mg twice daily). Common side effects include nausea and vomiting, insomnia, headache, abnormal dreams, constipation or diarrhea, fatigue and malaise, upper respiratory tract infection, dyspnea, chest pain, abdominal pain, xerostomia, appetite changes, rash, and emotional disturbances. Varenicline carries a black-box warning for serious neuropsychiatric symptoms including behavior changes, hostility, agitation, depression, and suicidality. Nurses must caution patients and their family about this warning and advise them to contact their provider immediately if suicidal thoughts or actions occur. Varenicline was designated pregnancy category C; it is unknown whether it will harm the fetus or if it is excreted in breast milk, therefore a decision should be made to either discontinue breastfeeding or discontinue the drug, taking into account the importance of the drug to the mother.

BOX 7.2 Electronic Cigarettes (e-Cigarettes)

Electronic cigarettes are a tobacco product often marketed as a tool to stop smoking; however, marketing is also aimed at children and adolescents. A reported 2.4 million middle and high school students use e-cigarettes, also known as *Hookah Pens, e-Hookahs,* and *Vape Pipes.* E-cigarettes aerosolize "e-juice," a mixture of flavorings, propylene glycol (a toxic component of antifreeze), glycerin, and nicotine. The vapor from e-cigarettes contains heavy metals and formaldehyde, a breakdown product of propylene glycol. Because of this, the second-hand aerosol from e-cigarettes is also potentially harmful. Some of the flavors used in e-cigarettes contain carcinogens and other harmful chemicals. For example, the butter flavoring may contain diacetyl, the chemical used to give popcorn a buttery flavor and which causes irreversible lung disease when inhaled, a disease referred to a *popcorn lung*.

According to the CDC, e-cigarettes are no safer than traditional tobacco cigarettes, nor are they a more effective method of quitting smoking than counseling and drug-assisted treatments. When users try to quit e-cigarettes, they experience the same withdrawal symptoms as users of traditional tobacco cigarettes, including irritability, depression, restlessness, and anxiousness. E-cigarettes increase the risk for myocardial infarction due to hypertension, tachycardia, and hardening of the arteries secondary to nicotine. Nicotine has been shown to adversely affect adolescent brain development, leading to cognitive and behavioral issues. There are over 500 brands of e-cigarettes, each of which contains *some* level of nicotine—even those that claim they do not. E-juice refill cartridges often contain more nicotine than is indicated on the label.

In August 2016, the FDA began regulation of all tobacco products, including e-cigarettes, cigars, hookah tobacco, and pipe tobacco. The sale of all tobacco products, including e-cigarettes, will be prohibited to those under the age of 18; packaging and marketing of all tobacco products, including e-cigarettes, will require the display of health warnings; and the FDA will be able to stop manufacturers from making statements about their products that have not been proven by research.

Nurses who work with children and adolescents must be diligent in asking about the use of e-cigarettes and providing counseling concerning the dangers of using them. Related to this, they must ask about media and Internet usage and teach young people critical viewing skills; that is, they must help young people understand that what appears in the media does not always represent reality; often, it is a representation of someone or something's special interest. Nurses must urge children and adolescents who use e-cigarettes to quit, and they must provide the help needed to achieve sustained remission.

To advocate for their patients, nurses must keep in mind that 80% of those with TUD who attempt to quit relapse in the first month; only 3% remain abstinent at 6 months. Patients with TUD require multiple attempts at quitting before they achieve sustained remission.

Box 7.2 discusses **e-cigarettes** (electronic cigarettes).

Other Substance Use Disorders

Cough and Cold Products

One in 10 adolescents has used cough and cold products to get high. Cough and cold products contain ingredients that are psychoactive when taken in higher-than-recommended amounts (sometimes up to 25 times the recommended dose). Dextromethorphan (DXM), an antitussive that can be purchased without a prescription, and promethazine-codeine cough syrup, available by prescription only, are the products most frequently misused. Using DXM is known on the street as "robotripping" or "skittling"; when taken in higher-than-recommended amounts, users may experience euphoria, dissociative effects, or hallucinations. Side effects of DXM include nausea and vomiting, stomach pain, confusion, dizziness, double or blurred vision, slurred speech, impaired coordination, tachycardia, drowsiness, numbness, and disorientation. Many of the DXM-containing products that are used to get high also contain other drugs, such as antihistamines, analgesics, or decongestants. High doses of these drugs can lead to hepatic damage or failure, cardiovascular effects, and coma.

Promethazine-codeine cough syrup can result in relaxation and euphoria when taken in higher-than-recommended amounts; when combined with soda, it is referred to as *Syrup, Sizzurp, Purple*

drank, Barre, or *Lean*. Hard candy may be added for flavor. (See the previous section on OUD for information concerning codeine, an opioid drug).

There are no FDA-approved medications to treat substance use disorders related to cough and cold products. More research is needed to find out if behavioral therapies can be used to treat such misuse.

Anabolic-Androgenic Steroids

An anabolic-androgenic steroid (AAS) is a synthetic agent used to treat conditions caused by low levels of testosterone in the body, such as delayed puberty, hypogonadism, and cachexia related to chronic disease states. By binding to androgen receptors, these prescription drugs (e.g., danazol, fluoxymesterone, nandrolone, and oxandrolone) exert *anabolic effects,* such as growth of muscle and bone and red blood cell production, and *androgenic effects,* such as production of primary and secondary sexual characteristics. Anabolic-androgenic steroids have been used to enhance athletic and sexual performance and physical appearance in all age groups. Evidence indicates AAS use by athletes ranges from 1% to 6%. Street names of these drugs include Juice, Gym Candy, Pumpers, Stackers, and Roids. The drug may be taken orally or may be administered IM in doses 10 to 100 times higher than what would be recommended for medical conditions.

Short-term effects of AAS use include headache, acne, fluid retention in the hands and feet, oily skin, yellowing of the skin and whites of the eyes, aggression, extreme mood swings, anger, paranoid jealousy, extreme irritability, delusions, impaired judgment, and infection at the injection site. Long-term effects include kidney damage or failure, liver damage, high blood pressure, enlarged heart, or changes in cholesterol leading to increased risk of stroke or heart attack. Additionally, men may experience shrunken testicles, infertility, baldness, development of breasts, and an increased risk for prostate cancer. Women may experience excess facial and body hair, male-pattern baldness, menstrual cycle changes, enlargement of the clitoris, and deepened voice. Adolescents who use anabolic steroids may experience stunted bone growth and height.

BOX 7.3 Dehydroepiandrosterone

Dehydroepiandrosterone (DHEA), a precursor to testosterone and estrogen, can be found in many dietary supplements. Many people take supplements that contain DHEA in the belief that it will slow aging, increase energy levels, and build bone and muscle strength. However, there is no evidence to support these claims. Small studies have noted that DHEA may be effective in the relief of mild depression and skin changes associated with aging. Side effects include oily skin and acne, hair loss, nausea, hypertension, menstrual changes, deepening of the voice in women, fatigue, headache, irregular heartbeat, insomnia, and hypercholesterolemia. Long-term effects include stunting of growth, aggressive behavior, mood swings, and hepatic toxicity. Nurses who care for patients who take dietary supplements containing DHEA should be sure to counsel them about the risks and benefits associated with DHEA use.

Withdrawal from AAS use may lead to mood swings, fatigue, restlessness, loss of appetite, and decreased sex drive. Nurses must be alert when caring for persons withdrawing from AAS use because withdrawal may cause depression lasting up to a year, which can result in suicide attempts. Antidepressants and behavioral therapy may be helpful.

Box 7.3 discusses dehydroepiandrosterone (DHEA) and its risks and benefits.

Special Needs of Patients with Substance Use Disorder

Surgical Patients

Patients with substance use disorder are at high risk for drug interactions, postoperative complications, and death when surgery is required. An assessment of drug use and application of the CAGE questionnaire, a screening tool for alcohol misuse, should be part of all patient histories. Respiratory changes in persons with TUD make introduction of endotracheal and suction tubes more difficult and increase the risk for postoperative respiratory problems. During the postoperative period, nurses should be alert for signs and symptoms of drug interactions with pain medications or anesthesia and for signs of withdrawal.

Special precautions must be taken for the patient with AUD who requires surgery. Alcohol use may be overlooked in an accident victim if there are injuries that cause CNS depression. In addition, many persons are undiagnosed as persons with AUD at the time of admission for elective surgery. The patient with AUD may require an increased level of anesthesia, which can increase the risk for cardiovascular instability in susceptible patients. Delirium may be triggered by surgery and abstinence. After surgery, patients with AUD may develop withdrawal syndrome, indicated by tremors, mild anxiety, gastric distress, and headache; left untreated, withdrawal may progress to withdrawal seizures or delirium tremens (DT), manifested by hallucinations, disorientation, tachycardia, hypertension, hyperthermia, agitation, and diaphoresis. Symptoms may develop anywhere from 6 hours to 5 days after the last drink; left untreated, alcohol withdrawal syndrome can be fatal. The goal of treatment is the alleviation of symptoms and the provision of supportive care with fluids and nutrition.

Pain Management

Although health care personnel may be reluctant to administer narcotic analgesics to persons with substance use disorder, there is no evidence that providing narcotic analgesia to these patients in any way worsens their disease. *When patients experience pain, the goal is to treat the pain.* All patients should be treated with dignity and respect. Withholding adequate analgesia due to misconceptions leads to unnecessary suffering and harm and is a breach of the ethical principles central to nursing care. Addressing substance use disorder is *not* a priority when a patient is in pain.

When patients acknowledge substance use disorder, it is important to determine which drug is used and the amount taken each day. If the patient misuses opioids, it is often best to avoid further exposure to the drug of choice because recommended opioid doses do not provide adequate pain relief due to tolerance. Paradoxically, significantly increasing the dose of opioid in an effort to achieve pain control can induce hyperalgesia, where patients become abnormally sensitive to pain. Effective doses of other analgesics can be determined if daily doses of the drug of choice are known. Nonopioid and adjuvant analgesics and nonpharmacologic pain relief measures may also be used, particularly when the person with opioid use disorder is on drug-assisted treatment with buprenorphine or naltrexone.

The Nurse with Substance Use Disorder

Substance use disorder is no more prevalent among nurses than it is among the rest of the population. However, nurses care for others during the most vulnerable times of their life; nurses literally have the lives of others in their hands, and they are therefore held to a higher standard than other professionals. Drug use is a serious concern in health care professions. The most commonly used drugs include *Cannabis*, cocaine, narcotics, opiates, alcohol, and nicotine. It is estimated that 10% to 15% of nurses have substance use disorder.

Contributing Factors

Factors that contribute to drug use among nurses have been identified as job stress, the emotional demands of nursing, long hours and shift rotations, and easy access to drugs. Additionally, nurses internalize their feelings in order to stay in control during crisis and have little to no time to decompress. Nurses take care of others before themselves.

Characteristics

Signs and symptoms of substance use disorder may be indicated by changes in personality and behavior, including alterations in job performance, unexplained absence from the unit, arriving to work late and leaving early, poor judgment and errors (e.g., medication errors), alteration of verbal and telephone orders and illogical documentation.

Signs and symptoms of substance use disorder also include physical changes. Behaviors related to influence of the drug or signs of withdrawal may also be present, such as subtle changes in appearance, self-imposed isolation, inappropriate responses to situations (i.e., both verbal and emotional), confusion, lapses in memory and decreased levels of alertness.

Discrepancies in controlled-drug handling and records may indicate drug diversion, the deliberate redirecting of a drug from a patient or facility to the employee for personal use. Indications of drug diversion include frequent narcotic wastage, multiple corrections to medication records and other documentation, and frequent reports of uncontrolled pain from patients.

Nurses often enable drug use among coworkers by covering up their mistakes or tardiness, excusing their behavior, or simply ignoring obvious signs and symptoms. When it is recognized that a nurse is impaired, help for the nurse requires sharing observations and concerns with the nurse and supervisor to provide the means for rehabilitation. For more information related to substance use disorder among nurses, please go to the National Council of State Boards of Nursing (NCSBN) website at www.ncsbn.org.

Management

In most states, nurses may enter nondisciplinary programs designed for evaluation and treatment. These programs include compliance monitoring during treatment and recovery as well as abstinence monitoring upon the nurse's return to work. These programs allow nurses to maintain their licenses. The goals of these programs are to protect the safety of the public, to maintain the integrity of the profession, and to ensure that the nurse is offered the possibility of treatment and rehabilitation before the license to practice is revoked or the job is terminated. Further information can be found at www.ncsbn.org/substance-use-in-nursing.htm.

Given the prevalence of drug use, all nurses care for patients who use drugs, regardless of whether the use has been identified as substance use disorder. Therefore, it is important for nurses to identify patients who misuse drugs and to intervene. Knowledge of the most commonly misused drugs and their treatments are critical to sustained remission and promotion of healthy lifestyles.

Nursing Process: Patient-Centered Collaborative Care

Tobacco Use Disorder

Assessment

- Ask the patient to identify any barriers or impediments to quitting.
- Assess current smoking status and smoking history.
- Assess for feelings of hopelessness, depression, and apathy.
- Assess health history.
- Assess the patient's decision-making capacity.
- Determine the willingness of the patient to attempt to quit.
- Have the patient identify negative consequences of smoking and the potential benefits of quitting.
- Identify the cultural context of the patient's smoking pattern.
- Identify the patient's locus of control.
- Identify what rewards for quitting are most important to the patient.

Nursing Diagnoses

- Health Maintenance, Ineffective related to the presence of adverse personal habits (smoking)
- Powerlessness related to perceived lack of control over the ability to give up nicotine
- Decision-Making, Readiness for Enhanced in expressing a desire to enhance understanding and meaning of choices
- Health Management, Readiness for Enhanced in expressing desire to learn measures to stop smoking
- Health Behavior, Risk-Prone related to smoking

Planning

- The patient begins to identify ways to achieve control over nicotine use.
- The patient demonstrates positive health maintenance behaviors as evidenced by keeping scheduled appointments and participating in a tobacco cessation program.
- The patient identifies and uses available resources.

Nursing Interventions

- Advise the patient to keep a list of "slips" and "near-slips" to learn to avoid their causes.
- Assist the patient with problem solving.
- Define your role as the patient's advocate.
- Encourage the patient to avoid environments and activities previously associated with smoking.
- Enhance the patient's sense of autonomy by involving the patient in decision making.
- Help the patient choose the best method to quit smoking based on patient preferences and anticipated benefits.
- Refer the patient to support groups or programs available in the community.
- Schedule frequent follow-up contacts with the patient to offer encouragement and help the patient deal with relapses.
- Set a quit date with the patient, ideally within 1 to 2 weeks.
- Teach the patient about drug-assisted treatment available to assist in smoking cessation.
- Teach the patient to anticipate the withdrawal symptoms and challenges of quitting.

Evaluation

- To avoid relapse, evaluate the effectiveness of the cessation plan, including the use of drug-assisted treatment and support systems.

Critical Thinking Case Study

LM, a 57-year-old man, is admitted to the surgical unit in preparation for back surgery after conservative treatment for a recent back injury failed to relieve his pain. His wife tells the nurse she hopes the surgery will be successful. She confides that her husband has just been sitting around the house drinking more beer than usual because he has not been able to work. LM appears relaxed and unconcerned about his anticipated surgery. He jokes with the nurse, telling her that he would be cured if "a cute young thing like her would only rub his back."

1. What assessments of LM's alcohol use should the nurse make and communicate to the surgeon and anesthesiologist before he is further prepared for surgery?
2. During LM's postoperative period, when will the nurse expect signs of withdrawal syndrome to occur?
3. What early signs and symptoms would alert the nurse to the development of withdrawal syndrome?
4. What goal of treatment during LM's postoperative period is related to alcohol withdrawal syndrome?

NCLEX Study Questions

1. When caring for a patient recovering from an episode of opioid toxicity, the nurse determines that the patient has opioid use disorder based on which finding?
   a. Withdrawal symptoms
   b. A history of daily use
   c. Craving that results in drug-seeking behaviors
   d. Intravenous, rather than oral, use of the drug
2. A patient hospitalized with a fractured femur following an automobile accident develops nausea and vomiting, abdominal cramps, and restlessness. The nurse suspects that the patient is experiencing which reaction?
   a. Opioid withdrawal
   b. Alcohol toxicity
   c. Flashbacks from LSD use
   d. Nicotine withdrawal
3. Which treatments will the nurse anticipate administering to a patient who has been admitted with alcohol toxicity? (Select all that apply.)
   a. Naloxone
   b. Thiamine
   c. Intravenous fluids
   d. Naltrexone
   e. Intravenous glucose solution
   f. Flumazenil
4. A nurse observes another nurse taking oral opioids from the medication room at the hospital. Which is the best action for the nurse who observes drug diversion to take?
   a. Report the finding to the nursing supervisor to enable the nurse's participation in a nondisciplinary program.
   b. Ignore the situation to protect the nurse from dismissal and possible loss of licensure.
   c. Confront the nurse and demand that the drugs be returned before someone notices their absence.
   d. Ask the nurse to request pain medications from a physician rather than stealing them from the hospital.
5. A patient is to start disulfiram to help with alcohol use disorder. The nurse providing medication education about the drug will include which topics in the education plan? (Select all that apply.)
   a. Importance of taking the medication every day
   b. That better results are experienced when a support group helps with treatment adherence
   c. Common food and hygiene products that contain alcohol
   d. That disulfiram treatment should be stopped 1 day before alcohol consumption
   e. That disulfiram works by disrupting the metabolism of alcohol
   f. That use of alcohol with disulfiram may cause nausea and vomiting and may even be fatal

Answers: 1, c; 2, a; 3, b, c, e; 4, a; 5, a, b, c, e, f.

UNIT II
Pharmacotherapy and Drug Administration

OUTLINE

Introduction
8. The Nursing Process and Patient-Centered Care
9. Safety and Quality
10. Drug Administration
11. Drug Calculations

Introduction

The nursing process is utilized by nurses for the appropriate delivery of patient care and for drug administration. Chapter 8 discusses the nursing process and patient-centered care. It supports the nurse in prioritizing medication delivery by following the steps of the nursing process. Chapter 9 discusses safety and quality in drug administration. The nursing student will discuss the patients' and nurses' rights and the culture of safety in drug administration. Chapter 10 provides current guidelines of drug routes used by the nurse. Chapter 11 provides practice in drug calculation and dosage. This information is vital in the study of nursing and for the safe delivery of patient care.

The Nursing Process and Patient-Centered Care

OUTLINE

Nursing Process: Patient-Centered Collaborative Care
- Assessment
- Nursing Diagnosis
- Planning
- Implementation of Nursing Interventions
- Evaluation

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Discuss Quality and Safety Education for Nurses (QSEN) and Nursing Alliance for Quality Care (NAQC) guidelines in relation to medication safety.
- Differentiate the steps of the nursing process and their purpose in relation to drug therapy.
- Develop patient-centered goals.
- Discuss at least eight principles for health teaching related to drug therapy plans.
- Describe at least six culturally sensitive health-teaching tips.
- Analyze the nurse's role related to drug therapy plans.

KEY TERMS

assessment, p. 77
culturally sensitive, p. 79
evaluation, p. 80
goal setting, p. 78
implementation, p. 78
nursing diagnosis, p. 77
planning, p. 78

In their everyday practice, nurses have many important tasks; however, drug administration is at the top of the list. It is estimated that about 40% of the nurse's time is spent on drug administration, and knowledge of these drugs is essential to patient safety. If unsure about a patient's medication, consult the health care provider for clarification.

Nurses are often the first line of defense against drug errors in patient care. Federal, state, and local authorities issue regulations and guidelines for practice, and each state has a nurse practice act that defines the scope and function under which the nurse practices. Health care institutions also

have policies that help nurses follow federal and state guidelines and regulations.

This chapter focuses on the nursing process as it relates to pharmacology and the safe administration of patient drugs with a focus on patient- and family-centered care. Chapter 9 offers additional information on safety in pharmacotherapy.

QSEN The Quality and Safety Education for Nurses (QSEN) initiatives guide nurses in the practice of safe, comprehensive care. QSEN offers competencies to provide structure and encourages professional development while advocating for safe patient care. QSEN equips nurses with competencies to improve the quality and safety of the health care system in which they work.

QSEN The QSEN competencies are as follows:

1. *Patient- and family-centered care:* Recognize the patient as the source of control and full partner in providing compassionate and coordinated care based on respect for patient preferences, values, and needs.
2. *Collaboration and teamwork:* Function effectively in nursing and inter-professional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality patient care.
3. *Evidence-based practice:* Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.
4. *Quality improvement:* Continuously improve the quality and safety of health care systems by using data to monitor outcomes of care processes and improvement methods to design and test changes.
5. *Safety:* Minimize risk of harm to patients and providers through both system effectiveness and individual performance.
6. *Informatics:* Use information and technology to communicate, manage knowledge, mitigate error, and support decision making.

QSEN QSEN competencies are integrated throughout the book and are highlighted in special features such as "Patient Safety" boxes and high-alert drug icons.

The Nursing Alliance for Quality Care (NAQC) is an organization that supports quality patient-centered health care. The NAQC in partnership with the American Nurses Association (ANA) has published guidelines that support the core principles of patient-centered quality care. These guidelines aim to foster "the patient relationship as the cornerstone of patient safety and quality." The NAQC's mission is to advance the highest quality, safety, and value of consumer-centered health care for all individual patients, their families, and their communities. NAQC believes it is the nurse's role to cultivate successful patient and family engagement, and that fostering family engagement is an essential component in reducing drug errors. The nurse serves as a patient advocate by supporting the patient's right to practice informed decision making and by maintaining patient-centered engagement in the health care setting. These guidelines include nurses at all levels of education and across all health care settings. Both QSEN and NAQC principles are fundamental to patient-centered practice and safety in pharmacotherapy.

Nursing Process: Patient-Centered Collaborative Care

The nursing process is a five-step decision-making approach that includes (1) assessment, (2) diagnosis, (3) planning, (4) implementation, and (5) evaluation. The purpose of the nursing process is to identify, diagnose, and treat human responses to health and illness. The nursing process is the essential core of practice for nurses. It supports the nurse in prioritizing the safe, timely delivery of drug administration. The nursing process is continuous and moves back and forth between the various steps. Careful attention to each phase of the process promotes the patient's success with the prescribed medication regimen. These steps are discussed as each relates to health teaching and drug therapy.

Assessment

During the **assessment** phase, the nurse is gathering information from the patient about the patient's health and lifestyle. Assessment includes both subjective and objective data. Always perform a complete, systemic assessment of the patient's body systems. In this assessment, the nurse asks the patient questions about the illness and about the drug regimen. The nurse can also get information from family members, health professionals, and the medical record. The assessment phase is paramount because the nurse will use the information gathered to form the basis of the patient's plan of care, which includes drug administration. Careful attention to each phase of the nursing process encourages the patient's success with the prescribed medication regimen.

Subjective Data

Subjective data include information provided verbally by the patient, family members, friends, or other sources. The patient must verbalize subjective data, which are imperceptible by the nurse's senses. The nurse may ask open-ended questions that allow the patient to answer directly, such as "Please tell me about your current medications." The nurse may help the patient explain or describe subjective data but must never speak for the patient. Subjective data comprise what the patient personally has to say about his or her medications, health problems, and lifestyle. Examples of pertinent information that the nurse can use to help solicit subjective data from the patient concerning medication administration include the following:

- Current health history, including family history
- Swallowing problems (dysphagia)
- Signs and symptoms of the patient's illness verbalized by the patient
- Current concerns about the patient's:
  - Knowledge about medications and side effects
  - Over-the-counter (OTC) remedies, nutritional supplements, herbal remedies, and contraceptives
  - Knowledge of side effects to report to the physician
  - Attitude and beliefs about taking medications
- Allergies
- Financial barriers
- Use of tobacco, alcohol, and caffeine
- Cultural dietary barriers
- The patient's home safety needs
- Caregiver needs and support system

Enhancing the patient's adherence to the drug therapy regimen is an essential component of health teaching. The patient's attitudes and values about taking medication are important considerations when determining readiness to learn. Attitudes and values should be considered when planning interventions to support the patient's decision to adopt healthy behaviors related to medications. In addition, the patient's social support system should be emphasized. This special support system is unique to the individual and may be composed of persons who assist in preparing drugs, organizing pills, and ordering medications. A support system can alert a patient to side effects, encourage actions that promote medication compliance, and notify the health care provider if a problem arises.

Objective Data

Objective data are what the nurse directly observes about the patient's health status. It involves collecting the patient's health information by using the senses: seeing, hearing, smelling, and touching. Objective data collection provides additional information about the patient's symptoms and also targets the organs most likely to be affected by drug therapy. For example, if a drug is nephrotoxic, the patient's creatinine clearance should be assessed.

The following are examples of objective data concerning medication administration:

- Physical health assessment
- Laboratory and diagnostic test results
- Data from the physician's notes (i.e., health history)
- Measurement of vital signs
- The patient's body language

Nursing Diagnosis

A **nursing diagnosis** is made based on analysis of the assessment data, and it determines the type of care the patient will receive. When data show an abnormality during the assessment, it can serve as the defining characteristic of a problem to support the appropriate nursing diagnosis; and more than one applicable nursing diagnosis may be generated. The nurse formulates nursing diagnoses and uses them to guide the development of a care plan to provide patient-centered quality care.

Common nursing diagnoses related to drug therapy include the following:

- Pain, Acute or Chronic, related to surgery
- Confusion, Acute related to an adverse reaction to medication
- Health Maintenance, Ineffective related to not receiving recommended preventive care
- Knowledge, Deficient related to effects of anticoagulant medication
- Noncompliance related to forgetfulness
- Health Management, Ineffective related to lack of finances

Use of nursing diagnoses is beneficial to patient care because it facilitates the development of an individualized care plan for each patient. It is important to note that a *nursing diagnosis* is different from a *medical diagnosis*, which identifies a disease condition and the results of diagnostic tests and procedures.

To review the complete list of NANDA nursing diagnoses please see http://faculty.mu.edu.sa/public/uploads/1380604673.6151NANDA%202012.pdf.

Planning

During the **planning** phase, the nurse uses the data collected to set goals or expected outcomes and interventions. Goals or expected outcomes should address the problems in the patient's nursing diagnosis. Goals are patient centered, describe the specific activity, and include a time frame for achievement and reevaluation. Planning includes the development of nursing interventions used to assist the patient in meeting goals. In order to develop patient-centered goals and outcomes, collaboration with the patient and/or family is necessary. Effective **goal setting** has the following qualities:

- The expected change is realistic, measurable, and includes reasonable deadlines.
- The goal is acceptable to both the patient and nurse.
- The goal is dependent on the patient's decision-making ability.
- The goal is shared with other health care providers, including family or caregivers.
- The goal identifies components for evaluation.

Examples of well-written comprehensive goals include the following:

- The patient will independently administer the prescribed dose of 4 units of regular insulin by the end of the fourth session of instruction.
- The patient will prepare a 3-day medication recording sheet that correctly reflects the prescribed medication schedule by the end of the second session of instruction.

Implementation of Nursing Interventions

The **implementation** phase is the part of the nursing process in which the nurse provides education, drug administration, patient care, and other interventions necessary to assist the patient

in accomplishing the established goals. In most practice settings, administration of drugs and assessment of the drug's effectiveness are important nursing responsibilities. (See Chapter 9 for more information.)

Patient Teaching

It is important for the nurse to keep in mind factors that help promote patient learning. The patient must be ready to learn and must make an investment in learning. If the patient buys into wanting to practice good health principles, learning can be successful. The nurse and patient together must become fully engaged in the learning process. Timing is another important factor. What is the best time for the patient to learn? Is the patient a morning or night person? People seem to learn best if the time between the learning and use is short. The environment should be conducive to learning with a temperature that is comfortable and an environment that is quiet. It is important for the nurse to recognize that certain barriers to learning exist. Pain is an obstacle, and the patient's teaching should be postponed until pain is relieved. Be mindful of language barriers. If the patient does not speak the same language as the nurse, an interpreter may be needed. The patient's age may be another important obstacle. If the patient is young, or perhaps elderly and forgetful, a family member or significant other will need to be present.

Patient teaching is essential to the patient's recovery. It allows the patient to become informed about his or her health problems and to participate in creating interventions that can lead to good health outcomes. It is within the scope and practice of the nurse to embrace patient education and to use health-teaching strategies.

Nurses have a primary role in teaching both patients and families about drug administration. It is important that all teachings be tailored to the patient's educational level and that the patient trusts the nurse for learning to begin. When possible, it is always important to include a family member or friend in the teaching to provide support to the patient with reminders and encouragement; they can also detect possible side effects that may occur in the patient. The following are important principles to remember when teaching patients about their medications:

- *General.* Instruct the patient to take the drug as prescribed. Consistency in adhering to the prescribed drug regimen is important.
  - Provide simple written instructions to the patient with the doctor and pharmacy names and telephone numbers.
  - Instruct the patient to notify the health care provider if any of the following occur:
    - The dose, frequency, or time of the drug is adjusted.
    - A female patient becomes pregnant.
    - An OTC medication or supplement is added.
- *Side effects.* Give the patient instructions that will help minimize any side effects (e.g., avoid direct sunlight with drugs that can cause photosensitivity or sunburn). Advise patients of any expected changes in the color of urine or stool, and counsel the patient who has dizziness caused by orthostatic hypotension to rise slowly from a sitting to a standing position.
- *Self-administration.* Perform an ongoing assessment of the patient's motor skills and abilities. Remember that modifications may be necessary to the teaching plan based on the assessment.

BOX 8.1 Patient Teaching Card

Name of drug: Acetaminophen 325 mg
Reason for taking the drug: Minor aches, pains, and fever
Dosage: One or two tablets as needed every 4-6 hours; max 4 g/day or 6 tabs/day
Time to take the drug: 8:00 am/2:00 pm/8:00 pm
Possible side effects: Nausea, upper stomach pain, itching, loss of appetite, dark urine, and jaundice
Possible adverse effects: Overdosage can affect the liver and cause hepatotoxicity.
Notify health care provider: If side effects occur
Health care provider's telephone #: _____
Warning:

- *Never* take this medication with alcohol.
- If pregnant or nursing, notify the health care provider prior to taking the medication.

- Instruct the patient on drug administration according to the prescribed route: eye or nose instillation, subcutaneous injection, suppository, oral/mucosal (e.g., swish-and-swallow suspensions), and inhaled via a metered-dose inhaler with or without a spacer. Include a return demonstration in the instructions when appropriate.
- The use of drug cards is a helpful teaching tool (Box 8.1). Drug cards can be obtained from the health care provider or from the drug manufacturer. They are helpful components for teaching. Drug cards may include the name of the drug, the reason for taking the drug, the drug dosage, times to take the drug, possible side effects, possible adverse effects and when to notify the care provider, and specific things that should or should not be done while taking the medication (e.g., take with food, do not crush tablets).

- *Diet.* Advise the patient about foods to include in their diet and foods to avoid. Many foods interact with certain drugs. Depending on the nature of the interaction, certain foods have the ability to decrease drug absorption, increase the risk of drug toxicity, or create other problems that make them an important safety concern.
- *Cultural considerations.* The nurse must apply knowledge of cultural considerations to individualize a teaching plan (Box 8.2). A **culturally sensitive** nurse is alert to the patient's cultural expectations. Begin by identifying your own cultural beliefs, practices, and values in order to keep them separate from those of the patient.
  Additional suggestions include the following:
- Space instruction over several sessions if appropriate.
- Review community resources related to the patient's nursing and medical diagnoses.
- Collaborate with the patient and family and other health care staff and agencies to mobilize resources to meet the patient's needs.
- Identify patients at risk for noncompliance with the regimen. Alert the health care provider and pharmacist so they can develop a plan to minimize the number of drugs and the number of times drugs are administered.

BOX 8.2 Culturally Sensitive Health-Teaching Tips

- Prior to the teaching, learn the ethnicity of the patient and arrange for an interpreter who speaks the patient's language. The use of family members as interpreters should be avoided because they may not be able to interpret medical terminology and may hinder communication on the part of the patient.
- Allow time for patients to respond to questions. Ask open-ended questions, and have patients demonstrate their understanding of treatments rather than verbalizing them.
- Be flexible in the timing of medication administration, such as with patients who are praying or fasting.
- Always be culturally sensitive when providing fluids to patients when administering medications. Ask in advance, and provide warm water when requested.
- Does your patient's culture have specific laws to follow concerning food preparation?
- Be mindful of body language. Many cultures are uncomfortable with too much eye contact, touching, or hugging.

BOX 8.3 Points for Patients and Families to Remember

- Medications should be taken as prescribed by your health care provider. If problems arise with the dose or timing, or if side effects occur, contact your medical provider.
- If drugs are placed in a drug box, keep the original labeled container.
- Keep all drugs out of the reach of children.
- Before using any over-the-counter drugs, including vitamins and nutritional supplements, check with your health care provider. This includes the use of aspirin, ibuprofen, and laxatives. Consider asking the pharmacist before buying or using a product.
- Bring all drugs with you when you visit the health care provider.
- Know the purpose of each medication and under what circumstances to notify the health care provider.

- Do not drink alcoholic beverages around the time you take your medications. Alcohol is absolutely contraindicated with certain medications, and it may alter the action and absorption of medications.
- Be aware that smoking tobacco also alters the absorption of some medications (e.g., theophylline-type drugs, antidepressants, pain medications). Consult your health care provider or pharmacist for specific information.

- Evaluate the patient's understanding of the medication regimen on a regular basis.
- Empower the patient to take responsibility for drug management.
- General points to remember and tips for successful patient education are presented in Box 8.3.

Many people take multiple drugs simultaneously several times each day, which presents a challenge to patients, their families, and nurses. This complex activity of taking several drugs can be segmented into several simple tasks that include the following:

- Drug boxes obtained from a local pharmacy can be used to prepare a day's or week's supply of medication. The boxes sort the drugs according to the time of day each pill is to be taken.
- A recording sheet may be helpful. When the drug is administered, the patient or family member marks the sheet, which is designed to meet the patient's individual needs. For example, the time can be noted by the patient, or it can be entered beforehand, with the patient marking the designated time the dose should be taken. A generic format follows:

Medication	Dosage	Day of Week						
	(mg Daily)	S	M	T	W	Th	F	S
Captopril	12.5							
Digoxin	0.25							
Furosemide	40							

- Alternatives to recording sheets are also available, and alarm reminder devices may be used.

Throughout the teaching plan, the nurse promotes patient independence (e.g., self-administering, safely storing, and ordering of the drug regimen). Always keep in mind patients' goals and outcomes when teaching. Box 8.4 presents a checklist for health teaching in drug therapy.

Evaluation

In the **evaluation** phase of the nursing process, the nurse determines whether the goals and teaching objectives are being met. The nurse continues to use ongoing assessment data to evaluate the successful attainment of the patient's objectives and goals. If the objectives and goals are not met, the nurse will revise the objectives, goals, and interventions to ensure success. If the objectives, goals, and interventions are met, the nurse will document the successful attainment in the nursing plan of care.

BOX 8.4 Checklist for Health Teaching in Drug Therapy

- Reinforce the importance of drug adherence.
- Prior to giving the patient written material, ensure the patient can read.
- Always complete a health history and physical assessment on the patient.
- Assess all of the drugs on the patient's profile for possible drug interactions.
- Explain the reason the patient is taking the drug, the time it should be administered, and whether it should be taken with or without food.
- Review the side effects and adverse reactions, and make sure the patient has the doctor's telephone number and knows when to notify the health care provider or pharmacist.
- Discern whether the patient needs baseline and monthly lab work to monitor drug levels.
- Keep in mind that patient validation of learning may include a return demonstration of psychomotor skills (insulin administration).

- Show the patient how to record drug administration on a sheet of paper by indicating time of day.
- Discuss the patient's financial resources, and if needed, consult a social worker for resources.
- Discuss the patient's support system, such as family or friends as caregivers.
- Provide the patient with a list of community resources.

Critical Thinking Case Study

Mr. J.S. is a 66-year-old man who just arrived on the medical surgical unit following an appendectomy. He is complaining of pain. You are the nurse assigned to care for Mr. J.S.

1. What critical assessment data do you need to identify and collect?
2. Formulate a nursing diagnosis based on your assessment data.
3. Describe two nursing interventions to assist the patient.
4. What criteria would you use to evaluate the effectiveness of the nursing interventions?

NCLEX Study Questions

1. During a medication review session, a patient says, "I just do not know why I am taking all of these pills." Based on this piece of subjective data, which diagnosis will the nurse identify?
   a. High risk for injury
   b. Knowledge deficit
   c. High risk for aspiration
   d. Anxiety
2. The nurse is developing goals in collaboration with a patient. Which is the best goal statement?
   a. The patient will self-administer albuterol by tomorrow.
   b. The patient will self-administer the prescribed dose of albuterol by the end of the second teaching session.
   c. The patient will independently self-administer the prescribed dose of albuterol by the end of the second teaching session.
   d. The patient will organize his or her medications by tomorrow.
3. When developing an effective medication teaching plan, which component will the nurse identify as *most* essential?
   a. Written instructions
   b. The patient's readiness to learn
   c. Use of colorful charts
   d. A review of community resources
4. When developing an individualized medication teaching plan, which topics will the nurse include? (Select all that apply.)
   a. The importance of adherence to the prescribed drug regimen
   b. How to administer medication(s) according to the prescribed route
   c. The side/adverse effects that should be reported to the health care provider
   d. If a drug is inadvertently missed, whether to double the next dose
   e. Notifying the physician prior to taking over-the-counter drugs or supplements
5. The Nursing Alliance for Quality Care's focus is for health care providers to strive for which goal?
   a. Safety in medication administration
   b. Confidentiality as determined by the patient
   c. Development of a patient relationship and family engagement
   d. Patient independence within the family
6. The Quality and Safety Education for Nurses' focus on safety is *best* exemplified by which competency?
   a. Patient advocacy
   b. Technology-enhanced medication administration
   c. Infection control
   d. Patient- and family-centered collaborative care
7. Which teaching strategy is most likely to succeed in health teaching with the patient and family?
   a. Have the patient verbalize why they are taking the drug.
   b. Have the patient answer closed-ended questions.
   c. Have the patient demonstrate information.
   d. Have the patient identify pills by color.

Answers: 1, b; 2, c; 3, b; 4, a, b, c, e; 5, c; 6, d; 7, c.

Safety and Quality

OUTLINE

"Five-Plus-Five" Rights of Medication Administration
- Right Patient
- Right Drug
- Right Dose
- Right Time
- Right Route
- Right Assessment
- Right Documentation
- Right to Education
- Right Evaluation
- Right to Refuse

Nurses' Rights When Administering Medication

- The Joint Commission National Patient Safety Goals
- Drug Reconciliation
- Disposal of Medications
- Sharps Safety

Safety Risks With Medication Administration
- Counterfeit Drugs
- Dosage Forms: To Crush or Not to Crush

High-Alert Medications
Look-Alike and Sound-Alike Drug Names
Other Factors in the Prevention of Medication Errors
- Nursing Process: Patient-Centered Collaborative Care— Medication Safety

Resources for Preventing Errors in Medication Administration
Pregnancy Categories and Subsections
Guidelines for Medication Administration
Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Describe the original "five-plus-five" rights of medication administration.
- Analyze safety risks with medication administration.
- Discuss the culture of safety and include the Institute of Medicine's "To Err is Human" and the American Nurses Association's "Just Culture" impact on nursing.
- Discuss safe disposal of medications.
- Discuss high-alert drugs and strategies for safe administration.

- Discuss the nurse's rights when administering medications.
- Discuss safety regulations for pregnancy.
- Apply the nursing process to safe administration of medications.

According to the Institute for Healthcare Informatics, spending on prescription medicines increased by 10.3% in the United States during 2014. A total of $373.9 billion is spent on prescription medications yearly. In 2014, over 4.3 billion prescriptions were filled in the United States. Recently, the *Journal of Patient Safety* published a study that concluded that as many as 440,000 people die each year from preventable medical errors.

The focus of this chapter is quality and safety. It involves a discussion of safety initiatives and interventions that include the "five-plus-five" rights of medication administration, the nurse's rights when administering medications, the culture of safety, and The Joint Commission (TJC) Patient Safety Goals. Also included are high-alert drugs, look-alike and sound-alike drugs, and dosage forms to crush or not to crush. (See Chapter 8, which reviews the Quality and Safety Education for Nurses [QSEN] initiatives from www.qsen.org.)

"Five-Plus-Five" Rights of Medication Administration

The "five-plus-five" rights of medication administration are important goals for medication safety. The nurse following these guidelines will give (1) the right patient (2) the right drug in (3) the right dose via (4) the right route at (5) the right time. The "plus five" refers to the five additional rights that have been recommended: (1) right assessment, (2) right documentation, (3) the patient's right to education, (4) right evaluation, and (5) the patient's right to refuse. The original five rights and the subsequent additions are important; however, additional interventions are necessary to ensure the patient's positive response to the administered drug. Although nurses work together with health care providers and pharmacists to provide safe medication practices, it is the nurse who works closely with the patient and follows the patient's response to the medication. The rights and interventions necessary for safe drug administration will be reviewed in this chapter.

Right Patient

The **right patient** determination is essential. TJC requires two forms of identification before drug administration.

- Ask the patient to state his or her full name and birth date, and compare these with the patient's identification (ID) band and the medication administration record (MAR).
- Many facilities have electronic health records (EHRs) that allow the nurse to directly scan the bar code from the patient's ID band. Once the band is scanned, the nurse can see the patient's medication record.

Additional nursing implications include the following:

- Most hospitals have color-coded ID bands that include bands coded for allergy, do not resuscitate (DNR), fall risk, and restricted extremity. Always check facility policies for the use of color-coded bands and their meanings.
- Verify the patient's identification each time a medication is given.
- If the patient is an adult with a cognitive disorder or a child, verify the patient's name with a family member. In the event a family member is unavailable and the patient is unable to self-identify, follow the facility's policy. Many facilities have policies that include a photo ID on the band with the patient's name and birth date affixed to the band.
- Distinguish between two patients with the same first or last name by placing "name-alert" stickers as warnings on the medical records.

Right Drug

The nurse must accurately determine the **right drug** prior to administration. When working with an EHR, once the bar code on the patient's wristband has been scanned, the patient's drug profile will appear on the computer screen. The nurse will then scan the patient's medication label, and it will automatically validate the time, date, and the nurse administering the patient's medication. If it is not the correct medication, the nurse will receive an alert and will be unable to proceed in the MAR until the correct medication is scanned.

Both federal and state legislation governs who can write a prescription order. Medication orders are prescribed by a licensed health care provider (HCP) under authority from the state to prescribe drugs. Those disciplines that have prescriptive authority are medical doctor (MD), dentist (doctor of dental surgery [DDS]), podiatrist (doctor of podiatric medicine [DPM]), certified nurse practitioner (CNP), advanced practice registered nurse (APRN), physician assistant (PA), veterinarian, chiropractor, and optometrist. In addition, medical clinical psychiatrists and pharmacists have prescriptive authority with strict guidelines set by the state. Prescriptions may be handwritten by the HCP, delivered as a telephone order (T/O) or verbal order (V/O), or directly entered into the patient's EHR. Handwritten prescriptions are written on a provider's legal prescription pad and are filled by a pharmacist.

Sometimes providers order medications by directly speaking to the nurse. All telephone orders or verbal orders for medications are either handwritten by the nurse taking the order or entered directly into a computer and "read back" to ensure accuracy. The nurse will write the name of the prescribing provider and will include that the order was read back, and affixing his or her signature

to the order will complete it. After dictating a verbal order, the provider must sign it within 24 hours. If the order is a controlled medication, most facilities require two licensed nurses to listen to the order and sign it. Nursing students are not allowed to accept or take provider orders, but they may administer the medication after it has been verified by a registered nurse.

Many hospitals are implementing computerized physician order entry (CPOE) systems to handle HCP medication orders. This method of ordering medications can help decrease drug errors by decreasing transcription errors. HCPs using a CPOE will directly input the prescription into the patient's EHR; the order is electronically signed by the HCP and is sent directly to the pharmacy, and it is recorded as part of the patient's MAR. A strong safety feature is the ability to identify drug interactions with the patient's current drugs and any newly prescribed medications.

The use of computerized ordering systems has added speed and a measure of safety to the order process. Orders can be written from virtually any location and can be sent electronically, but the computer will not process the order unless all necessary information is included. Because the order is computerized, illegible orders or signatures are prevented. Before the nurse can administer the medication, both the pharmacy and the nurse must validate the accuracy of the patient's prescription order in the EHR.

The components of a drug order are as follows (Fig. 9.1):

- Patient name and birth date
- Date the order is written
- Provider signature or name if an electronic order, T/O, or V/O

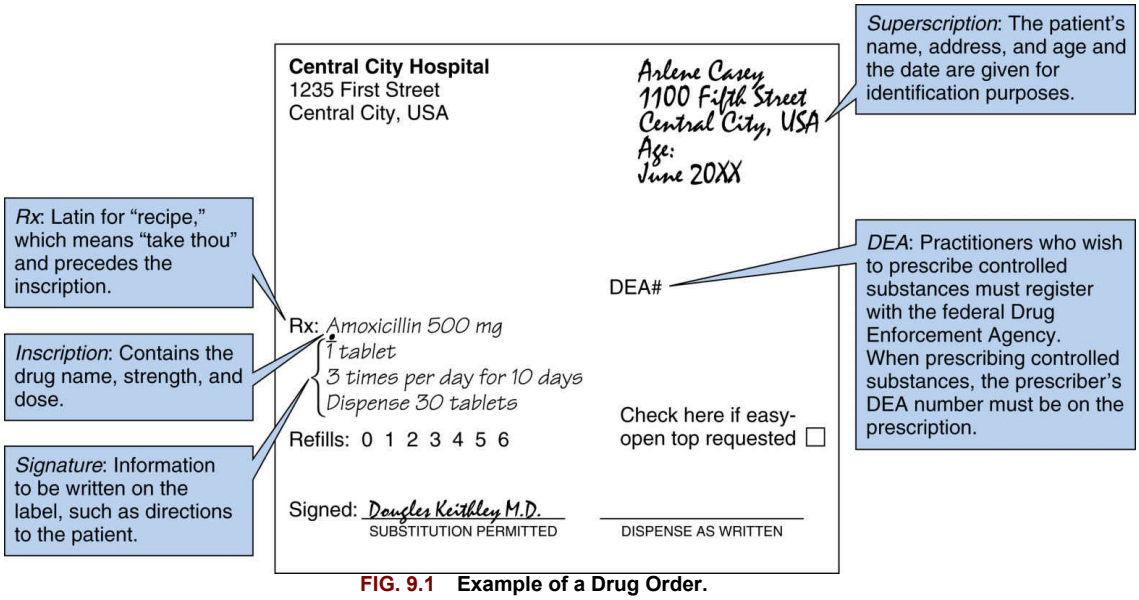

FIG. 9.1 Example of a Drug Order.

From Medical School Headquarters. (n.d.) *Prescription writing 101.* Retrieved from http://medicalschoolhq.net/prescription-writing-101

- Signature of licensed staff who took the T/O or V/O, if applicable
- HCPs who wish to prescribe controlled drugs must register with the federal Drug Enforcement Agency (DEA). When prescribing controlled substances, the HCP's DEA number must be on the prescription.
- Drug name and strength
- Drug frequency or dose (e.g., once daily)
- Route of administration
- Duration of administration (e.g., × 7 days, × 3 doses, when applicable)
- Number of patient refills
- Number of pills to be dispensed
- Any special instructions for withholding or adjusting dosage based on nursing assessment, drug effectiveness, or laboratory results

It is the nurse's responsibility to administer the drug as ordered by the provider, and if the drug order is incomplete, the drug should not be administered. Verification of a questionable order must be done in a timely manner. The HCP is usually contacted, and the conversation is documented.

Nurses must become familiar with the components of a drug order and must question any incomplete or unclear orders. Nurses are legally liable if they give a prescribed drug and the dosage is incorrect, or if the drug is contraindicated for the patient's health status. Once the drug has been administered, the nurse becomes liable for the predicted effects of that drug.

Medication administration is never considered just a process of "passing" drugs. Nurses must use critical thinking skills and assess whether the medication is correct for the patient's diagnosis. The nurse must ask critical questions: Is the dose appropriate? What is the patient's expected response? Also, the nurse must teach the patient about the drug's side effects and when it is necessary for the patient to notify the HCP.

To avoid drug errors, the drug label should be read three times: (1) when you pick up the medication and remove it from the drug cabinet, (2) as you prepare the drug for administration, and (3) when you administer the drug.

Nursing interventions related to drug orders can ensure correct administration of medications:

- The nurse should verify the identity of the patient by comparing the name on the wristband with the name on the MAR for accuracy.
- Always use two patient identifiers, such as having patients repeat their name and date of birth.
- The nurse should be familiar with the patient's health history and should have performed a head-to-toe assessment on the patient, including a complete set of vital signs.
- Always review the patient's lab work prior to the administration of drugs.
- Read the drug order carefully. If the order is unclear, verify it with the HCP before administering the drug.
- Know the patient's allergies.
- Know the reason the patient is to receive the medication.
- Check the drug label by identifying the drug name, the amount of the drug (tablet or volume), and its suitability for administration by the intended route.
- Check the dosage calculations.
- Know the date the medication was ordered and any ending date (e.g., for controlled substances and antibiotics and for limited or a specific number of doses). Some agencies have automatic stop orders that are generally facility specific. Examples of such orders include controlled drugs that need to be renewed every 48 hours, antibiotics to be renewed every 7 to 14 days, and cancellation of all medications when the patient goes to surgery.
- All orders—including first-dose, one-time, and as-needed (PRN) medication orders—should be checked against the original orders.

Right Dose

The **right dose** refers to verification by the nurse that the dose administered is the amount ordered and that it is safe for the patient for whom it is prescribed. The right dose is based on the patient's physical status. Many medications require the patient's weight in order to determine the right dose. Usually pediatrics, medical-surgical, and critical care situations require weight to complete the drug calculation and determine the correct dose (heparin and digoxin drip are examples of medications calculated according to weight). The nurse determines if the drug is safe to administer according to the drug's pharmacodynamics (action) and the patient's vital signs. Renal and hepatic functions are important considerations because many drugs are cleared through the kidneys and metabolized by the liver. Prior to drug administration, it is important that the nurse carefully review the patient's most current lab results. A chemistry panel includes renal and liver function and sodium and potassium levels. Also, the nurse should review the hematology labs, which include a complete blood count (CBC), red blood cells (RBCs), hemoglobin, hematocrit, and platelets. It is most important that the nurse check the drug's correct dose range in a reliable drug resource book or by consulting with a pharmacist. In most cases, the right dose for a specific patient is within the recommended range for the particular drug. Nurses must calculate each drug dose accurately.

Nurses use dimensional analysis or ratio and proportion when calculating a drug dose (see Chapter 11). Always recheck the drug calculation if the dose is within a fraction or if it is an extremely large dose. Consult another nurse or the pharmacist when in doubt.

Today, most drugs are dispensed through automated dispensing cabinets (ADCs), computerized drug storage cabinets that store and dispense medications near the point of care while controlling and tracking drug distribution. The patient's drugs are stocked in the cabinet by the pharmacist and are accessed under the patient's name, and the nurse is able to select and pull the patient's drugs

from the cabinet. This technology improves patient care by promoting accurate and quick access to medications, locked storage for all medications, and electronic tracking for controlled substances. Automation of drug administration saves time and decreases costs associated with drug administration.

Another method of dispensing drugs is the **unit dose method**, in which drugs are individually wrapped and labeled for single-dose use for each patient. The unit dose method has reduced dosage errors because no calculations are required. Some facilities still use a multidose vial from the ADC. If this occurs, the nurse will have to complete a calculation in order to retrieve the correct amount ordered by the physician from the vial. If there is any medication left in the vial, it is disposed of according to the facility's policy for disposal of drugs.

An important nursing intervention related to the right dose includes calculating the drug dose correctly. If in doubt about the amount to be administered, consult with a nurse peer to validate the correct amount. In some settings, two registered nurses (RNs) are required to check the dosage for certain medications, such as insulin and heparin.

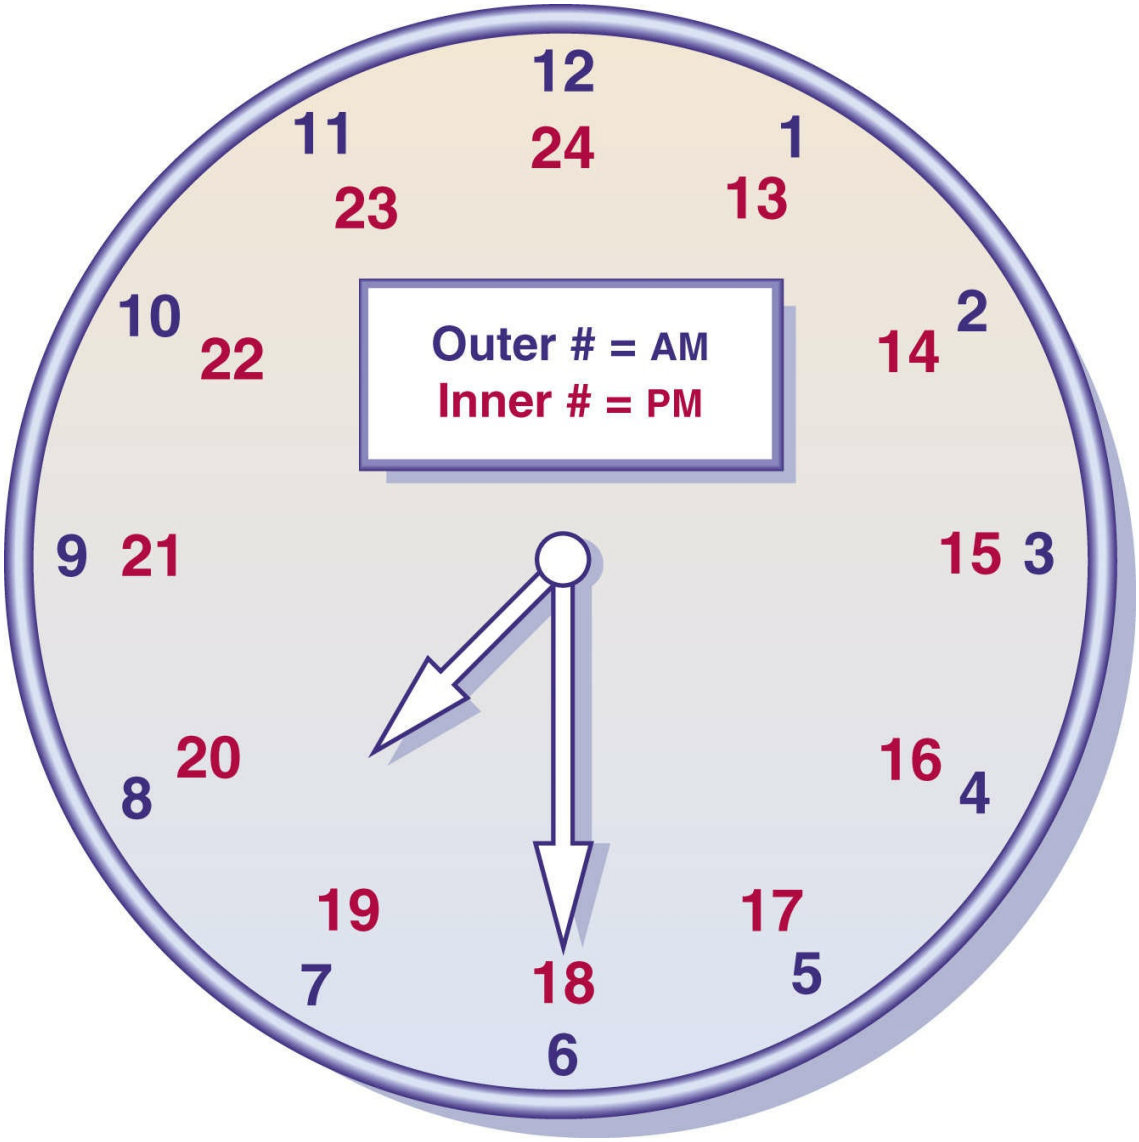

FIG. 9.2 **Military Time.**

Right Time

The **right time** refers to the time the prescribed dose is ordered to be administered. Daily drug dosages are given at specified intervals, such as twice a day (bid), three times a day (tid), four times a day (qid), or every 6 hours (every 6hrs); this is so the plasma level of the drug is maintained at a therapeutic level. Every drug cannot be given exactly when ordered, therefore health care agencies have policies that specify a range of times within which drugs can be administered (check your agency's policy). When a drug has a long half-life, it is usually given once a day. Drugs with a short half-life are given several times a day at specified intervals. Some drugs are given before meals, whereas others must be given with meals.

Use of military time, which is based on a 24-hour clock (Fig. 9.2), reduces administration errors and decreases documentation. Many nursing settings use military time rather than standard time. Nursing interventions related to the right time include the following:

- Administer drugs at the specified times (refer to agency policy).
- Administer drugs that are affected by food, such as tetracycline, 1 hour before or 2 hours after meals.
- Give food with drugs that can irritate the stomach (gastric mucosa)—for example, potassium and aspirin. Some medications are absorbed better after eating.

- Adjust the medication schedule to fit the patient's lifestyle, activities, tolerances, or preferences as much as possible.
- Check whether the patient is scheduled for any diagnostic procedures that contraindicate the administration of medications, such as endoscopy or fasting blood tests. Determine whether the medication should be given before or after the test based on the policy.
- Check the expiration date. If the date has passed, discard the medication or return it to the pharmacy, depending on the policy.
- Administer antibiotics at even intervals (e.g., every 8 hours rather than three times daily) throughout the 24-hour period to maintain therapeutic blood levels.
- Patients who require dialysis usually have blood pressure medications stopped prior to dialysis because dialysis can decrease blood pressure. However, some doctors order the medications to be given prior to dialysis. If any questions arise, check with the HCP before proceeding.

Right Route

The right route is necessary for adequate or appropriate absorption. The **right route** is ordered by the health care provider and indicates the mechanism by which the medication enters the body. The more common routes of **absorption** include oral, with drug in the form of a liquid, elixir, suspension, pill, tablet, or capsule; sublingual, under the tongue for venous absorption; buccal, between the cheek and gum; via a feeding tube; topical, applied to the skin; by inhalation (aerosol sprays); via otic (eye), ophthalmic (ear), or nasal (spray) instillation; by suppository (rectal or vaginal); and through the five parenteral routes: (1) intradermal, (2) subcutaneous (subcut), (3) intramuscular (IM), (4) intravenous (IV), or (5) intraosseous (IO).

Nursing interventions related to the right route include the following:

- Assess the patient's ability to swallow before administering oral medications; make sure the patient has not been ordered nothing by mouth (NPO).
- Do not crush or mix medications in other substances without consulting a pharmacist or a reliable drug reference. Do not mix medications in an infant's formula feeding.
- If the medication must be mixed with another substance, explain this to the patient. For example, elderly patients may use applesauce or yogurt to mix their medications to make them easier to swallow. Medications should be administered one at a time in the substance.
- Best Practice Guidelines and TJC state that drugs must be identifiable up until the point of delivery. When administering many drugs at one time, it is *not* recommended to mix drugs together. The correct practice is to administer one pill at a time. When a patient has an enteral tube, it is important to follow these guidelines; this allows the nurse to flush the tube before and after each pill or liquid is administered to prevent the tube from clogging. In the event that a patient's drug inadvertently falls to the ground, the nurse will be able to identify, discard, and replace the pill.
- Instruct the patient that medications must be swallowed with water and not juice, which can interfere with the absorption of certain medications; however, it is recommended that iron be taken with orange juice or vitamin C supplements to aid in the absorption of the iron.
- Use aseptic technique when administering drugs. Sterile technique is required with the parenteral routes.
- Administer drugs at the appropriate sites for the route.
- Stay with the patient until oral drugs have been swallowed.

Right Assessment

The **right assessment** requires the collection of appropriate baseline data before administration of a drug. Examples of assessment data include taking a complete set of vital signs and checking lab levels prior to drug administration. This may also include both apical heart rate and potassium level prior to administering digitalis; blood pressure level prior to administering an antihypertensive drug; blood glucose levels before insulin administration; or respirations with blood pressure prior to administering an opioid. It is also important for the nurse to identify high-risk patients, such as patients with medication allergies, patients on dialysis, those with liver disease, diabetic patients, cardiac and pulmonary patients, and the elderly and pediatric populations. If at-risk patients are identified, precautions can be taken to reduce risk.

FIG. 9.3 Bar code reader used to scan the patient's wristband. From Kee, J. L. & Marshall, S. M. (2017). *Clinical calculations: With applications to general and specialty areas* (8th ed.). St. Louis: Elsevier.

Right Documentation

The **right documentation** requires the nurse to record immediately the appropriate information about the drug administered. Many systems are available for documenting drug administration. The most common is the paper medication administration record (MAR), which the pharmacy will furnish. Facility policies vary, but when nurses administer a drug, they place their initials next to the name of the drug on the paper MAR. The nurse's initials verify that the medication was administered. Both paper and computerized MARs include information about the drug to be administered, including (1) the name of the drug, (2) the dose, (3) the route, (4) the time and date, and (5) the nurse's initials or signature.

Now popular and becoming common in most facilities is computerized charting, in which the nurse enters a personal identification and password to gain entry into the system. By scanning the patient's identification band (Fig. 9.3), which includes the patient's bar code information, the nurse accesses the patient's personal MAR with the emergency medical record (EMR) system. Once the nurse scans the bar code on the patient's medication package, the administration is validated in the computerized MAR. The computerized system interfaces with other departments, including the pharmacy, laboratory, and sometimes the physician's office.

Documentation of the patient's response to the medication is required with a variety of medications such as (1) opioid and nonopioid analgesics (Ask, how effective was pain relief?); (2) sedatives (How effective was relaxation?); and (3) antiemetics (Was nausea/vomiting decreased or eliminated?). The nurse continues to assess the patient's response to the medication (Was there any gastrointestinal irritation or skin sensitivity?) and documents this in the patient's plan of care. Keep in mind that patient responses are not necessarily verbal; they could be physiologic (e.g., blood pressure decreasing in response to an antihypertensive). With the paper MAR and a pen, the nurse documents the response in the nursing notes. The computerized MAR allows for documentation of the patient's response directly into the plan of care. Delay in charting may result in forgetting to chart the medication, and another nurse can inadvertently administer the drug, assuming it was not given because it was not charted. Therefore it is important to remember that drugs *must* be signed off on when the drug is administered. Graphic formats or computerized systems (Fig. 9.4) assist in the accurate and timely recording of drugs administered.

Right to Education

The **right to education** requires that patients receive accurate and thorough information about the drugs they are taking and how each drug relates to their particular condition. Patient teaching also includes why the patient is taking the drug, the expected result of the drug, possible side effects of the drug, any dietary restrictions or requirements, skill of administration with return demonstration, and laboratory test result monitoring. This right is a principle of **informed consent**, which is the individual having the necessary knowledge to make a decision. Informed patients and families are critical to preventing medication errors.

Right Evaluation

The **right evaluation** determines the effectiveness of the drug based on the patient's response to the drug. Evaluation in this context asks whether the medication did for the patient what it was supposed to do. It is essential that the nurse evaluate the therapeutic effect of the medication by assessing the patient for side effects and adverse drug reactions. Evaluation is ongoing and is an important aspect of patient safety.

Right to Refuse

The patient has the **right to refuse** the medication, and it is the nurse's responsibility to determine the reason for the refusal, explain to the patient the risks involved with refusal, and reinforce the important benefits of and reasons for taking the medication. When a medication is refused, the refusal must be documented immediately, and follow-up is always required. The primary nurse and health care provider should be informed because the omission may pose a specific threat to the patient (e.g., a change in the lab values with insulin and warfarin).

All medication errors are potentially serious. A medication error may involve one or more types of errors such as administration of the wrong medication or IV fluid; the incorrect dose or rate; administration to the wrong patient, by the incorrect route, or at the incorrect scheduled interval; administration of a known allergic drug; omission of a dose; or discontinuation of medication or IV fluid that was not ordered to be discontinued.

Nurses' Rights when Administering Medication

In addition to the rights of medication administration, there are six rights for nurses who administer medications. These rights provide an additional layer of safety by ensuring that the nurse has what is needed to provide safe medication administration.

The nurses' six rights are (1) the right to a complete and clear order; (2) the right to have the correct drug, route (form), and dose dispensed; (3) the right to have access to information; (4) the right to have policies to guide safe medication administration; (5) the right to administer medications safely and to identify problems in the system; and (6) the right to stop, think, and be vigilant when administering medications. These rights can assist in increasing the safety of medication administration.

In addition, the American Nurses Association (ANA) published a bill of rights for nurses in 2015 that contains seven premises concerning workplace expectations and environments that nurses from across the United States recognize as necessary for safe nursing practice. The *Bill of Rights* supports nurses in workplace situations and includes issues such as unsafe staffing, mandatory overtime, and health and safety issues in the workplace. These issues are essential to meet the responsibilities of patient care, including safe drug administration and the responsibility nurses have to themselves. (For more information, see http://nursingworld.org/DocumentVault/NursingPractice/FAQs.aspx.) Facilities have an obligation to both nurses and patients to educate and to provide guidelines and policies concerning patient safety in all aspects of patient care. Many disciplines are involved in medication administration, and the different departments must work together to provide a method of drug delivery and administration in a safe environment for the patient and the nurse. This can be done by having modern equipment, staff education opportunities, policies and procedures, and communication among the different departments involved in drug administration.

Culture of Safety

The National Council for Medication Error Reporting (2009) defines medication error as "any preventable event that may cause or lead to inappropriate medication use or harm to a patient."

Much progress has been made since the landmark Institute of Medicine (IOM) report in 1999, *To Err Is Human: Building a Safer Health Care System.* The report served as a basis for creating an awareness of patient safety systems in health care and led to the development of safety tools that have been instrumental in decreasing the number of drug errors. Over the last 15 years, drug administration and the margin of error have shown some improvement with the development of bar coding, CPOE systems, EHRs, and ADCs. However, there is still much work ahead.

The ANA supports the concept of **Just Culture** in its position statement (2010), and it encourages organizations to avoid using punitive approaches in reporting drug errors because they focus on punishing individuals for reporting such errors. In a Just Culture, individuals would be encouraged to report drug errors so the system can be repaired and the problem fixed. A Just Culture does not hold individual practitioners responsible for a failing system, although it does not tolerate disregard for a patient or gross misconduct. (For more information on Just Culture, see http://nursingworld.org/psjustculture.)

In a true culture of safety, everyone in the organization is committed and driven to keep patients safe from harm. Risk management is a process that identifies weaknesses in the system. It then allows changes to be made in order to minimize the effects of adverse patient outcomes. Most organizations have a risk management department staffed with nurse managers and risk managers who conduct **root cause analysis (RCA)**, a method of problem solving used to identify potential workplace errors. Such analysis presents opportunities for learning and focuses on strategies that can be put in place to correct problems.

Drug administration is a vulnerable area where the possibility for error is high. If a patient dies as the result of a drug error, it is called a **sentinel event**, an unanticipated event in a health care setting that results in death or serious harm to a patient unrelated to the natural course of the patient's illness. TJC tracks these events in a database to ensure they are adequately analyzed and that unsafe processes are caught and resolved. The most common occurrence of sentinel events is medication errors, and of those, the most frequently implicated drug was potassium chloride (KCl). Most often, KCl was mistaken for sodium chloride, heparin, or furosemide (See http://www.ismp.org/Tools/jcahosentinelevent.asp).

TABLE 9.1

"Do Not Use" Abbreviations

In 2004, the Joint Commission created a "Do Not Use List" of abbreviations that should be written out to avoid misinterpretation. In 2010, National Patient Safety Goal (NPSG) 02.02.01 was integrated into the Information Management (IM) standards as elements of performance 2 and 3 under IM 02.02.01.

Abbreviation	Preferred
q.d., Q.D.	Write "daily" or "every day."
q.o.d., Q.O.D.	Write "every other day."
U	Write "unit."
IU	Write "International Unit."
MS, MSO_4	Write "morphine sulfate."
$MgSO_4$	Write "magnesium sulfate."
.5 mg	Use a zero before a decimal point when the dose is less than a whole unit (e.g., write *0.5 mg*).
1.0 mg	Do not use a decimal point or zero after a whole number (write *1 mg*).

Visit www.jointcommission.org and www.ismp.org for more detailed safety information concerning "Do Not Use" abbreviations.

The Joint Commission National Patient Safety Goals

Additionally, TJC has taken steps to support safety and quality care in the workplace. In 2004, they first announced their National Patient Safety Goals (NPSGs), which focus on problems in health care safety and how to solve them. The goals are written for a variety of health care settings including ambulatory health care, behavioral health care, critical access hospitals, home care, hospitals, laboratory services, long-term care (Medicare/Medicaid), and office-based surgery. These goals are updated and published annually. Once a goal becomes a standard, the goal number is retired and is not used again, and the standard must be adopted by all Joint Commission–accredited agencies. Two important goals that have already become standards for all TJC-accredited

organizations are the "do not use" abbreviations (Table 9.1) and the list of acceptable abbreviations (Table 9.2; visit TJC's website at http://www.jointcommission.org and the Institute for Safe Medication Practices website at http://www.ismp.org for current detailed safety information).

Another safety feature is the U.S. Food and Drug Administration's (FDA) black-box warning system. When a prescription drug is known to be effective for some patients but may cause serious side effects in others, the FDA will require the drug's printed materials to carry a warning about the adverse effects surrounded by a black box. A black-box warning is the strongest form of warning issued by the FDA about a drug. (For more information on the use of black-box warnings, see https://www.verywell.com/black-box-warnings-1124107 and for specific drug information, see www.fda.gov and insert black-box into the site's search box.)

TABLE 9.2

Acceptable Abbreviations

These abbreviations are frequently used in drug therapy and must be known by the nurse, but also check your facility's list of medical abbreviations. It is now a Joint Commission standard that each facility have a list of acceptable medication abbreviations.

Abbreviation	Meaning
Drug Measurements and Drug Forms	
cap	Capsule
elix	Elixir
ER	Extended Release
g	Gram
gtt	Drops
kg	Kilogram
L	Liter
m^2	Square meter
mcg	Microgram
mEq	Milliequivalent
mg	Milligram
mL	Milliliter
NKA	No known allergies
NKDA	No known drug allergies
oz	Ounce
SR	Sustained release
One-Half tablet	Half-tablet
supp	Suppository
susp	Suspension
Tbsp, tbs, or T	Tablespoon
tsp	Teaspoon

Routes of Medication Administration	
ID	Intradermal
Inj	Injection
IM	Intramuscular
IV	Intravenous
IVPB	Intravenous piggyback
KVO	Keep vein open
PO	By mouth
subQ, subcut, or subcutaneous	Subcutaneous
Subling	Sublingual (under tongue)
TKO	To keep open
vag	Vaginal

Times of Administration	
Prior Usage	**Current Usage**
ã	before
ac	before meals
ad lib	as desired
bid (Twice a day)	bid
c̄	with
hr (hour)	hr or hrs
hs	bedtime
NPO (nothing by mouth)	NPO
pc	after meals
PCA (patient-controlled analgesia)	PCA
per (Through, by [route])	per
prn (As needed)	PRN
q	every or each
qh or q1h	every hr or every 1 hr
qid (Four times daily)	qid
q2h, q4h, etc.	every 2 hrs, every 4 hrs, etc.
s̄ (Without)	without
stat	immediately, at once
tid (Three times a day)	tid

Please visit www.jointcommission.org and www.ismp.org for more detailed safety information concerning “Acceptable Abbreviations.”

Drug Reconciliation

Drug reconciliation is an important component of the culture of safety. It is defined as the process of identifying the most accurate list of all medications that the patient is taking at transitions in care, which includes admissions and discharges from a hospital to another health care setting such as long-term care. Correct drug reconciliation is important because it prevents discrepancies that can cause a drug error. One in five patients experience an adverse event transitioning from hospital to home (see https://www.jointcommission.org/sentinel_event_alert_issue_35_using_medication_reconciliation_t

Drug reconciliation was created to provide drug continuity during care transitions, thereby promoting patient safety. For this reason, the nurse should advise patients to do the following:

- Always carry a list of personal drug information in case of an emergency.
- Update this list of drugs whenever a change occurs.
- Bring a list of medications to each doctor appointment.

The Agency for Healthcare Research and Quality (AHRQ) has published a list of patient tools and resources that can help patients play an active role in their own safety. It can be accessed at http://www.ahrq.gov/professionals/quality-patient-safety/patient-safety-resources/index.html.

NPSG 03.06.01 from TJC requires facilities to find out, record, and share information on any drugs patients are taking, and it requires them to compare that list of drugs with a list of any new drugs being given (see http://www.jointcommission.org/assets/1/6/2015_npsg_hap.pdf) and, for patient teaching, (see www.ahrq.gov/consumer/20tips.pdf).

BOX 9.1 Medications Recommended for Disposal by Flushing

Medicine	Active Ingredient
Abstral, tablets (sublingual)	Fentanyl
Actiq, oral transmucosal lozenge	Fentanyl citrate
Avinza, capsules (extended release)	Morphine sulfate
Belbuca, soluble film (buccal)	Buprenorphine hydrochloride
Buprenorphine Hydrochloride, tablets (sublingual)	Buprenorphine hydrochloride
Buprenorphine Hydrochloride; Naloxone Hydrochloride, tablets (sublingual)	Buprenorphine hydrochloride; Naloxone hydrochloride
Butrans, transdermal patch system	Buprenorphine
Daytrana, transdermal patch system	Methylphenidate
Demerol, tablets	Meperidine hydrochloride
Demerol, oral solution	Meperidine hydrochloride
Diastat/Diastat AcuDial, rectal gel	Diazepam
Dilaudid, tablets	Hydromorphone hydrochloride
Dilaudid, oral liquid	Hydromorphone hydrochloride
Dolophine hydrochloride, tablets	Methadone hydrochloride
Duragesic, patch (extended release)	Fentanyl
Embeda, capsules (extended release)	Morphine sulfate; naltrexone hydrochloride
Exalgo, tablets (extended release)	Hydromorphone hydrochloride
Fentora, tablets (buccal)	Fentanyl citrate
Hysingla ER, tablets (extended release)	Hydrocodone bitartrate
Kadian, capsules (extended release)	Morphine sulfate
Methadone hydrochloride, oral solution	Methadone hydrochloride
Methadose, tablets	Methadone hydrochloride
Morphabond, tablets (extended release)	Morphine sulfate
Morphine sulfate, tablets (immediate release)	Morphine sulfate
Morphine sulfate, oral solution	Morphine sulfate
MS Contin, tablets (extended release)	Morphine sulfate
Nucynta ER, tablets (extended release)	Tapentadol
Onsolis, soluble film (buccal)	Fentanyl citrate
Opana, tablets (immediate release)	Oxymorphone hydrochloride
Opana ER, tablets (extended release)	Oxymorphone hydrochloride
Oxecta, tablets (immediate release)	Oxycodone hydrochloride
Oxycodone hydrochloride, capsules	Oxycodone hydrochloride
Oxycodone hydrochloride, oral solution	Oxycodone hydrochloride
Oxycontin, tablets (extended release)	Oxycodone hydrochloride
Percocet, tablets	Acetaminophen; oxycodone hydrochloride
Percodan, tablets	Aspirin; oxycodone hydrochloride
Suboxone, film (sublingual)	Buprenorphine hydrochloride; Naloxone hydrochloride
Targiniq ER, tablets (extended release)	Oxycodone hydrochloride; Naloxone hydrochloride
Xartemis XR, tablets	Oxycodone hydrochloride; Acetaminophen
Xtampza ER, capsules (extended release)	Oxycodone
Xyrem, oral solution	Sodium oxybate
Zohydro ER, capsules (extended release)	Hydrocodone bitartrate
Zubsolv, tablets (sublingual)	Buprenorphine hydrochloride; Naloxone hydrochloride

From U.S. Food and Drug Administration. (n.d.). *Medicines recommended for disposal by flushing: Listed by medicine and active ingredient.* Retrieved from http://www.fda.gov/downloads/drugs/resourcesforyou/consumers/buyingusingmedicinesafely/ensuringsafeuseofmedicine/safed

Disposal of Medications

The FDA and DEA issue guidelines for appropriate disposal of prescription drugs based on the Secure and Responsible Disposal Act issued by Congress in 2010, which encourages both public and

private entities to develop secure, convenient, and responsible methods for collecting and destroying medications and controlled substances. It also recommends a decrease in the amount of controlled substances released into the environment, especially into water and sewage systems.

General guidelines include take-back events, mail-back programs, and collection receptacles. Facilities may contract with an independent or local collection program authorized by the state and the DEA to dispose of medical waste and hazardous materials. The drugs are disposed of in a receptacle that must comply with strict security and record-keeping requirements as established by the FDA and DEA. The waste is then incinerated by the company.

Consumers who do not have DEA-authorized collectors or medicine take-back programs can follow these simple steps:

1. Remove medications from the original packaging and mix them (do not crush tablets or capsules) with an unpalatable substance such as dirt, kitty litter, or used coffee grounds. This method is intended to make medications less attractive to people and animals.
2. Place the mixture in a container such as a sealed plastic bag.
3. Throw the container in the household trash.
4. Scratch out all personal information on the prescription label before disposing of the empty container.

Unless specifically instructed, do not flush drugs down the toilet, where they will pollute the environment and pose a danger to humans and animals. (Exceptions to this rule are listed in Box 9.1.) Nurses and patients can consult a pharmacist with questions related to medication disposal. Pharmacists are always available to answer questions on how to properly dispose of unused medications.

Sharps Safety

U.S. hospital-based health care professionals experience over 384,000 needlestick injuries each year (see http://www.cdc.gov/sharpssafety/index.html). The Occupational Safety and Health Administration (OSHA) Needlestick Safety and Prevention Act (NSPA) of 2000 resulted from the ANA's campaign Safe Needles Save Lives. The NSPA requires that employers implement safer medical devices for their employees, provide a safe and secure workplace environment with educational opportunities, and develop written policies to help prevent sharps injuries.

Twelve years after the NSPA, the University of Virginia's International Healthcare Worker Safety Center, in collaboration with the ANA and many health care colleagues, issued a consensus statement and call to action (2012) to increase awareness of the risk of needlesticks, a hazard health care workers face daily in the line of duty. The consensus statement and call to action provides a framework of the progress made and a look at what is needed in the future to continue to protect health care workers from the risk of needlesticks (see http://www.medicalcenter.virginia.edu/safetycenter/Consensus_statement_sharps_injury_preventio

Safety Risks with Medication Administration

Every year in the United States, 1.5 million preventable drug errors occur. Data support that a hospitalized patient is subject to one medication administration error per day. The majority of medication errors occur in the transcription stage (56%), followed by the nurse administration stage (41%), and finally the doctor prescribing stage (39%).

Examples of risks to safety include the following:

- *Tablet splitting.* In an effort to counteract steeply rising drug costs, some patients are cutting their pills in half. However, this is not recommended by the FDA. The only time tablet splitting is advisable is when it is specified by the pharmacist on the label. Splitting tablets is risky because the patient may not receive an equal distribution of the medication with each dose. Some tablets are not recommended for splitting and are difficult to split. The FDA recommends that a patient get advice directly from the pharmacist to determine whether tablet splitting is appropriate for a particular drug.
- *Buying drugs over the Internet.* Consumers may find it convenient to order drugs over the Internet, but precautions must be taken because drugs sold online may be too old, too strong, or too weak to be effective. Online sources may sell expired medications without the consumer knowing. The FDA suggests drugs obtained from these sites may not be made using safe standards, are unsafe to use with other medications, and may be expired. Patients should look for websites that (1) require a prescription from a health care provider; (2) have a licensed pharmacist to answer questions and a contact person to consult if problems arise; (3) are located in the United States; and (4) are licensed by the state board of pharmacy. Some sites may sell counterfeit drugs.

Counterfeit Drugs

Counterfeit drugs look like the desired drug but may have no active ingredient, the wrong active ingredient, or the wrong amount of active ingredient. Improper packaging and contamination can also be problems. Counterfeit drugs may look remarkably like the real thing! To report suspected counterfeit products, call the FDA Office of Counterfeit Issues at 1-800-551-3989 or email DrugSupplyChainIntegrity@fda.hhs.gov.

TABLE 9.3

Abbreviations for Sustained- or Extended-Release Medications

Abbreviation	Meaning
CD	Controlled delivery
CR	Controlled release
DR	Delayed release
ER	Extended release
IM	Immediate release
LA	Long acting
MR	Modified release
SA	Sustained action (Ambiguous, can also mean short acting)
SR	Sustained release
TR	Timed release
XR	Extended release
XT	Extended release

To reduce the risk of exposure to counterfeit drugs, patients should purchase drugs only from licensed pharmacies. Refer to the National Association of Boards of Pharmacy (NABP) at www.nabp.net for information.

Dosage Forms: To Crush or Not to Crush

Although some drugs can be used crushed, some should not be crushed. Always consult with the pharmacist or, when possible, the health care provider prior to crushing a patient's drug. Also, consult a reliable drug guide to confirm the medication is crushable. Do not crush any extended- or sustained-release drugs because this will change the pharmacokinetic phase of the drug. There is no industry standard for sustained- or extended-release abbreviations, which can cause confusion and drug errors. Table 9.3 includes abbreviations for sustained- and extended-release drugs. For a current complete listing of drugs that should not be crushed, see Do-Not-Crush-List, Institute for Safe Medication Practices at http://www.ismp.org/tools/donotcrush.pdf.

High-Alert Medications

High-alert drugs can cause significant harm to the patient. If a high-alert medication is given in error, it can have a major effect on the patient's organs; this includes cardiac, respiratory, vascular, and neurologic systems. A medication can also affect the sympathetic and parasympathetic nervous systems. Specific high-alert medications as listed by the Institute for Safe Medication Practices (ISMP) include epinephrine, subcutaneous; epoprostenol, IV; insulin; magnesium sulfate injection; methotrexate, nononcologic oral use; opium tincture; oxytocin, IV; nitroprusside sodium for injection; potassium chloride concentrate for injection; potassium phosphate injection; promethazine, IV; and vasopressin, IV or IO. Please note that all forms of insulin, subcutaneous and IV, are considered high-alert medications. For additional classes and categories of high-alert medications, visit the Institute for Safe Medication Practice's website at http://www.ismp.org/. These lists are provided to reduce the risk of errors, but specific strategies can optimize safety when dealing with high-alert drugs:

1. Simplify the storage, preparation, and administration of high-alert drugs.
2. Write policies concerning safe administration.
3. Improve information and education.
4. Limit access to high-alert medications.
5. Use labels and automated alerts.
6. Use redundancies (automated or independent double-checks).
7. Closely monitor the patient's response to the medication (possibly the most important step).

Look-Alike and Sound-Alike Drug Names

Nurses should be aware that certain drug names sound alike and are spelled similarly. Examples of drugs involved in medication errors and recognized as confusing drug names include *Amaryl* (glimepiride) with *Reminyl* (galantamine); *captopril* with *carvedilol*; *Depakote* (valproic acid) with *Depakote ER* (divalproex sodium); *Depo-medrol* with *Solu-medrol* (methyprednisolones); *ephedrine* with *epinephrine*; and *Humalog* mix 75/25 with *Humulin* 70/30 (insulins). The FDA, ISMP, and TJC advocate the use of "tall-man" letters as a safety strategy to reduce confusion between similar-sounding drugs. For example, rispiridone is written as *rispiriDONE,* and ropinirole is written as *rOPINIRole* to call attention to differences in spelling. Tall-man letters should be used for computer listing and storage labeling for look-alike and sound-alike drug names, and this is now standard; the list may be found at https://www.ismp.org/tools/confuseddrugnames.pdf. Nursing students must familiarize themselves with this list.

Other Factors in the Prevention of Medication Errors

Creating a distraction-free environment is critical to safe administration of medications. Data show that interruptions are responsible for 45% of medication errors (https://www.ismp.org/newsletters/acutecare/articles/20081204.asp). To avoid drug errors, many facilities are creating medication safety zones by implementing policies that provide for a medication room or safety area. When a nurse enters this safety zone, he or she is not to be disturbed. The zone offers a quiet atmosphere in which nurses can dispense medications from a Pyxis system and prepare them for administration. The patient's medical record is available to the nurse in the safety zone, which has proper lighting and a design conducive to safe preparation of medications. Overall, the nurse's role is best achieved by the application of the nursing process.

Nursing Process: Patient-Centered Collaborative Care

Medication Safety

Assessment

- Assess the patient's vital signs and perform a head-to-toe physical assessment.
- Assess the patient's current laboratory results such as hematology labs, chemistry panel, and other pertinent labs pertaining to the patient's diagnosis and designated medication profile.
- Assess the patient's history, including current diagnostics and ability of the patient to swallow (for oral medications).
- Assess medication orders for completeness. Know the purpose and the expected effect of medications and interactions, including over-the-counter (OTC) and herbal preparations. Question the primary care provider if the prescription is unclear or seems inappropriate for the client's condition.
- Make a determination using critical thinking skills when applying the assessment data and lab values in regard to whether it is safe to administer the patient's medications. Report to the provider any abnormal findings in regard to any medications along with the medications not administered.
- Refuse to give a medication if you believe it to be unsafe, and notify the patient's provider and nurse manager.

Planning

- Calculate doses accurately, and if necessary, verify dosages with a colleague or pharmacist.
- Measure doses accurately and double-check high-alert medications.
- Avoid distractions during drug preparation.

Nursing Interventions

- Use relevant resources appropriately.
- Calculate doses correctly.
- Avoid skin contamination or inhalation of substances to minimize your own exposure.
- Wash your hands.
- Administer only medications you prepared.
- Identify the patient using two forms of identification.
- Administer medications according to the five-plus-five rights: right patient, right drug, right dose, right time, and right route plus right assessment, right documentation, right evaluation, right to education, and right to refuse.
- Remain with the patient until the medication has been taken.
- Discard needles and syringes in appropriate containers; be alert to sharps safety.
- Use aseptic/sterile technique appropriate for the route of administration.
- Thoroughly document drug administration in the designated format in a timely manner.
- Document a patient's refusal to take a medication, and notify the health care provider.

Patient Teaching

- Counsel patients and families on anticipated effects of medications.

- Counsel patients on side effects and adverse reactions and what to report promptly to a health care provider.
- Advise patients what foods to eat or avoid.
- Advise patients whether to take medications before, with, or after meals to promote optimal absorption.

Evaluation

- Evaluate the patient's response to the medication, recognize side effects, and document and report these appropriately.
- Evaluate the patient's understanding of the expected results from the medication and what to report to the health care provider.
- Evaluate the effectiveness of medications administered to treat the condition for which they were prescribed.
- Omit or delay doses as indicated by the patient's condition, and if not administered, report this to the provider.

Resources for Preventing Errors in Medication Administration

Several resources address medication errors and their prevention:

- The Institute for Safe Medication Practices provides accurate medication safety information. The ISMP also provides knowledge and understanding of the system-based causes of medication errors, based largely on interdisciplinary reviews of thousands of reports to its national Medication Error Reporting Program (MERP) as well as hundreds of visits to health care organizations nationwide.
- The FDA database of medication errors and "near misses" assists all health care personnel to identify, implement, and evaluate strategies to prevent medication errors. It is strongly suggested that health care workers report errors and near misses to the FDA. Reports are confidential.
- When the nurse is unsure about a dosage, potential side effects, expected therapeutic effects, contraindications, or adverse reactions, an external resource—a drug reference book, pharmacist, or an acceptable technology resource (e.g., Micromedex, Epocrates)—should be consulted to determine the correct answer.
- The FDA MedWatch Program, through their official site found at http://www.fda.gov/safety/medwatch/default.htm, provides current information on notifications for drug recalls, counterfeit products, and safety alerts.

Pregnancy Categories and Subsections

In 2015, the FDA replaced the lettered pregnancy categories A, B, C, D, and X on prescription drug labeling. After much research, the FDA decided that the previous lettering did not effectively communicate the risk a drug may have during pregnancy and lactation and in females and males with reproductive potential. It was thought to be overly simplistic and could easily be misinterpreted. The new labeling system provides a broader explanation based on current available information of the benefits and risks medications can have to the mother, the fetus, and the breastfeeding child. The new subsections are listed as Pregnancy (includes Labor and Delivery), Lactation (includes Nursing Mothers), and Females and Males of Reproductive Potential (Fig. 9.5). The Pregnancy subsection provides information relevant to the use of the drug in pregnant women, such as dosing, potential risks to the fetus, information about whether a registry collects and maintains data on how pregnant women are affected when they use the drug, and relevant information to help health care providers make prescribing and counseling decisions. The Lactation subsection provides information about using the drug while breastfeeding, such as the amount of the drug in breast milk and potential effects on the breast-fed child. The Females and Males of Reproductive Potential subsection includes information about pregnancy testing, contraception, and infertility as it relates to the drug. For more information, see http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093

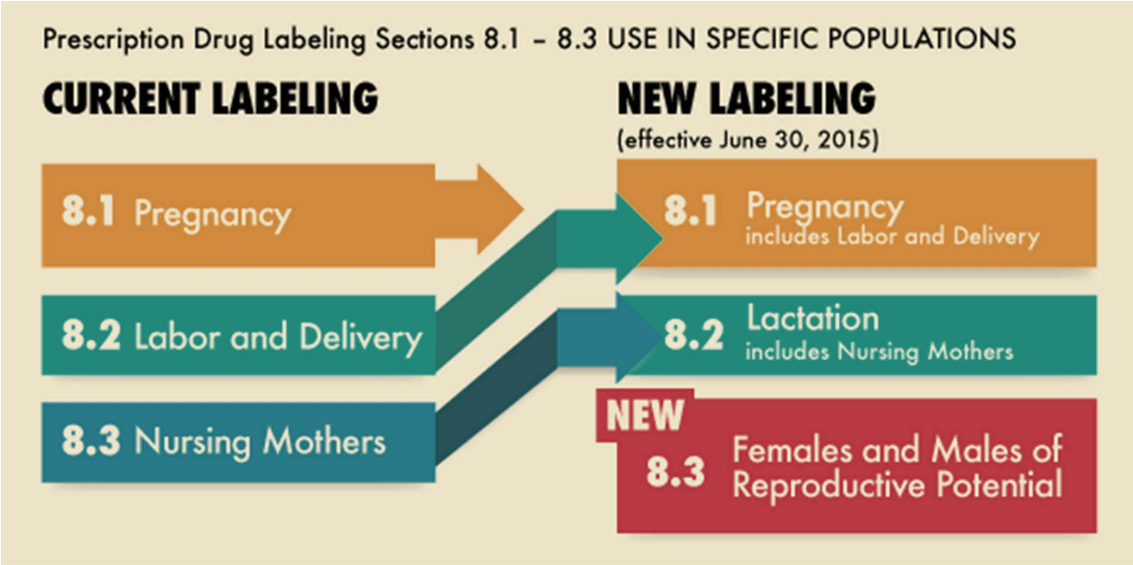

FIG. 9.5 U.S. Food and Drug Administration Pregnancy Categories.

Guidelines for Medication Administration

General guidelines for correct administration of medications are listed in Box 9.2. Nurses should follow these guidelines to enhance safety when administering medications. Application of the nursing process to medication administration is presented in Chapter 8.

BOX 9.2 Guidelines for Correct Administration of Medications

Preparation

1. Perform hand hygiene.
2. Access patient's medication administration record (MAR) via chart or electronic health record (EHR).
3. Check patient medications with the health care provider's order for accuracy.
4. Obtain the patient's medications from Pyxis, remote stock, or pharmacy while checking the medication label with the patient's drug order for accuracy.
5. Check drug allergies.
6. Prepare medications for only one patient at a time.
7. Calculate the medication dose and perform a double check of the calculation.
8. Check the expiration date on the drug label, and use the drug only if the date is current.
9. While preparing the medication, check the drug label against the MAR for accuracy.
10. If a unit dose is prescribed, open the packet at the patient's bedside.
11. If a liquid is prescribed, measure it in a calibrated syringe and put it into a drug cup (see Fig. 10.2).
12. Never leave medications unattended.

Administration

13. Administer only drugs that you have prepared.
14. Identify patients using at least two patient identifiers (e.g., name and birth date). Compare the patient's name and birth date on the MAR, computer printout, or EHR with the information on the patient's identification (ID) bracelet. If possible, ask patients to state their name and birth date.
15. Assist patients into an appropriate position, depending on the route of administration.
16. Compare labels on medications with the MAR prior to administering drugs to a patient.
17. Explain each medication and its action to the patient.
18. For patients who cannot hold medications, place the cup to their lips. Introduce one drug at a time, and do not rush the patient.
19. Stay with the patient until all the medications have been taken.
20. Dispose of used supplies and perform hand hygiene.
21. Evaluate the patient's response to the medications.
22. Educate patients and family members about medication actions and side effects.

Recording

23. Report any drug errors immediately to the patient's health care provider and to the nurse manager; complete an incident report per your facility's policy.
24. Record effectiveness and results of medication administered, especially medications administered as needed (prn).
25. Record drugs that were refused and report these to the patient's health care provider along with the reason given for the refusal.
26. Record the amount of fluid taken with medications on an input and output chart.

Critical Thinking Case Study

Ms. C.J., a patient on the medical-surgical unit, was admitted 2 days before with a diagnosis of exacerbation of heart failure. This morning her blood pressure is 175/80 mm Hg. She denies chest pain but states that she has been experiencing shortness of breath. She tells the nurse she uses three pillows to be able to breathe at night while sleeping. Her baseline weight at admission was 170 lb, but this morning's scale indicates a 4-lb weight gain, and +3 pitting edema to the lower extremities is evident. The nurse telephones the doctor and receives an order for furosemide 40 mg by mouth (PO) twice daily and metoprolol 25 mg PO daily to start immediately.

1. How will the nurse identify Ms. C.J. prior to administering medications?
2. Which labs should the nurse review prior to administering furosemide and metoprolol?
3. What safety measures should the nurse use when obtaining the medications from the Pyxis system and administering the drugs to Ms. C.J.?
4. The nurse scans the medications in the electronic health record (EHR) and medication administration record (MAR) and administers the metoprolol. When she attempts to administer the furosemide, the patient states, "I don't want the water pill." What is the nurse's next action?
5. What important information should the nurse document into Ms. C.J.'s medical record 30 minutes after administering the medications?

NCLEX Study Questions

1. A patient asks about disposal of medications. What are the nurse's best responses? (Select all that apply.)
   a. Mix medications with coffee grounds or cat litter before disposal.
   b. Pour medications down the sink.
   c. Remove identifying information on the original container.
   d. Pulverize all tablets before disposal.
   e. Dilute the medication with bleach before disposal.
2. The nurse educator on the unit receives a list of high-alert drugs. Which strategy is recommended to decrease the risk of errors with these medications? (Select all that apply.)
   a. Store medications alphabetically on an easy-access shelf for quick retrieval.
   b. Limit access to these drugs.
   c. Use special labels for these drugs.
   d. Provide increased information to staff.
   e. Standardize the ordering and preparation of these drugs.
3. The nurse is aware that The Joint Commission has recommended which abbreviation be on the "Do Not Use" list for ordering or documenting medications?
   a. qd
   b. NPO
   c. Subling
   d. bid
4. A patient refuses to take the prescribed medication. Which is the nurse's best response to this patient?
   a. Explain the benefits and side effects of the drug.
   b. Leave the medication at the patient's bedside to be taken later.
   c. Persuade the patient to take the medication.
   d. Explain the risks of not taking the medication.
5. What information is essential for the nurse to know related to right documentation? (Select all that apply.)
   a. The necessity to document all medications given at the end of a shift
   b. The correct site of injectable medication
   c. Patient response to an antiemetic
   d. Patient's blood pressure prior to giving an antihypertensive
   e. Date and time of dose and necessity for the nurse's initials/signature
6. The nurse prepares to administer medications. Which are complete drug orders? (Select all that apply.)
   a. Aspirin 81 mg PO daily
   b. Multivitamin
   c. Vitamin D 2000 units PO
   d. Ciprofloxacin hydrochloride (Cipro) 500 mg PO q12h × 7d
   e. Promethazine 50 mg IV q3-6h PRN for nausea

Answers: 1, a, c; 2, b, c, d, e; 3, a; 4, d; 5, b, c, d, e; 6, a, d, e.

Drug Administration

OUTLINE

Self-Administration of Medication
Forms and Routes of Drug Administration
- Tablets and Capsules
- Liquids
- Transdermals
- Topicals
- Instillations
- Inhalations
- Nasogastric and Gastrostomy Tubes
- Suppositories
- Parenteral Administration of Medications

Nursing Implications for Administration of Parenteral Medications
- Sites
- Equipment
- Technique

Developmental Needs of Pediatric Patients
Technological Advances
- Nursing Process: Patient-Centered Collaborative Care—Overview of Medication Administration

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Identify the different routes of administration.
- Compare and contrast the various sites for parenteral therapy.
- Explain the equipment and technique used in parenteral therapy.
- Explain the Z-track intramuscular injection technique.
- Analyze the nursing interventions related to administration of medications by various routes.
- Apply the nursing process to the administration of medication.

KEY TERMS

buccal, p. 97
inhalation, p. 98
instillations, p. 98

intradermal, p. 101

Administration of medications is a complex but routine nursing activity, and nurses play a significant role in preparing, administering, teaching, and evaluating their patients' responses to the drugs they administer. Whether in an acute care, clinic, restorative, or home setting, nurses work closely with patients and their family members. Patients must receive adequate training to self-administer medications upon discharge, therefore nurses must be knowledgeable about the many aspects of drug administration that include pharmacology, pharmacokinetics, safety practices, and legal aspects of medication administration along with anatomy and physiology and dosage calculations. Nurses must have specific knowledge concerning their patients' diagnoses, allergies, diagnostics, and laboratory results (see Chapter 9).

Self-Administration of Medication

The Institute for Safe Medication Practices (ISMP) website offers a booklet for safe practices in self-medication administration for consumers and the health care professionals responsible for teaching and evaluating consumers. The free booklet is called "Your Medicine: Play It Safe," available at https://www.ismp.org/consumers/safemeds.pdf.

Forms and Routes of Drug Administration

A variety of forms and routes are used for the administration of drugs. These include sublingual, buccal, oral (tablets, capsules, liquids, suspensions, and elixirs), transdermal, topical, instillation (drops and sprays), inhalation, nasogastric and gastrostomy tubes, **suppositories**, and parenteral forms (Fig. 10.1).

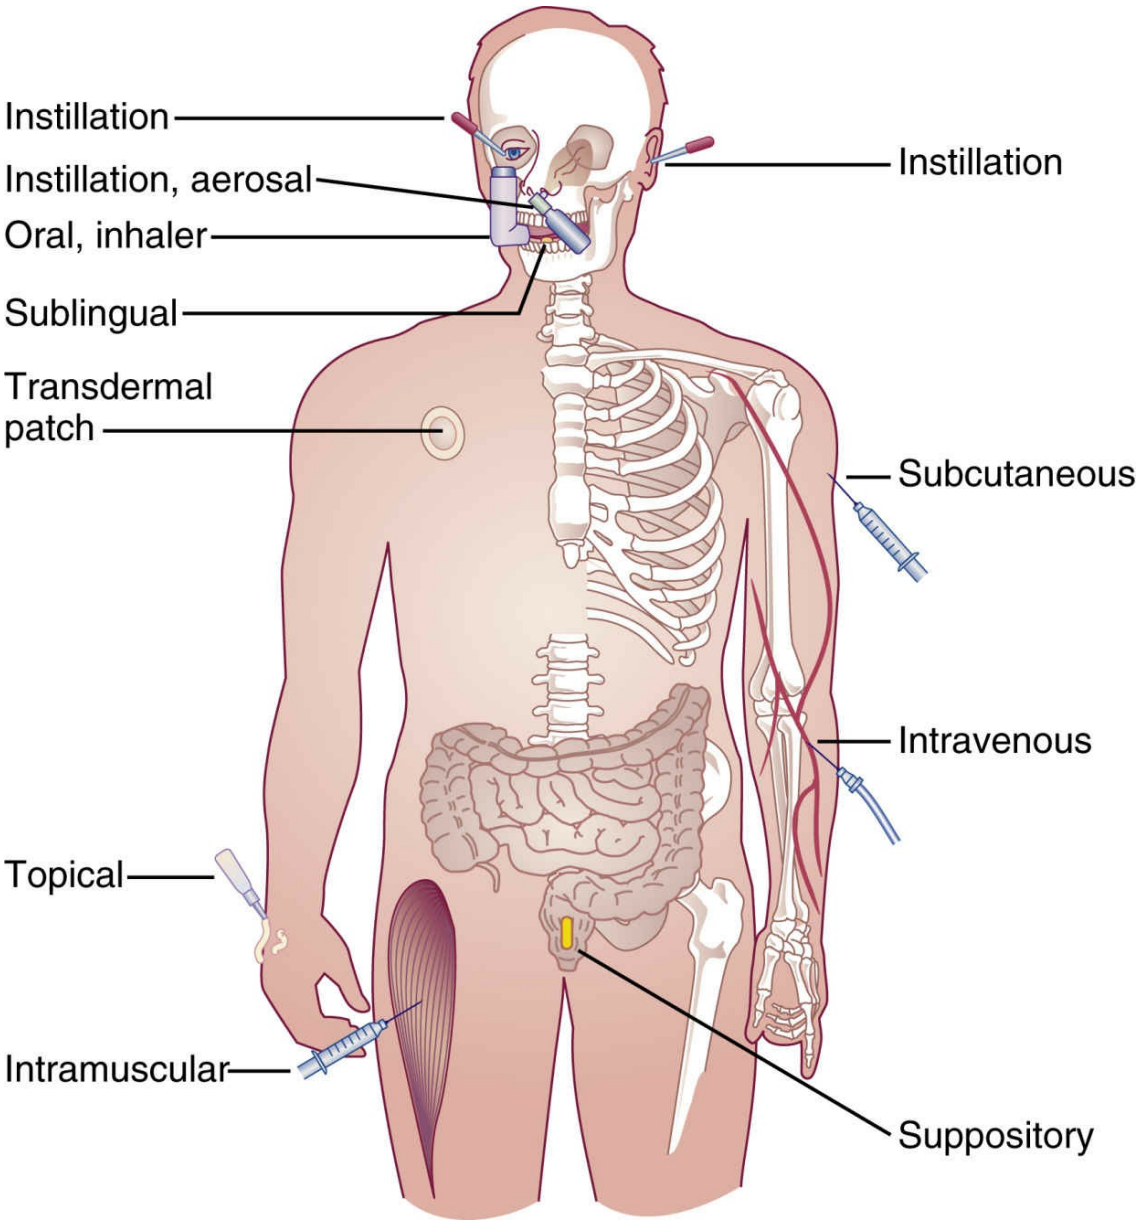

FIG. 10.1 **Routes for Medication Administration.**

Tablets and Capsules

- Tablets and capsules are the most common drug forms; they are convenient and less expensive and do not require additional supplies for administration.
- Oral drugs are not given to patients who are vomiting, who lack a gag reflex, or who are comatose.
- Do not mix a drug with large amounts of foods or beverages. Patients may not be able to consume them and will not get the full dose of medication. Do not mix drugs in infant formula.
- Enteric-coated and timed-release capsules must be swallowed whole to maintain a therapeutic drug level. If crushed, the initial excessive drug release poses a risk of toxicity such that it could lead to a potentially fatal overdose. Crushing can increase the rate of absorption, and it can cause oropharyngeal irritation. To maintain a therapeutic drug level, enteric-coated and timed-release medications must be swallowed whole so the drug is released gradually. These medications should never be cut in half or crushed for administration. Advise the patient or family member to notify the health care provider or pharmacist if the patient is having difficulty swallowing the medication. Instruct the patient to never cut or crush medications unless advised by the health

care provider or pharmacist that cutting or crushing is safe. In acute care settings, the nurse should follow the agency's policy for changing or altering drugs. Most policies indicate to notify the health care provider or pharmacist if the patient is unable to swallow the drug. Many drugs can be given in liquid or intravenous (IV) form or in a non–extended-release form.
- Be aware of medications with "extended release" in the name that should never be cut in half or crushed (e.g., guaifenesin tablets can be changed to liquid form).
- Administer irritating drugs with food to decrease gastrointestinal (GI) discomfort.
- Administer drugs on an empty stomach if food interferes with medication absorption.
- Drugs given via **sublingual** (under the tongue) or **buccal** (between the cheek and gum) routes remain in place until fully absorbed, therefore no food or fluid should be taken while the medication is in place.
- If patients have difficulty opening child-resistant caps, have them request non–child-resistant caps from the pharmacist.

Liquids

- Forms of liquid medication include elixirs, emulsions, and suspensions. *Elixirs* are sweetened, hydroalcoholic liquids used in the preparation of oral liquid medications. *Emulsions* are a mixture of two liquids that are not mutually soluble. *Suspensions* are liquids in which particles are mixed but not dissolved.
- Read the labels to determine whether diluting or shaking is required.
- Make sure your facility has plastic dosing cups that measure in milliliters and not the archaic drams. One dram is equivalent to 3.7 mL. To avoid mix-ups, it is always best to measure the prescribed dose of liquid medication in a syringe calibrated for milliliters (mL) and to then squirt the medication into the oral measuring cup. According to the U.S. Pharmacopeial Convention (USP), a proposed change is required for all facilities to supply dosing cups with legible markings in metric units (Fig. 10.2).

Transdermals

- **Transdermal** medication is stored in a patch placed on the skin and is absorbed through the skin to produce a systemic effect. A patch may be left in place for as little as 12 hours or as long as 7 days depending on the drug. Transdermal drugs provide more consistent blood levels than oral and injectable forms, and they avoid GI absorption problems associated with oral products. To prevent skin breakdown, transdermal patches should be rotated to different sites and should not be reapplied over the exact same area every time. Additionally, the area should be thoroughly cleansed before administration of a new transdermal patch.
- Perform hand hygiene and apply gloves when administering medicated patches to prevent transfer of medication; advise the patient to do the same for self-administration. Never cut the patch in half.
- Advise patients to secure the patch with tape, being careful not to apply the tape too tightly, which could alter the drug delivery.

Topicals

- **Topical** medications are most frequently applied to the skin by painting or spreading the medication over an area and applying a moist dressing or leaving the area exposed to air. Such medications can be applied to the skin in several ways, such as with a glove, tongue blade, or cotton-tipped applicator. Nurses should never apply a topical medication without first protecting their own skin with gloves.

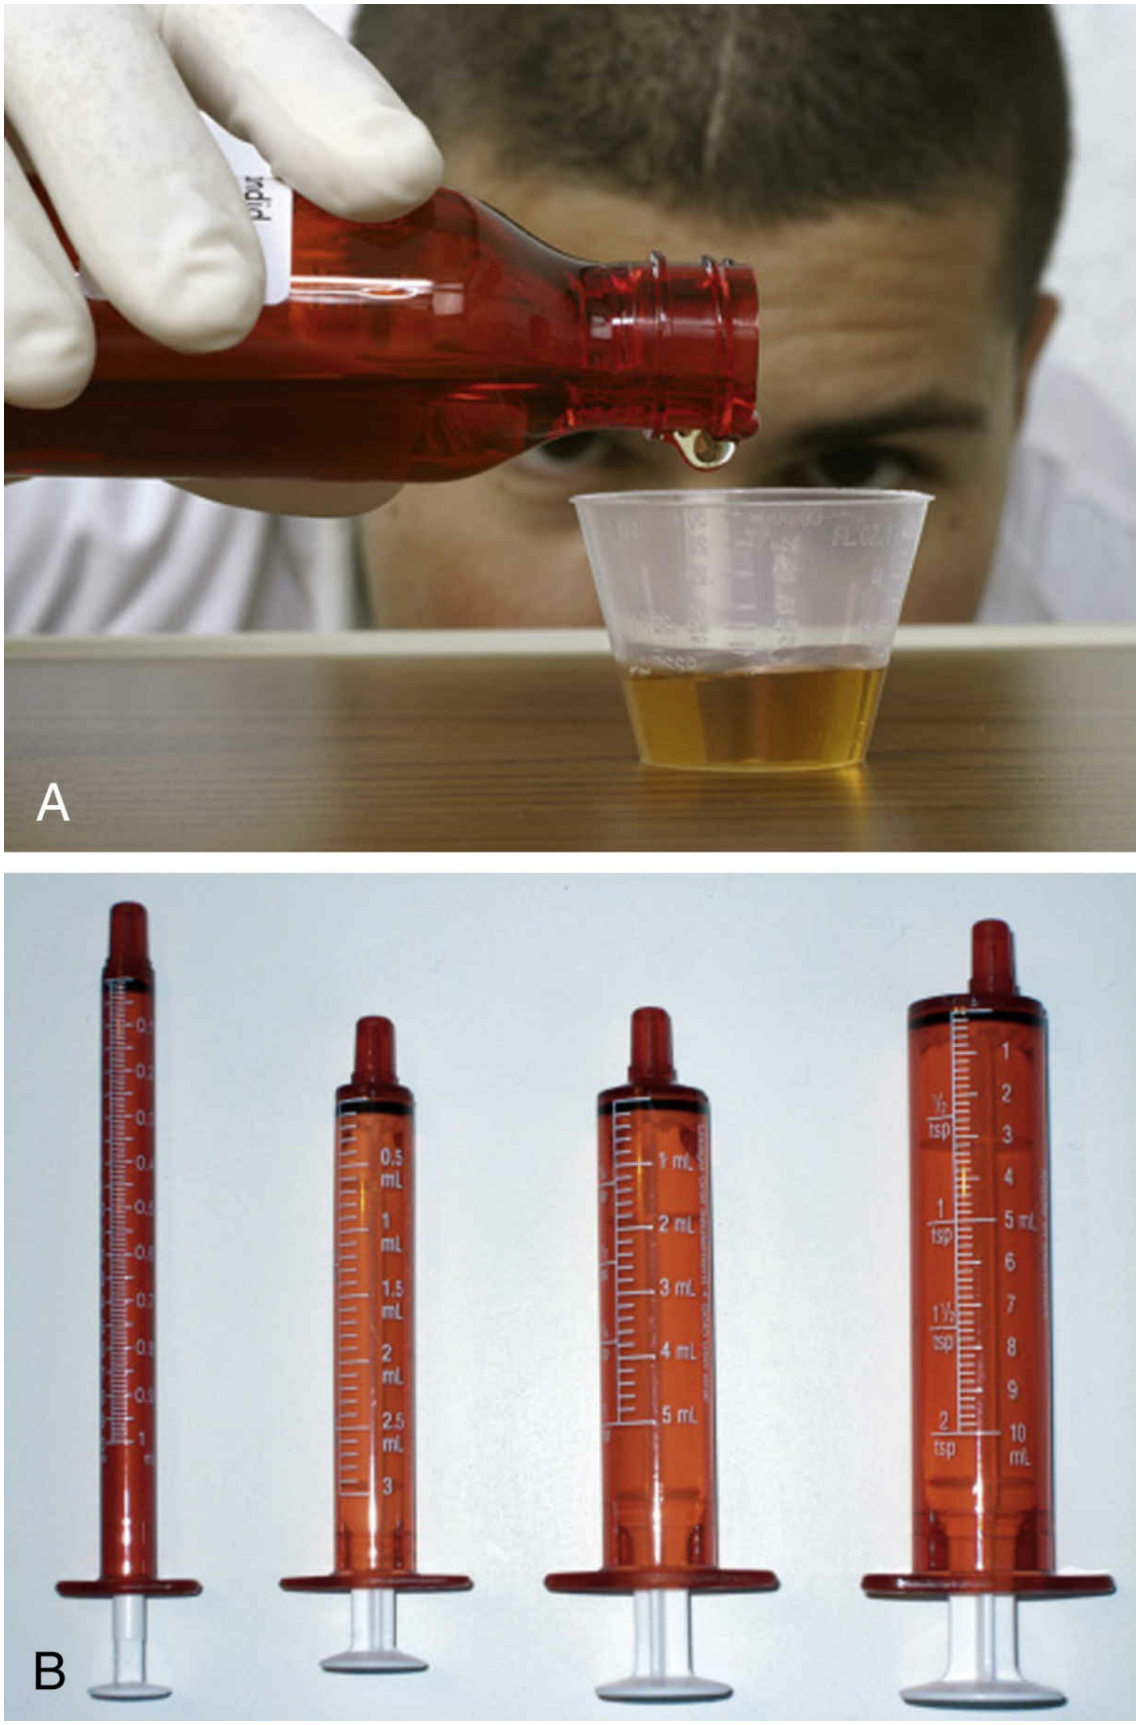

FIG. 10.2 A, Pour desired volume of liquid so base of meniscus is level with mL increment on plastic dosing cup. B, Measure liquid medication in a mL syringe and squirt liquid into dosing cup. From Potter, P. A., et al. (2017). *Fundamentals of nursing* (9th ed.). St. Louis: Elsevier.

- Use the appropriate technique to remove the medication from the container, and apply it to clean, dry skin when possible. Do not contaminate the drug in a container; instead, use gloves or an applicator.
- Gloves and applicators that come in contact with a patient should not be reinserted into the container. Estimate the amount needed and remove it from the container, or use a fresh sterile applicator each time the container is entered.

Instillations

Instillations are liquid medications usually administered as drops, ointments, or sprays in the following forms:

- Eyedrops (Box 10.1 and Fig. 10.3)
- Eye ointments (Box 10.2 and Fig. 10.4)
- Eardrops (Box 10.3 and Fig. 10.5)
- Nose drops and sprays (Box 10.4 and Figs. 10.6 and 10.7)

Inhalations

- **Metered-dose inhalers (MDIs)** are handheld devices used to deliver a number of commonly prescribed asthma and bronchitis drugs to the lower respiratory tract (Box 10.5) via **inhalation**. When the airway becomes constricted, the drug is needed quickly. When properly used, MDIs get up to 12% to 14% of the drug deep into the lungs with each puff. MDIs act faster than drugs taken by mouth, and fewer side effects occur because the drug goes right to the lungs and not to other parts of the body. Some MDIs have a counter to indicate the number of inhalations used. For those that do not, ask the pharmacist the number of inhalations the inhaler will provide, then count the number of inhalations used. Every effort should be made to have the patient know how much medication is in the canister and to anticipate and obtain refills in a timely manner.

BOX 10.1 Administration of Eyedrops

1. Perform hand hygiene and wear gloves.
2. Instruct patients to lie down or sit back in a chair, and have them look at the ceiling.
3. Remove any discharge by gently wiping from the inner to outer canthus. Use a separate cloth for each eye.
4. Gently draw the skin down below the affected eye to expose the conjunctival sac (see Fig. 10.3).
5. Notify patients immediately before drops are administered so they are prepared to avoid blinking when drops hit the conjunctiva.
6. Administer the prescribed number of drops into the center of the sac. If the drug is placed directly on the cornea, it can cause discomfort or damage. Avoid touching eyelids or eyelashes with the dropper.
   a. Gently press on the lacrimal duct with a sterile cotton ball or tissue for 1 to 2 minutes after instillation to prevent systemic absorption through the lacrimal canal.
   b. Instruct patients to keep their eyes closed for 1 to 2 minutes after application to promote absorption.

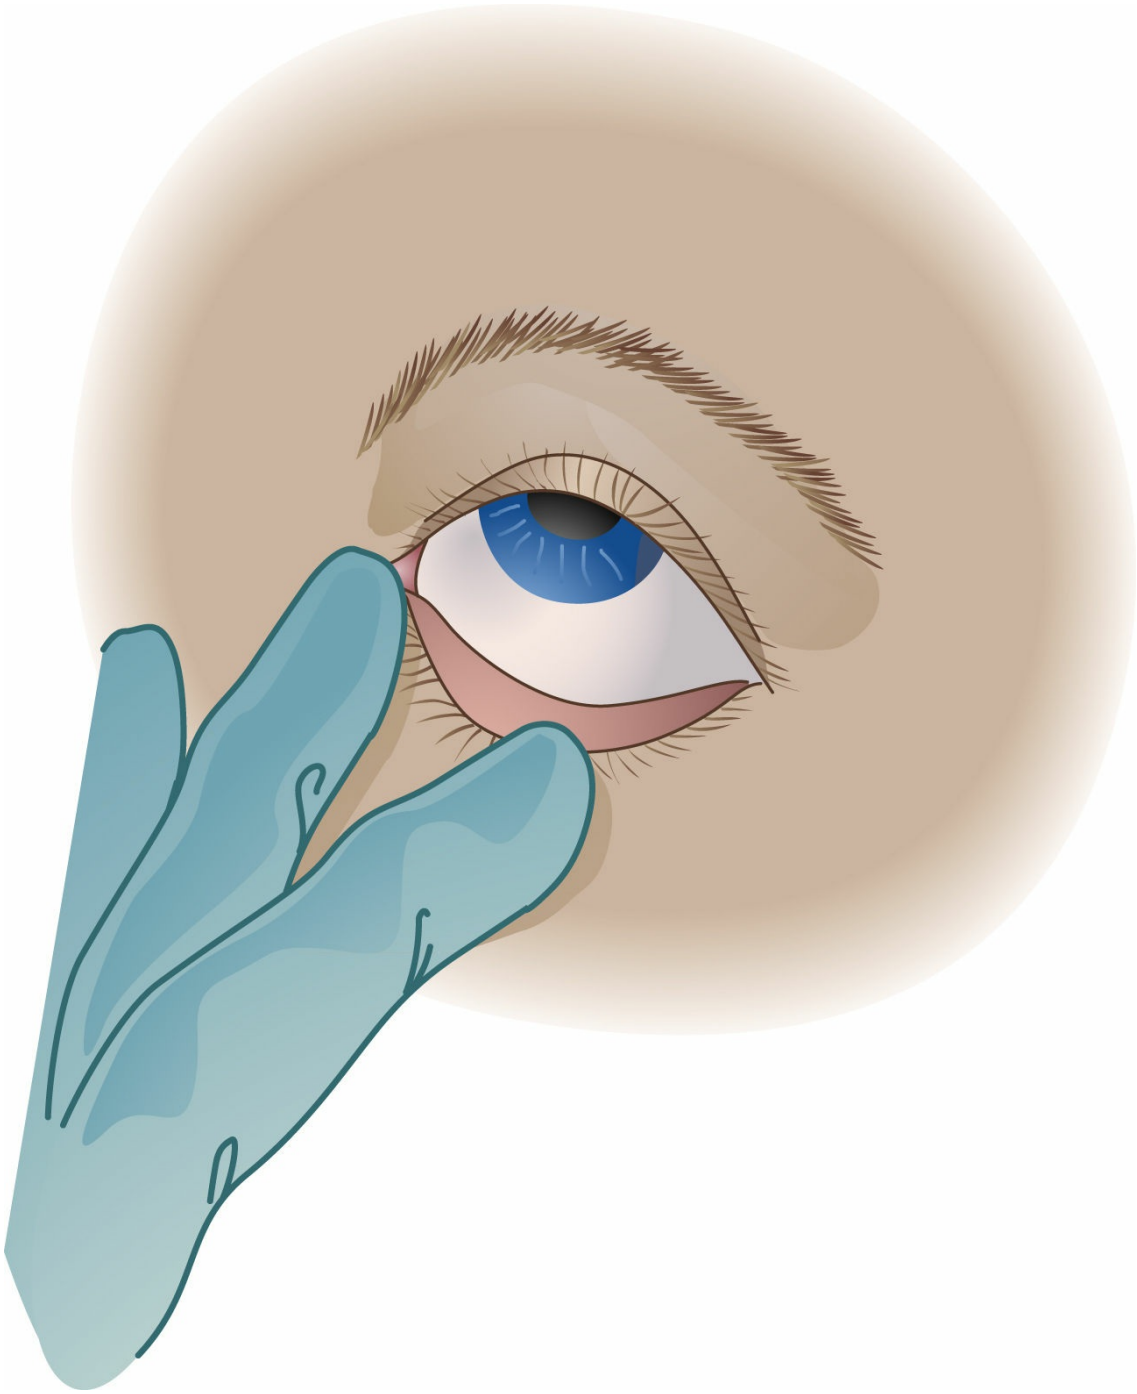

FIG. 10.3 Administering Eyedrops.
Gently pull down on the skin below the eye to expose the conjunctival sac. Apply drops to the middle third of the sac, and apply gentle pressure over the lacrimal duct after administration.

BOX 10.2 Administration of Eye Ointment

1. Perform hand hygiene and wear gloves.
2. Instruct patients to lie down or sit down, and have them look at the ceiling.
3. Remove any discharge by gently wiping outward from the inner canthus. Use a separate cloth for each eye.
4. Gently draw the skin down below the affected eye to expose the conjunctival sac.
5. Prepare patients by explaining that ointment will be placed in the eye so they can help by not

blinking.
6. Squeeze a strip of ointment (about ¼ inch unless stated otherwise) onto the conjunctival sac (see Fig. 10.4). Medication placed directly on the cornea can cause discomfort or damage. Avoid touching eyelids or eyelashes with the applicator tip.
7. Instruct patients to close their eyes for 2 to 3 minutes.
8. Instruct patients to expect blurred vision for a short time. If possible, apply at bedtime.

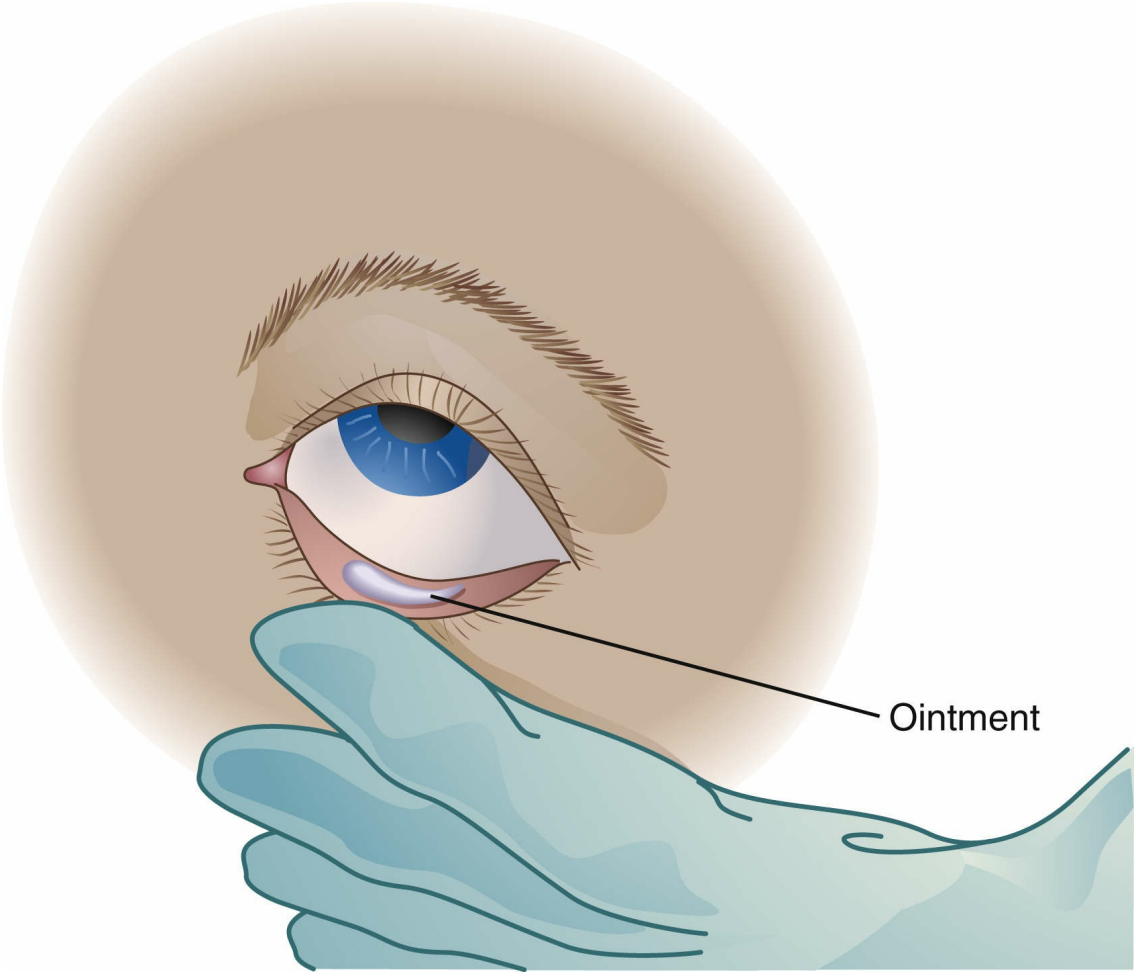

FIG. 10.4 Administering Eye Ointment.
Squeeze a ¼-inch–wide strip of ointment into the conjunctival sac.

BOX 10.3 Administration of Eardrops

1. Perform hand hygiene and wear gloves.
2. Ensure the medication is at room temperature.
3. Instruct patients to sit up with the head tilted slightly toward the unaffected side. This position straightens the external ear canal for better visualization. Maintain this position for 2 to 3 minutes to facilitate drops reaching the affected area (see Fig. 10.5).
4. Pull down and back on the auricle for a child younger than 3 years of age. For a child older than 3 years or an adult, pull upward and outward on the auricle.
5. Instill the prescribed number of drops. Take measures to avoid allowing drops to fall directly on the tympanic membrane. Drops should be aimed at the side of the ear canal and should be allowed to run down into the ear.
6. Do not contaminate the dropper.

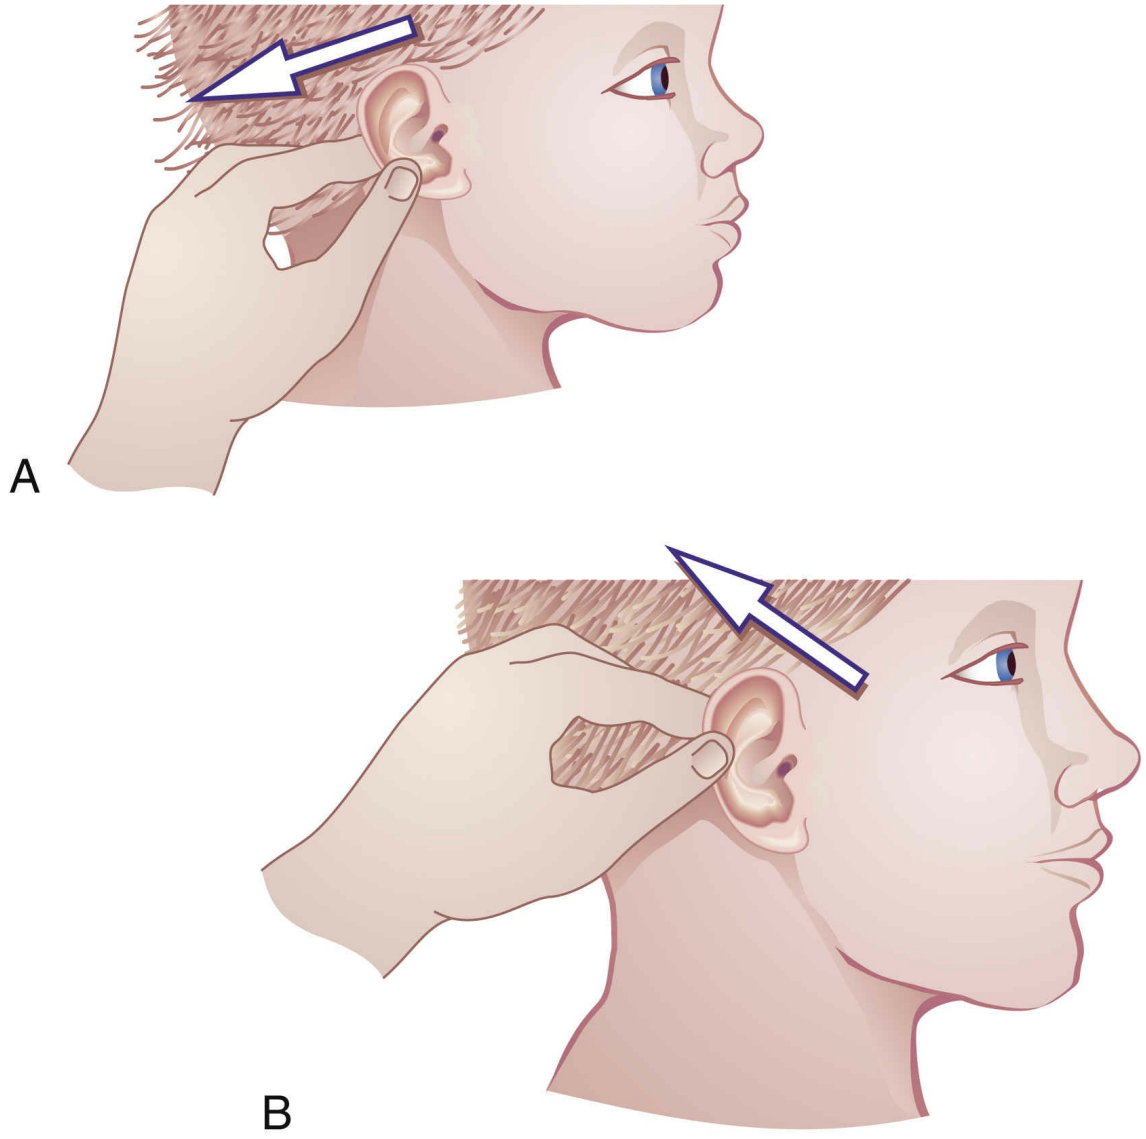

FIG. 10.5 Administering Eardrops.
A, Straighten the external ear canal by pulling the auricle down and back in children under 3 years of age.
B, In patients older than 3 years of age, including adults, pull the auricle upward and outward.

BOX 10.4 Administration of Nose Drops and Sprays

1. Perform hand hygiene and wear gloves.
2. Advise patients to blow their nose.
3. Advise patients to tilt the head back for drops to reach the frontal sinus and to tilt the head to the affected side to reach the ethmoid sinus (see Figs. 10.6 and 10.7).
4. Administer the prescribed number of drops or sprays without touching the tip of the medication applicator to the nasal passages.
5. Some sprays have instructions to close one nostril, tilt the head to the closed side, and hold the breath or breathe through the nose for 1 minute.
6. If a patient is using a nasal spray to reach the sinuses, proper head position is with the patient looking down at the feet with the spray tip aimed toward the eye.
7. Advise the patient to keep the head tilted back for 5 minutes after instillation of drops.

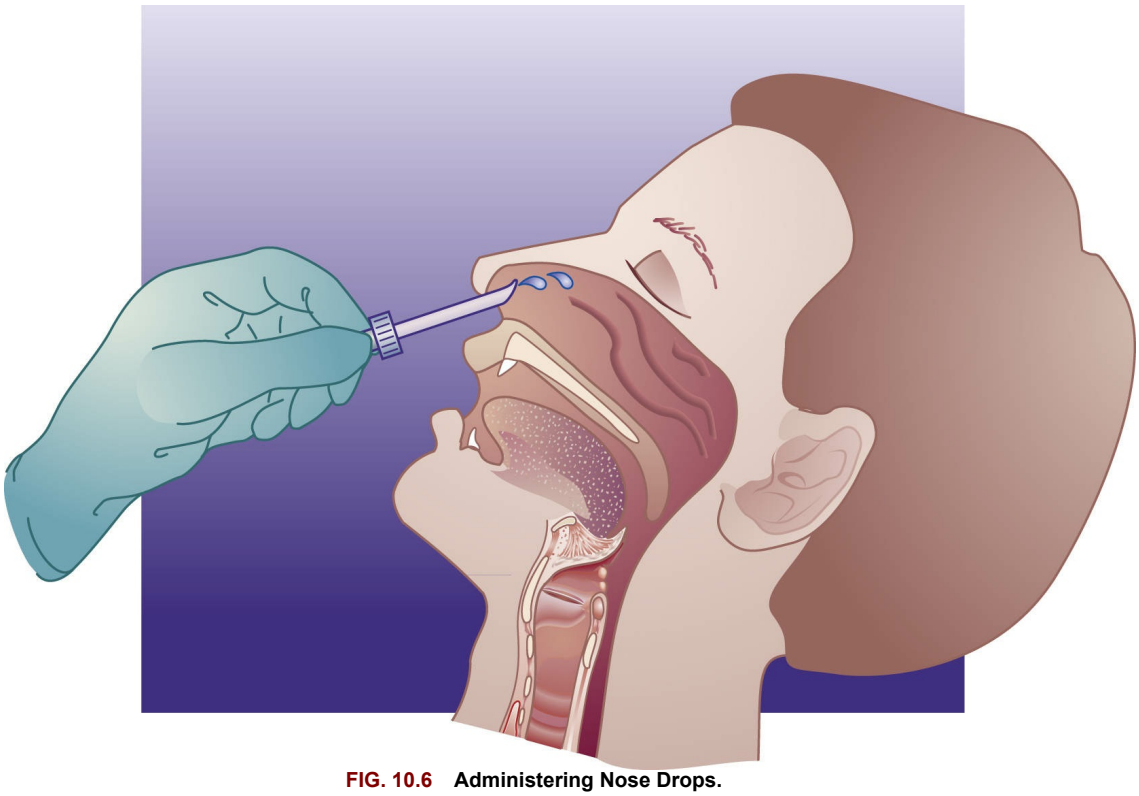

FIG. 10.6 **Administering Nose Drops.**

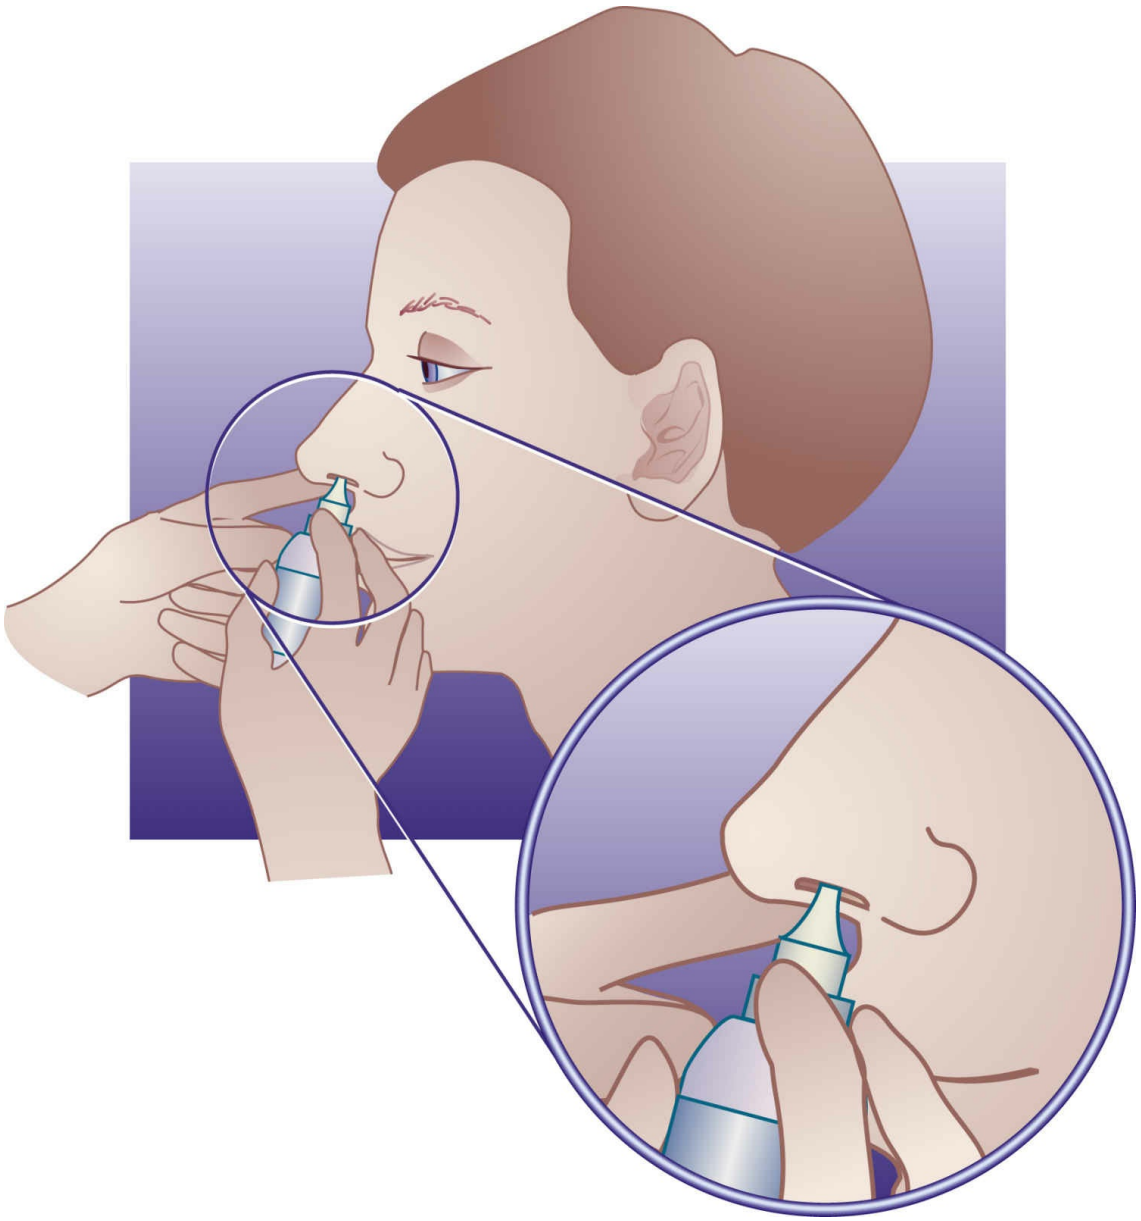

FIG. 10.7 **Administering Nasal Spray.**

- Take special measures when handling the capsules used in some MDIs to prevent the transfer of medication (e.g., powder from a punctured capsule can get on the nurse's hands and transfer to the eyes or absorb into the skin).
- **Spacers** are devices used to enhance the delivery of medications from the MDI (Fig. 10.8). A *nebulizer* is a device that changes a liquid medication into a fine mist or aerosol that has the ability to reach the lower, smaller airways. Handheld nebulizers deliver a very fine particle in a spray of medication.
- When administering drugs via an MDI or nebulizer, the preferred patient position is the semi-Fowler or high Fowler position.
- Instruct the patient on the correct use and cleaning of MDIs or nebulizers.

Nasogastric and Gastrostomy Tubes

- Before administering drugs, always check for proper tube placement of any feeding tube that enters the mouth, nose, or abdomen, and always assess the gastric residual. Return any aspirated gastric fluid to the stomach. (Check the agency's policy for tube placement and residual; see Chapter 14.)

- Place patient in a high Fowler position or elevate the head of bed at least 30 degrees to avoid aspiration.
- Make sure the drug is crushable. If it is a capsule, assess whether it can be opened to be administered through the tube.
- Remove the plunger from the syringe and attach it to the feeding tube, release the clamp, and allow the medication to flow in properly by gravity.
- Ensure proper identification of each drug up until the time of administration. Do this by administering one drug at a time. Flush with 10 to 15 mL of water in between each administration to maintain patency of the tubing.

BOX 10.5 Correct Use of a Metered-Dose Inhaler

1. Explain what a metered dose is, and warn the patient about overuse and side effects of the drug.
2. Explain the steps for administering drug using a squeeze-and-breathe metered-dose inhaler (MDI), and demonstrate the steps when possible. Consult a pharmacist for details if necessary.
3. Insert the medication canister into the plastic holder.
4. If a spacer is used, insert the MDI into the end of the spacer.
5. Shake the inhaler vigorously five or six times before using. Remove the cap from the mouthpiece.
6. Have the patient breathe out through the mouth and exhale.
7. An MDI may be positioned in one of two ways:
   a. With the mouth closed around the MDI with the opening toward the back of the throat
   b. With the device positioned 1 to 2 inches from the mouth
   c. If a spacer is used, the patient closes the mouth around the mouthpiece of the spacer. Avoid covering the small exhalation slots with the lips.
8. With the inhaler properly positioned, have the patient hold the inhaler with the thumb at the mouthpiece and the index finger and middle finger at the top (see Fig. 10.8).
9. Instruct the patient to take a slow, deep breath through the mouth and during inspiration, to push the top of the medication canister once.
10. Have patients hold the breath for 10 seconds then exhale slowly through pursed lips.
11. If a second dose is required, wait 1 to 2 minutes, and repeat the procedure by first shaking the canister in the plastic holder with the cap on.
12. When it is first used or if it has not been used recently, test the inhaler by spraying it into the air before administering the metered dose.
13. If a glucocorticoid inhalant is to be used with a bronchodilator, wait 5 minutes before using an inhaler that contains a steroid.
14. Teach patients to self-monitor their pulse rate.
15. Caution against overuse because side effects and tolerance may result.
16. Teach patients to monitor the amount of medication remaining in the canister. Advise patients to ask a health care provider or pharmacist to estimate when a new inhaler will be needed based on the dosing schedule.
17. Teach patients to rinse their mouth after using an MDI. This is especially important when using a steroid drug. Rinsing the mouth helps to prevent irritation and secondary infection to oral mucosa.
18. Advise patients to avoid smoking.
19. Teach patients to do daily cleaning of equipment; this should include (1) washing the hands; (2) taking apart all the washable parts of the equipment and washing them with warm water; (3) rinsing; (4) placing the parts on a clean towel and covering them with another clean towel to air dry; and (5) storing the parts in a clean plastic bag once completely dry. Alternate two sets of washable equipment to make this process easier.

- When finished with drug administration, flush tubing with 30 mL of water or whichever amount is recommended by the agency's policy. Always record the amount of water used with the administration of drugs on the patient's input sheet.
- Clamp the tube and remove the syringe.
- If the patient has a nasogastric tube to suction, clamp the tube for 30 minutes to allow medication

to be absorbed before placing the patient back on suction.

FIG. 10.8 Metered-Dose Inhaler With a Spacer.
(From Potter, P. A., et al. (2017). *Fundamentals of nursing* (9th ed.). St. Louis: Elsevier.)

Suppositories

A suppository is a solid medical preparation that is cone- or spindle-shaped for insertion into the rectum, globular or egg-shaped for use in the vagina, or pencil-shaped for insertion into the urethra. Suppositories are made from glycerinated gelatin or high-molecular weight polyethylene glycols and are common vehicles for a variety of drugs. A suppository is a useful route in babies, in uncooperative patients, and in cases of vomiting or certain digestive disorders.

Rectal Suppositories

- Medications administered as suppositories or enemas can be given rectally for local and systemic absorption. The numerous small capillaries in the rectal area promote medication absorption.
- The foil around the suppository is removed, and the suppository may be lubricated before insertion.
- During insertion, place the suppository past the internal anal sphincter; otherwise, the suppository will be expelled before it can dissolve and be absorbed into the mucosa.
- Some suppositories tend to soften at room temperature and therefore may be refrigerated before use.
- Explain administration procedures to the patient and provide for patient privacy.

- Use gloves for insertion.
- Instruct the patient to lie in the Sims position and to breathe slowly through the mouth to relax the anal sphincter.
- Apply a small amount of water-soluble lubricant to the tip of the unwrapped suppository, and gently insert the suppository beyond the internal sphincter (Fig. 10.9).
- Ask the patient to remain flat or on one side for at least 30 minutes to prevent expulsion of the suppository.
- Observe for effects of the suppository that correlate with the medication's onset, peak, and duration.

Vaginal Medications

Vaginal drugs are available as suppositories, foams, jellies, or creams. They are individually packaged in foil wrappers and are sometimes stored in the refrigerator to prevent the solid, oval-shaped suppositories from melting. Foams, jellies, creams, and suppositories are generally inserted into the vagina with an applicator supplied with the medication (Fig. 10.10); gloves should be worn, and the patient should be in the lithotomy position. Advise patients to remain lying for a time sufficient to allow medication absorption; times vary depending on the medication. After insertion, provide the patient with a sanitary pad. If the patient is able, she may want to insert vaginal drugs herself.

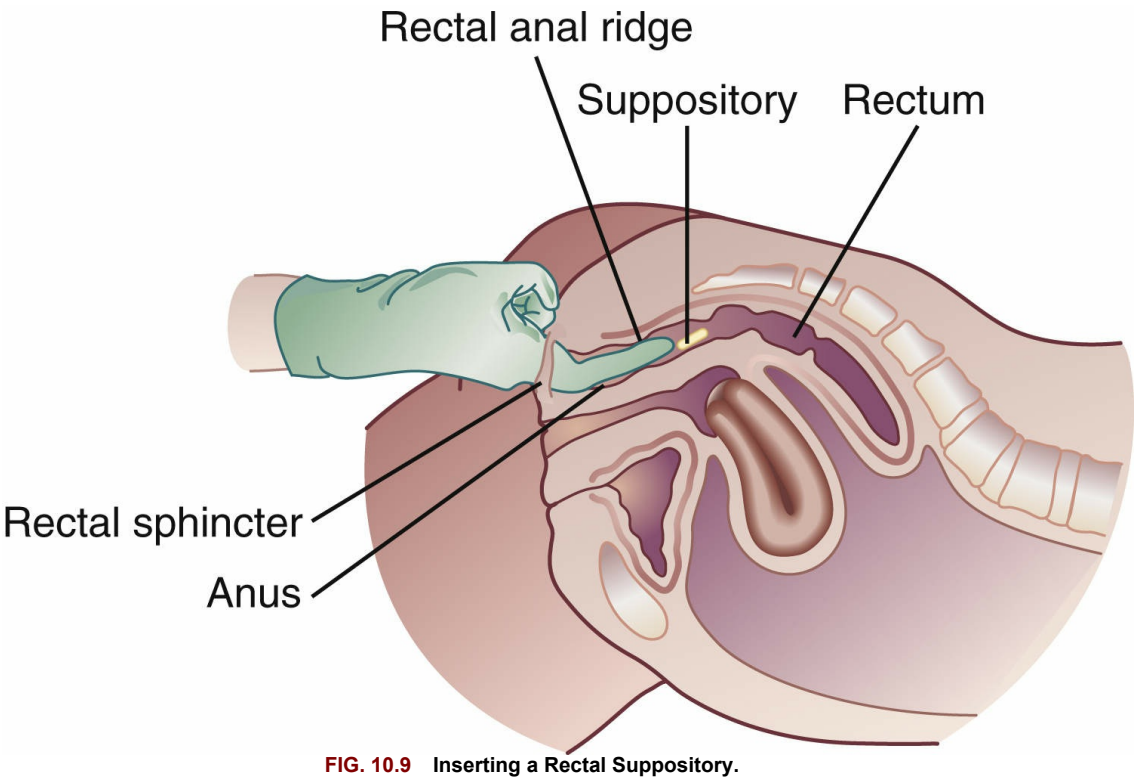

FIG. 10.9 **Inserting a Rectal Suppository.**

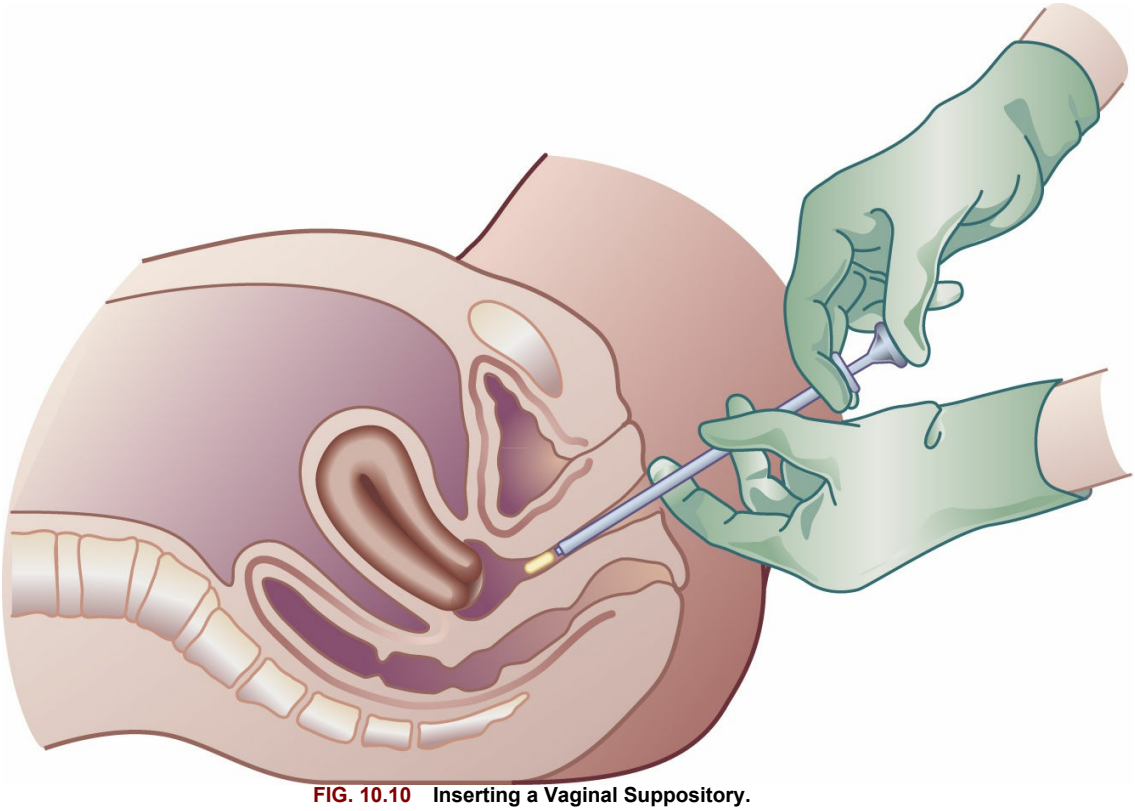

FIG. 10.10 Inserting a Vaginal Suppository.

Parenteral Administration of Medications

Safety is a special concern with **parenteral** drugs, which are administered via injection. Manufacturers have responded with safety features to help decrease or eliminate needlestick injuries and possible transfer of blood-borne diseases such as hepatitis and human immunodeficiency virus (HIV; Fig. 10.11 shows examples of safety needles). Methods of parenteral administration include **intradermal**, **subcutaneous**, **intramuscular**, **Z-track technique**, **intravenous**, and **intraosseous** administration. A description of each follows with special considerations noted for the pediatric patient.

Intradermal (ID)

Action

- Local effect
- Administered for skin testing (e.g., tuberculin screening, allergy testing and testing for other drug sensitivities, some immunotherapy for cancer).

FIG. 10.11 **Safety Needles.**

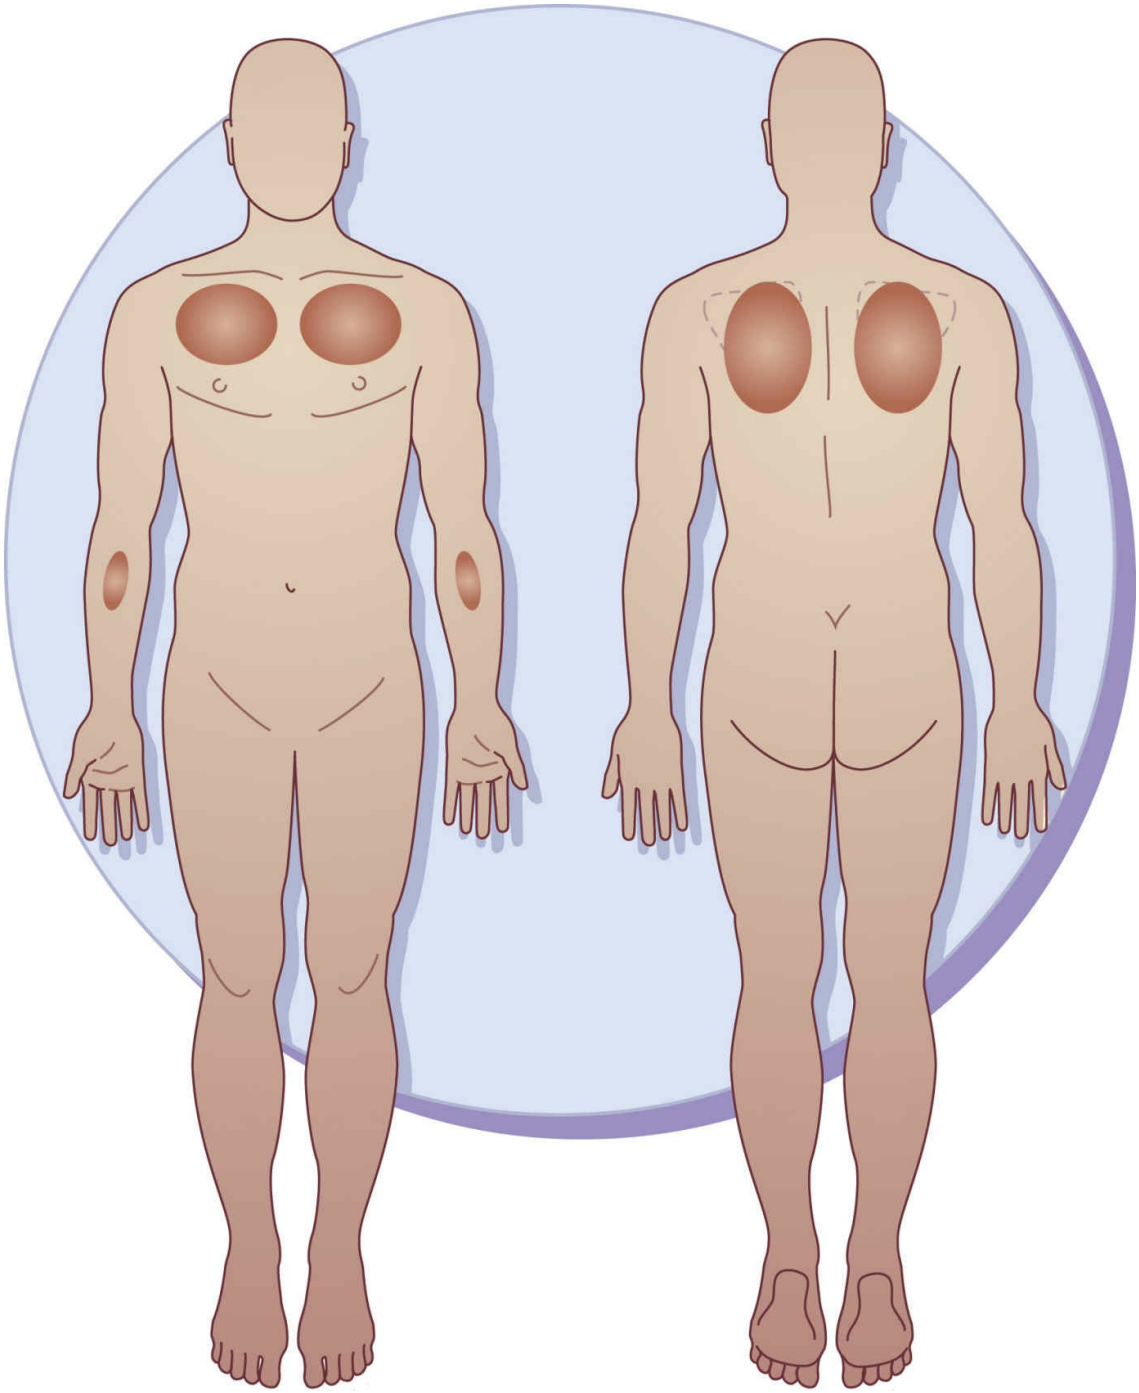

FIG. 10.12 **Common Sites for Intradermal Injection.**

Sites

- Locations are chosen so an inflammatory reaction can be observed. Preferred areas are lightly pigmented, free of lesions, and hairless such as the ventral mid-forearm, clavicular area of the chest, or scapular area of the back (Fig. 10.12).

Equipment

- Needle: 25 to 27 gauge, ¼ to ½ inch long, tuberculin syringe
  Syringe: 1 mL calibrated in increments of (0.01) hundredth mL represented on syringe as 0.1 mL to 1 mL. Syringe holds up to 1 mL of solution; however, tuberculin skin tests require injection of a small amount of solution (usually 0.01 to 0.1 mL) to ensure formation of bleb.

Technique

- Perform hand hygiene and wear gloves.
- Cleanse the area with a circular motion using aseptic technique.
- Hold the skin taut.
- Insert the needle, bevel up, at a 10- to 15-degree angle; the out6115 of the needle should be visible under the skin (Fig. 10.13).
- Inject the medication slowly to form a bleb (or wheal). A small amount is injected so the volume will not interfere with bleb formation or cause a systemic reaction. If the bleb does not appear, the needle has been injected subcutaneously. Document according to facility policy and inform the health care provider. The nurse may need to obtain orders to repeat the procedure.
- Remove the needle slowly, and do not recap it.
- Do *not* massage the area, and also instruct the patient not to do so.
- Mark the area with a pen, and ask the patient not to wash it off until the response can be "read" by a health care provider.
- It is not recommended to put an adhesive bandage over the testing site because it can alter the results of the test.
- Assess for allergic reaction in 24 to 72 hours; measure the diameter of any local reaction. For tuberculin testing, measure only the indurated area; do not include the area of erythema in the measurement.

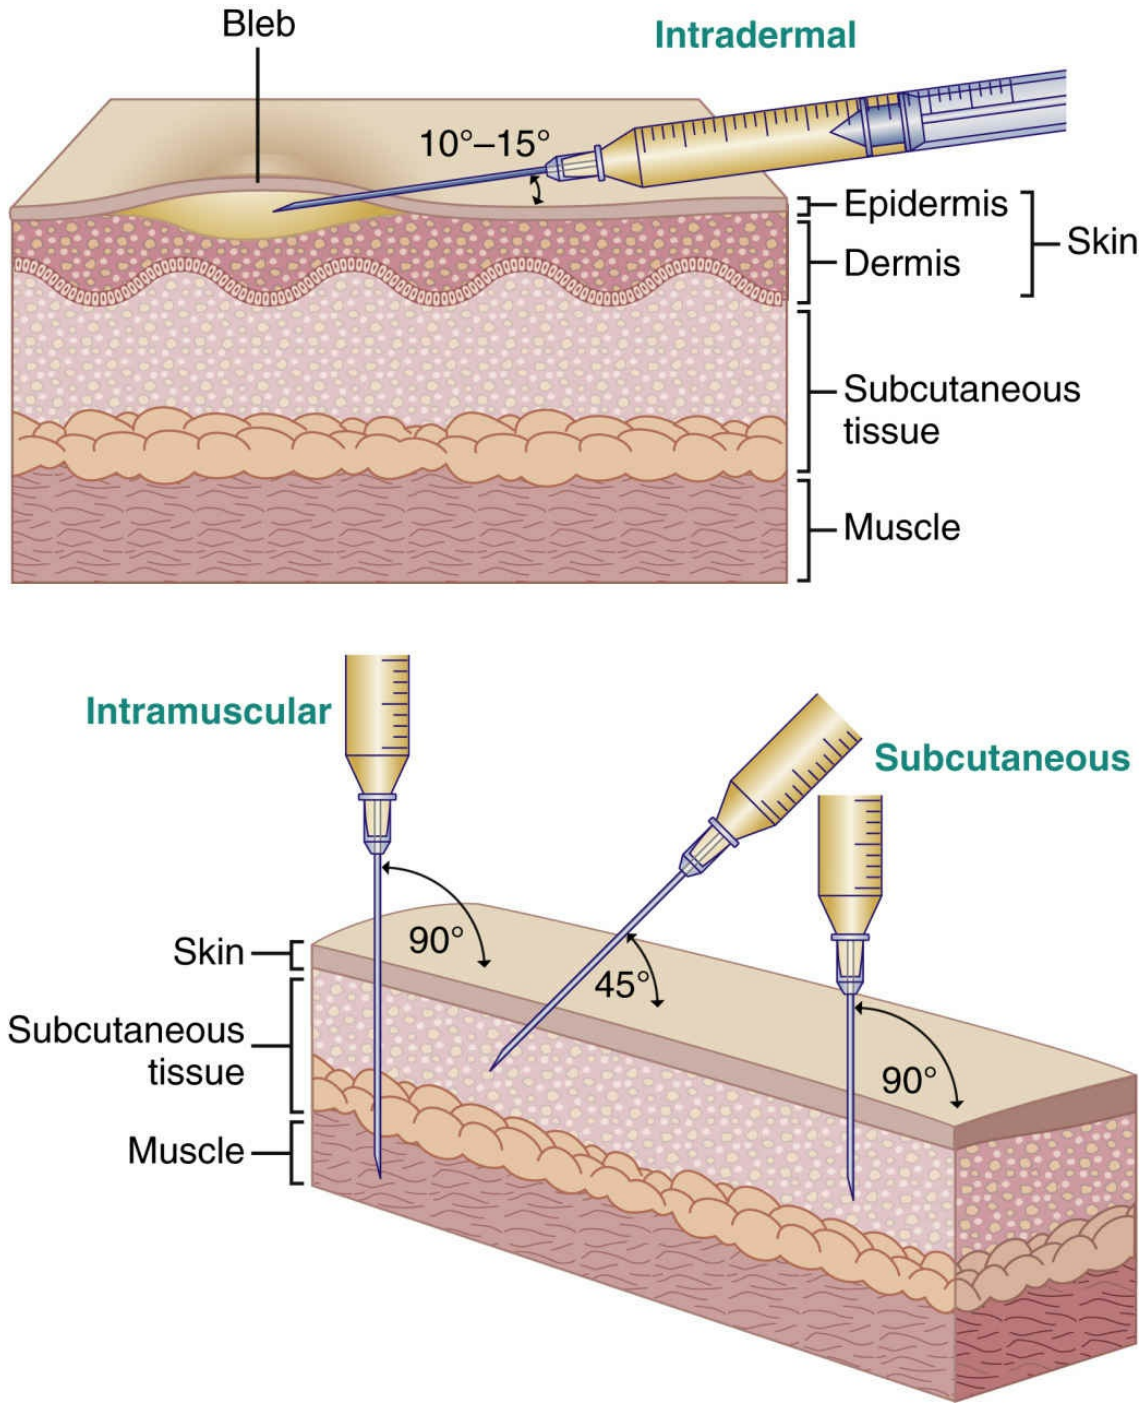

FIG. 10.13 **Needle Angles for Intradermal, Subcutaneous, and Intramuscular Injections.**

Subcutaneous (subcut)

Action

- Systemic effect
- Sustained effect; absorbed mainly through capillaries; usually slower in onset than with the intramuscular (IM) route.

Sites

- Locations for subcut injections are chosen for adequate fat-pad size. Areas such as the upper outer

aspect of the arms; the abdomen, at least 2 inches from the umbilicus, and the anterior thighs are important subcut sites (Fig. 10.14). Sites should be rotated with subcut injections, such as with insulin and heparin.
- Usually, 0.5 to 1 mL of solution is given subcutaneously. A larger amount (2 mL) of medication may have to be divided and administered at two sites. Larger amounts add to the patient's discomfort and predispose to poor absorption. Refer to agency policy for the maximum amount of medication to be administered via this route.

Equipment

- Needle: 25 to 27 gauge; ⅜ to ⅝ inch long
- The length of the needle and the angle of the needle insertion are based on the amount of subcutaneous tissue present. The shorter, ⅜-inch needle should be inserted at a 90-degree angle, and the longer, ⅝-inch needle is inserted at a 45-degree angle (see Fig. 10.13).
- Syringe: 1 to 3 mL (injection of solution is usually 0.5 to 1 mL)
- Insulin syringe measured in units for use with insulin only

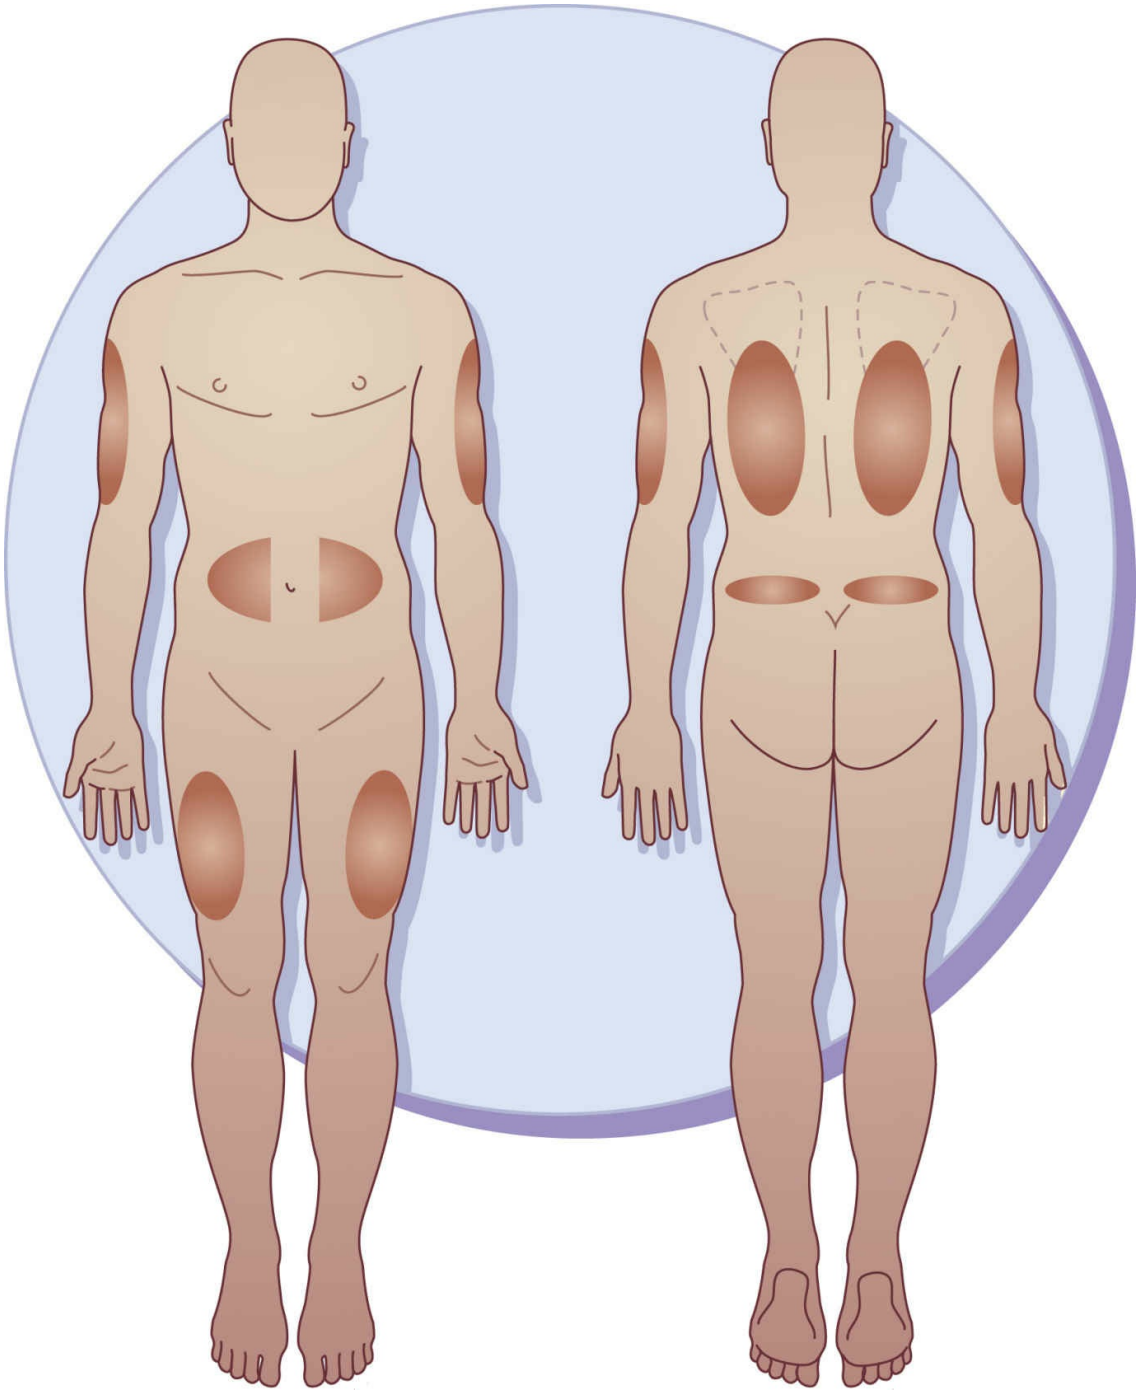

FIG. 10.14 **Common Sites for Subcutaneous Injections.**

Technique

- Perform hand hygiene and wear gloves.
- Cleanse the area with a circular motion using aseptic technique.
- Grasp or gently pinch the area of the patient's loose fatty tissue with the fingers of your nondominant hand.
- Insert the needle quickly.
- Release the pinch and use the hand to stabilize the syringe.
- Do not aspirate.
- Inject the medication slowly.
- Remove the needle quickly; do not recap.

- Apply gentle pressure to the injection site to prevent bleeding or oozing into the tissue with subsequent bruising and tissue damage, especially if the patient is on anticoagulant therapy.
- Apply a bandage if needed.

Intramuscular (IM)

Action

- Systemic effect
- Usually a more rapid effect of drug than with a subcut route
- Used for solutions that are more viscous and irritating for adults, children, and infants
- IM injections are associated with many risks, so the nurse should use accurate, careful technique when administering an IM injection and should check the agency's policy.

Sites

Locations are chosen for adequate muscle size and minimal major nerves and blood vessels in the area. Other considerations include the volume of drug administered, needle size, angle of injection, patient position, site location, and advantages and disadvantages of the site. Underweight patients should be evaluated for sites with adequate muscle.

Equipment

- Needle: 18 to 25 gauge; ⅝ to 1½ inches long. Patient's weight, age, and the amount of adipose tissue influence needle length.

Technique

- Perform hand hygiene and apply gloves.
- Same as for subcut injection with two exceptions: Flatten the skin area using the thumb and index finger and inject between them, and insert the needle at a 90-degree angle into the muscle (see Fig. 10.13).
- Syringe: 1 to 3 mL (usually no more than 1 to 1.5 mL of solution is injected), although this varies based on the intended site, the age of the patient, and the developed muscle site. (Check the agency's policy.)

Preferred Intramuscular Injection Sites

Table 10.1 shows the four sites along with the patient positioning and advantages and disadvantages of each injection site.

- *Ventrogluteal* (Fig. 10.15). Located near the gluteus medius, a deep muscle, and away from major nerves, this site is well suited for Z-track injections. Volume of drug is 1 to 1.5 mL, administered with an 18- to 25-gauge, 1½-inch needle. The gauge and length of the needle depends on the medication to be administered and the size of the patient. Slightly angle the needle toward the iliac crest. The ventrogluteal is the preferred site for most injections given to adults and all children, including infants of any age.
- *Dorsogluteal* (Fig. 10.16). Do not use this site for IM injections. Studies have demonstrated that the exact location of the sciatic nerve varies from person to person, and if a needle hits the sciatic nerve, the client can experience an adverse outcome, including permanent or partial paralysis of the involved leg.
- *Deltoid* (Fig. 10.17). This muscle is easy to find, but it is not well developed in many adults. The volume of drug administered is 0.5 to 1 mL, with a 23- to 25-gauge, ⅝- to 1½-inch needle. Place the needle at a 90-degree angle to the skin or slightly toward the acromion. There is risk for injury because of the nerves and arteries that lie within the upper arm along the humerus. Use this site for small medication volumes or when other sites are inaccessible. This site is not used in infants or children due to underdeveloped muscles.
- *Vastus lateralis* (Fig. 10.18). The vastus lateralis is a good site for multiple injections. It is frequently used in infants (less than 12 months) receiving immunizations and is often used in older children and toddlers receiving immunizations. If a long needle is used, insert it with caution to avoid sciatic nerve or femoral structures. The volume of drug administered is 0.5 mL in infants (maximum [max] 1 mL), 1 mL in pediatric patients, and 1 to 1.5 mL in adults (max 2 mL).

Z-Track Injection Technique

The Z-track injection technique shown in Fig. 10.19 is recommended when administering IM injections to help minimize local skin irritation by sealing the medication in the muscle tissue. The ventrogluteal site is preferred. Using aseptic technique, draw up the medication. Replace the first needle with a second needle of appropriate gauge and length to penetrate the muscle tissue and to deliver the medication to the selected site. Holding the skin taut, inject the needle deep into the muscle, and if there is no blood return on aspiration, slowly inject the medication. Allow the needle to remain inserted for 10 seconds for the medication to disperse evenly rather than channeling back up the track of the needle.

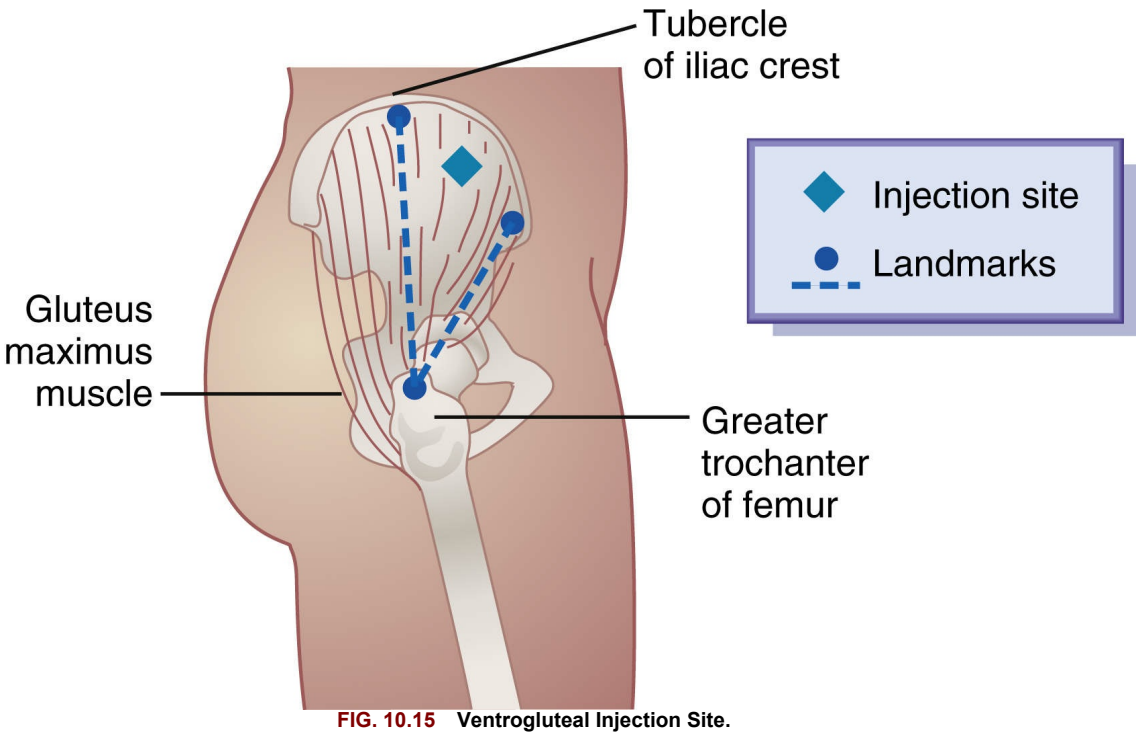

FIG. 10.15 **Ventrogluteal Injection Site.**

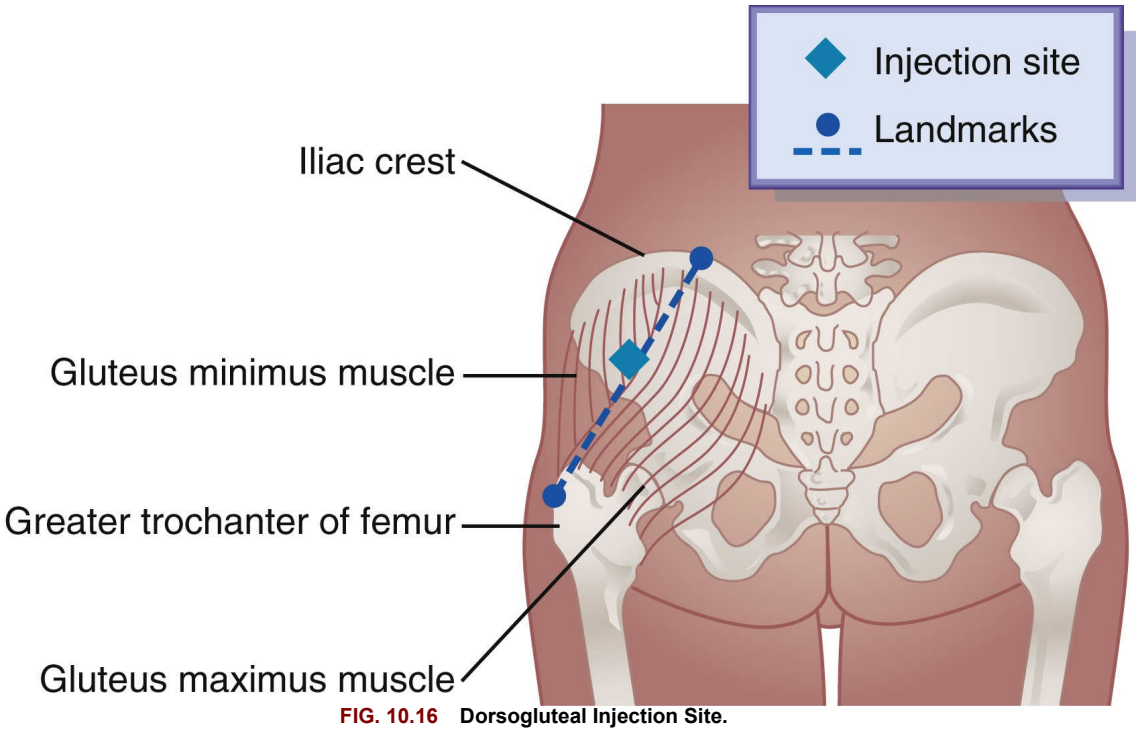

FIG. 10.16 **Dorsogluteal Injection Site.**
This site is no longer used.

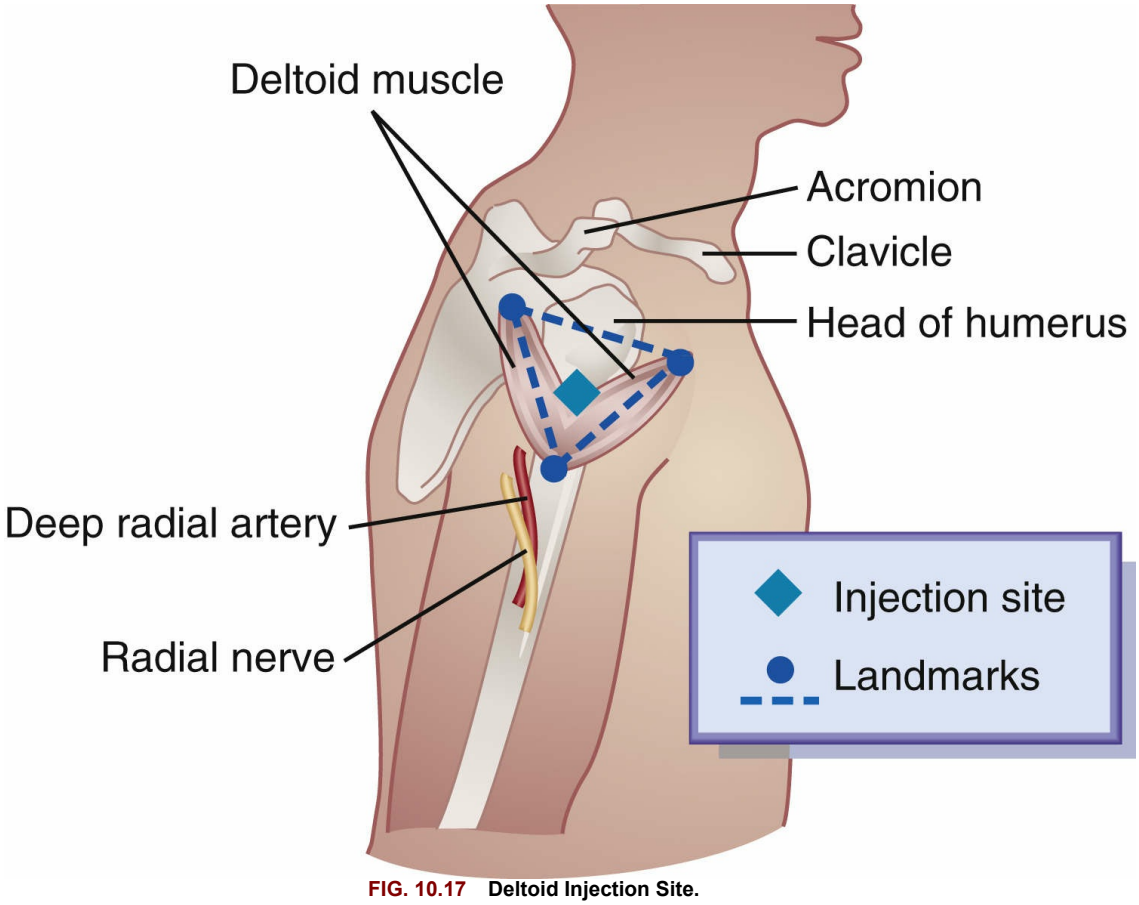

FIG. 10.17 **Deltoid Injection Site.**

TABLE 10.1

Intramuscular Injection Sites: Patient Position, Advantages, and Disadvantages

Site	Patient Position	Anatomic Landmark
Ventrogluteal	Supine, lateral	Locate the ventrogluteal muscle by placing the heel of the hand over the greater trochanter of the patient's hip with the wrists perpendicular to the femur. Use the right hand for the patient's left hip and the left hand for the right hip. Point the thumb toward the patient's groin, the index finger toward the anterior superior iliac spine, and extend the middle finger back along the iliac crest toward the buttock. The index finger, the middle finger, and the iliac crest form a V-shaped triangle; the injection site is the center of the triangle (see Fig. 10.15). The ventrogluteal is the preferred site for most injections given to adults and all children, including infants of any age.
Dorsogluteal	Prone	This site is no longer used because it is detrimental to the patient.
Deltoid	Lateral, prone, sitting, supine	Palpate the lower edge of the patient's acromion process, which forms the base of a triangle in line with the midpoint of the lateral aspect of the upper arm. The injection site is in the center of the triangle, about 1 to 2 inches below the acromion process. Or locate the site by placing four fingers across the deltoid muscle with the top finger along the acromion process. The injection site is then three fingerwidths below the acromion process (see Fig. 10.17).
Vastus lateralis	Sitting, supine Flex knee to help relax muscle if supine	Located on the anterior lateral aspect of the thigh, it extends in an adult from a handbreadth above the knee to a handbreath below the greater trochanter of the femur. Use the middle third of the muscle for injection. With young children or cachectic patients, it helps to grasp the body of the muscle during injection to ensure delivery of the drug into the muscle. Vastus lateralis is frequently used in infants (less than 12 months) receiving immunizations and is often used in older children and toddlers receiving immunizations. (see Fig. 10.18).

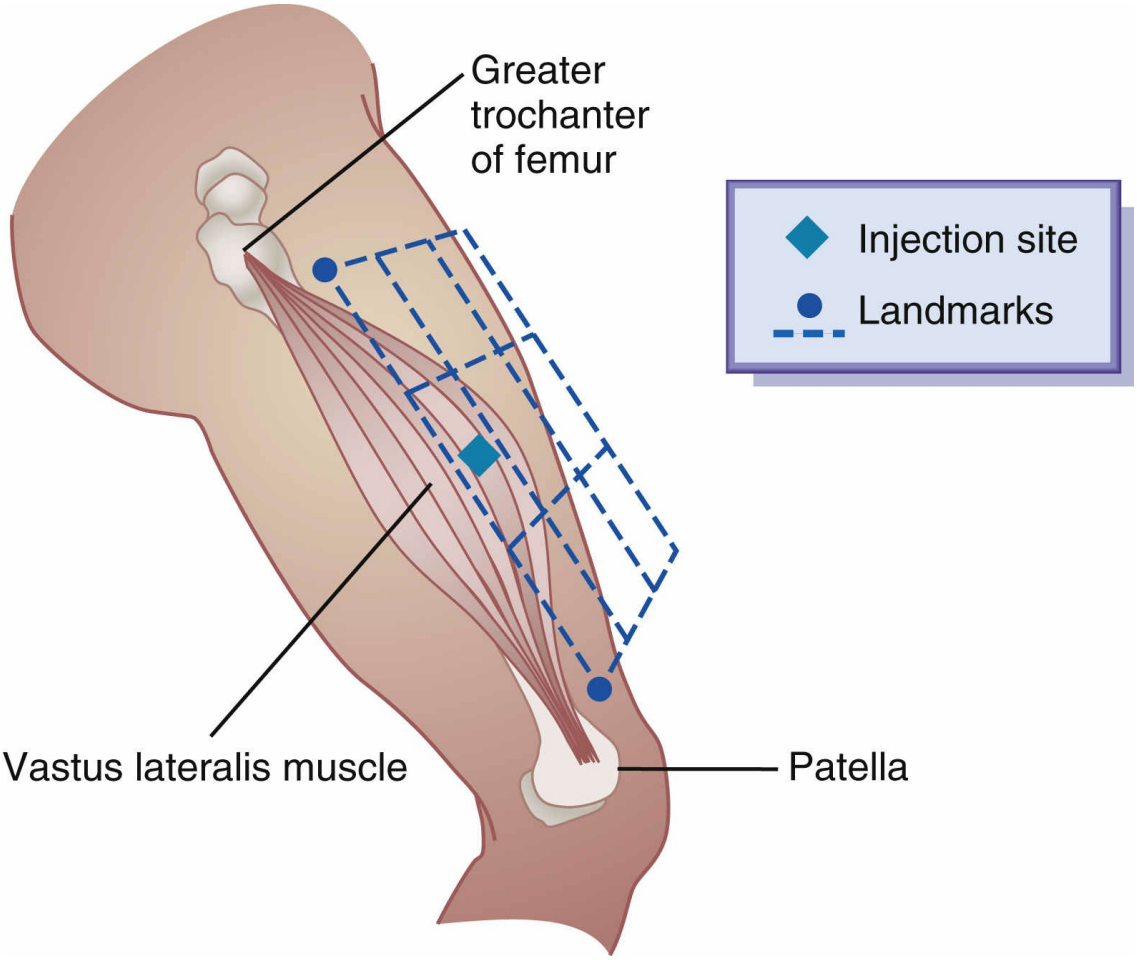

FIG. 10.18 **Vastus Lateralis Injection Site in Children.**

Intravenous (IV)

Action

- Systemic effect
- More rapid than IM or subcut routes

Sites

Accessible peripheral veins are preferred (e.g., cephalic or cubital vein of arm, dorsal vein of hand; Fig. 10.20). When possible, ask the patient about his or her preference, and avoid needless body restriction. In newborns, the veins of the feet, lower legs, and head may also be used after other sites have been exhausted.

Equipment

- Needle
  - Adults: 20 to 21 gauge, 1 to 1½ inches
  - Infants: 24 gauge, 1 inch
  - Children: 22 gauge, 1 inch
  - Larger bore for viscous drugs and whole blood and a large volume for rapid infusion
- Electronic IV delivery device, an infusion controller, or pump
- May use a mixture of lidocaine/prilocaine anesthetic if appropriate

Technique

- Perform hand hygiene and apply gloves.
- Apply a tourniquet.
- Apply anesthetic 1 hour before the procedure on unbroken skin.
- Cleanse the area using aseptic technique with an appropriate solution.
- Insert a butterfly or catheter, and feed it up into the vein until blood returns. Remove the tourniquet.
- Stabilize the needle or IV catheter, and apply dressing to site.
- Flush the catheter with sodium chloride or sterile water to check for site patency.
- Monitor flow rate, distal pulses, skin color and temperature, and insertion site.
- Consult agency policy regarding IV fluids, intermittent IV (IVPB), and direct IV (IV push) drugs. The pharmacy adds medications to the IV bag to avoid error; except in some specialty areas that allow it, nurses should *never* add medications to the bag.

Intraosseous (IO)

The intraosseous (IO) method of drug administration involves the infusion of medication directly into the bone marrow (Fig. 10.21). IO administration is used when IV access is not possible; it is maintained for 24 to 72 hours, after which another means of access is obtained. It is mostly used in infants and toddlers who have poor IV access and in emergency situations when IV access is impossible. Contraindications include fracture in the insertion limb, infection at the insertion site, severe osteoporosis, and other bone abnormalities.

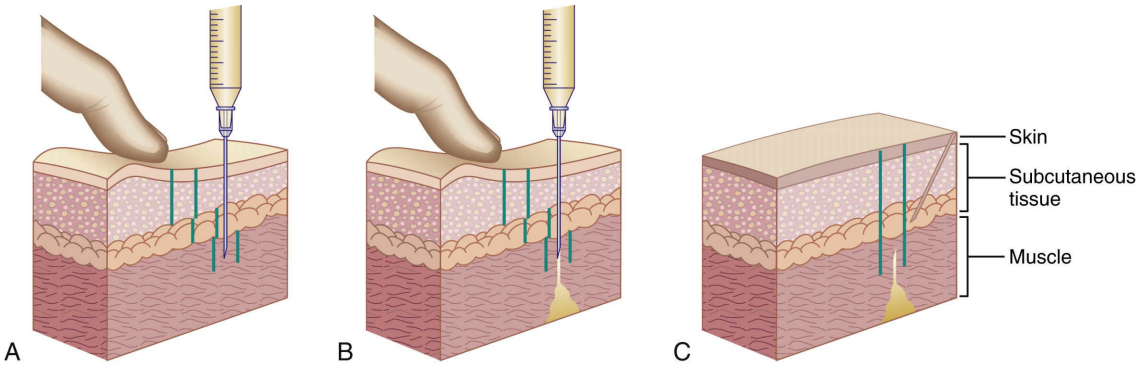

FIG. 10.19 Z-Track Injection.
A, Use a deep muscle, such as in the ventrogluteal injection, and pull skin approximately 1 to 1½ inches laterally to one side, and hold it taut with the nondominant hand. B, Inject the needle deep into the muscle, and if no blood returns on aspiration, slowly inject the medication. C, Wait 10 seconds before withdrawing the needle and releasing the skin. This technique prevents medication entering subcutaneous tissue.

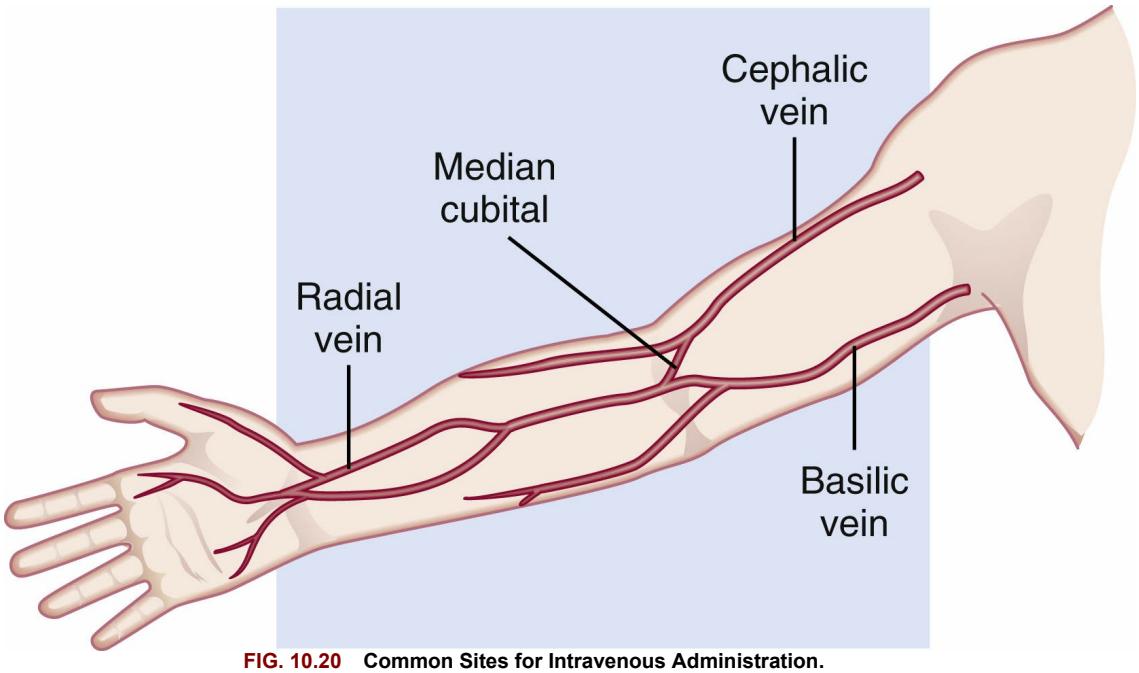

FIG. 10.20 **Common Sites for Intravenous Administration.**

Nursing Implications for Administration of Parenteral Medications

Sites

- The ventrogluteal site is preferred for IM injections in adults and children, including infants of any age, because the gluteal muscle is a deep muscle, situated away from major nerves and blood vessels.
- For infants less than 12 months and toddlers not walking alone, the vastus lateralis is the preferred site for immunizations.
- The dorsogluteal muscle is no longer used for IM injections. Research has shown that if this site is used, the patient can experience serious complications.

Equipment

- The syringe size should approximate the volume of medication to be administered.
- Use the tuberculin syringe for amounts less than 1 mL.
- Use the filter needle to draw up drugs taken from a glass vial or ampule. Change the needle before administration to prevent tissue irritation from any glass fragment or drug left on the needle.

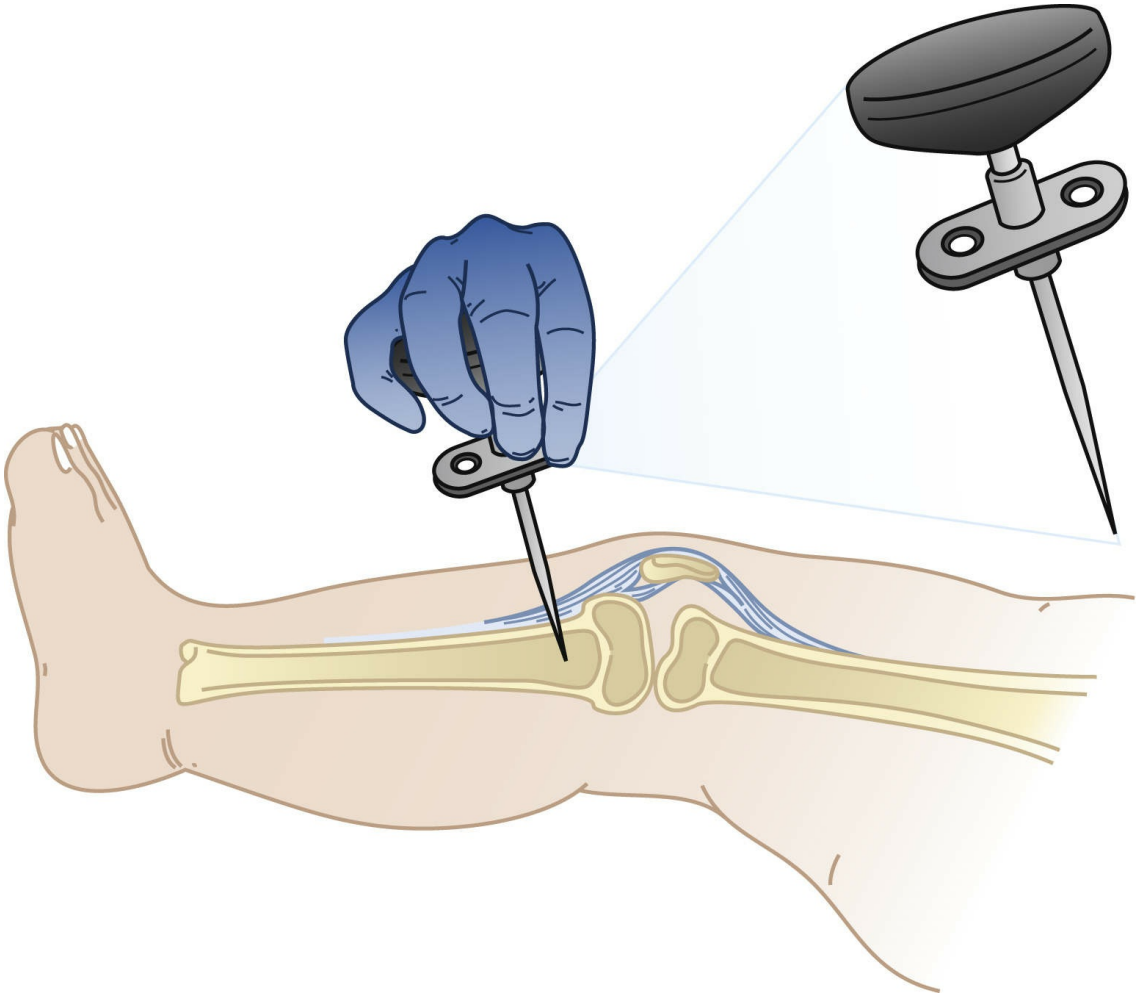

FIG. 10.21 **Intraosseous Access.**

Technique

- Perform hand hygiene and apply gloves.
- Correctly identify the patient.
- Explain the procedure to the patient.
- Position the patient.
- Follow the rights of medication administration (see Chapter 9).
- Inspect the site, choose the correct anatomic markers, and assess skin for breakdown.
- Inject the drug slowly to minimize tissue damage.
- Stabilize the skin during needle removal to reduce pain.
- Do not administer injections if sites are inflamed, edematous, or lesioned (e.g., moles, scars).
- Rotate the injection site to enhance absorption of the drug.
- Document the injection site.
- Observe the patient to evaluate drug effectiveness.
- Report any untoward reactions immediately.
- Multiple products are available to reduce the pain of parenteral drug administration (e.g., lidocaine, prilocaine, and benzocaine/tetracaine).

Developmental Needs of Pediatric Patients

Anticipate patients' developmental needs. Examples of needs associated with administration of medications include the following (refer to Chapter 5 for additional examples):

- Stranger anxiety (infant): Act to instill a sense of safety and security in the infant.
- Hospitalization, illness, or injury viewed as punishment (3 to 6 years of age): Allow control when appropriate; obtain the child's view of the situation; encourage activities, positive relationships, and expression of feelings in an acceptable manner. Include family or support person if appropriate.
- Fear of the procedure (3 to 6 years of age): Explain procedures carefully; use less intrusive routes, such as the oral route, whenever possible; allow children to give "play" injections to a doll or stuffed animal.

Technological Advances

Advances in drug administration therapy continue to enhance safety, increase accessibility to sites, promote patient mobility, and improve patient adherence. Examples of these advances include the following:

- Pain-free delivery of insulin through a transdermal patch
- Insulin pumps that deliver insulin based on monitoring of serum glucose level
- Intelligent infusion technology that programs IV infusions based on scanned information
- Aerosolized antibiotics
- Expanding use of medicinal plants in medicine
- Robotic mixing of antineoplastic drugs

Current technological advances found in many facilities today include computerized order entry and electronic medical records systems, electronic medication administration records, bar code administration records, smart pumps, and point-of-care technologies. These advances have been implemented to help reduce medication errors and improve the delivery of safe and effective patient care.

Nursing Process: Patient-Centered Collaborative Care

Overview of Medication Administration

Assessment

- Obtain appropriate vital signs and relevant laboratory test results for future comparisons and to evaluate therapeutic response.
- Determine the patient's level of consciousness, risk for aspiration, and ability to take medications.
- Obtain a drug history that includes drug allergies.
- Identify patients at high risk for reactions.
- Assess the patient's capability to follow the therapeutic regimen.
- Assess possible contraindications to certain medication regimens.

Nursing Diagnoses

- Injury, Risk for related to possible reaction
- Management, Readiness for Enhanced Learning related to the medication regimen

Planning

- Identify goals.
- Promote therapeutic response and prevent or minimize adverse reactions.
- Identify strategies to promote adherence to the drug regimen.
- Identify interventions that foster patient independence.

Nursing Interventions

- Prepare equipment and environment and perform hand hygiene.
- Check for allergies and other assessment data.
- Check the drug label three times; check the expiration date, and apply the rights of medication administration.
- Be certain of drug calculations; verify the dose with another RN, licensed personnel, or pharmacy as necessary.
- Measure liquids in a milliliter syringe, and squirt the medication into a plastic measuring cup calibrated in milliliters.
- Avoid contact with topical and inhalation preparations by wearing gloves.
- Verify patient by using two patient identifiers.
- Administer only drugs you have prepared.
- Assist the patient into the appropriate position.
- Discard needles and syringes in a sharps container. Do not recap needles.
- Keep all drugs stored properly, especially in regard to temperature, light, and moisture.

- The drug should be identifiable up until the time of patient administration.
- Follow agency policy related to discarding drugs and controlled substances.
- Report drug errors immediately.
- Document all appropriate information in a timely manner.
- Record effectiveness of administered drugs, their side effects or adverse effects, and the reason given when any drug was refused.

Patient Teaching

General

- Emphasize safety.
- Monitor the patient's physical abilities regularly as needed.
- Store medications in original, labeled containers with child-resistant caps when needed.
- Provide patients and family with written instructions about the drug regimen; provide audio instructions if the patient or family are visually impaired or unable to read.
- Advise patients and family about expected therapeutic effects, anticipated onset of action, and expected duration of treatment.
- Educate patients and family on possible side effects or signs of an adverse reaction.
- Instruct patients and family about possible drug–laboratory test interactions.
- Advise patients of nonpharmacologic measures to promote therapeutic response.
- Encourage patients and family to have an adequate supply of necessary medications available.
- Caution against the use of over-the-counter (OTC) preparations, including herbal remedies, without first contacting the health care provider.
- Reinforce the importance of follow-up appointments with a health care provider.
- Encourage patient to wear a medical alert band with drugs or allergies indicated.
- As needed, encourage lifestyle changes associated with drug administration (e.g., smoking cessation, exercise, limiting salt or fat intake).
- Encourage use of community resources to assist with patient and family needs.

Diet

- Advise patients and family about possible drug-food interactions and contraindicated foods, if any.
- Advise patients and family about possible drug-alcohol interactions.

Self-Administration

- Advise patients and family regarding drug dose and dosing schedule.
- Teach patients and family about psychomotor skills related to the drug regimen.
- Provide patients and family with contact information for questions and concerns.

Side Effects

- Counsel patients and family about general side effects and adverse reactions of the medications.
- Teach patients and family to monitor drug effects as appropriate (e.g., check blood pressure if the drug is to treat hypertension).
- Advise patients and family when and how to notify the health care provider.

Cultural Considerations

- Assess personal beliefs of patients and family.
- Modify communications to meet the cultural needs of patients and family.
- Communicate respect for culture and cultural practices of patients and family.

Evaluation

- Evaluate the effectiveness of the drugs administered.
- Identify the expected time frame of the desired response from the drug; consider modification of therapy as needed.
- Determine patient satisfaction with the therapeutic regimen.

Critical Thinking Case Study

Ms. J.B., a diabetic on oral hypoglycemic medication, is being discharged from 24-hour observation care. The health care provider orders regular, subcutaneous (subcut) insulin and syringes. Home health is ordered with instructions for the nurse to provide detailed teaching concerning insulin administration. As the nurse assigned to discharge Ms. J.B., explain the following information included in the discharge teaching about subcut injections:

1. Common subcut injection sites
2. The angle of the needle's insertion
3. How the skin is held prior to inserting the needle
4. Choosing the correct needle gauge for a subcut injection
5. Maximum amounts of solution administered in a subcut site
6. An explanation of what occurs after the needle is inserted
7. The final step after the drug is injected

NCLEX Study Questions

1. The nurse is administering oral medications to a patient. Which are important considerations? (Select all that apply.)
   a. Administer irritating drugs with food.
   b. Avoid mixing medications in infant formula.
   c. Enteric-coated capsules may be chewed or crushed.
   d. Oral medication should be stopped if the patient is vomiting.
   e. Cut all transdermal patches to the correct dose.
2. The clinic nurse is preparing to administer an intradermal injection. Which supplies are most appropriate for this procedure?
   a. A 21-gauge, ⅝-inch needle
   b. A 27-gauge, ⅝-inch needle and a 3-mL syringe
   c. A 25-gauge needle and an insulin syringe
   d. A 25-gauge needle and a tuberculin syringe
3. The nurse is administering an intramuscular injection to a 5-year-old child. Choose the correct site the nurse will use.
   a. Intravenous
   b. Dorsogluteal
   c. Deltoid
   d. Ventrogluteal
4. The nurse administers a variety of drugs to a patient. Which statement by the patient indicates a need for further teaching?
   a. I do not eat or drink when I have sublingual nitroglycerin in place.
   b. I mix all of these meds in my dessert and hope I am not too full to finish it.
   c. I keep the meds in their original labeled containers.
   d. I store medications away from children and pets.
5. The nurse is teaching a patient to use an inhaler. What common teaching point is essential for the nurse to include?
   a. Cleaning the metered-dose inhaler or nebulizer is not recommended.
   b. The semi-Fowler or high Fowler position is recommended.
   c. Spacers decrease delivery of medication.
   d. Nebulizers change medications to a large-particle powder mist.
6. A 3-year-old patient has an intramuscular medication ordered. What is the most appropriate approach to gain the child's cooperation?
   a. Engage the help of a second nurse to hold the child.
   b. Give a pretend injection to a toy animal.
   c. Restrain the patient's upper extremities.
   d. Ask family members to leave the room.
7. The nurse prepares to administer oral medications to a patient. What nursing intervention is needed in addition to the "five-plus-five" rights to ensure safety?
   a. Assess the patient for risk of aspiration.
   b. Mix two of the four medications into the meal.
   c. Administer drugs on a full stomach if food interferes with medication absorption.
   d. Administer irritating drugs without food to decrease gastrointestinal discomfort.
8. A patient is to start on a lidocaine transdermal patch. What is essential for the nurse to include in the patient's teaching? (Select all that apply.)

a. Wear gloves when applying the patch.
b. Cut the patch in half if a reduced dose is needed.
c. Wear gloves when removing the patch.
d. Rotate placement of patch to different sites.
e. Remove the patch if it becomes loose.

Answers: 1, a, b, d; 2, d; 3, d; 4, b; 5, b; 6, b; 7, a; 8, a, c, d.

11

Drug Calculations

Overview

Nurses perform basic mathematical operations on a regular basis when preparing drugs for administration. To accurately calculate drug dosages, a systematic process is used. The same process should be used for every drug calculation so that a step is not missed. Missed steps could lead to errors that may cause serious harm or death to the patient.

This chapter is subdivided into five sections: 11A, Systems of Measurement With Conversion Factors; 11B, Calculation Methods—Enteral and Parenteral Drug Dosages; 11C, Calculating Dosages—Drugs That Require Reconstitution; 11D, Calculation Methods—Insulin Dosages; and 11E, Calculation Methods—Intravenous Flow Rates. Five calculation methods are explained. The three methods generally used are (1) the basic formula, (2) a ratio and proportion/fractional equation, and (3) dimensional analysis. The nurse should select one of these methods for the calculation of drug dosages. The other two methods are used to individualize drug dosing by body weight and body surface area (BSA). Numerous drug labels are used in the drug calculation problems to familiarize the reader with the information on a typical drug label. Answers for the practice problems can be found at the end of each section in this chapter.

To calculate correct dosages, knowing how to convert from one unit to another is essential because this is the basis for most drug calculations. Two systems of measurement, metric and household, are used to measure drugs and solutions. The metric system, also known as the *International System of Units (SI),* is the internationally accepted system of measure, although the household system is commonly used for community and home settings. Chapter 9 lists and discusses currently approved abbreviations used in drug dosages.

Keeping in mind that the goal is to prepare and administer drugs in a safe and correct manner, the following recommendations are offered:

- Think. Focus on each step of the problem. This applies to both simple and difficult problems.
- Read accurately. Pay particular attention to the location of the decimal point and to the operation to be performed, such as conversion from one system of measurement to another.
- Picture the problem.
- Identify an expected range for the answer. The dose should be *reasonable.*
- Seek to understand the problem. Do not merely master the mechanics of the mathematical operations. Seek a second opinion to ensure that the calculation is correct.
- To decrease drug errors, always perform *three checks* prior to administering a drug: (1) when retrieving the drug from a dispensing system, (2) when preparing the drug, and (3) just prior to administering the drug to the patient.

Objectives

- Discuss the metric and household systems of measurement.
- Convert larger units to smaller units and smaller units to larger units within the metric system.
- Convert larger units to smaller units and smaller units to larger units within the household system.
- Convert between metric and household measurements.

OUTLINE

Metric System
- Conversions Within the Metric System
- Practice Problems: Metric System Conversions

Household System
- Conversions Within the Household System
- Practice Problems: Household System Conversions

Metric System

The **metric system** is a decimal system based on the power of 10. The basic units of measure used in dosage calculations include the **gram** (g, gm, G, Gm) for weight, **liter** (L) for volume, and **meter** (m, M) for linear measurement or length. Prefixes such as *nano, micro, milli, centi,* and *kilo* indicate the size of the units in powers of 10 of the base unit and stand for a specific degree of magnitude: for instance, *kilo* stands for thousands, *milli* for one thousandth, and *centi* for one hundredth. To be able to convert a quantity, one of the values must be known, such as a gram (g, G), liter (l, L), meter (m), milligram (mg), milliliter (mL), millimeter (mm), or microgram (mcg). Grams, liters, and meters are larger units, whereas milligrams, milliliters, millimeters, and micrograms are smaller units. Because the conversion between degrees of magnitude always involves multiplying by a power of 10, converting from one magnitude to another is relatively easy.

Conversions Within the Metric System

Common conversions used to calculate drug dosages using the metric system are listed in Table 11A.1.

Grams and milligrams are related by three factors of 10 according to this relationship. In the first illustration below, the larger unit (gram) is converted to the smaller unit (milligram). In the second illustration, the smaller unit is converted to the larger unit.

$$1\text{ g} = 1\text{ mg} \times 10^{3} = 1000\text{ mg}$$

and

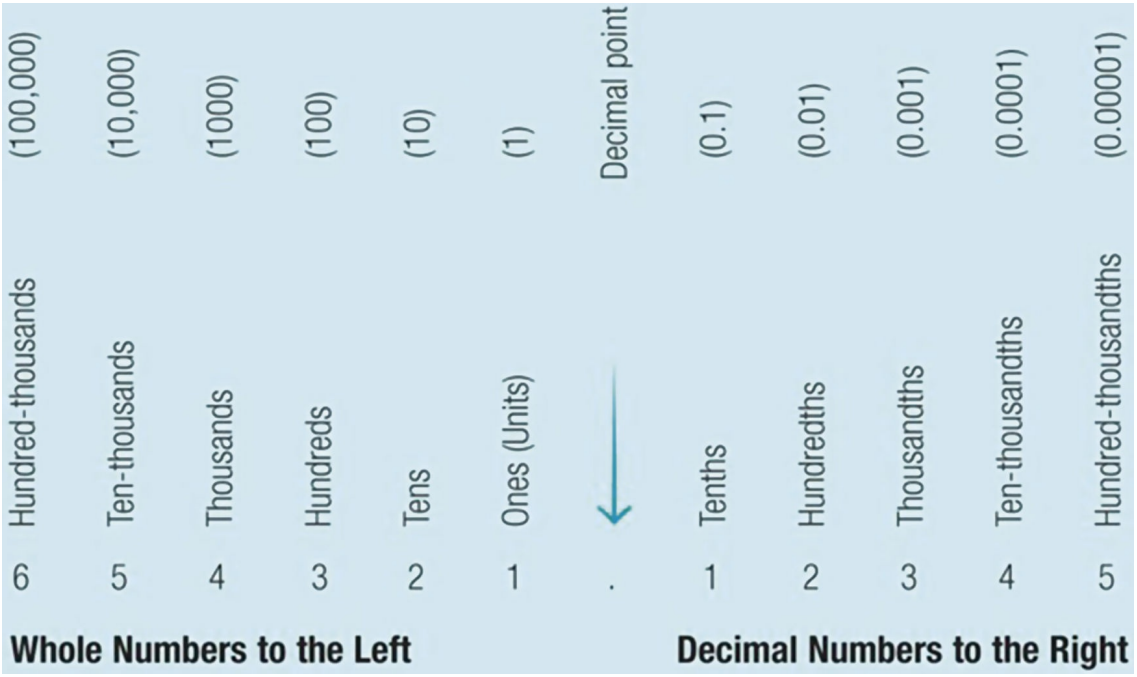
$$1000\text{ mg} = 1\text{ g} \times 10^{-3} = 1\text{ g}$$

The easiest way to convert larger units to smaller units is to move the decimal point the appropriate number of spaces to the *right.* In the illustration below, grams have been converted to milligrams by moving the decimal point three spaces to the right:

$$1\text{ g} = 1.000 = 1000\text{ mg}$$

To convert smaller units to larger units, move the decimal point the appropriate number of spaces to the *left.* In the illustration below, milligrams have been converted to grams by moving the decimal point three spaces to the left (thousandths):

$$1000\text{ mg} = 1.000 = 1\text{ g}$$



Remember: When changing larger units to smaller units, move the decimal point to the *right*; when changing smaller units to larger units, move the decimal point to the *left*. There should always be a zero (0) placed before the decimal point, called a *leading zero,* to alert the reader that the number is less than 1. For example, *0.5* clearly indicates a value of ½. If the number was to be written as *.5,* the reader could mistake the number for *5.* Do not leave extraneous zeroes after a decimal point

(trailing zeroes). The reader may perceive a number that is many times larger than the desired dose. For example, *1.0* could be misread as *10*.

TABLE 11A.1

Metric and English Units of Measurement

Units	Equivalent Units of Measurement		
Weight	1 kilogram (kg, Kg)	=	1000 g = 2.2 lb
	1 gram (g, gm, G, Gm)	=	1000 mg
	1 milligram (mg)	=	1000 mcg
	1 microgram (mcg)	=	1000 ng (nanograms)
Volume	1 liter (L)	=	1000 mL (milliliters)
Length	1 kilometer (km)	=	1000 m
	1 meter (m, M)	=	100 cm
	1 centimeter (cm)	=	10 mm
	2.54 cm	=	1 inch
	25.4 millimeters (mm)	=	1 inch

Practice Problems

Metric System Conversions

Larger to Smaller Units	Smaller to Larger Units
1. Change 2 g to mg	4. Change 1500 mg to g
2. Change 0.5 g to mg	5. Change 3000 mcg to mg
3. Change 2.5 L to mL	6. Change 500 mL to L

Household System

Because of the lack of standardization of spoons, cups, and glasses, **household measurement** is not as accurate as the metric system, therefore measurements are approximate (Table 11A.2). According to the official U.S. Pharmacopeia, a teaspoon (t) is considered to be equivalent to 5 mL in the metric system. Three teaspoons equal 1 tablespoon (T), therefore 1 T equals 15 mL. **Ounces** (oz) are fluid ounces in the household measurement system, and there are 2 T in 1 oz therefore 1 ounce equals 30 mL in the metric system.

TABLE 11A.2

Household Equivalents

1 measuring cup	**=**	**8 oz or 240 mL (1 oz = 30 mL)**
1 medium-size glass (tumbler size)	=	8 oz or 240 mL
1 ounce (oz)	=	2 tablespoons or 30 mL
1 tablespoon (T)	=	3 teaspoons or 15 mL
1 teaspoon (t)	=	60 drops (60 gtt)

Conversions Within the Household System

When converting larger units to smaller units within the household system, multiply the requested number by the basic equivalent value.

Examples

Household System Conversions

Larger Units to Smaller Units

1. Convert 2 T to t.
   The equivalent value of 1 T is 3 t.
   To solve the problem, multiply 2 T with 3 t to get 6 t.
2. Convert 2 T to milliliters (mL).
   The equivalent value of 1 T is 15 mL.
   To solve the problem, multiply 2 T with 15 mL to get 30 mL.
   When converting smaller units to larger units in the household system, divide the requested number of units by the basic equivalent value.

Smaller Units to Larger Units

1. Convert 6 t to T.
   The equivalent value of 3 t is 1 T.
   To solve the problem, divide 6 t by 3 t to get 2 T.
2. Convert 30 mL to T.
   The equivalent value of 15 mL is 1 T.
   To solve the problem, divide 30 mL by 15 mL to get 2 T.

Because household measurements are not as accurate as the metric measurements, instruct patients and caregivers to obtain an approved drug-measuring device to dispense liquid medicine, such as the following:

1/4 tsp
1/2 tsp
3/4 tsp
1 tsp
1 mL
2 mL
3 mL
4 mL
5 mL

Practice Problems

Household System Conversions

Remember: To change larger units to smaller units, *multiply* the requested number of units by the basic equivalent value. To change smaller units to larger units, *divide* the requested number of units by the basic equivalent value.

Larger to Smaller Units	Smaller to Larger Units
1. Change 3 oz to T	4. Change 3 T to oz
2. Change 5 T to t	5. Change 12 t to T
3. Change 2 T to mL	6. Change 45 mL to t

Answers to Practice Problems

Metric System Conversions

Converting From Larger Units to Smaller Units

The gram is three factors of 10 greater than the milligram, so the decimal point is moved three spaces to the right.

1. If 1 g = 1000 mg; then
   2 g = 2 × 10^3= 2000 mg
   or
   2 g = 2000. = 2000 mg
2. If 1 g = 1000 mg; then
   0.5 g = 0.5 × 10^3 = 500 mg
   or
   0.5 g = 0500. = 500 mg
3. If 1 L = 1000 mL; then
   2.5 L = 2.5 × 10^3 = 2500 mL
   or
   2.5 L = 2500. = 2500 mL

Moving From Smaller Units to Larger Units

The milligram is three factors of 10 smaller (less) than the gram, so the decimal point is moved three spaces to the left.

4. If 1000 mg = 1 g; then
   1500 mg = 1500× 10^{-3} = 1.5 g
   or
   1500 mg = 1.500 = 1.5 g
   (Note there are no trailing zeroes [no 00] after the decimal.)
5. If 1000 mcg = 1 mg; then
   3000 mcg = 3000× 10^{-3} = 3 mg
   or
   3000 mcg = 3.000 = 3 mg
   (Note there are no trailing zeroes [no 000] after the decimal.)
6. If 1000 mL = 1 L; then
   500 mL = 500 × 10^{-3} = 0.5 L
   or
   500 mL = 0.500 = 0.5 L
   (Note that a leading zero was placed before the decimal.)

Household System Conversions

Converting From Larger Units to Smaller Units

1. If 1 oz = 2 T, then
   3 oz = 3 × 2 T = 6 T
2. If 1 T = 3 t, then
   5 T = 5 × 3 t = 15 t
3. If 1 T = 15 mL, then
   2 T = 2 × 15 mL = 30 mL

Converting From Smaller Units to Larger Units

4. If 2 T = 1 oz, then
   3 T = 3 ÷ 2 T = 1.5 oz

5. If 3 t = 1 T, then
   12 t = 12 ÷ 3 t = 4 T
6. If 15 mL = 1 T and 1 T = 3 t, then
   15 mL = 3 t; so
   (45 mL ÷ 15 mL) × 3 t = 3 × 3 t = 9 t

SECTION 11B

Calculation Methods—Enteral and Parenteral Drug Dosages

KEY TERMS

basic formula (BF), p. 117
body surface area (BSA), p. 125
body weight (BW), p. 124
controlled substance, p. 114
dimensional analysis (DA), p. 119
drug label, p. 117
fractional equation (FE), p. 118
ratio and proportion (RP), p. 117
square root method, p. 125
trade name, p. 114
units, p. 120

Objectives

- Interpret drug labels.
- Calculate drug dosages using the basic formula, the ratio and proportion/fractional equation method, and the dimensional analysis method.
- Convert all measures to the same system and unit of measure within the system before calculating final drug dosages.
- Calculate drug dosages according to body weight.
- Calculate drug dosages according the body surface area using the West nomogram.
- Calculate drug dosages according the body surface area using the square root method.

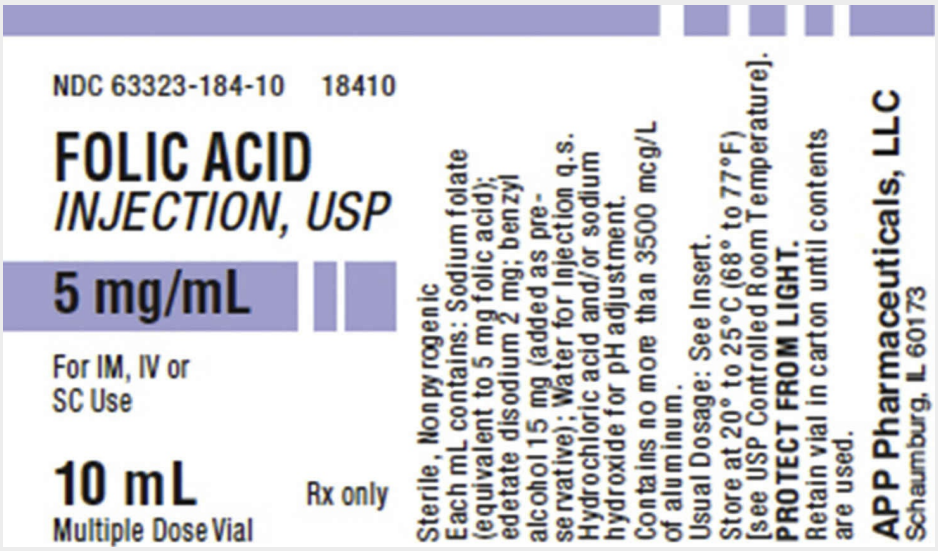
Answers to Practice Problems

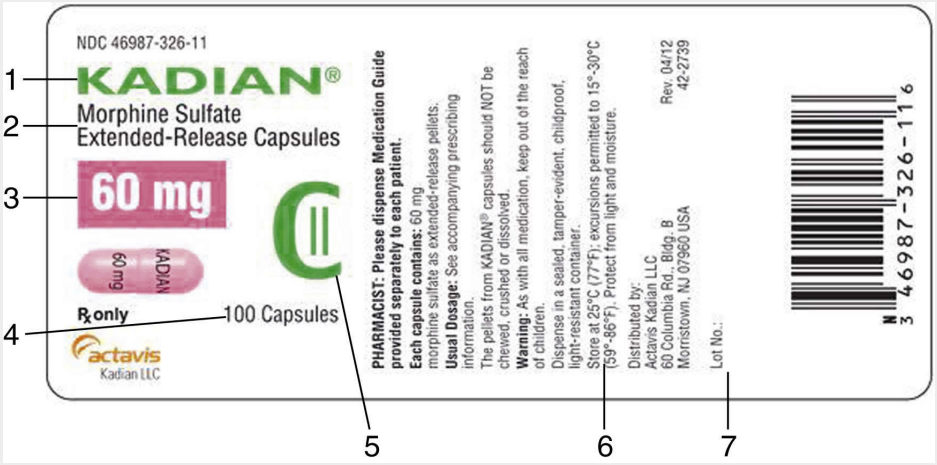
Interpreting Drug Labels

Pharmaceutical companies usually label their drugs with the brand name, also called the **trade name**, first in large letters with the generic name, then in smaller letters. Labels for generic drugs may have only the generic name of the drug listed. The formulation or the drug amount per tablet, capsule, or unit of liquid (for oral and parenteral doses) is printed on the drug label. Other information found on drug labels includes lot number, expiration date, proper storage of the drug, and whether it is a controlled substance. Two examples of drug labels are given below, the first for an oral drug and the second for a parenteral drug. The third example shows additional information provided on drug labels.



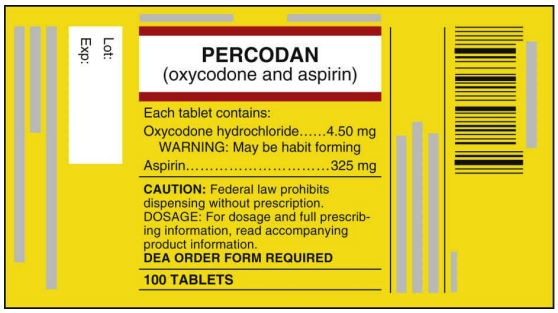
Examples

Interpreting Enteral Drug Labels

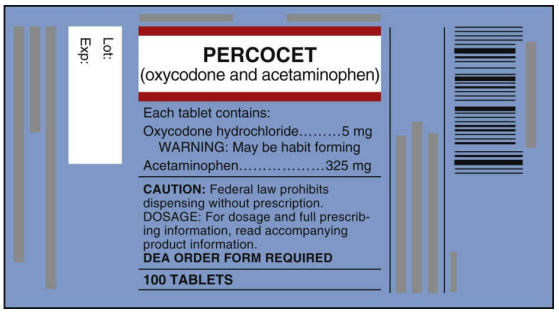


1. *Tylenol* is the brand (trade) name, *acetaminophen* is the generic name, and the formulation is 500 mg per caplet. That the container holds 100 caplets is irrelevant when calculating the drug dosage.

2. This label lists the generic name only (folic acid). The formulation is 5 mg per mL. There are 10 mL in the vial, which is an irrelevant number when calculating the drug dosage.



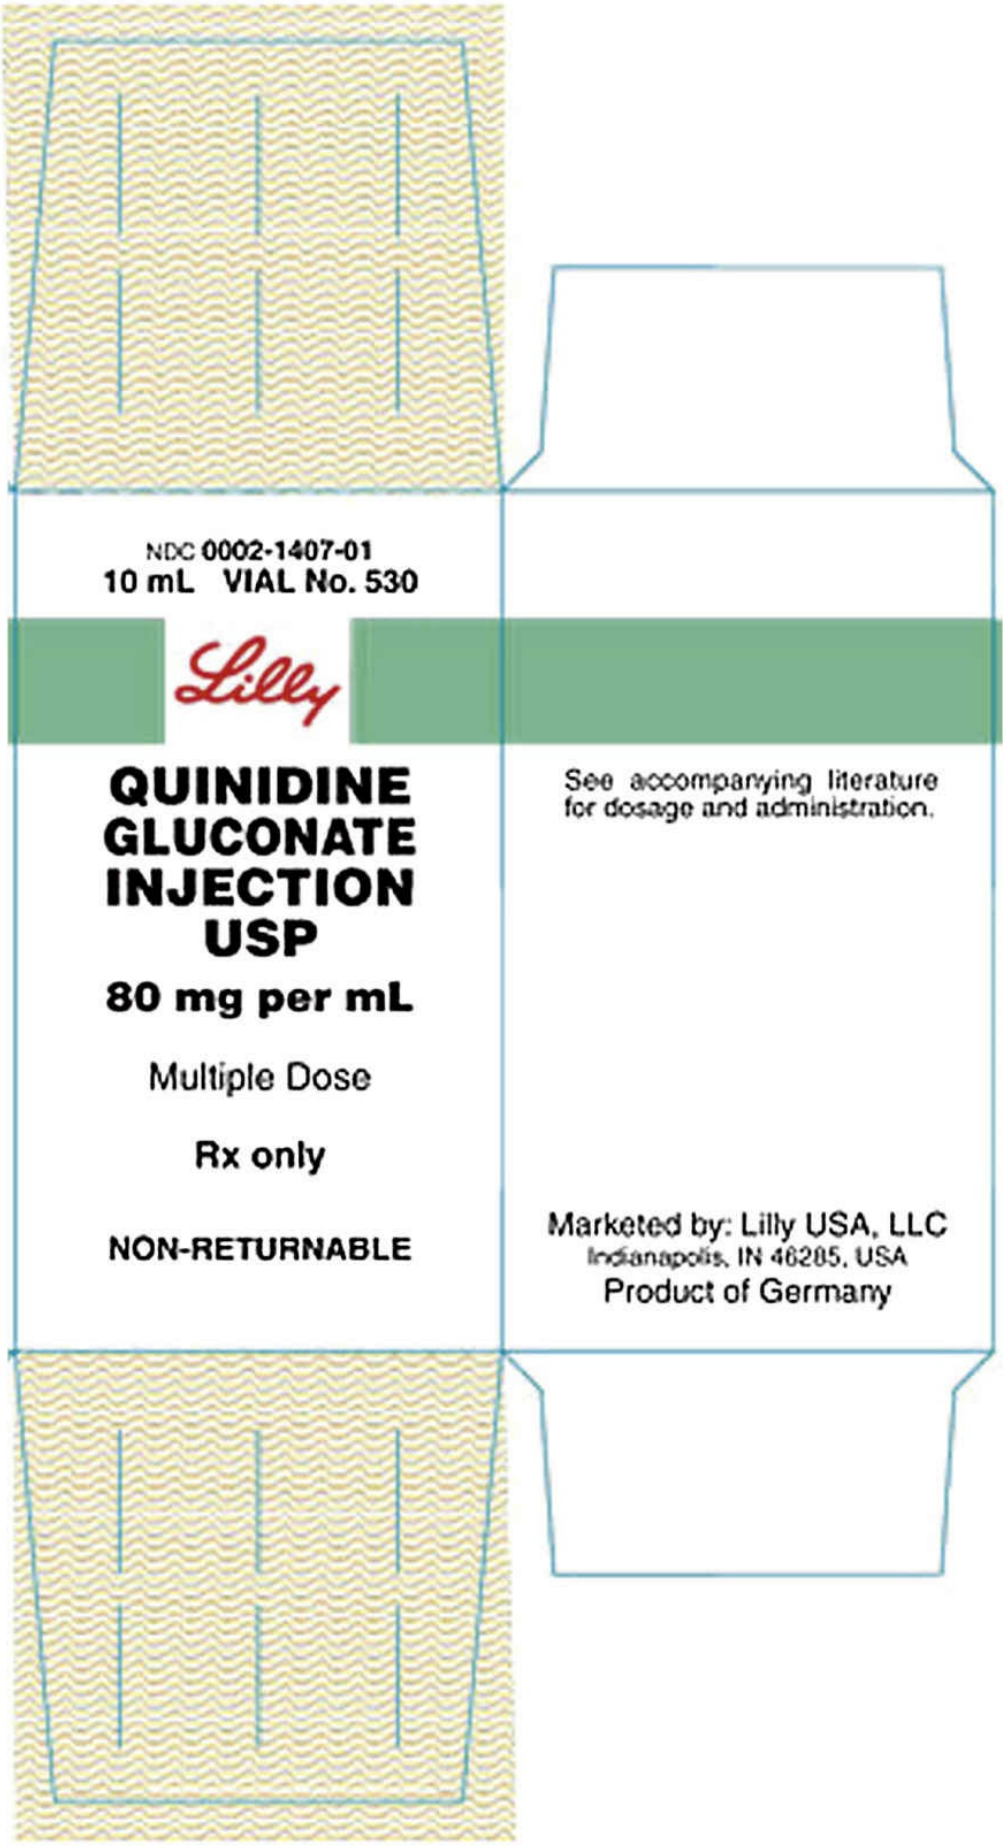
3. *Kadian*[1] is the brand (trade) name and *morphine sulfate*[2] is the generic name. The formulation[3] is 60 mg per capsule, and the container holds 100[4] capsules. It is a schedule II[5] drug, which is a **controlled substance** because of its potential for abuse. The label indicates how the drug is to be stored[6], and the lot number[7] also appears.



Precautions when Reading Drug Labels

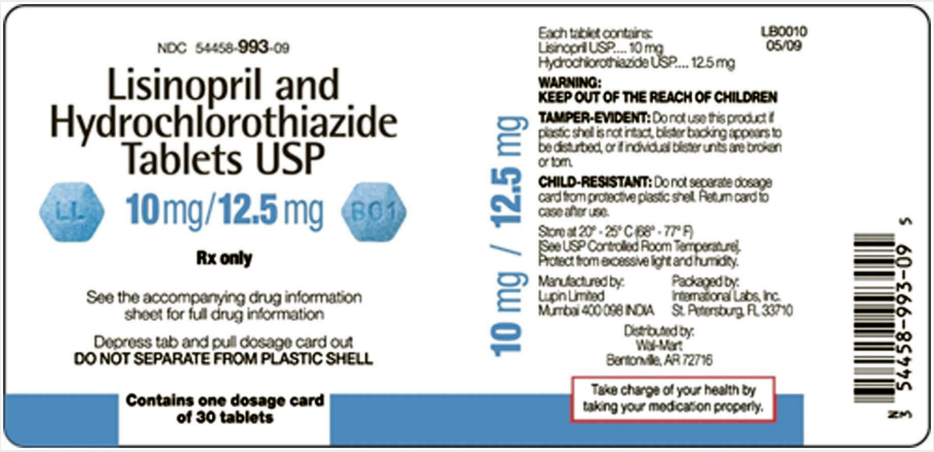
Be aware of drug names that sound or look alike; for example, note the similarity between the trade names *Percodan* and *Percocet*. Percocet, which contains oxycodone and acetaminophen, is the preparation most commonly prescribed.

Percodan contains oxycodone and aspirin, and a patient may be allergic to aspirin or should not take aspirin because of a stomach ulcer. Acetaminophen can cause liver toxicity; in persons with normal liver function, the maximum dosage of acetaminophen is 3000 mg per 24 hours.



Note the similarity between *quinine sulfate* and *quinidine gluconate.* These drugs differ greatly. Quinine is prescribed for malaria, whereas quinidine is prescribed for cardiac arrhythmias.

To decrease medication errors, the nurse administering the drug should perform a minimum of three label checks with the patient's medication administration record (MAR).



NDC 0002-1407-01
10 mL VIAL No. 530
Lilly
QUINIDINE GLUCONATE INJECTION USP
80 mg per mL
Multiple Dose
Rx only
NON-RETURNABLE
See accompanying literature for dosage and administration.

Indianapolis, IN 46285, USA
Product of Germany

Practice Problems

Reading Drug Labels

1.

a. What are the generic names? _____
b. What are the trade names? _____
c. Is this drug a controlled substance? _____
d. What is the amount of the drug and the form? _____
e. How many tablets are in the package? _____
f. How should this drug be stored? _____

2.

a. What is the generic name? _____
b. What is the trade name? _____
c. Is this drug a controlled substance? _____
d. What is the amount of the drug and the form? _____
e. How many tablets are in the package? _____
f. How should this drug be stored? _____

3.

a. What is the generic name? _____
b. What is the trade name? _____
c. Is this drug a controlled substance? _____
d. What is the concentration of the drug? _____
e. What is the total volume? _____
f. How should this drug be stored? _____

Methods of Drug Calculation

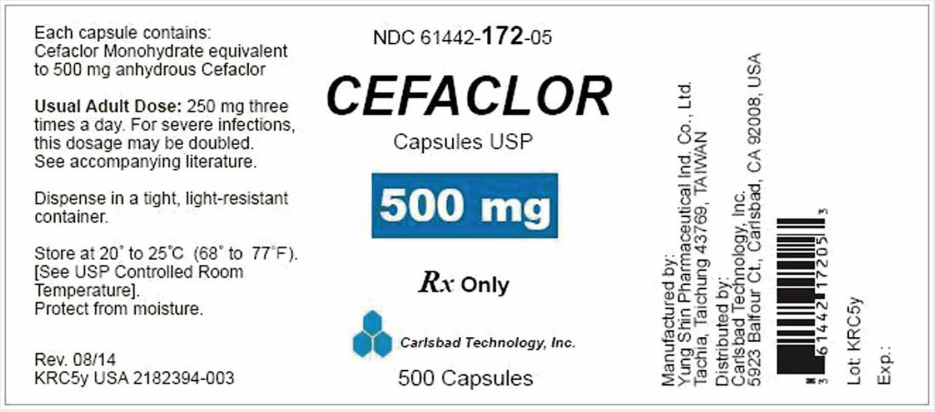
Generally, calculations are made for one dose. For example, if the order states that a patient is to be given 500 mg of a drug three times a day, you would calculate the amount of drug that is equivalent to 500 mg. Occasionally, nurses calculate the full daily dose, which in this case would be 1500 mg (500 mg times three doses).

The three general methods for the calculation of drug dosages are the (1) basic formula (BF), (2) ratio and proportion/fractional equation (RP/FE), and (3) dimensional analysis (DA). These methods are used to calculate most enteral and parenteral drug dosages. The nurse should select one of the methods to calculate drug dosages and use that method consistently. All but the dimensional analysis requires using the same units of measure. It is most helpful to convert to the system used on the **drug label**. If the drug is ordered in grams (g, G) and the drug label gives the dose in milligrams (mg), convert grams to milligrams (the measurement on the drug label) and proceed with the drug calculation.

For drugs that require individualized dosing, calculation by body weight (BW) or by body surface area (BSA) may be necessary. These last two methods are mostly used for the calculation of pediatric dosages and for drugs used in the treatment of cancer (antineoplastic drugs). BW and BSA methods of calculation are also useful for individuals whose BW is low, who are obese, or who are older adults.

Method 1

Basic Formula



The **basic formula (BF)** is easy to recall:

$$\frac{D}{H} \times V = A$$

Where:
D is the *desired* dose (as ordered)
H is the drug on *hand* (available)
V is the *vehicle* or *volume* of a drug form (tablet, capsule, liquid [mL])
A is the *amount* calculated to be given to the patient.

Examples Using the Basic Formula

1. Order: Cefaclor 0.5 g PO bid
   Available: Cefaclor 500 mg capsule

How many capsules should the patient receive per dose? (This is a two-step process.)

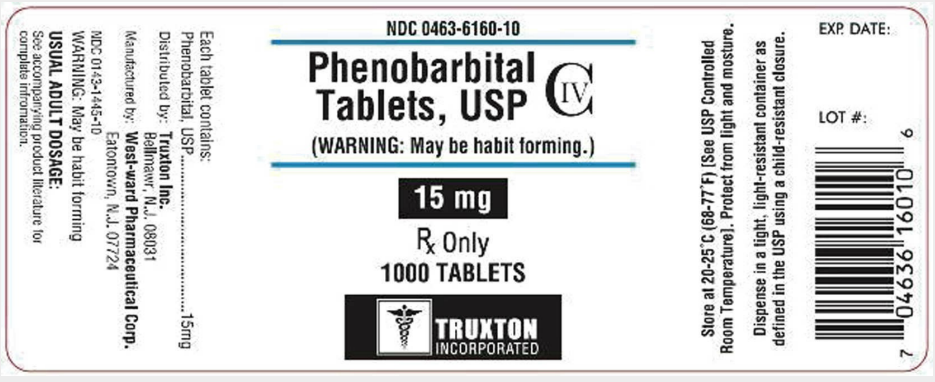
a. The unit of measure that is ordered (grams) and the unit of measure on the label (milligrams) are from the same system of measurement—the metric system. Conversion to the same unit as on the label is necessary to solve the problem. Because the label is in milligrams, convert grams to milligrams.

To convert grams (large value) to milligrams (smaller value), move the decimal point three spaces to the right as discussed earlier:

$$0.5\ \text{g} = 500\ \text{mg}\ (0.500 \text{ is converted to } 500 \text{ mg}); \text{ then}$$

$\frac{D}{H} \times V$; where $D = 500$ mg, $H = 500$ mg,

b. and V = 1 capsule; then



$$\frac{D}{H} \times \text{V} = \frac{500\ \text{mg}}{500\ \text{mg}} \times 1\ \text{capsule} = 1\ \text{capsule}$$

Answer: 500 mg, or 1 tablet

The nurse will administer 1 tablet per dose.

2. Order: Phenobarbital 30 mg PO STAT

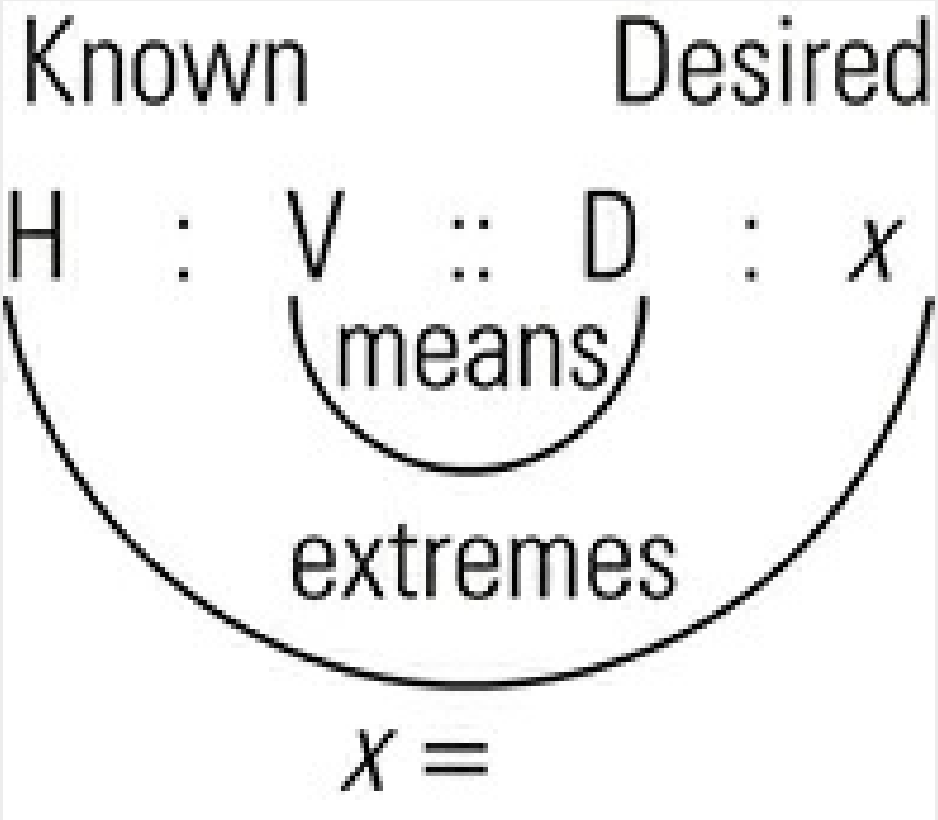
Available: Phenobarbital 15 mg per tablet

How many tablets should the patient receive per dose?

The dosage is ordered in milligrams and the unit of measure on the label is also expressed in milligrams. There is no need for conversion.

$$\frac{D}{H} \times V; \text{ then}$$

$$\frac{30\text{ mg}}{15\text{ mg}} \times 1\text{ tablet} = 2\text{ tablets}$$



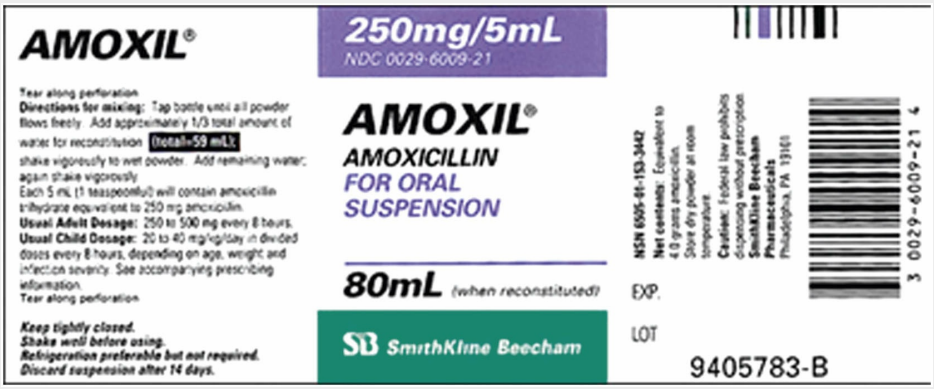
Answer: 30 mg = 2 tablets
The nurse will administer 2 tablets per dose.

Method 2

Ratio and Proportion/Fractional Equation

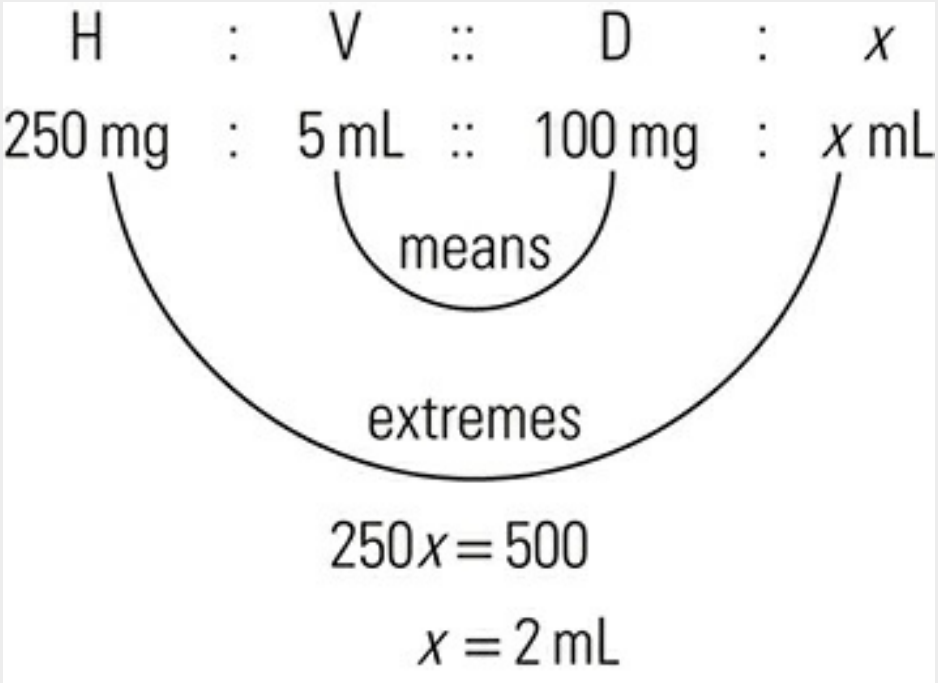
Ratio and Proportion: Linear Method

The ratio and proportion (RP) method can be expressed linearly or as a fraction (a fractional equation). The linear setup is as follows:



Where:
D is the *desired* dose (as ordered)
H is the drug on *hand* (available)

V is the *vehicle* or *volume* of a drug form (tablet, capsule, liquid [mL])
x is the *unknown amount* to give to the patient
The double colon symbol (::) stands for "as" or "equal to"

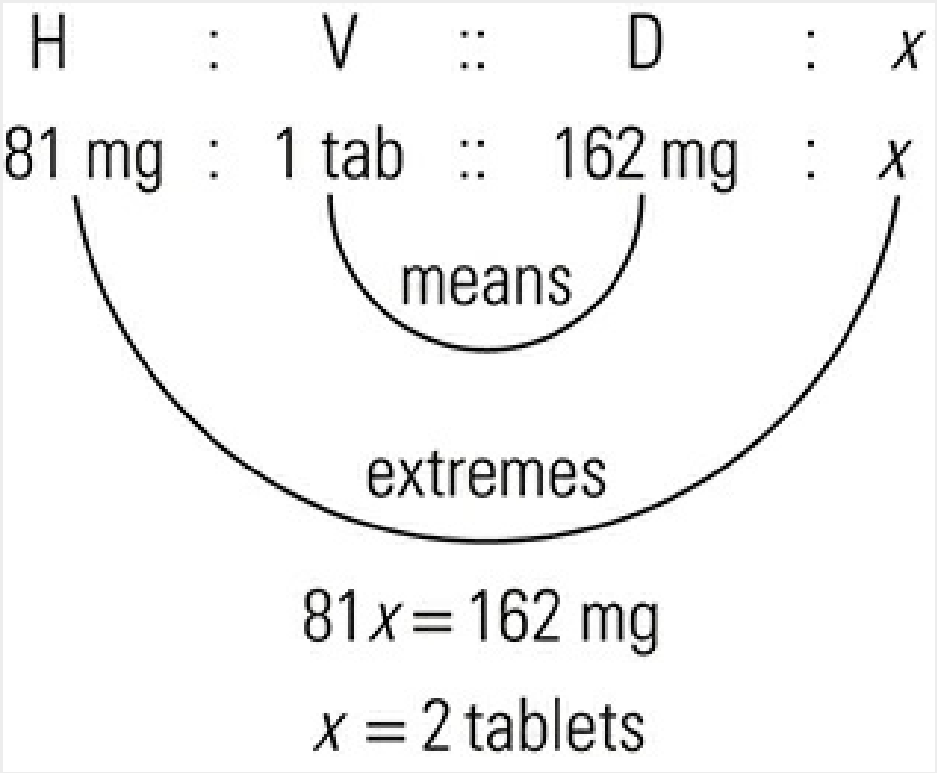


Multiply the extremes and the means $(Hx :: VD)$. Solve for x $\left(\frac{Hx}{H} :: \frac{VD}{H}\right)$; H is the divisor $\left(x = \frac{VD}{H}\right)$.

Examples Using Ratio and Proportion: Linear Method

1. Order: Amoxicillin 100 mg PO qid
   Available: Amoxicillin 250 mg per 5 mL

How many milliliters should the patient receive per dose?
Conversion is not needed because both are expressed in the same unit of measure.



Answer: Amoxicillin 100 mg = 2 mL
The nurse will administer 2 mL per dose.

2. Order: Aspirin 162 mg PO once daily
   Available: Aspirin 81 mg per tablet

How many tablets should the patient receive per dose?

Answer: Aspirin 162 mg = 2 tablets
The nurse will administer 2 tablets per dose.

Fractional Equation

The **fractional equation (FE)** setup is written as a fraction and is more commonly used than the linear setup. This setup will be used to illustrate RP/FE for the rest of this chapter.

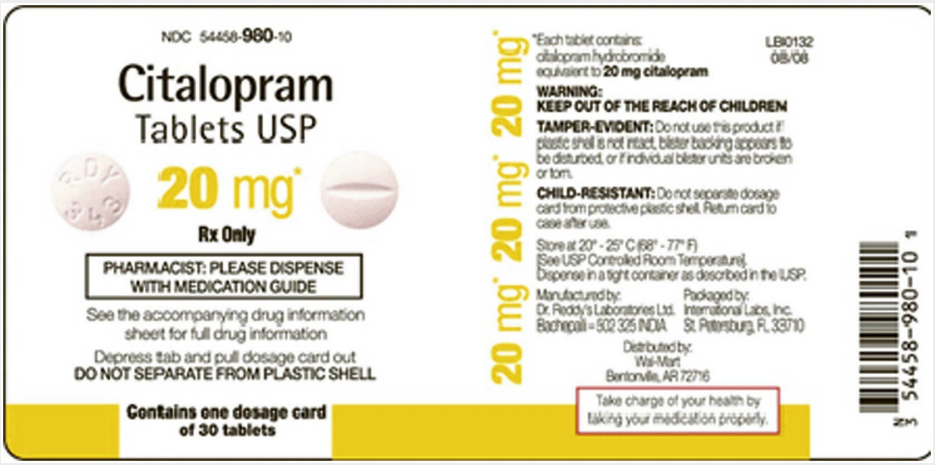
$$\frac{H}{V} = \frac{D}{x}; \text{ where } \frac{H}{V} \frac{\text{(dosage on hand)}}{\text{(vehicle)}} \quad \frac{D}{x} \frac{\text{(desired dosage)}}{\text{(unknown)}}$$

Cross-multiply and solve for x, where $Hx = VD; \text{then } x = \frac{VD}{H}$.

Examples Using the Fractional Equation—Fraction Method

1. Order: Ciprofloxacin 500 mg PO q12h
   Available: Ciprofloxacin 250 mg per tablet

How many tablet(s) should the patient receive per dose?



$$\frac{H}{V} = \frac{D}{x}$$

Where:
H = 250 mg
V = tablet (tab)
D = 500 mg
x = unknown number of tablets

$$\frac{250 \text{ mg}}{1 \text{ tab}} = \frac{500 \text{ mg}}{x \text{ tab}}$$

Cross-multiply and solve for x.
$250x = 500$
$x = 2$
Answer: 500 mg = 2 tablets
The nurse will administer 2 tablets per dose.

2. Order: Citalopram 10 mg PO once daily
   Available: Citalopram 20 mg per tablet

$$\frac{H}{V} = \frac{D}{x}$$

$$\frac{20\text{ mg}}{1\text{ tab}} = \frac{10\text{ mg}}{x\text{ tab}}$$

Cross-multiply and solve for x.
$20x = 10$
$x = 0.5$ tablet (1/2 tab)
(Note that this tablet is scored to allow it to be split in half.)
Answer: $x = 0.5$ tablet
The nurse will administer 0.5 tablet per dose.
(For the duration of this chapter, any RP or FE calculation will be shown using the FE method.)

Method 3

Dimensional Analysis

Dimensional analysis (DA) is a calculation method known as *units and conversions*. The *D*, *H*, and *V* are still used in DA. The advantage of DA is that all the steps for calculating drug dosages are conducted in one equation without having to remember various formulas. However, conversion factors still need to be memorized.

Steps for Dimensional Analysis

1. Identify the unit/form (tablet, capsule, mL) of the drug to be calculated. Place the unit/form to one side of the equal sign (=). *This is your desired unit/form.*
2. Determine the *known* dose and unit/form from the drug label that matches the unit/form of the desired dosage. Place this on the other side of the equal sign.
3. Continue with additional fractions using a multiplication operation between each fraction until

all but that one unit you want is eliminated.
4. Multiply the numerators and multiply the denominators.
5. Solve for *x* (the unknown).

Examples Using Dimensional Analysis

1. Order: Amoxicillin 500 mg PO q8h
   Available: 250 mg per capsule

How many capsules (cap) will the nurse administer per dose?

a/b. $\text{cap} = \frac{1\ \text{cap}}{250\ \text{mg}}$ (*H* = on-*hand*)

c. Notice that the drug form "cap" to the left of the equal sign is the same as the "cap" in the numerator to the right of the equal sign. (We must determine how many capsules need to be administered for the dose to be 500 mg). The available capsule is 250 mg; this is placed in the denominator.

d. The available strength (250 mg) is the denominator, and the unit/form "mg" must match the next numerator, which is the ordered dose of 500 mg (*desired dose*). The next *denominator* would be *x cap* (*unknown*) or it would be left blank.

$$\text{cap} = \frac{1\ \text{cap}}{250\ \cancel{\text{mg}}} \times \frac{500\ \cancel{\text{mg}}}{x\ \text{cap}}$$

e. Cancel out the *mg,* multiply the numerators, then multiply the denominators.

f. Solve for *x* by isolating *x;* reduce the resulting fraction. (Reducing fractions could be done earlier). What remain are *cap* and *2.*

$$\frac{500}{250x}; \text{then } x = 2\ \text{cap}$$

Answer: 2 capsules
When conversions are needed (e.g., between milligrams and grams) a conversion factor (CF) is needed to calculate dosages using the basic formula or RP/FE, requiring a multistep process. When using DA, there should *only* be the one unknown value in the equation (x). This will be especially important when calculating dosages that involve milligrams per kilogram (mg/kg) or milligrams per meters squared (mg/m^2).

2. Order: Amoxicillin 0.5 g PO q8h
Available: 250 mg per capsule
How many capsules will the nurse administer?
A conversion is needed between grams and milligrams. Following the steps for DA, the equation looks like this:

$$H \times CF \times \frac{D}{unknown} =$$

$$\text{cap} = \frac{1 \text{ cap}}{250 \cancel{\text{mg}}} \times \frac{1000 \cancel{\text{mg}}}{1 \cancel{\text{g}}} \times \frac{0.5 \cancel{\text{g}}}{x \text{ cap}} = \frac{1000 \times 0.5}{250}$$
$$= \frac{500}{250} = 2 \text{ capsules of amoxicillin}$$

As with other methods of calculation, the three components are *D*, *H*, and *V* as indicated in the above problem. With dimensional analysis, the conversion factor (CF) is built into the equation and is included when the ordered drug's unit of measurement and the drug available differ. If the same units of measurement are used, the conversion factor is eliminated from the equation, as shown in the first example.

3. Order: Acetaminophen 1 g PO q6h PRN for headache
Available: Acetaminophen 325 mg per tablet

Conversion factor: 1000 mg = 1 g
How many tablet(s) should be given?

$$\text{tab} = \frac{1\ \text{tab}}{325\ \cancel{\text{mg}}} \times \frac{1000\ \cancel{\text{mg}}}{1\ \cancel{\text{g}}} \times \frac{1\ \cancel{\text{g}}}{x\ \text{tab}} = \frac{1000}{325} = 3.07$$

Answer: 1000 mg [1 g] = 3 tablets
The nurse will administer 3 tablets per dose.

Rounding Rules

Notice when to round. Tablets and caplets can be rounded to the nearest half if they are scored (see the image for citalopram). Some tablets are scored in fourths. In this case, the dosage can be rounded to the nearest fourth. However, tablets and caplets that are extended release, sustained release, controlled release, or enteric coated should not be split because splitting or crushing these preparations destroys the properties that render the drug long lasting. For this reason, capsules are rounded to the nearest whole number. Liquid drugs can be rounded to the nearest tenth; the exception to this rule is when calculating dosages of drops, which are rounded to the nearest whole number.

When rounding, determine how many places beyond the decimal point are appropriate. The general rounding rules are:
1. If a number to the right of the digit needs to be rounded and is 4 or less, round down. For example, when rounding 1.343 to the hundredth place, the number becomes 1.34. Rounding 1.343 to the tenth place, it becomes 1.3. Rounding 1.343 to a whole number, it becomes 1.
2. If a number to the right of the digit needs to be rounded and is 5 or greater, round up. For example, when rounding 1.745 to the hundredth place, the number becomes 1.75. Rounding 1.745 to the tenth place, it becomes 1.7. Rounding 1.745 to a whole number, it becomes 2.

Calculating Dosages for Drugs Measured in Units or Milliequivalents

Some medications, such as heparin and insulin, are measured in units. Typically, units are not converted into any other measure.

Example

Drug Measured in Units

1. Order: Heparin 2500 units subcut daily
   Available: Heparin 10,000 units per mL in a multiple-dose vial (10 mL)

Basic Formula

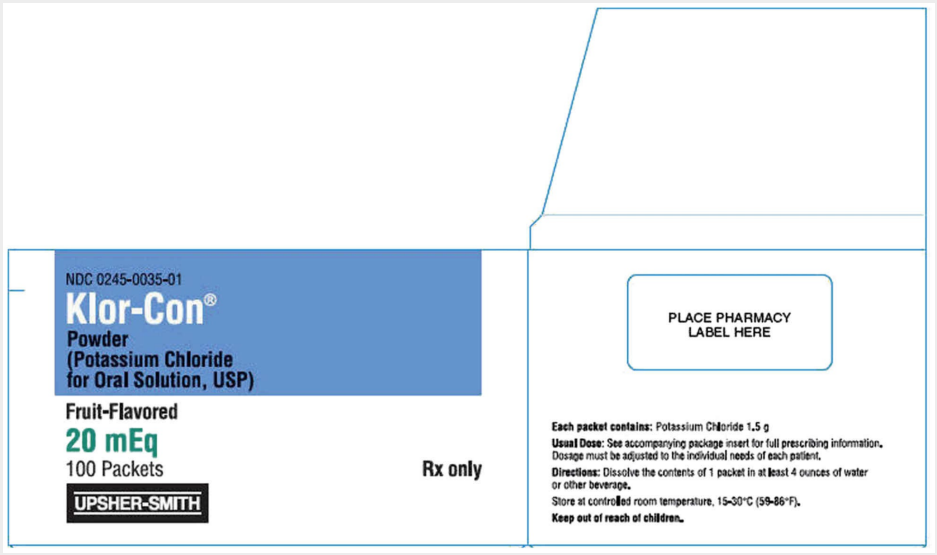
$$\frac{D}{H} \times V = \frac{2500\ \cancel{\text{units}}}{10000\ \cancel{\text{units}}} \times 1\ \text{mL} = \frac{25}{100} = 0.25\ \text{mL}$$

Ratio and Proportion/Fractional Equation Methods

$$\frac{H}{V} = \frac{D}{x} = \frac{10000 \text{ units}}{1 \text{ mL}} = \frac{2500 \text{ units}}{x \text{ mL}}$$

$$10000\,x = 2500$$

Cross-multiply: $x = 0.25$ mL
Answer: Heparin 2500 units = 0.25 mL = 0.3 mL



Dimensional Analysis

$$\text{mL} = \frac{1 \text{ mL}}{10000 \text{ ~~units~~}} \times \frac{2500 \text{ ~~units~~}}{x}$$

$$= \frac{2500}{10000}$$

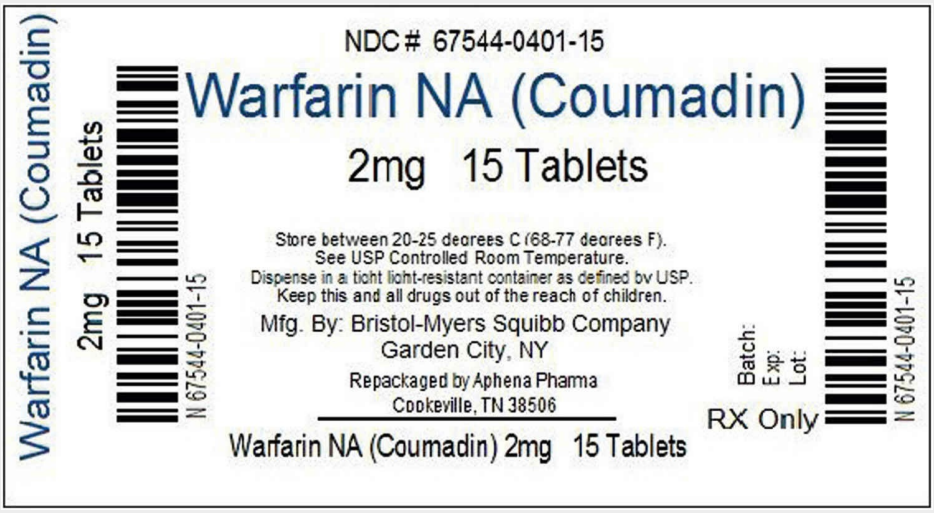
$$= 0.25 \text{ mL} = 0.3 \text{ mL (per the rounding rule)}$$

Electrolytes are often ordered in milliequivalents (mEq). An example is pictured below.

Practice Problems

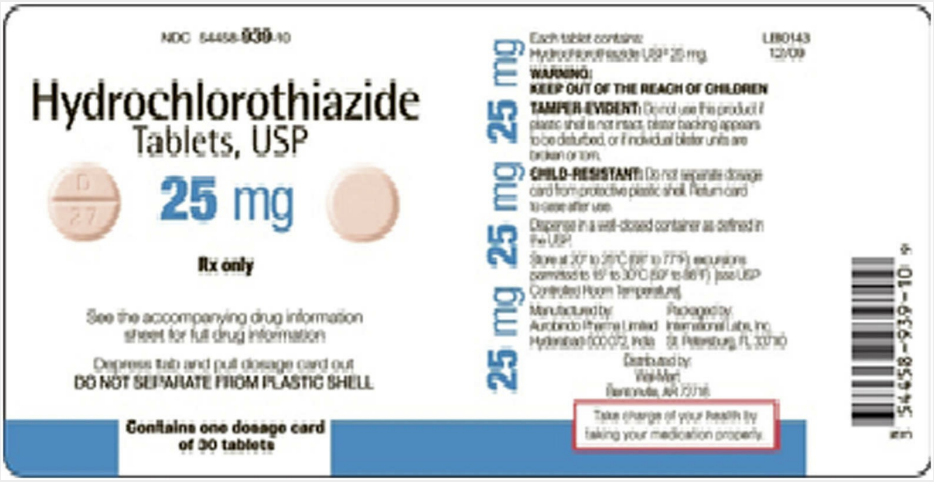
Enteral and Parenteral Drugs Using Basic Formula, Ratio and Proportion/Fractional Equation, or Dimensional Analysis

1. Order: Ranitidine 150 mg PO q12h



Available: Ranitidine 75 mg per tablet
Administer how many tablets per dose? _____

2. Order: Doxycycline 100 mg PO q12h
Available: Doxycycline 100 mg capsules

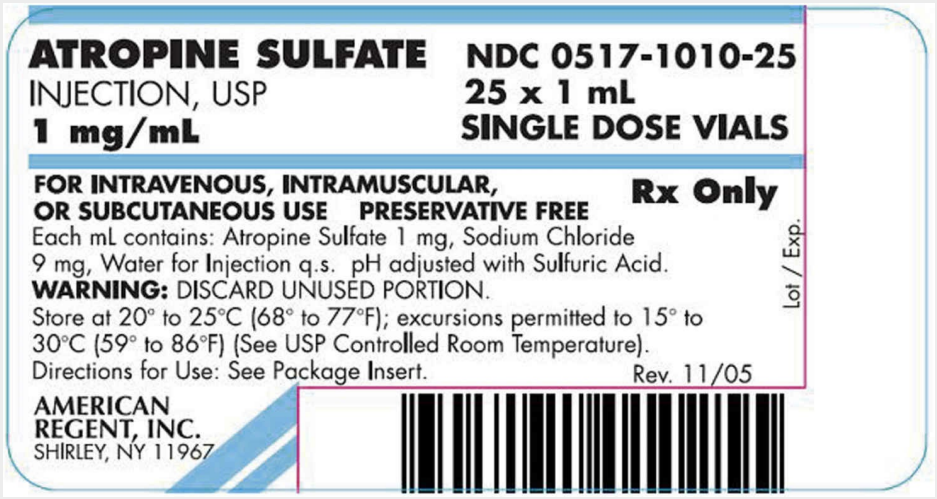


Administer how many capsules per dose? _____

3. Order: Warfarin 2 mg PO once daily
   Available: Warfarin 2 mg tablets

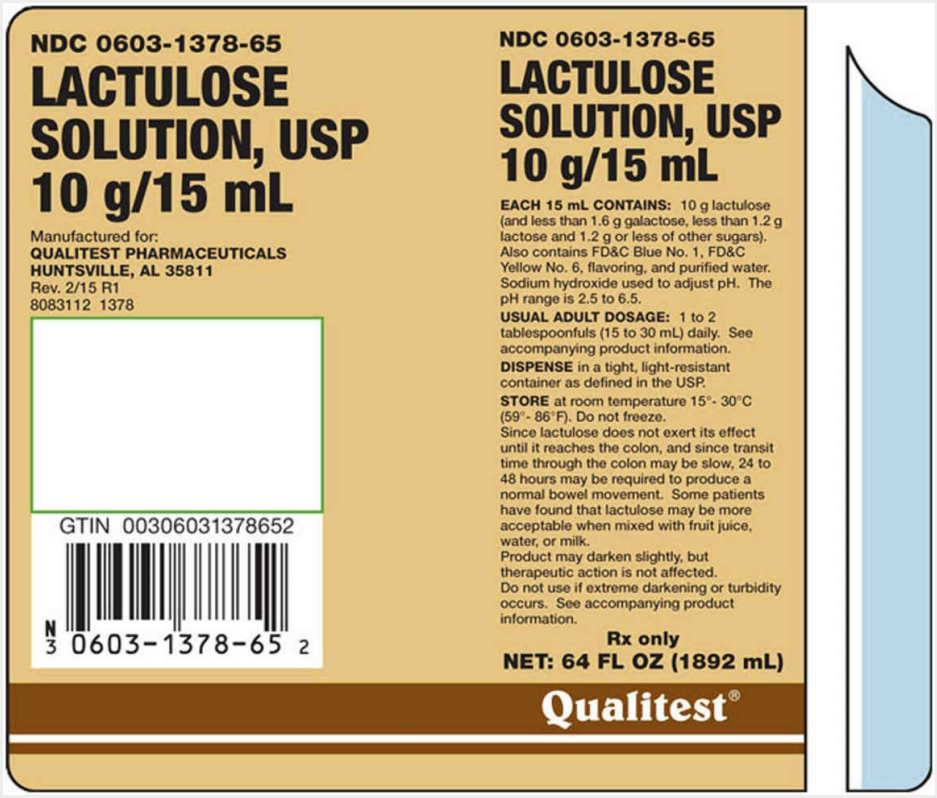
Administer how many tablets per dose? _____

4. Order: Hydrochlorothiazide 12.5 mg PO every morning
   Available: Hydrochlorothiazide 25 mg tablets



Administer how many tablets per dose? _____

5. Order: Furosemide 20 mg IM STAT
   Available: Furosemide 10 mg per mL



Administer how many milliliters per dose? _____
(Note that this label can be confusing to the reader. The concentration is 10 mg per mL, and it is a 4 mL vial, so the vial contains 40 mg.)

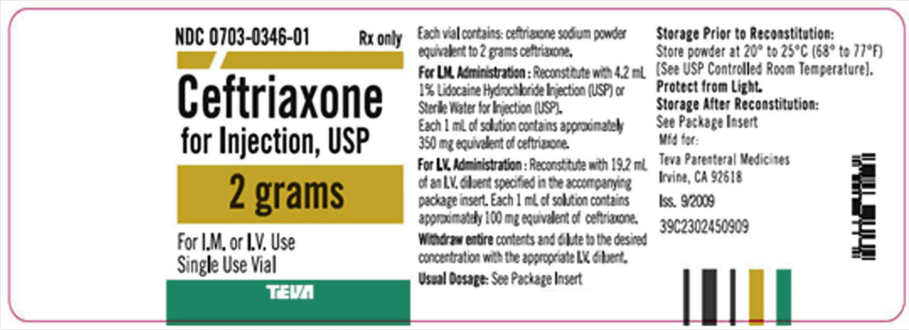
6. Ordered: Atropine sulfate 0.4 mg subcut STAT
   Available: Atropine sulfate 1 mg per mL

Administer how many milliliters for the STAT dose? _____
(There could be a point of confusion with this label. The concentration is 1 mg/mL in each vial, and there are 25 vials in the package.)

7. Ordered: Lactulose solution 20 g by mouth tid
   Available: Lactulose solution 10 g per 15 mL

Administer how many milliliters per dose? _____

8. Ordered: Phenytoin oral solution 0.25 g PO bid
   Available: Phenytoin oral solution 125 mg per 5 mL



Administer how many milliliters per dose? _____

9. Order: Heparin 7500 units subcut now; 3500 units subcut daily
   Available: 5000 units per mL single-dose vial

a. Administer how many milliliters for the now dose? _____
b. Administer how many milliliters for the daily dose? _____
c. How many vial(s) of heparin are needed? _____

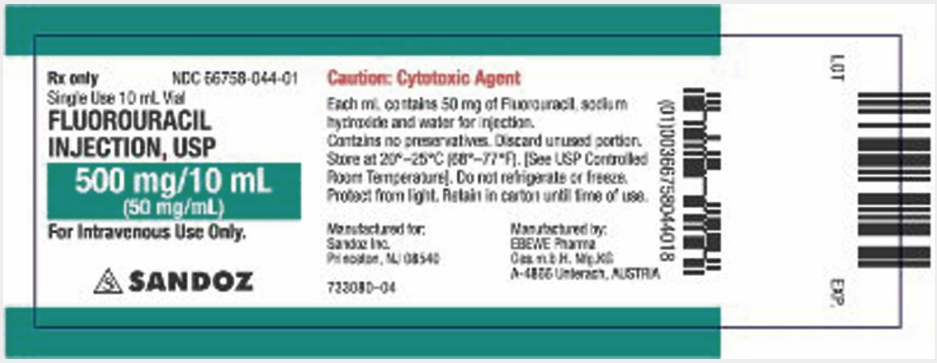
10. Order: Ceftriaxone 1.5 g IM now
Available: Ceftriaxone 2 g vial

a. How many milliliters of diluent is needed for reconstitution? _____
b. What is the final drug concentration? _____
c. How many milliliters will the nurse administer for the now dose? _____

Method 4

Body Weight

The **body weight (BW)** method of calculation allows for individualization of the drug dosage and involves the following three steps:



1. Convert pounds to kilograms; 2.2 lb is equivalent to 1 kg.
2. Determine the drug dose for the body weight by multiplying as follows:

$$\text{Drug dose} \times \text{body weight} = \text{patient's dose}$$

3. Follow the basic formula, ratio and proportion/fractional equation, or dimensional analysis method to calculate the drug dosage.

Examples of Using Body Weight for Drug Calculation

1. Order: Fluorouracil 12 mg per kg per day intravenous (IV) for a patient who weighs 176 lb
Available: Two vials of fluorouracil 50 mg per mL

How many milliliters should the nurse administer per day?

Basic Formula

a. The first step is to convert pounds to kilograms by dividing the number of pounds the patient weighs by 2.2 (1 kg = 2.2 lb).

$$176 \text{ lb} \div 2.2 = 80 \text{ kg}$$

b. The second step is to multiply the ordered dose by the patient's weight in kilograms.

$$\text{mg} \times \text{kg} = \text{patient dose}$$

$$12 \text{ mg} \times 80 \text{ kg} = 960 \text{ mg per day}$$

c. The third step is to determine the volume in milliliters to administer 960 mg.

$$\frac{D}{H} \times V = \frac{960 \cancel{\text{mg}}}{50 \cancel{\text{mg}}} \times 1 \text{ mL}$$
$$= 19.2 \text{ mL}$$

Dimensional Analysis

(Notice that the conversion factors are included in this one equation.)

$$mL = \frac{1\ mL}{50\ \cancel{mg}} \times \frac{12\ \cancel{mg}}{1\ \cancel{kg}} \times \frac{1\ \cancel{kg}}{2.2\ \cancel{lbs}} \times \frac{176\ \cancel{lbs}}{x\ mL}$$

$$= \frac{2112\ mL}{110}$$

$$= 19.2\ mL$$

(Because you can administer tenths of liquid medications, round to the nearest tenth.

2. Order: Cefaclor oral suspension 20 mg per kg per day in three divided doses for a pediatric patient who weighs 66 lb
   Available: Cefaclor oral suspension 125 mg per 5 mL

How many milliliters will the nurse administer per dose? _____

Basic Formula

a. Convert pounds to kilograms.

$$66\ lb \div 2.2\ lb = 30\ kg$$

b. Multiply the desired dosage with the patient's weight in kg
   20 mg × 30 kg = 600 mg per day
c. Divide by the number of doses needed for the day.

600 mg ÷ 3 doses = 200 mg per dose

d. Using the basic formula, determine the mL per dose.

$$\frac{D}{H} \times V = \frac{200\ \cancel{mg}}{125\ \cancel{mg} \times 5\ mL}$$

$$= 8\ mL$$

Dimensional Analysis

$$mL = \frac{5\ mL}{125\ \cancel{mg}} \times \frac{20\ \cancel{mg}}{1\ \cancel{kg}} \times \frac{1\ \cancel{kg}}{2.2\ \cancel{lbs}} \times \frac{66\ \cancel{lbs}}{3\ doses}$$

$$= \frac{6600\ mL}{825\ mg}$$

$$= 8\ mL\ per\ dose$$

Method 5

Body Surface Area—West Nomogram

The measurement of **body surface area (BSA)** is the most precise method for calculating drug dosages. BSA can be measured using the West nomogram or the square root method.

The BSA by the West nomogram (Fig. 11B.1) is measured in square meters (m^2) and is

determined by the patient's height and weight. Determine where the height and weight intersect on the nomogram scale; the height and weight can be in inches and pounds or centimeters and kilograms depending on the column used, but the systems of measurement must match. Centimeters and kilograms are both within the metric system and are most commonly used for the calculation of BSA. To calculate a drug dosage, multiply the dose ordered with the patient's BSA.

Examples of Using Body Surface Area: Drug Calculation

1. Drug dosage will be determined using the West nomogram and the square root calculations for a patient who is 70 inches tall and weighs 160 lb.

Determining Body Surface Area Using the West Nomogram

Using Inches and Pounds

Draw a straight line from *70* in the *inches* column to *160* in the *pounds* column (Fig. 11B.2). Note that the line intersects between 1.9 and 2 square meters.

Using Centimeters and Kilograms

The patient is 178 cm tall (1 in = 2.54 cm) and weighs 73 kg (2.2 lb = 1 kg). The height and the weight were rounded to whole numbers. Draw a straight line from 178 in the *centimeters* column to 73 in the *kilograms* column (Fig. 11B.3). Note that the line also intersects between 1.9 and 2. For the purposes of calculation, 1.95 can be used.

Determining Body Surface Area Using the Square Root Method

The most precise way to determine BSA is to use the **square root method** for the calculation. When calculating the BSA in household measurement (inches and pounds), the following formula applies:

$$\text{BSA} = \sqrt{\frac{\text{height (inches)} \times \text{weight (pounds)}}{3131\ \text{(constant)}}}$$

$$= \sqrt{\frac{70\ \text{in} \times 160\ \text{lb}}{3131}}$$

$$= \sqrt{\frac{11200}{3131}}$$

$$= \sqrt{3.6}$$

$$\sqrt{3.6} = 1.9\,\text{m}^2$$

When calculating the BSA using the metric system (centimeters and kilograms), the following formula applies:

$$\text{BSA} = \sqrt{\frac{\text{height (centimeters)} \times \text{weight (kilograms)}}{3600\ \text{(constant)}}}$$

$$= \sqrt{\frac{178\,\text{cm} \times 73\,\text{kg}}{3600}} = \sqrt{\frac{12994}{3600}} = \sqrt{3.6}$$

$$\sqrt{3.6} = 1.9\,\text{m}^2$$

(Numbers have been rounded to the nearest tenth, which is common for adults.)

Note that both results using the square root method agree and are more precise than using the West nomogram. The variance of 0.05 from the lowest calculated BSA to the highest calculated BSA is negligible.

2. The following drug dosage for this patient is calculated using a BSA of 1.9 m^2

Order: CISplatin 20 mg per m^2 intravenous (IV) today

Available: CISplatin 1 mg per mL

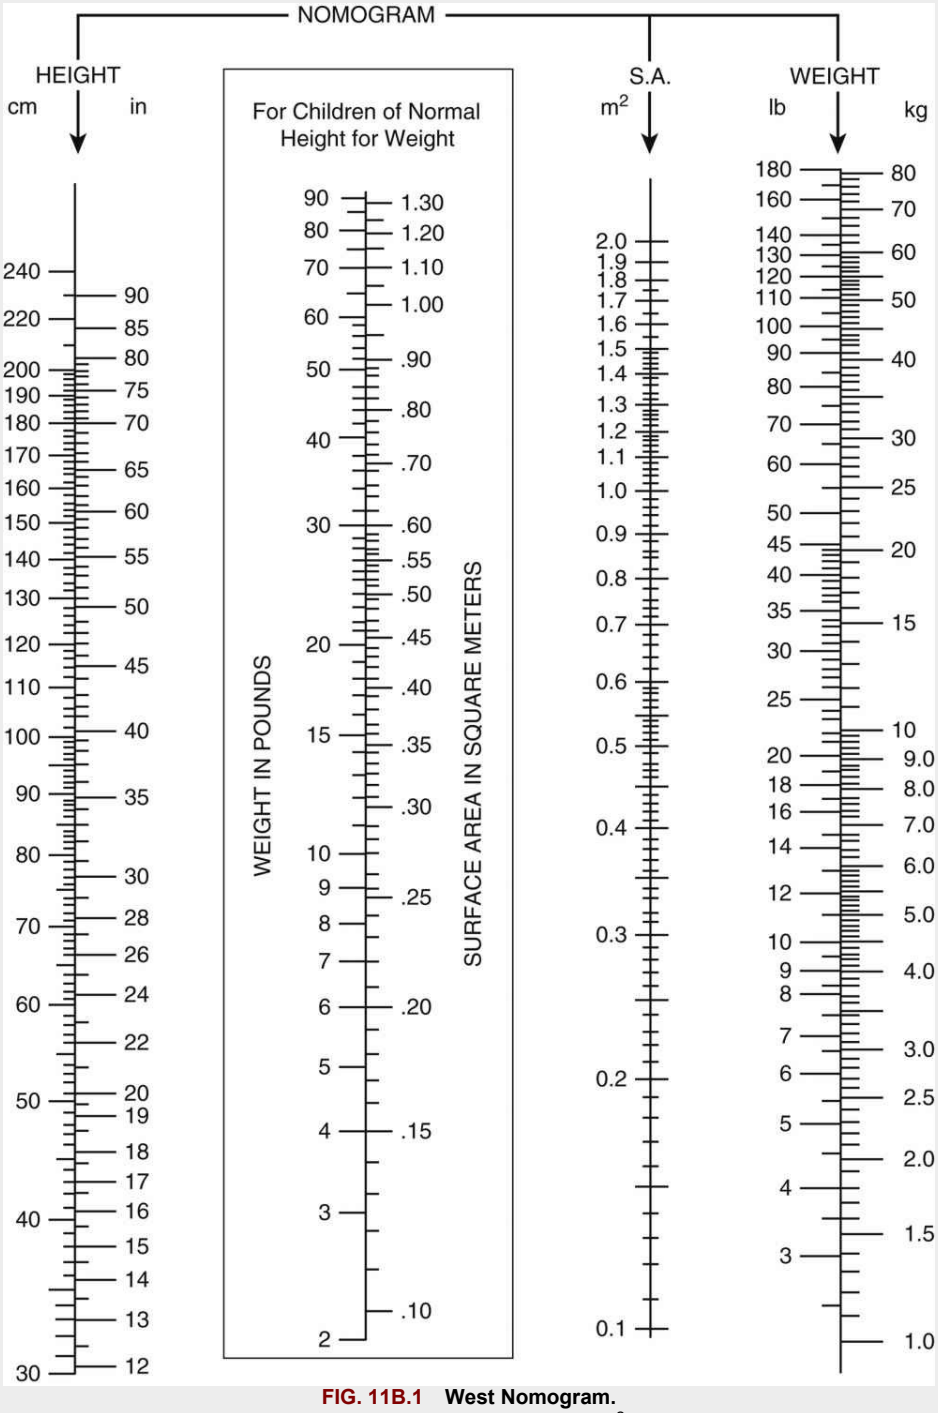


FIG. 11B.1 West Nomogram.

The outside columns are used to calculate the meters squared (m^2) of adults. The middle column is used to calculate the meters squared of children. (Modified from data by Boyd, E., & West, C. D. [2011]. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme III, et al. [Eds.], *Nelson textbook of pediatrics* [19th ed]. Philadelphia, PA: Saunders.)

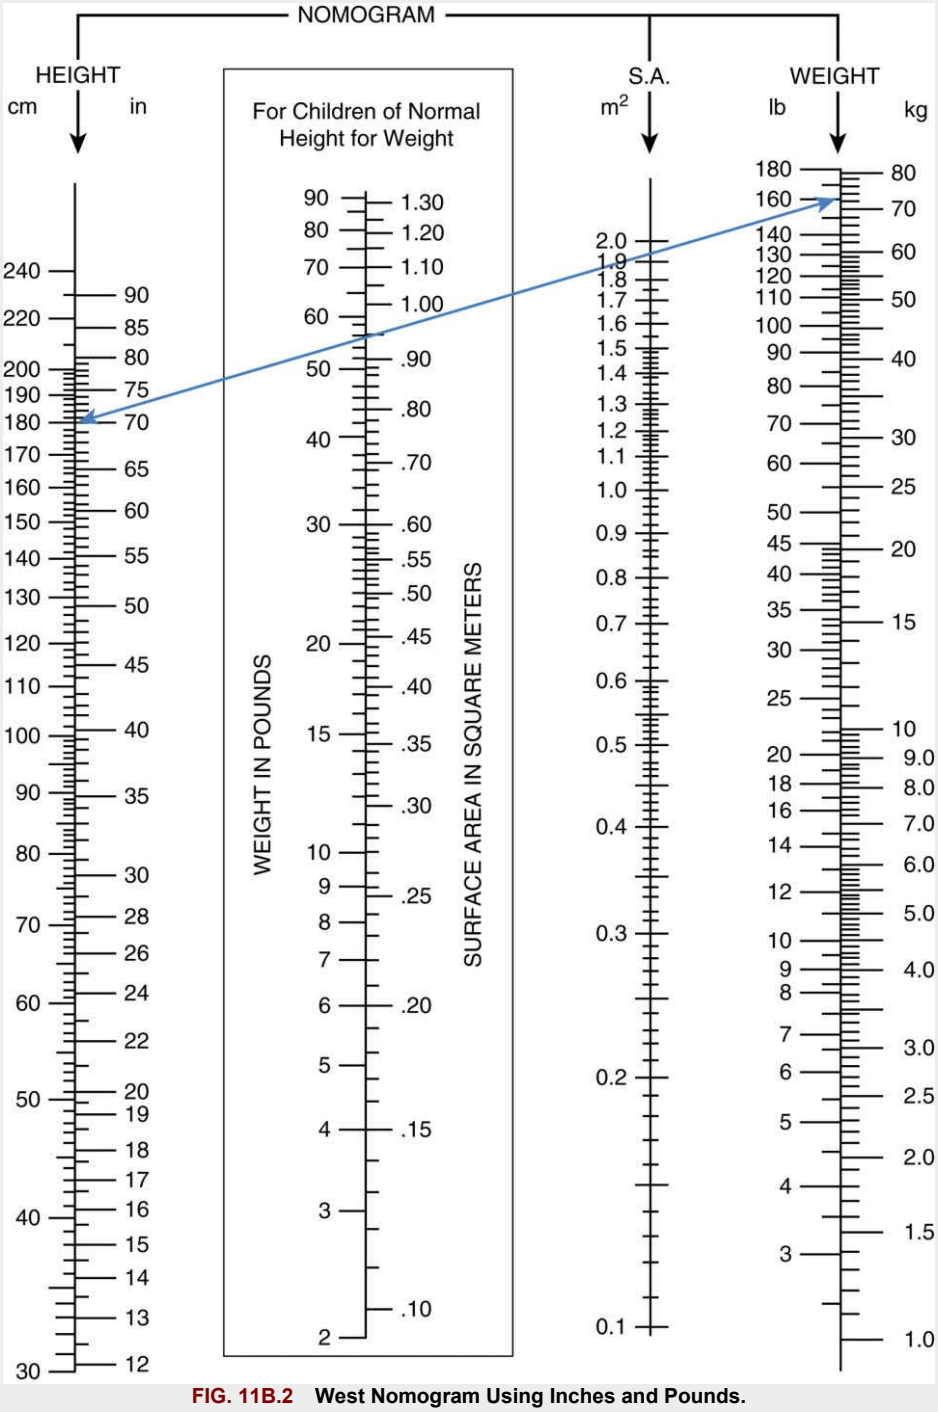

FIG. 11B.2 West Nomogram Using Inches and Pounds.

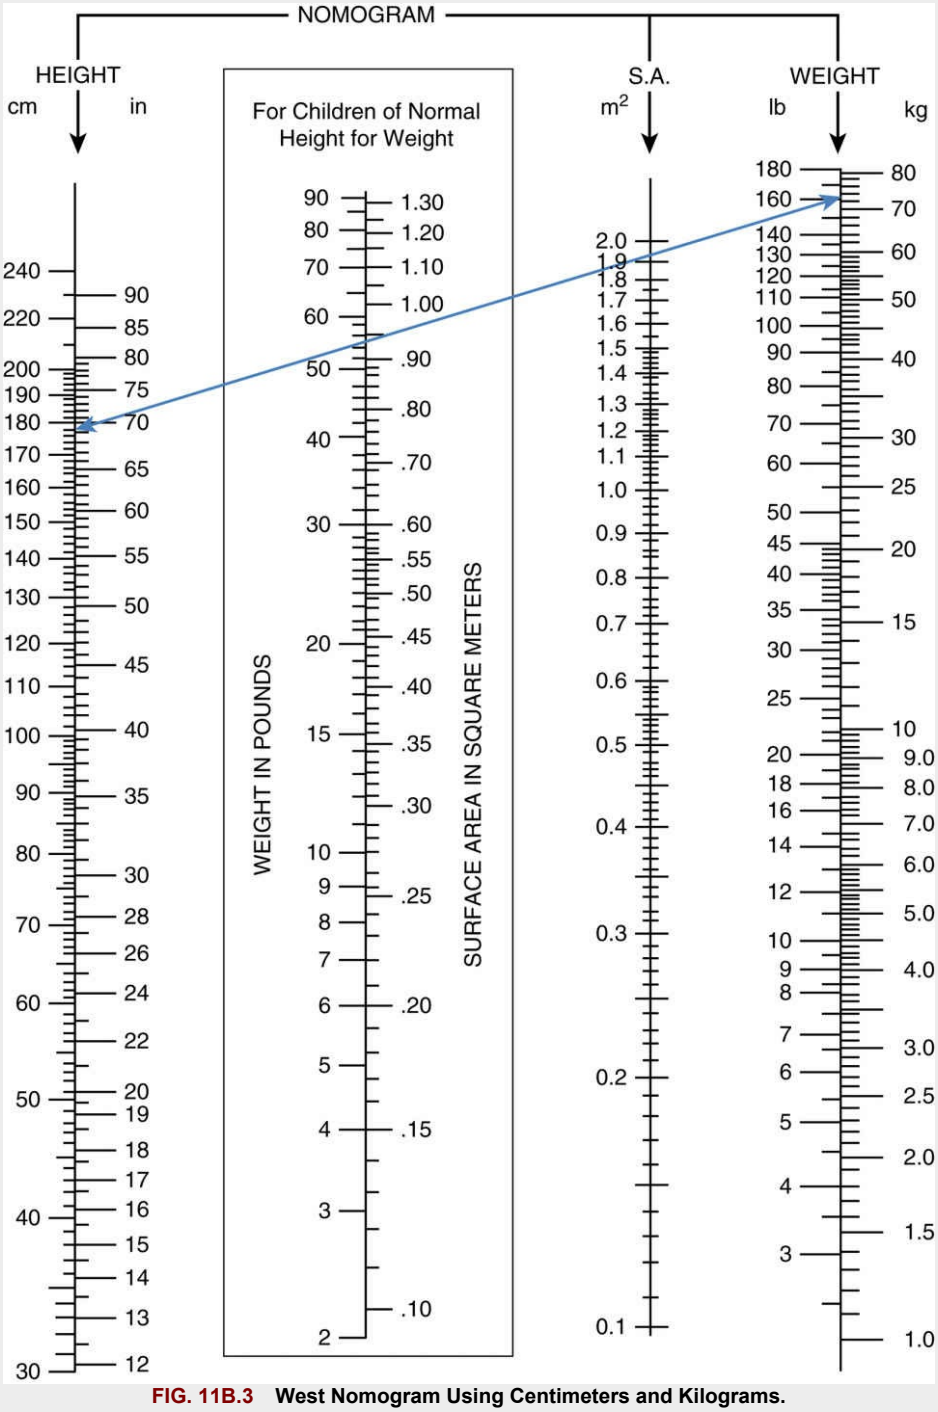
(Modified from data by Boyd, E., & West, C. D. [2011]. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme III, et al. [Eds.], *Nelson textbook of pediatrics* [19th ed]. Philadelphia, PA: Saunders.)



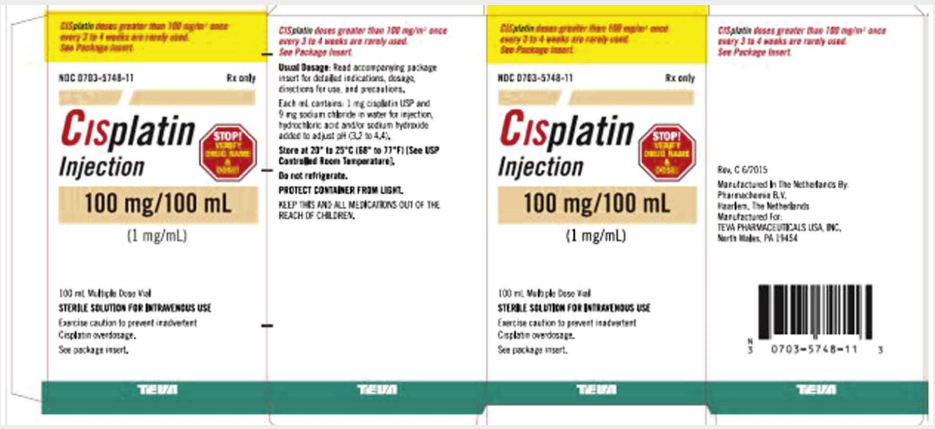


FIG. 11B.3 West Nomogram Using Centimeters and Kilograms.

(Modified from data by Boyd, E., & West, C. D. [2011]. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme III, et al. [Eds.], *Nelson textbook of pediatrics* [19th ed]. Philadelphia, PA: Saunders.)

(Note that the label also states 100 mg per 100 mL. Using the lowest numbers listed on a drug label helps to prevent errors by eliminating extraneous zeroes.)

a. How many milligrams are ordered?

To calculate the child's dose, multiply 20 mg with 1.9 m^2 to get 38 mg

b. How many milliliters will the nurse administer?

Basic Formula

$$\frac{D}{H} \times V$$

$$= \frac{38 \text{ mg}}{1 \text{ mg}} \times 1 \text{ mL}$$

$$= 38 \text{ mL}$$

Ratio and Proportion/Fractional Equation

$$\frac{H}{V} = \frac{D}{x}$$

$$\frac{1\ \cancel{mg}}{1\ mL} = \frac{38\ \cancel{mg}}{x}$$

$$x = 38\ \text{mL}$$

Dimensional Analysis

$$mL = \frac{1\ mL}{1\ \cancel{mg}} \times \frac{1000\ \cancel{mg}}{1\ \cancel{g}} \times \frac{38\ \cancel{mg}}{x}$$

$$x = 38\ \text{mL}$$

Answer: The nurse will administer 38 mL of CISplatin intravenously.

3. Calculating a pediatric dose based on BSA using the West nomogram and the square root method is illustrated below:
   Ordered: Vincristine 2 mg per m^2 today
   Available: Vincristine 1 mg per mL

How many milliliters will the nurse administer?

This pediatric patient's height and weight fall within the normal percentiles. The child weighs 44 lb (20 kg).

a. Using the center column on the West nomogram, the child's BSA is *0.8* m^2.

b. Use the square root method to calculate BSA using inches and pounds if the child is 36 inches tall.

$$\text{BSA} = \sqrt{\frac{36\text{ in} \times 44\text{ lb}}{3131}} = \sqrt{\frac{1584}{3131}} = \sqrt{0.51}$$

$$= 0.71\ \text{m}^2$$

(Rounding numbers to the hundredth place is common when calculating pediatric dosages.)

c. Use the square root method to calculate BSA using centimeters and kilograms.

$$\text{BSA} = \sqrt{\frac{91.4\ \text{cm} \times 20\ \text{kg}}{3600}} = \sqrt{\frac{1828}{3600}} = \sqrt{0.51}$$

$$= 0.71\ \text{m}^2$$

d. The more precise number, 0.71 m^2, will be used to calculate the drug dosage.

Basic Formula

e. Determine desired dose based on the above BSA.

f. The desired dose is calculated by multiplying 2 mg with 0.71 m^2 to get 1.42 mg.

g. Solve for the desired unit of measure.

$$\frac{D}{H} \times V$$

$$\frac{1.42\ \cancel{\text{mg}}}{1\ \cancel{\text{mg}}} \times 1\ \text{mL}$$

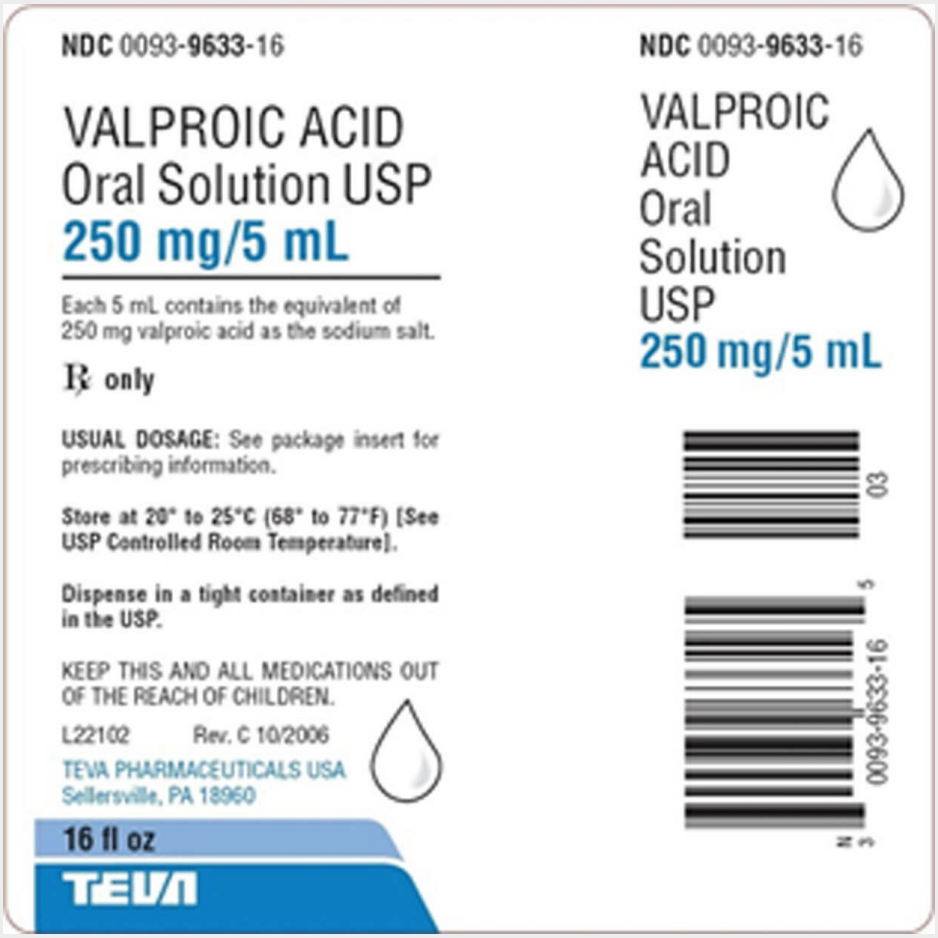
$$= 1.4\ \text{mL}$$

The dose was rounded to the tenth place to accommodate the calibrations on a syringe.

Dimensional Analysis

h. Determine BSA (we will use the calculated BSA from above, 0.71 m^2).
i. Solve for the desired unit of measure.

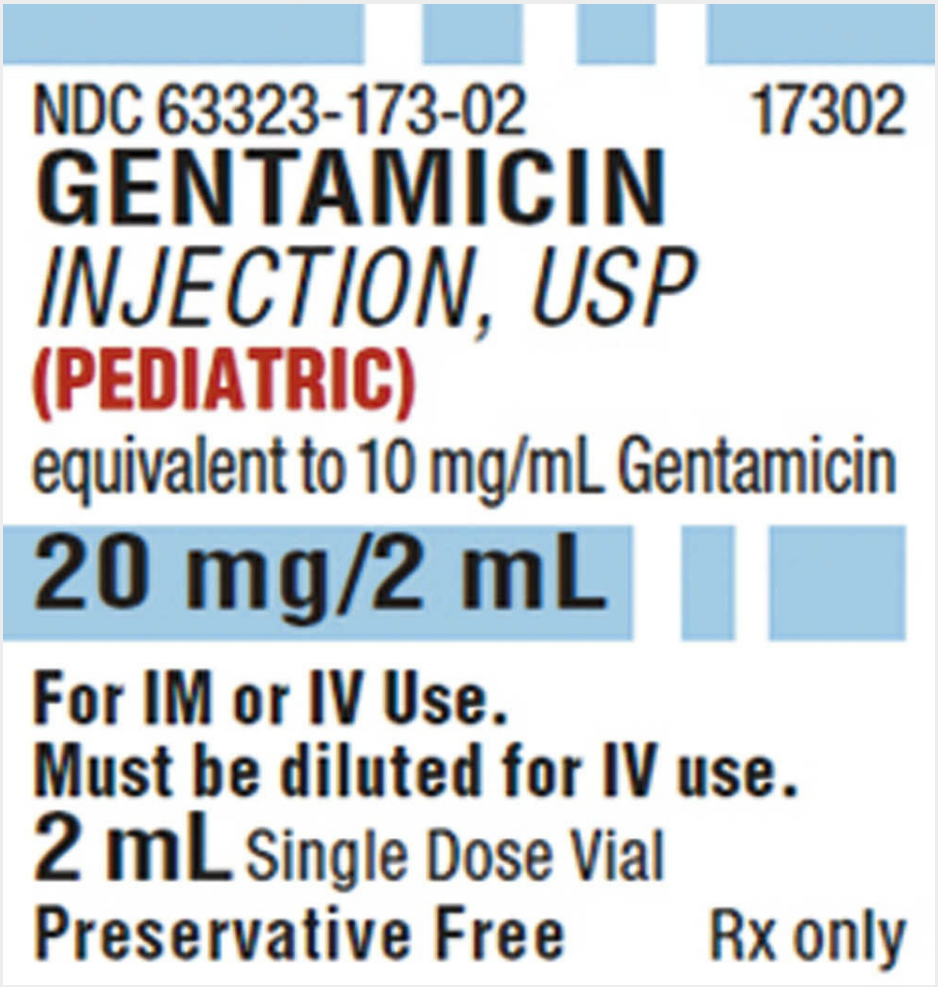
$$mL = \frac{1\ mL}{1\ \cancel{mg}} \times \frac{2\ \cancel{mg}}{1\ \cancel{m^2}} \times \frac{0.71\ \cancel{m^2}}{x}$$



$$= 1.4\ mL$$

The dose was rounded to the tenth place to accommodate the calibrations on a syringe.

Practice Problems



Calculating Dosages Based on Body Weight

1. Order: Valproic acid oral solution PO 15 mg per kg per day in two divided doses for a pediatric patient who weighs 66 lb
   Available: Valproic acid oral solution 250 mg per 5 mL

a. How many kilograms does the child weigh? _____
b. How many milligrams per *day* should the child receive? _____
c. How many milligrams per *dose* should the child receive? _____
d. How many *milliliters* per dose should the child receive? _____

2. Order: Gentamicin 2.5 mg per kg q8h IM for a pediatric patient who weighs 33 lb
Available: Gentamicin 10 mg per mL

a. How many kilograms does the child weigh? _____
b. How many milligrams per dose will the child receive? _____
c. How many milliliters per dose will the child receive? _____

Practice Problems

Calculating Dosages Based on Body Surface Area—Square Root Method

1. Order: Carboplatin 300 mg per m^2 per intravenous (IV) infusion today for a patient 66 inches tall who weighs 176 lb
   Available: Carboplatin 10 mg/mL

a. Use the square root method to determine the patient's square meters based on inches and pounds.
b. What is the dosage in milligrams? _____
c. How many milliliters will the patient receive? _____

2. Order: Fluorouracil 350 mg per m^2 per day IV for a patient 164 cm tall who weighs 66.8 kg.
a. Use the square root method to determine the patient's square meters based on centimeters and kilograms.
b. How many milligrams would the patient receive? _____

Answers to Practice Problems

Reading Drug Labels

1.
   a. Lisinopril and hydrochlorothiazide
   b. There is no trade name
   c. No
   d. Lisinopril 10 mg; hydrochlorothiazide 12.5 mg per tablet
   e. 30 tablets
   f. At room temperature (68° to 77° F)
2.
   a. Furosemide
   b. Lasix
   c. No
   d. 40 mg per tablet
   e. 100 tablets
   f. Room temperature (59° to 86° F)
3.
   a. Hydromorphone
   b. Dilaudid
   c. Yes, Schedule II
   d. 1 mg per mL (oral)
   e. 473 mL = 473 mg
   f. Room temperature (59° to 86° F)

Enteral and Parenteral Drugs

All answers will be shown using dimensional analysis.

1. $\text{tab} = \frac{1\text{tab}}{75\cancel{\text{mg}}} \times \frac{150\cancel{\text{mg}}}{x} = 2\text{tabs}$
2. $\text{cap} = \frac{1\text{cap}}{100\cancel{\text{mg}}} \times \frac{100\cancel{\text{mg}}}{x} = 1\text{cap}$
3. $\text{tab} = \frac{1\text{tab}}{2\cancel{\text{mg}}} \times \frac{2\cancel{\text{mg}}}{x} = 1\text{tab}$
4. $\text{tab} = \frac{1\text{tab}}{25\cancel{\text{mg}}} \times \frac{12.5\cancel{\text{mg}}}{x} = 0.5\text{ tab}$
5. $\text{mL} = \frac{1\text{mL}}{10\cancel{\text{mg}}} \times \frac{20\cancel{\text{mg}}}{x} = 2\text{ mL}$
6. $\text{mL} = \frac{1\text{mL}}{1\cancel{\text{mg}}} \times \frac{0.4\cancel{\text{mg}}}{x} = 0.4\text{ mL}$
7. $\text{mL} = \frac{15\text{ mL}}{10\cancel{\text{g}}} \times \frac{20\cancel{\text{g}}}{x} = 30\text{mL}$
8. $\text{mL} = \frac{5\text{ mL}}{125\cancel{\text{mg}}} \times \frac{1000\cancel{\text{mg}}}{1\text{ g}} \times \frac{0.25\text{ g}}{x} = 10\text{ mL}$
9.
   a. $\text{mL} = \frac{1\text{ mL}}{5000\cancel{\text{units}}} \times \frac{7500\cancel{\text{units}}}{x} = 1.5\text{ mL}$
   (Note that units is spelled out rather than using only U, which could be mistaken for a zero.)
   b. $\text{mL} = \frac{1\text{ mL}}{5000\cancel{\text{units}}} \times \frac{3500\cancel{\text{units}}}{x} = 0.7\text{ mL}$
   (Note "units" is spelled out rather than using "U," which could be mistaken for a zero.)
   c. 1.5 mL + 0.7 mL = 2.2 mL, so 2 vials are needed
10.
   a. 4.2 mL
   b. 50 mg per mL

c. $mL = \frac{1\ mL}{350\ \cancel{mg}} \times \frac{1000\ \cancel{mg}}{1\ g} \times \frac{1.5\ g}{x} = 4.28$
= 4.3 mL per rounding rule(administer in two separate injections)

Calculating Dosages Based on Body Weight

1.
a. 66 lb ÷ 2.2 = 30 kg
b. 15 mg × 30 kg = 450 mg/day
c. 450 mg ÷ 2 = 225 mg/dose
d. $mL = \frac{5\ mL}{250\ \cancel{mg}} \times \frac{225\ \cancel{mg}}{x} = 4.5mL$

Dimensional analysis

$$mL = \frac{5\ mL}{250\ \cancel{mg}} \times \frac{15\ \cancel{mg}}{1\ \cancel{kg}} \times \frac{1\ \cancel{kg}}{2.2\ \cancel{lb}} \times \frac{66\ \cancel{lb}}{2\ dose} = 4.5mL/dose$$

2.
a. 33 lb ÷ 2.2 = 15 kg
b. 2.5 mg × 15 kg = 37.5 mg
c. $mL = \frac{1\ mL}{10\ \cancel{mg}} \times \frac{37.5\ \cancel{mg}}{x} = 3.8\ mL$

Dimensional analysis

$$mL = \frac{1\ mL}{10\ \cancel{mg}} \times \frac{2.5\ \cancel{mg}}{1\ \cancel{kg}} \times \frac{1\ \cancel{g}}{2.2\ \cancel{lb}} \times \frac{33\ \cancel{lb}}{x} = 3.8\ mL$$

Calculating Dosages Based on Body Surface Area—Square Root Method

1.
a. $BSA = \sqrt{\frac{66in \times 176lbs}{3131}} = \sqrt{\frac{11,616}{3131}} = 1.93\ m^2$
b. mg/m^2 = 300 mg × 1.93 m^2 = 579 mg
c. $mL = \frac{1mL}{10\cancel{mg}} \times \frac{300\cancel{mg}}{\cancel{m^2}} \times \frac{1.93\ \cancel{m^2}}{x} = 57.9\ mL$
2. $mg/m^2 = \frac{350mg}{m^2} \times \sqrt{\frac{66.8kg \times 164cm}{3600}} = 610.6mg$

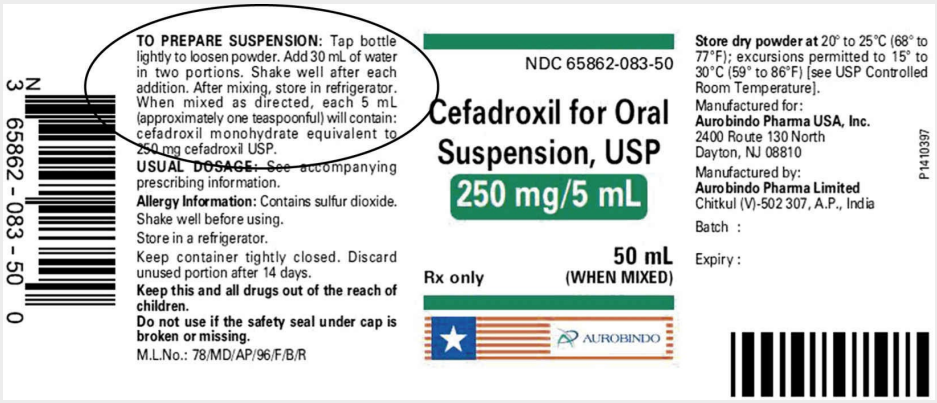
Answers to Practice Problems



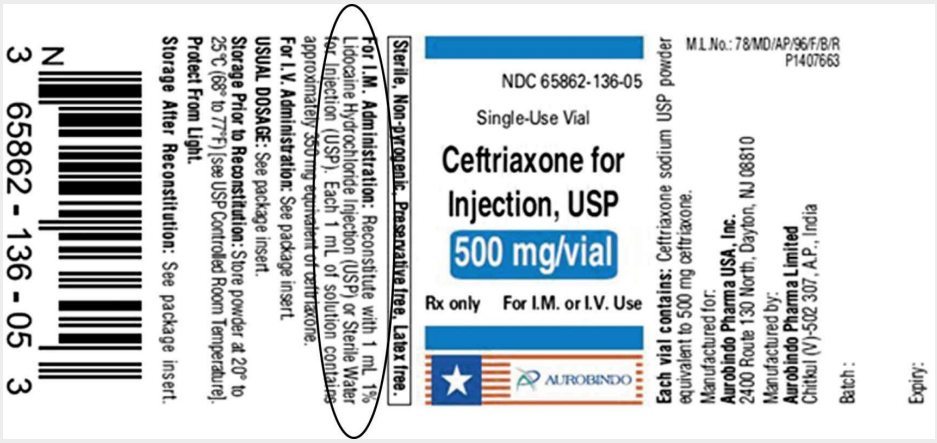
Calculating Suspensions and Solutions

Both enteral and parenteral drugs may come in powder form due to the drug's instability in liquid. The liquid used to reconstitute a dry powder is called a **diluent**. Diluents can be sterile water intended for injection, 0.9% saline solution, or a special liquid supplied by the manufacturer. The nurse must follow directions for reconstitution on the label exactly. Below is a label of an oral preparation that requires reconstitution.

Examples

Drug Reconstitution

1. Below is a label for reconstituting cefadroxil.



Read the left side of the label that says *To Prepare Suspension*. Note that 30 mL of water in two portions is needed to liquefy the powder. This is an oral drug, so drinking water can be used. The nurse is instructed to shake the powder loose to prevent clumping. Add 15 mL of water and shake well. Add another 15 mL of water and shake well. Now that the powder has been reconstituted into a **suspension**, each 5 mL of liquid contains 250 mg of cefadroxil. The entire bottle has 50 mL when mixed, a number that is irrelevant when calculating a dose. Now the equation can be set up for calculation of a dosage.
Order: Cefadroxil oral solution 1 g PO q12h
Available: Cefadroxil oral solution 250 mg per 5 mL
How many milliliters will the nurse administer per dose?

Dimensional Analysis

$$\text{mL} = \frac{5\ \text{mL}}{250\ \cancel{\text{mg}}} \times \frac{1000\ \cancel{\text{mg}}}{1\ \text{g}} \times \frac{1\ \text{g}}{x} = 20\ \text{mL per dose}$$

2. Below is a label of a parenteral drug that requires reconstitution.

Read the left side of the label. For intramuscular (IM) injection, it states to reconstitute with 1 mL of 1% lidocaine hydrochloride (this diluent is sometimes used when a medication is very painful when given IM) *or* 1 mL sterile water for injection. After this preparation is reconstituted and shaken, each milliliter contains 350 mg. The figure *500 mg* in the center of the label is the dose contained in the *whole vial*. If the medication is to be given intravenously, the instructions are written in the package insert. The nurse will need to read the drug insert to determine proper reconstitution for the intravenous (IV) route.

Order: Ceftriaxone 250 mg IM q12h

Available: Ceftriaxone 350 mg per 1 mL

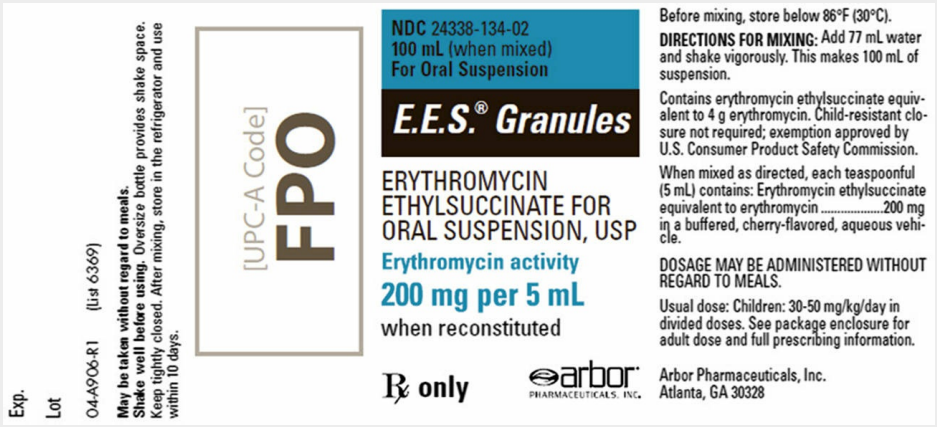
How many milliliters will the nurse administer per dose? _____

How many milliliters will be administered every 24 hours? _____

Dimensional Analysis

$$\text{mL/dose} = \frac{1\ \text{mL}}{350\ \cancel{\text{mg}}} \times \frac{250\ \cancel{\text{mg}}}{x} = 0.7\ \text{mL/dose}$$

(rounded to the nearest tenth)



$$\text{mL/d} = \frac{1\ \text{mL}}{350\ \cancel{\text{mg}}} \times \frac{250\ \cancel{\text{mg}}}{x} \times \frac{24\ \cancel{\text{h}}}{1\ \text{day}} \times \frac{1}{12\ \cancel{\text{h}}}$$

$$= 1.4\ \text{mL/d (rounded to the nearest tenth)}$$

Practice Problems

Drug Reconstitution

1.

a. How many milliliters of diluent are needed?
b. What is the final concentration?
c. How many milliliters are administered for an order to give 500 mg?

2.

a. How many milliliters of diluent are needed for initial mixing?
b. How many total milliliters of diluent are used?
c. What is the final concentration for each drug?
d. How many milliliters are administered to give amoxicillin 500 mg/clavulanate 125 mg?

Considerations when Calculating Dosages of Oral Drugs

Most drugs are administered orally. Oral drugs are available in tablet, caplet, capsule, powder, and liquid forms. Oral medications are absorbed by the gastrointestinal (GI) tract, mainly from the small intestine.

Oral medications have several advantages: (1) the patient can often take oral medications without assistance, (2) the cost of oral medications is usually less than that of parenteral preparations, and (3) oral medications are easy to store. The disadvantages include (1) variation in absorption as a result of food in the GI tract and pH variation of GI secretions, (2) irritation of the gastric mucosa by certain drugs (e.g., potassium chloride), and (3) destruction or partial inactivation of the drugs by liver enzymes. Oral drugs (tablets, capsules, liquids) that may irritate the gastric mucosa should be taken with 6 to 8 ounces of fluids or should be taken with food.

Tablets, Capsules, and Liquids

Tablets come in different forms and drug strengths. Many tablets are scored and thus can be readily broken when half of the drug amount is needed. **Capsules** are gelatin shells that contain powder or timed-release pellets (beads). Capsules that are **sustained release** (pellet) or controlled release *should not* be crushed and diluted because the medication will be absorbed at a much faster rate than indicated by the manufacturer. Many medications sold in tablet form are also available in liquid form. When the patient has difficulty taking tablets, the oral liquid form of the medication is given. The liquid form can be in a suspension, syrup, elixir, or tincture. Some liquid medications that irritate the stomach, such as potassium chloride, are diluted. The tincture form is always diluted.

Tablets that are **enteric coated** (with a hard shell) must *not* be crushed because the medication could irritate the gastric mucosa. Enteric-coated drugs pass through the stomach into the small intestine where the drug's enteric coating dissolves, and then absorption occurs. Fig. 11C.1 shows the different forms of tablets and capsules.

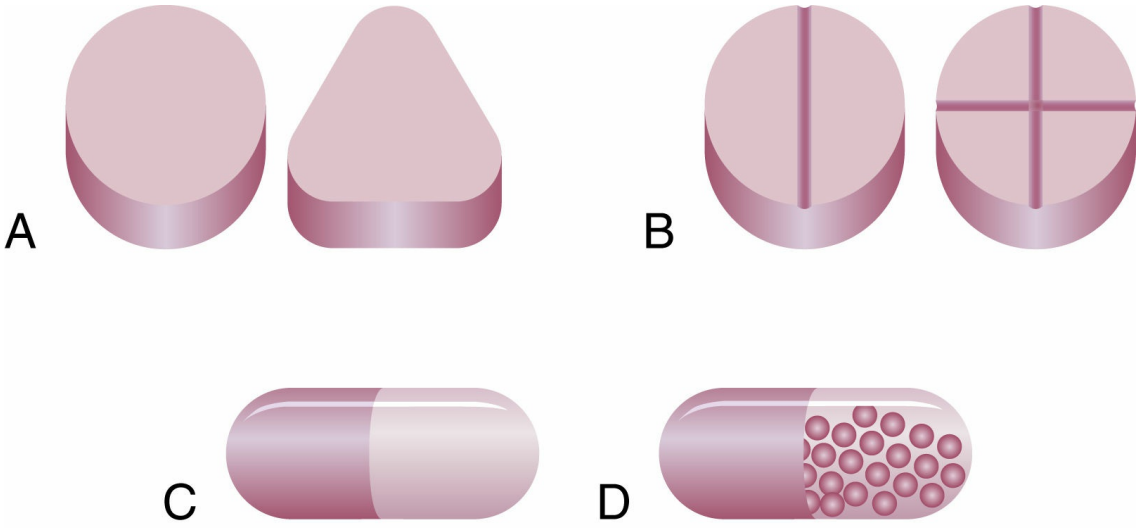


FIG. 11C.1 Shapes of Tablets and Capsules.

Liquid medications are poured into a medicine cup that is calibrated (i.e., ounces, teaspoons, tablespoons, and milliliters). Fig. 11C.2 shows the markings on a medicine cup.

Drugs Administered via Nasogastric Tube

Oral medications can be administered through a nasogastric or other feeding tube for enteral

administration. If the patient is receiving a **tube feeding**, the drug should *not* be mixed with the feeding solution**.** Mixing the medications in a large volume of tube feeding solution decreases the amount of drug the patient receives for a specific time. The medication (but *not* timed-release or sustained-release capsules and psyllium hydrophilic mucilloid) should be diluted in 15 to 30 mL of water or other desired fluid unless otherwise instructed. The medication is administered through the tube via a syringe, followed by another 15 to 30 mL of water to ensure that the drug reaches the stomach and is not left in the tube. Check the policy at your institution.

Considerations when Calculating Dosages of Parenteral Drugs

When medications cannot be taken by mouth because of (1) an inability to swallow, (2) a decreased level of consciousness, (3) an inactivation of the drug by gastric juices, or (4) a desire to increase the effectiveness of the drug, the parenteral route may be the route of choice. **Parenteral** medications are administered under the skin (intradermally [ID]), into the fatty tissue (subcutaneously [subcut]), within the muscle (intramuscularly [IM]), or in the vein (intravenously [IV]). IV preparations are discussed in Section 11E.

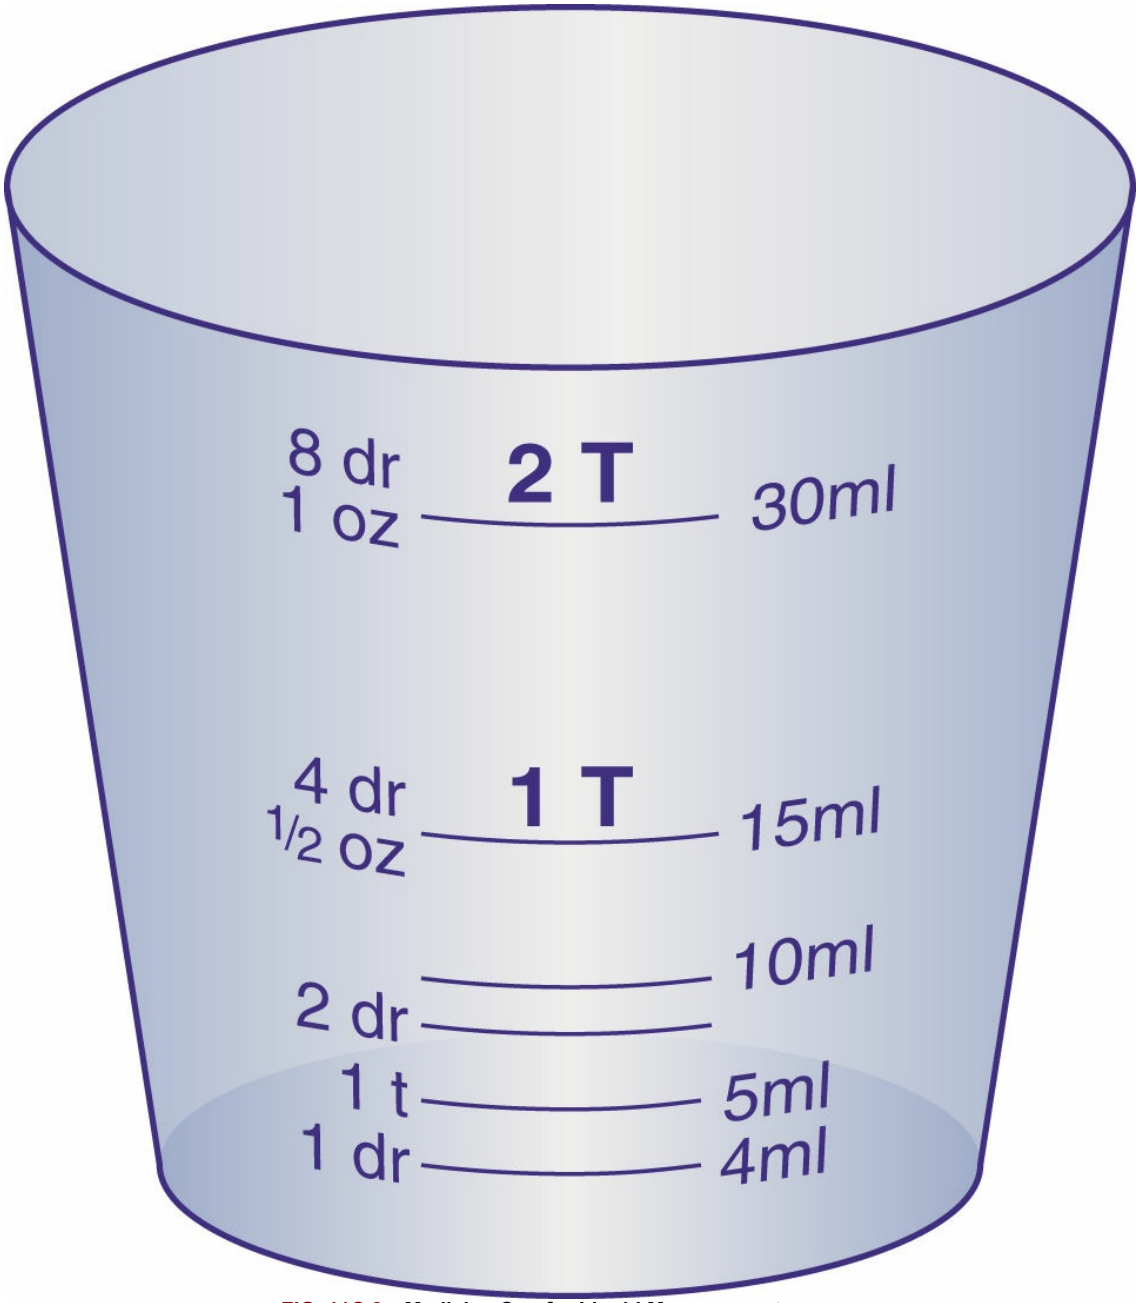

FIG. 11C.2 Medicine Cup for Liquid Measurement.

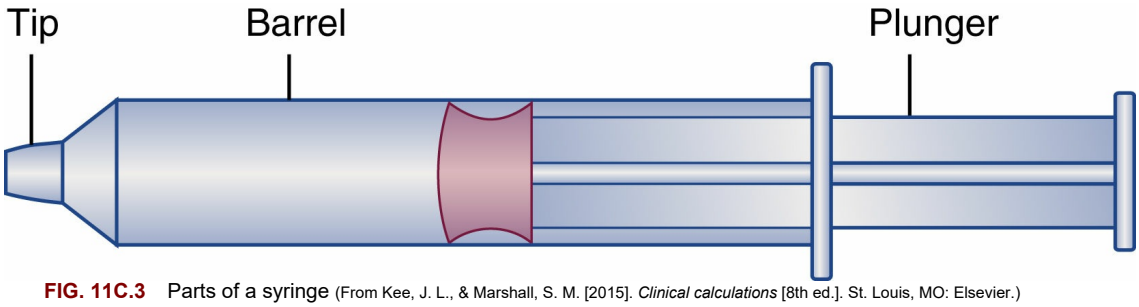

FIG. 11C.3 Parts of a syringe (From Kee, J. L., & Marshall, S. M. [2015]. *Clinical calculations* [8th ed.]. St. Louis, MO: Elsevier.)

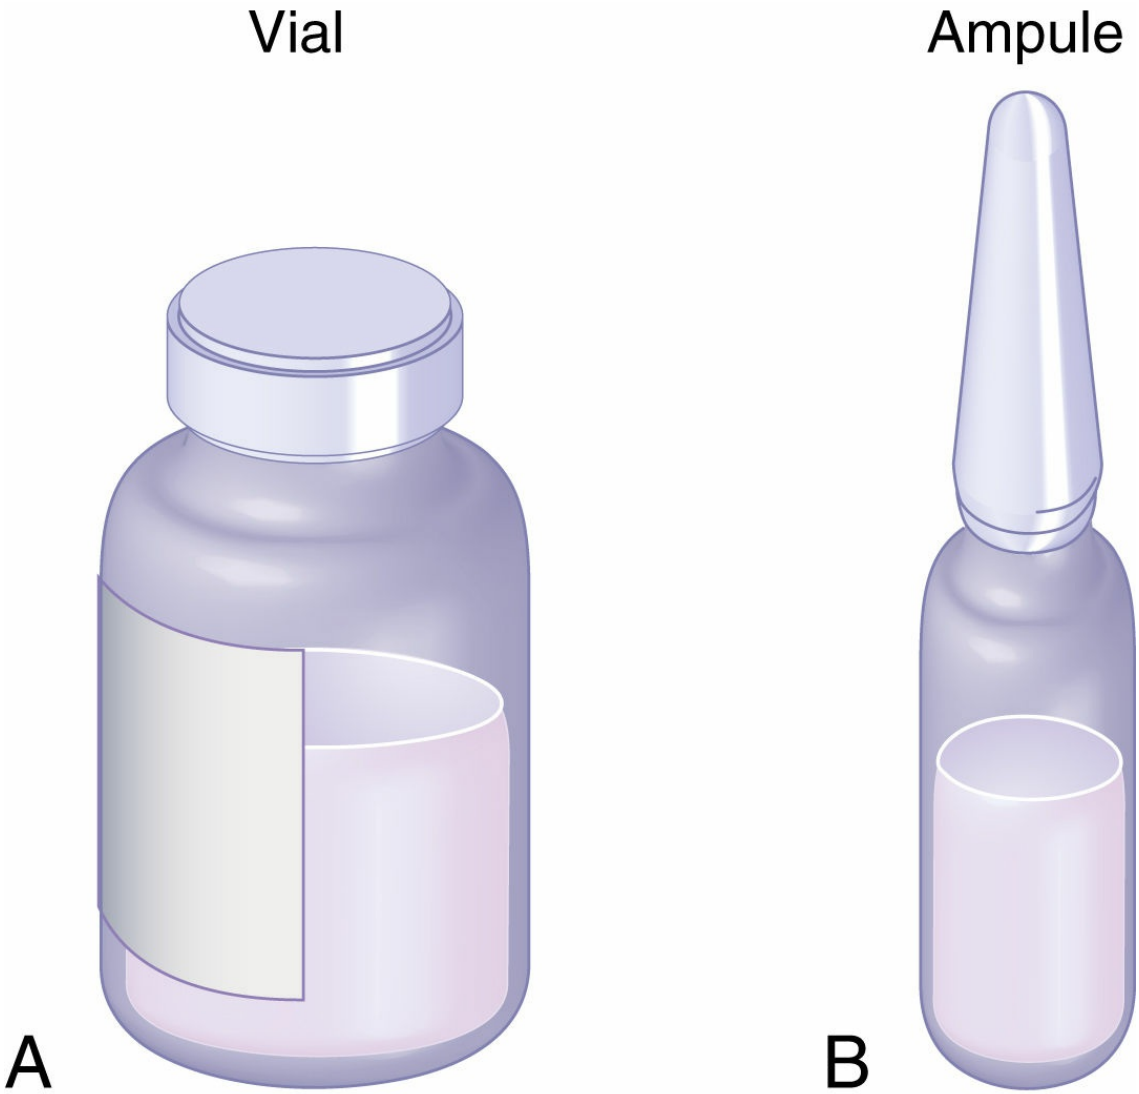

FIG. 11C.4 Vial and Ampule.
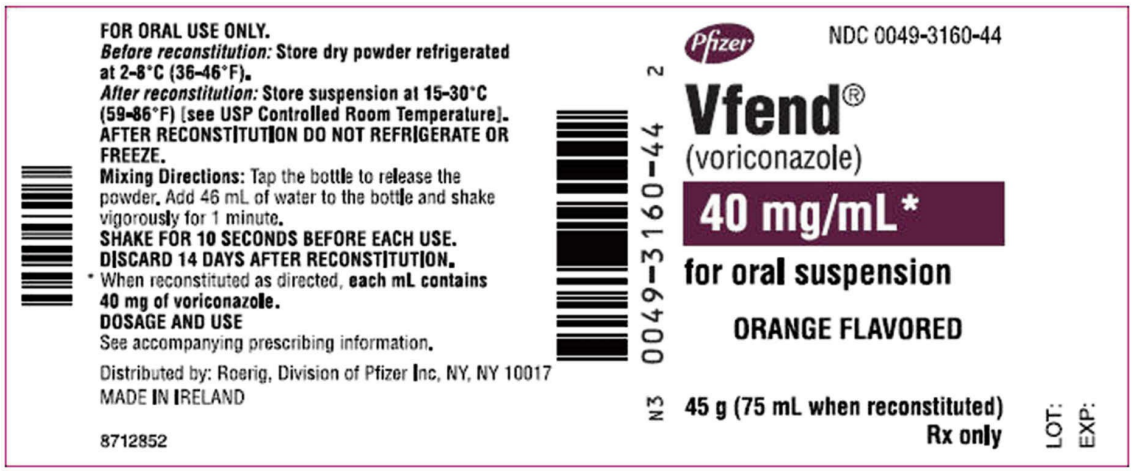
(From Kee, J. L., & Marshall, S. M. [2013]. *Clinical calculations* [7th ed.]. St. Louis, MO: Elsevier.)

Injectable Preparations



The appropriate drug container (vial or ampule) and the correct selection of needle and syringe are essential in the preparation of the prescribed drug dose. The route of administration is part of the medication order.

Syringes

The **syringe** is composed of a barrel (outer shell), plunger (inner part), and the tip where the needle joins the syringe (Fig. 11C.3). Syringes are available in various types and sizes, including tuberculin and insulin syringes. Syringes prefilled with drugs may be glass, plastic, or metal. The tip of the syringe, inside of the barrel, and the plunger should remain sterile.

Vials and Ampules

A **vial** is usually a small glass vacuum container with a self-sealing rubber top. Some are multiple-dose vials, and when properly stored, they can be used over time. An **ampule** is a glass container with a tapered neck for snapping open and using only once. Caution is advised when snapping an ampule to prevent skin laceration. Also, glass fragments can occur, therefore a filter needle must be used to withdraw medication. Fig. 11C.4 shows a vial and an ampule. Drugs that deteriorate readily in liquid form are packaged in powder form in vials for storage. Once the dry form of the drug is reconstituted (usually with sterile or bacteriostatic water or 0.9% saline), the drug is used immediately or must be refrigerated. Check the accompanying drug circular for specific storage lengths and other instructions. Once the drug in a multidose vial is reconstituted, the vial should be labeled with the date and time of reconstitution and the initials of the person who reconstituted the drug. The shelf life of a reconstituted drug is determined by the manufacturer and can be found on the drug label.

Drug labels on vials and ampules provide the (1) generic and brand name of the drug; (2) drug dose in weight (in milligrams [mg], grams [g], or milliequivalents [mEq]) and volume (milliliters [mL]); (3) expiration date; and (4) directions for administration. If the drug is in powdered form, mixing instructions and dose equivalents (e.g., milligrams per milliliter) may be given.

Answers to Practice Problems

Drug Reconstitution

1.
   a. 77 mL
   b. 200 mg per 5 mL
   c. $mL = \frac{5mL}{200\cancel{mg}} \times \frac{500\ \cancel{mg}}{x} = 12.5\ mL$

2.
   a. $65 \div 3 = 21.6 \times 2 = 43.3mL \left(\frac{2}{3}\text{ of } 65\ mL\right)$
   b. 65 mL
   c. Amoxicillin 250 mg and Clavulanic acid 62.5 mg per 5 mL
   d. $Amoxicillin: mL = \frac{5mL}{250\cancel{mg}} \times \frac{500\cancel{mg}}{xmL} = 10mL$

$Clavulanic acid: mL = \frac{5mL}{62.5\cancel{mg}} \times \frac{125\cancel{mg}}{xmL} = 10mL$

   (Note that the amoxicillin and clavulanic acid were both 10 mL, therefore a total of 10 mL will be given for a 500 mg/250 mg dose.)

SECTION 11D

Calculation Methods—Insulin Dosages

KEY TERMS

tuberculin syringe, p. 137
units, p. 137

Objectives

- Discuss the difference between syringes calibrated in units and milliliters.
- Identify the different types of insulin syringes.
- Calculate drug dosages in units.
- Correlate the dosages in units with the appropriate syringe.

OUTLINE

Drug Calculation in Units
    Practice Problems: Insulin
Answers to Practice Problems

Drug Calculation in Units

Drugs are most commonly measured in grams, milligrams, or micrograms. However, some are measured in **units**. This includes insulin and heparin. Typically, units are not converted to any other measure. Heparin infusions are discussed in Section 11E.

Insulin is prescribed and measured in U.S. Pharmacopeia (USP) units. Most insulins are produced in concentrations of 100 units per mL. Insulin should be administered with an insulin syringe, which is calibrated to correspond with the concentration of 100 units of insulin per mL in the vial. For example, if the prescribed insulin dosage is 30 units, using an insulin syringe calibrated to 100 units per mL, withdraw insulin from the vial to the 30-unit mark (Fig. 11D.1). ❗ *(Note that 30 units is* not *interchangeable with 30 mL or 0.3 mL.)*

U-100 insulin syringes are available in various sizes, such as low-dose insulin syringes that hold a total of 0.3 mL or 0.5 mL. The size of the insulin syringe does not alter the calibration of 100 units per mL. The U.S. Food and Drug Administration (FDA) has now approved a U-500 insulin syringe specifically dedicated to be used with regular U-500 insulin. The U-100 and U-500 insulin syringes are *not* interchangeable. Some insulin is available in insulin pen injectors and insulin pumps. These are further illustrated in Chapter 47.

Administering insulin with a tuberculin syringe should be *avoided.* Although both syringes have 1 mL capacities, the **tuberculin syringe** is calibrated in milliliters rather than units. It is critical that the correct type and dose of insulin is administered to avoid severe aberrations of the patient's blood glucose. Chapter 47 provides information on the different types of insulin.

Calculating Critical Care Drugs

Answers to Practice Problems

Intravenous Therapy

Intravenous (IV) therapy is used to administer fluids that contain water, dextrose, vitamins, electrolytes, and drugs. Today an increasing number of drugs are administered by the IV route for direct absorption and fast action. Methods of IV administration include intermittent bolus; **IV push (IVP)**, usually with a syringe; intermittent infusions; **IV piggyback (IVPB)**; and continuous infusions. Drugs given IVP are usually small in volume and are administered over a few seconds to a few minutes. Medications administered by this route have a rapid onset of action, and calculation errors can have serious and even fatal consequences. The nurse must read drug inserts carefully to obtain administration information and must give attention to the amount of drug that can be given per minute. If the drug is pushed into the bloodstream at a rate faster than that specified in the drug literature, adverse reactions can occur.

IVPBs contain a larger volume of diluent and are administered over a longer period (e.g., 30 minutes, 1 hour, 3 hours). Continuous infusions, referred to as **primary IV fluid**, flow continuously until the container of solution is changed or the order for the infusion is stopped.

Many IV drugs irritate the veins, therefore they are diluted prior to administration. The amount of diluent used depends on the drug; drugs given by IVP can be diluted in small amounts of diluent, whereas other drugs are diluted in a large volume of fluid given over a specific period, such as 4 to 8 hours. Continuous IV infusion replaces fluid loss, maintains fluid balance, and serves as a vehicle for IV drugs.

The current trend in IV medication administration is the use of premixed IV drugs in 50- to 500-mL containers. These premixed IV medications are prepared by the manufacturer or by the hospital pharmacy. The problems of contamination and drug errors are decreased with the use of premixed IV medications. Each IV solution container has separate tubing to prevent admixture. With the use of premixed IV solution containers, the cost is higher, but the risk of medication error is lower. Because not all medication can be premixed in the solution, nurses will continue to prepare some drugs for IV administration.

Nurses have an important role in the preparation and administration of IV solutions such as 0.9% sodium chloride (normal saline, [NS]), 0.45% sodium chloride (½NS), 5% dextrose in water (D_5W), and Lactated Ringer's solution (LR) and also IV drugs. Chapter 12 further discusses different types of IV solutions. The nursing functions and responsibilities during IV preparation include the following:

- Gathering equipment
- Knowing IV sets, including drop factors
- Calculating appropriate IV flow rates
- Mixing and diluting drugs in IV fluids
- Knowing the pharmacokinetics and pharmacodynamics of drugs and their adverse effects

Nursing responsibilities continue with assessment of the patient for expected outcomes and adverse effects of the therapy in addition to assessment of the IV site. The nurse calculates the **IV flow rate** according to the IV tubing's drop factor, the volume of fluids to be administered, the length of time for infusion, and whether an electronic infusion device will be used. IV infusions are ordered to be delivered in some unit of measure over time (e.g., mL/h, mcg/kg/min, unit/h, drops per minute [gtt/min]). Nurses calculate the rate of infusion in milliliters per hour when using an electronic infusion device. If the nurse needs to manually regulate the rate, the flow rate is calculated in drops per minute. The type and size of IV administration tubing must be known when calculating drops per minute.

FIG. 11E.1 Intravenous Infusion Sets.
(From Morris, D. G. [2014]. *Calculate with confidence* [6th ed.]. St. Louis, MO: Elsevier.)

Intravenous Administration Sets

IV administration sets (Fig. 11E.1) include printed information on the packaging cover, such as the **drop factor**, or the number of drops per milliliter (Fig. 11E.2). A set that delivers large drops (10 to 20 gtt/mL) is a **macrodrip set**, and one that delivers small drops (60 gtt/mL) is a **microdrip (minidrip) set** (see Fig. 11E.2). A macrodrip IV set is commonly used for adults, and a microdrip IV set is used when small amounts of drug or more precise administration is warranted.

At times, primary IV fluids are given at a slow rate, ordered to **keep vein open (KVO)**, also called **to keep open (TKO).** The reasons for KVO include a suspected or potential emergency situation for rapid administration of fluids and drugs and the need for an open line to give IV drugs at specified hours. For KVO, a microdrip set (60 gtt/mL) and a 250-mL IV solution bag may be used. KVO is usually regulated to deliver 10 to 30 mL/h.

Drugs prescribed as IVPB (Fig. 11E.3) are administered via separate tubing for IV drugs, the **secondary IV line set**, which is connected into a port (rubber stopper) on the IV connector on the continuous or **primary IV line set**; the port should be above the IV pump.

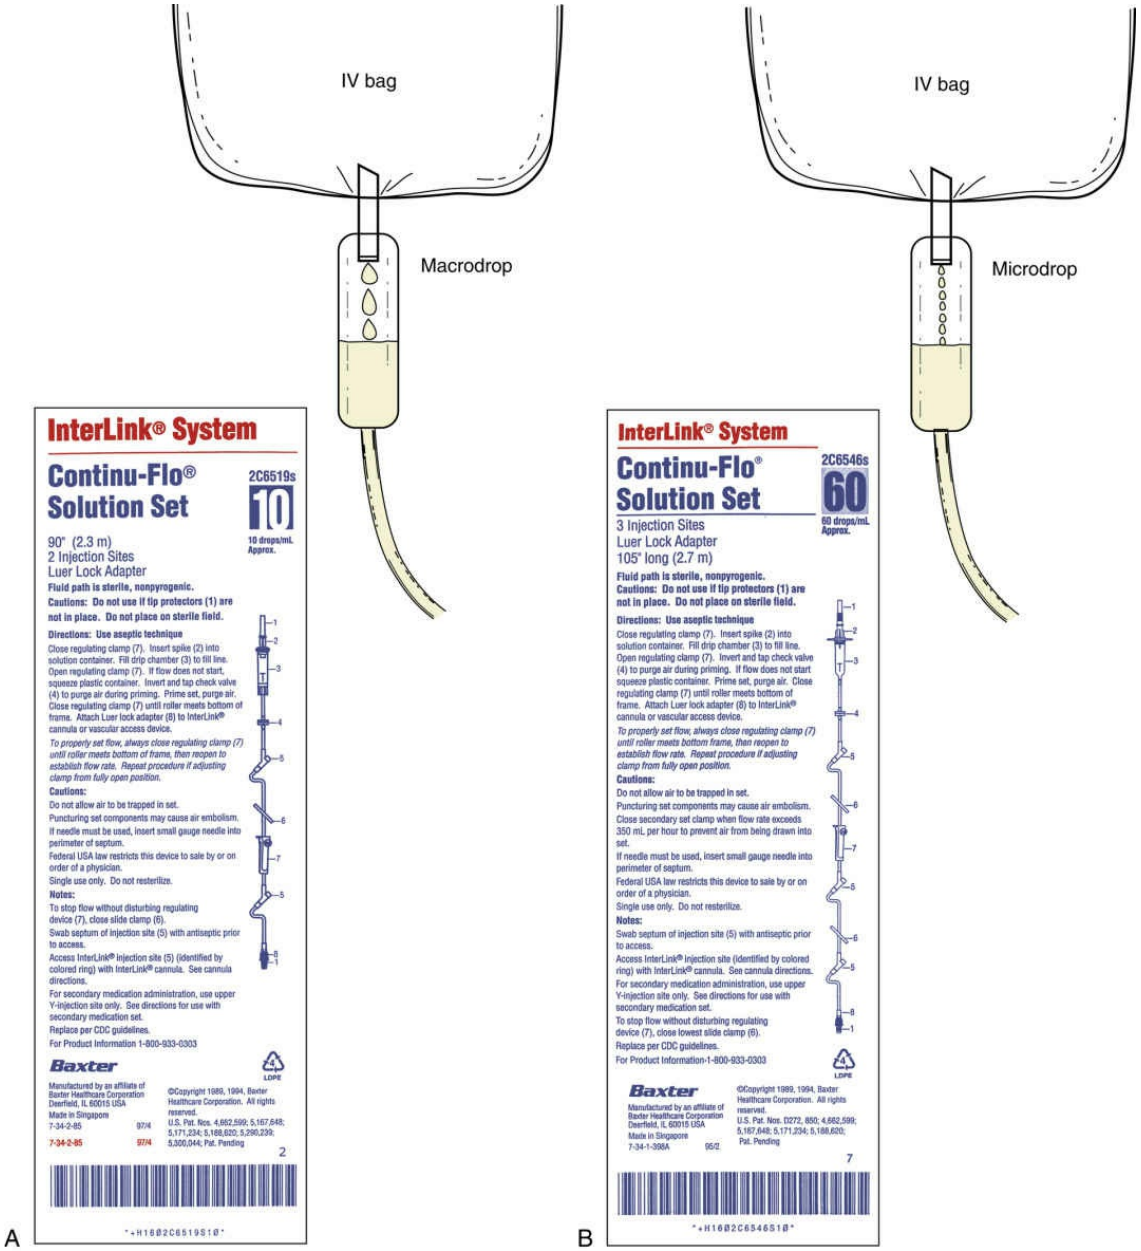

FIG. 11E.2 Macrodrip and Microdrip Intravenous Sets.
(From Morris, D. G. [2014]. *Calculate with confidence* [6th ed.]. St. Louis, MO: Elsevier.)

Secondary Intravenous Administration Sets

Two secondary IV administration sets available to administer IV drugs are the calibrated cylinder (volume-controlled chamber) with tubing (Fig. 11E.4)—such as the Buretrol, Volutrol, and Soluset—and the secondary IV set, which is similar to a regular IV set except the tubing is shorter. The cylinder can be used with a primary or secondary line and when measurement of small-volume IV therapy needs to be more accurate, such as in pediatric or critical care settings. The volume-controlled chamber holds up to 150 mL of solution. The secondary IV line set is primarily used to **piggyback** onto a primary line (IVPB). The cylinder and some secondary IV tubing contain a port to inject medications.

When using a calibrated cylinder, such as the Buretrol, add 15 mL of IV solution, such as 0.9% sodium chloride, to flush the drug out of the IV line after the drug infusion is completed. The flush volume is added to the patient's intake. Check hospital policy for guidance.

Intermittent Infusion Adapters and Devices

When continuous IV infusion is to be discontinued but the patient still requires IV access, the IV tubing is removed and a saline lock is attached. Saline locks have ports (stoppers) where needles and needleless or IV tubing can be inserted as needed to continue drug therapy. The use of a saline lock increases the patient's mobility by not having an IV line tagging along, and it is cost effective because less IV tubing, solution, and equipment are needed. Fig. 11E.5 shows examples of needleless infusion devices.

Electronic Infusion Devices

Pumps are **electronic intravenous devices** used in hospitals and some community settings. Such IV pumps are set to deliver a prescribed rate of volume. IV pumps deliver IV solution against resistance. If the flow is obstructed, an alarm sounds, however the alarm does not sound until the pump has exerted its maximum pressure to overcome resistance. Pumps do not recognize infiltration, therefore the nurse must frequently assess the IV site. When an electronic IV device is used, the flow rate is set in milliliters per hour (mL/h).

IV pumps are recommended for use with all IV therapy, however some noncritical IV solutions and drugs can be administered using gravity by manually calculating drops per minute. Ongoing nursing assessment is essential with any IV therapy to ensure proper duration of administration.

Several electronic infusion devices are available that include electronic volumetric pumps (IV pumps), syringe pumps, and **patient-controlled analgesia (PCA)** devices. Fig. 11E.6 shows a variety of electronic IV regulators for the administration of IV solutions and drugs. Part A shows a syringe pump, part B shows a single-channel infusion pump, and part C shows a dual-channel infusion pump. Part D shows a PCA pump, part E shows the Alaris System large-volume pump with PCA, and part F shows the Medley pump module attached to the Medley programming module.

(From Morris, D. G. [2014]. *Calculate with confidence* [6th ed.]. St. Louis, MO: Elsevier.)

Safety Considerations for Intravenous Infusions

All IV infusions and sites should be checked frequently. Common problems associated with IV infusions are kinked tubing, infiltration, and so-called free-flow IV rates. If IV tubing kinks, the flow is interrupted and the prescribed amount of fluid will not be given. The access site can also clog, which obstructs the flow. When **infiltration** occurs, IV fluid extravasates into the tissues and not into the vascular space. Trauma occurs to the tissues around the IV site. A **free-flow** IV rate refers to a rapid infusion of IV fluids that is faster than prescribed, which can cause fluid overload due to rapid infusion. Because of the possibility of a free-flow IV rate, electronic infusion pumps with multiple safety features are commonly used today.

Electronic infusion pumps are not without flaws, and mechanical problems can occur. Also, incorrectly programming an infusion pump can result in an incorrect infusion rate. Frequent monitoring of IV infusions can prevent complications of IV therapy such as fluid overload, thrombus formation, and infiltration.

PCA is another method used to administer drugs intravenously (see Fig. 11E.6). The objective of PCA is to provide a uniform serum concentration of the medication, thus avoiding drug peaks and valleys. This method is designed to meet the needs of patients who require at least 24 to 48 hours of frequent intramuscular (IM) or IV narcotic injections.

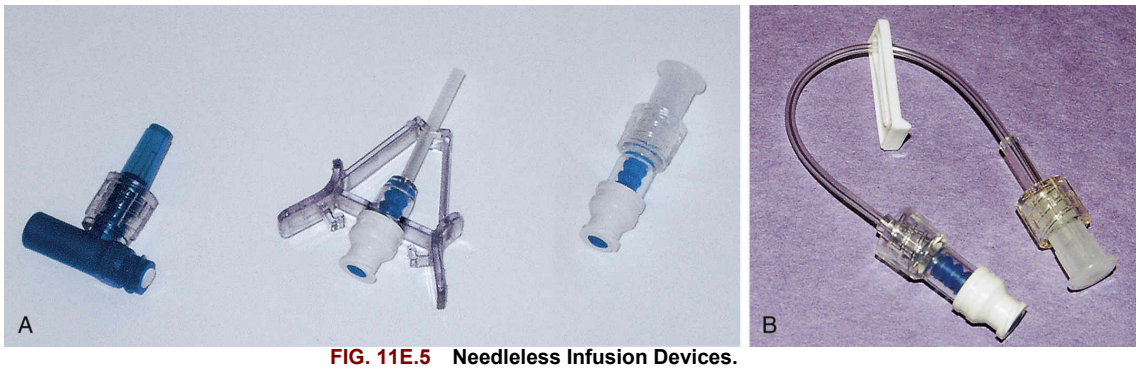

FIG. 11E.5 Needleless Infusion Devices.

(From Kee, J. L., & Marshall, S. M. [2013]. *Clinical calculations* [7th ed.]. St. Louis, MO: Elsevier.)

FIG. 11E.6 Electronic Infusion Devices.
A, Syringe pump. **B,** Single-channel infusion pump. **C,** Dual-channel infusion pump. **D,** Patient-controlled analgesia (PCA) pump. **E,** Alaris System large-volume pump with PCA. **F,** Medley pump module attached to Medley programming module. (From Kee, J. L., & Marshall, S. M. [2013]. *Clinical calculations* [7th ed.]. St. Louis, MO: Elsevier.)

Several reasons for the use of PCA include (1) effective pain control without the patient feeling oversedated, (2) considerable reduction in the amount of narcotic used (approximately one half that of IM delivery), and (3) patients' feelings of having greater control over their pain.

Choices are available in the delivery of PCA. The pump can be programmed to administer the prescribed medication (1) at patient demand, (2) continuously, or (3) continuously and supplemented by patient demand (see Chapter 25).

The health care provider's order must include the following:

- Drug ordered
- Loading dose, administered by the health care provider to obtain a baseline serum concentration of analgesic
- PCA dose, administered each time the patient activates the button
- Lockout interval, the time during which the drug cannot be administered
- Dose limit, the maximum amount the patient can receive during a specified time

Patient Teaching

- Inform the patient that the pain should be tolerable but not necessarily absent.
- Advise the patient of the pump's safety features, including the alarms.
- Instruct the patient in the use of the control button (medication is administered when the button is *released*).
- Instruct the patient to report any side effects or adverse reactions to the drug.
- Have naloxone, the reversal agent for opioids, easily accessible.
- Instruct patients, family members, and caregivers that the PCA button is to be depressed only by the patient.

Calculating Intravenous Flow Rate: Milliliters Per Hour

Regardless of the method used to determine the rate, the nurse should have the following information before calculating the flow rate: (1) the volume to be infused, (2) the drop factor of the infusion set, and (3) the time frame or how long to infuse the fluid. As with previous drug calculations, the nurse should select one method, be familiar with it, and consistently use it to calculate IV flow rate. When delivering IV drugs via electronic devices, the flow rate is calculated for milliliters per hour (mL/h).

Example

Calculating Milliliters per Hour

1. Order: 500 mL of 0.45% sodium chloride (½NS) to be infused over 8 hours.
What is the flow rate?

Basic Formula

$$\frac{\text{Amount of solution}}{\text{Hours to administer}} = \text{milliliters per hour(mL/h)}$$

$$x\ \text{mL/h} = \frac{500\ \text{mL}}{8\ \text{h}}$$

$$= 62.5\ \text{mL/h}$$

If the infusion pump can be programmed to deliver partial milliliters, set the pump to deliver 62.5 mL/h (round to the nearest tenth); if the infusion pump cannot be set to deliver partial milliliters, the nurse would set the pump to infuse at 63 mL/h (round to the nearest whole number, according to the rounding rule).

Ratio and Proportion/Fractional Equation

$$\frac{\text{Total volume}}{\text{time (h)}} = \frac{x\,\text{mL}}{1\,\text{h}}$$

$$\frac{500\,\text{mL}}{8\,\text{h}} = \frac{x\,\text{mL}}{1\,\text{h}}$$

$$8x = 500$$

$$x = 62.5\,\text{mL/h}$$

Dimensional Analysis

$$\text{mL/h} = \frac{\text{amount of solution}}{\text{time in hours}}$$

(Dimensional analysis for this particular problem is set up similar to the basic formula.)

2. Order: 1000 milliliters of 0.9% sodium chloride (NS) to infuse at 75 milliliters per hour. What is the total infusion time in hours and minutes?

Dimensional Analysis

$$\text{time (h and min)} = \frac{1\,\text{h}}{75\,\cancel{\text{mL}}} \times \frac{1000\,\cancel{\text{mL}}}{x\,\text{time}}$$

$$= \frac{1000}{75} = 13.33 \text{ h; and}$$

$$0.33 \text{ h} \times 60 \text{ min} = 19.8 \text{ min} = 20 \text{ min}$$

Answer: Total infusion time is 13 h and 20 min.

3. Using the total time in example 2 above, what time will the infusion complete if the initial infusion was started at 2:00 PM?
   Convert 2:00 PM to military time (1400 h), then add 13 h and 20 min.

$$1400 + 1320 = 2720 = 3{:}20$$

4. Infuse Lactated Ringer's solution (LR) 1000 milliliters over 12 hours.
   What is the flow rate?
   Answer: $\text{mL/h} = \frac{1000 \text{ mL}}{12 \text{ h}} = 83.3 \text{ mL/h}$
5. D_5 ½NS has been infusing at 125 mL/h.
   After 5½ hours, the IV infiltrated, and the infusion had to be stopped. How many milliliters are left in the IV bag?

Dimensional Analysis

Answer: $\text{If mL} = \frac{125 \text{ mL}}{1 \text{ h}} \times \frac{5.5 \text{ h}}{x \text{ mL}} = 687.5 \text{ mL used,}$
then 1000 mL − 687.5 mL = 312.5 mL left in the bag

Calculating Intravenous Flow Rate: Drops Per Minute

When an electronic device is not used and the nurse manually regulates the IV rate, the nurse must calculate the number of drops per minute (gtt/min). The flow rate in drops per minute is determined by the size of the IV tubing (gtt/mL) as discussed earlier in this chapter. To convert hours to minutes, multiply the hours with 60 minutes.

Example

Calculating Drops per Minute

1. Order: 500 milliliters of 0.45% sodium chloride (½NS) to be infused over 8 hours. IV tubing reads 10 drops per milliliter. What is the flow rate in drops per minute?
   (The question is asking for flow rate with a given drop factor. When drop factor is involved in computing flow rate, solve for drops per minute.)

Basic Formula

$$\text{gtt/min} = \frac{\text{amount of solution in mL} \times \text{gtt factor}}{\text{time in h} \times 60\ \text{min}}$$

$$\text{gtt/min} = \frac{500\ \text{mL} \times 10\ \text{gtt/mL}}{8\ \text{h} \times 60\ \text{min}}$$

$$= 10.4\ \text{gtt/min} = 10\ \text{gtt/min}$$ (A partial drop cannot be administered.)

Ratio and Proportion/Fractional Equation

a. Determine milliliters per hour.
b. Determine drops per minute.

$$\frac{500\ \text{mL}}{8\ \text{h}} = \frac{x}{1\ \text{h}}$$

$$62.5\ \text{mL/h;}\ \text{then}$$

$$\frac{62.5\ \text{mL/h}}{60\ \text{min}} = \frac{x}{10\ \text{gtt/mL}}$$

$$62.5 \times 10 = 60\,x$$

$$x = 10.4\ \text{gtt/min} = 10\ \text{gtt/min}$$

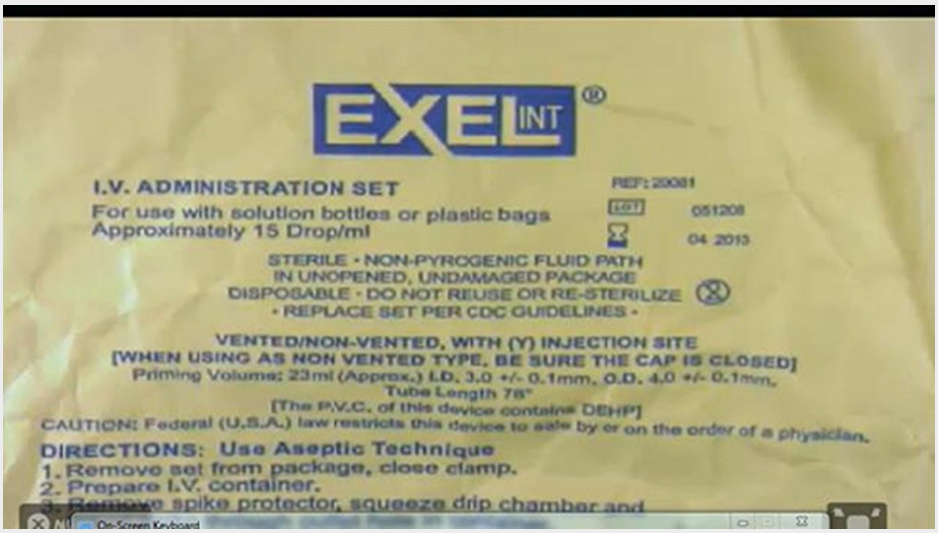
Dimensional Analysis

$$\frac{\text{gtt}}{\text{min}} = \frac{10\ \text{gtt}}{\cancel{\text{mL}}} \times \frac{500\ \cancel{\text{mL}}}{8\ \cancel{\text{h}}} \times \frac{1\ \cancel{\text{h}}}{60\ \text{min}}$$

$$= \frac{10\ \text{gtt} \times 500}{8 \times 60\ \text{min}}$$

$$= \frac{5000\ \text{gtt}}{480\ \text{min}}$$

$$= 10.41\ \text{gtt/min} = 10\ \text{gtt/min}$$



2. Order: A client is to receive D_5 ½NS at 75 mL/h. The drop factor is 20 gtt/mL. What is the flow rate?
   (The question is asking for flow rate with a given drop factor. When drop factor is involved in computing flow rate, solve for drops per minute.)

Dimensional Analysis

$$\frac{\text{gtt}}{\text{min}} = \frac{20\ \text{gtt}}{\cancel{\text{mL}}} \times \frac{75\ \cancel{\text{mL}}}{1\ \cancel{\text{h}}} \times \frac{1\ \cancel{\text{h}}}{60\ \text{min}}$$

$$= 25\ \text{gtt/min}$$

3. Order: 1 L of 0.9% sodium chloride (NS) to be infused over 12 hours.
   What is the flow rate with the following IV tubing?

Answer: $\text{gtt/min} = \frac{15 \text{ gtt}}{1 \cancel{\text{mL}}} \times \frac{1000 \cancel{\text{mL}}}{12 \cancel{\text{h}}} \times \frac{1 \cancel{\text{h}}}{60 \text{ min}} = 20.8$

$= 21 \text{ gtt/min (per the rounding rule)}$

Practice Problems

Calculating Intravenous Therapy: Flow Rate

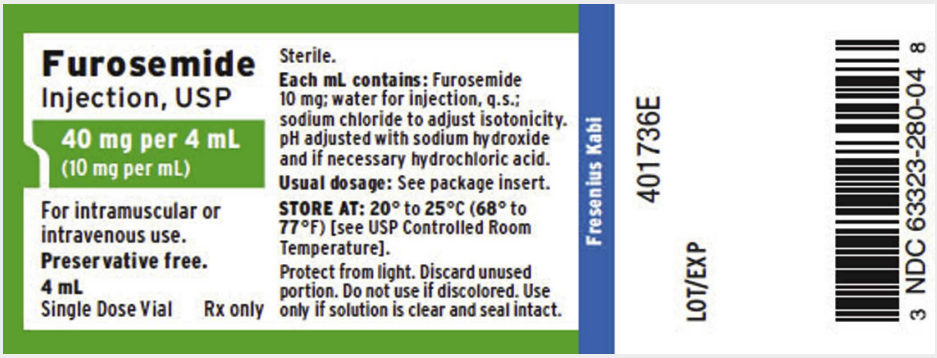
1. Order: 1000 mL of D_5 ½NS to infuse over 12 hours.
   Available: Microdrip set with a drop factor of 60 gtt/mL
   a. Calculate the IV flow rate in drops per minute. _____
2. Order: 3 L of IV solution to infuse over 24 hours: with 1 L of D_5W and 2 L of D_5 ½NS
   a. One liter is equal to how many milliliters? _____
   b. Each liter should infuse for how many hours? _____
   c. The institution uses a set with a drop factor of 15 gtt/mL. How many drops per minute should the patient receive per liter of fluid? _____
3. Order: 250 mL of D_5W over 3 hours
   a. Determine the flow rate. _____
4. Order: 1000 mL of D_5 ½NS, 1 vial of multiple vitamin (MVI), and 10 mEq of potassium chloride (KCl) to be infused over 10 hours
   Available: 1000 mL of D_5 1⁄2 NS; MVI: 1 vial = 10 mL; KCl 20 mEq/20 mL vial Macrodrip set, 15 gtt/mL; microdrip set, 60 gtt/mL
   a. What is the total volume of the solution?
   b. How many drops per minute should the patient receive using the macrodrip set and the microdrip set?
   c. The IV pump is set at how many milliliters per hour?

Practice Problems

Calculating Intravenous Therapy: Direct Injection

1. Order: Protamine sulfate 40 mg IV STAT; IV infusion not to exceed 5 mg per min
   Available:

   a. How many milliliters should the patient receive? _____
   b. How many minutes should protamine be administered? _____
2. Order: Morphine sulfate 5 mg IV q3h PRN
   Available:



Instructions are to dilute the dose with 5 mL of NS and to administer 2.5 to 15 mg over 5 minutes.

a. How many milliliters of morphine should the patient receive? _____

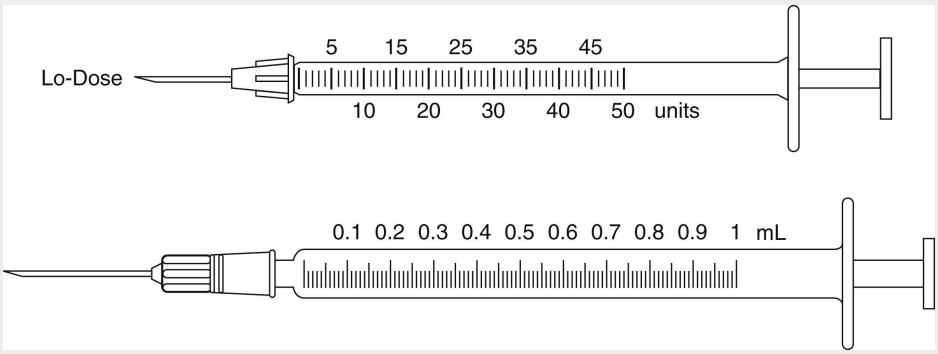
b. For how many minutes should morphine be administered? _____

3. Order: Furosemide 80 mg IV now

Available:

Drug insert states rate of administration is 20 mg/min.

a. How many milliliters will the nurse administer? _____



b. How long should furosemide be given? _____

4. Order: Regular insulin 20 units IV for blood glucose over 600

Available:

Indicate by shading the appropriate syringe to show the amount of insulin to give.

5. Order: Digoxin 0.375 mg IV over 5 min
   Available: Digoxin 0.25 mg/mL
   How many milliliters will the nurse administer? _____
   (When giving drugs by direct IV, always verify the compatibility of the IV solution and the drug; otherwise, precipitation can result. Incompatibility can be avoided if the IV tubing is flushed with a compatible solution of either normal saline or sterile water before and after administration.)

Calculating Intravenous Heparin Infusions

Like insulin, heparin is prescribed in unit dosages. Heparin is a high-alert drug that is available in multiple concentrations from 10 units/mL to 50,000 units/mL. It is important for the nurse to identify the label dosage strength and verify the patient's medication administration record; significant risk of causing serious injury or death can occur with errors. Heparin labels must be read carefully to ensure the correct drug is being administered. The following heparin labels are examples of available strengths. Note that *only one* is indicated for heparin flush (100 units/mL). All other labels indicate "NOT for Lock Flush."

Heparin can be given as a direct IV injection and as a continuous infusion. Direct IV injection was

discussed earlier in this chapter. IV infusion is calculated in units per hour.

Example

Calculating Intravenous Heparin Therapy

1. Ordered: 1000 mL D_5W with heparin sodium 20000 units to infuse at 30 mL/h
   Calculate the units per hour.
   Answer: $\text{units/h} = \frac{20000 \text{ units}}{1000 \cancel{\text{mL}}} \times \frac{30 \cancel{\text{mL}}}{1 \text{ h}} = 600 \text{ units/h}$
2. Order: Heparin sodium 750 units/h
   Available: Heparin sodium 25000 units in 500 mL D_5W
   Calculate the milliliters per hour.
   Answer: $\text{mL/h} = \frac{500 \text{ mL}}{25000 \cancel{\text{units}}} \times \frac{750 \cancel{\text{units}}}{1 \text{ h}} = 15 \text{ mL/h}$
3. Heparin sodium 80 units/kg IV bolus is ordered followed by heparin sodium infusion at 15 units/kg/h for a patient who weighs 175 lb.
   Available:

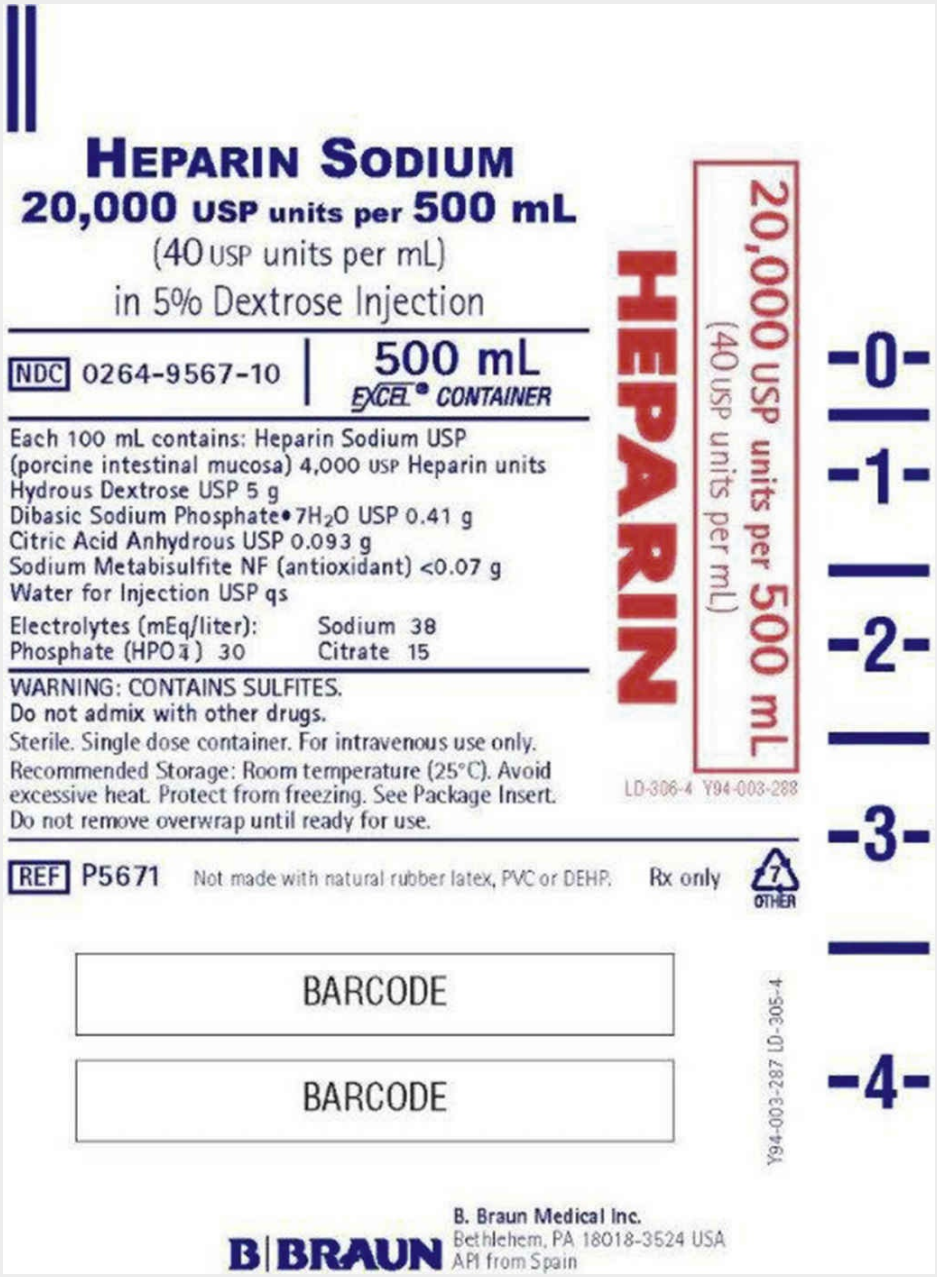
a. Calculate the amount of bolus in units and milliliters to administer.

b. Calculate flow rate in units per hour.
c. Calculate flow rate in milliliters per hour.

Answer:

a. $$\text{units} = \frac{80 \text{ units}}{1 \cancel{\text{kg}}} \times \frac{1 \cancel{\text{kg}}}{2{,}2 \cancel{\text{lbs}}} \times \frac{175 \cancel{\text{lb}}}{x} = 6364 \text{ units bolus}$$

$$\text{mL} = \frac{1 \text{ mL}}{100 \cancel{\text{units}}} \times \frac{6364 \cancel{\text{units}}}{x} = 63{.}6 \text{ mL bolus}$$



b. $$\text{units/h} = \frac{15 \text{ units}}{1 \cancel{\text{kg}}} \times \frac{1 \cancel{\text{kg}}}{2{,}2 \cancel{\text{lb}}} \times \frac{175 \cancel{\text{lb}}}{x} = 1193 \text{ units/h}$$

c. $$\text{mL/h} = \frac{1 \text{ mL}}{100 \cancel{\text{units}}} \times \frac{15 \cancel{\text{units}}}{1 \cancel{\text{kg}}} \times \frac{1 \cancel{\text{kg}}}{2{,}2 \cancel{\text{lb}}} \times \frac{175 \cancel{\text{lb}}}{x}$$
$$= 11{,}9 \text{ mL/h}$$

Practice Problems

Intravenous Heparin Therapy

1. Ordered: Heparin sodium 800 units/h
   Available: Heparin sodium 40 units/mL

Calculate the flow rate. _____

2. Order: 250 mL 0.9% sodium chloride (NS) with heparin sodium 25000 units to infuse at 35 mL/h
   Calculate units per hour. _____
3. Order: Heparin flush mediport every 3 days.
   Which heparin product is appropriate?

4. Order: Bolus with heparin at 80 units/kg, then initate heparin infusion at 20 units/kg/hour for a patient who weighs 150 lb.
   Available: Heparin sodium 25000 units in 500 mL 5% dextrose in water (D_5W).
   a. Calculate bolus dose in units. _____
   b. Calculate bolus dose in milliliters. _____
   c. What is the flow rate of the heparin infusion? _____
5. Order: Infuse heparin sodium 25000 units in 1000 mL of NS at 30 mL/h.
   Calculate units per hour. _____

Calculating Critical Care Drugs

Most drugs administered in critical care are **titrated** (adjusted) according to the patient's response to the drug therapy. The patient is monitored closely for therapeutic effects and any adverse events. When calculating critical care drugs, any method previously discussed is effective, however dimensional analysis is the best method because units and conversion factors are calculated in one equation.

Example

Calculating Critical Care Therapy

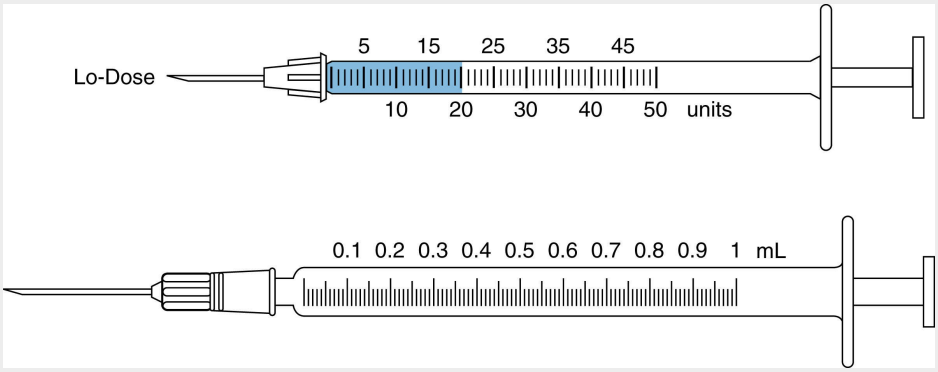
1. Order: Infuse dopamine at 5 mcg/kg/min to maintain systolic blood pressure above 110 mm Hg. The patient weighs 130 lb.
   Available: Dopamine hydrochloride (HCl) 200 mg in 250 mL of 5% dextrose in water (D_5W)
   Calculate milliliters per hour.
   Answer: mL/h = $\frac{250\ \text{mL}}{200\ \cancel{\text{mg}}} \times \frac{1\ \cancel{\text{mg}}}{1000\ \cancel{\text{mcg}}} \times \frac{5\ \cancel{\text{mcg}}}{1\ \cancel{\text{kg}}} \times \frac{1\ \cancel{\text{kg}}}{2.2\ \cancel{\text{lb}}} \times \frac{130\ \cancel{\text{lb}}}{1\ \cancel{\text{min}}} \times \frac{60\ \cancel{\text{min}}}{1\ \text{h}} = 22.2\ \text{mL/h}$
   (All the conversion factors for milligrams per microgram, pounds per kilogram, and units are eliminated except for milliliters and hours.)
2. Order: Dobutamine HCl 2 mcg/kg/min, titrated to maintain hemodynamic goals in a patient who weighs 180 lb
   Available: Dobutamine HCl 250 mg in 500 mL of D_5W
   Calculate micrograms per kilograms per minute.
   Calculate milliliters per hour.
   Answer: $\text{mcg/kg/min} = \frac{2\ \text{mcg}}{1\ \cancel{\text{kg}}} \times \frac{1\ \cancel{\text{kg}}}{2.2\ \cancel{\text{lb}}} \times \frac{180\ \cancel{\text{lb}}}{x\ \text{min}} = 163.6\ \text{mcg/kg/min}$

$$\text{mL/h} = \frac{500\ \text{mL}}{250\ \cancel{\text{mg}}} \times \frac{1\ \cancel{\text{mg}}}{1000\ \cancel{\text{mcg}}} \times \frac{2\ \cancel{\text{mcg}}}{1\ \cancel{\text{kg}}} \times \frac{1\ \cancel{\text{kg}}}{2.2\ \cancel{\text{lb}}} \times \frac{180\ \cancel{\text{lb}}}{1\ \cancel{\text{min}}} \times \frac{60\ \cancel{\text{min}}}{1\ \text{h}} = 19.6\ \text{mL/h}$$

   (Be aware of sound-alike drugs, dopamine and dobutamine. *Dopamine* is an adrenergic agonist that affects dopamine receptors. *Dobutamine* is a beta_1-adrenergic agonist and does *not* affect dopamine receptors. They both have inotropic properties and are used as vasopressors.)
3. Order: Isoproterenol 2 mg in 250 mL of D_5W to infuse at 8 mcg/min
   Calculate milliliters per hour.
   Answer: mL/h = $\frac{250\ \text{mL}}{2\ \cancel{\text{mg}}} \times \frac{1\ \cancel{\text{mg}}}{1000\ \cancel{\text{mcg}}} \times \frac{8\ \cancel{\text{mcg}}}{1\ \cancel{\text{min}}} \times \frac{60\ \cancel{\text{min}}}{1\ \text{h}} = 60\ \text{mL/h}$
   Additional practice problems for all drug calculations are available in the Study Guide and on the Evolve website.

Answers to Practice Problems

Calculating Intravenous Therapy—Flow Rate



All answers are provided using dimensional analysis.

1. IV flow rate: $\text{gtt/min} = \frac{60\text{gtt}}{1\cancel{\text{mL}}} \times \frac{1000\cancel{\text{mL}}}{12\cancel{\text{hr}}} \times \frac{1\cancel{\text{hr}}}{60\text{min}} = 83\ \text{gtt/min}$
2.
   a. 1 L = 1000 mL
   b. 1 L over 8 h each $\left(\frac{24\ \text{hr}}{3\ \text{L}} = 8\ \text{h/L}\right)$
   c. Flow rate: $\text{gtt/min} = \frac{15\text{gtt}}{1\cancel{\text{mL}}} \times \frac{3000\cancel{\text{mL}}}{24\cancel{\text{hr}}} \times \frac{1\cancel{\text{hr}}}{60\text{min}} = \frac{45,000\text{gtt}}{1440\text{min}} = 31\text{gtt/min}$
3. Flow rate: $\text{mL/hour} = \frac{250\ \text{mL}}{3\ \text{hr}} = 83.3\text{mL/hr}$
4.
   a. Total volume = 1030 mL
   b. Macro drip set: $\text{gtt/min} = \frac{15\text{gtt}}{1\cancel{\text{mL}}} \times \frac{1030\cancel{\text{mL}}}{10\cancel{\text{h}}} \times \frac{1\cancel{\text{h}}}{60\text{min}} = \frac{15,450\text{gtt}}{600\text{min}} = 25.75$ gtt/min = 26 gtt/min after rounding to the nearest whole number
   Micro drip set: $\text{gtt/min} = \frac{60\text{gtt}}{1\cancel{\text{mL}}} \times \frac{1030\cancel{\text{mL}}}{10\cancel{\text{h}}} \times \frac{1\cancel{\text{h}}}{60\text{min}} = \frac{61,800\text{gtt}}{600\text{min}} = 103\ \text{gtt/min}$
   c. IV pump: $\text{mL/h} = \frac{1030\text{mL}}{10\text{h}} = 103\text{mL/h}$

Calculating Intravenous Therapy—Direct Injection

All answers are provided using dimensional analysis.

1.
   a. 4 mL
   b. $\text{min} = \frac{1\text{min}}{5\cancel{\text{mg}}} \times \frac{40\ \cancel{\text{mg}}}{\text{x}} = 8\ \text{min or}\ 0.5\ \text{mL/min}$
2.
   a. $\text{mL} = \frac{1\text{mL}}{10\cancel{\text{mg}}} \times \frac{5\cancel{\text{mg}}}{\text{x}} = 0.5\text{mL}$
   b. Because 2.5 to 5 mg can be given over 5 minutes, 5 mg is given over 5 minutes.
3.
   a. $\text{mL} = \frac{1\text{mL}}{10\cancel{\text{mg}}} \times \frac{80\ \cancel{\text{mg}}}{\text{x}} = 8\ \text{mL}$
   b. $\text{min} = \frac{1\text{min}}{20\cancel{\text{mg}}} \times \frac{80\ \cancel{\text{mg}}}{\text{x}} = 4\ \text{min or}\ 2\ \text{mL/min}$
4.

(The top syringe is calibrated in units, the bottom syringe is in milliliters.)

5. Administer: $mL = \frac{1\,mL}{0.25\,\cancel{mg}} \times \frac{0.375\,\cancel{mg}}{x} = 1.5\,mL$

Intravenous Heparin Therapy

1. Flow rate in mL/h = $\frac{1\,mL}{40\,\cancel{units}} \times \frac{800\,\cancel{units}}{1\,h} = 20\,mL/h$
2. $units/h = \frac{25000\ units}{250\,\cancel{mL}} \times \frac{35\,\cancel{mL}}{1\,h} = 3500\ units/h$
3.

4.
   a. Bolus in $\text{units} = \frac{80\text{units}}{1\text{kg}} \times \frac{1\text{kg}}{2.2\text{lbs}} \times \frac{150\text{lbs}}{x} = 5454.5\text{units}$
   b. Bolus in $\text{milliliters} = \frac{500\text{mL}}{25000\text{units}} \times \frac{80\text{units}}{1\text{kg}} \times \frac{1\text{kg}}{2.2\text{lbs}} \times \frac{150\text{lbs}}{x} = 109.1\text{mL}$
   c. $\text{Flow rate in mL/h} = \frac{500\text{mL}}{25,000\text{units}} \times \frac{20\text{units}}{1\text{kg}} \times \frac{1\text{kg}}{2.2\text{lb}} \times \frac{150\text{lb}}{x} = 27.3\text{mL/h}$
5. $\text{units/h} = \frac{25000\text{units}}{1000\text{mL}} \times \frac{30\text{mL}}{1\text{ h}} = 750\text{units/h}$

UNIT III
Maintenance of Homeostasis

OUTLINE

Introduction
12. Fluid Volume and Electrolytes
13. Vitamin and Mineral Replacement
14. Nutritional Support

Introduction

Nutrients, electrolytes, vitamins, and minerals are vital to every human being. Fluid volume and electrolytes are discussed in Chapter 12. Electrolytes assist in preserving adequate body functioning. Poor dietary intake and many disease processes contribute to electrolyte imbalances. Vitamins and minerals, discussed in Chapter 13, are needed in correct portions for good health. Nutrition is discussed in Chapter 14, which includes information on both enteral and parenteral nutrition. Nutrients aid the body in human growth and development and play a vital role in maintaining health.

Nutrients, electrolytes, vitamins, and minerals work together to maintain the internal functioning of the body and to create an environment of homeostasis. All living organisms strive to create a relatively constant internal environment, while the body adjusts to changes within or outside of its systems. If imbalance of these chemical components occurs, it is necessary to identify the underlying cause and to correct it.

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Describe osmolality and tonicity.
- Describe the classifications of intravenous fluids.
- Discuss the functions of major electrolytes.
- Differentiate between intracellular and extracellular electrolytes.
- Discuss the importance of blood and blood products.
- Apply the nursing process to fluid volume deficit and fluid volume excess.
- Describe major signs and symptoms of deficiency and excess of potassium, sodium, calcium, magnesium, chloride, and phosphorus.
- Explain the methods used to correct potassium, calcium, and magnesium excess.
- Apply the nursing process to the care of the patient experiencing potassium, sodium, calcium, and magnesium imbalances.

Fluid and electrolyte balance is necessary to maintain homeostasis. An equal balance of intake and output helps the human body maintain proper equilibrium within all body systems. Intake and output of water is regulated by the kidneys and the pulmonary system and by hormonal and neural functions. Fluid and electrolyte balance is the foundation upon which nurses make important decisions concerning patient care.

To function normally, body cells must have fluid and electrolytes in the right compartments and in the right amounts. Total body fluid is contained in two major compartments: the *intracellular fluid* (ICF) is contained within the body's cells, and the *extracellular fluid* (ECF) comprises all the fluid outside of the cells. The ECF is further divided into three subcompartments: the *interstitial compartment* bathes and surrounds the tissue cells; the *intravascular compartment* contains the plasma and blood vessels; and the *transcellular compartment,* also known as the *third-space,* contains mucus and gastrointestinal (GI), cerebrospinal, pericardial, synovial, and ocular fluids. Table 12.1 shows the sum of fluids within all compartments, which constitutes the total body water (TBW). Fluids move freely between the intracellular and extracellular compartments to maintain balance and homeostasis.

The TBW of a 70-kg (154-lb) man is approximately 60% (40 L). This percentage varies with age, gender, and percentage of body fat. Neonates are 75% to 80% water, whereas older adults are 45% to 55% water. Women tend to have less body water than men due to the effects of hormones and higher amount of adipose tissue, which contains very little water.

Water that moves through the compartments of the body contains electrolytes. **Electrolytes** are substances that separate or dissociate into ions (charged particles) in solution, and they are

abundant in both ICF and ECF. Ions carry either a positive charge (**cation**) or a negative charge (**anion**). Major cations and anions are listed in Table 12.2. Electrolyte balance is essential for normal physiologic functioning and is closely linked with fluid balance. In addition, most electrolytes interact with hydrogen ions to maintain an acid-base balance. Electrolyte balance must be kept within a narrow range to maintain homeostasis. Many illnesses and body system alterations cause electrolyte imbalances. Electrolytes are important because they carry electrical impulses to other cells in the body.

The major electrolytes in body fluids are sodium, potassium, calcium, magnesium, chloride, phosphorus, sulfate, hydrogen, and bicarbonate ions and many proteins. Electrolyte concentrations differ in ICF and ECF. Table 12.3 lists the major cations and anions found in body fluids.

Administering intravenous (IV) fluids and electrolyte replacements may be thought of as routine nursing care; however, both require as much diligence and critical thinking as administration of any medication. This chapter describes fluid replacement strategies, pharmacologic management of specific electrolyte imbalances, and nursing care of patients with fluid and electrolyte imbalances.

Homeostasis

Homeostasis maintains a constant internal balance within the body despite the effects of a constantly changing external environment. Two principles stand out when considering homeostasis and fluid and electrolyte balance. The first principle is that anions and cations must be balanced within each compartment and remain electrically neutral. The amount of fluid within each compartment remains constant, and compartments work continuously to maintain fluid balance and replace and exchange ions to maintain neutrality. The second principle is that the fluid compartments remain in osmotic equilibrium except for transient changes.

TABLE 12.1

Adult Body Fluid Volume

Fluid Compartment	Percentage
Intracellular fluid	40%
Extracellular fluid	20%
Interstitial fluid	15%
Intravascular fluid	5%
Transcellular fluid	Approximately 1-2 L total but generally not included in calculations
Total body fluid	60%

Electrolyte Concentration in Body Fluids

Intracellular Fluid	Extracellular Fluid
Major Cations	**Major Cations**
Potassium Magnesium Sodium	Sodium Potassium Calcium Magnesium

Major Anions	Major Anions
Phosphorus	Chloride Phosphorus

Movement of fluid and particles between and within compartments is controlled by a number of processes, including *osmosis,* the movement of water across a semipermeable membrane from areas of low solute concentration to those of high solute concentration; *diffusion,* movement of molecules from an area of high concentration to one of low concentration; *hydrostatic pressure,* the force within a fluid compartment; *osmolality,* which describes the concentration of fluids; and *active transport,* which requires metabolic activity and expenditure of energy to move a substance across a cell membrane. The number of solutes in a solution is expressed as a unit of measurement called the **osmole**, which is particularly useful when referencing osmotic solutions.

Osmolality

Osmolality refers to the number of particles dissolved in the serum, primarily sodium, urea (blood urea nitrogen [BUN]), and glucose. It also is a measure of the concentration of solutes per kilogram in urine. Normal serum osmolality ranges from 275 to 295 mOsm/kg. As the number of particles increases, the concentration of the solution also increases. The change in the concentration of particles will affect chemical behavior and movement of water. Sodium is the primary electrolyte in the ECF and keeps water in this compartment.

The following three types of fluid concentration are based on the osmolality of body fluids:

1. **Isoosmolar** fluid has the same weight proportion of particles (e.g., sodium, glucose) and water.

2. **Hypoosmolar** fluid contains fewer particles than water.
3. **Hyperosmolar** fluid contains more particles than water. The plasma/serum osmolality (concentration of circulating body fluids) can be calculated if the serum sodium level is known or the sodium, glucose, and BUN levels are known.

Hypoosmolality of body fluid may be the result of excess water intake or fluid overload (edema) caused by an inability to excrete excess water. *Hyperosmolality* of body fluid could be caused by severe diarrhea, increased salt and solute (protein) intake, inadequate water intake, diabetes, ketoacidosis, or sweating.

The terms *osmolality* and *tonicity* are similar but not identical. *Osmolality* refers to the concentration of particles in a solution. **Tonicity** is used primarily as a measurement of the concentration of IV solutions compared with the osmolality of body fluids.

Fluid Replacement

General Considerations

All routes of fluid intake and loss must be considered when assessing fluid balance. General guidelines can be used as the basis for establishing fluid needs. The recommended water intake for a healthy adult is about 2300 to 2900 mL per day; oral intake accounts for 1200 to 1500 mL, solid foods about 800 to 1100 mL, and oxidative metabolism about 300 mL daily.

Patients lose water daily through various routes: kidneys, skin, lungs, and GI tract. The kidneys, the major organ regulating fluid loss, produce 1200 to 1500 mL of urine daily. *Insensible water loss* is continuous and occurs daily through the skin and lungs without awareness and is not measurable. *Sensible water loss* occurs through the lungs/respiration (500 mL/day) and perspiration/skin (500 to 600 mL/day) and through the GI tract/feces (200 mL/day) and is measurable. The minimum urinary output for an adult is 0.5 to 1 mL/kg/h or 35 to 70 mL/h for a 70-kg patient.

Daily water requirements differ according to the patient's age and medical problems. Intravenous fluids (IVFs) are ordered based on an evaluation of the patient's fluid and electrolyte balance, fluid requirements, and fluid needs. Several questions must be addressed: Is the purpose of IV therapy replacement or maintenance? What are the patient's water, electrolyte, and protein requirements? The patient's weight, caloric needs, and body surface area are other important considerations. Illness and surgery increase the amount of fluids lost and affect fluid and electrolyte needs. Ongoing assessment and monitoring of the patient's responses to fluid and electrolyte therapy is vital for patients with fluid and electrolyte imbalances.

Intravenous Solutions

With fluid volume deficit (FVD) from the extracellular body compartment, fluid is lost from the interstitial and vascular spaces. Different types and concentrations of IVFs are available to replace body fluid losses.

Types of Intravenous Solutions

The three general classifications of IV solutions used for fluid replacement are crystalloids (with and without added electrolytes), colloids, and blood and blood products.

Crystalloids

Crystalloid solutions contain fluids and electrolytes and are able to freely cross capillary walls. They do not contain any proteins, which are necessary to maintain the colloidal oncotic pressure that prevents water from leaving the intravascular space. Crystalloids are used as short-term maintenance fluids and to treat dehydration and electrolyte imbalances. Crystalloids cause early plasma expansion but have a shorter duration of action than colloid solutions.

The three major classifications of crystalloid IVFs are isotonic, hypotonic, and hypertonic (Table 12.4):

- **Isotonic** solutions have the same approximate osmolality as ECF or plasma. Because of the osmotic equilibrium, water does not enter or leave the cell, therefore there is no effect on red blood cells (RBCs). Isotonic solutions are primarily used for hydration and to expand ECF volume, because the fluid remains in the intravascular space.
- **Hypotonic** solutions exert less osmotic pressure than ECF, which allows water to move into the cell. IV infusions of hypotonic solutions result in an increased solute concentration in the intravascular space, causing fluid to move into the intracellular and interstitial spaces. Excessive infusion of hypotonic solutions may cause hemolysis, decreased blood pressure, and decreased IVF volume.
- **Hypertonic** solutions exert greater osmotic pressure than ECF, resulting in a higher solute concentration than the serum. When administered, hypertonic IVF fluids pull water from the interstitial space to the ECF via osmosis and cause cell shrinkage. Patients receiving hypertonic solutions must be monitored carefully for signs of circulatory overload (because of the increase in ECF volume).

Parenteral solutions that contain dextrose are available in different concentrations and in

combination with other solutions, such as normal saline and lactated Ringer's solution. Dextrose solutions provide hydration and some calories and increase glucose levels in the blood. The pharmacist will use dextrose solutions to dilute IV medications for administration. The addition of dextrose to an IV solution affects the tonicity of the solution after it is infused. Five-percent dextrose solutions are hypertonic when added to normal saline or lactated Ringer's solution.

The Infusion Nursing Society's Practice Guidelines recommend that dextrose solutions higher than 10% should be given via a central vein. An exception is 50% dextrose, which may be given in small amounts via a peripheral vein to correct hypoglycemia. Dextrose can be irritating to veins as a result of the pH of the solution (3.4 to 4). If hypertonic solutions are not diluted and are given peripherally, there is a risk of vein irritation, damage, and thrombosis. Long-term use of hypertonic solutions may result in electrolyte depletion, increased intravascular volume, fluid overload, water intoxication, and pulmonary edema. Rapid infusions of dextrose solutions may cause hyperglycemia, which can lead to osmotic diuresis and fluid and electrolyte imbalance.

TABLE 12.4

Tonicity of Intravenous Solutions

Tonicity of Solution and Osmolality (mOsm/kg)	Examples of IVF and Approximate* Osmolarity (mOsm/L)	General Indications and Cautions for Use
Isotonic (280-300)	Lactated Ringer's (LR) (273) Ringer's solution (275) 0.9% Sodium Chloride (NaCl) (308) 5% Dextrose in water (252)	LR provides electrolytes and is used for rehydration in all types of dehydration and FVD. Use cautiously in patients with renal failure (contains K^+). Use cautiously in alkalosis and liver disease; liver converts LR to bicarbonate.
		Hydration
		Corrects dehydration and sodium depletion Replaces GI losses Dextrose provides some calories. Use with caution in patients with cardiac or renal disease because of risk for FVE. Do not administer isotonic solutions to patients with known or suspected ICP.
Hypotonic (<280)	0.45% NaCl (154) 0.33% NaCl (115) 0.225% NaCl (77)	Replaces cellular fluid; treats intracellular dehydration (diabetic ketoacidosis, hyperosmolar hyperglycemic state) Provides free water to allow excretion of body wastes Dextrose provides some calories. Do not administer hypotonic solutions to patients with known or suspected ICP or patients with liver disease, shock, trauma, or burns (risk of depleting intravascular volume). Monitor for signs of FVD; monitor for worsening hypovolemia due to a decrease in vascular volume.
Hypertonic (>300)	3% NaCl (513) 5% Dextrose and 0.45% NaCl (406) 5% Dextrose and 0.9% NaCl (560) 5% Dextrose in LR (525) 10% Dextrose and water (505) 50% Dextrose and water (2526)	Increases serum osmolality Corrects severe hyponatremia; decreases ICP in patients with cerebral edema Dextrose provides some calories. Use with caution; may cause intravascular volume overload and pulmonary edema; administer slowly and carefully with infusion control pump and constant monitoring; monitor electrolytes and monitor for signs of FVE. Avoid prolonged use. Contraindicated for patients with cardiac or renal disease and for those with dehydration or diabetic ketoacidosis Higher concentrations of dextrose (>10%) must be given through a central venous access device; may be added to amino acid solutions as total parenteral nutrition.

>, Greater than; <, less than; *FVD*, fluid volume depletion; *FVE*, fluid volume excess; *GI*, gastrointestinal; *ICP*, intracranial pressure; *K*, potassium; *LR*, lactated Ringer's solution.

* Refer to manufacturer's label on individual bags of intravenous fluids (IVFs) for exact osmolarity.

Sodium solutions are available in various concentrations and tonicities. Isotonic solutions are primarily used for hydration to expand the ECF and during blood product transfusions. Rapid infusion of isotonic saline solutions may lead to hypernatremia, fluid volume excess (FVE), and electrolyte depletion. Long-term use should also be avoided because normal saline provides no calories. Hypotonic solutions are also used for hydration and to treat hyperosmolar diabetes. Hypertonic saline solutions are used to treat severe hyponatremia or hypochloremia; careful monitoring of electrolyte levels is important to avoid excess replacement.

Balanced electrolyte solutions, such as lactated Ringer's solution and Ringer's solution, contain electrolytes (no magnesium) and minimal calories with the addition of dextrose. Their primary use is hydration and electrolyte replacement. However, they do not provide adequate electrolytes for maintenance therapy for patients with limited or no oral intake. Lactated Ringer's solution is similar to plasma in electrolyte content. Lactate is added as a buffering agent and is metabolized to bicarbonate. Complications of infusions of Ringer's and lactated Ringer's include fluid overload, excess electrolytes, and metabolic acidosis with long-term therapy. Because lactate is metabolized in the liver, lactated Ringer's is contraindicated for patients with liver disease.

Colloids

Colloid solutions contain protein or other large molecular substances that increase **osmolarity** without dissolving in the solution. Because of their size, the particles are unable to pass through the semipermeable membranes of the capillary walls and stay within the intravascular compartment; thus colloids are also known as *plasma expanders*. They act by increasing the colloidal oncotic pressure and pulling fluids from the interstitial space into the plasma, increasing blood volume. The composition of colloid solutions includes proteins, carbohydrates, and lipids. Colloids typically

have small and large particles, except albumin, whose particles are all one size. Commonly used colloids are shown in Table 12.5.

TABLE 12.5

Common Colloid Solutions

Common Solutions	Indications	Nursing Implications	Adverse Effects and Contraindications
High–molecular-weight dextran (6% dextran 70 and 75; synthetic colloids)	Treatment of shock caused by hemorrhage, burns, or trauma Maximum volume-expansion effect 1 h after administration With normal renal functioning, increased volume is excreted within 24 h.	Administer colloid solutions with an 18-g or larger needle. Dextran solutions are not a substitute for blood products and have no oxygen-carrying capacity. Can be used emergently if cross-matching or blood products are unavailable May interfere with laboratory testing for typing and cross-matching; draw necessary blood samples before administration. Increased volume may cause dilution of Hgb and Hct. Assess fluid volume status; may cause circulatory overload. Monitor for signs and symptoms of FVE.	Bleeding, hypotension, wheezing, urticaria, chest tightness, nausea, and vomiting Severe anaphylaxis reactions and death can occur. Contraindicated for patients with impaired hepatic or renal disease, heart failure, and bleeding disorders Monitor pulse, BP, CVP, and urine output every 5-15 min for the first hour and hourly thereafter.
Low–molecular-weight dextran 40 (6%) (synthetic colloids)	Intraoperative prophylaxis of venous and pulmonary embolism Early fluid replacement and treatment of hypovolemic shock	Same as for high–molecular-weight dextran	Same as for high–molecular-weight dextran
Hydroxyethyl starch 6% (hetastarch) A synthetic polymer closely related to human albumin	Early fluid replacement and treatment of hypovolemic shock, burns Maximum volume expansion occurs shortly after infusion is completed; duration of action is 24-36 h	Hetastarch 6% with 0.9% NaCl is isotonic (310 mOsm/L) Hetastarch 6% with 7.2% NaCl is hypertonic Does not interfere with blood typing and cross-matching Assess fluid volume status; may cause circulatory overload	Severe anaphylactic reaction Interferes with platelet function, increases bleeding time Contraindicated for patients with bleeding disorders and renal, cardiac, or liver disease
Albumin (5% and 25%) Prepared from human blood and blood products; considered a blood product	Regulates plasma volume and tissue-fluid balance 5% solution is isotonic and is used to treat hypovolemia 25% solution is hypertonic and is generally used for patients with fluid and sodium restrictions	Assess fluid volume status; may cause circulatory overload.	Contraindicated in patients with heart failure or severe anemia Hold ACEIs at least 24 h before administering albumin due to the risk of adverse reactions, including hypotension and flushing.

ACEI, Angiotensin-converting enzyme inhibitor; *BP,* blood pressure; *CVP,* central venous pressure; *FVE,* fluid volume excess; *g,* gauge; *h,* hour; *Hct,* hematocrit; *Hgb,* hemoglobin; *min,* minute; *NaCl,* sodium chloride.

Blood and Blood Products

Nurses complete a thorough patient assessment prior to, during, and after administration of blood products. Each facility has a policy and procedure for blood transfusions, and each registered nurse is oriented in the correct procedure. Blood products include packed RBCs (PRBCs), plasma, platelets, and cryoprecipitate. A unit of PRBCs contains concentrated RBCs with most of the plasma and platelets removed; the approximate volume is 350 mL/unit. The approximate volume of a unit of whole blood is 500 mL/unit. Infusing PRBCs over whole blood offers an advantage because packed cells allow an increase in oxygen-carrying capacity with a smaller volume. One unit of whole blood elevates the hemoglobin by approximately 0.5 to 1 g/dL, and one unit of PRBCs elevates the hematocrit by three points.

It is important for nurses to understand the specific blood components prior to beginning the infusion. Proper product-to-patient identification is paramount in preventing transfusion reactions. Reducing errors that increase during blood administration is a focus of the Joint Commission's National Patient Safety Goals of 2015. Also, the National Healthcare Safety Network's Hemovigilance Module was developed to increase patient safety and decrease costs associated with transfusion-related adverse events (see www.cdc.gov/nhsn/acute-care-hospital/bio-hemo).

Blood components are administered with a 19-gauge needle, cannula, or catheter. A "Y" tubing set is used with a microaggregate filter with one arm of the "Y" for isotonic saline solution and the other arm for the blood product. The maximum rate of infusion is 4 hours per unit, beginning with removal of the unit from the refrigerator. If the transfusion is not finished by the 4-hour mark, the transfusion bag must be returned to the blood bank, and a new bag of blood is issued to complete the transfusion. *Never* add medications to the unit of blood.

Loop diuretics are often prescribed to patients receiving whole blood or PRBCs to prevent circulatory overload, particularly in patients who are at risk for developing pulmonary edema and FVE. The patient may also be premedicated with an antihistamine (e.g., diphenhydramine) and hydrocortisone to decrease the possibility of a transfusion reaction. For patients receiving multiple blood transfusions, the serum ionized calcium level should be monitored. Both PRBCs and whole blood products are processed using sodium citrate and citric acid for anticoagulation; multiple blood transfusions can result in a decrease in the plasma calcium levels.

IV fat emulsion, also known as *lipid emulsion,* is a component of parenteral nutrition for patients who are unable to get nutrition through an oral diet (see Chapter 14). Fat emulsion can supply up to 30% of the patient's caloric intake and is usually recommended for patients who are unable to tolerate oral or enteral feedings for 7 days or more. The contents of fat emulsion are primarily soybean or safflower and triglycerides with egg phospholipids added as an emulsifier. Parenteral

nutrition provides essential nutrients intravenously, including proteins, carbohydrates, electrolytes, trace minerals, and vitamins. Fat emulsion is often added to parenteral nutrition formulas by the pharmacist. The patient must have a centrally or peripherally inserted vascular access device to receive parenteral nutrition formulas. Nausea, vomiting, and elevated temperature have been reported when fat emulsion is infused quickly. It is used cautiously in patients at risk for fat embolism, such as with a fractured femur, and in patients with an allergy to eggs or soybeans and those with pancreatitis, bleeding disorders, liver failure, and respiratory disease.

Nursing Process: Patient-Centered Collaborative Care

Fluid Imbalance

Assessment

- Identify patients at risk for fluid volume deficit (FVD) and fluid volume excess (FVE).
- Contributing factors for FVD include prolonged inadequate intake, excessive losses due to bleeding or trauma, and gastrointestinal losses. Contributing factors for FVE include heart failure, liver disease, kidney failure, excessive sodium intake, and excessive or too rapid infusion of intravenous fluids (IVFs).
- Assess the patient's history to identify factors that may contribute to FVD and FVE.
- Differentiate between causes of FVD, including hypovolemia and dehydration, and causes of FVE, including heart failure and kidney and liver diseases.
- Assess the patient's vital signs and note usual baseline values. Report abnormal findings.
- Assess the patient's laboratory values. Plasma or serum osmolality is the primary indicator of the patient's hydration status.
- Determine the patient's input and output.
- Obtain urine specific gravity. The normal range is 1.005 to 1.030 g/mL.
- Check the types of IVF ordered per day, including the amount to be infused, the hourly rate, and the solution for tonicity and electrolyte content. Consider if fluid ordered is appropriate for the patient's history and clinical condition. If any questions arise, collaborate with the health care provider to determine appropriate fluid replacement for the patient. Excessive administration of IVF containing sodium to patients with altered regulatory mechanisms may precipitate FVE.
- Assess the patient's current weight and baseline weight.

Nursing Diagnoses

- Fluid Volume, Deficient related to fluid loss and/or inadequate fluid intake or failure of regulatory mechanisms
- Fluid Volume, Excess related to altered regulatory mechanisms and excess fluid or sodium intake

Planning

- The patient will exhibit balanced fluid volume.
- The patient will have balanced intake and output over a 24-hour period.
- With FVD, the patient will experience hydration as evidenced by moist mucous membranes, elastic skin turgor, and vital signs within normal limits; adequate urine output; urine specific gravity between 1.005 and 1.010 g/mL; stable weight; and no changes in mental status.
- With FVE, the patient will not exhibit signs of circulatory overload as evidenced by absence of signs and symptoms of edema or anasarca, having clear lung sounds, being free of jugular venous distension, and vital signs within normal limits.
- Patient and family will verbalize an understanding of teaching and factors related to FVD or FVE as evidenced by notifying the doctor of signs. For FVD, signs include excessive thirst, confusion, decreased urine output, nausea, vomiting, diarrhea, and weakness; for FVE, signs include swelling in the body, such as swelling of the feet; difficulty breathing; anxiety; and changes in urine output.

Nursing Interventions

General

- Monitor and record vital signs; assess trends and deviation from baseline and document findings. Report significant changes to the health care provider.
- Measure and record intake and output every 4 hours. Identify sources of excessive intake or fluid losses.
- Measure urine specific gravity. Readings greater than 1.025 g/mL indicate concentrated urine, whereas those less than 1.010 g/mL indicate dilute urine.
- Use strict aseptic technique when inserting IV access devices. Check IV site for patency and signs of complications such as phlebitis and infiltration. Adhere to agency policy regarding site rotation and dressing and tubing changes. Avoid contamination when administering IV medications. Follow evidence-based practice guidelines, and implement interventions to decrease central line–associated infections.
- Monitor IV infusions at least hourly, and ensure that the prescribed amount infuses hourly. Set the IV pump correctly, and validate the correct drip rate.
- Measure the patient's weight daily and compare it with the baseline measurement. A gain of 1 kg (2.2 lb) is equivalent to 1 L of fluid.

Fluid Volume Deficit

- Administer isotonic IVF as ordered.
- Monitor strict intake and output hourly. Encourage frequent oral intake if the patient is able to drink. Provide oral care if the patient is unable to perform independently. Moisturize skin to prevent dryness, and reposition the patient every 2 hours, padding bony prominences; monitor frequently for skin breakdown and pressure.
- Monitor for signs and symptoms of FVD as a result of hypovolemia, including thirst (usually the first sign of dehydration), restlessness, headaches, inability to concentrate, dry mucous membranes, poor skin turgor, tachycardia, changes in mental status, and slightly decreased systolic blood pressure.
- Recognize late symptoms of hypovolemia that include cyanosis, cold clammy skin, weak thready pulse, confusion, and oliguria.
- Monitor vital signs for indications of FVD, including increased temperature, weak pulse, tachycardia (early sign), hypotension, and tachypnea.
- Assess for orthostatic hypotension and use safety precautions when transferring the patient from bed to chair, avoiding abrupt changes in position. Other signs and symptoms of FVD include flattened neck veins; weight loss; decreased skin turgor; dry mucous membranes; decreased capillary refill; pale, cool, clammy skin; and muscle weakness.
- Monitor laboratory values associated with FVD daily, including increased hemoglobin and hematocrit; urine specific gravity greater than 1.030 g/mL; and increased sodium, BUN, creatinine, electrolyte levels, and serum osmolality.

Fluid Volume Excess

- Monitor and record vital signs that indicate FVE, including tachycardia, bounding pulse, tachypnea, increased blood pressure, and increased pulse pressure. Other signs and symptoms of FVE include altered mental status; generalized edema (use +1 to +4 scale to quantify edema); anasarca; constant, irritated cough; dyspnea; orthopnea; crackles; pulmonary congestion; muffled heart sounds; fatigue; increased central venous pressure; jugular vein distension; and increased urine output. Listen to lung sounds for crackles, and monitor respirations.
- Monitor laboratory results associated with FVE daily, including elevated BUN, hemoglobin and hematocrit, sodium, serum osmolality, and urine specific gravity below 1.010. Monitor electrolytes for imbalances, and monitor creatinine and albumin levels. Chest radiography may reveal pulmonary congestion. Monitor intake and output, and note trends that reflect decreased urine output.
- Monitor daily weight for sudden increases.
- Administer diuretics as ordered; implement fluid and sodium restrictions. Recommend a nutritionist consult if warranted. Position the patient with the head of bed elevated 30 to 45 degrees to facilitate respiration. Monitor edematous areas for signs of pressure and altered skin integrity and provide meticulous skin care; reposition the patient at least every 2 hours.

Patient Teaching

General

- Instruct patients that thirst means a mild fluid deficit. Oral fluid intake is the best means of

fluid replacement for a patient with FVD.
- Advise patients to report vomiting or diarrhea. When these occur constantly or over several days, severe fluid volume and electrolyte imbalance can result.
- If a patient has FVE, fluid may be restricted. Instruct patients on limited intake of fluids around the clock.
- Assist patients in planning a typical 24-hour fluid intake based on individual fluid needs. Encourage patients to monitor fluid intake and output, and advise them to report to their health care provider any abnormal findings such as changes in urination patterns, fatigue, shortness of breath, weight gain (>3 lb in 2 days or 1.4 kg) or loss, peripheral edema, or tight shoes and rings.
- Provide a sodium-restricted diet as appropriate if ordered.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate culturally acceptable food choices.

Evaluation

- The patient's vital signs should remain within normal limits.
- Fluid intake is balanced with output. Urine output is adequate for age, weight, and history.
- The patient and family understand the treatment plan and expected outcomes.
- IVFs are administered as ordered without complications or harm to the patient.

Electrolytes

Potassium

Potassium (K^+) is the major intracellular cation, and 98% of the body's potassium is found within the cells; only 2% is found in the ECF. Potassium is essential for neuromuscular activity and cellular metabolism, and potassium levels affect cardiac and skeletal muscle activity.

Potassium moves in and out of the cells under the influence of the potassium-sodium pump. It maintains the concentration difference in the cells by pumping potassium into the cells and pumping sodium out. Acid-base balance also influences potassium levels. *Acidotic* conditions tend to pull potassium out of cells, whereas *alkalotic* conditions tend to put potassium back into cells. The kidneys are the primary route for potassium loss, eliminating about 90% of the daily potassium intake. An inverse relationship exists between sodium and potassium reabsorption in the kidneys. Aldosterone also plays a role in the excretion of potassium.

Daily dietary intake is necessary because potassium is poorly stored in the body. Recommended daily potassium intake is about 4.7 g (4700 mg), either in potassium-rich foods or as potassium supplements. Foods rich in potassium include tuna and fruits and vegetables such as mangoes, oranges, avocados, tomatoes, cucumbers, spinach, strawberries, and bananas.

Functions

Potassium is necessary for transmission and conduction of nerve impulses and for contraction of skeletal, cardiac, and smooth muscles. It is also necessary for normal kidney function and for the enzyme action used to change carbohydrates to energy (glycolysis) and amino acids to protein. Potassium promotes glycogen storage in hepatic cells, regulates the osmolality of cellular fluids, and plays a role in acid-base balance.

Hypokalemia

Hypokalemia, or potassium deficit, occurs with serum levels below 3.5 mEq/L. Most cases of hypokalemia are caused by excessive loss rather than deficient intake. Whenever cells are damaged from trauma, injury, surgery, or shock, potassium leaks from the cells into the intravascular fluid and is excreted by the kidneys. With cellular loss of potassium, potassium shifts from the blood plasma into the cell to restore the cellular potassium balance; hypokalemia usually results. GI sources of potassium loss include vomiting, diarrhea, suctioning, recent ileostomy formation, draining fistulae, and diuretic therapy. Between 80% and 90% of potassium in the body is excreted in the urine; another 8% is excreted in the feces. Other causes of potassium loss include burns, total parenteral nutrition therapy, alkalosis, prolonged laxative use, excessive licorice consumption, corticosteroid use, increased aldosterone levels, and decreased magnesium levels.

Hypokalemia may not be symptomatic until potassium levels fall below 3.0 mEq/L. It is important to recognize early signs and symptoms to prevent severe hypokalemia, which can result in cardiac arrest and death. Early clinical manifestations include fatigue, muscle weakness, anorexia, nausea, and vomiting. Muscle weakness does not usually occur until potassium levels fall below 2.5 mEq/L. Weakness usually begins in the lower extremities, progresses to the trunk, and may result in paralysis; respiratory muscle involvement may result in respiratory arrest. Quadriceps weakness may be one of the earliest signs of hypokalemia. Severe signs and symptoms include paresthesias, leg cramps, decreased bowel motility and paralytic ileus, confusion, rhabdomyolysis and myoglobinuria, atrial and ventricular dysrhythmias, and cardiac arrest. Electrocardiogram (ECG) changes include flattened or inverted T waves and depressed ST segments. Patients at risk for hypokalemia-induced dysrhythmias include older adults, those with heart disease or coexisting hypomagnesemia, and those on digoxin or other antiarrhythmics. Certain drugs, such as potassium-wasting diuretics and cortisone preparations, promote potassium loss. Patients receiving these drugs should increase their potassium intake by consuming foods rich in potassium or by taking potassium supplements as prescribed by their health care provider. Keep in mind that potassium-sparing diuretics do not deplete potassium stores, so patients would not be requested to increase potassium intake or to take supplements. Serum potassium levels should be monitored periodically for abnormalities.

Treatment for hypokalemia due to excessive potassium loss depends on the severity of the deficit.

Patients with low-normal serum potassium levels may be advised to consume additional foods high in potassium. Usual dietary potassium intake for adults is 4.7 g (4700 mg) daily. Management goals for patients with hypokalemia include preventing and treating life-threatening complications, replacing potassium and returning levels to normal, and diagnosing and correcting the cause of the deficiency.

Potassium replacements can be given orally or intravenously (Box 12.1). Table 12.6 lists the potassium preparations used to treat hypokalemia, and Prototype Drug Chart 12.1 compares the pharmacokinetics and pharmacodynamics of oral and IV potassium preparations.

Pharmacodynamics

Potassium maintains neuromuscular activity. Onset of action of oral potassium is unknown; with IV potassium, onset is rapid. Duration of action of potassium is also unknown; however, it may vary according to the dose taken. Continuous cardiac monitoring and serum potassium levels should be closely monitored when large doses are administered. To raise the serum potassium level by 1 mEq, the patient should receive 100 to 200 mEq of IV potassium.

Hyperkalemia

Hyperkalemia is defined as a serum potassium level above 5.0 mEq/L. Causes include excessive intake, impaired renal excretion, or a shift from intracellular to extracellular spaces. The most common causes are renal failure and medications that interfere with potassium excretion. Renal disease or kidney failure results in potassium accumulating in the intravascular fluid, which results in hyperkalemia. Persons at risk for developing hyperkalemia include premature infants, older adults, and those with a history of genitourinary disease, adrenal insufficiency, cancer, poorly controlled diabetes, or polypharmacy. Hyperkalemia manifests primarily as cardiac and neuromuscular symptoms. Signs and symptoms include cardiac dysrhythmias that include characteristic changes on the ECG, such as early tachycardia followed by bradycardia; paresthesia of the face, tongue, hands, and feet; and GI hyperactivity, including nausea, diarrhea, and abdominal cramping. Metabolic acidosis may also be present.

BOX 12.1 Oral and Intravenous Potassium Preparations

Oral Potassium (K^+) Preparations

- Potassium bicarbonate: In most cases, K^+ chloride should be used, except for renal tubular acidosis (hyperchloremic acidosis), in which case K^+ bicarbonate is more appropriate. (Potassium acetate should be available for intravenous administration.)
- Potassium phosphate: For treatment and prevention of hypokalemia and hypophosphatemia
- Potassium gluconate: Available as elixir or tablet
- Potassium chloride: For treatment and prevention of K^+ depletion, it will maintain acid-base balance. It is available as a liquid, powder, tablet, capsule, controlled-release microencapsulated tablet, enteric-coated tablet, and effervescent tablet and parenteral use.

Nursing Implications for Oral Preparations

- Tablets and capsules should be administered with or after meals followed by a large glass of water while the patient is sitting up to decrease gastrointestinal irritation. The patient should remain upright at least 30 minutes after administration. Use of tablets and capsules should be reserved for patients who cannot tolerate liquid preparations.
  - Dissolve effervescent tablets in 3 to 8 oz of cold water. Ensure the tablet is fully dissolved.
  - Powders and liquid solutions should be diluted in 3 to 8 oz of cold water or juice.
  - Dilute liquid forms before administering via an enteral feeding tube.
- Do not chew or crush enteric-coated or extended-release tablets or capsules.
- Advise patients not to suck on tablets to avoid oral ulceration. Extended-release forms may not be crushed or chewed.
- Advise patients to avoid salt substitutes.
- Patients on K^+ therapy should have levels drawn to monitor progress.
- Explain to patients the need to take medications as directed, especially when concurrent digoxin or diuretics are taken.

Nursing Implications for Intravenous Potassium Administration*

- Intravenous (IV) therapy is indicated for patients who are unable to tolerate oral therapy or in addition to oral therapy for patients with severe hypokalemia.
- Medication errors involving too rapid an infusion or bolus IV administration of K^+ chloride or K^+ acetate have resulted in fatalities.
- *Never* administer K^+ via IV push or bolus.

Continuous Infusion K^+ Acetate*

- Do not administer undiluted. Each single dose *must* be diluted and thoroughly mixed in 100-1000 mL of dextrose, saline, in Ringer's or lactated Ringer's solutions, or in dextrose/saline and dextrose/Ringer's or lactated Ringer's combinations. Usually limited to 10 mEq/100 mL or 40 mEq/1000 mL via a peripheral line. Pain is associated with peripheral infusion; administer central vein when possible.
- Rate: Infuse slowly at a rate up to 10 mEq/hr in adults or 0.5 mEq/kg/hr in children in general care areas. Check hospital policy for maximum infusion rates. (The maximum rate in a monitored setting is 40 mEq/hr in adults or 1 mEq/kg/hr in children.)

Continuous Infusion K^+ Chloride*

- Do not administer undiluted; fatalities have occurred. Concentrated products have black caps on vials or black stripes above the constriction on ampules and are labeled with a warning about dilution requirements. Each single dose must be diluted and thoroughly mixed in 100-1000 mL of IV solution and is usually limited to 10 mEq/L to 20mEq/L via a peripheral line. Administer central vein when possible.
- Rate: Infuse slowly at a rate up to 10 mEq/hr in adults or 0.5 mEq/kg/hr in children in general care areas. Check the hospital policy for maximum infusion rates (maximum rate in a monitored setting is 40 mEq/hr in adults or 1 mEq/kg/hr in children). Use an infusion pump.
- Monitor the IV site and infusion carefully to avoid extravasation and infiltration.
- Too rapid an infusion may cause fatal hyperkalemia.
- Symptoms of toxicity: Slow, irregular heartbeat; fatigue; muscle weakness; paresthesia; confusion; dyspnea; peaked T waves; depressed ST segments; prolonged QT segments; widened QRS complexes; loss of P waves; and cardiac arrhythmias.

* The Institute for Safe Medication Practices (ISMP) has listed potassium as a high-alert medication because of the high risk of causing significant harm to a patient when administered in error.

TABLE 12.6

Potassium Supplements

Preparation	Drug
Oral liquid	Potassium chloride: 10% = 20 mEq/15 mL, 20% = 40 mEq/15 mL
Oral tablet or capsule	Potassium chloride: Enteric-coated tablet, effervescent tablet
Intravenous (IV) potassium	Potassium chloride may be diluted in dextrose, sodium chloride, and lactated Ringer's and Ringer's solutions. IV potassium is available premixed with many of these IV solutions.

Management goals are to eliminate the cause of the excess potassium, shift potassium back into the cells, increase potassium excretion, decrease potassium intake, and prevent further episodes of hyperkalemia. For mild hyperkalemia, foods rich in potassium are usually restricted. Treatment strategies for hyperkalemia are outlined in Box 12.2.

Effect of Drugs on Potassium Balance

Potassium-wasting diuretics are a major cause of hypokalemia. Diuretics are divided into two categories: potassium-wasting and potassium-sparing drugs. *Potassium-wasting diuretics* cause excretion of potassium and other electrolytes, such as sodium and chloride, in the urine. *Potassium-sparing diuretics* cause retention of potassium, but sodium and chloride are excreted in the urine.

Laxatives, corticosteroids, antibiotics, and potassium-wasting diuretics are the major drug classifications that can cause hypokalemia. Other drug classifications that may cause hyperkalemia include oral and IV potassium salts, central nervous system (CNS) agents, and potassium-sparing diuretics. Tables 12.7 and 12.8 list some drugs that affect potassium balance.

PROTOTYPE DRUG CHART 12.1 Potassium

Drug Class	Dosage
Electrolyte Pregnancy category: A*	Treatment of hypokalemia: A: PO: 40-100 mEq/d in divided doses Prevention of hypokalemia during diuretic therapy: A: PO: 20-40 mEq/d in one to two divided doses; single dose not to exceed 20 mEq. Treatment of hypokalemia: A: IV: 10-20 mEq/dose (*max:* 40 mEq/dose) to infuse over 2 to 3 h (*max* infusion rate: 40 mEq/h) A: IV: Do not administer undiluted; use solution for IV infusion; infuse slowly at a rate up to 10 mEq/h.
Contraindications	**Drug-Lab-Food Interactions**
Renal insufficiency or failure, Addison disease, hyperkalemia, severe dehydration, acidosis, potassium-sparing diuretics, in patients with known hypersensitivity *Caution:* Cardiac and renal disease, burns, hypomagnesemia	Drug: Any disease or condition in which high potassium levels may occur through potassium retention or other processes Food: Excessive intake of licorice may cause hypokalemia and sodium retention; salt substitutes contain potassium.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Well absorbed following oral administration Distribution: Enters extracellular fluid and is then actively transported into cells Metabolism: Excreted 80%-90% in urine by the kidneys and 10% in feces Half-life: UK Protein binding: UK	PO: Onset: UK Peak: 1-2 h Duration: UK IV: Onset: Rapid Peak: End of infusion Duration: UK
Therapeutic Effects/Uses	
To correct potassium deficit and treat hypokalemic alkalosis, strengthen cardiac and muscular activities, and to prevent hypokalemia in at-risk patients	
Mode of Action: Transmits and conducts nerve impulses; contracts skeletal, smooth, and cardiac muscles	
Side Effects	**Adverse Reactions**
Nausea, vomiting, diarrhea, abdominal cramps, irritability, rash (rare); phlebitis with IV administration	Hyperkalemia (older adults with renal impairment); oliguria, ECG changes (peaked T waves, widened QRS complex, prolonged PR interval), GI ulceration *Life threatening:* Cardiac dysrhythmias, respiratory distress, ventricular fibrillation, cardiac arrest

A, Adult; *d,* day; *ECG,* electrocardiography; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *max,* maximum; *PO,* by mouth; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

BOX 12.2 Hyperkalemia: Treatments and Rationales

Potassium Restriction

- Restriction of potassium intake will slowly lower the serum level.
- For mild hyperkalemia (slightly elevated K^+ levels [5.4 to 5.6 mEq/L]), potassium restriction is normally effective.

Intravenous Sodium Bicarbonate

- By elevating the pH level, potassium moves back into cells and lowers the serum level.
- This is a temporary treatment.

10% Calcium Gluconate

- Decreases irritability of myocardium resulting from hyperkalemia
- A temporary treatment that does not promote K^+ loss
- Caution: Administering 10% calcium gluconate to a patient on digitalis can cause digitalis toxicity.

Insulin and Glucose (10% to 50%)

- Moves potassium back into cells
- A temporary treatment effective for approximately 6 hours and not always as effective when repeated

Sodium Polystyrene Sulfonate

- Sodium polystyrene sulfonate is used to treat high levels of potassium in the blood for severe hyperkalemia; may cause hypocalcemia, hypomagnesemia, and sodium retention.
- Can be administered orally or rectally

Oral Administration

- Sodium polystyrene sulfonate: PO (Adults) 15 g 1-4 times daily in water (up to 40 g 4 times daily)

Rectal Administration

- Sodium polystyrene sulfonate: (Adults) 30-50 g as a retention enema; repeat as needed every 6

hr
- Sodium polystyrene sulfonate: (Children) PO/rectal: 1 g/kg/dose every 6 hr
- Constipation is a common adverse effect. Assess bowel function daily and monitor for fecal impaction. A mild laxative may be prescribed.

hr, Hour; K^+, potassium; *PO,* by mouth.

Nursing Process: Patient-Centered Collaborative Care

Potassium

Assessment

- Assess for signs and symptoms of potassium imbalance. Symptoms of *hypokalemia* include nausea and vomiting; polyuria; cardiac dysrhythmias; abdominal distension; and soft, flabby muscles. Symptoms of *hyperkalemia* include oliguria, nausea, abdominal cramps, tachycardia and later bradycardia, weakness, and numbness or tingling in the extremities.
- Assess serum potassium level; a normal level is 3.5 to 5.0 mEq/L. Report serum potassium deficits or excesses to the health care provider.
- Obtain baseline vital signs and electrocardiogram (ECG) readings and report abnormal findings. Vital signs and ECG results can be compared with future readings.
- Check for signs and symptoms of digitalis toxicity when the patient is receiving a digitalis preparation and a potassium-wasting diuretic or a cortisone preparation. A decreased serum potassium level enhances the action of digitalis and increases the likelihood of digitalis toxicity. Signs and symptoms of digitalis toxicity are nausea, vomiting, anorexia, bradycardia (pulse rate <60 or markedly decreased), cardiac dysrhythmias, and visual disturbances.

Nursing Diagnoses

- Knowledge, Deficient related to medications and foods affecting potassium levels
- Cardiac Output, Decreased related to excess serum potassium
- Activity Intolerance related to muscle weakness

Planning

- The patient's serum potassium level will be within normal ranges (K^+ 3.5-5.0 mEq/L).
- The patient will verbalize understanding of the potassium imbalance and can state methods to decrease recurrence.
  - Patients with hypokalemia will eat potassium-rich foods.
  - Patients with hyperkalemia will avoid potassium-rich foods.

Nursing Interventions

- Give oral potassium with a sufficient amount of water or juice (at least 8 oz) and with meals. Potassium is extremely irritating to the gastric mucosa.
- Always hang potassium-containing IV solutions for administration via a calibrated infusion pump. Potassium IV solutions should always be diluted and thoroughly mixed in 100 to 1000 mL of IV solution and must be infused slowly (generally no faster than 10 mEq/hr).
- Potassium should *never* be given intramuscularly or as an IV bolus or push. Giving IV potassium directly into the vein causes cardiac dysrhythmias, cardiac arrest, and death. (Potassium chloride is one of the agents used in lethal injection because rapid infusion results in immediate cardiac arrest.)
- Check the amount of urine output. Potassium accumulation occurs if a patient is receiving potassium and urine output is below 25 mL/h or below 600 mL/d. Remember that 80% to 90% of potassium is excreted in the urine. Report results to the health care provider.
- Monitor serial potassium levels frequently in addition to those of serum creatinine, BUN, glucose, electrolytes, and arterial blood gases. Report abnormal results to the health care provider.
- Monitor ECG. With *hypokalemia,* there is a flat or inverted T wave, a depressed ST segment, and a prolonged QT interval. With *hyperkalemia,* there is a narrow and peaked T wave, a widened QRS complex, a prolonged PR interval, flattened or absent T waves, and a depressed ST

segment.
- Monitor the patient's response to activity, and plan frequent rest periods due to muscle weakness associated with potassium imbalances.
- Check the IV site for infiltration if a patient is receiving IV potassium. Potassium can cause extravasation and tissue necrosis if it infiltrates into subcutaneous tissue. Discontinue IV fluids immediately if infiltration occurs.
- Monitor patients receiving medications for hyperkalemia for signs and symptoms of continuing hyperkalemia or iatrogenic hypokalemia.

Patient Teaching

General

- Advise patients to have the serum potassium level checked at regular intervals as prescribed by the primary health care provider when taking medications that affect potassium levels.
- Instruct patients to drink a full glass of water when taking oral potassium supplements. Potassium preparations can be taken during or after a meal. Explain to patients that potassium is very irritating to the stomach.
- Encourage patients to comply with the prescribed potassium dose, regular laboratory tests, and medical follow-up related to the health problem and drug regimen.
- Instruct patients on the signs and symptoms of hypokalemia and hyperkalemia to report to their physician.

Diet

- Instruct patients who are taking medications that promote potassium loss to eat potassium-rich foods.
- Instruct patients at risk for potassium imbalances regarding dietary sources of potassium and the potassium content of foods.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate the patient's serum potassium level and ECG. The cardiac rhythm should return to patient's normal baseline without dysrhythmias. The serum potassium level should remain within the normal range. Report to the health care provider if the level does not return to normal, in which case the potassium replacements and diet may need modification.

TABLE 12.7

Drugs That Cause Hypokalemia

Substances	Rationale
Aspirin	Causes changes in acid-base balance
Laxatives Enemas (hyperosmolar)	Abuse can cause potassium depletion.
Corticosteroids	Absorption of calcium is reduced.
Cortisone	Cortisone causes electrolyte disturbances.
Diuretics *Loop:* Furosemide, torsemide *Thiazide*: hydrochlorothiazide	Diuretics deplete potassium through urination.
Prednisone	Steroids promote potassium loss and sodium retention.
Sodium polystyrene sulfonate (Kayexalate)	Kayexalate exchanges a potassium ion for a sodium ion.
Antibiotic I: Amphotericin B, polymyxin B, gentamicin, neomycin, amikacin, tobramycin	These have a toxic effect on renal tubules and thus decrease potassium reabsorption.
Antibiotic II: Penicillin, ampicillin, carbenicillin, ticarcillin, nafcillin, piperacillin	These enhance potassium excretion by the presence of nonabsorbable anions.
Alpha-adrenergic blockers Insulin and glucose	These promote movement of potassium into cells, thus lowering the serum potassium level.
$Beta_2$ agonists: Terbutaline, albuterol Cardiac glycoside: Digoxin	These promote potassium loss. Used with caution in patients with electrolyte imbalances; can result in toxicity.

Sodium

Sodium is the major cation in the ECF. The normal serum sodium level is 135 to 145 mEq/L. A serum sodium level below 135 mEq/L is called **hyponatremia**, and a serum sodium level above 145 mEq/L is called **hypernatremia**. Sodium and chloride imbalances typically occur together. The most serious problems associated with serum sodium deficit (hyponatremia) are cerebral edema, altered

mental status, confusion, and seizure. In sodium excess imbalances (hypernatremia), a rapid decrease occurs in intracellular water to the brain, which results in cerebral dehydration, seizure, and coma.

The dietary requirement for sodium is 2000 mg to 4000 mg daily. Sodium-rich foods include bacon, luncheon meats, corned beef, decaffeinated coffee, ham, tomato juice, pickles, and soda crackers.

Functions

Sodium is found in most body fluids; it plays a major role in fluid volume balance and is the primary determinant of plasma osmolality. Sodium combines readily with chloride (Cl^-) or bicarbonate (HCO_3) to promote acid-base balance. Sodium is important for the maintenance of neuromuscular irritability for conduction of nerve impulses. In conjunction with neural and hormonal mediators, the kidney maintains normal serum sodium concentrations through renal tubular reabsorption. The serum sodium level reflects the ratio of sodium to water, not necessarily the loss or gain of sodium.

TABLE 12.8

Drugs That Cause Hyperkalemia

Substances	Rationale
Potassium chloride (oral or IV), potassium salt substitutes, potassium penicillin, potassium phosphate (KPO_4) enema, potassium-sparing diuretics	Excess ingestion or infusion can cause potassium excess.
Angiotensin-converting enzyme inhibitors: Captopril, quinapril, and ramipril	These increase the state of hypoaldosteronism (decrease sodium and increase potassium) and impair renal potassium excretion.
Angiotensin II–receptor antagonists, losartan potassium	These decrease adrenal synthesis of aldosterone; potassium is retained and sodium is excreted.
Beta-adrenergic blockers: Propranolol, nadolol	These decrease cellular uptake of potassium and decrease Na-K-ATPase function.
Digoxin	The therapeutic dose is not affected; however, with overdose, potassium excess may occur.
Heparin	Heparin inhibits adrenal aldosterone production.
Low–molecular-weight heparin	LMWHs suppress aldosterone and decrease potassium homeostasis; renal excretion of potassium is reduced.
Immunosuppressive drugs: Cyclosporine, tacrolimus, cyclophosphamide	These reduce potassium excretion by induction of hypoaldosteronism and loss of potassium from cells.
Nonsteroidal antiinflammatory drugs: Ibuprofen, indomethacin	NSAIDs impair potassium homeostasis and block cellular potassium uptake.
Succinylcholine	Succinylcholine allows for leakage of potassium out of the cells.
CNS agents: Barbiturates, sedatives, opioids, heroin, amphetamines	Use of these substances is usually characterized by muscle necrosis and cellular shift of potassium from cells to serum.

ATPase, Adenosine triphosphatase; *CNS*, central nervous system; *IV*, intravenous; *K*, potassium; *LMWH*, low–molecular-weight heparin; *Na*, sodium; *NSAID*, nonsteroidal antiinflammatory drug.

Hyponatremia

Hyponatremia is caused by a loss of sodium-containing fluids, deficient intake, or water gain. Sodium loss can result from vomiting, diarrhea, nasogastric suctioning, burns, wound drainage, trauma, renal failure, heart failure, third spacing, syndrome of inappropriate antidiuretic hormone (SIADH), excessive hypertonic IVF, surgery, and thiazide diuretics.

Hyponatremia may occur with hypovolemia and hypervolemia, and thirst is usually the first symptom of sodium deficit; symptoms will depend on the onset and degree of deficit. Signs and symptoms of hyponatremia due to water shifting into cells are primarily neuromuscular and gastrointestinal and include muscle weakness, decreased deep tendon reflexes, headaches, lethargy, confusion, seizures, coma, abdominal cramps, nausea and vomiting, tachycardia and hypotension, pale skin, and dry mucous membranes. Signs of hyponatremia associated with decreased ECF (hypovolemia) include tachycardia; weak, thready pulse; and decreased blood pressure progressing to orthostatic hypotension. If hyponatremia is caused by increased ECF (hypervolemia), signs and symptoms include jugular vein distension, weight gain, edema, and increased blood pressure.

Oral sodium replacement is the preferred treatment if the patient is able to tolerate oral intake or if the deficit is mild. Sodium may also be replaced via enteral feeding tubes. For a serum sodium level between 125 and 135 mEq/L, IV normal saline (0.9% sodium chloride) may increase sodium content in vascular fluid. For a serum sodium level below 120 mEq/L, a hypertonic 3% or 5% saline solution may be necessary.

Hypernatremia

Hypernatremia can be caused by sodium gain, sodium retention, or water loss. Causes include excessive oral sodium intake, deficient water intake, hypertonic tube feedings, hypertonic IVF,

hyperaldosteronism, Cushing syndrome, corticosteroid use, and acute kidney failure. Other causes include vomiting, diarrhea, burns, diabetes insipidus, and mineralocorticoid excess.

Signs of fluid imbalance depend on the cause; water loss presents with symptoms of FVD, whereas sodium gain presents with symptoms of FVE. Signs and symptoms of hypernatremia are dry, sticky mucous membranes; flushed, dry skin; agitation; elevated body temperature; rough, edematous, dry tongue; nausea and vomiting; anorexia; tachycardia; hypertension; muscle twitching; hyperreflexia; seizures; and coma.

Management of hypernatremia depends on the cause and severity of the deficit. Frequent monitoring of sodium levels is necessary while the underlying cause is being treated. When the serum sodium level is elevated above 145 mEq/L, sodium restriction is indicated. Treatments include administration of IVF and diuretics.

Nursing Process: Patient-Centered Collaborative Care

Sodium

Assessment

- Assess the patient for signs and symptoms of sodium imbalance. Symptoms of *hyponatremia* are muscle weakness, headaches, lethargy, confusion, seizures, abdominal cramps, nausea and vomiting, tachycardia and hypotension, pale skin, and dry mucous membranes. Symptoms of *hypernatremia* are flushed, dry skin; agitation; elevated body temperature; rough, dry tongue; nausea and vomiting; anorexia; tachycardia; hypertension; muscle twitching; and hyperreflexia.
- Check the serum sodium level. Report critically low sodium levels (<125 mEq/L) to the health care provider because prompt medical care is required.
- Obtain a history of health problems that may lead to sodium loss or excess.

Nursing Diagnoses

- Fluid Volume, Imbalanced (excess) related to water retention
- Fluid Volume, Imbalanced (deficit) related to nasogastric suctioning
- Confusion, Acute related to electrolyte imbalance

Planning

- The patient's serum sodium level will be within normal range (135-145 mEq/L in 3 to 5 days).

Nursing Interventions

- Monitor the prescribed medical regimen for correction of hyponatremia or hypernatremia.
- Instruct patients on the signs and symptoms of hyponatremia and hypernatremia, and instruct them to notify their health care provider if any of these occur.
- Monitor serum sodium levels and report abnormal levels.

Patient Teaching

- Instruct patients with hypernatremia to avoid foods high in sodium, using salt when cooking, and adding salt to food at the table.
- Emphasize the importance of reading labels on food products.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate the patient's serum sodium level. Report if the sodium imbalance continues.
- Monitor fluid intake and output carefully; monitor daily weights.
- Assess patients for signs of circulatory overload and deficit.

Calcium

Calcium is found in approximately equal proportions in ICF and ECF. The total serum calcium

range is 8.6 to 10.2 mg/dL. A calcium deficit (<8.6 mg/dL) is called **hypocalcemia**, and a calcium excess (>10.2 mg/dL) is called **hypercalcemia**. Over 90% of the body's calcium is found in bones and teeth. Of the remaining calcium found in the blood, about 50% is bound to protein, primarily albumin. Another 40% is free and is not bound to protein and is called the *ionized form* of calcium; it can leave the vascular space and be active in cellular functions. Normal ionized calcium levels are reported separately (4.64 to 5.28 mg/dL).

Calcium levels are affected by acid-base balance and plasma albumin levels. When an individual is acidotic (decreased plasma pH), there is a decrease in calcium binding to the albumin, which leads to more ionized calcium. During alkalosis (increased plasma pH), increases in calcium binding lead to decreased ionized calcium. Alterations in serum albumin levels affect the interpretation of total calcium levels. Low albumin levels result in a drop in the total calcium level, although the level of ionized calcium is not affected.

Functions

Calcium promotes normal nerve and muscle contraction and plays a role in cardiac excitability. This cation also maintains normal cellular permeability and promotes blood clotting by converting prothrombin into thrombin. Calcium is also needed for formation of bone and teeth. Calcium levels are regulated by parathyroid hormone and calcitonin. Calcium functions are closely related to magnesium and phosphorus, and calcium and phosphorus have an inverse relationship; that is, increased calcium levels result in decreased phosphorus levels.

Vitamin D is needed for calcium absorption from the GI tract. Aspirin and anticonvulsants can alter vitamin D, affecting calcium absorption. Loop or high-ceiling diuretics (see Chapter 38), steroids (cortisone), magnesium preparations, and phosphate preparations promote calcium loss. Conversely, thiazide diuretics increase serum calcium levels.

Hypocalcemia

Inadequate calcium intake causes calcium to leave bone to maintain a normal serum calcium level. Because of calcium loss from bones (bone demineralization), pathologic fractures may occur if calcium deficit persists. Common causes of hypocalcemia include hyperphosphatemia, acute pancreatitis, widespread bony metastases, hypoparathyroidism, alkalosis, diarrhea, alcoholism, malnutrition, use of loop diuretics, vitamin D deficiency, and multiple blood transfusions.

Signs and symptoms of hypocalcemia reflect calcium's role in nerve transmission and heart and muscle function. Neurologic and neuromuscular symptoms include anxiety, irritability, and tetany; twitching; hyperactive deep tendon reflexes; spasms of hands, wrist, feet, and ankles; spasmodic contractions; laryngeal spasm; and seizures. Positive Chvostek and Trousseau signs are classic signs of hypocalcemia associated with tetany. Cardiovascular manifestations include decreased cardiac output; dysrhythmias; and ECG changes that include a prolonged QT interval, elongated ST segment, and ventricular tachycardia (torsades de pointes). Hypocalcemia also causes a diminished response to digitalis; other signs are dry, brittle nails and dry hair and skin.

Calcium preparations can be administered orally or intravenously. The treatment depends on the cause, degree of deficit, and clinical condition of the patient. IV calcium replacement should be administered only to acutely symptomatic patients. Calcium preparations are combined with various salts such as chloride, carbonate, and gluconate. There is a threefold difference in the primary cation between calcium gluconate, which contains 4.65 mEq Ca^{++}/gram, and calcium chloride, which contains 13.6 mEq Ca^{++}/gram. When ordering IV calcium, this difference has important implications. Calcium chloride is more irritating when given intravenously. Both calcium chloride (CaCl) and calcium gluconate (CaGl), both 10%, can be used for acute hypocalcemia and during cardiac resuscitation. Calcium gluconate has the same action on the heart as digitalis: it increases the force of systolic contractions. Prototype Drug Chart 12.2 describes the pharmacokinetics and pharmacodynamics of calcium preparations.

PROTOTYPE DRUG CHART 12.2 Intravenous Calcium

Drug Class	Dosage
Electrolyte Pregnancy category: C* Drug forms: Tablet, capsule, gelcap, liquid; IV calcium chloride (CaCl) and calcium gluconate (CaGl) *IV form is a high-alert drug.* ⚡	A: Hypocalcemia 1-2 g/d in 3-4 divided doses A: Antacid 0.5-1.5 g as needed A: Hyperphosphatemia (end-stage renal) 1 g with each meal, increase to 4 to 7 g as needed; administer PO with water; ⚡ $Ca^{+}Cl^{-}$ & $Ca^{+}Gl^{-}$ A: IV 100 mg/mL = 0.45 mEq calcium/mL in compatible IV solution (Na+Cl, dextrose 5%, dextrose 10%); IV doses are recommend for patients with tetany
Contraindications	**Drug-Lab-Food Interactions**
Hypercalcemia, patients receiving digitalis glycosides, renal calculi, severe respiratory insufficiency, cardiac disease OB: Hypercalcemia may increase risk of fetal complications.	Drug: Increased risk of digoxin toxicity with calcium channel blockers, tetracyclines, fluoroquinolones, phenytoin, iron salts, etidronate, risedronate, thiazides, sodium polystyrene sulfonate Food: Cereals, spinach, rhubarb Lab: May affect serum calcium or ionized calcium, sodium, potassium, magnesium, albumin, and parathyroid hormone.
Pharmacokinetics	**Pharmacodynamics**
Absorption: From GI tract, requires vitamin D Distribution: Readily enters ECF; also crosses placenta and enters breast milk Metabolism and excretion: Excreted mostly in the feces; 20% eliminated by the kidneys Half-life: UK	PO: Onset: UK Peak: UK Duration: UK IV: Onset: Immediate Peak: Immediate Duration: 0.5-2 h
Table Continued	

⚡ Safety alert from the Institute for Safe Medication Practices	⚡ Errors with IV calcium gluconate (CaGl) and chloride (CaCl) have occurred secondary to confusion over which salt is ordered. Clarify incomplete orders. Confusion has occurred with milligram doses of CaCl and CaGl, which are not equal. Cl and Gl forms are routinely available on most hospital crash carts; physicians should specify the form of calcium desired, and doses should be expressed in mEq.
Therapeutic Effects/Uses	
To correct calcium deficit or tetany symptoms, prevent osteoporosis	
Mode of Action: Transmits nerve impulses, contracts skeletal and cardiac muscles, maintains cellular permeability, and promotes strong bone and teeth growth	
Side Effects	**Adverse Reactions**
PO: Nausea, vomiting, constipation, pain, drowsiness, headache, muscle weakness	Hypercalcemia, ECG changes (shortened QT interval), metabolic alkalosis, heart block, rebound hyperacidity *Life threatening:* Renal failure, cardiac dysrhythmias, cardiac arrest

A, Adult; *d,* day; *ECF,* extracellular fluid; *ECG,* electrocardiogram; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *OB,* obstetric; *PO,* by mouth; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

The patient's renal functioning should be assessed before administering IV calcium chloride; this solution contains aluminum, which can be toxic if renal insufficiency exists. IV calcium should be administered cautiously in patients who take digitalis because an increase in serum calcium increases the risk of digitalis toxicity. Calcium chloride 10% solution should be administered slowly via an infusion-control pump, and the patient should be monitored frequently. Care should be taken to prevent extravasation; local extravasation may cause tissue necrosis and sloughing. Refer to agency policy if infiltration occurs. Too rapid an infusion may cause cardiac syncope and decreased blood pressure from peripheral vasodilation. Oral calcium preparations are available in tablets, capsules, gelcaps, and powders.

Patients with hypocalcemia should be assessed for hypomagnesemia, hypokalemia, and acid-base imbalances, and any abnormalities should be corrected. Hypomagnesemia should be corrected first; low magnesium levels may prevent the patient from responding to treatment for hypocalcemia.

Pharmacokinetics

Vitamin D promotes calcium absorption from the GI tract; phosphorus inhibits calcium absorption. The pH affects the amount of ionized calcium. When pH is decreased (acidic), there is more free ionized calcium because it has been released from protein-binding sites. With an increased pH (alkalosis), more calcium is bound to protein.

Hypercalcemia

Elevated serum calcium may be a result of hyperparathyroidism, malignancy, hypophosphatemia, excessive calcium intake, prolonged immobilization, multiple fractures, and drugs such as thiazide diuretics and steroids. Signs and symptoms of hypercalcemia are fatigue, muscle weakness, depressed deep tendon reflexes, confusion, impaired memory, anorexia, nausea, vomiting, constipation, and kidney stones of calcium composition. ECG changes include shortened QT interval and ST segment; the patient may exhibit decreased heart rate and dysrhythmias.

TABLE 12.9

Drugs That Affect Calcium Balance

Substances	Rationale
Drugs that Cause Hypocalcemia	
Magnesium sulfate	Inhibits parathyroid hormone secretion and decreases serum calcium level
Estrogens Aminoglycosides: Gentamicin, amikacin, tobramycin	Can alter vitamin D metabolism needed for calcium absorption
Phosphate preparations: Oral, enema, intravenous; sodium phosphate, potassium phosphate	Can increase serum phosphorus level and decrease serum calcium level
Corticosteroids: Cortisone, prednisone	Decreases calcium mobilization and inhibits calcium absorption
Diuretics: Loop (e.g., furosemide)	Reduces calcium absorption from renal tubules

Drugs that Cause Hypercalcemia	
Calcium salts Calcium acetate Vitamin D	Excess ingestion of calcium and vitamin D and infusion of calcium can increase serum calcium level.
Intravenous fat emulsion	Can increase serum calcium level
Diuretics: Thiazides, chlorthalidone	Can induce hypercalcemia
Lithium	Increases parathyroid hormone secretion

Effect of Drugs on Calcium Balance

Phosphate preparations, corticosteroids, loop diuretics, aspirin, anticonvulsants, magnesium sulfate, and plicamycin are some of the drugs that can lower serum calcium levels. Excess calcium salt ingestion or infusion and thiazide diuretics can all contribute to an increased serum calcium level. Table 12.9 lists some drugs that affect calcium balance.

TABLE 12.10

Calcium Preparations

Calcium Name	Drug Form	Drug Dose
Oral		
Calcium carbonate	650- to 1500-mg tablets	400 mg/g*
Calcium citrate	200- to 950-mg tablets	210 mg/g*
Calcium gluconate	500- to 972-mg tablets	93 mg/g*

Intravenous		
Calcium chloride	10 mL	270 mg/g*; 13.5 mEq
Calcium gluconate	10 mL	93 mg/g*; 4.65 mEq

* Elemental calcium is 1 g.

Clinical Management of Calcium Imbalance

Clinical management of hypocalcemia consists of oral supplements and IV calcium. Table 12.10 lists oral and IV preparations of calcium salts, their dosages, and drug forms. Calcium carbonate can cause GI upset because it produces carbon dioxide. For better calcium absorption, calcium supplements should contain vitamin D, and oral calcium should be taken 30 minutes before meals.

The goal for managing hypercalcemia is to correct the underlying cause of serum calcium excess. IV saline solution and drugs such as calcitonin and loop diuretics can be used to promote rapid urinary excretion of calcium.

Nursing Process: Patient-Centered Collaborative Care

Calcium

Assessment

- Assess the patient for signs and symptoms of calcium imbalance. Signs and symptoms of *hypocalcemia* are tetany, muscle cramps, bleeding tendencies, and weak cardiac contractions. Signs and symptoms of *hypercalcemia* are flabby muscles, pain over bony areas, and kidney stones of calcium composition.
- Assess for Trousseau sign, muscular spasm of the hand and wrist when pressure is applied to vessels and nerves of the upper arm, and Chvostek sign, spasm of facial muscles resulting from tapping on the facial nerve.
- Check serum calcium levels; a normal total calcium level is 8.6 to 10.2 mg/dL. Report abnormal test results.
- Assess albumin levels; low levels of albumin decrease total calcium levels.
- Obtain baseline vital signs and ECG readings. Report abnormal findings.
- Gather a current patient drug history. If the patient is receiving digoxin, calcium enhances the effect of digoxin. An elevated serum calcium level can cause digitalis toxicity, signs and symptoms of which include nausea, vomiting, anorexia, bradycardia (pulse rate <60 or markedly decreased), cardiac dysrhythmias, and visual disturbances. Thiazide diuretics can increase the serum calcium level. Drugs that decrease the effect of calcium are calcium channel blockers, tetracycline, and sodium chloride.

Nursing Diagnoses

- Nutrition, Imbalanced: Less than Body Requirements related to gastrointestinal discomfort
- Tissue Integrity, Impaired related to numbness and tingling of hands
- Activity Intolerance related to neurologic or neuromuscular changes

Planning

- The patient's serum calcium level will be within normal range.
- Tetany symptoms will cease.
- The patient will eat calcium-rich foods or take calcium supplements as ordered.
- Patients with hypercalcemia will avoid calcium-rich foods.

Nursing Interventions

- Monitor vital signs and report abnormal findings. Compare with baseline vital signs.
- Bradycardia is a sign of digitalis toxicity.
- Administer IVFs slowly with 10% calcium gluconate or chloride. The pharmacist will add or decrease calcium to the solutions as ordered by the provider and will dilute in compatible solutions (e.g., normal saline [NS], D5W, D10W).
- Check the IV site for infiltration. Calcium can cause tissue necrosis and sloughing if it infiltrates into subcutaneous tissue. Concentrations of calcium chloride (CaCl) of 20 mg/mL are usually recommended for central lines; concentrations of no more than 1 mg/mL have been recommended for peripheral lines.
- Monitor serum total calcium and ionized calcium levels.
- Monitor ECGs. In hypocalcemia, the ST segment is lengthened and the QT interval is prolonged. In hypercalcemia, the ST segment is decreased and the QT interval is shortened.

Patient Teaching

General

- Instruct patients to avoid overuse of antacids and chronic use of laxatives. Overuse of certain antacids may cause alkalosis, decreasing calcium ionization. Chronic use of laxatives decreases calcium absorption from the gastrointestinal tract. Suggest high-fiber foods for improving bowel elimination.
- Encourage patients taking calcium supplements to check with the pharmacist to ensure that the calcium tablet is absorbable.
- Advise patients to take oral calcium supplements with meals or after meals to increase absorption.

- Instruct patients to report symptoms of hypercalcemia, including muscle weakness and pain over bony areas. Remind patients to report any chest pain or urinary problems because calcium can cause ECG changes and renal stones.
- Instruct patients to report symptoms of hypocalcemia, including neuromuscular signs such as numbness, tingling sensations in fingers and toes, and muscle cramps. Wheezing may develop from bronchospasm, dysphagia, voice changes, fatigue, and seizures.

Diet

- Instruct the patient to consume high-calcium foods such as milk and dairy products.
- Remind the patient that foods rich in protein and vitamin D enhance calcium absorption.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate the patient's serum calcium and electrolyte levels. Report if the calcium imbalance continues.
- Monitor patients for neuromuscular and cardiac manifestations of calcium imbalance.

Magnesium

Magnesium is most plentiful in the ICF, and it plays a role in maintaining normal calcium and potassium balance. Magnesium deficit often occurs with hypokalemia and hypocalcemia. The normal serum magnesium level is 1.5 to 2.5 mEq/L. Magnesium deficit is called **hypomagnesemia**, and magnesium excess is called **hypermagnesemia**. The daily magnesium requirement is 8 to 20 mEq.

Functions

Magnesium promotes transmission of neuromuscular activity and is an important mediator of neural transmission in the CNS. Alterations in serum magnesium levels profoundly affect neuromuscular excitability and contractility. Like potassium, magnesium promotes contraction of the myocardium. Magnesium activates many enzymes for metabolism of carbohydrates and protein and is responsible for transportation of sodium and potassium across cell membranes.

Serum magnesium deficit increases the release of acetylcholine from the presynaptic membrane of the nerve fiber, which increases neuromuscular excitability. Serum magnesium excess has a sedative effect on the neuromuscular system, which can result in loss of deep tendon reflexes. Cardiac (ventricular) dysrhythmias, hypotension, and heart block can occur as a result of hypomagnesemia.

Hypomagnesemia is probably the most undiagnosed electrolyte deficiency. This is most likely because it is asymptomatic until the serum magnesium level approaches 1 mEq/L. To correct severe hypomagnesemia, IV magnesium sulfate is usually given. For hypermagnesemia, calcium gluconate may be given to decrease the serum magnesium level.

Effect of Drugs on Magnesium Balance

Prolonged parenteral nutrition without magnesium supplements can decrease magnesium levels. Also, diuretics, certain antibiotics, laxatives, and steroids are drug groups that promote magnesium loss. Like hypokalemia, hypomagnesemia enhances the action of digitalis and causes digitalis toxicity. Chronic alcoholism, prolonged fasting, starvation, or increased renal losses can promote hypomagnesemia.

TABLE 12.11

Drugs That Affect Magnesium Balance

Drugs	Rationale
Drugs that Cause Hypomagnesemia	
Diuretics: Furosemide, ethacrynic acid	Promote urinary loss of magnesium
Antibiotics: Gentamicin, tobramycin, capreomycin, amphotericin B	Can cause magnesium loss via kidneys
Laxatives, cisplatin	Abuse can cause magnesium loss via the gastrointestinal tract.

Drugs that Cause Hypermagnesemia	
Magnesium salts (oral and enema: magnesium hydroxide, magnesium sulfate, magnesium citrate, magnesium sulfate)	Excessive use can increase serum magnesium level. Use of excessive magnesium sulfate in treatment of toxemia can cause hypermagnesemia.

Magnesium sulfate corrects hypomagnesemia and symptoms of digitalis toxicity. It is common practice after bypass surgery or myocardial infarction for patients to be given magnesium sulfate orally, even when blood levels are normal, to prevent ventricular arrhythmias in the perioperative period.

Excess intake of magnesium salts is the major cause of serum magnesium excess. Commonly used medications that may cause hypermagnesemia include laxatives and antacids. A patient with chronic kidney disease who ingests products that contain magnesium will have a problem with excess magnesium. Patient teaching regarding prolonged or frequent use of laxatives, particularly in older adults, is an important intervention in preventing electrolyte imbalance. Table 12.11 lists some drugs that affect magnesium balance.

Nursing Process: Patient-Centered Collaborative Care

Magnesium

Assessment

- Assess the patient for signs and symptoms of magnesium imbalance. Signs and symptoms of *hypomagnesemia* are tetany-like symptoms caused by hyperexcitability (tremors, twitching of the face) and ventricular tachycardia that leads to ventricular fibrillation and hypertension. Signs and symptoms of *hypermagnesemia* are lethargy, drowsiness, weakness and paralysis, loss of deep tendon reflexes, hypotension, and heart block.
- Check serum magnesium levels for magnesium imbalance. Symptoms of magnesium deficit may not be seen until the serum level is below 1 mEq/L.
- Observe patients receiving digitalis preparations for digitalis toxicity. Like potassium deficit, magnesium deficit enhances the action of digitalis, causing digitalis toxicity.

Nursing Diagnoses

- Nutrition, Imbalanced: Less than Body Requirements related to insufficient intake of magnesium-rich foods
- Cardiac Output, Decreased related to hypomagnesemia or hypermagnesemia
- Knowledge, Deficient related to signs and symptoms of hypomagnesemia or hypermagnesemia

Planning

- The patient's serum magnesium level is within normal range (2.4 to 4.4 mg/dL).
- The patient will not experience life-threatening symptoms of magnesium imbalance such as CNS symptoms (confusion, coma) and cardiac dysrhythmias (premature ventricular contractions and ventricular fibrillation).

Nursing Interventions

- Report to the health care provider if a patient is ordered nothing by mouth (NPO) and is receiving IVFs without magnesium salts for a prolonged period.
- Monitor vital signs.
- Monitor urinary output. Most of the body's magnesium is excreted by the kidneys. Report if urine output falls below 600 mL/day.
- Monitor for digitalis toxicity (e.g., nausea, vomiting, bradycardia) in patients who have hypomagnesemia and are taking digoxin. Magnesium deficit enhances the action of digitalis

preparations.
- Monitor vital signs and compare with baseline values. Report abnormal findings to the health care provider.
- Monitor serum electrolyte results. Report low serum potassium or calcium levels because low serum magnesium levels may be attributed to hypokalemia or hypocalcemia. When correcting a potassium deficit, potassium is not replaced in cells until magnesium is replaced. A serum magnesium level of 1 mEq/L or less can cause cardiac arrest.
- Check for Trousseau and Chvostek signs of severe hypomagnesemia. Tetany symptoms occur with both magnesium and calcium deficits.
- Have IV calcium gluconate available for emergency reversal of hypomagnesemia from overcorrection of a magnesium deficit.

Patient Teaching

- Advise patients with hypomagnesemia to eat foods rich in magnesium (green vegetables, fruits, fish, grains, and nuts).
- Instruct patients with hypermagnesemia to avoid routine use of laxatives and antacids that contain magnesium. Suggest that patients check drug labels and speak with a pharmacist.
- Instruct patients on signs and symptoms of hypomagnesemia and hypermagnesemia.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate culturally acceptable food choices.

Evaluation

- Evaluate the patient's serum magnesium level. Report if the magnesium imbalance continues.
- Have the patient repeat the signs and symptoms of hypomagnesemia and hypermagnesemia, and instruct them to report these to their health care provider.

Chloride

Chloride is the principal anion of ECF. The chloride ion is a major contributor to acid-base balance, gastric juice acidity, and the osmolality of ECF. A normal serum chloride level is 96 to 106 mEq/L. **Hypochloremia** is a decreased serum chloride level, and **hyperchloremia** is an elevated level. With increased serum osmolality (>300 mOsm/kg), there are more sodium and chloride ions proportional to the water. Sodium and chloride frequently work in combination. For example, during sodium retention, chloride is also frequently retained, resulting in increased water retention. Clinical manifestations of hypochloremia include tremors, twitching, and slow, shallow breathing. With severe chloride loss, decreased blood pressure is seen. Clinical manifestations of hyperchloremia include weakness; lethargy; deep, rapid breathing; and eventual unconsciousness.

Phosphorus

Phosphorus is the primary anion in ICF and is the second most abundant element in the body. The majority of the body's phosphorus is found as phosphate, therefore these two terms are used interchangeably.

Both phosphorus and calcium levels are regulated by parathyroid hormone (PTH) and need vitamin D for absorption from the GI tract. A reciprocal relationship exists between phosphorus and calcium. High serum phosphate levels cause low calcium levels; low calcium levels stimulate the release of PTH, which decreases reabsorption of phosphorus.

A normal serum phosphorus level is 2.4 to 4.4 mEq/L. Regulation of phosphate balance requires adequate renal functioning because the kidneys are the major route of phosphate excretion.

Phosphorus is essential in bone and teeth formation and for neuromuscular activity. Phosphorus is an important component of nucleic acids (DNA and RNA) and assists in energy transfer in cells, helps maintain cellular osmotic pressure, and supports the acid-base balance of body fluids. Clinical manifestations of **hypophosphatemia** include muscle weakness, tremors, paresthesia, bone pain, hyporeflexia, seizures, hyperventilation, anorexia, and dysphagia. Symptoms of **hyperphosphatemia** are similar to those of hypocalcemia and include hyperreflexia, tetany,

positive Chvostek and Trousseau signs, flaccid paralysis, muscular weakness, tachycardia, nausea, diarrhea, and abdominal cramps. Phosphorus-rich foods include whole-grain cereals, nuts, milk, and meat. Phosphorus deficiency can result from decreased intestinal absorption, malnutrition, alcoholism, vomiting, diarrhea, use of concentrated glucose solutions, respiratory alkalosis, glycosuria, hypokalemia, hypomagnesemia, or use of thiazide diuretics. Hypophosphatemia may lead to hemolytic anemia, platelet dysfunction, and reduced oxygen transport. Hyperphosphatemia is most often related to chronic kidney disease. Increased intake in the form of laxatives may also increase serum levels.

Treatment of phosphorus imbalance is aimed at eliminating or reducing the cause. Monitoring phosphorus, calcium, and magnesium levels and assessing the patient for signs of electrolyte and acid-base imbalance are important nursing interventions. Phosphorus replacement is guided by the degree of deficit, onset, and patient presentation. Oral intake is the preferred route of replacement. IV phosphorus is available for treatment of patients who are unable to tolerate oral replacements or those with severe deficits. Potassium phosphate is an Institute for Safe Medication Practices (ISMP) high-alert medication used for IV phosphorus replacement. Potassium phosphate must be diluted before use and must be infused slowly using an infusion-control pump. Too rapid an infusion may cause potassium toxicity in patients with severe renal or adrenal insufficiency. The IV insertion site must be monitored for infiltration; potassium phosphate may cause tissue necrosis and sloughing if infiltration occurs. Phosphorus, potassium, and calcium levels and renal function should be monitored during and after infusion. Use of potassium phosphate is contraindicated in patients with hyperkalemia or hypocalcemia.

Hyperphosphatemia in patients with chronic kidney disease is treated with restriction of dietary phosphorus, phosphorus-binding medications such as calcium acetate, or dialysis. Hyperphosphatemia can lead to secondary hyperparathyroidism and osteodystrophy.

Critical Thinking Case Study

Mr. K.W. is 72 years of age and has had vomiting and diarrhea for 2 days. He takes digoxin 0.25 mg and hydrochlorothiazide 50 mg daily. His serum potassium level is 3.2 mEq/L. He complains of being dizzy, and his blood pressure is slightly lower than usual. The nurse assesses his physiologic status and notes that his muscles are weak and flabby, his abdomen is distended, and peristalsis is diminished.

1. What signs and symptoms indicate that Mr. K.W. is in potassium imbalance?
2. What contributing factors caused Mr. K.W.'s potassium imbalance?
3. What interventions should be performed for alleviating this potassium imbalance?
4. How much potassium chloride would be needed to elevate Mr. K.W.'s serum potassium by 1 mEq?

Mr. K.W. is ordered IV infusions of 1 L of 5% dextrose with 30 mEq of potassium chloride (KCl) and 1 L of 5% dextrose in 0.45% sodium chloride (NaCl). He is also prescribed PO KCl 15 mEq/10mL three times per day for 2 days.

5. Can KCl be given intramuscularly, subcutaneously, or as an IV bolus (push)? Explain your answer.
6. What instructions should the nurse give Mr. K.W. for taking oral potassium supplements?
7. What happens if Mr. K.W.'s urine output decreases while he is receiving IV and oral potassium? Explain the responsibilities of the nurse?
8. Because Mr. K.W. is taking a diuretic and digoxin, what should the nurse include with patient teaching? Give examples.

NCLEX Study Questions

1. Three days after a patient's total colectomy and ileostomy, he has a nasogastric tube for continuous suction and a Foley catheter for continuous drainage. The night nurse reports a high output from the ileostomy. The patient's pulse is irregular, and he reports leg weakness. Based on this situation, the nurse would correctly suspect what type of imbalance?
   a. Hypokalemia
   b. Hyperkalemia
   c. Hyponatremia
   d. Hypercalcemia
2. A patient is receiving intravenous (IV) potassium supplements. What is the most important nursing implication when administering this drug?
   a. IV potassium supplements may only be administered via a central vascular access device.
   b. IV potassium must be diluted before administration and delivered by infusion pump.
   c. IV potassium must be chilled before administration.
   d. IV potassium preparations do not contain preservatives.
3. A patient is receiving 10 mEq of potassium chloride in 100 mL of normal saline intravenously to infuse over 1 hour via infusion pump. The patient has a 22-gauge peripheral IV in his right forearm and reports pain at the insertion site; the nurse notes that the site is reddened, warm, and tender to the touch. Which action would the nurse take?
   a. Aspirate and check for blood return, and then slow the IV rate.
   b. Discontinue the IV, and then have a central line inserted to administer the potassium.
   c. Stop the infusion, and discontinue the IV immediately.
   d. Apply warm compresses to the IV site.
4. The health care provider orders a hypertonic crystalloid IV solution for a 70-year-old patient with cerebral edema. Which assessment should the nurse report immediately to the provider?
   a. Improved blood pressure, increased urinary output, and stable vital signs
   b. Hyperglycemia, decreased urinary output, and increased level of consciousness
   c. Thirst, dry mouth, cool extremities, and decreased urinary output
   d. Headache, irritability, confusion, widening pulse pressure, and decreased level of consciousness
5. A patient is receiving fluid replacement. The nurse's health teaching with this patient includes which suggestions? (Select all that apply.)
   a. Measure weight daily.
   b. Know that thirst means a mild fluid deficit.
   c. Monitor fluid intake.
   d. Avoid the use of calcium supplements.
   e. Monitor output.
6. A patient gained 4.4 lb (2 kg), and it has been determined that the weight gain is caused by fluid retention. The nurse correctly estimates that the weight gain may be equivalent to approximately how much fluid?
   a. 1 L
   b. 2 L
   c. 6 L
   d. 8 L
7. A patient has hypernatremia. Which components are appropriate to include in the nursing care plan? (Select all that apply.)
   a. Seizure precautions

b. Need to keep appointments for laboratory tests and with the health care provider
c. Signs and symptoms of hypernatremia (muscle cramps, weakness, fatigue)
d. Need for fluid restrictions
e. Need to read food labels

8. The nurse is reviewing the medication list of a patient with hypokalemia. Which products may be contributing to the cause of this imbalance? (Select all that apply.)
a. Cortisone
b. Licorice
c. Azithromycin
d. Estrogen
e. Digoxin

Answers: 1, a; 2, b; 3, c; 4, d; 5, a, b, c, e; 6, b; 7, a, b, d, e; 8, a, b, e.

Vitamin and Mineral Replacement

OUTLINE

Vitamins
- Fat-Soluble Vitamins
- Water-Soluble Vitamins
- Nursing Process: Patient-Centered Collaborative Care— Vitamins

Minerals
- Iron
- Copper
- Zinc
- Chromium
- Selenium
- Nursing Process: Patient-Centered Collaborative Care— Anti-anemia Mineral: Iron

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Discuss the four justifications for the use of vitamin supplements.
- Differentiate between water-soluble and fat-soluble vitamins.
- Relate food sources and deficiency conditions associated with each vitamin.
- Explain the need for iron and foods that are high in iron.
- Explain the uses for iron, copper, zinc, chromium, and selenium.
- Describe the nursing interventions, including patient teaching, related to vitamin and mineral uses.

KEY TERMS

adequate intake (AI), p. 176
estimated average requirement (EAR), p. 176
fat-soluble vitamins, p. 177
iron, p. 183
minerals, p. 183
recommended dietary allowance (RDA), p. 177
tolerable upper intake level (UL), p. 177
water-soluble vitamins, p. 180

http://evolve.elsevier.com/McCuistion/pharmacology

Vitamins and minerals are needed in the correct portions for normal body function. Most vitamin and mineral nutrients can be safely obtained through the diet. Overuse of vitamins and minerals occurs easily, especially if the nutrients are coming from pills instead of food. It is important to check all supplements with the patient's provider.

Vitamins

Vitamins are organic substances that are necessary for normal metabolic functions and for tissue growth and healing. The body needs only a small amount of vitamins daily, which can be obtained through the diet. A well-balanced diet has all of the vitamins and minerals needed for body functioning. The intake of vitamins should be increased by people experiencing periods of rapid body growth; those who are pregnant or breastfeeding; patients with debilitating illnesses; those with malabsorptive issues, such as Crohn disease; and those with inadequate diets, which includes alcoholics and some geriatric patients. Children who have poor nutrient intake and are malnourished may need vitamin replacement. People on "fad" or restrictive diets may have vitamin deficiencies, as may those who are unable to afford or do not select a wide variety of foods.

The sale of vitamins in the United States is a multibillion-dollar business. About 73% of the population uses a variety of nutritional supplements. Older women and people with higher education are typical users of nutritional supplements. Numerous vitamins and herbal medications are available for specialized needs such as cholesterol, memory, menopause, and prostate support. Before purchasing these agents, the patient should discuss with their health care provider the use and health benefits of multiple vitamins and herbal medications. Vitamin supplements are not necessary if the individual is healthy and consumes a well-balanced daily diet on a regular basis.

The Food and Nutrition Board of the Institute of Medicine (IOM) has established the Dietary Reference Intakes (DRIs).

The DRI nutrient recommendations include these components:

1. **Adequate intake (AI)** is the consumption and absorption of sufficient food, vitamins, and essential minerals necessary to maintain health.
2. **Estimated average requirement (EAR)** is the daily intake of a specific nutrient estimated to meet the requirement in 50% of healthy people in an age- and sex-specific group.

TABLE 13.1

Deficiencies That Require Use of Vitamin Supplements

Categories	Deficiencies
Inability to metabolize and absorb vitamins	Diarrhea, infectious and inflammatory diseases (e.g., Crohn disease, celiac disease)
Inability to use vitamins	Liver disease (cirrhosis, hepatitis), renal disease, certain hereditary deficiencies
Increased vitamin losses	Fever from infectious processes, hyperthyroidism, hemodialysis, cancer, starvation, crash diets
Increased vitamin requirements	Early childhood, pregnancy, debilitating disease (cancer, alcoholism), gastrointestinal surgery, special diets

3. **Recommended dietary allowance (RDA)** is the amount of vitamins, minerals, or other essential nutrients that should be ingested every day by a normal person engaged in average activities. RDAs are increased for patients who are experiencing increased activity, children who are growing, and women who are pregnant and lactating. RDAs assume a state of wellness and are of little use in patients who are ill.
4. **Tolerable upper intake level (UL)** is the maximum level of continuing daily nutrient intake that is likely to pose no risk to the health of most of those in the age group for which it has been established.

Vitamin deficiencies can cause cellular and organ dysfunction that may result in slow recovery from illness. Vitamin supplements are necessary for the vitamin deficiencies described in Table 13.1, but vitamins are frequently taken prophylactically rather than therapeutically.

With the goal of facilitating better nutrition, the U.S. Department of Agriculture (USDA) has developed Choose My Plate, part of a communications initiative based on its *2010 Dietary Guidelines for Americans.* Available at www.ChooseMyPlate.gov, Choose My Plate is an interactive tool that helps Americans to eat more healthfully (Fig. 13.1). This website offers a variety of features, including both consumer and professional information.

The Food and Nutrition Board at the IOM publishes the U.S. RDA for daily dose requirements of each vitamin. The U.S. Food and Drug Administration (FDA) requires that all vitamin products be labeled according to the vitamin content and the proportion of the RDA provided by the vitamin product. Individuals should be encouraged to check the RDA listed on the vitamin label to determine whether the product provides the RDA dose requirements. The RDA may need to be modified for patients who are ill.

Megadoses of vitamins are available and are advertised for specific health conditions, but high

doses of some vitamins can be toxic. Patients should be advised to contact their health care provider before taking these products. Megadoses of fat-soluble vitamins (A, D, E, and K) may cause toxic effects, whereas megadoses of water-soluble vitamins are eliminated via the urine and thus are generally not toxic. Adverse reactions—kidney stones and nerve damage, respectively—have been reported from vitamin C and vitamin B6. However, it is also claimed that B vitamins may positively influence metabolism in older adults.

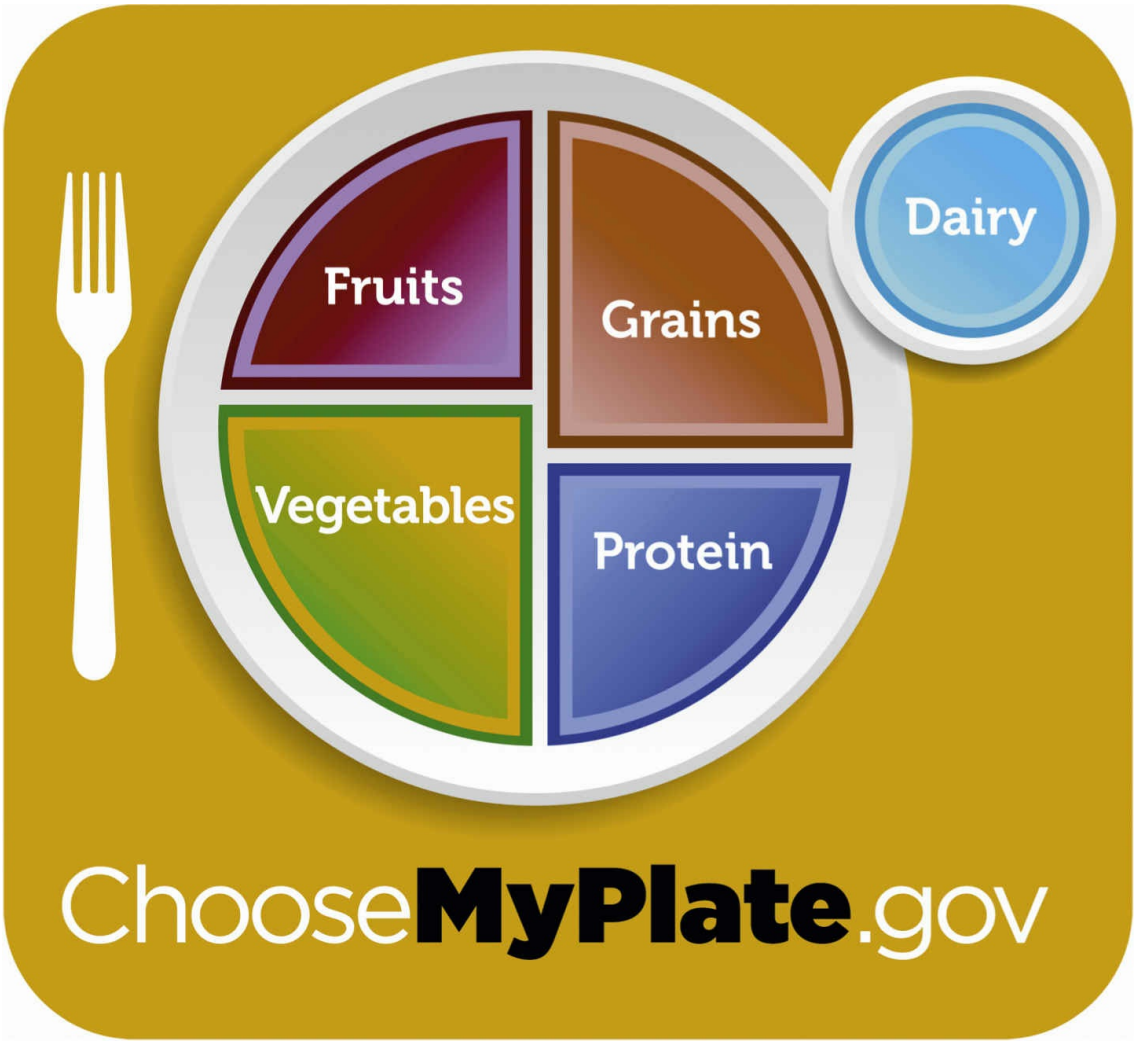

FIG. 13.1 The U.S. Department of Agriculture's ChooseMyPlate.

Table 13.2 lists fat- and water-soluble vitamins, their functions, suggested food sources, and related deficiency conditions.

Fat-Soluble Vitamins

Vitamins fall into two general categories: fat-soluble and water-soluble. The **fat-soluble vitamins** are A, D, E, and K. They are metabolized slowly; can be stored in fatty tissue, liver, and muscle in significant amounts; and are excreted in the urine at a slow rate. Vitamins A and D are toxic if taken in excessive amounts over time. Current research shows that vitamin D toxicity is quite rare, and its symptoms are fairly nonspecific. Given that many people are found to be vitamin D deficient, it is not uncommon to see high-dose vitamin D therapy (e.g., 50,000 units/week).

Foods rich in vitamins A, D, E, and K are shown in Table 13.2.

Vitamin A

Vitamin A (retinol and beta-carotene) are essential for bone growth and for maintenance of epithelial tissues, skin, eyes, and hair. Vitamin A has antioxidant properties. Studies show that women who take vitamin A have a 20% decrease in breast cancer as opposed to those who do not take vitamin A. However, excessive doses can be toxic. During pregnancy, excessive amounts of vitamin A (>6000 IU) might have a teratogenic effect (i.e., it can cause birth defects) on the fetus. Prototype Drug Chart 13.1 describes the pharmacologic data on vitamin A. Intramuscular administration is used in acutely ill patients.

Pharmacokinetics

Vitamin A is absorbed in the gastrointestinal (GI) tract, and 90% is stored in the liver; however, this function can be inhibited with liver disease. Massive doses of vitamin A can cause hypervitaminosis. Signs and symptoms include hair loss, peeling skin, anorexia, abdominal pain, lethargy, nausea, and vomiting.

The upper limit (UL) for vitamin A is 3000 mcg/daily = 10,000 IU). Vitamin A toxicity affects multiple organs, especially the liver. Mineral oil, cholestyramine, alcohol, and antihyperlipidemic drugs decrease the absorption of vitamin A. Vitamin A is excreted through the kidneys and feces.

TABLE 13.2

Vitamins: Functions, Suggested Food Sources, and Deficiency Conditions

Vitamin	Function	Food Sources	Deficiency Conditions
A (Retinol)	Required for development and maintenance of healthy eyes, gums, teeth, skin, hair, glands, and immune function	Darkly colored fruits and vegetables like carrots, cantaloupe, mangoes, spinach, pumpkin, and sweet potatoes *Natural vitamin A is found only in foods of animal origin: dairy products, meat, fish oil, and fish.	Night blindness is often the first indication of deficiency. Skin lesions and dysfunction of mucous membranes also occur.
B1 (Thiamine)	Promotes carbohydrate metabolism (energy) and is required for good function of nervous system and heart	Enriched, fortified whole-grain products, especially breads and cereals; pork is the richest source of the natural vitamin.	Deficiency causes beriberi, cardiovascular complications, edema, neurologic disorders, ataxia, diplopia.
B2 (Riboflavin)	Promotes body's use of carbohydrates, proteins, and fats and is required for tissue integrity	Milk, enriched breads and cereals, yogurt, cheese, and organ meats	Sore throat, cracks in skin at the corners of the mouth, and cheilosis (cracks in the lips) signal deficiency.
B6 (Pyridoxine)	Important in metabolism, protein synthesis, and formation of RBCs	Ready-to-eat cereals, meat, fish, poultry, starchy vegetables (white potatoes), noncitrus fruits, and organ meats	Neuritis, convulsions, seborrheic dermatitis, anemia, depression, and confusion can result from deficiency.
B12 (Cobalamin)	Functions as a nucleic acid to help form RBCs and aids in functioning of the nervous system	Liver, kidney, fish, milk, eggs, chicken, turkey	Low levels can cause gastrointestinal disorders, poor growth, and anemias.
Folic acid	Essential in the synthesis of DNA, assists with intestinal functioning, and prevents certain anemias	Leafy green vegetables, yellow fruits and vegetables, yeast, organ meats, black-eyed peas, lentils	Decreases occur in WBC count and clotting factors, along with anemias (pernicious), thalassemia, intestinal disturbances, and depression.
Table Continued			

Vitamin	Function	Food Sources	Deficiency Conditions
Pantothenic acid	Essential in multiple biochemical processes such as gluconeogenesis, metabolism of carbohydrates and synthesis of fatty acids, and biosynthesis of steroid hormones and acetylcholine	Present in virtually all foods	Natural deficiency is unknown in humans.
Niacin	In all body tissues; necessary for energy-producing reactions and assists nervous system	In many foods of plant and animal origin including liver, poultry, fish, potatoes, peanuts, and cereal bran	Pellagra (rough skin), abdominal pain, headache, memory loss, anorexia, and insomnia can occur.
Biotin	Involved in synthesis of fatty acids and carbohydrates and in energy production	Eggs, milk, leafy green vegetables, liver, kidney	Natural deficiency is unknown in humans.
C (Ascorbic acid)	Helps tissue repair and growth, required for formation of collagen	Citrus fruits, cantaloupe, tomatoes, leafy green vegetables, green peppers, potatoes, strawberries, kiwi fruit	Deficiency leads to poor wound healing, bleeding gums, scurvy, and faulty bone and tooth development.
D (Calciferol)	Promotes phosphorus and calcium balance, important for strong teeth and bones	Vitamin D–fortified milk, cereal, eggs, fatty fish, and liver	Rickets can occur in children, osteomalacia in adults.
E (Alpha-tocopherol)	Protects fatty acids and promotes formation and functioning of RBCs, muscle, and other tissues	Whole-grain cereals, wheat germ, green vegetables, sunflower seeds, milk, eggs, meat, avocadoes, asparagus, vegetable oils	Breakdown of RBCs can occur with deficiency.
K	Essential for blood clotting	Leafy green vegetables, liver, cheese, egg yolk, vegetable oil, tomatoes	Increased clotting time leads to increased bleeding and hemorrhage.

RBC, Red blood cell; *WBC*, white blood cell.

Pharmacodynamics

Vitamin A is necessary for many biochemical processes. It aids in the formation of the visual pigment needed for night vision. This vitamin is needed in bone growth and development, and it promotes the integrity of the mucosal and epithelial tissues. An early sign of vitamin A deficiency (hypovitaminosis A) is night blindness. This may progress to dryness and ulceration of the cornea and cause blindness.

Vitamin A taken orally is readily absorbed from the GI tract and peaks in 3 to 5 hours. Its duration of action is unknown. Because vitamin A is stored in the liver, the vitamin may be available to the body for days, weeks, or months.

Vitamin D

Vitamin D has a major role in regulating calcium and phosphorus metabolism, and it is needed for calcium absorption from the intestines. Dietary vitamin D is absorbed in the small intestine and requires bile salts for absorption. There are two compounds of vitamin D: vitamin D2, *ergocalciferol*, a synthetic fortified vitamin D, and vitamin D3, *cholecalciferol*, a natural form of vitamin D influenced by ultraviolet sunlight on the skin. Over-the-counter (OTC) vitamin D supplements usually contain vitamin D3. Once absorbed, vitamin D is converted to calcifediol (also known as *25-hydroxycholecalciferol*) in the liver. Calcifediol is then converted to an active form, calcitriol, in the kidneys. Studies have suggested that vitamin D taken with calcium can reduce the incidence of fractures.

PROTOTYPE DRUG CHART 13.1 Vitamin A

Drug Class	Dosage
Retinol Fat-soluble vitamin Pregnancy category A*	*Daily requirements*†: A: 700 mcg/day (females); 900 mcg/day (males); 770 mcg/day (pregnancy); 1300 mcg/day (lactating females).C: 300 mcg/day-700 mcg/day (depending on age)
	Severe deficiency: A: >3000 mcg/day C: 600 mcg/day-1700 mcg/day (depending on age)
Contraindications	Drug-Lab-Food Interactions
Hypervitaminosis A, pregnancy, polysorbate-80 sensitivity	Drug: Mineral oil may decrease absorption of vitamin A, oral contraceptives and warfarin increase vitamin A levels, tetracyclines interfere with absorption.
	Lab: May increase BUN, calcium, cholesterol, and triglycerides; may lower erythrocyte and leukocyte counts
	Food: None known
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 1 h	PO: Onset: quickly
Distribution: PB: UK	Peak: 3-5 h
Metabolism: t½: Days/weeks/months	Duration: UK
Excretion: Excreted in urine	
Therapeutic Effects/Uses	
To treat vitamin A deficiency (biliary tract or pancreatic disease, colitis, cirrhosis, celiac disease, sprue) and skin disorders, to prevent night blindness, and to promote bone development Mode of Action: Essential for growth, bone and teeth development, vision, integrity of skin and mucous membranes, and reproduction	
Side Effects	Adverse Reactions
Headache, fatigue, drowsiness, irritability, anorexia, vomiting, diarrhea, dry skin, visual changes	Anaphylactic shock and anaphylactoid reactions, increased intracranial pressure, hypervitaminosis A, thrombocytopenia, cholestasis, hepatomegaly, metabolic acidosis, hypotension

>, Greater than; *A,* adult; *BUN,* blood urea nitrogen; *C,* child; *h*, hour; *PB*, protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

† Daily requirements, see: https://fnic.nal.usda.gov/sites/fnic.nal.usda.gov/files/uploads/recommended_intakes_individuals.pdf

Calcitriol, the active form of vitamin D, functions as a hormone, and along with parathyroid hormone (PTH) and calcitonin, it regulates calcium and phosphorus metabolism. Calcitriol and PTH stimulate bone reabsorption of calcium and phosphorus. Excretion of vitamin D is primarily in bile; only a small amount is excreted in the urine. If serum calcium levels are low, more vitamin D is activated; when serum calcium levels are normal, activation of vitamin D is decreased. The normal adult RDA of vitamin D is 1000 mg daily (600 IU/day).

Excess vitamin D ingestion (>4000 IU/day) results in hypervitaminosis D and may cause hypercalcemia (an elevated serum calcium level). Anorexia, nausea, and vomiting are early symptoms of vitamin D toxicity.

Vitamin E

Vitamin E has antioxidant properties that protect cellular components from being oxidized and protect red blood cells (RBCs) from hemolysis. Vitamin E depends on bile salts, pancreatic secretion, and fat for its absorption. Vitamin E is stored in all tissues, especially the liver, muscle, and fatty tissue. About 75% of vitamin E is excreted in bile.

Although early evidence had suggested the potential for vitamin E to reduce cardiovascular disease (CVD), more recent outcome studies have not shown benefits with vitamin E. Currently, the American Heart Association guidelines do not recommend vitamin E therapy for women as a preventative measure for CVD. Vitamin E has been of interest for its antioxidant properties, and it has been used off label for various conditions, including Alzheimer disease.

The RDA of vitamin E in adults is 30 IU daily and should not exceed the upper limit (UL) of 1000 mg/day in oral intake. The dosage is determined by nutritional intake or degree of deficiency by the health care provider. Side effects of large doses of vitamin E may include fatigue, weakness, nausea, GI upset, headache, bleeding, and breast tenderness. Vitamin E may prolong the prothrombin time (PT), and patients taking warfarin should have their PT monitored closely. Iron and vitamin E should not be taken together because iron can interfere with the body's absorption and use of vitamin E.

Vitamin K

Vitamin K occurs in three forms. Vitamin K1 (phytonadione) is the most active form and is a synthetic type of vitamin K made by plants, and it represents the bulk of dietary vitamin K. Vitamin K2 (menaquinone) is synthesized by probiotic bacteria in the digestive tract. Vitamin K3 (menadione) is another synthetic form of vitamin K. After vitamin K is absorbed, it is stored

primarily in the liver and in other tissues. Half of vitamin K comes from the intestinal flora, and the remaining portion comes from the diet. The RDA for an adult male is 120 mcg/day, and for an adult female the RDA is 90 mcg/day. The IOM has not been able to determine a tolerable upper level for vitamin K, so always speak to the health care provider prior to increasing the dose of vitamin K.

Vitamin K is needed for synthesis of prothrombin and clotting factors VII, IX, and X. For oral anticoagulant overdose, vitamin K1 (phytonadione) is the only vitamin K form available for therapeutic use and is most effective in preventing hemorrhage. Vitamin K is used for two purposes: as an antidote for oral anticoagulant overdose and to prevent and treat the hypoprothrombinemia of vitamin K deficiency. Spontaneous hemorrhage may occur with vitamin K deficiency due to lack of bile salts and malabsorption syndromes that interfere with vitamin K uptake (e.g., celiac disease). Newborns are vitamin K deficient, thus a single dose of phytonadione is recommended immediately after delivery. This practice is common in the United States but is controversial in other countries because it can elevate the bilirubin level and can cause hyperbilirubinemia with a risk of kernicterus. Oral and parenteral forms of phytonadione are available; intravenous (IV) administration is dangerous and may cause death.

Water-Soluble Vitamins

Water-soluble vitamins are the B-complex vitamins and vitamin C. This group of vitamins is not usually toxic unless taken in extremely excessive amounts. Water-soluble vitamins are not stored by the body, so consistent, steady supplementation is required. Water-soluble vitamins are readily excreted in the urine. Protein binding of water-soluble vitamins is minimal. Foods that are high in vitamin B are grains, cereals, breads, and meats. There are reports that B vitamins may promote a sense of well-being and increased energy as well as decreased anger, tension, and irritability. Citrus fruits and green vegetables are high in vitamin C. If the fruits and vegetables are cut or cooked, a large amount of vitamin C is lost.

Vitamin B Complex

Vitamin B1 (thiamine), vitamin B2 (riboflavin), vitamin B3 (nicotinic acid, or niacin), and vitamin B6 (pyridoxine) are four vitamins in the vitamin B–complex group that are water soluble. This is a common group of vitamins administered in the clinical setting, especially to patients with alcoholism.

Thiamine deficiency can lead to the polyneuritis and cardiac pathology seen in beriberi or to Wernicke encephalopathy that progresses to Korsakoff syndrome, conditions most commonly associated with alcohol abuse. Wernicke-Korsakoff syndrome is a significant central nervous system (CNS) disorder characterized by confusion, nystagmus, diplopia, ataxia, and loss of recent memory. If not treated, it can cause irreversible brain damage. IV administration of thiamine is recommended for treatment of Wernicke-Korsakoff syndrome. Thiamine must be given before giving any glucose to avoid aggravation of symptoms.

Riboflavin may be given to manage dermatologic problems such as scaly dermatitis, cracked corners of the mouth, and inflammation of the skin and tongue. To treat migraine headache, riboflavin is given in larger doses than for dermatologic concerns.

Niacin is given to alleviate pellagra and hyperlipidemia, for which large doses are required. Chapter 41 offers a discussion of niacin use to reduce cholesterol levels. However, large doses may cause GI irritation and vasodilation, resulting in a flushing sensation.

Pyridoxine is administered to correct vitamin B6 deficiency. It may also help alleviate the symptoms of neuritis caused by isoniazid (INH) therapy for tuberculosis. Vitamin B6 is essential as a building block of nucleic acids, in RBC formation, and in synthesis of hemoglobin. Pyridoxine is used to treat vitamin B6 deficiency caused by lack of adequate diet, inborn errors of metabolism, or drug-induced deficiencies secondary to INH, penicillamine, or cyclosporine (or hydralazine) therapy. It is also used to treat neonates with seizures refractive to traditional therapy. Vitamin B6 deficiencies may occur in alcoholics along with deficiencies of other B-complex vitamins. Patients with diabetes or alcoholism may benefit from daily supplementation. Pyridoxine is readily absorbed in the jejunum and is stored in the liver, muscle, and brain. It is metabolized in the liver and excreted in the urine.

Vitamin C

Vitamin C (ascorbic acid) is absorbed from the small intestine. Vitamin C aids in the absorption of iron and in the conversion of folic acid. Vitamin C is not stored in the body and is excreted readily in the urine. A high serum vitamin C level that results from excessive dosing of vitamin C is excreted by the kidneys unchanged. Vitamin C is used in the treatment of scurvy, which is rare in developed countries but seen in individuals who consume few fruits and vegetables. Also, scurvy is seen in people who are on restricted diets or who abuse alcohol or drugs.

The recommended daily allowance of vitamin C (adult dose) is 75 mg/day for women and 90 mg/day for men to prevent deficiency. Some individuals take greater amounts. Massive doses of vitamin C can cause GI upset. Prototype Drug Chart 13.2 details pharmacologic data on vitamin C.

Pharmacokinetics

Vitamin C is absorbed readily through the GI tract and is distributed throughout the body fluids. The kidneys completely excrete vitamin C mostly unchanged.

Pharmacodynamics

Vitamin C is needed for carbohydrate metabolism and protein and lipid synthesis. Collagen synthesis also requires vitamin C because it is part of the intercellular matrix that binds cells together and aids in wound healing. Smoking decreases serum vitamin C levels. Vitamin C in doses greater than 500 mg aids iron absorption; however, it can decrease the effect of oral anticoagulants.

PROTOTYPE DRUG CHART 13.2 Vitamin C

Drug Class	Dosage
Water-soluble vitamin	*Daily requirements*†:
Pregnancy category A* (C if used above RDA)	A: 75 mg/d (female); 90 mg/d (men); 85 mg/d (pregnancy); 115 mg/d (lactating females); (smokers require 35 mg/d more than nonsmokers) C: PO: 15-75 mg/d (depending on age)
	Severe deficit: Scurvy:
	A: PO/IM/IV: 150-250 mg bid (larger doses have shown no additional benefit)
	C: PO/IM/IV: 100-300 mg/d in divided doses
Contraindications	Drug-Lab-Food Interactions
Caution: Renal calculi, hemochromatosis, anemia (sickle cell, sideroblastic), thalassemia, diabetes mellitus, breastfeeding	Decreases ascorbic acid uptake when taken with salicylates; may decrease effect of oral anticoagulants; may decrease elimination of aspirins Lab: May decrease bilirubin and urinary pH; may increase uric acid and uric oxalate
	Food: None known
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Quickly	PO: Absorbed orally through active transport
Distribution: PB: 25%	Onset: >2 d
Metabolism: t½: UK	Peak: UK
Excretion: In the urine; unchanged with high doses	Duration: UK
Therapeutic Effects/Uses	
To prevent and treat vitamin C deficiency (scurvy), to increase wound healing, and for burns; preserves integrity of blood vessels Mode of Action: A water-soluble vitamin, it is essential for collagen formation and tissue repair (bones, skin, blood vessels) and for synthesis of lipids, protein, and carnitine	
Side Effects	Adverse Reactions
Oral: Nausea, vomiting, diarrhea, heartburn, headache Parenteral: Flushing, headache, dizziness, soreness at injection site	Kidney stones, crystalluria, hyperuricemia, hemolytic anemia *Life threatening:* Sickle cell crisis, deep venous thrombosis

A, Adult; *bid,* twice a day; *C,* child; *d,* day; *IM,* intramuscular; *IV,* intravenous; *PB,* protein binding; *PO,* by mouth; *RDA,* recommended dietary allowance; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

† Daily requirements, see: https://fnic.nal.usda.gov/sites/fnic.nal.usda.gov/files/uploads/recommended_intakes_individuals.pdf

The use of large doses of vitamin C is questionable. Large doses of any vitamin can cause toxicity. Most authorities believe that vitamin C does not prevent the common cold, cure advanced cancer, or treat schizophrenia. Moreover, large doses of vitamin C can cause nausea, abdominal cramps, and diarrhea. If taken with aspirin or sulfonamides, it may cause crystal formation in the urine. Vitamin C directly irritates the intestinal mucosa in the GI tract. This is why the Food and Nutrition Board has set 2 g/day as the adult UL for vitamin C. Large doses of vitamin C can decrease the effect of oral anticoagulants. If large doses of any vitamin are to be discontinued, a gradual reduction of the dosage is necessary to avoid vitamin deficiency.

Folic Acid (Folate)

Folic acid is absorbed from the small intestine, and the active form of folic acid—folate—is circulated to all tissues. One third of folate is stored in the liver, and the rest is stored in tissues. It is

excreted 80% in bile and 20% in urine.

Folic acid is essential for body growth. It is needed for DNA synthesis, and without folic acid, cellular division is disrupted. Chronic alcoholism, poor nutritional intake, malabsorption syndromes, pregnancy, and drugs that cause inadequate absorption (phenytoin, barbiturates) or folic acid antagonism (methotrexate, triamterene, trimethoprim) are causes of folic acid deficiencies. Symptoms of folic acid deficiencies include anorexia, nausea, stomatitis, diarrhea, fatigue, alopecia, and blood dyscrasias (megaloblastic anemia, leukopenia, thrombocytopenia). These symptoms are usually not noted until 2 to 4 months after folic acid storage is depleted.

Folic acid deficiency during the first trimester of pregnancy can affect the development of the CNS of the fetus. This may cause neural tube defects (NTDs) such as spina bifida, defective closure of the bony structure of the spinal cord, or anencephaly, lack of brain mass formation. The U.S. Public Health Services recommends that all women who may become pregnant consume 400 mcg of supplemental folic acid each day in addition to the folate they get with food. Synthetic folate is more stable than folic acid obtained from food: bioavailability is greater than 85% with synthetic folate and less than 59% for food-sourced folic acid. Some evidence suggests that 400 to 500 mcg (0.4 to 0.5 mg) of folic acid per day can decrease the incidence of coronary artery disease (CAD). It is thought that folic acid decreases the amino acid homocysteine in the blood, which may contribute to heart disease.

Excessive doses of folic acid may mask signs of vitamin B12 deficiency, which is a risk in older adults. Patients taking phenytoin to control seizures should be cautious about taking folic acid. This vitamin can lower the serum phenytoin level, which could increase the risk of seizures; the phenytoin dose would need to be adjusted in such patients. This is a complex interaction that is not fully understood, but it is thought that 1 mg or less per day of folic acid is safe in patients with controlled epilepsy.

Vitamin B12

Vitamin B12, like folic acid, is essential for DNA synthesis. Vitamin B12 aids in the conversion of folic acid to its active form. With active folic acid, vitamin B12 promotes cellular division. It is also needed for normal hematopoiesis (development of RBCs in bone marrow) and to maintain nervous system integrity, especially of the myelin.

The gastric parietal cells produce an intrinsic factor that is necessary for the absorption of vitamin B12 through the intestinal wall. Without the intrinsic factor, little or no vitamin B12 is absorbed. After absorption, vitamin B12 binds to the protein transcobalamin II and is transferred to the tissues. Most vitamin B12 is stored in the liver and is slowly excreted, and it can take 2 to 3 years for stored vitamin B12 to be depleted and for a deficit to be noticed.

Vitamin B12 deficiency is uncommon unless there is a disturbance of the intrinsic factor and intestinal absorption. Pernicious anemia (lack of the intrinsic factor) is the major cause of vitamin B12 deficiency, but deficiency can also develop in strict vegetarians who do not consume meat, fish, or dairy products. Other possible causes of vitamin B12 deficiency include malabsorption syndromes (cancer, celiac disease, and certain drugs), gastrectomy, Crohn disease, and liver and kidney diseases. Vitamin B12 deficiency is commonly seen with the use of metformin and proton pump inhibitors (e.g., omeprazole). Symptoms may include numbness and tingling in the lower extremities, weakness, fatigue, anorexia, loss of taste, diarrhea, memory loss, mood changes, dementia, psychosis, megaloblastic anemia with macrocytes (overenlarged erythrocytes [RBCs]) in the blood, and megaloblasts (overenlarged erythroblasts) in the bone marrow.

To correct vitamin B12 deficiency, cyanocobalamin in crystalline form can be given intramuscularly for severe deficits. It cannot be given intravenously because of possible hypersensitive reactions. Cyanocobalamin can be given orally and is commonly found in multivitamin preparations. It can also be given as a subcutaneous injection.

Nursing Process:Patient-Centered Collaborative Care

Vitamins

Assessment

- Check the patient for vitamin deficiency before the start of therapy and regularly thereafter.

Explore such areas as inadequate nutrient intake, debilitating disease, and gastrointestinal (GI) disorders.
- Obtain a 24- and 48-hour diet history analysis.
- When possible, obtain levels to assess serum blood levels.

Nursing Diagnoses

- Nutrition, Imbalanced related to inadequate intake of food sources of vitamins
- Knowledge, Deficient related to food sources of vitamins
- Decision Making, Readiness for Enhanced related to food choices and vitamin supplementation

Planning

- The patient will eat a well-balanced diet.
- The patient with vitamin deficiency will take vitamin supplements as prescribed.
- The patient will demonstrate knowledge of vitamins contained in food sources.

Nursing Interventions

- Administer vitamins with food to promote absorption.
- Store vitamins in light-resistant containers.
- Use the supplied calibrated dropper for accurate dosing when administering vitamins in drop form. Solutions may be administered mixed with food or drink.
- Administer vitamins intramuscularly for patients who are unable to take vitamins by the oral route (e.g., those with GI malabsorption syndrome).
- Recognize the need for vitamin E supplements for infants receiving vitamin A to avoid the risk of hemolytic anemia.
- Monitor serum blood levels of any suspected vitamin or mineral deficiency.

Patient Teaching

General

- Advise patients to take the prescribed amount of vitamins.
- Counsel patients to read vitamin labels carefully and discuss with a health care provider prior to taking any vitamin or supplement.
- Advise patients to consult with a health care provider or pharmacist regarding interactions with prescription and over-the-counter medications.
- Discourage patients from taking a large dose of vitamins over a long period unless prescribed for a specific purpose by a health care provider. To discontinue long-term use of high-dose vitamin therapy, a gradual decrease in vitamin intake is advised to avoid vitamin deficiency.
- Inform patients that missing vitamins for 1 or 2 days is not a cause for concern because deficiencies do not occur for some time.
- Advise patients to check expiration dates on vitamin containers before purchasing them. Potency of vitamins is reduced after the expiration date.
- Counsel patients to avoid taking mineral oil with vitamin A on a regular basis because it interferes with absorption of the vitamin; mineral oil also interferes with vitamin K absorption. If needed, take mineral oil at bedtime.
- Explain to patients that there is no scientific evidence that large doses of vitamin C will cure a cold.
- Alert patients not to take large doses of vitamin C with aspirin or sulfonamides because crystals may form in the kidneys and urine.
- Alert patients to avoid excessive intake of alcoholic beverages. Alcohol can cause vitamin B–complex deficiencies.

Diet

- Advise patients to eat a well-balanced diet. Vitamin supplements are not necessary if the person is healthy and receives proper nutrition on a regular basis.
- Educate patients about foods rich in vitamin A, including milk, butter, eggs, and leafy green and yellow vegetables. Foods rich in various vitamins are listed in Table 13.2.

Side Effects

- Advise patients that nausea, vomiting, headache, loss of hair, and cracked lips (symptoms of hypervitaminosis A) should be reported to the health care provider. Early symptoms of hypervitaminosis D are anorexia, nausea, and vomiting.

Cultural Considerations

- Food and food choices have strong cultural roots. Determine the patient's preferred and culturally meaningful foods, and incorporate them into the food and supplement plan.
- Use interpreters as appropriate.
- Glucose-6-phosphate dehydrogenase (G-6-PD) deficiency is common among people of Arabic and Chinese heritage.

Evaluation

- Evaluate the patient's understanding of the purpose of vitamins and their correct use.
- Evaluate the effectiveness of the patient's diet for inclusion of appropriate amounts and types of food. Have the patient periodically keep a diet chart for a full week to determine typical nutrition.
- Determine whether the patient with malnutrition is receiving appropriate vitamin therapy.

Minerals

Various **minerals**—such as iron, copper, zinc, chromium, and selenium—are needed for body function.

Iron

Iron (ferrous sulfate, gluconate, or fumarate) is vital for hemoglobin regeneration. Sixty percent of the iron in the body is found in hemoglobin, and one of the causes of anemia is iron deficiency. A normal diet contains 5 to 20 mg of iron per day. Foods rich in iron include liver, lean meats, egg yolks, dried beans, green vegetables like spinach, and fruit. Food and antacids slow the absorption of iron, and vitamin C increases iron absorption.

During pregnancy, iron requirements increase due to the expansion of maternal blood volume and production of RBCs by the fetus. The iron needs of pregnant women are too great to be met through their diet, therefore supplementation is needed. About 27 mg/day are recommended during pregnancy and for 2 to 3 months after delivery.

The dose of iron for infants up to 12 months old is 11 mg/day, and for children from 1 to 8 years of age, it is 7 to 10 mg/day. Males from 9 to 50 years of age require 8 to 11 mg/day. Females 9 to 13 years of age require 8 mg/day; 14 to 18 years of age, 15 mg/day; 19 to 50 years of age, 18 mg/day; and women over 50 years of age require 8 mg/day. Prototype Drug Chart 13.3 describes the pharmacologic data on iron.

Pharmacokinetics

Iron is absorbed by the intestines and enters the plasma as heme, or it may be stored as ferritin. Although food decreases absorption by 25% to 50%, it may be necessary to take iron preparations with food to avoid GI discomfort. Vitamin C at doses greater than 500 mg may slightly increase iron absorption, whereas tetracycline, quinolone antibiotics (ciprofloxacin, levofloxacin, etc.), and antacids can decrease absorption (Complementary and Alternative Therapies 13.1).

Pharmacodynamics

Iron replacement is given primarily to correct or control iron-deficiency anemia, which is diagnosed by a laboratory blood smear. Positive findings for this anemia are microcytic (small), hypochromic (pale) erythrocytes (RBCs). Clinical signs and symptoms include fatigue, weakness, shortness of breath, pallor, and, in cases of severe anemia, increased GI bleeding. The dosage of ferrous sulfate for prophylactic use is 300 to 324 mg/day.

The onset of action for iron therapy takes days, and its peak action does not occur for days or weeks; therefore the patient's symptoms are slow to improve. Increased hemoglobin and hematocrit levels occur within 3 to 7 days.

About 30% to 50% of adults on parenteral nutrition have been shown to have iron deficiency. Pediatric patients are at a 40% to 84% risk of developing an iron deficiency.

Iron toxicity is a serious cause of poisoning in children. As few as 10 tablets of ferrous sulfate (3 g) taken at one time can be fatal within 12 to 48 hours; hemorrhage from the ulcerogenic effects of unbound iron leads to shock, therefore parents should be strongly cautioned against leaving iron tablets that look like candy (M&Ms) within a child's reach. (Most iron products are distributed in bubble packs.) There is also danger of children overdosing on adult or children's multivitamins that contain iron.

Copper

Copper is needed for the formation of RBCs and connective tissues. Copper is a cofactor of many enzymes, and its function is in the production of the neurotransmitters norepinephrine and dopamine. Excess serum copper levels may be associated with Wilson disease, an inborn error of metabolism that allows for large amounts of copper to accumulate in the liver, kidneys, brain, and cornea (brown or green Kayser-Fleischer rings).

PROTOTYPE DRUG CHART 13.3 Iron

Drug Class	Dosage
Ferrous sulfate, ferrous gluconate, ferrous fumarate Mineral to decrease anemia Note: Various iron products are not exchangeable on a milligram-to-milligram basis because each contains different amounts of elemental iron. Pregnancy category: A*	*Daily requirements*†: A: 15-18 mg/d (female); 8 mg/d (men); 27 mg/d (pregnancy); 9 mg/d (lactating females) C: 1-2 mg/kg/d in 1-2 divided doses (maximum: 15 mg/d) *Deficiency:* 2-3 mg/kg/d in 2-4 divided doses or 60-100 mg bid *Mild deficiency:* 3 mg/kg/d in 1-2 divided doses *Severe deficiency:* 4-6 mg/kg/d in 3 divided doses
Contraindications	Drug-Lab-Food Interactions
Hemolytic anemia, hemosiderosis, peptic ulcer, ulcerative colitis *Caution:* Bronchial asthma, iron hypersensitivity	Increased effect of iron with vitamin C; decreased effect of tetracycline, antacids, penicillamine Lab: May increase bilirubin; may decrease calcium Food: None known
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 10%-30% intestines	PO: Onset: 4 d
Distribution: PB: UK Metabolism: t½: 6 h Excretion: In urine, feces, and sweat	Peak: 7-14 d Duration: 3-4 months
Therapeutic Effects/Uses	
To prevent and treat iron-deficiency anemia Mode of Action: Enables RBC development and oxygen transport via hemoglobin	
Side Effects	Adverse Reactions
Nausea, vomiting, diarrhea, constipation, epigastric pain; elixir may stain teeth.	May aggravate existing GI conditions and may cause pallor or drowsiness *Life threatening:* Iron poisoning (mostly in children) may result in cardiovascular collapse, metabolic acidosis Toxicity: Nausea, vomiting, diarrhea (green then tarry stools), hematemesis, pallor, cyanosis, shock, coma

A, Adult; *bid,* two times a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *PB,* protein binding; *PO,* by mouth; *RBC,* red blood cell; *t½,* half-life; *UK,* unknown.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 13.1 Iron

Chamomile, feverfew, peppermint, and St. John's wort interfere with the absorption of iron and other minerals.

A prolonged copper deficiency may result in anemia that cannot be corrected by taking iron supplements. Abnormal blood and skin changes caused by a copper deficiency include a decrease in white blood cell count, glucose intolerance, and a decrease in skin and hair pigmentation. Mental retardation may also occur in the young. Copper deficiency in patients receiving parenteral nutrition ranges from 30% to 56% and includes both adults and children.

The RDA for copper is 900 mcg/day. Most adults consume about 1 mg/day. Foods rich in copper are shellfish (crab, oysters), liver, nuts, seeds (sunflower, sesame), legumes, and cocoa.

Zinc

Zinc is important to many enzymatic reactions, and it is essential for normal growth and tissue repair, wound healing, and taste and smell. The use of zinc has greatly increased in the past few years; some believe zinc can alleviate symptoms of the common cold and shorten its duration, although studies have disputed this claim. Large amounts of zinc can be toxic. Zinc in lozenge form can cause nausea and can leave an unpleasant taste, and zinc in nasal sprays has caused patients to lose their sense of smell. Patients should always check with a health care provider prior to taking zinc. The adult RDA is 8 to 11 mg/day. Foods rich in zinc include beef, lamb, eggs, and leafy and root vegetables.

Large doses, more than 150 mg, may cause a copper deficiency, a decrease in high-density lipoprotein (HDL) cholesterol ("good" cholesterol), and a weakened immune response. Zinc can inhibit tetracycline absorption. Patients taking zinc and an antibiotic should not take them together; zinc should be taken at least 2 hours after taking an antibiotic. About 10% of adults on long-term parenteral nutrition develop a zinc deficiency. Infants and children have a much higher rate of deficiency (20% to 30%). Zinc is the most common deficiency likely to occur in parenteral nutrition because zinc is lost in the patient's stool.

Chromium

Chromium is said to be helpful in the control of type 2 diabetes (non–insulin-dependent diabetes). It is thought that this mineral helps to normalize blood glucose by increasing the effects of insulin on the cells. If a patient is taking large doses of chromium and an oral hypoglycemic agent or insulin, the glucose level should be monitored closely for a hypoglycemic reaction. The dose of an oral hypoglycemic drug or insulin may need to be decreased. Some patients with impaired glucose tolerance and those who do not have diabetes may benefit by taking chromium. In addition, chromium claims to promote weight loss and muscle building. Multivitamin and mineral preparations contain chloride salt of chromium.

There is no RDA for chromium; however, 25 to 35 mcg/day is considered within the normal range for adults and children older than 9 years of age. Foods rich in chromium include meats, whole-grain cereals, and brewer's yeast.

Selenium

Selenium acts as a cofactor for an antioxidant enzyme that protects protein and nucleic acids from oxidative damage. Selenium works with vitamin E. It is thought that selenium has an anticarcinogenic effect, and doses lower than 200 mcg may reduce the risk of lung, prostate, and colorectal cancer. Excess doses of more than 200 mcg might cause weakness, hair loss, dermatitis, nausea, diarrhea, and abdominal pain. Also, there may be a garlic-like odor from the skin and breath.

The RDA for selenium is 40 to 75 mcg (the lower dose is recommended for women, higher dose for men). Foods rich in selenium include meats, especially liver; seafood; eggs; and dairy products.

Nursing Process: Patient-Centered Collaborative Care

Anti-anemia Mineral: Iron

Assessment

- Obtain a history of current drugs and herbs the patient is taking.
- Obtain a medical history of health problems such as anemia.
- Assess the patient for signs and symptoms of iron-deficiency anemia, such as fatigue, malaise, pallor, shortness of breath, tachycardia, and cardiac dysrhythmia.
- Assess the patient's red blood cell (RBC) count, hemoglobin, hematocrit, iron level, and reticulocyte count before the start of and throughout therapy.

Nursing Diagnoses

- Nutrition, Imbalanced related to inadequate intake of food sources of iron
- Knowledge, Deficient regarding food sources of iron
- Decision Making, Readiness for Enhanced related to food choices and vitamin/mineral supplementation

Planning

- The patient will name at least six foods high in iron content.
- The patient will consume foods rich in iron.
- Patients with iron-deficiency anemia or with low hemoglobin will take iron replacement as recommended by their health care provider, resulting in laboratory results within the desired range.

Nursing Interventions

- Encourage patients to eat a nutritious diet to obtain sufficient iron. Iron supplements are not needed unless a person is malnourished or pregnant or has abnormal menses.
- Store vitamins in light-resistant containers.
- Administer iron intramuscularly by the Z-track method to avoid leakage of iron into the subcutaneous tissue and skin, resulting in irritation and stains to the skin.

Patient Teaching

General

- Advise patients to take the tablet or capsule between meals with at least 8 ounces of juice or water to promote absorption. If gastric irritation occurs, instruct the patient to take supplements with food.
- Advise patients to swallow the tablet or capsule whole.
- Encourage patients to maintain an upright position for 30 minutes after taking oral iron preparations to prevent esophageal corrosion from reflux.
- Do not administer the iron tablet within 1 hour of ingesting antacids, milk, or milk products, such as ice cream or yogurt.
- Counsel patients that certain herbal supplements can decrease absorption of iron and other minerals (see Complementary and Alternative Therapies 13.1).
- Advise patients to increase fluids, activity, and dietary bulk to avoid or relieve constipation. Slow-release iron capsules decrease constipation and gastric irritation.
- Instruct adults not to leave iron tablets within reach of children. If a child swallows many tablets, induce vomiting and immediately call the local poison control center; the telephone number is in the front of most telephone books (include this number on emergency reference lists).
- Encourage patients to take only the prescribed amount of drug to avoid iron poisoning. Be alert to the iron in multivitamin preparations.
- Be alert that iron content varies among iron salts, therefore do not substitute one for another.
- Advise patients that drug treatment for anemia is generally less than 6 months.

Diet

- Counsel patients to include iron-rich foods in their diet, such as lean meats, egg yolk, dried beans, green vegetables, and fruit.

Side Effects

- Advise patients taking a liquid iron preparation to use a straw to prevent discoloration of tooth enamel.
- Alert patients that the drug turns stools a harmless black or dark green.
- Instruct patients about signs and symptoms of toxicity, including nausea, vomiting, diarrhea, pallor, hematemesis, shock, and coma, and report these occurrences to the health care provider.

Cultural Considerations

- Ask about cultural practices and incorporate them as appropriate.
- Use an interpreter as needed.

Evaluation

- Evaluate the effectiveness of iron therapy by determining that the patient is not fatigued or short of breath and that the hemoglobin level is within the desired range.

Critical Thinking Case Study

CB is pregnant and is taking two 325-mg tablets of ferrous sulfate daily. She has a 2-year-old daughter.

1. What precautions should CB take in regard to the container of ferrous sulfate? Explain your answer.
2. CB asks if she can take iron in the morning before breakfast. How should the nurse respond?
3. CB asks the nurse if any side effects are associated with taking iron. What would be an appropriate response?
4. CB asks if she should include foods high in iron in her daily diet. How should the nurse respond?

NCLEX Study Questions

1. The nurse is reviewing a patient's laboratory test results and current medications and notes that the patient's prothrombin time is prolonged. The nurse checks the patient's medication list. What vitamin or mineral might be contributing to this?
   a. Vitamin A
   b. Selenium
   c. Vitamin D
   d. Vitamin E
2. A patient comes to the office with a chief complaint of hair loss and peeling skin. The nurse notes that many vitamins and minerals are on the list of medications that the patient reports using to treat liver disease. The patient's complaint may be caused by an excess of what vitamin or mineral?
   a. Vitamin A
   b. Zinc
   c. Vitamin C
   d. Vitamin D
3. The nurse routinely includes health teaching about vitamins to patients. Vitamin D has a major role in which process?
   a. Ensuring night and color vision
   b. Regulating calcium and phosphorous metabolism
   c. Body growth
   d. DNA and prothrombin synthesis
4. The nurse is doing preconception counseling with a patient. The patient asks why she must take folic acid (folate) during pregnancy. What is the nurse's response?
   a. Folic acid prevents neural tube defects such as spina bifida, defective closure of the bony structure of the spinal cord, and anencephaly, lack of brain mass formation.
   b. Folic acid lowers blood glucose in diabetic patients.
   c. Folic acid works in the gastrointestinal system to prevent celiac disease.
   d. Folic acid will prevent migraine headaches in pregnant women.
5. A prenatal patient tells the nurse that she is not taking vitamins because she heard that vitamins may cause damage to the fetus if she becomes pregnant. What is the nurse's best response?
   a. Vitamins can only help you and your baby.
   b. Take extra vitamins now to make up for missed doses.
   c. Megadoses of vitamins can be harmful in the first trimester.
   d. Taking vitamin doses above the recommended daily allowance is not recommended.
6. A patient asks the nurse for information about fat-soluble vitamins. What is the nurse's best response?
   a. Fat-soluble vitamins are metabolized rapidly.
   b. Fat-soluble vitamins cannot be stored in the liver.
   c. Fat-soluble vitamins are excreted slowly in urine.
   d. Fat-soluble vitamins can never be toxic.
7. A patient complains of night blindness. The nurse correctly recommends which foods?
   a. Skim milk and peas
   b. Fortified milk and eggs
   c. Nuts and yeast
   d. Enriched breads and cereals

8. A patient diagnosed with alcoholism has questions about his medications. The nurse correctly explains that alcoholism can be associated with deficiency of which vitamin?
   a. A
   b. B12
   c. D
   d. K
9. A patient complains of anorexia, nausea, and vomiting. The patient's list of medications includes multiple large doses of vitamins. The nurse notes that the patient's complaints may be related to early signs of toxicity of which vitamin?
   a. A
   b. B
   c. C
   d. D
10. A patient takes iron on a daily basis. Which comment from the patient suggests the need for health teaching related to iron?
   a. I will swallow the tablet whole.
   b. I take the tablet immediately before I go to bed.
   c. I know that multivitamins might include iron.
   d. I keep the tablets out of children's reach.
11. A patient asks the nurse, "What does copper do for me? I think it must be bad for me." What is the nurse's best response?
   a. Copper is needed for red blood cell formation.
   b. Be sure to include nuts and seeds in your diet.
   c. Why do you think copper is bad for you?
   d. Are you taking 5 mg of copper a day?

Answers: 1, d; 2, a; 3, b; 4, a; 5, c; 6, c; 7, b; 8, b; 9, d; 10, b; 11, c.

Nutritional Support

OUTLINE

Different Types of Nutritional Support
- Oral Feeding
- Enteral Nutrition
- Nursing Process: Patient-Centered Collaborative Care— Enteral Nutrition
- Parenteral Nutrition
- Nursing Process: Patient-Centered Collaborative Care— Total Parenteral Nutrition

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Explain the differences between enteral and parenteral nutrition.
- Describe the routes for enteral feedings.
- Discuss examples of enteral solutions and explain their differences.
- Explain the advantages and differences of the methods used to deliver enteral nutrition.
- Describe the complications that may occur with use of enteral and parenteral nutrition.
- Discuss the nursing interventions for patients receiving enteral and parenteral nutrition.

KEY TERMS

bolus, p. 190
continuous feedings, p. 190
cyclic method, p. 190

Nutrients are substances that nourish and aid in the development of the body. Nutrients provide energy, promote growth and development, and regulate body processes. Inadequate nutrient intake can cause malnutrition. Patients experiencing chronic or critical illnesses that result in surgery or hospitalization are at risk for malnutrition. Without adequate **nutritional support**, the body's metabolic processes slow down or stop. This can greatly diminish organ functioning and have a poor response on the patient's immune system.

The length of time a person may survive without nutrients is influenced by body weight and composition, genetics, health, and hydration. Patients who are critically ill may only tolerate a lack of nutrient support for a short period before organ failure occurs. Recovery is more rapid for patients who have experienced trauma, burns, or critical illness if nutrition is started within 24 to 48 hours of admission. Administration of enteral nutrition early on restores intestinal motility, maintains gastrointestinal (GI) function, reduces the movement of bacteria and other organisms, improves wound healing, decreases the incidence of infection, and ultimately decreases the length of the hospital stay. Early nutritional support improves the patient's general health and produces favorable outcomes.

In addition to nutrients, both hydration and electrolyte balance must be considered. If all three are not addressed, preventable complications like constipation, urinary tract infection, and pressure ulcers can occur. The requirements for fluid balance are usually between 30 and 35 mL/kg/day. A healthy person requires 2000 calories per day; critically ill patients require 50% more than the normal energy requirement (approximately 3000 calories per day). If a patient has a 10% weight loss within the last 3 to 6 months and has had little or no nutrition for more than 5 days, nutritional supplementation should be considered. Nutrition and hydration are essential components necessary for everyday life.

Different Types of Nutritional Support

Oral Feeding

Many patients require nutritional supplementation due to malnutrition or anorexia (e.g., a deficiency of certain nutrients, vitamins, or minerals). Many factors can affect appetite: psychological stress about a patient's illness and problems with family, finances, and employment are just a few of the many challenges a patient may experience. If the patient can swallow and has a working GI tract, oral nutritional supplementation between meals can help increase caloric intake. Many commercially available products can be used to supplement intake. These are marketed as puddings, bars, and supplemental nutritional drinks.

Enteral Nutrition

Enteral nutrition (EN) involves the delivery of nutrition or fluid via a tube into the GI tract, which requires a functional, accessible GI tract. Depending on the different pathologies present, EN may be used for short-term nutritional supplementation, such as with reduced appetite or swallowing difficulties, or long-term nutritional supplementation for malabsorption disorders or increased catabolism.

Routes for Enteral Feedings

A multidisciplinary team approach is used when a decision is required in regard to which feeding route to use. Many factors are considered: the patient's condition, preferences, the length of the feeding, physiologic conditions, tolerance, and the integrity of the patient's GI tract.

The gastrointestinal routes used for enteral tube feedings are the nasogastric, nasoduodenal/nasojejunal, gastrostomy or **jejunostomy routes** (Fig. 14.1). The nasogastric and gastrostomy routes deliver food directly to the stomach. The nasoduodenal/nasojejunal and the jejunostomy routes deliver food after the stomach or below the pyloric sphincter and are used for patients at risk for aspiration. These gastrointestinal routes deliver food by a tube inserted through the nose (nasogastric, nasoduodenal/nasojejunal) or directly into the GI tract (gastrostomy or jejunostomy) through the abdominal wall. The nasogastric, nasoduodenal, and nasojejunal routes are for short-term nutrition of less than 4 weeks' duration. If long-term nutrition is required, the patient may receive a gastrostomy or a jejunostomy tube placed in the stomach or small bowel by a surgical, endoscopic, or fluoroscopic procedure.

The **gastrointestinal tubes** are small in diameter, are made of urethane or silicone, and are flexible and long. They are radiopaque, which makes their position easy to identify by x-ray. These tubes easily clog, especially when using thick feedings and when the patient's medications are crushed and put down the tube. Always flush the tube before and after medication administration and when determining residual volume, so the tube remains patent and does not clog. If the tube becomes clogged, a new tube may have to be placed, which results in extra discomfort to the patient. It is important to note that these tubes can become dislodged, knotted, or kinked during patient coughing or vomiting. The **gastrostomy tube**, also known as the *percutaneous endoscopic gastrostomy* (PEG) tube and the jejunostomy (J) tube are placed surgically, endoscopically, or radiologically. With the PEG tube, the patient must have an intact GI system. For patients with chronic reflux, a J-tube is placed either endoscopically or with laparoscopic surgery. Usually, the doctor orders intravenous (IV) antibiotics to decrease the risk of infection. After placement, always check your facility's policy prior to initiating the tube feeding and use correct nursing procedure when putting medication and food through the tubes. Before the initial feeding, the policy in most facilities is to confirm correct placement of the tube with an x-ray.

Enteral Solutions

Many different types of enteral formulas are used for enteral feedings. These solutions differ according to their various nutrients, caloric values, and osmolality. The four groups of enteral solutions are (1) polymeric (milk-based, blenderized foods and commercially prepared whole nutrient formulas); (2) modular formulas (protein, glucose, polymers, and lipids); (3) elemental/monomeric formulas (predigested nutrients that are easier to absorb); and (4) specialty

formulas designed to meet specific nutritional needs in certain illnesses such as liver failure, pulmonary disease, or HIV infection (Table 14.1). Some of the components of enteral solutions include (1) carbohydrates in the form of dextrose, sucrose, lactose, starch, or dextrin (the first three are simple sugars that are absorbed quickly); (2) protein in the form of intact or hydrolyzed proteins or free amino acids; and (3) fat in the form of corn, soybean, or safflower oil (some have a higher oil content than others). With all EN, sufficient water is needed to maintain hydration.

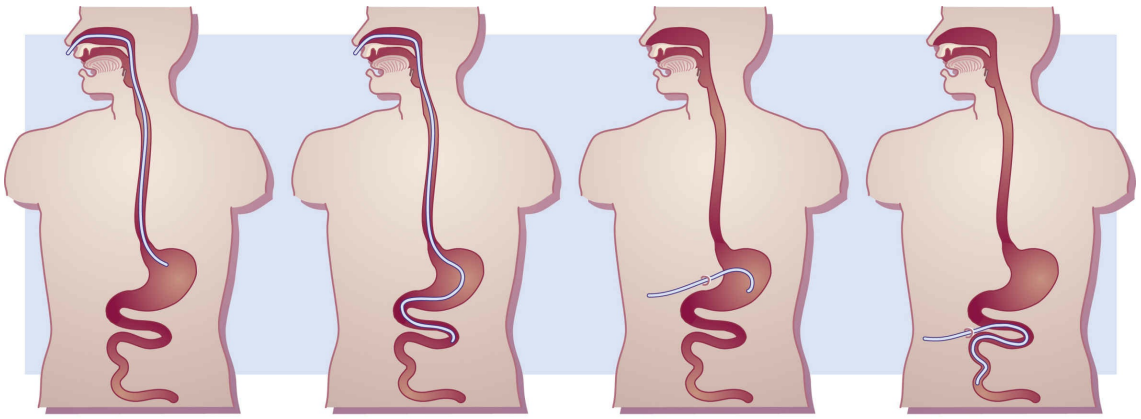

FIG. 14.1 Types of Gastrointestinal Tubes Used for Enteral Feedings.
A *nasogastric* tube is passed from the nose into the stomach. A weighted *nasoduodenal/nasojejunal* tube is passed through the nose into the duodenum/jejunum. A *gastrostomy* tube is introduced through a temporary or permanent opening on the abdominal wall (stoma) into the stomach. A *jejunostomy* tube is passed through a stoma directly into the jejunum.

Methods for Delivery

Enteral feedings are given by continuous infusion pump, intermittent infusion by gravity, intermittent bolus by syringe, and cyclic feedings by infusion pump. **Continuous feedings** are prescribed for the critically ill and for those who receive feedings into the small intestine. The enteral feedings are given by an infusion pump such as the Kangaroo pump, which is set to control the flow at a slow rate over 24 hours. **Intermittent enteral feedings** are administered every 3 to 6 hours over 30 to 60 minutes by gravity drip or infusion pump. At each feeding, 300 to 400 mL of solution is administered. **Intermittent infusion** is considered an inexpensive method for administering EN. The **bolus** method was the first method used to deliver enteral feedings, and with this method, 250 to 400 mL of solution is rapidly administered through a syringe into the tube four to six times a day. This method takes about 15 minutes each feeding, but it may not be tolerated well by the patient because a massive volume of solution is given in a short period. The bolus method may cause nausea, vomiting, aspiration, abdominal cramping, and diarrhea; a healthy patient can normally tolerate the rapidly infused solution, therefore this method is reserved for ambulatory patients. The **cyclic method** is another type of continuous feeding infused over 8 to 16 hours daily (day or night). Administration during daytime hours is suggested for patients who are restless or for those who have a greater risk for aspiration. The nighttime schedule allows more freedom during the day for patients who are ambulatory.

TABLE 14.1
Commercial Preparations for Enteral Feeding

Type of Formula	Commercial Preparation	Description
Polymeric	Boost Ensure Fibersource Isocal Osmolite Resource Ultracal	• Supplements prescribed for patients who can digest and absorb nutrients without difficulty • Usually taste good • Most commonly prescribed formula • May be used as tube feeding, meal replacement, or oral supplement • Contains protein, carbohydrates, and fat • Blenderized forms are infrequently used because they are more likely to clog the feeding tubes because of their high viscosity.
Modular	Duocal MCT Oil Microlipid	• Contains specific nutrients, usually a single macronutrient (carbohydrates, proteins, or fat) • Tailored to the individual's needs • Complex to design • Many fail to meet the patient's nutritional needs.
Elemental/Monomeric	Criticare HN Peptamen Liquid Crucial Peptamen Vivonex	• Predigested proteins, simple carbohydrates, plus a small amount of oil or a blend of triglycerides • Good choice for patients who lack the ability to digest or who have small bowel absorption problems • Patients with feeding tubes in the lower gastrointestinal tract • Contain very little residue • Appropriate for patients who require bowel rest
Specialty Formulas	*Pediatric* A2Milk *Renal* Nepro Suplena *HIV* ENU	• Specialty formulas are specific to the patient's diagnosis with macronutrients and modular nutrients • Designed to meet the nutritional needs related to the specific illness such as liver failure, pulmonary disease, diabetes, HIV infection, renal or pediatric nutritional needs

Complications

Dehydration can occur in patients receiving enteral nutrition. Diarrhea is a common complication that can lead to dehydration. High-protein formulas can also cause dehydration, and hyperosmolar solutions can draw water out of the cells in an attempt to maintain serum isoosmolality. Fluid intake is monitored, and if appropriate, fluid is added to the patient's daily regimen of feedings. Unless contraindicated, it is recommended that 30 to 35 mL/kg/day be maintained for fluid balance in most patients.

Aspiration pneumonitis is one of the most serious and potentially life-threatening complications of tube feedings. It can occur when the contents of the tube feeding enter the patient's lungs from the GI tract. Consequences range from coughing and wheezing to infection, tissue necrosis, and respiratory failure. An important nursing intervention is to check the agency's policy for specific guidelines prior to initiating EN. It is imperative that the nurse check for gastric residual by gently aspirating the stomach contents before initiating enteral feeding and thereafter every 4 hours between feedings. Usually, if the residual is greater than 150 mL (check the agency policy), the nurse holds the feeding, and the residual is checked again in 1 hour. If the residual still exceeds this amount, the provider is notified. Large residuals mean the patient may have an obstruction or a problem that is important to correct prior to continuing the feeding.

Another common problem of enteral feeding is diarrhea. Rapid administration of feedings, contamination of the formula, low-fiber formulas, tube movement, and various drugs can all cause diarrhea. Check for drugs that can cause diarrhea; these may be antibiotics or sorbitol in liquid medications. Diarrhea can usually be managed or corrected by decreasing the rate of infusion, diluting the solution with water, changing the solution, discontinuing the drug, increasing the patient's daily water intake, or administering an enteral solution that contains fiber. Constipation is another common problem that frequently occurs. It can be easily corrected by changing the formula, increasing water, or requesting a laxative.

Patients who have a long history of poor caloric intake are at risk for refeeding syndrome, which describes a cascade of metabolic and electrolyte imbalances that occur as a result of feeding a patient who is nutritionally starved for a prolonged period. Long-term undernutrition causes loss of electrolytes, vitamins, and minerals; this affects biologic processes and organ systems and can lead to abnormally low serum levels of potassium, phosphate, and magnesium that can result in cardiac arrhythmias, respiratory distress, and death. When a malnourished patient is overfed, physiologic burdens occur that put demands on cellular function and body organs. Prevention of refeeding syndrome involves ensuring that feeding begins slowly, at calorie levels below maintenance needs, and is gradually advanced.

Monitoring is essential when the patient is receiving EN. Recommended parameters to monitor include blood chemistry, blood urea nitrogen (BUN), creatinine, and electrolytes; glucose; triglycerides; serum proteins; intake and output; and weight. Frequency of monitoring is patient dependent and should be implemented during the entire EN process.

Enteral Safety

The nurse has an important role in administering tube feedings safely. Some of the important safety concerns are patient position, aspiration risk, residual volumes, and tube position. The head of the

bed should be elevated to 30 to 45 degrees during the feeding, and if intermittent, keep the head of the bed elevated for 30 to 60 minutes after the feeding. By elevating the head of the bed, the risk of aspiration is decreased. Ensure the patient has audible bowel sounds by performing a GI assessment with auscultation. This ensures a working GI tract. Always check the gastric residual volume prior to initiating tube feedings and every 4 to 6 hours if the feedings are continuous. Always confirm the position of newly inserted tubing before beginning the first feeding. Initially, after the tube is placed, most agencies require an x-ray to confirm placement. Always follow the agency's policy and procedure for initial confirmation of placement. Prior to each enteral feeding, placement should be confirmed to ensure the tubing has not moved and is still in the GI tract. Some agencies require pH testing of gastric secretions, whereas others recommend listening for gurgling sounds after inserting air into the tubing. Each of these measures has limitations, so more than one bedside test may be used for confirmation. Always check the agency guidelines. Electromagnetic tracking devices are being associated with reduced tube misplacement, although this technique is still new and is not available to everyone.

The American Society for Parenteral and Enteral Nutrition (ASPEN) works to improve the quality of nutrition through its guidelines and standards. ASPEN advocates for high-priority issues about nutrition. They work in conjunction with the National Institutes of Health (NIH) and the Center for Medicare and Medicaid Services (CMS) to improve funding and education in the field of enteral and parenteral nutrition. ASPEN was first to issue guidelines, in 2002, for the use of parenteral and enteral nutrition in adults and pediatric populations, and it continues to update, educate, and monitor use of safe practices. Another agency that advocates for safety in both enteral and parenteral nutrition is the National Institute for Health and Care Excellence (NICE), which dedicates itself to the practice of health care in society and provides guidance and quality standards for public health care issues that include but are not limited to enteral and parenteral nutrition. NICE set the standard that all patients should be screened for malnutrition and treated by a multidisciplinary team of health care professionals. It also stipulates that patients and caregivers should be given adequate training for self-care if they so desire.

The Joint Commission (2014) issued an alert on the seriousness of tube misconnections, which can result in severe injury or death to the patient. One situation involved a feeding administration tube that was inadvertently connected to a tracheostomy tube, which caused serious harm to the patient. It is most important to trace all lines from the site of origin back to the patient to avoid dislodgement and misconnection errors.

Enteral Medications

Many mistakes can occur during enteral tube feedings. These mistakes are often the result of administering drugs that are incompatible with administration through a tube, failure to prepare the drug properly, and use of faulty techniques. These problems can result in an occluded feeding tube, reduced drug effect, or drug toxicity and can cause patient harm or death.

When administering nonliquid drugs through an enteral tube, the nurse should always ensure that the drug is crushable. (For a current and complete listing of drugs that should not be crushed, see http://www.ismp.org/tools/donotcrush.pdf or consult with a pharmacist.) Also, validate with the pharmacist that the drug will dissolve in water and that it can be absorbed through the enteral route. Drugs that cannot be dissolved are timed-release, enteric-coated, and sublingual forms and bulk-forming laxatives; these medications should *not* be crushed. Prepare each medication separately so that the medication is identifiable up until the time of delivery. Open capsules separately and check with the pharmacist about whether the capsule contents can be crushed. Crush the solid dosage forms after ensuring the medications are crushable, and dissolve each medication separately in about 15 mL of water. The drug must be in liquid form or dissolved in water prior to administration through enteral tubing. Properly dilute liquid medication with water when administering it through the feeding tube. *Never* mix medications with feeding formulas. Prior to and after the drug is administered, flush with about 15 mL of water. Proper flushing ensures that the drug has been delivered and the tube is clear. Once the tube has been flushed, the feeding can be restarted after the drug is given.

Many drugs can be given to patients who require tube feeding to aid in absorption and digestion and to promote gastric emptying; these include pancreatic enzymes, probiotics, antiemetics, proton pump inhibitors, and drugs to prevent gastric ulcers.

It is essential to know the importance of temporarily stopping the infusion when certain types of

drugs are administered. Some medications require that the feeding be stopped for as long as 30 minutes to allow for adequate absorption.

Nursing Process: Patient-Centered Collaborative Care

Enteral Nutrition

Assessment

- Confirm that the feeding tube is securely in place.
- Assess the patient's tolerance of enteral feeding, including possible gastrointestinal disturbance (nausea, cramping, diarrhea).
- Determine urine output and record it for future comparisons.
- Obtain the patient's weight and use it for future comparisons.
- Listen for bowel sounds. Report diminished or absent bowel sounds immediately to the health care provider. Also palpate the abdomen for distension.
- Assess baseline laboratory values and compare these with future laboratory results.

Nursing Diagnoses

- Fluid Volume, Deficient related to inadequate fluid intake or excess fluid loss
- Diarrhea related to enteral feedings
- Aspiration related to enteral feedings via a gastrointestinal route
- Nutrition, Imbalanced: Less than Body Requirements related to an inability to absorb nutrients or tolerate oral intake

Planning

- The patient will not aspirate during enteral feedings, especially those given via gastrointestinal route.
- The patient will receive adequate nutritional support through enteral feedings.
- The complication of diarrhea related to enteral feedings will be managed.

Nursing Interventions

- Check the tube placement by aspirating gastric secretions or by injecting air into the tube to listen by stethoscope for air movement in the stomach. (Follow agency guidelines.)
- Determine gastric residual before the enteral feeding. When the residual is more than 100 to 150 mL, hold the feeding for 1 hour and recheck the residual. If it is still over 100 to 150 mL, notify the health care provider.
- Check the continuous route for gastric residual every 4 to 6 hours. If the residual is greater than 100 to 150 mL, stop the infusion for 1 hour and recheck.
- Raise the head of the bed to a 30- to 45-degree angle at all times during infusion of tube feedings. If elevating the head of the bed is contraindicated, position the patient on the right side.
- Deliver enteral feedings according to the method ordered: bolus, continuous, intermittent, or cyclic.
- Flush the feeding tube as appropriate: for intermittent feeding, flush with 30 mL before and after; for continuous feeding, flush with 30 mL every 4 hours. When administering drugs through the tube, use a 30 mL flush of water at the beginning and end of administration; flush with 15 mL of water between administration of each drug.
- Monitor for adverse effects of enteral feedings, such as diarrhea. To manage or correct diarrhea, decrease the enteral feeding flow rate, and as diarrhea lessens, slowly increase the feeding rate. The enteral solution may be diluted, with the provider's order, and then gradually increased to full strength. Determine whether side effects of drugs could be causing diarrhea.
- Monitor vital signs and report abnormal findings.
- Give additional water during the day to prevent dehydration. Consult with the health care provider.
- Weigh the patient to determine weight gain or loss. Compare with the baseline weight. Patients should be weighed at the same time each day with the same scale and the same amount of clothing.

- Change the feeding bag daily. Do not add the new solution to the old solution in the feeding bag. The nutritional solution should be at room temperature.

Patient Teaching

- Instruct patients to report any problems related to enteral feedings, such as diarrhea, sore throat, and abdominal cramping.

Cultural Considerations

- Respect cultural beliefs concerning refusal to receive enteral or parenteral nutrition. Explain the need for adequate nutrition, and find ways that nutritional needs can be met.
- Use an interpreter as appropriate.

Evaluation

- Determine that the patient is receiving the prescribed nutrients daily and is free of complications associated with enteral feedings.

Parenteral Nutrition

The terms parenteral nutrition (PN), total parenteral nutrition (TPN), and hyperalimentation (HA) are used synonymously. PN is the administration of nutrients by a route other than the GI tract (e.g., the bloodstream). If a patient is not eligible for EN because of a nonfunctioning GI tract or intestinal failure, PN is delivered intravenously. The word "total" suggests that the patient is receiving all of the required nutrients, fluid, and electrolyte requirements in the bag. In some circumstances, PN and EN may be given concurrently. The delivery of both EN and PN is used when the GI tract is partially functioning or if the patient is being weaned off of PN. Parenteral nutrition has many risks, so the option of EN should be fully explored before starting PN. Suggested indications for patients who require PN are those with bowel obstruction, prolonged paralytic ileus, inflammatory bowel disease, or severe pancreatitis, and those who require bowel rest following complex GI surgery. Also, patients with greater nutritional needs sometimes require PN, such as those who have sustained severe trauma or burns and the severely malnourished.

Solutions for parenteral nutrition include amino acids, carbohydrates, electrolytes, fats, trace elements, vitamins, and water. PN is individualized according to the patient's general health needs. Each element of the prescription can be manipulated according to changes in the patient's clinical requirements. The entire process requires a multidisciplinary team approach that involves the nurse, nutritionist, and pharmacist with the patient's provider leading the care team. Commercially prepared PN base solutions are available and contain dextrose and protein in the form of amino acids. The pharmacist can add prescribed electrolytes, vitamins, and trace elements to customize the solution to meet the patient's needs. Calories are provided by carbohydrates in the form of dextrose and by fat in the form of fat emulsion. Carbohydrates provide 60% to 70% of calorie (energy) needs. Amino acids (proteins) provide about 3.5% to 20% of a patient's energy needs. PN has a high glucose concentration. Fat emulsion (lipid) therapy provides an increased number of calories, usually 30%, and is a carrier of fat-soluble vitamins. The recommended energy intake is 25 to 35 cal/kg/day in a nonobese patient. Solutions differ for pediatric patients, who have varied fluid needs and require more energy per kilogram.

High glucose concentrations are irritating to peripheral veins, so PN is administered through either a peripherally inserted central catheter (PICC) via the cephalic or basilica vein, or a central venous catheter via the subclavian or internal jugular vein; this depends on the tonicity of the concentration. The rapid blood flow of the central veins allows placement of the catheter in the vena cava, which has the greatest blood flow of any vein in the body and reduces the risk of thrombophlebitis. If the treatment is used for short-term therapy (<4 weeks), a PICC line is inserted. If the treatment will last longer than 4 weeks, a central line catheter is placed. PN must always be administered by an infusion pump to allow for an accurate flow rate. PN enhances wound healing and provides the necessary nutrients to prevent cellular catabolism. Policies and procedures for PN therapy may vary by region and facility and must be researched and followed accordingly.

Complications

Complications associated with PN can result from catheter insertion and PN infusion. See Table 14.2 for a list of PN complications.

Air embolism occurs when air enters into the central line catheter system. To prevent air embolism during dressing, cap, and tubing changes, ask the patient to turn his or her head in the opposite direction of the insertion site and to take a deep breath, hold it, and bear down. This is called the **Valsalva maneuver**, and it will increase intrathoracic venous pressure while preventing the risk of air embolism. Always keep the clamp on the central line tubing closed except when in use.

Use strict aseptic technique when changing IV tubing and dressings at the insertion site. PN solution has a high concentration of glucose and is an excellent medium for bacterial growth. Monitor the patient's temperature closely, and if fever occurs, suspect sepsis. Always follow the facility's policy for the correct protocol in changing the PN solutions (12 to 24 hours), IV tubing (24 hours), and central line dressing (48 hours). Keep the prepared PN solutions refrigerated, and administer the full amount within the designated time according to the agency's policy.

TABLE 14.2

Complications of Total Parenteral Nutrition

Complication	Explanation/Cause	Symptoms
Catheter Insertion		
Pneumothorax	An abnormal collection of air or gas in the pleural space that causes the lung to collapse **Cause:** Punctured lung or lung injury	Sharp chest pain, decreased breath sounds, tachycardia, absence of breath sounds on the affected side
Hemothorax	A collection of blood in the space between the chest wall and the lung (the pleural cavity) **Cause:** Trauma is the most common cause.	Anxiety; chest pain; low blood pressure; pale, cool, and clammy skin; rapid heart rate; rapid, shallow breathing; restlessness; shortness of breath
Total Parenteral Nutrition Infusion		
Air embolism	A pathologic condition caused by a gas bubble in the vascular system **Cause:** Disconnected IV tubing; the catheter system opens, and air enters IV tubing during changes.	Coughing, shortness of breath, chest pain, cyanosis, hypotension, apprehension
Infection	The result of the body's inability to fight off foreign microorganisms that may cause damage or disease if left untreated **Cause:** Poor aseptic technique or catheter or solution contamination	Fever/temperature greater than 100°F (37.7°C), chills, increased WBC, redness or drainage
Hyperglycemia	High blood glucose **Cause:** Fluid infused too rapidly, insufficient insulin coverage, infection	Nausea, headache, weakness, thirst, elevated blood glucose (>200 mg/dL), restlessness, confusion, Kussmaul respirations
Hypoglycemia	Low blood glucose **Cause:** Fluids discontinued abruptly, too much insulin being administered	Diaphoresis, shakiness, weakness, low blood glucose level (<70 mg/dL), hunger, anxiety
Hypervolemia	Condition characterized by excessive fluid volume **Cause:** Increased IV rate, renal dysfunction, heart failure, hepatic failure	Weight gain greater than desired; jugular venous distension; full, bounding pulse; lung crackles; headache; hypertension

IV, intravenous; *WBC*, white blood cell.

Hyperglycemia occurs primarily as a result of the hypertonic dextrose solution, but it also occurs when the infusion rate for PN is too rapid. In some cases, the pharmacist can add insulin to the PN solution if ordered by the provider. Assess the patient carefully for glucose intolerance. The infusion is started at a slow rate of 40 to 60 mL/hour as prescribed. Monitor the patient's blood glucose level every 4 to 6 hours until stable and then every 24 hours or according to the facility's policy. Many providers will order sliding-scale insulin for their patients receiving PN.

The sudden interruption of PN therapy can cause hypoglycemia, therefore it is wise to keep a bag of 10% dextrose in the patient's room. In the event that the next bag of PN is late in arriving from the pharmacy, the bag of dextrose can be hung to avoid hypoglycemia. Gradually decrease the infusion rate when PN is discontinued, and monitor the patient's blood glucose level.

Nursing Process: Patient-Centered Collaborative Care

Total Parenteral Nutrition

Assessment

- Obtain baseline vital signs for future comparisons.
- Confirm baseline weight.
- Determine laboratory results (electrolytes, glucose, protein [prealbumin], and white blood cell levels frequently change during parenteral nutrition [PN] therapy). Early laboratory results are useful for future comparisons.
- Check urine output and report abnormal findings.
- Carefully read the label on the bag of PN solution. Compare the ingredients to the health care provider's order.
- Assess the PN insertion site for erythema, edema, swelling, tenderness, and drainage.

Nursing Diagnoses

- Fluid Volume, Imbalanced related to excess fluid infusion, renal dysfunction, or osmotic diuresis resulting from hyperosmolar PN solution
- Nutrition, Imbalanced related to altered nutritional support
- Infection, related to PN solution due to high glucose concentration
- Breathing Pattern, Ineffective related to complication from insertion of a subclavian line
- Knowledge, Deficient related to PN therapy

Planning

- The patient's nutrient needs will be met via PN.
- Infection will be avoided as evidenced by the patient remaining fever free.

Nursing Interventions

- Check the full set of vital signs and report changes.
- Determine body weight and compare it with the baseline weight.
- Monitor laboratory results—especially white blood cell count, electrolytes, protein, and glucose—and report abnormal findings.
- Compare laboratory results with baseline findings to assess any changes.
- Measure fluid intake and output. Fluid volume deficit or excess may occur due to the hyperosmolar content of the PN solution.
- Monitor temperature changes for possible infection or a febrile state. Use aseptic technique when changing dressings and solution bags.
- Check the blood glucose level according to your agency's policy. Initially, glucose levels may be high.
- Refrigerate PN solution that is not in use. High glucose concentration is an excellent medium for bacterial growth.
- Monitor the flow rate of PN. Start with 60 to 80 mL/hour, and increase slowly to the ordered level to avoid hyperglycemia.
- If PN finishes before the next time it is due to be administered, hang a bag of dextrose 10% to avoid hypoglycemia.
- During tubing and dressing changes, have the patient perform a Valsalva maneuver (taking a deep breath, holding it, and bearing down). Always clamp tubing during bag and tubing changes to prevent air embolus.
- Check for signs and symptoms of overhydration—coughing, dyspnea, engorged neck veins, or chest rhonchi—and report any findings.
- Follow your agency's policy for dressing and tubing changes.
- Do not draw blood from or administer medications through the central line, and do not check central venous pressure via the PN line. Results could be invalid.

Patient Teaching

- Provide emotional support to patients and family before and during PN therapy.
- Be available to discuss the patient's concerns or refer the patient to the appropriate health care provider.
- Instruct patients to notify their health care provider immediately if they experience discomfort or reactions.
- Keep the patient informed of the progress and effectiveness of PN.

Cultural Considerations

- Respect the patient's cultural beliefs about refusing PN.
- Explain reasons for adequate nutrition, and find ways to meet nutritional needs.
- Use an interpreter as appropriate.

Evaluation

- Evaluate the patient's positive and negative response to PN therapy.
- Determine periodically whether the patient's serum electrolytes, protein, and glucose levels are within desired ranges.
- Evaluate nutritional status by weight changes, energy level, feelings of well-being, symptom control, and healing.
- Evaluate patient and family understanding of the purpose and possible complications of PN therapy.

Critical Thinking Case Study

BD experienced trauma after being involved in an automobile accident. She has been in the intensive care unit for 5 days and is unable to eat. BD experienced compression of her abdomen and will need gastrointestinal (GI) exploratory surgery. BD is receiving D5 0.45% sodium chloride (NaCl). Her sodium (Na^+) level is 125 mEq/L, potassium (K^+) level is 3.1 mEq/L, glucose is 70 mg/dL, magnesium is 2.0 mEq/L, and phosphorus is 3.0 mg/dL.

1. Will BD receive enteral or parenteral nutrition and why?
2. After a review of BD's labs, which electrolytes do you expect to see the provider order in the parenteral nutrition (PN) bag?
3. BD will need central line placement. What complications will you assess BD for after the insertion of the central line and during the parenteral infusion?
4. The PN has been infusing without any problems, and BD seems to be tolerating it well. You notice 200 mL of the PN is left in the bag after it has been infusing for 24 hours. What is the best nursing response?
5. Describe nursing interventions related to PN.

NCLEX Study Questions

1. The nurse is determining a patient's gastric residual before administering an enteral feeding; the last feeding was 240 mL. The patient will be discharged on enteral feedings. It is important to include in the teaching plan that a residual of more than which amount would indicate delayed gastric emptying (based on the last feeding)?
   a. 60 mL
   b. 125 mL
   c. 150 mL
   d. 175 mL
2. The nurse is assisting a patient with self-administration of an enteral feeding. It is important to include in the teaching plan that the feeding should be administered at which temperature?
   a. Slightly warmed
   b. Chilled
   c. Ice cold
   d. Room temperature
3. The nurse is reviewing the plan of care for a patient receiving enteral therapy. What is the most common complication of enteral therapy?
   a. Aspiration
   b. Constipation
   c. Diarrhea
   d. Muscle weakness
4. Which is appropriate nursing care for a patient receiving total parenteral nutrition (TPN) in an acute care setting? (Select all that apply.)
   a. Monitor blood glucose levels.
   b. Measure intake and output each shift.
   c. Administer blood products through the TPN line.
   d. Monitor the TPN insertion site for erythema, leaking, or edema.
   e. Monitor the patient's weight monthly for significant changes.
5. A patient has been on TPN for 1 month, and there is an order to discontinue TPN tomorrow. The nurse contacts the health care provider because sudden interruption of TPN therapy may cause which condition?
   a. Dehydration
   b. Tremors
   c. Urinary retention
   d. Hypoglycemia
6. A patient is receiving TPN at home. The visiting nurse assists the family with the care plan, which includes changing the TPN solution and tubing. What is the recommended initial frequency for changing the tubing?
   a. Every 24 hours
   b. Every 36 hours
   c. Every 48 hours
   d. Every 72 hours
7. The nurse is reviewing the care plan with a patient using enteral nutrition (EN). Which interventions by the nurse are appropriate for this strategy? (Select all that apply.)
   a. Check the continuous route for gastric residual every 2 to 4 hours.
   b. Raise the head of the bed to a 30- to 45-degree angle before administering EN.
   c. Change the feeding bag every 3 days.

d. Report diminished or absent bowel sounds to the health care provider.

e. Explain that any diarrhea the patient experiences is related to the nutrition.

8. The nurse is to administer enteral medications to a patient who cannot swallow and is receiving continuous enteral feedings. Which is correct concerning administration of the enteral medications?

a. Ordered medications are added to the enteral feeding solution.

b. Liquid medications are diluted, given as a bolus, and followed with water.

c. Extra amounts of water are used to dissolve timed-release medications.

d. Undiluted hyperosmolar medications may be given to a patient on fluid restriction.

Answers: 1, c; 2, d; 3, c; 4, a, b, d; 5, d; 6, a; 7, a, b, d; 8, b.

UNIT IV
Autonomic Nervous System Drugs

OUTLINE

Introduction
15. Adrenergic Agonists and Antagonists
16. Cholinergic Agonists and Antagonists

Introduction

The *central nervous system* (CNS) is the body's primary nervous system and consists of the brain and spinal cord. The *peripheral nervous system* (PNS), located outside the brain and spinal cord, is made up of two divisions: the autonomic and the somatic. After interpretation by the CNS, the PNS receives stimuli and initiates responses to these stimuli.

The *autonomic nervous system* (ANS), also called the *visceral system,* acts on smooth muscles and glands. Its functions include control and regulation of the heart, respiratory system, gastrointestinal tract, bladder, eyes, and glands. The ANS is an involuntary nervous system, over which we have little or no control: we breathe, our hearts beat, and peristalsis continues without our realizing it. However, unlike the ANS, the *somatic nervous system* is a voluntary system that innervates skeletal muscles, over which there is control.

The two sets of neurons in the autonomic component of the PNS are the (1) afferent, or *sensory,* neurons and the (2) efferent, or *motor,* neurons. The *afferent neurons* send impulses to the CNS, where they are interpreted. The *efferent neurons* receive the impulses (information) from the brain and transmit these impulses through the spinal cord to the effector organ cells. The efferent pathways in the ANS are divided into two branches: the sympathetic and the parasympathetic nerves. Collectively, these two branches are called the *sympathetic nervous system* and the *parasympathetic nervous system* (Fig. IV.1).

The sympathetic and parasympathetic nervous systems act on the same organs but produce opposite responses to provide homeostasis (balance; Fig. IV.2). Drugs act on the sympathetic and parasympathetic nervous systems by either stimulating or depressing responses.

Sympathetic Nervous System

The sympathetic nervous system is also called the *adrenergic system* because at one time, it was believed that *adrenaline* was the neurotransmitter that innervated smooth muscle. However, that neurotransmitter is *norepinephrine*.

The adrenergic receptor organ cells are of four types: alpha$_1$, alpha$_2$, beta$_1$, and beta$_2$ (Fig. IV.3). Norepinephrine is released from the terminal nerve ending and stimulates the cell receptors to produce a response.

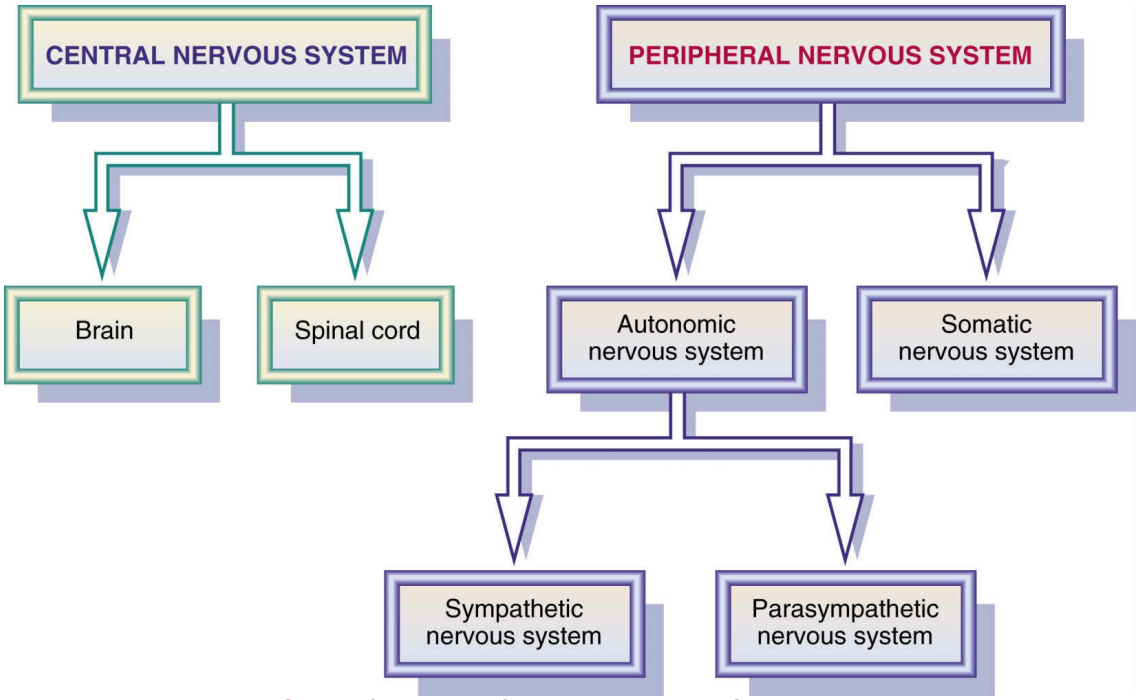

FIG. IV.1 Subdivisions of the Peripheral Nervous System.

Parasympathetic Nervous System

The parasympathetic nervous system is called the *cholinergic system* because the neurotransmitter at the end of the neuron that innervates the muscle is acetylcholine.

The cholinergic receptors at organ cells are either nicotinic or muscarinic, meaning that they are stimulated by the alkaloids nicotine and muscarine, respectively (see Fig. IV.3). Acetylcholine stimulates the receptor cells to produce a response, but the enzyme acetylcholinesterase may inactivate acetylcholine before it reaches the receptor cell.

Drugs that mimic the neurotransmitters norepinephrine and acetylcholine produce responses opposite to each other in the same organ; Table IV.1 lists the organ responses from drugs that act on these systems. For example, an *adrenergic drug* (sympathomimetic) *increases* the heart rate, whereas a *cholinergic drug* (parasympathomimetic) *decreases* the heart rate (see Fig. IV.2). However, a drug that mimics the sympathetic nervous system and a drug that blocks the parasympathetic nervous system can cause similar responses in the organ. For instance, the sympathomimetic and the parasympatholytic (blocks impulses from PNS) drugs both *increase* heart rate; the adrenergic blockers and the cholinergic drugs both *decrease* heart rate.

Many name classifications are given to drugs that mimic or block both the sympathetic and the parasympathetic nervous systems (Table IV.2). The nurse must become familiar with these names. Drug names and specific actions are discussed in Chapter 15, Adrenergic Agonists and Antagonists, and Chapter 16, Cholinergic Agonists and Antagonists.

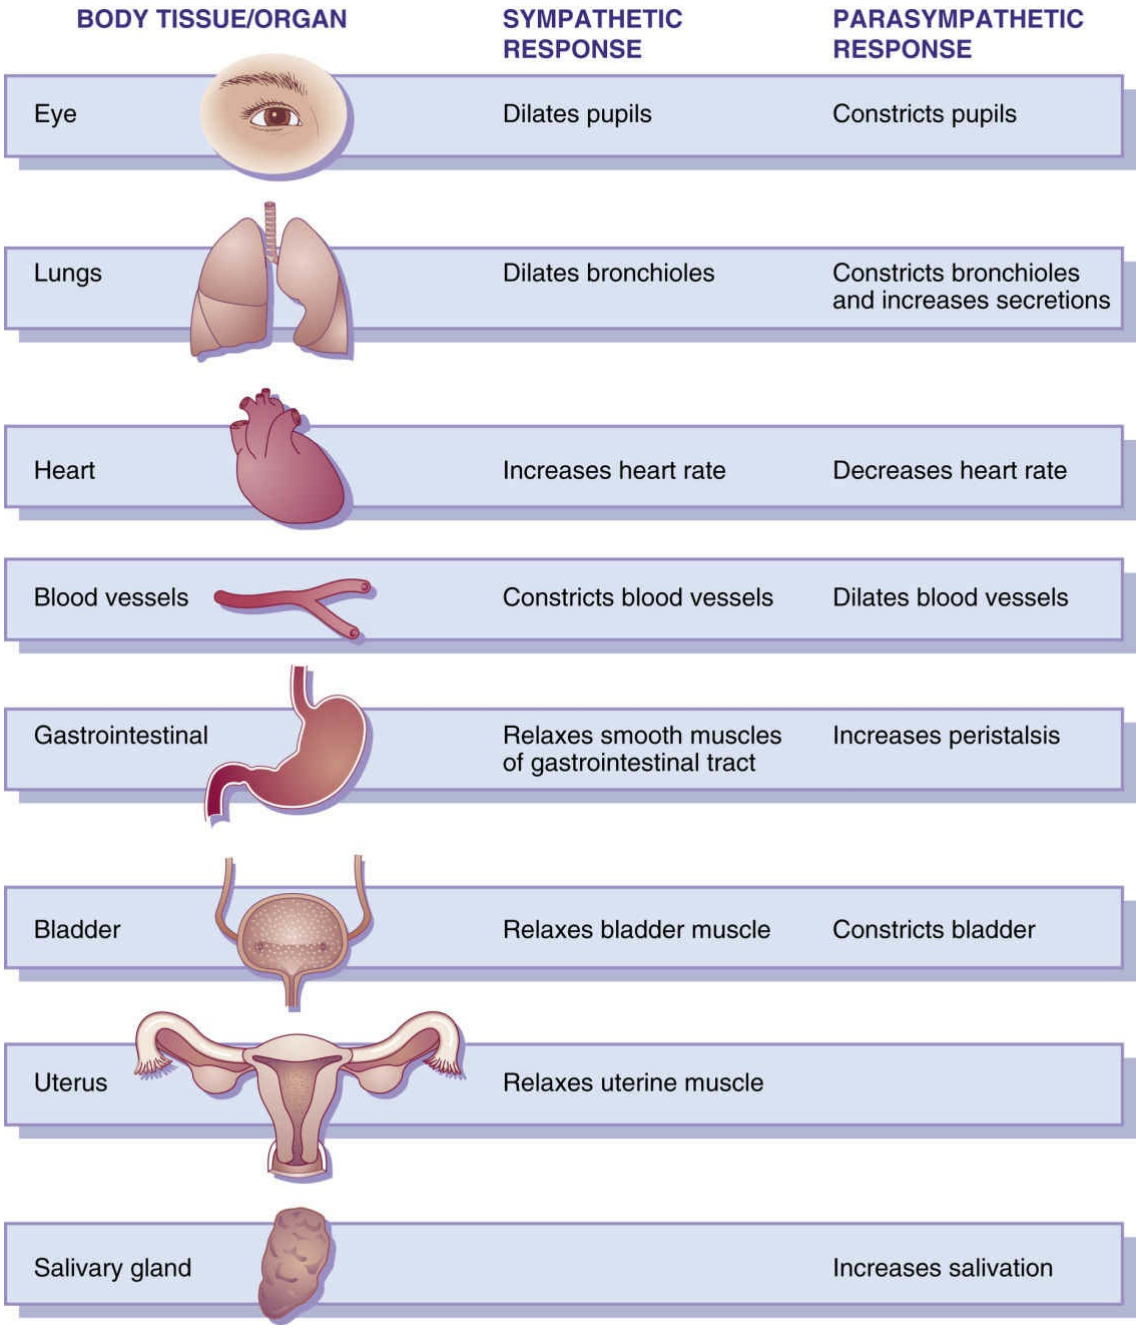

FIG. IV.2 Sympathetic and Parasympathetic Effects on Body Tissues.
The sympathetic and parasympathetic nervous systems have opposite responses on body tissues and organs.

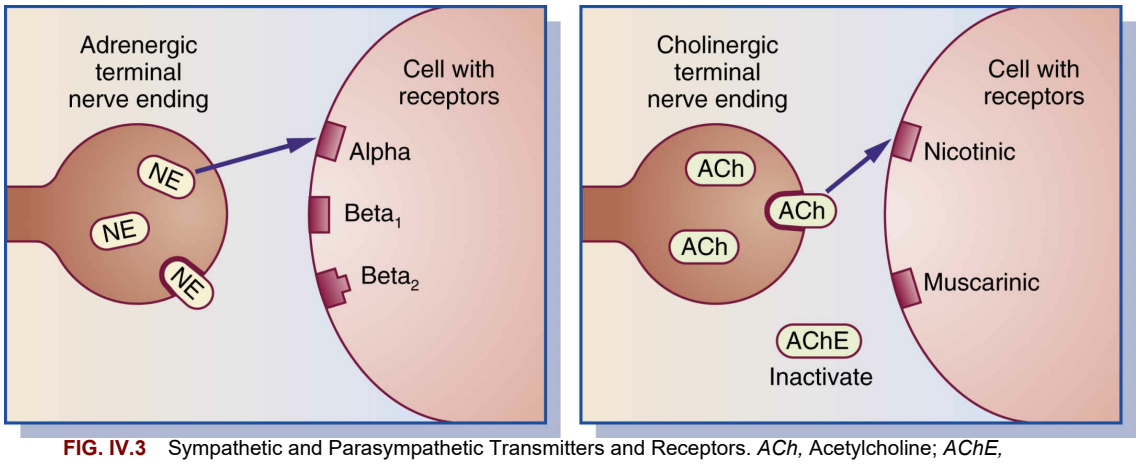

FIG. IV.3 Sympathetic and Parasympathetic Transmitters and Receptors. *ACh,* Acetylcholine; *AChE,* acetylcholinesterase; *NE,* norepinephrine.

TABLE IV.1

Sympathetic and Parasympathetic Responses to Drugs

Sympathetic	Parasympathetic	Response
Sympathomimetic	Parasympathomimetic	Opposite response
Sympatholytic	Parasympatholytic	Opposite response
Sympathomimetic	Parasympatholytic	Similar response
Sympatholytic	Parasympathomimetic	Similar response

TABLE IV.2

Autonomic Nervous System Stimulants: Sympathetic and Parasympathetic

Sympathetic Stimulants	**Parasympathetic Stimulants**
Direct-Acting	
Sympathomimetics (Adrenergics, Adrenomimetics, or Adrenergic Agonists)	***Parasympathomimetics (Cholinergics or Cholinergic Agonists)***
Action:	Action:
Increase blood pressure	Decrease blood pressure
Increase pulse rate	Decrease pulse rate
Relax bronchioles	Constrict bronchioles
Dilate pupils of eyes	Constrict pupils of eyes
Relax uterine muscles	Increase urinary contraction
Increase blood glucose	Increase peristalsis
	Indirect-Acting
	Cholinesterase Inhibitors (Anticholinesterase)
	Action:
	Increase muscle tone

Sympathetic Depressants	Parasympathetic Depressants
Sympatholytics (adrenergic blockers, adrenolytics, or adrenergic antagonists)	*Parasympatholytics (anticholinergics, cholinergic antagonists, or antispasmodics)*
Action:	Action:
Decrease pulse rate	Increase pulse rate
Decrease blood pressure	Decrease mucous secretions
Constrict bronchioles	Decrease gastrointestinal motility
	Increase urinary retention
	Dilate pupils of eyes

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Explain major responses to stimulation of adrenergic receptors.
- Differentiate between selective and nonselective adrenergic agonists.
- Contrast the uses of alpha and beta antagonists.
- Compare general side effects of adrenergic agonists and adrenergic antagonists.
- Describe nursing interventions, including patient teaching, associated with adrenergic agonists and adrenergic antagonists.
- Apply the nursing process for the patient taking beta-adrenergic antagonists.
- Compare the indications of adrenergic agonists and adrenergic antagonists.

KEY TERMS

adrenergic agonists, p. 199
adrenergic antagonists (adrenergic blockers), p. 206
adrenergic neuron antagonists (adrenergic neuron blockers), p. 207
adrenergic receptor, p. 199
alpha antagonists (alpha blockers), p. 206
beta antagonists (beta blockers), p. 203
catecholamines, p. 201

nonselective, p. 202
selective, p. 203
sympatholytics, p. 199
sympathomimetics, p. 199

http://evolve.elsevier.com/McCuistion/pharmacology
This chapter discusses two groups of drugs that affect the sympathetic nervous system—adrenergic agonists, or **sympathomimetics**, and *adrenergic antagonists,* also called *adrenergic blockers* or **sympatholytics**—along with their dosages and uses.

Patient Safety

Intravenous (IV) adrenergic agonists and antagonists are high-alert medications because they can cause significant harm to a patient in the event of a medication error.

Adrenergic Agonists

Drugs that stimulate the sympathetic nervous system are called *adrenergic agonists*, *adrenergics*, or *sympathomimetics* because they mimic the sympathetic neurotransmitters norepinephrine and epinephrine. They act on one or more **adrenergic receptor** sites located in the effector cells of muscles such as the heart, bronchiole walls, gastrointestinal (GI) tract, urinary bladder, and ciliary muscles of the eye. There are many adrenergic receptors. The four main receptors are $alpha_1$, $alpha_2$, $beta_1$, and $beta_2$, which mediate the major responses described in Table 15.1 and illustrated in Fig. 15.1.

The alpha-adrenergic receptors are located in the blood vessels, eyes, bladder, and prostate. When the $alpha_1$ receptors in vascular tissues (vessels) of muscles are stimulated, the arterioles and venules constrict; this increases peripheral resistance and blood return to the heart, circulation improves, and blood pressure is increased. When too much stimulation occurs, blood flow is decreased to the vital organs.

The $alpha_2$ receptors are located in the postganglionic sympathetic nerve endings. When stimulated, they inhibit the release of norepinephrine, which leads to a decrease in vasoconstriction. This results in vasodilation and a decrease in blood pressure.

TABLE 15.1

Effects of Adrenergic Agonists at Receptors

Receptor	Physiologic Responses
$Alpha_1$	Increases force of heart contraction; vasoconstriction increases blood pressure; mydriasis (dilation of pupils) occurs; secretion in salivary glands decreases; urinary bladder relaxation and urinary sphincter contraction increases
$Alpha_2$	Inhibits release of norepinephrine; dilates blood vessels; produces hypotension; decreases gastrointestinal motility and tone
$Beta_1$	Increases heart rate and force of contraction; increases renin secretion, which increases blood pressure
$Beta_2$	Dilates bronchioles; promotes gastrointestinal and uterine relaxation; promotes increase in blood glucose through glycogenolysis in the liver; increases blood flow in skeletal muscles

The $beta_1$ receptors are located primarily in the heart but are also found in the kidney. Stimulation of the $beta_1$ receptors increases myocardial contractility and heart rate.

The $beta_2$ receptors are found mostly in the smooth muscles of the lung and GI tract, the liver, and the uterine muscle. Stimulation of the $beta_2$ receptor causes (1) relaxation of the smooth muscles of the lungs, which results in bronchodilation; (2) a decrease in GI tone and motility; (3) activation of glycogenolysis in the liver and increased blood glucose; and (4) relaxation of the uterine muscle, which results in a decrease in uterine contraction (Fig. 15.2; see also Table 15.1).

Other adrenergic receptors are dopaminergic and are located in the renal, mesenteric, coronary, and cerebral arteries. When these receptors are stimulated, the vessels dilate and blood flow increases. Only dopamine can activate these receptors.

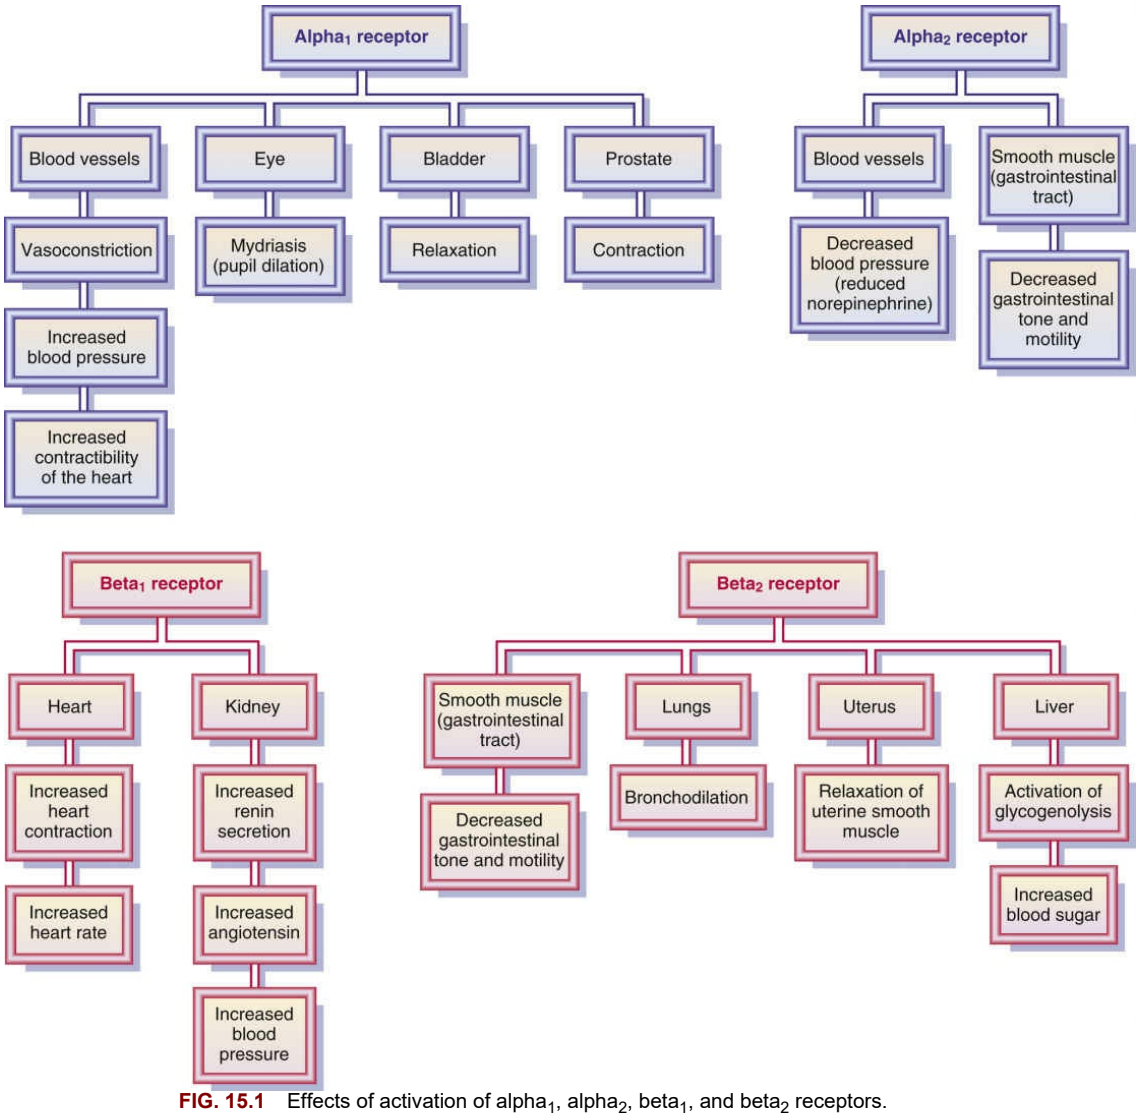

FIG. 15.1 Effects of activation of alpha$_1$, alpha$_2$, beta$_1$, and beta$_2$ receptors.

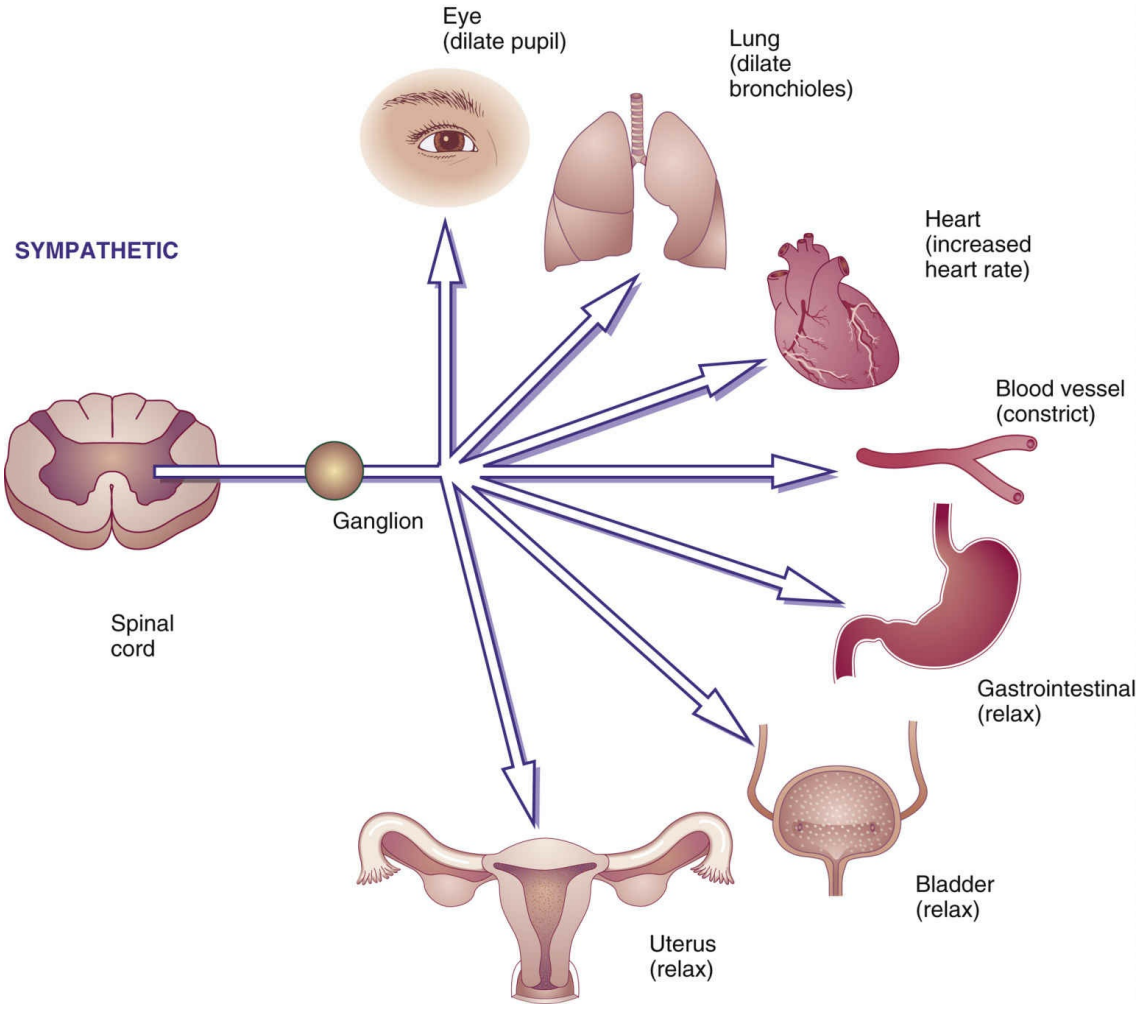

FIG. 15.2 Sympathetic responses. Stimulation of the sympathetic nervous system or use of sympathomimetic (adrenergic agonist) drugs can cause the pupils and bronchioles to dilate; heart rate to increase; blood vessels to constrict; and muscles of the gastrointestinal tract, bladder, and uterus to relax, thereby decreasing contractions.

Inactivation of Neurotransmitters

After the neurotransmitter (e.g., norepinephrine) has performed its function, the action must be stopped to prevent prolonging the effect. Transmitters are inactivated by (1) *reuptake* of the transmitter back into the neuron (nerve cell terminal), (2) enzymatic *transformation* or degradation, and (3) *diffusion* away from the receptor. The mechanism of norepinephrine reuptake plays a more important role in inactivation than does the enzymatic action. Following the reuptake of the transmitter in the neuron, the transmitter may be degraded or reused. The two enzymes that inactivate norepinephrine are monoamine oxidase (MAO), which is *inside* the neuron, and catechol-*O*-methyltransferase (COMT), which is *outside* the neuron.

Drugs can prolong the action of the neurotransmitter (e.g., norepinephrine) by either inhibiting reuptake, which prolongs the action of the transmitter, or inhibiting the degradation by enzymatic action.

Classification of Sympathomimetics

The sympathomimetic (adrenergic agonist) drugs that stimulate adrenergic receptors are classified into three categories according to their effects on organ cells. Categories include (1) direct-acting sympathomimetics, which directly stimulate the adrenergic receptor (e.g., epinephrine or norepinephrine); (2) indirect-acting sympathomimetics, which stimulate the release of

norepinephrine from the terminal nerve endings (e.g., amphetamine); and (3) mixed-acting (both direct- and indirect-acting) sympathomimetics, which stimulate the adrenergic receptor sites and stimulate the release of norepinephrine from the terminal nerve endings (e.g., ephedrine, Fig. 15.3).

Pseudoephedrine is an example of a mixed-acting sympathomimetic: It acts indirectly by stimulating the release of norepinephrine from the nerve terminals, and it acts directly on the alpha$_1$ and beta$_1$ receptors. Pseudoephedrine, like epinephrine, increases heart rate. It is not as potent a vasoconstrictor as epinephrine, and the risk of hemorrhagic stroke and hypertensive crisis is less. Pseudoephedrine is helpful to relieve nasal and sinus congestion without rebound congestion.

Catecholamines are the chemical structures of a substance, either endogenous or synthetic, that can produce a sympathomimetic response. Examples of endogenous catecholamines are epinephrine, norepinephrine, and dopamine. The synthetic catecholamines are isoproterenol and dobutamine. Noncatecholamines such as phenylephrine, metaproterenol, and albuterol stimulate the adrenergic receptors. Most noncatecholamines have a longer duration of action than the endogenous or synthetic catecholamines.

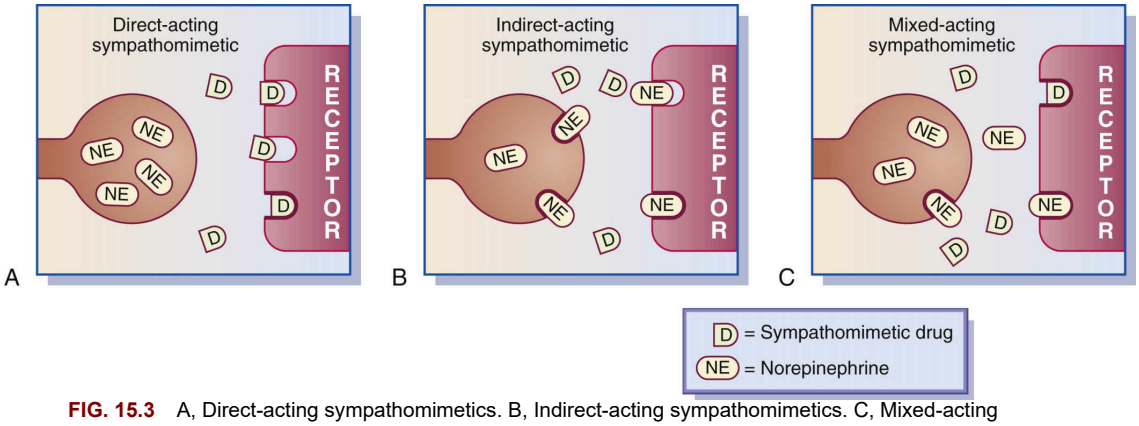

FIG. 15.3 A, Direct-acting sympathomimetics. B, Indirect-acting sympathomimetics. C, Mixed-acting sympathomimetics.

Many of the adrenergic agonists stimulate more than one of the adrenergic receptor sites. An example is epinephrine, which acts on alpha$_1$-, beta$_1$-, and beta$_2$-adrenergic receptor sites. The responses from these receptor sites include increase in blood pressure, pupil dilation, increase in heart rate (tachycardia), and bronchodilation. In anaphylactic shock, epinephrine is useful because it increases blood pressure, heart rate, and airflow through the lungs. Because epinephrine affects different adrenergic receptors, it is **nonselective**. Additional side effects result when more responses occur than are desired. Pseudoephedrine is commonly used for illegal production of amphetamine and methamphetamine. National regulatory measures control pseudoephedrine drug sales with individual limits of 3.6 g/day and 9 g within 30 days. Identifications are scanned with each purchase. The database is linked nationally and keeps a 2-year tally. Prototype Drug Chart 15.1 lists the pharmacologic behavior of epinephrine.

Epinephrine

Pharmacokinetics

Epinephrine can be administered subcutaneously, intravascularly (vastus lateralis), intravenously, topically, by inhalation, or via intracardiac administration. It is not given orally because it is rapidly metabolized in the GI tract and liver, which results in unstable serum levels. The half-life of epinephrine and the percentage by which the drug is protein bound are unknown. Epinephrine is metabolized by the liver and is excreted in the urine.

Pharmacodynamics

Epinephrine is frequently used in emergencies to treat anaphylaxis, a life-threatening allergic response. Epinephrine is a potent inotropic (myocardial contraction–strengthening) drug that increases cardiac output, promotes vasoconstriction and systolic blood pressure elevation, increases

heart rate, and produces bronchodilation. High doses can result in cardiac dysrhythmia, which necessitates electrocardiogram (ECG) monitoring. Epinephrine can also cause renal vasoconstriction, thereby decreasing renal perfusion and urinary output.

The onset of action and peak concentration times are rapid. The use of decongestants with epinephrine has an additive effect. When epinephrine is administered with digoxin, cardiac dysrhythmia may occur. Beta blockers can antagonize the action of epinephrine. Tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs) allow epinephrine's effects to be intensified and prolonged.

PROTOTYPE DRUG CHART 15.1 Epinephrine

Drug Class	Dosage
Sympathomimetic: adrenergic agonist	Anaphylaxis:
Pregnancy category: C*	A: subcut/IM: 0.3 mg EpiPen auto injector, may repeat in 5-20 min PRN; *max*: 2 doses
	IV: 0.1-0.25 mg of 0.1 mg/mL solution, may repeat q5-15min PRN; may follow with 1-4 mcg/min infusion
Contraindications	**Drug-Lab-Food Interactions**
Cardiac tachydysrhythmias, cerebral arteriosclerosis, labor, closed-angle glaucoma *Caution:* Hypertension, prostatic hypertrophy, hyperthyroidism, pregnancy, diabetes mellitus	Drug: Increased effects with TCAs and MAOIs; methyldopa and beta blockers antagonize epinephrine effects; digoxin may cause dysrhythmias with epinephrine. Lab: Increased blood glucose, serum lactic acid
Pharmacokinetics	**Pharmacodynamics**
Absorption: subcut/IM/IV: Rapidly; inactivated in GI tract Distribution: PB: UK Metabolism: t½: <5 min Excretion: In urine and breast milk	Subcut: Onset: 5-10 min Peak: 20 min Duration: 1-4 h IM: Onset: variable Duration: 1-4 h IV: Onset: Immediate Peak: 2-5 min Duration: 5-10 min Inhaled: Onset: 1 min Peak: 3-5 min Duration: 1-3 hours Intraocular: Onset: 1 min to 1 h Duration: 1-24 h
Therapeutic Effects/Uses	
To treat nasal congestion, allergic reaction, anaphylaxis, asthma, bronchospasm, angioedema, status asthmaticus, cardiac arrest, cardiac resuscitation	
Mode of Action: Acts on alpha and beta receptors; promotion of CNS and cardiac stimulation and bronchodilation; strengthens cardiac contraction, increases cardiac rate and cardiac output; reduces mucosal congestion by inhibiting histamine release; reverses anaphylactic reactions	
Side Effects	**Adverse Reactions**
Anorexia, nausea, vomiting, restlessness, tremors, agitation, sweating, headache, pallor, insomnia, weakness, dizziness, hyperglycemia	Palpitations, tachycardia, hypertension, dyspnea. Tissue necrosis of IV site upon infiltration *Life threatening:* Ventricular fibrillation, pulmonary edema

<, Less than; *A*, adult; *CNS*, central nervous system; *GI*, gastrointestinal; *h*, hours; *IM*, intramuscular; *IV*, intravenous; *MAOI*, monoamine oxidase inhibitor; *max*, maximum; *min*, minute; *PB*, protein binding; *PRN*, as needed; *q5min*, every 5 minutes; *subcut*, subcutaneous; *t½*, half-life; *TCA*, tricyclic antidepressant; *UK*, unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Side Effects and Adverse Reactions

Undesired side effects frequently result when the adrenergic drug dosage is increased or when the drug is nonselective. Side effects commonly associated with adrenergic agonists include hypertension, tachycardia, palpitations, restlessness, tremors, dysrhythmia, dizziness, urinary retention, nausea, vomiting, dyspnea, and pulmonary edema.

Names of adrenergic drugs, the receptors they activate, dosage information, and common uses are listed in Table 15.2. Epinephrine is also discussed in Chapter 55 as one of the drugs used during emergencies.

Albuterol

Albuterol sulfate, a $beta_2$-adrenergic agonist, is **selective** for $beta_2$-adrenergic receptors, so the response is relaxation of bronchial smooth muscle and bronchodilation. A patient with asthma may tolerate albuterol better than isoproterenol, which activates $beta_1$ and $beta_2$ receptors, because albuterol's action is more selective; it activates only the $beta_2$ receptors of smooth muscle in the lungs and uterus and in the vasculature that supplies the skeletal muscles. By using selective sympathomimetics, fewer undesired adverse effects will occur. However, high dosages of albuterol may affect $beta_1$ receptors, causing an increase in heart rate. Prototype Drug Chart 15.2 lists the drug data related to albuterol.

Pharmacokinetics

Albuterol sulfate is well absorbed from the GI tract and is extensively metabolized by the liver. The

half-life of albuterol via oral inhalation is 2.7 to 6 hours.

Pharmacodynamics

The primary use of albuterol is to prevent and treat bronchospasm. With inhalation, the onset of action of albuterol is 5 to 15 minutes by inhalation, and the duration of action is 2 to 6 hours.

Side Effects and Adverse Reactions

Tremors, restlessness, and nervousness are the most common side effects of oral or inhalation albuterol. If albuterol is taken with an MAOI, a hypertensive crisis can result. Other side effects include tachycardia, palpitations, dizziness, dysrhythmia, nausea, vomiting, and urinary retention. **Beta antagonists (beta blockers)** may inhibit the action of albuterol. Albuterol and the $beta_2$ drugs are also discussed in Chapters 36 and 39, respectively.

Nursing Process: Patient-Centered Collaborative Care

Adrenergic Agonists

Assessment

- Record baseline vital signs for future comparisons.
- Assess the patient's drug history.
- Determine patient's health history. Most adrenergic agonists are contraindicated if the patient has a cardiac dysrhythmia, narrow-angle glaucoma, or cardiogenic shock.
- Determine baseline glucose level.

Nursing Diagnoses

- Sleep Pattern, Disturbed related to the adverse drug effect of insomnia
- Knowledge, Deficient related to drug administration

Planning

- Patient's vital signs will be within acceptable ranges.
- Patient will experience therapeutic effects by improved blood pressure, breathing pattern, and cardiac output.

Nursing Interventions

- Administer IV epinephrine 1 mg (10 mL of a 1:10,000 concentration per American Heart Association [AHA] guidelines) for cardiac resuscitation; may repeat every 3 to 5 minutes. Follow each dose with a 20-mL saline flush to ensure proper delivery. Normally, epinephrine is administered 1 mg IV over 1 minute or more.
- Monitor IV site frequently when administering norepinephrine bitartrate or dopamine because extravasation of these drugs causes tissue damage and necrosis within 12 hours. These drugs should be diluted sufficiently in IV fluids.
- Administer antidote, phentolamine mesylate, 5 to 10 mg, diluted in 10 to 15 mL of normal saline infiltrated into the area for IV extravasation of norepinephrine and dopamine.
- Record patient's vital signs. Report signs of increasing blood pressure and increasing heart rate. If the patient receives an alpha-adrenergic agonist intravenously for shock, check the blood pressure every 3 to 5 minutes or as indicated to avoid severe hypertension.
- Monitor ECG for dysrhythmia when adrenergic agonists are given intravenously.
- Report side effects of adrenergic drugs such as tachycardia, palpitations, tremors, dizziness, and increased blood pressure.
- Check patient's urinary output and assess for bladder distension. Urinary retention can result from a high drug dose or continuous use of adrenergic agonists.
- Offer food to the patient when giving adrenergic agonists to avoid nausea and vomiting.
- Evaluate blood glucose levels in patients with diabetes mellitus for potential elevation.

Patient Teaching

General

- Advise the patient to read labels on all over-the-counter (OTC) drugs for cold symptoms and

diet pills. Many of these have properties of sympathetic drugs (adrenergic agonists, sympathomimetics) and should not be taken if a patient is hypertensive or has diabetes mellitus, cardiac dysrhythmia, or coronary artery disease.
- Explain that continuous use of nasal sprays or drops that contain adrenergic agonists may result in rebound nasal congestion (inflamed and congested tissue).

Self-Administration

- Encourage the patient to take medication as prescribed.
- Advise the patient and family on proper administration of the drug and allow a return demonstration. Cold medications by spray or drops in the nostrils should be used with the head in an upright position. Use of nasal spray while lying down can cause systemic absorption. Coloration of nasal spray or drops might indicate deterioration.
- Notify the health care provider if an EpiPen is needed more than twice a week.
- Encourage the patient to have an EpiPen readily available at all times and to store additional medication in a cool, dark place. Refrigeration is not recommended.
- Teach the patient and family that the EpiPen must be used immediately upon the initial occurrence of difficulty breathing, wheezing, hoarseness, hives, itching, or swelling of the lips and tongue.
- Teach the patient to administer the EpiPen properly. Inspect the solution for particles or discoloration prior to administration. Do not use if particles are pink to brown in color. Take care to inject subcutaneously and not intradermally, and be sure to apply sufficient pressure to activate the EpiPen while holding the device in place for 5 to 10 seconds. The EpiPen should be inserted into the outer thigh. After administration, massage the injection site for 10 seconds to promote absorption and reduce vasoconstriction and tissue irritation.

Side Effects

- Encourage the patient to report side effects such as rapid heart rate, palpitations, rash, itching, flushing, chest pain, irregular heartbeat, vomiting, or numbness of fingers and toes to a health care provider because the dose may require adjustment.

Cultural Considerations

- Decrease language barriers for patients with language difficulties and for those who do not work in the health care field by decoding the jargon of the health care environment.

Evaluation

- Evaluate the patient's response to the adrenergic agonist.
- Evaluate vital signs, and report abnormal findings. Epinephrine stimulates alpha$_1$ (increases blood pressure), beta$_1$ (increases heart rate), and beta$_2$ (dilates bronchial tubes) receptors. Albuterol stimulates beta$_2$ receptors.
- Report possible drug-drug interactions. Beta blockers decrease the effect of epinephrine and albuterol. OTC cold and allergy drugs, caffeine, alcohol, herbs, and dietary supplements may lead to interactions.

PROTOTYPE DRUG CHART 15.2 Albuterol

Drug Class	Dosage
Beta$_2$-adrenergic agonist Pregnancy category: C*	Acute bronchospasm: A/adol: MDI: 2 inhal (90 mcg/inhal) q4-6h Bronchospasm prophylaxis: Immediate release: A/adol: PO: 2-4 mg q6-8h; *max:* 32 mg/d C 6-12 y: PO: Initially 2 mg tid/qid; *max*: 24 mg/d Extended release: A/adol: PO: 4-8 mg q12h; *max*: 32 mg/d C 6-12 y: PO: Initially 4 mg q12h; *max*: 24 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, milk protein hypersensitivity *Caution:* Cardiac dysrhythmia, coronary artery disease, severe cardiac disease, hypertension, hyperthyroidism, diabetes mellitus, renal dysfunction, advanced age, seizures, MAOI therapy, pregnancy	Drug: Increased effect with other sympathomimetics; may increase effect with MAOIs and TCAs Antagonize effect with beta blockers Lab: May increase glucose level slightly; may decrease serum potassium level
Pharmacokinetics	**Pharmacodynamics**
Absorption: Well absorbed from the GI tract after oral administration; well absorbed from respiratory tract after inhalation Distribution: PB: 10% Metabolism: t½: Oral inhal: 2.7-6 h Excretion: 80%-100% excreted in the urine	Immediate release: PO: Onset: 30 min Peak: 2-3 h Duration: 4-6 h Extended release: PO: Onset: UK Peak: UK Duration: 8-12 h Inhal: Onset: 5-15 min Peak: 0.5-2 h Duration: 2-6 h
Therapeutic Effects/Uses	
To treat asthma and for prophylaxis and treatment of bronchospasm	
Mode of Action: Stimulates beta$_2$-adrenergic receptors in the lungs, which relaxes the bronchial smooth muscle, thus causing bronchodilation	
Side Effects	**Adverse Reactions**
Tremor, dizziness, drowsiness, nervousness, restlessness, agitation, anxiety, sweating, headache, nasopharyngitis, insomnia, weakness, nausea, diarrhea, muscle cramps	Palpitations, tachycardia, hypertension, infection, hyperglycemia, hypokalemia *Life threatening:* Cardiac dysrhythmia, angioedema, bronchospasm, Stevens-Johnson syndrome

TABLE 15.2

Adrenergic Agonists: Alpha$_1$, Beta$_1$, and Beta$_2$

Drug	Route and Dosage	Uses and Considerations
Epinephrine; alpha$_1$, beta$_1$, and beta$_2$	See Prototype Drug Chart 15.1.	
Ephedrine hydrochloride, ephedrine sulfate; alpha$_1$, beta$_1$, and beta$_2$	A: PO: 25-50 mg q3-4h PRN; *max:* 150 mg/d C >2 y: PO: 2-3 mg/kg/d in 4-6 divided doses; *max:* 3 mg/kg/d A: subcut/IM/IV: 12.5-25 mg; *max:* 150 mg/24 h	To treat hypotensive states, bronchospasm, and asthma. Drug resistance may occur with prolonged use of ephedrine. If this occurs, stop the drug for 3-5 days and then resume. May cause weakness, restlessness, headache, dizziness, tremor, tachycardia, and palpitations. Pregnancy category: C*; PB: UK; t½: 3-6 h
Norepinephrine bitartrate; alpha$_1$ and beta$_1$	A: IV: Initially 8-12 mcg/min inf, titrate to maintain adequate BP; *max*: 30 mcg/min continuous infusion	To treat hypotension and cardiogenic and septic shock. Monitor blood pressure and rhythm every 2-5 min during infusion. May cause anxiety, headache, bradycardia, dysrhythmia, peripheral edema, dyspnea, and tissue necrosis. Pregnancy category: C*; PB: UK; t½: UK
Dopamine hydrochloride; alpha$_1$ and beta$_1$	A: IV/inf: Initially 2-5 mcg/kg/min; gradually increase; *max:* 50 mcg/kg/min Adol/C/infants: IV: Initially 1-5 mcg/kg/min; gradually increase PRN; *max:* 20 mcg/kg/min	To treat hypotension, heart failure, septic shock, and cardiogenic shock. May cause hypotension, hypertension, bradycardia, dysrhythmia, headache, angina, dyspnea, GI distress, and tissue necrosis. Pregnancy category: C*; PB: UK; t½: 2 min
Midodrine hydrochloride; alpha$_1$	A: PO: 10 mg tid; *max:* 30 mg/d	To treat orthostatic hypotension. Do not administer within 4 h of bedtime. May cause hypertension, paresthesias, pruritus, urinary retention, and piloerection. Pregnancy category: C*; PB: UK; t½: 25 min
Phenylephrine hydrochloride; alpha$_1$	Nasal decongestant: A/C 6-12 y: 2-3 sprays each nostril q4h PRN; *max*: 3 sprays each nostril in 4 h for 3 d	To treat sinus and nasal congestion. Have patient blow nose before drug is administered. May cause headache, burning, stinging, sneezing, nasal discharge, and nausea. Pregnancy category: C*; PB: UK; t½: 2.1-3.4 h
Pseudoephedrine hydrochloride; alpha$_1$, alpha$_2$, and beta$_1$	Nasal decongestant: A: PO: 60 mg q4-6h; *max:* 240 mg/d C 6-11 y: PO: 30 mg q4-6h; *max:* 120 mg/d C 2-5 y: PO: 15 mg q4-6h; *max:* 60 mg/d Extended release: A: PO: 120 mg q12h; *max:* 240 mg/d	To treat nasal congestion due to common cold and allergic rhinitis; an OTC drug but controlled; contraindicated in hypertension, cardiac disease, emphysema, peptic ulcer disease, and urinary retention. Use with caution in diabetes mellitus. May cause hypertension, dysrhythmia, tachycardia, palpitations, drowsiness, dizziness, headache, seizure, blurred vision, photosensitivity, restlessness, insomnia, anorexia, and nausea. Pregnancy category: C*; PB: UK; t½: 9-16h
Albuterol; beta$_2$	See Prototype Drug Chart 15.2.	
Metaproterenol sulfate; beta$_2$	A/adol/C >9 y: PO: 20 mg tid/qid; *max*: 80 mg/d Older adults: PO: 10 mg tid/qid; *max*: 80 mg/d A/C >12 y: MDI: 2-3 puffs q3-4h; *max:* 12 puffs/d	To treat acute bronchospasm, asthma, and COPD. May cause tachycardia, palpitations, tremor, nausea, and headache. Pregnancy category: C*; PB: UK; t½: UK
Dobutamine hydrochloride; beta$_1$	A/adol/C: IV: Initially 0.5-1 mcg/kg/min; titrate dose gradually so HR does not elevate >10% of baseline; AHA recommends effective dose of 2-20 mcg/kg/min; *max:* 20 mcg/kg/min	To treat heart failure and cardiogenic shock and for cardiac surgery. May cause dysrhythmia, tachycardia, angina, palpitations, muscle spasms, headache, hypertension, hypokalemia, and dyspnea. Pregnancy category: C*; PB: UK; t½: 2 min
Terbutaline sulfate; beta$_2$	Bronchodilation: A/adol >15y: PO: 2.5-5 mg tid; *max:* 15 mg/d Adol <15y/C >12 y: PO: 2.5 mg tid; *max:* 7.5 mg/d A: subcut: Initially 0.25 mg, may repeat in 15-30 min PRN; *max*: 0.5 mg in 4 h	For asthma, COPD, and prophylaxis and treatment of bronchospasm. May cause nervousness, tremors, dizziness, drowsiness, headache, hyperglycemia, and hypokalemia. Pregnancy category: B*; PB: 25%; t½: 11-16 h

Central-Acting Alpha Agonists

Clonidine and Methyldopa

Clonidine is a selective alpha$_2$-adrenergic agonist used primarily to treat hypertension. Alpha$_2$ drugs are central acting and produce vasodilation by stimulating alpha$_2$ receptors in the central nervous system (CNS), leading to a decrease in blood pressure (see Chapter 39).

Alpha$_2$ drugs act by decreasing the release of norepinephrine from sympathetic nerves and by decreasing peripheral adrenergic receptor activation. Clonidine may produce bradycardia and sedation at very low doses.

Methyldopa is an alpha-adrenergic agonist that acts within the CNS. This drug is taken up into the brainstem neurons and is converted to alpha-methylnorepinephrine, an alpha$_2$-adrenergic agonist that leads to alpha$_2$ activation. The decrease of sympathetic outflow from the CNS reduces peripheral resistance, causing vasodilation and a reduction in blood pressure (see Chapter 39). Currently, methyldopa is not used much as an antihypertensive due to the development of other antihypertensives that have fewer side effects.

Side Effects and Adverse Reactions

Additional undesired side effects of central-acting alpha-adrenergic agonists include headache, nasal congestion, drowsiness, nightmares, constipation, and edema. Ejaculation dysfunction and elevated hepatic enzymes may also occur.

Adrenergic Antagonists (Adrenergic Blockers)

Drugs that block the effects of adrenergic neurotransmitters are called *adrenergic antagonists, adrenergic blockers,* or *sympatholytics.* They act as antagonists to adrenergic agonists by blocking the alpha- and beta-receptor sites. Most **adrenergic antagonists (adrenergic blockers)** block either the alpha receptor or the beta receptor. They block the effects of the neurotransmitter either directly by occupying the receptors or indirectly by inhibiting the release of the neurotransmitters norepinephrine and epinephrine. Table 15.3 lists the effects of alpha blockers and beta blockers at receptors.

Alpha-Adrenergic Antagonists

Drugs that block or inhibit a response at the alpha-adrenergic receptor site are called *alpha-adrenergic antagonists, adrenergic blockers,* or *alpha blockers.* Alpha-blocking agents are divided into two groups: *selective* alpha blockers block $alpha_1$, and *nonselective* alpha blockers block $alpha_1$ and $alpha_2$. Because alpha-adrenergic antagonists can cause orthostatic hypotension and reflex tachycardia, many of these drugs are not as frequently prescribed as beta antagonists.

TABLE 15.3

Effects of Adrenergic Blockers at Receptors

Receptor	Responses
$Alpha_1$	Vasodilation: decreases blood pressure; reflex tachycardia might result; mydriasis (constriction of pupil) occurs; suppresses ejaculation; reduces contraction of smooth muscle in bladder neck and prostate gland
$Beta_1$	Decreases heart rate; reduces force of contractions
$Beta_2$	Constricts bronchioles; contracts uterus; inhibits glycogenolysis, which can decrease blood glucose

Alpha antagonists (alpha blockers) promote vasodilation, causing a decrease in blood pressure. If vasodilation is long-standing, orthostatic hypotension can result. Dizziness may also be a symptom of a drop in blood pressure. As blood pressure decreases, pulse rate usually increases to compensate for the low blood pressure and inadequate blood flow. Alpha antagonists can be used to treat peripheral vascular disease such as Raynaud disease. Vasodilation occurs, permitting more blood flow to the extremities. These drugs are also helpful in decreasing symptoms of benign prostatic hyperplasia (BPH). Alpha antagonists are also discussed in Chapter 39.

Beta-Adrenergic Antagonists

Beta-adrenergic antagonists, more commonly called *beta blockers,* decrease heart rate, and a decrease in blood pressure usually follows. Some beta blockers are nonselective, blocking both $beta_1$ and $beta_2$ receptors. Not only does the heart rate decrease because of $beta_1$ blocking, bronchoconstriction also occurs. Nonselective beta blockers block both $beta_1$ and $beta_2$ and should be used with extreme caution in any patient who has chronic obstructive pulmonary disease (COPD) or asthma.

Propranolol hydrochloride was the first beta blocker prescribed to treat angina, cardiac dysrhythmia, hypertension, and heart failure. This medication may also be given for migraine prophylaxis. Propranolol has many side effects, partly because of its nonselective response in blocking both $beta_1$ and $beta_2$ receptors.

A selective adrenergic antagonist has a greater affinity for certain receptors. If the desired effect is to decrease pulse rate and blood pressure, a selective $beta_1$ blocker such as atenolol or metoprolol tartrate may be ordered.

Intrinsic sympathomimetic activity (ISA) is a term used to describe the ability of certain beta blockers to bind with a beta receptor to prevent strong agonists from binding to that receptor, producing complete activation. Nonselective beta blockers that have ISA include carvedilol, penbutolol, and pindolol. The selective blocker (blocks $beta_1$ only) that has ISA is acebutolol, and such an agent may be recommended for hypertensive patients who are experiencing bradycardia.

Atenolol, a selective $beta_1$ blocker, is one of the most frequently prescribed drugs in the United States. Atenolol decreases sympathetic outflow to the periphery and suppresses the renin-

angiotensin-aldosterone system (RAAS) response. It is contraindicated in bradycardia, heart block, cardiogenic shock, acute heart failure, and sick sinus syndrome. Prototype Drug Chart 15.3 describes the pharmacologic behavior of atenolol.

Beta blockers are useful in treating mild to moderate hypertension, angina, heart failure, and myocardial infarction (MI). Beta blockers should not be abruptly discontinued but rather should be tapered off over 1 to 2 weeks to avoid tachycardia, hypertension, severe angina, dysrhythmia, and MI. The use of beta blockers as antihypertensives, antidysrhythmics, and drugs for angina is discussed in Chapters 37 and 39. Table 15.4 lists the alpha and beta blockers and their dosages, uses, and considerations.

PROTOTYPE DRUG CHART 15.3 Atenolol

Drug Class	Dosage
$Beta_1$-adrenergic blocker Trade name: Tenormin Pregnancy category: D*	Hypertension: A: PO: Initially 25-50 mg/d; may increase to 100 mg/d after 7 d; *max*: 100 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Sinus bradycardia, heart block greater than first degree, cardiogenic shock, pulmonary edema, acute bronchospasm, uncompensated cardiac failure, pregnancy, lactation *Caution:* Renal dysfunction, diabetes mellitus	Drug: Increased absorption with atropine and other anticholinergics, decreased effects with NSAIDs, increased risk of hypoglycemia with insulin and sulfonylureas, increased hypotension with prazosin and terazosin, increased lidocaine and verapamil levels with toxicity
Pharmacokinetics	**Pharmacodynamics**
Absorption: 50% absorbed in GI tract Distribution: PB: 10% Metabolism: t½: 6-7 h Excretion: Urine and feces	PO: Onset: 1 h Peak: 2-4 h Duration: 24 h
Therapeutic Effects/Uses	
To treat hypertension, angina, and prophylaxis and treatment of acute myocardial infarction	
Mode of Action: Selectively blocks beta $_1$-adrenergic receptor sites, decreases sympathetic outflow to the periphery, suppresses renin-angiotensin-aldosterone system	
Side Effects	**Adverse Reactions**
Drowsiness, dizziness, depression, weakness, nausea, diarrhea, cool extremities, erectile dysfunction	Bradycardia, hypotension, heart failure, dyspnea *Life threatening:* Bronchospasm, dysrhythmia, thrombocytopenia

A, Adult; *d*, day; *GI*, gastrointestinal; *h*, hour; *max*, maximum; *NSAID*, nonsteroidal antiinflammatory drug; *PB*, protein binding; *PO*, by mouth; *t½*, half-life.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Pharmacokinetics

Atenolol crosses the blood-brain barrier and is 50% to 60% absorbed by the GI tract. The protein-binding capacity is 6% to 16%. Atenolol has a half-life of 2.5 to 8 hours and is eliminated in urine.

Pharmacodynamics

By blocking $beta_1$ receptors, atenolol decreases the heart rate, peripheral vascular resistance, force of cardiac contractions, and cardiac output and reduces both systolic and diastolic blood pressure. It is available in tablets and for IV administration. The onset of action of the oral preparation is 1 hour; peak time is 2 to 4 hours, and duration of action is 24 hours. This drug is effective for once-daily dosing, especially for patients who do not adhere to drug-dose schedules that require dosing several times a day.

Drug Interactions

Many drugs interact with atenolol. Nonsteroidal antiinflammatory drugs (NSAIDs) decrease the hypotensive effect of atenolol. Hypotension can be potentiated if atenolol is taken with another antihypertensive, although this may be the desired result. When atenolol is given concurrently with atropine and other anticholinergics, absorption is increased. The risk of hypoglycemia is increased when the patient is taking insulin and sulfonylureas.

Side Effects and Adverse Reactions

The side effects commonly associated with beta blockers are bradycardia, hypotension, headache, dizziness, cold extremities, hypoglycemia, and bronchospasm. Other side effects of beta-adrenergic blockers include cardiac dysrhythmia, flushing, hypotension, weakness, erectile dysfunction, depression, and pulmonary edema. Usually the side effects are dose related.

Adrenergic Neuron Antagonists

Drugs that block the release of norepinephrine from the sympathetic terminal neurons are called **adrenergic neuron antagonists (adrenergic neuron blockers)**. The clinical use is to decrease blood pressure. For example, reserpine is an antihypertensive agent that closely resembles alpha- and beta-adrenergic blockers; it also reduces the serotonin and catecholamine transmitters, depletion of which may lead to severe mental depression (Complementary and Alternative Therapy 15.1). Reserpine is discussed in more detail in Chapter 39.

TABLE 15.4

Adrenergic Antagonists

Drug	Route and Dosage	Uses and Considerations
Phentolamine mesylate; $alpha_1$	Catecholamine extravasation: A: Subcut: 5-10 mg in 10 mL NS injected into extravasation area to prevent dermal necrosis	Antidote for dopamine, dobutamine, phenylephrine, epinephrine, and catecholamine extravasation to prevent dermal necrosis. Redness and tissue warmth are signs of effective treatment. May cause pain at injection site. Pregnancy category: C*; PB: UK; t½: 19 min
Doxazosin mesylate; $alpha_1$	Hypertension: A: PO: Initially 1 mg/d at bedtime; *max:* 16 mg/d	To treat hypertension and BPH. Extended release tabs are not FDA approved for treatment of hypertension. May cause dizziness, headache, weakness, visual impairment, and orthostatic hypotension. Pregnancy category: C*; PB: 98%; t½: 22 h
Prazosin hydrochloride; $alpha_1$	A: PO: Initially 1 mg bid/tid; maint: 6-15 mg/d in divided doses; *max:* 20 mg/d Older A: PO: Initially 1 mg qd/bid; *max:* 20 mg/d	To treat hypertension. May cause headache, dizziness, drowsiness, fatigue, nausea, weakness, and palpitations. Pregnancy category: C *; PB: 97%; t½: 2-4 h
Terazosin hydrochloride; $alpha_1$	Hypertension: A: PO capsules: Initially 1 mg at bedtime; maint: 1-5 mg/d; *max:* 20 mg/d BPH: A: PO capsules: Initially 1 mg at bedtime; maint: 5-10 mg/d; *max*: 20 mg/d	To treat hypertension and BPH. May cause nasal congestion, dizziness, drowsiness, headache, peripheral edema, orthostatic hypotension, weakness, and depression. Pregnancy category: C*; PB: 90%-94%; t½: 12 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Carvedilol; $alpha_1$, $beta_1$, and $beta_2$	Post MI: Regular release: A: PO: 3.125-6.25 mg bid; *max:* 50 mg/d Extended release: A: Initially 10-20 mg/d; *max:* 80 mg/d	To treat hypertension and HF and for prophylaxis and treatment of acute MI. May cause drowsiness, dizziness, orthostatic hypotension, bradycardia, hyperglycemia, diarrhea, weight gain, and weakness. Pregnancy category: C*; PB: 98%; t½: 7-11 h
Labetalol; $alpha_1$, $beta_1$, and $beta_2$	A: PO: Initially 100 mg bid; dose may be increased q2-3d; maint: 200-400 mg bid; *max:* 2400 mg/d A: IV bolus: Initially 20 mg over 2 min; repeat 40-80 mg over 2 min at 10-min interval; *max:* 300 mg/d	To treat hypertension. May cause hypotension, dizziness, headache, weakness, nausea, erectile/ejaculation dysfunction, and depression. Pregnancy category: C*; PB: 50%; t½: 2.5-8 h
Propranolol hydrochloride; $beta_1$ and $beta_2$	Hypertension: A: PO: Initially: 40 mg bid; may increase q3-7d; maint: 160-480 mg/d in 2-3 divided doses; *max:* 640 mg/d Angina: A: PO: Initially 10-20 mg bid/qid, increase q3-7d; maint: 160-320 mg/d in 2-4 divided doses Extended release: A: PO: 80 mg/d; may increase q3-7d; maint: 160-320 mg/d	To treat hypertension, angina, and dysrhythmia; for prophylaxis and treatment of MI; and for migraine prophylaxis. May cause cold extremities, agitation, fatigue, dizziness, sleep disorder, visual impairment, bradycardia, hyperkalemia, and seizures. Pregnancy category: C*; PB: 90%; t½: 2-6 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Nadolol; $beta_1$ and $beta_2$	A: PO: Initially 40 mg/d; maint: 40-80 mg/d; *max:* 320 mg/d for hypertension and 240 mg/d for angina	To treat hypertension and angina. Contraindicated in bronchial asthma. Use with caution in COPD because it blocks $beta_2$ receptors. May cause dizziness, drowsiness, fatigue, insomnia, bradycardia, hypotension, palpitations, cold extremities, and dysrhythmias. Side effects, usually mild and temporary at onset, diminish over time. Pregnancy category: C*; PB: 30%; t½: 10-24 h
Pindolol; $beta_1$ and $beta_2$	A: PO: Initially 5 mg bid; maint: 10-30 mg in 2-3 divided doses; *max:* 60 mg/d	To treat hypertension. Contraindicated in asthma and second- and third-degree heart block. Use with caution in COPD. May cause bradycardia, hypotension, edema, cold extremities, fatigue, dizziness, insomnia, myalgia, arthralgia, dysrhythmias, visual impairment, and elevated liver enzymes. Pregnancy category: B*; PB: 40%-60%; t½: 3-4 h
Sotalol; $beta_1$ and $beta_2$	Atrial flutter/fibrillation: A: PO: 80 mg bid; may increase gradually; *max*: 320 mg/d	To treat ventricular tachycardia, atrial flutter, and atrial fibrillation. Correct hypokalemia and hypomagnesemia before initiating therapy. Abrupt discontinuation may trigger dysrhythmias or MI. Gradually reduce dose over 1-2 weeks. May cause bradycardia, palpitations, chest pain, dyspnea, fatigue, dizziness, headache, and weakness. Pregnancy category: B*; PB: 0%; t½: 12 h
Timolol maleate; $beta_1$ and $beta_2$	Hypertension: A: Subcut: 5-10 mg in 10 mL NS injected into extravasation area to prevent dermal necrosis	To treat hypertension and glaucoma and for migraine prophylaxis. Contraindicated in patients with asthma, COPD, bradycardia, and HF. May cause blurred vision, bradycardia, fatigue, dizziness, dyspnea, pulmonary edema, and dysrhythmias. Pregnancy category: C*; PB: 10%; t½: 3-4 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Selective Beta-Adrenergic Blockers		
Metoprolol tartrate; $beta_1$	Angina: Regular release: A: PO: Initially 25-50 mg bid; maint: 100-400 mg/d in 2 divided doses Extended release: A: PO: Initially 100 mg/d; maint: 100-400 mg/d; *max:* 400 mg/d	To treat hypertension, angina, HF, and acute MI. May cause bradycardia, dizziness, drowsiness, fatigue, hypotension, depression, diarrhea, heart failure, and dysrhythmias. Pregnancy category: C*; PB: 10%; t½: 3-4 h
Atenolol; $beta_1$	See Prototype Drug Chart 15.3.	
Acebutolol hydrochloride; $beta_1$	Hypertension: A: PO: Initially: 400 mg/d; maint: 400-800 mg/d; *max:* 1200 mg/d Older adults: Initially 200 mg/d; *max:* 800 mg/d	To treat hypertension and dysrhythmias. Check apical pulse; do not give if <60 beats/min. May cause bradycardia, hypotension, dizziness, fatigue, headache, nausea, diarrhea, and constipation. Pregnancy category: B*; PB: 26%; t½: 3-4 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Betaxolol; $beta_1$	Hypertension: A: PO: 10 mg/d; *max:* 20 mg/d Older adult: 5 mg/d; *max:* 20 mg/d	To treat hypertension and glaucoma. Ophthalmic preparation is used to decrease IOP. May cause bradycardia, headache, dizziness, fatigue, nausea, and chest pain. Pregnancy category: C*; PB: 50%; t½: 15 h
Bisoprolol fumarate; $beta_1$	A: PO: Initially: 2.5-5 mg/d; *max:* 20 mg/d	To treat hypertension. Long-acting beta blocker. May cause bradycardia, drowsiness, headache, fatigue, sweating, elevated hepatic enzymes, bronchospasm, and peripheral edema. Pregnancy category: C*; PB: 30%; t½: 9-12 h
Esmolol hydrochloride; $beta_1$	Dysrhythmia: A: IV: LD: 500 mcg/kg/min for 1 min, then 50 mcg/kg/min for 4 min; *max:* 500 mg LD, 300 mcg/kg/min infusion Hypertension: A: IV: 80 mg bolus IV over 30 sec, then 150 mcg/kg/min IV infusion; *max*: 300 mcg/kg/min	To treat supraventricular tachydysrhythmia and hypertension. Contraindications include heart block, bradycardia, cardiogenic shock, and acute HF; may cause hypotension, dizziness, nausea, and hyperglycemia. Pregnancy category: C*; PB: 55%; t½: 9 min

COMPLEMENTARY AND ALTERNATIVE THERAPIES 15.1 Reserpine

St. John's wort may antagonize the hypotensive effects of reserpine.

Nursing Process: Patient-Centered Collaborative Care

Adrenergic Neuron Antagonists

Assessment

- Obtain baseline vital signs and ECG for future comparisons. Bradycardia and a decrease in blood pressure are common cardiac effects of adrenergic neuron blockers.
- Determine what drugs the patient currently takes. Report if any are diuretics, NSAIDs, digoxin, MAOIs, or CNS depressants.
- Obtain a health history. Depression, peptic ulcer, and heart failure may result from taking an adrenergic neuron blocker, and these drugs could potentiate preexisting conditions.

Nursing Diagnoses

- Cardiac Output, Decreased related to hypotension and bradycardia
- Falls, Risk for
- Fatigue related to medication adverse effects
- Sexual Dysfunction related to adverse effects of erectile and ejaculatory dysfunction
- Noncompliance related to undesired adverse effects of erectile dysfunction

Planning

- Patient will adhere to the drug regimen.
- Patient's vital signs will be within the desired range.

Nursing Interventions

- Monitor vital signs. Report marked changes such as marked decreases in blood pressure and heart rate.
- Report any complaints of excessive dizziness, lightheadedness, early morning insomnia, mental depression, or chest pain.
- Assist patient with ambulation to avoid falls from orthostatic hypotension, which is more common with high doses.
- Note any complaint of stuffy nose because vasodilation may result, and nasal congestion can occur.

Patient Teaching

General

- Encourage the patient to adhere to the drug regimen.
- Advise the patient that the therapeutic effects of adrenergic neuron antagonists may not occur

for 2 to 3 weeks after initiation of therapy.

Self-Administration

- Teach the patient and family how to take pulse and blood pressure.
- Encourage the patient to take adrenergic neuron antagonists at the same time every day and not to discontinue it without permission from the health care provider.

Side Effects

- Encourage the patient to avoid orthostatic (postural) hypotension by slowly rising from supine or sitting positions to standing.
- Inform patients and family of possible psychological changes when taking adrenergic neuron antagonists, which occur because of catecholamine depletion. Psychological changes can include depression, sleep disorders, emotional lability, memory impairment, confusion, nightmares, and hallucinations.
- Warn patients that adrenergic neuron antagonists may cause erectile or ejaculation dysfunction, which is usually dose related.
- Advise patients not to drive or operate dangerous equipment until the drug response is known.

Cultural Considerations

- Obtain an interpreter when necessary. Do not rely on family members, who may not fully disclose because of honor or shame.
- Discuss the interpreter's ethnicity and the language desired when translation is needed. Provide an interpreter with the same ethnic background and gender if possible, especially when sensitive topics are being addressed.

Evaluation

- Evaluate effectiveness of the adrenergic neuron blocker. Vital signs must be stable within the desired range.

Critical Thinking Case Study

An older adult patient has asthma, and an adrenergic agonist is selected for treatment.
1. What are the drug advantages and disadvantages associated with the use of an adrenergic agonist, such as metaproterenol or albuterol, for this patient? Explain your answer.
2. Is age a factor in drug selection? Explain your answer.

An older adult patient has hypertension and asthma. An adrenergic blocker is selected for treatment.
1. What are the drug advantages and disadvantages associated with the use of doxazosin, prazosin, propranolol, metoprolol, and atenolol for this patient? Explain your answer.
2. What needs to be included when teaching this patient about the use of an adrenergic blocker?

NCLEX Study Questions

1. The nurse will monitor the patient taking albuterol for which conditions? (Select all that apply.)
   a. Palpitations
   b. Hypertension
   c. Hypoglycemia
   d. Bronchospasm
   e. Uterine contractions
2. Nadolol is prescribed for a patient. The nurse realizes that this drug is a beta-adrenergic blocker and that this drug classification is contraindicated for patients with which condition?
   a. Hypothyroidism
   b. Angina pectoris
   c. Bronchial asthma
   d. Liver dysfunction
3. The nurse realizes that $beta_1$ receptor stimulation is differentiated from $beta_2$ stimulation in that stimulation of $beta_1$ receptors leads to which condition?
   a. Increased bronchodilation
   b. Decreased uterine contractility
   c. Increased myocardial contractility
   d. Decreased blood flow to skeletal muscles
4. A patient is given epinephrine, an adrenergic agonist (sympathomimetic). The nurse should monitor the patient for which condition?
   a. Decreased pulse
   b. Pupil constriction
   c. Bronchial constriction
   d. Increased blood pressure
5. A patient who is taking epinephrine is also taking several other medications. The nurse should realize that there is a possible drug interaction with which drugs? (Select all that apply.)
   a. Albuterol
   b. Metoprolol
   c. Propranolol
   d. Digoxin
   e. Methyldopa
6. A patient is prescribed metoprolol to treat hypertension. It is important for the nurse to monitor the patient for which condition? (Select all that apply.)
   a. Bradycardia
   b. Hypotension
   c. Ankle edema
   d. Decreased respirations
   e. Increased respirations
7. The nurse is administering atenolol to a patient. Which concurrent drugs does the nurse expect to most likely cause an interaction? (Select all that apply.)
   a. Ginseng supplement
   b. A nonsteroidal antiinflammatory drug, such as aspirin
   c. Atropine, an anticholinergic
   d. Haloperidol
   e. Methyldopa

Answers: 1, a, b, d; 2, c; 3, c; 4, d; 5, b, c, d; 6, a, b; 7, b, c.

- Antiparkinson-Anticholinergic Drugs
- Nursing Process: Patient-Centered Collaborative Care—Anticholinergic Drugs: Atropine
- Anticholinergics for Treating Motion Sickness

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Compare the responses of cholinergic agonist and antagonist drugs.
- Differentiate between direct-acting and indirect-acting cholinergic agonists.
- Contrast the major side effects of cholinergic agonists and antagonists.
- Differentiate the uses of cholinergic agonists and antagonists.
- Apply the nursing process, including patient teaching, associated with cholinergic agonists and antagonists.
- Apply the nursing process for the patient taking neostigmine, a reversible cholinesterase inhibitor.

The two groups of drugs that affect the parasympathetic nervous system are the **cholinergic agonists**—muscarinic agonists or **parasympathomimetics**—and the **cholinergic antagonists (blocking agents)**—muscarinic antagonists, **parasympatholytics**, or more commonly called **anticholinergics**. The Unit IV opener offers a discussion and comparison of the *parasympathetic* nervous system (parasympathomimetics and parasympatholytics) and the *sympathetic* nervous system.

Cholinergic Agonists

Drugs that stimulate the parasympathetic nervous system are called *cholinergic agonists,* or *parasympathomimetics,* because they mimic the parasympathetic neurotransmitter acetylcholine. The neurotransmitter located at the ganglions and the parasympathetic terminal nerve endings is **acetylcholine (ACh)**. It innervates cholinergic receptors in organs, tissues, and glands. The two types of cholinergic receptors are **muscarinic receptors**, which stimulate smooth muscle and slow the heart rate, and **nicotinic receptors** (neuromuscular), which affect the skeletal muscles. Many cholinergic agonists are nonselective because they can affect both the muscarinic and the nicotinic receptors. However, there are selective cholinergic agonists for the muscarinic receptors that do *not* affect the nicotinic receptors. Fig. 16.1 illustrates the effects of parasympathetic, or cholinergic, stimulation.

There are two types of cholinergic agonists: **direct-acting cholinergic agonists** act on receptors to activate a tissue response (Fig. 16.2A), and **indirect-acting cholinergic agonists** inhibit the action of the enzyme **cholinesterase (ChE)**, also called **acetylcholinesterase (AChE),** by forming a chemical complex that allows acetylcholine to persist and attach to the receptor (Fig. 16.2B). Drugs that inhibit ChE are called *cholinesterase inhibitors, acetylcholinesterase inhibitors,* or *anticholinesterases.* ChE may destroy acetylcholine before it reaches the receptor or after it has attached to the site. By inhibiting or destroying the ChE, more acetylcholine is available to stimulate the receptor and to remain in contact with it longer.

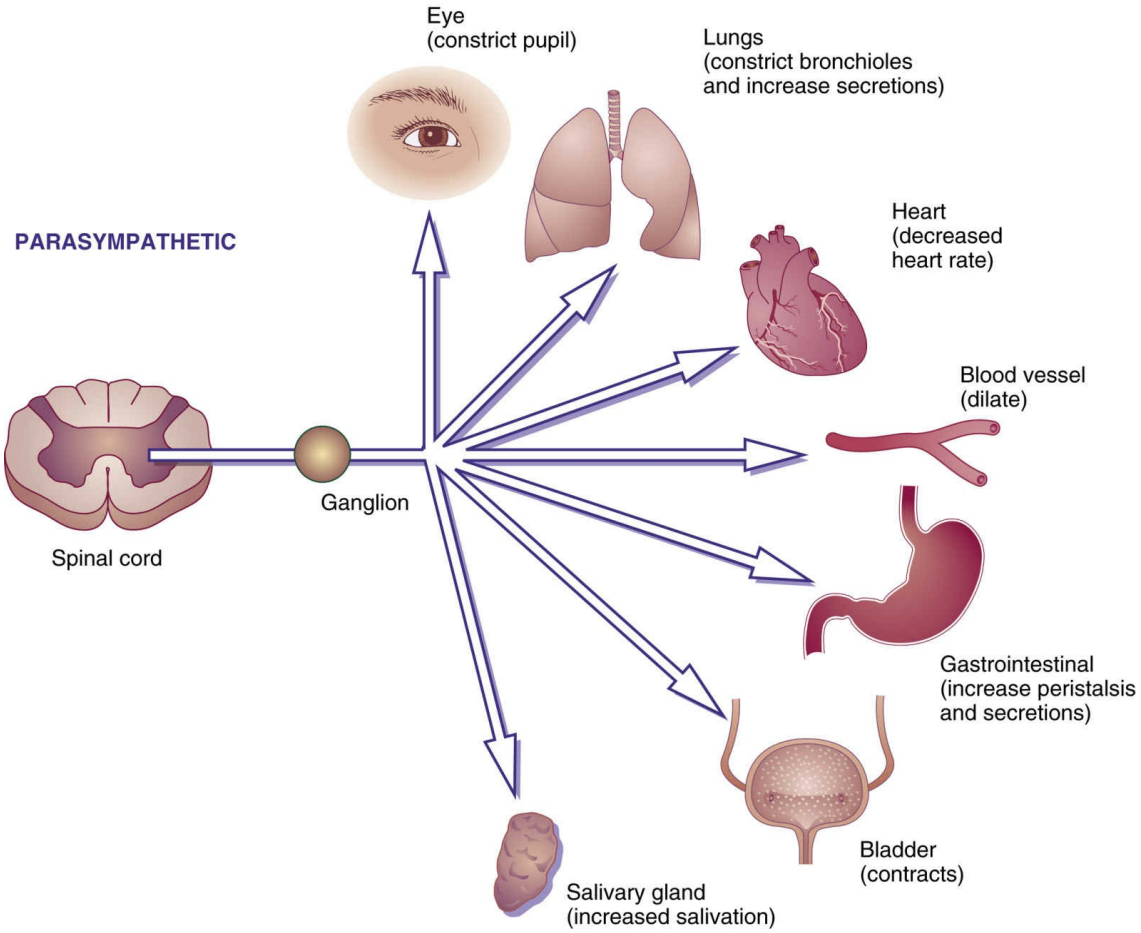

FIG. 16.1 Parasympathetic responses. Stimulation of the parasympathetic nervous system or use of parasympathomimetic drugs will cause the pupils to constrict, bronchioles to constrict and bronchial secretions to increase, heart rate to decrease, blood vessels to dilate, peristalsis and gastric secretions to increase, the bladder muscle to contract, and salivary glands to increase salivation.

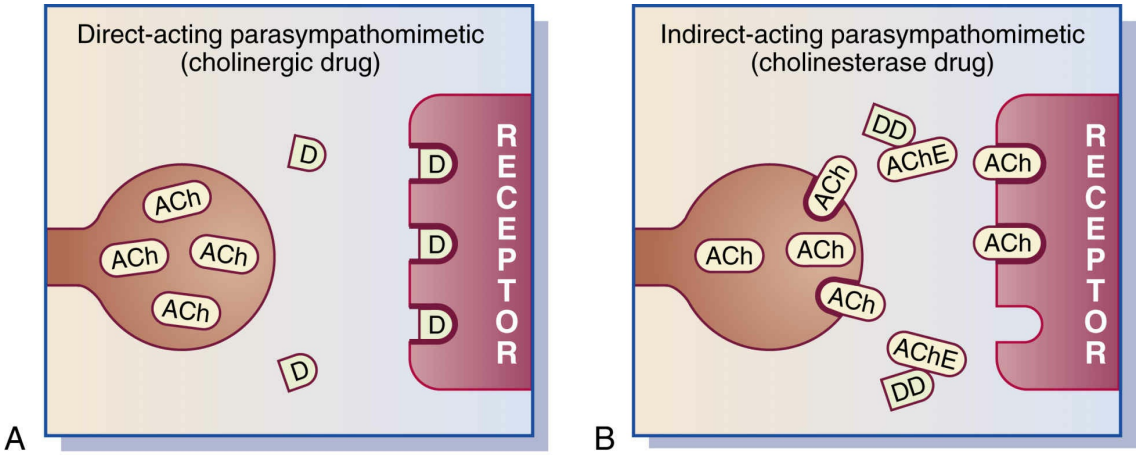

FIG. 16.2 A, Direct-acting parasympathomimetic (cholinergic agonist). Cholinergic agonists resemble acetylcholine and act directly on the receptor. B, Indirect-acting parasympathomimetic (cholinesterase inhibitor). Cholinesterase inhibitors inactivate the enzyme acetylcholinesterase (cholinesterase), thus permitting acetylcholine to react to the receptor. *ACh,* Acetylcholine; *AChE,* acetylcholinesterase or cholinesterase; *D,* cholinergic agonist; *DD,* cholinesterase inhibitor (anticholinesterase).

Cholinesterase inhibitors can be separated into reversible and irreversible inhibitors. The *reversible inhibitors* bind the ChE for several minutes to hours, and the *irreversible inhibitors* bind the

enzyme permanently. The resulting effects vary with how long the ChE is bound.

The major responses of cholinergic agonists are to stimulate bladder and gastrointestinal (GI) tone, constrict the pupils of the eyes, known as **miosis**, and increase neuromuscular transmission. Other effects of cholinergic agonists include decreased heart rate and blood pressure and increased salivary, GI, and bronchial glandular secretions. Table 16.1 lists the functions of direct- and indirect-acting cholinergic agonists.

TABLE 16.1

Effects of Cholinergic Agonists

Body Tissue	Response
Cardiovascular[a]	Decreased heart rate, lowered blood pressure because of vasodilation, and slowed conduction of atrioventricular node
Gastrointestinal[b]	Increased tone and motility of smooth muscle of stomach and intestine, increased peristalsis, and relaxed sphincter muscles
Genitourinary	Contraction of muscles of the urinary bladder, increased tone of ureters, relaxed bladder sphincter muscles, and stimulated urination
Ocular[b]	Increased pupillary constriction or miosis (pupil becomes smaller) and increased accommodation (flattening or thickening of eye lens for distant or near vision)
Glandular[a]	Increased salivation, perspiration, and tears
Bronchial (lung)[a]	Stimulation of bronchial smooth muscle contraction and increased bronchial secretions
Striated muscle[b]	Increased neuromuscular transmission and maintenance of muscle strength and tone

[a] Tissue responses to large doses of cholinergic agonists.

[b] Major tissue responses to normal doses of cholinergic agonists.

Direct-Acting Cholinergic Agonists

Many drugs classified as direct-acting cholinergic agonists are primarily selective to the muscarinic receptors but are nonspecific because the muscarinic receptors are located in the smooth muscle of the GI and genitourinary tracts, glands, and heart. Bethanechol chloride, a direct-acting cholinergic agonist, acts on the muscarinic (cholinergic) receptor and is used primarily to increase urination in the treatment of urinary retention and neurogenic bladder. Metoclopramide hydrochloride (HCl) is a direct-acting cholinergic agonist that is usually prescribed to treat gastroparesis, nausea, and gastroesophageal reflux disease (GERD). In low doses, metoclopramide enhances gastric motility and thus accelerates gastric emptying time. Prototype Drug Chart 16.1 details the pharmacologic behavior of bethanechol, a classic cholinergic agonist.

Pharmacokinetics

Bethanechol chloride is poorly absorbed from the GI tract. The percentage of protein binding and the half-life are unknown. The drug is most likely excreted in the urine.

Pharmacodynamics

The principal use of bethanechol is to promote urination by stimulating the muscarinic cholinergic receptors in the detrusor muscle to contract the bladder and produce urine output. Because of the increased tone of the detrusor muscle, the onset of action is 30 to 90 minutes after taking an oral dose of bethanechol, and the duration is 2 hours. Bethanechol also increases peristalsis in the GI tract, and the drug should be taken on an empty stomach 1 to 2 hours before meals to minimize nausea and vomiting.

Side Effects and Adverse Reactions

Mild to severe side effects of most muscarinic agonists, such as bethanechol, include hypotension, tachycardia, blurred vision, excessive salivation, increased gastric acid secretion, abdominal cramps, diarrhea, bronchoconstriction, and, in some cases, cardiac dysrhythmias. This group of agents should be prescribed cautiously for patients with low blood pressure and low heart rates. Muscarinic agonists are contraindicated for patients with intestinal or urinary tract obstruction, severe bradycardia, or active asthma.

PROTOTYPE DRUG CHART 16.1 Bethanechol Chloride

Drug Class	Dosage
Cholinergic: Parasympathomimetic Pregnancy category: C*	Urinary retention A: PO: Initially 5-10 mg tid/qid; maint: 10-50 mg tid/qid; *max:* 200 mg/d A: Subcut: 5 mg tid/qid; *max:* 40 mg/d
Contraindications	Drug-Lab-Food Interactions
Contraindicated: Intestinal or urinary tract obstruction, IBS, bradycardia, hypotension, COPD, asthma, peptic ulcer, hyperthyroidism, seizures, parkinsonism	Drug: Decreases bethanechol effect with antidysrhythmics (e.g., procainamide); ganglionic blocking agents (e.g., mecamylamine) cause significant hypotension following severe abdominal symptoms. False test results (amylase, lipase) may result. Atropine, flavoxate, and opiates counteract bethanechol action. Lab: Increases AST, bilirubin, amylase, lipase
Pharmacokinetics	Pharmacodynamics
Absorption: Poorly absorbed PO Distribution: PB: UK Metabolism: t½: UK Excretion: In urine	PO: Onset: 0.5-1.5 h Peak: 1-2 h Duration: 2 h Subcut: Onset: 5-15 min Peak: 15-30 min Duration: 2 h
Therapeutic Effects/Uses	
To treat urinary retention and neurogenic bladder	
Mode of Action: Stimulates the cholinergic (muscarinic) receptors; promotes contraction of the bladder; increases GI secretions and peristalsis, pupillary constriction, and bronchoconstriction	
Side Effects	Adverse Reactions
Nausea, vomiting, diarrhea, abdominal cramps, hypersalivation, sweating, headache, dizziness, flushing, urinary urgency and frequency	Tachycardia weakness *Life threatening:* Bronchospasm

A, Adult; *AST,* aspartate aminotransferase; *COPD,* chronic obstructive pulmonary disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *IBS,* irritable bowel syndrome; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q3-4d,* every 3 to 4 days; *qid,* four times a day; *subcut,* subcutaneous; *t½,* half-life; *tid,* three times a day; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Direct-Acting Cholinergic Agonists: Eye

Pilocarpine is a direct-acting cholinergic agonist that constricts the pupils of the eyes, thus opening the Schlemm canal to promote drainage of aqueous humor (fluid). This drug is used to treat glaucoma by relieving (intraocular) fluid pressure in the eye and to promote miosis in eye surgery and examinations. Pilocarpine also acts on the nicotinic receptor, as does carbachol. Both agents are discussed in more detail in Chapter 44. An oral form of pilocarpine is used to relieve xerostomia (dry mouth).

Indirect-Acting Cholinergic Agonists

The indirect-acting cholinergic agonists do not act on receptors; instead, they inhibit or inactivate the enzyme cholinesterase, permitting acetylcholine to accumulate at the receptor sites (see Fig. 16.2B). This action gives them the name *cholinesterase (ChE) inhibitors, acetylcholinesterase (AChE) inhibitors,* or *anticholinesterases,* of which there are two types: reversible and irreversible.

Nursing Process: Patient-Centered Collaborative Care

Cholinergic Agonist, Direct Acting: Bethanechol

Assessment

- Assess baseline vital signs for future comparisons.
- Assess urine output (should be >1500 mL/day).
- Obtain patient history of health problems such as peptic ulcer, urinary obstruction, or asthma. Cholinergic agonists can aggravate symptoms of these conditions.

Nursing Diagnoses

- Urinary Retention related to surgical anesthesia administration
- Anxiety related to wheezing
- Skin Integrity, Risk for Impaired
- Breathing Pattern, Ineffective related to excess mucous secretions in lungs

Planning

- Patient will have increased bladder tone after taking cholinergic agonists.

Nursing Interventions

- Monitor vital signs. Heart rate and blood pressure decrease when large doses of cholinergics are taken. Orthostatic hypotension is a side effect of cholinergic agonists, such as bethanechol.
- Record fluid intake and output. Decreased urinary output should be reported because it may be

related to urinary obstruction.
- Give cholinergic agonists 1 hour before or 2 hours after meals to minimize nausea and vomiting. If a patient complains of gastric pain, the drug may be given with meals.
- Check serum amylase, lipase, aspartate aminotransferase (AST), and bilirubin levels. These laboratory values may increase slightly in a patient taking cholinergic agonists.
- Observe the patient for side effects such as gastric pain or cramping, diarrhea, increased salivary or bronchial secretions, tachycardia, and orthostatic hypotension.
- Auscultate breath sounds for rales, crackling sounds from fluid congestion in the lungs, or rhonchi, rough sounds resulting from mucous secretions in the lungs. Cholinergic agonists can increase bronchial secretions.
- Have intravenous (IV) atropine sulfate (0.6 mg to 1.2 mg) available as an antidote for cholinergic overdose. Early signs of overdosing include flushing, salivation, sweating, nausea, and abdominal cramps.
- Increase bathing frequency and linen change when needed. Diaphoresis (excessive perspiration) may occur.
- Monitor for possible cholinergic crisis (overdose), including symptoms of muscular weakness and increased salivation.

Patient Teaching

- Teach patients to take the cholinergic agonist as prescribed. Compliance with the drug regimen is essential.
- Direct patients to report severe side effects, such as profound dizziness or a decrease in heart rate below 60 beats/minute.
- Teach patients to arise from a lying position slowly to avoid dizziness. This is most likely a result of orthostatic hypotension.
- Encourage patients to maintain effective oral hygiene if excess salivation occurs.
- Advise patients to report any difficulty in breathing as a result of respiratory distress.

Cultural Considerations

- Use both hands to show respect when offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders.
- Recognize the importance of including women in decision making and disseminating health information. The extended family structure is important for teaching health strategies and providing support.

Evaluation

- Determine the effectiveness of the cholinergic agonist or anticholinesterase drug.
- Evaluate the stability of patient vital signs, and note the presence of side effects or adverse reactions.

The function of the enzyme cholinesterase is to break down acetylcholine into choline and acetic acid. A small amount of cholinesterase can break down a large amount of acetylcholine in a short period. A cholinesterase inhibitor drug binds with cholinesterase, allowing acetylcholine to activate the muscarinic and nicotinic cholinergic receptors. This action permits skeletal muscle stimulation, which increases the force of muscular contraction. Because of this action, cholinesterase inhibitors are useful to increase muscle tone for patients with myasthenia gravis (a neuromuscular disorder). By increasing acetylcholine, additional effects occur, such as increases in GI motility, bradycardia, miosis, bronchial constriction, and increased micturition.

The primary use of *reversible* cholinesterase inhibitors is to treat myasthenia gravis; another use is to treat Alzheimer disease. The primary clinical indication for *irreversible* cholinesterase inhibitors is glaucoma.

Reversible Cholinesterase Inhibitors

Reversible cholinesterase inhibitors are used to produce pupillary constriction in the treatment of glaucoma and to increase muscle strength in patients with myasthenia gravis. Drug effects persist for several hours. Drugs used to increase muscular strength in myasthenia gravis include neostigmine (short acting), pyridostigmine bromide (moderate acting), ambenonium chloride (long acting), and edrophonium chloride (short acting, for diagnostic purposes). These drugs are

discussed in more detail in Chapter 21. A reversible anticholinesterase drug is physostigmine, which is used as an antidote for atropine to reverse anticholinergic toxicity. Ophthalmic agents are further discussed in Chapter 44.

Side Effects

Common side effects from reversible cholinesterase inhibitors are hypotension, bradycardia, sweating, hypersalivation, and GI distress, which includes anorexia, nausea, vomiting, abdominal pain, and diarrhea. Caution for reversible cholinesterase inhibitors is required for patients who have bradycardia, asthma, peptic ulcers, or hyperthyroidism. Cholinesterase inhibitors are contraindicated for patients with intestinal or urinary obstruction.

Irreversible Cholinesterase Inhibitors

Irreversible cholinesterase inhibitors are potent agents because of their long-lasting effects. The enzyme cholinesterase must be regenerated before the drug effect diminishes, a process that may take days or weeks. These drugs are used to produce pupillary constriction.

Table 16.2 lists examples of cholinergic drugs and their standard dosages and common uses.

Cholinergic Antagonists

Drugs that inhibit the actions of acetylcholine by occupying the acetylcholine receptors are called *cholinergic antagonists (blocking agents), muscarinic antagonists, anticholinergics, cholinergic blocking agents, antispasmodics,* or *parasympatholytics.* The major body tissues and organs affected by the anticholinergic group of drugs are the heart, respiratory tract, GI tract, urinary bladder, eyes, and exocrine glands. By blocking the parasympathetic nerves, the sympathetic (adrenergic) nervous system dominates. Anticholinergics and adrenergic agonists produce many of the same responses.

TABLE 16.2

Cholinergic Agonists

Drug	Route and Dosage	Uses and Considerations
Direct-Acting Cholinergic Agonists		
Bethanechol chloride	See Prototype Drug Chart 16.1.	
Metoclopramide hydrochloride	Postoperative nausea/vomiting: A: IM/IV: 10 mg q4-6h; *max*: 20 mg single dose	For GERD, gastroparesis, nausea and vomiting; increases gastric emptying time. May cause drowsiness, fatigue, restlessness, headache, EPS, and NMS. Pregnancy category: B*; PB: 30%; t½: 2.5-6 h
Carbachol	Ophthalmic: 0.75%-3%, 1-2 gtt, 3 daily	To treat IOP, glaucoma, miosis; see Chapter 44.
Pilocarpine hydrochloride	Ophthalmic: 0.5%-4%, 1 gt	To treat IOP, glaucoma, miosis; see Chapter 44.
Cholinesterase Inhibitor		
Donepezil hydrochloride	See Chapter 20, Table 20.5.	To treat Alzheimer disease. See Chapter 20.
Rivastigmine	See Chapter 20, Table 20.5.	To treat Alzheimer disease. See Chapter 20.
Indirect-Acting Cholinergics or Cholinesterase Inhibitors for the Eye		
Echothiophate iodide	0.03%-0.25%, 1 gt daily or bid	To treat glaucoma; see Chapter 44.
Reversible Cholinesterase Inhibitors: Myasthenia Gravis		
Ambenonium chloride	A: PO: Initially 5 mg tid/qid; dose may be increased q48h; maint: 15-100 mg/d in divided doses; *max*: 200 mg/d	To treat myasthenia gravis; long acting. May cause hypersalivation, sweating, diarrhea, blurred vision, urinary frequency, and nausea. Pregnancy category: C*; PB: UK; t½: UK
Edrophonium chloride	Myasthenia gravis: A: IV: 2 mg over 15-30 seconds, then 8 mg if no response in 45 seconds A: IM: 10 mg; may repeat with 2 mg in 30 min	To diagnose myasthenia gravis and treat neuromuscular blockade reversal. Monitor pulse, respiratory rate, BP, neurologic status, and ECG frequently during administration. May cause GI distress, hypersalivation, diplopia, dysphonia, dysarthria, sweating, bradycardia, hypotension, and seizures. Pregnancy category: C*; PB: UK; t½: 67-185 min
Neostigmine methylsulfate	Myasthenia gravis: A: PO: 15 mg tid; increase gradually; maint: 15-375 mg/d; *max:* 375 mg/d A: Subcut/IM: 0.5 mg q4-6h PRN; *max:* 0.5 mg/dose 0.04 mg/kg q2-4h	To treat myasthenia gravis, urinary retention, and ileus and for neuromuscular blockade reversal. May cause dizziness, headache, nausea, vomiting, bradycardia, hypotension, tachycardia, muscle cramps, and dyspnea. Pregnancy category: C*; PB: 15%-25%; t½: 42-60 min
Physostigmine salicylate	A: IV/IM: 0.5-2 mg/dose, repeat q10-30min PRN C: IV/IM: 0.02 mg/kg/dose, repeat q5-10min PRN; *max:* 2 mg total	To treat anticholinergic syndrome, glaucoma. Contraindicated in asthma because it can worsen bronchoconstriction. May cause sweating, hypersalivation, GI distress, bradycardia, hypotension, seizures, confusion, muscle weakness, and bronchospasm. Pregnancy category: C*; PB: UK; t½: UK
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Pyridostigmine bromide	Myasthenia gravis: Regular release: A: PO: 60-120 mg tid/qid; maint: 60-1500 mg/d in 3-4 divided doses C: PO: 1 mg/kg q4-6h; *max*: 1 mg/kg/dose Sustained release: A: PO: 180-540 mg daily or bid A: IM/IV: 2 mg q2-3h	To treat myasthenia gravis and neuromuscular blockade reversal and for nerve gas exposure prophylaxis. May cause nausea, vomiting, abdominal cramps, bradycardia, blurred vision, headache, bronchospasm, sweating, hypersalivation, and increased urinary frequency. Pregnancy category: C*; PB: 10%; t½: oral 3 h, IV 1.5 h
Antidote for Irreversible and Reversible Cholinesterase Inhibitors		
Pralidoxime chloride	Cholinesterase inhibitor toxicity: A: IV: 1-2 g in 100 mL of saline solution infused over 15-30 min; follow with 250 mg q5min PRN	To treat cholinesterase inhibitor toxicity and organophosphate pesticide toxicity. May cause dizziness, blurred vision, headache, drowsiness, tachycardia, hypertonia, and dry mouth. Pregnancy category: C*; PB: UK; t½: 74-77 min

A, Adult; *bid,* two times a day; *BP,* blood pressure; *C,* child; *d,* day; *ECG,* electrocardiogram; *EPS,* extrapyramidal syndrome symptoms; *GERD,* gastroesophageal reflux disease; *GI,* gastrointestinal; *gt,* drop; *gtt,* drops; *h,* hour; *IM,* intramuscular; *IOP,* intraocular pressure; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q4-6h,* every 4 to 6 hours; *qid,* four times a day; *subcut,* subcutaneous; *t½,* half-life; *tid,* three times a day; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Anticholinergic and cholinergic agonists have opposite effects. The major responses to anticholinergics are a decrease in GI motility, a decrease in salivation, dilation of pupils—also called **mydriasis**—and an increase in pulse rate. Other effects of anticholinergics include decreased bladder contraction, which can result in urinary retention, and decreased rigidity and tremors related to neuromuscular excitement. An anticholinergic can act as an antidote to the toxicity caused by cholinesterase inhibitors and organophosphate ingestion. The various effects of anticholinergics are described in Table 16.3.

Muscarinic receptors are a type of cholinergic receptor involved in tissue and organ responses to

anticholinergics because anticholinergics inhibit the actions of acetylcholine by occupying these receptor sites. Fig. 16.3 illustrates this action of anticholinergic drugs; these drugs may also block the effect of direct-acting parasympathomimetics, such as bethanechol and pilocarpine, and of indirect-acting parasympathomimetics, such as physostigmine and neostigmine.

Atropine

Atropine sulfate, first derived from the belladonna plant *(Atropa belladonna)* and purified in 1831, is a classic anticholinergic—or muscarinic antagonist—drug. Scopolamine was the second belladonna alkaloid produced. Atropine and scopolamine act on muscarinic receptors, but they have little effect on nicotinic receptors except in high doses. Atropine is useful primarily as a preoperative medication to decrease salivary secretions and as an agent to increase heart rate when bradycardia is present. Atropine can also be used as an antidote for muscarinic agonist poisoning caused by an overdose of a cholinesterase inhibitor or a muscarinic drug such as bethanechol. However, if a patient takes atropine or an atropine-like drug (e.g., an antihistamine), side effects can occur. Prototype Drug Chart 16.2 details the pharmacologic behavior of atropine.

TABLE 16.3

Effects of Anticholinergic Drugs

Body Tissues	Responses
Cardiovascular	Heart rate increases with large doses; small doses can decrease heart rate.
Gastrointestinal (GI)	Relaxed smooth muscle tone of GI tract, decreased GI motility and peristalsis; gastric and intestinal secretions are decreased.
Urinary tract	Relaxed bladder detrusor muscle and increased constriction of internal sphincter; urinary retention can result.
Ocular	Dilated pupils (mydriasis) and paralyzed ciliary muscles (cycloplegia) cause a decrease in accommodation.
Glandular	Salivation, perspiration, and bronchial secretions are decreased.
Bronchial	Bronchi are dilated, and bronchial secretions decrease.
Central nervous system	Tremors and rigidity of muscles are decreased; drowsiness, disorientation, and hallucinations can result from large doses.

Synthetic anticholinergic drugs are also used as antispasmodics to treat peptic ulcers and intestinal spasticity. One example is propantheline bromide, which has been available for several decades. It decreases gastric secretions and GI spasms in duodenal ulcers. Since the introduction of the histamine (H_2) blockers, anticholinergic agents such as propantheline are rarely used to decrease gastric secretions.

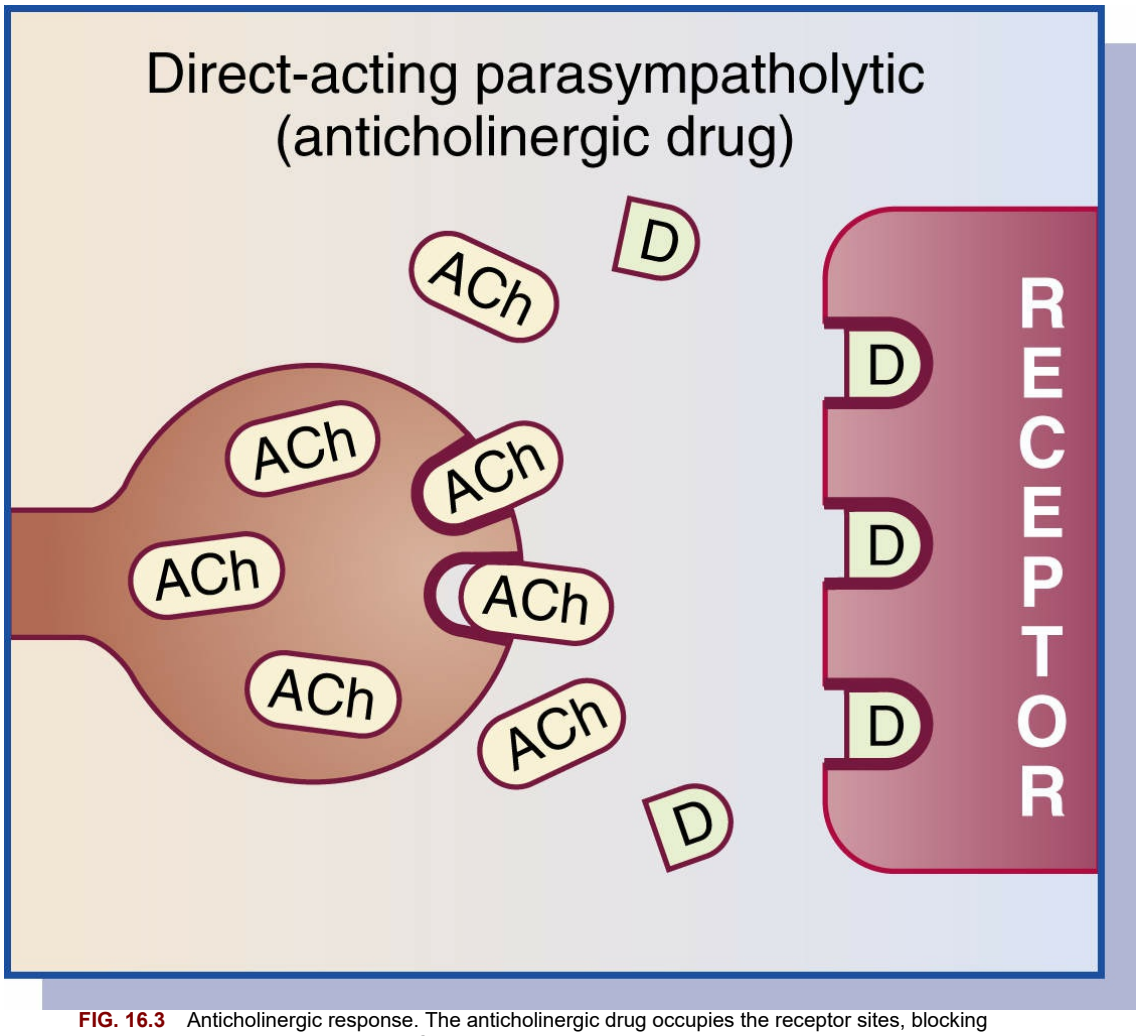

FIG. 16.3 Anticholinergic response. The anticholinergic drug occupies the receptor sites, blocking acetylcholine. *ACh,* Acetylcholine; *D,* anticholinergic drug.

Pharmacokinetics

Atropine sulfate is well absorbed orally and parenterally. It crosses the blood-brain barrier and exerts its effect on the central nervous system (CNS). The protein binding is unknown. It crosses the placenta. Atropine has a short half-life of 2 to 3 hours, so there is little cumulative effect. Most of the absorbed atropine is excreted in the urine (75% to 95%).

Pharmacodynamics

Atropine sulfate blocks acetylcholine by occupying the muscarinic receptor. It increases the heart rate by blocking vagus stimulation and promotes dilation of the pupils by paralyzing the iris sphincter. The two most frequent uses of atropine are to decrease salivation and respiratory secretions preoperatively and to treat sinus bradycardia by increasing the heart rate. Atropine also is used ophthalmically for mydriasis and cycloplegia before eye exams and to treat inflammation of the iris (iritis) and uveal tract.

Its onset of action for the intramuscular (IM) route is 10 to 30 minutes, and it peaks at 30 minutes. The duration is 4 hours. The onset of action for the IV route is immediate, and peak action occurs in 5 minutes.

Side Effects and Adverse Reactions

The common side effects of atropine and atropine-like drugs include dry mouth, decreased perspiration, blurred vision, tachycardia, constipation, and urinary retention. Other side effects and adverse reactions are nausea, headache, dry skin, abdominal distension, hypotension or hypertension, impotence, photophobia (intolerance of bright light), and coma.

Antiparkinson-Anticholinergic Drugs

Studies indicate that anticholinergics affect the CNS as well as the parasympathetic nervous system. Anticholinergics affect the CNS by suppressing the tremors and muscular rigidity of parkinsonism, but they have little effect on mobility and muscle weakness. As a result of these findings, several anticholinergic drugs were developed for the treatment of parkinsonism (e.g., trihexyphenidyl hydrochloride, biperiden, and benztropine). These drugs can be used alone in the early stages of parkinsonism; they may be used in combination with levodopa/carbidopa to control parkinsonism, or they can be used alone to treat pseudoparkinsonism, which results from the side effects of the phenothiazines in antipsychotic drugs. Drugs used to treat parkinsonism are described in more detail in Chapter 20. Prototype Drug Chart 16.3 lists the drug data related to benztropine, which is used for parkinsonism.

PROTOTYPE DRUG CHART 16.2 Atropine

Drug Class	Dosage
Anticholinergic: Parasympatholytic Pregnancy category: C*	Bradycardia: A: IV: 0.5-1 mg, repeat q5min PRN up to 2 mg
	C: IV: 0.01-0.03 mg/kg/dose; *max:* 0.4 mg/dose Aspiration prophylaxis: A: PO: 2 mg 30-60 min prior to induction A/C >20 kg: subcut/IV/IM: 0.2-1 mg 30-60 min before anesthesia
Contraindications	**Drug-Lab-Food Interactions**
Narrow-angle glaucoma, obstructive GI disorders, paralytic ileus, ulcerative colitis, tachycardia, BPH, myasthenia gravis, myocardial ischemia, hypersensitivity	Drug: Increases anticholinergic effect with phenothiazines, antihistamines, TCAs, amantadine, quinidine; high-dose anticholinergics may decrease effects of carbidopa/levodopa by delaying GI absorption; anticholinergics may enhance therapeutic effects at therapeutic doses.
Caution: Renal or hepatic disorders, COPD, heart failure	
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO/IM: Well absorbed Distribution: PB: UK; crosses the placenta Metabolism: t½: 2-3 h Excretion: 75% Excreted in urine	IM: Onset: 10-30 min Peak: 0.5 h Duration: 4 h IV: Onset: Immediate Peak: 5 min Duration: UK
Therapeutic Effects/Uses	
Preoperative medication to reduce salivation, increase heart rate for bradycardia, and dilate pupils for ocular diagnostic exams	
Mode of Action: Inhibits acetylcholine by occupying the receptors; increases heart rate by blocking vagus stimulation; promotes pupil dilation by blocking iris sphincter muscle	
Side Effects	**Adverse Reactions**
Dry mouth, nausea, headache, amnesia, constipation, dry skin, flushing, mydriasis, blurred vision, anxiety, photophobia, palpitations, urinary retention, hyperreflexia, ataxia	Tachycardia, paradoxic bradycardia, hypertension, hypotension, angina, pulmonary edema, seizures *Life threatening:* Dysrhythmias, laryngospasm, Stevens-Johnson syndrome (rare), coma

A, Adult; *BPH,* benign prostatic hyperplasia; *C,* child; *COPD,* chronic obstructive pulmonary disease; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q5min,* every 5 minutes; *subcut,* subcutaneous; *t½,* half-life; *TCA,* tricyclic antidepressant; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Anticholinergic Drugs: Atropine

Assessment

- Obtain baseline vital signs for future comparisons. Tachycardia is a side effect that occurs with large doses of anticholinergics such as atropine sulfate.
- Assess urine output. Urinary retention may occur.
- Check the patient's medical history. Atropine and atropine-like drugs are contraindicated in patients with narrow-angle glaucoma, obstructive GI disorders, paralytic ileus, ulcerative colitis, benign prostatic hypertrophy, or myasthenia gravis.
- Obtain the patient's drug history. Phenothiazines and antidepressants increase the effect of anticholinergics.

Nursing Diagnoses

- Urinary Retention related to atropine administration
- Oral Mucous Membrane, Impaired related to decreased oral secretions
- Injury, Risk for
- Constipation, Risk for

Planning

- Patient secretions will be decreased before surgery.
- Patient will not have side effects that may become a health problem.

Nursing Interventions

- Monitor patient vital signs. Report if tachycardia occurs.
- Determine fluid intake and output. Encourage patients to void before taking the medication, and report decreased urine output; anticholinergics can cause urinary retention. Maintain adequate fluid intake.
- Assess bowel sounds. Absence of bowel sounds may indicate paralytic ileus resulting from a decrease in GI motility (peristalsis).
- Examine for constipation caused by a decrease in GI motility. Encourage ingestion of foods that are high in fiber, intake of adequate amounts of fluids, and exercise if possible.
- Use bed alarms for patients who are confused and debilitated. Atropine could cause CNS stimulation (excitement, confusion) or drowsiness.
- Provide mouth care. Atropine decreases oral secretions and can cause dryness.
- Administer IV atropine undiluted or diluted in 10 mL of sterile water. Rate of administration is 1 mg or some fraction thereof per minute.

Patient Teaching

General

- Direct patients to avoid hot environments and excessive physical exertion. Elevations in body temperature can result from diminished sweat gland activity.
- Teach patients with narrow-angle glaucoma to avoid atropine-like drugs. Anticholinergics cause mydriasis and increase intraocular pressure (IOP). Instruct patients to check labels on over-the-counter (OTC) drugs to determine whether they are contraindicated for glaucoma.
- Instruct patients not to drive a motor vehicle or participate in activities that require alertness. Drowsiness is common.
- Tell patients with mydriasis following an eye examination to use sunglasses in bright light because of photophobia.

Side Effects

- Advise patients of common side effects such as dry mouth, decreased urination, and constipation that can occur as a result of anticholinergic use.
- Direct patients to increase fluid intake and consumption of high-fiber foods to prevent constipation when taking anticholinergics for a prolonged period.
- Instruct patients to urinate before taking the anticholinergic because urinary retention can be a problem.
- Advise patients to report any marked decrease in urine output.
- Suggest that patients use hard candy, ice chips, or chewing gum. Maintain effective oral hygiene if a patient's mouth is dry. Anticholinergics decrease salivation.
- Encourage patients to use eye drops to moisten dry eyes that result from decreased lacrimation (tearing).

Cultural Considerations

- Obtain an interpreter when necessary. Do not rely on family members, who may not fully disclose because of honor, guilt, or lack of understanding of medical terminology.
- Ask open-ended questions; have patients demonstrate, rather than verbalize, their understanding of treatments. Because politeness may prevail, do not assume that a positive response means a definite yes.

Evaluation

- Evaluate patient response to the anticholinergic.
- Determine whether constipation, urinary retention, or increased pulse rate is a problem.

Pharmacokinetics

Benztropine is well absorbed from the GI tract. Its protein-binding percentage and half-life are unknown. It is excreted in the urine.

Pharmacodynamics

Benztropine decreases involuntary movement and diminishes the signs and symptoms of tremors and muscle rigidity that occur with parkinsonism and pseudoparkinsonism. It is available as an oral tablet and as parenteral IM and IV injections. Alcohol and other CNS depressants potentiate sedation. Anticholinergics, phenothiazines, and tricyclic antidepressants (TCAs) may increase the anticholinergic effects of benztropine. The side effects are similar to those of other anticholinergic drugs.

Anticholinergics for Treating Motion Sickness

The effects of anticholinergics on the CNS benefit patients who are prone to motion sickness. An example of such an anticholinergic, classified as an antihistamine for motion sickness, is scopolamine. It is available topically as a skin patch placed behind the ear. Prevention of motion sickness is also provided via wristbands and ginger, including ginger gum or candy. Transdermal scopolamine is delivered over 3 days and is frequently prescribed for activities such as flying, cruising on the water, and bus or automobile trips. Other drugs classified as antihistamines for motion sickness are dimenhydrinate, cyclizine, and meclizine hydrochloride. Most of these drugs can be purchased over the counter with the exception of scopolamine.

PROTOTYPE DRUG CHART 16.3 Benztropine

Drug Class	Dosage
Antiparkinson: anticholinergic agent Pregnancy category: C*	Antiparkinsonism: A: PO/IM: 0.5-6 mg/d at bedtime; *max:* 8 mg/d
	Extrapyramidal symptoms except tardive dyskinesia (drug induced)
	A: PO/IM/IV: 1-4 mg qd/bid; *max:* 8 mg/d
Contraindications	Drug-Lab-Food Interactions
Closed-angle glaucoma, tardive dyskinesia, dementia, myasthenia gravis; contraindicated for children *Caution:* Tachycardia, cardiac disease, autonomic neuropathy, prostatic hypertrophy, psychosis	Drug: Increases anticholinergic effect with phenothiazines, tricyclic antidepressants, and other anticholinergics
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Well absorbed	PO: Onset: 1 h
Distribution: PB: UK	Peak: 7 h
Metabolism: t½: UK	Duration: 6-10 h
Excretion: In urine	
Therapeutic Effects/Uses	
To decrease involuntary symptoms of parkinsonism or drug-induced parkinsonism	
Mode of Action: Blocks cholinergic (muscarinic) receptors, thus decreasing acetylcholine to reduce excess cholinergic activity (involuntary movements); also blocks dopamine reuptake to prolong dopamine effects and decrease involuntary movement	
Side Effects	Adverse Reactions
Nausea, vomiting, dry mouth, constipation, anhidrosis, dizziness, headache, drowsiness, blurred vision, confusion, depression, hallucinations, hypohidrosis, weakness, hyperthermia, and paresthesia	Tachycardia, urinary retention, ocular hypertension *Life threatening:* Ileus

A, Adult; *bid,* two times a day; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *qd,* once daily; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Examples of anticholinergic drugs and their dosages and common uses are found in Table 16.4. Dosages may vary according to age, sex, and weight. Because anticholinergic drugs can increase intraocular pressure, they should not be administered to patients diagnosed with glaucoma.

Side Effects and Adverse Reactions

Side effects of antihistamines used as anticholinergics include dry mouth, visual disturbances (especially blurred vision resulting from pupillary dilation), constipation secondary to decreased GI peristalsis, urinary retention related to decreased bladder tone, tachycardia (when taken in large doses), hypotension, skin rash, muscle weakness, and flushing.

TABLE 16.4
Anticholinergics

Drug	Route and Dosage	Uses and Considerations
Anticholinergics: Gastrointestinal or Cholinergic Blockers		
Atropine sulfate	See Prototype Drug Chart 16.2.	
Dicyclomine hydrochloride	A: PO: Initially 20 mg qid; *maint:* 20-40 mg qid for 2 wks; *max:* 160 mg/d A: IM: 20 mg q4-6h for 1-2 d; *max:* 80 mg/d	For treatment of IBS; avoid use in patients with glaucoma or ulcerative colitis, and use caution in paralytic ileus; may cause dry mouth, dizziness, drowsiness, blurred vision, weakness, and nausea. Pregnancy category: B*; PB: UK; t½: 9-10 h
Glycopyrrolate	Preoperative: aspiration prophylaxis A/adol >16 y: IM: 4 mcg/kg 30 min to 1 h before induction	For duodenal ulcer, aspiration prophylaxis. Contraindicated in patients with narrow-angle glaucoma, obstructive GI tract, and ulcerative colitis. May cause flushing, dry mouth, headache, drowsiness, dizziness, weakness, anhidrosis, seizures, nausea, vomiting, constipation, urinary retention, and erectile dysfunction. Pregnancy category: B*; PB: UK; t½: 0.5-3 h
Hyoscyamine SO_4	Regular release: A/adol/C >12 y: PO/SL: 0.125-0.25 mg q4h PRN; *max*: 1.5 mg/d Extended release: A/adol/C >12 y: 0.375-0.75 mg q12h; *max*: 1.5 mg/d A: subcut/IM/IV: 0.25-0.5 mg bid/qid	Treatment of aspiration prophylaxis, gastric and duodenal ulcer, and IBS. Contraindicated in patients with narrow-angle glaucoma and severe ulcerative colitis. May cause confusion, blurred vision, dysphagia, anhidrosis, constipation, palpitations, urinary retention, and erectile dysfunction. Pregnancy category: C*; PB: 50%; t½: 3.5 h
Methscopolamine bromide	A: PO: 2.5 mg tid ac and 2.5-5 mg at bedtime; *max:* 12.5 mg/d	For gastric and duodenal ulcer. Avoid use in patients with ulcerative colitis, myasthenia gravis, and ileus. Cautious use with prostatic hypertrophy. May cause confusion, blurred vision, anhidrosis, dry mouth, ageusia, constipation, palpitations, tachycardia, urinary retention, and erectile dysfunction. Pregnancy category: C*; PB: UK; t½: UK
Propantheline bromide	A: PO: 15 mg tid ac; 30 mg at bedtime. Older adults: 7.5 mg tid ac	Antispasmodic for duodenal ulcer. Contraindicated in glaucoma and myasthenia gravis. Use caution with prostatic hypertrophy. May cause confusion, anhidrosis, dysphagia, constipation, palpitations, hypotension, blurred vision, urinary retention, and erectile dysfunction. Pregnancy category: C*; PB: UK; t½: 1.6 h
Scopolamine	Motion sickness: A: Transdermal: 1.5 mg patch behind ear 4 h before antiemetic is needed; *max*: 1 patch q3d A: PO: 250-800 mcg 1 h before antiemetic is needed; *max*: 2.4 mg/d Nausea/vomiting: A: subcut: 0.6-1 mg; *max*: 2.4 mg/d	For motion sickness, nausea, and vomiting. May cause drowsiness, confusion, blurred vision, tachycardia, dry mouth, dysphagia, constipation, photosensitivity, and urinary retention. Pregnancy category: C*; PB: 30%; t½: 8 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Cholinergic Antagonists: Eye		
Cyclopentolate hydrochloride	0.5%-2% sol, 1-2 gtt	For mydriasis and cycloplegia for eye examination; see Chapter 44.
Homatropine	2%-5% sol, 1-2 gtt	For mydriasis and cycloplegia (paralysis of ciliary muscle resulting in loss of accommodation) for eye examination; see Chapter 44.
Tropicamide	0.5%-1% sol, 1-2 gtt	For mydriasis and cycloplegia for eye examination; see Chapter 44.
Anticholinergic-Antiparkinson Drugs		
Benztropine mesylate	See Prototype Drug Chart 16.3.	
Trihexyphenidyl hydrochloride	Parkinsonism: A: PO: Initially 1 mg tid with meals; maint: 6-10 mg/d, usually tid with meals and at bedtime; *max*: 15 mg/d Extended release: A: PO: 5-10 mg after breakfast; *max*: 15 mg/d Drug-induced EPS: A: PO: 1 mg/d, increase to 5-15 mg/d in divided doses; *max*: 15 mg/d	Treatment of parkinsonism and drug-induced EPS. Abrupt discontinuation may lead to exacerbation of parkinsonism symptoms and/or NMS. Monitor IOP frequently. May cause dizziness, anxiety, memory impairment, insomnia, dry mouth, nausea, vomiting, restlessness, tachycardia, NMS, and urinary retention. Pregnancy category: C*; PB: UK; t½: UK; see Chapter 20.
Anticholinergic–Antimuscarinic Drugs		
Tolterodine tartrate	See Prototype Drug Chart 16.4.	
Others		
Ipratropium bromide	A: MDI: 2 inhal tid/qid; *max:* 12 inhal/d	For bronchospasm prophylaxis, allergic rhinitis, common cold, COPD. May cause headache, dyspnea, epistaxis, and nasopharyngitis. Pregnancy category: B *; PB: UK; t½: 2 h; see Chapter 36.

A, Adult; *ac,* before meals; *adol,* adolescent; *bid,* two times a day; *C,* child; *COPD,* chronic obstructive pulmonary disease; *d,* day; *EPS,* extrapyramidal syndrome; *ER,* extended release; *GI,* gastrointestinal; *gtt,* drops; *h,* hours; *IBS,* irritable bowel syndrome; *IM,* intramuscular; *inhal,* inhalation; *IOP,* intraocular pressure; *IV,* intravenous; *maint:* maintenance; *max,* maximum; *MDI,* metered-dose inhaler; *min,* minute; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q4-6h,* every 4 to 6 hours; *qid,* four times a day; *SL,* sublingual; *sol,* solution; *subcut,* subcutaneous; *t½,* half-life; *tid,* three times a day; *UK,* unknown; *wks,* weeks; *y,* years.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 16.4 Tolterodine Tartrate

Drug Class	Dosage
Antimuscarinic agent: anticholinergic Pregnancy category: C*	Immediate release: A: PO: 1-2 mg bid; *max*: 4 mg/d Extended release: A: PO: 2-4 mg/d; *max*: 4 mg/d
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, urinary retention, gastric paresis, GI obstruction, glaucoma, and lactation *Caution:* Alcoholism, cardiovascular disease, hypertension, bradycardia, heart failure, GERD, paralytic ileus, ulcerative colitis, diabetes mellitus, myasthenia gravis, urinary tract obstruction, prostatic hypertrophy, renal or hepatic dysfunction	Drug: Increased effects with amantadine, amoxapine, bupropion, clozapine, cyclobenzaprine, disopyramide, maprotiline, olanzapine, orphenadrine, H_1 blockers, phenothiazines, and TCAs; decreased effects with azole antifungals (e.g., ketoconazole) or macrolide antibiotics (e.g., erythromycin), cyclosporine, and fluoxetine Food: Grapefruit juice may increase drug levels.
Pharmacokinetics	Pharmacodynamics
Absorption: GI absorption is decreased with food intake. Distribution: PB: 96% Metabolism: t½: IR, 2-4 h; SR, 6.9-18 h Excretion: Urine and feces	PO: Onset: UK Peak: IR, 1-2 h; SR, 2-6 h Duration: UK
Therapeutic Effects/Uses	
To decrease urinary frequency, urgency, and incontinence	
Mode of Action: Blocks cholinergic (muscarinic) receptors selectively in the urinary bladder	
Side Effects	Adverse Reactions
Dry mouth, eyes, and skin; headache, drowsiness, dizziness, vertigo, blurred vision, confusion, diarrhea, abdominal pain, constipation, dyspepsia, dysuria, fatigue, weight gain, arthralgia, and urinary retention	Angioedema, chest pain, tachycardia, peripheral edema *Life threatening:* Stevens-Johnson syndrome

A, Adult; *bid,* two times a day; *d,* day; *GERD,* gastroesophageal reflux disease; *GI,* gastrointestinal; H_1, histamine 1; *h,* hours; *IR,* immediate release; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *SR,* sustained release; *t½,* half-life; *TCA,* tricyclic antidepressant; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Critical Thinking Case Study

JS, a 70-year-old man, is scheduled for surgery to remove gallstones. He has been in fairly good health. His only other clinical problem is a slight tremor in his hands. His primary physician would like him to start on benztropine after surgery for his tremor. Preoperative medications, meperidine 75 mg and atropine sulfate 0.4 mg, were given intramuscularly 1 hour before surgery.

1. What are the advantages of giving atropine sulfate before surgery?
2. What are some contraindications of atropine sulfate?
3. If a patient received an atropine-like drug for several months, what assessments should be made related to its effects?
4. How does atropine sulfate differ from bethanechol chloride? This patient will receive benztropine after he heals from surgery for his tremors.
5. What classification of drug is benztropine and how does it work? Explain your answer.
6. What patient teaching should the nurse include related to the use of benztropine?

NCLEX Study Questions

1. A patient is receiving bethanechol. The nurse realizes that the action of this drug is to treat which condition?
   a. Glaucoma
   b. Urinary retention
   c. Delayed gastric emptying
   d. Gastroesophageal reflux disease
2. The nurse teaches the patient receiving atropine to expect which side effect?
   a. Diarrhea
   b. Bradycardia
   c. Blurred vision
   d. Frequent urination
3. When benztropine is ordered for a patient, the nurse acknowledges that this drug is an effective treatment for which condition?
   a. Parkinsonism
   b. Paralytic ileus
   c. Motion sickness
   d. Urinary retention
4. Dicyclomine is an anticholinergic, which the nurse realizes is given to treat which condition?
   a. Mydriasis
   b. Constipation
   c. Urinary retention
   d. Irritable bowel syndrome
5. The nurse realizes that cholinergic agonists mimic which parasympathetic neurotransmitter?
   a. Dopamine
   b. Acetylcholine
   c. Cholinesterase
   d. Monoamine oxidase
6. The nurse is administering bethanechol, a cholinergic agonist, and should know that the expected cholinergic effects include which of the following?
   a. Increased heart rate
   b. Decreased peristalsis
   c. Decreased salivation
   d. Increased pupil constriction
7. When a patient has a cholinergic overdose from excessive dosing of bethanechol, the nurse anticipates administration of which drug as the antidote?
   a. Atropine
   b. Tolterodine
   c. Benztropine
   d. Metoclopramide

Answers: 1, b; 2, c; 3, a; 4, d; 5, b; 6, d; 7, a.

UNIT V
Central and Peripheral Nervous System Drugs

OUTLINE

Introduction
17. Stimulants
18. Depressants
19. Antiseizure Drugs
20. Drugs for Parkinson's Disease and Alzheimer Disease
21. Drugs for Neuromuscular Disorders and Muscle Spasms

Introduction

The nervous system is composed of all nerve tissues: brain, spinal cord, nerves, and ganglia. The purpose of the nervous system is to receive stimuli and transmit information to nerve centers for an appropriate response. There are two types of nervous systems: the central nervous system and the peripheral nervous system.

The central nervous system (CNS), composed of the brain and spinal cord, regulates body functions (Fig. V.1). The CNS interprets information sent by impulses from the peripheral nervous system (PNS) and returns the instruction through the PNS for appropriate cellular actions. Stimulation of the CNS may either increase nerve cell (neuron) activity or block nerve cell activity.

The PNS consists of two divisions: the somatic nervous system (SNS) and the autonomic nervous system (ANS). The SNS is voluntary and acts on skeletal muscles to produce locomotion and respiration. The ANS, also called the *visceral system,* is involuntary; it controls and regulates the functioning of the heart, respiratory system, gastrointestinal system, and glands. The ANS, a large nervous system that functions without our conscious control, has two subdivisions: the sympathetic and the parasympathetic nervous systems.

The sympathetic nervous system of the ANS is called the *adrenergic system* because its neurotransmitter is norepinephrine. The parasympathetic nervous system is called the *cholinergic system* because its neurotransmitter is acetylcholine. Because organs are innervated by both the sympathetic and the parasympathetic systems, they can produce opposite responses. The sympathetic response is excitability, and the parasympathetic response is inhibition.

The sympathetic and the parasympathetic nerve pathways originate from different locations in the spinal cord. These nervous systems send information by two types of nerve fibers, preganglionic and postganglionic, and by the ganglion between these fibers (Fig. V.2). The preganglionic nerve fiber carries messages from the CNS to the ganglion, and the postganglionic fiber transmits impulses from the ganglion to body tissues and organs.

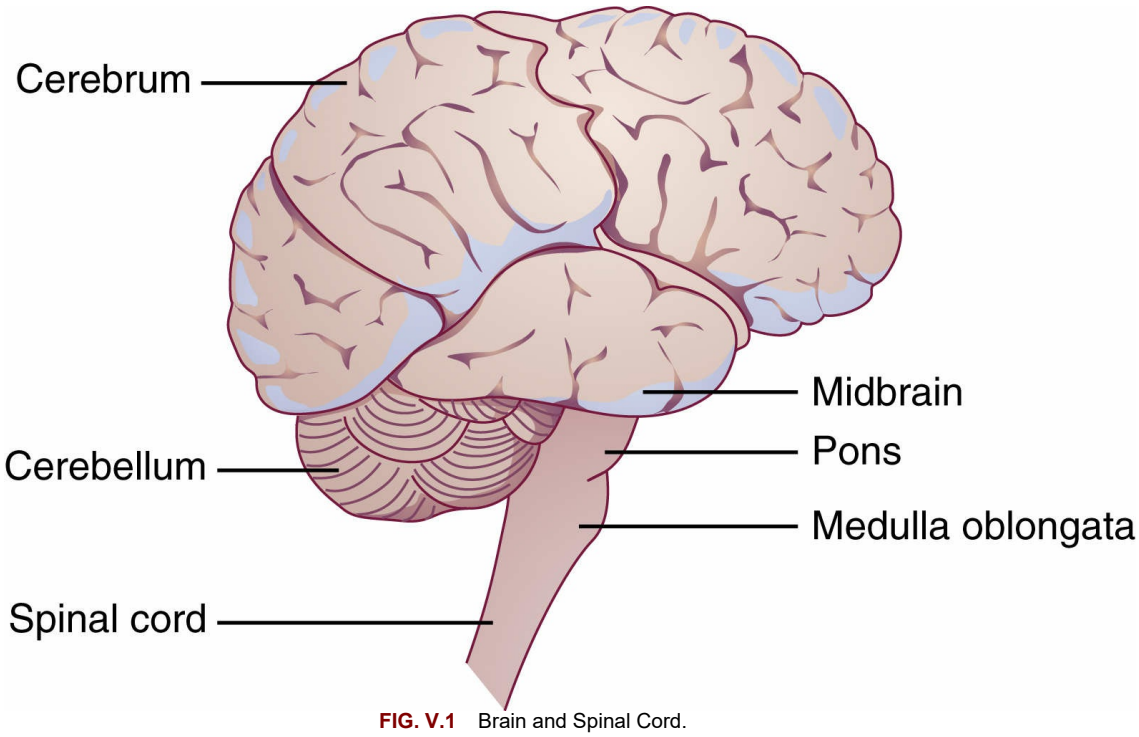

FIG. V.1 Brain and Spinal Cord.

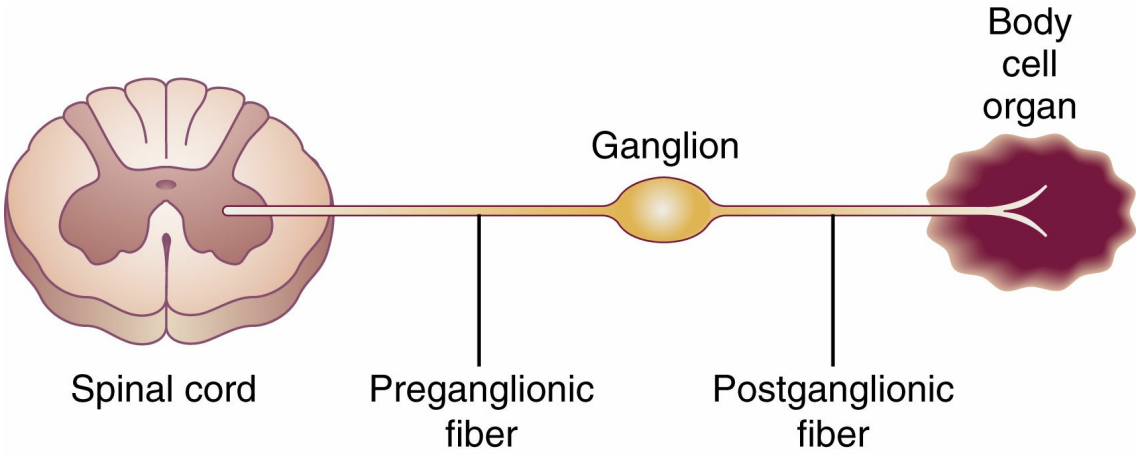

FIG. V.2 Preganglionic and Postganglionic Nerve Fibers.

The sympathetic nervous system is also called the *thoracolumbar division* of the ANS, because the preganglionic fibers originate from the thoracic segment (T1 to T12) and the upper lumbar segment (L1 and L2) of the spinal cord. The sympathetic preganglionic fibers from the spinal cord to the ganglion are short, and the sympathetic postganglionic fibers from the ganglion to the body cells are long. Fig. V.3 illustrates the sympathetic preganglionic fibers from the spinal cord.

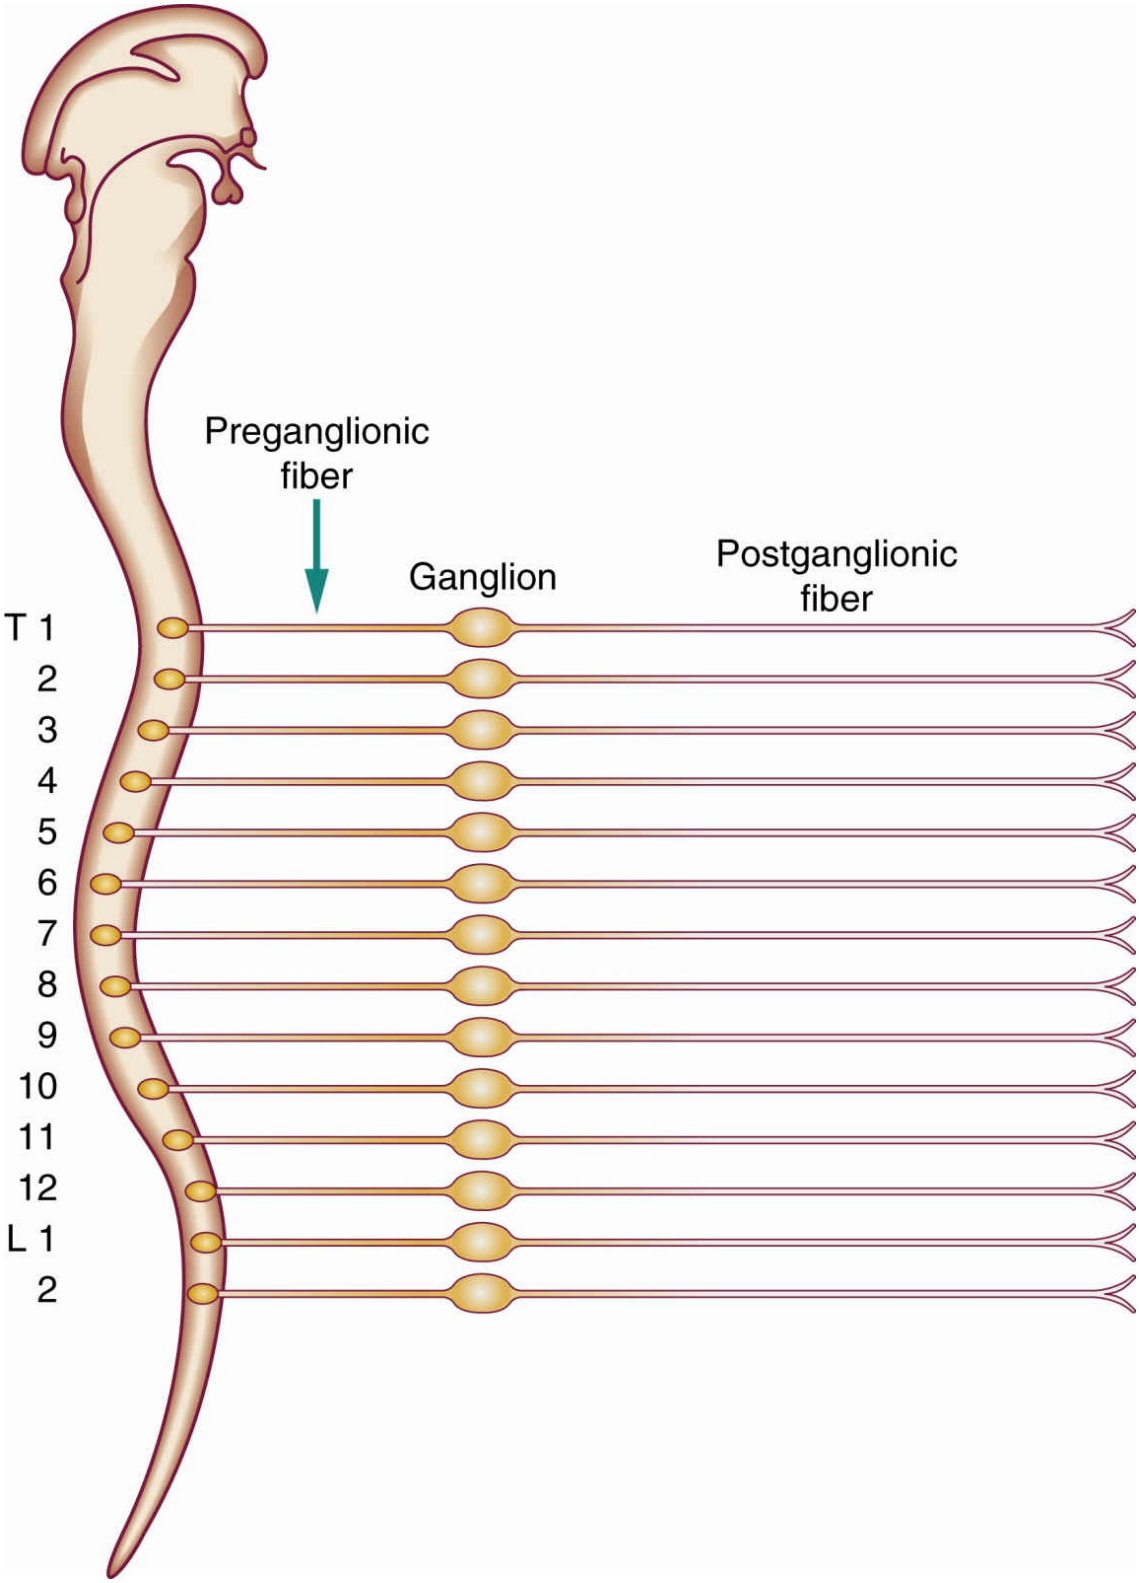

FIG. V.3 Sympathetic Nerve Fibers.

The parasympathetic nervous system is called the *craniosacral division* of the ANS because the preganglionic fibers originate with cranial nerves III, VII, IX, and X from the brainstem and sacral segments S2, S3, and S4 of the spinal cord. The parasympathetic preganglionic fibers are long from the spinal cord to the ganglion, and the parasympathetic postganglionic fibers are short from the ganglion to the body cells. Fig. V.4 illustrates the parasympathetic preganglionic fibers from the

spinal cord.

Drugs that stimulate and depress the CNS are discussed in Chapter 17 and Chapter 18, respectively. Drugs used to control seizures are discussed in Chapter 19, and they are also considered CNS depressants. Drugs used to treat neuromuscular disorders such as parkinsonism, myasthenia gravis, multiple sclerosis, and Alzheimer disease have varying effects on the nervous system and muscles. These are discussed in Chapters 20 and 21.

Fig. V.5 shows a schematic breakdown of the nervous systems in the body.

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Explain the effects of stimulants on the central nervous system (CNS).
- Compare attention-deficit/hyperactivity disorder (ADHD) and narcolepsy.
- Differentiate the action of drugs used for ADHD and narcolepsy.
- Contrast the common side effects of amphetamines, anorexiants, analeptics, doxapram, and caffeine.
- Apply the nursing process for the patient taking CNS stimulants.
- Apply the nursing process for the patient taking doxapram.

KEY TERMS

amphetamines, p. 226

Numerous drugs can stimulate the **central nervous system (CNS)**, which involves the brain and spinal cord and regulates body functions. Medically approved use of CNS stimulants is limited to the treatment of attention-deficit/hyperactivity disorder in children, narcolepsy, and the reversal of respiratory distress. The major groups of CNS stimulants include **amphetamines** *and caffeine,* which stimulate the cerebral cortex of the brain; **analeptics** *and caffeine,* which act on the brainstem and

medulla to stimulate respiration; and **anorexiants** such as diethylpropion, which are thought to suppress appetite by stimulating the satiety center in the hypothalamic and limbic areas of the brain. Amphetamines and related anorexiants are greatly abused. Long-term use of amphetamines can produce psychological **dependence** or **tolerance**, conditions in which larger and larger doses of a drug are needed to reproduce the initial response. These medications are recommended for short-term use only (up to 12 weeks). Gradually increasing a drug dose and then abruptly stopping the drug may result in depression and withdrawal symptoms.

Pathophysiology

Attention-deficit/hyperactivity disorder (ADHD) might be caused by a dysregulation of the transmitter's serotonin, norepinephrine, and dopamine. ADHD occurs primarily in children, usually before the age of 7 years, and may continue through the teenage years. In some cases, it may not be identified until early adulthood. The incidence of ADHD is three to seven times more common in boys than in girls. Characteristic behaviors of the various types of ADHD include inattentiveness, inability to concentrate, restlessness (fidgety), hyperactivity (excessive and purposeless activity), inability to complete tasks, and impulsivity.

The child with ADHD may display poor coordination, and there may be abnormal electroencephalograph (EEG) findings. Intelligence is usually not affected, but learning disabilities are often present. This disorder has also been called *minimal brain dysfunction, hyperactivity in children, hyperkinesis,* and *hyperkinetic syndrome with learning disorder.* Some professionals state that ADHD is often incorrectly diagnosed and results in many children receiving unnecessary treatment for months or years.

Narcolepsy is characterized by falling asleep during normal waking activities, such as driving a car or talking with someone. Sleep paralysis, the condition of muscle paralysis that is normal during sleep, usually accompanies narcolepsy and affects the voluntary muscles. The narcoleptic is unable to move and may collapse.

Amphetamines

Amphetamines stimulate the release of the **neurotransmitters** norepinephrine and dopamine from the brain and sympathetic nervous system (peripheral nerve terminals) and inhibit the reuptake of these transmitters. Amphetamines ordinarily cause euphoria and increased alertness, but they can also cause insomnia, restlessness, tremors, irritability, and weight loss. Cardiovascular problems such as increased heart rate, palpitations, cardiac dysrhythmia, and increased blood pressure can result from cardiac stimulation and vasoconstriction with continuous use of amphetamines. These drugs have a high potential for abuse, tolerance, and dependence. Excessive use may lead to psychosis.

The half-life of amphetamines varies from 9 to 13 hours. Amphetamines and dextroamphetamine are prescribed for narcolepsy and ADHD when amphetamine-like drugs are ineffective.

Side Effects and Adverse Reactions

Amphetamines can cause adverse effects in the CNS and the cardiovascular, gastrointestinal (GI), and endocrine systems. Side effects and adverse reactions include dizziness, headache, euphoria, confusion, blurred vision, restlessness, insomnia, tachycardia, hypertension, heart palpitations, dysrhythmias, dry mouth, anorexia, weight loss, diarrhea, constipation, seizures, tremors, and erectile dysfunction.

Amphetamine-Like Drugs for Attention-Deficit/Hyperactivity Disorder and Narcolepsy

Methylphenidate and dexmethylphenidate, classed as amphetamine-like drugs, are given to increase a child's attention span and cognitive performance (e.g., memory, reading) and to decrease impulsiveness, hyperactivity, and restlessness. Methylphenidate is also used to treat narcolepsy. Because of the potential for abuse of methylphenidate, it is classified as a Controlled Substance Schedule (CSS) II drug. Prototype Drug Chart 17.1 illustrates the pharmacokinetics, pharmacodynamics, and therapeutic effects of methylphenidate in the treatment of ADHD and narcolepsy. Amphetamine and amphetamine-like drugs should not be taken in the evening or before bedtime because insomnia may result.

PROTOTYPE DRUG CHART 17.1 Methylphenidate

Drug Class	Dosage
Amphetamine-like drug: CNS stimulant	ADHD:
CSS II Pregnancy category: C*	Immediate release: A/adol: PO: 20-30 mg/d in 2-3 divided doses 30-40 min before breakfast and lunch; *max:* 60 mg/d C 6-12 y: PO: 5-10 mg before breakfast and lunch; *max:* 60 mg/d
	Extended release: A: PO: 18-36 mg/d in the morning; *max:* 72 mg/d C: PO: 18 mg/d; *max:* 54 mg/d or 2 mg/kg/d Adol/C >6 y: Transdermal patch: Initially 10 mg/9 h patch/d in the morning; *max*: 30 mg/9 h patch/d
	Narcolepsy: A: PO: 10-60 mg/d in 2-3 divided doses; *max*: 72 mg/d C >6 y: PO: Initially 5 mg bid 30 min before meals; *max*: 60 mg/d
Contraindications	Drug-Lab-Food Interactions
Hyperthyroidism, anxiety, Tourette syndrome, glaucoma, psychosis, mental depression, hereditary fructose intolerance *Caution:* Children <6 y, psychosis, depression, substance abuse, MI, alcoholism, bipolar disorder, dysrhythmias, seizures, radiographic contrast administration, pregnancy	Drug: May increase stimulatory effects of sympathomimetics and psychostimulants; may reduce effect of antihypertensives; increases effects of oral anticoagulants, barbiturates, anticonvulsants, and TCAs; increases hypertensive crisis with MAOIs Food: Caffeine may increase effects.
Pharmacokinetics	Pharmacodynamics
Absorption: Well absorbed from GI tract Distribution: PB: 10%-33% Metabolism: t½: 1.3-7.7 h Excretion: 90% excreted unchanged in urine	PO: Onset: 0.5-1 h Regular release: Peak 1.9 h Duration: 3-6 h Extended release: Peak 4.7 h Duration: 8 h
Therapeutic Effects/Uses	
To correct hyperactivity caused by ADHD, increase attention span, and control narcolepsy	
Mode of Action: Research suggests modulation of serotonergic pathways occurs by affecting changes in dopamine transport.	
Table Continued	

Side Effects	Adverse Reactions
Anorexia, dry mouth, nausea, vomiting, dizziness, insomnia, irritability, tremors, euphoria, blurred vision, headache, abdominal pain, anemia	Tachycardia, hypertension, growth suppression, palpitations, seizures, transient weight loss in children *Life threatening:* Exfoliative dermatitis, stroke, thrombocytopenia, hepatotoxicity

>, Greater than; <, less than; *A,* adult; *ADHD,* attention-deficit/hyperactivity disorder; *adol,* adolescent; *bid,* twice a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *TCA,*

tricyclic antidepressant; *y,* year.

TABLE 17.1

Amphetamines and Amphetamine-Like Drugs

Drug	Route and Dosage	Uses and Considerations
Amphetamines		
Amphetamine sulfate CSS II	ADHD: Immediate release tab: A/Adol/C >6 y: PO: Initially 5 mg/d or bid, increase by 5 mg/d weekly until desired response; *max*: 60 mg/d C 3-5 y: PO: 2.5 mg/d Extended release: Suspension: A/adol/C >6 y: PO: 2.5-5 mg in morning; *max*: 20 mg/d	For narcolepsy, ADHD, obesity. Dosage should be minimal to control symptoms in ADHD. May cause growth inhibition, agitation, confusion, weight loss, and tremor. Pregnancy category: C*; PB: UK; t½: 10-13 h
Dextroamphetamine sulfate CSS II	ADHD: A/adol: PO: 5 mg/d or bid C 6-12 y: PO: 5 mg/d or bid C 3-5 y: PO: 2.5 mg/d	For ADHD and narcolepsy. May cause headache, anorexia, abdominal pain, euphoria, psychosis, hostility, weight loss, growth inhibition, aggression, and cardiac events. Pregnancy category: C*; PB: UK; t½: 10-12 h
Lisdexamfetamine dimesylate CSS II	ADHD: A: PO: 30 mg/d in the morning, may increase 10-20 mg/d weekly, *max:* 70 mg/d C >6 y: PO: 20-30 mg/d in the morning; *max*: 70 mg/d	For ADHD. May cause anorexia, insomnia, irritability, psychosis, suicidal ideation, aggression, and cardiac events including sudden death. Contraindicated within 14 days of MAOI therapy. Pregnancy category C*; PB: UK; t½: <1 h
Amphetamine-Like Drugs		
Methylphenidate hydrochloride CSS II	See Prototype Drug Chart 17.1.	
Modafinil CSS IV	A: PO: 200 mg/d in the morning; *max*: 400 mg/d	For narcolepsy and sleep apnea. May cause headache, dizziness, anorexia, nausea, diarrhea, agitation, irritability, and nervousness. Pregnancy category: C*; PB: 60%; t½: 15 h
Dexmethylphenidate hydrochloride	Immediate release: A and C >6 y: PO: 2.5 mg bid; *max:* 20 mg/d Extended release: A: PO: 10 mg/d in the morning; *max:* 40 mg/d C >6 y: PO: 5 mg/d in the morning, may increase 5 mg/wk; *max:* 30 mg/d	For ADHD. May cause headache, restlessness, dry mouth, psychosis, aggression, agitation, hostility, insomnia, tremors, anorexia, weight loss, abdominal pain, palpitations, and cardiac events. May cause sudden death in patients with structural cardiac abnormalities. Pregnancy category: C*; PB: UK; t½: 2.2 h
Armodafinil	A and C >17 y: PO: 150-250 mg/d in the morning; *max:* 250 mg/d	For narcolepsy and sleep apnea. May cause headache, nausea, depression, and suicidal ideation. Pregnancy category: C *; PB: 60%; t½: 15 h

>, Greater than; <, less than; *A,* adult; *ADHD,* attention-deficit/hyperactivity disorder; *adol,* adolescent; *bid,* twice a day; *C,* child; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Modafinil is an amphetamine-like stimulant that increases wakefulness in patients with sleep disorders such as narcolepsy. Its mechanism of action is not fully known.

Methylphenidate is the most frequently prescribed drug used to treat ADHD. Table 17.1 lists the amphetamines and amphetamine-like drugs and their dosages, uses, and considerations, including common side effects and a few serious adverse effects.

Pharmacokinetics

Methylphenidate is well absorbed from the GI mucosa and is usually administered to children twice a day before breakfast and lunch. Because food affects its absorption rate, this drug should be given 30 to 45 minutes before meals. Methylphenidate should be given 6 hours or more before sleep because it can cause insomnia. Transdermal patches may be worn for 9 hours. This drug is excreted in the urine, and 40% of methylphenidate is excreted unchanged.

Nursing Process: Patient-Centered Collaborative Care

Central Nervous System Stimulant: Methylphenidate Hydrochloride

Assessment

- Determine whether the patient has a history of heart disease, hypertension, hyperthyroidism, parkinsonism, or glaucoma; in such cases, this drug is usually contraindicated.
- Assess vital signs to be used for future comparisons. Closely monitor patients with cardiac disease because this drug may cause tachycardia, hypertension, and stroke.
- Assess patient mental status, such as mood, affect, and aggressiveness.
- Evaluate height, weight, and growth of children.

- Assess complete blood count (CBC), differential white blood cells (WBCs), and platelets before and during therapy.

Nursing Diagnoses

- Health Behavior, Risk-Prone (e.g., impulsiveness, short attention span, distractibility) that interfere with peer relationships, learning, and discipline
- Family Processes, Interrupted related to dysfunctional behavior
- Development, Risk for Delayed
- Knowledge, Deficient related to inexperience with methylphenidate drug regimen

Planning

- Patient's hyperactivity will be decreased.
- Patient's attention span will increase.
- Patient's blood pressure and heart rate will be within normal limits.
- Patient will behave in a calm manner.

Nursing Interventions

- Monitor vital signs and report irregularities.
- Evaluate height, weight, and growth of children.
- Observe patients for withdrawal symptoms such as nausea, vomiting, weakness, and headache.
- Monitor patients for side effects such as insomnia, restlessness, nervousness, tremors, irritability, tachycardia, and elevated blood pressure. Report findings.

Patient Teaching

General

- Teach patients to take the drug before meals.
- Advise patients to avoid alcohol consumption.
- Encourage use of sugarless gum to relieve dry mouth.
- Teach patients to monitor weight twice a week and report weight loss.
- Advise patients to avoid driving and using hazardous equipment when experiencing tremors, nervousness, or increased heart rate.
- Teach patients not to abruptly discontinue the drug; the dose must be tapered to avoid withdrawal symptoms. Consult a health care provider before modifying doses.
- Encourage patients to read labels on over-the-counter (OTC) products because many contain caffeine. A high plasma caffeine level could be fatal.
- Teach nursing mothers to avoid taking all CNS stimulants (e.g., caffeine). These drugs are excreted in breast milk and can cause hyperactivity or restlessness in infants.
- Direct families to seek counseling for children with ADHD. Drug therapy alone is not an appropriate therapy program. Notify school nurse of drug therapy regimen.
- Explain to patients and family that long-term use may lead to drug abuse.

Diet

- Advise patients to avoid foods that contain caffeine (e.g., coffee, tea, chocolate, soft drinks, and energy drinks).
- Encourage parents to provide children with a nutritious breakfast because the drug may have anorexic effects.

Side Effects

- Teach patients about drug side effects and the need to report tachycardia and palpitations.
- Monitor children for onset of Tourette syndrome.

Cultural Considerations

- Decrease language barriers by decoding the jargon of the health care environment for those who have language difficulties or are not in the health care field.

Evaluation

- Evaluate effectiveness of drug therapy, level of hyperactivity, and presence of adverse effects.
- Monitor weight, sleep patterns, and mental status.
- Evaluate patient knowledge of methylphenidate therapy.

Pharmacodynamics

Methylphenidate helps to correct ADHD by decreasing hyperactivity and improving attention span. This drug may also be prescribed for treating narcolepsy. Amphetamine-like drugs are considered generally more effective in treating ADHD than are amphetamines, which are generally avoided because they have a higher potential for abuse, habituation, and tolerance. Sympathomimetics (e.g., pseudoephedrine) and psychostimulants (e.g., caffeine) taken concurrently with methylphenidate increase stimulatory effects of irritability, nervousness, tremors, and insomnia. Concurrent use of monoamine oxidase inhibitors (MAOIs) may cause hypertensive crisis. Methylphenidate potentiates the action of CNS stimulants, such as caffeine, and inhibits the metabolism of some barbiturates, such as phenobarbital, which can lead to increased blood levels and potential toxicity.

Anorexiants and Analeptics

Anorexiants

Anorexiants cause a stimulant effect on the hypothalamic and limbic regions of the brain to suppress appetite. Most of the anorexiants used to suppress appetite (Table 17.2) do not have the serious side effects associated with amphetamines. For weight-loss attempts, emphasis should be placed on a nutritious diet, exercise, and behavior modification. Reliance on appetite suppressants should be discouraged. Individuals who take anorexiants should be under the care of a health care provider.

Side Effects and Adverse Reactions

Children younger than 12 years should not be given anorexiants, and self-medication with anorexiants should be discouraged. Long-term use of these drugs frequently results in such severe side effects such as nervousness, restlessness, irritability, insomnia, heart palpitations, and hypertension.

Analeptics

Analeptics, which are CNS stimulants, mostly affect the brainstem and spinal cord but also affect the cerebral cortex. The primary use of an analeptic is to stimulate respiration. One subgroup of analeptics is the xanthines (methylxanthines), of which caffeine and theophylline are the main drugs. Depending on the dose, caffeine stimulates the CNS, and large doses stimulate respiration. Newborns with respiratory distress might be given caffeine to increase respiration. Theophylline is used mostly to relax the bronchioles; however, it has also been used to increase respiration in newborns. Refer to Chapter 36 for further discussion of theophylline. Table 17.2 lists the analeptics and their dosages, uses, and considerations, including common side effects and a few serious adverse effects.

Side Effects and Adverse Reactions

Side effects from caffeine are similar to those from anorexiants: nervousness, restlessness, tremors, twitching, palpitations, and insomnia. Other side effects include diuresis (increased urination), GI irritation (e.g., nausea, diarrhea), and, rarely, tinnitus (ringing in the ears). Excess caffeine affects the CNS and heart and can cause dysrhythmias and convulsions. High doses of caffeine in coffee, chocolate, and cold-relief medications can cause psychological dependence. The half-life of caffeine is approximately 5 hours; however, the half-life is prolonged in patients with liver disease and in patients who are taking oral contraceptives or are pregnant. Caffeine is contraindicated during pregnancy because its effect on the fetus is unknown.

TABLE 17.2

Anorexiants and Analeptics

Drug	Route and Dosage	Uses and Considerations
Anorexiants		
Benzphetamine hydrochloride CSS III	A/adol: PO: 25-50 mg daily; *max:* 150 mg/d	Short-term (8-12 wk) treatment for obesity. Use caution with diabetes mellitus, hypertension, seizures, and Tourette syndrome. A potential for abuse exists. May cause restlessness, dry mouth, dysgeusia, and anorexia. Pregnancy category: X*; PB: UK, t½: UK
Diethylpropion hydrochloride CSS IV	A: PO: 25 mg tid 1 h before meals ; *max*: 75 mg/d Sustained release: A: PO: 75 mg/d mid morning; *max:* 75 mg/d	Short-term use for obesity. Contraindicated within 14 days of MAOI therapy and with severe hypertension or glaucoma. Use caution with psychosis, diabetes mellitus, seizures, hypertension, and Tourette syndrome. May cause headache, insomnia, dry mouth, hypertension, and dependence. Pregnancy category: B*; PB: UK; t½: 4-8 h
Phentermine hydrochloride CSS IV	A/adol >16 y: PO: 15-37.5 mg/d in the morning; *max*: 37.5 mg/d	Short-term use for obesity. Contraindicated with dysrhythmias, heart failure, or glaucoma and within 14 days of MAOI therapy. Use caution with diabetes mellitus, hypertension, Tourette syndrome, seizures, and renal impairment. May cause euphoria, dysphoria, dry mouth, dysgeusia, and constipation. Pregnancy category: X*; PB: 17.5 h; t½: 19-24 h
Phentermine-topiramate	Extended release: A: PO: 3.75 mg phentermine/23 mg topiramate/d for 14 d in the morning, then 7.5 mg phentermine/46 mg topiramate/d; *max:* 15 mg phentermine/92 mg topiramate/d	Used short term for obesity. May cause headache, dry mouth, tachycardia, paresthesia, suicidal ideation, attention difficulty, depression, insomnia, and hypokalemia. Evaluate weight loss in 12 weeks. Pregnancy category: X*; PB: 17.5% phentermine, 15%-41% topiramate; t½: 19-24 h phentermine, 65 h topiramate
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Phendimetrazine	A: PO: 17.5-35 mg bid/tid, 1 h before meals; *max*: 210 mg/d Extended release: A: PO: 105 mg/d 30-60 min before breakfast	Used short term for obesity. May cause headache, insomnia, dizziness, restlessness, dry mouth, blurred vision, constipation, tachycardia, palpitations, hypertension, tremor, erectile dysfunction, and tolerance. Pregnancy category: X*; PB: UK; t½: 1.9-9.8 h
Liraglutide	Obesity: A: Subcut: Initially 0.6 mg/d for 1 wk; *max*: 3 mg/d for obesity	Used short term for obesity and type 2 diabetes mellitus. May cause headache, anorexia, nausea, vomiting, constipation, diarrhea, tachycardia, palpitations, suicidal ideation, and hypoglycemia. Use appropriate precautions for handling and disposal of hazardous agent. Pregnancy category: Saxenda (for obesity) X*, Victoza (for diabetes mellitus) C*; PB: >98%; t½: 13 h
Naltrexone hydrochloride/bupropion hydrochloride	A: PO: 8 mg naltrexone/90 mg bupropion/d in the morning; *max*: 32 mg naltrexone/360 mg bupropion/d	Used short term for obesity. May cause headache, dizziness, insomnia, nausea, vomiting, constipation, psychosis, suicidal ideation, liver dysfunction, hypertension, and tachycardia. Contraindicated with uncontrolled hypertension, seizures, and MAOI therapy. Evaluate weight loss in 12 weeks. Pregnancy category: X*; PB: 21% naltrexone, 84% bupropion; t½: 5 h naltrexone, 21 h bupropion
Serotonin 2C Receptor Agonist		
Lorcaserin	A: PO: 10 mg bid; *max*: 20 mg/d	Used short term for obesity. May cause headache, confusion, back pain, infection, hypertension, peripheral edema, hypoglycemia, and suicidal ideation. Pregnancy category: X*; PB: 70%; t½: 11 h
Analeptics		
Methylxanthines		
Caffeine citrate	Neonatal apnea: Infant: PO/IV: 20-25 mg/kg loading dose, then after 24 h, 5-10 mg/kg/d	For neonatal apnea. Monitor closely for seizures, and intracranial hemorrhage. May cause tachycardia, palpitations, tremors, gastritis, urinary frequency, and withdrawal. Pregnancy category: C*; PB: 36%; t½: A: 3-7 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Theophylline	A/adol >15 y: IV: 0.4 mg/kg/h; *max*: 900 mg/d Older adults: IV: 0.3 mg/kg/h; *max*: 400 mg/d C >12 y: IV: 0.5 mg/kg/h C 9-11 y: IV: 0.7 mg/kg/h C 1-8 y: IV: 0.8 mg/kg/h Infants 6-52 wk: IV: (0.008) (age in wk) + 0.21 = mg/kg/h	For bronchospasm prophylaxis, COPD, asthma, status asthmaticus, and neonatal apnea. May cause headache, insomnia, nausea, vomiting, seizures, dysrhythmias, hypokalemia, and palpitations. Pregnancy category: C*; PB: 40%; t½: 6.5-10.5 h
Doxapram	A: IV: 0.5 mg-1 mg/kg single injection, may repeat at 5-min intervals; *max*: 4 mg/kg cumulative dose	For postanesthesia respiratory depression. Has narrow margin of safety. Other therapeutic measures used first. May cause headache, dizziness, confusion, tachycardia, flushing, sweating, cough, dyspnea, laryngospasm, and skeletal muscle hyperactivity. Pregnancy category: B*; PB: UK; t½: 2.4-4.1 h

>, Greater than; *A,* adult; *adol,* adolescent; *bid,* twice a day; *C,* child; *COPD,* chronic obstructive pulmonary disease; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *IV,* intravenous; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *subcut,* subcutaneous; *t½,* half-life; *tid,* three times a day; *UK,* unknown; *wk,* week; *y,* years.

Critical Thinking Case Study

MP, a 7-year-old child, has been diagnosed with attention-deficit/hyperactivity disorder. The physician is considering putting the child on medication.

1. What symptoms does a child with attention-deficit/hyperactivity disorder display?
2. What medication might be prescribed? What class of drugs does the medication fall under?
3. What behavioral improvements might be seen after medication administration?
4. What physical assessment should be completed before medication administration?
5. What teaching should the nurse include related to the use of methylphenidate?

NCLEX Study Questions

1. When a 12-year-old child is prescribed methylphenidate, which is most important for the nurse to monitor?
   a. Temperature
   b. Respirations
   c. Intake and output
   d. Height and weight
2. Several children are admitted for diagnosis with possible attention-deficit/hyperactivity disorder. Which is most important for the nurse to observe?
   a. A girl who is lethargic
   b. A girl who lacks impulsivity
   c. A boy with smooth coordination
   d. A boy with an inability to complete tasks
3. The nurse monitoring a patient for methylphenidate withdrawal should observe the patient for which condition?
   a. Tremors
   b. Insomnia
   c. Weakness
   d. Tachycardia
4. The nurse is teaching a patient to self-administer medications. The nurse knows that which drug is used to treat narcolepsy?
   a. Modafinil
   b. Atomoxetine
   c. Lisdexamfetamine
   d. Phendimetrazine
5. A newborn patient is in respiratory distress. The nurse anticipates preparation for which medication to be given?
   a. Modafinil
   b. Armodafinil
   c. Theophylline
   d. Amphetamine

Answers: 1, d; 2, d; 3, c; 4, a; 5, c.

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Differentiate the types and stages of sleep.
- Explain several nonpharmacologic ways to induce sleep.
- Differentiate among these adverse effects: hangover, dependence, tolerance, withdrawal symptoms, and rapid eye movement (REM) rebound.
- Discuss the uses of benzodiazepines.
- Apply the nursing process for the patient taking benzodiazepines for hypnotic use.
- Differentiate nursing interventions related to barbiturates, benzodiazepines, nonbenzodiazepines, and melatonin agonist hypnotics.
- Compare the stages of anesthesia.
- Explain the uses for topical anesthetics.
- Differentiate general and local anesthetics and their major side effects.

Drugs that are central nervous system (CNS) depressants cause varying degrees of depression (reduction in functional activity) within the CNS. The degree of depression depends primarily on the drug and the amount of drug taken. The broad classification of CNS depressants includes sedative-hypnotics, general anesthetics, analgesics, opioid and nonopioid analgesics, anticonvulsants, antipsychotics, and antidepressants. The last five groups of depressant drugs are presented in separate chapters. Sedative-hypnotics and general anesthetics are discussed in this chapter.

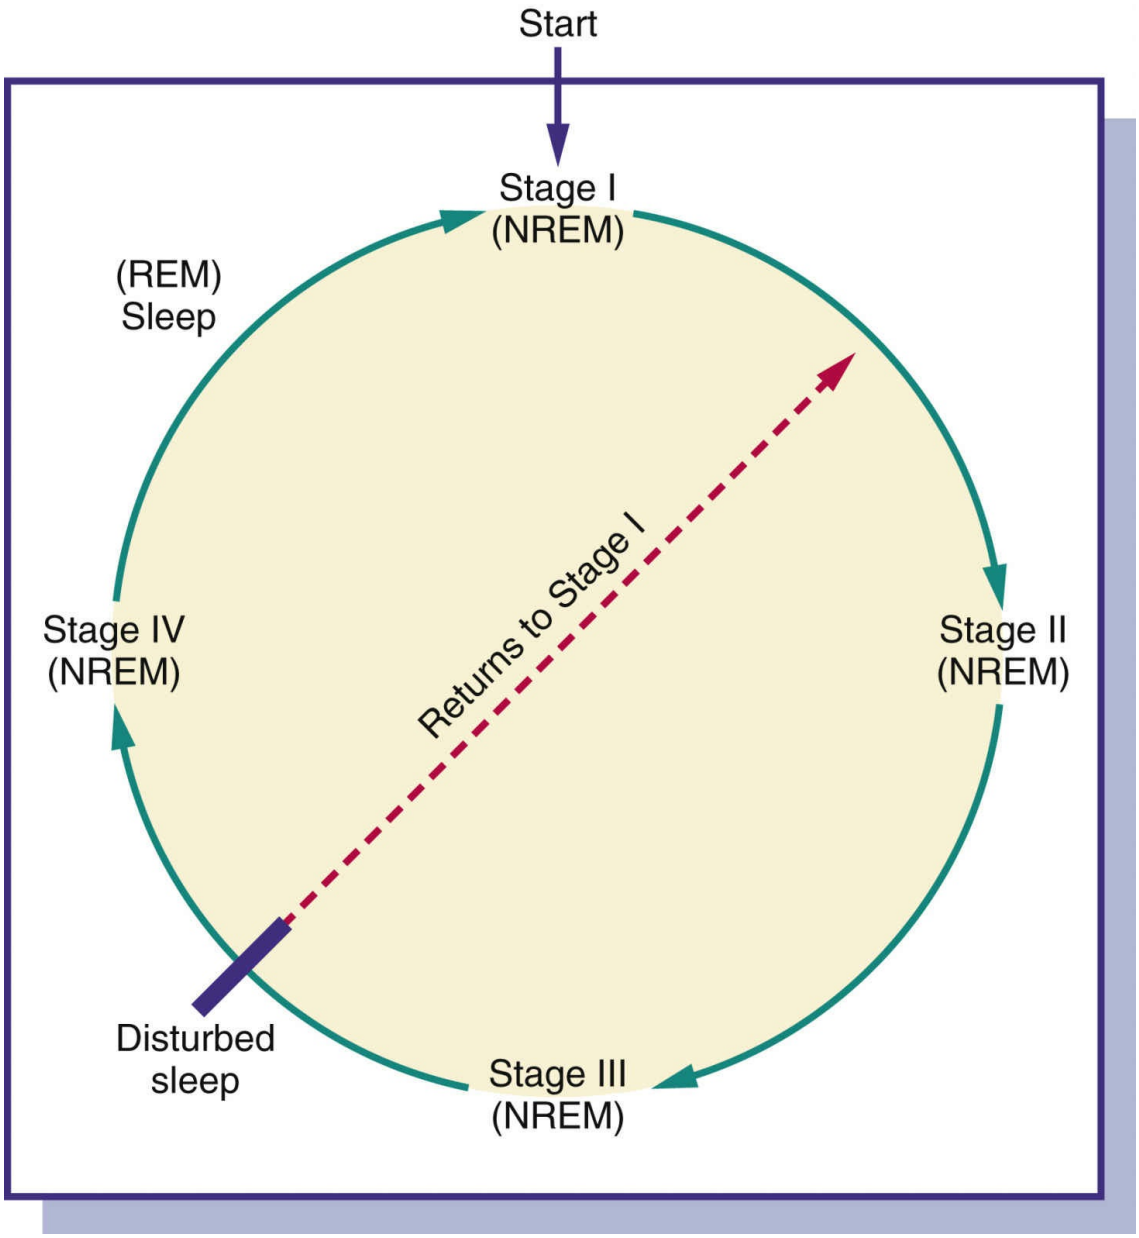

FIG. 18.1 Types and stages of sleep. *NREM,* Nonrapid eye movement (four stages); *REM,* rapid eye movement (dreaming).

Types and Stages of Sleep

Sleep disorders such as **insomnia**, the inability to fall asleep or remain asleep, occur in 10% to 30% of Americans. Insomnia occurs more frequently in women, and the incidence increases with age.

People spend approximately one third of their lives, or as much as 25 years, sleeping. Normal sleep is composed of two definite phases: **rapid eye movement (REM)** and **nonrapid eye movement (NREM) sleep**. Both REM and NREM sleep occur cyclically at about 90-minute intervals during sleep (Fig. 18.1). The four succeedingly deeper stages of NREM sleep end with an episode of REM sleep, and the cycle begins again. If sleep is interrupted, the cycle begins again with stage 1 of NREM sleep. Individuals perform better during their waking hours if they experience all types and stages of sleep.

During REM sleep, individuals experience most of their recallable dreams. Children have few REM sleep periods and have longer periods of stage 3 and 4 NREM sleep. Older adults experience a decrease in stage 3 and 4 NREM sleep and have frequent waking periods.

It is difficult to rouse a person during REM sleep, and the period of REM sleep episodes becomes longer during the sleep process. Frequently, if a person is roused from REM sleep, a vivid, bizarre dream may be recalled. If these dreams are unpleasant, they may be called *nightmares.* Sleepwalking or nightmares that occur in children take place during NREM sleep.

Nonpharmacologic Methods

Before using sedative-hypnotics or over-the-counter (OTC) sleep aids, various nonpharmacologic methods should be used to promote sleep. Once the nurse discovers why the patient cannot sleep, the following ways to promote sleep may be suggested:

1. Arise at a specific hour in the morning.
2. Take few or no daytime naps.
3. Avoid drinks that contain caffeine and alcohol 6 hours before bedtime. Also avoid smoking nicotine products for 6 hours before bedtime.
4. Avoid heavy meals or strenuous exercise before bedtime.
5. Take a warm bath, listen to quiet music, or perform other soothing activities before bedtime.
6. Decrease exposure to loud noises.
7. Avoid drinking copious amounts of fluids before sleep.
8. Drink warm milk before bedtime.

Sedative-Hypnotics

Sedative-hypnotics are commonly ordered for treatment of sleep disorders. The mildest form of CNS depression is **sedation**, which diminishes physical and mental responses at lower dosages of certain CNS depressants but does not affect consciousness. Sedatives are used mostly during the daytime. Increasing the drug dose can produce a **hypnotic effect**—not hypnosis but a form of "natural" sleep. Sedative-hypnotic drugs are sometimes the same drug; however, certain drugs are used more often for their hypnotic effect. With very high doses of sedative-hypnotic drugs, anesthesia may be achieved.

Sedatives were first prescribed to reduce tension and anxiety. Barbiturates were initially used for their antianxiety effect until the early 1960s, when benzodiazepines were introduced. Because of the many side effects of barbiturates and their potential for physical and mental dependency, they are now less frequently prescribed.

The Centers for Disease Control and Prevention cite that approximately 70 million Americans have chronic sleep problems and suffer from sleep deprivation. The cost is billions of dollars in lost productivity, and millions of dollars are spent each year on OTC sleep aids. The primary ingredient in OTC sleep aids is an antihistamine such as diphenhydramine.

Hypnotics may be short or intermediate acting. Short-acting hypnotics are useful in achieving sleep because they allow the patient to awaken early in the morning without experiencing lingering side effects. Intermediate-acting hypnotics are useful for sustaining sleep; however, after using one, the patient may experience residual drowsiness, or **hangover**, in the morning. This may be undesirable if the patient is active and requires mental alertness. The ideal hypnotic promotes natural sleep without disrupting normal patterns of sleep and produces no hangover or undesirable effect. Table 18.1 lists the common side effects and adverse reactions associated with sedative-hypnotic use and abuse.

Hypnotic drug therapy should usually be short term to prevent drug **dependence** and **tolerance**. Interrupting hypnotic therapy can decrease drug tolerance, but abruptly discontinuing a high dose of hypnotic taken over a long period can cause **withdrawal symptoms**. In such cases, the dose should be tapered to avoid withdrawal symptoms. As a general rule, the lowest dose should be taken to achieve sleep. Patients with severe respiratory disorders should avoid hypnotics, which could cause an increase in respiratory depression. Usually, hypnotics are contraindicated during pregnancy. Ramelteon is the only major sedative-hypnotic approved for long-term use. This drug may be used for treating chronic insomnia.

TABLE 18.1

Common Side Effects and Adverse Reactions of Sedative-Hypnotics

Side Effects and Adverse Reactions	Explanation of the Effects
Hangover	A hangover is residual drowsiness resulting in impaired reaction time. The intermediate- and long-acting hypnotics are frequently the cause of drug hangover. The liver biotransforms these drugs into active metabolites that persist in the body, causing drowsiness.
REM rebound	REM rebound, which results in vivid dreams and nightmares, frequently occurs after taking a hypnotic for a prolonged period then abruptly stopping. However, it may occur after taking only one hypnotic dose.
Dependence	Dependence is the result of chronic hypnotic use. Physical and psychological dependence can result. Physical dependence results in the appearance of specific withdrawal symptoms when a drug is discontinued after prolonged use. The severity of withdrawal symptoms depends on the drug and dosage. Symptoms may include muscular twitching and tremors, dizziness, orthostatic hypotension, delusions, hallucinations, delirium, and seizures. Withdrawal symptoms start within 24 hours and can last for several days.
Tolerance	Tolerance results when there is a need to increase the dosage over time to obtain the desired effect. It is mostly caused by an increase in drug metabolism by liver enzymes. The barbiturate drug category can cause tolerance after prolonged use. Tolerance is reversible when the drug is discontinued.
Excessive depression	Long-term use of a hypnotic may result in CNS depression, which is characterized by lethargy, sleepiness, lack of concentration, confusion, and psychological depression.
Respiratory depression	High doses of sedative-hypnotics can suppress the respiratory center in the medulla.
Hypersensitivity	Skin rashes and urticaria can result when taking barbiturates. Such reactions are rare.

CNS, Central nervous system; *REM*, rapid eye movement.

The category of sedative-hypnotics includes barbiturates, benzodiazepines, and nonbenzodiazepines, among others. Each category is discussed separately. Prototype drug charts are included for benzodiazepines and nonbenzodiazepines.

Barbiturates

Barbiturates were introduced as a sedative in the early 1900s. They are classified as long, intermediate, short, and ultrashort acting.

- The *long-acting* group includes phenobarbital and mephobarbital, which are used to control seizures in epilepsy.
- The *intermediate-acting* barbiturates, such as butabarbital, are useful as sleep sustainers for maintaining long periods of sleep. Because these drugs take approximately 1 hour for the onset of sleep, they are not prescribed for those who have trouble getting to sleep. Vital signs should be closely monitored in persons who take intermediate-acting barbiturates.
- The *short-acting* barbiturate secobarbital may be used for procedure sedation. Vital signs should be closely monitored in persons who take short-acting barbiturates.

Barbiturates should be restricted to short-term use (2 weeks or less) because of their numerous side effects, including tolerance to the drug. In the United States, barbiturates are classified under the Controlled Substances Act as Schedule II for short-acting, Schedule III for intermediate-acting, and Schedule IV for long-acting hypnotics. In Canada, barbiturates are classified as Schedule G. Barbiturates are listed in Table 18.2.

Pharmacokinetics

Pentobarbital has been available for nearly half a century and was the hypnotic of choice until the introduction of benzodiazepines in the 1960s. It has a slow absorption rate and is moderately protein bound. The long half-life is mainly because of the formation of active metabolites resulting from liver metabolism.

Pharmacodynamics

Pentobarbital and secobarbital are used primarily for short-term treatment of insomnia. Other uses include control of seizures, preoperative anxiety, and sedation induction. They have a rapid onset with a short duration of action and are considered short-acting barbiturates. The onset of action of pentobarbital is slower when administered intramuscularly (IM) than when administered orally (PO).

Patient Safety

Do not confuse:

- **Phenobarbital,** a long-acting barbiturate used to control seizures, with **pentobarbital,** an ultrashort-acting barbiturate used as a general anesthetic.

Many drug interactions are associated with barbiturates. Alcohol, narcotics, and other sedative-hypnotics used in combination with barbiturates may further depress the CNS. Pentobarbital increases hepatic enzyme action, causing an increased metabolism and decreased effect of drugs such as oral anticoagulants, glucocorticoids, tricyclic antidepressants, and quinidine. Pentobarbital may cause hepatotoxicity if taken with large doses of acetaminophen.

Benzodiazepines

Selected benzodiazepines, minor tranquilizers and anxiolytics, were introduced with chlordiazepoxide in the 1960s as antianxiety agents. This drug group is ordered as sedative-hypnotics for inducing sleep. Several benzodiazepines marketed as hypnotics include flurazepam, alprazolam (Prototype Drug Chart 18.1), temazepam, triazolam, estazolam, and quazepam (Table 18.3). Increased anxiety might be the cause of insomnia for some patients, so lorazepam and diazepam can be used to alleviate the anxiety. These drugs are classified as Schedule IV according to the Controlled Substances Act. The benzodiazepines increase the action of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) to the GABA receptors. Neuron excitability is reduced.

TABLE 18.2

Sedative-Hypnotics: Barbiturates and Other Drugs

Drug	Route and Dosage	Uses and Considerations
Barbiturates: Short-Acting		
Secobarbital sodium CSS II	Sedation induction: A: PO: 200-300 mg 1-2 h before procedure A: PO: 100 mg at bedtime	For sedation induction and insomnia. Use only short term as effectiveness is lost in about 2 weeks. May cause confusion, drowsiness, constipation, withdrawal, sleep-related behaviors, nightmares, and suicidal ideation. Pregnancy category: D*; PB: 30%-45%; t½: 15-40 h
Barbiturates: Intermediate-Acting		
Butabarbital sodium CSS III	Anxiety: A: PO: 15-30 mg tid/qid Insomnia, sedation induction: A: PO: 50-100 mg, 1-1.5 h before procedure or sleep	To manage anxiety, sedation induction, and insomnia. Use short term (<14 days), and avoid alcohol with all barbiturates. May cause ataxia, drowsiness, sleep-related behaviors, confusion, agitation, bradycardia, hypotension, headache, nightmares, depression, and angioedema. This drug is no longer accepted for use in older adults or debilitated adult patients for insomnia. Pregnancy category: D*; PB: 50%; t½: 100 h
Barbiturates: Long-Acting		
Phenobarbital CSS IV	Sedation induction: A: PO/IM: 30-120 mg/d	Used for seizure control, sedation induction, and insomnia. May cause ataxia, depression, bradycardia, hypotension, dizziness, confusion, drowsiness, headache, impaired judgment, nightmares, constipation, and erectile dysfunction. Monitor for respiratory depression. Pregnancy category: D*; PB: 20%-45%; t½: 50-120 h for adults, 37-69 h for children, 47-63 h for infants

<, Less than; *A,* adult; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *IM,* intramuscular; *PB,* protein binding; *PO,* by mouth; *qid,* four times a day; *t½,* half-life; *tid,* three times a day.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 18.1 Alprazolam

Drug Class	Dosage
Sedative-hypnotic: benzodiazepine CSS: IV Pregnancy category: D*	Immediate release: A: PO: Initially 0.25-0.5 mg tid, may increase q3-4d; *max:* 4 mg/d Older A: PO: Initially 0.125 bid/tid, may increase q3-4d; *max:* 4mg/d Extended release: A: PO: Initially 0.5-1 mg/d in the morning, may increase q3-4d; *max:* 10 mg/d Older A: PO: Initially 0.5 mg/d, may increase q3-4d; *max:* 10 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Respiratory depression, acute alcohol intoxication, psychotic reactions, recent respiratory depressants, hypersensitivity *Caution:* Older adults, sleep apnea, renal or liver dysfunction, depression, suicidal ideation, drug abuse	Drug: Decreases respiration with alcohol, CNS depressants; azole antifungals (ketoconazole), antibiotics (erythromycin), aprepitant, cimetidine, diltiazem, and verapamil increase blood levels of alprazolam; rifabutin, rifampin, cortisone, and phenytoin decrease blood levels; alprazolam increases digoxin and lithium levels Food: Grapefruit increases alprazolam levels; green tea decreases alprazolam effects.
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: 90% absorbed from GI tract Distribution: PB: 90% Metabolism: t½: IR, 6.3-26.9 h; ER, 11-16 h; Dtab, 7.9-19.2 h Excretion: In urine as metabolites	PO: Onset: 15-30 min Peak: IR, 1-2 h; ER, 9 h; Dtab, 1.5-2 h Duration: UK
Therapeutic Effects/Uses	
To treat anxiety and panic disorders	
Mode of Action: CNS depression, binds receptors in limbic system and reticular formation, increases GABA to GABA receptors; shift of chloride ions leads to less excitability and stabilizes neuronal membranes.	
Side Effects	**Adverse Reactions**
Lethargy, drowsiness, dizziness, headache, constipation, anterograde amnesia, memory impairment, fatigue, agitation, ataxia, increased appetite, blurred vision, decreased and increased libido, dry mouth, nausea, edema, weight gain/loss	Depression, tolerance, dependence, withdrawal, hypotension, tachycardia, seizures *Life threatening:* Hepatic failure, Stevens-Johnson syndrome

A, Adult; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *Dtab,* disintegrating tablet; *ER,* extended release; *GABA,* gamma-aminobutyric acid; *GI,* gastrointestinal; *h,* hour; *IR,* immediate release; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *tid,* three times a day; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 18.3

Sedative-Hypnotics: Benzodiazepines, Nonbenzodiazepines, and Opioid Agonists

Drug	Route and Dosage	Uses and Considerations
Benzodiazepines		
Alprazolam CSS IV	See Prototype Drug Chart 18.1.	
Estazolam CSS IV	A: PO: 1-2 mg at bedtime; *max*: 2 mg/d Older adults: PO: 0.5-1 mg at bedtime; *max*: 2 mg/d	For treatment of insomnia. Should not be used longer than 6 weeks. May cause tolerance, dizziness, drowsiness, anterograde amnesia, confusion, ataxia, edema, dependence, withdrawal, and sleep-related behaviors. Pregnancy category: X*; PB: 93%; t½: 10-24 h
Lorazepam CSS IV	Insomnia: A: PO: 2-4 mg at bedtime; *max*: 10 mg/d Older adults: PO: 1-2 mg at bedtime; *max*: 10 mg/d	Used for sedation induction and to reduce anxiety, insomnia, and seizures. May cause tolerance, drowsiness, dizziness, hypotension, blurred vision, anterograde amnesia, memory impairment, agitation, nightmares, sleep-related behaviors, and suicidal ideation. Pregnancy category: D*; PB: 91%; t½: 12 h
Temazepam CSS IV	Insomnia: A: PO: 15-30 mg at bedtime; *max*: 30 mg/d Older adults: PO: 7.5 mg at bedtime; *max*: 30 mg/d	To treat insomnia. May cause tolerance, drowsiness, dizziness, confusion, palpitations, hypotension, dependence, withdrawal, anterograde amnesia, and sleep-related behavior. Pregnancy category: X*; PB: 98%; t½: 8-15 h
Triazolam CSS IV	Insomnia: A: PO: 0.125-0.25 mg at bedtime; *max:* 0.5 mg/d Older adults: PO: 0.125 mg at bedtime; *max*: 0.25 mg/d	For management of insomnia. Should not be used longer than 7-10 d at a time to avoid tolerance. Avoid alcohol and smoking when taking triazolam. May cause tolerance, drowsiness, dizziness, ataxia, confusion, visual impairment, headache, tachycardia, depression, dependence, withdrawal, anterograde amnesia, and sleep-related behaviors. Pregnancy category: X*; PB: 90%; t½: 1.5-5.5 h
Benzodiazepine Antagonists		
Flumazenil	A: IV: 0.2 mg over 30 s; may repeat after 45 s, then repeat q1min PRN; *max:* 4 doses	For management of benzodiazepine toxicity and sedation reversal. May cause drowsiness, dizziness, blurred vision, ataxia, seizures, hyperacusis, palpitations, vomiting, and dry mouth. Pregnancy category: C*; PB: 50%; t½: 41 to 79 min
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Nonbenzodiazepines		
Zolpidem tartrate CSS IV	See Prototype Drug Chart 18.2.	
Eszopiclone CSS IV	Insomnia: A: PO: Initially 1 mg at bedtime; maint: 2-3 mg at bedtime; *max*: 3 mg/d Older adults: PO: 1-2 mg at bedtime; *max*: 2 mg/d	To treat insomnia. May cause headache, dizziness, drowsiness, unpleasant taste, sleep-related behaviors, infection, depression, and suicidal ideation. Pregnancy category: C*; PB: 52%-59%; t½: 6 h
Zaleplon CSS IV	Insomnia: A: PO: 10 mg at bedtime; *max:* 20 mg Older adults: PO: 5 mg at bedtime; *max:* 10 mg/d	For ultrashort-term treatment of insomnia. May cause headache, dizziness, drowsiness, nausea, abdominal pain, and sleep-related behaviors. Pregnancy category: C*; PB: 60%; t½: 1 h
Melatonin Agonist		
Ramelteon	A: PO: 8 mg within 30 min of bedtime; *max*: 8 mg/d	For treatment of insomnia. May cause dizziness, drowsiness, fatigue, depression, suicidal ideation, and sleep-related behaviors. Pregnancy category: C*; PB: 82%; t½: 1-2.6 h
Opioid Agonists		
Alfentanil CSS II	A: IV: 130-245 mcg/kg over 3 min as induction; maint: 0.5-1.5 mcg/kg/min; *max*: dependent on procedure duration	For general anesthesia induction and maintenance and sedation maintenance. Must be administered by someone trained in general anesthetic administration. May cause dizziness, confusion, dysrhythmias, hypotension or hypertension, respiratory depression, bronchospasm, tachycardia, bradycardia, chest wall rigidity, nausea, and vomiting. Use caution in patients with head trauma and liver dysfunction. Pregnancy category: C*; PB: 88%-92%; t½: 90-111 min
Sufentanil CSS II	A: IV: 8-30 mcg/kg increments or infusion for induction; maint: 0.5-10 mcg/kg intermittent or continuous IV; *max*: dependent on procedure duration	For general anesthesia induction and maintenance, obstetric anesthesia, and severe pain. Must be administered by someone trained in general anesthetic administration. May cause drowsiness, pruritus, bradycardia, hypertension or hypotension, dysrhythmia, chest wall rigidity, bronchospasm, respiratory depression, urinary retention, nausea, and vomiting. Pregnancy category: C*; PB: 93%; t½: 164 min
Remifentanil	A: IV: 0.5-1 mcg/kg/min continuous infusion	For general anesthesia induction and maintenance and moderate to severe pain. Must be administered by someone trained in general anesthetic administration. May cause dizziness, pruritus, confusion, chest wall rigidity, hypotension, bradycardia, dysrhythmias, nausea, and vomiting. Pregnancy category: C*; PB: 70%; t½: 10-20 min

A, Adult; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q1min,* once per minute; *s,* second; *t½,* half-life.

Nursing Process: Patient-Centered Collaborative Care

Sedative-Hypnotics: Benzodiazepines

Assessment

- Obtain a drug history of current drugs and complementary and alternative therapies that the patient is taking, especially CNS depressants, which would potentiate respiratory depression and hypotensive effects.
- Assess baseline vital signs for future comparisons.
- Determine whether the patient has a history of insomnia or anxiety disorders.
- Assess renal function. Urine output should be 1500 mL/day. Renal impairment could prolong drug action by increasing the half-life of the drug.

Nursing Diagnoses

- Sleep Deprivation related to adverse effect of insomnia
- Injury, Risk for breathing pattern ineffective
- Breathing Pattern, Ineffective related to CNS depression
- Sexuality Pattern, Ineffective related to adverse effect of erectile dysfunction

Planning

- Patient will receive adequate sleep when taking benzodiazepines.

Nursing Interventions

- Monitor vital signs, especially respirations and blood pressure.
- Use a bed alarm for older adults and for patients receiving a hypnotic for the first time. Confusion can occur, and injury could result.
- Observe the patient for adverse reactions, especially an older adult or a debilitated patient.
- Examine the patient's skin for rashes. Skin eruptions may occur in patients taking benzodiazepines.

Patient Teaching

General

- Teach patients to use nonpharmacologic methods to induce sleep such as taking a warm bath, listening to quiet music, drinking warm fluids, and avoiding drinks with caffeine for 6 hours before bedtime.
- Encourage patients to avoid alcohol and antidepressant, antipsychotic, and opioid drugs while taking benzodiazepines. Respiratory depression can occur when these drugs are combined.
- Warn patients that certain complementary and alternative therapy products may interact with benzodiazepines (Complementary and Alternative Therapies 18.1). These products may need to be discontinued, or the prescription drug dose may need to be modified.
- Advise patients not to drive a motor vehicle or operate machinery when using benzodiazepines. Caution is always encouraged.
- Encourage patients to check with a health care provider about OTC sleeping aids. Drowsiness may result from taking these drugs, therefore caution while driving is advised.

Side Effects

- Advise patients to report adverse reactions such as cognitive changes and paradoxical reactions to their health care provider. Drug selection or dosage might need to be changed.
- Teach patients that benzodiazepines should be gradually withdrawn, especially if they have been taken for several weeks. Abrupt cessation may result in withdrawal symptoms such as tremors and muscle twitching.

Cultural Considerations

- Use an interpreter as needed, and involve extended family in health teaching and support.
- Provide written instruction or videos in the patient's preferred language.

Evaluation

- Assess the effectiveness of benzodiazepines.
- Evaluate respiratory status to ensure that respiratory depression has not occurred.

Patient Safety

Do not confuse:

- **Lorazepam,** a benzodiazepine used to reduce anxiety, with **alprazolam,** a benzodiazepine used to treat anxiety and insomnia.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 18.1 Sedatives

- Kava kava should not be taken in combination with CNS depressants such as barbiturates and opioids. This product may increase the sedative effect.
- Valerian, when taken with alcohol and other CNS depressants such as barbiturates, may increase the sedative effects of the prescribed drug.

Benzodiazepines (except for temazepam) can suppress stage 4 of NREM sleep, which may result in vivid dreams or nightmares and can delay REM sleep. Benzodiazepines are effective for sleep disorders for several weeks longer than other sedative-hypnotics; to prevent REM rebound, however, they should not be used for longer than 3 to 4 weeks.

Triazolam is a short-acting hypnotic with a half-life of 2 to 5 hours. It does not produce any active metabolites. Adverse effects of anterograde amnesia or memory impairment occur more frequently with triazolam than with other benzodiazepines, and the risk increases with higher doses and with concurrent alcohol or opioid ingestion. Currently, it is seldom prescribed and should not be taken longer than 7 to 10 days.

One adverse effect closely associated with benzodiazepines is anterograde amnesia, an impaired ability to recall events that occur after dosing. Associated with anterograde amnesia are sleep-related behaviors, such as preparing and eating meals, sleep driving, engaging in sex, or making phone calls during sleep without any memory of the event. Alcohol and CNS depressants increase the risk of sleep-related behaviors.

Small doses of benzodiazepines are recommended for patients with renal or hepatic dysfunction. For benzodiazepine overdose, the benzodiazepine antagonist flumazenil may be prescribed. Benzodiazepines prescribed as antianxiety drugs are discussed in Chapter 22.

Pharmacokinetics

Benzodiazepines are well absorbed through the gastrointestinal (GI) mucosa. They are rapidly metabolized in the liver to active metabolites. Benzodiazepines have an intermediate half-life of usually 8 to 24 hours. These drugs are highly protein bound, and more free drug is available when benzodiazepines are taken with other highly protein-bound drugs, which increases the risk for adverse effects.

Pharmacodynamics

Benzodiazepines are used to treat insomnia by inducing and sustaining sleep. They have a rapid onset of action and intermediate- to long-acting effects. The normal recommended dose of a benzodiazepine may be too much for the older adult, so half the dose is recommended initially to prevent overdosing.

Nonbenzodiazepines

Zolpidem is a nonbenzodiazepine that differs in chemical structure from benzodiazepines. It is used for short-term treatment (<10 days) of insomnia. Its duration of action is 6 to 8 hours with a short half-life of 1.4 to 6.73 hours. Zolpidem is metabolized in the liver to three inactive metabolites and is excreted in bile, urine, and feces. When zolpidem is prescribed for older adults, the dose should be decreased. Table 18.3 lists the benzodiazepines and nonbenzodiazepines used as sedative-hypnotics and their dosages, uses, and considerations including common side effects and a few serious adverse effects. Zolpidem is described in Prototype Drug Chart 18.2.

PROTOTYPE DRUG CHART 18.2 Zolpidem Tartrate

Drug Class	Dosage
Sedative-hypnotic: Nonbenzodiazepine CSS IV Pregnancy category: C*	Immediate release: A males: PO: 5-10 mg at bedtime; *max:* 10 mg/dA females/older adults: PO: 5 mg at bedtime; *max:* 5 mg/d SL tabs/oral spray: A: PO: 5-10 mg at bedtime; *max:* 10 mg/d Older adults: PO: 5 mg at bedtime; *max:* 5 mg/d Extended release: A: PO: 6.25-12.5 mg at bedtime; *max:* 12.5 mg/d Older adults: PO: 6.25 mg at bedtime, *max:* 6.25 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity to benzodiazepine, respiratory depression, lactation *Caution:* Renal or liver dysfunction; mental depression, suicidal ideation; pregnancy; children, older adults, and debilitated individuals	Drug: Decreases CNS function with alcohol, CNS depressants, anticonvulsants, and phenothiazines; increased levels with azole antifungals; decreased levels with rifampin Food: Decreases absorption
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: well absorbed Distribution: PB: 92% Metabolism: t½: 1.4-8.4 h Excretion: In bile, urine, and feces	PO: Immediate release: Onset: 30 min Peak: 90 min Duration: 6-8 h SL/spray mist: Onset: UK Peak: 35-82 min Duration: UK Extended release: Onset: UK Peak: UK Duration: UK
Therapeutic Effects/Uses	
To treat insomnia	
Mode of Action: CNS depression, neurotransmitter inhibition	
Side Effects	**Adverse Reactions**
Drowsiness, lethargy, headache, hot flashes, hangover (residual sedation), irritability, dizziness, ataxia, visual impairment, anxiety, nausea and vomiting, edema, erectile dysfunction, anterograde amnesia, memory impairment, nightmares, binge eating	Tolerance, psychological or physical dependence, withdrawal; sleep-related behaviors, hypotension, angioedema, dysrhythmias, depression, suicidal ideation *Life threatening:* Pulmonary edema, renal failure

A, Adult; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *SL,* sublingual; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Melatonin Agonists

Ramelteon is in the newest category of sedative-hypnotics called *melatonin agonists.* Ramelteon is the first hypnotic approved by the U.S. Food and Drug Administration (FDA) that is *not* classified as a controlled substance. This drug acts by selectively targeting melatonin receptors to regulate circadian rhythms in the treatment of insomnia. Ramelteon has not been shown to decrease REM sleep. This new drug has a half-life of 1 to 2.6 hours. Adverse effects of ramelteon include drowsiness, dizziness, fatigue, headache, nausea, and suicidal ideation.

Sedatives and Hypnotics for Older Adults

Identifying the cause of insomnia in an older adult should be the first diagnostic consideration, and nonpharmacologic methods should be used before sleep medications are prescribed. Because of physiologic changes in older adults, the use of hypnotics can cause a variety of side effects.

Barbiturates increase CNS depression and confusion in older adults and should *not* be taken for sleep. The short- to intermediate-acting benzodiazepines—such as estazolam, temazepam, and triazolam—are considered to be safer than barbiturates. Long-acting hypnotic benzodiazepines such as flurazepam, quazepam, and diazepam should be avoided. In many cases, older adults should be instructed to take the prescribed benzodiazepine no more than four times a week to avoid side effects and drug dependency. They can choose selected nights to take the hypnotic.

The main sleep problem experienced by older adults is frequent nighttime awakening. Reports have shown that older women experience more troublesome sleep patterns than men. Sleep disturbance may be caused by discomfort or pain. Occasionally a nonsteroidal antiinflammatory drug (NSAID) such as ibuprofen may alleviate the discomfort that prevents sleep.

Nursing Process: Patient-Centered Collaborative Care

Sedative-Hypnotics: Nonbenzodiazepines

Assessment

- Assess baseline vital signs and laboratory tests (e.g., aspartate aminotransferase [AST], alanine aminotransferase [ALT], bilirubin) for future comparisons.
- Obtain a drug history. Taking CNS depressants with nonbenzodiazepine hypnotics can depress respirations.

- Ascertain the patient's problem with sleep disturbance.

Nursing Diagnoses

- Sleep Deprivation related to anxiety
- Fatigue related to insomnia
- Injury, Risk for

Planning

- Patient will remain asleep for 6 to 8 hours.

Nursing Interventions

- Monitor vital signs. Check for signs of respiratory depression (slow, irregular breathing patterns).
- Use bed alarm for older adults or patients receiving nonbenzodiazepines for the first time. Confusion may occur, and injury may result.
- Observe patient for side effects of nonbenzodiazepines such as hangover (residual sedation), lightheadedness, dizziness, or confusion.

Patient Teaching

General

- Teach patients to use nonpharmacologic methods to induce sleep (taking a warm bath, listening to music, drinking warm fluids such as milk, avoiding drinks with caffeine after dinner).
- Encourage patients to avoid alcohol, antidepressants, antipsychotics, and narcotic drugs while taking nonbenzodiazepines. Severe respiratory depression may occur when these drugs are combined.
- Advise patients to take nonbenzodiazepine before bedtime. Alprazolam takes effect within 15 to 30 minutes.
- Suggest that patients urinate before taking nonbenzodiazepines to prevent sleep disruption.
- Encourage patients to check with a health care provider about OTC sleeping aids.
- Warn the patient to use caution while driving as drowsiness may occur.

Side Effects

- Advise patients to report adverse reactions such as hangover to a health care provider. Drug selection or dosage may need to be changed if hangover occurs.

Cultural Considerations

- Ask patients about methods family members have used to promote sleep.
- Suggest nonpharmacologic alternatives that may be effective in inducing sleep.

Evaluation

- Evaluate effectiveness of sedative-hypnotics in promoting sleep.
- Determine whether side effects such as hangover occur after several days of taking a sedative-hypnotic. Another hypnotic may be prescribed if side effects persist.

Anesthetics

Anesthetics are classified as *general* and *local*. General anesthetics depress the CNS, alleviate pain, and cause a loss of consciousness. The first anesthetic, nitrous oxide ("laughing gas"), was used for surgery in the early 1800s. It is still an effective anesthetic and is frequently used in dental procedures and surgery.

Pathophysiology

Several theories exist regarding how inhalation anesthetics cause CNS depression and a loss of consciousness. The differing theories suggest the following about inhalation anesthetics:
1. The lipid structure of cell membranes is altered, resulting in impaired physiologic functions.
2. The inhibitory neurotransmitter GABA is activated to the GABA receptor that pushes chloride ions into the neurons. This greatly decreases the fire action potentials of the neurons.
3. The ascending reticular activating system is altered, and the neurons cease to transmit information (stimuli) to the brain.

Balanced Anesthesia

Balanced anesthesia is a combination of drugs frequently used in general anesthesia. Balanced anesthesia may include the following:
1. A hypnotic given the night before
2. Premedication with an opioid analgesic or benzodiazepine (e.g., midazolam) plus an anticholinergic (e.g., atropine) given about 1 hour before surgery to decrease secretions
3. A short-acting nonbarbiturate such as propofol
4. An inhaled gas, often a combination of an inhalation anesthetic, nitrous oxide, and oxygen
5. A muscle relaxant given as needed

Balanced anesthesia minimizes cardiovascular problems, decreases the amount of general anesthetic needed, reduces possible postanesthesia nausea and vomiting, minimizes the disturbance of organ function, and decreases pain. Because the patient does not receive large doses of general anesthetics, fewer adverse reactions occur; and recovery is enhanced by allowing quicker mobility.

Stages of General Anesthesia

General anesthesia proceeds through four stages (Table 18.4). The surgical procedure is usually performed during the third stage. If an anesthetic agent is given immediately before inhalation anesthesia, the third stage can occur without the early stages of anesthesia being observed. However, if the drug is given slowly, all stages of anesthesia are usually observed.

Assessment Before Surgery

The patient's response to anesthesia may differ according to variables related to the health status of the individual. These variables include age (young and older adults), a current health disorder (e.g. cardiovascular, pulmonary, renal, liver), pregnancy, history of heavy smoking, and frequent use of alcohol and drugs. These problems must be identified *before* surgery because the type and amount of anesthetic required may need to be adjusted.

Inhalation Anesthetics

During the third stage of anesthesia, inhalation anesthetics—that is, gas or volatile liquids administered as gas—are used to deliver general anesthesia. Certain gases, notably nitrous oxide, are absorbed quickly, have a rapid action, and are eliminated rapidly. Cyclopropane was a popular inhalation anesthetic from 1930 to 1960, but because of its highly flammable state as ether, it is no longer used. In the late 1950s, halothane was introduced as a nonflammable alternative. Other inhalation drugs used as anesthetics include enflurane, isoflurane, desflurane, and sevoflurane.

Inhalation anesthetics typically provide smooth induction. Upon discontinuing administration of halothane, isoflurane, and enflurane, recovery of consciousness usually occurs in approximately 1

hour. Recovery from desflurane and sevoflurane is within minutes. Inhalation anesthetics are usually combined with a nonbarbiturate, such as propofol; a strong analgesic, such as morphine; and a muscle relaxant, such as pancuronium, for surgical procedures.

Adverse effects from inhalation anesthetics include respiratory depression, hypotension, dysrhythmias, and hepatic dysfunction. In patients at risk, these drugs may trigger malignant hyperthermia. The newer drugs primarily cause less nausea and vomiting than the older anesthetics.

Intravenous Anesthetics

Intravenous (IV) anesthetics may be used for general anesthesia or for the induction stage of anesthesia. For outpatient surgery of short duration, an IV anesthetic might be the preferred form of anesthesia. Propofol, droperidol, etomidate, and ketamine hydrochloride are commonly used to provide a total intravenous anesthetic (TIVA). IV anesthetics have a rapid onset and short duration of action. Table 18.5 describes the inhalation and IV anesthetics used for general anesthesia.

Midazolam and propofol are commonly administered for the induction and maintenance of anesthesia or for conscious sedation for minor surgery or procedures like intubation and mechanical ventilation. Patients are sedated and relaxed but, depending upon the dose, they are responsive to commands.

TABLE 18.4

Stages of Anesthesia

Stage	Name	Description
1	Analgesia	Begins with consciousness and ends with loss of consciousness; speech is difficult, sensations of smell and pain are lost, dreams and auditory and visual hallucinations may occur; this stage may be called the *induction stage.*
2	Excitement or delirium	Produces a loss of consciousness caused by depression of the cerebral cortex; confusion, excitement, or delirium occur, and induction time is short.
3	Surgical	Surgical procedure is performed during this stage. There are four phases: surgery is usually performed in phase 2 and upper phase 3. As anesthesia deepens, respirations become shallower, and the respiratory rate is increased.
4	Medullary paralysis	Toxic stage of anesthesia in which respirations are lost, and circulatory collapse occurs; ventilatory assistance is necessary.

TABLE 18.5

Inhalation and Intravenous Anesthetics

Drug	Induction Time	Considerations
Inhalation: Volatile Liquids		
Halothane	Rapid	Highly potent anesthetic; recovery is rapid; could decrease blood pressure, has a bronchodilator effect, and is contraindicated in obstetrics.
Methoxyflurane	Slow	Used during labor; drug dose is usually less than other anesthetics and does not suppress uterine contraction; could cause hypotension. This drug is contraindicated in renal disorders.
Enflurane	Rapid	Can depress respiratory function; ventilatory support may be necessary. This drug should not be used during labor because it could suppress uterine contractions; avoid use in patients with seizure disorders.
Isoflurane	Rapid	Frequently used in inhalation therapy; has a smooth and rapid induction of anesthesia and rapid recovery; could cause hypotension and respiratory depression. This drug should not be used during labor because it suppresses uterine contractions. Cardiovascular effect is minimal.
Desflurane	Rapid	Volatile liquid anesthetic; recovery is rapid after anesthetic administration has ceased; could cause hypotension and respiratory depression.
Sevoflurane	Rapid	For induction and maintenance during surgery; sevoflurane may be given alone or combined with nitrous oxide.
Inhalation: Gas		
Nitrous oxide ("laughing gas")	Very rapid	Must be administered at no less than a mixture of 21% oxygen; potency is low. Recovery is rapid with minimal cardiovascular effect.
Intravenous (Ultrashort-Acting Barbiturates)		
Methohexital sodium	Rapid	Has short duration; frequently used for induction and with other drugs as part of balanced anesthesia; an inhalation anesthesia usually follows.
Thiamylal sodium	Rapid	Used for induction of anesthesia and as anesthesia for electroshock therapy
Benzodiazepines		
Diazepam	Moderate to rapid	For induction of anesthesia; no analgesic effect
Midazolam	Rapid	For induction of anesthesia and for endoscopic procedures; IV drug can cause conscious sedation and should be avoided if a cardiopulmonary disorder is present.
Others		
Droperidol and fentanyl	Moderate to rapid	A neuroleptic analgesic when combined with fentanyl (potent opiate narcotic); frequently used with a general anesthetic, can also be used as a preanesthetic drug and is also used for diagnostic procedures; may cause hypotension and respiratory depression.
Etomidate	Rapid	Etomidate is used for short-term surgery, for induction of anesthesia, or with a general anesthetic to maintain the anesthetic state.
Ketamine hydrochloride	Rapid	Used for short-term surgery or for induction of anesthesia; increases salivation, blood pressure, and heart rate; may be used for diagnostic procedures; avoid use in patients with a history of psychiatric disorders.
Propofol	Rapid	For induction of anesthesia; may be used with general anesthesia; duration of action is short; may cause hypotension and respiratory depression. Pain can occur at the injection site, so a local anesthetic (lidocaine) may be administered intravenously prior to injection of propofol to decrease pain.
Fospropofol	Rapid	For induction and maintenance of anesthesia; may cause hypotension and respiratory depression

Adverse effects from IV anesthetics include respiratory and cardiovascular depression. Propofol supports microbial growth and may increase the risk for bacterial infection. Discarding opened

vials within 6 hours is a necessary precaution in the prevention of sepsis.

Topical Anesthetics

Use of topical anesthetic agents is limited to mucous membranes, broken or unbroken skin surfaces, and burns. Topical anesthetics come in different forms: solutions, liquid sprays, ointments, creams, gels, and powders. Topical anesthetics decrease the sensitivity of nerve endings in the affected area.

Local Anesthetics

Local anesthetics block pain at the site where the drug is administered by preventing conduction of nerve impulses. Local anesthetics are useful in dental procedures, suturing skin lacerations, short-term (minor) surgery at a localized area, blocking nerve impulses (nerve block) below the insertion of a spinal anesthetic, and diagnostic procedures such as lumbar puncture and thoracentesis. Local anesthetics may also be used to perform regional blocks—such as brachial plexus, axillary, femoral, or sciatic blocks—to provide analgesia for surgery of the upper or lower extremities.

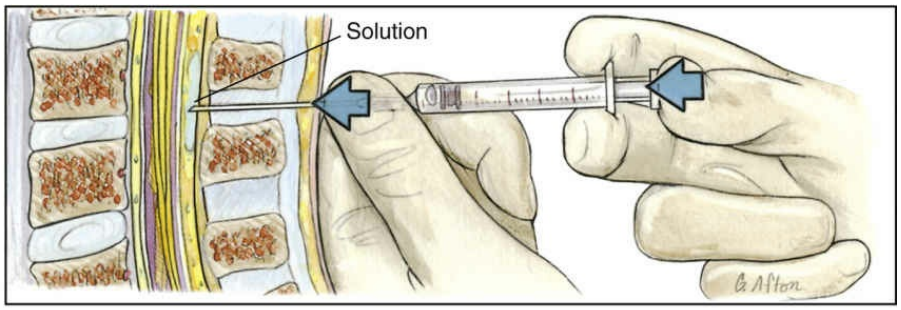
TABLE 18.6

Local Anesthetics

Anesthetics	Type	Uses and Considerations
Short Acting (30 Min to 1 Hour)		
Chloroprocaine hydrochloride	Ester	For infiltration, caudal, and epidural anesthesia; onset of action is 6 to 12 minutes.
Procaine hydrochloride	Ester	For nerve block, infiltration, epidural, and spinal anesthesia; useful in dentistry; use with caution in patients allergic to ester-type anesthetics.
Moderate Acting (1 to 3 Hours)		
Lidocaine hydrochloride	Amide	For nerve block, infiltration, epidural, and spinal anesthesia; allergic reaction is rare. Lidocaine is used to treat cardiac dysrhythmias (see Chapter 37).
Mepivacaine hydrochloride	Amide	For nerve block, infiltration, caudal, and epidural anesthesia; may be used in dentistry
Prilocaine hydrochloride	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia; may be used in dentistry
Long Acting (3 to 10 Hours)		
Bupivacaine hydrochloride	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia
Dibucaine hydrochloride	Amide	For topical use (creams and ointment) to affected areas
Etidocaine hydrochloride	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia
Tetracaine hydrochloride	Ester	For spinal anesthesia (high and low saddle block); also for topical use to affected areas, such as the eye to anesthetize the cornea, the nose and throat for bronchoscopy, and the skin for relief of pain and pruritus (itching)

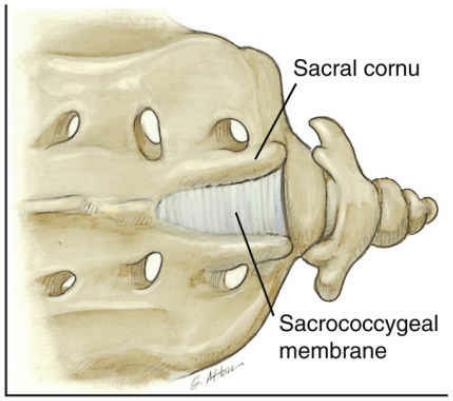
Most local anesthetics are divided into two groups, the *esters* and the *amides*, according to their basic structures. The amides have a very low incidence of allergic reaction.

The first local anesthetic used was cocaine hydrochloride in the late 1800s. Procaine hydrochloride, a synthetic of cocaine, was discovered in the early 1900s. Lidocaine hydrochloride was developed in the mid-1950s to replace procaine except in dental procedures. Lidocaine has a rapid onset and a long duration of action, is more stable in solution, and causes fewer hypersensitivity reactions than procaine. Since the introduction of lidocaine, many local anesthetics have been marketed. Table 18.6 describes the various types of local anesthetics according to short-, moderate-, and long-acting effects.

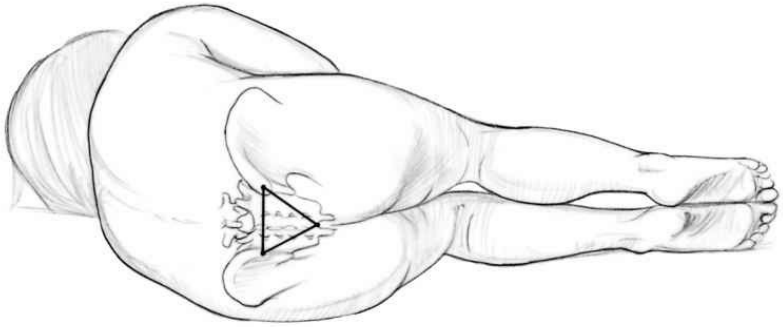


Orthopedic joint surgeries, mastectomy, cesarean delivery, hysterectomy, hernia repair, and cholecystectomy frequently use the postoperative pain control provided by an anesthetic pump. For example, the patient who has a bilateral hernia repair has a catheter inserted into the deep fascia of the lower abdomen. A continuous flow of bupivacaine, a local anesthetic, is delivered via a Y-connector to both sides. By controlling pain with this delivery method, the patient is allowed increased mobility; reduced opioid use, which reduces associated drowsiness and nausea; and a reduced hospital stay.

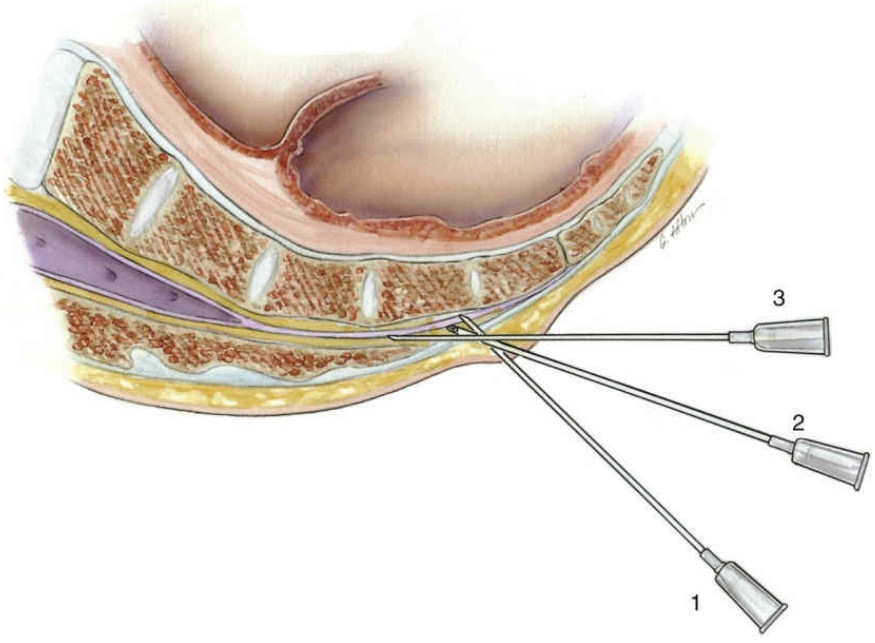
Spinal Anesthesia



Spinal anesthesia requires that a local anesthetic be injected into the subarachnoid space below the first lumbar space (L1) in adults and the third lumbar space (L3) in children. If the local anesthetic is given or spreads too high in the spinal column, the respiratory muscles could be affected, and respiratory distress or respiratory failure could result. A postdural-puncture headache might result following spinal anesthesia (a "spinal"), possibly because of a decrease in cerebrospinal fluid pressure caused by a leak of fluid at the needle insertion point. Encouraging the patient to remain



flat following surgery with spinal anesthesia and to take increased fluids usually decreases the likelihood of leaking spinal fluid. Postdural-puncture headaches occur most frequently in females and in younger patients, and obstetric patients have the highest incidence. Hypotension also can result following spinal anesthesia due to the ensuing sympathetic blockade and predisposing factors that include sensory block location, history of hypertension, and chronic alcohol intake.



Various sites of the spinal column can be used for a **nerve block** with a local anesthetic (Fig. 18.2). A **spinal block** results from the penetration of the anesthetic into the subarachnoid space, which is the space between the pia mater membrane and the arachnoid membrane. An **epidural block** is the placement of the local anesthetic in the epidural space just posterior to the spinal cord or the dura mater. The epidural space is located between the posterior longitudinal ligament on the anterior side and the ligamentum flavum posteriorly. A **caudal block** is an epidural block placed by administering a local anesthetic through the sacral hiatus. A **saddle block** is given at the lower end of the spinal column to block the perineal area. Blood pressure should be monitored during administration of these types of anesthesia because a decrease in blood pressure resulting from the drug and procedure might occur. Further discussion of labor and delivery drugs can be found in Chapter 50.

FIG. 18.2 A, Administration of solution for epidural placement. B, Caudal anesthesia.

Nursing Process: Patient-Centered Collaborative Care

Anesthetics

Assessment

- Assess baseline vital signs.
- Obtain a drug and health history, noting drugs that affect the cardiopulmonary system.

Nursing Diagnoses

- Pain, Acute related to injury
- Breathing Pattern, Ineffective related to CNS depression

Planning

- Patient will participate in preoperative preparation and will understand postoperative care.
- Patient's vital signs will remain stable following surgery.

Nursing Interventions

- Monitor the postoperative state of sensorium. Report if a patient remains excessively nonresponsive or confused.
- Observe preoperative and postoperative urine output. Report deficit of hourly or 8-hour urine output.
- Monitor vital signs following general and local anesthesia; hypotension and respiratory depression may result.
- Administer an analgesic or a narcotic-analgesic with caution until the patient fully recovers from the anesthetic. To prevent adverse reactions, the dosage might need to be adjusted if the patient is under the influence of an anesthetic.

Patient Teaching

- Explain to patients the preoperative preparation and postoperative nursing assessment and interventions.

Cultural Considerations

- Allow adequate time for information processing for the patient whose first language is not English to avoid an inaccurate response or no response. Allow time for patients and their families to respond to questions, especially when a language barrier is present.
- Speak clearly and slowly, giving time for translation. Obtain an interpreter if necessary.

Evaluation

- Evaluate the patient's response to the anesthetics. Continue to monitor for adverse reactions.

Nurses play an important role in patient assessment before and after general and local anesthesia is administered. Preparing the patient for surgery by explaining the preparations and completing the preoperative orders, including premedications, is necessary to enhance the safety and effectiveness of anesthesia and surgery.

Critical Thinking Case Study

JZ, a 72-year-old woman, has difficulty staying asleep. She asks the nurse whether she should take a sleeping medication, such as lorazepam, before bedtime.

1. Before JZ takes any sleep aid or hypnotic, what nursing assessments should be made?
2. Describe a nursing plan that may help alleviate JZ's sleep disturbance.
3. Would JZ be a candidate for taking a benzodiazepine? Explain your answer.
4. What follow-up plan should the nurse have related to JZ's sleep problem?

NCLEX Study Questions

1. It is important for the nurse teaching the patient regarding secobarbital to include which information about the drug?
   a. It is a short-acting drug that may cause one to awaken early in the morning.
   b. It is an intermediate-acting drug that frequently causes rapid eye movement rebound.
   c. It is an intermediate-acting drug that frequently causes a hangover effect.
   d. It is a long-acting drug that is frequently associated with dependence.
2. A patient taking lorazepam asks the nurse how this drug works. The nurse should respond by stating that it is a benzodiazepine that acts by which mechanism?
   a. Depressing the central nervous system, leading to a loss of consciousness
   b. Depressing the central nervous system, including the motor and sensory activities
   c. Increasing the action of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) to GABA receptors
   d. Creating an epidural block by placement of the local anesthetic into the epidural space
3. A patient is taking ramelteon for insomnia. The nurse prepares a care plan that includes monitoring of the patient for side effects/adverse reactions of this drug. Which is a side effect of ramelteon?
   a. Insomnia
   b. Bradycardia
   c. Laryngospasm
   d. Sleep-related behaviors
4. A patient received spinal anesthesia. Which is most important for the nurse to monitor?
   a. Loss of consciousness
   b. Hangover effects and dependence
   c. Hypotension and headaches
   d. Excitement or delirium
5. A nurse is teaching a patient about zolpidem. Which is important for the nurse to include in the teaching of this drug?
   a. The maximum dose is 20 mg/day.
   b. It is used for short-term treatment less than 10 days.
   c. For older adults, the dose is 15 mg at bedtime.
   d. The drug should only be used for 21 days or less.
6. A patient is taking triazolam. Which instructions about this drug are important for the nurse to include?
   a. It may be used as a barbiturate for only 4 weeks.
   b. Use as a nonbenzodiazepine to reduce anxiety.
   c. It may cause agranulocytosis and thrombocytopenia.
   d. Avoid alcohol and smoking while taking this drug.
7. A patient is to receive conscious sedation for a minor surgical procedure. Which drug administration should the nurse expect? (Select all that apply.)
   a. Propofol to reduce anxiety
   b. Lidocaine to provide local anesthesia
   c. Midazolam to promote sedation and following of commands
   d. Ketamine for rapid induction and prolonged duration of action
   e. Phenobarbital for short-acting duration of sleep

Antiseizure Drugs

OUTLINE

International Classification of Seizures
Antiseizure Drugs
- Pharmacophysiology: Action of Antiseizure Drugs
- Hydantoins
- Barbiturates
- Succinimides
- Benzodiazepines
- Iminostilbenes
- Valproate
- Antiseizure Drugs and Pregnancy
- Antiseizure Drugs and Febrile Seizures
- Nursing Process: Patient-Centered Collaborative Care—Antiseizure Drugs: Phenytoin
- Antiseizure Drugs and Status Epilepticus

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Contrast the two international classifications of seizures with characteristics of each type.
- Differentiate between the types of seizures.
- Summarize the pharmacokinetics, side effects and adverse reactions, therapeutic plasma level, contraindications for use, and drug interactions of phenytoin.
- Compare the actions of hydantoins, long-acting barbiturates, succinimides, benzodiazepines, iminostilbenes, and valproate.
- Apply the nursing process to antiseizure drugs, including patient teaching.

Millions of people in the United States have active epilepsy, a **seizure** disorder that results from abnormal electric discharges from the cerebral neurons characterized by a loss or disturbance of consciousness and usually involuntary, uncontrolled movements. The **electroencephalogram (EEG)**, computed tomography (CT), and magnetic resonance imaging (MRI) are useful in diagnosing epilepsy. The EEG records abnormal electric discharges of the cerebral cortex. Of all seizure cases, 75% are considered to be primary, or **idiopathic** (of unknown cause), and the remainder are secondary to brain trauma, brain **anoxia** (absence of oxygen), infection, or cerebrovascular disorders (e.g., cerebrovascular accident [CVA], stroke). Epilepsy is a chronic, usually lifelong disorder. The majority of persons with seizure disorder had their first seizure before 20 years of age.

Seizures that are not associated with epilepsy could result from fever, hypoglycemic reaction, electrolyte imbalance (hyponatremia), metabolic imbalance (acidosis or alkalosis), and alcohol or drug use. When these conditions are corrected, the seizures cease. Recurrent seizures may result from birth and perinatal injuries, head trauma, congenital malformations, neoplasms (tumors), or idiopathic, or unknown, causes.

International Classification of Seizures

There are various types of seizures, such as **tonic-clonic** (formerly known as *grand mal*), **absence** (formerly known as *petit mal*), and **psychomotor**. The International Classification of Seizures (Table 19.1) describes two seizure categories: generalized and partial. A person may also have mixed seizures that comprise more than one type.

TABLE 19.1

International Classification of Seizures

Category	Characteristics
Generalized seizure	Seizures involve both cerebral hemispheres of the brain.
Tonic-clonic seizure	Also called *grand mal seizure,* the most common form; in the *tonic phase,* skeletal muscles contract or tighten in a spasm that lasts 3 to 5 seconds; in the *clonic phase,* a dysrhythmic muscular contraction occurs with a jerkiness of legs and arms that lasts 2 to 4 minutes.
Tonic seizure	Sustained muscle contraction
Clonic seizure	Dysrhythmic muscle contraction
Absence seizure	Also called *petit mal seizure;* brief loss of consciousness lasts less than 10 seconds with fewer than three spike waves on the electroencephalogram (EEG) printout. This type usually occurs in children.
Myoclonic seizure	Isolated clonic contraction or jerks that last 3 to 10 seconds may be limited to one limb (focal myoclonic) or may involve the entire body (massive myoclonic); may be secondary to a neurologic disorder such as encephalitis or Tay-Sachs disease.
Atonic seizure	Head drop, loss of posture, and sudden loss of muscle tone occurs. If lower limbs are involved, the patient could collapse.
Infantile spasms	Muscle spasm
Partial seizure	Involves one hemisphere of the brain; no loss of consciousness occurs in simple partial seizures, but there is a loss of consciousness in complex partial seizures.
Simple seizure	Occurs in motor, sensory, autonomic, and psychic forms; no loss of consciousness occurs.
Motor	Formerly called the *Jacksonian seizure,* this type involves spontaneous movement that spreads; it can develop into a generalized seizure.
Sensory	Visual, auditory, or taste hallucinations
Autonomic response	Paleness, flushing, sweating, or vomiting
Psychological	Personality changes
Complex seizure	Loss of consciousness occurs, and the patient does not recall behavior immediately before, during, and immediately after the seizure.
Psychomotor	Complex symptoms include automatisms (repetitive behavior such as chewing or swallowing motions), behavioral changes, and motor seizures.
Cognitive	Confusion or memory impairment
Affective	Bizarre behavior
Compound	May lead to generalized seizures such as tonic or tonic-clonic

Antiseizure Drugs

Drugs used for epileptic seizures are called **antiseizure drugs**, *anticonvulsants,* or *antiepileptic drugs* (AEDs). Antiseizure drugs stabilize nerve cell membranes and suppress the abnormal electric impulses in the cerebral cortex. These drugs prevent seizures but do not eliminate the cause or provide a cure. Antiseizure drugs are classified as central nervous system (CNS) depressants.

With the use of antiseizure drugs, seizures are controlled in approximately 70% of patients. These drugs are usually taken throughout the person's lifetime; however, the health care provider might discontinue the medication if no seizures have occurred after 3 to 5 years in some cases.

Many types of antiseizure drugs are used to treat seizures, including the hydantoins (phenytoin), long-acting barbiturates (phenobarbital, mephobarbital, primidone), succinimides (ethosuximide), benzodiazepines (diazepam, clonazepam), carbamazepine, and valproate (valproic acid). Antiseizure drugs are not indicated for all types of seizures. For example, phenytoin is effective in treating tonic-clonic and partial seizures but is not effective in treating absence seizures.

Pharmacophysiology: Action of Antiseizure Drugs

Antiseizure drugs work in one of three ways: (1) by suppressing sodium influx through the drug binding to the sodium channel when it is inactivated, which prolongs the channel inactivation and thereby prevents neuron firing; (2) by suppressing the calcium influx, which prevents the electric current generated by the calcium ions to the T-type calcium channel; or (3) by increasing the action of gamma-aminobutyric acid (GABA), which inhibits neurotransmitters throughout the brain. The drugs that suppress sodium influx are phenytoin, fosphenytoin, carbamazepine, oxcarbazepine, valproic acid, topiramate, zonisamide, and lamotrigine. Valproic acid and ethosuximide are examples of drugs that suppress calcium influx. Examples of drug groups that enhance the action of GABA are barbiturates, benzodiazepines, and tiagabine. Gabapentin promotes GABA release.

Hydantoins

The first antiseizure drug used to treat seizures was phenytoin, a hydantoin discovered in 1938 and still commonly used for controlling seizures. **Hydantoins** inhibit sodium influx, stabilize cell membranes, reduce repetitive neuronal firing, and limit seizures. By increasing the electrical stimulation threshold in cardiac tissue, it also acts as an antidysrhythmic. It has a slight effect on general sedation, and it is nonaddicting. However, this drug should *not* be used during pregnancy because it can have a **teratogenic** effect on the fetus.

Patient Safety

Do not confuse:

- **Cerebyx,** a hydantoin antiseizure drug, with **Celebrex,** a nonsteroidal antiinflammatory drug (NSAID). The names of these drugs look and sound alike but are different in their pharmacology.

Drug dosage for phenytoin and other antiseizure drugs is age related. Newborns, persons with liver disease, and older adults require a lower dosage because of a decrease in metabolism that results in more available drug. Conversely, individuals with an increased metabolic rate, such as children, may require an increased dosage. The drug dosage is adjusted according to the therapeutic plasma or serum level. Phenytoin has a narrow therapeutic range of 10 to 20 mcg/mL, which is generally considered equivalent to 1 to 2 mcg/mL unbound or free phenytoin. The benefits of an antiseizure drug become apparent when the serum drug level is within the therapeutic range. Typically, if the drug level is below the desired range, the patient is not receiving the required drug dosage to control seizure activity. If the drug level is above the desired range, drug toxicity may result. Monitoring the therapeutic serum drug range is of utmost importance to ensure drug effectiveness. Prototype Drug Chart 19.1 lists the pharmacologic data associated with phenytoin.

Pharmacokinetics

Phenytoin is slowly absorbed from the small intestine. It is a highly protein-bound (90% to 95%) drug, therefore a decrease in serum protein or albumin can increase the free phenytoin serum level. With a small to average drug dose, the half-life of phenytoin is approximately 24 hours, but the range can be from 7 to 42 hours. Phenytoin is metabolized to inactive metabolites, and this portion is excreted in the urine.

Pharmacodynamics

The pharmacodynamics of orally administered phenytoin include onset of action within 30 minutes to 2 hours, peak serum concentration in 1.5 to 6 hours, steady state of serum concentration in 7 to 10 days, and a duration of action dependent on the half-life of up to 45 hours. Oral phenytoin is most commonly ordered as a sustained-release (SR) capsule. The peak SR concentration time is 4 to 12 hours.

Intravenous (IV) infusion of phenytoin should be administered by direct injection into a large vein via a central line or peripherally inserted central catheter (PICC). The drug may be diluted in saline solution; however, dextrose solution should be avoided because of drug precipitation. The manufacturer recommends use of an in-line filter when the drug is administered as an infusion. IV phenytoin, 50 mg or a fraction thereof, should be administered over 1 minute for adults and at a rate of 25 mg/min for older adults. Infusion rates of more than 50 mg/min may cause severe hypotension or cardiac dysrhythmias, especially for older and debilitated patients. Local irritation at the injection site may be noted, and **sloughing**—formation of dead tissue that separates from living tissue—may occur. The IV line should always be flushed with saline before and after each dose to reduce venous irritation. Intramuscular (IM) injection of phenytoin irritates tissues and may cause damage. For this reason, and because of its erratic absorption rate, phenytoin is *not* given by the IM route.

PROTOTYPE DRUG CHART 19.1 Phenytoin

Drug Class	Dosage
Anticonvulsant: Hydantoin Pregnancy category: D*	Seizure prophylaxis: A: PO: 4-7 mg/kg/d in 2-3 divided doses
	Status epilepticus: A/adol/C/infants: IV: LD: 15-20 mg/kg, then in 10 min may give 5-10 mg/kg PRN; *max:* LD: 30 mg/kg, rate: 50 mg/min and 25 mg/min for older adults Therapeutic serum range: 10-20 mcg/mL Toxic level: 30-50 mcg/mL
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, heart block, bradycardia, Adams-Stokes syndrome *Caution:* Hyponatremia, hypotension, hypoglycemia, suicidal ideation, myasthenia gravis, thyroid disease, alcoholism, diabetes mellitus, renal and hepatic impairment, Asian	Drug: Increased effects with cimetidine, isoniazid, chloramphenicol; decreased effects with folic acid, calcium, antacids, sucralfate, vinblastine, cisplatin
	Decreases effects of anticoagulants, oral contraceptives, antihistamines, corticosteroids, theophylline, cyclosporine, quinidine, dopamine, and rifampin
	Food: Decreases effects of folic acid, calcium, and vitamin D because absorption is decreased by phenytoin
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Slowly absorbed; IM: Erratic rate of absorption Distribution: PB: 90%-95% Metabolism: t½: 7-42 h Excretion: In urine, small amount; in bile and feces, moderate amounts	PO: Onset: 0.5-2 h Peak: 1.5-6 h Duration: 6-12 h IV: Onset: Within minutes to 1 h Peak: 2 h moderate amount Duration: >12 h
Therapeutic Effects/Uses	
To prevent tonic-clonic and partial seizures and status epilepticus	
Mode of action: Reduces motor cortex activity by altering ion transport	
Side Effects	Adverse Reactions
Headache, diplopia, nystagmus, confusion, dizziness, drowsiness, insomnia, fatigue, ataxia, tremor, rash, gingival hyperplasia, anorexia, nausea, vomiting, hirsutism, pink-red/brown discoloration of urine	Leukopenia, hepatic impairment, depression, hyperglycemia, bradycardia, peripheral neuropathy, purple glove syndrome *Life threatening:* Aplastic anemia, thrombocytopenia, agranulocytosis, Stevens-Johnson syndrome, hypotension, ventricular fibrillation, suicidal ideation

>, Greater than; *A,* adult; *adol,* adolescent; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Side Effects and Adverse Reactions

The adverse effects of hydantoins include psychiatric effects such as depression, suicidal ideation, Stevens-Johnson syndrome, ventricular fibrillation, and blood dyscrasias, such as thrombocytopenia (low platelet count), leukopenia (low white blood cell count), and purple glove syndrome (swollen, discolored, and painful extremities that may require amputation). Patients on

hydantoins for long periods might have elevated blood glucose (hyperglycemia) that results from the drug inhibiting the release of insulin. Less severe side effects include nausea, vomiting, **gingival hyperplasia** (overgrowth of gums or reddened gums that bleed easily), constipation, drowsiness, headaches, slurred speech, confusion, alopecia, hirsutism, and **nystagmus** (constant, involuntary, cyclical movement of the eyeball).

Drug-Drug Interactions

Drug interaction is common with hydantoins because they are highly protein bound. Hydantoins compete with other drugs (e.g., anticoagulants, aspirin) for plasma protein-binding sites. The hydantoins displace anticoagulants and aspirin, causing more free-drug availability and increasing their activity. Barbiturates, rifampin, and chronic ingestion of ethanol increase hydantoin metabolism. Drugs like sulfonamides and cimetidine can increase the action of hydantoins by inhibiting liver metabolism, which is necessary for drug excretion. Antacids, calcium preparations, sucralfate, and antineoplastic drugs also decrease the absorption of hydantoins. Antipsychotics and certain herbs can lower the **seizure threshold**, the level at which seizure may be induced, and they increase seizure activity (Complementary and Alternative Therapies 19.1). The patient should be closely monitored for seizure occurrence.

Barbiturates

Phenobarbital, a long-acting barbiturate, is prescribed to treat tonic-clonic, partial, and myoclonic seizures and **status epilepticus**, a rapid succession of epileptic seizures. Barbiturates reduce seizures by enhancing the activity of GABA, an inhibitory neurotransmitter. Possible teratogenic effects and other side effects related to phenytoin are less pronounced with phenobarbital. The therapeutic serum range of phenobarbital is 20 to 40 mcg/mL. Risks associated with the use of phenobarbital include sedation and tolerance to the drug. Discontinuance of phenobarbital should be gradual to avoid recurrence of seizures.

Succinimides

The succinimide drug group is used to treat absence seizures. Succinimides act by decreasing calcium influx through the T-type calcium channels. The therapeutic serum range of ethosuximide is 40 to 100 mcg/mL. Adverse effects include blood dyscrasias, renal and liver impairment, and systemic lupus erythematosus.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 19.1 Antiseizure Drugs

- Evening primrose and borage may lower the seizure threshold when taken with antiseizure drugs. The antiseizure dose may need modification.
- Ginkgo may decrease phenytoin effectiveness.

Benzodiazepines

The benzodiazepines that have antiseizure effects are clonazepam, clorazepate dipotassium, lorazepam, and diazepam. Clonazepam is effective in controlling absence and myoclonic seizures, but tolerance may occur 6 months after drug therapy starts; consequently, clonazepam dosage must be adjusted. Clorazepate dipotassium is administered for treating partial seizures.

Diazepam is administered by IV to treat status epilepticus. The drug has a short-term effect; thus other antiseizure drugs, such as phenytoin or phenobarbital, must be given during or immediately after administration of diazepam.

Iminostilbenes

Carbamazepine, an iminostilbene, is used to control tonic-clonic and partial seizures. Carbamazepine is also used for psychiatric disorders (e.g., bipolar disorder), trigeminal neuralgia

(as an analgesic), and alcohol withdrawal. The therapeutic serum range of carbamazepine is 4 to 12 mcg/mL.

A potentially toxic interaction can occur when grapefruit juice is taken with carbamazepine, and drug concentrations must be carefully monitored.

Valproate

Valproic acid is prescribed for tonic-clonic, absence, and mixed types of seizures, although the safety and efficacy of this drug has not been established for children younger than 2 years of age. Care should be taken when giving this drug to very young children and to patients with liver disorders because hepatotoxicity is one of the possible adverse reactions. Liver enzymes should be monitored. The therapeutic serum range for a patient with seizures is 50 to 100 mcg/mL.

Table 19.2 lists the various antiseizure drugs and their dosages, uses, and considerations, including common side effects and a few serious adverse effects. Table 19.3 lists selected antiseizure drugs frequently prescribed to treat seizure disorders.

Antiseizure drug dosages usually start low and gradually increase over a period of weeks until the serum drug level is within therapeutic range or the seizures cease. Serum antiseizure drug levels should be closely monitored to prevent toxicity.

Antiseizure Drugs and Pregnancy

During pregnancy, seizure episodes increase 25% in women with epilepsy. Hypoxia that may occur during seizures places both the pregnant woman and her fetus at risk.

Many antiseizure drugs have teratogenic properties that increase the risk for fetal malformations. Phenytoin and carbamazepine have been linked to fetal anomalies such as cardiac defects and cleft lip and palate. It has been reported that valproic acid is known to cause major congenital malformations in infants in 4% to 8% of pregnant women who take the drug. As expected, the highest incidence of birth defects occurs when the woman takes combinations of antiseizure drugs.

TABLE 19.2

Anticonvulsants

Drug	Route and Dosage	Uses and Considerations
Barbiturates		
Phenobarbital CSS IV	Status epilepticus: A/C: IV: 15-18 mg/kg; *max:* 30 mg/kg Adol/C/infants: IV: 15-20 mg/kg; *max*: 40 mg/kg Seizure prophylaxis: A: PO/IM/IV: 1-3 mg/kg/d in 1-2 divided doses Adol/C >7 y: PO/IM/IV: 3-6 mg/kg/d in 1-2 divided doses Infants/C <6 y: PO/IM/IV: 4-8 mg/kg/d in 1-2 divided doses Therapeutic serum range: 15-40 mcg/mL	For tonic-clonic, myoclonic, and partial seizures; status epilepticus; sedation induction and maintenance; and insomnia. May cause dizziness, drowsiness, confusion, hypotension, bradycardia, ataxia, constipation, erectile dysfunction, depression, and suicidal ideation. High doses for adults may lead to dependence, respiratory depression, and coma. Pregnancy category: D*; PB: 20%-45%; t½: A: 50-120 h; C: 37-69 h, Infants: 47-63 h
Primidone	Seizure prophylaxis: A/adol/C >8 y: PO: 125-250 mg/d at bedtime; maint: 750-1500 mg/d; *max:* 2g/d C <8 y: PO: 50-125 mg/d; maint: 10-25 mg/kg/d in 3-4 divided doses; *max:* 25 mg/kg/d Neonates: 12-20 mg/kg/d in 2-4 divided doses; *max*: 20 mg/kg/d Therapeutic serum range: 5-12 mcg/mL	For tonic-clonic and partial seizures. Take with food if drug causes GI distress. May cause confusion, hypotension, respiratory depression, Stevens-Johnson syndrome, dependence, depression, and suicidal ideation. Pregnancy category: D*; PB: 20%-45%; t½: 10-12 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Benzodiazepines (Anxiolytics)		
Clonazepam CSS IV	Seizure prophylaxis: A/adol >30 kg: PO: Initially 1.5 mg/d in 3 divided doses; gradually increase dose q3d until seizures are controlled *max:* 20 mg/d C <10 y <30 kg: PO: Initially 0.01-0.03 mg/kg/d in 3 divided doses; *max:* 0.2 mg/kg/d	For absence and myoclonic seizures, Lennox-Gastaut syndrome, and panic disorder. May cause dizziness, drowsiness, ataxia, fatigue, dependence, depression, and suicidal ideation. Pregnancy category: D*; PB: 85%; t½: 22-33 h
Clorazepate CSS IV	Seizure prophylaxis: A/adol: PO: 7.5 mg bid/tid; *max:* 60 mg/d C 9-12 y: PO: 3.75-7.5 mg bid; *max:* 60 mg/d	May be used for partial seizures, anxiety, and alcohol withdrawal. May cause blurred vision, amnesia, confusion, dizziness, drowsiness, tolerance, dependence, withdrawal, hypotension, depression, and suicidal ideation. Pregnancy category: D*; PB: 97%; t½: 30-200 h
Diazepam CSS IV	Status epilepticus: A: IV: 5-10 mg at 10-15 min intervals; *max:* 30 mg C >5 y: IV 1 mg/kg q2-5 min slowly; *max:* 10 mg C <5 y: IV: 0.2-0.5 mg q2-5min; *max:* 5 mg Seizure prophylaxis: A: PO: 2-10 mg bid-qid Older A: PO: 2-2.5 mg qd-bid Adol/C/infants >6 mo: PO: 1-2.5 mg tid-qid	For status epilepticus (drug of choice), partial and tonic-clonic seizures, muscle spasms, anxiety, sedation induction, and alcohol withdrawal. May cause confusion, drowsiness, dysarthria, fatigue, tolerance, dependence, withdrawal, paradoxical aggressiveness, and rage. Administer IV slowly to avoid respiratory depression and hypotension; Pregnancy category: D*; PB: 99%; t½: 30-60 h
Lorazepam CSS IV	Status epilepticus: A: IV: 4 mg at 2 mg/min may repeat in 10-15 min	To control status epilepticus, anxiety, and insomnia and for sedation induction. May cause blurred vision, drowsiness, dizziness, headache, respiratory depression, dependence, and suicidal ideation. Pregnancy category: D*; PB: 91%; t½: 12 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Hydantoins		
Fosphenytoin	Status epilepticus: A: IV: Initially 15-20 mg PE/kg; do not exceed 150 mg PE/min; may give additional 5-10 mg PE/kg PRN; *max*: 30 mg PE/kg	For tonic-clonic and partial seizures and status epilepticus. IV fosphenytoin should only be given if oral phenytoin is not an option. Dilute in D_5W or 0.9% NaCl. May cause dizziness, drowsiness, nystagmus, gingival hyperplasia, tinnitus, ataxia, headache, pruritus, and hypotension. Use mandated precautions for handling and disposal of hazardous agent. Pregnancy category: D*; PB: 95%-99%; t½: 7-42 h
Phenytoin	See Prototype Drug Chart 19.1.	
Iminostilbene		
Carbamazepine	Seizure prophylaxis: A/adol: PO: 200 mg bid; maint: 800-1200 mg/d; *max*: 1600 mg/d C 6-12 y: 100 mg bid; *max:* 1 g/d C <6 y: PO: 10-20 mg/kg/d in divided doses; *max*: 35 mg/kg/d Therapeutic serum range: 4-12 mcg/mL	For tonic-clonic and partial seizures, trigeminal neuralgia, neuropathic pain, and bipolar disorder. May cause dizziness, drowsiness, headache, blurred vision, ataxia, nausea, vomiting, weakness, anemia, agranulocytosis, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: D*; PB: 76%; t½: 25-65 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Oxcarbazepine	Immediate release: A/adol >16 y: PO: Initially 300 mg bid; increase to 2400 mg/d C 4-16 y: PO: Initially 8-10 mg/kg/d in 2 divided doses Extended release: A: PO: Initially 600 mg/d; maint: 1200-2400 mg/d	For partial seizures. Drug-level monitoring is not necessary. May cause dizziness, drowsiness, confusion, depression, diplopia, headache, nausea, vomiting, fatigue, ataxia, Stevens-Johnson syndrome, and infection. Use mandated procedure for handling and disposal of hazardous agent. Pregnancy category: C*; PB: 40%; t½: 2 h
Eslicarbazepine	A: PO: Initially 400 mg/d, may increase weekly; maint: 800-1600 mg/d; *max*: 1600 mg/d	For partial seizures. May cause dizziness, drowsiness, fatigue, headache, diplopia, nausea, vomiting, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: C*; PB: 40%; t½: 13-20 h
Succinimides		
Ethosuximide	A/adol/C >6 y: PO: Initially 250 mg bid; increase dose gradually; maint: 20-40 mg/kg/d; *max:* 1.5 g/d C 3-6 y: PO: Initially 15 mg/kg/d in 2 divided doses; maint: 15-40 mg/kg/d Therapeutic serum range: 40-100 mcg/mL	For absence seizures. Gastric irritation is common, so this drug may be taken with food. May cause dizziness, drowsiness, headache, nightmares, gingival hyperplasia, dyspepsia, ataxia, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: C*; PB: UK; t½: A, 60 h; C, 30 h
Valproate		
Valproate, valproic acid	Seizure prophylaxis: A/C >10 y: PO: 10-15 mg/kg/d in 2-3 divided doses; *max:* 60 mg/kg/d Therapeutic serum range: 50-100 mcg/mL	For partial, myoclonic, absence, and tonic-clonic seizures; bipolar disorder; and migraine prophylaxis. Avoid during pregnancy. Administer with food or increase dosing slowly to avoid GI distress. May cause dizziness, drowsiness, diplopia, asthenia, insomnia, ataxia, nausea, vomiting, diarrhea, suicidal ideation, and thrombocytopenia. Pregnancy category: D*; PB: 90%; t½: 6-16 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Miscellaneous		
Acetazolamide	Seizure prophylaxis: A: PO: 8-30 mg/kg/d in up to 4 divided doses; maint: 375-1000 mg/d; *max:* 1 g/d	For absence seizures, altitude sickness, glaucoma, and edema. Maintain adequate fluid intake to prevent renal impairment. May cause dizziness, drowsiness, confusion, depression, headache, ataxia, hypokalemia, hyponatremia, hypoglycemia, hyperglycemia, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 90%; t½: 10-15 h
Gabapentin	Seizure prophylaxis: A/adol: PO: Initially 300 mg tid; maint: 900-1800 mg/d in 3 divided doses; *max:* 3600 mg/d and max time between doses 12 h C 3-12 y: 10-15 mg/kg/d in 3 divided doses; maint: 25-35 mg/kg/d; *max:* 50 mg/kg/d	For partial seizures, restless leg syndrome, and neuropathic pain. May cause dizziness, drowsiness, hostility, nystagmus, fatigue, peripheral edema, and suicidal ideation. Give with food to avoid GI upset. High doses are limited to short-term use. Gradually reduce dose upon discontinuation. Pregnancy category: C*; PB: 3%; t½: 5-7 h
Lamotrigine	Partial seizures: Immediate release: A/adol >16 y: PO: Initially 50 mg/d; maint: 250 mg bid Extended release: A/adol: PO: Initially 50 mg/d; maint: 250-300 mg/d	For partial and tonic-clonic seizures, Lennox-Gastaut syndrome, and bipolar disorder. May cause dizziness, drowsiness, blurred vision, fatigue, nausea, vomiting, diarrhea, abdominal pain, ataxia, and suicidal ideation. Discontinue if rash appears; patient may develop *life-threatening* Stevens-Johnson syndrome. Pregnancy category: C*; PB: 55%; t½: 14-59 h
Levetiracetam	Immediate release: A: PO: Initially 500 mg bid; may increase dose q2wk; maint: 1500 mg bid; *max:* 3 g/d Extended release: A/adol/C >12 y: PO: 1 g/d; *max*: 3 g/d	For partial, tonic-clonic, and myoclonic seizures. May cause drowsiness, irritability, headache, anorexia, weakness, hypertension, Stevens-Johnson syndrome, psychosis, and suicidal ideation. Unlikely to cause drug interactions with commonly prescribed medications. Pregnancy category: C*; PB: <10%; t½: 6-8 h
Brivaracetam	A/adol >16 y: PO/IV: Initially 50 mg bid; *max*: 200 mg/d	For partial seizures. May cause dizziness, drowsiness, weakness, ataxia, nystagmus, psychosis, and suicidal ideation. Pregnancy category: C *; PB: <20%; t½: 9 h
Tiagabine	A/C >12 y: PO: 4 mg/d; maint: 32-56 mg/d; *max:* A, 56 mg/d; C, 32 mg/d	For partial seizures. May cause dizziness, drowsiness, memory impairment, depression, nausea, tremor, weakness, ataxia, infection, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: C*; PB: 96%; t½: 7-9 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Topiramate	Immediate release: A/adol/C >10 y: PO: Initially 25 mg bid; *max*: 400 mg/d Extended release: A/adol/C >10 y: PO: 50 mg/d; *max:* 400 mg/d	For partial and tonic-clonic seizures, Lennox-Gastaut syndrome, and migraine prophylaxis. May cause dizziness, drowsiness, memory impairment, nystagmus, infection, fatigue, dysgeusia, anorexia, paresthesia, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: D*; PB: 15%-41%; t½: 21 h
Zonisamide	A/adol >16 y: PO: 100 mg/d; may increase after 2 wk; *max:* 600 mg/d	For partial seizures. May cause dizziness, drowsiness, headache, confusion, insomnia, agitation, memory impairment, depression, fatigue, ataxia, anorexia, nausea, Stevens-Johnson syndrome, and suicidal ideation. Contraindicated for patients sensitive to sulfonamides. Pregnancy category: C*; PB: 40%; t½: 63 h
Magnesium sulfate	Preeclampsia or eclampsia: A: IV: Initially 4-6 g infusion of 1-2 g/h for at least 24 h or 4-5 g IM in alternate buttocks q4h until seizures cease; *max:* 20 g/48 h	For seizures caused by eclampsia or preeclampsia. Monitor Mg levels, BP, respirations, deep tendon reflexes, and urine output. May cause flushing, diaphoresis, hypotension, bradycardia, weakness, hyporeflexia, dysrhythmias, respiratory and cardiac arrest. Use extreme caution with myasthenia gravis. Pregnancy category: A*; PB: 30%; t½: UK
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Pregabalin	Partial seizures: A: PO: Initially 150 mg/d in 2-3 divided doses; *max:* 600 mg/d	For partial seizures, neuropathic pain, and fibromyalgia. May cause drowsiness, dizziness, blurred vision, dry mouth, tremor, peripheral edema, weight gain, ataxia, rhabdomyolysis, Stevens-Johnson syndrome, and suicidal ideation. Pregnancy category: C*; PB: 0%; t½: 6 h
Lacosamide	A/adol >17 y: PO/IV: Initially 100 mg bid; maint: 300-400 mg/d in 2 divided doses; *max*: 400 mg/d	For partial seizures. May cause dizziness, drowsiness, blurred vision, nystagmus, headache, ataxia, tremor, fatigue, nausea, and suicidal ideation. Pregnancy category: C *; PB: 15%; t½: 13 h
Ezogabine	A: PO: Initially 150 mg/d in 2-3 divided doses; maint: 200-400 mg tid; *max:* 1200 mg/d Older adult: PO: Initially 50 mg tid; *max:* 750 mg/d	For partial seizures. May cause dizziness, drowsiness, confusion, blurred vision, vision loss, fatigue, skin discoloration, tremor, and suicidal ideation. Pregnancy category: C*; PB: 80%; t½: 7 h
Felbamate	A/adol >14 y: PO: Initially 1200 mg/d in 3-4 divided doses; *max*: 3600 mg/d	For partial seizures and Lennox-Gastaut syndrome. May cause dizziness, diplopia, nervousness, anorexia, nausea, vomiting, constipation, aplastic anemia, and suicidal ideation. Pregnancy category: C*; PB: 22%-35%; t½: 13-23 h
Perampanel	A/C >12 y: PO: Initially 2 mg/d at bedtime; *max*: 12 mg/d	For partial and tonic-clonic seizures. May cause dizziness, drowsiness, headache, fatigue, irritability, psychosis, suicidal ideation. *Black-box warning* cautions *life-threatening* psychiatric and behavioral reactions such as aggression, hostility, anger, and homicidal ideation. Notify health care provider if any changes in mood, behavior, or personality occur. Pregnancy category: C*; PB: 95%-96%; t½: 105 h

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Antiseizure drugs tend to act as inhibitors of vitamin K, contributing to hemorrhage in infants shortly after birth. Frequently, pregnant women taking antiseizure drugs are given an oral vitamin K supplement during the last week or 10 days of the pregnancy, or vitamin K is administered to the infant soon after birth.

Antiseizure drugs also increase the loss of folate (folic acid) in pregnant women, thus pregnant individuals should take daily folate supplements.

Antiseizure Drugs and Febrile Seizures

Seizures associated with fever usually occur in children between 3 months and 5 years of age. Epilepsy develops in approximately 2.5% of children who have had one or more febrile seizures. Prophylactic antiseizure drug treatment such as phenobarbital or diazepam may be indicated for high-risk patients. Valproic acid should not be given to children younger than 2 years of age because of its possible hepatotoxic effect.

TABLE 19.3

Selected Anticonvulsants For Seizure Disorders

Seizure Disorder	Drug Therapy
Tonic-clonic	Phenytoin
	Carbamazepine
	Fosphenytoin
	Valproic acid
	Lamotrigine
	Primidone
	Phenobarbital
	Diazepam
	Levetiracetam
	Topiramate
Partial (complex secondarily generalized)	Phenytoin
	Carbamazepine
	Oxcarbazepine
	Levetiracetam
	Primidone
	Phenobarbital
	Tiagabine
	Topiramate
	Zonisamide
	Gabapentin
	Valproic acid
	Diazepam
	Fosphenytoin
	Lamotrigine
	Eslicarbazepine
	Clorazepate
	Pregabalin
	Ezogabine
	Lacosamide
	Felbamate
Absence (petit mal)	Ethosuximide
	Valproic acid
	Clonazepam
Myoclonic, atonic, atypical absence	Valproic acid
	Levetiracetam
	Clonazepam
Status epilepticus	Diazepam
	Fosphenytoin
	Lorazepam
	Phenytoin
	Phenobarbital

Nursing Process: Patient-Centered Collaborative Care

Antiseizure Drugs: Phenytoin

Assessment

- Obtain a health history that includes current drugs and herbs the patient uses. Report and document any probable drug-drug or herb-drug interactions.
- Assess the patient's knowledge regarding the medication regimen.
- Check urinary output to determine whether it is adequate (>1500 mL/d).
- Determine laboratory values related to renal and liver function. If both blood urea nitrogen (BUN) and creatinine levels are elevated, a renal disorder should be suspected. Elevated serum liver enzymes (alkaline phosphatase, alanine aminotransferase, gamma-glutamyl transferase, 59-nucleotidase) indicate a hepatic disorder.

Nursing Diagnoses

- Injury, Risk for
- Oral Mucous Membranes, Impaired related to blood dyscrasias
- Nutrition, Imbalanced: Less than Body Requirements related to anorexia
- Falls, Risk for

Planning

- Patient's seizure frequency will diminish.
- Patient will adhere to antiseizure drug therapy.
- Patient's side effects from phenytoin will be minimal.

Nursing Interventions

- Monitor serum drug levels of antiseizure medication to determine therapeutic range (10 to 20 mcg/mL).
- Encourage patient's compliance with medication regimen.
- Monitor patient's complete blood count (CBC) levels for early detection of blood dyscrasias.
- Use seizure precautions (environmental protection from sharp objects, such as table corners) for patients at risk for seizures.
- Determine whether the patient is receiving adequate nutrients; phenytoin may cause anorexia, nausea, and vomiting.
- Advise female patients who are taking oral contraceptives and antiseizure drugs to use an additional contraceptive method.

Patient Teaching

General

- Teach patients to shake suspension-form medications thoroughly before use to adequately mix the medication to ensure accurate dosage.
- Advise patients not to drive or perform other hazardous activities when initiating antiseizure therapy as drowsiness may occur.
- Counsel female patients contemplating pregnancy to consult with a health care provider because phenytoin and valproic acid may have a teratogenic effect.
- Monitor serum phenytoin levels closely during pregnancy because seizures tend to become more frequent due to increased metabolic rates.
- Warn patients to avoid alcohol and other CNS depressants because they can cause an added depressive effect on the body.
- Explain to patients that certain herbs can interact with antiseizure drugs (see Complementary and Alternative Therapy Box 19.1), and dose adjustment may be required.
- Encourage patients to obtain a medical alert identification card, medical alert bracelet, or tag that indicates their diagnosis and drug regimen.
- Teach patients not to abruptly stop drug therapy but rather to withdraw the prescribed drug gradually under medical supervision to prevent seizure rebound (recurrence of seizures) and

status epilepticus.
- Counsel patients about the need for preventive dental checkups.
- Warn patients to take their prescribed antiseizure drug, get laboratory tests as ordered, and keep follow-up visits with health care providers.
- Teach patients not to self-medicate with over-the-counter (OTC) drugs without first consulting a health care provider.
- Advise patients with diabetes to monitor serum glucose levels more closely than usual because phenytoin may inhibit insulin release, causing an increase in glucose level.
- Inform patients of the existence of national, state, and local associations that provide resources, current information, and support for people with epilepsy.

Diet
- Coach patients to take antiseizure drugs at the same time every day with food or milk.

Side Effects
- Tell patients that urine may be a harmless pinkish red or reddish brown color.
- Advise patients to maintain good oral hygiene and to use a soft toothbrush to prevent gum irritation and bleeding.
- Teach patients to report symptoms of sore throat, bruising, and nosebleeds, which may indicate a blood dyscrasia.
- Encourage patients to inform health care providers of adverse reactions such as gingivitis, nystagmus, slurred speech, rash, and dizziness. (Stevens-Johnson syndrome begins with a rash.)

Cultural Considerations
- Communicate respect for cultural beliefs concerning refusal or reluctance to take antiseizure medications daily for life; use an interpreter and the extended family as needed to help the patient understand the importance of keeping to a prescribed drug regimen.
- Use a written drug schedule in the patient's preferred language to support adherence to the prescribed drug regimen.
- Encourage patient compliance with follow-up by a community nurse.
- Show patient videos or pictures in their own cultural group when language barriers exist to help strengthen compliance with health interventions.

Evaluation
- Evaluate effectiveness of drugs in controlling seizures.
- Monitor serum phenytoin levels to determine whether they are within the desired range. High serum levels of phenytoin are frequently indicators of phenytoin toxicity.
- Monitor patients for hydantoin overdose. Initial symptoms are nystagmus and ataxia (impaired coordination). Later symptoms are hypotension, unresponsive pupils, and coma. Respiratory and circulatory support, as well as hemodialysis, are usually used in the treatment of phenytoin overdose.

Antiseizure Drugs and Status Epilepticus

Status epilepticus, a continuous seizure state, is considered a medical emergency. If treatment is not begun immediately, death could result. The choices of pharmacologic agents are diazepam administered by IV or lorazepam followed by IV administration of phenytoin. For continued seizures, midazolam or propofol and then high-dose barbiturates are used. These drugs should be administered slowly to avoid respiratory depression.

The pharmacologic behavior of specific anticonvulsants, including a few common side effects and severe adverse effects, is summarized in Table 19.2.

Critical Thinking Case Study

SS, a 26-year-old woman, takes phenytoin 100 mg three times daily to control tonic-clonic seizures. She and her husband are contemplating starting a family.

1. What action should the nurse take in regard to the patient's family planning?
   SS complains of frequent upset stomach and bleeding gums when brushing her teeth.
2. To decrease GI distress, what can be suggested?
3. To alleviate bleeding gums, what patient teaching for SS may be included?
4. The nurse checks SS's serum phenytoin level. What are the indications of an abnormal serum level? What appropriate actions should be taken?

NCLEX Study Questions

1. The nurse witnesses a patient's seizure involving generalized contraction of the body followed by jerkiness of the arms and legs. The nurse reports this as which type of seizure?
   a. Myoclonic
   b. Absence
   c. Tonic-clonic
   d. Psychomotor
2. Phenytoin has been prescribed for a patient with seizures. The nurse should include which appropriate nursing intervention in the plan of care?
   a. Report an abnormal phenytoin level of 18 mcg/mL.
   b. Monitor complete blood count levels for early detection of blood dyscrasias.
   c. Encourage the patient to brush teeth vigorously to prevent plaque buildup.
   d. Teach the patient to stop the drug immediately when passing pinkish-red or reddish-brown urine.
3. When administering phenytoin, the nurse realizes more teaching is needed if the patient makes which statement?
   a. "I must shake the oral suspension very well before pouring it in the dose cup."
   b. "I cannot drink alcoholic beverages when taking phenytoin."
   c. "I should take phenytoin 1 hour before meals."
   d. "I will need to get periodic dental checkups."
4. A patient is having absence seizures. Which of the following does the nurse expect to be prescribed for this type of seizure? (Select all that apply.)
   a. Phenytoin
   b. Phenobarbital
   c. Valproic acid
   d. Clonazepam
   e. Ethosuximide
5. A patient is admitted to the emergency department with status epilepticus. Which drug should the nurse most likely prepare to administer to this patient? (Select all that apply.)
   a. Diazepam
   b. Midazolam
   c. Gabapentin
   d. Levetiracetam
   e. Topiramate
6. The nurse should monitor the patient receiving phenytoin for which adverse effect?
   a. Psychosis
   b. Nosebleeds
   c. Hypertension
   d. Gum erosion
7. A nurse administering valproic acid to a patient checks the laboratory values and finds a serum range for valproic acid of 150 mcg/mL. What should the nurse do?
   a. Increase the daily dose to get the patient's level into the therapeutic range.
   b. Hold the morning dose but give the other scheduled dosages for the day.
   c. Ask the patient if he or she is having any adverse effects from the medication.
   d. Hold the medication and notify the health care provider.

Answers: 1, c; 2, b; 3, c; 4, c, d, e; 5, a, b; 6, b; 7, d.

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Summarize the pathophysiology of Parkinson's disease and Alzheimer disease.
- Contrast the actions of anticholinergics, dopaminergics, dopamine agonists, monoamine oxidase B (MAO-B) inhibitors, and catechol-*O*-methyltransferase (COMT) inhibitors in the treatment of Parkinson's disease.
- Compare the side effects of various antiparkinson drugs.
- Apply the nursing process to anticholinergics, dopaminergics, and acetylcholinesterase inhibitors.
- Differentiate the phases of Alzheimer disease with corresponding symptoms.
- Compare the side effects/adverse effects of acetylcholinesterase inhibitors used to treat Alzheimer disease.

KEY TERMS

acetylcholinesterase (AChE) inhibitors, p. 263

Alzheimer disease, p. 256
bradykinesia, p. 256
dopamine agonists, p. 257
dyskinesia, p. 262
dystonic movement, p. 259
parkinsonism, p. 256
Parkinson's disease, p. 256
pseudoparkinsonism, p. 257

http://evolve.elsevier.com/McCuistion/pharmacology/

Parkinson's disease is a chronic, progressive, neurologic disorder that affects the extrapyramidal motor tract, which controls posture, balance, and locomotion. Parkinson's disease is the most common form of parkinsonism, which is considered a syndrome, or a combination of similar symptoms, because of its major features: rigidity (abnormal increased muscle tone), **bradykinesia** (slow movement), gait disturbances, and tremors. Rigidity increases with movement. Postural changes caused by rigidity and bradykinesia include the chest and head thrust forward with the knees and hips flexed, a shuffling gait, and the absence of arm swing. Other characteristic symptoms are masked facies (no facial expression), involuntary tremors of the head and neck, and pill-rolling motions of the hands. The tremors may be more prevalent at rest.

Alzheimer disease is a chronic, progressive, neurodegenerative condition with marked cognitive dysfunction. Various theories exist as to the cause of Alzheimer disease, with neuritic plaques, degeneration of the cholinergic neurons, and deficiency in acetylcholine among them.

Parkinson's Disease

In 1817, Dr. James Parkinson described six patients as having "shaking palsy." Three symptoms were described by Parkinson: (1) involuntary tremors of the limbs, (2) rigidity of muscles, and (3) slowness of movement. In the United States, approximately one million people have Parkinson's disease, and 60,000 new cases are diagnosed each year. Because Parkinson's disease generally affects patients 50 years of age and older, many consider the health problem to be part of the aging process caused by loss of neurons. The cardinal symptoms are rigidity, tremors, gait disturbance, and bradykinesia. Normally the symptoms have a gradual onset and are usually mild and unilateral in the beginning.

There are different types of parkinsonism. **Pseudoparkinsonism** frequently occurs as an adverse reaction to chlorpromazine, haloperidol, lithium, metoclopramide, methyldopa, and reserpine. In addition, parkinsonism symptoms could result from poisons, such as carbon monoxide and manganese, or from disorders, such as arteriosclerosis, encephalitis, infections, stroke, trauma, or Wilson disease (hepatolenticular degeneration). Parkinson's disease is the most common type, which is a degeneration of dopaminergic neurons leading to a lack of dopamine.

Nonpharmacologic Measures

Symptoms of Parkinson's disease can be lessened through the use of nonpharmacologic measures such as patient teaching, exercise, nutrition, and group support. Exercise can improve mobility and flexibility; the patient with Parkinson's disease should enroll in a therapeutic exercise program tailored to this disorder. A balanced diet with fiber and fluids helps prevent constipation and weight loss. Patients with Parkinson's disease and their family members should be encouraged to attend a support group to help cope with and understand this disorder.

Pathophysiology

Parkinson's disease is caused by an imbalance of the neurotransmitters dopamine and acetylcholine, and it is marked by degeneration of neurons of the extrapyramidal (motor) tract in the substantia nigra of the midbrain. The reason for the degeneration of neurons is unknown.

The two neurotransmitters within the neurons of the striatum of the brain are dopamine (DA), an inhibitory neurotransmitter, and acetylcholine (ACh), an excitatory neurotransmitter. DA is released from the dopaminergic neurons, and ACh is released from the cholinergic neurons. DA normally maintains control of ACh and inhibits its excitatory response. In Parkinson's disease, an unexplained degeneration of the dopaminergic neurons occurs, and an imbalance between DA and ACh results. With less DA production, the excitatory response of ACh exceeds the inhibitory response of DA. An excessive amount of ACh stimulates neurons that release gamma-aminobutyric acid (GABA). With increased stimulation of GABA, the symptomatic movement disorders of Parkinson's disease occur.

By the time early symptoms of Parkinson's disease appear, 80% of the striatal dopamine has already been depleted. The remaining striatal neurons synthesize DA from levodopa and release DA as needed. Before the next dose of levodopa, symptoms such as slow walking and loss of dexterity return or worsen, but within 30 to 60 minutes of receiving a dose, the patient's functioning is much improved.

Drugs used to treat Parkinson's disease replace the dopamine deficit and reduce the symptoms. These drugs fall into five categories: (1) anticholinergics, which block cholinergic receptors; (2) dopamine replacements, which stimulate DA receptors; (3) **dopamine agonists**, which stimulate DA receptors; (4) monoamine oxidase B (MAO-B) inhibitors, which inhibit the MAO-B enzyme that interferes with DA; and (5) catechol-*O*-methyltransferase (COMT) inhibitors, which inhibit the COMT enzyme that inactivates DA. Table 20.1 compares the various drugs for Parkinson's disease.

TABLE 20.1

Comparison of Drugs Used to Treat Parkinson's Disease

Drug	Purpose
Dopaminergics	
Carbidopa-levodopa	To decrease symptoms of Parkinson's disease and parkinsonism; carbidopa, a decarboxylase inhibitor, permits more levodopa to reach the striatum nerve terminals, where levodopa is converted to dopamine. With the use of carbidopa, less levodopa is needed.
Dopamine Agonists	
Amantadine	First used as an antiviral drug for influenza A, amantadine decreases symptoms of Parkinson's disease and parkinsonism. It can be used for early treatment of parkinsonism, which could delay the necessity of levodopa. It is effective in treating drug-induced parkinsonism and has fewer side effects than anticholinergics.
Bromocriptine	A D_2-dopamine receptor agonist, bromocriptine can be used for early treatment of Parkinson's disease. With increasing motor symptoms, it can be given with levodopa therapy.
Pramipexole, Ropinirole hydrochloride	These D_2- and D_3-dopamine receptor agonists can be used in combination with carbidopa-levodopa and have fewer side effects than older dopamine agonists.
Monoamine Oxidase B Inhibitors	
Selegiline hydrochloride	Selegiline inhibits catabolic enzymes of dopamine and extends its action. It can be used for early treatment of Parkinson's disease and parkinsonism. If given with carbidopa-levodopa, the dosage of carbidopa-levodopa is usually decreased.
Rasagiline	Rasagiline inhibits the breakdown of dopamine at synapses in the brain and allows neurons to reabsorb more dopamine for use later.
Catechol-*O*-Methyltransferase (COMT) Inhibitors	
Entacapone, Tolcapone	These inhibit the COMT enzyme and increase the concentration of levodopa. and are used in combination with levodopa-carbidopa. With COMT inhibitors, a smaller dose of levodopa is needed.
Anticholinergics and Antiparkinson Drugs	
	The first group of drugs used to treat Parkinson's disease before levodopa and dopamine agonists were introduced, these were useful in decreasing tremors related to Parkinson's disease. The major use of these agents currently is to treat drug-induced parkinsonism. Treatment starts with a low dosage that is gradually increased. Older adults are more susceptible to the many side effects of anticholinergics, and patients with memory loss or dementia should *not* be on anticholinergic therapy.

Anticholinergics

Anticholinergic drugs reduce the rigidity and some of the tremors characteristic of Parkinson's disease but have a minimal effect on bradykinesia. The anticholinergics are parasympatholytics that inhibit the release of acetylcholine. Anticholinergics are still used to treat drug-induced parkinsonism, or pseudoparkinsonism, a side effect of the antipsychotic phenothiazine drug group. Examples of anticholinergics used for Parkinson's disease include trihexyphenidyl and benztropine.

Nursing Process: Patient-Centered Collaborative Care

Antiparkinson Anticholinergic Agents

Assessment

- Obtain a health history. Report any history of glaucoma, gastrointestinal (GI) dysfunction, urinary retention, angina, or myasthenia gravis. All anticholinergics are contraindicated if a patient has glaucoma.
- Obtain a drug history. Report any probable drug-drug interactions, such as with phenothiazines, tricyclic antidepressants (TCAs), and antihistamines, which increase the effect of trihexyphenidyl.
- Assess baseline vital signs for future comparisons. The pulse rate may increase.
- Assess the patient's knowledge regarding the medication regimen.
- Determine usual urinary output as a baseline for comparison. Urinary retention may occur with continuous use of anticholinergics.

Nursing Diagnoses

- Mobility, Impaired Physical related to muscle rigidity, tremors, and bradykinesia
- Elimination, Impaired Urinary related to urinary retention
- Knowledge, Deficient related to unfamiliarity with drug regimen

Planning

- Patient will have decreased involuntary symptoms caused by Parkinson's disease or drug-induced parkinsonism.

Nursing Interventions

- Monitor vital signs, urine output, and bowel sounds. Increased pulse rate, urinary retention, and constipation are side effects of anticholinergics.
- Observe for involuntary movements.

Patient Teaching

General

- Advise patients to avoid alcohol, cigarettes, caffeine, and aspirin to decrease gastric acidity.

Side Effects

- Encourage patients to relieve a dry mouth with hard candy, ice chips, or sugarless chewing gum. Anticholinergics decrease salivation.
- Suggest that patients use sunglasses in direct sunlight because of possible photophobia.
- Advise patients to void before taking the drug to minimize urinary retention.
- Counsel patients who take an anticholinergic for control of symptoms of Parkinson's disease to have routine eye examinations because anticholinergics are contraindicated in patients with glaucoma.

Diet

- Encourage patients to ingest foods high in fiber and to increase fluid intake to prevent constipation.

Cultural Considerations

- Assess personal beliefs of patients and family, and modify communications to meet cultural needs; use an interpreter and community nurse follow-up as needed.

Evaluation

- Evaluate the patient's response to trihexyphenidyl or benztropine mesylate to determine whether Parkinson's disease symptoms are controlled.

Table 20.2 lists the anticholinergics and their dosages, uses, and considerations. Anticholinergics used to treat Parkinson's disease are also discussed in Chapter 16.

Dopaminergics

Carbidopa and Levodopa

The first dopaminergic drug was levodopa, which was introduced in 1961 but is no longer available in the United States. When introduced, levodopa was effective in diminishing symptoms of Parkinson's disease and increasing mobility; this is because the blood-brain barrier admits levodopa but not dopamine. The enzyme dopa decarboxylase converts levodopa to dopamine in the brain, but this enzyme is also found in the peripheral nervous system and allows 99% of levodopa to be converted to dopamine *before* it reaches the brain. Therefore only about 1% of levodopa taken is available to be converted to dopamine once it reaches the brain, and large doses are needed to achieve a pharmacologic response. These high doses could cause many side effects, including nausea, vomiting, dyskinesia, orthostatic hypotension, cardiac dysrhythmias, and psychosis.

Because of the side effects of levodopa and the fact that so much levodopa is metabolized before it reaches the brain, an alternative drug, carbidopa, was developed to inhibit the enzyme dopa decarboxylase. By inhibiting the enzyme in the peripheral nervous system, more levodopa reaches the brain. The carbidopa is combined with levodopa in a ratio of 1 part carbidopa to 10 parts levodopa. Fig. 20.1 illustrates the comparative action of levodopa and carbidopa-levodopa.

The advantages of combining levodopa with carbidopa are that more dopamine reaches the basal ganglia and that smaller doses of levodopa are required to achieve the desired effect. The disadvantage of the carbidopa-levodopa combination is that with more available levodopa, more side effects may occur, which may include nausea, vomiting, **dystonic movement** (involuntary abnormal movement), and psychotic behavior. The peripheral side effects of levodopa are not as prevalent; however, angioedema, palpitations, and orthostatic hypotension may occur. Prototype Drug Chart 20.1 lists the pharmacologic behavior of carbidopa-levodopa.

TABLE 20.2

Antiparkinson Drugs: Anticholinergics

Drug	Route and Dosage	Uses and Considerations
Benztropine mesylate	Parkinson's disease: A: PO/IM: Initially 0.5-1 mg/d at bedtime; *maint:* 0.5-6 mg/d; *max:* 8 mg/d Drug-induced parkinsonism: A: IV/IM/PO: 1-4 mg qd/bid	For Parkinson's disease, tremor, and drug-induced parkinsonism. Contraindicated in glaucoma and dementia. May cause blurred vision, ocular hypertension, weakness, dry mouth, nausea, constipation, anhidrosis, and urinary retention. Pregnancy category: C*; PB: UK; t½: UK
Trihexyphenidyl hydrochloride	Parkinson's disease: A: PO: Initially 1 mg, then increase by 2 mg q3-5d; maint: 6-10 mg/d; *max:* 15 mg/d Extended release:	For Parkinson's disease and drug-induced pseudoparkinsonism. May cause dizziness, drowsiness, increased intraocular pressure, anxiety, headache, insomnia, weakness, paresthesia, dry mouth, nausea, vomiting, constipation, restlessness, and urinary retention. Pregnancy category: C*; PB: UK; t½: UK

	A: PO: 5-10 mg after breakfast or in 2 divided doses 12 h apart Drug-induced parkinsonism: A: PO: Initially 1 mg; maint: 5-15 mg/d	

A, Adult; *bid,* two times a day; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *qd,* every day; *q3-5d,* every 3 to 5 days; *t½*, half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

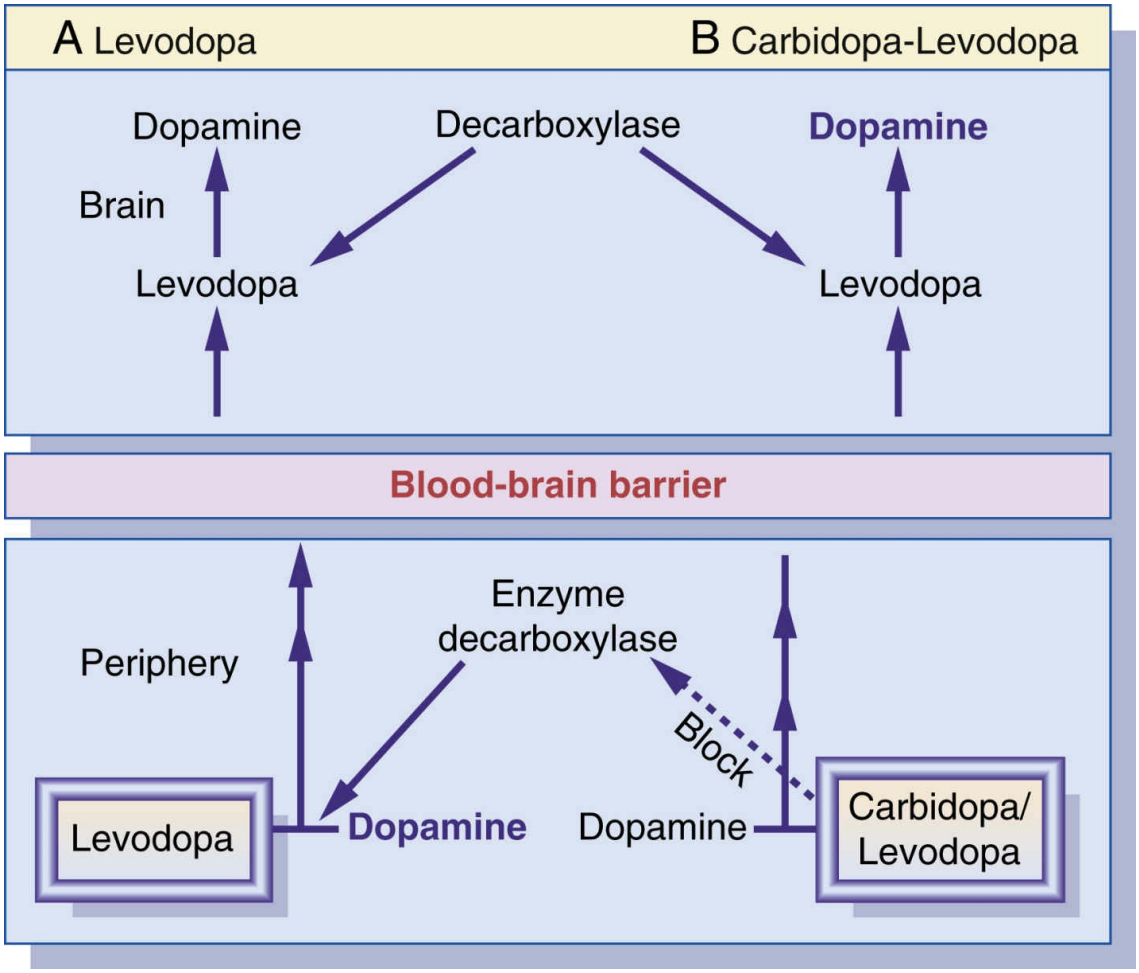

FIG. 20.1 **A**, When levodopa is used alone, only 1% reaches the brain because 99% converts to dopamine while in the peripheral nervous system. **B**, By combining carbidopa with levodopa, carbidopa can inhibit the enzyme decarboxylase in the periphery, thereby allowing more levodopa to reach the brain.

Nursing Process: Patient-Centered Collaborative Care

Antiparkinson Dopaminergic Agents: Carbidopa-Levodopa

Assessment

- Obtain vital signs to use for future comparisons.
- Assess patients for signs and symptoms of Parkinson's disease, including stooped forward posture, shuffling gait, masked facies, and resting tremors.
- Obtain a patient history that includes glaucoma, heart disease, peptic ulcers, kidney or liver disease, and psychosis.
- Obtain a drug history. Report if drug-drug interaction is probable. Drugs that should be avoided or closely monitored are carbidopa-levodopa, bromocriptine, and anticholinergics.

Nursing Diagnoses

- Mobility, Impaired Physical related to dizziness
- Activity Intolerance, Risk for
- Falls, Risk for
- Knowledge, Deficient related to unfamiliar medications

Planning

- Patient's symptoms of Parkinson's disease will be decreased or absent after 1 to 4 weeks of drug

therapy.

Nursing Interventions

- Monitor vital signs and electrocardiogram. Orthostatic hypotension may occur during early use of carbidopa-levodopa and bromocriptine. Instruct patients to rise slowly to avoid faintness.
- Observe for weakness, dizziness, or syncope, which are symptoms of orthostatic hypotension.
- Administer carbidopa-levodopa with low-protein foods. High-protein diets interfere with drug transport to the central nervous system (CNS).
- Observe for symptoms of Parkinson's disease.

Patient Teaching

General

- Urge patients not to abruptly discontinue the medication. Rebound Parkinson's disease (increased symptoms of Parkinson's disease) can occur.
- Inform patients that urine may be discolored and will darken with exposure to air. Perspiration may also be dark. Explain that both are harmless, but clothes may be stained.
- Advise patients to avoid chewing or crushing extended-release tablets.

Side Effects

- Encourage patients to report side effects and symptoms of dyskinesia. Explain that it may take weeks or months before symptoms are controlled.

Diet

- Suggest to patients that taking carbidopa-levodopa with food may decrease GI upset, but food will slow the rate of drug absorption.
- Urge patients who take high doses of selegiline to avoid foods high in tyramine such as aged cheese, red wine, cream, yogurt, chocolate, bananas, and raisins to prevent hypertensive crisis.

Amantadine and Bromocriptine

- Urge patients taking amantadine to report any signs of skin lesions, seizures, or depression. A history of these health problems should have been previously reported to a health care provider.
- Advise patients taking bromocriptine to report symptoms of lightheadedness when changing positions, a symptom of orthostatic hypotension.
- Warn patients to avoid alcohol when taking bromocriptine.
- Teach patients to check their heart rate and report rate changes or irregularity.
- Counsel patients not to abruptly stop the drug without first notifying a health care provider.

Cultural Considerations

- Recognize that various cultural groups will need guidance in understanding the disease process of Parkinson's disease. Support patients and family members who may be dismayed about the symptoms of Parkinson's disease and lack knowledge of the disease process.
- Secure an interpreter for patients who speak little or no English to support understanding of drug doses and schedules and recognition of severe side effects that need to be reported to a health care provider.

Evaluation

- Evaluate effectiveness of drug therapy in controlling symptoms of Parkinson's disease.
- Determine if there is an absence of side effects.
- Determine if the patient and family have increased knowledge of the drug regimen.

Dopamine Agonists

Other dopamine agonists, also called *dopaminergics,* stimulate the dopamine receptors. For example, amantadine hydrochloride is an antiviral drug that acts on the dopamine receptors. It may be taken alone or in combination with carbidopa-levodopa or an anticholinergic drug. Initially, amantadine produces improvement in symptoms of Parkinson's disease and parkinsonism in approximately two-thirds of patients, but this improvement is usually not sustained because drug tolerance develops. Amantadine can also be used to treat drug-induced parkinsonism.

Bromocriptine mesylate acts directly on dopamine receptors in the CNS, cardiovascular system, and GI tract. Bromocriptine is more effective than amantadine and the anticholinergics; however, it

is not as effective as carbidopa-levodopa in alleviating Parkinson's disease symptoms. Patients who do not tolerate carbidopa-levodopa are frequently given bromocriptine.

Monoamine Oxidase B Inhibitors

The enzyme MAO-B causes catabolism (breakdown) of dopamine. Selegiline inhibits MAO-B and thus prolongs the action of levodopa. It may be ordered for patients newly diagnosed with Parkinson's disease or parkinsonism. The use of selegiline could delay carbidopa-levodopa therapy by 1 year. It decreases "on-off" fluctuations. Rasagiline is an MAO-B inhibitor used for the treatment of Parkinson's disease.

Large doses of selegiline may inhibit MAO-A, an enzyme that promotes metabolism of tyramine in the GI tract. If they are not metabolized by MAO-A, ingestion of foods high in tyramine—such as aged cheese, red wine, and bananas—can cause a hypertensive crisis. Severe adverse drug interactions can occur between selegiline and various TCAs or selective serotonin reuptake inhibitors (SSRIs).

Catechol-*O*-Methyltransferase Inhibitors

The enzyme COMT inactivates dopamine. When taken with a levodopa preparation, COMT inhibitors increase the amount of levodopa concentration in the brain. Tolcapone was the first COMT inhibitor to be given with levodopa for advanced Parkinson's disease. This drug can affect liver cell function, therefore serum liver enzymes should be closely monitored. Entacapone does not affect liver function. In 2003, the U.S. Food and Drug Administration (FDA) approved a combination drug of dopaminergics (carbidopa and levodopa) and a COMT inhibitor (entacapone). With various dosage strengths available, this drug combination of carbidopa, levodopa, and entacapone provides greater dosing flexibility and individualization to the patient. This drug combination lessens the "wearing off" effects of levodopa that are sometimes experienced prior to the next dose.

Table 20.3 lists dopaminergics, dopamine agonists, MAO-B inhibitors, and COMT inhibitors with their dosages, uses, and considerations.

PROTOTYPE DRUG CHART 20.1 Carbidopa-Levodopa

Drug Class	Dosage
Antiparkinson: Dopamine replacement Pregnancy category: C*	Immediate release: A: PO: Initially 1 tablet containing 25 mg carbidopa/100 mg levodopa tid; maint: 25-250 mg tid/qid; *max:* 200/800 mg/d or 8 tablets/d A: Extended release tablets: Initially 50 mg carbidopa/200 mg levodopa bid; *max:* 1600 mg/d A: Extended release capsules: Initially 23.75 mg carbidopa/95 mg levodopa tid; *max:* 97.5 mg carbidopa/390 mg levodopa tid Enteral suspension: 2000 mg/d over 16 h
Contraindications	**Drug-Lab-Food Interactions**
Narrow-angle glaucoma; severe cardiac, renal, hepatic disease; suspicious skin lesions (activates malignant melanoma); MAOI therapy *Caution:* Peptic ulcer, impulse control syndrome, orthostatic hypotension, psychosis, seizure disorder, and suicidal ideation	Drug: Increased hypertensive crisis with MAOIs, decreased levodopa effect with anticholinergics and antipsychotics; with TCAs, may cause dyskinesia and hypertension; with methyldopa, may cause psychosis Food: High-protein foods decrease levodopa absorption. Lab: May increase BUN, AST, ALT, ALP, and LDH
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: Well absorbed Distribution: PB: Carbidopa: 36%; levodopa: UK Metabolism: t½: 1-2 h Excretion: In urine as metabolites	PO Onset: 15-30 min Peak: 1-3 h Duration: 5 h ER Onset: UK Peak: 2-3 h Duration: 4-5 h
Therapeutic Effects/Uses	
To treat Parkinson's disease and parkinsonism and to relieve tremors and rigidity	
Mode of Action: Transmission of levodopa to brain cells for conversion to dopamine; carbidopa blocks the conversion of levodopa to dopamine in the intestine and peripheral tissues.	
Side Effects	**Adverse Reactions**
Anorexia, nausea, vomiting, dysphagia, dyskinesia, erythema, fatigue, dizziness, headache, dry mouth, constipation, bitter taste, twitching, blurred vision, insomnia, excess dark sweating, urine discoloration (red, brown, or black)	Involuntary movements, angioedema, palpitations, orthostatic hypotension, urinary retention, priapism, psychosis, depression with suicidal ideation, hallucinations, sudden sleep onset, impulse control symptoms *Life threatening:* Agranulocytosis, hemolytic anemia, leucopenia, thrombocytopenia, cardiac dysrhythmias; abrupt discontinuation may cause neuroleptic malignant syndrome

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *bid,* two times a day; *BUN,* blood urea nitrogen; *d,* day; *h,* hour; *LDH,* lactic dehydrogenase; *maint,* maintenance; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *qid,* four times a day; *t½,* half-life; *TCA,* tricyclic antidepressant; *tid,* three times a day; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 20.3
Antiparkinson Dopaminergics

Drug	Route and Dosage	Uses and Considerations
Dopaminergics		
Carbidopa-levodopa	See Prototype Drug Chart 20.1	
Dopamine Agonists		
Amantadine hydrochloride	Parkinson's disease: A: PO: 100 mg bid; *max:* 400 mg/d	For Parkinson's disease, drug-induced parkinsonism, seasonal influenza prophylaxis, and influenza A virus infection. May cause dizziness, drowsiness, headache, anxiety, confusion, fatigue, insomnia, nausea, nightmares, irritability, orthostatic hypotension, and peripheral edema. Pregnancy category: C*; PB: 67%; t½: 11-15 h
Bromocriptine mesylate	A: PO: Initially 1.25 mg bid, gradually increase; *max:* 100 mg/d	For Parkinson's disease. May cause dizziness, drowsiness, orthostatic hypotension, headache, rhinitis, sinusitis, weakness, fatigue, nausea, constipation, and diarrhea. Pregnancy category: B*; PB: 90%-96%; t½: 3 h
Pramipexole dihydrochloride	Parkinson's disease: Immediate release: A: PO: Initially: 0.125 mg tid; *max:* 4.5 mg/d Extended release: A: PO: Initially 0.375 mg/d; *max:* 4.5 mg/d	For Parkinson's disease and restless leg syndrome. May cause dizziness, drowsiness, headache, confusion, abnormal dreams, insomnia, fatigue, weakness, orthostatic hypotension, hallucinations, dyskinesia, nausea, and constipation. Pregnancy category: C*; PB: 15%; t½: 8-12 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Ropinirole hydrochloride	Parkinson's disease: Immediate release: A: PO: Initially: 0.25 mg tid; titrate up on weekly basis; *max:* 24 mg/d Extended release: A: PO: Initially 2 mg/d for 1-2 wk, titrate up weekly; *max:* 24 mg/d	For Parkinson's disease and restless leg syndrome. May cause dizziness, drowsiness, headache, syncope, dyskinesia, fatigue, weakness, nausea, vomiting, hyperhidrosis, hypertension, and orthostatic hypotension. Pregnancy category: C*; PB: 40%; t½: 6 h
Monoamine Oxidase B Inhibitors		
Selegiline hydrochloride	A: PO: 5 mg bid with breakfast and lunch; *max:* 10 mg/d A: PO: Dtab: 1.25 mg/d for 6 wk, increase to 2.5 mg/d; *max:* 2.5 mg/d	For Parkinson's disease and parkinsonism. May cause dizziness, headache, orthostatic hypotension, dry mouth, nausea, impulse control disorder, and suicidal ideation. Pregnancy category: C*; PB: 85%; t½: 10 h
Rasagiline	A: PO: 0.5-1 mg/d; *max:* 1 mg/d	For Parkinson's disease. May cause headache, orthostatic hypotension, hypertension, dyskinesia, and nausea. Pregnancy category: C*; PB: 88%-94%; t½: 3 h
Catechol-*O*-Methyltransferase Inhibitors		
Tolcapone	A: PO: Initially 100 mg tid; *max:* 600 mg/d	For Parkinson's disease. May cause dizziness, drowsiness, headache, confusion, dyskinesia, dystonic reaction, excess dreams, insomnia, anorexia, nausea, diarrhea, constipation, muscle cramps, orthostatic hypotension, sudden sleep onset, and impulse control symptoms. Monitor liver enzymes frequently because tolcapone may cause fatal hepatotoxicity. Abrupt discontinuation may cause pyrexia, confusion, and NMS. Pregnancy category: C*; PB: 99%; t½: 2-3 h
Entacapone	A: PO: 200 mg with each dose of levodopa-carbidopa; *max:* 1600 mg/d	For Parkinson's disease. Used in combination with levodopa-carbidopa, it prolongs half-life of levodopa and decreases "on-off" fluctuations. Levodopa dose should be decreased when taken with a COMT inhibitor. May cause dizziness, nausea, diarrhea, abdominal pain, dyskinesia, hyperkinesis, sudden sleep onset, and impulse control symptoms. Abrupt discontinuation may cause NMS. Pregnancy category: C*; PB: 98%; t½: 1-2 h

A, Adult; *bid,* twice daily; *COMT,* catechol-*O*-methyltransferase; *d,* day; *Dtab,* disintegrating tablet; *h,* hour; *max,* maximum; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *tid,* three times a day; *wk,* weeks.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Precautions for Drugs Used to Treat Parkinson's Disease

Side Effects and Adverse Reactions

The common side effects of anticholinergics include dry mouth and dry secretions, urinary retention, constipation, blurred vision, and an increase in heart rate. Mental effects such as restlessness and confusion may occur in older adults.

The side effects of carbidopa-levodopa are numerous. GI disturbances are common because dopamine stimulates the chemoreceptor trigger zone (CTZ) in the medulla, which stimulates the vomiting center. Taking the drug with food can decrease nausea and vomiting, but food slows the absorption rate. **Dyskinesia**, impaired voluntary movement, may occur with high levodopa dosages. Cardiovascular side effects include orthostatic hypotension and increased heart rate during early use of levodopa. Nightmares, sudden sleep onset, impulse control symptoms, mental disturbances, and suicidal tendencies may occur.

Amantadine has few side effects, but they can intensify when the drug is combined with other antiparkinson drugs. Orthostatic hypotension, confusion, urinary retention, and constipation are common side effects of amantadine.

Side effects from bromocriptine are more common than from amantadine. These include GI disturbances (nausea), orthostatic hypotension, palpitations, chest pain, lower extremity edema, nightmares, delusions, and confusion. If bromocriptine is taken with carbidopa-levodopa, usually the drug dosages are reduced, and side effects and drug intolerance decrease.

Pramipexole and ropinirole can cause nausea, dizziness, somnolence, weakness, and

constipation. These drugs intensify the dyskinesia and hallucinations caused by levodopa. Pramipexole is also FDA approved for treatment of restless legs syndrome.

Large doses of selegiline may inhibit MAO-A. Hypertensive crisis can occur if foods high in tyramine—such as aged cheese, red wine, and bananas—are ingested concurrently.

Tolcapone may cause severe liver damage, and patients with liver dysfunction should *not* take this drug. Entacapone is not known to affect liver function. With entacapone, the urine can have a brownish orange discoloration; with tolcapone, the urine can have a dark discoloration. Both tolcapone and entacapone can intensify the adverse reactions of levodopa (e.g., hallucinations, orthostatic hypotension, constipation, dizziness) because these drugs prolong the effect of levodopa. Both tolcapone and entacapone may lead to intense, uncontrollable urges (sex, gambling, spending money) in addition to suddenly falling asleep. Patients should be warned to avoid driving and other potentially dangerous activities.

Contraindications

Anticholinergics or any drugs that have anticholinergic effects are contraindicated for patients with glaucoma. Those with severe cardiac, renal, or psychiatric health problems should avoid levodopa drugs because of adverse reactions. Patients with chronic obstructive lung diseases such as emphysema can have dry, thick mucous secretions caused by large doses of anticholinergic drugs.

Drug-Drug Interactions

Antipsychotic drugs block the receptors for dopamine. Carbidopa-levodopa taken with a monoamine oxidase inhibitor (MAOI) antidepressant can cause a hypertensive crisis.

Alzheimer Disease

Alzheimer disease is an incurable dementia illness characterized by chronic, progressive neurodegenerative conditions with marked cognitive dysfunction. Onset usually occurs between 45 and 65 years of age.

Pathophysiology

Many physiologic changes contribute to Alzheimer disease. Currently, theories related to the changes that cause Alzheimer disease include the following:

- Degeneration of the cholinergic neuron and deficiency in acetylcholine
- Neuritic plaques that form mainly outside of the neurons and in the cerebral cortex
- Apolipoprotein E_4 (apo E_4) that promotes formation of neuritic plaques, which binds beta-amyloid in the plaques
- Beta-amyloid protein accumulation in high levels that may contribute to neuronal injury
- Presence of neurofibrillary tangles with twists inside the neurons

Fig. 20.2 illustrates the normal neuron and the neuron affected by Alzheimer disease. The etiology of Alzheimer disease is unknown, although factors thought to influence the occurrence of Alzheimer disease are genetic predisposition, virus, infection, or inflammation that attacks brain cells as well as nutritional, environmental, and immunologic factors.

Alzheimer disease has three stages that include mild, moderate, and severe. The symptoms overlap stages. Generally, in the mild stage, which is the early-stage, the person has memory lapses, difficulty concentrating, misplaces objects, forgets what was just read, and has increased problems with planning and organizing. At this stage, the person may still drive, work, and interact socially.

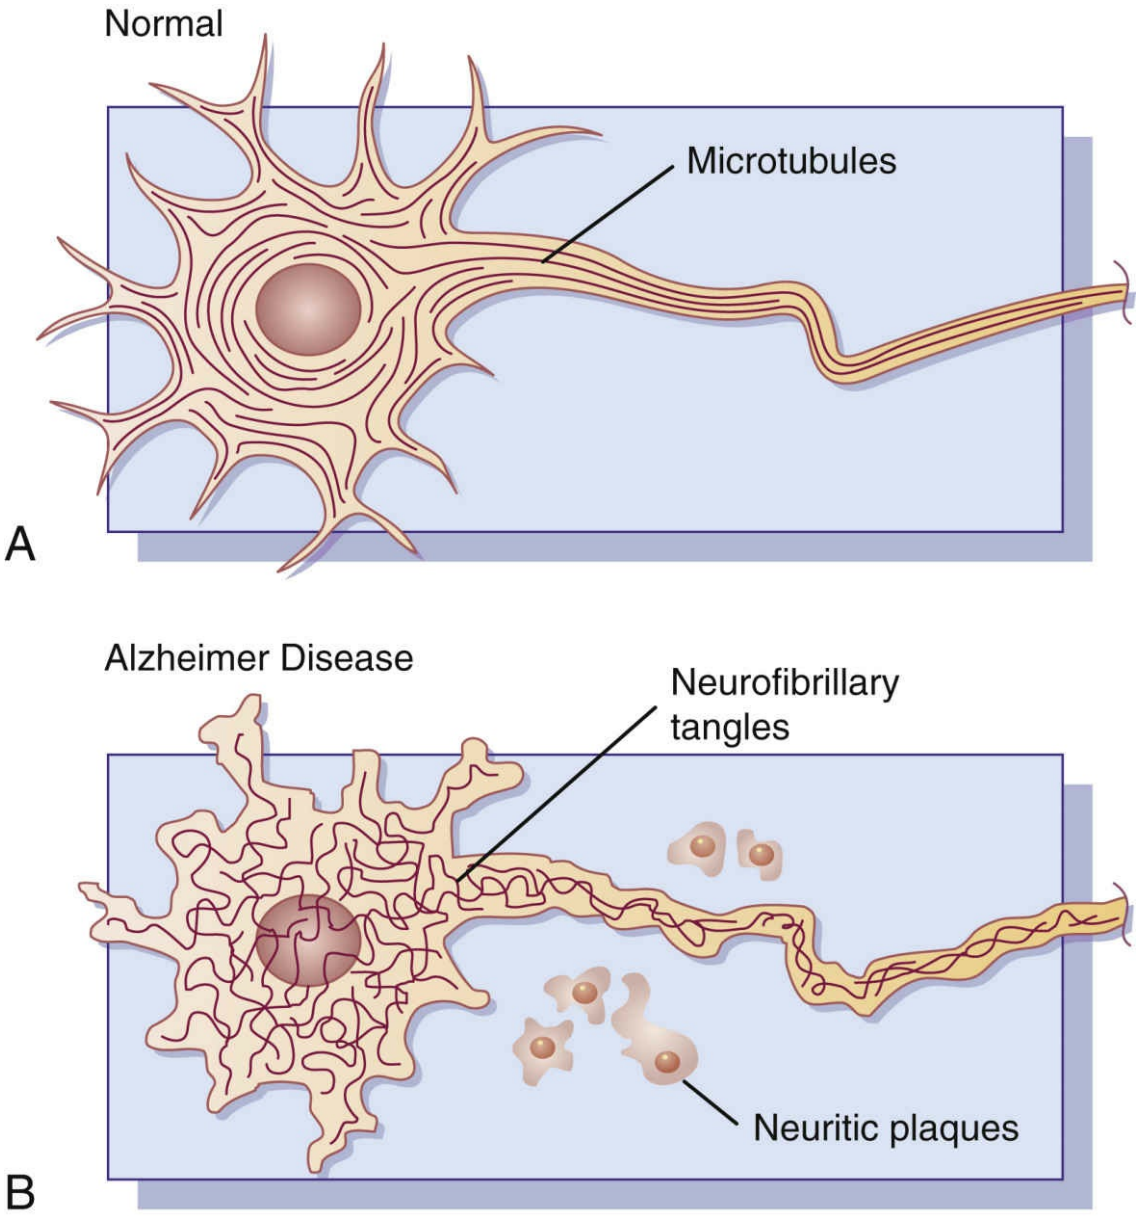

FIG. 20.2 Histologic changes in Alzheimer disease. **A**, Healthy neuron. **B**, Neuron affected by Alzheimer disease shows characteristic neuritic plaques and cellular neurofibrillary tangles.

The moderate stage (middle-stage) is the longest stage and may last many years. The person may be irritable, moody, withdrawn, display frustration and anger, have personality and behavioral changes (may refuse to bathe), has changes in sleep pattern, confusion regarding what day it is, inability to recall personal information (phone number and address), may wander and become lost, inability to perform routine tasks, and difficulty controlling bowels/bladder. In the severe stage the person forgets recent experiences and previously known individuals, requires high levels of assistance with activities of daily living, inability to respond to their environment or converse, inability to walk, sit, or swallow, becomes vulnerable to infections, especially pneumonia.

Acetylcholinesterase/Cholinesterase Inhibitors

The cure for Alzheimer disease is unknown. FDA-approved medications to treat Alzheimer disease symptoms include **acetylcholinesterase (AChE) inhibitors**. AChE is an enzyme responsible for breaking down ACh and is also known as *cholinesterase.* The AChE inhibitors are donepezil, memantine, galantamine, and rivastigmine, a drug that permits more ACh in the neuron receptors. Rivastigmine has effective penetration into the CNS, thus cholinergic transmission is increased.

These AChE inhibitors increase cognitive function for patients with mild to moderate Alzheimer disease. A reversible AChE inhibitor used to treat mild to moderate Alzheimer disease is galantamine.

Several drugs for treating Alzheimer disease are under investigation. Some of these are certain nonsteroidal antiinflammatory drugs (NSAIDs; piroxicam, indomethacin), calcium channel blockers, MAO-B inhibitors (selegiline), serotonin antagonists, CNS stimulants (methylphenidate), angiotensin-converting enzyme (ACE) inhibitors, and vitamin E.

Rivastigmine

Rivastigmine, an AChE inhibitor, is prescribed to improve cognitive function for patients with mild to moderate Alzheimer disease (Prototype Drug Chart 20.2). This drug increases the amount of ACh at the cholinergic synapses. Rivastigmine tends to slow the disease process and has fewer drug interactions than donepezil. Table 20.4 lists the AChE inhibitors used to treat Alzheimer disease.

Pharmacokinetics

Rivastigmine is absorbed faster through the GI tract without food. It has a relatively short half-life and is given twice a day. The dose is gradually increased. The protein-binding power is average.

Pharmacodynamics

Rivastigmine has been successful in improving memory in mild to moderate Alzheimer disease. The onset of action is 0.5 to 1.0 hour for topical application; peak action is 8 to 16 hours. When given orally, the peak is 1 hour. This drug is contraindicated for patients with liver disease because hepatotoxicity may occur. Cumulative drug effect is likely to occur in older adults and in patients with liver and renal dysfunction.

PROTOTYPE DRUG CHART 20.2 Rivastigmine

Drug Class	Dosage
Acetylcholinesterase inhibitor Pregnancy category: B*	A: PO: Initially: 1.5 mg bid with food; increase gradually after 2 wk to 3 mg bid; Maintenance: 3-6 mg bid; *max:* 12 mg/d Transdermal: Initially 4.6 mg/24 h; may increase after 4 wk to 9.5 mg/d; *max*: 13.3 mg/24 h
Caution	**Drug-Lab-Food Interactions**
Liver and renal diseases, urinary tract obstruction, orthostatic hypotension, bradycardia, asthma, COPD, seizures, peptic ulcer disease	Drug: Increased effect of theophylline, general anesthetics; TCAs decrease effect; increased effect with cimetidine; NSAIDs increase GI effects; tobacco increases clearance of rivastigmine. Lab: Increased ALT, AST
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: Food decreases absorption rate Distribution: PB: 40% Metabolism: t½: 1 h Excretion: In urine	PO: Onset: UK Peak: 1 h Duration: UK Transdermal: Onset: 30 min-1h Peak: 8-16 h Duration: 24 h
Therapeutic Effects/Uses	
Improves memory loss in Alzheimer disease	
Mode of Action: Elevates acetylcholine concentration	
Side Effects	**Adverse Reactions**
Anorexia, abdominal pain, nausea, vomiting, diarrhea, constipation, weight loss, dizziness, headache, depression, confusion, peripheral edema, dry mouth, dehydration, nystagmus	Seizures, bradycardia, orthostatic hypotension, cataracts, myocardial infarction, heart failure *Life threatening:* Hepatotoxicity, dysrhythmias, suicidal ideation, Stevens-Johnson syndrome

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *bid,* two times a day; *COPD,* chronic obstructive pulmonary disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *min,* minute; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *TCA,* tricyclic antidepressant; *UK,* unknown; *wk,* weeks.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 20.4
Acetylcholinesterase Inhibitors for Alzheimer Disease

Drug	Route and Dosage	Uses and Considerations
Donepezil	A: PO: Initially 5 mg/d, may increase after 4-6 wk; maint: 5-10 mg/d; *max*: 23 mg/d	For Alzheimer disease. May cause dizziness, insomnia, headache, anorexia, nausea, diarrhea, muscle cramps, weight loss, and infection. Pregnancy category: C*; PB: 95%; t½: 70 h
Rivastigmine	See Prototype Drug Chart 20.2.	
Memantine	Immediate release: A: PO: Initially 5 mg/d, may increase dose slowly over 3 wk in 5-mg increments; *max*: 20 mg/d Extended release: A: PO: Initially 7 mg/d, increase weekly; *max*: 28 mg/d	For Alzheimer disease. May cause dizziness, headache, cough, confusion, diarrhea, and constipation. Pregnancy category: B*; PB: 45%; t½: 60-80 h
Galantamine	Immediate release: A: PO: Initially 4 mg bid with food, may increase 4 mg every 4 wk if well tolerated; maint: 12 mg bid; *max*: 24 mg/d	For Alzheimer disease. May cause dizziness, headache, insomnia, fatigue, anorexia, abdominal pain, nausea, vomiting, diarrhea, weight loss, and suicidal ideation. Pregnancy category: C*; PB: 18%; t½: 7 h

	Extended release: A: PO: Initially 8 mg/d in the morning with food; increase at 4-wk intervals; *max*: 24 mg/d	

A, Adult; *bid,* twice a day; *d,* day; *h,* hour; *maint,* maintenance; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *wk,* week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Drug Treatment for Alzheimer Disease: Rivastigmine

Assessment

- Assess the patient's mental and physical abilities. Note limitation of cognitive function and self-care.
- Obtain a history that includes any liver or renal disease or dysfunction.
- Assess for memory and judgment losses. Elicit from family members a history of behavioral changes such as memory loss, declining interest in people or home, difficulty in following through with simple activities, and a tendency to wander from home.
- Observe for signs of behavioral disturbances such as hyperactivity, hostility, and wandering.
- Examine the patient for signs of aphasia or difficulty in speech.
- Note motor function.
- Determine family members' ability to cope with the patient's mental and physical changes.

Nursing Diagnoses

- Self-Care Deficit, Feeding related to memory loss
- Self-Care Deficit, Bathing related to memory loss
- Self-Care Deficit, Toileting related to memory loss
- Confusion, Chronic related to memory loss
- Family Processes, Interrupted related to decreased cognition
- Coping, Compromised Family related to overwhelming disruption of lifestyle
- Injury, Risk for
- Nutrition, Imbalanced: Less than Body Requirements related to anorexia, nausea, and vomiting

Planning

- Patient's memory will be improved.
- Patient will maintain self-care of body functions with assistance.

Nursing Interventions

- Maintain consistency in care.
- Assist the patient in ambulation and activity.
- Monitor for side effects related to continuous use of acetylcholinesterase inhibitors.
- Record vital signs periodically. Note signs of bradycardia and hypotension.
- Observe any patient behavioral changes, and note any improvement or decline.

Patient Teaching

General

- Explain to the patient and family the purpose for the prescribed drug therapy.
- Clarify times for drug dosing and schedule for increasing drug dosing to the family member responsible for the patient's medications.
- Teach family members about safety measures such as removing obstacles in the patient's path to avoid injury when the patient wanders.
- Inform family members of available support groups such as the Alzheimer Disease and Related Disorders Association.

Side Effects

- Inform patients and family members that the patient should rise slowly to avoid dizziness and loss of balance.
- Monitor routine liver function tests because hepatotoxicity is an adverse effect.

Diet

- Inform family members about foods that may be prepared for the patient's consumption and tolerance.

Cultural Considerations

- Recognize that various cultural groups may need guidance in understanding the Alzheimer disease process.
- Communicate respect for variant cultural beliefs and practices; help family members understand that their family member has a neurologic problem that may be part of the aging process. Explain how symptoms may become more progressive.

Evaluation

- Evaluate effectiveness of the drug regimen by determining whether the patient's mental and physical status shows improvement from drug therapy.

Critical Thinking Case Study

TR, a 79-year-old man, was diagnosed with Parkinson's disease 10 years ago. During his early treatment, he took selegiline. The drug dosage was increased to alleviate symptoms.

1. How does selegiline alleviate symptoms of Parkinson's disease ?
2. What dietary changes should be made during the time TR takes selegiline?

Because TR developed numerous side effects and adverse reactions to selegiline, the health care provider changed the drug to carbidopa-levodopa. TR asks the nurse why the drug was changed.

3. What are the similarities and differences between selegiline and carbidopa-levodopa?
4. What are the advantages of carbidopa-levodopa?

TR's family says they know a person with Parkinson's disease who takes the antiviral drug amantadine. The family asks whether amantadine is the same as carbidopa-levodopa and, if so, whether TR can take amantadine instead of carbidopa-levodopa.

5. What is the effect of amantadine on symptoms of Parkinson's disease?
6. What would be an appropriate response to the family's question concerning the use of amantadine for TR?
7. What are the uses for dopamine agonists and COMT inhibitors?
8. Certain anticholinergic drugs may be used to control Parkinson's disease symptoms. What is the action of these drugs, and what are their side effects? These anticholinergic drugs are usually prescribed for parkinsonism symptoms resulting from what?

NCLEX Study Questions

1. Which of the following assessment findings could the nurse see in a patient with Parkinson's disease? (Select all that apply.)
   a. An abrupt onset of symptoms
   b. Muscle rigidity
   c. Involuntary tremors
   d. Bradykinesia
   e. Bilateral muscle weakness
2. A patient is receiving carbidopa-levodopa for Parkinson's disease. What should the nurse know about this drug?
   a. Carbidopa-levodopa may lead to hypertension.
   b. Carbidopa-levodopa may lead to excessive salivation.
   c. Dopaminergic and anticholinergic therapy may lead to drowsiness and sedation.
   d. Dopaminergics and anticholinergics are contraindicated in patients with glaucoma.
3. The nurse has initiated teaching for a family member of a patient with Alzheimer disease. The nurse realizes more teaching is needed if the family member makes which statement?
   a. As the disease gets worse, the memory loss will get worse.
   b. There are several theories about the cause of the disease.
   c. Personality changes and hostility may occur.
   d. It may take several medications to cure the disease.
4. A patient is taking rivastigmine. The nurse should teach the patient and family which information about rivastigmine?
   a. Hepatotoxicity may occur.
   b. The initial dose is 6 mg three times a day.
   c. Gastrointestinal distress is a common side effect.
   d. Weight gain may be a side effect.
5. Which is a nursing intervention for a patient taking carbidopa-levodopa for Parkinson's disease?
   a. Encourage the patient to adhere to a high-protein diet.
   b. Inform the patient that perspiration may be dark and may stain clothing.
   c. Advise the patient that glucose levels should be checked with urine testing.
   d. Warn the patient that it may take 4 to 5 days before symptoms are controlled.
6. What would the nurse teach a patient who is taking anticholinergic therapy for Parkinson's disease? (Select all that apply.)
   a. Avoid alcohol, cigarettes, and caffeine.
   b. Relieve dry mouth with hard candy or ice chips.
   c. Use sunglasses to reduce photophobia.
   d. Urinate 2 hours after taking the drug.
   e. Receive routine eye examinations.
7. A patient is taking rivastigmine to improve cognitive function. What should the nurse teach the patient/family member to do? (Select all that apply.)
   a. Rise slowly to avoid dizziness.
   b. Remove obstacles from pathways to avoid injury.
   c. Closely follow the drug dosing schedule.
   d. Have frequent checks for hypertension.
   e. Receive regular liver function tests.

Answers: 1, b, c, d; 2, d; 3, d; 4, c; 5, b; 6, a, b, c, e; 7, a, b, c.

Drugs for Neuromuscular Disorders and Muscle Spasms

OUTLINE

Myasthenia Gravis
- Pathophysiology
- Acetylcholinesterase Inhibitors
- Nursing Process: Patient-Centered Collaborative Care— Drug Treatment for Myasthenia Gravis: Pyridostigmine

Multiple Sclerosis
- Four Classifications of Multiple Sclerosis
- Immunomodulators

Skeletal Muscle Relaxants
- Centrally Acting Muscle Relaxants
- Nursing Process: Patient-Centered Collaborative Care— Muscle Relaxant: Cyclobenzaprine

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Contrast the pathophysiology of myasthenia gravis and multiple sclerosis.
- Discuss the drug group used to treat myasthenia gravis.
- Discuss the drug group used to treat multiple sclerosis.
- Differentiate between the muscle relaxants used for spasticity and those used for muscle spasms.
- Apply the nursing process to drugs used to treat myasthenia gravis and muscle spasms.

KEY TERMS

acetylcholine (ACh), p. 267
acetylcholinesterase (AChE) inhibitor, p. 268
cholinergic crisis, p. 268
fasciculations, p. 268
miosis, p. 268
multiple sclerosis (MS), p. 267
muscle relaxants, p. 267
muscle spasms, p. 267
myasthenia gravis (MG), p. 267
myasthenic crisis, p. 268

http://evolve.elsevier.com/McCuistion/pharmacology

Myasthenia gravis (MG) is an acquired autoimmune disease that impairs the transmission of messages at the neuromuscular junction, resulting in fluctuating muscle weakness that increases with muscle use. MG causes fatigue and muscular weakness of the respiratory system, facial muscles, and extremities. Due to cranial nerve involvement, ptosis (drooping eyelid) and difficulty in chewing and swallowing occur. Respiratory arrest may result from respiratory muscle paralysis. The symptoms of MG are caused by autoimmune destruction of acetylcholine (ACh) sites and a resultant decrease in neuromuscular transmission.

Multiple sclerosis (MS) is a neuromuscular autoimmune disorder that attacks the myelin sheath of nerve fibers, causing lesions known as *plaques.* Although there are no definitive diagnostic tests, the sclerotic plaques are usually detected and measured by magnetic resonance imaging (MRI). Pharmacologic treatment is necessary to control the symptoms of this disorder.

Muscle spasms have various causes, including injury or motor neuron disorders that are associated with conditions such as MS, MG, cerebral palsy, spinal cord injuries (paraplegia [paralysis of the legs]), cerebrovascular accident (CVA [stroke]), or hemiplegia (paralysis of one side of the body). Spasticity of muscles can be reduced with the use of skeletal **muscle relaxants.**

Myasthenia Gravis

MG is a chronic autoimmune neuromuscular disease that affects approximately 20 in 100,000 persons. It is estimated that 60,000 Americans are affected. MG can occur in people of any ethnicity and sex; however, MG peaks in women around the childbearing years, whereas the peak onset in men is between 50 and 70 years. MG can also occur in people outside of this age range. Although it is not a genetic disorder, a familial tendency may be apparent.

Pathophysiology

MG results from a lack of acetylcholine receptor (AChR) sites. This autoimmune disorder involves an antibody response against an alpha subunit of the AChR site at the neuromuscular junction. Antibodies attack the AChR sites, obstructing the binding of ACh and eventually destroying the receptor sites. When AChR sites are reduced, ACh molecules are prevented from binding to receptors and stimulating normal neuromuscular transmission. The result is ineffective muscle contraction and muscle weakness. About 90% of patients with MG have anti-ACh antibodies that can be detected through serum testing.

The thymus gland is involved in systemic immunity that is active during infancy and early childhood, but the gland normally shrinks during adulthood. Approximately 60% of MG patients have thymic hyperplasia. It has been suggested in some cases that if the thymus gland is removed during the early onset of MG, clinical symptoms are greatly decreased. Thymectomy has been an option for patients younger than 50 years.

MG is characterized primarily by weakness and fatigue of the skeletal muscles. In 90% of cases, eyelid or extraocular muscles are involved. The patient may experience ptosis and diplopia (double vision). Other characteristics of MG include dysphagia (difficulty chewing and swallowing), dysarthria (slurred speech), and respiratory muscle weakness.

The group of drugs used to control MG are the acetylcholinesterase (AChE) inhibitors. They inhibit the action of the enzyme AChE. As a result of this action, more ACh is available to activate the cholinergic receptors and promote muscle contraction. The AChE inhibitors are classified as parasympathomimetics.

When muscular weakness in the patient with MG becomes generalized, **myasthenic crisis** may occur. This complication is a severe, generalized muscle weakness that may involve the muscles of respiration, such as the diaphragm and intercostal muscles. Triggers of myasthenic crisis include inadequate dosing of AChE inhibitors, infection, emotional stress, menses, pregnancy, surgery, trauma, hypokalemia, temperature extremes, and alcohol intake. Myasthenic crisis can also occur 3 to 4 hours after taking certain medications (e.g., aminoglycoside and fluoroquinolone antibiotics, calcium channel blockers, phenytoin, and psychotropics; Box 21.1). If muscle weakness remains untreated, death could result from paralysis of the respiratory muscles. Neostigmine, a fast-acting AChE inhibitor, can relieve myasthenic crisis.

Overdosing with AChE inhibitors may cause another complication of MG called **cholinergic crisis**, which is an acute exacerbation of symptoms. A cholinergic crisis usually occurs within 30 to 60 minutes after taking anticholinergic drugs. This complication is due to continuous depolarization of postsynaptic membranes that creates a neuromuscular blockade. The patient with cholinergic crisis often has severe muscle weakness that can lead to respiratory paralysis and arrest. Accompanying symptoms include **miosis** (abnormal pupil constriction), pallor, sweating, vertigo, excess salivation, nausea, vomiting, abdominal cramping, diarrhea, bradycardia, and **fasciculations** (involuntary muscle twitching).

Acetylcholinesterase Inhibitors

The first drug used to manage MG is neostigmine. It is a short-acting acetylcholinesterase inhibitor with a half-life of 0.5 to 1 hour. The drug must be given on time to prevent muscle weakness. The AChE inhibitor pyridostigmine has an intermediate action and is given every 4 to 6 hours (Table 21.1). Pyridostigmine is presented in Prototype Drug Chart 21.1.

BOX 21.1 Medications That May Exacerbate Myasthenia Gravis

Contraindicated Medication

D-Penicillamine

Medications That Exacerbate Symptoms in Most Patients

Aminoglycosides (gentamycin, streptomycin, neomycin)
Phenytoin
Macrolides (erythromycin)
Fluoroquinolones (ciprofloxacin)
Quinine, quinidine, procainamide
Lidocaine
Magnesium salt
Psychotropic medications, (e.g., lithium carbonate, phenothiazine, benzodiazepines, tricyclic antidepressants)
Neuromuscular blocking agents, (e.g., tubocurarine chloride, pancuronium, succinylcholine)

Pharmacokinetics

Pyridostigmine is poorly absorbed from the gastrointestinal (GI) tract. Half of the sustained-release capsule is absorbed readily, but the balance is poorly absorbed. The half-life of oral pyridostigmine is 3 to 7 hours, and it is 2 to 3 hours for intravenous (IV) administration. Because of its short half-life, pyridostigmine must be administered several times a day. The drug is metabolized by the liver and is excreted in the urine.

Pharmacodynamics

Pyridostigmine increases muscle strength in patients with muscular weakness resulting from MG. The onset of action of oral pyridostigmine is 30 to 45 minutes, the peak is 1 to 3 hours, and the duration is 3 to 4 hours. Overdosing of pyridostigmine can result in signs and symptoms of cholinergic crisis. This crisis requires emergency medical intervention because of respiratory muscle weakness.

Patients who do not respond to AChE inhibitors may require additional drug treatment such as with prednisone, plasma exchange, IV immune globulin, or immunosuppressive drugs. Prednisone is the drug of choice, but like other immunosuppressants, it reduces the presence of antibodies. Corticosteroids do not produce permanent remission, and the long-term side effects are significant.

The immunosuppressive agent azathioprine can be used in conjunction with a lower dose of prednisone. With azathioprine, the white blood cell (WBC) count and liver enzymes should be closely monitored to avoid leukopenia and hepatotoxicity.

Overdosing and underdosing of AChE inhibitors have similar symptoms: generalized muscle weakness, which can include the muscles of respiration, the diaphragm, and the intercostal muscles resulting in dyspnea (difficulty breathing), and dysphagia. Additional symptoms that may be present with overdosing are increased salivation (drooling), sweating, and bronchial secretions, along with miosis, bradycardia, and abdominal pain. All doses of AChE inhibitors should be administered *on time* because late administration of the drug could result in muscle weakness.

TABLE 21.1

Acetylcholinesterase Inhibitors for Myasthenia Gravis

Drug	Route and Dosage	Uses and Considerations
Edrophonium	A: IV 2 mg over 15-30 s; if no response, administer 8 mg; if cholinergic reaction occurs, administer 0.4-0.5 mg IV atropine. A: IM: 10 mg; if cholinergic reaction occurs, retest after 30 min with 2 mg to rule out false negative. C: <34 kg: IV: 1 mg, repeat in 45 s; if no response, give 1 mg q30-45s until response is seen; *max:* 5 mg C: >34 kg: IV: 2 mg, repeat with 1 mg if no response; *max:* 10 mg	For diagnosing MG. Will distinguish between myasthenic and cholinergic crisis. Ptosis should be absent in 1-5 min. Duration: IV: 5-10 min IM: 5-30 min Onset: Ultra–short-acting drug IV: Rapid 30-60 s IM: Rapid 2-10 min PB: UK; t½: 1.2-2 h Pregnancy category C*
Neostigmine	(The oral drug was discontinued in the United States.) A: IM/subcut: 0.5 mg/mL; 1 mg/mL; *max:* 5 mg A/C: IV: 0.03-0.07 mg/kg/d over 1 min Note: All anticholinesterase drugs should be discontinued 8 h before administration of neostigmine.	For controlling MG. Dose should be individualized to the patient. Must be given on time to prevent myasthenic crisis. Overdose can cause cholinergic reaction: nausea, abdominal cramps, excessive salivation, and sweating. Note: Large parenteral doses should be accompanied with IV atropine to counteract the side effects. PB: 15%-25%; t½: IM: 50-90 min; IV: 24-113 min

		Pregnancy category C*
Pyridostigmine	See Prototype Drug Chart 21.1.	

Immunosuppressant		
Azathioprine (for MG poorly controlled with AChE inhibitors)	A: PO: 50 mg daily × 1 wk; gradually increase to 2-3 mg/kg/d; *max:* 250 mg/d Dosage is based on total body weight. A: IV: Used only for those who cannot tolerate PO Dose is determined by a thiopurine methyltransferase (TPMT) test which is done prior to initiation of the drug. Contrainicated in very slow metabolizers (0.3%) and lower doses in slow metabolizers (about 11%).	Onset: 6-8 wk Peak: 12 wk Duration: UK t½: UK PB: 30% Monitor: WBC, AST, and ALT Pregnancy category D*

>, Greater than; <, less than; *A,* adult; *AChE*, acetylcholinesterase; *ALT;* alanine aminotransferase; *AST;* aspartate aminotransferase; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum dosage; *MG,* myasthenia gravis; *min*, minutes; *PB,* protein binding; *PO,* by mouth; *q,* every; *s*, second; *subcut*, subcutaneous; *t½,* half-life; *UK,* unknown; *wk,* weeks; *WBC,* white blood count.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Underdosing can result in myasthenic crisis, and overdosing can result in cholinergic crisis. Edrophonium is an ultra–short-acting AChE inhibitor that may be used to distinguish between myasthenic crisis and cholinergic crisis. These two crises have a similar major symptom: severe muscle weakness. After edrophonium is administered, if the symptoms are alleviated because of an increase in ACh, the cause is myasthenic crisis. However, if the muscle weakness becomes more severe, the cause is cholinergic crisis due to drug overdosing. Edrophonium may also be used to diagnose MG. Its ultrashort duration of 5 to 30 minutes increases muscle strength immediately. If ptosis is immediately corrected after administration of this drug, the diagnosis is most likely MG.

Side Effects and Adverse Reactions

Side effects and adverse reactions of AChE inhibitors include GI disturbances (nausea, vomiting, diarrhea, abdominal cramps), increased salivation and tearing, miosis (constricted pupil of the eye), blurred vision, bradycardia, and hypotension.

Nursing Process: Patient-Centered Collaborative Care

Drug Treatment for Myasthenia Gravis: Pyridostigmine

Assessment

- Obtain a drug history from the patient that includes all current medications.
- Observe the patient's drug profile for possible drug interactions.
- Patients should avoid atropine, atropine-like drugs, and muscle relaxants.
- Record baseline vital signs.
- Assess patient for signs and symptoms of myasthenic crisis, such as muscle weakness with difficulty breathing and swallowing.

Nursing Diagnoses

- Breathing Pattern, Ineffective related to weak respiratory muscles

PROTOTYPE DRUG CHART 21.1 Pyridostigmine

Drug Class	Dosage
Acetylcholinesterase (AChE) inhibitors	Myasthenia gravis: A: PO: 60 mg/d in divided doses; average dose is 600 mg/d; max PO route SR: A: PO: 180-540 mg/d or bid with at least 6 h between doses; max PO route
	A: IM/IV: 2 mg q2-3h C: PO: 1 mg/kg every 4-6 h; compare peak strength and activity 1 h after first dose and immediately before the next dose to individualize dose.
	C: IV/IM: 0.05-0.15 mg/kg; *max single dose:* 10 mg
Contraindications	Drug Interactions
GI and GU obstructions, ileus, bladder obstruction *Caution:* Asthma, bradycardia, seizure disorder, peptic ulcer, cardiac arrhythmias, renal impairment, hyperthyroidism, pregnancy, breastfeeding	Drug: Corticosteroids, neuromuscular blockers, aminoglycosides, local anesthetics, magnesium salts; increased toxicity with acetylcholinesterase inhibitors, atropine, tetracyclines, polymyxin B, bacitracin, digoxin, quinidine, and insecticides containing malathion; atropine decreases the effect of pyridostigmine.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Poorly absorbed SR: 50% absorbed Distribution: PB: UK Metabolism: (short half-life) t½: PO, 3-7 h; IV, 2-3 h	PO: Onset: 30-45 min Peak: 1-3 h; Duration: 3-4 h PO SR: Onset: 0.5-1 h Peak: UK; duration: 6-12 h IM: Onset: 15 min Peak: UK; duration: 2-4 h IV: Onset: Within minutes Peak: UK; duration: 2-3 h Pregnancy category C*
Therapeutic Effects/Uses	
Used to control and treat myasthenia gravis, for neuromuscular blockade reversal, and for nerve gas (soman) exposure prophylaxis	
Mode of Action: Promotes transmission of neuromuscular impulses across the myoneural junctions by preventing destruction of acetylcholine	
Side Effects	Adverse Reactions
Nausea, vomiting, diarrhea, headache, blurred vision, dizziness, abdominal pain, excess saliva and sweating, rash, and miosis	Hypotension, bradycardia *Life threatening:* Dyspnea, bronchospasm, respiratory distress, cardiac dysrhythmias, and seizures

A, Adult; *bid,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *GU,* genitourinary; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q,* every; *SR,* sustained release; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

- Activity Intolerance related to fatigue
- Anxiety related to possible recurrence of myasthenic crisis and dyspnea
- Knowledge, Deficient related to unfamiliar medications

Planning

- Patient's symptoms of muscle weakness and difficulty breathing and swallowing caused by MG will be eliminated or reduced in 2 to 3 days.

Nursing Interventions

- Monitor effectiveness of drug therapy (AChE inhibitors). Muscle strength should be increased. Both depth and rate of respirations should be assessed and maintained within normal range.
- Administer prescribed acetylcholinesterase inhibitor following dosage recommendations and nursing guidelines.
- Observe patient for signs and symptoms of cholinergic crisis caused by overdosing, such as muscle weakness, respiratory failure, increased salivation, sweating, and bronchial secretions along with miosis.
- Have an antidote for cholinergic crisis (atropine sulfate) readily available.

Patient Teaching

General

- Teach patients to take drugs as ordered to avoid recurrence of symptoms.
- Encourage patients to wear a medical identification bracelet or necklace that indicates health problems.

Side Effects

- Teach patients about the side effects of medication and when to notify the health care provider.
- Advise patients to report recurrence of symptoms of MG to the health care provider.

Diet

- Inform patients to take the drug before meals for best absorption. If gastric irritation occurs, take the drug with food.

Cultural Considerations

- Involve family members in teaching about prescriptive therapies and disease processes using simple and clear instructions.
- Communicate respect for the patient's cultural beliefs.
- Accommodate cultural values and assess the patient's understanding of adhering to the drug regimen. Instruct the patient to notify the health care provider prior to taking any medications other than what the provider has ordered.
- Stress that medications need to be taken as prescribed. Medications are ordered specifically for

each ailment. Unused drugs should be discarded, and use of medication by individuals other than the intended patient can have serious consequences.

Evaluation

- Evaluate effectiveness of the drug therapy to maintain muscle strength.
- Determine the absence of respiratory distress.
- Evaluate the correct use of the drug by the patient.

Multiple Sclerosis

Multiple sclerosis (MS) is an autoimmune disorder that attacks the myelin sheath of nerve fibers in the brain and spinal cord, which results in lesions called *plaques.* In the United States, MS affects approximately 400,000 persons aged 20 to 40 years, and most are Caucasian women. It is uncommon in African and Asian populations.

Although the cause of MS is unknown, it is thought that the disease develops in a genetically susceptible person as a result of environmental exposure, like an infection. The onset of MS is usually slow. It is a condition in which there are remissions and exacerbations of multiple symptoms. Common manifestations of MS are motor, sensory, neurologic, cerebellar, and emotional problems. Motor symptoms include weakness or paralysis of the limbs, muscle spasticity, and diplopia. Patients with MS experience sensory abnormalities, including numbness and tingling, blurred vision, vertigo, and tinnitus. Patients may experience neuropathic pain particularly in the low thoracic and abdominal areas. Cerebellar signs include nystagmus, ataxia, dysarthria, and dysphagia. Many patients experience severe fatigue. If the sclerotic plaque is located in the central nervous system (CNS), problems with bowel and bladder function and sexual and cognitive dysfunction can occur.

MS is difficult to diagnose. Most physicians use at least one other test besides the medical history and neurologic exam, such as MRI, visual evoked potential (VEP) testing, or analysis of cerebrospinal fluid (CSF), to confirm the diagnosis (see www.multiplesclerosis.net).

Four Classifications of Multiple Sclerosis

MS is classified into four primary patterns for treatment purposes:

- *Relapsing remitting MS (RRMS):* The patient experiences relapse with full recovery and residual deficit on recovery (affects 85%).
- *Primary progressive MS (PPMS):* Slowly worsening neurologic function is evident from the beginning with no relapses or remissions (affects 10%).
- *Secondary progressive MS (SPMS):* The initial course is relapsing remitting, followed by progression with or without occasional relapses, minor remissions, and plateaus (about 50% of people with RRMS develop SPMS within 10 years).
- *Progressive relapsing MS (PRMS):* This form is progressive from the onset, with clear acute relapses with or without full recovery (affects 5%).

There is no known cure for MS.

Immunomodulators

Immunomodulators are disease-modifying drugs (DMDs), also called *disease-modifying therapies* (DMTs), and they are the first line of treatment for patients with MS. DMDs can slow the progression of the disease and prevent relapses.

Immunomodulators include interferon beta-1a and interferon beta-1b (Prototype Drug Chart 21.2), which are popular drugs in the treatment of MS. Beta-1b and glatiramer acetate are administered subcutaneously either once daily or three times a week depending on the health care provider's orders. Teriflunomide is an oral drug that is administered daily. Alemtuzumab is a monoclonal antibody that requires a daily IV dose of 12 mg for 5 consecutive days, and in 12 months, an additional 12-mg dose for 3 consecutive days. It targets the part of the immune system that is thought to be harming people with MS. No two cases of MS are alike, so the drugs are tailored to the disease pattern and manifestations of the patient. See Table 21.2 for medications used in the treatment of MS.

Corticosteroids are used to manage exacerbations of MS. They work by reducing edema and acute inflammation at the site of demyelination.

Skeletal Muscle Relaxants

Muscle relaxants relieve muscular spasms and pain associated with traumatic injuries and spasticity from chronic debilitating disorders (e.g., MS, stroke [CVA], cerebral palsy, head and spinal cord injuries). Spasticity results from increased muscle tone from hyperexcitable neurons; this is caused by increased stimulation from the cerebral neurons or lack of inhibition in the spinal cord or at the skeletal muscles. The centrally acting muscle relaxants depress neuron activity in the spinal cord or brain, or they enhance neuronal inhibition on the skeletal muscles.

Centrally Acting Muscle Relaxants

The mechanism of action of centrally acting muscle relaxants is not fully known. Centrally acting muscle relaxants are used in cases of spasticity to suppress hyperactive reflex and for muscle spasms that do not respond to antiinflammatory agents, physical therapy, or other forms of therapy. Table 21.3 presents centrally acting muscle relaxants, and Prototype Drug Chart 21.3 gives the drug data for the centrally acting muscle relaxant cyclobenzaprine.

PROTOTYPE DRUG CHART 21.2 Beta-Interferon

Drug Class	Dosage
Immunomodulators: Interferon beta-1a Interferon beta-1b	*Beta-1a:* A: IM: 30 mcg once/wk A: Subcut: 22 or 44 mcg 3 × wk; give doses at least 48 h apart. *Beta-1b:* A: Subcut: 0.0625 mg every other day; increase by 0.0625 mg q2wk over a 6-wk period up to target of 0.25 mg every other day
Contraindications	**Drug Interactions**
Albumin hypersensitivity, hamster protein hypersensitivity	Antiretroviral NNRTIs; antiretroviral NRTIs; antiretroviral protease inhibitors; ethanol
Pharmacokinetics	**Pharmacodynamics**
Absorption: UK Distribution: UK Metabolism: t½: IM, 19 h; subcut: 69 h Excretion: UK Pregnancy category C*	Interferon beta-1a IM/Subcut: Onset: UK Peak 3-15 h; duration: UK Interferon beta-1b Subcut: Onset: Rapid Peak 16 h; duration: UK
Therapeutic Effects/Uses	
Interferon beta-1a has been shown to decrease both the number and severity of MS attacks (e.g., relapses) and to significantly slow the progression of physical disability associated with relapsing remitting MS.	
Mode of Action: Antiviral and immune-regulatory properties are produced by interacting with specific receptor sites on cell surfaces. It is not exactly known how interferon works to treat MS. Beta-interferon is produced by recombinant DNA technology.	
Side Effects	**Adverse Reactions**
Depression, dizziness, fatigue, suicidal ideation, vision problems, dyspnea, chest pain, edema, abdominal pain, autoimmune hepatitis, cystitis, neutropenia, injection site reaction, myalgia, arthralgia, muscle spasm, anaphylaxis, flulike symptoms	Increased myelosuppression may occur with other myelosuppressives including antineoplastics; concurrent use of hepatotoxic agents may increase risk of hepatotoxicity. Avoid concomitant use with immunomodulating natural products such as astragalus, echinacea, and melatonin.

A, adult; *h*, hours; *IM*, intramuscular; *MS,* multiple sclerosis; *NNRTI,* nonnucleoside reverse transcriptase inhibitor; *NRTI,* nucleoside reverse transcriptase inhibitor; *q,* every; *subcut*, subcutaneous; *t½,* half- life; *UK*, unknown; *wk*, weeks.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Spasticity

Skeletal muscle spasticity is muscular hyperactivity that causes contraction of the muscles, resulting in pain and limited mobility. Centrally acting muscle relaxants act on the spinal cord. Examples of centrally acting muscle relaxants used to treat spasticity are baclofen, dantrolene, and tizanidine. Diazepam, a benzodiazepine, has also been effective for treating spasticity (Complementary and Alternative Therapies 21.1).

COMPLEMENTARY AND ALTERNATIVE THERAPIES 21.1 Diazepam

Kava and valerian may potentiate central nervous system depression.

Patient Safety

Do not confuse…

- **Baclofen,** a skeletal muscle relaxant, with **Bactroban,** a topical antibacterial, or **Beclovent,** a corticosteroid inhalant.

Muscle Spasms

Various centrally acting muscle relaxants are used for muscle spasm to decrease pain and increase range of motion. They have a sedative effect and should not be taken concurrently with CNS depressants such as barbiturates, narcotics, and alcohol. These agents, with the exception of cyclobenzaprine, can cause drug dependence. In addition, dizziness and drowsiness are common side effects. Examples of this group of centrally acting muscle relaxants are carisoprodol, chlorzoxazone, cyclobenzaprine, metaxalone, methocarbamol, and orphenadrine citrate (see Table 21.3).

Pharmacokinetics

Cyclobenzaprine is well absorbed from the GI tract, and its half-life is moderate. Cyclobenzaprine is metabolized in the liver and excreted in urine (see Prototype Drug Chart 21.3).

Pharmacodynamics

Cyclobenzaprine alleviates muscle spasm associated with acute painful musculoskeletal conditions. When cyclobenzaprine is taken with alcohol, kava, valerian, sedative-hypnotics, barbiturates, or tricyclic antidepressants (TCAs), increased CNS depression occurs. The onset of action, peak concentration time, and duration of action for cyclobenzaprine are short.

TABLE 21.2

Drugs for Multiple Sclerosis

Drugs	Route and Dosage	Uses and Considerations
Immunomodulators		
Beta-Interferon Interferon beta-1a Interferon beta-1b	See Prototype Drug Chart 21.2.	
Glatiramer acetate	A: Subcut: 20 mg/mL once daily Subcut: 40 mg/mL 3 × wk	Treatment of relapsing remitting MS Distribution: Enters lymphatic and systemic circulation Onset/Peak/Duration: UK PB: UK; t½: UK Pregnancy category B*
Teriflunomide	A: PO: 7-14 mg once daily	Treatment of relapsing remitting MS Absorption: Well absorbed Distribution: UK PB: >99%; t½: 18-19 d Pregnancy category X*
Immunosuppressants		
Mitoxantrone	A: IV: 12 mg/m² q3mo	Treatment of secondary (chronic) progressive, progressive relapsing, or worsening relapsing remitting MS Absorption: Complete bioavailability Distribution: Widely distributed PB: UK; t½: 5-8 d Pregnancy category D*
Dimethyl fumarate	A: PO: 120 mg bid for 1 wk, then 240 mg bid	Treatment of relapsing forms of MS Absorption: Converted to active metabolite (MMF) by enzymes in the GI tract, blood, and tissue Distribution: UK PB: MMF 27%-45%; t½: MMF 1 h Pregnancy category C*

Sphingosine 1–Phosphate Receptor Modulators		
Fingolimod	A: PO: 0.5 mg once daily	Treatment of relapsing forms of MS Absorption: 93% following oral administration Distribution: 86% of drug into RBCs PB: >99.7%; t½: 6-9 h Pregnancy category C*

Monoclonal Antibody		
Alemtuzumab	A: IV: 12 mg/1.2 mL on 5 consecutive days (total dose of 60 mg) for first treatment course; follow 12 mo later with 12 mg IV for 3 consecutive days (total dose of 36 mg) for second treatment.	Onset: UK Peak: UK PB: UK; t½: 12 d Pregnancy category C*
Natalizumab	A: IV: 300 mg q4wk	Treatment to reduce frequency of exacerbations of relapsing MS Absorption: Complete bioavailability when given by IV route Distribution: UK PB: 99.7%; t½: 7-15 d Pregnancy category C*

>, Greater than; *A,* adult; *bid,* twice daily; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *MMF,* metabolite monomethyl fumarate; *mo,* months; *MS,* multiple sclerosis; *PB,* protein binding; *PO,* by mouth; *q,* every; *RBC,* red blood cell; *subcut,* subcutaneous; *t½,* half-life; *UK,* unknown; *wk,* weeks.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Side Effects and Adverse Reactions

The side effects from centrally acting muscle relaxants include drowsiness, dizziness, lightheadedness, headaches, and occasional GI sensitivity (e.g., nausea, vomiting, abdominal distress). Cyclobenzaprine and orphenadrine have anticholinergic effects (Complementary and Alternative Therapies 21.2).

COMPLEMENTARY AND ALTERNATIVE THERAPIES 21.2

Orphenadrine Citrate

Valerian and kava kava potentiate sedation.

TABLE 21.3
Muscle Relaxants

Drugs	Route and Dosage	Uses and Considerations
Anxiolytics		
Diazepam (CSS C-IV controlled substance; a long-acting benzodiazepam)	A: PO: 2 to 10 mg bid/qid Older adults: PO: 2 to 2.5 mg qd/bid A: IV/IM 2-10 mg, may repeat in 3-4 h C >6 mo: PO: 1 to 2.5 mg tid/qid Seizures: C: IM/IV: 0.05-0.3 mg/kg over 3-5 min q15-30min C >5 y: Max 10 mg q2-4h C <5 y: Max 5 mg q2-4h	Diazepam has many uses, one of which is to relieve muscle spasms associated with paraplegia, MS, MG, and cerebral palsy. It is also used for status epilepticus and acute seizure activity. Contraindication: Narrow-angle glaucoma PB: 98%; t½: A: 20 to 50 h (up to 100 h for metabolites) Pregnancy category D*

Muscle Relaxants		
Centrally Acting Muscle Relaxants (for Spasticity)		
Baclofen	A: PO: Initially 5 mg tid; increase gradually by 5 mg q3d; *max:* 80 mg/d divided over 4 doses	For muscle spasms caused by MS and spinal cord injury. Overdose may cause CNS depression. Drowsiness, dizziness, nausea, and hypotension may occur. PB: 30%; t½: 2.5 to 4 h; Pregnancy category C *
Tizanidine	A: PO: 4 mg q6-8h PRN; *max:* 36 mg/d	To manage spasticity, especially for spinal cord injury and MS. PB: 30%; t½: 2.5 h Pregnancy category C*
Spasticity (Direct Acting)		
Dantrolene sodium	A: PO: Initially 25 mg/d; increase gradually; *maint:* 100 mg bid/qid C >5 y: PO: Initially 0.5 mg/kg/d; increase dose gradually by 0.5 mg/kg tid/qid; *max:* 100 mg qid	For chronic neurologic disorders that cause spasms: SCI, cerebral palsy, stroke, and MS. Start with low doses (25 mg/d) and increase q4-7d. Avoid taking with alcohol or CNS depressants. PB: 95%; t½: 8 h Max dose depends on route of administration and indication. Pregnancy category C*
Centrally Acting Muscle Relaxants		
Carisoprodol	A: PO: 250-350 mg qid/daily	For relaxation of skeletal muscles. Has CNS depressant effects. Avoid taking with alcohol or CNS depressants. Should only be used on a short-term basis (2 to 3 wk). PB: UK; t½: 8 h; Pregnancy category C *; increased risk for addiction
Chlorzoxazone	A: PO: 250 to 500 mg tid/qid; *max:* 3 g/d	For relief of acute or severe muscle spasms. Not effective for cerebral palsy. Take with food to decrease GI upset. PB: UK; t½: 1.1 h; Pregnancy category C *
Methocarbamol	A: PO: Initially 1.5 g qid for 2-3/d; *maint:* 4 to 4.5 g/d in 3 to 6 divided doses; *max:* 8 g/d A: IM/IV 1-3 g/d q8h up to 3 d; repeat course after a 48-h rest.	For relief of acute muscle spasms; used for treatment of tetanus. Has CNS depressant effects (sedation). Avoid taking with alcohol or CNS depressants. Urine may turn green, brown, or black. Drowsiness may occur but usually decreases with continued drug use. PB: UK; t½: 1 to 2 h; Pregnancy category C *
Metaxalone	A: PO: Initially 400- 800 mg tid/qid; *max:* 3200 mg/d	Relief of acute painful muscle spasticity PB: UK; t½: 2-3 h; Pregnancy category UK *
Orphenadrine	A: PO: 100 mg bid; *max:* 200 mg/d A: IM/IV: 60 mg q12h; *max:* 120 mg/d	For relief of acute muscle spasm. Can be toxic with a mild overdose. Used in combination with aspirin and caffeine. Contraindication: MG PB: <20%; t½: 14 h; Pregnancy category C*
Depolarizing Skeletal Muscle Relaxant (Adjunct to Anesthesia)		
Succinylcholine	A: IV: 0.3-1.1 mg/kg over 10-30 s Short procedure: 1 mg/kg max Long procedure: 10 mg/min max	Used for surgical skeletal muscle relaxation and in endoscopy and intubation PB: UK; t½: UK; Pregnancy category C*
Nondepolarizing Skeletal Muscle Relaxants (Adjunct to Anesthesia)		
Neuromuscular blocking agent		
Pancuronium bromide	A/C >1 mo: IV: 0.04-0.1 mg/kg; then 0.01 mg/kg at 30- to 60-min intervals	Used in surgery for relaxation of skeletal muscle (e.g., abdominal wall). Does not cause hypotension. May cause respiratory depression. Assess cardio and respiratory status constantly. PB: 30%-87%; t½: 2 h; Pregnancy category C*
Table Continued		

Muscle Relaxants		
Vecuronium bromide Must be administered only by qualified clinicians	A/C >10 y: IV: 0.08-0.1 mg/kg initially, then after 25-40 min, give 0.01-0.15 mg/kg q12-15min or as a continuous infusion 0.001 mg/kg/min	For surgical skeletal muscle relaxation. Can be used for patients with asthma, renal disease, or limited cardiac reserve. Given after general anesthesia has been started. PB: 60%-90%; t½: 30-80 min Pregnancy category C*

>, Greater than; <, less than; *A,* adult; *bid,* twice a day; *C,* child; *cardio*, cardiovascular; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max*, maximum; *MG*, myasthenia gravis; *min*, minutes; *mo,* months; *MS,* multiple sclerosis; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q,* every; *qid,* four times a day; *s*, seconds; *SCI*, spinal cord injury; *t½,* half-life; *tid,* three times a day; *UK,* unknown; *wk*, weeks; *y,* year.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 21.3 Cyclobenzaprine

Drug Class	Dosage
Centrally acting muscle relaxants	A: PO: 5-10 mg tid; *max:* 30 mg/d tid; treatment beyond 2-3 wk is not recommended. A: PO: ER cap 15 mg/d; *max:* 30 mg/d
Contraindications	Drug-Lab-Food Interactions
AV block, acute MI, bradycardia, bundle-branch block, cardiac arrhythmias, children, cerebral palsy, diabetes mellitus, heart failure, hyperthyroidism, hypertension, hypokalemia, paralytic ileus, concurrent use of MAOI therapy, QT prolongation, SCI *Caution:* Seizure disorder, alcohol, CNS depressants, glaucoma, prostatic hypertrophy, urinary retention, hepatic disease, breastfeeding, driving or operating machinery, morbidity in geriatric patients, sunlight UV exposure	Drug: Increased CNS depression with alcohol, kava (*Piper methysticum*), valerian, barbiturates, TCAs, and other CNS depressants. Check resource book for multiple interactions. Take with food or milk to decrease GI upset.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Well absorbed Distribution: PB: 93% Metabolism: t½: 1-3 days Excretion: In urine	PO: Onset: 1 h Peak: 3-8 h Duration: 12-24 h Pregnancy category B*; PB: 93%
Therapeutic Effects/Uses	
For short-term treatment of muscle spasms	
Mode of Action: Relieves muscle spasms through a central action, possibly at the brainstem level	
Side Effects	Adverse Reactions
Anticholinergic effects (blurred vision, constipation, dry mouth, tachycardia, urinary retention); arrhythmias, confusion, drowsiness, dizziness, headache, nausea, nervousness, unpleasant taste, urinary retention	Allergic reactions, angioedema, MI, seizures, ileus

A, Adult; *AV*, atrioventricular; *cap*, capsule; *CNS,* central nervous system; *d,* day; *ER*, extended release; *GI,* gastrointestinal; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *MI,* myocardial infarction; *PB,* protein binding; *PO,* by mouth; *SCI*, spinal cord injury; *t½,* half-life; *TCA,* tricyclic antidepressant; *tid*, three times a day; *UV*, ultraviolet; *wk*, week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Muscle Relaxant: Cyclobenzaprine

Assessment

- Obtain a medical history. Cyclobenzaprine is contraindicated if the patient has cardiovascular disorders, hyperthyroidism, or hepatic impairment or is taking concurrent monoamine oxidase inhibitors (MAOIs).
- Obtain baseline vital signs.
- Assess the patient's health history to identify the cause of muscle spasm and determine whether it is acute or chronic.
- Observe the patient's drug history for possible drug interactions.
- Note whether the patient has a history of narrow-angle glaucoma or MG. Cyclobenzaprine and orphenadrine are contraindicated with these health problems.

Nursing Diagnoses

- Physical Mobility, Impaired related to dizziness and hyperactive reflexes
- Activity Intolerance related to drowsiness and hyperactive reflexes

Planning

- The patient will be free of muscular pain within 1 week.

Nursing Interventions

- Monitor serum liver enzyme levels of patients taking dantrolene and carisoprodol. Report to the health care provider elevated levels of liver enzymes such as alkaline phosphatase (ALP), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT).
- Record vital signs. Report abnormal results.
- Observe for CNS side effects (e.g., dizziness).

Patient Teaching

General

- Teach patients that the muscle relaxant should not be abruptly stopped. The drug should be tapered over 1 week to avoid rebound spasms.
- Advise patients not to drive, operate dangerous machinery, or make important life-changing decisions when taking muscle relaxants. These drugs have a sedative effect and can cause drowsiness.
- Inform patients that most of the centrally acting muscle relaxants for acute spasms are usually taken for no longer than 3 weeks.
- Teach patients to avoid alcohol and CNS depressants. If muscle relaxants are taken with these drugs, CNS depression may be intensified.
- Advise patients that these drugs must be used cautiously when pregnant or nursing.
- Patients should always check with the health care provider prior to stopping medications.

Side Effects

- Encourage patients to report side effects of the muscle relaxant: nausea, vomiting, dizziness, fainting, headache, and diplopia can occur. Dizziness and fainting are most likely caused by orthostatic (postural) hypotension.

Diet

- Advise patients to take muscle relaxants with food to decrease GI upset.

Cultural Considerations

- Use both hands to show respect when offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders.
- Demonstrate respect by addressing patients formally until told otherwise, and do not ask private questions in public.

Evaluation

- Evaluate the effectiveness of the muscle relaxant, and determine whether the patient's muscular pain or spasms have decreased or disappeared.

Critical Thinking Case Study

FR, a 29-year-old woman, was diagnosed with myasthenia gravis (MG) 2 years ago. She is receiving pyridostigmine 120 mg three times daily. Last evening, FR was involved in an automobile accident. She was taken to the emergency department unconscious and missed two evening doses of pyridostigmine.

1. How does pyridostigmine alleviate the symptoms of MG?
2. What are the potential side effects and adverse effects of pyridostigmine?
3. What problems are likely to develop following delayed pyridostigmine dosing?

FR is scheduled for surgery to repair a fractured right femur suffered in the accident. During surgery, FR develops bradycardia.

4. What medications may lead to drug interactions with pyridostigmine?
5. What problems may develop from pyridostigmine overdosing?
6. What are the similarities between myasthenic crisis and cholinergic crisis?

NCLEX Study Questions

1. When the nurse explains the pathophysiology of myasthenia gravis to a patient, which is the best explanation?
   a. Degeneration of cholinergic neurons and a deficit in acetylcholine lead to neuritic plaques and neurofibrillary tangles.
   b. A decreased amount of acetylcholine to cholinergic receptors produces weak muscles and reduced nerve impulses.
   c. Myelin sheaths of nerve fibers in the brain and spinal cord develop lesions or plaques.
   d. An imbalance of dopamine and acetylcholine leads to degeneration of neurons in midbrain and extrapyramidal motor tracts.
2. The nurse is teaching a patient recently diagnosed with multiple sclerosis about the disease. Which statement is *not* correct concerning multiple sclerosis?
   a. The disease has periods of exacerbations and remissions.
   b. Goals of treatment are to decrease the inflammation in the nervous system.
   c. Patients experience muscle weakness, vision problems, and fatigue.
   d. Multiple sclerosis is an autoimmune disorder that causes plaque to develop in the spinal cord.
3. A patient has spasticity following a spinal cord injury. The nurse anticipates that which drug will be prescribed to treat the patient's spasticity?
   a. Neostigmine
   b. Ropinirole
   c. Cyclobenzaprine
   d. Pyridostigmine
4. The nurse anticipates that the health care provider will prescribe which medication to treat a patient with relapsing remitting multiple sclerosis?
   a. Ambenonium
   b. Pyridostigmine
   c. Mitoxantrone
   d. Glatiramer acetate
5. The nurse is providing medication instructions to a patient with acute muscle spasms who has been prescribed cyclobenzaprine. Which statement indicates to the nurse that the patient understands the instructions?
   a. I plan to take this medication with a glass of milk.
   b. Cyclobenzaprine should be taken once daily at bedtime.
   c. I will only drink one glass of wine per day.
   d. I will be able to take this drug with grapefruit juice.
6. Which instructions will the nurse include in the teaching plan for a patient who is taking pyridostigmine? (Select all that apply.)
   a. Pyridostigmine must be taken on time.
   b. Take the prescribed dose every other week.
   c. Underdosing can result in myasthenic crisis.
   d. Overdosing can result in cholinergic crisis.
   e. Report the adverse effect of tachycardia to the health care provider.
7. A patient is beginning to take cyclobenzaprine for treatment of acute back spasms. Which interventions will the nurse include in the care of this patient? (Select all that apply.)
   a. Advise the patient to take this drug on an empty stomach.
   b. Inform the patient not to abruptly stop taking the muscle relaxant. The dose should be tapered down.

c. Tell the patient to report dizziness and double vision to the health care provider.

d. Advise the patient to avoid alcohol.

e. Taking narcotics at the same time can cause serious side effects.

8. The nurse is reviewing a patient's medication history for a patient who has just been prescribed cyclobenzaprine for treatment of back spasms. The nurse plans to contact the health care provider if the patient is taking which of these?

a. Atorvastatin

b. Conjugated estrogen

c. Valerian

d. Penicillin G procaine

9. The nurse is caring for a patient who has been diagnosed with myasthenia gravis. The patient is experiencing muscle weakness, dyspnea, bradycardia, and diaphoresis. The nurse anticipates that the health care provider will order which medication to distinguish between myasthenic crisis and cholinergic crisis?

a. Adrenocorticotropic hormone

b. Diazepam

c. Edrophonium

d. Mitoxantrone

Answers: 1, b; 2, b; 3, c; 4, d; 5, a; 6, a, c, d; 7, b, c, d, e; 8, c; 9, c.

UNIT VI
Mental and Behavioral Health Drugs

OUTLINE

Introduction
22. Antipsychotics and Anxiolytics
23. Antidepressants and Mood Stabilizers

Introduction

From moods and emotions flow the various thoughts and actions of individuals, which are communicated throughout the central nervous system (CNS) by chemical neurotransmitters. An impulse is communicated by traveling through the presynaptic neuron across the synaptic cleft and binding to a receptor on the postsynaptic neuron, as illustrated in Fig. VI.I.

Neurotransmitters are synthesized in the cytoplasm in the presynaptic neuron and are stored in vesicles, which safeguard neurotransmitters from being destroyed by enzymes. When an impulse arrives by way of an action potential at a presynaptic neuron, vesicles are triggered to move to the cell membrane wall and release the transmitter into the synaptic cleft.

Neurotransmitters function with the help of receptors, which are embedded in the membrane of the postsynaptic neuron. Receptors are configured in size and shape to interlock with specific transmitters. Immediately upon connection of neurotransmitters to receptors, an action is exerted and the transmitter is removed. Once released, transmitters can be broken down into inactive substances by enzymes, diffused away from the synapse into intracellular fluid, or returned to the presynaptic neuron in a process called *reuptake.*

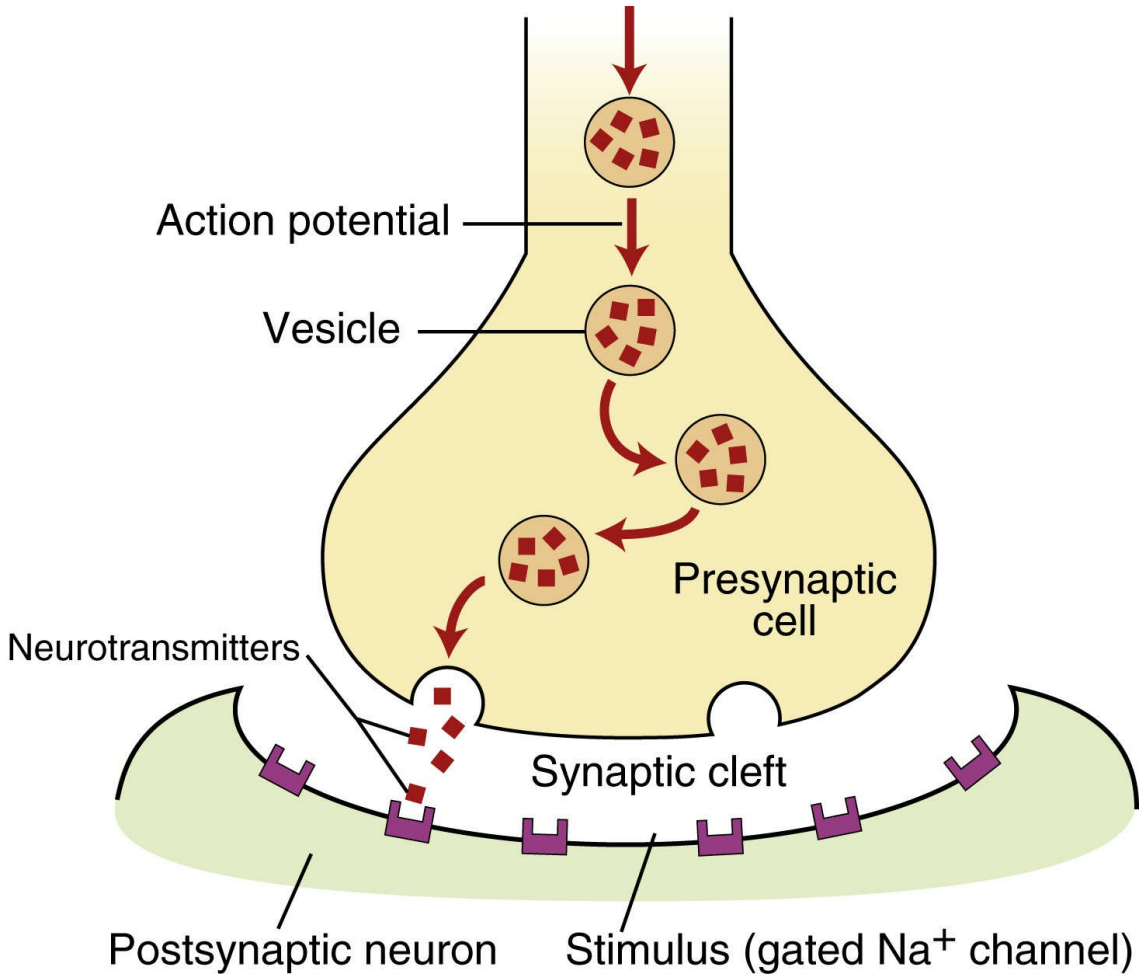

FIG. VI.I Chemical Neurotransmitters.

The major neurotransmitters that affect psychopathology include gamma-aminobutyric acid (GABA), serotonin, dopamine, norepinephrine, and acetylcholine. The GABA neurotransmitter is associated with the regulation of anxiety. When the level of GABA neurotransmitters is reduced, anxiety disorders may result. Benzodiazepines (antianxiety drugs) act by binding to a GABA receptor site, making the postsynaptic receptor more sensitive to GABA and its neurotransmission. This connection decreases the signs and symptoms of anxiety.

Serotonin neurotransmission is associated with arousal and general activity levels of the CNS. Serotonin functions to regulate sleep, wakefulness, and mood as well as the delusions, hallucinations, and withdrawal of schizophrenia. Antidepressants block the reuptake of serotonin into the presynaptic neuron. A structurally specific drug is more likely to affect only the specific receptors for which it is intended and not the receptors specific for other neurochemicals, which would produce unintended effects. Selective serotonin reuptake inhibitor (SSRI) drugs are specific and generally produce fewer side effects in the treatment of depression than older antidepressants such as monoamine oxidase inhibitors (MAOIs).

Dopamine-containing neurons are thought to be involved in the regulation of cognition, emotional responses, and motivation, and dopamine neurotransmitters are associated with schizophrenia and other psychoses. Antipsychotic drugs block dopamine receptors in the postsynaptic neuron.

Norepinephrine is associated with control of arousal, attention, vigilance, mood, affect, and anxiety. This neurotransmitter is involved with thinking, planning, and interpreting. Tricyclic antidepressants (TCAs) block the reuptake of norepinephrine into the presynaptic neuron and effectively treat depressive disorders. MAOIs inactivate norepinephrine, dopamine, and serotonin by inhibiting the monoamine oxidase enzyme to relieve signs and symptoms of depression.

Faulty release, reuptake, or elimination of neurotransmitters may lead to an imbalance of

neurotransmission and subsequent pathology. Disorders can then develop that can affect an individual's thoughts, feelings, and behaviors.

Knowledge of psychopharmacology is essential to psychiatric mental health nursing. A basic understanding of the actions of psychotropic drugs will help nurses rapidly comprehend and apply information and enhance the effectiveness of pharmacologic treatment. Essential responsibilities of the nurse administering psychotropic medications are to assess behavior, monitor for side effects, and educate the patient and family. These actions are crucial to successful psychopharmacologic therapy.

Drugs used to treat psychoses and anxiety are discussed in Chapter 22. Antidepressants and mood stabilizers are discussed in Chapter 23.

Antipsychotics and Anxiolytics

OUTLINE

Psychosis
Antipsychotic Agents
- Pharmacophysiologic Mechanisms of Action
- Adverse Reactions
- Phenothiazines
- Nonphenothiazines
- Antipsychotic Dosage for Older Adults
- Atypical Antipsychotics (Serotonin/Dopamine Antagonists)
- Nursing Process: Patient-Centered Collaborative Care—Phenothiazines and Nonphenothiazines

Anxiolytics
- Nonpharmacologic Measures
- Benzodiazepines
- Miscellaneous Anxiolytics
- Nursing Process: Patient-Centered Collaborative Care—Benzodiazepines

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Differentiate between antipsychotic and anxiolytic drug groups.
- Contrast the action, uses, side effects, and adverse effects of traditional typical and atypical antipsychotics.
- Plan nursing interventions, including patient teaching, for the patient taking antipsychotics and anxiolytics.
- Apply the nursing process to the patient taking an atypical antipsychotic, a typical antipsychotic, and an anxiolytic.

Central nervous system (CNS) depressants used to manage symptoms of psychosis and anxiety disorders include antipsychotics and anxiolytics, which may cause psychosis. Antipsychotics are also known as *neuroleptics* or *psychotropics,* but the preferred name for this group is either *antipsychotics* or *neuroleptics.* The term **neuroleptic** refers to any drug that modifies psychotic behavior and exerts an antipsychotic effect. Anxiolytics are also called *antianxiety drugs* or *sedative-hypnotics.* Certain anxiolytics are used to treat sleep disorders, seizures, and withdrawal symptoms from alcohol or other abuse substances. Some of these drugs are also used for conscious sedation and anesthesia supplementation. However, the anxiolytics described in this chapter are used specifically to treat anxiety and psychotic behaviors.

Psychosis

Psychosis, or loss of contact with reality, is manifested in a variety of mental or psychiatric disorders. Psychosis is usually characterized by more than one symptom, such as difficulty in processing information, disorganized thoughts, distortion of reality, delusions, hallucinations, incoherence, catatonia, and aggressive or violent behavior. **Schizophrenia**, a chronic psychotic disorder, is the major category of psychosis in which many of these symptoms are manifested.

The symptoms of schizophrenia usually develop in adolescence or early adulthood and are divided into three groups: (1) cognitive symptoms, (2) positive symptoms, and (3) negative symptoms. *Cognitive symptoms* are characterized by disorganized thinking, memory difficulty, and decreased ability to focus attention. *Positive symptoms* may be characterized by exaggeration of normal function (e.g., agitation), incoherent speech, hallucinations, delusions, and paranoia. *Negative symptoms* are characterized by a decrease or loss in function and motivation. A poverty or simplicity of speech, blunted affect, inertia, poor self-care, and social withdrawal are apparent. Negative symptoms tend to be more chronic and persistent. The typical, conventional, or traditional group of antipsychotics (first-generation antipsychotics) is more helpful for managing positive symptoms. A group of antipsychotics called *atypical* (second-generation antipsychotics) has been found to be the newest treatment for both positive and negative symptoms of schizophrenia.

Antipsychotics compose the largest group of drugs used to treat mental illness. Specifically, these drugs improve the thought processes and behavior of patients with psychotic symptoms, especially those with schizophrenia and other psychotic disorders. They are not used as a primary treatment for anxiety or depression. The theory is that psychotic symptoms result from an imbalance in the neurotransmitter **dopamine** in the brain. Sometimes these antipsychotics are called *dopamine antagonists.* Antipsychotics block D_2 dopamine receptors in the brain and thus reduce psychotic symptoms. Many antipsychotics block the chemoreceptor trigger zone (CTZ) and vomiting (emetic) center in the brain, producing an **antiemetic** (prevents or relieves nausea and vomiting) effect. However, when dopamine is blocked, symptoms of **extrapyramidal syndrome (EPS)** or **parkinsonism** (a chronic neurologic disorder that affects the extrapyramidal motor tract) such as tremors, masklike facies, rigidity, and shuffling gait may develop. Many patients who take high-potency antipsychotic drugs may require long-term medication for symptoms of parkinsonism.

Antipsychotic Agents

Antipsychotics are divided into two major categories: *typical* and *atypical.* The **typical antipsychotics**, introduced in 1952, are subdivided into phenothiazines and nonphenothiazines. *Nonphenothiazines* include butyrophenones, dibenzoxazepines, dihydroindolones, and thioxanthenes. The butyrophenones block only the neurotransmitter dopamine. The *phenothiazines* and the thioxanthenes block norepinephrine, causing sedative and hypotensive effects early in treatment.

Atypical antipsychotics make up the second category of antipsychotics. Clozapine, discovered in the 1960s and made available in Europe in 1971, was the first atypical antipsychotic agent. It was not marketed in the United States until 1990 because of adverse hematologic reactions. Atypical antipsychotics are effective for treating schizophrenia and other psychotic disorders in patients who do not respond to or are intolerant of typical antipsychotics. Because of their decreased side effects, atypical antipsychotics are often used instead of traditional typical antipsychotics as first-line therapy.

Pharmacophysiologic Mechanisms of Action

Antipsychotics block the actions of dopamine and thus may be classified as dopaminergic antagonists. There are five subtypes of dopamine receptors numbered D_1 through D_5. All antipsychotics block the D_2 (dopaminergic) receptor, which in turn promotes the presence of EPS, resulting in drug-induced pseudoparkinsonism in varying degrees. Atypical antipsychotics have a weak affinity to D_2 receptors and a stronger affinity to D_4 receptors, and they block the serotonin receptor. These agents cause fewer EPS than the typical (phenothiazine) antipsychotic agents, which have a strong affinity to D_2 receptors.

Adverse Reactions

Extrapyramidal Syndrome

Pseudoparkinsonism, which resembles symptoms of parkinsonism, is a major side effect of typical antipsychotic drugs. Symptoms of pseudoparkinsonism or EPS include stooped posture, masklike facies, rigidity, tremors at rest, shuffling gait, pill-rolling motions of the hands, and bradykinesia. When patients take high-potency typical antipsychotic drugs for extended periods, EPS is more pronounced. Patients who take low-strength antipsychotics such as chlorpromazine are not as likely to have symptoms of pseudoparkinsonism as those who take fluphenazine.

During early treatment with typical antipsychotic agents for schizophrenia and other psychotic disorders, two adverse extrapyramidal reactions that may occur are acute dystonia and akathisia. Tardive dyskinesia is a later phase of extrapyramidal reaction to antipsychotics. Use of anticholinergic drugs helps decrease pseudoparkinsonism symptoms, acute dystonia, and akathisia but has little effect on alleviating tardive dyskinesia. Complementary and Alternative Therapies 22.1 details interactions with antipsychotic agents.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 22.1

Antipsychotic Agents

- Kava kava may increase the risk and severity of dystonic reactions when taken with phenothiazines.
- Kava kava may increase the risk and severity of dystonia when taken concurrently with fluphenazine.

The symptoms of **acute dystonia** usually occur in 5% of patients within days of taking typical antipsychotics. Characteristics of the reaction include muscle spasms of the face, tongue, neck, and back; facial grimacing; abnormal or involuntary upward eye movement; and laryngeal spasms that can impair respiration. This condition is treated with an anticholinergic antiparkinson drug such as

benztropine. The benzodiazepine lorazepam may also be prescribed.

Akathisia occurs in approximately 20% of patients who take a typical antipsychotic drug. With this reaction, the patient has trouble standing still, is restless, paces the floor, and is in constant motion (e.g., rocks back and forth). Akathisia is best treated with a benzodiazepine such as lorazepam or a beta blocker such as propranolol.

Tardive dyskinesia is a serious adverse reaction that occurs in approximately 20% to 30% of patients who have taken a typical antipsychotic drug for more than 1 year. The prevalence is higher in cigarette smokers. The likelihood of developing tardive dyskinesia depends on the dose and duration of the antipsychotic factor. Characteristics of tardive dyskinesia include protrusion and rolling of the tongue, sucking and smacking movements of the lips, chewing motion, and involuntary movement of the body and extremities. In older adults, these reactions are more frequent and severe. The antipsychotic drug should be stopped in all who experience tardive dyskinesia, and another antipsychotic agent should be substituted. Benzodiazepines, calcium channel blockers, and beta blockers are sometimes helpful in decreasing tardive dyskinesia, although no one agent is effective for all patients. High doses of vitamin E may be helpful, and its use to treat tardive dyskinesia is currently under investigation. Clozapine has also been effective for treating tardive dyskinesia. Tetrabenazine, used to improve symptoms of Huntington disease, seems to be effective in treating tardive dyskinesia. Tetrabenazine reduces dopamine, norepinephrine, and serotonin levels. Amantadine has also been helpful in reducing drug-induced involuntary movements. Fig. 22.1 shows the characteristics of pseudoparkinsonism, acute dystonia, akathisia, and tardive dyskinesia.

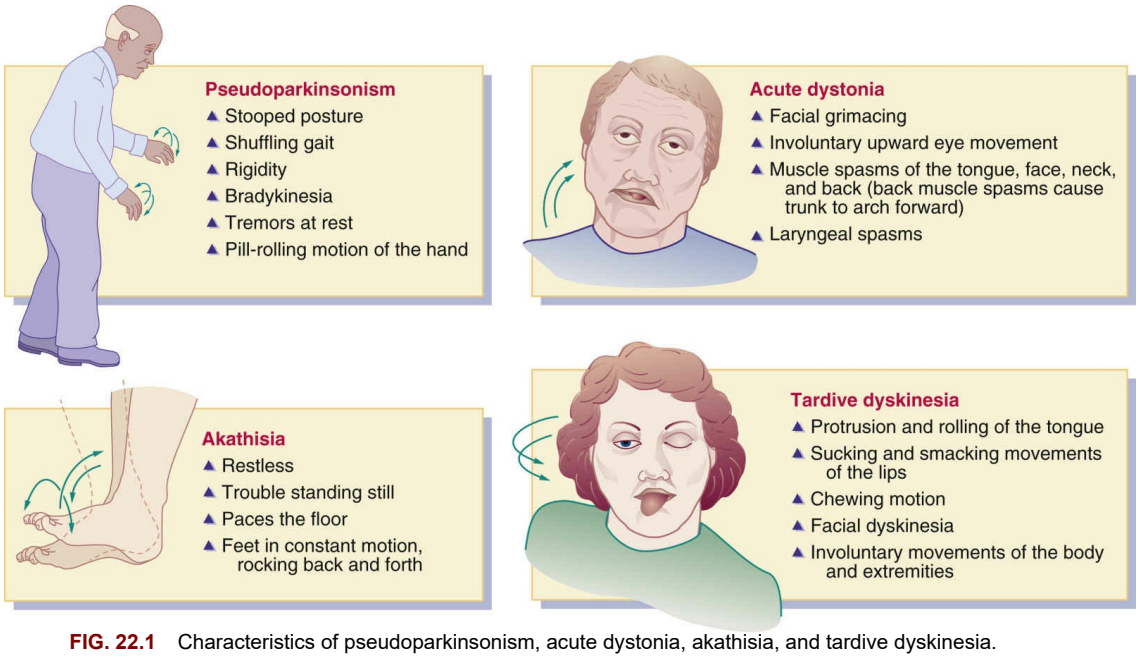

FIG. 22.1 Characteristics of pseudoparkinsonism, acute dystonia, akathisia, and tardive dyskinesia.

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome (NMS) is a rare but potentially fatal condition associated with antipsychotic drugs. Predisposing factors include excess agitation, exhaustion, and dehydration. NMS symptoms involve muscle rigidity, hyperthermia, altered mental status, profuse diaphoresis, blood pressure fluctuations, tachycardia, dysrhythmias, seizures, rhabdomyolysis, acute renal failure, respiratory failure, and coma. Treatment of NMS involves immediate withdrawal of antipsychotics, adequate hydration, hypothermic blankets, and administration of antipyretics, benzodiazepines, and muscle relaxants such as dantrolene.

Phenothiazines

Chlorpromazine hydrochloride was the first phenothiazine introduced for treating psychotic behavior in patients in psychiatric hospitals. The **phenothiazines** are subdivided into three groups: aliphatic, piperazine, and piperidine, which differ mostly in their side effects.

The *aliphatic phenothiazines* produce a strong sedative effect, decreased blood pressure, and may cause moderate EPS (pseudoparkinsonism). Chlorpromazine hydrochloride is in the aliphatic group and may produce pronounced **orthostatic hypotension**, low blood pressure that occurs when an individual assumes an upright position from a supine position.

The *piperazine phenothiazines* produce more EPS than other phenothiazines. They also cause dry mouth, urinary retention, and agranulocytosis. Examples of piperazine phenothiazines are fluphenazine and perphenazine.

The *piperidine phenothiazines* have a strong sedative effect, cause few EPS, have a low to moderate effect on blood pressure, and have no antiemetic effect. Thioridazine is an example of piperidine phenothiazines. Table 22.1 summarizes the effects of the phenothiazines.

Most antipsychotics can be given orally (tablet or liquid), intramuscularly (IM), or intravenously (IV). For oral use, the liquid form might be preferred because some patients may hide tablets in their cheek or under their tongue to avoid taking them. Mouth checks are necessary for noncompliant patients. In addition, the absorption rate is faster with the liquid form, and a peak serum drug level occurs in 2 to 3 hours. The antipsychotics are highly protein bound (>90%), and excretion of the drugs and their metabolites is slow. Phenothiazines are metabolized by liver enzymes into phenothiazine metabolites. Metabolites can be detected in the urine several months after the medication has been discontinued. Phenothiazine metabolites may cause a harmless pinkish to red-brown urine color. The *full* therapeutic effects of oral antipsychotics may not be evident for 3 to 6 weeks following initiation of therapy, but an observable therapeutic response may be apparent after 7 to 10 days.

TABLE 22.1

Effects of Phenothiazines (Varies Within Class)

Group	Sedation	Hypotension	EPS	Antiemetic

Atypical Antipsychotics				
risperidone	+	+	+/0	—

—, No effect; +, mild effect; ++, moderate effect; +++, severe effect; *EPS*, symptoms of extrapyramidal syndrome.

Noncompliance with antipsychotics is common. Medication teaching in the following areas is of utmost importance: (1) encourage the patient to take the medication as prescribed, (2) explain and emphasize essential information to compensate for the patient's knowledge deficit, and (3) provide an interpreter for patients whose first language is not English.

Prototype Drug Chart 22.1 shows the drug characteristics of fluphenazine, a phenothiazine antipsychotic used to manage psychosis. Box 22.1 shows the symptoms and suggested treatment for overdose of phenothiazines.

Pharmacokinetics

Oral absorption of fluphenazine is rapid and unaffected by food. This drug is strongly protein bound and has a long half-life, therefore the drug may accumulate in the body. Fluphenazine is metabolized by the liver, crosses the blood-brain barrier and placenta, and is excreted as metabolites primarily in the urine. With hepatic dysfunction, the phenothiazine dose may need to be decreased. Lack of drug metabolism in the liver will cause an elevation in serum drug level.

Pharmacodynamics

Fluphenazine is prescribed primarily for psychotic disorders. This drug has anticholinergic properties and should be cautiously administered to patients with glaucoma, especially narrow-angle glaucoma. Because hypotension is a side effect of these phenothiazines, any antihypertensives simultaneously administered can cause an additive hypotensive effect. Narcotics and sedative-hypnotics administered simultaneously with these phenothiazines can cause an additive CNS depression. Antacids decrease the absorption rate of both drugs and all phenothiazines, so they should be given 1 hour before or 2 hours after an oral phenothiazine.

PROTOTYPE DRUG CHART 22.1 Fluphenazine

Drug Class	Dosage
Antipsychotic: Neuroleptic piperazine phenothiazine Pregnancy category C*	A: PO: Initially 2.5-10 mg/d in 2-3 divided doses, increase gradually; maint: 1-5 mg/d; *max*: 40 mg/d Older adults: PO: 1-2.5 mg/d in 2-3 divided doses; maint: 1-5 mg/d; *max:* 40 mg/d Immediate release: A: IM: 1.25 mg single dose; maint: 2.5-10 mg/d in divided doses q6-8h; *max:* 10 mg/d Fluphenazine decanoate ER: A/adol/C >12 y: IM/subcut: : 12.5-25 mg q3wk; *max*: 100 mg/dose
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, subcortical brain damage, severe CNS depression, coma *Caution:* Dysrhythmias, paralytic ileus, urinary retention, BPH, leukopenia, neutropenia, agranulocytosis, hepatic and renal damage, hypotension, dementia in elderly patients, glaucoma, parkinsonism, seizure disorder	Drug: Increased depressive effects when taken with alcohol or other CNS depressants; $MgSO_4$, lithium, and beta blockers increase effects; antacids and antiparkinsonism drugs decrease effects. Complementary and alternative therapies: Kava kava may increase dystonia.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Rapidly absorbed Distribution: PB 91%-99% Metabolism: t½: HCl, 15 h; decanoate, 14 d Excretion: In urine	PO: Onset: HCl, 1 h; decanoate, 24 h Peak: HCl, 2 h; decanoate, 48-96 h Duration: HCl, 6-8 h; decanoate, 4 wk
Therapeutic Effects/Uses	
To manage symptoms of psychosis including schizophrenia	
Mode of Action: Blocks dopamine receptors in the brain and controls psychotic symptoms	
Side Effects	**Adverse Reactions**
Drowsiness, dizziness, headache, dry mouth, blurred vision, excess sweating, weight gain, constipation, urinary retention, peripheral edema, sexual dysfunction	Hypertension, hypotension, tachycardia, ileus, EPS, seizures, psychosis *Life threatening*: Agranulocytosis, leukopenia, neutropenia, hepatotoxicity, bronchospasm, dysrhythmias, NMS

>, Greater than; *A,* adult; *adol,* adolescent; *BPH,* benign prostatic hyperplasia; *C,* child; *CNS,* central nervous system; *d,* day; *ER,* extended release; *EPS,* symptoms of extrapyramidal syndrome; *h,* hours; *HCl,* hydrochloride; *IM,* intramuscular; *maint,* maintenance; *max,* maximum; *$MgSO_4$,* magnesium sulfate; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *q6-8h,* every 6 to 8 hours; *subcut,* subcutaneous; *t½,* half-life; *wk,* weeks; *y,* years.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

BOX 22.1 Symptoms and Suggested Treatment for Overdose of Phenothiazines

Symptoms

- Unable to arouse; blood pressure fluctuations; tachycardia; agitation; delirium; convulsions; dysrhythmias; neuroleptic malignant syndrome; extrapyramidal symptoms; and renal, cardiac, and respiratory failure

Treatment

- Maintain airway, gastric lavage, activated charcoal administration, adequate hydration, anticholinergics, and norepinephrine

The onset of action for fluphenazine hydrochloride is 1 hour, with a duration rate of 6 to 8 hours. Fluphenazine decanoate has delayed absorption, with an onset of action of 24 hours and a duration of 4 weeks.

Nonphenothiazines

The many groups of nonphenothiazine antipsychotics include butyrophenones, dibenzoxazepines, dihydroindolones, and thioxanthenes.

In the *butyrophenone* group, a frequently prescribed nonphenothiazine is haloperidol. Haloperidol's pharmacologic behavior is similar to that of the phenothiazines. It is a potent antipsychotic drug in which the equivalent prescribed dose is smaller than that of drugs of lower potency, such as chlorpromazine. The drug dose for haloperidol is 0.5 to 5 mg, whereas the drug dose for chlorpromazine is 10 to 25 mg. Long-acting preparations of haloperidol decanoate and fluphenazine decanoate are given for slow release via injection every 2 to 4 weeks. Administration precautions should be taken to prevent soreness and inflammation at the injection site. Because the medication is a viscous liquid, a large-gauge needle (e.g., 21 gauge) should be used with the Z-track method for administration in a deep muscle; Chapter 10 provides further explanation of the Z-track method of injection. The injection site should not be massaged, and sites should be rotated. These medications should not remain in a plastic syringe longer than 15 minutes. Prototype Drug Chart 22.2 provides the drug data related to haloperidol.

Pharmacokinetics

Haloperidol is absorbed well through the gastrointestinal (GI) mucosa. It has a long half-life and is highly protein bound, so the drug may accumulate. Haloperidol is metabolized in the liver and is excreted in urine and feces.

Pharmacodynamics

Haloperidol alters the effects of dopamine by blocking dopamine receptors, thus sedation and EPS may occur. The drug is used to control psychosis and to decrease agitation in adults and children. Dosages need to be decreased in older adults because of decreased liver function and potential side effects. Haloperidol may be prescribed for children with hyperactive behavior. Because it has anticholinergic activity, care should be taken when administering it to patients with a history of glaucoma.

Haloperidol has a similar onset of action, peak time of concentration, and duration of action as the phenothiazines. It has strong EPS effects. Skin and sun protection is necessary for prolonged use because of the possible side effect of photosensitivity.

PROTOTYPE DRUG CHART 22.2 Haloperidol and Haloperidol Decanoate

Drug Class	Dosage
Antipsychotic: Neuroleptic (nonphenothiazine) Pregnancy category C*	A/adol: PO: Initially 0.5-5 mg bid/tid; maint: 10-15 mg/d; *max*: 100 mg/d C 3-12 y: PO: Initially 0.25-0.5 mg/d in 2-3 divided doses; *max*: 0.15 mg/kg/d Deconate: A: IM: *max*: 100 mg first dose, 450 mg subsequent monthly doses
Contraindications	**Drug-Lab-Food Interactions**
Narrow-angle glaucoma; severe hepatic, renal, and cardiovascular diseases; bone marrow depression; parkinsonism; blood dyscrasias; CNS depression; subcortical brain damage; coma *Caution:* Alcoholism, dementia, glaucoma, dehydration, CAD, liver and renal damage, neutropenia, leukopenia	Drug: Increased sedation with alcohol, CNS depressants; increased toxicity with anticholinergics, CNS depressants, lithium; decreased effects with phenobarbital, carbamazepine; decreased effects with caffeine
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: 60% absorbed Distribution: PB: 92% Metabolism: t½: 12-22 h Excretion: In urine and feces	PO: Onset: 60-90 min Peak: 4-6 h Duration: 24-72 h IM: Onset: 15-30 min Peak: 20-40 min Duration: 4-8 h IM: Decanoate: Onset: UK Peak: 6 d Duration: 3-4 wk
Therapeutic Effects/Uses	
To treat acute psychoses, ADHD, schizophrenia, Tourette syndrome	
Mode of Action: Alters the effect of dopamine on the CNS; the mechanism for antipsychotic effects is unknown.	
Side Effects	**Adverse Reactions**
Drowsiness, orthostatic hypotension, headache, lethargy, tremor, dry mouth and eyes, blurred vision, insomnia, agitation, weight gain, sexual dysfunction	Tachycardia, seizures, urinary retention, EPS *Life threatening:* Laryngospasm, bronchospasm, dysrhythmias, NMS, agranulocytosis, leukopenia, neutropenia

A, Adult; *ADHD,* attention-deficit/hyperactivity disorder; *adol,* adolescent; *bid,* twice a day; *C,* child; *CAD,* coronary artery disease; *CNS,* central nervous system; *d,* day; *EPS,* symptoms of extrapyramidal syndrome; *h,* hour; *IM,* intramuscularly; *maint,* maintenance; *max,* maximum; *min,* minute; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *tid,* three times a day; *UK,* unknown; *wk,* week; *y,* year.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

From the *dibenzoxazepine* group, loxapine is a moderately potent agent. It has moderate sedative and orthostatic hypotensive effects and strong EPS effects.

The typical antipsychotic molindone hydrochloride from the *dihydroindolone* group is a moderately potent agent. It has low sedative and orthostatic hypotensive effects and strong EPS effects.

In the nonphenothiazine group known as *thioxanthenes* is thiothixene, a highly potent typical antipsychotic drug. It has side effects similar to those of molindone with low sedative and orthostatic hypotensive effects and strong EPS effects.

Side Effects and Adverse Reactions

Several side effects are associated with antipsychotics. The most common side effect for all antipsychotics is drowsiness. Many of the antipsychotics have some anticholinergic effects: dry mouth, increased heart rate, urinary retention, and constipation can occur. Blood pressure decreases with the use of antipsychotics; aliphatics and piperidines cause a greater decrease in blood pressure than the others.

EPS can begin within 5 to 30 days after initiation of antipsychotic therapy and are most prevalent with the phenothiazines, butyrophenones, and thioxanthenes. These symptoms include pseudoparkinsonism, akathisia, **dystonia** (prolonged muscle contractions with twisting, repetitive movements), and tardive dyskinesia. Tardive dyskinesia may develop in 20% of patients taking antipsychotics for long-term therapy. Antiparkinson anticholinergic drugs may be given to control EPS, but they are not always effective in treating tardive dyskinesia.

High dosing or long-term use of some antipsychotics can cause **blood dyscrasias** (blood cell disorders) such as agranulocytosis. The white blood cell (WBC) count should be closely monitored and reported to the health care provider if an extreme decrease in leukocytes is observed.

Dermatologic side effects seen early in drug therapy are pruritus and marked photosensitivity. Patients are urged to use sunscreen, hats, and protective clothing and to stay out of the sun.

Drug Interactions

Because phenothiazines lower the seizure threshold, dosage adjustment of an anticonvulsant may be necessary. If either aliphatic phenothiazine or the thioxanthene group is administered, a higher dose of anticonvulsant might be necessary to prevent seizures.

Antipsychotics interact with alcohol, hypnotics, sedatives, narcotics, and benzodiazepines to potentiate the sedative effects of antipsychotics. Atropine counteracts EPS and potentiates antipsychotic effects. Use of antihypertensives can cause an additive hypotensive effect.

Antipsychotics should *not* be given with other antipsychotic or antidepressant drugs except to control psychotic behavior for selected individuals who are refractory to drug therapy. Under ordinary circumstances, if one antipsychotic drug is ineffective, a different one is prescribed. Individuals should *not* take alcohol or other CNS depressants (e.g., narcotic analgesics, barbiturates) with antipsychotics because additive depression is likely to occur.

When discontinuing antipsychotics, the drug dosage should be reduced gradually to avoid sudden recurrence of psychotic symptoms and seizures. Table 22.2 lists common antipsychotic drugs—phenothiazines and nonphenothiazines—and their dosages, uses, and considerations, including common side effects and a few serious adverse effects.

Antipsychotic Dosage for Older Adults

Older adults usually require smaller doses of antipsychotics—from 25% to 50% less than young and middle-aged adults. Regular to high doses of antipsychotics increase the risk of severe side effects. Dosage amounts need to be individualized according to the patient's age and physical status. In addition, dosage changes may be necessary during antipsychotic therapy. Antipsychotics have a black box warning that states mortality is increased in elderly patients with dementia-related psychosis.

Atypical Antipsychotics (Serotonin/Dopamine Antagonists)

Atypical antipsychotics differ from typical traditional antipsychotics in that the atypical agents are effective in treating both positive and negative symptoms of schizophrenia. The typical

antipsychotics have not been effective in the treatment of negative symptoms. Two advantages of the atypical agents are that they are effective in treating negative symptoms and that they are unlikely to cause symptoms of EPS, including tardive dyskinesia. Atypical drugs available include clozapine, risperidone, olanzapine, ziprasidone, and aripiprazole. These agents have a greater affinity for blocking serotonin and dopaminergic D_4 receptors than primarily blocking the dopaminergic D_2 receptor responsible for mild and severe EPS. Weight gain, drowsiness, unsteady gait, headache, insomnia, depression, diabetes mellitus, and dyslipidemia are common side effects of atypical antipsychotics.

TABLE 22.2

Phenothiazines and Nonphenothiazines

Drug	Route and Dosage	Uses and Considerations
Chlorpromazine hydrochloride	Schizophrenia: A: PO: Initially 10-25 mg 2-4 times/d; maint: 200-400 mg/d; *max:* 1000 mg/d (2000 mg/d for short periods)	For acute psychosis, schizophrenia, intractable hiccups, nausea, and vomiting. May cause psychosis, seizures, weight gain, drowsiness, dry mouth, orthostatic hypotension, constipation, sexual dysfunction, life-threatening dysrhythmias, NMS, and EPS. Pregnancy category: C*; PB: 92%-97%; t½: 23-37 h
Fluphenazine hydrochloride	See Prototype Drug Chart 22.1.	
Perphenazine	Schizophrenia: A: PO: Initially 4-16 mg tid; after obtaining maximum response, gradually reduce dose; *max:* 24 mg/d (64 mg/d for short periods)	For schizophrenia, severe nausea and vomiting. May cause psychosis, seizures, weight gain, dizziness, drowsiness, dry mouth, appetite stimulation, and EPS. Pregnancy category: C*; PB: 91%-99%; t½: 9 h
Thioridazine hydrochloride	A: PO: Initially 50-100 mg tid; maint: 200-800 mg/d; *max:* 800 mg/d for short periods Adol/C >5 y: PO: Initially 0.5 mg/kg/d in divided doses; *max:* 3 mg/kg/d	For schizophrenia. May cause psychosis, seizures, weight gain, dizziness, drowsiness, dry mouth, appetite stimulation, nausea, vomiting, constipation, peripheral edema, hypotension, leukopenia, EPS, and life-threatening dysrhythmias. Pregnancy category: C*; PB: 91%-99%; t½: 5-27 h
Haloperidol	See Prototype Drug Chart 22.2.	
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Loxapine	Schizophrenia: A: PO: Initially 10 mg bid (50 mg in severely disturbed patients); maint: 60-100 mg/d; *max:* 250 mg/d	For schizophrenia and bipolar disorder. May cause seizures, dizziness, drowsiness, dry mouth, dysgeusia, hypotension, tachycardia, bronchospasm, EPS, and NMS. Pregnancy category: C*; PB: 96.6%; t½: 4-12 h
Molindone hydrochloride	A/adol/C >12 y: PO: Initially: 50-75 mg in 3-4 divided doses; *max:* 225 mg/d	For schizophrenia. May cause seizures, blurred vision, drowsiness, constipation, hypotension, tachycardia, EPS, and NMS. Pregnancy category: C *; PB: UK; t½: 1.5 h
Thiothixene hydrochloride	A/adol/C >12: PO: Initially 2 mg tid; maint: 20-30 mg/d; *max:* 60 mg/d	For schizophrenia. May cause blurred vision, dry mouth, constipation, weight gain, peripheral edema, hypotension, leukopenia, seizures, NMS, and EPS. Pregnancy category: C*; PB: 90%; t½: 34 h
Clozapine	A: PO: Initially: 12.5 mg/d or bid; gradually increase to maint: 300-450 mg/d in 3 divided doses; *max:* 900 mg/d	For schizophrenia. May cause dizziness, drowsiness, insomnia, hypersalivation, nausea, vomiting, constipation, hypotension, tachycardia, seizures, agranulocytosis, EPS, and NMS. Monitor white blood cell count. Gradually taper off over 1-2 wk upon discontinuation. Pregnancy category: B*; PB: 97%; t½: 4-12 h
Olanzapine	A: PO: Initially 5-10 mg/d; *max:* 20 mg/d Older adults: PO: Initially 5 mg/d; *max*: 20 mg/d Adol: PO: Initially 2.5-5 mg/d; maint: 10 mg/d; *max:* 20 mg/d	For schizophrenia, bipolar disorder, depression. May cause headache, dizziness, drowsiness, weakness, appetite stimulation, weight gain, hyperglycemia, hypercholesterolemia, hypertriglyceridemia, insomnia, seizures, NMS, and EPS. Pregnancy category: C*; PB: 93%; t½: 21-54 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Quetiapine	Schizophrenia: Immediate release: A/adol: PO: Initially 25 mg/bid; maint: 300-400 mg/d in divided doses; *max:* 800 mg/d Extended release: A: PO: 300 mg at bedtime; maint: 400-800 mg/d; *max:* 800 mg/d Adol/older adults: Initially 50 mg/d, *max:* 200-800 mg/d	For schizophrenia, bipolar disorder, and depression. May cause dizziness, drowsiness, headache, dry mouth, electrolyte imbalance, psychosis, seizures, nausea, hypercholesterolemia, hypertriglyceridemia, orthostatic hypotension, weight gain, weakness, and EPS. Pregnancy category: C*; PB: 83%; t½: 6 h
Asenapine	Schizophrenia: A: SL: Initially 5 mg bid; may increase after 1 wk, *max:* 20 mg/d	For schizophrenia and bipolar disorder. May cause dizziness, drowsiness, insomnia, headache, paresthesia, hypertriglyceridemia, seizures, asthenia, and EPS. Pregnancy category: C*; PB: 95%; t½: 24 h
Risperidone	Schizophrenia: A: PO: Initially 2 mg/d; maint: 4-8 mg/d; *max*: 16 mg/d Older adults: PO: Initially 0.5 mg bid; *max*: 16 mg/d Adol: PO: Initially 0.5 mg/d; maint: 1-6 mg/d; *max*: 6 mg/d	For management of schizophrenia and bipolar disorder. May cause dizziness, drowsiness, headache, insomnia, fatigue, appetite stimulation, nausea, vomiting, seizures, dysrhythmias, agranulocytosis, EPS, and NMS. Pregnancy category: C*; PB: 90%; t½: 20 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Ziprasidone	Schizophrenia: A: PO: 20 mg bid; may increase q2d; *max:* 80 mg/d A: IM: 10-20 mg; *max:* 40 mg/d	For schizophrenia and bipolar disorder. Dose should be taken with food; IM dose should not be given for more than 3 consecutive days. May cause dizziness, drowsiness, headache, insomnia, nausea, constipation, psychosis, seizures, weight gain, and EPS. Pregnancy category: C*; PB: 99%; t½: 7 h
Iloperidone	A: PO: Initially 1 mg bid; maint: 6-12 mg bid; *max:* 24 mg/d	For schizophrenia. May cause dizziness, drowsiness, nausea, dry mouth, weight gain, tachycardia, seizures, and EPS. Pregnancy category: C *; PB: 95%; t½: 23-37 h
Aripiprazole	See Prototype Drug Chart 22.3.	
Cariprazine	Schizophrenia: A: PO: Initially 1.5 mg/d; *max*: 6 mg/d	For schizophrenia and bipolar disorder. May cause insomnia, dizziness, headache, restlessness, weight gain, nausea, vomiting, constipation, seizures, suicidal ideation, and EPS. Pregnancy category: UK*; PB: 91%-97%; t½: 2 to 4 d
Brexpiprazole	Schizophrenia: A: PO: Initially 1 mg/d; maint: 2-4 mg/d; *max*: 4 mg/d	For schizophrenia and depression. May cause headache, drowsiness, weight gain, pharyngitis, seizures, suicidal ideation, NMS, and EPS. Pregnancy category: UK*; PB: 99%; t½: 91h
Paliperidone	Extended release tablet: A: PO: Initially 6 mg/d in the morning; may increase dose q5d, *max:* 12 mg/d A: IM ER: Initially 234 mg, then 1 wk later 156 mg; maint: 5 wk after first dose begin 117 mg/month; *max*: 234 mg q1month	For schizophrenia. May cause dizziness, drowsiness, headache, agitation, tachycardia, hypertriglyceridemia, weight gain, seizures, NMS, and EPS. Pregnancy category: C*; PB: 74%; t½: 23 h

>, Greater than; *A,* adult; *adol,* adolescent; *bid,* twice a day; *C,* child; *d,* day; *EPS,* symptoms of extrapyramidal syndrome; *ER,*

extended release; *h,* hour; *IM,* intramuscular; *maint,* maintenance; *max,* maximum; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *q2d,* every 2 days; *SL*, sublingual; *t½,* half-life; *tid,* three times a day; *UK,* unknown; *wk,* weeks; *y,* years.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Clozapine was the first atypical antipsychotic agent used to treat schizophrenia and other psychoses. It is not as likely to cause symptoms of EPS, although they may occur. Tremors and occasional rigidity have been reported. Serious adverse reactions of clozapine are seizures and agranulocytosis, a decrease in the production of granulocytes that involves the body's immune defenses. Currently, clozapine is only indicated for the treatment of severely ill schizophrenic patients who have not responded to traditional antipsychotic drugs. The WBC (leukocyte) count needs to be closely monitored for leukopenia; if the level falls below 3000 mm^3, clozapine should be discontinued. Seizures have been reported in 3% of patients taking the drug. Dizziness, sedation, tachycardia, orthostatic hypotension, and constipation are common side effects.

Another atypical agent used to treat the positive and negative symptoms of schizophrenia is risperidone. Its action is similar to that of clozapine, and the occurrence of EPS and tardive dyskinesia is low. It does not cause agranulocytosis. Paliperidone is the major active metabolite of risperidone and is an extended-release tablet with once-a-day dosing. Paliperidone should be swallowed whole and not chewed, divided, or crushed. The most common adverse effects include EPS, insomnia, headache, and akathisia.

Like clozapine and risperidone, the atypical antipsychotic olanzapine is effective for treating the positive and negative symptoms of schizophrenia.

Like all the other atypical antipsychotics, quetiapine is less likely to cause EPS. Severe tardive dyskinesia may occur but it is rare.

For individuals with cardiac dysrhythmias, ziprasidone must be prescribed with caution because its use may lead to a prolonged QT interval; electrocardiograms (ECGs) should be monitored. Ziprasidone is contraindicated in patients with a history of prolonged QT interval or with other concurrent drugs known to prolong QT interval. Patients taking quetiapine, clozapine, risperidone, olanzapine, ziprasidone, and aripiprazole should be monitored for hyperglycemia and other symptoms of diabetes mellitus.

Prototype Drug Chart 22.3 illustrates drug characteristics of aripiprazole, an atypical antipsychotic. When anxiety, hallucinations, agitation, mania, confusion, or depression and other symptoms are noted, the health care provider should check the medications that the patient is taking.

PROTOTYPE DRUG CHART 22.3 Aripiprazole

Drug Class	Dosage
Nonphenothiazine: Atypical antipsychotic Pregnancy category C*	Psychosis: A: PO: 10-15 mg/d, may increase q2wk; maint: 10-30 mg/d; *max:* 30 mg/d Adol >13 y: PO: 2 mg/d, may increase q2d; maint: 10 mg/d; *max:* 30 mg/d Extended release: A: IM: 400 mg/month
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, dehydration, alcohol intoxication, hypovolemia, agranulocytosis, neutropenia, leukopenia, heart failure, suicidal ideation, myocardial infarction, diabetes mellitus, hyperglycemia, hypotension, seizures, parkinsonism *Caution:* Dysrhythmias, dementia, CNS depression, hyperglycemia, hypotension, parkinsonism, seizures, agranulocytosis, neutropenia, leukopenia	Drug: Antidiabetic agents decrease drug levels and increase risk of hyperglycemia; alpha blockers and antihypertensives increase risk of hypotension; other antipsychotics enhance risk of NMS, EPS, anticholinergic effects, hypotension, and seizures; CNS depressants may increase sedation and orthostatic hypotension; SSRIs may increase risk of serotonin syndrome; calcium channel blockers may increase blood levels Food: Grapefruit juice may increase blood levels Herbal: St. John's wort may decrease blood levels Lab: Increased blood glucose
Pharmacokinetics	**Pharmacodynamics**
Absorption: Well absorbed, not affected by food Distribution: PB: 99% Metabolism: t½: 75 h; extended release 30-47 d Excretion: In urine and feces	PO: Onset: UK Peak: 3-5 h Duration: 24 h IM: Onset: UK Peak: 1-3 h Duration: 24 h ER: Peak: 5-7 d Duration: 36 d
Therapeutic Effects/Uses	
To manage schizophrenia, bipolar disorder, autism, depression, Tourette syndrome	
Mode of Action: Interferes with the binding of dopamine to dopamine (D_2) and serotonin 5-hydroxytryptamine ($5\text{-}HT_2$) receptors	
Side Effects	**Adverse Reactions**
Drowsiness, memory impairment, weight gain/loss, headaches, fatigue, blurred vision, photosensitivity, peripheral edema, amenorrhea, hyperglycemia, hypoglycemia, insomnia, anxiety, agitation, dizziness, constipation, nausea, vomiting, sexual dysfunction	Orthostatic hypotension, tachycardia, EPS, dysrhythmias, seizures *Life threatening:* Suicidal ideation, NMS, agranulocytosis, leukopenia, laryngospasm

>, Greater than; *A,* adult; *adol,* adolescent; *CNS,* central nervous system; *d,* day; *EPS,* symptoms of extrapyramidal syndrome; *ER,* extended release; *h,* hour; *IM,* intramuscularly; *maint,* maintenance; *max,* maximum; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *q2d,* every 2 days; *SSRI,* selective serotonin reuptake inhibitor; *t½,* half-life; *UK,* unknown; *wk,* week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Phenothiazines and Nonphenothiazines

Assessment

- Assess baseline vital signs for use in future comparisons.
- Obtain a patient health history that includes present drug therapy. If the patient is taking an anticonvulsant, the drug dose might need to be increased because antipsychotics tend to lower the seizure threshold.
- Assess mental status and cardiac, eye, and respiratory disorders before starting drug therapy, and continue daily assessment.

Nursing Diagnoses

- Relationship, Ineffective related to social withdrawal
- Loneliness, Risk for
- Sleep Pattern, Disturbed related to medication adverse effects
- Activity Intolerance related to sedation
- Confusion, Acute related to psychosis
- Self-Care Deficit, Bathing related to loss of motivation

Planning

- Patient's psychotic behavior will improve with medication, psychotherapy, and adjunct therapies.

Nursing Interventions

- Monitor vital signs. Orthostatic hypotension is likely to occur.
- Remain with patients while medication is taken and swallowed; some patients hide antipsychotics in the mouth to avoid taking them.
- Avoid skin contact with liquid concentrates to prevent contact dermatitis. Liquid must be protected from light and should be diluted with fruit juice.
- Administer oral doses with food or milk to decrease gastric irritation.
- Dilute oral solution of fluphenazine in fruit juice, water, or milk. Avoid apple juice and caffeinated drinks.
- Administer deep into muscle because drug irritates fatty tissue. Do *not* administer intravenously.
- Check blood pressure for marked decrease or increase 30 minutes after drug is injected.
- Do *not* mix in same syringe with heparin, pentobarbital, cimetidine, or dimenhydrinate.
- Chill suppository in refrigerator for 30 minutes before removing foil wrapper.
- Observe for EPS such as acute dystonia, akathisia, pseudoparkinsonism, and tardive dyskinesia (see Fig. 22.1) and report these promptly to the health care provider.
- Assess for symptoms of NMS: increased fever, pulse, and blood pressure; muscle rigidity; increased creatine phosphokinase and WBC count; altered mental status; acute renal failure; varying levels of consciousness; pallor; diaphoresis; tachycardia; and dysrhythmias.
- Record urine output; urinary retention may result.
- Monitor serum glucose level.
- Engage patient in interactions with staff, other patients, and attending therapies.

Patient Teaching

General

- Encourage patients to take the drug exactly as ordered. In schizophrenia and other psychotic disorders, antipsychotics do not cure the mental illness but do alleviate symptoms. Many patients on medication can function outside of an institutional setting. Adherence to a drug regimen is extremely important.

- Inform patients that medication may take 6 weeks or longer to achieve full clinical effect.
- Caution patients not to consume alcohol or other CNS depressants such as narcotics; these drugs intensify the depressant effect on the body.
- Recommend that patients not abruptly discontinue the drug. Seek advice from a health care provider before making any changes in dosage.
- Encourage patients to read labels on over-the-counter (OTC) preparations. Some are contraindicated when taking antipsychotics.
- Teach smoking cessation because smoking increases the metabolism of some antipsychotics.
- Guide patients to maintain good oral hygiene by frequently brushing and flossing teeth.
- Encourage patients to talk with a health care provider regarding family planning. The effect of antipsychotics on the fetus is not fully known; however, there may be teratogenic effects.
- Explain to the breastfeeding patient that phenothiazine passes into breast milk, possibly causing drowsiness and unusual muscle movement in the infant.
- Warn patients about the importance of routine follow-up examinations.
- Encourage patients to obtain laboratory tests on schedule. WBCs are monitored for 3 months, especially during the start of drug therapy. Leukopenia, or decreased WBCs, may occur. Be alert to symptoms of malaise, fever, and sore throat, which may be an indication of agranulocytosis, a serious blood dyscrasia.
- Teach patients, especially those taking clozapine, to report symptoms of infection promptly to the health care provider.
- Advise patients to wear an identification bracelet indicating the medication taken.
- Inform patients that tolerance to the sedative effect develops over a period of days or weeks.

Side Effects

- Direct patients to avoid potentially dangerous situations, such as driving, until drug dosing has been stabilized.
- Inform patients about EPS and instruct them to promptly report symptoms to a health care provider.
- Encourage patients to wear sunglasses for photosensitivity, to limit exposure to direct sunlight, and to use sunscreen and protective clothing to prevent a skin rash.
- Warn patients about orthostatic hypotension and possible dizziness.
- Teach patients who are taking aliphatic phenothiazines such as chlorpromazine that the urine might be pink or red-brown; this discoloration is harmless.
- Inform patients that changes may occur related to sexual functioning and menstruation. Women could have irregular menstrual periods or amenorrhea, and men might experience impotence and gynecomastia (enlargement of breast tissue).
- Suggest lozenges or hard candy if mouth dryness occurs. Advise patients to consult a health care provider if dry mouth persists for more than 2 weeks.
- Encourage patients to avoid extremes in environmental temperatures and exercise.
- Advise patients to rise slowly from sitting or lying to standing to prevent a sudden decrease in blood pressure.

Cultural Considerations

- Recognize that some cultural groups may have difficulty in believing and accepting the patient's disorder and the need for medication.

Evaluation

- Evaluate the effectiveness of the drug and whether the patient has acceptably reduced psychotic symptoms at the *lowest* dose possible.
- Ascertain whether the patient can cope with everyday living situations and attend to activities of daily living.
- Determine whether any side effects or adverse reactions to the drug have occurred.

Patient Safety

Do not confuse

- **Seroquel** with **Serzone,** an antidepressant, or **sertindole** with **Serlect.**

Anxiolytics

Anxiolytics, or *antianxiety drugs,* are primarily used to treat anxiety and insomnia. The major anxiolytic group is benzodiazepines, a minor tranquilizer group. Long before benzodiazepines were prescribed for anxiety and insomnia, barbiturates were used. Benzodiazepines are considered more effective than barbiturates because they enhance the action of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter within the CNS. Benzodiazepines have fewer side effects and may be less dangerous in overdosing. Long-term use of barbiturates causes drug tolerance and dependence and may cause respiratory distress. Currently, barbiturates are not drugs of choice for treating anxiety. Benzodiazepine-like drugs are used to treat insomnia. Selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs), and monoamine oxidase inhibitors (MAOIs) are used to treat various anxiety disorders. These drugs are discussed in Chapter 23.

TABLE 22.3

Approved Uses for Benzodiazepines

Prescribed Uses	Drugs
Anxiety	Alprazolam
	Chlordiazepoxide
	Chlorazepate
	Diazepam
	Lorazepam
Anxiety associated with depression	Alprazolam Clonazepam Lorazepam
Insomnia, short-term use	Estazolam
	Flurazepam
	Quazepam
	Temazepam
	Triazolam
Seizures and status epilepticus	Clonazepam Clorazepate Diazepam Lorazepam
Alcohol withdrawal	Clorazepate
	Chlordiazepoxide
	Diazepam
	Lorazepam
Skeletal muscle spasms	Diazepam
Preoperative medications	Chlordiazepoxide
	Diazepam
	Lorazepam
	Midazolam

Table 22.3 lists approved uses for benzodiazepines. Drugs used to treat insomnia, including benzodiazepines, are discussed in Chapter 18.

A certain amount of anxiety may make a person more alert and energetic, but when anxiety is excessive, it can be disabling, and anxiolytics may be prescribed. The action of anxiolytics resembles that of the sedative-hypnotics but *not* that of the antipsychotics.

There are two types of anxiety—primary and secondary. *Primary anxiety* is not caused by a medical condition or by drug use; *secondary anxiety* is related to selected drug use or medical or psychiatric disorders. Anxiolytics are not usually given for secondary anxiety unless the medical problem is untreatable, severe, and causes disability. In this case, an anxiolytic could be given for a short period to alleviate any acute anxiety attacks. These agents treat the symptoms but do not cure them. Long-term use of anxiolytics is discouraged because tolerance develops within weeks or months, depending on the agent. Drug tolerance can occur in less than 2 to 3 months in patients who take phenobarbital.

Nonpharmacologic Measures

Some of the symptoms of a severe attack of anxiety, or panic attack, include dyspnea (difficulty in breathing), choking sensation, chest pain, heart palpitations, dizziness, faintness, sweating, trembling and shaking, and fear of losing control. Before giving anxiolytics, nonpharmacologic measures should be used for decreasing anxiety. These measures might include using a relaxation technique, psychotherapy, or support groups.

Benzodiazepines

Benzodiazepines have multiple uses as anticonvulsants, sedative-hypnotics, preoperative drugs, substance abuse withdrawal agents, and anxiolytics. Most of the benzodiazepines are used mainly for severe or prolonged anxiety. Examples include chlordiazepoxide, diazepam, clorazepate dipotassium, lorazepam, and alprazolam. The most frequently prescribed benzodiazepine is lorazepam. Many of the benzodiazepines are used for more than one purpose.

Benzodiazepines are lipid soluble and are absorbed readily from the GI tract. They are highly protein bound (80% to 98%). Benzodiazepines are primarily metabolized by the liver and are excreted in urine, so the drug dosage for patients with liver or renal disease should be lowered accordingly to avoid possible cumulative effects. Traces of benzodiazepine metabolites could be present in the urine for weeks or months after the person has stopped taking the drug. These are Controlled Substance Schedule IV (CSS IV) drugs.

The first benzodiazepine, chlordiazepoxide, became widely used for its sedative effect in 1962. Diazepam was the most frequently prescribed drug in the early 1970s. Lorazepam is the prototype drug of benzodiazepine and is described in Prototype Drug Chart 22.4.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 22.2

Benzodiazepines

Kava kava should not be combined with benzodiazepines because it increases the sedative effect.

Pharmacokinetics

Lorazepam is highly lipid soluble, and the drug is rapidly absorbed from the GI tract. The drug is highly protein bound, and the half-life is 12 hours. Lorazepam is excreted primarily in the urine.

Pharmacodynamics

Lorazepam acts on the limbic, thalamic, and hypothalamic levels of the CNS. The onset of action is 15 to 30 minutes for IM administration and 1 to 5 minutes IV. The serum levels of most oral doses of benzodiazepines peak in 2 hours. Oxazepam levels peak in 3 hours. The duration of action varies, but the average is 16 hours when given orally; when given IV, the duration of action is 6 to 8 hours.

It is recommended that benzodiazepines be prescribed for no longer than 3 to 4 months. Beyond 4 months, the effectiveness of the drug lessens. Table 22.4 lists the anxiolytics and their dosages, uses, and considerations, including common side effects and a few serious adverse effects.

Miscellaneous Anxiolytics

The anxiolytic buspirone hydrochloride binds to serotonin and dopamine receptors. It may not be effective until 1 to 2 weeks after continuous use. It has fewer of the side effects of sedation and physical and psychological dependency associated with many benzodiazepines. The most common side effects of buspirone include drowsiness, dizziness, headache, nausea, nervousness, and excitement. It is important to note that buspirone has an interaction with grapefruit juice that can lead to toxicity. To avoid this interaction, buspirone users should be advised to limit intake of grapefruit juice to 8 ounces daily or half of a grapefruit.

PROTOTYPE DRUG CHART 22.4 Lorazepam

Drug Class	Dosage
Anxiolytic: Benzodiazepine Pregnancy category D*	Anxiety: A/C >12 y: PO: initially 2-3 mg in divided doses; increase gradually PRN; maint: 1-10 mg/d in divided doses; *max:* 10 mg/d Older adults: PO: 1-2 mg/d in divided doses; *max:* 10 mg/d
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, narrow-angle glaucoma *Caution:* Hepatic or renal dysfunction, alcohol intoxication, depression, seizures, CNS depression, pregnancy, suicidal ideation	Drug: Increases CNS depression when taken with alcohol, CNS depressants, and anticonvulsants; cimetidine increases lorazepam plasma levels, increases phenytoin levels, decreases levodopa effects; smoking and caffeine decrease antianxiety effects; oral contraceptives decrease effects
Pharmacokinetics	Pharmacodynamics
Absorption: Rapid from GI tract Distribution: PB: 91% Metabolism: t½: 12 h Excretion: In urine	PO: Onset: UK Peak: 2 h Duration: 12-24 h IM: Onset: 15-30 min Peak: 3 h Duration: 6-8 h IV: Onset: 1-5 min Peak: UK Duration: 6-8 h
Therapeutic Effects/Uses	
To control anxiety and to treat status epilepticus; for sedation induction; for insomnia	
Mode of Action: Potentiates GABA effects by binding to specific benzodiazepine receptors and inhibiting GABA neurotransmission	
Side Effects	Adverse Reactions
Drowsiness, dizziness, weakness, confusion, headache, blurred vision, nausea, vomiting, anorexia, restlessness, hallucinations, amnesia, ataxia	Hypertension, hypotension, bradycardia, dependence, seizures *Life threatening:* Suicidal ideation, NMS, respiratory depression

TABLE 22.4
Anxiolytics

Drug	Route and Dosage	Uses and Considerations
Benzodiazepines		
Alprazolam CSS IV	Immediate release: A: PO: Initially 0.25-0.5 mg tid, may increase q3-4d, *max:* 4 mg/d Older A: PO: Initially 0.125 bid/tid, may increase q3-4d; *max:* 4mg/d Extended release: A: PO: Initially 0.5-1 mg/d in the morning may increase q3-4d; *max:* 10 mg/d Older A: PO: Initially 0.5 mg/d may increase q3-4d; *max:* 10 mg/d	For anxiety, panic disorders, and generalized anxiety disorder. May cause dizziness, drowsiness, anxiety, dry mouth, dysarthria, fatigue, confusion, nausea, constipation, tolerance, dependence, withdrawal, weight gain/loss, and tachycardia. Reduce dose gradually upon discontinuation. Pregnancy category: D*; PB: 90%; t½: 11-16 h
Chlordiazepoxide hydrochloride CSS IV	Anxiety disorders: A: PO: 5-10 mg tid/qid; for severe anxiety: 20-25 mg tid/qid; *max:* 100 mg/d Older adult: PO: 5-10 mg/d; maint: 5 mg bid/qid; *max:* 300 mg/d C >6 y: PO: 5 mg bid/qid; *max:* 30 mg/d Acute alcohol withdrawal: A: PO: 50-100 mg q4-6h until agitation is controlled; *max:* 300 mg/d	For anxiety, alcohol withdrawal syndrome (DTs). May cause drowsiness, confusion, dysarthria, constipation, ataxia, tolerance, dependence, withdrawal, and amnesia. Taper off gradually upon discontinuation. Pregnancy category: D*; PB: 96%; t½: 5-30 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Clorazepate dipotassium CSS IV	Anxiety: A: PO: 30 mg/d in divided doses; maint: 15-60 mg/d; *max:* 60 mg/d Older adults: 7.5-15 mg/d in divided doses; maint: 15-60 mg/d; *max:* 60 mg/d	For anxiety, alcohol withdrawal syndrome, and partial seizures. May cause drowsiness, dizziness, confusion, blurred vision, hypotension, tolerance, dependence, withdrawal, amnesia, depression, and suicidal ideation. Avoid taking alcohol or CNS depressants with clorazepate. Taper off gradually upon discontinuation. Pregnancy category: D*; PB: 97%; t½: 30-200 h
Diazepam CSS IV	Anxiety: A: PO: 2-10 mg bid/qid; *max:* 40 mg/d Older adults: PO: 2-2.5 mg qd/bid; *max:* 40 mg/d Adol/C >6 months: PO: 1-2.5 mg tid/qid; *max:* 0.6 mg/kg q8h A: IM/IV: 2-5 mg; repeat in 3-4 h PRN	For anxiety, muscle spasms, alcohol withdrawal, seizures, status epilepticus, and sedation induction. May cause drowsiness, confusion, dysarthria, fatigue, paradoxical aggression, dependence, tolerance, and withdrawal. Pregnancy category: D*; PB: 99%; t½: 30-60 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Lorazepam CSS IV	See Prototype Drug Chart 22.4.	
Oxazepam CSS IV	Anxiety: A/adol: PO: Initially 10-15 mg tid/qid; for severe symptoms, 15-30 mg tid/qid; *max:* A 120 mg/d, adol 60 mg/d Older adults: PO: 10 mg tid; *max:* 60 mg/d	For anxiety and acute alcohol withdrawal. May cause dizziness, drowsiness, blurred vision, amnesia, confusion, dependence, tolerance, and withdrawal. Taper off gradually upon discontinuation. Pregnancy category: D*; PB: 85%-95%; t½: 5-15 h
Azapirones		
Buspirone hydrochloride	A: PO: Initially: 7.5 mg bid; maint: 15-30 mg/d in divided doses; *max:* 60 mg/d Older adults: PO: 5 mg bid; maint: 15-30 mg/d in divided doses; *max:* 60 mg/d	For anxiety and generalized anxiety disorder. Takes several weeks before anxiolytic effects occur. May cause drowsiness, dizziness, headache, nausea, seizures, serotonin syndrome, EPS, and suicidal ideation. Pregnancy category: B*; PB: 86%; t½: 2-4 h
Benzodiazepine Antagonists		
Flumazenil	A: IV: Initially 0.2 mg over 15-30 s; repeat 0.2 mg at 1-min intervals; *max:* 3 mg/h C/adol: IV: 0.01 mg/kg over 15 s, repeat at 1-min intervals; *max:* 0.1 mg/kg/h	For sedation reversal and benzodiazepine toxicity. Flumenazil should not be used with antipsychotics or antidepressants. May cause dizziness, blurred vision, resedation, ataxia, agitation, insomnia, dry mouth, seizures, and dysrhythmias. Nursing Process: Patient-Centered Collaborative Care

Benzodiazepines

Assessment

- Assess for suicidal ideation.
- Obtain a history of the patient's anxiety reaction.
- Determine the patient's support system (family, friends, groups).
- Obtain a drug history. Report possible drug-drug interactions.

Nursing Diagnoses

- Anxiety related to situational crisis
- Mobility, Impaired Physical related to drowsiness and weakness
- Noncompliance related to adverse effects of medications.

Planning

- Patient's anxiety and stress will be reduced through nonpharmacologic methods, anxiolytic drugs, or support/group therapy.

Nursing Interventions

- Observe patient for side effects of anxiolytics. Recognize that drug tolerance and physical and psychological dependency can occur with most anxiolytics.
- Recognize that anxiolytic dosages should be lower for older adults, children, and debilitated persons than for middle-aged adults.
- Monitor vital signs, especially blood pressure and pulse; orthostatic hypotension may occur.
- Encourage family to be supportive of the patient.

Patient Teaching

General

- Advise patients not to drive a motor vehicle or operate dangerous equipment when taking anxiolytics because sedation is a common side effect.
- Warn patients not to consume alcohol or CNS depressants such as narcotics while taking an anxiolytic.
- Teach patients ways to control excess stress and anxiety with relaxation techniques such as long walks.
- Inform patients that an effective response may take 1 to 2 weeks.
- Encourage patients to follow drug regimens and not to abruptly stop taking a drug after prolonged use because withdrawal symptoms can occur. The drug dose is usually tapered when a drug is discontinued.

Side Effects

- Encourage patients to rise slowly from sitting to standing positions to avoid dizziness from orthostatic hypotension.

Cultural Considerations

- Use simple and clear instructions, modifying methods and materials to meet patient and family needs. Ask family members to assist with translation only if an interpreter is not available, and do not ask private questions in public.

Evaluation

- Evaluate the effectiveness of drug therapy by determining whether the patient is less anxious and more able to cope with stresses and anxieties.
- Determine whether the patient is taking the anxiolytic drug as prescribed and is adhering to patient teaching instructions.

Side Effects and Adverse Reactions

The side effects associated with benzodiazepines are sedation, dizziness, headaches, dry mouth, blurred vision, rare urinary incontinence, and constipation. Adverse reactions include leukopenia (decreased WBC count) with symptoms of fever, malaise, and sore throat; tolerance to the drug dosage with continuous use; and physical dependency. Box 22.2 lists guidelines for treating benzodiazepine overdose.

Benzodiazepines should not be abruptly discontinued because withdrawal symptoms are likely to occur. Withdrawal symptoms caused by short-term benzodiazepine use are similar to those from the sedative-hypnotics: agitation, nervousness, insomnia, tremor, anorexia, muscular cramps, and sweating; however, they are slow to develop, taking 2 to 10 days, and can last several weeks, depending on the benzodiazepine's half-life. When discontinuing a benzodiazepine, the drug dosage should be gradually decreased over a period of days, depending on dose or length of time on the drug. Withdrawal symptoms from long-term, high-dose benzodiazepine therapy include paranoia, delirium, panic, hypertension, and status epilepticus. Convulsions during withdrawal may be prevented with simultaneous substitution of an anticonvulsant. Alcohol and other CNS depressants should *not* be taken with benzodiazepines because respiratory depression can result. Tobacco, caffeine, and sympathomimetics decrease the effectiveness of benzodiazepines. Benzodiazepines are contraindicated during pregnancy because of possible teratogenic effects.

BOX 22.2 Suggested Treatment for Overdose of Benzodiazepines

1. Administer an emetic and follow with activated charcoal if the patient is conscious; use gastric lavage if the patient is unconscious.
2. Administer the benzodiazepine antagonist flumazenil intravenously if required.
3. Maintain an airway, give oxygen as needed for decreased respirations, and monitor vital signs.
4. Give intravenous vasopressors for severe hypotension.
5. Request a mental health consultation for the patient.

Critical Thinking Case Study

FS, a 35-year-old woman, is receiving risperidone, 3 mg twice daily, to control a psychotic disorder. She has taken the drug for 6 months but has recently become agitated and is complaining of insomnia.

1. What is the relation between FS's drug dose and her complaints? Explain your answer.
2. What further assessment should be made concerning FS and the drug regimen?
3. How does risperidone compare with other antipsychotics such as chlorpromazine and haloperidol regarding actions and adverse effects?

NCLEX Study Questions

1. The nurse suspects that a patient who is experiencing facial grimacing, involuntary upward eye movement, and muscle spasms of the tongue and face may have which condition?
   a. Akathisia
   b. Acute dystonia
   c. Tardive dyskinesia
   d. Pseudoparkinsonism
2. A patient asks the nurse to explain how antipsychotic drugs work to make him feel better. The nurse understands that antipsychotics act in which way?
   a. Blocking actions of dopamine
   b. Blocking actions of epinephrine
   c. Promoting prostaglandin synthesis
   d. Enhancing the action of gamma-aminobutyric acid
3. An antipsychotic agent, fluphenazine, is ordered for a patient with psychosis. The nurse understands that this agent can lead to symptoms of extrapyramidal syndrome (EPS). What are the symptoms of EPS?
   a. Parkinsonism
   b. Nausea and vomiting
   c. Hyperthermia and dysrhythmias
   d. Tremors, rigidity, and shuffling gait
4. An atypical antipsychotic is prescribed for a patient with psychosis. The nurse understands that this category of medications includes which drugs? (Select all that apply.)
   a. Clozapine
   b. Fluphenazine
   c. Haloperidol
   d. Olanzapine
   e. Aripiprazole
5. A patient is prescribed lorazepam. What does the nurse know to be true regarding lorazepam?
   a. It is used to treat anxiety, status epilepticus, insomnia, and sedation induction
   b. It has a maximum adult dose of 25 mg/day.
   c. It causes plasma levels to be decreased when combined with cimetidine.
   d. It interferes with the binding of dopamine receptors.
6. A patient is receiving aripiprazole. Which nursing intervention(s) will the nurse include in the patient's care plan? (Select all that apply.)
   a. Administer before meals on an empty stomach to facilitate absorption.
   b. Remain with the patient until medication is swallowed.
   c. Monitor vital signs to detect orthostatic hypotension.
   d. Assess the patient for evidence of neuroleptic malignant syndrome.
   e. Observe the patient for acute dystonia, akathisia, and tardive dyskinesia.
7. A patient appears to have had an overdose of phenothiazines. The nurse anticipates that which intervention(s) may be used to treat phenothiazine overdose? (Select all that apply.)
   a. Gastric lavage
   b. Adequate hydration
   c. Maintaining an airway
   d. Fluphenazine
   e. Risperidone

f. Activated charcoal administration

Antidepressants and Mood Stabilizers

OUTLINE

Depression
- Pathophysiology
- Complementary and Alternative Therapy for Depression

Antidepressant Agents
- Tricyclic Antidepressants
- Selective Serotonin Reuptake Inhibitors
- Serotonin Norepinephrine Reuptake Inhibitors
- Atypical Antidepressants
- Monoamine Oxidase Inhibitors
- Nursing Process: Patient-Centered Collaborative Care—Antidepressants

Mood Stabilizers
- Nursing Process: Patient-Centered Collaborative Care—Mood Stabilizer: Lithium

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Contrast the various categories of different antidepressants and give an example of one drug for each category.
- Describe the side effects and adverse reactions of antidepressants.
- Plan nursing interventions, including patient teaching, for antidepressants (tricyclic antidepressants [TCAs], monoamine oxidase inhibitors [MAOIs], selective serotonin reuptake inhibitors [SSRIs], serotonin norepinephrine reuptake inhibitors [SNRIs], and atypical antidepressants).
- Explain the uses of lithium and its serum/plasma therapeutic ranges, side effects and adverse reactions, and nursing interventions.
- Apply the nursing process to the patient taking lithium, carbamazepine, and valproic acid.

KEY TERMS

antidepressants, p. 294
atypical antidepressants, p. 297
bipolar disorder, p. 295
depression, p. 294
dysphoria, p. 295
monoamine oxidase inhibitors (MAOIs), p. 297
reactive depression, p. 294

selective serotonin reuptake inhibitors (SSRIs), p. 296
serotonin norepinephrine reuptake inhibitors (SNRIs), p. 297
tricyclic antidepressants (TCAs), p. 295

Antidepressants are used for depressive episodes accompanied by feelings of hopelessness and helplessness. They can be prescribed for 1 month to 12 months or perhaps longer.

Mood-stabilizer agents such as lithium are effective for bipolar disorder. Drug therapy for treating bipolar disorder is discussed in this chapter.

Depression

Depression is the most common mental illness, affecting approximately 14.8 million Americans. Fewer than 50% of individuals with depression seek treatment despite the fact that about 70% of individuals with depression have a full remission with effective treatment. Women between the ages of 25 and 45 years are two to three times more likely than men to experience major depression. Depression is characterized primarily by mood changes and loss of interest in normal activities and is second only to hypertension as the most common chronic clinical condition.

Contributing causes of depression include genetic predisposition, social and environmental factors, and biologic conditions. Some signs of major depression include loss of interest in most activities, depressed mood, weight loss or gain, insomnia or hypersomnia, loss of energy, fatigue, feelings of despair, decreased ability to think or concentrate, and suicidal thoughts. Approximately 66% of all suicides are related to depression. Depressed men, especially older Causcasian men, are more likely to commit suicide successfully than are depressed women. Antidepressants can mask suicidal ideation.

The three types of depression are (1) *reactive,* (2) *major,* and (3) *bipolar disorder,* previously referred to as *manic depression*. **Reactive depression** usually has a sudden onset after a precipitating event (e.g., depression resulting from a loss, such as death of a loved one). The patient knows why he or she is depressed and may call this "the blues." Usually, this type of depression lasts for months, and a benzodiazepine agent may be prescribed. *Major depression* is characterized by loss of interest in work and home, inability to concentrate and complete tasks, difficulty sleeping or excessive sleeping, feelings of fatigue and worthlessness, and deep depression, also known as **dysphoria**. Major depression can be either *primary,* unrelated to other health problems, or *secondary* to a health problem such as a physical or psychiatric disorder or drug use. Antidepressants have been effective in treating major depression. **Bipolar disorder** involves swings between two moods, the manic (euphoric) and the depressive (dysphoric); lithium was originally the drug of choice for treating this type of disorder. Other mood stabilizers such as carbamazepine; valproic acid, or divalproex; and lamotrigine are also currently first-line drugs of choice for bipolar disorder.

Pathophysiology

Many theories exist as to the cause of major depression. A common one suggests an insufficient amount of brain monoamine neurotransmitters (norepinephrine, serotonin, perhaps dopamine). It is thought that decreased levels of serotonin permit depression to occur, and decreased levels of norepinephrine cause depression. However, there can be other physiologic causes of depression, and social and environmental factors play a role.

Complementary and Alternative Therapy for Depression

St. John's wort and *Gingko biloba* have been suggested for the management of mild depression, but these should not be taken along with prescription antidepression medications. St. John's wort can decrease reuptake of the neurotransmitters serotonin, norepinephrine, and dopamine. The use of these and many complementary and alternative products should be discontinued 1 to 2 weeks before surgery. The patient should check with a health care provider regarding complementary and alternative therapies (Complementary and Alternative Therapies 23.1).

COMPLEMENTARY AND ALTERNATIVE THERAPIES 23.1 Selective Serotonin Reuptake Inhibitors

- Feverfew may interfere with SSRI antidepressants such as fluoxetine.
- St. John's wort interacts with SSRIs, which may cause serotonin syndrome (dizziness, headache, sweating, and agitation).

Antidepressant Agents

Antidepressants are divided into five groups: (1) tricyclic antidepressants (TCAs), or tricyclics; (2) selective serotonin reuptake inhibitors (SSRIs); (3) serotonin norepinephrine reuptake inhibitors (SNRIs); (4) atypical antidepressants that affect various neurotransmitters; and (5) monoamine oxidase inhibitors (MAOIs). TCAs and MAOIs were marketed in the late 1950s, and many of the SSRIs and atypical antidepressants were available in the 1980s. The SSRIs and SNRIs are popular antidepressants because they do not cause sedation, hypotension, anticholinergic effects, or cardiotoxicity as do many of the TCAs. However, users of SSRIs can experience sexual dysfunction, but this can be managed. With unpleasant side effects or lack of improvement, the patient is usually changed to another category of drug.

Tricyclic Antidepressants

Tricyclic antidepressants (TCAs) are used to treat major depression because they are effective and are less expensive than SSRIs and other drugs. Imipramine was the first TCA marketed in the 1950s.

The action of TCAs is to block the uptake of the neurotransmitters norepinephrine and serotonin in the brain. The clinical response of TCAs occurs after 2 to 4 weeks of drug therapy. If there is no improvement after 2 to 4 weeks, the antidepressant is slowly withdrawn and another antidepressant is prescribed. *Polydrug therapy*, the practice of giving several antidepressants or antipsychotics together, should be avoided if possible because of potential serious side effects.

The effectiveness of TCAs in treating major depression is well documented. This group of drugs elevates mood, increases interest in daily living and activity, and decreases insomnia. For agitated depressed persons, amitriptyline, doxepin, or trimipramine may be prescribed because of their highly sedative effect. TCAs are often given at night to minimize problems caused by their sedative action. When discontinuing TCAs, the drugs should be gradually decreased to avoid withdrawal symptoms such as nausea, vomiting, anxiety, and akathisia. Imipramine hydrochloride is used for the treatment of enuresis (involuntary discharge of urine during sleep in children).

The TCA drugs include amitriptyline, imipramine, trimipramine, doxepin, desipramine, nortriptyline, and protriptyline. The TCA drugs desipramine and nortriptyline are major metabolites of imipramine and amitriptyline.

Pharmacokinetics

Amitriptyline is strongly protein bound. The half-life is 10 to 50 hours, and a cumulative drug effect may result. Amitriptyline is primarily excreted in urine.

Pharmacodynamics

Amitriptyline is well absorbed, but antidepressant effects develop slowly over several weeks. The onset of the antidepressant effect of amitriptyline is 1 to 3 weeks, and the peak concentration is 2 to 5 hours. Drug doses are decreased for older patients to reduce side effects.

Side Effects and Adverse Reactions

The TCAs have many side effects: orthostatic hypotension, sedation, anticholinergic effects, cardiotoxicity, and seizures. Rising from a sitting position too rapidly can cause dizziness and lightheadedness (*orthostatic hypotension*), so the patient should be instructed to rise slowly to an upright position. The TCAs block the histamine receptors, thus sedation is likely to occur initially but decreases with continuous use of the drug. Because TCAs block the cholinergic receptors, they can cause anticholinergic effects such as tachycardia, urinary retention, constipation, dry mouth, and blurred vision. Other side effects of TCAs include allergic reactions (skin rash, pruritus, and petechiae) and sexual dysfunction (erectile dysfunction and amenorrhea). Most TCAs can cause blood dyscrasias (leukopenia, thrombocytopenia, and agranulocytosis) that require close monitoring of blood cell counts. Amitriptyline may lead to symptoms of extrapyramidal syndrome (EPS). Clomipramine can cause neuroleptic malignant syndrome (NMS). Because the seizure threshold is decreased by TCAs, patients with seizure disorders may need TCA dose adjustment. The most serious adverse reaction to TCAs is cardiotoxicity, such as dysrhythmias that may result from high doses of the drug. The therapeutic serum range of TCAs should be monitored.

Drug Interactions

Alcohol, hypnotics, sedatives, and barbiturates potentiate central nervous system (CNS) depression when taken with TCAs. Concurrent use of MAOIs with amitriptyline may lead to cardiovascular instability and toxic psychosis. Antithyroid medications taken with amitriptyline may increase the risk of dysrhythmias.

Selective Serotonin Reuptake Inhibitors

Selective serotonin reuptake inhibitors (SSRIs) block the reuptake of serotonin into the nerve terminal of the CNS, thereby enhancing its transmission at the serotonergic synapse. These drugs do *not* block the uptake of dopamine or norepinephrine, and they do *not* block cholinergic and alpha$_1$-adrenergic receptors. SSRIs are more commonly used to treat depression than are TCAs, and they have fewer side effects than TCAs.

The primary use of SSRIs is for major depressive disorders. They are also effective for treating anxiety disorders such as obsessive-compulsive disorder (OCD), panic disorders, phobias, posttraumatic stress disorder (PTSD), and other forms of anxiety. Fluvoxamine is useful for treating OCD in children and adults. SSRIs have also been used to treat eating disorders and selected drug abuses. Miscellaneous uses for SSRIs include decreasing premenstrual tension syndrome, preventing migraine headaches, and preventing or minimizing aggressive behavior in patients with borderline personality disorder.

The SSRIs include fluoxetine, fluvoxamine, sertraline, paroxetine, citalopram, and escitalopram. Fluoxetine has been effective in 50% to 60% of patients who fail to respond to TCA therapy (*TCA-refractory depression*). The U.S. Food and Drug Administration (FDA) approved a weekly delayed-release fluoxetine dose of 90 mg. However, before taking the weekly dose, the patient should respond to a daily maintenance dose of 20 mg/day without serious effects.

Many SSRIs have an interaction with grapefruit juice that can lead to possible toxicity. It is recommended that daily intake be limited to 8 ounces of grapefruit juice or one half of a grapefruit.

Prototype Drug Chart 23.1 describes the drug characteristics of the SSRI fluoxetine.

Pharmacokinetics

Fluoxetine is strongly protein bound, and the half-life is 4 to 6 days; therefore a cumulative drug effect may result from long-term use. Fluoxetine is metabolized and excreted by the kidneys.

Pharmacodynamics

Fluoxetine is well absorbed; however, its antidepressant effect develops slowly over several weeks. The onset of fluoxetine's antidepressant effect is between 1 and 12 weeks, and peak concentration with consistent therapy is at 6 to 8 hours after ingestion. The drug dose for older adults should be decreased to reduce side effects.

PROTOTYPE DRUG CHART 23.1 Fluoxetine

Drug Class	Dosage
Antidepressant: Selective serotonin reuptake inhibitor Pregnancy category: C*	Regular release: A: PO: Initially 20 mg/d in the morning; *max:* 80 mg/d Delayed release: A: PO: 90 mg/wk; *max:* 90 mg/wk
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity *Caution:* Myocardial infarction, with MAOIs, dehydration, breastfeeding, suicidal ideation, liver disease, osteoporosis, glaucoma, seizure disorder, diabetes mellitus, malnourished, anticoagulant therapy, diarrhea	Drug: Increased effects of CNS and respiratory depression, hypotensive effect with alcohol and CNS depressants; increased bleeding potential with aspirin, NSAIDs, anticoagulants; MAOIs and SSRIs increase risk of serotonin syndrome. Complementary and alternative therapy: St. John's wort increases risk for serotonin syndrome; increased effect of hypoglycemics
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: well absorbed Distribution: PB: 94.5% Metabolism: Fluoxetine: t½: 4-6 d Excretion: Excreted primarily in urine	PO: Onset: 3-4 wk Peak: 6-8 h Duration: UK
Therapeutic Effects/Uses	
To treat depression, bipolar disorder, bulimia disorder; obsessive-compulsive disorder; panic disorder; and premenstrual dysphoric disorder	
Mode of Action: Serotonin is increased in nerve cells because of blockage from nerve fibers.	
Side Effects	**Adverse Reactions**
Headache, dizziness, drowsiness, insomnia, anxiety, asthenia, memory impairment, mydriasis, tremors, dry mouth, akathisia, anorexia, nausea, diarrhea, weight loss, erectile dysfunction	Seizures, angioedema, hyponatremia, hypokalemia, hyperkalemia, hypoglycemia, dehydration, bleeding, osteoporosis *Life threatening:* Stevens-Johnson syndrome, hepatic dysfunction, suicidal ideation

A, Adult; *CNS,* central nervous system; *d,* day; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein binding; *PO,* by mouth; *SSRI,* selective serotonin reuptake inhibitor; *t½,* half-life; *UK,* unknown; *wk,* week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Side Effects and Adverse Reactions

Fluoxetine produces common side effects such as dry mouth, blurred vision, insomnia, headache, nervousness, anorexia, nausea, diarrhea, and suicidal ideation. Fluoxetine has fewer side effects than amitriptyline.

Some patients may experience sexual dysfunction when taking SSRIs. Men have discontinued taking fluoxetine after experiencing a decrease in sexual arousal. Some women have become anorgasmic while males reported erectile dysfunction and delayed ejaculation when taking paroxetine HCl. The side effects often decrease or cease over the 1- to 4-week period of waiting for the therapeutic effect to emerge.

PROTOTYPE DRUG CHART 23.2 Venlafaxine

Drug Class	Dosage
Antidepressant: Serotonin norepinephrine reuptake inhibitor Pregnancy category: C*	Immediate release: A: PO: 75 mg/d in 2 -3 divided doses; *max:* 225 mg/d for outpatients, 375 mg/d for inpatients Extended release: A: PO: Initially 37.5-75 mg once daily; *max:* 225 mg/d
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity *Caution:* With MAOIs, CNS depression, SIADH, anticoagulant therapy, pregnancy, breastfeeding, in children, suicidal ideation, renal impairment, hepatic disease, bleeding, narrow-angle glaucoma, seizures, malnourishment, hypovolemia, hypokalemia, hyponatremia, hyperthyroidism, MI, heart failure	Drug: Increased effects of CNS, respiratory depression, and hypotensive effect with alcohol and CNS depressants; drug levels and toxicity increase with cimetidine and haloperidol; bleeding is increased with anticoagulants and aspirin; risk of serotonin syndrome and NMS is increased with other SNRIs, SSRIs, serotonin receptor agonists (triptans), and amphetamines. *Life threatening:* Hypertensive crisis and death may occur with MAOIs; St. John's wort may cause serotonin syndrome (tachycardia, hypertension, confusion, twitching, hyperreflexia, and hyperthermia).
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Well absorbed Distribution: PB: 27% Metabolism: t½: 5 h Excretion: Primarily in urine	Immediate release: PO: Onset: UK Peak: 2-4 h Duration: UK Extended release: PO: UK Peak: 5.5 h Duration: UK
Therapeutic Effects/Uses	
To treat depression, generalized anxiety disorder, social anxiety disorder, panic disorder	
Mode of Action: Serotonin and norepinephrine are increased in nerve cells because of blockage from nerve fibers.	
Side Effects	Adverse Reactions
Drowsiness, dizziness, insomnia, headache, euphoria, amnesia, blurred vision, mydriasis, dry mouth and eyes, excess sweating, weakness, diarrhea, weight loss, nausea, anorexia, constipation	Tachycardia, seizure, hypertension, serotonin syndrome *Life threatening:* Suicidal ideation, NMS, SIADH, renal failure, Stevens-Johnson syndrome

A, Adult; *CNS,* central nervous system; *d,* day; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *MI,* myocardial infarction; *NMS,* neuroleptic malignant syndrome; *PB,* protein binding; *PO,* by mouth; *SIADH,* syndrome of inappropriate antidiuretic hormone secretion; *SNRI,* serotonin norepinephrine reuptake inhibitor; *SSRI,* selective serotonin reuptake inhibitor; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Serotonin Norepinephrine Reuptake Inhibitors

Venlafaxine was the first of the **serotonin norepinephrine reuptake inhibitors (SNRIs)** approved for major depression in 1993. SNRIs inhibit the reuptake of serotonin and norepinephrine, increasing availability in the synapse. SNRIs are used for major depression. Other approved uses are for generalized anxiety disorder and social anxiety disorder. Other SNRIs include duloxetine and desvenlafaxine. The concurrent interaction of venlafaxine and St. John's wort may increase the risk of serotonin syndrome and NMS. Prototype Drug Chart 23.2 describes the drug characteristics of venlafaxine.

Pharmacokinetics

Venlafaxine is well absorbed. The protein-binding capacity is 27%, and the half-life is 5 hours. Venlafaxine is mostly excreted in the urine.

Pharmacodynamics

The onset and duration of venlafaxine are unknown. The peak action is 2 to 4 hours for immediate-release tablets and 5.5 hours for extended-release tablets.

Side Effects and Adverse Effects

Side effects for venlafaxine include drowsiness, dizziness, insomnia, headache, euphoria, amnesia, blurred vision, and ejaculation dysfunction. Adverse effects of this drug are hypertension, tachycardia, angioedema, seizures, and suicidal ideation.

Atypical Antidepressants

Atypical antidepressants, or *second-generation antidepressants,* became available in the 1980s and have been used for major depression, reactive depression, and anxiety. They affect one or two of the three neurotransmitters: serotonin, norepinephrine, and dopamine. One of the first atypical antidepressants marketed was amoxapine; others are maprotiline, nefazodone, and trazodone.

Amoxapine and maprotiline are sometimes considered to be TCAs because of their pharmacologic similarities. Atypical antidepressants should *not* be taken with MAOIs and should not be used within 14 days after discontinuing MAOIs. Trazodone may have a potential drug interaction with ketoconazole, ritonavir, and indinavir that may lead to increased trazodone levels and adverse effects.

Monoamine Oxidase Inhibitors

Another group of antidepressants is the **monoamine oxidase inhibitors (MAOIs)**. The enzyme monoamine oxidase (MAO) inactivates norepinephrine, dopamine, epinephrine, and serotonin. By inhibiting MAO, the levels of these neurotransmitters rise. Two forms of MAO enzyme exist in the body: MAO-A and MAO-B. These enzymes are found primarily in the liver and brain. MAO-A inactivates dopamine in the brain, whereas MAO-B inactivates norepinephrine and serotonin. The MAOIs are nonselective and inhibit both MAO-A and MAO-B. Inhibition of MAO by MAOIs is thought to relieve the symptoms of depression. Four MAOIs are currently prescribed: (1) tranylcypromine sulfate, (2) isocarboxazid, (3) selegiline HCl, and (4) phenelzine sulfate. These MAOIs are detailed in Table 23.1.

For the treatment of depression, MAOIs are as effective as TCAs; however, because of adverse reactions, such as the risk of hypertensive crisis resulting from food and drug interactions, only 1% of patients who take antidepressants take an MAOI. Currently, MAOIs are not the antidepressants of choice and are usually prescribed when the patient does not respond to TCAs or second-generation antidepressants. However, MAOIs are still used for mild, reactive, and atypical depression (chronic anxiety, hypersomnia, fear). MAOIs and TCAs should not be taken together when treating depression.

TABLE 23.1

Antidepressants

Drug	Route and Dosage	Uses and Considerations
Tricyclic Antidepressants (TCAs)		
Amitriptyline hydrochloride	A: PO: 50-100 mg/d; *max:* 300 mg/d for inpatients, 150 mg/d for outpatients Older adults: PO: 10-25 mg at bedtime; *max:* 150 mg/d Therapeutic serum range: 120-150 ng/mL	For depression. May cause drowsiness, dizziness, blurred vision, memory impairment, headache, insomnia, orthostatic hypotension, dysrhythmias, dry mouth, excess sweating, constipation, weight gain/loss, lethargy, tremor, paresthesia, seizures, and suicidal ideation. Pregnancy category: C*; PB: 95%; t½: 10-50 h
Clomipramine hydrochloride	A: PO: Initially 25 mg/d, may increase to 100 mg/d in divided doses with meals; after titration, entire dose may be given at bedtime; *max:* 250 mg/d Adol/C >10 y: PO: Initially 25 mg/d, then 3 mg/kg/d; *max:* 200 mg/d	For depression and OCD. Give initially with meals to decrease GI side effects, later, give at bedtime to reduce daytime sedation. May cause tremor, dizziness, drowsiness, headache, visual impairment, insomnia, fatigue, dry mouth, anorexia, nausea, constipation, weight gain, sexual dysfunction, and pseudoparkinsonism, especially in older adults in high doses. Pregnancy category: C*; PB: 97%; t½: 36 h
Desipramine hydrochloride	A: PO: Initially 50-75 mg/d in 2-4 divided doses, increased gradually; maint: 100-200 mg/d; *max:* 300 mg/d for inpatients, 200 mg/d for outpatients Older adults: Initially 25 mg/d at bedtime; maint: 100 mg/d in divided doses; *max:* 150 mg/d Adol: PO: Initially 25-50 mg/d at bedtime; maint: 100 mg/d; *max:* 150 mg/d Therapeutic serum range: 125-300 ng/mL	For depression. Take with food if GI distress occurs. May administer at bedtime to decrease daytime sedation. May cause dizziness, drowsiness, headache, memory impairment, tremor, paresthesia, dry mouth, urinary retention, orthostatic hypotension, and suicidal ideation. Pregnancy category: C*; PB: 90%; t½: 7-60 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Doxepin hydrochloride	A: PO: Initially 75 mg/d at bedtime; or in 2 -3 divided doses; maint: 75-150 mg/d; *max:* 300 mg/d Adol/C >12 y: PO: Initially 25-50 mg/d; *max:* 100 mg/d Therapeutic serum range: 110-250 ng/mL	For depression and anxiety. May cause dizziness, drowsiness, blurred vision, orthostatic hypotension, dry mouth, sexual dysfunction, sleep-related behaviors, and suicidal ideation. Pregnancy category: C*; PB: 80%; t½: 6-8 h
Imipramine hydrochloride	A: PO: Initially 75-100 mg/d; maint: 150-200 mg/d; *max:* 200 mg/d for outpatients, 300 mg/d for inpatients Adol/older adults: Initially 30-40 mg/d at bedtime; maint: 75-100 mg/d; *max:* Adol 100 mg/d, older adults 200 mg/d for outpatients, 300 mg/d for inpatients Therapeutic serum range: 125-250 ng/mL	For depression. Optimal response may take 1-3 weeks. Can be taken at bedtime to lessen dangers from sedative effect. Take with food if GI distress occurs, and avoid taking with alcohol or CNS depressants. May cause dizziness, drowsiness, fatigue, headache, blurred vision, dry mouth, orthostatic hypotension, tremor, urinary retention, seizures, and suicidal ideation. Pregnancy category: UK*; PB: 85%-95%; t½: 8-16 h
Nortriptyline hydrochloride	A: PO: Initially 25-50 mg tid/qid; *max:* 150 mg/d Adol/older adults: PO: Initially 10-25 mg/d at bedtime; maint: 30-50 mg/d; *max:* 150 mg/d Therapeutic serum range: 50-150 ng/mL	For depression. May cause dizziness, drowsiness, headache, fatigue, orthostatic hypotension, dry mouth, seizures, and suicidal ideation. Pregnancy category: C*; PB: 93%-95%; t½: 16-90 h
Protriptyline hydrochloride	A: PO: Initially 5-10 mg tid/qid; *max:* 60 mg/d Older adults: PO: Initially 5 mg or less tid; *max:* 30 mg/d Therapeutic serum range: 70-250 ng/mL	For depression. Has little sedative effect. May cause dizziness, headache, blurred vision, confusion, insomnia, tremor, dry mouth, nausea, orthostatic hypotension, and suicidal ideation. Gradually taper the dose when discontinuing. Pregnancy category: C*; PB: 90%; t½: 54-92 h
Trimipramine maleate	A: Initially 75 mg/d in divided doses; *max:* 200 mg/d for outpatients, 300 mg/d for inpatients Adol/older adults: Initially 50 mg/d in divided doses; *max:* 100 mg/d	For depression. May cause dizziness, drowsiness, fatigue, tremor, headache, dry mouth, orthostatic hypotension, weight gain, and suicidal ideation. Gradually taper the dose when discontinuing. Pregnancy category: C*; PB: 95%; t½: 20-26 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Selective Serotonin Reuptake Inhibitors (SSRIs)		
Citalopram	A: PO: Initially 20 mg/d, may increase after 1 wk to 40 mg/d; *max:* 40 mg/d A >60 y: PO: 20 mg/d; *max:* 20 mg/d	For depression. Limit to 20 mg daily if concurrently taking omeprazole. Wait 14 days after stopping MAOIs to avoid serotonin syndrome. May cause drowsiness, insomnia, dry mouth, excess sweating, nausea, ejaculation dysfunction, seizures, prolonged QT, and angioedema. Pregnancy category: C*; PB: 80%; t½: 35 h
Fluoxetine hydrochloride	See Prototype Drug Chart 23.1.	
Paroxetine hydrochloride	Depression: Regular-release tablets: A: PO: Initially 20 mg/d; *max:* 50 mg/d Older adults: PO: Initially 10 mg/d; *max:* 40 mg/d Controlled-release tablets: A: PO: Initially 25 mg/d in the morning; *max:* 62.5 mg/d Older adults: PO: Initially 12.5 mg/d; *max:* 50 mg/d	For depression, general anxiety disorder, social anxiety disorder, PTSD, and OCD. May cause dizziness, drowsiness, insomnia, headache, asthenia, dry mouth, nausea, constipation, diarrhea, tremors, orthostatic hypotension, sexual dysfunction, and suicidal ideation. Pregnancy category: D*; PB: 93%-95%; t½: 15-21 h
Sertraline hydrochloride	Depression: A: PO: 25-50 mg/d; *max:* 200 mg/d	For depression, OCD, PTSD, panic disorder, social anxiety disorder. *Do not* take with MAOIs or TCAs. Take with food if GI distress occurs. May cause dizziness, drowsiness, headache, insomnia, nausea, diarrhea, orthostatic hypotension, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 98%; t½: 26 h
Fluvoxamine	OCD: Adol/A: PO: Initially 50 mg/d at bedtime; maint: 100-200 mg/d; *max:* 300 mg/d Adol 12-17 y: PO: 25 mg/d at bedtime; *max:* 300 mg/d Extended release: A: PO: 100 mg/d at bedtime; maint: 100-300 mg/d; *max:* 300 mg/d	For OCD and social anxiety disorder. May cause dizziness, drowsiness, headache, insomnia, dry mouth, asthenia, anorexia, nausea, diarrhea, sexual dysfunction, and Stevens-Johnson syndrome. *Caution:* Do not use in patients with hepatic disorders. Pregnancy category: C *; PB: 80%; t½: 15.6 h immediate release, 16.3 h extended release
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Escitalopram	Depression: A: PO: 10 mg/d, may increase to 20 mg/d after 1 wk; *max:* 20 mg/d Older adults: PO: 10 mg/d; *max:* 10 mg/d Adol/C >12 y: PO: 10 mg/d; *max:* 20 mg/d	For depression and generalized anxiety disorder. May cause drowsiness, headache, insomnia, nausea, orthostatic hypotension, ejaculation dysfunction, agranulocytosis, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 56%; t½: 27-32 h
Vilazodone	A: PO: Initially 10 mg/d for 1 wk; maint: 20-40 mg/d with food; *max:* 40 mg/d	For depression. Common side effects include dizziness, headache, dry mouth, insomnia, nausea, diarrhea, serotonin syndrome, and suicidal ideation. Pregnancy category: C*; PB: 96%-99%; t½: 25 h
Nefazodone	A: PO: Initially 100 mg bid; maint: 300-600 mg/d; *max:* 600 mg/d Older adult: Initially 50 mg bid; maint: 300-600 mg/d in 2 divided doses; *max:* 600 mg/d	For depression. May cause headache, drowsiness, dizziness, insomnia, blurred vision, dry mouth, weakness, infection, nausea, diarrhea, constipation, and suicidal ideation. Pregnancy category: C*; PB: 99%; t½: 1.5-2 h
Trazodone hydrochloride	Immediate release:A: PO: Initially 150 mg/d in divided doses; *max:* 400 mg/d for outpatients, 600 mg/d for inpatients Older A: PO: Initially 25-50 mg at bedtime, *maint:* 75-150 mg/d; *max:* 400 mg/d for outpatients, 600 mg/d for inpatients Extended release: A: PO: Initially 150 mg/d at bedtime, *max:* 375 mg/d	For depression. Can be taken at bedtime to lessen dangers from sedative effect. May cause drowsiness, dizziness, blurred vision, headache, insomnia, fatigue, dry mouth, orthostatic hypotension, tachycardia, nausea, vomiting, and suicidal ideation. Take with food to decrease GI distress. Pregnancy category: C*; PB: 85%-95%; t½: 9-13 h
Vortioxetine	A: PO: Initially 10 mg/d; maint: 5-20 mg/d; *max:* 20 mg/d	For depression. May cause dizziness, dry mouth, nausea, diarrhea, sexual dysfunction, and suicidal ideation. Gradually taper off upon discontinuation. Contraindicated within 14 days of an MAOI. Pregnancy category: C*; PB: 98%; t½: 66 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Atypical (Second-Generation) Antidepressants		
Amoxapine	A/adol >16 y: PO: Initially 50 mg bid/tid; *max:* 400 mg/d for outpatients, 600 mg/d for inpatients Older adults: PO: 25 mg bid/tid; *max:* 300 mg/d	For depression. May cause drowsiness, dizziness, dry mouth, increased appetite, constipation, EPS, and suicidal ideation. Do *not* take with MAOIs or TCAs. Taper off gradually when discontinuing. Pregnancy category: C*; PB: >90%; t½: 6.5-30 h
Maprotiline hydrochloride	A: PO: Initially 25 mg tid or 75 mg at bedtime; *max:* 225 mg/d for inpatients, 150 mg/d for outpatients Older adults: Initially 25 mg at bedtime; maint: 50-75 mg/d; *max:* 225 mg/d for inpatients, 150 mg/d for outpatients	For depression. May cause dizziness, drowsiness, dry mouth, seizures, and suicidal ideation. Gradually taper off when discontinuing. Pregnancy category: B *; PB: 88%; t½: 27-58 h
Norepinephrine Dopamine Reuptake Inhibitors (NDRIs)		
Bupropion hydrochloride	Depression: Immediate release: A: PO: Initially 100 mg bid; *max:* 450 mg/d, 150 mg/dose Sustained release: A: PO: Initially 150 mg/d in the morning; maint: 200 mg bid; *max*: 400 mg/d, 200 mg single dose Extended release: A: PO: 150 mg/d in the morning; *max*: 450 mg/d	For depression, seasonal affective disorder, and nicotine withdrawal. May cause dizziness, insomnia, lethargy, headache, blurred vision, dry mouth, diaphoresis, agitation, tachycardia, weight loss, and suicidal ideation. Avoid use in patients with a history of seizures. Gradually taper off when discontinuing. Pregnancy category: C*; PB: 84%; t½: 8-24 h immediate release, 20-37 h sustained and extended release
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Miscellaneous Antidepressants		
Mirtazapine	A: PO: Initially 15 mg at bedtime; maint: 15-45 mg/d; *max:* 45 mg/d Older adults: PO: Initially 7.5 mg at bedtime, then 15-30 mg/d; *max:* 45 mg/d	For depression. May cause dizziness, drowsiness, restlessness, increased appetite, dry mouth, constipation, weight gain, hypercholesterolemia, and suicidal ideation. Pregnancy category: C*; PB: 85%; t½: 20-40 h
Serotonin Norepinephrine Reuptake Inhibitors (SNRIs)		
Desvenlafaxine	Extended release: A: PO: Initially 50 mg/d; *max:* 400 mg/d	For depression. May cause dizziness, drowsiness, insomnia, dry mouth, nausea, excess sweating, fatigue, withdrawal, and suicidal ideation. Taper off gradually over 2 to 3 weeks. Pregnancy category: C*; PB: 30%; t½: 11 h
Duloxetine	Depression: A: PO: Initially 20 mg/d; maint: 60 mg/d; *max:* 120 mg/d	For major depression, diabetic neuropathy, fibromyalgia, generalized anxiety disorder, musculoskeletal pain, and osteoarthritis. May cause dizziness, drowsiness, headache, insomnia, anxiety, asthenia, dry mouth, anorexia, nausea, constipation, and suicidal ideation. Wait 14 days after stopping MAOIs to use this drug. Gradually taper off when discontinuing. Pregnancy category: C*; PB: 90%; t½: 9.2-19.1 h
Venlafaxine	See Prototype Drug Chart 23.2.	
Levomilnacipran	A: PO: Initially 20 mg/d for 2 d, then 40 mg/d; maint: 40-120 mg/d; *max*: 120 mg/d	For depression. May cause orthostatic hypotension, excess sweating, nausea, constipation, and suicidal ideation. Contraindicated within 14 d of MAOI use. Gradually taper off when discontinuing. Pregnancy category: C*; PB: 22%; t½: 12 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Monoamine Oxidase Inhibitors (MAOIs)		
Isocarboxazid	A/adol >16 y: PO: Initially 10 mg bid; maint: 40 mg/d in divided doses; *max:* 60 mg/d	For depression. May cause dizziness, headache, dry mouth, weight gain, seizure, withdrawal, and suicidal ideation. Avoid tyramine-rich foods such as cheese, sour cream, wine, beer, figs, cured meat (sausage, salami), soy sauce, anchovies, shrimp, raisins, raspberries, bananas, and chocolate, and avoid drugs such as TCAs. Antidepressant effect may take 1-6 weeks. Taper off gradually when discontinuing. Pregnancy category: C*; PB: UK; t½: 2.5 h
Phenelzine sulfate	A/adol >16 y: PO: Initially 15 mg tid; maint: 60-90 mg/d; *max:* 90 mg/d	For depression. May cause dizziness, drowsiness, headache, blurred vision, nystagmus, edema, ejaculation dysfunction, orthostatic hypotension, hypertensive crisis, and suicidal ideation. Avoid tyramine-rich foods. Gradually taper off when discontinuing. Pregnancy category: UK*; PB: UK; t½: 12 h
Tranylcypromine sulfate	A: PO: Initially 15 mg bid; *max:* 60 mg/d	For depression. May cause dizziness, insomnia, blurred vision, constipation, orthostatic hypotension, peripheral edema, weight gain, erectile dysfunction, withdrawal, and suicidal ideation. Avoid tyramine-rich foods. Pregnancy category: C*; PB: UK; t½: 2.5 h
Selegiline hydrochloride	Depression: A: PO: 7.5 mg/d; *max*: 10 mg/d A: Transdermal: 6 mg/d; *max:* 12 mg/d	For depression and parkinsonism. May cause dizziness, dry mouth, confusion, nausea, orthostatic hypotension, impulse control disorder, and suicidal ideation. Avoid tyramine-rich foods. Taper off gradually when discontinuing. Pregnancy category: C*; PB: 85%; t½: PO 10 h, transdermal 18-25 h
Mood Stabilizers		
Lithium citrate	See Prototype Drug Chart 23.3.	
Carbamazepine	Bipolar disorder: Extended-release capsule: A:PO: Initially 200 mg bid; *max:* 1600 mg/d Therapeutic serum level: 4-12 mcg/mL	For bipolar disorder, seizures, neuropathic pain, trigeminal neuralgia. Contraindicated in bone marrow depression. May cause dizziness, drowsiness, headache, blurred vision, ataxia, pruritus, nausea, vomiting, weakness, anemia, agranulocytosis, and suicidal ideation. Gradually taper off when discontinuing. Pregnancy category: D*; PB: 76%; t½: 25-65 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Divalproex	Bipolar disorder: Delayed release: A: PO: Initially 750 mg/d in divided doses; *max:* 3000 mg/d or 60 mg/kg/d Extended release: A: PO: Initially 25 mg/kg/d; *max:* 60 mg/kg/d Therapeutic range: 50-100 mcg/mL	For bipolar disorder, seizures, and migraine prophylaxis. May cause dizziness, drowsiness, insomnia, asthenia, blurred vision, nausea, vomiting, diarrhea, thrombocytopenia, and suicidal ideation. Give with food to avoid GI distress. Pregnancy category: C*; PB: 90%; t½: 6-16 h
Lamotrigine	Bipolar disorder: A: PO: Initially 25 mg/d for 2 wk, then 50 mg/d for 2 wk, then 100 mg/d for 1 wk; thereafter give 200 mg/d	For bipolar disorder, seizures, Lennox-Gastaut syndrome. May cause dizziness, drowsiness, blurred vision, pharyngitis, nausea, vomiting, ataxia, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 55%; t½ 14-59 h
Cariprazine	Bipolar disorder: A: PO: Initially 1.5 mg/d; day 2 give 3 mg/d; maint: 1.5-6 mg/d; *max:* 6 mg/d	For bipolar disorder and schizophrenia. May cause insomnia, dizziness, headache, dry mouth, restlessness, weight gain, nausea, constipation, EPS, and suicidal ideation. Pregnancy category: UK*; PB: 91%-97%; t½: 2-4 d
Aripiprazole	Bipolar disorder: A: PO: Initially 15 mg/d; *max:* 30 mg/d Adol/C >10 y: PO: Initially 2 mg/d; *max:* 30 mg/d	For bipolar disorder, schizophrenia, autism, depression, Tourette syndrome. May cause drowsiness, fatigue, headache, anxiety, agitation, insomnia, EPS, nausea, vomiting, hyperglycemia, and suicidal ideation. Pregnancy category: UK*; PB: 99%; t½: 75 h, extended release 30-47 d

Drug and Food Interactions

Certain drug and food interactions with MAOIs can be fatal. Any drugs that are CNS stimulants or sympathomimetics, such as vasoconstrictors and cold medications that contain phenylephrine and pseudoephedrine, can cause a hypertensive crisis when taken with an MAOI. In addition, foods that contain tyramine—aged cheese (cheddar, Swiss, bleu), cream, yogurt, coffee, chocolate, bananas, raisins, Italian green beans, liver, pickled foods, sausage, soy sauce, yeast, beer, and red wines—have sympathomimetic-like effects and can cause a hypertensive crisis. MAOI users *must avoid* these types of food and drugs. Frequent blood pressure monitoring is essential, and patient teaching regarding foods and over-the-counter (OTC) drugs to avoid is an important nursing responsibility. Because of the danger associated with hypertensive crisis, many psychiatrists will not prescribe MAOIs for depression unless other drugs have failed to be effective for the patient. However, this group of drugs is effective for treating depression if taken properly.

In teaching patients about the foods and drugs to avoid when taking MAOIs, some individuals respond better to verbal instructions and education with reinforcement from videos than to printed communications. Complementary and Alternative Therapies 23.2 details complementary and alternative therapy interactions with MAOIs.

Side Effects and Adverse Reactions

Side effects of MAOIs include CNS stimulation (agitation, restlessness, and insomnia), orthostatic hypotension, and anticholinergic effects.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 23.2 Monoamine Oxidase Inhibitors

- Ginseng, ephedra (Ma-huang), and St. John's wort may lead to palpitations, heart attack, and hypertensive crisis when taken with antidepressant MAOIs.
- Ginseng may lead to manic episodes when taken in combination with MAOIs such as tranylcypromine sulfate.
- An excessive dose of anise may interfere with MAOIs.
- An increased use of brewer's yeast with MAOIs can increase blood pressure.

Nursing Process: Patient-Centered Collaborative Care

Antidepressants

Assessment

- Assess the patient's baseline vital signs and weight for future comparisons. TCAs should be avoided in patients with cardiovascular disease and hypertension and should be used cautiously in patients with seizure disorders.
- Note the patient's hepatic and renal function by assessing urine output (>1500 mL/day), blood urea nitrogen (BUN), and serum creatinine and hepatic enzyme levels.
- Obtain a health history of episodes of depression; assess mental status, and assess for suicidal tendencies.
- Secure a drug history of the current drugs, alcohol, and herbs the patient is taking. CNS depressants can cause an additive effect. Antidepressants that cause anticholinergic-like symptoms are contraindicated if a patient has glaucoma.
- Assess for tardive dyskinesia and NMS, including hyperpyrexia, muscle rigidity, tachycardia, and cardiac dysrhythmias.

Nursing Diagnoses

- Self-Directed Violence, Risk for
- Anxiety related to situational crises

- Social Isolation related to feelings of sadness
- Coping, Ineffective related to negative thought patterns
- Hopelessness related to feelings of despair
- Knowledge, Deficient related to inexperience with medication
- Health Maintenance, Impaired related to lack of interest

Planning

- Patient's depression or bipolar behavior will be decreased.

Nursing Interventions

- Observe patients for signs and symptoms of depression: mood changes, insomnia, apathy, or lack of interest in activities.
- Monitor vital signs. Orthostatic hypotension is common. Check for anticholinergic-like symptoms such as dry mouth, increased heart rate, urinary retention, and constipation. Check weight two to three times per week.
- Monitor patients for suicidal tendencies when marked depression is present.
- Observe patients for seizures when anticonvulsants are taken; antidepressants lower the seizure threshold, and the anticonvulsant dose might need to be increased.
- Monitor for drug-drug and food-drug interactions. Sympathomimetic-like drugs and foods that contain tyramine may cause a hypertensive crisis if taken with MAOIs.
- Check patients for extremely high blood pressure when taking MAOIs.
- Provide patients with a list of foods to avoid when taking MAOIs to avoid hypertensive crisis. These foods include cheese, red wine, beer, liver, bananas, yogurt, and sausage.

Patient Teaching

General

- Teach patients to take the medication as prescribed. Compliance is important.
- Inform patients that full effectiveness of a drug may not be evident until 1 to 2 weeks after the start of therapy.
- Encourage patients to keep medical appointments.
- Caution patients not to consume alcohol or any CNS depressants because of their addictive effect.
- Inform patients that many complementary and alternative therapy products interact with antidepressants, especially MAOIs and SSRIs. Complementary and alternative therapies may need to be discontinued, or the antidepressant drug dosage may need to be modified (see Complementary and Alternative Therapies 23.1 and 23.2).
- Warn patients not to drive or be involved in potentially dangerous mechanical activity until stabilization of the drug dose has been established.
- Advise patients not to abruptly stop taking the drug. The drug dose should be gradually decreased by a health care provider.
- Encourage patients planning pregnancy to consult with a health care provider about possible teratogenic effects of the drug on the fetus.
- Advise patients to take the drug with food if gastrointestinal (GI) distress occurs.

Side Effects

- Advise patients that antidepressants may be taken at bedtime to decrease dangers from the sedative effect, and suggest they check with a health care provider. Transient side effects include nausea, drowsiness, headaches, and nervousness.

Cultural Considerations

- Explain to Asian patients taking an antipsychotic (such as TCA or lithium) that the dose may need to be decreased. Explain to Hispanic patients that the dose for the antidepressant may be lower than is required for other cultural groups.

Evaluation

- Evaluate the effectiveness of the drug therapy regarding whether a patient's depression is controlled or has ceased.

Mood Stabilizers

Mood stabilizers are used to treat bipolar affective disorder. Lithium was the first drug used to manage this disorder. Some refer to lithium as an *antimania drug* effective in controlling manic behavior that arises from underlying bipolar disorder. Lithium has a calming effect but may cause some memory loss and confusion. It controls any evidence of flight of ideas and hyperactivity. If the person stops taking lithium, manic behavior may return. Lithium, carbamazepine, valproic acid or divalproex, and lamotrigine are currently first-line drugs for bipolar disorder.

Lithium is an inexpensive drug that must be closely monitored, and it has a narrow therapeutic serum range of 0.8 to 1.2 mEq/L. Serum lithium levels greater than 1.5 mEq/L may produce early signs of toxicity. The serum lithium level should be monitored biweekly until the therapeutic level has been obtained, and then it must be monitored at least every 1 to 2 months on the maintenance dose. Serum sodium levels also need to be monitored because lithium tends to deplete sodium. Lithium must be used with caution, if at all, by patients taking diuretics. Prototype Drug Chart 23.3 lists the pharmacologic behavior of lithium.

Pharmacokinetics

More than 95% of lithium is absorbed through the GI tract. The half-life of lithium ranges from 18 to 36 hours. Because of its long half-life, cumulative drug action may result. Lithium is metabolized by the liver, and most of the drug is excreted unchanged in the urine.

Pharmacodynamics

Lithium is prescribed mostly for the stabilization of bipolar affective disorder. The onset of action is fast, but the patient may not achieve the desired effect for 5 to 6 days. Increased sodium intake increases renal excretion, so the sodium intake needs to be closely monitored. Increased urine output can result in body fluid loss and dehydration, therefore adequate fluid intake of 1 to 2 L should be maintained daily.

Antiseizure drugs such as carbamazepine, lamotrigine, and divalproex/valproic acid have been used in place of lithium for some patients. These agents are further discussed in Chapter 19. The antipsychotic drugs olanzapine, ziprasidone, and aripiprazole are approved to treat acute mania and mixed episodes of bipolar disorder. Antipsychotic drugs are discussed further in Chapter 22.

Side Effects and Adverse Reactions

The many side effects of lithium—dry mouth, thirst, increased urination (loss of water and sodium), weight gain, bloated feeling, metallic taste, and edema of the hands and ankles—can be annoying to the patient. If taken during pregnancy, lithium may have teratogenic effects.

Lithium and nonsteroidal antiinflammatory drugs (NSAIDs) should *not* be given together, as NSAIDs may increase lithium levels. Caffeine and loop diuretics may decrease lithium levels. Lithium should be prescribed with extreme caution for patients who have a cardiovascular disease due to an increased risk of lithium toxicity. Frequent monitoring of lithium levels is necessary. Caution must also be used in patients with thyroid disease, as hypothyroidism may occur.

PROTOTYPE DRUG CHART 23.3 Lithium

Drug Class	Dosage
Mood stabilizer Pregnancy category: D*	Regular release: A/adol/C >12 y: PO: Initially 600 mg tid; maint: 900-1800 mg/d in 3-4 divided doses Extended release: A/adol/C >12 y: PO: 900 mg bid Therapeutic drug range: 0.8 -1.2 mEq/L
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity *Caution:* Hepatic and renal disease, pregnancy, lactation, breastfeeding, cardiac disease, dehydration, hyponatremia, hypokalemia, children, older adults, hypertension, infection, bradycardia, thyroid disease, seizure disorder, alcoholism	Drug: May increase lithium level with thiazide diuretics, methyldopa, haloperidol, NSAIDs, antidepressants, carbamazepine, calcium channel blockers, spironolactone, ACE inhibitors, sodium bicarbonate, phenothiazines; may increase lithium excretion with theophylline, aminophylline; may increase risk of serotonin syndrome with SSRIs and SNRIs; may increase hyperglycemia with antidiabetics; caffeine may decrease lithium levels, and CNS stimulants and direct renin inhibitors may increase risk of mania. Lab: Increased urine and blood glucose, protein; decreased serum sodium level Food: Increase sodium intake; lithium may cause sodium depletion Complementary and alternative therapy: Use of St. John's wort, kava kava, and valerian may lead to neurotoxicity.
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: Well absorbed Distribution: PB: UK Metabolism: t½: 18-36 Excretion: 98% in urine, mostly unchanged	PO: Onset: UK Peak: 0.5-3 h Duration: 24 h Extended release: Onset: UK Peak: 4-12 h Duration: UK
Therapeutic Effects/Uses	
To treat bipolar disorder, manic episodes	
Mode of Action: Alteration of ion transport in muscle and nerve cells; increased receptor sensitivity to serotonin	
Side Effects	**Adverse Reactions**
Headache, memory impairment, blurred vision, metallic taste, thirst, dry mouth, dental caries, drowsiness, dizziness, ataxia, tremors, anorexia, nausea, vomiting, diarrhea, polyuria, dehydration, hypotension, abdominal pain, restlessness, erectile dysfunction, weight gain/loss, abnormally dry skin	Urinary and fecal incontinence, hyperglycemia, proteinurea, leukocytosis, nephrotoxicity *Life threatening:* Cardiac dysrhythmias, seizures, angioedema, cardiac arrest, serotonin syndrome, neuroleptic malignant syndrome

Nursing Process: Patient-Centered Collaborative Care

Mood Stabilizer: Lithium

Assessment

- Assess for suicidal ideation.
- Assess baseline vital signs for future comparisons.
- Evaluate neurologic status, including gait, level of consciousness, reflexes, and tremors.
- Note hepatic and renal function by assessing urine output (>600 mL/day) and whether BUN and serum creatinine and liver enzyme levels are within normal range. Assess for toxicity. Draw weekly blood levels initially and then every 1 to 2 months. Therapeutic serum levels for lithium are 0.8 to 1.2 mEq/L. Signs and symptoms of serum levels above 1.5 mEq/L are nausea and vomiting, diarrhea, ataxia, blurred vision, confusion, and tremors. Above 2.5 mEq/L, signs and symptoms of toxicity progress to include seizures, cardiac dysrhythmias, coma, and permanent neurologic impairment. At 3.5 mEq/L or higher, signs of toxicity are potentially lethal. Withhold medication and notify a health care provider immediately if any of these occur.
- Obtain a health history of episodes of depression or manic-depressive behavior.
- Obtain a drug history. Diuretics, tetracyclines, methyldopa, probenecid, and NSAIDs such as ibuprofen decrease renal clearance of lithium, causing drug accumulation.

Nursing Diagnoses

- Injury, Risk for
- Coping, Ineffective related to manic behavior
- Noncompliance related to lack of adequate education regarding lithium

Planning

- The patient's manic-depressive behavior will be decreased.

Nursing Interventions

- Observe patients for signs and symptoms of depression: mood changes, insomnia, apathy, or lack of interest in activities.
- Monitor vital signs. Hypotension is common.

- Draw blood samples for lithium levels immediately before the next dose (8 to 12 hours after the previous dose).
- Monitor for signs of lithium toxicity. Report high (>1.5 mEq/L) serum lithium levels immediately to a health care provider.
- Monitor patients for suicidal tendencies when marked depression is present.
- Evaluate urine output and body weight. Fluid volume deficit may occur as a result of polyuria.
- Observe patients for fine- and gross-motor tremors and presence of slurred speech, which are signs of adverse reaction.
- Assist patients in conserving energy when in a manic phase.
- Check cardiac status. Loss of fluids and electrolytes may cause cardiac dysrhythmias.
- Monitor serum electrolytes, and report abnormal findings.

Patient Teaching

General

- Teach patients to take lithium as prescribed. Emphasize the importance of adherence to the therapy, laboratory tests, and follow-up visits with a health care provider. If lithium is stopped, manic symptoms will reappear.
- Encourage patients to keep medical appointments. Have patients check with a health care provider before taking OTC preparations.
- Warn patients not to drive a motor vehicle or engage in potentially dangerous mechanical activity until a stable lithium level is established.
- Advise patients to maintain adequate fluid intake (2 to 3 L/day initially and 1 to 2 L/day maintenance). Fluid intake should increase in hot weather.
- Teach patients to take lithium with meals to decrease gastric irritation.
- Inform patients that effectiveness of the drug may not be evident until 1 to 2 weeks after the start of therapy. Compliance in taking the prescribed lithium doses on a daily basis is a major problem with bipolar patients. Sometimes, when a patient has a period of emotional stability, he or she does not believe that the drug is needed and may stop taking the lithium.
- Advise patients planning pregnancy to consult with a health care provider about possible teratogenic effects of the drug on the fetus, especially during the first 3 months.
- Encourage patients to wear or carry an identification tag or bracelet indicating the drug taken.

Diet

- Advise patients to avoid caffeine products (coffee, tea, cola) because they can aggravate the manic phase of bipolar disorder by decreasing lithium levels.
- Advise patients to maintain adequate sodium intake and to avoid crash diets that affect physical and mental health.

Side Effects

- Advise patients to contact a health care provider if they experience symptoms of toxicity. Early symptoms include diarrhea, drowsiness, loss of appetite, muscle weakness, nausea, vomiting, slurred speech, and trembling. Late symptoms include blurred vision, confusion, increased urination, convulsions, severe trembling, and unsteadiness.

Cultural Considerations

- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of honor, shame, or lack of understanding of medical terminology.

Evaluation

- Evaluate the effectiveness of the drug therapy. Patient is free of bipolar behavior.
- Allow patients to verbalize their understanding of symptoms of toxicity.
- Determine whether the patient demonstrates a subsiding or resolution of symptoms.

Critical Thinking Case Study

ST, a 37-year-old woman, is receiving fluoxetine 20 mg in the evening for depression. ST complains of insomnia and GI upset.

1. What could you suggest to ST to help her avoid insomnia? Explain your answer.
2. How might ST avoid GI upset when taking fluoxetine? What food should be avoided?

ST states that she does not think the fluoxetine is helping. She states that she has heard about complementary and alternative therapies that may be taken for depression. She has also heard that fluoxetine can be taken weekly.

3. Is ST's fluoxetine dose within normal dosage range? Explain your answer.
4. How would you respond to ST about the use of certain complementary and alternative therapies for depression?
5. What would your response be concerning the use of fluoxetine in a weekly dose?

NCLEX Study Questions

1. A patient is admitted with bipolar affective disorder. The nurse acknowledges which medication as one used to treat this disorder for some patients in place of lithium?
   a. Thiopental
   b. *Gingko biloba*
   c. Fluvoxamine
   d. Divalproex
2. The nurse realizes that some complementary and alternative therapies interact with selective serotonin reuptake inhibitors. Which complementary and alternative therapy interaction may cause serotonin syndrome?
   a. Feverfew
   b. Ma-huang
   c. St. John's wort
   d. *Gingko biloba*
3. A selective serotonin reuptake inhibitor is prescribed for a patient. The nurse knows that which drug is a selective serotonin reuptake inhibitor?
   a. Paroxetine
   b. Amitriptyline
   c. Divalproex sodium
   d. Bupropion Hydrochloride
4. A patient is taking tranylcypromine sulfate for depression. What advice should the nurse include in the teaching plan for this medication?
   a. Warn the patient about severe hypotension.
   b. Instruct the patient to avoid beer and cheddar cheese.
   c. Encourage the patient to take ginseng and ephedra.
   d. Encourage the patient to eat fruit such as bananas.
5. Which statement is true concerning lithium?
   a. The maximum dose is 3.4 g/day.
   b. The therapeutic drug range is 2.5 to 3.5 mEq/L.
   c. Lithium increases receptor sensitivity to gamma-aminobutyric acid.
   d. Concurrent nonsteroidal antiinflammatory drugs (NSAIDs) may increase lithium levels.
6. When a patient is taking an antidepressant, what should the nurse do? (Select all that apply.)
   a. Monitor the patient for suicidal tendencies.
   b. Observe the patient for orthostatic hypotension.
   c. Teach the patient to take the drug with food if gastrointestinal distress occurs.
   d. Tell the patient that the drug may not have full effectiveness for 1 to 2 weeks.
   e. Advise the patient to maintain adequate fluid intake of 2 L/day.
7. A patient is taking lithium. The nurse should be aware of the importance of which nursing intervention(s)? (Select all that apply.)
   a. Observe the patient for motor tremors.
   b. Monitor the patient for hypotension.
   c. Draw lithium blood levels immediately after a dose.
   d. Advise the patient to drink 750 mL/day of fluid in hot weather.
   e. Advise the patient to avoid caffeinated foods and beverages.
   f. Teach the patient to take lithium with meals to decrease gastric irritation.

Answers: 1, d; 2, c; 3, a; 4, b; 5, d; 6, a, b, c, d; 7, a, b, e, f.

UNIT VII
Pain and Inflammation Management Drugs

OUTLINE

Introduction
24. Antiinflammatories
25. Analgesics

Introduction

Inflammation is a reaction to tissue injury caused by the release of chemical mediators that trigger both a vascular response and the migration of fluid and cells—leukocytes, or white blood cells—to the injured site. The chemical mediators are histamines, kinins, and prostaglandins. *Histamine,* the first mediator in the inflammatory process, causes dilation of the arterioles and increases capillary permeability, allowing fluid to leave the capillaries and flow into the injured area. *Kinins,* such as bradykinin, also increase capillary permeability and the sensation of pain. *Prostaglandins* cause an increase in vasodilation, capillary permeability, pain, and fever. Antiinflammatory agents, such as nonsteroidal antiinflammatory drugs (NSAIDs) and steroids (cortisone preparations), inhibit chemical mediators and thus decrease the inflammatory process. Fig VII.1 illustrates the process of chemical mediators acting on injured tissues. The five responses to tissue injury are called the *cardinal signs of inflammation:* redness, swelling, pain, heat, and loss of function.

Inflammation may or may not be the result of an infection; only a small percentage of inflammations are caused by infection. Other causes of inflammation include trauma, surgical interventions, extreme heat or cold, and caustic chemical agents. Antiinflammatory drugs reduce fluid migration and pain, lessening loss of function and increasing the patient's mobility and comfort.

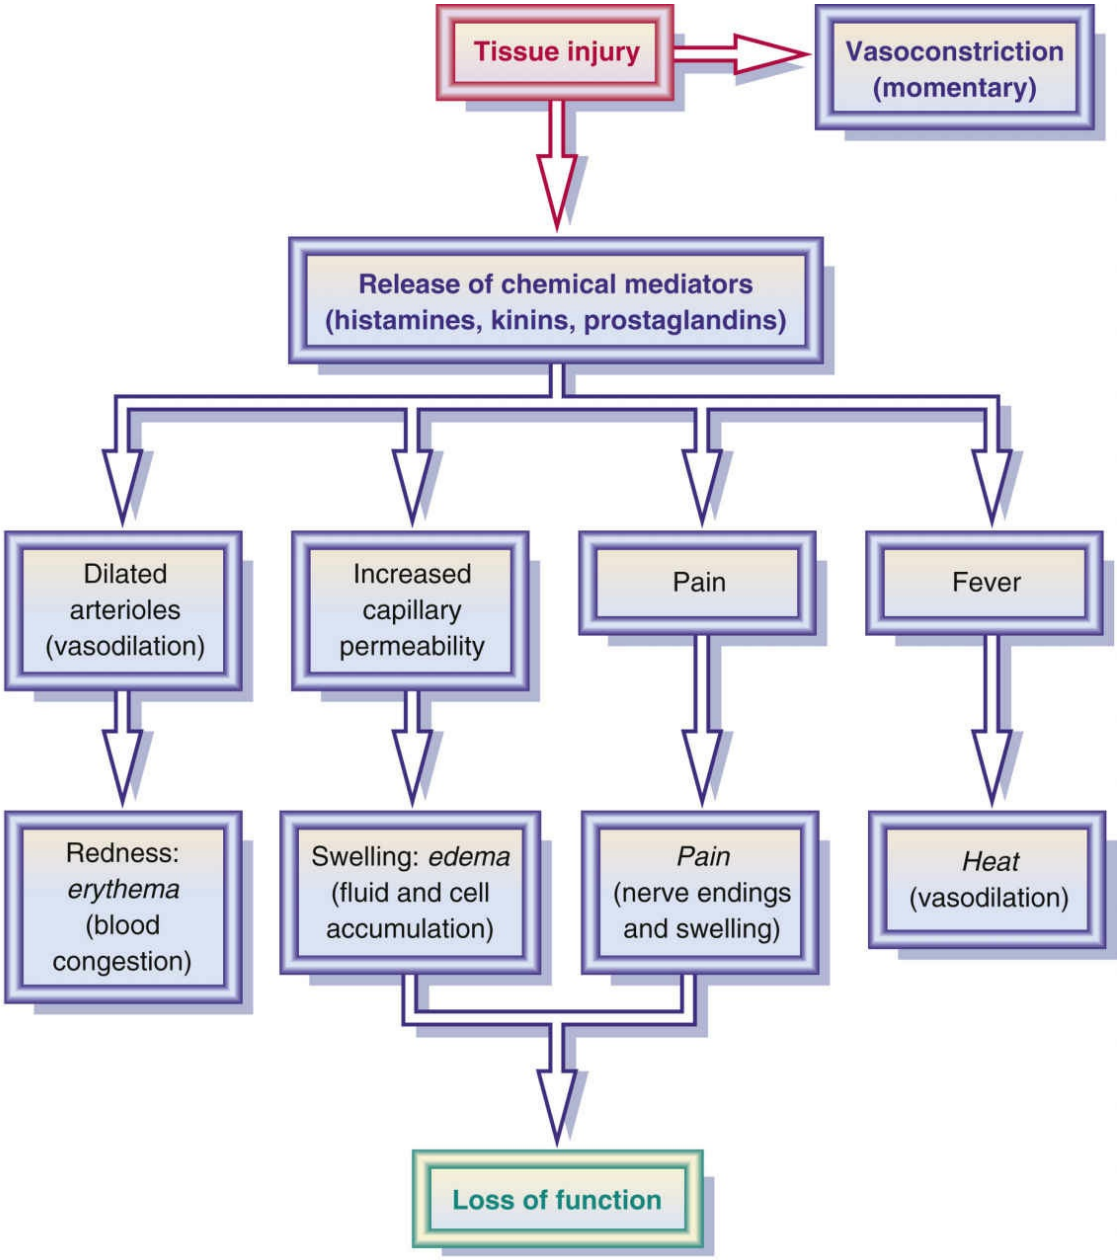

FIG. VII.1 Chemical Mediator Response to Tissue Injury.

24

Antiinflammatories

OUTLINE

Pathophysiology
Antiinflammatory Agents
Nonsteroidal Antiinflammatory Drugs
- Salicylates
- Nursing Process: Patient-Centered Collaborative Care—Salicylate: Aspirin
- *Para*-Chlorobenzoic Acid
- Phenylacetic Acid Derivatives
- Propionic Acid Derivatives
- Fenamates
- Oxicams
- Nursing Process: Patient-Centered Collaborative Care—Nonsteroidal Antiinflammatory Drug: Ibuprofen
- Selective COX-2 Inhibitors
- Use of NSAIDs in Older Adults

Corticosteroids
Disease-Modifying Antirheumatic Drugs
- Immunosuppressive Agents
- Immunomodulators
- Nursing Process: Patient-Centered Collaborative Care—Infliximab
- Antimalarials

Antigout Drugs
- Antiinflammatory Gout Drug: Colchicine
- Uric Acid Biosynthesis Inhibitors
- Uricosurics
- Nursing Process: Patient-Centered Collaborative Care—Antigout Drug: Allopurinol

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Explain the pathophysiologic basis of the five cardinal signs of inflammation.
- Compare the action of various nonsteroidal antiinflammatory drugs (NSAIDs).
- Explain the use of disease-modifying antirheumatic drugs (DMARDs).
- Differentiate between the side effects and adverse reactions of NSAIDs and DMARDs.
- Correlate the nursing processes associated with NSAIDs and corticosteroids, including patient teaching.
- Apply the nursing process to the patient taking DMARDs.
- Compare the action of various antigout medications.

KEY TERMS

COX-2 inhibitors, p. 311
cyclooxygenase (COX), p. 308
disease-modifying antirheumatic drugs (DMARDs), p. 315
gout, p. 318
immunomodulators, p. 316
immunosuppressives, p. 316
infection, p. 307
inflammation, p. 307
nonsteroidal antiinflammatory drugs (NSAIDs), p. 308
prostaglandins, p. 308
uricosurics, p. 319

Inflammation is a response to tissue injury and infection. When the inflammatory process occurs, a vascular reaction takes place in which fluid, elements of blood, leukocytes (white blood cells [WBCs]), and chemical mediators accumulate at the injured tissue or infection site. The process of inflammation is a protective mechanism in which the body attempts to neutralize and destroy harmful agents at the site of injury and to establish conditions for tissue repair.

Although a relationship exists between inflammation and infection, these terms should *not* be used interchangeably. **Infection** is caused by microorganisms and *results* in inflammation, but not all inflammations are caused by infections.

Pathophysiology

The five characteristics of inflammation, called *the cardinal signs of inflammation,* are (1) redness, (2) swelling (edema), (3) heat, (4) pain, and (5) loss of function. Table 24.1 gives the description and explanation of the cardinal signs of inflammation. Inflammation also has two phases: the *vascular phase,* which occurs 10 to 15 minutes after an injury, and the *delayed phase.* The vascular phase is associated with vasodilation and increased capillary permeability, during which blood substances and fluid leave the plasma and go to the injured site. The delayed phase occurs when leukocytes infiltrate the inflamed tissue.

TABLE 24.1

Cardinal Signs of Inflammation

Signs	Description and Explanation
Erythema (redness)	Redness occurs in the first phase of inflammation. Blood accumulates in the area of tissue injury because of the release of the body's chemical mediators (kinins, prostaglandins, and histamine). These chemical mediators dilate the arterioles.
Edema (swelling)	Swelling is the second phase of inflammation. Plasma leaks into the interstitial tissue at the injury site. Kinins and histamine increase capillary permeability.
Heat	Heat at the inflammatory site can be caused by increased blood accumulation and may result from pyrogens, substances that produce fever, which interfere with the temperature-regulating center in the hypothalamus.
Pain	Pain is caused by tissue swelling and release of chemical mediators.
Loss of function	Function is lost because of the accumulation of fluid at the tissue injury site and because of pain, which decreases mobility at the affected area.

Various chemical mediators are released during the inflammation process. Among these are **prostaglandins**, chemical mediators that have been isolated from the exudate at inflammatory sites. Prostaglandins have many effects that include vasodilation, relaxation of smooth muscle, increased capillary permeability, and sensitization of nerve cells to pain.

Cyclooxygenase (COX) is the enzyme responsible for converting arachidonic acid into prostaglandins and their products. This synthesis of prostaglandins causes inflammation and pain at a tissue injury site. Cyclooxygenase has two enzyme forms, COX-1 and COX-2. *COX-1* protects the stomach lining and regulates blood platelets, and *COX-2* triggers inflammation and pain.

Antiinflammatory Agents

Drugs such as aspirin inhibit the biosynthesis of prostaglandin and are therefore called *prostaglandin inhibitors.* Because prostaglandin inhibitors affect the inflammatory process, they are more commonly called *antiinflammatories or antiinflammatory drugs.*

Antiinflammatories also relieve pain (analgesic), reduce elevated body temperature (antipyretic), and inhibit platelet aggregation (anticoagulant). Aspirin is the oldest antiinflammatory drug, but it was first used for its analgesic and antipyretic properties. As a result of searching for a more effective drug with fewer side effects, many other antiinflammatories or prostaglandin inhibitors have been discovered. Although these drugs have potent antiinflammatory effects that mimic the effects of corticosteroids (cortisone), they are *not* chemically related to corticosteroids and therefore are called **nonsteroidal antiinflammatory drugs (NSAIDs)**. Most NSAIDs are used to decrease inflammation and pain for patients who have some type of musculoskeletal condition.

Nonsteroidal Antiinflammatory Drugs

NSAIDs include aspirin and aspirin-like drugs that inhibit the enzyme COX, which is needed for the biosynthesis of prostaglandins. Chapters 25 and 40 present expanded discussions of NSAIDs in their roles as analgesics and anticoagulants, respectively. These drugs may be called *prostaglandin inhibitors* with varying degrees of analgesic and antipyretic effects, but they are used primarily as antiinflammatories to relieve inflammation and pain. Their antipyretic effect is less than their antiinflammatory effect. With several exceptions, NSAID preparations are not suggested for use in alleviating mild headaches and mildly elevated temperature. Preferred drugs for headaches and fever are aspirin (adults only for fever), acetaminophen, and ibuprofen. NSAIDs are more appropriate for reducing swelling, pain, and stiffness in joints.

Most NSAIDs cost more than aspirin. Other than aspirin, the only NSAIDs that can be purchased over the counter (OTC) are ibuprofen and naproxen. All other NSAIDs require a prescription. Examples of prescription products on the market that contain NSAID contents alone or in combination include celecoxib, meloxicam, oxaprozin, nabumetone, sulindac, and ketorolac. If a patient can take aspirin for the inflammatory process without gastrointestinal (GI) upset, salicylate products are usually recommended.

There are seven groups of NSAIDs:

1. Salicylates
2. *Para*-chlorobenzoic acid derivatives, or indoles
3. Phenylacetic acids
4. Propionic acid derivatives
5. Fenamates
6. Oxicams
7. Selective COX-2 inhibitors

The first six NSAID groups on the list are known as *first-generation NSAIDs,* and the COX-2 inhibitors are called *second-generation NSAIDs.*

Table 24.2 provides dosage information and considerations for use for the most commonly used NSAIDs. The half-lives of NSAIDs differ greatly; some have a short half-life of 2 hours, and others have a moderate to long half-life of 6 to 24 hours. Aspirin should not be taken with an NSAID because of the potentiation of side effects. In addition, combined therapy does not increase effectiveness.

Salicylates

Aspirin comes from the family of salicylates derived from salicylic acid. Aspirin is also called *acetylsalicylic acid (ASA)* after the acetyl group used in its composition. The abbreviation frequently used for aspirin is *ASA.*

Aspirin was developed in 1899 by Adolph Bayer, making it the oldest antiinflammatory agent. It was the most frequently used antiinflammatory agent before the introduction of ibuprofen. Aspirin is a prostaglandin inhibitor that decreases the inflammatory process. It is also considered an antiplatelet drug for patients with cardiac or cerebrovascular disorders; aspirin decreases platelet aggregation, and thus blood clotting is decreased. Because high doses of aspirin are usually needed to relieve inflammation, gastric distress—which includes anorexia, dyspepsia, nausea, vomiting, diarrhea, constipation, abdominal pain, heartburn, and flatulence—is a common problem. In such cases, enteric-coated (EC) tablets may be used. Aspirin should *not* be taken with other NSAIDs because it decreases the blood level and effectiveness of NSAIDs.

TABLE 24.2

Antiinflammatory Agents: Nonsteroidal

Drug	Route and Dosage	Uses and Considerations
First-Generation NSAIDs		
Salicylates		
Aspirin	See Prototype Drug Chart 24.1.	
Diflunisal	A/adol: PO: 250-500 mg bid; *max:* 1500 mg/d	For mild to moderate pain, osteoarthritis, and rheumatoid arthritis. Avoid if hypersensitive to aspirin. May cause rash, headache, GI distress, GI bleeding, and elevated hepatic enzymes. Pregnancy category: C*; PB: 99%; t½: 8-12 h
Salicylate Derivatives		
Olsalazine sodium	A: PO: 500 mg q12h; *max:* 3 g/d in divided doses or 1 g/dose	For ulcerative colitis. May cause headache, arthralgia, and GI distress. Pregnancy category: C *; PB: 99%; t½: 1 h
Sulfasalazine	Rheumatoid arthritis: A: PO: Initially 0.5-1 g/d; maint: 2 g/d in 2-3 divided doses; *max:* 3 g/d	For ulcerative colitis and rheumatoid arthritis. Avoid if allergic to sulfonamides or aspirin. May cause dizziness, rash, headache, GI distress, and oligospermia. Pregnancy category: B*; PB: 99%; t½: 5-7 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Para-Chlorobenzoic Acid (Indoles)		
Indomethacin	Rheumatoid arthritis: Regular release: A: PO: 25 mg bid/tid with food; *max:* 200 mg/d Sustained release: A: PO: 75 mg/d; *max:* 150 mg/d	For mild to severe pain, acute gout, tendinitis, ankylosing spondylitis, and arthritis. May cause dizziness, headache, GI distress, and GI bleeding. Take with food. Avoid if allergic to aspirin. Pregnancy category: C*; PB: 99%; t½: 2.6-11.2 h
Sulindac	Rheumatoid arthritis: A: PO: 150-200 mg bid; *max:* 400 mg/d	For arthritis, bursitis, ankylosing spondylitis, and tendinitis. May cause dizziness, headache, rash, GI distress, elevated hepatic enzymes, and GI bleeding. Take with food or milk. Pregnancy category: C*; PB: 93%; t½: 8 h
Tolmetin	A: PO: Initially: 400 mg tid; *maint:* 600-1800 mg/d in divided doses; *max:* 1.8 g/d Adol/C >2 y: PO: 20 mg/kg/d in divided doses; *max:* 30 mg/kg/d	For osteoarthritis, rheumatoid arthritis, and juvenile rheumatoid arthritis. May cause dizziness, headache, asthenia, weakness, edema, weight loss/gain, hypertension, GI distress, and stroke. Take with food. Pregnancy category: C, D*; PB: 99%; t½: 1-2 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Phenylacetic Acid		
Diclofenac sodium	Osteoarthritis: Immediate release: A: PO: 35-50 mg bid/tid; *max*: 150 mg/d Extended release: A: PO: 100 mg/d; *max*: 150 mg/d	For mild to severe pain, rheumatoid arthritis, osteoarthritis, and spondylitis. May cause headache, ocular pain, GI bleeding, and stroke. Take with food. Pregnancy category: C, D*; PB: 99%; t½: 2 h
Etodolac	Arthritis: Regular release: A: PO: Initially 300 mg bid/tid; maint: 600-1200 mg/d; *max:* 1200 mg/d Extended release: A: PO: 400-1000 mg/d; *max*: 1200 mg/d	For mild to moderate pain, rheumatoid arthritis, and osteoarthritis. May cause dizziness, asthenia, GI distress, duodenal ulcers, GI bleeding, and stroke. Take with food. Pregnancy category: C*; PB: 99%; t½: 6-7 h
Ketorolac tromethamine	Short-term pain: A/adol >17 y >50 kg: PO: Initially 20 mg dose, then 10 mg q4-6h; *max:* 40 mg/d Older A/adol >17 y <50 kg: PO: Initially 10 mg dose, then10 mg q4-6h; *max:* 40 mg/d A/adol >17 y >50 kg: IM/IV: 30 mg q6h; *max:* 120 mg/d Older A/adol >17 y <50 kg: 15 mg q6h; *max:* 60 mg/d Nasal spray: A >50 kg: Intranasal: 1 spray each nostril q6-8h; *max*: 4 doses Older A <50 kg: Intranasal: 1 spray 1 nostril q6-8h; *max*: 4 doses	For short-term moderate to severe pain management of 5 days or less and for ocular inflammation. First injectable NSAID. May cause dizziness, drowsiness, headache, GI distress, edema, GI bleeding/perforation, elevated hepatic enzymes, and ocular inflammation. Pregnancy category: C, D*; PB: 99%; t½: PO, 2.4-9 h; IM, 3.5-9.2 h
Propionic Acid		
Fenoprofen calcium	Rheumatoid arthritis: A: PO: 400-600 mg tid/qid; *max:* 3200 mg/d	For mild to moderate pain, osteoarthritis, and rheumatoid arthritis. Most effective after 2-3 weeks. May cause drowsiness, dizziness, weakness, itching, GI distress, palpitations, and stroke. Take with food. Pregnancy category: C, D*; PB: 99%; t½: 2.5-3 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Flurbiprofen sodium	A: PO: 200-300 mg/d in 2-4 divided doses; *max:* 300 mg/d	For mild to moderate pain, osteoarthritis, and rheumatoid arthritis. May cause dizziness, blurred vision, GI distress, and GI bleeding. Take with food. Pregnancy category: C, D*; PB: 99%; t½: 3-9 h
Ibuprofen	See Prototype Drug Chart 24.2.	
Ketoprofen	Arthritis: Immediate release: A: PO: Initially 50 mg qid or 75 mg tid (older A, initially 50 mg tid or 75 mg bid); *max:* 300 mg/d Extended release: A: PO: 200 mg/d; *max:* 200 mg/d Older A: PO: 100-150 mg/d; *max:* 200 mg/d	For mild to moderate pain, osteoarthritis, and rheumatoid arthritis. May cause headache, insomnia, dreams, GI distress, elevated hepatic enzymes, and stroke. Take with food or 8 oz of water to avoid GI distress. Pregnancy category: C, D*; PB: 99%; t½: Immediate release, 0.9-3.3 h; Extended release, 5.4 h
Naproxen	A: PO: 250-500 mg bid; *max:* 1500 mg/d C >2 y: PO: 5 mg/kg bid; *max:* 15 mg/kg/d	For mild to moderate pain, osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, gout, bursitis, and dysmenorrhea. May cause drowsiness, dizziness, headache, elevated hepatic enzymes, GI distress, and bleeding. Take with food or with a full glass of water. Pregnancy category: C*; PB: 99%; t½: 12-17 h
Oxaprozin	A: PO: 600-1200 mg/d; *max:* 1800 mg/d	For osteoarthritis and rheumatoid arthritis. May cause rash and GI distress or bleeding. Take with food. Pregnancy category: C, D *; PB: 99%; t½: 41.4 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Anthranilic Acids (Fenamates)		
Meclofenamate	Arthritis: A/adol >14 y: PO: 200-400 mg/d in 3-4 divided doses; *max:* 400 mg/d	For mild to moderate pain, osteoarthritis, and rheumatoid arthritis. May cause dizziness, headache, rash, severe GI distress/bleeding, and stroke. Take with food. Pregnancy category: C, D*; PB: 99%; t½: 2 h
Mefenamic acid	A/adol >14 y: PO: Initially: 500 mg; then 250 mg q6h PRN; *max:* 1250 mg/d	For mild to moderate pain and dysmenorrhea. May cause dizziness, headache, GI distress (especially diarrhea), elevated hepatic enzymes, angioedema, GI bleeding, renal dysfunction, and stroke. Drug is usually discontinued after 7 days. Pregnancy category: C, D*; PB: 90%; t½: 2 h
Oxicams		
Piroxicam	A: PO: 20 mg/d; *max:* 20 mg/d Older A: PO: 10 mg/d; *max:* 20 mg/d	For osteoarthritis and rheumatoid arthritis. Effective at 2 weeks. May cause edema, dizziness, headache, rash, itching, GI distress, elevated hepatic enzymes, GI bleeding, renal dysfunction, and stroke. Pregnancy category: C, D*; PB: 99%; t½: 50 h
Meloxicam	A: PO: 7.5-15 mg/d; *max:* 15 mg/d	For osteoarthritis and rheumatoid arthritis. Some COX-2 selectivity. May cause dizziness, headache, insomnia, edema, GI distress, and elevated hepatic enzymes. Pregnancy category: C, D*; PB: 99%; t½: 15-20 h
Naphthylalkanones		
Nabumetone	A: PO: 500-1000 mg qd/bid; *max:* 2000 mg/d	For osteoarthritis and rheumatoid arthritis. Inhibits COX-2 more so than COX-1. Causes fewer GI problems but may cause GI distress, dizziness, headache, tinnitus, rash, itching, edema, and stroke. Pregnancy category: C*; PB: 99%; t½: 24 h
COX-2 Inhibitors (Second-Generation NSAIDs)		
Celecoxib	See Prototype Drug Chart 24.3.	

A, Adult; *adol,* adolescent; *bid,* twice a day; *C,* child; *COX,* cyclooxygenase; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein binding; *PO,* by mouth; *PRN,* as needed; *q12h,* every 12 hours; *qd,* every day; *qid,* four times a day; *t½,* half-life; *tid,* three times a day; *y,* year; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

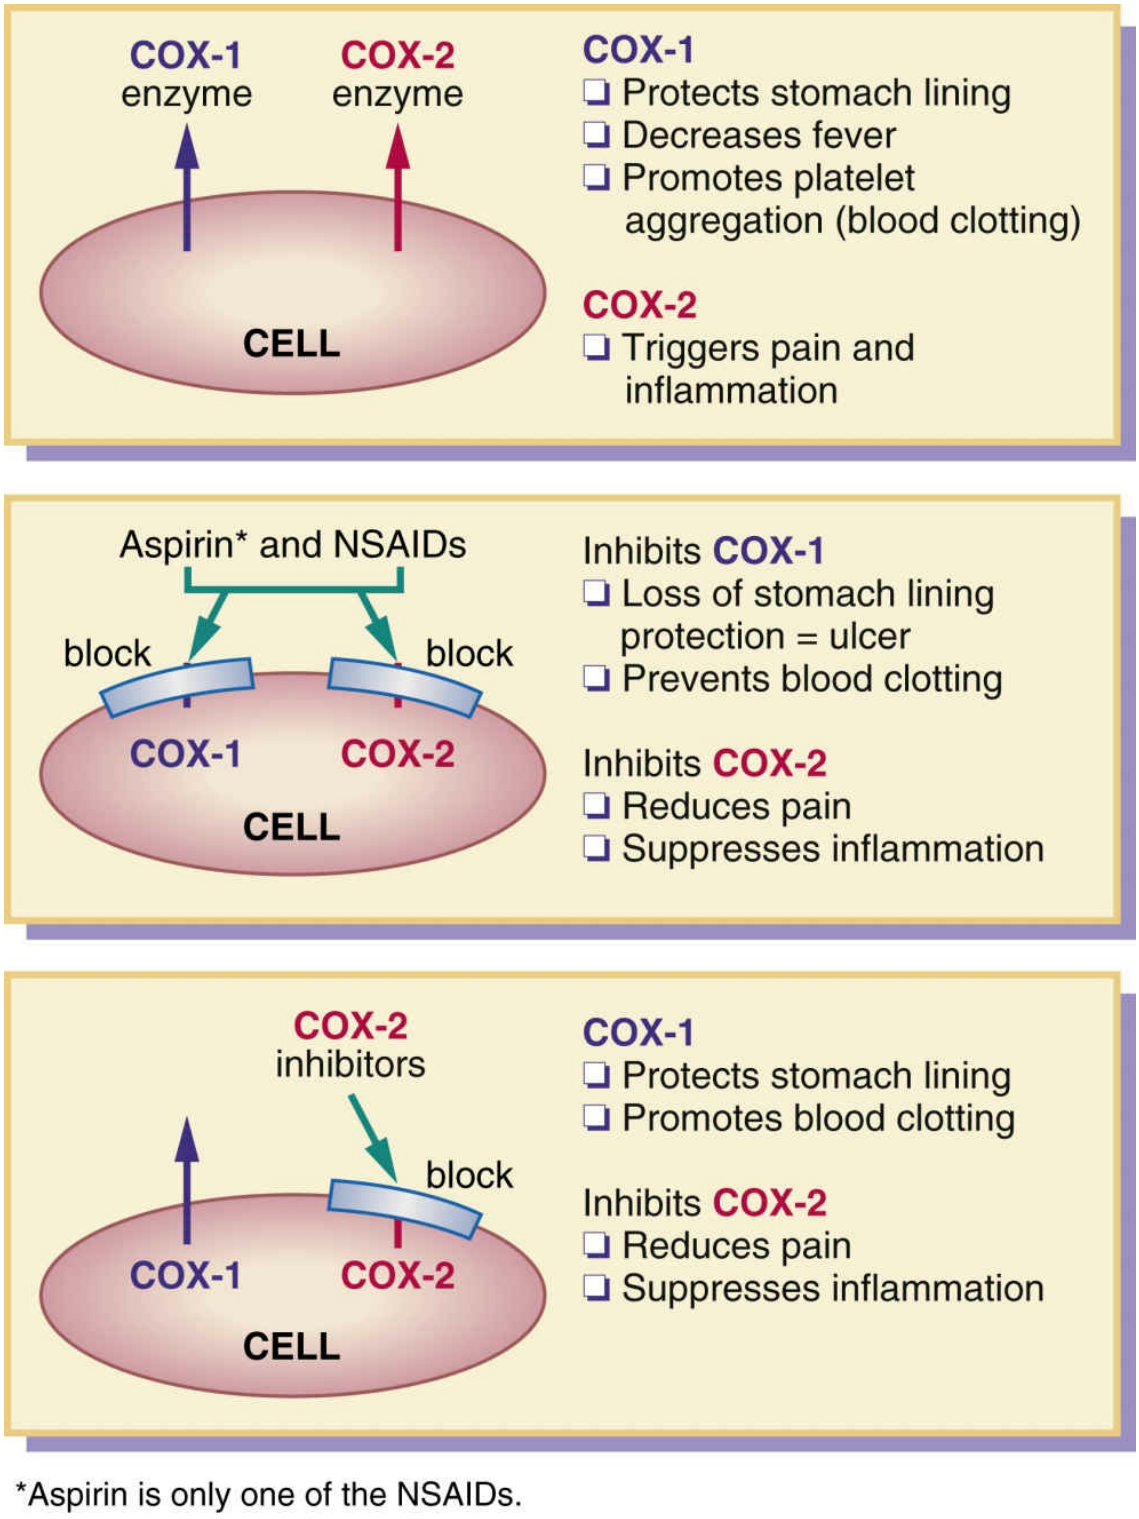

FIG. 24.1 Uses of COX-1 and COX-2 inhibitors.

Aspirin and other NSAIDs relieve pain by inhibiting the COX enzyme, which is needed for the biosynthesis of prostaglandins. As mentioned earlier, the two enzyme forms of cyclooxygenase, COX-1 and COX-2 (Fig. 24.1), serve different purposes: COX-1 protects the stomach lining and regulates blood platelets, promoting blood clotting, whereas COX-2 triggers pain and inflammation at the injured site. NSAIDs usually inhibit or block *both* COX-1 and COX-2. Inhibition of COX-1 produces the desirable effect of decreasing platelet aggregation, but it has the undesirable effect of decreasing protection to the stomach lining; therefore stomach bleeding and ulcers may occur with

aspirin and NSAID agents. When COX-2 is inhibited, pain and fever are reduced and inflammation is suppressed, but COX-2 inhibitors do *not* cause gastric ulceration, and they have no effect on platelet function.

Newer NSAIDs, called **COX-2 inhibitors**, block only COX-2 and not COX-1. These drugs leave protection for the stomach lining intact, so no gastric bleeding or ulcers result, but they still deliver relief for pain and inflammation.

A COX-2 inhibitor approved by the U.S. Food and Drug Administration (FDA) is celecoxib. Drugs similar to COX-2 inhibitors include meloxicam and nabumetone, which allow some stomach protection. Patients at risk for stroke or heart attack who take aspirin to prevent blood clotting (decreased platelet aggregation) would not benefit from COX-2 inhibitors. If the COX-1 enzyme was not blocked, increased blood clotting would remain even though the stomach lining is protected.

PROTOTYPE DRUG CHART 24.1 Aspirin

Drug Class	Dosage
Analgesic: Antiinflammatory drug Pregnancy category: D*	Arthritis: A: PO: 3 g/d in divided doses
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity to salicylates or NSAIDs, flu or virus symptoms in children, GI bleeding *Caution:* Renal or hepatic disorders, gout, alcoholism, anticoagulant therapy, GI bleeding, bone marrow suppression, head trauma, immunosuppression, pregnancy	Drug: Increased risk of bleeding with anticoagulants and other NSAIDs; increased risk of hypoglycemia with oral hypoglycemic drugs; increased ulcerogenic effect with glucocorticoids; decreased effects of ACE inhibitors, loop diuretics, and probenecid; effects are decreased by corticosteroids. Lab: Decreased cholesterol, potassium, T_3, and T_4 levels; increased uric acid, PT, and bleeding time
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 80%-100% Distribution: PB: 90%-95%, crosses placenta Metabolism: *t½*: Varies with dosage; low doses 15-20 min, high doses 2-18 h Excretion: 50% in urine	PO: Onset: 15-30 min Peak: 1-2 h Duration: 4-6 h
Therapeutic Effects/Uses	
To reduce pain and inflammatory symptoms, decrease fever, and inhibit platelet aggregation; for osteoarthritis and rheumatoid arthritis	
Mode of Action: Inhibition of prostaglandin synthesis, inhibition of hypothalamic heat-regulator center	
Side Effects	Adverse Reactions
Dizziness, drowsiness, headache, anorexia, nausea, vomiting, diarrhea, heartburn, abdominal pain, rash	Tinnitus, hearing loss, GI ulceration and bleeding *Life threatening:* Agranulocytosis, hemolytic anemia, leukopenia, bronchospasm, anaphylaxis, thrombocytopenia, Reye syndrome, hepatotoxicity

A, Adult; *ACE*, angiotensin-converting enzyme; *d*, day; *GI*, gastrointestinal; *h*, hour; *min*, minute; *NSAID*, nonsteroidal antiinflammatory drug; *PB*, protein binding; *PO*, by mouth; *PT*, prothrombin time; *t½*, half-life; T_3, triiodothyronine; T_4, thyroxine.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Many researchers believe that COX-2 inhibitors may prevent some types of cancer, such as colon cancer. Fruits and vegetables block the COX-2 enzyme naturally, protecting the colon from malignant growths.

Pharmacokinetics

Aspirin is well absorbed from the GI tract (Prototype Drug Chart 24.1). It can cause GI distress, which includes anorexia, nausea, vomiting, diarrhea, and abdominal pain, so it should be taken with water, milk, or food. The EC or buffered form can decrease gastric distress. EC tablets should not be crushed or broken.

Aspirin has a short half-life. It should not be taken during the last trimester of pregnancy because it could cause premature closure of the ductus arteriosus in the fetus. Aspirin should not be taken by children with flu symptoms because it may cause the potentially fatal Reye syndrome.

Pharmacodynamics

Like other NSAIDs, aspirin inhibits prostaglandin synthesis by inhibiting COX-1 and COX-2, thus it decreases inflammation and pain. The onset of action for aspirin is within 30 minutes. It peaks in 1 to 2 hours, and the duration of action is an average of 4 to 6 hours. The action for the rectal preparation of aspirin can be erratic because of blood supply and fecal material in the rectum; it may take a week or longer for a therapeutic antiinflammatory effect.

Hypersensitivity to Salicylate Products

Patients may be hypersensitive to aspirin. Tinnitus (ringing in the ears), vertigo (dizziness), and bronchospasm—especially in asthmatic patients—are symptoms of aspirin overdose or

hypersensitivity to aspirin.

Salicylates are present in numerous foods such as prunes, raisins, and licorice and in spices such as curry and paprika.

Nursing Process: Patient-Centered Collaborative Care

Salicylate: Aspirin

Assessment

- Determine a medical history. Ask the patient about previous gastric distress, gastric bleeding, or liver disease. Aspirin can cause gastric irritation, and it prolongs bleeding time by inhibiting platelet aggregation.
- Obtain a drug history. Report if a drug-drug interaction is probable.

Nursing Diagnoses

- Injury, Risk for
- Pain, Chronic related to tissue swelling of rheumatoid arthritis (RA)

Planning

- The patient's pain will be reduced within 12 to 24 hours.
- The patient's inflammation will be reduced within 1 week.

Nursing Interventions

- Monitor serum salicylate (aspirin) level when a patient takes high doses of aspirin for chronic conditions such as arthritis. The normal therapeutic range is 15 to 30 mg/dL. Mild toxicity occurs at a serum level greater than 30 mg/dL, and severe toxicity occurs above 50 mg/dL.
- Observe the patient for signs of bleeding such as dark tarry stools, bleeding gums, petechiae (round red spots), ecchymosis (excessive bruising), and purpura (large red spots) when the patient takes high doses of aspirin.

Patient Teaching

General

- Advise patients not to take aspirin with alcohol or with drugs that are highly protein bound, such as the anticoagulant warfarin. Aspirin displaces drugs like warfarin from the protein-binding site, causing increased anticoagulant levels.
- Suggest that patients inform their dentist before a dental visit if they are taking high doses of aspirin.
- Instruct patients to discontinue aspirin approximately 7 days before surgery to reduce risk of bleeding (with the health care provider's approval).
- Advise patients to keep aspirin bottles out of reach of children.
- Educate parents to call the poison control center immediately if a child has taken a large or unknown amount of aspirin or acetaminophen.
- Warn patients not to administer aspirin for virus or flu symptoms in children. Reye syndrome (vomiting, lethargy, delirium, and coma) has been linked with aspirin and viral infections. Acetaminophen is usually prescribed for cold and flu symptoms.
- Inform patients that aspirin tablets can cause GI distress.
- Inform patients with dysmenorrhea to take acetaminophen instead of aspirin 2 days before and during the first 2 days of the menstrual period.

Side Effects

- Direct patients to report side effects such as drowsiness, tinnitus (ringing in the ears), headaches, flushing, dizziness, GI distress, GI bleeding, visual changes, and seizures.

Diet

- Instruct patients to take aspirin and ibuprofen with food, at mealtime, or with plenty of fluids. EC aspirin helps prevent GI distress.

Cultural Considerations

- Provide additional explanation as needed related to the purpose of the drug and its side effects.

Evaluation

- Evaluate the effectiveness of aspirin in relieving pain. If pain persists, another analgesic such as ibuprofen may be prescribed.
- Determine whether the patient shows any of the side effects of aspirin.

Para-Chlorobenzoic Acid

One of the first NSAIDs introduced was indomethacin, a *para*-chlorobenzoic acid. It is used for rheumatoid arthritis (RA), gouty arthritis, and osteoarthritis and is a potent prostaglandin inhibitor. It is highly protein bound (99%) and displaces other protein-bound drugs, resulting in potential toxicity. It has a moderate half-life (2.6 to 11.2 hours). Indomethacin is very irritating to the stomach and should be taken with food.

Two other *para*-chlorobenzoic acid derivatives—sulindac and tolmetin—produce less severe adverse reactions than indomethacin. Tolmetin is not as highly protein bound as indomethacin and sulindac, and it has a short half-life. This group of NSAIDs may cause sodium and water retention and increased blood pressure.

Phenylacetic Acid Derivatives

Diclofenac sodium, a phenylacetic acid derivative, has a plasma half-life of 2 hours. Its analgesic and antiinflammatory effects are similar to those of aspirin, but it has minimal to no antipyretic effects. It is indicated for RA, osteoarthritis, and ankylosing spondylitis. Diclofenac is available in oral, extended-release, and topical 1% gel preparations. Side effects and adverse reactions are similar to those of other NSAIDs, with far less detrimental reactions when using a topical preparation.

Ketorolac, another phenylacetic acid derivative, is the first injectable NSAID. Like other NSAIDs, it inhibits prostaglandin synthesis, but it has greater analgesic properties than other antiinflammatory agents. Ketorolac is recommended for short-term management of pain. For postsurgical pain, it has shown analgesic efficacy equal or superior to that of opioid analgesics. It is administered intramuscularly in doses of 30 to 60 mg every 6 hours for adults. Ketorolac is also available in oral, intravenous (IV), and intranasal preparations.

Propionic Acid Derivatives

The propionic acid group is a relatively new group of NSAIDs. These drugs are aspirin-like but have stronger effects and create less GI irritation. Drugs in this group are highly protein bound, so drug interactions might occur, especially when given with another highly protein-bound drug. Propionic acid derivatives are better tolerated than other NSAIDs. Gastric upset occurs, but it is not as severe as with aspirin and indomethacin. Severe adverse reactions such as blood dyscrasias are not frequently seen. Ibuprofen is the most widely used propionic acid NSAID, and it may be purchased OTC in lower doses (200 mg). Prototype Drug Chart 24.2 details the pharmacologic behavior of ibuprofen. Five other propionic acid agents are fenoprofen calcium, naproxen, ketoprofen, flurbiprofen, and oxaprozin.

Pharmacokinetics

Ibuprofens are well absorbed from the GI tract. These drugs have a short half-life but are highly protein bound. If ibuprofen is taken with another highly protein-bound drug, severe side effects may occur. The drug is metabolized in the liver to inactivate metabolites and is excreted as inactive metabolites in the urine.

PROTOTYPE DRUG CHART 24.2 Ibuprofen

Drug Class	Dosage
NSAID: Propionic acid derivative Pregnancy category: C (D third trimester) *	A: PO: 400-800 mg tid/qid; *max:* 3200 mg/d
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, coronary artery bypass graft surgery *Caution:* Bleeding disorders, pregnancy, lactation, systemic lupus erythematosus, asthma, peptic ulcer, anticoagulant therapy, renal or hepatic disease	Drug: Increased bleeding time with oral anticoagulants; increased effects of phenytoin, sulfonamides, warfarin; decreased effect with aspirin; may increase severe side effects of lithium
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Well absorbed Distribution: PB: 90%-99% Metabolism: t½: 2-4 h Excretion: In urine, mostly as inactive metabolites; some in bile	PO: Onset: 30 min-1 h Peak: 2-4 h Duration: 6-8 h
Therapeutic Effects/Uses	
To reduce inflammatory process; to relieve pain; antiinflammatory effect for arthritic conditions; to reduce fever	
Mode of Action: Inhibition of prostaglandin synthesis, thus relieving pain and inflammation	
Side Effects	Adverse Reactions
Headache, dizziness, anorexia, nausea, vomiting, diarrhea, edema, rash, fluid retention	Hearing loss, tinnitus, bleeding *Life threatening:* Anemia, neutropenia, thrombocytopenia, nephrotoxicity, anaphylaxis

A, Adult; *d,* day; *h,* hour; *max,* maximum; *min,* minute; *NSAID*, nonsteroidal antiinflammatory drug; *PB,* protein binding; *PO,* by mouth; *qid,* four times a day; *t½*, half-life; *tid,* three times a day.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Pharmacodynamics

Ibuprofen inhibits prostaglandin synthesis and are therefore effective in alleviating inflammation and pain. They have a short onset of action, peak concentration time, and duration of action. It may take several days for the antiinflammatory effect to be evident.

Many drug interactions are associated with ibuprofen. Because ibuprofen can increase the effects of warfarin, sulfonamides, many of the cephalosporins, and phenytoin, it should be avoided with these drugs. However, when taken with aspirin, its effect can be decreased. Hypoglycemia may result when ibuprofen is taken with insulin or an oral hypoglycemic drug, and risk of toxicity is high when ibuprofen is taken concurrently with calcium channel blockers.

Fenamates

The fenamate group includes potent NSAIDs used for acute and chronic arthritic conditions. As with most NSAIDs, gastric irritation is a common side effect; patients with a history of peptic ulcer should avoid taking fenamates. Other side effects include edema, dizziness, tinnitus, and pruritus. Two fenamates are meclofenamate sodium monohydrate and mefenamic acid.

Oxicams

Piroxicam and meloxicam, oxicams, are indicated for long-term arthritic conditions such as RA and osteoarthritis. They too can cause gastric problems such as ulceration and epigastric distress, but the incidence is lower than for some other NSAIDs. Oxicams are well tolerated, and their major advantage over other NSAIDs is their long half-life, which allows them to be taken only once daily.

Full clinical response to piroxicam may take 1 to 2 weeks. This drug is also highly protein bound and may interact with another highly protein-bound drug when taken together. Piroxicam should *not* be taken with aspirin or other NSAIDs.

General Side Effects and Adverse Reactions With First-Generation NSAIDs

Most NSAIDs tend to have fewer side effects than aspirin when taken at antiinflammatory doses, but gastric irritation is still a common problem when NSAIDs are taken without food. In addition, sodium and water retention may occur. Alcoholic beverages consumed with NSAIDs may increase gastric irritation and should be avoided.

Nursing Process: Patient-Centered Collaborative Care

Nonsteroidal Antiinflammatory Drug: Ibuprofen

Assessment

- Check the patient's history for allergy to NSAIDs such as ibuprofen. If an allergy is present,

notify the health care provider.
- Obtain a drug and herbal history, and report any possible drug-drug or herb-drug interactions. NSAIDs can increase the effects of phenytoin, sulfonamides, and warfarin. Most NSAIDs are highly protein bound and can displace other highly protein-bound drugs like warfarin.
- Determine the medical history. NSAIDs are contraindicated if a patient has severe renal or liver disease, peptic ulcer, or bleeding disorder.
- Assess for GI distress and peripheral edema, which are common side effects of NSAIDs.

Nursing Diagnoses

- Injury, Risk for
- Activity Intolerance, Risk for

Planning

- The patient's inflammatory process will subside in 1 to 3 weeks.

Nursing Interventions

- Observe the patient for bleeding gums, petechiae, ecchymoses, or black tarry stools. Bleeding time can be prolonged when NSAIDs are taken, especially with a highly protein-bound drug such as warfarin (anticoagulant).
- Report if a patient has GI discomfort. Administer NSAIDs at mealtime or with food to prevent GI upset.
- Monitor vital signs and check for peripheral edema, especially in the morning.
- Do not give directions such as "take one blue pill" at a specified time. Instead, provide the name and the dosage of medications.

Patient Teaching

General

- Advise patients not to take aspirin and acetaminophen with NSAIDs. Taking an NSAID with aspirin could cause GI upset and possibly GI bleeding.
- Advise patients to avoid alcohol when taking NSAIDs. GI distress or gastric ulcer may result.
- Alert patients that many complementary and alternative therapy products may interact with NSAIDs and could cause bleeding. Doses of NSAIDs and/or herbs may need to be modified to avoid possible bleeding (Complementary and Alternative Therapies 24.1).
- Direct patients to inform the dentist or surgeon before a procedure if they are taking ibuprofen or other NSAIDs for a continuous period.
- Warn female patients not to take NSAIDs 1 to 2 days before menstruation to avoid heavy menstrual flow. If discomfort occurs, acetaminophen is usually prescribed.
- Advise pregnant patients to avoid NSAIDs. Congenital abnormalities may occur when NSAIDS are taken during early pregnancy, and excess bleeding might occur during delivery.
- Inform patients that it may take several weeks to experience the desired drug effect of some NSAIDs and disease-modifying antirheumatic drugs (DMARDs).

Side Effects

- Educate patients about the common side effects of NSAIDs. GI distress, peripheral edema, purpura or petechiae, and dizziness can occur. Report occurrences of side effects.

Diet

- Advise patients to take NSAIDs with meals or snacks to reduce GI distress.

Cultural Considerations

- Recognize that patients from various cultural backgrounds respond to pain and inflammation in various ways. In some cultures, the use of drugs to alleviate pain and inflammation is not acceptable. Herbal medicine and acupuncture can be used to alleviate pain.
- Be supportive of patients' methods for pain control. Explain the purpose of medications and their actions and side effects.

Evaluation

- Evaluate the effectiveness of the drug therapy, such as a decrease in pain and in swollen joints and an increase in mobility.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 24.1 Nonsteroidal Antiinflammatory Drugs

Dong quai, feverfew, garlic, ginger, and ginkgo may cause bleeding when taken with nonsteroidal antiinflammatory drugs (NSAIDs).

Selective COX-2 Inhibitors

Cyclooxygenase-2 (COX-2) inhibitors, second-generation NSAIDs, became available in the last several years to decrease inflammation and pain. Most NSAIDs are nonselective inhibitors that inhibit COX-1 and COX-2. By inhibiting COX-1, protection of the stomach lining is decreased, and clotting time is also decreased, which may benefit the patient with cardiovascular or coronary artery disease (CAD). Selective COX-2 inhibitors are the drugs of choice for patients with severe arthritic conditions who need high doses of an antiinflammatory drug, because large doses of NSAIDs may cause peptic ulcer and gastric bleeding.

Currently, only one drug, celecoxib, is classified as a COX-2 inhibitor. Nabumetone is a similar drug that can be used; however, it is not considered a true COX-2 inhibitor, although it does inhibit COX-2 more than COX-1. Celecoxib is described in Prototype Drug Chart 24.3.

Use of NSAIDs in Older Adults

Older adults frequently use NSAIDs to treat pain associated with inflammation caused by osteoarthritis, RA, and neuromuscular-skeletal disorders. As older adults age, the number of drugs taken daily increases; therefore drug interactions are more common, especially when numerous drugs are taken with NSAIDs. With the use of NSAIDs, GI distress—including ulceration—is four times more common in older adults, and hospitalization is often necessary.

The introduction of COX-2 inhibitors (second-generation NSAIDs) has decreased the incidence of GI problems associated with NSAID use; however, edema is likely to occur. Renal function should be evaluated, and older adults should increase their fluid intake for adequate hydration. To decrease possible complications, the NSAID dose should be lowered.

Corticosteroids

Corticosteroids such as prednisone, prednisolone, and dexamethasone are frequently used as antiinflammatory agents. This group of drugs controls inflammation by suppressing or preventing many of the components of the inflammatory process at the injured site. Corticosteroids have been widely prescribed for arthritic conditions, and although they are not the drug of choice for arthritis because of their numerous side effects, they are frequently used to control arthritic flareups.

The half-life of a corticosteroid is long (>24 hours), and it is administered once a day in a large prescribed dose. When discontinuing long-term steroid therapy, the dosage should be tapered over a period of 5 to 10 days. Steroids are discussed in more detail in Chapter 46.

PROTOTYPE DRUG CHART 24.3 Celecoxib

Drug Class	Dosage
Nonsteroidal antiinflammatory: COX-2 inhibitor Pregnancy category: C, D (third trimester) *	Arthritis: A: PO: 100-200 mg qd/bid; *max:* 800 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, coronary artery bypass surgery *Caution:* Renal or hepatic dysfunction, angina, hypertension, dysrhythmias, heart failure, anemia, dehydration, peptic ulcer disease, GI bleeding or perforation, concurrent anticoagulant therapy, steroids, alcoholism, immunosuppression	Drug: Decreased effect of ACE inhibitors, increased INR and GI bleeding with warfarin and SNRIs, may increase toxicity with lithium, fluoroquinolones may increase the risk of seizures; fluconazole and ketoconazole increase celecoxib levels. Complementary and alternative therapies: Ginkgo biloba may increase bleeding risk.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Well absorbed in GI tract Distribution: PB: 97% Metabolism: t½: 11.2 h Excretion: Primarily in feces	PO: Onset: UK Peak: 3 h Duration: UK
Therapeutic Effects/Uses	
To treat osteoarthritis and rheumatoid arthritis, to relieve dysmenorrhea and moderate to severe pain, for ankylosing spondylitis	
Mode of Action: Inhibits COX-2, which normally promotes prostaglandin synthesis and inflammatory response, but does not inhibit COX-1	
Side Effects	**Adverse Reactions**
Headache, dizziness, sinusitis, abdominal pain, nausea, flatulence, diarrhea, rash	Peripheral edema, bleeding, hypertension *Life threatening:* Stroke

A, Adult; *ACE,* angiotensin-converting enzyme; *bid,* twice a day; *COX,* cyclooxygenase; *d,* day; *GI,* gastrointestinal; *h,* hour; *INR,* international normalized ratio; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *qd,* every day; *SNRI,* serotonin norepinephrine reuptake inhibitor; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Disease-Modifying Antirheumatic Drugs

When NSAIDs do not control immune-mediated arthritic disease sufficiently, other drugs, although more toxic, can be prescribed to alter the disease process. The **disease-modifying antirheumatic drugs (DMARDs)** include immunosuppressive agents, immunomodulators, and antimalarials. DMARDs help alleviate the symptoms of RA for the 2 million persons in the United States affected by the disorder. DMARDs are described in Table 24.3. Other indications for use of DMARDs include osteoarthritis, psoriatic arthritis, severe psoriasis, ankylosing spondylitis, Crohn disease, and ulcerative colitis.

Immunosuppressive Agents

Immunosuppressives are used to treat refractory RA, arthritis that does not respond to antiinflammatory drugs. In low doses, selected immunosuppressive agents have been effective in the treatment of RA. Drugs such as azathioprine, cyclophosphamide, and methotrexate—primarily used to suppress cancer growth and proliferation—might be used to suppress the inflammatory process of RA when other treatments fail. In one study of patients receiving cyclophosphamide, few new erosions of joint cartilage were present, suggesting that the disease process was not active.

Immunomodulators

Immunomodulators treat moderate to severe RA by disrupting the inflammatory process and delaying disease progression. Interleukin 1 (IL-1) receptor antagonists and tumor necrosis factor (TNF) blockers are two groups of drugs classified as immunomodulators.

Anakinra, an IL-1 receptor antagonist, blocks activity of IL-1 by inhibiting it from binding to interleukin receptors located in cartilage and bone. IL-1 is a proinflammatory cytokine that contributes to synovial inflammation and joint destruction. Anakinra is administered subcutaneously. The peak is 3 to 7 hours, and the half-life is 4 to 6 hours.

TNF blockers bind to TNF and block it from attaching to TNF receptors on synovial cell surfaces. By neutralizing TNF, a contributor to synovitis, the inflammatory disease process is delayed. Etanercept was the first TNF blocker developed. It is administered subcutaneously, and the half-life ranges from 72 to 132 hours. Signs and symptoms of RA are suppressed rapidly with etanercept therapy but reappear if the drug is discontinued. Other TNF blockers include infliximab, adalimumab, and leflunomide. Infliximab is administered intravenously over at least 2 hours, adalimumab is administered subcutaneously, and leflunomide is administered orally. Infliximab is described in Prototype Drug Chart 24.4.

Both IL-1 receptor antagonists and TNF blockers predispose the patient to severe infections; they are contraindicated in active infection and should be discontinued when an infection occurs. Immunomodulators are usually very expensive.

Nursing Process: Patient-Centered Collaborative Care

Infliximab

Assessment

- Determine a medical history. Ask patient if there is any history of seizures, diabetes mellitus, multiple sclerosis, or kidney or liver disease. Aspirin can cause gastric irritation. It prolongs bleeding time by inhibiting platelet aggregation.
- Obtain baseline complete blood count (CBC) and renal and liver function tests.

Nursing Diagnoses

- Mobility, Impaired Physical related to severe pain
- Pain, Chronic related to tissue swelling from RA

Planning

- The patient's pain will be reduced within 12 to 24 hours.

- The patient's inflammation will be reduced within 1 week.

Nursing Interventions

- Obtain a negative tuberculosis skin test prior to initiating infliximab therapy.
- Monitor patients for signs and symptoms of infection. If a serious infection occurs while a patient is receiving infliximab therapy, antibiotic therapy should be initiated, and infliximab should be discontinued.
- Monitor laboratory tests for blood dyscrasias (CBC) and renal and liver function (blood urea nitrogen [BUN], serum creatinine, alkaline phosphatase [ALP], aspartate aminotransferase [AST], alanine aminotransferase [ALT]).
- Flush IV tubing with normal saline before and after administration. Deliver IV medication through a 1.2-micron or smaller filter.
- Administer each dose over a minimum of 2 hours.
- Discontinue IV dose of infliximab if the patient develops acute infusion reaction (e.g., chest pain, fever, chills, dyspnea, pruritus, urticaria, hypotension, or hypertension).
- Monitor patients up to 2 hours after infusion for acute infusion reaction.

Patient Teaching

General

- Encourage patients to keep medical appointments and to have regularly scheduled laboratory tests that include CBC and renal and liver function tests for early detection of blood dyscrasias and renal and liver damage.
- Advise patients to avoid live vaccines while taking infliximab.

Side Effects

- Teach patients to report dizziness, chills, depression, dyspnea, severe infections, seizures, fatigue, or rash immediately.
- Teach patients to report severe infections immediately.

Cultural Considerations

- Provide additional explanation as needed related to the disease process and the purpose of the drug and its side effects.
- Identify conflicts in values and beliefs.
- Suggest follow-up by a community health nurse to determine patient compliance with the drug regimen and the effectiveness of the prescribed drug therapy.

Evaluation

- Evaluate patient response to the DMARD. If pain persists, the drug regimen may need modification.
- Determine the presence of adverse reactions. Drug therapy for pain may need to be changed.

Antimalarials

Antimalarial drugs may be used to treat RA when other methods of treatment fail. The mechanism of action of antimalarials in suppressing RA is unclear. The effect may take 4 to 12 weeks to become apparent. Antimalarials are usually used in combination with NSAIDs in patients whose arthritis is not under control.

TABLE 24.3

Antiinflammatory Drugs: Disease-Modifying Antirheumatic Drugs

Drug	Route and Dosage	Uses and Considerations
Golimumab	A: Subcut: 50 mg every month	For RA, psoriatic arthritis, ankylosing spondylitis, and ulcerative colitis. May cause injection-site reaction, aplastic anemia, leukopenia, neutropenia, thrombocytopenia, infection, URI, and elevated hepatic enzymes. Pregnancy category: B*; PB: UK; t½: 2 wk
Anakinra	A: Subcut: 100 mg/d; *max:* 100 mg/d	For RA. May cause injection-site reaction, headache, fever, GI distress, arthralgia, nasopharyngitis, infection, and neutropenia. Pregnancy category: B*; PB: UK; t½: 4 to 6 h
Etanercept	A: Subcut: 50 mg 1-2 times/wk; *max:* 100 mg/wk C >2 y: Subcut: 0.8 mg/kg/wk; *max:* 50 mg/wk	For RA, psoriatic arthritis, and ankylosing spondylitis. May cause injection-site reaction, diarrhea, influenza, infection, and URI. Pregnancy category: B*; PB: UK; t½: 72-132 h
Infliximab	See Prototype Drug Chart 24.4.	
Rituximab	Rheumatoid arthritis: A: IV: 1000 mg on day 1 and day 15 with methotrexate, then q24wk Give methylprednisolone 100 mg or equivalent prior to each dose to decrease infusion reactions.	For RA, chronic lymphocytic leukemia, and non-Hodgkin lymphoma. May cause infusion-site reaction, dizziness, headache, insomnia, pain, fever, chills, fatigue, peripheral edema, anemia, hypertension, hypotension, angioedema, GI distress, increased hepatic enzymes, hyperglycemia, cough, rhinitis, epistaxis, neuropathy, weakness, and arthralgia. Pregnancy category: C*; PB: UK; t½: 83.9-407 h

Adalimumab	A: Subcut: 40 mg q2wk	For RA, psoriatic arthritis, Crohn disease, ulcerative colitis, and ankylosing spondylitis. May cause injection-site reaction, headache, nausea, infection, rash, and URI. Pregnancy category: B*; PB: UK; t½: 10 to 20 d
Leflunomide	A: PO: Initially 100 mg/d for 3 d; maint: 20 mg/d	For RA. May cause hypertension, dizziness, headache, alopecia, rash, GI distress, asthenia, elevated hepatic enzymes, infection, and URI. Pregnancy category: X*; PB: 99%; t½: 2 wk
Abatacept	A >100 kg: IV: 1 g over 30 min q2wk for 3 doses, then 1 g q4wk A 60-100 kg: IV: 750 mg over 30 min q2wk for 3 doses, then q4wk	For RA. May cause dizziness, headache, GI distress, infection, URI, hypertension, influenza, and infusion-related reaction. Pregnancy category: C*; PB: UK; t½: 14.3 d
Tofacitinib	A: PO: 5 mg bid; *max*: 5 mg bid	For RA. May cause headache, GI distress, hypertension, elevated hepatic enzymes, hypercholesterolemia, infection, and URI. Pregnancy category: C*; PB: 40%; t½: 3 h
Tocilizumab	A: IV: 4 mg/kg over 1 h q4wk initially; *max:* 800 mg/dose A: Subcut: 162 mg q2wk; *max*: 162 mg/dose	For RA and juvenile idiopathic arthritis. May cause infusion/injection-related reaction, headache, hyperlipidemia, elevated hepatic enzymes, neutropenia, URI, angioedema, and hypertension. Pregnancy category: C*; PB: UK; t½: subcut 5-13 d; IV, 11-13 d
Secukinumab	A: Subcut: 300 mg wks 0-4, followed by 300 mg q4wk; *max:* 300 mg/dose	For psoriasis, psoriatic arthritis, and ankylosing spondylitis. May cause oral ulceration, infection, nasopharyngitis, hypersensitivity, and diarrhea. Pregnancy category: B*; PB: UK; t½: 22-31 d
Apremilast	A: PO: Initially 10 mg in the morning; day 2, 10 mg bid; day 3, 10 mg in morning, and 20 mg in evening; day 4, 20 mg bid; day 5, 20 mg in morning, and 30 mg in evening; maint: 30 mg bid starting on day 6; *max*: 60 mg/d	For psoriatic arthritis and psoriasis. May cause headache, URI, nausea, vomiting, diarrhea, weight loss, infection, and suicidal ideation. Pregnancy category: C*; PB: 68%; t½: 6-9 h
Canakinumab	Adol/C >2 y >7.5 kg: Subcut: 4 mg/kg q4wk; *max*: 4 mg/kg/dose	For systemic juvenile idiopathic arthritis. May cause headache, dizziness, GI distress, injection-site reaction, weight gain, musculoskeletal pain, nasopharyngitis, influenza, infection, leukopenia, and neutropenia. Pregnancy category: C*; PB: UK; t½: 26 d

A, Adult; *adol,* adolescent; *bid,* twice daily; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q2,* every two; *RA,* rheumatoid arthritis; *Subcut,* subcutaneous; *t½,* half-life; *UK,* unknown; *URI,* upper respiratory infection; *wk,* week; *y,* year; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 24.4 Infliximab

Drug Class	Dosage
Immunomodulator: Tumor necrosis factor blocker Pregnancy category: B*	Rheumatoid arthritis: A: IV: Initially 3 mg/kg over 2 h; then 3 mg/kg wks 2 and 6; *max*: 10 mg/kg/dose Crohn disease: A: IV: Initially 5 mg/kg over 2 h and on wks 2 and 6; maint: 5-10 mg/kg q8wk
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, heart failure *Caution:* Renal or hepatic dysfunction, bone marrow suppression, diabetes mellitus, COPD, immunosuppression, multiple sclerosis, seizures, corticosteroid therapy, with older adults	Drug: May decrease effectiveness of vaccines; concurrent immunosuppressives may increase risk for infection or adverse effects
Pharmacokinetics	**Pharmacodynamics**
Absorption: UK Distribution: UK Metabolism: t½: 7-12 d Excretion: UK	IV: Onset: 2 wk Peak: UK Duration: UK
Therapeutic Effects/Uses	
To treat psoriasis, rheumatoid arthritis, psoriatic arthritis, spondylitis, ulcerative colitis, and Crohn disease	
Mode of Action: Binds to TNF and blocks it from attaching to TNF receptors on synovial cell surfaces; reduces infiltration of inflammatory cells and delays inflammatory process	
Side Effects	**Adverse Reactions**
Headache, dizziness, cough, fatigue, chills, flushing, fever, anxiety, nausea, vomiting, diarrhea, constipation, flatulence, abdominal pain, weight loss, rash, alopecia, dry skin, pharyngitis	Severe infections, chest pain, hypotension, hypertension, seizures, arthralgia, bone fractures, increased hepatic enzymes, anemia, neutropenia, pancytopenia, Stevens-Johnson syndrome

A, Adult; *COPD,* chronic obstructive pulmonary disease; *d,* day; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *q8,* every 8; *t½,* half-life; *TNF,* tumor necrosis factor; *UK,* unknown; *wk,* week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Antigout Drugs

Gout is an inflammatory condition that attacks joints, tendons, and other tissues. It may be called *gouty arthritis.* The most common site of acute gouty inflammation is at the joint of the big toe. Gout is characterized by a uric acid metabolism disorder and a defect in purine (products of certain proteins) metabolism, which results in an increase in urates (uric acid salts) and an accumulation of uric acid (hyperuricemia) or an ineffective clearance of uric acid by the kidneys. Uric acid solubility is poor in acid urine, and urate crystals may form, causing urate calculi. Gout may appear as bumps, or *tophi,* in the subcutaneous tissue of earlobes, elbows, hands, and at the base of the great toe. In addition to tophi, the complications of untreated or prolonged periods of gout include gouty arthritis, urinary calculi, and gouty nephropathy.

To promote uric acid excretion and to prevent renal calculi, fluid intake should be increased while taking antigout drugs. Foods high in purine—such as organ meats, sardines, salmon, gravy, herring, liver, and meat soups—and alcohol, especially beer, should be avoided. Alcohol causes both an overproduction and underexcretion of uric acid. To reduce acidity, acetaminophen should be taken for discomfort instead of aspirin (salicylic acid).

Antiinflammatory Gout Drug: Colchicine

The first drug used to treat gout was colchicine, introduced in 1936. This antiinflammatory gout drug inhibits the migration of leukocytes to the inflamed site. It is effective in alleviating acute symptoms of gout, but it is not effective for decreasing inflammation that occurs in other inflammatory disorders. Colchicine does not inhibit uric acid synthesis and does not promote uric acid excretion. It should not be used if the patient has a severe renal, cardiac, or GI problem. Gastric irritation is a common problem, so colchicine should be taken with food. With high doses, nausea, vomiting, diarrhea, or abdominal pain occurs in approximately 75% of patients taking the drug.

Colchicine is well absorbed in the GI tract, and its peak concentration time is within 2 hours. Most of the drug is excreted in the feces, but 10% to 20% is excreted in the urine.

Uric Acid Biosynthesis Inhibitors

Allopurinol, first marketed in 1963, is *not* an antiinflammatory drug; instead, it inhibits the final steps of uric acid biosynthesis and therefore lowers serum uric acid levels, preventing the precipitation of an attack. This drug is frequently used as a prophylactic to prevent gout, and it is a drug of choice for patients with chronic tophaceous gout. Allopurinol is also indicated for gout patients with renal impairment. It is useful for patients who have renal obstructions caused by uric acid stones and for patients with blood disorders such as leukemia and polycythemia vera. It is also given to patients who do not respond well to uricosuric drugs such as probenecid. Increased fluid intake is recommended to promote diuresis and alkalinization of the urine. Prototype Drug Chart 24.5 presents the pharmacologic behavior of febuxostat, another uric acid biosynthesis inhibitor.

Pharmacokinetics

Eighty percent of allopurinol is absorbed from the GI tract. Biosynthesis of uric acid occurs in the liver in pure form and as active metabolites. The half-life of the drug itself is 1 to 2 hours, and it is 20 to 24 hours for its active metabolites. The protein-binding percentage is unknown. Approximately 80% to 100% of allopurinol and its metabolites are excreted in urine.

Pharmacodynamics

Allopurinol inhibits the production of uric acid by inhibiting the enzyme xanthine oxidase, which is needed in the synthesis of uric acid. Allopurinol also improves the solubility of uric acid. Its onset of action occurs within 30 to 60 minutes; its peak time averages 2 to 4 hours. Allopurinol has a long duration of action.

PROTOTYPE DRUG CHART 24.5 Febuxostat

Drug Class	Dosage
Antigout: Uric acid biosynthesis inhibitor Pregnancy category: C*	A: PO: 40-80 mg/d; *max:* 120 mg/d
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, severe renal disease *Caution:* Hepatic disorder, cardiac disease	Drug: Increased effect of theophylline, azathioprine, didanosine, mercaptopurine, pegloticase
	Lab: Increased AST, ALT, BUN
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 49% absorbed Distribution: PB: 99.2% Metabolism: t½: 5-8 h Excretion: 49% in urine	PO: Onset: UK Peak: 1-1.5 h Duration: UK
Therapeutic Effects/Uses	
To treat gout and hyperuricemia	
Mode of Action: Blocks hypoxanthine and xanthine metabolism to reduce uric acid synthesis to decrease uric acid blood and urine concentrations	
Side Effects	Adverse Reactions
Dizziness, headache, anorexia, dry mouth, vomiting, diarrhea, flatulence, arthralgia, pruritus, erectile dysfunction	Hepatic impairment, angioedema, bradycardia, gout, hyperglycemia, hyperlipidemia, hypertriglyceridemia *Life threatening:* Thrombocytopenia, neutropenia, leukopenia, pancytopenia, hepatic impairment, dysrhythmias, Steven-Johnson syndrome

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *d,* day; *h,* hour; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Alcohol, caffeine, and thiazide diuretics increase the uric acid level. Use of ampicillin or amoxicillin with allopurinol increases the risk of rash formation. Allopurinol can increase the effect of warfarin and oral hypoglycemic drugs.

Uricosurics

Uricosurics increase the rate of uric acid excretion by inhibiting its reabsorption. These drugs are effective in alleviating chronic gout, but they should not be used during acute attacks. Probenecid is a uricosuric that has been available since 1945. It blocks the reabsorption of uric acid and promotes its excretion. Probenecid can be taken with colchicine. To begin initial therapy for relieving symptoms of gout and inhibiting uric acid reabsorption, small doses of colchicine should be given before adding probenecid. If gastric irritation occurs, probenecid should be taken with meals. It has an average half-life of 1.7 to 31.2 hours and is 34% to 44% protein bound.

Another uricosuric is sulfinpyrazone. This drug is a metabolite of phenylbutazone and is more potent than probenecid. Sulfinpyrazone should be taken with meals or with antacids to prevent gastric irritation. Severe blood dyscrasias might occur, especially in patients with a history of blood dyscrasias. Table 24.4 gives dosages and considerations for the commonly used antigout drugs.

Side Effects and Adverse Reactions

Side effects may include flushed skin, sore gums, and headache. Kidney stones resulting from the uric acid could be prevented by increasing water intake and maintaining a urine pH above 6. Blood dyscrasias occur rarely. Aspirin use should be avoided because it causes uric acid retention.

Nursing Process: Patient-Centered Collaborative Care

Antigout Drug: Allopurinol

Assessment

- Obtain a medical history of any gastric, renal, cardiac, or liver disorders. Antigout drugs are excreted via kidneys, so sufficient renal function is needed. Drug dosage and drug selection might need to be changed.
- Obtain a drug history. Report possible drug-drug interactions.
- Assess serum uric acid value for future comparisons.
- Record urine output. Use initial urine output for future comparisons.
- Check laboratory tests such as BUN, serum creatinine, ALP, AST, ALT, and lactate dehydrogenase [LDH], and compare with future laboratory test results.

Nursing Diagnoses

- Tissue Integrity, Impaired related to inflammation of the great toe

- Pain, Acute related to tissue swelling

Planning

- Patient's pain from gout will be absent or controlled without side effects.

Nursing Interventions

- Report GI symptoms, gastric pain, nausea, vomiting, or diarrhea for patients taking antigout drugs. Administer these drugs with food to alleviate gastric distress.
- Record urine output. Because the drugs and uric acid are excreted through the urine, kidney stones might occur, so both water intake and urine output should be increased.
- Monitor laboratory tests for renal and liver function (BUN, serum creatinine, ALP, AST, ALT).

Patient Teaching

General

- Encourage patients to keep medical appointments and to have regularly scheduled laboratory tests for renal and liver function and CBC. Some antigout drugs may cause blood dyscrasias, so blood tests should be monitored.
- Instruct patients to increase fluid intake; it will increase drug and uric acid excretion.

Side Effects

- Advise patients to report to a health care provider any side effects of antigout drugs such as anorexia, nausea, vomiting, diarrhea, stomatitis, dizziness, rash, pruritus, and metallic taste.
- Advise patients to have a yearly eye examination because visual changes can result from prolonged use of allopurinol.

Diet

- Warn patients to avoid alcohol and caffeine because they can increase uric acid levels.
- Suggest that patients not take large doses of vitamin C while taking allopurinol; kidney stones may occur.
- Tell patients not to ingest foods high in purine content such as organ meats, salmon, sardines, gravy, and legumes. Foods with purine increase uric acid levels.
- Direct patients to report any gastric distress. Encourage them to take antigout drugs with food or at mealtime.

Cultural Considerations

- Provide additional explanation as needed related to the disease process and the purpose of the drug and its side effects.
- Identify conflicts in values and beliefs.
- Suggest follow-up by a community health nurse to determine patient compliance with the drug regimen and the effectiveness of the prescribed drug therapy.

Evaluation

- Evaluate response to the antigout drug. If pain persists, the drug regimen may need modification.
- Determine the presence of adverse reactions. Drug therapy for gout pain may need to be changed.

TABLE 24.4

Antigout Drugs

Drug	Route and Dosage	Uses and Considerations
Antiinflammatory Gout Drugs		
Colchicine	Acute gout attack: A/adol >16 y: PO: Initially 1.2 mg; then 0.6 mg in 1 h; *max:* 2.4 mg/d Prophylaxis: A/adol >16 y: PO: 0.6 mg qd/bid; *max:* 1.2 mg/d	For gout. Not for patients with renal or gastric disorders. May cause nausea, vomiting, diarrhea, elevated hepatic enzymes, anemia, agranulocytosis, leukopenia, neutropenia, thrombocytopenia, pancytopenia, and rhabdomyolysis. Take with food. Pregnancy category: C*; PB: 34%-44%; t½: 1.7-31.2 h
Uric Acid Biosynthesis Inhibitors		
Allopurinol	Gout: A: PO: Initially 100 mg/d; *max:* 800 mg/d	For gout, hyperuricemia, and renal calculi. May cause nausea, vomiting, diarrhea, anemia, and GI bleeding. Pregnancy category: C *; PB: UK; t½: 1-2 h
Febuxostat	See Prototype Drug Chart 24.5.	
Uricosurics		
Probenecid	A: PO: Initially 250 mg bid for 1 wk; maint: 500 mg bid; *max:* 2 g/d	For hyperuricemia and gout. May cause dizziness, flushing, headache, fever, GI distress, and anemia. Increase fluid intake. Pregnancy category: B *; PB: 75%-95%; t½: 1-2 h, oxypurinol metabolite approximately 24 h

A, Adult; *adol,* adolescent; *bid,* twice a day; *d,* day; *GI,* gastrointestinal; *h,* hour; *maint,* maintenance; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *qd,* every day; *t½,* half-life; *UK,* unknown; *wk,* week; *y,* year; >, greater than.

Critical Thinking Case Study

PQ, a 72-year-old woman, had taken 650 mg of aspirin four times a day for 8 months to alleviate her chronic symptoms of pain and inflammation associated with arthritis. Four weeks ago, a peptic ulcer developed.

1. Explain the process by which PQ could have a peptic ulcer. How could this have been prevented?
2. Compare the similarities and differences in the side effects of salicylates with those of acetic acid agents, propionic acid agents, COX-2 inhibitors, and phenylacetic acid.
3. What patient teaching points should PQ receive before and during the time she takes aspirin?
4. How would COX-2 inhibitors prevent the development of a peptic ulcer?
5. Would DMARDs be more helpful in alleviating PQ's symptoms? Explain your answer.
6. Compare the differences in the various types of DMARDs.

NCLEX Study Questions

1. A patient is taking ibuprofen. The nurse understands that COX-1 and COX-2 inhibitors are different in that ibuprofen is more likely than celecoxib to cause which adverse effect?
   a. Fever
   b. Constipation
   c. Peptic ulcer disease
   d. Metallic taste when eating
2. When teaching a patient who is receiving allopurinol, what should the nurse encourage the patient to do?
   a. Eat more meat.
   b. Increase vitamin C intake.
   c. Have annual eye examinations.
   d. Take medication 2 hours before meals.
3. A patient is admitted to the hospital with an acute gout attack. The nurse expects that which medication will be ordered to treat acute gout?
   a. Colchicine
   b. Allopurinol
   c. Probenecid
   d. Sulfinpyrazone
4. A patient is taking aspirin for arthritis. Which adverse reaction should the nurse teach the patient to report to the health care provider?
   a. Tinnitus
   b. Seizures
   c. Sinusitis
   d. Palpitations
5. The nurse is teaching a patient about taking aspirin. Which are important points to include? (Select all that apply.)
   a. Advise the patient to avoid alcohol while taking aspirin.
   b. Instruct the patient to take aspirin before meals on an empty stomach.
   c. Instruct the patient to inform the dentist of the aspirin dosage before having dental work.
   d. Instruct the patient to inform the surgeon of the aspirin dosage before having surgery.
   e. Suggest that aspirin may be given to children for flu symptoms.
6. A patient is taking infliximab and asks the nurse what side effects/adverse reactions to expect from this drug. The nurse lists which side effects? (Select all that apply.)
   a. Fatigue
   b. Headache
   c. Chest pain
   d. Renal damage
   e. Severe infections

Answers: 1, c; 2, c; 3, a; 4, a; 5, a, c, d; 6, a, b, c, e.

NCLEX Study Questions

OBJECTIVES

- Differentiate between acute and chronic pain.
- Compare indications for nonopioid and opioid analgesics.
- Describe the serum therapeutic ranges of aspirin and acetaminophen.
- Contrast the side effects of aspirin and opioids.
- Explain the methadone treatment program.
- Discuss nursing interventions and patient teaching related to nonopioid and opioid analgesics.
- Formulate a nursing process for a patient with morphine patient-controlled analgesia.

Pain is an unpleasant sensory and emotional experience related to tissue injury. Due to the subjective nature of pain, the nurse must be knowledgeable and skillful in the assessment and measurement of pain to achieve optimal pain management.

Pain management is regarded as such a significant component of nursing care that pain has become known as the "fifth vital sign." The Joint Commission (TJC) has incorporated the assessment, documentation, and management of pain into its standards, which reflect the importance of this vital sign. The nurse's role is to assess the patient's pain level, alleviate the patient's pain through nonpharmacologic and pharmacologic treatments, thoroughly document the patient's response to treatment, and teach patients and their significant others to manage pain control when appropriate.

An individual's **pain threshold** reflects the level of stimulus needed to create a painful sensation, and individual genetic makeup contributes to the variations in pain threshold from person to person. The mu (μ) opioid receptor gene controls the number of μ-receptors present. When an individual has a large number of μ-receptors, the pain threshold is high, and pain sensitivity is reduced.

The amount of pain a person can endure without having it interfere with normal functioning is called **pain tolerance**. This psychological aspect of pain varies greatly in individuals because it is subjective and because pain tolerance is influenced by factors such as age, gender, culture, ethnicity, previous experience, anxiety level, and specific circumstances, such as a traumatic event.

Analgesics, both nonopioid and opioid, are prescribed for the relief of pain. The choice of analgesic depends upon the severity of the pain. Mild to moderate pain is frequently relieved with the use of nonopioid, also known as *nonnarcotic,* analgesics. Moderate to severe pain usually requires an opioid, or *narcotic,* analgesic.

Drugs used for pain relief are presented in this chapter. Many of the same nonopioid analgesics that are taken for pain, such as the **nonsteroidal antiinflammatory drugs (NSAIDs)**, are also taken for antiinflammatory purposes. This application for these drugs is covered in Chapter 24.

The most common classification of pain is by duration. Acute pain can be mild, moderate, or severe and is usually associated with a specific tissue injury. The onset of acute pain is usually sudden and of short duration lasting less than 3 months. Chronic pain usually has a vague origin

and gradual onset with a prolonged duration (more than 3 months) of long-lasting discomfort.

Pain may also be classified by its origin. **Nociceptors**, sensory receptors for pain, are activated by noxious stimuli—mechanical, thermal, and chemical—in peripheral tissues. When tissue damage occurs, injured cells release chemical mediators that affect the exposed nerve endings of the nociceptors. Pain that originates from tissue injury is nociceptor pain, which includes somatic pain—that is, pain from structural tissues such as bones and muscles—and visceral (organ) pain. **Neuropathic pain** is an unusual sensory disturbance that often involves neural supersensitivity. This pain is due to injury or disease of the peripheral nervous system (PNS) or central nervous system (CNS). The patient with neuropathic pain usually complains of burning, tingling, or electric shock sensations in the affected area, often triggered by light touch. Diabetic neuropathy associated with diabetes mellitus is an example of peripheral neuropathic pain. Severe, intractable pain from a herniated disk or spinal cord injury is evidence of neuropathic pain from the CNS.

Pathophysiology

The most common pain theory is called the *gate theory*, proposed by Melzack and Wall in 1965. According to this theory, tissue injury activates nociceptors and causes the release of chemical mediators such as substance P, prostaglandins, bradykinin, histamine, serotonin, acetylcholine, glutamate, adenosine triphosphate, leukotrienes, and potassium. These substances initiate an action potential along a sensory nerve fiber and sensitize pain receptors. Nociceptive action potentials are transmitted via afferent nerve fibers. One type of pain fiber that primarily transmits impulses from the periphery is the A-delta (A-δ) fiber. Because A-δ pain fibers are wrapped in a myelin sheath, they transmit impulses rapidly in acute pain. The C-fiber is a type of pain fiber that is small and unmyelinated, and because C-fibers are unmyelinated, they transmit impulses slowly. C-fibers are more often associated with chronic, dull pain.

A pain signal begins at the nociceptors in the periphery and proceeds throughout the CNS. Knowing how and where pharmacologic agents work is essential to controlling pain. The body produces neurohormones called **endorphins** (peptides) that naturally suppress pain conduction, although the method is not completely understood. Opioids such as morphine activate the same receptors as endorphins to reduce pain. NSAIDs control pain at the peripheral level by blocking the action of cyclooxygenase, a pain-sensitizing chemical, and interfering with the production of prostaglandins. Cortisone decreases pain by blocking the action of phospholipase, reducing the production of both prostaglandins and leukotrienes. In neuropathic pain, anticonvulsant drugs inhibit the transmission of nerve impulses by stabilizing the neuronal membrane and inactivating peripheral sodium channels.

To ascertain severity of pain, the health care provider should ask the patient to rate the degree of pain on a scale of 0 to 10, with 10 being the worst or most severe pain. For example, a patient who indicates a pain level of 9 may verbalize a decrease in pain to a level of 7 within 30 to 45 minutes after receiving pain medication. Many scales and instruments are available to the nurse for assessment and measurement of the patient's pain level. Table 25.1 lists the types of pain and the drug groups that may be effective in relieving each type.

Undertreatment of Pain

Undertreatment of pain is a major issue in health care today. The National Pharmaceutical Council and TJC state that up to 75% of patients have unrelieved pain. Some reasons for undertreatment are sociocultural variables that mediate a patient's willingness to acknowledge being in pain, the patient's inability to describe pain, the patient's fear of addiction, the nurse's inability to measure pain, lack of regular pain-assessment rounds, attitudes of the health care team, an unwillingness to believe the patient's report of pain, inaccurate knowledge on the part of the health care provider concerning addiction and tolerance, and prescription of an inadequate analgesic dose.

Unrelieved pain leads to a multitude of harmful effects that involve almost all organs of the body. As a result of unrelieved pain, the patient may develop increased respiratory and heart rates, hypertension, increased stress response, urinary retention, fluid overload, electrolyte imbalance, glucose intolerance, hyperglycemia, pneumonia, atelectasis, anorexia, paralytic ileus, constipation, weakness, confusion, and infection.

In addition to psychological and physical suffering, inadequate pain management leads to high health care costs. It is estimated that the cost of extended hospital stays, readmissions to the hospital, and outpatient visits due to inadequate pain management exceeds $200 billion per year.

TABLE 25.1

Types of Pain

Type of Pain	Definition	Drug Treatment
Acute	Pain occurs suddenly, is of short duration (less than 3 months), and responds to treatment; it can result from trauma, tissue injury, inflammation, or surgery.	Mild pain: Nonopioid drugs, such as acetaminophen and NSAIDs Moderate pain: Combination of nonopioid and opioid drugs, such as oxycodone and acetaminophen Severe pain: Potent opioids, such as morphine or hydrocodone
Chronic	Pain persists for more than 3 months and is difficult to treat or control.	Nonopioid drugs are suggested. Opioids, if used, should meet these criteria: • Oral or transdermal • Long duration of action • Include adjunct therapy • Cause minimal respiratory depression
Cancer	Pain occurs from pressure on nerves and organs, blockage to blood supply, or metastasis to bone.	NSAIDs and opioid drugs administered PO, transdermally, via IM or IV routes, intrathecally, or with PCA
Somatic	Pain is in skeletal muscle, ligaments, and joints.	Nonopioids: NSAIDs; also act as antiinflammatories and muscle relaxants
Superficial	Pain is from surface areas such as skin and mucous membranes.	Mild pain: Nonopioid Moderate pain: Combination of opioid and nonopioid analgesic drugs
Vascular	Pain occurs from vascular or perivascular tissues contributing to headaches or migraines.	Nonopioid drugs
Visceral	Pain is from smooth muscle and organs.	Opioid drugs

IM, Intramuscular; *IV,* intravenous; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PCA,* patient-controlled analgesia; *PO,* by mouth.

Nonopioid Analgesics

Nonopioid analgesics such as aspirin, acetaminophen, ibuprofen, and naproxen are less potent than opioid analgesics and are used to treat mild to moderate pain. Nonopioids are usually purchased over the counter, but cyclooxygenase 2 (COX-2) inhibitors require a prescription. Nonopioids are effective for the dull, throbbing pain of headaches, dysmenorrhea (menstrual pain), inflammation, minor abrasions, muscular aches and pain, and mild to moderate arthritis. Most analgesics also have an antipyretic effect and will lower an elevated body temperature. Some, such as aspirin, have antiinflammatory and antiplatelet effects as well.

Nonsteroidal Antiinflammatory Drugs

All NSAIDs have an analgesic effect as well as an antipyretic and antiinflammatory action. NSAIDs such as aspirin, ibuprofen, and naproxen can be purchased as over-the-counter (OTC) drugs. Aspirin, a salicylate NSAID, is the oldest nonopioid analgesic drug still in use. Adolf Bayer marketed the original formulation in 1899, and currently aspirin can be purchased under many names and with added ingredients.

The American Academy of Pediatrics, Centers for Disease Control and Prevention (CDC), U.S. Food and Drug Administration (FDA), National Reye's Syndrome Foundation, U.S. Surgeon General, and World Health Organization (WHO) recommend aspirin products not be given to children and adolescents younger than 19 years of age during episodes of fever or viral illnesses because of the danger of Reye syndrome. Reye syndrome is a rare but serious condition associated with viral infections treated with salicylates that causes swelling of the brain and liver. In these circumstances, acetaminophen is recommended instead of aspirin.

In addition to its analgesic, antipyretic, and antiinflammatory properties, aspirin decreases platelet aggregation (clotting). Some health care providers may therefore prescribe one 81-mg, 162-mg, or 325-mg aspirin tablet every day or one 325-mg tablet every other day as a preventive measure against transient ischemic attacks (TIAs, or ministrokes), heart attacks, or any thromboembolic episode. Aspirin is discussed in depth in Chapter 24 along with other NSAIDs.

Aspirin and other NSAIDs relieve pain by inhibiting biosynthesis of prostaglandin by different forms of the COX enzyme. As explained in Chapter 24, NSAIDs inhibit or block both COX-1 and COX-2 enzymes, while COX-2 inhibitors are selective and only inhibit COX-2 enzyme. Inhibition of COX-1 decreases protection of the stomach lining while inhibition of COX-2 decreases inflammation and pain. As a result of an NSAID's inhibition of COX-1, gastric irritation and bleeding may occur. Aspirin is the drug of choice for alleviating pain and inflammation in arthritic conditions, but when given in high doses, severe gastrointestinal (GI) irritation and possible ulceration develop in approximately 20% of patients. Some pharmaceutical companies have developed antiinflammatory and analgesic drugs that inhibit only COX-2. The COX-2 inhibitors were developed to eliminate the GI side effects associated with aspirin and other NSAIDs. COX-2 inhibitors are discussed in depth in Chapter 24.

Side Effects and Adverse Reactions

A common side effect of NSAIDs is gastric distress, including anorexia, nausea, vomiting, and diarrhea. These drugs should be taken with food, at mealtime, or with a full glass of fluid to help reduce this problem. Excessive bleeding might occur as a side effect if an NSAID is taken for dysmenorrhea during the first 2 days of menstruation. Adverse effects of salicylate toxicity includes tinnitus, vertigo, hyperventilation, and potential metabolic acidosis.

Some patients are hypersensitive to aspirin. Dyspnea, bronchospasm, and urticaria are some of the symptoms that indicate anaphylaxis to salicylate products. Certain foods also contain salicylates: prunes, raisins, paprika, and licorice. Those with a hypersensitivity to aspirin and salicylate products may be sensitive to other NSAIDs. This hypersensitivity may be related to inhibition of the COX enzyme by the salicylate.

PROTOTYPE DRUG CHART 25.1 Acetaminophen

Drug Class	Dosage
Analgesic Pregnancy category: B, C*	A/adol/C >12 y >60 kg: PO/PR: 325-650 mg q4-6h PRN; *max:* 3000 mg/d; rectal supp: 650 mg qid Adol/C <60 kg: PO/PR: 10-15 mg/kg q4-6h PRN; *max:* 75 mg/kg/d Neonates: PO/PR: 10-15 mg/kg q6-8h PRN; *max:* 60 mg/kg/d TDM: 10-20 mcg/mL
Contraindications	Drug-Lab-Food Interactions
Acetaminophen hypersensitivity, severe hepatic disease *Caution:* Renal disease, alcoholism, severe hypovolemia, chronic malnutrition	Increased effect with caffeine, diflunisal Decreased effect with oral contraceptives, antacids, anticholinergics, cholestyramine, charcoal, barbiturates, carbamazepine, and phenytoin
Pharmacokinetics	Pharmacodynamics
Absorption: Rapidly absorbed PO; rectal absorption is erratic. Distribution: PB: 10%-25%; crosses the placenta, excreted in breast milk Metabolism: t½: 2-3 h Excretion: In urine as metabolites	PO: Onset: 10-30 min Peak: 30-60 min Duration: 3-5 h Rectal: Onset: UK Peak: UK Duration: 4-6 h
Therapeutic Effects/Uses	
To decrease pain and fever	
Mode of Action: Inhibition (weak) of prostaglandin synthesis, inhibition of hypothalamic heat-regulator center	
Side Effects	Adverse Reactions
Headache, insomnia, anorexia, nausea, vomiting, constipation, rash	Oliguria, elevated hepatic enzymes *Life threatening:* Hepatotoxicity, hemolytic anemia, agranulocytosis, leukopenia, neutropenia, thrombocytopenia, renal failure

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Acetaminophen

The analgesic acetaminophen, a para-aminophenol derivative, was first marketed in the mid-1950s as an analgesic and antipyretic drug used for muscular aches and pains and for fever caused by viral infections in infants, children, adults, and older adults. It is a popular nonprescription drug: it constitutes 25% of all OTC drugs sold. Acetaminophen is a nonopioid drug, but it is *not* an NSAID. Because acetaminophen does not have the antiinflammatory properties of aspirin, it is not the drug of choice for any inflammatory process. Acetaminophen is a safe, effective drug when used at therapeutic doses, causes little to no gastric distress, and does not interfere with platelet aggregation. Complementary and Alternative Therapies 25.1 describes the use of these products in pain relief. An intravenous (IV) formulation was approved by the FDA for treating pain and fever. It should be administered undiluted over 15 minutes. There is no link between acetaminophen and Reye syndrome, and unlike aspirin and NSAIDs, it does not increase the potential for excessive bleeding if taken for dysmenorrhea (Prototype Drug Chart 25.1).

Pharmacokinetics

Acetaminophen is well absorbed from the GI tract. Rectal absorption may be erratic because of the presence of fecal material or a decrease in blood flow to the colon. Because of acetaminophen's short half-life, it can be administered every 4 hours as needed with a maximum dose of 4 g/day for adults. However, it is suggested that a patient who frequently takes acetaminophen limit the dose to 2000 mg/day (2 g/day) to avoid the possibility of hepatic or renal dysfunction. More than 85% of acetaminophen is metabolized to drug metabolites by the liver.

Large doses or overdoses can be toxic to the hepatic cells, so when large doses are administered over a long period, the serum level of acetaminophen should be monitored. The therapeutic serum range is 10 to 20 mcg/mL. Hepatic enzyme levels (aspartate aminotransferase [AST], alanine aminotransferase [ALT], alkaline phosphatase [ALP]) and serum bilirubin should also be monitored. Ingesting alcohol concurrently with acetaminophen may lead to hepatic injury, hepatic failure, and death. When acetaminophen toxicity occurs, acetylcysteine is the antidote, which reduces liver injury by converting toxic metabolites to a nontoxic form.

Pharmacodynamics

Acetaminophen weakly inhibits prostaglandin synthesis, which decreases pain sensation. It is effective in eliminating mild to moderate pain and headaches and is useful for its antipyretic effect. Acetaminophen does not possess antiinflammatory action. When given orally, its onset of action is within 10 to 30 minutes, and the duration of action is 3 to 5 hours. Severe adverse reactions may occur with an overdose, so acetaminophen in liquid or chewable form should be kept out of children's reach.

Side Effects and Adverse Reactions

An overdose of acetaminophen can be extremely toxic to liver cells; death could occur in 1 to 4 days from hepatic necrosis. If a child or adult ingests excessive amounts of acetaminophen tablets or liquid, a poison control center should be contacted immediately, and the child or adult should be taken to the emergency department. Early symptoms of hepatic damage include nausea, vomiting, diarrhea, and abdominal pain.

Table 25.2 lists the commonly used nonopioid analgesics and their dosages, uses, and considerations.

Nursing Process: Patient-Centered Collaborative Care

Analgesic: Acetaminophen

Assessment

- Obtain a medical history of liver dysfunction. Overdosing or extremely high doses of acetaminophen can cause hepatotoxicity, hepatic failure, and death.
- Ascertain the severity of pain. Nonopioid NSAIDs, such as ibuprofen, or an opioid may be necessary to relieve pain.

Nursing Diagnoses

- Injury, Risk for
- Pain, Acute related to edema from the surgical incision

Planning

- The patient's pain will be relieved or diminished.

Nursing Interventions

- Check hepatic enzyme tests such as ALT, ALP, gamma-glutamyl transferase (GGT), 5′-nucleotidase, and bilirubin for elevations in patients who take high doses of acetaminophen or overdoses.

Patient Teaching

General

- Teach patients to keep acetaminophen out of children's reach. Acetaminophen for children is available in flavored tablets and liquid, and high doses can cause hepatotoxicity, hepatic failure, and death.
- Advise patients not to self-medicate with acetaminophen for more than 10 days. Teach adult caregivers not to medicate children for more than 5 days without a health care provider's approval.
- Direct parents to call a poison control center immediately if a child has taken a large or unknown amount of acetaminophen.
- Teach patients to check acetaminophen dosages on the label of OTC drugs. Do not exceed the recommended dosage. The suggested safe maximum adult acetaminophen dosage is 4 g/day to avoid hepatic damage (see Prototype Drug Chart 25.1).
- Teach patient to avoid alcohol ingestion while taking acetaminophen.

Side Effects

- Encourage patients to report side effects. Overdosing can cause severe hepatic damage, hepatic failure, and death.
- Check the serum acetaminophen level if toxicity is suspected. The therapeutic serum level is 10 to 20 mcg/mL; the toxic level is greater than 200 mcg/mL 4 hours after ingestion and is usually associated with hepatotoxicity. The antidote for acetaminophen is acetylcysteine. Dosage is based on the serum acetaminophen level.

Cultural Considerations

- Involving the extended family may be important for teaching health strategies and providing support.

Evaluation

- Evaluate the effectiveness of acetaminophen in relieving pain using consistent pain scale. If pain persists, another analgesic may be needed.
- Determine whether the patient is taking the recommended dosage. Observe and report any side effects.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 25.1 Capsaicin

Capsaicin, which is found naturally in cayenne pepper, is selective for C-fiber nociceptors and relieves some arthritis pain in topical cream or gel form.

Opioid Analgesics

Opioid analgesics, called **opioid agonists**, are prescribed for moderate and severe pain. In the United States, the Harrison Opioid Act of 1914 required that all forms of opium be sold with a prescription and that it no longer be used as a nonprescription drug. The Controlled Substances Act of 1970 classified drugs with high abuse potential, opioids among them, in five schedule categories according to their potential for drug abuse (see Chapter 7). **Addiction** is defined as a psychological and physical dependence upon a substance beyond normal voluntary control, usually after prolonged use of a substance.

Morphine, a prototype opioid, is obtained from the sap of seed pods of the opium poppy plant. Codeine is another drug obtained from opium. In the past decades, many synthetic and semisynthetic opioids have been developed, for example, meperidine.

Although nonopioid analgesics act on the PNS at the pain receptor sites, opioid analgesics act mostly on the CNS. Opioids act primarily by activating the μ-receptors, but they also exert a weak activation of the kappa (κ) receptors. Analgesia, respiratory depression, euphoria, and sedation are effects of μ-receptor activation. Activation of κ-receptors leads to analgesia and sedation but has no effect on respiratory depression and euphoria.

TABLE 25.2
Analgesics

Generic	Route and Dosage	Uses and Considerations
Para-aminophenol		
Acetaminophen	See Prototype Drug Chart 25.1.	
Nonsteroidal Antiinflammatory Drugs (NSAIDS)		
Aspirin	Pain: A: PO/PR: 325 to 650 mg, q4h PRN; *max:* 4 g/d	For relief of headaches, pain, inflammation, fever, and mild anticoagulant to prevent thromboembolism. May cause GI distress, dizziness, drowsiness, tinnitus, hearing loss (reversible), and bleeding. Aspirin should be taken with food. Avoid with alcohol. Avoid in children and teenagers younger than 19 years during episodes of fever or viral illnesses. Pregnancy category: D*; PB: 90%-95%; t½: 15-20 min
Diflunisal	Pain: A/adol >50 kg: PO: Initially 1000 mg; maint: 500 mg q8-12h; *max:* 1500 mg/d Older A/adol <50 kg: PO: Initially 500 mg; maint: 250 mg q8-12h; *max:* 1500 mg/d	For mild to moderate pain, osteoarthritis, and RA. May cause headache, dizziness, insomnia, fatigue, rash, GI distress and bleeding, and elevated hepatic enzymes. Pregnancy category: C*; PB: 99%, t½: 8-12 h
Propionic Acid		
Ibuprofen	Pain: A: PO: 400 mg q4-6h; *max:* 3200 mg/d A/adol >17 y: IV: 400-800 mg over 30 min q6h; *max:* 3200 mg/d	For reducing fever, mild to severe pain, osteoarthritis, and RA. May cause GI distress, tinnitus, hearing loss, fluid retention, nephrotoxicity, edema, anemia, thrombocytopenia, and neutropenia. Should be taken with food, at mealtime, or with plenty of fluids. Pregnancy category: C*; PB: 90%-99%; t½: 2-4 h
Naproxen	Pain: A: PO: Initially 500 mg, then 250 mg q6-8h; *max:* 1250 mg/d	For mild to moderate pain, osteoarthritis, RA, bursitis, ankylosing spondylitis, gout, and dysmenorrhea. May cause drowsiness, dizziness, headache, rash, skin eruptions, elevated hepatic enzymes, GI distress, and bleeding. Pregnancy category: C*; PB: 99%; t½: 12-17 h
Ketorolac	A/adol >17 y >50 kg: PO: Initially 20 mg, maint: 10 mg q4-6h PRN; *max:* 40 mg/d Older A/adol >17 y <50 kg: PO: 10 mg q4-6h PRN; *max:* 40 mg/d A/adol >17 y >50 kg: IM/IV: 30 mg q6h PRN; *max:* 120 mg/d Older A/adol >17 y <50 kg: IM/IV: 15 mg q6h PRN; *max:* 60 mg/d	For short-term pain management (5 days or less). May cause dizziness, drowsiness, edema, headache, GI distress, GI bleeding and perforation, elevated hepatic enzymes, and ocular inflammation. Pregnancy category: C*; PB: 99%; t½: PO, 2.4-9 h; IM, 3.5-9.2 h
Oxicams		
Meloxicam	A: PO: 7.5-15 mg/d; *max:* 15 mg/d	For pain from osteoarthritis and RA. May cause dizziness, headache, insomnia, edema, GI distress, and elevated hepatic enzymes. Pregnancy category: C, D *; PB: 99%; t½: 15-20 h
Naphthylalkanones		
Nabumetone	A: PO: 1000 mg/d or 500 mg bid; *max:* 2000 mg/d	For pain from osteoarthritis and RA. May cause dizziness, headache, tinnitus, rash, itching, GI distress, edema, and cardiovascular thrombotic events. Pregnancy category: C*; PB: 99%; t½: 24 h
Cyclooxygenase 2 (COX-2) Inhibitors		
Celecoxib	Pain: A >18 y: PO: initially 400 mg followed by additional 200 mg on day 1 as needed; maint: 200 mg bid; *max:* 800 mg/d	For moderate to severe pain, osteoarthritis, and RA. May cause dizziness, headache, hypertension, edema, bleeding, and cardiovascular thrombotic events. Use caution in patients with severe renal or liver disorders and for those allergic to salicylates or sulfonamides. Pregnancy category: C, D*; PB: 97%; t½: 11.2 h

Miscellaneous		
Tramadol	Immediate release: A/adol >17 y: PO: Initially: 25 mg/d; maint: 50-100 mg q4-6h PRN; *max:* 400 mg/d, 300 mg/d for A >75 y Extended release: A: PO: 100 mg/d; *max:* 300 mg/d	For moderate to severe pain. Contraindicated in severe alcoholism or with use of opioids and CNS depressants. May cause nausea, vomiting, drowsiness, dizziness, weakness, constipation, headache, anxiety, and agitation. Pregnancy category: C*; PB: 20%; t½: 6.3 h for immediate release, 7.9 h for extended release
Table Continued		

Miscellaneous		
Indomethacin	Pain: Regular release: A: PO: 75-150 mg/d in 3-4 divided doses with food for 7-14 d; *max:* 200 mg/d Extended release: A: PO: 75 mg daily/bid with food for 7-14 d; *max:* 150 mg/d	For mild to severe pain, gout, tendinitis, osteoarthritis, RA, and ankylosing spondylitis. May cause dizziness, headache, GI distress, and GI bleeding. Take with food. Avoid if allergic to aspirin. Pregnancy category: C*; PB: 99%; t½: 2.6-11.2 h

A, Adult; *adol,* adolescent; *bid,* twice a day; *CNS,* central nervous system; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max,* maximum dosage; *min,* minute; *PB,* protein binding; *PO,* by mouth; *PR,* per rectum; *PRN,* as needed; *q,* every; *RA,* rheumatoid arthritis; *t½,* half-life; *y,* year; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 25.2 Sedatives

Opioids taken with kava, valerian, and St. John's wort may increase sedation.

Opioids not only suppress pain impulses but also suppress respiration and coughing by acting on the respiratory and cough centers in the medulla of the brainstem. One example of such an opioid is morphine, a potent analgesic that can readily depress respirations. Codeine is not as potent as morphine (1/15 to 1/20 as potent), but it also relieves mild to moderate pain and suppresses cough, which allows it also to be classified as an antitussive. Most opioids, with the exception of meperidine, have an antitussive (cough suppression) effect. The opioids have two isomers, levo and dextro. The levo-isomers of opioids produce an analgesic effect only; however, both levo- and dextro-isomers possess an antitussive response. The dextro-isomers do not cause physical dependence, but the levo-isomers do. Synthetic cough suppressants are discussed in Chapter 35.

In addition to pain relief and antitussive effects, many opioids possess antidiarrheal effects. Common side effects with high doses of most opioids include nausea and vomiting, particularly in ambulatory patients; constipation; a moderate decrease in blood pressure; and orthostatic hypotension. High doses of opioids may also cause respiratory depression; urinary retention, usually in older adults; and antitussive effects. See Complementary and Alternative Therapies 25.2 for interactions with opioids.

Morphine

Morphine, an extraction from opium, is a potent opioid analgesic (Prototype Drug Chart 25.2). Morphine is effective against acute pain resulting from acute myocardial infarction (AMI) and cancer, relieves dyspnea resulting from pulmonary edema, and may be used as a preoperative medication to relieve anxiety. Although it is effective in relieving severe pain, it can cause respiratory depression, orthostatic hypotension, miosis, urinary retention, constipation resulting from reduced bowel motility, and cough suppression. An antidote for morphine excess or overdose is the opioid antagonist naloxone.

PROTOTYPE DRUG CHART 25.2 Morphine Sulfate

Drug Class	Dosage
Opioid CSS II Pregnancy category: C*	Regular release: A: PO: Initially 10-30 mg q4h PRN Extended release: A: PO: 15 mg q8-12h PRN or 30 mg/d A: IV/IM/subcut: 2-10 mg/70 kg q3-4h PRN Adol/C/Infants >6 mo: IV/IM/subcut: 0.05-0.2 mg/kg q2-4h PRN
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, CNS or respiratory depression, status asthmaticus, increased intracranial pressure, shock, alcoholism, ileus, hypovolemia *Caution:* Respiratory insufficiency, renal or hepatic diseases; urinary retention; sleep apnea; older adults	Drug: Increased effects of alcohol, sedative-hypnotics, antipsychotic drugs, muscle relaxants Complementary and Alternative Therapies: St. John's wort may decrease drug effect (see Complementary and Alternative Therapies 25.2). Lab: Increased AST, ALT
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO, varies; IV, rapid Distribution: PB: 30%-35%; crosses placenta, excreted in breast milk Metabolism: t½: 1.5-2 h Excretion: 90% in urine	PO: Onset: Variable Peak: 1 h Duration: 4-5 h; SR, 8-12 h Subcut/IM: Onset: 15-30 min Peak: 50-90 min Duration: UK IV: Onset: Rapid Peak: 20 min Duration: 3-5 h
Table Continued	

Therapeutic Effects/Uses	
To relieve moderate to severe pain	
Mode of Action: Depression of the CNS; depression of pain impulses by binding with opiate receptors in the CNS	
Side Effects	**Adverse Reactions**
Anorexia, nausea, vomiting, abdominal pain, diarrhea, constipation, flatulence, fever, drowsiness, dizziness, agitation, anxiety, sedation, confusion, depression, urinary retention, rash, blurred vision, miosis, weakness, flushing, euphoria, pruritus	Hypotension, urticaria, seizures, ileus, psychological dependence *Life threatening:* Respiratory depression

A, Adult; *adol,* adolescent; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *mo,* month; *PB,* protein binding; *PO,* by mouth; *PRN,* as necessary; *q,* every; *subcut,* subcutaneous; *SR,* sustained release; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Pharmacokinetics

Morphine may be taken orally, although GI absorption can be somewhat erratic. For quick relief of severe pain, such as with AMI, or for fast relief of anxiety and to reduce hypertension, it is given intravenously. Morphine is 30% to 35% protein bound and may also be administered rectally and epidurally. Oral morphine undergoes first-pass hepatic metabolism, meaning the liver metabolizes the drug before morphine is available to the rest of the body. Only a small amount of morphine crosses the blood-brain barrier to produce an analgesic effect. It has a short half-life of 1.5 to 2 hours, and 90% is excreted in the urine. Morphine crosses the placenta and is excreted in breast milk.

Pharmacodynamics

Morphine binds with the opiate receptor in the CNS. Parenterally, the onset of action is rapid, especially when administered intravenously. Onset of action is slower for subcutaneous (subcut) and intramuscular (IM) injections. The duration of action with most types of drug administration is 3 to 5 hours; with controlled-release morphine sulfate tablets, duration is 8 to 12 hours.

Nursing Process: Patient-Centered Collaborative Care

Opioid Analgesic: Morphine Sulfate

Assessment

- Obtain a medical history. Contraindications for morphine include severe respiratory disorders, increased intracranial pressure, and severe renal disease. Morphine may cause seizures.
- Determine a drug history and check for drug allergies. Report if a drug-drug interaction is probable. Morphine increases the effects of alcohol, sedatives and hypnotics, antipsychotic drugs, and muscle relaxants, and it can cause respiratory depression.
- Assess vital signs, noting the rate and depth of respirations, as well as pupil size for future comparisons; opioids commonly decrease respirations and systolic blood pressure and may cause miosis.
- Monitor urinary output; morphine can cause urinary retention.
- Assess the type of pain, location, and duration before giving opioids.

Nursing Diagnoses

- Pain, Acute related to surgical tissue injury
- Breathing Pattern, Ineffective related to excess morphine dosage
- Falls, Risk for
- Constipation related to morphine

Planning

- The patient's pain will be reduced or alleviated.

Nursing Interventions

- Administer morphine before pain reaches its peak to maximize effectiveness of the drug.
- Monitor vital signs at frequent intervals to detect respiratory changes. Fewer than 10 respirations per minute can indicate respiratory distress.
- Record the patient's urine output because urinary retention is a side effect of morphine. Urine output should be at least 600 mL/day.
- Check bowel sounds for decreased peristalsis; constipation is a side effect of morphine. A dietary change or mild laxative might be needed.
- Check for pupil changes and reaction. Pinpoint pupils can indicate morphine overdose.
- Have naloxone available as an antidote to reverse respiratory depression if morphine overdose occurs.
- Validate the dose of morphine before administration. Check older adults for alertness and orientation because confusion is a side effect of morphine. Use side rails and take other safety precautions as necessary.

Patient Teaching

General

- Encourage patients not to use alcohol or CNS depressants with any opioid analgesics such as morphine. Respiratory depression can result, as well as dizziness and the potential fall risk.
- Suggest nonpharmacologic measures to relieve pain as the patient recuperates from surgery. As recovery progresses, a nonopioid analgesic may be prescribed.

Side Effects

- Alert patients that with continuous use, opioids such as morphine can become addicting. If addiction occurs, inform patients about methadone treatment programs and other resources in the area.
- Encourage patients to report dizziness while taking morphine. Dizziness could be due to orthostatic hypotension. Advise patients to ambulate with caution or only with assistance.
- Teach patients to report difficulty in breathing, blurred vision, and headaches.

Cultural Considerations

- Identify conflicts in values and beliefs about pain and pain management.
- Respect cultural and religious differences concerning refusal of opioid analgesics.
- Incorporate traditional practices into Western medicine whenever possible.

Evaluation

- Evaluate the effectiveness of morphine in lessening or alleviating pain using a consistent pain scale. If pain persists after several days, the dose should be increased or the opioid should be changed.
- Determine the stability of vital signs. Any decrease in respiration or blood pressure should be reported.

Meperidine

One of the first synthetic opioids, meperidine became available in the mid-1950s. It is classified as a Schedule II drug according to the Controlled Substances Act. Meperidine has a shorter duration of action than morphine, and its potency varies according to the dosage. Meperidine can be given orally or via IM and IV routes, and it is primarily effective in GI procedures. It does not have the antitussive property of opium preparations.

During pregnancy, meperidine is preferred to morphine because it does not diminish uterine contractions and causes less neonatal respiratory depression. Meperidine causes less constipation

and urinary retention than morphine. Meperidine is not indicated for patients with chronic pain, severe liver dysfunction, sickle cell disease, a history of seizures, severe coronary artery disease (CAD), or cardiac dysrhythmias. When older adults and patients with advanced cancer receive large doses of meperidine, neurotoxicity (e.g., nervousness, tremors, agitation, irritability, seizures) are reported. Meperidine should *not* be prescribed for long-term use; the dosage is frequently limited to 150 mg/dose for a period no longer than 48 to 72 hours.

Meperidine is metabolized in the liver to an active metabolite, therefore the dose should be decreased for patients with hepatic or renal insufficiency. It is excreted in the urine in a metabolite form called *normeperidine*. Meperidine should not be taken with alcohol or sedative-hypnotics because combination of these drugs causes an additive CNS depression. A major side effect of meperidine is a decrease in blood pressure, which should be monitored, especially if the patient is an older adult.

Table 25.3 lists opioids and their dosages, uses, and considerations.

Patient Safety

Do not confuse…

- **Meperidine** (opioid analgesic) with **morphine** (opioid analgesic), **meprobamate** (antianxiety), or **hydromorphone** (opioid analgesic).
- **Demerol** (opioid analgesic) with **Desyrel** (antidepressant) **or Dilaudid** (opioid analgesic).

Hydromorphone

Hydromorphone is a semisynthetic opioid similar to morphine. The analgesic effect is approximately six times more potent than that of morphine with fewer hypnotic effects and less GI distress. This opioid has a faster onset and shorter duration of action than morphine. Hydromorphone is classified as a Schedule II drug according to the Controlled Substances Act. Tolerance to hydromorphone increases gradually.

This drug is given orally, rectally, or via subcut, IM, and IV routes for the relief of moderate to severe pain. When given intravenously, dilution of each dose with 5 mL of sterile water or normal saline is preferred. Direct IV administration of 2 mg or less should be given over 2 to 3 minutes. Hydromorphone is readily absorbed in the body and is excreted in the urine. Respirations should be monitored closely, and adequate hydration should be provided.

Side Effects and Adverse Reactions

Many side effects are known to accompany the use of opioids. Of particular importance are signs of respiratory depression (respiration <10/min). Other side effects include **orthostatic hypotension** (decrease in blood pressure when rising from a sitting or lying position), drowsiness, dizziness, weakness, confusion, constipation, and urinary retention. In addition, pupillary constriction (a sign of toxicity), tolerance, and psychological and physical dependence may occur with prolonged use.

Increased metabolism of opioids contributes to tolerance, which causes an increased need for higher doses of the opioid. If chronic use of the opioid is discontinued, symptoms of withdrawal that result from cessation of drug administration usually occur within 24 to 48 hours after the last opioid dose. **Withdrawal syndrome** is caused by physical dependence. Symptoms of withdrawal syndrome include irritability, diaphoresis (sweating), restlessness, muscle twitching, tachycardia, and increased blood pressure. Withdrawal symptoms from opioids are unpleasant but not as severe or life threatening as those that accompany withdrawal from sedative-hypnotics, a process that may lead to seizures.

TABLE 25.3

Opioids: Opium and Synthetics

Generic	Route and Dosage	Uses and Considerations
Codeine sulfate, codeine phosphate CSS II	A: PO/subcut/IM: 15-60 mg q4h PRN; *max:* 360 mg/d Adol <17 y/C >6 y: PO/subcut/IM: 0.5-1	For mild to moderate pain and as an antitussive. May cause drowsiness, dizziness, headache, anxiety, insomnia, euphoria, miosis, fatigue, confusion, respiratory depression, GI distress, constipation, tolerance, and dependence. Pregnancy category: C*; PB: 7%, t½: 3-4 h

	mg/kg q4-6h PRN; *max:* 60 mg/dose	
Hydrocodone bitartrate CSS II	Pain: A: PO: Initially 2.5-10 mg hydrocodone/300-660 mg acetaminophen q4-6h PRN	For moderate to severe pain. May cause dizziness, drowsiness, confusion, euphoria, headache, miosis, GI distress, constipation, dependence, tolerance, and respiratory depression. Do not abruptly discontinue. Taper off upon discontinuation. Pregnancy category: C*; PB: 36%; t½: 7-9 h
Hydromorphone hydrochloride CSS II	A: PO: Initially 2.5-10 mg q4-6h PRN A: IM/subcut: 1-2 mg q2-3h PRN A: IV: 0.2-1 mg over 2-3 min q2-3h PRN Rectal: 3 mg q6-8h PRN	For moderate to severe pain. May cause dizziness, drowsiness, headache, miosis, euphoria, fatigue, insomnia, dry mouth, GI distress, constipation, weakness, orthostatic hypotension, urinary retention, tolerance, dependence, and respiratory depression. Pregnancy category: C*; PB: 8%-19%; t½: Immediate release, 2-3 h; extended release, 11 h
Meperidine CSS II	Pain: A: PO/subcut/IM/IV: 50-150 mg q3-4h PRN, give IV over 4-5 min; *max:* 150 mg/dose C: PO/subcut/IM/IV: 1-1.8 mg/kg q3-4h PRN; *max:* 150 mg/dose as a single dose	For moderate to severe pain and sedation induction and maintenance. May cause dizziness, drowsiness, flushing, headache, euphoria, miosis, fatigue, GI distress, constipation, hypotension, tolerance, dependence, and respiratory depression. Pregnancy category: C, D*; PB: 65%-75%; t½: 3-5 h
Morphine sulfate CSS II	See Prototype Drug Chart 25.2.	
Oxycodone hydrochloride CSS II	Immediate release: A: PO: Initially 5-15 mg q4-6h PRN Extended release: A: PO: 10 mg q12h PRN	For moderate to severe pain. Avoid taking drug over an extended period of time. May cause dizziness, drowsiness, confusion, headache, miosis, dry mouth, GI distress, constipation, weakness, and itching. Take with food to avoid GI distress. Pregnancy category: B*; PB: 45%; t½: Immediate release, 3-5 h; extended release, 4.5 h
Oxycodone with acetaminophen and oxycodone with aspirin CSS II	Immediate release: A: PO: 1-2 tabs (2.5-10 mg oxycodone/325 mg acetaminophen) q6h PRN Extended release: A: PO: 2 tabs q12h With aspirin: A: PO: 1 tab (2.25 mg oxycodone/325 mg aspirin) q6h PRN; max: 12 tabs/d	For moderate to severe pain. May cause dizziness, drowsiness, headache, euphoria, miosis, hypotension, itching, dry mouth, GI distress, constipation, dependence, tolerance, elevated hepatic enzymes, and weakness. Take with food or liquid. Pregnancy category: C*; PB: 45%-99%; t½: 2-4 h
Fentanyl CSS II	Pain: A: IM/IV: 2-20 mcg/kg (slow IV over 1-2 min) Chronic severe pain: Transdermal patch: Initially 25 mcg/h patch A: Transmucosal: Initially 200 mcg sucked (not chewed) over 15 min	For moderate to severe pain and anesthesia induction and maintenance. May cause drowsiness, dizziness, euphoria, miosis, headache, confusion, weakness, bradycardia, hypokalemia, edema, GI distress, constipation, dry mouth, tolerance, dependence, and respiratory depression. Pregnancy category: C*; PB: 80%-85%; t½: IV, 2-4 h; transdermal, 20-27 h; transmucosal, 3-14 h
Methadone CSS II	Pain: A: PO/subcut/IM: Initially 2.5 mg q8-12h PRN	For moderate to severe pain, opiate agonist dependence and withdrawal. Similar to morphine but longer duration of action. Used in drug abuse programs. Helps alleviate craving for opioids. May cause dizziness, drowsiness, blurred vision, agitation, confusion, euphoria, hallucinations, seizure, headache, bradycardia, dysrhythmias, hypotension, edema, diaphoresis, dry mouth, GI distress, weakness, urinary retention, tolerance, dependence, and respiratory depression. Pregnancy category: C*; PB: 85%-90%; t½: 2-3 h

Contraindications

Use of opioid analgesics is contraindicated for patients with head injuries. Opioids decrease respiration, which promotes carbon dioxide (CO_2) retention leading to increased intracranial pressure.

Opioid analgesics given to a patient with a respiratory disorder only intensify the respiratory distress. In a patient with asthma, opiates decrease respiratory drive while simultaneously increasing airway resistance.

Opioids may cause hypotension and are not indicated for patients in shock or for those who have very low blood pressure. If an opioid is necessary, the dosage needs to be adjusted accordingly; otherwise, the hypotensive state may worsen. For an older adult or a person who is debilitated, the opioid dose usually needs to be decreased.

Morphine is the opioid analgesic prototype; all other opioids are measured in comparison to morphine.

Combination Drugs

To treat moderate to severe pain, combination drugs that comprise an NSAID and an opioid analgesic may be used. Examples are ibuprofen and hydrocodone, a combination of an NSAID and

an opioid. Another combination for the treatment of mild to moderate pain is acetaminophen and codeine. When using a combination of drugs, smaller doses of each drug are required, thereby decreasing side effects. Also, using a combination of drugs for pain helps to decrease drug dependency that may result from possible long-term use of an opioid agent.

Patient-Controlled Analgesia

Patient-controlled analgesia (PCA) is an alternative route for opioid administration for self-administered pain relief as needed. Usually a loading dose (e.g., 2 to 10 mg of morphine) is given initially to achieve pain relief. Within predetermined safety limits, the patient controls administration of the opioid analgesic based on the amount of pain. To receive the opioid, the patient pushes a button on the PCA device, which releases a specific dose of analgesic (e.g., 1 mg morphine) into the IV line. The nurse sets the PCA pump with the opioid analgesic dose prescribed by the health care provider by regulating the time intervals (every several minutes) at which the drug can be received. A lockout mechanism on the electronically controlled infusion pump prevents the patient from constantly pushing the button and causing a drug overdose. The PCA device maintains a near-constant analgesic level, avoiding episodes of severe pain or oversedation. It is imperative that the patient, not the family or the nurse, control the PCA device to avoid overdosing. Morphine is used most often for PCA, but fentanyl and hydromorphone may also be given.

Transdermal Opioid Analgesics

Transdermal opioid analgesics provide continuous, around-the-clock pain control that is helpful to patients who suffer from chronic pain. The transdermal method is not useful for acute or postoperative pain. An example of a transdermal opioid analgesic is fentanyl, which is administered via a transdermal patch. This patch comes in various strengths—12.5, 25, 50, 75, and 100 mcg/h. Maximum serum fentanyl levels occur within 24 hours of when the patch is first applied. Fentanyl is also available for IM and IV use. Fentanyl is more potent than morphine. For older adults, the use of a lower fentanyl transdermal dose is usually suggested. The health care provider must exercise caution when prescribing fentanyl for patients who weigh less than 110 pounds.

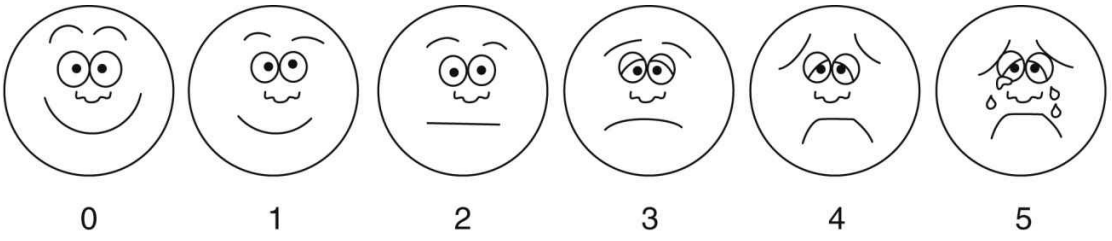
Analgesic Titration

Analgesics may be titrated to increase or decrease the dosage. Usually postoperative pain will decrease over time, and analgesics will be titrated downward. However, the patient with cancer-related pain usually has a continual increase in pain and will require an upward titration. Titration can be accomplished by changing the dose, the interval between doses, the route of administration, or the drug. When titrating analgesics, the dosage is decided after assessing the patient's respiratory rate and pain level.

Opioid Use in Special Populations

Children

Pain management in children is complex because it is more difficult to assess their pain. Some children will not verbalize discomfort when they are in severe pain, and some are fearful of treatments like injections that relieve pain. Nurses should use age-appropriate communication skills to ascertain a child's need for pain relief. The "ouch scale" illustrated in Fig. 25.1 can be helpful in determining a child's level of pain. Also, the parent may help identify the presence and degree of the child's pain. Crying and whining may be indicators of a need for pain relief or may represent other needs.



A child, like an adult, should be given medication before the pain becomes severe. The use of oral liquid medication for pain relief, if appropriate, is generally more acceptable to the child. The nurse may alleviate the child's fear and help with drug compliance by using drawings and pictures related to areas of pain in the body and pain relief with smiling faces.

Older Adults

Usually, adults who are 65 years of age or older require adjustment to drug doses to avoid severe side effects. Merely decreasing the usual adult dosage of opioid analgesic is not always the answer for older adults. Many take an array of medications for their health problems, increasing the possibility of drug interactions and drug side effects. In older adults, side effects from the use of opioids are more pronounced; therefore the nurse must closely monitor for adverse reactions in older adults who take opioid analgesics. As a person ages, liver and renal functions decrease, causing the rate of metabolism and excretion of the drug to decrease. As a result, drug accumulation may occur.

Older adults tend to have different beliefs and fears than younger generations regarding opioids. They may believe that pain is inevitable due to aging, or they may fear addiction. Older adults may not want to report pain because they do not want to be a burden. The nurse must perform pain assessment with a supportive approach in an unhurried manner and should give the patient accurate drug information.

Pain assessment may be more difficult with older adults due to the decrease in cognitive and sensory-perceptual abilities. Dementia or hearing and visual deficits may interfere with communication. The nurse may need to rely on a more thorough physical assessment to discover the presence of pain, because self-reporting may not be reliable.

1. Explain to the child that each face is for a person who feels happy because he has no pain (hurt, or whatever word the child uses) or feels sad because he has some or a lot of pain.

2. Point to the appropriate face and state, "This face is ..."
   0-"very happy because he doesn't hurt at all."
   1-"hurts just a little bit."
   2-"hurts a little more."
   3-"hurts even more."
   4-"hurts a whole lot."
   5-"hurts as much as you can imagine, although you don't have to be crying to feel this bad."

3. Ask the child to choose the face that best describes how he feels. Be specific about which pain (e.g., "shot" or incision) and what time (e.g., now? earlier? before lunch?).

FIG. 25.1 A scale used to rate the intensity of pain in children. From Hockenberry, M. (2013). *Wong's essentials of pediatric nursing* (9th ed.). St. Louis: Mosby.

In the presence of decreased renal and hepatic function, drugs that tend to be more toxic in older adults include meperidine, pentazocine, and propoxyphene. Analgesics are usually metabolized in the liver and are excreted in the urine. Usual doses of analgesics in older adults may result in excessive sedation and prolonged duration of action. Chronologic age is one of several factors that influence medication use and dosage. Comorbidity must also be considered.

Cognitively Impaired Individuals

Any cognitively impaired individual may be unable to report pain adequately. The nurse should

use a measurement scale that is appropriate for the patient. Some physical signs of pain include moans, grimacing, clenched teeth, noisy respirations, and restlessness.

Oncology Patients

Cancer pain is managed according to three levels of analgesia based on the WHO "ladder" as follows:

Step 1—Mild Pain: Nonopioids with or without an adjuvant medication
Step 2—Moderate Pain: Nonopioids and mild opioids with or without an adjuvant medication
Step 3—Severe Pain: Stronger opioids at higher dosage levels with or without an adjuvant medication

Opioids are titrated for oncology patients until pain relief is achieved or the side effects become intolerable. For effective pain management in patients with cancer, extremely high doses may be required. There are no set dosage limits for oncology patients.

Individuals With a History of Substance Use Disorder

Often patients with a history of substance use disorder require pain medication. A thorough pain assessment is necessary to find out the cause of pain. The nurse needs to know that opioids are effective and safe in this population, even though larger doses in greater frequency may be required. Studies have shown that withholding opioids in this population has not increased recovery from addiction. However, opioid agonist-antagonists such as pentazocine should be avoided in chemically dependent patients because these drugs may precipitate withdrawal syndrome.

Adjuvant Therapy

Medications used as **adjuvant analgesics** have been developed for other purposes and were later found to be effective for pain relief in neuropathy. Adjuvant therapy is usually used along with a nonopioid and opioid analgesic. Examples of adjuvant analgesics include anticonvulsants, antidepressants, corticosteroids, antidysrhythmics, and local anesthetics.

Antiseizure medications such as gabapentin act on the peripheral nerves and CNS by inhibiting spontaneous neuronal firing. They are used for neuropathic pain and for prevention of migraine headaches. Tricyclic antidepressants (TCAs) such as amitriptyline prevent the reuptake of serotonin and norepinephrine in the cells. Lower doses of TCAs than those usually prescribed for depression are effective in treating peripheral neuropathy. Corticosteroids serve as effective analgesics by reducing nociceptive stimuli. Antidysrhythmics such as mexiletine block sodium channels to reduce pain. Local anesthetics—for example, a lidocaine patch—can provide effective analgesia by interrupting the transmission of pain signals to the brain.

Adjuvant medications potentiate opioid analgesia for severe persistent pain in diabetic neuropathy, cancer, migraine headaches, and rheumatoid arthritis. When any of the adjuvant medications are used in conjunction with an NSAID and an opioid, dosages may be kept lower to reduce adverse effects.

Treatment for Opioid-Addicted Individuals

Refer to Chapter 7 for a discussion of therapies for addiction.

Opioid Agonist-Antagonists

Opioid agonist-antagonists, medications in which an opioid antagonist is added to an opioid agonist, may be used to decrease opioid abuse. Pentazocine, an opioid agonist-antagonist analgesic, can be given orally as a tablet or by injection (subcut, IM, and IV). Pentazocine is classified as a Schedule IV drug. Butorphanol tartrate, buprenorphine, and nalbuphine hydrochloride are examples of other opioid agonist-antagonist analgesics. Reports say that pentazocine and butorphanol can cause dependence. Opioid agonist-antagonist drugs are not given for cancer pain because of the risk of potential CNS toxicity from the high doses required. These analgesics are considered safe for use during labor, but their safety during early pregnancy has not been established.

Prototype Drug Chart 25.3 details the pharmacologic behavior of nalbuphine, and Table 25.4 lists the various opioid agonist-antagonists.

Pharmacokinetics

Nalbuphine can be administered orally or via IM, subcut, or IV routes. It is rapidly absorbed parenterally. Nalbuphine has a short half-life. It is metabolized in the liver and excreted in the urine.

Pharmacodynamics

Nalbuphine is effective in alleviating moderate to severe pain. The onset of action is rapid, and peak time occurs within 30 minutes with IV administration. The duration of action is the same for all routes of administration: approximately 5 hours.

PROTOTYPE DRUG CHART 25.3 Nalbuphine

Drug Class	Dosage
Opioid agonist-antagonist Pregnancy category: B*	A: IV/IM/subcut: 10 mg q3-6h; *max:* 20 mg/dose, 160 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity *Caution:* History of alcohol or drug abuse, respiratory insufficiency, head injury, increased ICP, biliary tract disease, renal or hepatic dysfunction	Drug: CNS depression is potentiated with alcohol or other CNS depressants.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Readily occurs parenterally Distribution: PB: <30%; crosses placenta, excreted in breast milk Metabolism: t½: 3-6 h Excretion: In urine, bile, and feces	Onset: 2-3 min IV; <15 min IM/subcut Peak: 30 min IV; 30 min IM Duration: 3-4 h IV; 3-6 h IM/subcut
Therapeutic Effects/Uses	
To relieve moderate to severe pain and for anesthesia induction and maintenance	
Mode of Action: Inhibits pain impulses transmitted in the CNS by binding with opiate receptors and increasing pain threshold	
Side Effects	**Adverse Reactions**
Dizziness, drowsiness, headache, dry mouth, nausea, vomiting, diaphoresis	Bradycardia, tachycardia, hypotension, hypertension, dyspnea *Life threatening:* Respiratory depression

A, Adult; *CNS,* central nervous system; *d,* day; *h,* hour; *ICP,* intracranial pressure; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein binding; *q,* every; *subcut,* subcutaneous; *t½,* half-life; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 25.4
Opioid Agonist-Antagonists

Generic	Route and Dosage	Uses and Considerations
Buprenorphine hydrochloride CSS V	Pain: A: IM/IV: Initially, 0.3 mg (older adults 0.15 mg); may repeat in 30-60 min, then q6-8h PRN; *max:* 0.6 mg/dose IM, 0.3 mg/dose IV	For moderate to severe pain, opiate dependence, and withdrawal. Avoid alcohol and CNS depressants. May cause dizziness, drowsiness, miosis, headache, anxiety, insomnia, euphoria, flushing, diaphoresis, GI distress, weakness, hypotension, and respiratory depression. Pregnancy category: C*; PB: 96%; t½: IV 1.2-7.2 h, transdermal 26 h, sublingual 37 h
Butorphanol tartrate CSS IV	A: IM: 2 mg q3-4h PRN Older A: IM: 1 mg q6h PRN A: IV: 1 mg q3-4h PRN Older A: IV: 0.5 mg q6h PRN A: Nasal spray: 1 mg (1 spray into 1 nostril), may apply additional spray in 60-90 min as needed q3-4h PRN	For moderate to severe pain and anesthesia induction and maintenance. May cause dizziness, drowsiness, insomnia, anxiety, confusion, euphoria, headache, tinnitus, paresthesia, GI distress, nasal congestion, palpitations, dependence, tolerance, and respiratory depression. Pregnancy category: C*; PB: 80%; t½: 4.8-5.8 h

Table Continued

Generic	Route and Dosage	Uses and Considerations
Nalbuphine hydrochloride CSS IV	See Prototype Drug Chart 25.3.	
Pentazocine lactate CSS IV	A/adol >17 y: Subcut/IM/IV: 30 mg q3-4 h PRN; *max:* 360 mg/d	For moderate to severe pain and anesthesia induction and maintenance. May cause miosis, dizziness, drowsiness, euphoria, headache, confusion, insomnia, irritability, nightmares, GI distress, flushing, hypotension, blurred vision, tachycardia, tolerance, and dependence. Pregnancy category: C*; PB: UK; t½: 1.5-10 h

A, Adult; *adol,* adolescent; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minutes; *PB,* protein binding; *PRN,* as needed; *q,* every; *subcut,* subcutaneous; *t½,* half-life; *UK,* unknown; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Patient Safety

Do not confuse…

- **Nubain,** a narcotic agonist-antagonist analgesic for moderate to severe pain, with **Nebcin,** an aminoglycoside antibiotic, or **Nuprin,** an OTC analgesic, antipyretic NSAID.

Nursing Process: Patient-Centered Collaborative Care

Opioid Agonist-Antagonist Analgesic: Nalbuphine

Assessment

- Obtain a drug history from the patient. Report if a drug-drug interaction is probable. When taken with nalbuphine, CNS depressants can cause respiratory depression.
- Note baseline vital signs for future comparisons.
- Assess the type of pain, duration, and location before giving the drug.

Nursing Diagnosis

- Pain, Acute related to trauma
- Knowledge Deficit related to lack of familiarity with a drug

Planning

- The intensity of the patient's pain will be lessened.

Nursing Interventions

- Monitor vital signs. Note any changes in respirations.
- Check bowel sounds and the date of the last bowel movement to identify constipation. Decreased peristalsis may result in constipation. A mild laxative may be necessary.
- Determine urine output. Report if urine output is less than 30 mL/h or less than 600 mL/day.
- Administer IV nalbuphine undiluted. Do not mix with barbiturates.

Patient Teaching

General

- Warn patients not to use alcohol or CNS depressants while taking nalbuphine. Respiratory depression can occur.
- Suggest nonpharmacologic methods for lessening pain, such as changing position or ambulation.

Side Effects

- Advise patients to report side effects of nalbuphine: dizziness, headaches, constipation, dysuria, rash, or blurred vision. Hallucinations, tachycardia, and respiratory depression are adverse reactions that might occur.

Cultural Considerations

- Accept various cultural groups' use of alternative methods for relief of pain.

Evaluation

- Evaluate the effectiveness of nalbuphine in relieving pain. If ineffective, another opioid analgesic may need to be ordered.
- Determine stability of vital signs. Note whether a change in respirations, pulse rate, or blood pressure occurs. Report abnormal findings.

Opioid Antagonists

Opioid antagonists are antidotes for drug toxicity of natural and synthetic opioid analgesics. The opioid antagonists have a higher affinity to the opiate receptor site than the opioid being taken. An **opioid antagonist** blocks the receptor and displaces any opioid that would normally be at the receptor, which inhibits the opioid action. Indications for opioid antagonists include reversal of postoperative opioid depression and opioid overdose.

Naloxone is administered via an IM or IV route, and naltrexone hydrochloride is administered orally by tablet or liquid. These drugs are perfect examples of pharmacologic antagonists because they reverse the respiratory and CNS depression (sedation and hypotension) caused by opioids. Table 25.5 lists the opioid antagonists.

When receiving opioid antagonists, the patient should be monitored continuously. The opioid action may exceed that of opioid antagonists, and further analgesia may be needed. For example, fentanyl and a combination of drugs given during surgery may lead to excessive respiratory depression. Naloxone may be given as an opioid antidote. The patient's respiratory and CNS status should be monitored closely for indications of analgesic reversal (tachycardia, nausea, vomiting, and sweating) and the possible need for further analgesia. The patient receiving naloxone should also be observed for bleeding because this drug may cause an elevated partial thromboplastin time.

TABLE 25.5

Opioid Antagonists

Generic	Route and Dosage	Uses and Considerations
Naloxone hydrochloride	Opiate agonist overdose: A: IV/IM/Subcut: 0.4-2 mg; may repeat q2-3 min; *max:* 2 mg/dose or 10 mg total Adol/C >5 y >20 kg: IV: 2 mg q2-3min; *max:* 2 mg/dose C <5 y <20 kg: IV: 0.1 mg/kg; may repeat q2-3min; *max:* 0.1 mg/dose	For opioid overdose and opioid-induced respiratory depression. Dose often needs repeating as the half-life is shorter than opioids and the opioid effects may reoccur. May cause flushing, agitation, hypotension or hypertension, tachycardia, hyperhidrosis, nausea, vomiting, and dyspnea. Pregnancy category: C*; PB: UK; t½: 30-81 min
Naltrexone hydrochloride	A: PO: 50 mg/d with food for 12 wk; *max:* 150 mg/d A: IM: 380 mg/dose q4wk; *max:* 380 mg/dose	For opioid agonist and alcohol dependence. Decreases but does not prevent craving for opioids. Patient must be opioid free for 7-10 days prior. May cause dizziness, headache, insomnia, anxiety, GI distress, arthralgia, myalgia, weakness, injection site reaction, elevated hepatic enzymes, and suicidal ideation. Pregnancy category: C*; PB: 21%-28%; t½: PO, 4 h; IM, 5-10 d

A, Adult; *adol,* adolescent; *C,* child; *d,* day; *GI,* gastrointestinal; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q,* every; *subcut,* subcutaneous; *t½,* half-life; *UK,* unknown; *wk,* weeks; *y,* years; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Headaches: Migraine and Cluster

Migraine headaches are characterized by a unilateral throbbing head pain accompanied by nausea, vomiting, and photophobia. These symptoms frequently persist for 4 to 24 hours and for several days in some cases. Two thirds of migraine headaches are experienced by women in their twenties and thirties. Symptoms usually decrease or are absent during pregnancy and menopause. The intensity of migraine pain can disrupt daily activities.

Pathophysiology

The exact etiology of migraine headaches are unknown, although many theories exist. A common theory suggests a series of neurovascular events initiates a migraine headache. Neuronal hyperexcitability occurs in the cerebral cortex, especially in the occipital cortex. Specific factors that trigger a migraine headache include foods, monosodium glutamate, aspartame, fatigue, stress, too much or too little sleep, missed meals, odors, light, hormone changes, drugs, and weather. Foods such as cheese, chocolate, and red wine can trigger an attack.

The two types of migraine are *migraines associated with an aura,* which occurs minutes to 1 hour before onset, and *migraines without aura.*

Cluster headaches are characterized by a severe, unilateral, nonthrobbing pain usually located around the eye. They occur in a series of cluster attacks in which one or more attacks occur every day for several weeks. Cluster headaches are not associated with an aura and do not cause nausea and vomiting. Men are more commonly affected by cluster headaches than women are.

Treatment of Migraine Headaches

Preventive treatment for migraines includes (1) beta-adrenergic blockers, such as propranolol and atenolol; (2) anticonvulsants, such as valproic acid and gabapentin; and (3) TCAs, such as amitriptyline and imipramine.

Treatment of a migraine attack depends on the intensity of pain. Drugs used to treat migraines include analgesics, opioid analgesics, ergot alkaloids, and selective serotonin (5-HT) receptor agonists, also known as *triptans.* For mild migraine attacks, aspirin, acetaminophen, or NSAIDs such as ibuprofen or naproxen may be prescribed. Aspirin may be used in combination with caffeine. Meperidine and butorphanol nasal spray are opioid analgesics that are occasionally used.

Antimigraine medication should be taken early during a migraine attack. Nausea and vomiting might occur, and antiemetics decrease these symptoms. Dihydroergotamine, an ergot alkaloid, can be administered subcutaneously, intramuscularly, intravenously, and by means of a nasal spray.

The triptans, 5-HT receptor agonists, are the most recently developed group of drugs for the treatment of migraine headaches. Sumatriptan, a selective serotonin receptor agonist with a short duration of action, was the first triptan drug. It is considered more effective than ergot alkaloids in treating acute migraine attacks. Table 25.6 lists the ergot alkaloids and the selective serotonin (5-HT) receptor agonists and their dosages, uses, and considerations.

Patient Safety

Do not confuse…

- **Sumatriptan** with **zolmitriptan.** Both drugs are triptans but have different dosages.
- **Amerge,** a triptan used for migraines, with **Amaryl,** a sulfonylurea used for diabetes mellitus, or **Altace**, an angiotensin-converting enzyme (ACE) inhibitor used for hypertension and heart failure.

Prototype Drug Chart 25.4 provides further information on the pharmacology of sumatriptan.

TABLE 25.6

Drugs Used to Treat Severe Migraine Headaches

Drug	Route and Dosage	Uses and Considerations
Ergot Alkaloids		
Dihydroergotamine mesylate	A: Intranasal: 1 spray (0.5 mg) in each nostril; may repeat in 15 min; *max:* 4 sprays (2 mg total dose), 3 mg/d, 4 mg/wk A: IM/subcut/IV: 1 mg; may repeat q1h until resolved; *max:* Subcut/IM, 3 mg/dose; IV, 2 mg/dose, 6 mg/wk	For migraine and cluster headaches. May cause rhinitis, dysgeusia, and GI distress. Pregnancy category: X*; PB: 90%-93%; t½: 9-10 h

Selective Serotinin Receptor Agonists (Triptans)		
Sumatriptan	See Prototype Drug Chart 25.4.	
Naratriptan	A: PO: 1-2.5 mg; may repeat in 4 h; *max:* 5 mg/d	For migraines. Avoid if a patient has uncontrolled hypertension, IHD, or prior MI. May cause dizziness, drowsiness, blurred vision, GI distress, and bradycardia. Pregnancy category: C*; PB: 28%-31%; t½: 6 h
Rizatriptan benzoate	A: PO: 5-10 mg; may repeat q2h; *max:* 30 mg/d	For migraines. Avoid if a patient has uncontrolled hypertension, CAD, or acute MI. May cause dizziness, drowsiness, dry mouth, nausea, weakness, paresthesia, and fatigue. Pregnancy category: C*; PB: 14%; t½: 2-3 h
Zolmitriptan	A: PO: 1.25-2.5 mg; may repeat in 2 h; *max:* 5 mg/dose; 10 mg/d Oral disintegrating tab: 2.5 mg; *max:* 5 mg/dose, 10 mg/d Nasal inhalation: A/adol/C >12 y: 2.5-5 mg in 1 nostril; may repeat in 2 h; *max:* 10 mg/d	For migraines. Avoid in uncontrolled hypertension, IHD, and prior MI. May cause dizziness, drowsiness, dysgeusia, dry mouth, nausea, paresthesia, hyperesthesia, and weakness. Pregnancy category: C*; PB: 25%; t½: 3 h
Almotriptan	A/C >12 y: PO: 6.25-12.5 mg; may repeat in 2 h; *max:* 25 mg/d	For migraines. May cause drowsiness, dizziness, paresthesia, and GI distress. Pregnancy category: C *; PB: 35%; t½: 3-4 h
Frovatriptan	A: PO: 2.5 mg; may repeat in 2 h; *max:* 7.5 mg/d	For migraines. May cause dizziness, dysgeusia, dry mouth, GI distress, paresthesia, and fatigue. Pregnancy category: C *; PB: 15%; t½: 26 h
Eletriptan	A: PO: 20-40 mg; may repeat in 2 h; *max:* 40 mg/dose, 80 mg/d	For migraines. May cause dizziness, drowsiness, hyperhidrosis, dry mouth, nausea, weakness, and paresthesia. Pregnancy category: C *; PB: 85%; t½: 4-5 h

A, Adult; *adol,* adolescent; *C,* child; *CAD,* coronary artery disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *IHD,* ischemic heart disease; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q,* every; *subcut,* subcutaneous; *t½,* half-life; *tab,* tablet; *wk,* week; *y,* years; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 25.4 Sumatriptan

Drug Class	Dosage
5-HT receptor agonist: Antimigraine Pregnancy category: C*	A: PO: 25-100 mg for 1 dose, may repeat in 2 h; *max:* 100 mg/dose, 200 mg/d A: Subcut: 6 mg, may repeat with 6 mg after 1 h; *max:* 6 mg/dose, 12 mg/d A: Intranasal: 5-20 mg in 1 nostril, may repeat after 2 h; *max:* 40 mg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, CAD, peripheral vascular disease, hypertension, cerebrovascular disease *Caution:* Renal or hepatic dysfunction, obesity, DM, smoking, seizures, older adults	Drug: Risk of vasospasm and blood pressure elevation with dihydroergotamine and other ergot alkaloids; increased levels and toxicity within 2 weeks of MAOIs; increased risk of serotonin syndrome or neuroleptic malignant syndrome with SSRIs
Pharmacokinetics	**Pharmacodynamics**
Absorption: Rapidly absorbed following subcut injection Distribution: PB: 14%-21% Metabolism: t½: 1.9 h Excretion: Urine and feces	PO: Onset: 60 min Peak: 2-4 h; duration: 24-48 h Subcut: Onset: 10 min Peak: 5-20 min; duration: 24-48 h Intranasal: Onset: 15 min Peak: 1-1.5 h; duration: 24-48 h
Table Continued	

Therapeutic Effects/Uses	
To treat migraine and cluster headaches	
Mode of Action: Causes vasoconstriction of cranial arteries to relieve migraine attacks	
Side Effects	**Adverse Reactions**
Dizziness, vertigo, headache, paresthesia, fatigue, flushing, drowsiness, dysgeusia, nausea, vomiting, injection site reaction, pruritis	Hypotension, hypertension, AV block, angina, dysrhythmias, bradycardia, elevated hepatic enzymes, thromboembolism, seizures
	Life threatening: Coronary artery vasospasm, MI, cardiac arrest, suicidal ideation

5-HT, Serotonin; *A,* adult; *AV,* atrioventricular; *CAD,* coronary artery disease; *d,* day; *DM,* diabetes mellitus; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein binding; *PO,* by mouth; *SSRI,* selective serotonin reuptake inhibitor; *subcut,* subcutaneous; *t½,* half-life.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Critical Thinking Case Study

RJ, a 79-year-old man, underwent abdominal surgery for resection of his colon. After the surgery, his physician prescribed morphine 10 mg every 3 to 4 hours as needed. RJ did not ask for pain medication because he worried he might become addicted. A day after the surgery, RJ's nurse noted that he was restless and grimaced whenever he moved in bed. He refused to breathe deeply or cough when instructed to do so. The nurse compared RJ's vital signs to his baseline findings and noted an increased pulse rate and a drop in systolic blood pressure of 6 mm Hg.

1. Should the nurse give morphine? Explain your answer.
2. What would your reaction be to RJ in regard to his restlessness, grimacing, and refusal to breathe deeply and cough?
3. What is the significance of the change in vital signs?
4. What classic side effects of opioid analgesics should the nurse assess?
5. What are some possible nonpharmacologic measures that might be helpful in alleviating RJ's pain?

The second postoperative day, RJ began asking for morphine every 3 hours. On the fifth day, the physician discontinued RJ's morphine and prescribed acetaminophen with codeine.

6. Why was the opioid analgesic order changed?
7. RJ does not want to ambulate. What is an appropriate nursing response?

NCLEX Study Questions

1. A patient requires a nonopioid medication. The nurse knows that which medication will cause the least gastrointestinal distress?
   a. Aspirin
   b. Ketorolac
   c. Celecoxib
   d. Ibuprofen
2. A patient states during a medical history that he takes several acetaminophen tablets throughout the day for acute pain. The nurse teaches the patient that the dosage should not exceed which amount?
   a. 1 g/day
   b. 3 g/day
   c. 4 g/day
   d. 6 g/day
3. For the patient receiving periodic morphine via intravenous push, which of the following findings would be of utmost concern to the nurse?
   a. Increased temperature
   b. Decreased bowel sounds
   c. Decreased respirations
   d. Increased red blood cell count
4. A patient is admitted to the emergency department with signs of respiratory depression following self-injection with hydromorphone. The admitting nurse knows that which drug will reverse respiratory depression caused by opioid overdose?
   a. Fentanyl
   b. Naloxone
   c. Butorphanol
   d. Sufenta
5. Assessing a patient following intravenous morphine administration, the nurse notes cold, clammy skin; a pulse of 40 beats/min; respirations of 10 breaths/min; and constricted pupils. Which medication will the patient likely need next?
   a. Naloxone
   b. Meloxicam
   c. Pentazocine
   d. Propoxyphene
6. For the patient who is taking acetaminophen, what should the nurse do? (Select all that apply.)
   a. Monitor routine liver enzyme tests.
   b. Encourage the patient to check package labels of over-the-counter drugs to avoid overdosing.
   c. Report side effects immediately, as toxicity can cause severe hepatic damage.
   d. Teach the female patient that oral contraceptives can increase the effect of acetaminophen.
   e. Teach the patient that caffeine decreases the effects of acetaminophen.
7. For the patient who is taking nalbuphine, what should the nurse do? (Select all that apply.)
   a. Monitor any changes in respirations.
   b. Instruct the patient to report bradycardia.
   c. Administer intravenous nalbuphine undiluted.
   d. Explain to the patient to expect an excessive amount of urine output.
   e. Instruct the patient to avoid alcohol when taking nalbuphine to avoid respiratory depression.

8. A patient is having a migraine attack. The nurse should know that which drugs are used to treat migraine attacks?

a. Triptans

b. Anticonvulsants

c. Tricyclic antidepressants

d. Beta-adrenergic blockers

Answers: 1, c; 2, b; 3, c; 4, b; 5, a; 6, a, b, c; 7, a, c, e; 8, a.

UNIT VIII
Antimicrobial Drugs

OUTLINE

Introduction
26. Antibacterials
27. Antituberculars, Antifungals, and Antivirals
28. Antimalarials, Anthelmintics, and Peptides

Introduction

Disease-producing microorganisms may be gram-positive or gram-negative bacteria, viruses, protozoans, or fungi. The degree to which they are pathogenic depends on the microorganism and its virulence. This unit discusses drugs prescribed to combat disease-producing microorganisms.

Bacteria are single-celled organisms that lack a true nucleus and nuclear membrane. Most bacteria have a rigid cell wall, and the structure of the cell wall determines the shape of the bacteria. One classification of bacteria involves the appearance or shape under a microscope. A bacillus is a rod-shaped organism, whereas cocci are spherical. When cocci appear in clusters, they are called *staphylococci*; when cocci are arranged in chains, they are called *streptococci*. Bacteria reproduce by cell division about every 20 minutes. Chapter 26, Antibacterials, discusses substances that inhibit bacterial growth or that kill bacteria and other microorganisms.

Tuberculosis (TB) is caused by the acid-fast bacillus *Mycobacterium tuberculosis.* Antitubercular drugs treat persons with active TB and those exposed to active TB. Antifungals treat infection caused by a fungus. A fungal infection may be superficial or systemic. Fungi known as *dermatophytes* can cause superficial fungal infections that involve the integumentary system, which includes mucous membranes, hair, nails, and moist skin areas. Systemic fungal infections may involve the lungs, central nervous system (CNS), or abdomen. With the exception of human immunodeficiency virus (HIV), viruses are self-limiting illnesses that usually do not require treatment with specific antivirals. Current antivirals target influenza, herpes, and hepatitis. Viruses enter healthy cells and use their deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) to generate more viruses. The growth cycle of viruses depends on the host cell enzymes and cell substrates for viral replication. Three categories of drugs are covered in Chapter 27: Antituberculars, Antifungals, and Antivirals. Although these differ from one other significantly, each category contains drugs that inhibit or kill organisms that cause disease.

Malaria is a life-threatening disease caused by protozoan parasites of several species of the genus *Plasmodium* that are carried by infected *Anopheles* mosquitoes. Malaria remains one of the most prevalent protozoan diseases, although antimalarial drugs provide treatment and prophylaxis. Helminths are large parasitic worms that live and lay eggs in warm, moist soil where sanitation and hygiene are poor. Transmission occurs from infected soil to a person, and the helminth then feeds on host tissues. The most common site for helminthiasis is the intestine. Other sites for parasitic infestation are the lymphatic system, blood vessels, and liver. Antimicrobial peptides are broad-spectrum antimicrobials with activity against bacteria, viruses, and fungi. Peptides are derived from cultures of *Bacillus subtilis*, and this group appears to interfere with bacterial cell membrane function. Chapter 28—Antimalarials, Anthelmintics, and Peptides—discusses these antimicrobial drugs.

OBJECTIVES

- Explain the mechanisms of action of antibacterial drugs.
- Differentiate between bacteria that are naturally resistant and those that have acquired resistance to an antibiotic.
- Summarize the three general adverse effects associated with antibacterial drugs.
- Differentiate between narrow-spectrum and broad-spectrum antibiotics.
- Compare the effects of the natural, broad-spectrum (extended), penicillinase-resistant, and antipseudomonal penicillins.
- Contrast the effects of first-, second-, third-, fourth-, and fifth-generation cephalosporins.
- Apply the nursing process for patients receiving penicillins and cephalosporins.
- Describe the pharmacokinetics and pharmacodynamics of erythromycin.
- Apply the nursing process for tetracyclines, including patient teaching.
- Summarize the nurse's role in detecting ototoxicity and nephrotoxicity associated with the administration of aminoglycosides.
- Explain the importance for ordering peak and trough concentration levels for aminoglycosides.
- Develop a teaching plan for a patient prescribed a fluoroquinolone (quinolone).
- Contrast the nursing interventions for each of the drug categories: macrolides, tetracyclines, aminoglycosides, and fluoroquinolones.

- Differentiate between short-acting and intermediate-acting sulfonamides.
- Compare the similarities and differences between the sulfonamides and sulfadiazine.
- Explain the pharmacokinetics of the sulfonamides.
- Apply the nursing process to the patient taking trimethoprim-sulfamethoxazole.
- Develop a teaching plan for a patient prescribed metronidazole.

This chapter discusses the antibacterials and their effects and includes mechanisms of antibacterial action, body defenses, resistance to antibacterials, use of antibacterial combinations, general adverse reactions to antibacterials, and narrow- and broad-spectrum antibiotics.

The groups of antibacterials discussed in this chapter include penicillins, cephalosporins, macrolides (erythromycin, clarithromycin, and azithromycin), lincosamides, glycopeptides, ketolides, tetracyclines, glycylcyclines, aminoglycosides, fluoroquinolones (quinolones), lipopeptides, sulfonamides, and nitroimidazoles.

The penicillins, macrolides, lincosamides, tetracyclines, and sulfonamides are primarily **bacteriostatic** drugs, those that inhibit bacterial growth, but they may also be **bactericidal** (bacteria killing), depending on the drug dose, serum level, and the **pathogen** (the disease-producing microorganism). Cephalosporins, glycopeptides, aminoglycosides, and fluoroquinolones are bactericidal drugs.

Macrolides, lincosamides, glycopeptides, and ketolides are discussed together because they have spectrums of antibiotic effectiveness similar to that of penicillin, although they differ in structure.

Drugs from these groups are used as penicillin substitutes, especially in individuals who are allergic to penicillin. Erythromycin is the drug frequently prescribed if the patient has a hypersensitivity to penicillin.

Sulfonamides are one of the oldest antibacterial agents used to combat infection. When penicillin was initially marketed, the sulfonamide drugs were not widely prescribed because penicillin was considered a "miracle drug." However, use of sulfonamides has increased as a result of newer sulfonamides and drugs that combine a sulfonamide with an antibacterial agent in preparations such as trimethoprim-sulfamethoxazole.

Pathophysiology

Bacteria, known as *prokaryotes,* are single-celled organisms that lack a true nucleus and nuclear membrane. Most bacteria have a rigid cell wall, and the structure of the cell wall determines the shape of the bacteria. One classification of bacteria involves the appearance or shape under a microscope. A *bacillus* is a rod-shaped organism, and *cocci* are spherical. When cocci appear in clusters, they are called *staphylococci;* when they are arranged in chains, they are called *streptococci.* Bacteria reproduce by cell division ranging from 12 minutes to 24 hours.

Another classification of bacteria involves staining properties of the cell. The Gram-staining method was devised in 1882 by Hans Christian Gram, a Danish bacteriologist. Gram staining determines the ability of the bacterial cell wall to retain a purple stain by a basic dye. Crystal violet is normally used in the staining process but may be substituted with methylene blue. If bacteria retain a purple stain, they are classified as gram-positive microorganisms. Those bacteria not stained are known as gram-negative microorganisms. Examples of gram-positive bacteria include *Staphylococcus aureus, Streptococcus pneumoniae,* group B *Streptococcus* (GBS), and *Clostridium perfringens.* Examples of gram-negative bacteria include *Neisseria meningitides, Escherichia coli,* and *Haemophilus influenzae.*

Bacteria produce toxins that cause cell lysis (cell breakdown). Many bacteria produce the enzyme beta-lactamase, which destroys beta-lactam antibiotics such as penicillins and cephalosporins.

Antibacterial Drugs

Antibacterials/Antibiotics

Although the terms *antibacterial, antimicrobial,* and *antibiotic* are frequently used interchangeably, there are some subtle differences in meaning. **Antibacterials** and **antimicrobials** are substances that inhibit bacterial growth or kill bacteria and other **microorganisms**—microscopic organisms that include viruses, fungi, protozoa, and rickettsiae. Technically, the term *antibiotic* refers to chemicals produced by one kind of microorganism that inhibit the growth of or kill another. For practical purposes, however, these terms may be used interchangeably. Several drugs, including antiinfective and chemotherapeutic agents, have actions similar to those of antibacterial and antimicrobial agents. Antibacterial drugs do not act alone in destroying bacteria. Natural body defenses, surgical procedures to excise infected tissues, and dressing changes may be needed along with antibacterial drugs to eliminate the infecting bacteria.

Antibacterial drugs are either obtained from natural sources or are manufactured. The use of moldy bread on wounds to fight infection dates back 3500 years. In 1928, British bacteriologist Alexander Fleming noted that a mold that had contaminated his bacterial cultures was inhibiting bacterial growth. The mold was *Penicillium notatum,* thus Fleming called the substance *penicillin.* Sulfonamide, a synthetic antibacterial, was introduced in 1935. In 1939, Howard Florey expanded on Fleming's findings and purified penicillin so it could be used commercially. Penicillin was used during World War II and was marketed in 1945.

TABLE 26.1

Mechanisms of Action of Antibacterial Drugs

Action	Effect	Drugs
Inhibition of cell-wall synthesis	Bactericidal effect Enzyme breakdown of cell wall Inhibition of enzyme in synthesis of cell wall	Penicillin Cephalosporins Bacitracin Vancomycin
Alteration of membrane permeability	Bacteriostatic or bactericidal effect Increases membrane permeability Cell lysis caused by loss of cellular substances	Amphotericin B Nystatin Polymyxin Colistin
Inhibition of protein synthesis	Bacteriostatic or bactericidal effect Interferes with protein synthesis without affecting normal cell Inhibits steps of protein synthesis	Aminoglycosides Tetracyclines Erythromycin Lincomycin
Inhibition of synthesis of bacterial RNA and DNA	Inhibits synthesis of RNA and DNA in bacteria Binds to nucleic acid and enzymes needed for nucleic acid synthesis	Fluoroquinolones
Interference with cellular metabolism	Bacteriostatic effect Interferes with steps of metabolism within cells	Sulfonamides Trimethoprim Isoniazid Nalidixic acid Rifampin

For drugs with a narrow therapeutic index, such as the aminoglycosides, peaks and troughs of serum antibiotic levels are monitored to determine whether the drug is within the therapeutic range for its desired effect. If the serum *peak* level is too high, drug toxicity could occur. If the serum *trough* level (drawn minutes before administration of the next drug dose) is below the therapeutic range, the patient is not receiving an adequate antibiotic dose to kill the targeted microorganism.

Mechanisms of Antibacterial Action

Five mechanisms of antibacterial action are responsible for the inhibition of growth or destruction of microorganisms: (1) inhibition of bacterial cell-wall synthesis, (2) alteration of membrane permeability, (3) inhibition of protein synthesis, (4) inhibition of the synthesis of bacterial ribonucleic acid (RNA) and deoxyribonucleic acid (DNA), and (5) interference with metabolism within the cell (Table 26.1).

Pharmacokinetics

Antibacterial drugs must not only penetrate the bacterial cell wall in sufficient concentrations but also have an affinity for (attraction to) the binding sites on the bacterial cell. The length of time the drug remains at the binding sites increases the effect of the antibacterial action. This time factor is controlled by the pharmacokinetics—the distribution, half-life, and elimination—of the drug.

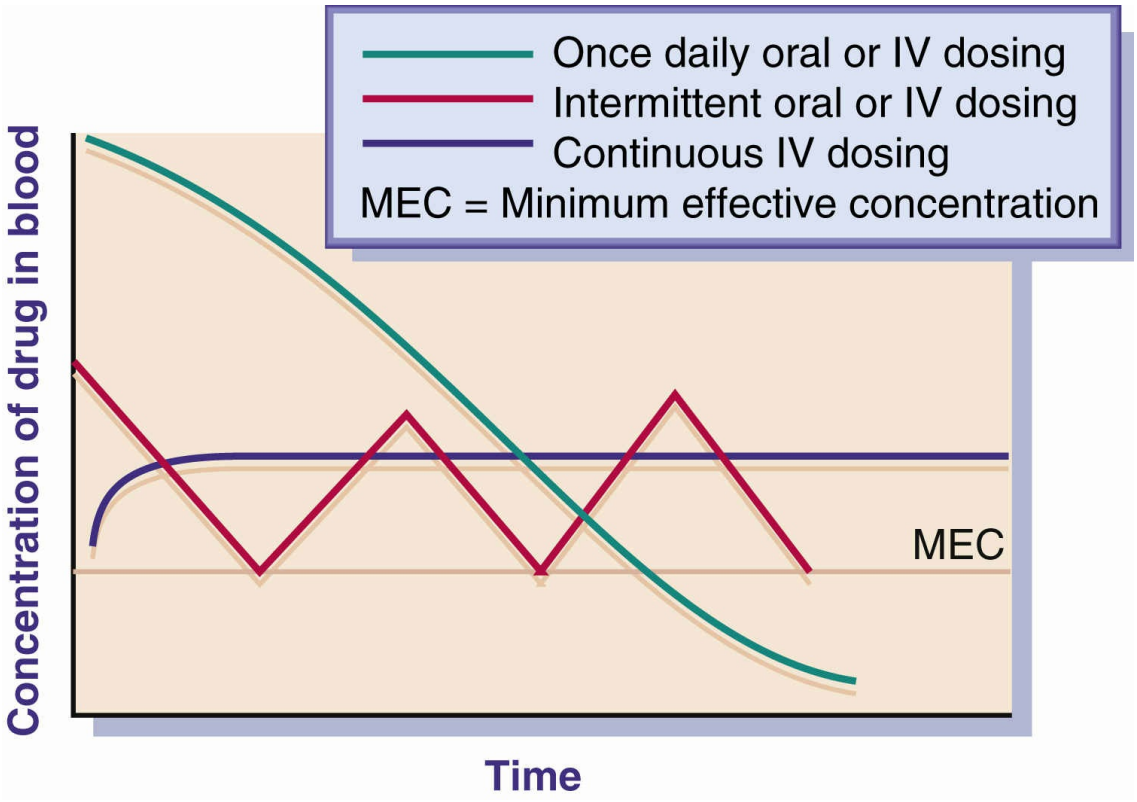

FIG. 26.1 **Effects of Concentrated Drug Dosing.**

Antibacterials that have a longer half-life usually maintain a greater concentration at the binding site, therefore frequent dosing is not required. Most antibacterials are not highly protein bound, with a few exceptions (e.g., oxacillin, ceftriaxone, cefprozil, cloxacillin, nafcillin, clindamycin). Protein binding does not have a major influence on the effectiveness of most antibacterial drugs. The steady state of the antibacterial drug occurs after the fourth to fifth half-lives, and after the seventh half-life, the drug is eliminated from the body, mainly through urine.

Pharmacodynamics

The drug concentration at the site and the exposure time for the drug play important roles in bacterial eradication. Antibacterial drugs are used to achieve the minimum effective concentration (MEC) necessary to halt the growth of a microorganism. Many antibacterials have a bactericidal effect against the pathogen when the drug concentration remains constantly above the MEC during the dosing interval. Duration of use of the antibacterial varies according to the type of pathogen, site of infection, and immunocompetence of the host. With some severe infections, a continuous infusion regimen is more effective than intermittent dosing because of constant drug concentration and time exposure. Once-daily antibacterial dosing—such as with aminoglycosides, macrolides, and fluoroquinolones—has been effective in eradicating pathogens and has not caused severe adverse reactions (ototoxicity, nephrotoxicity) in most cases. The ease of compliance with once- or twice-daily drug dosing also increases the patient's adherence to the drug regimen.

Fig. 26.1 illustrates the effect of three methods of drug dosing. The drug dose is effective when it remains above the MEC.

Body Defenses

Body defenses and antibacterial drugs work together to stop the infectious process. The effect that antibacterial drugs have on an infection depends not only on the drug but also on the host's defense mechanisms. Factors such as age, nutrition, immunoglobulins, white blood cells (WBCs), organ function, and circulation influence the body's ability to fight infection. Older adults and undernourished individuals have less resistance to infection than younger, well-nourished populations. If the host's natural body defense mechanisms are inadequate, drug therapy might not be as effective. As a result, drug therapy may need to be closely monitored or revised. When

circulation is impeded, an antibacterial drug may not be distributed properly to the infected area. In addition, **immunoglobulins**—antibody proteins such as IgG and IgM—and other elements of the immune response system, such as WBCs needed to combat infections, may be depleted in individuals with poor nutritional status.

Resistance to Antibacterials

Bacteria can be either sensitive or resistant to certain antibacterials. When bacteria are *sensitive* to a drug, the pathogen is inhibited or destroyed; however, if bacteria are *resistant*, the pathogen continues to grow despite administration of that antibacterial drug.

Bacterial resistance can result naturally, called **inherent resistance**, or it may be acquired. A natural, or inherent, resistance occurs without previous exposure to the antibacterial drug. For example, the gram-negative bacterium *Pseudomonas aeruginosa* is inherently resistant to penicillin G. An **acquired resistance** is caused by prior exposure to the antibacterial. Although *S. aureus* was once sensitive to penicillin G, repeated exposures have caused this organism to evolve and become resistant to that drug. Penicillinase, an enzyme produced by the microorganism, is responsible for causing its penicillin resistance. Penicillinase metabolizes penicillin G, causing the drug to be ineffective; however, penicillinase-resistant penicillins that are effective against *S. aureus* are now available.

Antibiotic resistance is a major problem. In the early 1980s, pharmaceutical companies thought that enough antibiotics were on the market, so they concentrated on developing antiviral and antifungal drugs. As a result, fewer new antibiotics were developed during the 1980s. Now pharmaceutical companies have developed many new antibiotics, but antibiotic resistance continues to develop, especially when antibiotics are used frequently. As bacteria reproduce, some mutation occurs, and eventually the mutant bacteria survive the effects of the drug. One explanation is that the mutant bacterial strain may have grown a thicker cell wall.

In large health care institutions, there is a tendency toward drug resistance in bacteria. Mutant strains of organisms have developed, thus increasing their resistance to antibiotics that were once effective against them. Infections acquired while patients are hospitalized are called **health care acquired infections** (previously known as nosocomial infections). Many of these infections are caused by drug-resistant bacteria, and this can prolong hospitalization, which is costly to both the patient and third-party health care insurers.

Another problem related to antibiotic resistance is that bacteria can transfer their genetic instructions to another bacterial species, and the other bacterial species then becomes resistant to that antibiotic as well. Bacteria can also pass along high resistance to a more virulent and aggressive bacterium (e.g., *S. aureus,* enterococci).

Methicillin was the first penicillinase-resistant penicillin; it was developed in 1959 in response to the resistance of *S. aureus.* In 1968, strains of *S. aureus* were beginning to become resistant to methicillin. Highly resistant bacteria, so-called methicillin-resistant *S. aureus* (MRSA), became resistant not only to methicillin but to all penicillins and cephalosporins as well. Resistance that was once found only in hospitals began to emerge in 1981 in the community. Methicillin is now off the market, and the treatment of choice for MRSA is vancomycin. Other effective drugs used to treat MRSA include linezolid, tedizolid, daptomycin, trimethoprim-sulfamethoxazole, doxycycline, clindamycin, *and* televancin, a glycopeptide antiinfective.

Many enterococcal strains are resistant to penicillin, ampicillin, gentamicin, streptomycin, and vancomycin. Another big resistance problem is vancomycin-resistant *Enterococcus faecium* (VREF), which can cause death in persons with weakened immune systems. The incidence of VREF in hospitals has increased, and a strain of MRSA has also been reported to be resistant to vancomycin (vancomycin-resistant *S. aureus,* or VRSA). One antibiotic after another is ineffective against new resistant strains of bacteria, and major medical problems result. As new drugs are developed, drug resistance will probably also develop.

Pharmaceutical companies and biotech firms are working on new classes of drugs to overcome the problem of bacterial resistance to antibiotics. A class of antibiotics known as *oxazolidinones* was discovered by a pharmaceutical company in 1988, but the company could not overcome the toxicity problems with this class of drug; however, another pharmaceutical company has taken the compound and made it less toxic. This antibiotic, linezolid, is effective against MRSA, VREF, and penicillin-resistant streptococci. Quinupristin-dalfopristin, which consists of two streptogramin antibacterials, is marketed in a 30:70 combination for intravenous (IV) use against life-threatening

infection caused by VREF and for treatment of bacteremia, *S. aureus*, and *Streptococcus pyogenes.*

Another way to attack antimicrobial resistance is to develop drugs that disable the antibiotic-resistant mechanism in the bacteria. Patients would take the antibiotic-resistance disabler along with the antibiotic already on the market, making the drug effective again. Developing a bacterial vaccine is another way to combat bacteria and lessen the need for antibiotics. The bacterial vaccine against pneumococcus has been effective in decreasing the occurrence of pneumonia and meningitis among various age groups.

Antibiotic misuse, a major problem today, increases antibiotic resistance. Studies reveal that 23% to 37.8% of patients in hospitals receive antibiotics, and 50% of this population is receiving antibiotics inappropriately. When antibiotics are taken unnecessarily—such as for viral infections, when no bacterial infection is present—or incorrectly (e.g., skipping doses, not taking the full antibiotic regimen), resistance to antibacterials may develop. Consumer education is important because many patients *demand* antibiotics for viral conditions, even though antibiotics are ineffective against viruses; however, viral infections that persist could compromise the body's immune system and thus promote a secondary bacterial infection. The nurse should teach patients about the proper use of antibiotics to prevent situations that promote drug resistance to bacteria.

Cross-resistance can also occur among antibacterial drugs that have similar actions, such as the penicillins and cephalosporins. To ascertain the effect antibacterial drugs have on a specific microorganism, culture and sensitivity (C&S) or antibiotic susceptibility laboratory testing is performed. C&S can detect the infective microorganism present in a sample (e.g., blood, sputum, swab) and the best drug to kill it. The organism causing the infection is determined by culture, and antibiotics the organism is sensitive to are determined by sensitivity. The susceptibility or resistance of one microorganism to several antibacterials can be determined by the C&S test. Multiantibiotic therapy, or daily use of several antibacterials, delays the development of microorganism resistance.

Use of Antibiotic Combinations

Combination antibiotics should not be routinely prescribed or administered except for specific uncontrollable infections. Usually a single antibiotic will successfully treat a bacterial infection; however, when severe infection persists and is of an unknown origin or has been unsuccessfully treated with several single antibiotics, a combination of two or three antibiotics may be suggested. Before beginning antibiotic therapy, a culture or cultures should be taken to identify the bacteria.

When two antibiotics are combined, the result may be additive, potentiative, or antagonistic. The *additive* effect is equal to the sum of the effects of two antibiotics. The *potentiative* effect occurs when one antibiotic potentiates the effect of the second antibiotic, *increasing* its effectiveness. The *antagonistic* result is achieved with combination of a drug that is bactericidal, such as penicillin, and a drug that is bacteriostatic, such as tetracycline; when these two drugs are used together, the desired effect may be greatly *reduced*.

General Adverse Reactions to Antibacterials

Three major adverse reactions associated with the administration of antibacterial drugs are (1) allergic (hypersensitivity, anaphylaxis) reactions, (2) superinfection, and (3) organ toxicity. Table 26.2 describes these adverse reactions, all of which require close monitoring of the patient.

Narrow-Spectrum and Broad-Spectrum Antibiotics

Antibacterial drugs can be classified as either narrow spectrum or broad spectrum. The **narrow-spectrum antibiotics** are primarily effective against one type of organism. For example, penicillin and erythromycin are used to treat infections caused by gram-positive bacteria. Certain **broad-spectrum antibiotics**, such as tetracycline and cephalosporins, can be effective against both gram-positive and gram-negative organisms. Because narrow-spectrum antibiotics are selective, they are more active against those single organisms than the broad-spectrum antibiotics. Broad-spectrum antibiotics are frequently used to treat infections when the offending microorganism has not been identified by the C&S test.

TABLE 26.2

General Adverse Reactions to Antibacterial Drugs

Type	Considerations

Allergy or hypersensitivity	Allergic reactions to drugs may be mild or severe. Examples of mild reactions are rash, pruritus, and hives. An example of a severe response is anaphylactic shock, which results in vascular collapse, laryngeal edema, bronchospasm, and cardiac arrest. Severe allergic reaction generally occurs within 20 minutes, and shortness of breath is often the first symptom of anaphylaxis. Mild allergic reaction is treated with an antihistamine, whereas anaphylaxis requires treatment with epinephrine, bronchodilators, and antihistamines.
Superinfection	Superinfection is a secondary infection that occurs when the normal microbial flora of the body are disturbed during antibiotic therapy. Superinfections can occur in the mouth, respiratory tract, intestine, genitourinary tract, and skin. Fungal infections frequently result in superinfections, although bacterial organisms (e.g., *Proteus, Pseudomonas, Staphylococcus*) may be the offending microorganisms. Superinfections rarely develop when drug is administered for less than 1 week, and they occur more commonly with the use of broad-spectrum antibiotics. For fungal infection of the mouth, nystatin is frequently used.
Organ toxicity	The liver and kidneys are involved in drug metabolism and excretion, and antibacterials may result in damage to these organs. For example, aminoglycosides can be nephrotoxic and ototoxic.

SECTION 26A

Penicillins and Cephalosporins

Penicillins

Penicillin, a natural antibacterial agent obtained from the mold genus *Penicillium,* was introduced to the military during World War II and is considered to have saved many soldiers' lives. It became widely used in 1945 and was considered a "miracle drug." With the advent of penicillin, many patients survived who would have normally died from wound and severe respiratory infections.

Penicillin's beta-lactam ring structure interferes with bacterial cell-wall synthesis by inhibiting the bacterial enzyme that is necessary for cell division and cellular synthesis. The bacteria die of cell lysis (cell breakdown). The penicillins can be both bacteriostatic and bactericidal, depending on the drug and dosage. Penicillin G is primarily bactericidal.

Penicillins are mainly referred to as *beta-lactam antibiotics.* Bacteria can produce a variety of enzymes, such as beta-lactamases, that can inactivate penicillin and other beta-lactam antibiotics such as the cephalosporins. The beta-lactamases, which attack penicillins, are called *penicillinases.*

Penicillin G was the first penicillin administered orally and by injection. With oral administration, only about one third of the dose is absorbed. Because of its poor absorption, penicillin G given by injection (IV and intramuscular [IM]) is more effective in achieving a therapeutic serum penicillin level. Because it is an aqueous drug solution, aqueous penicillin G has a short duration of action, and the IM injection is very painful. As a result, a longer-acting form of penicillin, procaine penicillin (milky color), was produced to extend the activity of the drug. Procaine (an anesthetic) in the penicillin decreases the pain related to injection.

Penicillin V was the next type of penicillin produced. Although two thirds of the oral dose is absorbed by the gastrointestinal (GI) tract, it is a less potent antibacterial drug than penicillin G. Penicillin V is effective against mild to moderate infections, including anthrax as a weapon of bioterrorism.

Initially, penicillin was overused. It was first introduced for the treatment of staphylococcal infections, but after a few years, mutant strains of *Staphylococcus* developed that were resistant to penicillins G and V because of the bacterial enzyme penicillinase, which destroys penicillin. This led to the development of new broad-spectrum antibiotics with structures similar to penicillin to combat infections resistant to penicillins G and V.

Food in the stomach does not significantly alter absorption of penicillin V, so it should be taken after meals. Amoxicillins are penicillins that are unaffected by food.

Broad-Spectrum Penicillins (Aminopenicillins)

Broad-spectrum penicillins are used to treat both gram-positive and gram-negative bacteria. They are not, however, as broadly effective against all microorganisms as they were once considered to be. This group of drugs is costlier than penicillin and therefore should not be used when ordinary penicillins, such as penicillin G, are effective. The broad-spectrum penicillins are effective against some gram-negative organisms such as *E. coli, H. influenzae, Shigella dysenteriae, Proteus mirabilis,* and *Salmonella* species. However, these drugs are not penicillinase resistant; because they are readily inactivated by beta-lactamases, they are ineffective against *S. aureus.* Examples of this group are ampicillin and amoxicillin (Table 26.3). Amoxicillin is the most prescribed penicillin derivative for adults and children.

Penicillinase-Resistant Penicillins (Antistaphylococcal Penicillins)

Penicillinase-resistant penicillins (antistaphylococcal penicillins) are used to treat penicillinase-producing *S. aureus.* Dicloxacillin is an oral preparation of these antibiotics, whereas nafcillin and oxacillin are IM and IV preparations. This group of drugs is *not* effective against gram-negative organisms and is less effective than penicillin G against gram-positive organisms. See Prototype Drug Chart 26.1 and Table 26.3 to compare the similarities and differences in the broad-spectrum penicillin amoxicillin and the penicillinase-resistant penicillin dicloxacillin.

Extended-Spectrum Penicillins (Antipseudomonal Penicillins)

The antipseudomonal penicillins are a group of broad-spectrum antibiotics effective against *P. aeruginosa,* a gram-negative bacillus that is difficult to eradicate. These drugs are also useful against many gram-negative organisms such as *Proteus, Serratia, Enterobacter,* and *Acinetobacter* species and also *Klebsiella pneumoniae*. The antipseudomonal penicillins are *not* penicillinase resistant. Their pharmacologic action is similar to that of aminoglycosides, but they are less toxic.

TABLE 26.3

Antibacterials: Penicillins

Generic	Route and Dosage	Uses and Considerations
Basic Penicillins		
Penicillin G procaine	Severe pneumococcal pneumonia: A/adol/C >27 kg: IM: 600,000-1.2 million units/d for at least 10 d Infants/C <27 kg: IM: 300,000 units/d for at least 10 d	For treating anthrax, diphtheria, endocarditis, syphilis, and skin and respiratory infections. May cause anaphylaxis, angioedema, headache, GI distress, superinfection, CDAD, and tongue discoloration. Pregnancy category: B*; PB: 60%; t½: UK
Penicillin G benzathine	Upper respiratory infection: A: IM: 1.2 million units as a single dose Adol/C >27 kg: IM: 900,000 units as a single dose C/infants <27 kg: IM: 600,000 units as a single dose	For treating syphilis and respiratory infections and for rheumatic fever prophylaxis. May cause anaphylaxis, angioedema, GI distress, tongue discoloration, headache, superinfection, and CDAD. Pregnancy category: B*; PB: 60%; t½: UK
Penicillin G sodium	Streptococcal infection: A: IM/IV: 5-24 million units/d in divided doses q4-6h; *max:* 80 million units/d Infants/C/adol: IM/IV: 200,000-300,000 units/kg/d in divided doses q4-6h; *max:* 300,000 units/kg/d	For treating septicemia, gas gangrene, tetanus, anthrax, STIs, meningitis, diphtheria, pericarditis, endocarditis, and respiratory infections. May cause anaphylaxis, angioedema, GI distress, tongue discoloration, superinfection, and CDAD. Pregnancy category: B*; PB: 45%-68%; t½: 20-30 min
Penicillin VK	Upper respiratory infection: A/adol/C >12 y: PO: 250-500 mg q6h; *max:* 2 g/d	For treating ulcerative gingivitis, otitis media, and respiratory and skin infections and for endocarditis prophylaxis. May cause anaphylaxis, angioedema, rash, GI distress, oral candidiasis, tongue discoloration, superinfection, and CDAD. Not recommended in renal failure. Pregnancy category: B*; PB: 75%-89%; t½: UK
Broad-Spectrum Penicillins		
Amoxicillin	See Prototype Drug Chart 26.1.	
Amoxicillin-clavulanate	Lower respiratory infection: Immediate release: A/adol/C >40 kg: PO: 500 mg amoxicillin and 125 mg clavulanate q8h Extended release: A/adol/C >40 kg: PO: 2000 mg amoxicillin and 125 mg clavulanate q12h	For treating otitis media, sinusitis, and respiratory, skin, and urinary tract infections. May cause anaphylaxis, angioedema, GI distress, tongue discoloration, superinfection, and CDAD. Pregnancy category: B*; PB: 18%-25%; t½: 1-1.3 h
Ampicillin	Respiratory infection: A/adol/C >20 kg: PO: 250 mg four times daily Adol/C/infants <20 kg: PO: 50 mg/kg/d in four divided doses A/adol/C >40 kg: IM/IV: 250-500 mg q6h A/adol/C/infants <40 kg: IM/IV: 25-50 mg/kg/d IV in divided doses q6-8h or 150-200 mg/kg/d IM/IV in divided doses q6h	For meningitis, endocarditis, septicemia, gastroenteritis, and skin, respiratory, and urinary tract infections. May cause anaphylaxis, angioedema, rash, stomatitis, tongue discoloration, GI distress, superinfection, and CDAD. Pregnancy category: B*; PB: 20%; t½: 1-1.5 h
Ampicillin sulbactam	Skin infections: A: IM/IV: 1 g ampicillin/0.5 g sulbactam q6h Adol/C >40 kg: IV: 1 g ampicillin/0.5 g sulbactam q6h Adol/C <40 kg: IV: 200 mg/kg/d ampicillin/100 mg/kg/d sulbactam in divided doses q6h	For treating skin, respiratory, intraabdominal, and gynecologic infections. May cause anaphylaxis, angioedema, phlebitis, rash, GI distress, tongue discoloration, CDAD, and superinfection. Pregnancy category: B*; PB: 15%-25%; t½: 1-1.5 h
Penicillinase-Resistant Penicillins		
Dicloxacillin sodium	A/adol/C >40 kg: PO: 125-500 mg q6h; *max:* 4 g/d Adol/C/infants <40 kg: PO: 12.5-50 mg/kg/d in divided doses q6h	For treating bacteremia, endocarditis, and bone/joint, skin structure, and respiratory infections. May cause anaphylaxis, angioedema, myalgia, rash, GI distress, tongue discoloration, CDAD, superinfection, and renal dysfunction. Pregnancy category: B*; PB: 95%-99%; t½: 30-42 min
Nafcillin	A: IM/IV: 500 mg-2 g q4h; *max:* 6 g/d	For treating endocarditis, meningitis, bacteremia, and skin, respiratory, and bone/joint infections. May cause anaphylaxis, angioedema, tongue discoloration, GI distress, CDAD, superinfection, phlebitis, and injection site reaction. Pregnancy category: B*; PB: 70%-90%; t½: 0.5-1.5 h
Oxacillin sodium	Mild/moderate infection: A/adol/C >40 kg: IM/IV: 250 mg-500 mg q4-6h; *max:* 6 g/d Adol/C/infants <40 kg: IM/IV: 50-100 mg/kg/d in divided doses q4-6h	For treating endocarditis, meningitis, bacteremia, and skin, respiratory, and bone/joint infections. May cause anaphylaxis, angioedema, rash, GI distress, tongue discoloration, CDAD, superinfection, and injection site reaction. Pregnancy category: B*; PB: 89%-94%; t½: 0.5 h
Extended-Spectrum Penicillins		
Piperacillin tazobactam	Moderate/severe respiratory infection: A: IV: 3 g piperacillin/3.375 g tazobactam over 30 min q6h for 7-10 d; *max:* 16 g piperacillin/2 g tazobactam/d	For treating PID and skin, intraabdominal, and respiratory infections. May cause anaphylaxis, angioedema, GI distress, CDAD, rash, and superinfection. Pregnancy category: B*; PB: 30%; t½: 0.7-1.5 h

A, Adult; *adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minutes; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *q,* every; *STI,* sexually transmitted infection; *t½,* half-life; *UK,* unknown; *y,* year; >, greater than; <, less than.

PROTOTYPE DRUG CHART 26.1 Amoxicillin

Drug Class	Dosage
Amoxicillin: Broad-spectrum penicillin Pregnancy category: B*	Respiratory infection: Immediate release: A: PO: 250-875 mg q8-12h; *max:* 1750 mg/d Adol/C/infants >3 mo: PO: 20-40 mg/kg/d in divided doses; *max:* 500 mg/dose Neonates/infants <3 mo: PO: 30 mg/kg/d in divided doses q12h
Contraindications	**Drug-Lab-Food Interactions**
Allergy to penicillin, hypersensitivity, asthma, inflammatory bowel disease, pseudomembranous colitis, ulcerative colitis Amoxicillin: Mononucleosis *Caution:* Hypersensitivity to cephalosporins Amoxicillin: Renal impairment	Drug: Increased effect with aspirin, allopurinol, probenecid; increased bleeding with oral anticoagulants; increased effect of methotrexate; decreased effect with tetracycline, erythromycin Lab: Increased serum AST, ALT, BUN, and creatinine; increased PT, INR Food: Decreased effect with acidic fruits and juices
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: >80% in the GI tract Distribution: PB: 20% Metabolism: t½: 1-1.5 h Excretion: 70% in urine	PO: Onset, duration: UK Peak: 1-2 h
Therapeutic Effects/Uses	
For rheumatic fever prophylaxis and to treat otitis media, tonsillitis, sinusitis, and gastric/duodenal ulcers, and skin, respiratory, and urinary tract infections. Amoxicillin is effective against *Helicobacter pylori and Escherichia coli* and species of *Haemophilus, Enterococcus, Proteus, Staphylococci,* and *Streptococci.*	
Mode of Action: Amoxicillin inhibits the enzyme in cell-wall synthesis and has a bactericidal effect.	
Side Effects	**Adverse Reactions**
Nausea, vomiting, diarrhea, abdominal pain, rash, stomatitis, dysgeusia, tongue and tooth discoloration, headache, dizziness, anxiety, confusion, edema, insomnia, crystalluria, dermatitis	Superinfection (vaginitis) *Life threatening:* Anaphylaxis, angioedema, hemolytic anemia, eosinophilia, leukopenia, thrombocytopenia, CDAD, Stevens-Johnson syndrome, hepatic damage, seizures

A, Adult; *Adol,* adolescent; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *INR,* international normalized ratio; *max,* maximum dosage; *mo,* months; *PB,* protein binding; *PO,* by mouth; *PT,* prothrombin time; *q,* every; *t½,* half-life; *UK,* unknown; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Table 26.3 lists the drugs in the four categories of penicillin-type antibacterials. The administration routes (oral, IM, or IV) of various types of penicillins, along with the cephalosporins, are available on the Evolve website.

Beta-Lactamase Inhibitors

When a broad-spectrum antibiotic such as amoxicillin is combined with a beta-lactamase enzyme inhibitor such as clavulanic acid, the resulting antibiotic combination inhibits the bacterial beta-lactamases, making the antibiotic effective and extending its antimicrobial effect. There are three beta-lactamase inhibitors: (1) clavulanic acid, (2) sulbactam, and (3) tazobactam. These inhibitors are not given alone but are combined with a penicillinase-sensitive penicillin such as amoxicillin, ampicillin, or piperacillin. The combination drugs currently marketed include amoxicillin-clavulanic acid (for oral use) and ampicillin-sulbactam and piperacillin-tazobactam (for use parenterally).

Pharmacokinetics

Amoxicillin is well absorbed from the GI tract, whereas dicloxacillin is only partially absorbed. Protein-binding power differs between the two drugs—amoxicillin is 20% protein bound, but dicloxacillin is highly protein bound (95%). Drug toxicity may result when other highly protein-bound drugs are used with dicloxacillin. Both drugs have short half-lives. Sixty percent of amoxicillin is excreted in the urine; dicloxacillin is excreted in bile and urine.

Pharmacodynamics

Both amoxicillin and dicloxacillin are penicillin derivatives and are bactericidal. These drugs interfere with bacterial cell-wall synthesis, causing cell lysis. Amoxicillin may be produced with or without clavulanic acid, an agent that prevents the breakdown of amoxicillin by decreasing resistance to the antibacterial drug. The addition of clavulanic acid intensifies the effect of amoxicillin. The amoxicillin–clavulanic acid preparation and amoxicillin trihydrate have similar pharmacokinetics and pharmacodynamics as well as similar side effects and adverse reactions. When probenecid is taken with amoxicillin or dicloxacillin, the serum antibacterial levels may be increased. The effects of amoxicillin are decreased when taken with erythromycin and tetracycline. The onset of action, serum peak concentration time, and duration of action for amoxicillin and dicloxacillin are very similar.

Geriatrics

Most beta-lactam antibiotics are excreted via the kidneys. With older adults, assessment of renal

function is most important. Serum blood urea nitrogen (BUN) and serum creatinine should be monitored. With a decrease in renal function, the antibiotic dose should be decreased.

Side Effects and Adverse Reactions

Common adverse reactions to penicillin administration are hypersensitivity and **superinfection**, the occurrence of a secondary infection when the flora of the body are disturbed (see Table 26.2). Anorexia, nausea, vomiting, and diarrhea are common GI disturbances, often referred to as GI distress. This may be alleviated some by taking penicillin with food. Rash is an indicator of a mild to moderate allergic reaction; severe allergic reaction leads to anaphylactic shock. Clinical manifestations of a severe allergic reaction include laryngeal edema, severe bronchoconstriction with stridor, and hypotension. Allergic effects occur in 5% to 10% of persons receiving penicillin compounds, therefore close monitoring during the first and subsequent doses of penicillin is essential.

Drug Interactions

The broad-spectrum penicillins, amoxicillin and ampicillin, may decrease the effectiveness of oral contraceptives. Potassium supplements can increase serum potassium levels when taken with potassium penicillin G or V. When penicillin is mixed with an aminoglycoside in IV solution, the actions of both drugs are inactivated.

Other Beta-Lactam Antibacterials

Like penicillins, these beta-lactam antibacterials preferentially bind to specific penicillin-binding proteins located inside the bacterial cell wall and are bactericidal. This group includes aztrenam, imipenem/cilastatin, and meropenem. Aztrenam's effectiveness is limited to aerobic gram-positive infections. Imipenem/cilastatin and meropenem are effective against a broader spectrum of activity than many other beta-lactam antibacterials. These three antibacterials are less nephrotoxic than many other antibacterials. Table 26.4 describes these other beta-lactam antibacterials and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

Side effects and adverse reactions to aztrenam, imipenem/cilastatin, and meropenem include headache, nausea, vomiting, diarrhea, anemia, eosinophilia, and neutropenia. Rash may also occur. Severe adverse reactions include anaphylaxis, angioedema, seizures, and *Clostridium difficile*–associated diarrhea.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Penicillins

Assessment

- Assess for allergy to penicillin or cephalosporins. The patient who is hypersensitive to amoxicillin should not take *any* type of penicillin products because severe allergic reaction could occur. A small percentage of patients who are allergic to penicillin could also be allergic to a cephalosporin product.
- Evaluate laboratory results, especially liver enzymes. Report elevated alkaline phosphatase (ALP), alanine aminotransferase (ALT), and aspartate aminotransferase (AST).
- Record urine output. If amount is inadequate (<30 mL/h or <600 mL/day), the drug or drug dosage may need to be changed.

Nursing Diagnoses

- Infection, Risk for
- Skin Integrity, Risk for Impaired
- Noncompliance with drug regimen related to decreased finances
- Nutrition, Imbalanced: Less than Body Requirements related to nausea and vomiting

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Obtain a sample (e.g., swab, blood, sputum) for laboratory culture and antibiotic sensitivity testing (C&S test) to discern the infective organism before antibiotic therapy is started.
- Monitor for signs and symptoms of superinfection, especially in patients taking high doses of an antibiotic for a prolonged time. Signs and symptoms include stomatitis (mouth ulcers), genital discharge (vaginitis), and anal or genital itching.

TABLE 26.4

Other Beta-Lactam Antibiotics

Generic	Route and Dosage	Uses and Considerations
Aztreonam	Severe infections: A: IM/IV: 1-2 g q8-12h; *max:* 8 g/d	For treating septicemia and intraabdominal, skin, respiratory, and urinary tract infections. May cause anaphylaxis, angioedema, fever, rash, nasal congestion, cough, wheezing, GI distress, CDAD, neutropenia, injection site reaction, and superinfection. Pregnancy category: B*; PB: 56%-65%; t½: 1.7-2.1h
Ertapenem	Skin infections: A/adol: IM/IV: 1 g/d for 7-14 d; *max:* 1 g/d for 7-14 d C/infants >3 mo: IM/IV: 15 mg/kg; *max:* 1 g/d for 7-14 d	For bacteremia, community-acquired pneumonia, complicated UTI, skin, pelvic, and intraabdominal infections. May cause anaphylaxis, diarrhea, vomiting, abdominal pain, constipation, headache, drowsiness, fever, elevated hepatic enzymes, injection site reaction, superinfection, and anemia. Pregnancy category B*; PB: 95%; t½: 4.5 h
Imipenem	Urinary tract infection:	For treating septicemia, endocarditis, and gynecologic, intraabdominal, respiratory, urinary tract, skin, and bone/joint infection. May

and cilastatin	A: IV: 250-500 mg q6h; *max*: 4 g/d Adol/C/infants >3 mo: IV: 15-25 mg/kg/dose q6h; *max:* Adol/C - 4 g/d; Infants - 100 mg/kg/d	cause anaphylaxis, angioedema, rash, GI distress, tongue discoloration, dysgeusia, CDAD, seizures, eosinophilia, thrombocytosis, elevated hepatic enzymes, and superinfection. Pregnancy category: C*; PB: 20%-40%; t½: 1 h
Meropenem	Skin infections: A/adol/C >50 kg: IV: 500 mg-1 g q8h; *max:* 1 g q8h Adol/C/infants >3 mo, <50 kg: IV: 10-20 mg/kg q8h; *max:* 40 mg/kg/dose	For treating meningitis and intraabdominal, respiratory, and skin infections. May cause anaphylaxis, angioedema, headache, rash, GI distress, glossitis, constipation, CDAD, anemia, seizure, and superinfection. Pregnancy category: B*; PB: 2%: t½: 1.2 h

A, Adult; *adol*, adolescent; *C*, child; *CDAD*, *Clostridium difficile*–associated diarrhea; *d*, day; *GI*, gastrointestinal; *h*, hour; *IM*, intramuscular; *IV*, intravenous; *max*, maximum; *mo*, months; *PB*, protein binding; *PO*, by mouth; *q*, every; *t½*, half-life; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

- Examine the patient for allergic reaction to the penicillin product, especially after the first and second doses. This may be a mild reaction, such as a rash, or a severe reaction, such as respiratory distress or anaphylaxis.
- Have epinephrine available to counteract a severe allergic reaction.
- Do not mix aminoglycosides with a high-dose or extended-spectrum penicillin G because this combination may inactivate the aminoglycoside.
- Assess the patient for bleeding if high doses of penicillin are being given; a decrease in platelet aggregation (clotting) may result.
- Monitor body temperature and the infected area.
- Dilute antibiotic for IV use in an appropriate amount of solution as indicated in the package insert.

Patient Teaching

General

- Teach patients to always take the *entire* prescribed penicillin product, such as amoxicillin, until the bottle is empty. If only a portion of the penicillin is taken, drug resistance to that antibacterial agent may develop in the future.
- Advise patients allergic to penicillin to wear a medical alert bracelet or necklace and to carry a card that indicates the allergy. Patients should notify their health care providers of any allergy to penicillin when reporting their health history.
- Keep drugs out of reach of small children. Request childproof containers.
- Tell patients to report any side effects or adverse reactions that may occur while taking the drug.
- Encourage patients to increase fluid intake; fluids can aid in regulating body temperature and in excreting the drug.
- Warn patients or the parents of children taking antibiotics that chewable tablets must be chewed or crushed before swallowing.
- Advise female patients of childbearing years to use an additional form of birth control while taking penicillins.

Diet

- Advise patients to take medication with food to avoid gastric irritation.

Cultural Considerations

- Recognize that patients and family members from various cultural backgrounds may have alternative practices for alleviating infections. Accept adjunctive alternative methods if these are not harmful to the patient.
- Request a translator to obtain a history of symptoms related to infection and any allergies to antibiotics if the patient does not speak English.

Evaluation

- Evaluate the effectiveness of antibacterial agents by determining whether the infection has resolved and whether any side effects, including superinfection, have occurred.

TABLE 26.5

Activity of the Five Generations of Cephalosporins

Generation	Activity
First	Effective mostly against gram-positive bacteria (streptococci and most staphylococci) and some gram-negative bacteria (*Escherichia coli* and species of *Klebsiella, Proteus, Salmonella,* and *Shigella*)
Second	Same effectiveness as first generation but with a broader spectrum against other gram-negative bacteria such as *Haemophilus influenzae, Neisseria gonorrhoeae* and *N. meningitidis, Enterobacter* species, and several anaerobic organisms
Third	Same effectiveness as first and second generations and also effective against gram-negative bacteria (*Pseudomonas aeruginosa* and *Serratia* and *Acinetobacter* species) but with increased resistance to destruction by beta-lactamases
Fourth	Similar to third-generation drugs and highly resistant to most beta-lactamase bacteria with broad-spectrum antibacterial activity and good penetration to cerebrospinal fluid; effective against *E. coli, P. aeruginosa,* and *Klebsiella, Proteus,* and *Streptococcus* species and certain staphylococci
Fifth	Similar characteristics of third and fourth generations, also broad spectrum, and the only cephalosporins effective against methicillin-resistant *Staphylococcus aureus* (MRSA)

Cephalosporins

In 1948, a fungus called *Emericellopsis minimum* (*Cephalosporium acremonium)* was discovered in seawater at a sewer outlet off the coast of Sardinia. This fungus was found to be active against gram-positive and gram-negative bacteria and resistant to beta-lactamase, an enzyme that acts against the beta-lactam structure of penicillin. In the early 1960s, cephalosporins were used with clinical effectiveness. For cephalosporins to be effective against numerous organisms, their molecules were chemically altered, and semisynthetic cephalosporins were produced. Like penicillin, the cephalosporins have a beta-lactam structure and act by inhibiting the bacterial enzyme necessary for cell-wall synthesis. Lysis to the cell occurs, and the bacterial cell dies.

First-, Second-, Third-, Fourth-, and Fifth-Generation Cephalosporins

Cephalosporins are a major antibiotic group used in hospitals and in health care offices. These drugs are bactericidal with actions similar to penicillin. For antibacterial activity, the beta-lactam ring of cephalosporins is necessary.

Five groups of cephalosporins have been developed, identified as *generations.* Each generation is effective against a broader spectrum of bacteria, an increased resistance to destruction by beta-lactamases, and an increased ability to reach cerebrospinal fluid (Table 26.5).

Not all cephalosporins are affected by the beta-lactamases. First-generation cephalosporins are effective against most gram-positive bacteria and are destroyed by beta-lactamases, but not all second-generation cephalosporins are affected by beta-lactamases. Second-generation cephalosporins are effective against gram-positive and some gram-negative bacteria. Third-generation cephalosporins are resistant to beta-lactamases. They have broad-spectrum antibacterial activity and are effective against *P. aeruginosa*. The fourth-generation cephalosporin, cefepime, has broad-spectrum activity, is highly resistant to beta-lactamases, and has good penetration to cerebrospinal fluid. The fifth-generation cephalosporins are broad-spectrum drugs effective against MRSA.

Approximately 10% of persons allergic to penicillin are also allergic to cephalosporins because both groups of antibacterials have similar molecular structures. If a patient is allergic to penicillin and taking a cephalosporin, the nurse should watch for a possible allergic reaction to the cephalosporin, although the likelihood of a reaction is small.

Only a few cephalosporins are administered orally. These include cephalexin, cefadroxil, cefaclor, cefuroxime, cefdinir, cefprozil, cefixime, cefpodoxime, cefditoren, and ceftibuten. The rest of the cephalosporins are administered IM and IV. Prototype Drug Chart 26.2 describes the drug data related to ceftriaxone.

Pharmacokinetics

Cefazolin is administered IM and IV, and cefaclor is given orally. The protein-binding power of cefazolin is greater than that of cefaclor. The half-life of each drug is short, and the drugs are excreted 60% to 80% unchanged in the urine.

Pharmacodynamics

Cefazolin and cefaclor inhibit bacterial cell-wall synthesis and produce a bactericidal action. For IM and IV use of cefazolin, the onset of action is almost immediate, and peak concentration time is 5 to 15 minutes with IV use. The peak concentration time for an oral dose of cefaclor is 30 to 60 minutes.

When probenecid is administered with either of these drugs, urine excretion of cefazolin and cefaclor is decreased, which increases the action of the drug. The effects of cefazolin and cefaclor can be decreased if the drug is given with tetracyclines or erythromycin. These drugs can cause

false-positive laboratory results for proteinuria and glucosuria, especially when they are taken in large doses.

Table 26.6 lists the cephalosporins by their designated generation and also gives dosages, uses, and considerations.

Side Effects and Adverse Reactions

The side effects and adverse reactions to cephalosporins include GI disturbances (nausea, vomiting, diarrhea), alteration in blood clotting time (increased bleeding) with administration of large doses, and **nephrotoxicity** (toxicity to the kidney) in individuals with a preexisting renal disorder.

Drug Interactions

Drug interactions can occur with certain cephalosporins and alcohol. For example, alcohol consumption may cause a disulfiram-like reaction (flushing, dizziness, headache, nausea, vomiting, and muscular cramps) while taking cefotetan. Uricosuric drugs increase the excretion rate of uric acid by inhibiting its reabsorption. Taking uricosurics concurrently can decrease the excretion of cephalosporins, thereby greatly increasing serum levels.

PROTOTYPE DRUG CHART 26.2 Ceftriaxone

Drug Class	Dosage
Ceftriaxone: Third-generation cephalosporin Pregnancy category: B*	Intraabdominal, skin, and bone/joint infections: A: IM/IV: 1-2 g q12-24h; *max:* 4 g/d Adol/C/infants: IM/IV: 50-75 mg/kg/d in divided doses q12-24h; *max:* 100 mg/kg/d
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity to cephalosporins, gallbladder disease, pseudomembranous colitis, renal impairment *Caution:* Bleeding, receiving calcium IVs, hypersensitivity to penicillins, vitamin K deficiency, anticoagulants, diabetes mellitus, hepatic dysfunction	Drug: Increased nephrotoxicity with loop diuretics, aminoglycosides, calcium salts, and vancomycin; increased bleeding with anticoagulants Lab: May increase AST, ALT, ALP, LDH, PT, and INR
Pharmacokinetics	**Pharmacodynamics**
Absorption: IM, IV Distribution: PB: 85%-95% Metabolism: t½: 6-9 h Excretion: In urine	IM: Onset, duration: UK Peak: 1.5-4 h IV: Onset: Immediate; duration: UK Peak: 30 min
Therapeutic Effects/Uses	
For treating otitis media, meningitis, appendicitis, gonorrhea, septicemia, and surgical infection prophylaxis, and skin, respiratory, bone/joint, gynecologic, and urinary tract infections. Ceftriaxone is effective against *Klebsiella, Haemophilus, Clostridium, Citrobacter, Bacteroides, Acinetobacter, Neisseria, Proteus, Salmonella, Serratia, Shigella, Staphylococci, Staphylococci,* and *Escherichia coli.*	
Mode of Action: Inhibits bacterial cell-wall synthesis causing cell lysis; bactericidal effect	
Side Effects	**Adverse Reactions**
Anorexia, nausea, dyspepsia, dysgeusia, stomatitis, glossitis, vomiting, diarrhea, abdominal cramps, flatulence, rash, flushing, diaphoresis, fever, pruritus, headaches, dizziness, edema, injection site reaction	Superinfection, bleeding, epistaxis, angioedema, palpitations, biliary obstruction, cholelithiasis, elevated hepatic enzymes, jaundice, hematuria *Life threatening:* Seizures, anaphylaxis, agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, neutropenia, eosinophilia, renal failure, CDAD, Stevens-Johnson syndrome

A, Adult; *Adol,* adolescent; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *h,* hour; *IM,* intramuscular; *INR,* international normalized ratio; *IV,* intravenous; *LDH,* lactic dehydrogenase; *max,* maximum; *min,* minute; *PB,* protein binding; *PT,* prothrombin time; *q,* every; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Cephalosporins

Assessment

- Assess for allergy to cephalosporins or penicillins. If a patient is allergic to one type or class of cephalosporin, that patient should not receive any other type of cephalosporin or penicillin.
- Record vital signs and urine output. Report abnormal findings, which may include elevated temperature or decreased urine output.
- Evaluate laboratory results, especially those that indicate renal and liver function (BUN, serum creatinine, AST, ALT, ALP, and bilirubin). Use these laboratory results for baseline values, and report any abnormal findings.

Nursing Diagnoses

- Skin Integrity, Risk for Impaired
- Infection, Risk for
- Noncompliance with the drug regimen related to lack of knowledge relevant to regimen behavior
- Nutrition, Imbalanced: Less than Body Requirements related to nausea and vomiting

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Culture the infected area before cephalosporin therapy is started. The organism causing the infection can be determined by culture, and the antibiotics the organism is sensitive to are determined by sensitivity. If antibiotic therapy is started before culture result is reported, the antibiotic may need to be changed after C&S test results are received.

Patient Teaching

General

- Keep drugs out of reach of children. Request childproof containers.
- Tell patients to report signs of superinfection, such as mouth ulcers or discharge from the anal or genital area.
- Advise patients to ingest buttermilk, yogurt, or an acidophilus supplement to prevent superinfection of the intestinal flora.

TABLE 26.6

Antibacterials: Cephalosporins

Generic	Route and Dosage	Uses and Considerations
First Generation		
Cefadroxil	UTI: A: PO: 1-2 g/d in 1-2 divided doses for 3-7 d; *max:* 2 g/d Adol/C/infants: PO: 30 mg/kg/d in 2 divided doses; *max:* 30 mg/kg/d	For treating pharyngitis, tonsillitis, and urinary tract and skin infections. May cause anaphylaxis, angioedema, fever, rash, arthralgia, GI distress, CDAD, elevated hepatic enzymes, nephritis, superinfection, and Stevens-Johnson syndrome. Well absorbed by the GI tract and not affected by food. Pregnancy category: B*; PB: UK; t½: 1-2 h
Cefazolin sodium	URI and UTI: A: IM/IV: 250 mg-1 g q8h; *max:* 12 g/d Adol/C/infants >1 mo: IM/IV: 25-100 mg/kg/d in 3 divided doses; *max:* 6 g/d	For treating endocarditis, septicemia, and skin, bone/joint, biliary, respiratory, and urinary tract infections. May cause anaphylaxis, angioedema, rash, GI distress, CDAD, superinfection, seizures, injection site reaction, Stevens-Johnson syndrome, and elevated hepatic enzymes. Pregnancy category: B*; PB: 75%-85%; t½: 1-2 h
Cephalexin	URI: A: PO: 250-500 mg q6-12h; *max:* 4 g/d Adol/C: PO: 25-100 mg/kg/d in 2-4 divided doses; *max:* 4 g/d	For treating otitis media and skin, bone/joint, respiratory, and urinary tract infections. May cause anaphylaxis, nephritis, GI distress, CDAD, rash, elevated hepatic enzymes, eosinophilia, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 10%-15%; t½: 1 h
Second Generation		
Cefaclor	URI: Immediate release: A/adol: PO: 250-500 mg q8h; *max:* 1.5 g/d C/infants >1 mo: PO: 20-40 mg/kg/d divided q8h; *max:* 1 g/d Extended release: A/adol >16 y: PO: 375 mg q12h for 10 d; *max:* 1 g/d	For pharyngitis, tonsillitis, otitis media, and skin, skin structures, respiratory, and urinary tract infections. May cause anaphylaxis, headache, rhinitis, rash, GI distress, CDAD, seizure, Stevens-Johnson syndrome, and superinfection. Pregnancy category: B*; PB: 25%; t½: 1 h
Cefotetan	UTI: A: IM/IV: 500 mg-2 g q12-24h; *max:* 6 g/d	For treating PID and gynecologic, intraabdominal, respiratory, urinary tract, skin, and bone/joint infections. May cause anaphylaxis, angioedema, GI distress CDAD, seizures, bleeding, hypoprothrombinemia, anemia, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 75%-90%; t½: 3-4.5 h
Cefoxitin sodium	Respiratory infection: A: IM/IV: 1-2 g q6-8h; *max:* 12 g/d Adol/C/infants >3 mo: IM/IV: 80-100 mg/kg/d in divided doses q6-8h; *max:* 12 g/d	For treating septicemia and intraabdominal, gynecologic, skin, respiratory, bone/joint, and urinary tract infections. May cause anaphylaxis, GI distress, anemia, seizure, renal dysfunction, Stevens-Johnson syndrome, and superinfection. Pregnancy category: B*; PB: 73%; t½: 40-60 min
Cefprozil monohydrate	Skin infection: A: PO: 250-500 mg/d or q12h for 10 d; *max:* 1 g/d C 2-12 y: PO: 20 mg/kg q12h for 10 d; *max:* 30 mg/kg/d	For treating otitis media and respiratory and skin infections. May cause anaphylaxis, angioedema, GI distress, CDAD, elevated hepatic enzymes, Stevens-Johnson syndrome, and superinfection. Pregnancy category: B*; PB: 36%; t½: 1.3 h
Cefuroxime	Respiratory infection: A/adol: PO: 250-500 mg q12h for 5-10 d A: IM/IV: 750 mg-1.5 g q8h Adol/C/infants >3 mo: IM/IV: 50-100 mg/kg/d in divided doses q6-8h	For treating meningitis, Lyme disease, otitis media, gonorrhea, septicemia, and skin, respiratory, urinary tract, and bone/joint infections. May cause anaphylaxis, rash, GI distress, CDAD, elevated hepatic enzymes, seizure, Stevens-Johnson syndrome, and superinfection. Pregnancy category: B*; PB: 33%-50%; t½: 1-2 h
Third Generation		
Cefdinir	Skin infection: A/adol: PO: 300 mg q12h for 10 d; *max:* 600 mg/d	For treating otitis media, acute sinusitis, tonsillitis, and respiratory, and skin infections. May cause anaphylaxis, headache, rash, GI distress, CDAD, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 60%-70%; t½: 1.7 h
Cefixime	Respiratory infection: A/adol/C >45 kg: PO: 400 mg/d in divided doses q12-24h; *max:* 400 mg/d Infant >6 mo/C <45 kg: PO: 8 mg/kg/d in divided doses q12-24h; *max:* 8 mg/kg/d	For treating otitis media, tonsillitis, gonorrhea, and respiratory and urinary tract infections. May cause anaphylaxis, headache, dizziness, GI distress, CDAD, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 65%-70%; t½: 3-4 h
Cefotaxime	A/adol/C >50 kg: IM/IV: 1-2 g q6-12h; *max:* 12 g/d Adol/C/infants <50 kg: IM/IV: 50-225 mg/kg/d in divided doses q4-8h; *max:* 225 mg/kg/d	For treating bacteremia, septicemia, meningitis, typhoid fever and gynecologic, skin, bone/joint, intraabdominal, respiratory, and urinary tract infections. May cause anaphylaxis, rash, pruritus, GI distress, CDAD, nephritis, eosinophilia, injection site reaction, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 13%-38%; t½: 1-2 h

Table Continued

Third Generation		
Cefpodoxime	Respiratory infection: A/adol/C >12 y: PO: 200 mg q12h for 14 d; *max:* 800 mg/d	For treating otitis media, tonsillitis, sinusitis, gonorrhea, proctitis, and skin, respiratory, and urinary tract infections. May cause anaphylaxis, headache, rash, GI distress, CDAD, superinfection, and nephritis. Food enhances drug absorption. Pregnancy category: B*; PB: 22%-33%; t½: 3 h
Ceftazidime	Intraabdominal infection: A: IM/IV: 1-2 g q8-12h; *max:* 6 g/d C/infants >1 mo: IV: 30-50 mg/kg q8h; *max:* 150 mg/kg/d	For treating bacteremia, meningitis and gynecologic, intraabdominal, skin, respiratory, bone/joint, and urinary tract infections. May cause anaphylaxis, angioedema, dizziness, injection site reaction, GI distress, CDAD, eosinophilia, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 10%; t½: 1.5-2 h
Ceftriaxone	See Prototype Drug Chart 26.2.	
Ceftibuten	Bronchitis: A/adol/C >12 y: PO: 400 mg/d for 10 d; *max:* 400 mg/d	For treating otitis media, tonsillitis, and respiratory infections. May cause anaphylaxis, rash, fever, dysgeusia, GI distress, CDAD, superinfection, eosinophilia, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 65%; t½: 2-2.5 h
Cefditoren	A/adol/C >12 y: PO: 200-400 mg bid for 10-14 d; *max:* 800 mg/d	For treating tonsillitis and respiratory and skin infections. May cause anaphylaxis, dizziness, headache, GI distress, CDAD, hematuria, hyperglycemia, superinfection, and Stevens-Johnson syndrome. Avoid in patients with milk-protein hypersensitivity. Pregnancy category: B*; PB: 88%; t½: 1.6 h
Ceftazidime and avibactam	Urinary tract infection: A: IV: 2 g ceftazidime/0.5 g avibactam over 2 h q8h for 7-14 d; *max:* 6 g ceftazidime/1.5 g avibactam/d	For treating intraabdominal and urinary tract infections. May cause anxiety, headache, dizziness, rash, dysgeusia, GI distress, constipation, CDAD, elevated hepatic enzymes, hypokalemia, superinfection, and renal dysfunction. Pregnancy category: B*; PB: 5%-10%; t½: 1.5-2 h

Fourth Generation		
Cefepime	Moderate to severe pneumonia: A/adol >16 y: IV: 1-2 g q12h for 10 d; *max:* 6 g/d Adol <16 y/C/infants >2 mo: IV: 50 mg/kg q12h for 10 d; *max:* 150 mg/kg/dose	For treating bacteremia and respiratory, skin, intraabdominal, and urinary tract infections. May cause anaphylaxis, headache, confusion, fever, rash, GI distress, CDAD, hallucinations, seizure, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 16%-19%; t½: 2-2.3 h

Fifth Generation		
Ceftaroline fosamil	A/ adol >33 kg: IV: 600 mg q12h for 5-14 d; *max:* 1200 mg/d	For treating skin and respiratory infections. May cause anaphylaxis, headache, fever, rash, GI distress, and CDAD. Pregnancy category: B * PB: 20%; t½: 1.6-2.6 h
Ceftolozane and tazobactam	Intraadbdominal infection: A: IV: 1 g ceftolozane/0.5 g tazobactam q8h for 4-14 d; *max:* 3 g ceftolozane/1.5 g tazobactam/d	For treating intraabdominal and urinary tract infections. May cause headache, insomnia, GI distress, constipation, CDAD, fever, and hypokalemia. Pregnancy category: B*; PB: 16%-30%; t½: 0.91-3.12 h

A, Adult; *adol,* adolescent; *bid,* two times a day; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscularly; *IV,* intravenously; *max,* maximum; *min,* minutes; *mo,* month; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *q,* every; *t½,* half-life; *UK,* unknown; *URI,* upper respiratory infection; *UTI,* urinary tract infection; *y,* years; <, less than; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

- Instruct patients to take the complete course of medication, even when symptoms of infection have ceased.
- Infuse all IV cephalosporins over 30 minutes or as ordered to prevent pain and irritation.
- Observe for hypersensitivity reactions.

Side Effects

- Warn patients to report any side effects from use of oral cephalosporin drugs; these may include anorexia, nausea, vomiting, headache, dizziness, itching, and rash.

Diet

- Advise patients to take medication with food if gastric irritation occurs.
- Encourage patients to take an adequate amount of fluids to avoid dehydration from diarrhea.

Cultural Considerations

- Allow adequate time for information processing for patients whose first language is not English. Failing to do so may result in an inaccurate response or no response.
- Provide time for patients to respond to questions, especially when there is a language barrier.
- Speak clearly and slowly, giving time for translation. Obtain an interpreter if necessary.

Evaluation

- Evaluate the effectiveness of the cephalosporin by determining whether the infection has ceased and that no side effects, including superinfection, have occurred.

SECTION 26B

Macrolides, Oxazolidinones, Lincosamides, Glycopeptides, Ketolides, Tetracyclines, and Glycylcyclines

Macrolides

Macrolide antibiotics—which include azithromycin, clarithromycin, and erythromycin—are called *broad-spectrum antibiotics*. Erythromycin, the first macrolide, was derived from the funguslike bacteria *Streptomyces erythreus* and was first introduced in the early 1950s. Macrolides bind to the 50S ribosomal subunits and inhibit protein synthesis. At low to moderate drug doses, macrolides have a bacteriostatic effect, and with high drug doses, their effect is bactericidal. Macrolides can be administered orally or by IV but not intramuscularly because it is too painful. IV macrolides should be infused slowly to avoid unnecessary pain (phlebitis).

Gastric acid destroys erythromycin in the stomach, therefore acid-resistant salts are added (e.g., ethylsuccinate, stearate, estolate) to decrease breakdown into small particles (dissolution) in the stomach. This allows the drug to be absorbed in the intestine. Normally, food does not hamper the absorption of acid-resistant macrolides. Table 26.7 lists the dosages, uses, and considerations of macrolides.

Macrolides are active against most gram-positive bacteria and are moderately active against some gram-negative bacteria, although resistant organisms may emerge during treatment. Macrolides are used to treat mild to moderate infections of the respiratory tract, sinuses, GI tract, and skin and soft tissue in addition to treating diphtheria, impetigo contagiosa, and sexually transmitted infections (STIs).

Erythromycin is the drug of choice for the treatment of mycoplasmal pneumonia and Legionnaires' disease. Clarithromycin is also available in a once-a-day extended-release tablet to be taken for 7 days. Azithromycin is frequently prescribed for upper and lower respiratory infections, STIs, and uncomplicated skin infections. Table 26.7 lists the drugs developed from the derivatives of erythromycin, and Prototype Drug Chart 26.3 details the pharmacologic behavior of azithromycin.

Pharmacokinetics

Clarithromycin and erythromycin are readily absorbed from the GI tract, mainly by the duodenum. Azithromycin is incompletely absorbed from the GI tract, and only 37% reaches systemic circulation. Azithromycin and erythromycin can be administered intravenously, but intermittent infusions should be diluted in normal saline (NS) or in 5% dextrose in water (D_5W) to prevent phlebitis or burning sensations at the injection site. Azithromycin 500 mg should be diluted in 250 to 500 mL of fluid, and erythromycin lactobionate 1 g should be diluted in 200 to 1000 mL. Macrolides are excreted in bile, feces, and urine. Because only a small amount is excreted in urine, renal insufficiency is not a contraindication for macrolide use.

Pharmacodynamics

Macrolides suppress bacterial protein synthesis. The onset of action of oral preparations of erythromycin is 1 hour, peak concentration time is 4 hours, and duration of action is 6 hours. Newer macrolides have a longer half-life and are administered less frequently. Clarithromycin is administered twice a day for immediate release, and the extended-release formulation is administered once a day. Azithromycin has up to a 40- to 68-hour half-life and is prescribed to be taken only once a day for 5 days.

Side Effects and Adverse Reactions

Side effects and adverse reactions to macrolides include GI disturbances such as nausea, vomiting, diarrhea, and abdominal cramping. Severe diarrhea occurs when antibacterials kill normal flora, allowing an overgrowth of *Clostridium difficile.* This superinfection is called *Clostridium difficile*–associated diarrhea (CDAD), also known as pseudomembraneous colitis. A release of bacterial toxins causes injury, inflammation, and bleeding in the colon lining. This condition causes abdominal cramping, 5 to 10 watery diarrheal stools per day, and bloody stools. Frequency of stools may increase to 20 per day in severe cases. Conjunctivitis may develop as a side effect of azithromycin, and the patient should avoid wearing contact lenses if this occurs. Allergic reactions to erythromycin are rare. **Hepatotoxicity** (liver toxicity) can occur when erythromycin and azithromycin are taken in high doses with other hepatotoxic drugs, such as acetaminophen (high doses), phenothiazines, and sulfonamides. Liver damage is usually reversible when the drug is

discontinued. Erythromycin should not be taken with clindamycin or lincomycin because they compete for receptor sites.

TABLE 26.7

Antibacterials: Macrolides, Oxazolidinones, Lincosamides, Glycopeptides, Ketolides, and Lipopeptides

Generic	Route and Dosage	Uses and Considerations
Macrolides		
Azithromycin	See Prototype Drug Chart 26.3.	
Clarithromycin	Skin infections: Immediate release: A: PO: 250 mg q12h for 7-14 d; *max:* 1 g/d Adol/C/infants >6 mo: PO: 7.5 mg/kg q12h for 10 d; *max:* 15 mg/kg/d	For treating otitis media, tonsillitis, duodenal ulcer due to *Helicobacter pylori,* and skin, respiratory, and soft-tissue infections. May cause anaphylaxis, headache, insomnia, rash, dysgeusia, tooth discoloration, GI distress, CDAD, superinfection, myasthenia, seizures, Stevens-Johnson syndrome, and renal failure. Pregnancy category: C*; PB: 42%-70%; t½: 3-7 h
Erythromycin base	Respiratory infections: A: PO: 250-500 mg q6h; *max:* 4 g/d Adol/C/infants: PO: 30-50 mg/kg/d in divided doses; *max:* 2 g/d A/adol/C/infants: IV: 15-20 mg/kg/d in divided doses q6h; *max:* 4 g/d	For treating acne, impetigo, tonsillitis, urethritis, STIs, Legionnaires' disease, PID, diphtheria, and respiratory and skin infections. May cause skin irritation, reversible hearing loss, superinfection, dysrhythmias, GI distress, CDAD, seizures, elevated hepatic enzymes, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 73%-81%; t½: 1.5-2 h
Fidaxomicin	A: PO: 200 mg bid for 10 d; *max:* 400 mg/d	For treating CDAD. May cause anaphylaxis, angioedema, anemia, neutropenia, GI distress and bleeding, and elevated hepatic enzymes. Pregnancy category: B *; PB: UK; t½: 6.9-16.5 h
Oxazolidinones		
Linezolid	Respiratory infection: A/adol/C >12 y: PO/IV: 600 mg q12h for 10-14 d; *max:* 1200 mg/d C <12 y/infants/neonates: PO/IV: 10 mg/kg q8h for 10-14 d; *max:* 10 mg/kg q8h	For treating bacteremia, sepsis, MRSA, VREF, and respiratory and skin infections. May cause anaphylaxis, headache, rash, seizure, tongue/tooth discoloration, GI distress, dizziness, thrombocytopenia, anemia, peripheral neuropathy, CDAD, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 31%; t½: 4.26-5.4 h
Tidezolid	A: PO/IV: 200 mg/d for 6 d; *max:* 200 mg/d	For treating skin infections. May cause headache, GI distress, CDAD, anemia, neutropenia, thrombocytopenia, peripheral neuropathy, and serotonin syndrome. Pregnancy category: C*; PB: 70%-90%; t½: 12 h
Lincosamides		
Clindamycin hydrochloride	Lower respiratory infection: A: PO: 150-450 mg q6h for 7-21 days Adol/C: PO: 8-20 mg/kg/d divided doses q6-8h A/adol >16y: IM/IV: 300 mg q6-12h; *max:* 2700 mg/d Adol <16y/C/infants: IM/IV: 20-40 mg/kg/d in divided doses q6-8h	For treating PID, acne, bacteremia, septicemia, MRSA, and respiratory, intraabdominal, skin, gynecologic, and bone/joint infections. May cause anaphylaxis, xerosis, dysgeusia, GI distress, CDAD, erythema, pruritus, elevated hepatic enzymes, superinfection, and Stevens-Johnson syndrome. Should be taken with full glass of water. Pregnancy category: B*; PB: 92%-94%; t½: 2-3 h
Lincomycin	A: IM: 600 mg q12-24h Adol/C/Infants >1 mo: IM: 10 mg/kg q12-24h A: IV: 600 mg-1 g q8-12h; *max:* 8 g/d Adol/C/Infants >1 mo: IV: 10-20 mg/kg/d in divided doses q8-12h; *max:* 20 mg/kg/d	For treating bacteremia, septicemia, and intraabdominal, respiratory, bone/joint, and skin infections. May cause anaphylaxis, angioedema, glossitis, stomatitis, GI distress, CDAD, pancytopenia, Stevens-Johnson syndrome, superinfection, injection site reaction, and hypotension if given by too-rapid IV infusion. Pregnancy category: B*; PB: 72%; t½: 2-11.5 h
Glycopeptides		
Vancomycin hydrochloride	*Clostridium difficile* infection: A: PO: 125 mg four times daily for 10 d; *max:* 2 g/d Therapeutic range: Trough: 10-20 mcg/mL	For treating bacteremia, septicemia, endocarditis, MRSA, CDAD, and respiratory, skin, and bone/joint infections. May cause anaphylaxis, hypotension, fever, headache, flushing, GI distress, peripheral edema, hypokalemia, neutropenia, ototoxicity, nephrotoxicity, disulfiram-like reaction to alcohol, red man syndrome, superinfection, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 55%; t½: 4-6 h
Oritavancin	Skin infection: A: IV: 1200 mg as a single dose over 3 h; *max:* 1200 mg	For treating skin infections, MRSA, and cellulitis. May cause angioedema, wheezing, bronchospasm, dizziness, headache, phlebitis, peripheral edema, elevated hepatic enzymes, GI distress, and CDAD. Pregnancy category: C*; PB: 85%; t½: 245 h
Telavancin	A: IV: 10 mg/kg/d over 60 min for 7-21 d; *max:* 10 mg/kg/d	For treating MRSA and respiratory and skin infections. May cause anaphylaxis, headache, insomnia, chills, dizziness, pruritus, rash, dysgeusia, GI distress, CDAD, red man syndrome, nephrotoxicity, and superinfection. Pregnancy category: C*; PB: 93%; t½: 8-9 h
Ketolides		
Telithromycin	A: PO: 800 mg/d for 7-10 d; *max:* 800 mg/d	For treating MRSA and community-acquired pneumonia. May cause anaphylaxis, dizziness, dysgeusia, GI distress, CDAD, hepatotoxicity, dysrhythmias, and myasthenia. Pregnancy category: C*; PB: 60%-70%; t½: 10 h
Lipopeptides		
Daptomycin	Skin infection: A: IV: 4 mg/kg/d for 7-14 d; *max:* 6 mg/kg/d	For treating MRSA, endocarditis, bacteremia, and skin infections. May cause anaphylaxis, rash, pruritis, anemia, insomnia, GI distress, edema, chest pain, hypertension, headache, hyperhidrosis, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 90%-93%; t½: 7.7-8.3 h

A, Adult; *Adol,* adolescent; *bid,* twice daily; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minutes; *mo,* month; *MRSA*, methicillin-resistant *Staphylococcus aureus*; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *q,* every; *STI,* sexually transmitted infection; *t½,* half-life; *UK,* unknown; *VREF,* vancomycin-resistant *Enterococcus faecium*; *wk,* weeks; *y,* years; <, less than; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 26.3 Azithromycin

Drug Class	Dosage
Antibacterial macrolide Pregnancy category: B*	Upper respiratory infection: A: PO: 500 mg on day 1, then follow with 250 mg/d for 4 days
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, hepatic dysfunction *Caution:* Bradycardia, hypokalemia, hypomagnesemia, dysrhythmias, renal dysfunction	Drug: Increases effects of digoxin, cyclosporine, and warfarin; decreases effects of penicillins and clindamycin
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: 38% absorbed Distribution: PB: 51% Metabolism: t½: 68 h Excretion: In bile, a small amount in urine	PO: Onset, duration: UK Peak: 2-3 h Extended release: Peak: 5 h IV: Onset, duration, peak: UK
Therapeutic Effects/Uses	
For treating bacterial conjunctivitis, otitis media, tonsillitis, sinusitis, PID, STIs, and skin and respiratory infections. For patients who are allergic to penicillin. Azithromycin is effective against species of *Clostridium, Haemophilus, Chlamydia, Mycobacterium, Neisseria, Staphyloccus,* and *Streptococcus.*	
Mode of Action: Inhibits the steps of protein synthesis; bacteriostatic or bactericidal effect	
Side Effects	**Adverse Reactions**
Blurred vision, ocular irritation, photosensitivity, headache, tinnitus, drowsiness, dizziness, fever, fatigue, tongue discoloration, dysgeusia, anorexia, nausea, vomiting, diarrhea, abdominal cramps, pruritus, rash, injection site reaction, weakness	Superinfection, hearing loss, angioedema, seizures, elevated hepatic enzymes, hyperbilirubinemia *Life threatening:* Hepatotoxicity, anaphylaxis, bronchospasm, CDAD, leukopenia, anemia, Stevens-Johnson syndrome

A, Adult; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *h,* hour; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *STI,* sexually transmitted infection; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Drug Interactions

Macrolides can increase serum levels of theophylline (a bronchodilator), carbamazepine (an anticonvulsant), and warfarin (an anticoagulant). If these drugs are given with macrolides, their drug serum levels should be closely monitored. To avoid severe toxic effects, erythromycin should not be used with other macrolides. Antacids may reduce azithromycin peak levels when taken at the same time.

Extended Macrolide Group

Derivatives of erythromycin have been effective in the treatment of numerous organisms. Like erythromycin, they also inhibit protein synthesis. Many of these macrolides have a longer half-life and are administered once a day. After the introduction of erythromycin, the first extended macrolide drug developed was clarithromycin, which has been effective against many bacterial infections. Clarithromycin is administered twice a day for immediate-release form, and the extended-release formulation is given once a day. Another extended macrolide is azithromycin. This drug has a long half-life of 40 to up to 68 hours, therefore it is only prescribed once a day for 5 days.

Elimination of these drugs is via bile and feces. Azithromycin is frequently prescribed for upper and lower respiratory tract infections, STIs, and uncomplicated skin infections.

When erythromycin is given concurrently with verapamil, diltiazem, clarithromycin, fluconazole, ketoconazole, and itraconazole, erythromycin blood concentration and the risk of sudden cardiac death increase. Table 26.7 lists the drugs developed from the derivatives of erythromycin.

Common side effects of clarithromycin are nausea, diarrhea, and abdominal discomfort. With azithromycin, the side effects of nausea, diarrhea, and abdominal pain are common.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Macrolides

Assessment

- Assess vital signs and urine output. Report abnormal findings.
- Check laboratory tests (liver enzyme values) to determine liver function. Order liver enzyme tests periodically for patients taking large doses of azithromycin for a continuous period.
- Obtain a history of drugs the patient currently takes. The peak level of azithromycin may be decreased by antacids.

Nursing Diagnoses

- Infection, Risk for
- Tissue Integrity, Risk for Impaired

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Obtain a sample from the infected area and send it to the laboratory for C&S testing before starting azithromycin therapy. Antibiotic therapy can be initiated after obtaining the culture sample.
- Monitor vital signs, urine output, and laboratory values, especially liver enzymes (ALP, ALT, AST, and bilirubin).
- Monitor the patient for liver damage resulting from prolonged use and high dosage of macrolides such as azithromycin. Signs of liver dysfunction include elevated liver enzyme levels and jaundice.
- Administer oral azithromycin 1 hour before or 2 hours after meals. Give with a full glass of water, *not* fruit juice. Give the drug with food if GI upset occurs. Chewable tablets should be chewed, *not* swallowed whole.
- Dilute in an appropriate amount of solution as indicated in the drug circular for IV azithromycin.
- Administer antacids either 2 hours before or 2 hours after azithromycin.

Patient Teaching

General

- Instruct patients to take the full course of the antibacterial agent as prescribed. Drug compliance is most important for all antibacterials (antibiotics).

Side Effects

- Encourage patients to report side effects, including adverse reactions (nausea, vomiting, diarrhea, abdominal cramps, itching).
- Teach patients to report any evidence of superinfection, secondary infection resulting from drug therapy; for some patients, stomatitis or vaginitis may occur.
- Tell patients to report the onset of loose stools or diarrhea. CDAD should be ruled out.

Cultural Considerations

- Recognize that patients and family members from various cultural backgrounds may need a written schedule that shows when the drug should be taken. Have instructions available in the language the patient speaks or reads most easily, and emphasize reporting possible side effects to the health care provider.

Evaluation

- Evaluate the effectiveness of azithromycin by determining whether the infection has been controlled or has ceased and that no side effects, including superinfection, have occurred.

Oxazolidinones

Like macrolides, oxazolidinones inhibit protein synthesis on the 50S ribosomal subunit of bacteria. This action prevents formation of 70S initiation complex which is necessary for bacterial reproduction. Linezolid and tidezolid are examples of oxazolidinones. Drugs in this antibacterial classification are bacteriostatic or bactericidal and are effective against gram-positive infections. Table 26.7 lists the oxazolidinones.

Side Effects and Adverse Reactions

Side effects and adverse reactions to linezolid and tidezolid include headache, nausea, vomiting, diarrhea, anemia, and thrombocytopenia. Rash may also occur. Severe adverse reactions include CDAD and serotonin syndrome.

Lincosamides

Like erythromycin, lincosamides inhibit bacterial protein synthesis and have both bacteriostatic and bactericidal actions, depending on drug dosage. Clindamycin and lincomycin are examples of lincosamides. Clindamycin is more widely prescribed than lincomycin because it is active against most gram-positive organisms, including *S. aureus* and anaerobic organisms. It is not effective against gram-negative bacteria (e.g., *E. coli* and *Proteus* and *Pseudomonas* species). Clindamycin is absorbed better than lincomycin through the GI tract and maintains a higher serum drug concentration. Clindamycin is considered more effective than lincomycin and has fewer toxic effects. Table 26.7 lists the lincosamides.

Side Effects and Adverse Reactions

Side effects and adverse reactions to clindamycin and lincomycin include GI irritation, which may manifest as nausea, vomiting, and stomatitis. Rash may also occur. Severe adverse reactions include colitis and anaphylactic shock.

Drug Interactions

Clindamycin and lincomycin are incompatible with aminophylline, phenytoin, barbiturates, and ampicillin.

Glycopeptides

Vancomycin, a glycopeptide bactericidal antibiotic, was widely used in the 1950s to treat staphylococcal infections. Vancomycin is used against drug-resistant *S. aureus* and in cardiac surgical prophylaxis for individuals with penicillin allergies. Serum vancomycin levels should be monitored.

Vancomycin has become ineffective for treating enterococci. Quinupristin-dalfopristin is a combined antibacterial used to treat life-threatening VREF infections. Antibiotic-resistant enterococci can cause staphylococcal endocarditis.

Telavancin, a glycopeptide, treats selected gram-positive bacteria and skin infections. This drug is a semisynthetic derivative of vancomycin with bactericidal action against MRSA. Telavancin has an advantage of once-daily dosing. Oritavancin has the further advantage of being administered in a single dose.

Pharmacokinetics

Vancomycin is given orally for treatment of staphylococcal enterocolitis and antibiotic-associated pseudomembranous colitis due to *C. difficile.* When vancomycin is given orally, it is not absorbed systemically and is excreted in the feces. Vancomycin is also given intravenously for septicemia, for severe infections due to MRSA, and for bone, skin, and lower respiratory tract infections that do not respond or are resistant to other antibiotics. Intermittent vancomycin doses should be diluted in 100 mL for 500 mg and 200 mL for 1 g of D_5W, NS, or Lactated Ringer's (LR) and should be administered over 60 to 90 minutes. Vancomycin is excreted in the urine when given by IV route. It is 55% protein bound, and the half-life is 4 to 6 hours.

Pharmacodynamics

Vancomycin inhibits bacterial cell-wall synthesis and is active against several gram-positive microorganisms. The peak action is 30 minutes after the end of the infusion.

Side Effects and Adverse Reactions

Vancomycin may cause nephrotoxicity and ototoxicity. **Ototoxicity** results in damage to the auditory or vestibular branch of cranial nerve VIII. Such damage can result in permanent hearing loss (auditory branch) or temporary or permanent loss of balance (vestibular branch). Side effects may include chills, dizziness, fever, rashes, nausea, vomiting, and thrombophlebitis at the injection site. Too-rapid injection of IV vancomycin can cause a condition known as *red man syndrome* or *red neck syndrome.* Characterized by red blotching of the face, neck, and chest, this is a toxic effect rather than an allergic reaction. Other adverse effects include eosinophilia, neutropenia, and Stevens-Johnson syndrome. Severe hypotension, tachycardia, generalized tingling, and, rarely, cardiac arrest are also known adverse reactions.

Drug Interactions

Dimenhydrinate can mask ototoxicity when taken with vancomycin. The risk of nephrotoxicity and ototoxicity may be potentiated when vancomycin is taken with furosemide, aminoglycosides, amphotericin B, colistin, cisplatin, and cyclosporine. Vancomycin may inhibit methotrexate excretion and can increase methotrexate toxicity. The absorption of oral vancomycin may be decreased when given with cholestyramine and colestipol.

Ketolides

Ketolides are structurally related to macrolides. The first drug in this class, telithromycin, is used for adults 18 years of age and older to treat mild to moderate community-acquired pneumonia. This disorder is usually caused by *S. pneumoniae* and *H. influenzae.*

Pharmacokinetics

Telithromycin is given orally and is well absorbed by the GI tract; it is unaffected by food intake. Telithromycin is excreted in the feces and urine. It is 60% to 70% protein bound, and the half-life is 10 hours.

Pharmacodynamics

Telithromycin inhibits protein synthesis in microorganisms by binding to the bacterial ribosomal RNA site of the 50S subunit, resulting in bacterial cell death. The peak action is 1 hour.

Side Effects and Adverse Reactions

Side effects and adverse reactions to telithromycin include visual disturbances (blurred vision and diplopia), headache, dizziness, altered taste, nausea, vomiting, diarrhea, and liver failure. Telithromycin may also lead to an exacerbation of myasthenia gravis.

Drug Interactions

Telithromycin levels are increased when taken concurrently with antilipidemics (simvastatin, lovastatin, and atorvastatin), itraconazole, ketoconazole, and benzodiazepines. Class 1A or class III antidysrhythmics may lead to life-threatening dysrhythmias. Blood levels of telithromycin are decreased when taken with rifampin, phenytoin, carbamazepine, or phenobarbital, producing a subtherapeutic drug level. Telithromycin can increase levels of cisapride and pimozide, which can lead to toxicity; these two drugs are therefore contraindicated for the patient taking telithromycin. Digoxin, metoprolol, midazolam, ritonavir, sirolimus, and tacrolimus levels are increased when taken concurrently with telithromycin. Concurrent use of telithromycin with ergot alkaloid derivatives leads to ergot toxicity (severe peripheral vasospasm and impaired sensation).

Tetracyclines

Tetracyclines, isolated from *Streptomyces aureofaciens* in 1948, were the first broad-spectrum antibiotics effective against gram-positive and gram-negative bacteria and many other organisms—mycobacteria, rickettsiae, spirochetes, and chlamydiae, to name a few. Tetracyclines act by inhibiting bacterial protein synthesis and have a bacteriostatic effect.

Tetracyclines are not effective against *S. aureus* (except for the newer tetracyclines), nor are they effective against *Pseudomonas* or *Proteus* species, but they can be used against *Mycoplasma pneumoniae.* Tetracycline in combination with metronidazole and bismuth subsalicylate is useful in treating *Helicobacter pylori,* a bacterium in the stomach that can cause peptic ulcer. For years, oral and topical tetracyclines have been used to treat severe acne vulgaris, and low doses are usually prescribed to minimize the toxic effect of the drug.

The tetracyclines are frequently prescribed for oral use, although they are also available for IV use to treat severe infections (Prototype Drug Chart 26.4). The newer oral preparations of tetracyclines (i.e., doxycycline, minocycline) are more rapidly and completely absorbed. Tetracyclines should not be taken with magnesium and aluminum antacid preparations, milk products containing calcium, or iron-containing drugs because these substances bind with tetracycline and prevent absorption of the drug. It is suggested that tetracyclines, except for doxycycline and minocycline, be taken on an empty stomach 1 hour before or 2 hours after mealtime; the absorption of doxycycline and minocycline is improved with food ingestion. Table 26.8 describes the tetracycline preparations and their dosages, uses, and considerations. The tetracyclines are listed according to whether they are short-, intermediate-, or long-acting drugs.

Although tetracyclines are widely used, they have numerous side effects, adverse reactions, toxicities, and drug interactions.

Side Effects and Adverse Reactions

GI disturbances such as nausea, vomiting, and diarrhea are side effects of tetracyclines. **Photosensitivity** (sunburn reaction) may occur in persons taking tetracyclines, especially demeclocycline. Pregnant patients should *not* take tetracycline during the first trimester of pregnancy because of possible teratogenic effects. Women in the last trimester of pregnancy and children younger than 8 years of age should also *not* take tetracycline because it irreversibly discolors the permanent teeth. Minocycline can cause damage to the vestibular part of the inner ear, which may result in difficulty maintaining balance. Outdated tetracyclines should always be discarded, because the drug breaks down into a toxic by-product. Nephrotoxicity (kidney toxicity) results when tetracycline is given in high doses with other nephrotoxic drugs. Because tetracycline can disrupt the microbial flora of the body, superinfection (secondary infection resulting from drug therapy) is another adverse reaction that might result.

PROTOTYPE DRUG CHART 26.4 Doxycycline

Drug Class	Dosage
Antibacterial: Tetracycline Pregnancy category: D*	Urinary track infection: A/adol/C >8 y, >45 kg: PO: 100 mg q12h on day 1, then 100 mg/d C >8 y, <45 kg: PO: 2.2 mg/kg q12h on day 1, then 2.2 mg/kg/d A/adol/C >8 y, >45 kg: IV: 200 mg on day 1, then 100-200 mg/d C >8 y, <45 kg: IV: 4.4 mg/kg on day 1, then 2.2-4.4 mg/kg/d in 1-2 divided doses
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity, sulfite hypersensitivity *Caution:* Renal and hepatic dysfunction, photosensitivity, hyperpigmentation	Drug: May increase effects of digoxin and warfarin; doxycycline absorption decreases with sucralfate, antacids, iron, calcium, magnesium, zinc, barbiturates, phenytoin, quinapril, and rifampin; decreases effects of oral contraceptives, ciprofloxacin, and penicillin; may alter lithium levels Lab: Decreases serum potassium level Food: Dairy products decrease effect.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 100% absorbed Distribution: PB: 23%-93% Metabolism: t½: 14-24 h Excretion: Urine and feces	PO: Onset, duration: UK Peak: 1.5-4 h IV: Onset: Rapid Peak, duration: UK
Therapeutic Effects/Uses	
For treating acne, anthrax, amebiasis, gingivitis, plague, STIs, rickettsia, and respiratory, urinary tract, and skin infections. Doxycycline is effective against *Escherichia coli* and MRSA, and species of *Clostridium, Haemophilus, Enterococcus, Chlamydia, Neisseria, Klebsiella, Staphylococcus, Streptococcus, and Shigella.*	
Mode of Action: Inhibits the steps of protein synthesis; bacteriostatic or bactericidal	
Side Effects	Adverse Reactions
Abdominal pain, glossitis, dry mouth, tooth/nail discoloration, nausea, vomiting, diarrhea, headache, vision changes, diplopia, photosensitivity, rash, pruritus, injection site reaction	Superinfection, angioedema, hypertension, renal dysfunction *Life threatening:* Anaphylaxis, anemia, eosinophilia, thrombocytopenia, hepatotoxicity, increased intracranial pressure, CDAD, Stevens-Johnson syndrome

A, Adult; *adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *h,* hour; *IV,* intravenous; *MRSA,*

methicillin-resistant *Staphylococcus aureus*; *PB,* protein binding; *PO,* by mouth; *q,* every; *STI,* sexually transmitted infection; *t½,* half life; *UK,* unknown; *UTI,* urinary tract infection; *y,* year; <, less than; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 26.8

Antibacterials: Tetracyclines and Glycylcyclines

Generic	Route and Dosage	Uses and Considerations
Short-Acting Tetracycline		
Tetracycline	URI: A: PO: 1-2 g/d in 2-4 divided doses; *max:* 4 g/d Adol/C >8 y: PO: 25-50 mg/kg/d in 4 divided doses	For treating anthrax, plague, gingivitis, *Helicobacter pylori,* cholera, MRSA, STIs, and skin, urinary tract, and respiratory infections. May cause anaphylaxis, headache, diplopia, dermatitis, glossitis, tooth/tongue/nail discoloration, GI distress, CDAD, photosensitivity, nephrotoxicity, hepatotoxicity, and superinfection. Pregnancy category: D*; PB: 65%; t½: 6-12 h
Intermediate-Acting Tetracycline		
Demeclocycline Hydrochloride	Respiratory infection: A: PO: 150 mg q6h or 300 mg q12h; *max:* 1.2 g/d Adol/C >8 y: PO: 7-13 mg/kg/d in 2-4 divided doses	For treating acne, gingivitis, anthrax, cholera, plague, STIs, and skin, respiratory, and urinary tract infections. May cause anaphylaxis, angioedema, headache, photosensitivity, tooth discoloration, glossitis, GI distress, CDAD, elevated hepatic enzymes, Stevens-Johnson syndrome, and superinfection. Pregnancy category: D*; PB: 65%-90%; t½: 10-17 h
Long-Acting Tetracyclines		
Doxycycline hyclate	See Prototype Drug Chart 26.4.	
Minocycline Hydrochloride	Respiratory infection: A: PO/IV: Initially: 200 mg; maint: 100 mg q12h; *max:* 200 mg/d PO; 400 mg/d IV Adol/C >8 y: PO/IV: Initially: 4 mg/kg/d, followed by 2 mg/kg q12h	For treating anthrax, cholera, plague, meningitis, gingivitis, MRSA, STIs, acne, and respiratory, urinary tract, and skin infections. May cause anaphylaxis, dizziness, fatigue, headache, stomatitis, tongue/tooth discoloration, dental caries and pain, GI distress, CDAD, photosensitivity, hepatotoxicity, superinfection, pancytopenia, and Stevens-Johnson syndrome. Take drug with food. Pregnancy category: D*; PB: 76%; t½: 11-24 h
Glycylcyclines		
Tigecycline	A: IV: Initially: 100 mg over 30-90 min; maint: 50 mg q12h for 7-14 d; *max:* 100 mg/d	For treating community-acquired pneumonia, MRSA, and skin and intraabdominal infections. May cause anaphylaxis, dizziness, photosensitivity, headache, weakness, anemia, superinfection, GI distress, CDAD, and Stevens-Johnson syndrome. Pregnancy category: D*; PB: 71%-89%; t½: 27-42 h

A, Adult; *Adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minutes; *MRSA*, methicillin-resistant *Staphylococcus aureus*; *PB,* protein binding; *PO,* by mouth; *q,* every; *STI,* sexually transmitted infection; *t½,* half-life; *URI,* upper respiratory infection; *y,* year; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Drug Interactions

Antacids and iron-containing drugs can prevent absorption of tetracycline from the GI tract. Milk and foods high in calcium can inhibit tetracycline absorption. To avoid drug interaction, these should be taken at least 2 hours apart from tetracycline. Be aware that lipid-soluble tetracyclines, such as doxycycline and minocycline, are actually better absorbed from the GI tract when taken *with* milk products and food.

The desired action of oral contraceptives can be lessened when taken with tetracyclines. The activity of penicillins given with a tetracycline can be decreased because the tetracyclines could cause a bacterial resistance to the action of penicillin. Administering tetracycline with an aminoglycoside may increase the risk of nephrotoxicity.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Tetracyclines

Assessment

- Assess vital signs and urine output. Report abnormal findings.
- Check laboratory results, especially those that indicate renal and liver function (BUN, serum creatinine, AST, ALT, bilirubin).
- Obtain a history of dietary intake and drugs the patient currently takes. Dairy products,

antacids, iron, calcium, and magnesium decrease drug absorption. Digoxin absorption is increased, which may lead to digitalis toxicity.

Nursing Diagnoses

- Infection, Risk for
- Noncompliance with drug regimen related to denial of illness
- Skin Integrity, Risk for Impaired
- Nutrition, Imbalanced: Less than Body Requirements related to nausea and vomiting

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Obtain a sample for culture from the infected area and send it to the laboratory for C&S. Antibiotic therapy can be started after the culture sample has been taken.
- Administer tetracycline 1 hour before or 2 hours after meals for optimum absorption.
- Monitor laboratory values to assess liver and kidney function (in particular, liver enzymes, BUN, and serum creatinine).
- Record vital signs and urine output.

Patient Teaching

General

- Instruct patients to store tetracycline away from light and extreme heat. Tetracycline decomposes in light and heat and causes the drug to become toxic.
- Advise patients to check expiration dates on bottles of tetracycline; out-of-date tetracycline can be toxic.
- Inform female patients who are contemplating pregnancy to avoid taking tetracycline because of possible teratogenic effects.
- Warn parents that children younger than 8 years of age should not take tetracycline because it can cause discoloration of permanent teeth.
- Encourage patients to take the complete course of tetracycline as prescribed.

Side Effects

- Advise patients to use a sun block and protective clothing during sun exposure. Photosensitivity is associated with tetracycline.
- Encourage patients to report signs of a superinfection (mouth ulcers, anal or genital discharge).
- Advise patients to use additional contraceptive techniques and *not* to rely on oral contraceptives when taking the drug because contraceptive effectiveness may decrease.
- Teach patients to use effective oral hygiene several times a day to prevent or alleviate mouth ulcers (stomatitis).

Diet

- Educate patients to avoid milk products, iron, and antacids. Tetracycline should be taken 1 hour before or 2 hours after meals with a full glass of water. If GI upset occurs, the drug can be taken with nondairy foods.

Cultural Considerations

- Recognize that patients and family members from various cultural backgrounds may need a written schedule that shows when the drug should be taken. Explain how dairy products should not be taken with specific tetracyclines but that food helps with the absorption of minocycline and doxycycline.
- Provide a detailed explanation orally or in written form of the possible side effects that should be reported to the health care provider.

Evaluation

- Evaluate the effectiveness of tetracycline by determining whether the infection has been controlled or has ceased and that there are no side effects.

Glycylcyclines

Tigecycline is an antibiotic in a category called *glycylcyclines*, synthetic analogues of the tetracyclines (see Table 26.8). Tigecycline acts by blocking protein synthesis in bacterial cells, resulting in a bacteriostatic action. Indications for use are complicated skin infections and intraabdominal infections, including *S. aureus, E. coli, S. pyogenes, K. pneumoniae,* and *C. perfringens.*

Pharmacokinetics

Tigecycline is administered IV at an initial loading dose of 100 mg over 30 to 90 minutes, followed by 50 mg every 12 hours. The protein-binding capacity of tigecycline ranges from 71% to 89%, and the half-life is 27 to 42 hours. The drug is eliminated from the body in bile, feces, and urine, but biliary excretion is the primary route.

Pharmacodynamics

Tigecycline binds to the 30S ribosomal subunit and causes cell death. It has broad-spectrum activity against gram-positive and gram-negative bacterial pathogens.

Side Effects and Adverse Reactions

Because of their related structural formulas, many side effects of tigecycline are similar to those of tetracycline. The most common side effects of tigecycline involve the GI tract and include nausea, vomiting, abdominal pain, and diarrhea. Pseudomembranous colitis may occur but is rare. Other side effects are photosensitivity, headache, dizziness, insomnia, hypertension, hypotension, anemia, leukocytosis, and thrombocythemia. Hyperglycemia, hypokalemia, elevated BUN, and elevated liver enzymes may also occur.

Drug Interactions

Oral contraceptives may be less effective when given concurrently with tigecycline. Warfarin levels may be increased and may lead to bleeding when taken with tigecycline.

SECTION 26C

Aminoglycosides, Fluoroquinolones, and Lipopeptides

Aminoglycosides

Aminoglycosides act by inhibiting bacterial protein synthesis. The aminoglycoside antibiotics are used against gram-negative bacteria such as *E. coli* and *Proteus* and *Pseudomonas* species. Some gram-positive cocci are resistant to aminoglycosides, so penicillins or cephalosporins may be used.

Streptomycin sulfate, derived from the bacterium *Streptomyces griseus* in 1944, was the first aminoglycoside available for clinical use and was used to treat tuberculosis. Because of its ototoxicity and the bacterial resistance that can develop, it is infrequently used today. Despite its toxicity, streptomycin is the drug of choice to treat tularemia and plague.

Aminoglycosides are for serious infections, and they cannot be absorbed from the GI tract, nor can they cross into the cerebrospinal fluid; they cross the blood-brain barrier in children but not in adults. These agents are primarily administered IM and IV, except for a few aminoglycosides (e.g., neomycin) that may be given orally to decrease bacteria and other organisms in the bowel. Neomycin is frequently used as a preoperative bowel antiseptic.

The aminoglycosides currently used to treat *P. aeruginosa* infection include gentamicin, tobramycin, and amikacin. *P. aeruginosa* is sensitive to gentamicin. Amikacin may be used when there is bacterial resistance to gentamicin and tobramycin. Prototype Drug Chart 26.5 lists the drug data related to the aminoglycoside gentamicin.

Pharmacokinetics

Gentamicin is administered IM and IV. This drug has a short half-life, and the drug dose can be given three to four times a day. Excretion of this drug is primarily unchanged in the urine.

Pharmacodynamics

Gentamicin inhibits bacterial protein synthesis, has a bactericidal effect, and was previously designated pregnancy category D by the manufacturer and C by some experts. The onset of action is rapid or immediate, and the peak action for gentamicin is 30 minutes to 1 hour for IM and 30 minutes for IV administration.

To ensure a desired blood level, aminoglycosides are usually administered IV. The patient's blood levels are drawn periodically to determine the drug's peak (highest concentration) and trough (lowest concentration) blood levels. A therapeutic drug level can be maintained by monitoring the trough level, and peak levels are useful to monitor for toxicity. Many other antibiotics should be monitored as well to maintain effective blood levels.

IV aminoglycosides can be given concurrently with penicillins and cephalosporins but should not be mixed together in the same container. When combinations of antibiotics are given by IV, the IV line is flushed after each antibiotic has been administered to ensure that the antibiotic was completely delivered.

Side Effects and Adverse Reactions

Serious adverse reactions to aminoglycosides include ototoxicity and nephrotoxicity. Renal function, drug dose, and age are all factors that determine whether a patient will develop nephrotoxicity from aminoglycoside therapy. Careful drug dosing is especially important with younger and older patients. The nurse must assess changes in patients' hearing, balance, and urinary output. Prolonged use of aminoglycosides could result in a superinfection, and specific serum aminoglycoside levels should be closely monitored to avoid adverse reactions. Table 26.9 lists the aminoglycosides and their dosages, uses, and considerations.

Drug Interactions

When aminoglycosides are administered concurrently with penicillins, the desired effects of the aminoglycosides are greatly decreased; preferably, these drugs should be given several hours apart. The drug action of oral anticoagulants such as warfarin can increase when taken simultaneously with aminoglycoside administration, and the risk of ototoxicity increases when ethacrynic acid and an aminoglycoside are given.

PROTOTYPE DRUG CHART 26.5 Gentamicin Sulfate

Drug Class	Dosage
Antibacterial: Aminoglycoside Pregnancy category: D*	Respiratory infection: A: IM/IV: 3-5 mg/kg/d in 3-4 divided doses Adol/C: IM/IV: 2-2.5 mg/kg q8h TDM: Peak: 5-8 mcg/mL Trough: <1-2 mcg/mL
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity *Caution:* Renal disease, pseudomembranous colitis, neuromuscular disorders (myasthenia gravis, parkinsonism), hypocalcemia, dehydration, hearing impairment	Drug: Increases risk of ototoxicity with loop diuretics and methoxyflurane; increases risk of nephrotoxicity with NSAIDs, amphotericin B, cephalosporins, cisplatin, furosemide, and vancomycin Lab: Increases BUN, serum AST, ALT, LDH, bilirubin, and creatinine; decreases serum potassium and magnesium
Pharmacokinetics	**Pharmacodynamics**
Absorption: IM, IV Distribution: PB: 0%-30% Metabolism: t½: 2 h Excretion: Unchanged in urine	IM/IV: Onset: rapid Peak: IM 30-60 min, IV 30 min Duration: UK
Therapeutic Effects/Uses	
For treating endocarditis, meningitis, bacteremia, septicemia, and respiratory, intraabdominal, bone/joint, skin, and urinary tract infections. Gentamicin is effective against MRSA, *Pseudomonas aeruginosa, Escherichia coli, and* species of *Proteus, Enterococcus, Haemophilus, Klebsiella, Salmonella, Serratia, Staphylococcus,* and *Streptococcus.*	
Mode of Action: Inhibits bacterial protein synthesis; bactericidal effect	
Side Effects	**Adverse Reactions**
Anorexia, stomatitis, nausea, vomiting, alopecia, rash, pruritus, skin/ocular irritation, visual disturbances, photosensitivity, headache, dizziness, confusion, depression, tinnitus, weakness, arthralgia	Superinfection, peripheral neuropathy, laryngeal edema, hearing loss, hypokalemia, hypomagnesemia, hyponatremia *Life threatening:* Anaphylaxis, nephrotoxicity, thrombocytopenia, anemia, agranulocytosis, hepatic dysfunction, increased intracranial pressure

A, Adult; *Adol,* adolescent; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LDH,* lactic dehydrogenase; *min,* minutes; *MRSA*, methicillin-resistant *Staphylococcus aureus*; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein binding; *q,* every; *t½,* half-life; *TDM,* therapeutic drug monitoring; *UK,* unknown; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

TABLE 26.9
Antibacterials: Aminoglycosides

Generic	Route and Dosage	Uses and Considerations
Amikacin sulfate	Respiratory infections: A: IM/IV: 15 mg/kg/d in divided doses; *max:* 1.5 g/d Adol/C/infants: IM/IV: 15 mg/kg/d divided q8-12h; *max:* 1.5 g/d TDM: Peak: 25-35 mcg/mL; trough: <5 mg/mL	For treating meningitis, septicemia, bacteremia, and respiratory, urinary, bone/joint, skin, and intraabdominal infections. May cause GI distress, CDAD, anemia, ototoxicity, seizures, nephrotoxicity, and superinfection. Pregnancy category: C/D*; PB: 0%-11%; t½: 2 h
Gentamicin sulfate	See Prototype Drug Chart 26.5.	
Neomycin sulfate	Skin infections: A/adol/C: Topical: Apply a thin film of 0.5% cream or ointment to infected area up to four times daily. Hepatic coma: A: PO: 1-3 g q6h for 5-6 d; *max:* 12 g/d	For treating hepatic encephalopathy, skin infections, and bowel preparation. May cause stomatitis, rash, GI distress, eosinophilia, seizures, superinfection, neurotoxicity, nephrotoxicity, and ototoxicity. Pregnancy category: D*; PB: 0%-30%; t½: UK
Streptomycin sulfate	Respiratory infection: A: IM: 1-2 g/d in divided doses q6-12h; *max:* 4 g/d Adol/C/infants: IM: 20-40 mg/kg/d in divided doses q6-12h; *max:* 2 g/d TDM: Peak: 40-50 mcg/mL; trough: <5 mcg/mL	For treating meningitis, endocarditis, bacteremia, tuberculosis, plague, and respiratory and urinary tract infections. May cause anaphylaxis, angioedema, rash, headache, dizziness, GI distress, weakness, pancytopenia, ototoxicity, nephrotoxicity, and neurotoxicity. Pregnancy category: D*; PB: 35%; t½: 2-3 h
Tobramycin sulfate	Bone/joint infection: A: IM/IV: 3-5 mg/kg/d in divided doses; give IV over 30-60 min; *max:* 5 mg/d Adol/C/infants: IM/IV: 2.5 mg/kg/dose q8h; *max:* 6-7.5 mg/kg/d in 3-4 divided doses	For treating bacteremia, septicemia, PID, meningitis, and respiratory, urinary tract, intraabdominal, skin, and bone/joint infections. May cause anaphylaxis, headache, dizziness, dysgeusia, GI distress, CDAD, dysphonia, weakness, chest pain, superinfection, neurotoxicity, ototoxicity, nephrotoxicity, and Stevens-Johnson syndrome. Pregnancy category: D*; PB: 30%; t½: 2-3 h

A, Adult; *Adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minutes; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *q,* every; *t½,* half-life; *TDM,* therapeutic drug monitoring; *UK,* unknown; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care
Antibacterials: Aminoglycosides
Assessment

- Record vital signs and urine output. Compare these results with future vital signs and urine output. Nephrotoxicity is an adverse reaction to most aminoglycosides.
- Assess laboratory results to determine renal and liver function, including BUN, serum creatinine, ALP, ALT, AST, and bilirubin. Serum electrolytes should also be checked. Aminoglycosides may decrease serum potassium and magnesium levels.
- Obtain a medical history related to renal or hearing disorders. Large doses of aminoglycosides could cause nephrotoxicity or ototoxicity.

Nursing Diagnoses

- Infection, Risk for
- Tissue Integrity, Risk for Impaired
- Nutrition, Imbalanced: Less than Body Requirements related to an inability to ingest food
- Tissue Perfusion, Risk for Ineffective Peripheral

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Send a sample from the infected area to the laboratory for culture to determine the organism and its antibiotic sensitivity before the aminoglycoside is started.
- Monitor intake and output. Urine output should be at least 600 mL/day. Immediately report any decrease in urine output. Urinalysis may be ordered daily, and results should be checked for proteinuria, casts, blood cells, and appearance.
- Check for hearing loss. Aminoglycosides can cause ototoxicity.
- Evaluate laboratory results and compare with baseline values. Report abnormal results.
- Monitor vital signs. Note whether body temperature has decreased.
- Dilute gentamicin in 50 to 200 mL of NS or D_5W solution and administer IV over 30 to 60 minutes.
- Check that therapeutic drug monitoring (TDM) has been ordered for peak and trough drug levels. Blood should be drawn 45 to 60 minutes after drug has been administered for peak levels and minutes before next drug dosing for trough levels. Gentamicin peak values should be 5 to 8 mcg/mL, and trough values should be less than 1 to 2 mcg/mL.
- Monitor for signs and symptoms of superinfection; these include stomatitis (mouth ulcers), genital discharge (vaginitis), and anal or genital itching.

Patient Teaching

General

- Encourage patients to increase fluid intake unless fluids are restricted.

Side Effects

- Advise patients to report aminoglycoside side effects that include nausea, vomiting, tremors, tinnitus, pruritus, and muscle cramps.
- Direct patients to use a sun block and protective clothing during sun exposure because aminoglycosides can cause photosensitivity.

Cultural Considerations

- Do not give directions such as "take one blue pill" at a specified time. Instead, provide the name and dosage of the medication in the language the patient speaks and reads most easily.

Evaluation

- Evaluate the effectiveness of the aminoglycoside by determining whether the infection has ceased and whether any side effects have occurred.

Fluoroquinolones (Quinolones)

The mechanism of action of fluoroquinolones is to interfere with the enzyme DNA gyrase, which is needed to synthesize bacterial DNA. Their antibacterial spectrum includes bactericidal action on both gram-positive and gram-negative organisms. The fluoroquinolones are effective against some gram-positive organisms, such as *S. pneumoniae,* and also against *H. influenzae, P. aeruginosa,* and *Salmonella* and *Shigella* species. This group of antibiotics is useful in the treatment of urinary tract, bone, and joint infections; bronchitis; pneumonia; gastroenteritis; and gonorrhea. Table 26.10 lists the various fluoroquinolones.

Ciprofloxacin is a synthetic antibacterial related to nalidixic acid. This fluoroquinolone has a broad spectrum of action on gram-positive and gram-negative organisms, including *P. aeruginosa.* Ciprofloxacin is approved for use for urinary tract and lower respiratory tract infections and for skin, soft tissue, bone, and joint infections.

The use of fluoroquinolones as urinary antibiotics is discussed in Chapter 48. Prototype Drug Chart 26.6 lists the drug data related to levofloxacin. Levofloxacin is used primarily to treat respiratory problems such as community-acquired pneumonia, chronic bronchitis, acute sinusitis, and uncomplicated skin infections in addition to urinary tract infections.

Moxifloxacin is available for once-a-day oral and parenteral dosing. This drug is prescribed to treat the same infections other fluoroquinolones are effective against. Moxifloxacin is more active than levofloxacin against *S.pneumoniae.* It is also effective against some strains of *S. aureus* and enterococci but is not effective against VREF. The fluoroquinolones are included in Table 26.10.

TABLE 26.10

Antibacterials: Fluoroquinolones (Quinolones) and Unclassified Drugs

Generic	Route and Dosage	Uses and Considerations
Fluoroquinolones		
Ciprofloxacin Hydrochloride	UTI: Immediate release: A: PO: 250 mg q12h for 3 d; *max:* 1.5 g/d C: PO: 10-20 mg/kg q12h for 7-14 d; *max:* 40 mg/kg/d Extended release: A: PO: 500 mg for 3 d; *max:* 1 g/d A: IV: 200-400 mg q12h for 7-14 d; *max:* 1.2 g/d C: IV: 6-10 mg/kg/dose q8h for 10-21 d; *max:* 30 mg/kg/d	For treating STIs, anthrax, otitis media, and intraabdominal, gynecologic, bone/joint, skin, respiratory, and urinary tract infections. May cause anaphylaxis, dizziness, irritability, headache, retinal detachment, corneal deposits, ocular pruritus, tendon rupture, injection site reaction, dysgeusia, GI distress, CDAD, superinfection, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 20%-40%; t½: 4 h
Levofloxacin	See Prototype Drug Chart 26.6.	
Moxifloxacin	Sinusitis: A: PO/IV: 400 mg/d for 10 d; *max:* 400 mg/d	For treating sinusitis, PID, plague, and respiratory, intraabdominal, and skin infections. May cause anaphylaxis, visual impairment, ocular irritation/bleeding, conjunctivitis, retinal detachment, keratitis, hyperemia, headache, GI distress, CDAD, superinfection, nephrotoxicity, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 30%-50%; t½: 12 h
Ofloxacin	UTI: A: PO: 200 mg q12h for 3-10 d; *max:* 800 mg/d	For treating otitis media, PID, STIs, prostatitis, and respiratory, urinary tract, and skin infections. May cause anaphylaxis, headache, dizziness, dysgeusia, insomnia, GI distress, CDAD, pruritis, photosensitivity, visual disturbances, superinfection, tendon rupture, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 20%-40%; t½: 4-8 h

Unclassified Drugs		
Chloramphenicol	Septicemia: A/adol/C/infants: IV: 50-100 mg/kg/d in 4 divided doses; *max:* 100 mg/kg/d TDM: Meningitis Peak: 15-25 mcg/mL Trough: 5-15 mcg/mL All other infections, Peak: 10-20 mcg/mL Trough: 5-10 mcg/mL	For treating bacteremia, septicemia, typhoid fever, and meningitis. May cause anaphylaxis, angioedema, optic neuritis, headache, glossitis, stomatitis, GI distress, nephritis, neurotoxicity, anemia, and pancytopenia. Pregnancy category: C*; PB: 60%; t½: 4.1 h
Quinupristin-dalfopristin	Skin infections: A/C >12 y: IV: 7.5 mg/kg given over 1 h, q12h for at least 7 d; *max:* 15 mg/kg/d	For treating skin infections and VREF. May cause anaphylaxis, angioedema, infusion site reaction, arthralgia, myalgia, GI distress, CDAD, hyperbilirubinemia, edema, dysrhythmias, and superinfection. Pregnancy category: B*; PB: 11%-19%; t½: 0.7-0.85 h
Obiltoxaximab	A >40 kg: IV: 16 mg/kg as single dose A/adol/C/Infants <40 kg: IV: 24 mg/kg as single dose	For prophylaxis and treatment of anthrax. May cause anaphylaxis, headache, URI, cough, rash, pruritus, and injection site reaction. Pregnancy category: B *; PB: UK; t½: UK

A, Adult; *adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PID,* pelvic inflammatory disease; *PO,* by mouth; *q,* every; *STI,* sexually transmitted infection; *t½,* half-life; *TDM,* therapeutic drug monitoring; *UK,* unknown; *URI,* upper respiratory infection; *UTI,* urinary tract infection; *VREF,* vancomycin-resistant *Enterococcus faecium*; *y,* year; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Patient Safety

Fluoroquinolones,

especially levaquin, should be reserved for patients who have no other alternative treatment options for uncomplicated UTI, acute bacterial exacerbation of chronic bronchitis, or acute bacterial sinusitis due to disabling and potentially irreversible serious adverse reactions. These adverse reactions include tendon rupture, tendinitis, peripheral neuropathy, CNS effects, and exacerbation of myasthenia gravis. (Black Box Warning.)

Pharmacokinetics

Levofloxacin is well absorbed from the GI tract. It has a low protein-binding effect of 50% and a moderately short half-life of 6 to 8 hours. Levofloxacin is excreted unchanged in the urine.

Pharmacodynamics

Levofloxacin inhibits bacterial DNA synthesis by inhibiting the enzyme DNA gyrase. The drug has a high tissue distribution. If possible, it should be taken before meals because food slows the absorption rate; antacids also decrease the absorption rate. Levofloxacin increases the effect of oral hypoglycemics, theophylline, and caffeine.

Levofloxacin has an average onset of action of 30 minutes to 1 hour, and the peak concentration time is 1 to 2 hours. The duration of action is unknown.

PROTOTYPE DRUG CHART 26.6 Levofloxacin

Drug Class	Dosage
Antibacterials: Quinolone, fluoroquinolone Pregnancy category: C*	Sinusitis: A: PO/IV: 500 mg/d for 10 d or 750 mg/d for 5 d
Contraindications	**Drug-Lab-Food Interactions**
Severe renal disease, hypersensitivity to other quinolones, seizures, myasthenia gravis *Caution:* Renal and hepatic dysfunction, children and older adults, theophylline therapy, dehydration, rheumatoid arthritis, cardiac dysrhythmias	Drug: Increases effects of oral hypoglycemics, theophylline, and caffeine; increases levels of levofloxacin with corticosteroids, NSAIDs, and probenecid; decreases drug absorption with antacids, iron, and calcium; may increase warfarin effects Lab: Increased AST, ALT, prolonged bleeding time
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: well absorbed Distribution: PB: 24%-38% Metabolism: t½: 6-8 h Excretion: Unchanged in urine	PO: Onset: 0.5-1 h Peak: 1-2 h Duration: UK
Therapeutic Effects/Uses	
For treating sinusitis, cellulitis, impetigo, plague, anthrax, and respiratory, urinary tract, and skin infections. Levofloxacin is effective against *Escherichia coli, Clostridium perfringens,* and species of *Enterobacter, Haemophilus, Klebsiella, Neisseria, Proteus, Pseudomonas, Serratia, Staphylococcus,* and *Streptococcus.*	
Mode of Action: Interferes with the enzyme DNA gyrase, which is needed for bacterial DNA synthesis; bactericidal effect	
Side Effects	**Adverse Reactions**
Anorexia, dysgeusia, stomatitis, nausea, vomiting, diarrhea, abdominal cramps, flatulence, constipation, headache, blurred vision, dizziness, restlessness, confusion, depression, insomnia, weakness, nightmares, tremor, rash, injection site reaction, tinnitus, ocular irritation/pain, photosensitivity, weakness, tendon rupture (rare)	Palpitations, superinfection, edema, hypotension, peripheral neuropathy, crystalluria, myasthenia, hypoglycemia/hyperglycemia, retinal detachment *Life threatening:* Anaphylaxis, angioedema, anemia, leukopenia, agranulocytosis, thrombocytopenia, increased intracranial pressure, Stevens-Johnson syndrome, hepatotoxicity, nephrotoxicity, seizures, CDAD, dysrhythmias, suicidal ideation

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *DNA,* deoxyribonucleic acid; *h,* hour; *IV,* intravenous; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Fluoroquinolones

Assessment

- Record vital signs along with intake and urine output. Compare these results with future vital signs and urine output. Fluid intake should be at least 2000 mL/day.
- Assess laboratory results (BUN and serum creatinine) to determine renal function.
- Obtain a drug and diet history. Antacids and iron preparations decrease absorption of fluoroquinolones such as levofloxacin, and levofloxacin can increase the effects of theophylline

and caffeine and can also increase the effects of oral hypoglycemics. When levofloxacin is taken with nonsteroidal antiinflammatory drugs (NSAIDs), central nervous system (CNS) reactions may occur, which includes seizures.

Nursing Diagnoses

- Infection, Risk for
- Tissue Integrity, Risk for Impaired
- Noncompliance with drug regimen related to lack of understanding of importance of drug regimen

Planning

- The patient's infection will be controlled and ultimately eliminated.

Nursing Interventions

- Obtain a specimen from the infected site, and send it to the laboratory for C&S before initiating antibacterial drug therapy.
- Monitor intake and output. Urine output should be at least 750 mL per day. The patient should be well hydrated, and fluid intake should be greater than 2000 mL daily to prevent crystalluria (crystals in the urine). Urine pH should be below 6.7.
- Record vital signs and report any abnormal findings.
- Check laboratory results, especially BUN and serum creatinine. Elevated values may indicate renal dysfunction.
- Administer levofloxacin 2 hours before or after antacids and iron products for best absorption. Give with a full glass of water. If GI distress occurs, the drug may be taken with food.
- Dilute IV levofloxacin in an appropriate amount of solution (250 mg in 50 mL, 500 mg in 100 mL, 750 mg in 150 mL. NS, D_5W, D_5NS, D_5LR). Infuse over 60 minutes.
- Check for signs and symptoms of superinfection: stomatitis (mouth ulcers), furry black tongue, and anal or genital discharge or itching.
- Monitor serum theophylline levels when taken concurrently with levofloxacin, which can increase theophylline levels. Check for symptoms of CNS stimulation such as nervousness, insomnia, anxiety, and tachycardia.
- Monitor blood glucose. Levofloxacin can increase the effects of oral hypoglycemics.

Patient Teaching

General

- Teach patients to drink at least 6 to 8 glasses (8 oz) of fluid daily.
- Encourage patients to avoid caffeinated products.

Side Effects

- Direct patients to avoid operating motor vehicles or hazardous machinery while taking the drug, at least until drug stability has occurred, because of possible drug-related dizziness.
- Inform patients that photosensitivity is a side effect of most fluoroquinolones. Patients should wear sunglasses, sun block, and protective clothing when in the sun.
- Encourage patients to report side effects such as dizziness, nausea, vomiting, diarrhea, flatulence, abdominal cramps, tinnitus, rash, and tendon rupture (very rare). Older adults are more likely to develop side effects.

Cultural Considerations

- Demonstrate an interest in the patient's family and other personal matters to establish trust among some Hispanic and Appalachian patients.
- Solicit the patient's opinions and advice.

Evaluation

- Evaluate the effectiveness of the fluoroquinolone by determining whether the infection has ceased and the body temperature has returned within normal range.

Lipopeptides

Daptomycin is a U.S. Food and Drug Administration (FDA)- approved antibiotic in the category of *lipopeptides*. Daptomycin acts by binding to the bacterial membrane and causing rapid depolarization of its membrane potential, inhibiting protein, DNA, and RNA synthesis. This action results in bacterial cell death.

Indications for daptomycin include complicated skin infections due to gram-positive microorganisms, septicemia due to *S. aureus* infection, and infective endocarditis due to MRSA infection.

Pharmacokinetics

Daptomycin is administered by IV at a dose of 4 mg/kg daily. Each 500-mg vial of the medication is diluted in 10 mL of NS 0.9% and allowed to stand for 10 minutes. After gentle rotation of the vial to ensure dilution, further dilute in 50 to 100 mL of NS and administer over 30 minutes. Drug should *not* be mixed with dextrose-containing diluents. The protein-binding capacity is 90% to 93%, and half-life averages 8 hours. Daptomycin is primarily excreted by the kidneys.

Pharmacodynamics

Daptomycin binds to the bacterial membrane and causes cell death. An effective trough concentration of 5.9 mcg/mL is usually achieved by the third dose.

Side Effects and Adverse Reactions

Side effects that may occur when taking daptomycin include hypertension, hypotension, anemia, numbness, tingling, dizziness, insomnia, pain or burning on urination, nausea, vomiting, diarrhea, constipation, and pallor. More serious adverse effects that have occurred with daptomycin are chest pain, hypokalemia, hyperkalemia, hyperglycemia, hypoglycemia, bleeding, rhabdomyolysis, and pleural effusion.

Drug Interactions

When daptomycin is given with 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors (statins, such as simvastatin, atorvastatin), the risk of rhabdomyolysis and elevated levels of creatine phosphokinase (CPK) is increased. Daptomycin toxicity may be increased when given concurrently with tobramycin, and warfarin may lead to increased bleeding when taken with daptomycin.

Unclassified Antibacterial Drugs

Several antibacterials, such as chloramphenicol and quinupristin-dalfopristin, do not belong to any major drug group. Chloramphenicol was discovered in 1947 and exerts its bacteriostatic action by inhibiting bacterial protein synthesis. Because of the toxic effects of chloramphenicol, including blood dyscrasias related to bone marrow suppression, it is used only to treat serious infections. It is effective against gram-negative and gram-positive bacteria and many other microorganisms, such as rickettsiae, *Mycoplasma,* and *H. influenzae.*

Quinupristin-dalfopristin is effective for treating VREF bacteremia and skin infected by *S. aureus* and *S. pyogenes.* It acts by disrupting the protein synthesis of the organism. When administering the drug through a peripheral IV line, pain, edema, and phlebitis may occur.

Obiltoxaximab was FDA approved in 2016 for prophylaxis and treatment of anthrax. It prevents the lethal factor of anthrax from intracellular entry by inhibiting the binding of the protective antigen of *Bacillus anthracis* toxin to cellular receptors. This drug is administered IV as a single dose over 1 hour and 10 minutes.

SECTION 26D

Sulfonamides and Nitroimidazoles

Sulfonamides

Sulfonamides were first isolated from a coal tar derivative compound in the early 1900s and were produced for clinical use against coccal infections in 1935. Sulfonamides were the first group of drugs used against bacteria, although they are not classified as antibiotics because they were not obtained from biologic substances. The sulfonamides are bacteriostatic because they inhibit bacterial synthesis of folic acid, which is essential for bacterial growth. Humans do not synthesize folic acid, rather they acquire it through the diet, therefore sulfonamides selectively inhibit bacterial growth without affecting normal cells. Folic acid (folate) is required by cells for biosynthesis of RNA, DNA, and proteins.

TABLE 26.11

Antibacterials: Sulfonamides

Generic	Route and Dosage	Uses and Considerations
Short-Acting		
Sulfadiazine	Urinary tract infection: A: PO: Initially 2-4 g, then 2-4 g/d in 3-6 divided doses; *max:* 4 g/d Adol/C/infants >2 mo: PO: Initially 75 mg/kg, then 150 mg/kg/d in 4-6 divided doses; *max:* 6 g/d	For treating otitis media, meningitis, malaria, and UTIs and for rheumatic fever prophylaxis. May cause anaphylaxis, photosensitivity, headache, insomnia, seizure, crystalluria, stomatitis, GI distress, peripheral neuropathy, and Stevens-Johnson syndrome. Increase fluid intake to >2000 mL/d. Pregnancy category: C*; PB: 38%-48%; t½: 17 h
Intermediate-Acting		
Sulfasalazine	Ulcerative colitis: Uncoated tablets: A: PO: Initially 1 g q6-8h; maint: 500 mg q6h; *max:* 4 g/d Adol/C >6 y: PO: Initially 40-60 mg/kg/d in divided doses; maint: 30 mg/kg/d in divided doses; *max:* 2 g/d	For treating ulcerative colitis and rheumatoid arthritis. May cause anaphylaxis, headache, dizziness, stomatitis, GI distress, skin/urine discoloration, peripheral neuropathy, crystalluria, oligospermia, nephritis, hepatotoxicity, rash, hematuria, anemia, and Stevens-Johnson syndrome. Take drug after eating. Pregnancy category: B*; PB: 99%; t½: 5.7-7.6 h
Trimethoprim-sulfamethoxazole	See Prototype Drug Chart 26.7.	

A, Adult; *Adol,* adolescent; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *mo,* month; *PB,* protein binding; *PO,* by mouth; *q,* every; *t½,* half- life; *UTI,* urinary tract infection; *y,* year; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

The clinical usefulness of sulfonamides alone, not in combination, has decreased for several reasons. The availability and effectiveness of penicillin and other antibiotics has increased, and bacterial resistance to some sulfonamides can develop. Sulfonamides may be used as an alternative drug for patients who are allergic to penicillin. They are still used to treat urinary tract and ear infections and may be used for newborn eye prophylaxis. Sulfonamides are approximately 90% effective against *E. coli,* therefore they are frequently a preferred treatment for urinary tract infections, which are often caused by *E. coli.* They are also useful in the treatment of meningococcal meningitis and against *Chlamydia* species and *Toxoplasma gondii.* Sulfonamides are *not* effective against viruses and fungi.

Pharmacokinetics

Sulfonamide drugs are well absorbed by the GI tract and are well distributed to body tissues and the brain. The liver metabolizes the sulfonamide drug, and the kidneys excrete it.

Pharmacodynamics

Many sulfonamides are for oral administration because they are absorbed readily by the GI tract. They are also available in solution and as ointments for ophthalmic use and in cream form (silver sulfadiazine and mafenide acetate) for burns. Most of the early sulfonamides were highly protein bound and displaced other drugs by competing for protein sites. The two categories of sulfonamides, classified according to their duration of action, are *short-acting sulfonamides* that have a rapid absorption and excretion rate and *intermediate-acting sulfonamides* with moderate to slow absorption and a slow excretion rate.

Sulfadiazine is useful in prophylactic treatment of streptococcal infections in patients with rheumatic fever who are hypersensitive to penicillin. Older sulfonamides such as sulfadiazine are poorly soluble in urine and can cause crystallization, which could damage the kidneys if fluid and water intake are insufficient; however, newer sulfonamides have greater water solubility, therefore

crystal formations in the urine and renal damage are unlikely. Table 26.11 describes the sulfonamides.

Side Effects and Adverse Reactions

Side effects of sulfonamides may include an allergic response such as skin rash and itching. Anaphylaxis is uncommon. Blood disorders such as hemolytic anemia, aplastic anemia, and low WBC and platelet counts could result from prolonged use and high dosages. GI disturbances such as anorexia, nausea, and vomiting may also occur. The early sulfonamides were insoluble in acid urine, and **crystalluria** (crystals in the urine) and hematuria (blood in the urine) were common problems. Increasing fluid intake dilutes the drug, which helps prevent crystalluria. Photosensitivity, an excessive reaction to direct sunlight or ultraviolet (UV) light that leads to redness and burning of the skin, can also occur; therefore the patient should avoid sunbathing and excess ultraviolet light. **Cross-sensitivity**, a sensitivity or allergy to one sulfonamide that leads to sensitivity to another sulfonamide, might occur with the different sulfonamides but does not occur with other antibacterial drugs. Sulfonamides should be avoided during pregnancy to avoid congenital malformations, neural tube defects, and kernicterus.

Patient Safety **Preventing Medication Errors**

Do not confuse…

- **Septra**, an antibacterial sulfonamide, with **Sectral**, a beta-adrenergic antagonist used to manage dysrhythmias.
- **Sulfadiazine**, a short-acting antibacterial sulfonamide, with **sulfasalazine**, an intermediate-acting antibacterial sulfonamide.

Trimethoprim-Sulfamethoxazole

Trimethoprim-sulfamethoxazole (TMP-SMZ) contains one part trimethoprim and five parts sulfamethoxazole to produce a **synergistic effect** that increases the desired drug response. Trimethoprim is an antibacterial agent that interferes with bacterial folic acid synthesis just as sulfonamides do; it is classified as a urinary tract antiinfective that may be used alone for uncomplicated urinary tract infections, and it is also effective against the gram-negative bacteria *E. coli* and also *Proteus* and *Klebsiella* species. In the 1970s, trimethoprim was combined with sulfamethoxazole, an intermediate-acting sulfonamide, to prevent bacterial resistance to sulfonamide drugs and to obtain a better response against many organisms. Giving both drugs together in one compounded form causes bacterial resistance to develop much more slowly than if only one of the drugs were to be used alone.

TMP-SMZ is effective in treating urinary, intestinal, lower respiratory tract, and middle ear (otitis media) infections; prostatitis; and gonorrhea. It is also used to prevent *Pneumocystis carinii* in patients with acquired immunodeficiency syndrome (AIDS). Increased fluid intake is strongly recommended to avoid complications such as crystalluria. Prototype Drug Chart 26.7 describes the pharmacologic behavior of TMP-SMZ.

Pharmacokinetics

TMP-SMZ is well absorbed from the GI tract and is moderately protein bound. Its half-life is 8 to 12 hours, thus it is administered twice a day. It is excreted as unchanged metabolites in the urine.

Pharmacodynamics

Trimethoprim, a nonsulfonamide antibiotic, enhances the activity of the drug combination. TMP-SMZ blocks steps in the bacterial synthesis of protein and nucleic acid, producing a bactericidal effect.

TMP-SMZ can be administered orally or by IV. Orally the drug has a moderately rapid onset of action; drug action is immediate via the IV route. Serum peak concentration time for oral use is 1 to 4 hours and 30 minutes to 1 hour for IV use. TMP-SMZ increases the hypoglycemic response when

taken with sulfonylureas (oral hypoglycemic agents). It can also increase the activity of oral anticoagulants.

Side Effects and Adverse Reactions

Side effects of TMP-SMZ may include mild to moderate rashes, anorexia, nausea, vomiting, diarrhea, stomatitis, crystalluria, and photosensitivity. Serious adverse reactions are rare; however, agranulocytosis, aplastic anemia, and myocarditis have been reported as possible life-threatening conditions.

Topical and Ophthalmic Sulfonamides

Sulfonamides can be administered for topical and ophthalmic uses, but because topical use of sulfonamides can cause hypersensitivity reactions, they are used infrequently. Mafenide acetate is a sulfonamide derivative prescribed to prevent sepsis in cases of second- and third-degree burns. Silver sulfadiazine is another topical sulfonamide used to treat burns. Both of these drugs are discussed in more detail in Chapter 45.

PROTOTYPE DRUG CHART 26.7 Trimethoprim-Sulfamethoxazole (TMP-SMZ)

Drug Class	Dosage
Antibacterial: Sulfonamide Pregnancy category: D*	Chronic bronchitis: A: PO: TMP 160 mg, SMZ 800 mg q12h for 14 d
Contraindications	**Drug-Lab-Food Interactions**
Severe renal or hepatic disease, hypersensitivity to sulfonamides, megaloblastic or folate-deficiency anemia, pregnancy, breastfeeding, infants *Caution:* Diabetes mellitus, hypothyroidism, advanced age	Drug: Increased anticoagulant effect with warfarin; increased hypoglycemic effect with oral hypoglycemic drugs, increased potassium levels with ACE inhibitors and spironolactone, increased digoxin and sulfonylurea levels, increased phenytoin and methotrexate toxicity Lab: May increase BUN, serum creatinine, AST, ALT, and ALP
Pharmacokinetics	**Pharmacodynamics**
Absorption: PO: Well absorbed Distribution: PB: 44% for TMP; 70% for SMZ; crosses placenta Metabolism: t½: 8-10 h for TMP, 6-12 h for SMZ Excretion: In urine as metabolites	PO: Onset: UK Peak: 1-4 h Duration: UK IV: Onset: Immediate Peak: UK Duration: UK
Therapeutic Effects/Uses	
For treating otitis media, gastroenteritis, MRSA, and respiratory and urinary tract infections. TMP-SMZ is effective against *Escherichia coli,* MRSA,and species of *Enterobacter, Haemophilus, Pneumocystis, Streptococcus, Klebsiella, Proteus,* and *Shigella.*	
Mode of Action: Inhibits folic acid synthesis and protein synthesis of nucleic acids; bactericidal effect	
Side Effects	**Adverse Reactions**
Anorexia, stomatitis, nausea, vomiting, diarrhea, abdominal pain, weakness, rash, depression, headache, vertigo, insomnia, photosensitivity, tinnitus, arthralgia, myalgia	*Life threatening:* Anaphylaxis, angioedema, seizures, myocarditis, leukopenia, thrombocytopenia, hemolytic anemia, aplastic anemia, agranulocytosis, eosinophilia, neutropenia, hyperkalemia, hyponatremia, hypoglycemia, crystalluria, CDAD, Stevens-Johnson syndrome, renal failure

A, Adult; *ACE,* angiotensin-converting enzyme; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *h,* hour; *IV,* intravenous; *MRSA*, methicillin-resistant *Staphylococcus aureus*; *PB,* protein binding; *PO,* by mouth; *q,* every; *SMZ,* sulfamethoxazole; *TMP,* trimethoprim; *t½,* half-life; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Sulfacetamide sodium is a sulfonamide for ophthalmic and topical uses. In ophthalmic preparations (liquid drops and ointments), sulfacetamide sodium is used to treat ocular infections. It is often used as prophylactic treatment after an eye injury or after removal of a foreign body. Do *not* use ointment for the eye unless it has *ophthalmic* printed on the drug label. Sulfacetamide sodium is discussed in more detail in Chapter 44.

Topical sulfacetamide sodium *for the skin* is a cream, gel, lotion, or cleanser and is used to treat seborrheic dermatitis and acne. This dermatologic form is *not* used for the eye.

Nursing Process: Patient-Centered Collaborative Care

Antibacterials: Sulfonamides

Assessment

- Assess the patient's renal function by checking urinary output (>600 mL/day), BUN (normal, 8

to 25 mg/dL), and serum creatinine (normal, 0.5 to 1.5 mg/dL).
- Obtain a medical history from the patient. Sulfonamides such as TMP-SMZ are contraindicated for patients with severe renal or liver disease.
- Determine whether the patient is hypersensitive to sulfonamides. An allergic reaction can include rash, skin eruptions, and itching. A severe hypersensitivity reaction includes erythema multiforme—an erythematous macular, papular, or vesicular eruption that can cover the entire body—or exfoliative dermatitis, characterized by desquamation, scaling, and itching of the skin.
- Obtain a history of drugs the patient currently takes. Oral antidiabetic drugs (sulfonylureas) given with sulfonamides increase the hypoglycemic effect; use of warfarin with sulfonamides increases the anticoagulant effect.
- Assess baseline laboratory results, especially complete blood count (CBC). Blood dyscrasias may occur as a result of high doses of sulfonamides over a continuous period, causing life-threatening conditions.

Nursing Diagnoses

- Infection, Risk for
- Protection, Ineffective as evidenced by photosensitivity related to sulfonamides
- Elimination, Impaired Urinary related to prolonged high doses of sulfonamides

Planning

- The patient's infection will be controlled and ultimately alleviated.

Nursing Interventions

- Administer sulfonamides with a full glass of water. Extra fluid intake can prevent crystalluria and kidney stone formation.
- Record intake and output. To decrease the risk of crystalluria, fluid intake should be at least 2000 mL/day, and urine output should be at least 1200 mL/day. The sulfonamide sulfadiazine is more likely to cause crystalluria than combination drugs.
- Monitor vital signs. Note whether the patient's temperature has gone down.
- Observe the patient for hematologic reactions that may lead to life-threatening anemias. Early signs are sore throat, purpura, and decreasing WBC and platelet counts. Check CBC, and compare values with baseline findings.
- Check for signs and symptoms of superinfection. Symptoms include stomatitis (mouth ulcers), furry black tongue, anal or genital discharge, and itching.

Patient Teaching

General

- Encourage patients to drink several quarts of fluid daily while taking sulfonamides to avoid crystalluria.
- Advise pregnant patients to avoid sulfonamides during the last 3 months of pregnancy.
- Counsel patients not to take antacids with sulfonamides because antacids decrease the absorption rate of sulfonamide drugs.
- Warn patients with an allergy to one sulfonamide that all sulfonamide preparations should be avoided, with health care provider's approval, because of the possibility of cross-sensitivity. Observe the patient for rash or any skin eruptions.

Self-Administration

- Teach patients to take sulfonamides 1 hour before or 2 hours after meals with a full glass of water.

Side Effects

- Direct patients to report bruising or bleeding that could be a result of a drug-induced blood disorder. Advise patients to have their blood cell count monitored on a regular basis.
- Warn patients to wear sunglasses, avoid direct sunlight, and use sun block and protective clothing to decrease the risk of photosensitive reactions.

Cultural Considerations

- Respect cultural beliefs and values regarding alternative methods for treating infections. Explain the purpose of the drug therapy and how often the drug should be taken.

- Communicate that patients should increase fluid intake to 10 to 12 glasses per day. Written instructions in the patient's preferred language may be necessary if the patient's cultural background prevents understanding of the health problem and drug regimen.

Evaluation

- Evaluate the effectiveness of sulfonamide therapy by determining whether the infection has been alleviated and the blood cell count is within normal range.

TABLE 26.12

Antibacterials: Nitroimidazoles

Generic	Route and Dosage	Uses and Considerations
Metronidazole	CDAD: A: PO/IV: 500 mg q8h for 10-14 d; *max:* 4 g/d Adol/C: PO/IV: 30 mg/kg/d in 4 divided doses for 10 d; *max:* 2 g/d	For treating acne, amebiasis, bacterial vaginosis, endocarditis, meningitis, giardiasis, septicemia, trichomoniasis, CDAD, and bone/joint, *Helicobacter pylori,* gynecologic, skin, intraabdominal, and respiratory infection, and surgical infection prophylaxis. May cause headache, insomnia, dizziness, weakness, seizure, dry mouth, dysgeusia, GI distress, tongue/urine discoloration, peripheral neuropathy, superinfection, leukopenia, disulfiram-like reaction with alcohol, and Stevens-Johnson syndrome. Pregnancy category: B*; PB: 10%; t½: 8 h
Tinidazole	Intestinal amebiasis: A: PO: 2 g with food for 3 d; *max:* 2 g/d Adol/C >3 y: 50 mg/kg/d with food for 3-5 days; *max:* 2 g/d	For treating amebiasis, giardiasis, trichomoniasis, bacterial vaginosis, and anaerobic bacterial infections. May cause headache, dizziness, insomnia, dysgeusia, GI distress, tongue/urine discoloration, peripheral neuropathy, weakness, superinfection, seizures, leukpenia, angioedema, and Stevens-Johnson syndrome. Pregnancy category: C*; PB: 12%; t½: 12-14 h

A, Adult; *Adol,* adolescent; *C,* child; *CDAD, Clostridium difficile*–associated diarrhea; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *q,* every; *t½,* half- life; *y,* year; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nitroimidazoles

Nitroimidazoles act by disrupting DNA and protein synthesis in susceptible bacteria and protozoa. The nitroimidazoles are effective against *H. pylori* and bacterial species (such as *Bacteroides*, *Clostridium*, *Gardnerella*, *Prevotella, Peptococcus, Giardia*), and protozoa (such as *Trichomones vaginalis*). Nitroimidazoles are used for prophylaxis for surgical infections and to treat CDAD, anaerobic infections, amebiasis, giardiasis, trichomoniasis, bacterial vaginosis, and acne rosacea. Metronidazole and tinidazole are two of the most effective drugs available to treat anaerobic bacterial infections. Both nitroimidazoles are used with other agents to treat *H. pylori* infections associated with peptic and duodenal ulcers. Metronidazole was FDA approved in 1963 and tinidazole was approved in 2004.

Nitroimidazoles are primarily administered orally, parenterally, and topically. When metronidazole is given IV intermittently, it should be administered slowly over 30 to 60 minutes. Avoid contact with the eyes when using topical product. Table 26.12 lists nitroimidazoles and their dosages, uses, and considerations.

Pharmacokinetics

Both metronidazole and tinidazole are well absorbed from the GI tract and are usually not given parenterally unless the patient cannot tolerate oral medications. The protein-binding capacity of nitroimidazoles range from 10% to 12% and the half-life is 8 to 14 hours. These drugs are eliminated from the body via urine and feces.

Pharmacodynamics

Nitroimidazoles disrupt DNA and protein synthesis becoming bactericidal, amebicidal, and trichomonacidal. It is recommended that tinidazole be taken with food, but metronidazole can be given without regard to food. When metronidazole is used in the extended release form, it should be taken on an empty stomach. The topical form is only minimally absorbed. The peak action for both of these agents is 1 to 3 hours.

Side Effects and Adverse Reactions

Common side effects that may occur when taking nitroimidazoles include headache, dizziness, insomnia, weakness, dry mouth, dysgeusia, anorexia, nausea, vomiting, diarrhea, tongue/urine discoloration, and superinfection. More serious adverse reactions that have occurred with metronidazole and tinidazole are leukopenia, peripheral neuropathy, seizures, and Stevens-Johnson syndrome. A disulfiram-like reaction may occur when metronidazole is taken with excessive amounts of alcohol. Symptoms of disulfiram-like reaction include flushing, throbbing headache, visual disturbance, confusion, dyspnea, nausea, vomiting, tachycardia, syncope, and circulatory collapse.

Critical Thinking Case Study

JN, a 46-year-old woman, has a wound infection. The culture report states that the infection is due to *Pseudomonas aeruginosa,* and JN's temperature has risen to 104°F (40°C). Amikacin sulfate is to be administered intravenously in 100 mL of 5% dextrose in water (D_5W solution) over 45 minutes every 8 hours. The dosage is 15 mg/kg/day in three divided doses. JN weighs 165 pounds.

1. What is the drug classification of amikacin? How many milligrams of amikacin should JN receive every 8 hours?
2. What type of intravenous (IV) infusion should be used? What would be the IV flow rate?
3. When would a wound culture be obtained to determine the appropriate antibacterial agent? Explain your answer.
4. What are the similarities of amikacin to other aminoglycosides such as gentamicin? Would one aminoglycoside be preferred over another? Explain your answer.

The nurse assesses JN for hearing and urinary function before and during amikacin therapy.

5. Why should a hearing assessment be included?
6. JN's urine output in the last 8 hours was 125 mL. Explain the possible cause for the amount of urine output. What nursing action should be taken?
7. What laboratory tests monitor renal function?
8. The health care provider requests peak and trough serum amikacin levels. When should the blood samples to determine peak serum level and trough serum level be drawn?

NCLEX Study Questions

1. Amoxicillin is prescribed for a patient who has a respiratory infection. The nurse is teaching the patient about this medication and realizes that more teaching is needed when the patient makes which statement?
   a. This medication should not be taken with food.
   b. I will take my entire prescription of medication.
   c. I should report to the physician any genital itching.
   d. If I experience any excess bleeding, I will contact the health care provider.
2. A patient is taking a cephalosporin. The nurse anticipates which appropriate nursing intervention(s) for this medication? (Select all that apply.)
   a. Monitoring renal function studies
   b. Monitoring liver function studies
   c. Infusing intravenous medication over 30 minutes
   d. Monitoring the patient for mouth ulcers
   e. Advising the patient to stop the medication when he or she feels better
3. Penicillin G has been prescribed for a patient. Which nursing intervention(s) should the nurse perform for this patient? (Select all that apply.)
   a. Collect culture and sensitivity before the first dose.
   b. Monitor the patient for mouth ulcers.
   c. Instruct the patient to limit fluid intake to 1000 mL/day.
   d. Have epinephrine on hand for a potential severe allergic reaction.
   e. No particular interventions are required for this patient.
4. A patient is prescribed daptomycin. Which action(s) should the nurse implement? (Select all that apply.)
   a. Monitor blood values for toxicity.
   b. Dilute in 50 to100 mL of normal saline and administer intravenously over 30 minutes.
   c. Monitor the patient for allergic reactions such as rhabdomyolysis.
   d. Advise the patient to take the medication on an empty stomach, even if gastrointestinal distress occurs.
   e. Culture the infected area before administering the first dose.
5. A patient is taking azithromycin. Which nursing intervention(s) would the nurse plan to implement for this patient? (Select all that apply.)
   a. Monitor periodic liver function tests.
   b. Dilute with 50 mL of 5% dextrose in water for intravenous administration.
   c. Instruct the patient to report any loose stools or diarrhea.
   d. Instruct the patient to report evidence of superinfection.
   e. Teach the patient to take oral drug 1 hour before or 2 hours after meals.
   f. Advise the patient to avoid antacids from 2 hours prior to 2 hours after administration.
6. For which serious adverse effect should the nurse closely monitor a patient who is taking lincosamides?
   a. Seizures
   b. Ototoxicity
   c. Hepatotoxicity
   d. *Clostridium difficile*–associated diarrhea
7. The nurse enters a patient's room to find that his heart rate is 120, his blood pressure is 70/50, and he has red blotching of his face and neck. Vancomycin is running intravenous piggyback. The nurse believes that this patient is experiencing a severe adverse effect called *red man syndrome.*

What action will the nurse take?

a. Stop the infusion and call the health care provider.

b. Reduce the infusion to 10 mg/minute.

c. Encourage the patient to drink more fluids, up to 2 L/day.

d. Report onset of Stevens-Johnson syndrome to the health care provider.

8. A patient is receiving tetracycline. Which advice should the nurse include when teaching this patient about tetracycline?

a. Take sunscreen precautions when at the beach.

b. Take an antacid with the drug to prevent severe gastrointestinal distress.

c. Obtain frequent hearing tests for early detection of hearing loss.

d. Obtain frequent eye checkups for early detection of retinal damage.

9. A patient is taking levofloxacin. What does the nurse know to be true regarding this drug?

a. It is administered by intravenous only.

b. Levofloxacin may cause hypertension.

c. This drug is classified as an aminoglycoside.

d. An adverse effect is dysrhythmia.

10. Which instruction(s) will the nurse include when teaching patients about gentamicin? (Select all that apply.)

a. Patients should report any hearing loss.

b. Patients should use sunscreen when taking gentamicin.

c. Intravenous gentamicin will be given over 20 minutes.

d. Patients are monitored for mouth ulcers and vaginitis.

e. Peak levels will be drawn 30 minutes before the intravenous dose.

f. Patients should increase fluid intake.

11. Which nursing intervention(s) should the nurse consider for the patient taking ciprofloxacin? (Select all that apply.)

a. Obtain culture before drug administration.

b. Tell the patient to avoid taking ciprofloxacin with antacids.

c. Monitor the patient for tinnitus.

d. Encourage fluids to prevent crystalluria.

e. Infuse intravenous ciprofloxacin over 60 minutes.

f. Monitor blood glucose because ciprofloxacin can decrease effects of oral hypoglycemics.

12. A patient is taking sulfasalazine. What should the nurse teach the patient to do?

a. Drink at least 10 glasses of fluid per day.

b. Monitor blood glucose carefully to avoid hyperglycemia.

c. Avoid operating a motor vehicle because this drug may cause drowsiness.

d. Take this drug with an antacid to decrease the risk of gastrointestinal distress.

13. The nurse is teaching a patient about trimethoprim-sulfamethoxazole. Which instructions will the nurse plan to include? (Select all that apply.)

a. Report any bruising or bleeding.

b. Report any diarrhea or bloody stools.

c. Report any fever, rash, or sore throat.

d. Avoid unprotected exposure to sunlight.

e. Report thirst and polyuria.

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Compare first-line and second-line antitubercular drugs and give examples of each.
- Differentiate between the groups of antifungal drugs.
- Explain the uses of polyenes.
- Differentiate the adverse reactions of antitubercular, antifungal, and antiviral drugs.
- Apply the nursing process for patients taking antitubercular, antifungal, and antiviral drugs.

This chapter covers antituberculars, antifungals, and antivirals. Although these drug categories differ from one another, they each contain drugs that inhibit or kill organisms that cause disease.

Tuberculosis

Tuberculosis (TB) is caused by the acid-fast bacillus *Mycobacterium tuberculosis.* The number of TB cases had declined until the mid-1980s, when the number of cases started to increase. The increase in cases of TB was attributed to multiple factors, such as human immunodeficiency virus (HIV), increased immigration, and the spread of multidrug-resistant TB (MDR TB). According to the U.S. Department of Health and Human Services (DHHS), tuberculosis is one of the world's leading causes of death due to infectious diseases in persons older than 5 years of age. Each year, about 9 million people develop TB, and 2 million die because of it. With increased funding, prompt identification of persons with TB, appropriate initial treatment, and completion of treatments, the number of TB cases started declining again in the mid-1990s. However, MDR TB continues to be a serious health concern. Patients started on therapy for TB who do not finish the prescribed therapy can develop and spread resistant strains of *M. tuberculosis*.

Pathophysiology

TB is transmitted from one person to another by droplets dispersed in the air through coughing, sneezing, and speaking. TB microorganisms can be inhaled into the lungs, therefore persons in close contact with the infected patient are at highest risk of becoming infected. Others at high risk for contracting the disease include the immunocompromised (e.g., patients with HIV, diabetes, and renal failure and those taking certain medications, such as cortisol), people living or working in high-risk residential settings (e.g., nursing homes, shelters, correctional facilities), those who inject illegal drugs, and health care workers who serve high-risk patients.

Not everyone infected with TB will develop clinical manifestations, rather some will harbor the microorganisms and will have what is called **latent tuberculosis infection**; these persons are at risk of developing TB disease later, and only those with TB disease can infect others. Symptoms of TB disease include anorexia, cough with sputum production or blood, chest pain, fever, night sweats, weight loss, and positive acid-fast bacilli in the sputum. Isolating infectious persons and initiating treatment for TB disease as soon as possible is the best way to decrease transmission.

Nurses should be aware that persons coming to the United States from high-risk countries where TB disease is common may have been vaccinated with bacille Calmette-Guérin (BCG) as a child. This vaccine is seldom used in the United States. Previous vaccination with BCG may cause a positive reaction to skin testing; however, it does not affect interferon-gamma release assay (IGRA) blood testing.

Antitubercular Drugs

Antitubercular drugs (Table 27.1), which include antimycobacterials, treat persons with TB disease and those exposed to TB disease. Streptomycin was the first drug used in the treatment of TB disease in 1943. However, it was noted that patients began to deteriorate after 3 months of therapy due to drug resistance. In 1952, isoniazid (INH) began to see widespread use in the treatment of TB disease and was felt to be a "wonder drug." To this day, INH remains the first-line treatment for TB disease. INH is a bactericidal drug that inhibits tubercle cell-wall synthesis and blocks pyridoxine (vitamin B6), which is used for intracellular enzyme production. When INH is prescribed, pyridoxine may also be prescribed to avoid vitamin B deficiency and to minimize peripheral neuropathy. INH is administered orally. Prototype Drug Chart 27.1 lists the data for INH.

TABLE 27.1
Antitubercular Drugs

Generic	Route and Dosage	Uses and Considerations
First-Line Treatment for Tuberculosis Disease		
Ethambutol hydrochloride	A: PO: Based on lean body weight: 15-25 mg/kg/d	Used in combination with other antitubercular drugs. A common adverse effect is eye damage that causes blurred or changed vision, including color vision. Pregnancy category: B*; PB: 20%-30%; t½: 3-4 h
Isoniazid (INH)	See Prototype Drug Chart 27.1.	
Pyrazinamide	A/C: PO: 15-30 mg/kg/d or 50-70 mg/kg 2 ×/wk; *max:* 30 mg/kg/d	Used in combination with other antitubercular drugs. Can be given without regard to meals; promote fluid intake to decrease renal complications. Common adverse effects include hepatitis with patients exhibiting abdominal pain, abnormal hepatic transaminases, fatigue, anorexia, nausea or vomiting, jaundice, and icteric, dark urine. May also cause photosensitivity, angioedema, hepatic failure, and thrombocytopenia. Monitor LFTs and serum uric acid. Pregnancy category: C*; PB: 50%; t½: 9-10 h
Rifabutin	A: PO: 300 mg/d; *max:* 600 mg/d	May divide dose to 150 mg twice daily with GI concerns (e.g., nausea, vomiting). Pregnancy category: B*; PB: 85%; t½: Average 45 h
Rifampin†	A: PO: 10 mg/kg/d; *max:* 600 mg/d C: PO: 10-20 mg/kg/d; *max:* 600 mg/d	Used in combination with other antitubercular drugs. Best taken on an empty stomach. Contents of capsules may be mixed with applesauce or jelly. Pregnancy category: C*; PB: 80%; t½: 3-5 h
Rifapentine	Active: A/C ≥12 y: PO: 600 mg twice weekly Latent: A/C ≥2 y: Single weight-based dose weekly × 12 wk; *max:* 900 mg/wk	Rifapentine *must* be used in combination with other antitubercular drugs in patients with TB disease who are HIV negative or for latent TB infection to prevent progression to TB disease. Rifapentine has a longer half-life than rifampin; the interval between doses should be at least 72 h. Monitor for toxicity if drug is taken with an anticoagulant or anticonvulsant or with digoxin. Monitor for thrombocytopenia, ecchymosis, and indigestion. Do not use concurrently with oral contraceptives. Pregnancy category: C*; PB: 98%; t½: 13 h
Drugs For Multidrug-Resistant Tuberculosis		
(Used in combination with first-line drugs based on sensitivity)		
Aminosalicylate sodium	A: PO: 8-12 g/d in 2-3 divided doses C: PO: 200-300 mg/kg/d in 2-4 divided doses taken with food; *max:* 10 g/d	Used in combination with other antitubercular drugs as a second-line therapy. Administer as a suspension mixed in acidic liquid (e.g., applesauce, yogurt, or tomato or orange juice) without chewing. Nonacidic foods will dissolve the acid-resistant coating of the granules. GI disturbances (e.g., nausea, vomiting, diarrhea, abdominal pain) are the most common complaints. Pregnancy category: C*; PB: 50%-60%; t½: 26 min
Capreomycin	A ≤59 y: IV/IM: 15 mg/kg/d; *max:* 1 g/d A >59 y: IV/IM: 10 mg/kg/d; *max:* 750 mg/d	Used in combination with other antitubercular drugs. Inject into a large muscle mass. Because of possible nephrotoxicity, use caution when administering to patients with renal impairment. Other toxicity includes ototoxicity. Pregnancy category: C*; PB: UK; t½: 5.2-6.8 h
Table Continued		

Drugs For Multidrug-Resistant Tuberculosis		
Cycloserine	A: PO: 500-1000 mg/d in divided doses	Used in combination with other antitubercular drugs. May be taken without regard to food. Pyridoxine taken concurrently can relieve or prevent neurotoxic effects. Contraindicated in patients with a history of ETOH abuse, severe anxiety, major depression, psychosis, severe renal disease, and seizure disorders. Monitor cycloserine concentrations. Pregnancy category: C*; PB: UK; t½: 10 h
Ethionamide	A/C >12 y: PO: 15-20 mg/kg/d as a single dose or in 2-3 divided doses; *max:* 1 g/d	Used in combination with other antitubercular drugs. Contraindicated in severe hepatic impairment. An ophthalmologic exam should be done and blood glucose and hepatic function should be monitored before and periodically during treatment. Drug may be taken without regard to food. Pregnancy category: C*; PB: 30%; t½: 2 h
Streptomycin sulfate	A: IM: 15 mg/kg/d; *max:* 1 g/d C: IM: 20-40 mg/kg/d	Used in combination with other antitubercular drugs. Inject into a large muscle mass. Contraindicated in people with aminoglycoside hypersensitivity. Monitor for ototoxicity, nephrotoxicity, and neurotoxicity. Pregnancy category: D*; PB: 35%; t½: 2-3 h

A, Adult; *C,* child; *d,* day; *ETOH,* ethanol (alcohol); *GI,* gastrointestinal; *h,* hour; *HIV,* human immunodeficiency virus; *IM,* intramuscular; *IV,* intravenous; *LFT,* liver function test; *max,* maximum; *min,* minutes; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *TB,* tuberculosis; *UK,* unknown; *wk,* week; *y,* year; >, greater than; ≥, greater than or equal to; ≤, less than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

† Rifampin is the preferred agent from the class of rifamycins (rifabutin, rifampin, and rifapentine).

PROTOTYPE DRUG CHART 27.1 Isoniazid

Drug Class	Dosage
Antimycobacterial (antitubercular) Pregnancy category: C*	Latent TB infection: A: PO/IM: 300 mg/d *or* 900 mg/d 2 ×/wk with pyridoxine *or* 15 mg/kg with rifapentine 1 ×/wk C: PO/IM: 10-15 mg/kg/d *or* 20-30 mg/kg/d 2 ×/wk with pyridoxine *or* 15 mg/kg with rifapentine 1 ×/wk; *max:* 900 mg/d Do not give rifapentine to children under 2 y. TB disease: A: PO/IM: 5 mg/kg/d or 5 d/wk or 15 mg/kg once, twice, or thrice weekly; *max:* 900 mg/d Adol: PO/IM: 5-15 mg/kg/d or 5 d/wk *or* 15-40 mg/kg twice or thrice weekly C: PO/IM: 10-15 mg/kg once daily or 5 ×/wk *or* 20-40 mg/kg 2-3 ×/wk See the CDC website at www.cdc.gov for complete dosing regimens.
Contraindications	Drug-Lab-Food Interactions
Severe renal or hepatic disease, alcoholism, diabetic retinopathy; severe hypersensitivity to pyrazinamide or ethionamide; concurrent use with MAOI therapy	Drug: Potent inhibitor of CYP450 enzyme system; many drug-drug interactions can occur (see the package insert for a complete list). Increased effect with alcohol, rifampin, and cycloserine; decreased GI absorption while taking aluminum antacids; inhibits the metabolism of benzodiazepines, phenytoin, fosphenytoin, SSRIs, SNRIs, and valproic acid. MAOIs could potentiate the effects of INH. Food: Food decreases the rate and extent of drug absorption. Foods rich in histamine (e.g., aged cheese, tuna), tyramine (e.g., aged cheese, bananas, avocadoes, overripe fruit, fava beans, smoked meats and fish, soy sauce, yeast), and caffeine can increase the effects of INH. Herb: Green tea, guarana, and ginseng could potentiate the effects of INH.
	Lab: Increases AST, ALT, bilirubin
Pharmacokinetics	Pharmacodynamics
Absorption: Rapidly absorbed in the GI tract when given PO Distribution: PB: Nonsignificant Metabolism: t½: 1-4 h Excretion: 75% in urine; remainder in feces, saliva, and sputum	PO/IM: Onset: UK Peak: 1-2 h Duration: UK
Therapeutic Effects/Uses	
To treat active tuberculosis and as a prophylactic measure against tuberculosis	
Mode of Action: Bactericidal or bacteriostatic, depending on the drug concentration; inhibits bacterial cell-wall synthesis and MAO without affecting mitochondrial MAO, which interferes with the metabolism of tyramine and histamine. No cross-resistance with other antitubercular drugs occurs except with ethionamide. Pyridoxine supplementation reduces neurotoxic side effects.	
Side Effects	Adverse Reactions
Drowsiness, tremors, rash, blurred vision, photosensitivity, tinnitus, dizziness, nausea, vomiting, dry mouth, constipation, diarrhea with oral solution, injection site reaction with IM administration	Psychotic behavior, peripheral neuropathy, vitamin B6 deficiency, hyperglycemia, metabolic acidosis, optic neuritis *Life threatening:* Blood dyscrasias, seizures, thrombocytopenia, agranulocytosis, hepatotoxicity, exfoliative dermatitis

A, adult; *Adol*, adolescent; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *C,* child; *CDC,* Centers for Disease Control and Prevention; *CYP450,* cytochrome P450; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *INH,* isoniazid; *MAO,* monoamine oxidase; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *SNRI,* serotonin norepinephrine reuptake inhibitor; *SSRI,* selective serotonin reuptake inhibitor; *t½,* half-life; *TB,* tuberculosis; *UK,* unknown; *wk,* week; *y,* year.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

BOX 27.1 Determining When to Treat Latent Tuberculosis Infection

People with a positive tuberculin skin test (TST) reaction of ≥5 mm if they are:

- HIV positive
- Recent contacts of someone with active tuberculosis (TB disease)
- Persons with fibrotic changes on chest radiography consistent with old TB
- Organ transplant recipients
- Persons who are immunosuppressed for other reasons (e.g., those taking the equivalent of >15 mg/day of prednisone for 1 month or longer, those taking tumor necrosis factor alpha [TNF-α] antagonists)

People with a positive TST reaction of ≥10 mm if they are:

- Recent immigrants (<5 years) from high-prevalence countries
- Injection drug users
- Residents and employees of high-risk congregate settings (e.g., correctional facilities, nursing homes, homeless shelters, hospitals, and other health care facilities)
- Mycobacteriology laboratory personnel
- Children under 4 years of age or children or adolescents exposed to adults in high-risk categories

From http://www.cdc.gov/tb/topic/treatment/decideltbi.htm

Prophylactic antituberculars are drugs to prevent TB disease in individuals with latent TB infection. Prophylaxis is recommended for those who have a clinically significant result on tuberculin skin testing (≥5 mm for immunocompromised individuals or ≥10 mm for high-risk groups; Box 27.1) or a positive IGRA result. Patients who have converted from a negative to a positive TB skin test (TST) or from a negative to positive IGRA should be considered candidates for prophylactic therapy as well. Prototype Drug Chart 27.1 shows guidelines for latent TB infection treatment with INH.

Prophylactic therapy is contraindicated for persons with liver disease because INH is the primary antitubercular drug used, and it may cause INH-induced liver damage. Other antitubercular drugs may also cause liver damage if given in high doses over an extended period.

Single-drug therapy is ineffective in the treatment of TB disease due to drug resistance. Using a combination of antitubercular drugs has been shown to decrease bacterial resistance. Additionally,

using combination therapy has decreased the duration of treatment from 2 years to 6 to 9 months. Different combinations of drugs can be used with INH, rifampin, ethambutol, and pyrazinamide.

Antitubercular drugs are divided into two categories: first-line drugs that form the core of treatment regimens and drugs used in the treatment of drug-resistant TB. **First-line drugs**—those drugs chosen first, such as INH, rifampin, pyrazinamide, and ethambutol—are considered more effective and less toxic than drugs used in the treatment of drug-resistant TB. Drugs used in the treatment of drug-resistant TB, in which *M. tuberculosis* is resistant to at least one first-line drug, or MDR TB, in which *M. tuberculosis* is resistant to INH and rifampin plus one other first-line drug, are used in combination with first-line drugs to treat drug-resistant *M. tuberculosis.* See Table 27.1 for drugs used in the treatment of drug-resistant TB.

Combination therapy against TB disease is more effective in eradicating infection than any single drug. The treatment regimen is divided into two phases: the initial phase lasts 2 months, and the continuation phase consists of the next 4 or 7 months. The total treatment plan can be up to 9 months or longer, depending on response to drug therapy. If drug resistance develops, other antibacterial drugs such as aminoglycosides (streptomycin, kanamycin, amikacin) or fluoroquinolones (levofloxacin, ciprofloxacin, or ofloxacin) may be given as part of combination therapy. Combination therapy for drug-resistant TB disease consists of a minimum of three drugs, but preferably four to five drugs, administered as part of directly observed therapy to ensure adherence. Drug therapy should be managed by an expert in the disease, and susceptibility testing to determine drug resistance should be performed before drug therapy; however, treatment with first-line therapy should not be delayed if TB disease is suspected. Aminoglycoside antibiotics should not be taken if kidney dysfunction is present. When antibacterial agents are used continuously or at high doses, serum drug levels should be closely monitored to avoid drug toxicity.

Many drug-drug interactions and side effects occur with antituberculars. To increase adherence to drug therapy, direct observation therapy (DOT) is recommended.

Side Effects and Adverse Reactions

Side effects and adverse reactions to antituberculars differ according to the drug prescribed. For INH, peripheral neuropathy can be a problem, especially for those who are malnourished, have diabetes mellitus, or are alcoholics. This condition can be prevented if pyridoxine (vitamin B6) is administered. **Hepatotoxicity** (liver toxicity) is an adverse reaction to many antituberculars. Patients with moderate to severe liver dysfunction should *not* take these drugs. Patients with liver disease should have hepatic transaminases monitored closely. Patients may also develop headaches, blood dyscrasias, paresthesias, gastrointestinal (GI) distress (e.g., nausea, vomiting, diarrhea, dyspepsia), and ocular toxicity. An ophthalmic exam before and during treatment is warranted. INH may cause hyperglycemia, hyperkalemia, hypophosphatemia, and hypocalcemia. Rifampin turns body fluids orange, and soft contact lenses may be permanently discolored. It may also cause thrombocytopenia and GI intolerance. The patient taking ethambutol may develop dizziness, confusion, hallucinations, and joint pain. Streptomycin may lead to many adverse effects such as ototoxicity, optic nerve toxicity, encephalopathy, angioedema, central nervous system (CNS) and respiratory depression, nephrotoxicity, and hepatotoxicity.

Patient Safety

Do not confuse…

- *Rifampin* with other antituberculars such as *rifabutin* and *rifapentine.*

Special Populations

Pregnancy and Tuberculosis

The benefits of treating a pregnant woman with TB disease outweigh the risks of treatment. Women with untreated TB disease are at risk for passing the disease to their fetus and delivering an infant with low birthweight. The drugs used in initial treatment of TB disease do cross the placenta but do not appear to harm the fetus.

Treatment of latent TB infection in the pregnant woman includes INH daily or twice weekly for 9 months with pyridoxine supplementation. Three-month combination therapy of INH with rifapentinem, *referred to as 3HP,* is not recommended for pregnant women or those planning to become pregnant within 3 months.

The pregnant woman with TB disease should be treated with INH, rifampin, and ethambutol daily for 2 months followed by INH and rifampin daily or twice weekly for 7 months for a total of 9 months. Streptomycin should *not* be used due to potential harmful effects on the fetus. Pyrazinamide is also *not* recommended due to unknown effects on the fetus.

Tuberculosis and HIV Coinfection

HIV is a risk factor for the development of TB, and TB disease is one of the leading causes of death for people living with HIV. Left untreated, latent TB infection can quickly develop into TB disease. The recommended treatment for an adult with latent TB infection and HIV is INH daily for 9 months.

Adults with HIV and TB disease should be treated for 6 months with INH, rifabutin, pyrazinamide, and ethambutol during the initial phase. The 4-month continuation phase should consist of INH and rifabutin.

A pregnant woman with HIV and TB disease should be treated the same as a nonpregnant woman but with concern for the fetus when choosing drug therapy.

Pediatric Tuberculosis

Children are more likely than adults to be sickened more quickly by TB. Because of this, children with latent TB infection should be treated to prevent development of TB disease. The recommended treatment is INH for 9 months. Treatment of TB disease should be managed by a pediatric TB expert in conjunction with drug susceptibility studies. It is very important for the nurse to make sure parents understand that if a child stops taking the drugs before therapy is finished, the child can become sick again. Additionally, nurses should stress to parents that if drugs are not taken correctly, the bacteria may become drug resistant. Drug-resistant TB is harder and more expensive to treat.

Nursing Process: Patient-Centered Collaborative Care

Antitubercular Drugs

Assessment

- Determine any past instances of TB in the patient's health history—including the last purified protein derivative (PPD) tuberculin test and the reaction or the serum IGRA result, the last chest radiograph and result, and the last ophthalmic exam—along with any allergies.
- Obtain a general medical history from the patient. Most antitubercular drugs are contraindicated if the patient has severe hepatic disease.
- Check laboratory results for liver function studies, bilirubin, blood urea nitrogen (BUN), and serum creatinine. These baseline values can be compared with future laboratory test results.
- Evaluate the patient for signs and symptoms of paresthesia (tingling, numbness, or burning).
- Assess for hearing changes if the antitubercular drug regimen includes streptomycin. Drug-induced ototoxicity is the major irreversible toxicity of aminoglycosides.

Nursing Diagnoses

- Nonadherence, Risk for
- Infection, Risk for
- Knowledge, Deficient related to unfamiliarity with medications

Planning

- The patient's sputum test for acid-fast bacilli will be negative 2 to 3 months after the prescribed antitubercular therapy.

Nursing Interventions

- If INH is ordered, administer the drug 1 hour before or 2 hours after meals because food decreases the absorption rate. Other antitubercular drugs are given without regard to meals.
- Give pyridoxine (vitamin B6) as prescribed with INH to prevent peripheral neuropathy.
- Monitor serum liver enzyme levels. Elevated levels may indicate liver toxicity.
- Collect sputum specimens for acid-fast bacilli early in the morning. Usually three consecutive morning sputum specimens are sent to the laboratory.
- Encourage eye examinations for patients taking INH and ethambutol because these antitubercular drugs may cause visual disturbances.
- Emphasize the importance of complying with the drug regimen.

Patient Teaching

- Tell patients who take INH to take the drug 1 hour before meals or 2 hours after meals for better absorption.
- Direct patients to take antitubercular drugs as prescribed. Ineffective treatment and development of drug resistance might occur if drugs are taken intermittently or discontinued when symptoms are decreased or when the patient is feeling better. *Adherence to the drug regimen is essential to prevent the spread of drug-resistant* M. tuberculosis.
- Instruct patients not to take antacids while taking antitubercular drugs because they decrease drug absorption. Patients should also avoid alcohol because it increases the risk of hepatotoxicity.
- Advise patients to keep medical appointments and to participate in sputum testing, which is important in evaluating the effectiveness of drug regimens.
- Warn patients contemplating pregnancy to first check with their health care provider about taking the antitubercular drugs ethambutol and rifampin.
- Guide patients to report any numbness, tingling, or burning of hands and feet. Peripheral neuropathy is a common side effect of INH. Vitamin B6 prevents peripheral neuropathy.
- Encourage patients to avoid direct sunlight to decrease the risk of photosensitivity. Patients should use a sunscreen with a minimum sun protection factor (SPF) of 30 and ultraviolet A and B (UVA/UVB) protection while in the sun.
- Inform patients taking rifampin that urine, feces, saliva, sputum, sweat, and tears may turn a harmless red-orange color. Soft contact lenses may be permanently stained.
- Alert patients receiving ethambutol to take daily single doses to avoid visual problems. Divided doses of ethambutol may cause visual disturbances.
- Increase access to health care. Community involvement and culturally sensitive patient education are important. Explain to patients who have active TB that family members should get a TB skin test and may receive a prophylactic drug for 6 months to 1 year. Emphasize the importance of family members seeking medical care.
- Provide a written sheet for drug and treatment regimens in the language the patient speaks or reads most easily. Explain the importance of good hygiene (e.g., discarding tissues that contain sputum, separating dishes, using a dishwasher to clean dishes if possible).
- Understand the significance of community if multiple individuals in the same community are treated for latent TB infection. Make all attempts to place community members on a treatment plan to increase compliance through social support.

Evaluation

- Evaluate the effectiveness of the antitubercular drugs. Sputum specimens for acid-fast bacilli should be negative after taking antitubercular drugs for several weeks or months.

Fungus

Pathophysiology

An infection caused by a fungus may also be called *mycosis*, *tinea*, or *candidiasis.* A fungal infection may be local or systemic. Local fungal infections can be acquired by contact with an infected person. Fungi known as *dermatophytes* can cause local fungal infections involving the integumentary system, which includes mucous membranes, hair, nails, and moist skin areas. When *Candida albicans* affects the mouth, it is called *oral candidiasis* or *thrush.* Vaginal candidiasis is common in women who are pregnant, diabetic, immunocompromised, or taking certain medications (e.g., antibiotics, oral contraceptives, and dapagliflozin). Systemic fungal infections may involve the lungs, CNS, or abdomen and are usually transmitted to an individual through inhalation into the lungs. Fungal infections may be mild, such as tinea pedis (athlete's foot), or severe, such as fungal disease of the lungs or fungal meningitis.

Fungal infections are also classified as *opportunistic* or *primary.* **Opportunistic infections** usually occur in the immunocompromised or debilitated population (e.g., patients who have cancer or AIDS) or in those taking antibiotics, corticosteroids, chemotherapy, or other immunosuppressives. Fungi such as *Candida* species (yeast) are part of the normal flora of the mouth, skin, intestine, and vagina. An opportunistic infection, such as systemic candidiasis, may occur when the body's defense mechanisms are impaired such that they allow overgrowth of the fungus. Other opportunistic infections are aspergillosis, mucormycosis, *Pneumocystis* pneumonia, and fusariosis. Primary infections typically occur in immunocompetent persons and result from inhaled spores. Primary infections include coccidioidomycosis, blastomycosis, paracoccidioidomycosis, cryptococcosis, and histoplasmosis, including progressive disseminated histoplasmosis.

Antifungal Drugs

Antifungal drugs, also called **antimycotic drugs**, are used to treat fungal infections. Typically, antifungals are fungistatic or fungicidal depending upon the susceptibility of the fungus and the dosage. The antifungal drugs are classified into the following groups (Table 27.2):

- Polyenes (amphotericin B, nystatin)
- Azoles (fluconazole)

TABLE 27.2
Antifungal Drugs

Generic	Route and Dosage	Uses and Considerations
Polyenes		
Amphotericin B deoxycholate	A: IV: 0.25-1.5 mg/kg/d; *max:* 1.5 mg/kg/d	For a variety of systemic fungal infections. May require pretreatment with an analgesic, antihistamine, antipyretic, and corticosteroid for pain, fever, chills, or rigor. Electrolyte loss and nephrotoxicity can occur. Protect drug against light and infuse slowly via an in-line filter. Pregnancy category: B*; PB: 90%-95%; t½: 24 h
Nystatin	See Prototype Drug Chart 27.2.	
Azole Antifungals		
Fluconazole	See Prototype Drug Chart 27.3.	
Itraconazole	A: PO: 200-400 mg/d Other dosing regimens are available for severe infection or for patients who are immunocompromised.	For a variety of fungal infections. Targets CYP450 enzymatic pathway. Avoid concurrent use with PPIs, H_2 blockers, or antacids. Take on an empty stomach. Pregnancy category: C*; contraindicated in pregnancy and in those contemplating pregnancy; PB: 99%; t½: 34-42 h
Ketoconazole	Systemic: A: PO: 200-400 mg/d as a single dose C ≥2 y: PO: 3.3-6.6 mg/kg/d as a single dose Topical: A: Apply a sufficient amount to affected and surrounding areas once daily for 2 wk.	For a variety of fungal infections. Treatment may last 1 to 6 months for systemic infections. Take with food to avoid GI discomfort. Higher doses can inhibit adrenal cortisol synthesis. Pregnancy category: C*; PB: 84%-99%; t½: 2-8 h
Posaconazole	Oral candidiasis: A: PO: 100 mg/d up to 200 mg tid for 14-21 d Prophylactic: A: PO: 200-300 mg bid/tid A: IV: 300 mg bid initially, then 300 mg/d	For oral candidiasis and prophylactic treatment of invasive *Aspergillus* and *Candida* infections in immunosuppressed patients. Different formulations are not interchangeable. Ensure proper dosage formulation, strength, and frequency. Do not chew, divide, or crush delayed-release tablets. Administer with food or as an IV infusion via a central line with an in-line filter. Pregnancy category: UK* (avoid use during pregnancy); PB: >98%; t½: 20-66 h depending on formulation
Voriconazole	A/C: PO: Weight-based dosing: 200-400 mg q12h A/C: IV: 6 mg/kg q12h on day 1, then 3-4 mg/kg q12h	For aspergillosis, candidiasis, fusariosis, and scedosporiosis. Patients with HIV coinfection may need a higher dose. Grapefruit juice should be avoided. Take PO dose on an empty stomach. Pregnancy category: D*; PB: 58%; t½: 6 h to 6 d, depending on the dose
Antimetabolites		
Flucytosine	A: PO: 50-150 mg/kg/d in divided doses q6h for 7-10 d; *max:* 150 mg/kg/d TDM: 50-150 mcg/mL	Usually given in conjunction with amphotericin B to decrease the development of resistance to flucytosine. Fungal resistance occurs if drug is given alone. Fungal cells convert flucytosine to trace amounts of fluorouracil intracellularly. Monitor flucytosine concentrations, liver transaminases, and renal function. Pregnancy category: C*; PB: 2%-4%; t½: 2.5-6 h
Echinocandins		
Anidulafungin	A: IV: 100-200 mg loading dose on day 1, then 50-100 mg/d	For *Candida* infections. Infusion time is dose dependent. Monitor liver function tests. Pregnancy category: C*; PB: 99%; t½: 30-60 min
Caspofungin	A: IV: 70 mg on day 1, then 50 mg/d C ≥3 mo: IV: 70 mg/m² on day 1, then 50-70 mg/m²; *max*: 70 mg/d	For *Aspergillus* and *Candida* infections. Give IV as an infusion over 1 h. Monitor CBC and liver transaminases. Pregnancy category: C*; PB: 97%; t½: 9-50 h
Micafungin	A: IV: 100-150 mg/d C ≥4 mo: IV: 2-4 mg/kg/d; *max*: 100 mg/d	For *Candida* infection. Patients with HIV coinfection may require a higher dose. Does not have significant effect on the CYP450 enzyme system. To minimize excessive foaming, do not vigorously shake the vial. Infuse slowly over 1 h. Rapid infusion can cause histamine-mediated reactions. Pregnancy category: C*; PB: 99%; t½: 13-17 h
Miscellaneous Antifungals		
Griseofulvin	A: PO: 300-750 mg/d; can be given in 2-4 divided doses/d; *max:* 1000 mg/d C >2 y: PO: 5-20 mg/kg/d; *max*: 1000 mg/d	For tinea infection, including onychomycosis. Available in microsize and ultramicrosize; dosage depends on formulation. Give with a fatty meal to increase absorption. Tablets can be crushed and mixed with food; swallow without chewing. Pregnancy category: X*; PB: UK; t½: 9-24 h

A, Adult; *bid,* twice daily; *C,* child; *CBC,* complete blood count; *CYP450,* cytochrome P450; *d,* day; *GI,* gastrointestinal; *h,* hour; H_2, histamine 2; *HIV,* human immunodeficiency virus; *IV,* intravenous; *max,* maximum; *min,* minute; *mo,* month; *PB,* protein binding; *PO,* by mouth; *PPI,* proton pump inhibitor; *q,* every; *t½,* half-life; *TDM,* therapeutic drug monitoring; *tid,* three times daily; *UK,* unknown; *wk,* weeks; *y,* year; >, greater than; ≥, greater than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

- Antimetabolites (flucytosine)
- Echinocandins (caspofungin)
- Miscellaneous antifungals (griseofulvin)

Polyenes

Amphotericin B

The polyene antifungal drug of choice for severe systemic infection is amphotericin B, which is

effective against numerous fungal diseases that include histoplasmosis, cryptococcosis, coccidioidomycosis, aspergillosis, blastomycosis, and systemic candidiasis. Polyene antifungals act by binding to the fungal cell membrane to form open channels that increase cell permeability and leakage of intracellular components, especially potassium. Because of its toxicity, amphotericin B is administered with close supervision.

Pharmacokinetics

Amphotericin B is highly protein bound and has a long half-life. Only 5% of the drug is excreted in the urine. Renal disease does not affect the excretion of amphotericin B.

Pharmacodynamics

Amphotericin B is not absorbed from the GI tract, therefore it is administered intravenously in low doses for treating systemic fungal infections. Peak effect occurs 1 to 2 hours after intravenous (IV) infusion, and the duration is 24 hours.

Side Effects and Adverse Reactions

Side effects and adverse reactions for amphotericin B include fever, shaking, chills, flushing, loss of appetite, dizziness, nausea, vomiting, headache, shortness of breath, and tachypnea. These symptoms may occur 1 to 3 hours after the infusion has started. Pretreatment with acetaminophen, diphenhydramine, or hydrocortisone administered 30 to 60 minutes prior to infusion may alleviate these symptoms. Additionally, patients may experience hypotension, paresthesia, and thrombophlebitis. Amphotericin B is *highly toxic* and can cause nephrotoxicity and electrolyte imbalance, especially hypokalemia and hypomagnesemia (low serum potassium and magnesium levels). Urinary output, BUN, and serum creatinine levels must be closely monitored. Amphotericin B is also toxic to bone marrow, therefore complete blood counts should be monitored periodically.

Nystatin

Nystatin is another polyene antifungal drug that is administered orally or topically to treat *Candida* infection. It is available in suspension, cream, and ointment forms. Nystatin is poorly absorbed by the GI tract. The more common use of nystatin is as an oral suspension for *Candida* infection in the mouth (oral thrush). The suspension is swished in the mouth for several minutes to ensure contact with the mucous membranes and then is either spit out or swallowed. If the throat area is involved, the patient should also gargle with nystatin prior to swishing and swallowing or spitting. Prototype Drug Chart 27.2 lists the data for nystatin.

Azole Antifungals

The azole group is effective against candidiasis (local and systemic), coccidioidomycosis, cryptococcosis, histoplasmosis, and paracoccidioidomycosis. Ketoconazole was the first effective antifungal drug that was orally absorbed. Fluconazole, itraconazole, posaconazole, and voriconazole are other azole drugs used to treat systemic fungal infections. These antifungals can be taken orally, unlike amphotericin B and caspofungin, which are administered by the IV route only. Fluconazole, a systemic azole antifungal agent, is described in Prototype Drug Chart 27.3.

Azoles inhibit cytochrome P450 (CYP450) in fungal cells, interfering with the formation of ergosterol. Because ergosterol is a major sterol in the fungal cell membrane, cell permeability and leakage are increased. Numerous azoles are used in topical preparations (e.g., creams, ointments, powders, shampoos, sprays, and solutions) to treat candidiasis and tinea infections. Azoles and other topical antifungal agents are presented in Table 27.2.

Antimetabolites

The antimetabolite flucytosine acts by selectively penetrating the fungal cell, which converts the drug into fluorouracil, an antimetabolite that disrupts fungal DNA and RNA synthesis. Flucytosine is well absorbed from the GI tract, and it is used in combination with other antifungal drugs, such as amphotericin B. Antimetabolites are discussed further in Chapter 32.

PROTOTYPE DRUG CHART 27.2 Nystatin

Drug Class	Dosage
Antifungal antibiotic Pregnancy category: C*	A/C: PO susp: 4-6 mL swished in the mouth 4 ×/d for 7-14 d Infants: PO susp: 1-2 mL in each side of the mouth 4 ×/d for at least 48 h A/C: Top: Apply to affected area bid until healed. A: PO cap: 500,000 to 1 million units tid for at least 48 h
Contraindications	Drug-Lab-Food Interactions
Caution: Pregnancy, diabetes mellitus, paraben hypersensitivity, breastfeeding	Drug: Azole antifungals inhibit the synthesis of the fungal sterol ergosterol, which decreases the effectiveness of nystatin.
Pharmacokinetics	Pharmacodynamics
Absorption: Poorly absorbed in the GI the tract when given PO Absorption: Susp/top: Not absorbed from intact skin or mucous membranes Distribution: PB: UK Metabolism: t½: UK Excretion: PO: In feces	PO: Onset: 24-72 h; peak and duration: UK Susp/top: Onset, peak, and duration: UK
Therapeutic Effects/Uses	
To treat candidiasis	
Mode of Action: Binds to sterols (ergosterol) causing the loss of intracellular potassium and other cellular contents	
Side Effects	Adverse Reactions
PO: Diarrhea, nausea, vomiting, dyspepsia Top: Skin irritation	Top/susp: Pruritus, urticaria, rash, hyperglycemia *Life threatening:* PO/top/susp: Angioedema, bronchospasm, sinus tachycardia, Stevens-Johnson syndrome

A, Adult; *bid,* twice daily; *C,* child; *cap*, capsule; *d,* day; *GI,* gastrointestinal; *h,* hour; *PB,* protein binding; *PO,* by mouth; *susp*, suspension; *t½,* half-life; *tid,* three times daily; *Top*, topical; *UK,* unknown.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 27.3 Fluconazole

Drug Class	Dosage
Azole antifungal Pregnancy category: C/D*	Cryptococcal meningitis: A: PO/IV: 400 mg on day 1, then 200-400 mg/d C: PO/IV: 12 mg/kg on day 1, then 10-12 mg/kg/d Systemic candidiasis (candidemia): A: PO/IV: 800 mg on day 1, then 400 mg/kg/d C: PO/IV: 6-12 mg/kg/d Candiduria (UTI due to candidiasis): A: PO/IV: 200-400 mg/d Most other candidiasis: A: PO/IV: 200 mg on day 1, then 100 mg/d Other treatment regimens are available.
Contraindications	Drug-Lab-Food Interactions
Caution: Azole antifungal hypersensitivity, pregnancy, cardiac disease, renal or hepatic disease	Drug: Because this drug inhibits the CYP450 isoenzyme, many drug-drug interactions are possible. See package insert for complete detail. Increases PT in patients taking warfarin; increases hypoglycemia when taken with oral sulfonylureas; increases phenytoin, cyclosporine, and haloperidol levels; decreases fluconazole level with cimetidine and rifampin; decreases the effect of clopidogrel; increases incidences of QT prolongation with cisapride, terfenadine, thioridazine, ondansetron, and other CYP3A4 substrates Food: May be administered without regard to food Herb: Increases serum caffeine (e.g., with coffee, green tea, soft drinks, and guarana)
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Rapid and essentially complete Distribution: PB: 11%-12% Metabolism: t½: 20-50 h; does not undergo first-pass metabolism Excretion: 60%-80% in urine unchanged, 11% as metabolites	PO: Onset: Rapid Peak: 1-2 h Duration: UK IV: Onset, peak, and duration: UK
Table Continued	

Therapeutic Effects/Uses	
To treat *Candida* infections and cryptococcal meningitis; as prophylaxis for patients undergoing BMT or radiation therapy	
Mode of Action: Increases permeability of the fungal cell membrane by inhibiting ergosterol synthesis	
Side Effects	Adverse Reactions
PO: GI upset (e.g., nausea, vomiting, diarrhea, abdominal pain, dysgeusia, dyspepsia), rash, headache, hypokalemia	Elevated liver transaminases, hepatic failure, renal failure, fatal cardiac arrhythmias, toxic epidermal necrolysis

A, Adult; *BMT,* bone marrow transplant; *C,* child; *CYP,* cytochrome P; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *PB,* protein binding; *PO,* by mouth; *PT,* prothrombin time; *t½,* half-life; *UK,* unknown; *UTI,* urinary tract infection.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Echinocandins

Echinocandins are the newest class of antifungals. Three echinocandins are available in the United States: anidulafungin, caspofungin, and micafungin. The action of echinocandins is to inhibit biosynthesis of essential components of the fungal cell wall, which interferes with growth and reproduction of *Candida* and *Aspergillus* species. Echinocandins are administered intravenously because they are not absorbed in the GI tract. Phlebitis at the IV site and increased aspartate aminotransferase (AST) and alanine aminotransferase (ALT) are common adverse effects. Rapid

infusion can cause histamine-mediated reactions.

Patient Safety

Amphotericin B

The two formulations of amphotericin B are amphotericin B deoxycholate and liposomal amphotericin B. Dosing for each formulation is different, therefore caution is advised.

Nursing Process: Patient-Centered Collaborative Care

Antifungals

Assessment

- Obtain a medical history that includes any serious renal or hepatic disorders. Antifungal agents such as amphotericin B, fluconazole, flucytosine, and ketoconazole are contraindicated if the patient has a serious renal or liver disease.
- Check laboratory tests for liver function (alkaline phosphatase [ALP], ALT, AST, gamma-glutamyl transferase [GGT]), BUN, bilirubin, and serum creatinine because elevated levels can indicate liver or renal dysfunction. Use these test results for future comparisons.
- Assess any prior use of antifungals.
- Record baseline vital signs for future comparisons.

Nursing Diagnoses

- Knowledge, Deficient related to the treatment regimen
- Infection, Risk for
- Injury, Risk for

Planning

- The patient's fungal infection will be resolved without life-threatening adverse reactions.

Nursing Interventions

- Obtain a culture to determine the fungus type (e.g., *Candida*).
- Monitor the patient's urinary output; many antifungal drugs can cause nephrotoxicity.
- Check laboratory results for BUN, serum creatinine, ALP, ALT, AST, bilirubin, and electrolytes and compare these with baseline findings. Certain antifungals can cause hepatotoxicity and nephrotoxicity when high doses are taken for an extended period.
- Record vital signs and compare these with baseline findings.
- Observe for side effects and adverse reactions to antifungal drugs, which may include nausea, vomiting, headache, phlebitis, and signs and symptoms of electrolyte imbalance.

Patient Teaching

- Advise patients to take drugs as prescribed. Compliance is of the utmost importance because discontinuing a drug too soon may result in relapse.
- Instruct patients to keep appointments to monitor laboratory testing of serum liver enzymes, BUN, creatinine, and electrolytes.
- Advise patients not to consume alcohol.
- Educate patients on proper administration of topical preparations.
- Teach patients to avoid operating hazardous equipment or motor vehicles when taking antifungals that may cause visual changes, sleepiness, dizziness, or lethargy (e.g., amphotericin B, ketoconazole, or flucytosine).
- Encourage patients to report side effects such as nausea, vomiting, diarrhea, dermatitis, rash, dizziness, tinnitus, edema, and flatulence. These symptoms may occur when taking certain antifungal drugs.
- Respect the patient's apprehension and fear concerning the use of topical antifungal drugs and the desire to use alternative methods. Evaluate the patient's method of topical administration in

regard to safe practice. If the method is considered unsafe, explain why and suggest modifications. If appropriate, involve other persons for clarification.

Evaluation

- Evaluate the effectiveness of the antifungal drug by noting the diminishing or absence of the fungal infection.

Viruses

A **virus** is an obligate intracellular organism that must reside within a living host cell to survive and reproduce. Viruses enter healthy cells, live and reproduce within living cells, and use their DNA and RNA to generate more viruses. The growth cycle of viruses depends on host cell enzymes and cell substrates for viral replication. With the exception of HIV and certain kinds of viral hepatitis, viruses are self-limiting illnesses that usually do *not* require treatment with a specific antiviral. Current antivirals target influenza, herpes, and hepatitis.

Pathophysiology

Influenza, commonly called *the flu*, is a highly contagious viral infection that causes mild to severe illness that can result in hospitalization or even death. Influenza is usually seasonal and is more prevalent from fall to spring. There are three main types of influenza: A, B, and C. *Influenza A* causes a moderate to severe infection. There are two subtypes found in humans, designated by the hemagglutinin (H) and neuraminidase (N) proteins, H1N1 and H3N2, found on the viral surface. *Influenza B* usually causes mild illness in children. Two strains are currently found in humans: B/Yamagata and B/Victoria. *Influenza C* infection is a mild respiratory illness not thought to cause epidemics. Influenza is transmitted easily via contaminated droplets during coughing, sneezing, or talking. Droplets enter into the respiratory tract of the unaffected person and begin replication 24 hours before the appearance of symptoms. Usually influenza has an abrupt onset with the first symptoms being high fever, headache, fatigue, and myalgia (muscle aches). Chills, sore throat, nonproductive cough, watery nasal discharge, weakness, red watery eyes, and photophobia can also occur.

Herpesviruses are large viruses that cause infections. Among the most familiar are herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2); varicella-zoster viruses (HSV-3, or VZV), more commonly known as *chickenpox* and *shingles*; Epstein-Barr virus (EBV, or human herpesvirus 4 [HHV-4]); and cytomegalovirus (CMV, or human herpesvirus 5 [HHV-5]). HSV-1 is usually associated with cold sores (vesicular lesions) and is capable of **latency**, the establishment and maintenance of latent infection in nerve cell ganglia proximal to the site of infection. HSV-2 is usually associated with vesicular lesions and small ulcerations on the genitalia (genital herpes). The HSV-2 virus remains dormant by traveling through the peripheral nerves to the sacral dorsal nerve root ganglia. The reactivation and replication of latent HSV always occurs in the area supplied by the ganglia in which latency was established. Reactivation can be induced by various factors that include fever, trauma, emotional stress, sunlight, and menstruation. Both HSV-1 and HSV-2 are capable of causing recurrent infections, and both can replicate in the mucous membranes and skin of the oropharynx or genitalia. Virus is transmitted by contact with infectious lesions or secretions. Signs and symptoms usually include eruption of small pustules and vesicles; fever; headache; malaise; myalgia; and tingling, itching, and pain in the affected area.

The varicella-zoster virus (VZV, or HSV-3) causes chickenpox and shingles. Chickenpox is a highly contagious viral infection that causes generalized pruritic vesicles and fever. Serious illness, hospitalizations, and deaths from VZV have decreased by 90% since vaccination began in 1995; however, some outbreaks still occur. When a person who has previously been infected with chickenpox becomes older or develops a weakened immune system, VZV that has lain dormant in nerve root ganglia can reactivate. The reactivation, called **shingles,** is a painful vesicular rash along the region of skin innervated by the nerve root ganglia, or **dermatome**, where the virus had lain dormant. In addition to the rash, the patient may also develop fever, malaise, myalgia, and pain along the involved dermatome.

Epstein-Barr virus (EBV, or HHV-4) most commonly causes infectious mononucleosis, a condition manifested by fever, tonsillitis, and enlarged lymph nodes in the neck. EBV resides in lymphocytes, epithelial cells, and muscle cells and has a latency period.

Cytomegalovirus (CMV, or HHV-5) is a common viral infection that affects people of all ages. Most people infected with CMV do not exhibit symptoms and are unaware they have the virus. However, people with weakened immune systems—such as those with HIV, transplant recipients, and those taking immunosuppressant drugs—along with pregnant women, unborn babies, and neonates are at risk for developing signs and symptoms (e.g., lymphadenopathy and

splenomegaly). In susceptible individuals, CMV infection can lead to blindness (CMV retinitis) or fatal pneumonia.

Viral hepatitis infections, such as with hepatitis B and C viruses (HBV and HCV, respectively), are serious liver infections. Many people with HBV and HCV are unaware they have the virus. These viruses can persist undetected for years, increasing the likelihood of transmitting the disease to others. HBV and HCV are **blood-borne pathogens** spread through blood and body fluids. They are leading causes of hepatic cancer and the most common reason for hepatic failure and subsequent liver transplant. Signs and symptoms of viral hepatitis include fatigue, jaundice, abdominal pain, malaise, and nausea.

Non-HIV Antivirals

Antiviral drugs are used to prevent or delay the spread of viral infections. They inhibit viral replication by interfering with viral nucleic acid synthesis in the cell. Some groups of antiviral drugs are effective against various viruses, such as influenzas A and B, herpesviruses, HBV and HCV, and HIV. The non-HIV antiviral drugs are listed in Table 27.3. Interferon alfa-2a and -2b used to treat HBV and HCV are discussed in Chapter 34. Drugs for HIV are discussed in Chapter 29.

Influenza Antivirals

Current recommendations for the treatment of influenza type A and B are oseltamivir or zanamivir. These are neuraminidase inhibitors, a group of drugs that decrease the release of the virus from infected cells by inhibiting the activity of neuraminidase, a viral glycoprotein, thus decreasing viral spread and shortening the duration of flu symptoms. Zanamivir and oseltamivir should be taken within 48 hours of flu symptoms, but they are *not* substitutes for the influenza vaccines.

TABLE 27.3
Non-HIV Antivirals

Generic	Route and Dosage	Uses and Considerations
Antivirals: Influenza		
Amantadine hydrochloride	Influenza A: A <65 y/C >9 y: PO: 200 mg/d in 1-2 divided doses Older adults >65 y: 100 mg/d C 1-8 y: PO: 4.4-8.8 mg/kg/d in 2 divided doses; *max*: 150 mg/d	Primary use is as prophylaxis against influenza A. Because of resistance in circulating influenza A, amantadine is no longer recommended; influenza A is sensitive to oseltamivir and zanamivir. If used, amantadine should be started within 24-48 h of onset of signs/symptoms and continued for 24-48 h after resolution. Avoid aspirin-containing products in children with influenza virus. Can be taken without regard to food. Pregnancy category: C*; PB: 67%; t½: 11-15 h
Cidofovir	A: IV: 5 mg/kg every other week	For CMV retinitis in HIV-infected patients. Give concomitantly with hydration and probenecid to minimize renal toxicity. Use chemotherapeutic precautions, including preparing the drug under laminar flow and using protective gloves and gowns. *Contraindications:* Sulfonamide hypersensitivity, renal impairment Pregnancy category: C*; PB: <6%; t½: 6-48 h
Foscarnet	Acyclovir-resistant herpesvirus: A: IV: 40-80 mg/kg q8h CMV retinitis: A: IV: 90 mg/kg q12h or 60 mg/kg/d q8h	For CMV retinitis and acyclovir-resistant mucocutaneous HSV. Administer via slow IV infusion. Patient must be hydrated to minimize renal toxicity. Monitor renal function. Pregnancy category: C*; PB: 14%-17%; t½: 3-7 h
Oseltamivir phosphate	A/C >40 kg: PO: 75 mg bid for 5 d C 15-40 kg: PO: 30-60 mg bid for 5 d Infants ≥14 d: PO: 3 mg/kg bid for 5 d	Blocks the function of viral neuraminidase protein by stopping the release of viruses from infected cells. Effective against influenzas A and B. Treatment should begin within 48 h of flu symptoms. Also used as prophylaxis for influenza A within 48 h of exposure; treat for 10 d. Dose is based on weights. May be taken without regard to food. Monitor renal function. Pregnancy category: C*; PB: 3%, t½: 1-3 h
Rimantadine hydrochloride	A/C >10 y: PO: 100 mg bid; *max*: 200 mg/d Older adults: PO: 100 mg/d; *max*: 100 mg/d	Formerly used for prophylaxis and treatment against influenza A virus. If used, monitor renal and hepatic functions; dosing may need to be adjusted. Because of resistance in circulating influenza A, amantadines (e.g., amantadine, rimantadine) are *not* recommended; influenza A is sensitive to oseltamivir and zanamivir. Avoid aspirin-containing products in children with influenza. Pregnancy category: C*; PB: 40%; t½: 13-65 h
Zanamivir	Inhaler: A/C ≥7 y: 2 oral inhalations bid for 5 d Prophylaxis: A/C ≥5 y: 2 oral inhalations once daily for 10 or 28 d	Effective against influenzas A and B. Blocks the function of viral neuraminidase protein by stopping the release of viruses from infected cells. Treatment should begin within 48 h of flu symptoms. Take bronchodilators before zanamivir. Pregnancy category: C*; PB: <10%; t½: 2.5-5 h
Antivirals: Herpes Species		
Acyclovir	See Prototype Drug Chart 27.4.	Also available as a topical
Famciclovir	Herpes zoster: A: PO: 500 mg q8h for 7 d Herpes simplex: A: PO: 250 mg tid for 7-10 d Herpes genitalis: A: PO: 1000 mg bid for 1 d Herpes labialis: A: PO: 1500 mg single dose	For herpes zoster, herpes genitalis, herpes labialis, and HSV. Start treatment within 48 h of rash onset. Dose adjustment is necessary in patients coinfected with HIV. Monitor renal function; dose adjustment may be necessary with impaired renal function. Can be taken without regard to food. Pregnancy category: B*; PB: <20%; t½: 2-3 h
Ganciclovir sodium	A/C: IV: 5 mg/kg for 7-14 d; then 5 m/kg/dose once daily for 7 d A/C ≥2 y: Ophthal: 1 drop to each affected eye 5 ×/d until healed, then 1 drop tid for 7 d	For CMV infection in immunocompromised patients and for herpes simplex keratitis. Monitor for hematologic toxicity. Handle drugs according to guidelines for chemotherapeutics. *Contraindicated in patients with severe thrombocytopenia.* Monitor renal function; dose may need to be adjusted. Pregnancy category: C*; PB: 1%-2%; t½: 2-6 h
Penciclovir	A/C ≥12 y: Topical: Apply q2h while awake for 4 d	For recurrent herpes labialis (cold sores). Start within 1 h of onset of symptoms. Do not administer to mucous membranes. Pregnancy category: B*; PB: UK; t½: UK
Trifluridine	A/C ≥6 y: Ophthal: 1 gtt q2h to each affected eye while awake; *max:* 9 gtt/d	Used primarily for keratoconjunctivitis due to HSV. Remove contact lenses prior to use. If more than one ophthalmic drug is used, separate instillations by at least 5-10 min. Pregnancy category: C*; PB: UK; t½: 12 min

Table Continued

Antivirals: Herpes Species		
Valacyclovir hydrochloride	HSV: A/C ≥12 y: PO: 2 g q12h × 2 doses Herpes zoster: A: PO: 1 g tid for 7 d Varicella: C ≥2 y: 20 mg/kg tid for 5 d	Effective against varicella and HSV. May be taken without regard to food. Monitor kidney function. Half-life is increased in patients with ESRD. Pregnancy category: B*; PB: 14%-18%; t½: 2.5-3.3 h
Valganciclovir	CMV retinitis: A: PO: 900 mg bid CMV prophylaxis: A: PO: 900 mg once daily C ≥4 mo: PO: Dose is based on BSA: 7 × BSA × CrCl as a single dose; round the dose to the nearest 10-mg increment; *max*: 900 mg/d	For CMV disease prophylaxis and CMV retinitis in AIDS patients. As with ganciclovir, monitor renal function. May cause hematologic toxicity. Monitor CBC. Do not crush or break tablets. Oral solution is not recommended for adults and should not be mixed with other liquids. Pregnancy category: C*; PB: 1%-2% as ganciclovir; t½: 18 h

Antivirals: Hepatitis		
Adefovir dipivoxil (nucleotide analogue)	A/C ≥12 y: PO: 10 mg/d	For chronic HBV, used in combination with lamivudine. Can be taken without regard to food. Monitor renal function. Renal impairment may require dose adjustment. Monitor HBV DNA. Pregnancy category: C*; PB: <4%; t½: 7.5 h
Daclatasvir	A: PO: 30-90 mg once daily	For HCV with or without other comorbidities (e.g., liver transplant, decompensated cirrhosis, HIV). Must be given with sofosbuvir. Dose amount and duration depends on genotype. Monitor liver function and HCV RNA concentration. Monitor HIV RNA if patient has HIV. May be taken without regard to food. Pregnancy category: UK*; PB: 99%; t½: 12-15 h
Convenience drug pack with ombitasvir/ paritaprevir/ ritonavir and dasabuvir	A: PO: 1-day convenience pack with fixed dosage: ombitasvir 12.5 mg, paritaprevir 75 mg, ritonavir 50 mg × 2 tabs and dasabuvir 250 mg × 2 tabs	For HCV with or without cirrhosis. Monitor liver function and HCV RNA concentration. May take with food. Duration of treatment depends on genotype. Pregnancy category: B*; PB: 99.5%; t½: 5.5-6 h
Entecavir	A/C >30 kg: PO: 0.5-1 mg/d C <30 kg: PO: 0.15-0.9 mg/d; weight based	Nucleoside analogue for chronic HBV. Take on an empty stomach. Monitor liver function and HBV DNA viral load. Patients with renal impairment may need dose adjustment. Pregnancy category: C*; PB: 13%; t½: 128-149 h
Lamivudine	See Chapter 29.	Synthetic nucleoside analogue for HBV and HIV
Ledipasvir/ sofosbuvir	A: PO: ledipasvir 90 mg/sofosbuvir 400 mg fixed dose tab; 1 tab daily	For chronic HCV; includes patients with other comorbid conditions (e.g., decompensated liver disease, HIV, liver transplant) as combination therapy with sofosbuvir. Monitor liver function, HCV RNA concentration, and renal function. Must be taken with food if coadministering with ribavirin. Duration of treatment depends on genotype; dependent on genotype, ribavirin may be added. Pregnancy category: X*; PB: 99.8%; t½: 47 h
Ombitasvir, paritaprevir, ritonavir	A: PO: Ombitasvir 12.5 mg/paritaprevir 75 mg/ritonavir 50 mg fixed-dose tab; 2 tabs per day	For HCV without hepatic scarring or cirrhosis. Recommendation to administer with ribavirin for genotype 4. Monitor liver function and HCV RNA concentration. Take with food. Pregnancy category: B*; PB: 97%-99%; t½: 21-25 h (ombitasvir), 5.5 h (paritaprevir), 4 h (ritonavir)
Peginterferon alfa-2a	HBV: A: Subcut or IM: 30-35 million units/wk in divided doses × 16 wk C: Subcut: 3 million units/m² 3 ×/wk for 1 wk then increase to 6 million units HCV: A/C ≥3 y >61 kg: Subcut or IM: 3 million units 3 ×/wk C ≥3 y <61 kg: Subcut: 3 million units/m² 3 ×/wk	For HBV and HCV with compensated liver disease. See Chapter 34 for other uses and considerations. If severe reactions occur, reduce dose. For HCV, may be used in combination with ribavirin. Duration of treatment depends on HCV genotype.
Table Continued		

Antivirals: Hepatitis		
Ribavirin	RSV: C: Aerosol inhalation: 20 mg over 12-18 h/d for 3-7 d Hepatitis C, in combination therapy: A ≥75 kg: PO: 1200 mg/d in 2 divided doses A <75 kg: PO: 1000 mg/d in 2 divided doses C: PO: 15 mg/kg/d Other dosing regimens are available.	Effective for HCV when used as combination therapy with other antivirals. Aerosolized ribavirin therapy requires an experienced clinician. Health care workers should protect eyes when administering aerosol to prevent ocular irritation. Contraindicated during pregnancy. Dosage and duration, as well as coadministration of peginterferon alfa-2a or -2b dependent on genotype. Pregnancy category: X*; PB: NA; t½: 43-298 h
Simeprevir	A: PO: 150 mg once daily	For chronic HCV as combination therapy with sofosbuvir or peginterferon alfa and ribavirin. Duration dependent on genotype and presence of cirrhosis. Monitor liver transaminases, bilirubin, and HCV RNA concentrations. Take with food, and swallow capsules whole. Pregnancy category: C*; PB: 99.9%; t½: 10-13 h
Sofosbuvir	A: PO: 400 mg once daily	For chronic HCV as combination therapy with daclatasvir, ledipasvir, ribavirin, or peginterferon alfa/ribavirin. Drug combination and treatment duration are dependent upon genotype. Monitor HCV RNA concentration and renal function. May be taken without regard to food. Pregnancy category: B*; PB: 61%-65%; t½: 0.4 h (sofosbuvir) and 27 h (metabolite GS-41203)
Tenofovir disoproxil	A: PO: 300 mg once daily. Available as an oral powder in a 40 mg/scoop given with food	Nucleoside analogue for chronic HBV and HIV. Has an additive or synergistic activity when combined with other antiretroviral agents.

A, Adult; *AIDS,* acquired immunodeficiency syndrome; *bid,* twice daily; *BSA,* body surface area; *C,* child; *CBC,* complete blood count; *CMV,* cytomegalovirus; *CrCl,* creatinine clearance; *d,* day; *ESRD,* end-stage renal disease; *gtt,* drops; *h,* hour; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HIV,* human immunodeficiency virus; *HSV,* herpes simplex virus; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minutes; *mo,* month; *NA,* not applicable; *Ophthal,* ophthalmic solution; *PB,* protein binding; *PO,* by mouth; *q,* every; *RSV,* respiratory syncytial virus; *subcut,* subcutaneous; *t½,* half-life; *tab,* tablet; *tid,* three times daily; *UK,* unknown; *wk,* weeks; *y,* year; >, greater than; ≥, greater than or equal to; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Side Effects and Adverse Reactions

The side effects and adverse reactions of these two neuraminidase inhibitors include dizziness, headache, insomnia, vertigo, fatigue, and GI disturbances such as nausea, vomiting, and diarrhea. Nurses must be aware of a Food and Drug Administration (FDA) advisory that persons receiving oral oseltamivir should be monitored closely for abnormal behavior. Incidence of self-injury and delirium have been reported in postmarketing surveillance.

Herpes Antivirals

The synthetic purine nucleoside antiviral group is effective in interfering with the steps of viral nucleic acid (DNA) synthesis. Drugs in this group of nucleoside analogues include ribavirin,

acyclovir, famciclovir, ganciclovir sodium, valacyclovir, and valganciclovir. These drugs are effective in managing herpes simplex viruses (HSV-1, HSV-2), and VZV (chickenpox and shingles).

Acyclovir, famciclovir, and valacyclovir appear equally effective in the treatment of initial episodes and recurrent episodes of genital herpes, but famciclovir appears somewhat less effective for suppression of viral shedding. Topical antivirals for herpes simplex viruses include acyclovir, penciclovir, and trifluridine.

Cytomegalovirus Antivirals

Four antivirals are effective in treating CMV retinitis in persons with **acquired immunodeficiency syndrome (AIDS)**: ganciclovir, valganciclovir, cidofovir, and foscarnet. Ganciclovir and valganciclovir are synthetic purine nucleoside analogues. Ganciclovir was the first drug approved for treatment of CMV retinitis. Cidofovir is a nucleotide analogue that suppresses viral replication by inhibiting DNA polymerase. Foscarnet selectively inhibits viral-specific DNA polymerases and reverse transcriptases. Due to the emergence of drug resistance, many times it is necessary to use a combination of agents to effectively manage CMV retinitis (Prototype Drug Chart 27.4).

Side Effects and Adverse Reactions

A limiting factor in all antiviral therapy is hematologic toxicity. All patients should be closely monitored for signs of bone marrow suppression and toxicity, including thrombocytopenia, granulocytopenia, and leukopenia. Additionally, all antivirals should be dose adjusted in the setting of kidney dysfunction. Kidney function should be closely monitored during drug therapy because acute kidney failure can occur.

Side effects and adverse reactions to antiviral drugs include nausea, vomiting and diarrhea, headache, dizziness, rash and pruritus, and hematuria. Additionally, when antiviral drugs are administered IV, extravasation may lead to sloughing of the skin. Topical preparations can cause local irritations, and contact lenses should be removed prior to instilling ophthalmic antivirals.

PROTOTYPE DRUG CHART 27.4 Acyclovir Sodium

Drug Class	Dosage
Antiviral Pregnancy category: B*	Neonatal HSV: Neo/Inf <3 mo: IV: 20 mg/kg q8h for 10-21 d based on progression of disease HSV: A: PO: 200-400 mg for 7-10 days; amount, frequency, and duration depend on disease A: IV: 5-10 mg/kg q8h; amount, frequency, and duration depend on disease Herpes zoster virus, immunocompetent: A/C ≥12 y: PO: 800 mg q4h 5 ×/d Herpes zoster virus, immunocompromised and immunocompetent children: A/C ≥12 y: IV: 10 mg/kg q8h C <12 y: 10 mg/kg Herpes simplex encephalitis: A: IV: 5-10 mg/kg q8h until clinical resolution Inf/C ≥3 mo: IV: 10-15 mg/kg q8h for 14-21 d Inf <3 mo: 20 mg/kg q8h for 21 d Also available as a topical preparation for superficial candidiasis
Contraindications	Drug-Lab-Food Interactions
Known hypersensitivity to acyclovir and its components, milk protein hypersensitivity *Caution:* Renal impairment, electrolyte imbalance, dehydration, seizure disorder, nursing mothers, young children	Drug: Increased nephrotoxicity and neurotoxicity with aminoglycosides, probenecid, interferon, and ibuprofen; decreases effect of phenytoin; increases serum concentrations of other antivirals (e.g., tenofovir, entecavir) Lab: May increase AST, ALT, serum creatinine, BUN Food: Food does not affect absorption.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Poorly absorbed, 15%-30% Distribution: PB: 9%-33% Metabolism: t½: PO: 2.5-3.3 h Excretion: Mostly in urine	PO: Onset: UK; peak: 1.5-2 h; duration: UK IV: Onset: UK; peak: 1 h; duration: UK
Therapeutic Effects/Uses	
To treat herpes simplex and varicella-zoster viruses	
Mode of Action: Inhibits viral DNA synthesis and inhibits viral DNA polymerase and viral DNA chain; inactivates viral DNA polymerase	
Side Effects	Adverse Reactions
Nausea, anorexia, vomiting, diarrhea, headache, tremors, agitation, lethargy, rash, pruritus, increased bleeding time, phlebitis at IV site	Urticaria, anemia, paresthesias *Life threatening:* Crystalluria, neuropathy, seizures, nephrotoxicity (large doses), blood dyscrasias

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *HSV,* herpes simplex virus; *IV,* intravenous; *mo,* months; *Neo/Inf,* neonate/infant; *PB,* protein binding; *PO,* by mouth; *q,* every; *t½,* half-life; *UK,* unknown; *y,* year; <, less than; ≥, greater than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Antiviral: Acyclovir

Assessment

- Obtain a medical history from the patient that includes any serious renal or hepatic diseases.
- Determine baseline vital signs and obtain a complete blood count (CBC). Use these findings for comparisons with future results.
- Assess baseline laboratory results, particularly BUN, serum creatinine, liver function studies, bilirubin, and electrolytes. Use these results for future comparisons.
- Evaluate baseline vital signs and urine output. Report abnormal findings.

Nursing Diagnoses

- Infection, Risk for
- Injury, Risk for
- Knowledge, Deficient related to inexperience with antiviral medications

Planning

- Patient's symptoms of viral infections will be eliminated or diminished.

Nursing Interventions

- Check the patient's CBC. Report abnormal results (leukopenia, thrombocytopenia, low hemoglobin and hematocrit).
- Monitor other laboratory tests (BUN, serum creatinine, liver function studies); compare with baseline values.
- Record the patient's urinary output. An antiviral drug such as acyclovir can affect renal function.
- Monitor vital signs, especially blood pressure. Acyclovir and amantadine may cause orthostatic hypotension.
- Observe for signs and symptoms of side effects. Most antiviral drugs have many side effects.
- Check for superimposed infection (superinfection) caused by high doses and prolonged use of an antiviral drug such as acyclovir.
- Administer oral acyclovir as prescribed. Oral doses can be taken at mealtime.
- Dilute the antiviral drug in an appropriate amount of solution as indicated in the drug circular when giving intravenously. Administer IV drug over 60 minutes. Never give acyclovir as a bolus (IV push).

Patient Teaching

- Advise patients to maintain adequate fluid intake to ensure sufficient hydration for drug therapy and to increase urine output.
- Instruct patients with genital herpes to avoid spreading infection by practicing sexual abstinence or by using condoms correctly and consistently. Patients must be aware that while condoms reduce the transmission of disease, they may not eliminate it. Advise women with genital herpes to have a Pap test done as indicated by their health care provider. Cervical cancer is more prevalent in women with genital herpes simplex.
- Guide patients to report adverse reactions, including a decrease in urine output and CNS changes such as dizziness, anxiety, or confusion.
- Warn patients with dizziness resulting from orthostatic hypotension to arise slowly from a sitting to a standing position.
- Tell patients to report any side effects associated with the antiviral drug; this may include nausea and vomiting, diarrhea, increased bleeding time, rash, urticaria, and menstrual abnormalities.
- Teach non–English-speaking patients and family members how to properly use antivirals by providing materials in the patient's first language. Pictures may be helpful.

Evaluation

- Evaluate the effectiveness of the antiviral drug in eliminating the virus or in decreasing symptoms.
- Determine whether any side effects are present.

Hepatitis Antivirals

Viral hepatitis can be caused by at least five distinct viruses that affect the liver: hepatitis A virus (HAV), HBV, HCV, hepatitis D (delta hepatitis, HDV), and hepatitis E. Hepatitis A and E are self-limiting illnesses and do not usually require antiviral therapy. HBV and HCV can develop into chronic hepatitis; those with HBV can be coinfected with HDV. The Centers for Disease Control and Prevention (CDC) and the World Health Organization (WHO) have developed guidelines for screening, treatment, and surveillance of persons with HBV and HCV. Currently, HAV and HBV are vaccine preventable. Vaccines are discussed in Chapter 31.

No specific therapy exists for people with acute HBV. Instead, treatment is mostly supportive. Antivirals are given for people with chronic HBV and signs of liver disease progression to attempt to suppress viral replication and potentially halt liver disease and liver-related deaths. Treatment with antivirals is recommended for all people with chronic HBV who are at high risk of disease progression regardless of age. Currently, five antiviral drugs are approved for this indication: lamivudine, adefovir, entecavir, tenofovir, and peginterferon alfa-2a. Except for peginterferon alfa-2a, all of these are nucleoside analogues, and all have been shown to delay the progression of liver disease (e.g., cirrhosis, hepatic carcinoma). Adefovir inhibits reverse transcription, entecavir inhibits several major stages of viral replication, and lamivudine and tenofovir inhibit the synthesis of viral DNA; however, no antiviral therapy cures HBV. Lamivudine and adefovir are no longer the preferred agents in the treatment of HBV.

Hepatitis C is more prevalent among people who inject drugs. HCV is an RNA virus, whereas HBV is a DNA virus. As with HBV, HCV can cause chronic infection that leads to liver cirrhosis, liver failure, and hepatic carcinoma. No vaccine against HCV is currently available. In addition to peginterferon alfa-2a and -2b, ribavirin, protease inhibitors (e.g., simeprevir and paritaprevir), NS5A inhibitors (e.g., daclatasvir, ledipasvir, ombitasvir), and polymerase inhibitors (e.g., dasabuvir, sofosbuvir) can treat HCV. Many of these antivirals are prepackaged as combination therapy.

Persons with HCV should have genotype testing; HCV has 6 genotypes and more than 50 subtypes, and genotyping can help predict treatment response and duration of treatment. For example, genotypes 2 and 3 respond better to peginterferon alfa-2a or a combination of peginterferon alfa-2a and ribavirin than does genotype 1. Genotypes 2 and 3 only need 24 months of treatment, whereas genotype 1 requires 48 months. Genotype 1 is the most common genotype in the United States. The Infectious Diseases Society of America (IDSA) and the American Association for the Study of Liver Diseases (AASLD) have published treatment guidelines based on genotype (see http://www.hcvguidelines.org/node/72).

Table 27.3 lists the antivirals, uses, and considerations for viral hepatitis. Chapter 29 further illustrates nucleoside analogues.

Side Effects and Adverse Effects

Side effects range from mild to life threatening. Transient exacerbations of viral hepatitis can occur if antivirals are suddenly stopped. HBV and HCV can become resistant to antivirals, therefore routine monitoring of renal and hepatic functions are warranted in addition to monitoring viral load. Nucleoside analogues can cause hepatotoxicity or lactic acidosis, and dose adjustments are recommended in patients with renal impairment. Side effects for peginterferon include depression, fatigue, flulike symptoms, pancytopenia, alopecia, arthralgia, myalgia, anorexia, dysgeusia, thyroid dysfunction, and infection. Ophthalmic dysfunction can also occur (e.g., papilledema, vasculature obstruction). Ribavirin is teratogenic and can also cause hemolytic anemia, and protease inhibitors can cause skin reactions, dysgeusia, and photosensitivity.

Critical Thinking Case Study

CJ, a 41-year-old homeless man, has had a constant cough and night sweats for several months. He consumes about a fifth of liquor over 2 days. Acid-fast bacilli (AFB) smear on the sputum is positive. The health care provider orders a 6- to 9-month antitubercular drug regimen, with the time of therapy to be determined according to sputum and radiograph test results. For 2 months, CJ takes isoniazid (INH), rifampin, and pyrazinamide daily. For the next 4 to 7 months, CJ takes INH and rifampin biweekly.

1. What are some of CJ's risk factors for contracting tuberculosis (TB)? Give other risk factors for contracting TB.
2. CJ received first-line antitubercular drugs for treatment of TB. How can the health professional determine whether the drugs are effective in eradicating the bacillus *Mycobacterium tuberculosis*? Explain your answer.
3. What is the nurse's role in patient teaching concerning the drug regimen?
4. Name at least two serious adverse reactions that can occur when antitubercular drugs are given over an extended period.
5. What laboratory tests should be monitored while CJ takes isoniazid and rifampin? Why?
6. The health care provider orders pyridoxine to be given daily. Give the rationale for the use of pyridoxine.

NCLEX Study Questions

1. A patient is beginning isoniazid and rifampin treatment for tuberculosis. The nurse gives the patient which instruction?
   a. Do not skip doses.
   b. Take both drugs three times daily with food.
   c. Take an antacid with the drugs to decrease gastrointestinal distress.
   d. Take rifampin initially, and begin isoniazid after 2 months.
2. A patient taking isoniazid is worried about the side effects. Which of the following does the nurse realize is an adverse effect of the drug?
   a. Ototoxicity
   b. Hepatotoxicity
   c. Nephrotoxicity
   d. Optic nerve toxicity
3. The nurse teaches a patient taking amphotericin B to report which signs and symptoms to the health care provider?
   a. Change in sight
   b. Decrease in hearing
   c. Decrease in urine
   d. Painful red rash and blisters
4. A patient has been diagnosed with tuberculosis and is to begin antitubercular therapy with isoniazid, rifampin, and ethambutol. What should the nurse do? (Select all that apply.)
   a. Encourage periodic eye examinations.
   b. Instruct the patient to take medications with meals.
   c. Suggest that the patient take antacids with medications to prevent gastrointestinal distress.
   d. Advise the patient to report numbness and tingling of the hands or feet.
   e. Alert the patient that body fluids may develop a red-orange color.
   f. Teach the patient to avoid direct sunlight and to use sunblock.
5. Zanamivir is ordered for a patient. What does the nurse know about use of this drug?
   a. It is a treatment for herpes simplex virus type 2.
   b. Oral administration is for treatment of herpes simplex virus type 1.
   c. It treats varicella-zoster virus.
   d. Administration must be within 48 hours of onset of symptoms to be effective.
6. Acyclovir has been ordered for a patient with genital herpes. Which nursing interventions are appropriate for this patient? (Select all that apply.)
   a. Monitor the patient's blood urea nitrogen and creatinine.
   b. Monitor the patient's blood pressure for hypertension.
   c. Administer intravenous acyclovir over 30 minutes.
   d. Advise maintenance of adequate fluid intake.
   e. Monitor complete blood count for blood dyscrasias.
7. A mother of two children was just diagnosed with hepatitis C virus. Which of the following is *incorrect* about hepatitis C virus?
   a. A vaccine is available.
   b. Hepatitis C virus can be transmitted by blood and body fluids.
   c. Hepatitis C virus can cause hepatic carcinoma.
   d. Persons with hepatitis C virus can become chronic carriers.

Answers: 1, a; 2, b; 3, c; 4, a, d, e, f; 5, d; 6, a, d, e; 7, a.

- Polymyxins
- Bacitracin
- Metronidazole
- Nursing Process: Patient-Centered Collaborative Care—Antiinfectives: Peptides

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Explain the action of antimalarial drugs.
- Identify side effects and adverse reactions of antimalarial drugs.
- Correlate transmission with prevention in people with malaria.
- Apply the nursing process for people receiving antimalarial drugs.
- Explain the action of anthelmintic drugs.
- Identify adverse reactions of anthelmintic drugs.
- Correlate transmission with prevention in people with helminthic infections.
- Apply the nursing process for people receiving anthelmintic drugs.
- Explain the use of peptides as an antibacterial.
- Summarize the side effects and adverse reactions possible with peptides.
- Apply the nursing process for people taking antibacterials.

Antimalarial Drugs

Malaria is a life-threatening disease that was eliminated from the U.S. in the early 1950s. Since that time, 1500 to 2000 cases of malaria have been reported mostly by recent travelers. The **World Health Organization (WHO)** is an agency of the United Nations with the purpose of monitoring communicable and noncommunicable disease outbreaks globally. WHO reported an estimated 214 million new cases of malaria in 2015. Sub-Saharan Africa has the highest rate, at 88%. Malaria is caused by multiple species of protozoan parasites of the genus *Plasmodium* that are carried by infected *Anopheles* mosquitoes, and it remains one of the most prevalent protozoan diseases. After the mosquito infects the human, the protozoan parasite passes through two phases: the tissue phase and the erythrocytic phase. The **tissue phase** (invasion of body tissue) produces no clinical symptoms in the human, but the **erythrocytic phase** (invasion of the red blood cells) causes symptoms of chills, fever, and sweating. The incubation period is 10 to 35 days, followed by flulike symptoms. Preventing transmission of malaria can be done by controlling the mosquito firstly through insecticide-treated mosquito nets and secondly with spraying.

There are approximately 50 species of *Plasmodium,* four of which cause malaria: *P. malariae, P. ovale, P. vivax,* and *P. falciparum. P. vivax* is the most prevalent, whereas *P. falciparum* is the most severe. In spite of having over 200 million cases of malaria globally, in the United States malaria is confined mainly to persons who enter the country after having traveled abroad. The incidence of malaria has increased since 1960, primarily because of travel to regions in the world where malaria is endemic and drug-resistant malaria parasites have evolved.

Treatment of malaria depends on the type of *Plasmodium* and the organism's life cycle. Quinine was the only antimalarial drug available from 1820 until the early 1940s. **Antimalarial drugs** provide treatment and prophylaxis, and synthetic antimalarial drugs have since been developed that are as effective as quinine and cause fewer toxic effects. When drug-resistant malaria occurs, combinations of antimalarials are used to facilitate effective treatment. Chloroquine is a commonly prescribed drug for malaria. If drug resistance to chloroquine occurs, another antimalarial such as mefloquine hydrochloride (HCl) or combinations of antimalarials with or without antibiotics (e.g., tetracycline, doxycycline, clindamycin) may be prescribed.

Three methods used to eradicate malaria are **prophylaxis** (prevention), treatment for the acute attack, and prevention of relapse. Many synthetic antimalarials, chloroquine and primaquine among them, are used prophylactically. Chloroquine and mefloquine are frequently used to treat an acute malarial attack. Mefloquine HCl and the combination drug atovaquone-proguanil are used to treat chloroquine-resistant *P. falciparum.* Chloroquine and hydroxychloroquine can be toxic to children and may even cause death, therefore the drug dose should be closely monitored. Prototype Drug Chart 28.1 lists the drug data for chloroquine phosphate.

PROTOTYPE DRUG CHART 28.1 Chloroquine Phosphate

Drug Class	Dosage
Antimalarial Pregnancy category: C*	Acute malaria: 500 mg chloroquine phosphate (salt) = 300 mg chloroquine base; doses expressed as chloroquine base A: PO: 600 mg base (=1000 mg salt) x 1, then 300 mg base (=500 mg salt) x 1 in 6 h, then 300 mg base (=500 mg salt) x 1 at 24 h and 48 h C: PO: 10 mg base/kg x 1, then 5 mg base/kg x 1 at 6 h, 24 h, and 48 h Prophylaxis: 1-2 wk before exposure; discontinue 4 wk after exposure A: PO: 300 mg base (=500 mg salt) every 6 h x 2 doses, then 300 mg base (=500 mg salt) every week C: PO: 5 mg base/kg every 6 h x 2 doses before exposure, then 5 mg base/kg every week discontinuing 4 wk after exposure
Contraindications	Drug-Lab-Food Interactions
Chloroquine hypersensitivity, renal disease, psoriasis, ocular disease *Caution:* Alcoholism, liver dysfunction, G-6-PD deficiency, and with GI, neurologic (seizures, hearing impairment), and hematologic disorders; breastfeeding.	Drug: Increases effects of digoxin, neuromuscular blockers; decreased absorption with antacids and laxatives Lab: Elevated liver enzymes; decreased RBC count, hemoglobin, hematocrit; monitor ophthalmic exams.
Pharmacokinetics	Pharmacodynamics
Absorption: Well absorbed from GI tract Distribution: Widely distributed into body tissue PB: 50%-65% Metabolism: Partially in the liver Half-life: 1-2 months Excretion: Excreted slowly in urine	Onset: Rapid Peak: 1-2 h Duration: Days to weeks
Therapeutic Effects/Uses	
To treat acute malaria, as prophylaxis for malaria Mode of Action: Increased pH in the malaria parasite inhibits parasitic growth.	
Side Effects	Adverse Reactions
Anorexia, nausea, vomiting, diarrhea, abdominal cramps, fatigue, pruritus, headache, nervousness, visual impairment, insomnia, photosensitivity, hair discoloration	ECG changes, hypotension, psychosis, seizures; may cause dizziness, so use caution driving a vehicle; avoid sun exposure. *Life threatening:* Agranulocytosis, aplastic anemia, corneal opacity, macular degeneration, thrombocytopenia, ototoxicity, cardiovascular collapse

A, Adult; *C,* child; *ECG,* electrocardiogram; *G-6-PD,* glucose-6-phosphate dehydrogenase; *GI,* gastrointestinal; *h,* hour; *PB,* protein binding; *PO,* by mouth; *RBC,* red blood cell; *wk,* week.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Pharmacokinetics

Chloroquine phosphate is well absorbed from the gastrointestinal (GI) tract. It is moderately protein binding, and the drug has a long half-life. The first two doses have a loading dose effect. Because of the drug's long half-life, the next dose is given in 6 hours, the third and fourth doses are given at 24 and 48 hours. Chloroquine is metabolized in the liver to active metabolites and is excreted in the urine. Antimalarial drugs concentrate first in the liver; if the patient drinks large amounts of alcohol or has a liver disorder, the liver enzymes will require closer monitoring. Renal impairment may also occur as an adverse effect of antimalarials.

Pharmacodynamics

Chloroquine phosphate inhibits the malaria parasite's growth by interfering with its protein synthesis. Whether the drug is given orally or intramuscularly (IM), the onset of action is rapid. The peak effect is slower when given orally. The duration of effect of the drug is very long, from days to weeks.

Side Effects and Adverse Reactions

General side effects and adverse reactions to antimalarials include GI upset, cranial nerve VIII involvement (quinine and chloroquine), renal impairment (quinine), and cardiovascular effects (quinine).

Table 28.1 lists commonly ordered antimalarial drugs and their dosage, uses, and considerations. Note that *quinine* is an antimalarial drug, and *quinidine* is an antidysrhythmic drug. A medication guideline developed by the U.S. Food and Drug Administration (FDA) accompanies mefloquine each time it is dispensed. This type of guideline is used only for drugs that require monitoring for serious adverse effects. Adverse effects of mefloquine include severe anxiety, restlessness, disorientation, depression, hallucinations, paranoia, and suicidal thoughts, which may continue after the drug is discontinued.

Patient Safety

Do not confuse…

- *Quinine* (antimalarial) with *quinidine* (antidysrhythmic)
- *Hydroxychloroquine* (antimalarial drug) and *hydroxyurea* (chemotherapy drug)

TABLE 28.1

Antimalarials

Generic	Route and Dosage	Uses and Considerations
Chloroquine phosphate	See Prototype Drug Chart 28.1.	
Hydroxychloroquine sulfate	Acute malaria: A: PO: 800 mg, then 400 mg at 6, 18, 24, and 36 h Prophylaxis: A: 400 mg once every day for 7 d; begin 2 wk before exposure, continue after leaving endemic area, then continue for 8 wk. C: PO: 13 mg/kg/dose, then 6.4 mg/kg once every day for 7 d; begin 2 wk before exposure and continue for 8 wk after leaving endemic area.	Alternative to chloroquine. Dosage varies for treating malaria. Can be used adjunctively with primaquine. Give with meals to reduce GI distress. Administration requires an experienced clinician. *Caution:* During pregnancy, in patients with psoriasis or retinal disturbances, and with history of alcoholism or hepatic impairment Pregnancy category: C*; PB: 45%; t½: 32-50 d
Mefloquine hydrochloride	Treatment of mild/moderate disease: A: PO: Single dose: 1250 mg Malaria prophylaxis: A: PO: 250 mg/wk for 1-2 wk before travel and 4 wk after; take with plenty of water.	For prophylaxis and treatment of acute malaria. Contraindicated in people with cardiac conditions, seizures, psychosis, and alcoholism. Use with caution with hepatic impairment. Safety and efficacy have not been established for infants and children under 20 kg. Is secreted in breast milk. Pregnancy category: C*; PB: 98%; t½: 10-21 d
Primaquine phosphate	Malaria treatment: (26.3 mg primaquine phosphate = 15 mg primaquine base; doses are given as primaquine base) A: PO: 30 mg base/d for 14 d C: PO: 0.8 mg/kg for 14 d Malaria prophylaxis: A: PO: 30 mg base/d for 14 d; continue during stay in the endemic area and for 7 d after returning.	For malaria caused by *Plasmodium vivax, P. ovale,* and *P. falciparum* as well as for *Pneumocystis carinii* pneumonia. Can affect WBC production (granulocytopenia) and can cause acute hemolytic anemia in patients with G-6-PD deficiency. Pregnancy category: C*; PB: UK; t½: 6 h
Quinine	Acute malaria: A/Adol >16 y: PO: 648 mg q8h for 3-7 d C <16 y: 10 mg/kg/dose every 3-7 h for 7 d; *max:* 648 mg	Used in combination drug therapy (with tetracycline, clindamycin, or doxycycline) or for chloroquine-resistant malaria. Quinine may be used as step-down therapy from IV quinidine. Avoid in patients with hepatic or cardiac impairment, hypersensitivity to quinine drugs, hypoglycemia (it stimulates insulin; blood glucose levels should be monitored), and thrombocytopenia (monitor platelet count). Pregnancy category: C*; PB: 70%; t½: 8-21 h

Combination Antimalarial Drugs		
Atovaquone-proguanil combination tablet	A/C >40 kg: PO: 4 adult tabs of atovaquone 250 mg/proguanil 100 mg in a single dose (for a total of atovaquone 1000 mg/proguanil 400 mg) for 3 d C 31-40 kg: PO: 3 tabs atovaquone 250 mg/proguanil 100 mg in a single dose (for a total of atovaquone 750 mg/proguanil 300 mg) for 3 d C 21-30 kg: PO: 2 tabs atovaquone 250 mg/proguanil 100 mg in a single dose (for a total of atovaquone 500 mg/proguanil 200 mg) for 3 d C 11-20 kg: PO: 1 tab atovaquone 250 mg/proguanil 100 mg each day for 3 d	For acute and uncomplicated prophylaxis and treatment of malaria; effective for chloroquine-resistant strains. *Caution:* Renal and hepatic impairment Pregnancy category: C*; PB: 75%-99%; t½: 2-3 d/12-20 h
Artemether-lumefantrine combination tablet	A/C >35 kg: PO: 4 tabs of artemether 20 mg/lumefantrine 120 mg twice daily for 3 d, for a total of 6 doses C 25-35 kg: PO: 3 tabs artemether 20 mg/lumefantrine 120 mg twice daily for 3 d, for a total of 6 doses C 15-25 kg: PO: 2 tabs artemether 20 mg/lumefantrine 120 mg twice daily for 3 d, for a total of 6 doses C 5-15 kg: PO: 1 tab artemether 20 mg/lumefantrine 120 mg twice daily for 3 d for a total of 6 doses	For malaria infections that are both drug-sensitive and drug-resistant *P. falciparum.* Acts by inhibiting nucleic acid and protein synthesis. Rapid onset allows drug to control fever quickly. Has a cure rate >40%. Adverse effects include nystagmus, wheezing, hypokalemia, blood dyscrasias, and hepatomegaly. Pregnancy category: C*; PB: 95%-99%; t½: 2-3 h/3-6 d

A, Adult; *Adol,* adolescent; *C,* child; *d,* day; *G-6-PD,* glucose-6-phosphate dehydrogenase; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *q,* every; *t½,* half-life; *tabs,* tablets; *UK,* unknown; *WBC,* white blood cell; *wk,* week; *y,* year; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Antimalarials

Assessment

- Assess patient's hearing, especially if receiving quinine or chloroquine. These drugs may affect cranial nerve VIII.
- Assess patient for visual changes; this is especially important if a patient is taking chloroquine and hydroxychloroquine.
- Assess the patient's level of consciousness.
- Assess whether the patient has traveled out of the country to a malaria-endemic area.
- Obtain a patient history of malaria and whether antimalarial drugs were taken.
- Assess baseline urinary output.
- Assess whether the patient has allergies to any drugs.

Nursing Diagnoses

- Infection, Risk for
- Knowledge, Readiness for Enhanced
- Skin Integrity, Risk for Impaired
- Nutrition, Imbalanced: Less than Body Requirements

Planning

- The patient will exhibit vital signs at baseline level showing absence of malarial symptoms.
- The patient will take antimalarial drugs at the times and dosages prescribed.

- The patient will utilize preventive measures when in the outside environment.

Nursing Interventions

- Monitor renal and liver function by checking urine output (>600 mL/d) and liver enzymes.
- Report if the patient's serum liver enzymes are elevated or if renal function tests are abnormal.
- Monitor the patient for impaired consciousness, headache, or seizures.

Patient Teaching

- Advise patients traveling to malaria-endemic countries to receive prophylactic doses of an antimalarial drug before leaving, during the visit, and upon their return.
- Teach patients to take oral antimalarial drugs with food or at mealtime if GI upset occurs.
- Monitor patients returning from malaria-endemic areas for malarial symptoms.
- Inform patients who take chloroquine or hydroxychloroquine to report vision changes immediately.
- Advise patients to avoid consuming large quantities of alcohol.

Side Effects

- Direct patients to report signs and symptoms of anorexia, nausea, vomiting, diarrhea, abdominal cramps, pruritus, visual disturbances, and dizziness.

Cultural Considerations

- Advise patients returning from malaria-endemic areas to be tested for malaria if they experience chills, high fever, and profuse sweating.
- Provide patient education in clear, understandable language about any prescribed antimalarial drug.

Evaluation

- Evaluate the effectiveness of the antimalarial drug by determining that the patient is free of symptoms.
- Evaluate the patient's understanding of the medication regimen.

Anthelmintic Drugs

Helminths are large parasitic worms that live and lay eggs in warm, moist soil where sanitation and hygiene are poor (Centers for Disease Control and Prevention [CDC], 2013). Transmission occurs from infected soil to the person, whereupon the helminth then feeds on host tissue. The most common site for **helminthiasis** (worm infection) is the intestine. Other sites for parasitic infection are the lymphatic system, blood vessels, and liver. These parasites cause disability and developmental delays in children and adolescents.

Groups of helminths include (1) cestodes (tapeworms), (2) trematodes (flukes), (3) intestinal nematodes (roundworms), and (4) tissue-invading nematodes (tissue roundworms and filariae). They enter the human host via contaminated food, bites of carrier insects, or direct penetration of the skin. The cestodes (tapeworms) are segmented and enter the intestine via contaminated food. There are four species of cestodes: *Taenia solium* (pork tapeworm), *T. saginata* (beef tapeworm), *Diphyllobothrium latum* (fish tapeworm), and *Hymenolepis nana* (dwarf tapeworm). The segmented cestodes have heads and hooks or suckers that attach to the tissue.

The trematodes (flukes) are flat, nonsegmented parasites that feed on the host. Four types of trematodes exist: *Fasciola hepatica* (liver fluke), *Fasciolopsis buski* (intestinal fluke), *Paragonimus westermani* (lung fluke), and *Schistosoma* species (blood flukes).

Five types of nematodes may feed on intestinal tissue: *Ascaris lumbricoides* (giant roundworm), *Necator americanus* (hookworm), *Enterobius vermicularis* (pinworm), *Strongyloides stercoralis* (threadworm), and *Trichuris trichiura* (whipworm).

Two types of nematodes are tissue-invading: *Trichinella spiralis* (pork roundworm) and *Wuchereria bancrofti* (filariae). The pork roundworm *T. spiralis* can cause **trichinosis**, a disease caused by ingestion of raw or inadequately cooked pork that contains larvae of the *T. spiralis* parasite, which can be diagnosed by muscle biopsy. By thoroughly cooking pork, the roundworm is destroyed.

Side Effects and Adverse Reactions

The common side effects of **anthelmintics** (agents that destroy worms) include various manifestations of GI distress, such as anorexia, nausea, vomiting, and occasionally diarrhea and stomach cramps. The neurologic problems associated with anthelmintics are dizziness, weakness, headache, and drowsiness. Adverse reactions do not occur frequently because the drugs usually are given for a short period (1 to 3 days). Prototype Drug Chart 28.2 lists dosages and drug data for ivermectin, and Table 28.2 lists anthelmintic drugs prescribed to treat various types of parasitic worms.

PROTOTYPE DRUG CHART 28.2 Ivermectin

Drug Class	Dosage
Synthetic anthelmintic Pregnancy category: C*	Topically (for head lice only): Apply to affected area. Avoid contact with eyes and mouth. Onchocerciasis: A/C >15 kg: PO: 0.15 mg/kg single dose with retreatment in 3-12 months Strongyloidiasis: A/C >15 kg: PO: 0.2 mg/kg single dose followed with stool exam
Contraindications	**Drug-Lab-Food Interactions**
Pediatric dosage safety and efficacy have not been established. Contraindicated for those hypersensitive to the drug's components. *Caution:* Asthma, hepatic impairment; not recommended with breastfeeding	Take on an empty stomach with water. Monitor ophthalmic exams, and follow up with stool exams.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Well absorbed Distribution: Widely distributed within the body; does not cross blood-brain barrier Mode of Action: Binds with chloride ions, increases cell permeability, and kills the parasite PB: 93% Half-life: 18 h Metabolism: Liver Excretion: In feces (over 12 d) and urine (<1%)	Peak: 4 h
Therapeutic Effects/Uses	
Drug of choice for strongyloidiasis and onchocerciasis Follow up and retreat as necessary.	
Side Effects	**Adverse Reactions**
Dizziness, nausea, pruritus	Lymph node swelling, abdominal pain, ocular effects and opacity, tachycardia, and increased liver enzymes (AST, ALT)

A/C, Adult/child; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *d,* day; *h,* hour; *PB,* protein binding; *PO,* by mouth; <, less than; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more

information.

TABLE 28.2
Anthelmintics

Generic	Route and Dosage	Uses and Considerations
Bithionol	A: PO: 30-50 mg/kg in 2 daily doses given every other day with food for 10-15 doses	Effective against flukes. For *Paragonimus* or *Fasciola* species when a patient cannot receive praziquantel due to resistance or adverse effect.
Ivermectin	See Prototype Drug Chart 28.2.	
Praziquantel	A/C >4 y: PO: 20-25 mg/kg tid for 1-2 d	Anthelmintic/antiparasitic for treatment of beef, pork, and fish tapeworms; blood flukes; and liver, lung, and intestinal flukes. *Caution:* Dizziness can occur; caution patient to avoid driving and operating machinery; use with caution in patients with cardiac or hepatic impairment, seizures Pregnancy category: B*; PB: 80%-85%; t½: 0.8-1.5 h
Pyrantel pamoate	A/C >2 y: PO: Roundworm: 11 mg/kg, single dose Pinworm: 11 mg/kg every 2 wk x 2 doses Hookworm: 11 mg/kg daily x 3 doses *max:* 1 g	For giant roundworm, hookworm, and pinworm. Pregnancy category: C*; PB: UK; t½: UK

A, Adult; *C*, child; *d*, day; *h*, hour; *max*, maximum; *PB*, protein binding; *PO*, by mouth; *t½*, half-life; *tid*, three times a day; *UK*, unknown; *wk*, week; *y*, year; >, greater than; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Anthelmintics

Assessment

- Assess whether the patient has traveled to other countries.
- Assess the patient's health behavior when at home; also assess handwashing facilities, disposal of waste, access to safe drinking water, and whether the patient walks barefoot in soil.
- Obtain a history of foods the patient has eaten and how the food was prepared.
- Document whether any other person in the household has been checked for helminths (worms).
- Assess the patient for complaints of anal itching and abdominal discomfort.
- Assess baseline vital signs, and collect a stool specimen.

Nursing Diagnoses

- Coping, Defensive
- Activity Intolerance, Risk for
- Nutrition, Imbalanced: Less than Body Requirements
- Body Image, Disturbed
- Knowledge, Deficient
- Gastrointestinal Motility, Risk for Dysfunctional

Planning

- The patient will demonstrate handwashing before eating.
- The patient will explain how to prepare foods properly to avoid recurrence.
- The patient will identify changes needed at home to ensure sanitation in food preparation.
- The patient will describe methods of infection control within the home.

Nursing Interventions

- Discuss benefits of handwashing before eating and after working in the soil or with animals.
- Monitor intake and output.
- Collect the stool specimen in a clean container. Avoid having stool come in contact with water, urine, or chemicals, which could destroy parasitic worms.
- Administer the prescribed anthelmintic after meals to prevent or minimize occurrence of GI distress.
- Monitor adverse reactions, which can include wheezing, abdominal pain, and high fever.
- Check laboratory values of iron, iodine, and vitamin A to monitor nutritional status.

Patient Teaching

- Explain to the patient the importance of handwashing before meals and after going to the toilet.

The parasite can be transferred within the family if proper hygiene is not used.

- Advise the patient to take daily showers and not baths.
- Encourage the patient to change sheets, bedclothes, towels, and underwear daily.
- Advise the patient that a second course of anthelmintic may be necessary if helminthiasis persists after therapy.
- Emphasize the importance of taking the prescribed drug at the designated times and keeping health care appointments.
- Teach the patient to read all directions regarding over-the-counter (OTC) drugs before use.
- Warn the patient that drowsiness may occur and that operating a car or machinery should be avoided if this should happen.
- Teach the patient to report any side effects or adverse reactions to the health care provider.

Cultural Considerations

- Recognize that community involvement may be needed if an area is at high risk for poor sanitation.
- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of honor or shame or because of lack of understanding of medical terminology.

Evaluation

- Evaluate effectiveness of anthelmintic therapy and absence of side effects.
- Determine whether the patient is using proper hygiene to avoid the spread of parasitic worms.
- Evaluate the patient's knowledge of preventative measures for helminthiasis.

Peptides

The Center for Communicable Disease, a governmental health agency that prevents and reduces communicable diseases in the United States and globally, has launched an initiative for health care providers and patients to prevent **drug-resistant infection**. Antibiotic therapy is challenged by increasing occurrence of drug-resistant infections such as methicillin-resistant *Staphylococcus aureus* (MRSA) and carbapenem-resistant *Enterobacteriaceae* (CRE). Antimicrobial **peptides** provide a broad spectrum and bactericidal ability to kill a range of parasites and viruses. There is ongoing research in combining antibiotics as multidrug regimens, which in turn can reduce antibiotic resistance.

Peptides classifications include antiviral, antimicrobial, antifungal, and antiparasitic. The two groups of peptides used as antibiotics are the polymyxins and bacitracin. Peptides are derived from cultures of *Bacillus subtilis,* and this group appears to interfere with bacterial cell membrane function.

Colistimethate

Colistimethate is a polypeptide antibiotic that targets aerobic gram-negative bacteria. It is used to treat *Pseudomonas aeruginosa,* CRE, and *Klebsiella* and *Shigella* species. This antibiotic has the capacity to penetrate and disrupt the bacterial cell. Colistimethate is available in forms administrated IM, intravenously (IV), and by inhalation. Common reactions include dyspepsia, tingling, slurred speech, dizziness, paresthesia, pruritus, rash and fever. Serious reactions include nephrotoxicity, neurotoxicity, neuromuscular blockade, respiratory distress, apnea, superinfection and *C. difficile*–associated diarrhea. Acute respiratory distress syndrome can occur when the antibiotic is administered by inhalation.

Polymyxins

Polymyxins were one of the early groups of antimicrobials, but many of the early drugs were discontinued because of severe toxic reactions such as neurotoxicity and nephrotoxicity. Polymyxins are polypeptide antibiotics that consist of five different chemical compounds, polymyxins A through E. Currently, polymyxin B and polymyxin E (also known as colistin) are used in clinical practice. Polymyxins produce a bactericidal effect by interfering with the cell membrane of the bacterium, thereby causing cell death. They affect most gram-negative bacteria, such as *P. aeruginosa, Escherichia coli,* and *Klebsiella* and *Shigella* species.

The polymyxins are not absorbed through the oral route except for colistin, which exerts action on the colon and is excreted in the feces. Intramuscular injection of polymyxins produces intense pain at the injection site. Consequently, parenteral polymyxins are administered at a slow IV infusion rate. Table 28.3 lists antiinfective peptides with dosage and uses.

Severe Adverse Effects

High serum levels of polymyxins can cause nephrotoxicity and neurotoxicity. In nephrotoxicity, the blood urea nitrogen (BUN) and serum creatinine levels are elevated, but when the serum drug level decreases, renal toxicity is usually reversed. Signs and symptoms of neurotoxicity (toxicity of the nerves) include paresthesias—abnormal sensations such as numbness, tingling, burning, and prickling—and dizziness. Neurotoxicity is usually reversible when the drug is discontinued.

Bacitracin

Bacitracin has a polypeptide structure and acts by inhibiting bacterial cell-wall synthesis and damaging the cell-wall membrane, which results in death of the cell. The drug action can be bacteriostatic or bactericidal. Bacitracin is not absorbed by the GI tract; if given orally, it is excreted in the feces. Bacitracin is effective against most gram-positive bacteria and some gram-negative bacteria. OTC bacitracin ointment is available for application to the skin. The side effects of bacitracin include skin redness and rash, nausea, and vomiting. Severe adverse reactions are renal damage and ototoxicity, and mild to severe allergic reactions that range from hives to anaphylaxis may occur.

Metronidazole

Metronidazole is a synthetic antibiotic and antiprotozoal (nitroimidazole class) that works by disrupting the bacterial DNA and inhibiting cell synthesis, which causes cell death. Metronidazole as a protozoal treats *Trichomonas vaginalis*, amebiasis, and giardiasis; as an antibiotic, it is used for anaerobic bacteria, including *Helicobacter pylori,* a pathogen in GI infections. Additionally, this drug has immunosuppressive and antiinfective properties that treat rosacea. This drug can be added to multidrug regimens in order to reduce **antibiotic resistance**, which occurs when the bacteria are not sensitive to the antibiotic. Metronidazole can be administered orally, parenterally, topically, and intravaginally. Toxic reactions include neurologic disturbances such as seizures and peripheral neuropathies. Prototype Drug Chart 28.3 provides information on metronidazole.

Patient Safety

To avoid antibiotic resistance, counsel patients to:

- Ask their health care provider if they can be treated without antibiotics.
- Take antibiotics as prescribed.
- Never skip doses and complete all of the antibiotic, even if they feel better.
- Never take someone else's antibiotic.

TABLE 28.3

Antiinfectives

Generic	Route and Dosage	Uses and Considerations
Peptides		
Bacitracin	A/C: Topical: Apply a thin layer two or three times daily. A/C: Ophthalmic ointment: Apply a thin film to the affected eye q3-4h for 7-10 d.	Topical ointment is for skin infections; ophthalmic ointment is for eye infections. Pregnancy category: C*; PB: <20%; t½: UK
Colistimethate sodium	A/C: IM/IV: 2.5-5 mg/kg/d in divided doses; *max*: 5 mg/kg/d NEB: 75 mg every 12 h	For *Pseudomonas aeruginosa, Escherichia coli,* and *Klebsiella* and *Shigella* species; can be used for CRE infection. Pregnancy category: C*; PB: UK: t½: 2-3 h Treats multidrug-resistant strains of serious gram-negative infections (e.g. UTI, septicemia, bacteremia, meningitis, skin infections) when other antibiotics are ineffective or contraindicated. Side effects include GI discomfort, headache, and depression. Adverse reactions include respiratory failure, neurotoxicity, and nephrotoxicity. *Prolonged use may result in fungal or bacterial* superinfection. Use with caution in renal patients and in pregnancy. Pregnancy category: B*; PB: 10%; t½: 6-8 h

Additional Antiinfective Agents		
Metronidazole	See Prototype Drug Chart 28.3	
Polymyxin B	A/C: Ophthalmic: 25,000 U/kg/d A/C: Topical: 0.1%-0.25% A/C: IM: 25,000-30,000 U/kg in divided doses q4-6h	Routine IM administration is not recommended. Commonly used as an ophthalmic, otic, and topical treatment. Also combined with neomycin for urinary tract irrigation. *Caution:* In pregnancy and while breastfeeding; with IM administration, renal disease, hypersensitivity to the drug A polypeptide antibiotic for gram-negative bacteria including *P. aeruginosa, E. coli, Haemophilus influenzae, Enterobacter aerogenes,* and *Klebsiella* spp. Rarely used via the IM route because of toxic reactions (nephrotoxicity, neurotoxicity) and pain at the injection site. *Adverse reactions:* Facial swelling, difficulty breathing, paresthesias

A, Adult; *bid*, twice daily; *C*, child; *CNS*, central nervous system; *CRE*, carbapenem-resistant *Enterobacteriaceae*; *d*, day; *GI*, gastrointestinal; *h*, hour; *IM*, intramuscular; *IV*, intravenous; *max*, maximum; *NEB*, nebulizer; *PB*, protein binding; *PO*, by mouth; *q*, every; *t½*, half-life; *UK*, unknown; *UTI*, urinary tract infection; <, less than; ≥, greater than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 28.3 Metronidazole

Drug Class	Dosage
Antibacterial peptide, amebicide Systemic and topical Pregnancy category: B*	Topical: Apply a thin layer to the affected area. Systemic for anaerobic infections: A: IV: 15 mg/kg x 1, then 7.5 mg/kg q6h C: IV: 30 mg/kg/d in divided doses q6h (*max*: 4 g/d) Trichomoniasis: A and C >45 kg: PO: 2 g x 1 or 500 mg bid for 7 d C <45 kg: 15 mg/kg/day PO, divided doses q8h x 7 d Giardiasis: A: 250 mg q8h for 5-7 d Amebiasis: A: PO: 750 mg q8h for 5-10 d C: PO: 35-50 mg/kg divided dose q8h for 10-14 d *Clostridium difficile*–associated diarrhea: A: PO: 500 mg tid for 10-14 d C: PO: 30 mg/kg/d divided doses q6h x 7-10 d Bacterial vaginosis: A and C >45 kg: PO: 500 mg q12h x 7 d C <45 kg: PO: 15 mg/kg/d divided doses q12h x 7 d (*max*: 1 g/d)
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity to drug components, first trimester of pregnancy; breastfeeding should be withheld. *Caution:* Liver impairment and cardiac conditions, neoplastic disease	Alcohol is contraindicated. Take immediate-release tablet with food; take extended-release tablet on an empty stomach.
Pharmacokinetics	Pharmacodynamics
Absorption: Well absorbed orally; does not cross the blood-brain barrier Distribution: Bile, seminal fluid, bone, liver, lung, vagina Metabolism: PB: 10% Excretion: In urine (60%-80%) and feces (6%-15%) Half-life: 8 h	Oral: Peak: 1-3 h immediate-release tablet Peak: 5 h extended-release tablet
Therapeutic Effects/Uses	
Bactericidal in anaerobic infections such as *Helicobacter pylori*; antiprotozoal agent used for *Trichomonas vaginalis* vaginosis, giardiasis, *Clostridium difficile* infection, and amebiasis. Anaerobic infections include skin, intraabdominal, CNS, and lower respiratory infections and endocarditis. Can be applied topically twice daily for rosacea (0.75%). Mode of Action: Interacts with DNA to inhibit cell nucleic acid synthesis resulting in cell death	
Side Effects	Adverse Reactions
Headaches, nausea, flushing, dizziness, superinfection (*Candida* overgrowth) resulting in oral and vaginal candidiasis	Seizures, diarrhea, optic and peripheral neuropathy, hypersensitivity, pruritus, urticaria

A, Adult; *bid,* twice daily; *C,* child; *CNS,* central nervous system; *d,* day; *h,* hour; *IV,* intravenous; *max,* maximum; *PO,* by mouth; *q,* every; *tid,* three times daily ; <, less than; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Nursing Process: Patient-Centered Collaborative Care

Antiinfectives: Peptides

Assessment

- Assess whether the patient has any allergies to medications.
- Assess the patient's prior use of antimalarial drugs.
- Assess the patient's level of consciousness.
- Assess renal function and urinary output.
- Assess skin integrity and evaluate for skin rash and pruritus.

Nursing Diagnosis

- Allergy Response, Risk for
- Infection, Risk for
- Injury, Risk for
- Tissue Integrity, Risk for Impaired

Planning

- The patient will show liver and kidney laboratory values at baseline level.
- The patient's skin will be intact without pruritus, swelling, or rash.
- The patient will be able to explain how to properly take the prescribed drug.
- The patient will describe the side effects and adverse reactions that require notification of a health care provider.

Nursing Interventions

- Monitor lab values, including liver function tests (aspartate aminotransferase [AST], alanine aminotransferase [ALT]) and evaluation of renal function (BUN, creatinine clearance [CrCl]) and blood serum (platelet count, hemoglobin, hematocrit).
- Check urinary function by monitoring intake and output.
- Monitor the patient for an altered level of consciousness.

Patient Teaching

- Teach patients to read all instructions prior to taking medications.
- Inform patients to take all prescribed medication.

- Discuss possible side effects that can occur as a reaction to the drug.
- Instruct patients to check for signs of superinfection, such as white patches on the tongue.
- Advise patients to report all adverse reactions to a health care provider, including fever, diarrhea, trouble breathing, and decreased urination.
- Describe urinary signs that indicate impairment, such as decreased urinary flow.
- Advise patients to avoid alcohol.

Side Effects

- Direct patients to report all side effects and adverse reactions.

Cultural Considerations

- Provide patient information in a clear, concise manner using understandable terms about the action, dose, and precautions of antiinfectives.
- With the patient's approval, include family members to participate in teaching sessions.

Evaluation

- Evaluate effectiveness of treatment by absence of manifestations.
- Evaluate patient understanding of the medication regimen by encouraging patient feedback and questions.

Critical Thinking Case Study

SM is a 40-year-old male who has returned from working in a missionary health clinic in sub-Saharan Africa. He is experiencing fever, headache, and chills. SM states he took his antimalarial pills but stopped when he got to the clinic in Africa. Chloroquine is ordered.

1. Which key factors should be assessed in SM's history?
2. What is the significance of monitoring lab enzymes and hemoglobin?
3. Describe the correct method of preventive prophylaxis when taking antimalarial drugs.

NCLEX Study Questions

1. A patient is diagnosed with malaria and is prescribed mefloquine hydrochloride. The nurse anticipates that which lab test will be ordered?
   a. Liver enzymes
   b. Blood glucose
   c. Sputum culture and sensitivity
   d. White blood cell count
2. A patient is admitted to the hospital with multidrug-resistant urinary tract infection. Lab tests show *Pseudomonas aeruginosa.* Colistimethate sodium is ordered by intramuscular injection. The nurse understands that which of the following is the purpose for this drug?
   a. This drug prevents toxic adverse reactions.
   b. This drug treats aerobic gram-negative bacteria.
   c. This drug is safe for patients with renal impairments.
   d. This drug prevents antibiotic resistance.
3. A patient with a history of malaria who is being treated with chloroquine is in the clinic for a follow-up visit. What should the nurse advise the patient to do?
   a. Get frequent hearing checks.
   b. Take antimalarials before meals.
   c. Get frequent testing of stool specimens.
   d. Check your heart rate before taking this medication.
4. A patient is taking thiabendazole for trichinosis. What does the nurse realize about this condition and its treatment?
   a. The medication is given for 7 days.
   b. The medication should be avoided if the patient has renal disease.
   c. Family members should be checked for the same disease.
   d. Proper hygiene must be taught to avoid the spread of disease.
5. A 50-year-old woman is being discharged from the hospital after treatment for malaria. Which teaching topic would best inform the patient about adverse reactions?
   a. The occurrence of headaches
   b. Experiencing dizziness
   c. Developing mild pruritus
   d. Respiratory distress
6. A 30-year-old woman presents with a recurrence of *Trichomonas vaginalis* infection, and metronidazole is ordered. The patient's history reveals which of the following contraindications?
   a. A recent pregnancy test is negative.
   b. She previously took metronidazole and had no side effects.
   c. She drinks an occasional glass of wine.
   d. She takes an oral contraceptive.

Answers: 1, a; 2, b; 3, a; 4, d; 5, d; 6, c.

UNIT IX
Immunologic Drugs

OUTLINE

Introduction
29. HIV- and AIDS-Related Drugs
30. Transplant Drugs
31. Vaccines

Introduction

Immunity comprises those functions that protect people from the effects of invasion of the body by microscopic organisms such as bacteria, viruses, molds, spores, pollens, protozoa, and cells from other persons or animals. A person remains in harmony with these organisms as long as the organisms do not enter the body's internal environment. The body has various defenses (e.g., skin) that prevent microorganisms from gaining access to its internal environment. However, these defenses are not infallible, and invasion of the body's internal environment by microorganisms occurs often. A properly functioning immune system neutralizes, eliminates, or destroys the invading microorganisms. To do this without harming the body, immune system cells use defensive actions against only nonself proteins and cells. This means that immune system cells can differentiate between the body's own healthy cells and other nonself proteins and cells.

Nonself proteins and cells include (1) all foreign cells and microorganisms, (2) infected or debilitated body cells, and (3) self cells that have undergone malignant transformation into cancer cells. This ability to recognize self versus nonself, which is necessary to prevent healthy body cells from being destroyed along with the invaders, is called *self-tolerance.* Immune system cells are the only body cells capable of recognizing self from nonself.

Unique proteins on the surface of all body cells of each individual serve as a personal identification code for that person. The cell-surface proteins of one person are recognized as foreign by the immune system of another person. These are antigens—proteins capable of stimulating an immune response.

Immune function is generally most efficient when people are in their twenties and thirties; it slowly declines with increasing age. Older adults have marginal immune function, causing increased susceptibility to a variety of pathologic conditions.

Immune System Structure

The immune system is not confined to any one organ or body area. Instead, immune system cells originate in the bone marrow. Some of these cells mature in the bone marrow; others leave the bone marrow and mature in different body sites. After maturation, most immune system cells are released into the blood, where they circulate throughout the body and exert specific effects.

Immune System Function

The three processes necessary for immunity, together with the cells involved in these responses, can be categorized as inflammation, antibody-mediated immunity (humoral immunity), and cell-mediated immunity. Inflammation is discussed in the introduction to Unit VII. Full immunity, or *immunocompetence,* requires the adequate function and interaction of all three processes, although some functions of each overlap. Long-lasting immune actions are those generated by antibody-mediated immunity and cell-mediated immunity.

Antibody-Mediated Immunity

Antibody-mediated immunity (AMI), also called *humoral immunity,* involves antigen-antibody interactions that neutralize, eliminate, or destroy foreign proteins. Antibodies for these interactions are produced by populations of B lymphocytes.

Antigen-Antibody Interactions

Antigen-antibody interactions occur in the body's internal environment. To make an antibody that can exert its effects on a specific antigen, the body must first be exposed to that antigen to the degree that the antigen enters the body. Even when exposure includes penetration, not all exposures result in the stimulation of antibody production. Invasion by the antigen must occur in such large numbers that some of the antigen either evades detection by the normal nonspecific defenses or overwhelms the abilities of the inflammatory response to neutralize, eliminate, or destroy the invader.

Acquiring Antibody-Mediated Immunity

The two broad categories of immunity are *innate immunity* and *acquired immunity.* Innate immunity is a genetically determined characteristic of an individual, group, or species. A person either has or does not have innate immunity. For example, humans have many innate immunities to viruses and other microorganisms that cause specific diseases in animals. As a result, humans are not susceptible to diseases such as mange, distemper, hog cholera, or any of a variety of animal afflictions. This type of immunity cannot be developed or transferred from one person to another and is not an adaptive response to exposure or invasion by foreign proteins.

Acquired immunity is the immunity that every person's body makes, or can receive, as an adaptive response to invasion by foreign proteins. *Antibody-mediated immunity* is an acquired immunity that occurs either naturally or artificially and can be either active or passive. Active immunity occurs when antigens enter the body and the body responds by making specific antibodies against the antigen. This type of immunity is active because the body takes an active part in making the antibodies. *Active immunity* can occur under conditions that are either natural or artificial. Natural active immunity occurs when an antigen enters the body without human assistance, and the body responds by actively making antibodies against that antigen (e.g., chickenpox virus). Most of the time, the first invasion of the body by this antigen results in the person manifesting signs and symptoms of the disease. However, processes that occur in the body at the same time allow the person to acquire immunity to that antigen so that a second exposure to the same antigen will not cause illness. This type of immunity is the most effective and the longest lasting.

Artificial active immunity is a type of protection developed against illnesses that produce such serious side effects that total avoidance of the disease is most desirable. Small amounts of specific antigens are deliberately placed in the body via vaccination so that the body responds by actively making antibodies against the antigen. Because antigens used for this procedure have been specially processed to make them less likely to proliferate within the body, this exposure does not in itself cause the disease.

Examples of diseases for which artificially acquired active immunity can be obtained include tetanus, diphtheria, measles, smallpox, mumps, and rubella. This type of immunity lasts many years, although repeated but smaller doses of the original antigen are periodically required as a "booster" to maintain complete protection against the antigen.

Passive immunity occurs when antibodies against a specific antigen are in a person's body, but the person did not actively generate these antibodies. Instead, these antibodies are made in the body of

another person or animal and are then transferred to the body of a specific individual. Because these antibodies are foreign to the individual, the body recognizes the antibodies as nonself and takes steps to eliminate them relatively quickly. For this reason, passive immunity can provide only immediate, short-term protection against a specific antigen.

Cell-Mediated Immunity

Cell-mediated immunity (CMI), or *cellular immunity,* involves many leukocyte actions, reactions, and interactions that range from the simple to the complex. This type of immunity is provided by committed lymphocyte stem cells that mature in the secondary lymphoid tissues of the thymus and pericortical areas of lymph nodes. Certain CMI responses influence and regulate the activities of antibody-mediated immunity and inflammation by producing and releasing cytokines, therefore total immunocompetence relies on optimal CMI function.

The leukocytes that play the most important roles in CMI include several specific T-lymphocyte subsets along with a special population of cells known as *natural killer cells* (NK cells). T lymphocytes further differentiate into a variety of subsets, each of which has a specific function. The three T-lymphocyte subsets crucial to the development and continuation of CMI are helper/inducer T cells, suppressor T cells, and cytotoxic/cytolytic T cells.

Protection Provided by Cell-Mediated Immunity

Specific components of CMI assist in providing protection to the body by their highly developed abilities to differentiate self from nonself. The nonself cells most easily recognized by CMI are self cells that are infected by organisms that live within host cells and self cells that are mutated at the DNA level and are thus abnormal. CMI provides a surveillance system that rids the body of self cells that might potentially harm the body. CMI is critically important in preventing development of cancer and metastasis after exposure to carcinogens.

In this unit, Chapter 29 discusses drugs related to HIV and AIDS; Chapter 30 reviews drugs used in solid organ transplantation; and Chapter 31 covers vaccines.

OBJECTIVES

- Describe the life cycle of the human immunodeficiency virus (HIV) and relate it to the actions of pharmacologic drugs used in the treatment of HIV disease.
- Identify the common risk factors for HIV transmission.
- Describe the six classifications of antiretroviral therapy, and give examples of medications in each group.
- Explain specific issues of medication adherence to antiretroviral agents.
- Discuss the nurse's role in medication management and issues of adherence.
- Discuss medical management for preventing mother-to-child transmission of HIV infection during pregnancy.
- Discuss health care workers' exposure risks and relate the risk and type of exposure to recommendations.
- Apply the nursing process, including teaching, to the care of patients with HIV infection.

Since the acquired immunodeficiency syndrome (AIDS) epidemic began in the United States in the early 1980s, advancement of **antiretroviral therapy (ART)** has dramatically improved human immunodeficiency virus (HIV)-related morbidity and mortality and has reduced perinatal and behaviorally associated HIV transmission. The Centers for Disease Control and Prevention (CDC) reports that more than 1.2 million people in the United States are infected with HIV; between 10% and 15% of persons living with HIV do not know they have it. Approximately 50,000 new cases of HIV infection occur annually. Improvement of health, prolonging lives, reducing transmission risk, and suppression of HIV necessitates the use of combination treatments with antiretroviral drugs. Current clinical guidelines recommend ART for all persons infected with HIV-1, regardless of their viral load (CD4+ cell count). Prophylactic treatment of HIV-negative partners minimizes their risk of contracting HIV. It is critical that nurses educate patients regarding ART and, in partnership with the patient, develop strategies to optimize adherence.

Although strides have been made in the treatment of HIV/AIDS, challenges remain. One important aspect is increased drug **resistance** to current therapies. The makeup of the HIV DNA strands allows the virus to mutate from a drug-sensitive to a drug-resistant form. To minimize resistant strains, clinical and nonclinical providers and health departments need to strive for the highest possible adherence to ART. At each health care visit, persons with HIV and their partners should receive ongoing counseling to reinforce HIV prevention measures, screening for high-risk behaviors, diagnosis and treatment of sexually transmitted infections (STIs), and reinforcement of the importance of medication adherence. Open communication between the health care provider and patient should be fostered.

The goals for initiating ART are to (1) reduce HIV-associated morbidity and mortality, (2) prolong the duration and quality of life, (3) restore and preserve immunologic function, (4) maximally and durably suppress plasma HIV viral load, and (5) prevent HIV transmission.

HIV Infection: Pathophysiology

HIV is an RNA retrovirus. It is unable to survive and replicate unless it is inside a living human cell. HIV destroys CD4+ T cells, also called *helper T cells* or *CD4+ T lymphocytes*; these play a critical role in the human **immune response** through recognition of infectious and neoplastic processes. The destruction of CD4+ cells by HIV results in immune deficiency, so the CD4+ cell count is an indicator for immune function in those with HIV.

Normal CD4+ counts range from 500 to 1200 cells/mm^3. After initial infection, rapid viral replication occurs, resulting in a high level of HIV in circulation (high viral load); the virus then attacks and destroys CD4+ cells. There is a corresponding drop in CD4+ cells, which triggers an immune response that results in CD4+ cell replacement and HIV antibody production. HIV uses the CD4+ cell's apparatus to replicate itself and spread throughout the body. The CD4+ cells continue to drop as HIV viral load increases, which further weakens the person's natural immune system such that it cannot fight off infection and disease (e.g., cancer). Symptoms of HIV infection range from mild to severe and include fever, fatigue, pharyngitis, myalgia or arthralgia, lymphadenopathy, headache, and night sweats in those recently infected; these symptoms can be experienced 2 to 12 weeks after HIV exposure. This period is called *acute retroviral syndrome, acute seroconversion syndrome,* or *primary HIV infection.* At this stage, people are highly infectious and symptoms can often be mistaken, by both patient and health care provider, for a transient flulike illness. Consequently, few people are diagnosed during this time. Additionally, the time delay from infection to a positive HIV test result—the so-called **window period**—averages 10 to 14 days, but some do not seroconvert for 3 to 4 weeks. Almost all patients seroconvert within 6 months. For this reason, patients who are at risk for HIV infection and test negative should be counseled to have the test repeated in 3 months (the close of the window period). If HIV is strongly suspected, an HIV RNA quantitative test can be done. A viral load of 10,000 copies/mL usually indicates the virus is adequately suppressed.

HIV Life Cycle

The phases of the HIV life cycle (Fig. 29.1) are binding, fusion, reverse transcription, integration, replication, assembly, and budding. HIV begins its life cycle when it *binds* to CD4+ receptors on the surface of a CD4+ T lymphocyte. The virus then *fuses* with the host cell, allowing entrance into the CD4+ cell. After fusion, the virus releases RNA, its genetic material, into the host cell to be converted into HIV DNA. This *reverse transcription* (RT) lets the virus enter into the host cell's nucleus and *integrate* (combine) with the cell's DNA. The integrated HIV DNA, a provirus, creates copies of the HIV genomic material (*replication*) and shorter strands of RNA called *messenger RNA* (mRNA). The mRNA is used as a blueprint to make long chains of HIV proteins. The new HIV proteins and HIV RNA *assemble* into an immature, noninfectious HIV, which then pushes out of the host cell (*budding*). Finally, these immature HIV cells release HIV enzymes (proteases) that disassemble the long protein chains of immature HIV virus. The now individual proteins can combine to make copies of mature HIV and can then move on to infect other cells.

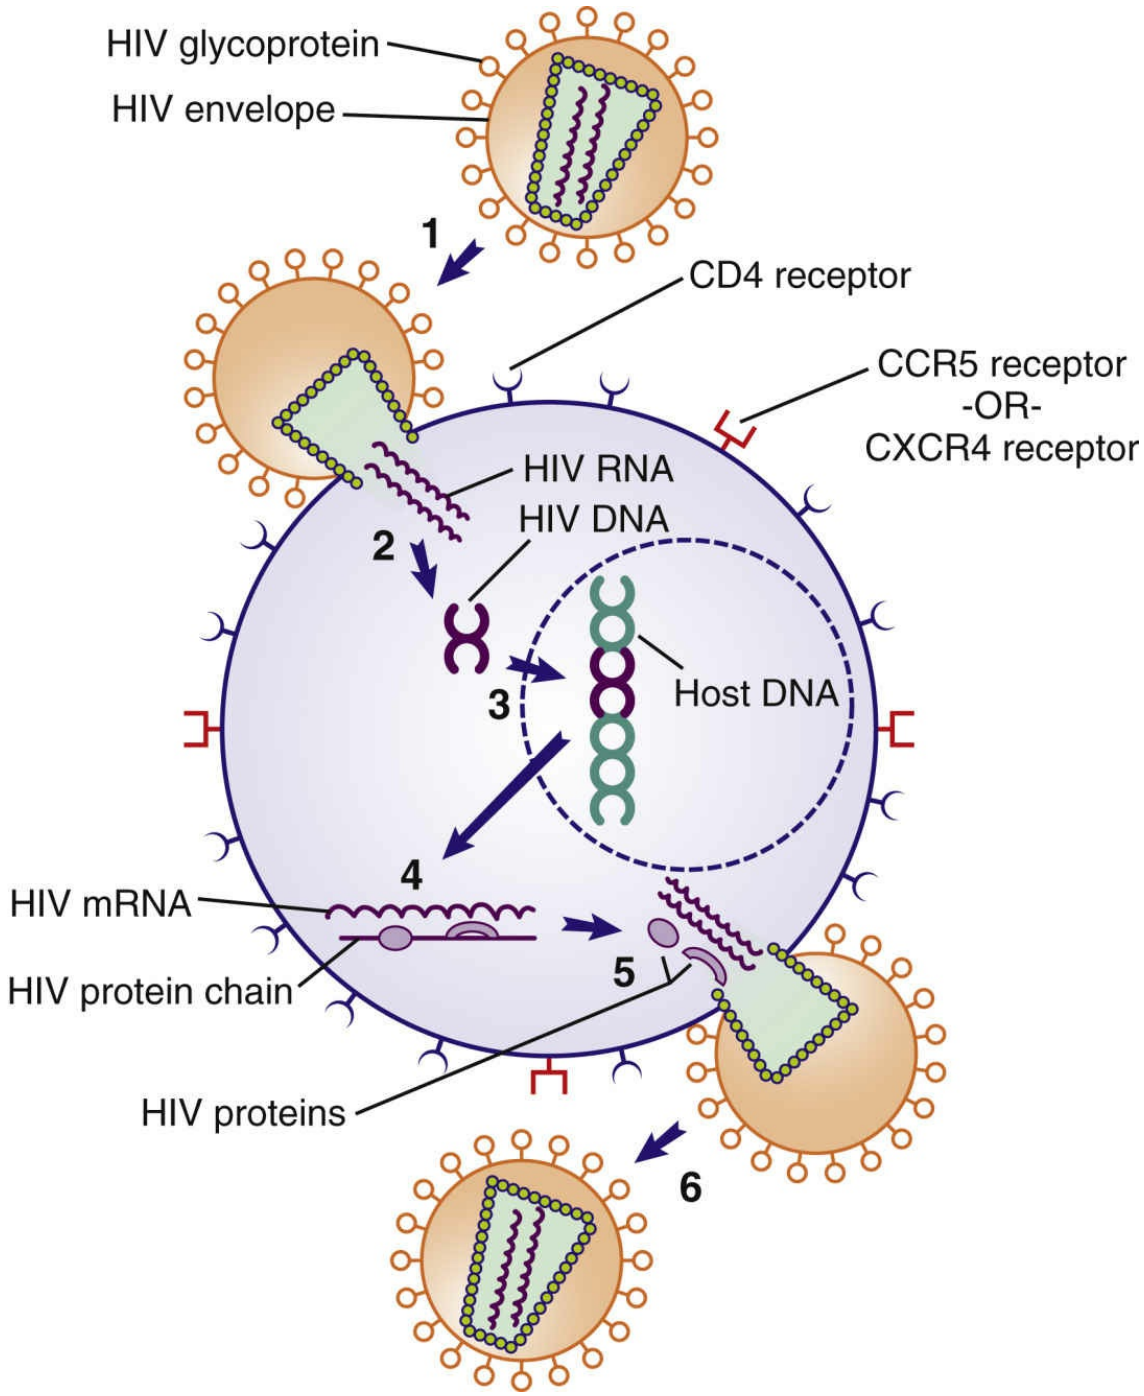

FIG. 29.1 **The Life Cycle of the Human Immunodeficiency Virus (HIV).**
(Courtesy National Institutes of Health)

HIV Transmission

HIV is spread via intimate contact with blood, semen, vaginal fluids, and breast milk. Transmission of the virus occurs primarily by (1) sexual contact, which includes oral, vaginal, and anal sex; (2) direct blood contact including intravenous (IV) drug use with shared needles or shared drug works, shared contaminated personal care items such as razors, and blood transfusions (now extremely rare in the United States); and (3) mother-to-child contact through shared maternal-fetal blood circulation, direct blood contact during delivery, or breast milk. Included in these modes are accidental needle injury, artificial insemination with donated semen, and organ transplant. Those at highest risk include persons who engage in unprotected sex, those with multiple sexual partners (either the patient or partner[s] of the patient), IV drug users who share needles or drug works, and infants born to women with HIV. The risk of mother-to-child transmission (MTCT) is 25% without ART; the risk decreases to 1% to 2% with successful use of ART. Other factors that increase the risk of MTCT are a mother with a viral load greater than 1000 copies/mL at delivery, premature rupture of the membranes, hepatitis C virus coinfection, preterm gestation, and vaginal delivery. HIV is not spread by air or water, mosquitoes or ticks, shaking hands, hugging, sharing toilets, sharing dishes or drinking glasses, or drinking fountains.

Laboratory Testing

Several laboratory tests are important for initial patient evaluation upon entry to care, during follow-up evaluation for those not on ART, and before and after initiation or modification of ART to assess for immunologic and virologic efficacy of treatment.

The laboratory tests used to determine when to initiate medication therapy and to monitor efficacy of therapy and indications for changing therapy are CD4+ T-cell count, plasma HIV RNA quantitative assay (or **viral load** test), and HIV resistance testing.

The count reflects the number of CD4+ cells circulating in the blood. The result is listed as an absolute number and a relative percentage. The absolute count can vary in the same patient depending on the laboratory used, the time of day laboratory blood work is drawn, or acute illness. The CD4+ percentage is a more stable reflection of the immune system and is used in conjunction with the absolute count to monitor health status and response to medication therapy. The patient should be encouraged to use the same laboratory at approximately the same time of day to promote consistency of results. The nurse should monitor the laboratory used because lab value references vary from laboratory to laboratory. The HIV viral load is indicative of the level of virus circulating in the blood and is the best determinant of treatment efficacy. A key goal of therapy is to achieve and maintain a viral load below the limits of detection (<20 to 40 copies/mL, depending on the assay used). This goal should be achieved in 16 to 24 weeks of therapy. Resistance to ART leads to treatment failure and the risk of transmitting drug-resistant virus. Determination of the presence of a drug-resistant strain of HIV is important to prevent ineffective treatment. Individuals who experience failure of ART should have drug-resistance testing, assessment of drug adherence, and a review of possible drug-drug and drug-food interactions and drug intolerability, treatment history, and HIV RNA and CD4+ cell counts.

Classification

HIV disease **staging and classification systems** are important tools for tracking and monitoring the HIV epidemic and for providing the clinician and patient with information about HIV disease stage and clinical management. The two major classification systems are the CDC staging system (revised in 2014) and the World Health Organization (WHO) system (revised in 2015).

The CDC system assesses the severity of HIV disease by CD4+ cell counts and by presence of specific HIV-related conditions; the system is based on the lowest documented CD4+ cell count (*nadir CD4+*) and on previously diagnosed HIV-related conditions. The WHO system is useful in resource-constrained settings without access to CD4+ cell measurements and classifies HIV disease based on clinical manifestations that clinicians and those with varying levels of HIV expertise and training can recognize in diverse settings.

Indications for Antiretroviral Therapy

ART has dramatically reduced HIV-associated morbidity and mortality. However, the CDC reported that in the United States, fewer than one-third of HIV-infected individuals have adequate viral suppression. Many individuals with HIV infection are undiagnosed or they are not retained within the health care system for routine monitoring.

A set of guidelines was developed by the U.S. Department of Health and Human Services Expert Panel on Antiretroviral Guidelines for Adults and Adolescents (the Panel). The Panel last updated the guidelines in 2016 and recommends ART for all HIV-infected individuals regardless of CD4+ count to reduce HIV-related morbidity and mortality and to prevent HIV transmission. The Panel also seeks to educate patients on the benefits and considerations for ART, especially the importance of adherence. The current guidelines for treatment-naïve persons with HIV include initial therapy with two nucleoside reverse transcriptase inhibitors (NRTIs) in combination with a third active antiretroviral (ARV) drug from one of three drug classes: an integrase strand transfer inhibitor (INSTI), a nonnucleoside reverse transcriptase inhibitor (NNRTI), or a protease inhibitor (PI) with a pharmacokinetic (PK) enhancer (booster) (cobicistat or ritonavir). All HIV-infected persons diagnosed with active tuberculosis (TB) should be started on antiretroviral and TB therapy. Rifamycin (rifabutin, rifampin) should be included in the TB regimen despite drug interactions. Chapter 27 further discusses antituberculars.

Suppression of HIV with ART may decrease inflammation and immune activation that is thought to contribute to higher rates of cardiovascular, kidney, and liver disease; neurologic complications; and malignancy in HIV-infected cohorts. If therapy is to be initiated, medications are selected based on results of genotypic resistance testing where applicable; comorbidities (e.g., liver disease, renal dysfunction, depression); potential drug-drug interactions; pregnancy status; and assessment of the patient's willingness and readiness to start therapy. Evaluation of medication readiness should include dosage regimen, pill burden, dosing frequency, food restrictions, side effects, and the patient's daily routine. Tools for promoting medication adherence (e.g., alarms, pill planners) and plans for management of potential medication side effects should be reviewed before medication initiation. The patient should be instructed in the need for a better than 95% medication adherence, the potential for development of medication resistance with less than optimal adherence, and the clinical implications of resistance.

Antiretroviral Drugs

NRTIs, NNRTIs, PIs, **fusion (entry) inhibitors**, CCR5 antagonists, and INSTIs make up the drugs used as ART. Table 29.1 lists dosages, uses, and considerations for several ARVs. More than 25 different ARVs have received U.S. Food and Drug Administration (FDA) approval, and various agents are available in fixed-dose combinations that contain two or more HIV medications from one or more drug classes. In addition to the above classes of antiretrovirals, PK enhancers are approved to be taken with some ARVs (e.g., PIs and certain INSTIs).

Since the 1980s, when zidovudine monotherapy showed survival benefits in advanced HIV patients, much progress has been made. Newer agents have improved adherence (e.g., fewer pills for more convenient dosing, formulation changes that reduce dosing frequency or pill burden, combination dosage forms with two or three drugs in one pill). Other improvements include increased potency, improved side-effect profile (e.g., decreased gastrointestinal [GI] effects), and PI enhancers.

ART is the standard of care in the treatment of HIV infection. Currently, there are six recommended regimens for treatment-naïve patients, five of which are INSTI based and one that is ritonavir-boosted–PI based. For treatment-naïve patients, ART generally consists of two NRTIs plus an INSTI, NNRTI, or PK-enhanced PI. Treatment-experienced patients who encounter drug resistance should begin a new regimen that includes two to three fully active drugs. Adding a single ARV is not recommended because of the increased risk of drug resistance to all ARVs. Furthermore, drug interruption is not recommended due to a risk of rapid increase of HIV RNA viral load and a decrease in CD4+ cell count.

The Panel reports that nevirapine (NVP) should not be given to ARV-naïve women whose CD4+ count is greater than 250 cells/mm^3 or to men with CD4+ greater than 400 cells/mm^3 due to a high incidence of hepatotoxicity; however, if no other ARV option is available, NVP can be administered, but patients should be closely monitored. On the other hand, the Panel reports no exceptions to stavudine plus zidovudine (antagonistic effect) and unboosted darunavir, saquinavir, or tipranavir (inadequate bioavailability).

INSTI-based regimens include the following:

- Dolutegravir-abacavir-lamivudine (DTG-ABC-3TC), but only for human leukocyte antigen (HLA)-B*5701–negative patients (presence of the *HLA-B*5701 allele* increases the risk of hypersensitivity to abacavir and is *not* recommended to individuals positive for the gene)
- Dolutegravir plus tenofovir disoproxil fumarate–emtricitabine (DTG plus TDF-FTC)
- Elvitegravir–cobicistat–tenofovir alafenamide–emtricitabine (EVG-c-TAF-FTC), but only for patients with pretreatment creatinine clearance (CrCl) greater than or equal to 30 mL/min
- Elvitegravir–cobicistat–tenofovir disoproxil fumarate–emtricitabine (EVG/c/TDF/FTC), but only for patients with pretreatment CrCl greater than or equal to 70 mL/min
- Raltegravir plus tenofovir disoproxil fumarate–emtricitabine (RAL plus TDF/FTC)

PI-based regimens include ritonavir-boosted darunavir plus tenofovir disoproxil fumarate–emtricitabine (DRV/r plus TDF/FTC).

Nucleoside/Nucleotide Reverse Transcriptase Inhibitors

Of the antiretroviral drugs, NRTIs were the first type of drug to treat HIV. NRTIs act by interfering with HIV viral RNA-dependent DNA polymerase, resulting in inhibition of viral replication. Seven NRTIs, also known as "nukes," are approved for use in the United States: zidovudine, didanosine, stavudine, lamivudine, abacavir, tenofovir, and emtricitabine. All but didanosine and stavudine are available in a fixed-dose combination with other classes of ARV drugs.

All NRTIs except didanosine can be taken without regard to food. Didanosine should be taken 30 minutes before or 2 hours after meals for optimal absorption. Fifty percent or more of NRTIs are excreted by the kidneys, therefore NRTIs require dosage adjustment in persons with renal insufficiency. With abacavir, dosage adjustment is recommended in individuals with hepatic insufficiency.

As a class, NRTIs are associated with changes in the body's metabolism secondary to mitochondrial toxicity. GI side effects such as nausea, diarrhea, and abdominal pain are transient and improve within the first 2 weeks of therapy. Rash is a common hypersensitivity reaction.

Complications include peripheral neuropathy, myopathy, pancreatitis, and lipoatrophy. Lipoatrophy—or wasting of fat on the extremities, face, and buttocks—is associated with chronic NRTI administration. Rare fatalities have occurred due to lactic acidosis and hepatic steatosis associated with NRTIs. Persons coinfected with hepatitis B virus (HBV) are at risk for severe acute exacerbation of their HBV upon discontinuation of emtricitabine, lamivudine, or tenofovir disoproxil fumarate.

TABLE 29.1
Antiretroviral Agents

Generic	Route and Dosage	Uses and Considerations
Nucleoside/Nucleotide Reverse Transcriptase Inhibitors (NRTIs)		
Abacavir (ABC) Also available as a component of fixed-dose combinations	Tablets: A/C ≥25 kg: PO: 300 mg bid or 600 mg once daily Solution: A: PO: 300 mg bid or 600 mg once daily C ≥3 mo: PO: 8 mg/kg/dose bid or 16 mg/kg/dose once daily	Used in combination with other ARVs. Screen for HLA-B*5701 before initiation. Hypersensitivity reactions are highest in patients who test positive for HLA-B *5701. Avoid in persons with cardiovascular risk factors. A black-box warning exists for hepatotoxicity or lactic acidosis. May be administered without regard to meals. Metabolized by alcohol dehydrogenase and glucuronyl transferase; ethanol decreases elimination of ABC. A reduced dose is recommended in persons with hepatic impairment. Pregnancy category: C*
Didanosine (DDI)	Extended-release capsule: A/C ≥60 kg: PO: 400 mg once daily A/C <60 kg: PO: 250 mg once daily C ≥6 y and 20-24 kg: 200 mg once daily Powder for oral solution: A ≥60 kg: PO: 400 mg once daily A <60 kg: PO: 250 mg once daily C: Dosage is based on age and weight. *Dosages are decreased if administered with TDF.*	DDI is not recommended for initial therapy due to inferior virologic efficacy. Used in combination with other ARVs. Metabolized by the liver. A black-box warning exists for hepatotoxicity or lactic acidosis and pancreatitis. Take on an empty stomach. ER capsules must be swallowed whole. Reduce the dose in persons with renal impairment. Pregnancy category: B*
Emtricitabine (FTC) Also available as a component of fixed-dose combinations	Capsule: A: PO: 200 mg once daily Solution: A: PO: 240 mg once daily C ≥3 mo: PO: 3 mg/kg/d	Used in combination with other ARVs. Metabolized by oxidation. A black-box warning exists for acute severe exacerbation of hepatitis B upon discontinuation of FTC and hepatitis or lactic acidosis. Otherwise, minimal toxicity is noted with FTC. Take without regard to meals. Reduce dose in patients with renal impairment. Pregnancy category: B*
Lamivudine (3TC) Also available as a component of fixed-dose combinations	HIV: Tablet: A/C ≥25 kg: PO: 300 mg once daily or 150 mg bid C <25 kg: Dosage is based on age and weight. Solution: A: PO: 300 mg once daily or 150 mg bid C ≥3 mo/Adol: PO: 8 mg/kg/dose once daily or 4 mg/kg/dose bid	Used in combination with other ARVs for treating HIV. Minimal toxicity with 3TC; a black-box warning exists for acute severe exacerbation of hepatitis B upon discontinuation of 3TC and hepatitis or lactic acidosis. Take without regard to meals. Adjust dosage in patients with renal insufficiency. Pregnancy category: C*
Stavudine (d4T)	A/C ≥60 kg: PO: 40 mg q12h A/C <60 kg: PO: 30 mg q12h	Used in combination with other ARVs for treating HIV. Crosses the blood-brain barrier. A black-box warning exists for hepatotoxicity or lactic acidosis and pancreatitis. Take without regard to meals. Adjust dosage in patients with renal insufficiency Pregnancy category: C*
Tenofovir (TDF)	See Prototype Drug Chart 29.2.	
Zidovudine (ZDV) Also available as a component of fixed-dose combinations	See Prototype Drug Chart 29.1.	

Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)		
Delavirdine (DLV)	A/C ≥16 y: PO: 400 mg tid	Used in combination with NRTIs. Take without regard to meals. Acidic food improves absorption, and 100-mg tablets may be dispersed in liquid prior to administration. DLV is metabolized extensively by the CYP450 isoenzymes. Pregnancy category: C*
Efavirenz (EFV) Also available as a component of fixed-dose combinations	See Prototype Drug Chart 29.3.	
Table Continued		

Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)		
Etravirine (ETR)	A/C ≥6 y and ≥30 kg: PO: 200 mg bid C ≥6 y but <30 kg: PO: 16-19 kg: 100 mg bid 20-24 kg: 125 mg bid 25-29 kg: 150 mg bid	Used in combination with NRTIs. However, patients with virologic failure on NNRTIs should not receive ETR solely with NRTIs. Administer after meals to enhance absorption. Tablets may be dispensed in water. Do not use grapefruit juice, carbonated beverages, or warm liquids. Do not add ETR to juice or milk without first adding it to water. Add more fluids to the glass to ensure the full dose is consumed. Metabolized by CYP450 enzymes; numerous drug-drug interactions exist. No dosage adjustment is needed in patients with renal insufficiency. Hypersensitivity reactions include rash, including Stevens-Johnson syndrome, and hepatitis that includes hepatic necrosis. Pregnancy category: B*
Nevirapine (NVP)	Immediate release: A: PO: 200 mg/d for 14 d, then 200 mg bid C: Dosage is based on age and weight. Extended release: A: PO: Initial dosing with IR as above for 14 d, then 400 mg ER once daily C ≥6 y: PO: 150 mg/m²/dose for 14 d, then 200-400 mg ER based on BSA	NVP should not be used as an initial treatment option for treatment-naïve patients because fatal toxicities can occur. Used in combination with other ARVs (NRTIs, NNRTIs, PIs). A black-box warning exists for females whose CD4+ counts are >250/mm³ because risk of hepatotoxicity is increased. Take without regard to meals. Do not crush or chew ER tablets. Metabolized by CYP450. NVP is contraindicated in persons with hepatic impairment because of increased risk for hepatotoxicity. Numerous drug-drug interactions exist. Discontinue with hepatotoxicity or rash, including Stevens-Johnson syndrome. Pregnancy category: B*
Rilpivirine (RPL) Also available as a component of fixed-dose combinations	A/C ≥12 y and ≥35 kg: PO: 25 mg once daily	Must be administered in combination with other ARVs. Take with a meal. Primarily metabolized by the liver. Numerous drug-drug interactions exist, and hepatotoxicity can occur. Monitor for depression, insomnia, cephalgia. Pregnancy category: C*

Protease Inhibitors (PIs)		
Atazanavir (ATV) Also available as a component of fixed-dose combinations	See Prototype Drug Chart 29.4.	
Darunavir (DRV) Also available as a component of fixed-dose combinations	A: PO: 600-800 mg bid C: Dosage is based on age and weight.	Used in combination with other ARVs. Must be administered with PK enhancer (cobicistat or low-dose ritonavir). Administer with food. DRV is metabolized by CYP450 isoenzymes. Adjust dosage in patients with hepatic insufficiency. Caution in patients with sulfa hypersensitivity. Monitor closely for rash, including Stevens-Johnson syndrome, toxic epidermal necrolysis, acute generalized exanthematous pustulosis, and erythema multiforme. Hepatotoxicity, DKA, and pancreatitis can occur. Other adverse effects include lipodystrophy, elevated transaminases, nausea, and diarrhea. Pregnancy category: C*
Fosamprenavir (FPV)	A: PO: 700 mg bid with ritonavir 100 mg PO bid C: PO: ≥6 mo: <11 kg: 45 mg/kg PO bid w/ritonavir 7 mg/kg PO bid 11-14 kg: 30 mg/kg PO bid w/ritonavir 3 mg/kg PO bid 15-19 kg: 23 mg/kg PO bid w/ritonavir 3 mg/kg PO bid >20 kg: 18 mg/kg up to 700 mg PO bid w/ritonavir 3 mg/kg up to 100 mg PO bid	Used in combination with other ARVs. A PK enhancer with low-dose ritonavir and twice-daily dosing are recommended. Monitor in patients with sulfa hypersensitivity; cross-reaction can occur. Metabolized by CYP450 isoenzymes and drug transporters. Dose adjustment is required in patients with hepatic impairment. Tablets can be taken without regard to meals. Oral suspension is taken on an empty stomach in adults and with food in children. Can readminister dose if emesis occurs within 30 min of administration. Adverse effects include rash, diarrhea, nausea, vomiting, headache, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, and possible increased bleeding in patients with hemophilia. Pregnancy category: C*
Table Continued		

Protease Inhibitors (PIs)		
Indinavir (IDV)	A: PO: 800 mg q12h	Used in combination with other ARVs and PK enhancers (e.g., ritonavir). CYP450 3A4 inhibitor and substrate. Adjust dosage in patients with hepatic insufficiency. For optimal absorption, take on an empty stomach. Hydrate with at least 1.5 L of fluid during a 24-h period. Adverse effects include nephrolithiasis, GI intolerance, nausea, indirect hyperbilirubinemia, headache, asthenia, blurred vision, dizziness, rash, metallic taste, thrombocytopenia, alopecia, hemolytic anemia, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Pregnancy category: C*
Lopinavir–ritonavir (LPV/r)	A: PO: 400/100 mg bid *or* 800/200 mg once daily C/Adol: PO: Dosage is based on weight.	Used in combination with other ARVs. CYP450 3A4 inhibitor and substrate. May take tablet with or without food; take oral solution with food. Adverse effects include GI intolerance, asthenia, PR interval prolongation, pancreatitis, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Pregnancy category: C*
Nelfinavir (NFV)	A/Adol: PO: 1250 mg bid or 750 mg tid C 2-13 y: PO: 45-55 mg/kg bid or 25-35 mg/kg tid	Used in combination with other ARVs. Not recommended in treatment-naïve patients as initial therapy. CYP450 3A4 inhibitor and substrate. Take with food; do not mix with acidic food or juice. Tablets can be dispersed in a small amount of water prior to mixing with food or juice. Nelfinavir oral powder may be added to water, milk, formula, soymilk, or dietary supplements. Do not mix nelfinavir oral powder with acidic food or juice (orange juice, apple juice, or applesauce). Do not mix nelfinavir with water in the original container. Adverse effects include diarrhea, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Persons with phenylketonuria should not take nelfinavir powder as it contains phenylalanine. Pregnancy category: B*
Ritonavir (RTV)	Other ARVs: A: PO: 600 mg bid C/Adol: Dosage is based on weight. Booster: A: PO: 100-400 mg in 1-2 divided doses C/Adol: Dosage is based on concomitant PI.	Used in combination with other ARVs and as a PK enhancer (booster) of other PIs. Dosage depends on use of RTV. CYP450 3A4 potent inhibitor; use extreme caution when administering other drugs, especially antihistamines, sedative hypnotics, antiarrhythmics, and ergot alkaloids. If coadministering with didanosine, separate drugs by 2 h. Take with food. Swallow tablets and capsules whole. Refrigerate capsules; RTV oral solution should not be refrigerated, but left at room temperature for up to 30 days. Adverse effects include GI intolerance, paresthesias, hepatitis, asthenia, hyperlipidemia, hyperglycemia, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Titrating the dosage may help to reduce side effects. RTV oral solution contains significant amounts of ethanol (43.2%) and propylene glycol (26.57%). Accidental ingestion by small children may lead to deadly ethanol or propylene glycol toxicity. Pregnancy category: B*
Saquinavir (SQV)	A: PO: 1000 mg bid	*Must* be dosed concurrently with low-dose ritonavir. SQV is not recommended for treatment-naïve adults due to its serious adverse effects. CYP450 3A4 inhibitor and substrate. Take with food. Adverse effects include nausea, diarrhea, headache, hyperlipidemia, elevated transaminase levels, hyperglycemia, PR and QT interval prolongation, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Contraindicated in patients with PR or QT prolongation, hypokalemia, or hypomagnesemia. Pregnancy category: B*
Table Continued		

Protease Inhibitors (PIs)		
Tipranavir (TPV)	A: PO: 500 mg bid C ≥2 y/Adol: PO: Dosage is based on weight.	Used in combination with other ARVs; *must* be coadministered with ritonavir. TPV has a black-box warning for hepatotoxicity and intracranial bleeding. CYP450 3A4 inducer and substrate. Take with food if coadministered with RTV tablets; if administered with RTV capsules or solutions, TPV can be taken regardless of food. Adverse effects include hepatotoxicity, rash hyperlipidemia, hyperglycemia, fat maldistribution, and risk of increased bleeding in patients with hemophilia. Use with caution in patients with sulfa hypersensitivity. Pregnancy category: C*

Fusion (Entry) Inhibitor (FI)		
Enfuvirtide (T20)	A/Adol >16 y: subcut: 90 mg bid C ≤16 y: subcut: Dosage is weight based and ranges from 27 to 90 mg bid.	Used in treatment-experienced patients in combination with other ARVs. Administer via subcut, and rotate site. Store vial at room temperature; once reconstituted, refrigerate and use within 24 h. Adverse effects include local injection site reaction (pain, erythema, induration, nodules, cysts, pruritus, ecchymosis), increased rate of bacterial pneumonia, hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, elevated transaminases), fatigue. To minimize local reactions, apply ice or heat after injection or gently massage the site to better disperse the drug. Pregnancy category: B*

CCR5 Antagonists		
Maraviroc (MRV)	A: PO: 150-600 mg bid	Used in combination with other ARVs. MRV is administered *only* to patients with CCR5-tropic HIV infection. Dosing depends on other drugs taken concomitantly. CYP3A substrate; drugs that inhibit or induce the enzymes will alter the pharmacokinetics of MRV. May take without regard to food. Concentration may increase in kidney dysfunction (CrCl <30), therefore caution is advised when used in renal-compromised patients; it is contraindicated in patients with CrCl <30 who are taking strong inhibitors and/or inducers of CYP3A. May need to adjust dose with concomitant CYP3A inhibitors or inducers (because of interactions) or with postural hypotension. Adverse effects include fever, upper respiratory tract infection, flatulence, orthostatic hypotension, hepatotoxicity, rash, cough, abdominal pain, and dizziness. Pregnancy category: B*

Integrase Strand Transfer Inhibitors (INSTIs)		
Dolutegravir (DTG) Also available as a component of fixed-dose combinations	A/C ≥12 y and ≥40 kg: PO: 50 mg once daily	Used in treatment-naïve or -experienced patients in combination with other ARVs. Metabolized by CYP3A4 enzyme. Can be taken without regard to meals. Take polyvalent cation products (e.g., Mg^{++}, Fe, and Ca^{++} salts); ASA on an empty stomach can reduce bioavailability of DTG. Adverse effects include headache, insomnia, rash, and liver injury. Pregnancy category: B*
Elvitegravir (EVG) Also available as a component of fixed-dose combinations	A: PO: 85-150 mg once daily depending on ritonavir and other ARVs taken concurrently	Used in treatment-naïve or -experienced patients in combination with other ARVs; unboosted EVG is not recommended. EVG is metabolized by CYP3A. Take with food. Adverse effects are rare, but nausea and vomiting can occur; suicide ideation, albeit rare, can also occur, especially in those with a history of psychiatric illness. Pregnancy category: B*
Raltegravir (RAV)	A: PO: 400 mg bid C/Adol: PO: Dosage is weight based.	Used in treatment-naïve or -experienced patients in combination with other ARVs. Does not affect the CYP450 isoenzymes, nor is it a substrate of CYP450 enzymes. Can be taken without regard to meals. Coated tablets are not bioequivalent with chewable tablets or powder for oral suspension; swallow coated tablets whole. Adverse effects include GI symptoms, headache, pyrexia, increased total cholesterol, fatigue, rhabdomyolysis, insomnia, and rash that includes Stevens-Johnson syndrome and epidermal necrolysis. Pregnancy category: C*

A, Adult; *Adol,* adolescent; *ARV,* antiretroviral; *ASA,* acetylsalicylic acid (aspirin); *bid,* twice a day; *BSA,* body surface area; *C,* child; Ca^{++}, calcium; *CrCl,* creatinine clearance; *CYP450,* cytochrome P450; *d,* day; *DKA,* diabetic ketoacidosis; *ER,* extended-release; *Fe,* iron; *GI,* gastrointestinal; *h,* hour; *HIV*, human immunodeficiency virus; *HLA,* human leukocyte antigen; *IR,* immediate release; Mg^{++}, magnesium; *min,* minute; *mo,* months; *PI,* protease inhibitor; *PK,* pharmacokinetic; *PO,* by mouth; *q,* every; *subcut,* subcutaneous; *tid,* three times a day; *y,* years; >, greater than; <, less than; ≥, greater than or equal to; ≤, less than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Drug interactions are minimal with NRTIs because these drugs are not metabolized by the cytochrome P450 (CYP450) isoenzymes. However, drug interactions can still occur: for example, ribavirin inhibiting phosphorylation of zidovudine can cause hematologic toxicities; and coadministration of ribavirin with didanosine is contraindicated because fatal hepatic failure can occur; didanosine coadministered with stavudine can worsen lactic acidosis and pancreatitis; allopurinol is contraindicated in individuals taking didanosine; and PIs can increase serum concentration of tenofovir disoproxil fumarate.

Prototype Drug Chart 29.1 gives pharmacologic data for zidovudine, and Prototype Drug Chart 29.2 shows the data for tenofovir.

Nonnucleoside Reverse Transcriptase Inhibitors

Five NNRTIs are used in the United States: delavirdine, efavirenz, etravirine, nevirapine, and rilpivirine. NNRTIs ("non-nukes") do not require intracellular metabolism; they directly bind to the reverse transcriptase (RT) enzymes and block DNA polymerization. The primary advantage of using NNRTIs is to reserve a PI-based therapy for future use. In general, an NNRTI regimen has a lower pill burden compared with most PI-based regimens. Major disadvantages are the prevalence of NNRTI-resistant viral strains and the low genetic barrier of NNRTIs for development of resistance. (Resistance testing is recommended for treatment-naïve patients before starting therapy.)

PROTOTYPE DRUG CHART 29.1 Zidovudine (ZDV)

Drug Class	Dosage
Nucleoside/nucleotide reverse transcriptase inhibitor (NRTI) Pregnancy category: C* Also available as a component of fixed-dose combinations	Prevention of maternal-fetal HIV transmission for HIV RNA >400 copies/mL: Intrapartum: IV: 2 mg/kg LD over 30-60 min followed by continuous infusion of 1 mg/kg/h until cord is clamped. For scheduled cesarean delivery, begin IV 3 h before surgery Neonates ≥35 wk: IV: 3 mg/kg q12h; increase to 9 mg/kg q12h after 4 wk of age Neonates ≥35 wk: PO: 4 mg/kg q12h; increase to 12 mg/kg q12h after 4 wk of age Treatment in combination with other ARV: A: PO: 200 mg q8h or 300 mg q12h A: IV: 1 mg/kg over 1 h q4h (total daily dose: 6 mg/kg/d). Initiate oral therapy as soon as possible. C ≥30 kg: PO: 300 mg bid; 9-29 kg: 9 mg/kg/dose bid; 4-8 kg: 12 mg/kg/dose bid
Contraindications	Drug-Lab-Food Interactions
Life-threatening allergies to ZDV or components of the preparation *Black Box Warning:* Hepatotoxicity, lactic acidosis, myopathy, bone marrow suppression *Caution:* Severe anemia (interruption of therapy or reduction in daily dose should be considered); renal impairment/failure; viral hepatitis	*Drug:* Ganciclovir, probenecid, valproic acid may increase concentration/adverse effects. Rifampin, interferon, and ritonavir may decrease concentration/effects. May potentiate hematologic toxicity with other drugs (e.g., interferon alfa, ganciclovir, primaquine, etc.), causing myelosuppression; interferon beta can increase ZDV levels leading to drug toxicity. Can be taken without regard to food. *Lab:* May increase ALT, AST
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 66%-70% Distribution: PB: <38%, crosses blood-brain barrier, crosses placenta, excreted in breast milk Metabolism: t½: 0.5-3 h; extensive first-pass effect in liver to GZDV (metabolite) Excretion: 63%-95% in urine as GZDV (metabolite)	Route: PO/IV Onset: UK Peak: 30-90 min; can be taken without regard to meals Duration: UK
Therapeutic Effects/Uses	
Management of patients with HIV infection, prevention of maternal-fetal HIV transmission	
Mode of Action: Inhibits viral enzyme reverse transcriptase and thymidine kinase, enzymes necessary for viral HIV replication.	
Side Effects	Adverse Reactions
Headache, malaise, nausea, anorexia, vomiting, asthenia (abnormal weakness and loss of energy), constipation, abdominal cramps/pain, arthralgia, rigors, dyspepsia, fatigue, insomnia, musculoskeletal pain, myalgia, neuropathy, elevated liver enzymes, anemia, fever, cough, hepatomegaly, rash, diarrhea, lipodystrophy, and stomatitis.	Severe anemia, lactic acidosis, pancreatitis, neutropenia, pancytopenia, seizures, congestive heart failure, myelosuppression, rhabdomyolysis, anaphylaxis, hyperlipidemia, insulin resistance, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

A, Adult; *ALT,* alanine aminotransferase; *ARV,* antiretroviral; AST, aspartate aminotransferase; *bid,* twice a day; *C,* child; *d,* day;

GZDV, 5'-glucuronyl zidovudine; *h,* hour; *HIV,* human immunodeficiency virus; *IV,* intravenously; *LD,* loading dose; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q,* every; *t½,* half-life; *UK,* unknown; *wk,* weeks; >, greater than; ≥, greater than or equal to; <, less than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Efavirenz (EFV) and rilpivirine are available as components of fixed-dose regimens. EFV should be taken on an empty stomach; delavirdine and nevirapine (NVP) can be taken without regard to food; all other NNRTIs should to be taken with food to enhance absorption. Except for NVP, all NNRTIs are metabolized by the liver and excreted in feces, whereas NVP is mostly excreted in urine.

EFV is the first-choice drug within the NNRTI class, and it is the only NNRTI that penetrates the cerebrospinal fluid (CSF). It should be used with caution in pregnancy because neural tube defects have been reported after early human gestational exposure. Because of CSF involvement, neuropsychiatric symptoms such as dizziness, sedation, nightmares, euphoria, or loss of concentration can occur. Common complications among all the NNRTIs are rashes, which includes Stevens-Johnson syndrome. Elevated liver transaminases and hepatotoxicity, including hepatic failure, can also occur.

Drug-drug interactions are many because of the extensive metabolizing effects by cytochrome P3A4 (CYP3A4). Acid reducers (e.g., antacids, H2-receptor antagonists, proton pump inhibitors [PPIs]) can decrease the bioavailability of rilpivirine, therefore coadministration of rilpivirine with PPIs is contraindicated; all other acid reducers can be taken at least 2 hours before or 4 hours after rilpivirine. Coadministration with drugs that induce or inhibit any of the CYP isoenzymes can alter the therapeutic effects of other drugs (e.g., anticonvulsants, antidepressants, anticoagulants, antiplatelets, antifungals, antimycobacterials, statins, and calcium channel blockers [CCBs]). Other drugs used concomitantly can alter NNRTI serum levels (e.g., corticosteroids, hepatitis antivirals, and St. John's wort). NNRTIs can decrease the efficacy of hormonal contraceptives, therefore individuals should use alternative means of contraception or additional contraceptive methods.

Prototype Drug Chart 29.3 presents the pharmacologic data for efavirenz.

Protease Inhibitors

PI-based regimens (one or two PIs plus two NRTIs) have revolutionized the treatment of HIV infection, especially with PK enhancement (boosters such as cobicstat and ritonavir); this has led to sustained viral suppression, improved immunologic function, and prolonged patient survival. PIs that have been approved by the FDA include atazanavir (ATV), atazanavir/cobicistat (ATV/c), darunavir (DRV), darunavir/cobicistat (DRV/c), fosamprenavir (FPV), indinavir (IDV), lopinavir/ritonavir (LPV/r), nelfinavir (NFV), saquinavir (SQV), ritonavir (RTV), and tipranavir (TPV). RTV as the sole PI is not recommended; instead, it should be used as a boosting agent with other PIs. TPV is only approved for ARV-experienced patients. Unlike NRTIs and NNRTIs, PIs act at the end of the HIV life cycle to target viral assembly by inhibiting the activity of protease, an enzyme used to cleave nascent proteins for final assembly of new virions, resulting in formation and release of immature, defective, and noninfectious virus particles. Each PI has unique characteristics based on clinical efficacy, side-effect profile, and pharmacokinetic properties. PIs are highly protein bound, metabolized by the liver, and primarily eliminated in feces.

PROTOTYPE DRUG CHART 29.2 Tenofovir Disoproxil Fumarate (TDF)

Drug Class	Dosage
Nucleoside/nucleotide reverse transcriptase inhibitor (NRTI) Pregnancy category: B* Also available as a component of fixed-dose combinations	HIV treatment: A/C ≥35 kg: PO: 300 mg once daily C ≥2 y and 28-34 kg: PO: 250 mg once daily C ≥2 y and 22-27 kg: PO: 100 mg once daily C ≥2 y and 17-21 kg: PO: 150 mg once daily Hepatitis B treatment: A/C ≥12 y and ≥35 kg: PO: 300 mg once daily
Contraindications	Drug-Lab-Food Interactions
Black Box Warning: Hepatitis B exacerbation, hepatotoxicity, lactic acidosis *Caution:* Renal and hepatic dysfunction	*Drug:* Concomitant use with streptozocin is contraindicated because it can increase risk of nephrotoxicity and ototoxicity. Tenofovir can decrease levels of some drugs (e.g., dabigatran, edoxaban) and increase levels of other drugs (e.g., adefovir, bacitracin, diltiazem, metformin); acyclovir, amikacin, cisplatin, ganciclovir, and gentamicin may increase levels and adverse effects of TDF. *Lab:* May increase triglycerides, AST, ALT, ALP
Pharmacokinetics	Pharmacodynamics
Absorption: PO: 25%-40% Distribution: PB: 7.2% Metabolism: t½: 17 h; is not metabolized by CYP450 isoenzymes; converted intracellularly by hydrolysis and phosphorylated to active tenofovir diphosphate Excretion: 70%-80% primarily in urine as unchanged drug	Route: PO Onset: UK Peak: 1 h (fasting), 2 h (food) Duration: UK
Therapeutic Effects/Uses	
Management of patients with HIV infection, treatment of chronic hepatitis B	
Mode of Action: Inhibits viral enzyme reverse transcriptase, an enzyme necessary for viral HIV replication, by competing with AMP as substrate	
Side Effects	Adverse Reactions
Diarrhea, nausea, vomiting, flatulence, insomnia, dizziness, depression, fever, hyperlipidemia, elevated transaminases, chest pain	Lactic acidosis, hepatomegaly, bone fractures, renal insufficiency, Fanconi syndrome

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AMP,* adenosine monosphosphate; *AST,* aspartate aminotransferase; *C,* child; *CYP,* cytochrome P; *h,* hour; *HIV,* human immunodeficiency virus; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* years; ≥, greater than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

PROTOTYPE DRUG CHART 29.3 Efavirenz (EFV)

Drug Class	Dosage
Nonnucleoside reverse transcriptase inhibitor (NNRTI) Pregnancy category: D* Also available as a component of fixed-dose combination.	Note: Take dose at bedtime to minimize CNS adverse effects; take on an empty stomach to reduce adverse reactions. A/C ≥40 kg: PO: 600 mg at bedtime C 32.5-40 kg: PO: 400 mg at bedtime C 25-32.5 kg: PO: 350 mg at bedtime C 20-25 kg: PO: 300 mg at bedtime C 15-20 kg: PO: 250 mg at bedtime C 10-15 kg: PO: 200 mg at bedtime Alternate dosing for children: 367 mg/m²/d Do not crush tablets. Capsules may be opened and sprinkled into a small amount of age-appropriate soft food or formula; administer within 30 min of mixing; no additional food for 2 h after dosing.
Contraindications	Drug-Lab-Food Interactions
Life-threatening allergies to EFV or components of the preparation; concurrent use with rifapentine, St. John's wort, dasabuvir, ombitasvir, paritaprevir, simeprevir, triazolam *Caution:* Patients with history of mental illness or drug abuse; liver impairment; seizure disorder	*Drug:* EFV can increase or decrease levels of warfarin, carbamazepine, nevirapine, phenobarbital, bupropion, sertraline, phenytoin, rifampin, CCBs, hormonal contraceptives, HMG-CoA reductase inhibitors; EFV can increase the levels of triazolam. Drugs that can increase or decrease EFV include dexamethasone, boceprevir, St. John's wort. *Food:* Avoid alcohol because of liver/CNS adverse effects; high-fat meals increase absorption. *Lab:* May cause a false-positive result for cannabinoid and benzodiazepine screening assays.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Increased following high-fat meal Distribution: PB: >99%, widely distributed (found in CSF) Metabolism: t½: 40-76 h; metabolized in liver; CYP3A4 inducer/inhibitor Excretion: 16%-61% in feces, primarily as unchanged drug; 14%-34% in urine, primarily as metabolite	Route: PO Onset: UK Peak: 3-5 h Duration: UK
Therapeutic Effects/Uses	
Treatment of HIV-1 infections	
Mode of Action: Binds directly to reverse transcriptase, blocking RNA- and DNA-dependent DNA polymerase activities, including HIV-1 replication	
Side Effects	Adverse Reactions
Rash, nausea, diarrhea, CNS effects (dizziness, insomnia, abnormal dreams/thinking, impaired concentration, amnesia, agitation, hallucinations, euphoria, anxiety)	Aggressive reaction, allergic reaction, convulsion, liver failure, neuropathy, suicide, abnormal vision, hyperlipidemia

A, Adult; *C,* child; *CCB,* calcium channel blocker; *CNS,* central nervous system; *CSF,* cerebrospinal fluid; *CYP3A4,* cytochrome P450 3A4; *d,* day; *h,* hour; *HMG-CoA,* hydroxymethylglutaryl coenzyme A; *min,* minutes; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; ≥, greater than or equal to; >, greater than.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

The Panel's recommended PI regimen is DRV/r plus two NRTIs (tenofovir disoproxil fumarate/emtricitabine [TDF/FTC]). RTV boosting is a relatively new concept and one of the mainstays of PI therapy. The potent inhibitory effect of RTV on the cytochrome P450 3A4 isoenzyme (CYP3A4) allows the addition of 100 mg to 400 mg of RTV to other PIs as a PK booster. This helps reduce dietary restrictions, increase drug exposure, inhibit metabolism, and maximize blood levels of the coadministered PI, thus reducing dosing frequency and pill burden and overcoming viral resistance. Because "boosted" regimens may be less complex, patients may be able to follow and tolerate them better.

Selection of a PI-based regimen should consider dosing frequency, food and fluid requirements, pill burden, drug interaction potential, and side-effect profile. PIs result in numerous metabolic abnormalities that include dyslipidemia and insulin resistance; PK enhancers can alter these adverse effects. Some PIs come with a risk factor for causing myocardial infarction (MI). When

initiating therapy with PIs, GI side effects (nausea, vomiting, and diarrhea) can be bothersome and may negatively affect adherence. Skin reactions such as rash, which includes Stevens-Johnson syndrome, can occur with PIs. Other adverse effects include hemolytic anemia, electrocardiogram (ECG) changes, and MI.

PROTOTYPE DRUG CHART 29.4 Atazanavir (ATV)

Drug Class	Dosage
Protease inhibitor Pregnancy category: B*	Also available as a component of fixed-dose combinations. Note: HIV guidelines recommend administering concurrently with a PK enhancer (cobicistat or RTV). Capsules and powder packets are not interchangeable. Capsules: A/C 6 y and ≥40 kg: PO: 300 mg plus RTV 100 mg once daily C 20-40 kg: PO: 200 mg with RTV 100 mg once daily C 15-20 kg: PO: 150 mg with RTV 100 mg once daily Powder: C 15-25 kg: PO: 250 mg (5 pk) plus 80 mg once daily C 5-15 kg: PO: 200 mg (4 pk) plus RTV 80 mg once daily Capsules must be swallowed whole. Powder may be mixed with age-appropriate food; use oral dosing syringe in persons unable to drink from a cup.
Contraindications	Drug-Lab-Food Interactions
Hypersensitivity to ATV or any component, concurrent use with alfuzosin, ergot derivatives, lovastatin, midazolam (oral), rifampin, simvastatin, St. John's wort *Caution:* Patients with preexisting conduction abnormalities (may prolong PR interval), hepatitis B or C, hepatic impairment, hemophilia A or B	*Drug:* Drug-drug interactions are numerous. Some known interactions include drugs that can decrease or decrease ATV; acid reducers, including H2-receptor antagonists and PPIs, carbamazepine, phenytoin, phenobarbital, itraconazole, rifampin, boceprevir, and St. John's wort. ATV can increase or decrease levels of dabigatran, warfarin, buspirone, rifabutin, amiodarone, BBs, CCBs, digoxin, corticosteroids, hormonal contraceptives, lovastatin, and simvastatin. *Lab:* May increase liver function tests, cholesterol, triglycerides, glucose *Food:* Bioavailability increases when taken with food.
Pharmacokinetics	Pharmacodynamics
Absorption: PO: Rapidly, increased with food Distribution: PB: 86% Metabolism: t½: 7-8 h (9-18 h when boosted with RTV). Metabolized in the liver; inhibitor of CYP450 isoenzymes Excretion: Primarily in feces (79%) but also in urine (13%)	Route: PO Onset: UK Peak: 2-3 h Duration: UK
Therapeutic Effects/Uses	
Treatment of HIV-1 infection	
Mode of Action: Inhibits HIV protease, rendering enzyme incapable of processing polyprotease precursors, thus rendering immature HIV particles noninfectious	
Side Effects	Adverse Reactions
Rash, nausea, vomiting, diarrhea, cough, fever	Atrioventricular block, hyperglycemia, diabetes mellitus, jaundice, hyperlipidemia, lipodystrophy, cholelithiasis, nephrolithiasis, elevated liver transaminases

A, Adult; *BB,* beta blocker; *C,* child; *CCB,* calcium channel blocker; *CYP450,* cytochrome P450; *h,* hour; *H2,* histamine 2; *HIV,* human immunodeficiency virus; *PB,* protein binding; *PK,* pharmacokinetic; *pk,* pack; *PO,* by mouth; *PPI,* proton pump inhibitor; *RTV,* ritonavir; *t½,* half-life; *UK,* unknown; *y,* year; ≥, greater than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

In patients with hepatic impairment, dosing adjustment may be necessary. All PIs inhibit the CYP450 system, which can lead to many drug-drug interactions. Drugs such as H2-receptor antagonists (e.g., cimetidine, famotidine, or ranitidine) should be given 10 or more hours before PIs. PPIs are not recommended in PI-experienced patients, and concomitant use with anticoagulants/antiplatelets should also be avoided. Ritonavir-boosted PIs can decrease warfarin levels. Anticonvulsants (e.g., carbamazepine, phenobarbital, phenytoin) are contraindicated with certain PIs, whereas some antidepressants (e.g., bupropion, selective serotonin reuptake inhibitors [SSRIs]) may need dose adjustments. Trazodone is contraindicated with saquinavir/ritonavir, and antimycobacterials and cardiac drugs can worsen cardiac toxicities. Many PIs without the ritonavir boost can increase drug levels of hormonal contraceptives, whereas boosted PIs can decrease the levels. It is important that nurses instruct patients to use an alternative contraceptive method when taking boosted PIs. Rifampin and rifapentine are contraindicated with PIs, as are many other classes of drugs (e.g., antiarrhythmics, antivirals for viral hepatitis, St. John's wort, hydroxymethylglutaryl coenzyme A [HMG-CoA] reductase inhibitors, and some hypnotics) due to a decrease in PI drug levels and toxic drug levels in the other classes of drugs. Benefits of corticosteroid use should outweigh the risks with concomitant administration with corticosteroids.

Prototype Drug Chart 29.4 presents the pharmacologic data for atazanavir.

Fusion (Entry) Inhibitors

Enfuvirtide (T20) is the only agent approved in this class. T20 acts by a mechanism that inhibits the fusion of the virus to healthy cell membranes, thus preventing HIV entry into healthy cells. T20 is indicated only in combination with other ARVs for patients with limited treatment options who require salvage therapy. It is not indicated for HIV-2. Before initiating a fusion (entry) inhibitor, immunoassay and subsequent testing for HIV-1/HIV-2 is recommended.

Enfuvirtide does not require dosage adjustment in patients with renal failure or hepatic

impairment. It is not metabolized by CYP enzymes and is not associated with any CYP-mediated drug-drug interactions. Injection-site reactions (e.g., subcutaneous nodules, redness) occur in up to 98% of patients. Other side effects reported include rash and diarrhea. Serious allergic reactions—including anaphylaxis, fever, and hypotension—have occurred in less than 1% of patients.

Chemokine (CCR5) Coreceptor Antagonists

Maraviroc (MVC), the only agent in this class, blocks the CCR5 coreceptor needed for CCR5-tropic HIV entry into immune cells, thus preventing viral replication. MVC is indicated in combination with other ARVs for treatment-experienced adult patients with evidence of viral replication and HIV-1 strains resistant to multiple antiretroviral therapy. The most common side effects are cough, pyrexia, upper respiratory tract infection, rash, abdominal pain, and dizziness. Because MVC is metabolized by the liver, drug-drug interactions exist.

Maraviroc is metabolized by the CYP3A substrate. Coadministration with St. John's wort or rifampin or other CYP3A inducers is not recommended due to reduced effectiveness of maraviroc. Rifapentine and some NRTI fixed-drug combinations are contraindicated with CCR5 coreceptor antagonists. Possible drug-induced hepatotoxicity with allergy-type features has been reported. Use caution in patients with liver or heart disease or a history of orthostatic hypotension and in those on medication that lowers blood pressure. Other adverse reactions include rash, musculoskeletal symptoms, upper respiratory infections, and pyrexia.

Integrase Strand Transfer Inhibitors

Integrase strand transfer inhibitors (INSTIs) such as dolutegravir (DTG), elvitegravir (EVG), and raltegravir (RTG) exert their action by interfering with integrase, the enzyme that HIV needs to multiply and divide, thus limiting the ability of the virus to replicate and infect new cells. INSTIs are used for the treatment of HIV-1 infections with at least two or three other ARVs in both treatment-naïve (recommended initial agent) and treatment-experienced patients. DTG and EVG are also available in fixed-dose combinations. INSTIs distribute into the CSF. DTG and RTG are metabolized by the UDP-glucuronosyltransferases (UGTs) 1A1-mediated glucuronidation pathway; EVG is metabolized by the CYP450 enzymes. Strong inducers (e.g., efavirenz, rifampin, rifabutin) or inhibitors (e.g., tenofovir, atazanavir) of UGT1A1 can significantly alter the concentration of RTG. DTG distributes into the CSF. Common side effects include rash, nausea, headache, insomnia, diarrhea, and pyrexia; liver injury can also occur. Caution is advised in patients at increased risk for muscle problems (e.g., myopathy, rhabdomyolysis), which includes patients who take medications that can cause these adverse effects, such as statins.

Immune Reconstitution Inflammatory Syndrome

Immune reconstitution inflammatory syndrome (IRIS) is related to a disease- or pathogen-specific inflammatory response in patients with ART being initiated or changed. IRIS comprises two distinct entities: *paradoxical IRIS* is an exacerbation of treated (successful or partial) opportunistic infection (OI), whereas *unmasking IRIS* is a response to undiagnosed or subclinical OI. Diagnosis is a challenge because there are no laboratory markers; it is a condition of exclusion. For example, new OI or concurrent illness must be excluded before IRIS can be diagnosed. CD4+ cells usually increase in patients with IRIS because of the acute inflammatory response. IRIS may occur in response to many diseases and pathogens, such as Kaposi sarcoma or infection with mycobacteria, viruses, bacteria, or fungi.

Risk factors for developing IRIS include a low CD4+ cell count when ART is initiated and a high baseline HIV RNA. Starting ART soon after initiation of treatment for recognized OI also increases risk for IRIS. Severity of IRIS ranges from mild to life threatening. Treatment varies according to the specific pathogen and clinical situation but typically includes continuing ART if possible, treating the OI as indicated, and adding antiinflammatory therapy (including corticosteroids) as needed.

The Nurse's Role in Antiretroviral Therapy

Thorough assessment of the patient's physiologic and psychosocial health needs and literacy levels is required initially and for the duration of care. Follow-up assessment after ART initiation should include drug side effects, adherence to the therapy regimen, and issues that affect medication adherence. Patients may confuse drug side effects with new onset of symptoms. Careful follow-up assessment can detect the need for additional medical care or drug management.

Adherence challenges are common with any drug therapy, but ART presents a greater challenge because patients are asked to achieve an adherence of 95% or greater. Nonadherence can result in HIV viral replication and can potentiate drug resistance. Multiple strategies for adherence are available and should be discussed with patients. Drug organizers, alarms on cell phones or mobile devices, medication "maps" with pictures, and drug diaries are available tools to improve adherence. Friends, family members, and personal support systems can also assist patients with adherence. Nurses can facilitate adherence by allowing sufficient time to educate patients about drugs, developing a trusting relationship, and building a partnership with the patient.

Nursing assessment for adherence should include asking the reasons for missing drug dosages. Reasons commonly include stigma, forgetting, feeling ill, side effects, not having the medicine when doses are due, pill fatigue (nonadherence due to the stress and monotony of constant pill swallowing), drug costs, loss of health insurance, and lack of transportation to the pharmacy. If barriers to adherence are identified, individualized plans should be addressed with the patient and the prescriber.

Patient education should include the purpose of each drug, the dosage schedule, food and fluid restrictions, recommended food choices, and storage of drugs. Additional suggestions include taking drugs during a daily routine, such as brushing teeth, or using a drug calendar to track drugs taken. The nurse should assess whether scheduled appointments to assist the patient with filling a drug organizer would be helpful until the patient is comfortable with completing this task. Discussion of anticipated drug side effects and management of drug side effects is necessary.

Nursing Process: Patient-Centered Collaborative Care

Antiretroviral Therapy

Assessment

- Obtain an in-depth patient history and assess physiologic and psychosocial needs.
- Assess for signs and symptoms related to clinical progression of HIV disease, and refer to medical care and psychological support as indicated.
- Perform a drug reconciliation that includes all prescription, over-the-counter (OTC), and herbal products. Assess for use of illegal and other nonprescription drugs. Report potential drug-drug or drug-herb interactions.
- Obtain a nutritional history to assess for nutritional deficits and for potential drug-food interactions. Assess for the potential need for therapeutic lifestyle change.
- Assess readiness to learn and discern the preferred method of instruction (written, verbal, pictorial).
- With each patient visit, conduct a pill count to determine treatment adherence.

Nursing Diagnoses

- Health Maintenance, Ineffective related to knowledge deficit about HIV/AIDS and the drug regimen.
- Health Management, Ineffective related to complex drug management
- Fear related to perceived stigma of HIV diagnosis
- Coping, Ineffective (patient) and/or Coping, Compromised Family (significant other) related to HIV diagnosis
- Infection, Risk for

Planning

- The patient will adhere to the drug regimen and will report any difficulties related to adherence.
- The patient will participate in medical treatment and in the spiritual and psychological support that best fits the patient's needs and belief system; the patient will verbalize fears.
- The patient will verbalize ways of maintaining self-health management such as a daily calendar and reminders.
- The patient will verbalize ways to cope with side effects of the drug regimen.
- The patient will verbalize signs and symptoms of potential infection and can reiterate when to notify the health care provider.
- The patient's viral load will become and remain undetectable.
- The patient will not experience secondary or opportunistic infections.

Nursing Interventions

- Provide information on the necessity of adhering to the drug regimen and regular health care. Inconsistent dosing can promote drug resistance. Effectiveness and side effects of ART need to be monitored and/or treated.
- Provide information on various methods of remembering to take drugs. Inconsistent dosing can increase the risk of drug resistance.
- Refer the patient for health care maintenance and appropriate health screening examinations, including Pap tests, ophthalmologic and dental examinations, and age- or risk-related colonoscopies. Side effects and adverse reactions are common in patients receiving ART.
- Refer the patient for spiritual support and for mental health or substance use counseling as needed.
- Provide opportunities for the patient and/or support persons to verbalize feelings.
- Encourage strategies to cope with the side effects of medications.
- Monitor laboratory reports for indications of decreasing CD4+ counts and/or rising viral load; inform the HIV health care provider.
- Refer the patient for nutritional counseling as needed.

Patient Teaching

General

- Educate patients about adherence to the therapeutic regimen by providing information on drugs and a timetable of dosing in patients' preferred method of learning.
- Explain how HIV can damage the immune system and promote infection.
- Explain common emotional responses.
- To decrease risk for exposure to infection, emphasize protective precautions as necessary, such as frequent hand washing, avoiding crowds, and receiving influenza vaccines.
- For patients of childbearing age, explain how HIV transmission to the unborn baby can occur.
- Teach about safe sex practices and other ways to prevent transmission of HIV.
- Inform patients that certain drugs—including OTC medications—and foods and herbal products may interact with antiretrovirals.

Self-Administration

- Assist patients in developing a system for taking the correct dose of the correct drugs at the correct time.
- Counsel patients about the importance of having an adequate supply of drugs to avoid interruption in the dosing schedule. Omission of drugs may result in deterioration of the patient's condition.
- For pediatric patients unable to swallow drugs, teach swallowing techniques.

Cultural Considerations

- Some members of certain cultural groups may distrust health care providers and may refuse treatment regimens that include research.
- Be aware that some cultures pressure women to reproduce regardless of health status.
- Remember that HIV remains a highly stigmatized disease in many cultures.
- Know that some religions prohibit the use of contraception.

Evaluation

- The patient will have at least a 95% drug adherence.

- Viral load will decrease or become undetectable.
- The patient and/or the significant other will openly discuss any fears or concerns related to HIV and ART.
- The patient will verbalize safe sex practices and methods to reduce HIV transmission.

In addition to patient assessment, education, and advocacy, nurses should identify problems that require additional investigation and research. Because of individual needs, research on strategies to promote adherence is needed. Whenever drug regimens change, nurses should contribute to the ongoing evaluation of the drug regimen, any side effects, and adverse event reporting. See Box 29.1 for HIV resources.

Opportunistic Infections

As HIV advances, patients are more vulnerable to malignancies and **opportunistic infections (OIs)**. Since the introduction of ART, there has been a dramatic reduction in the incidence of OIs among HIV-positive patients receiving ARVs. Although hospitalizations and deaths have decreased, OIs continue to be a leading cause of morbidity and mortality among patients with HIV. Prevention and treatment of OIs remain essential. The most common HIV-related OIs include pulmonary tuberculosis (TB), pneumococcal pneumonia, *Cryptosporidium,* fungal infections, Kaposi sarcoma, toxoplasmosis, histoplasmosis, and cytomegalovirus (CMV), among others.

BOX 29.1 HIV Resources

AIDS Info

The website www.aidsinfo.nih.gov provides information on HIV/AIDS clinical research, treatment, and prevention.

National HIV/AIDS Clinicians' Consultation Center

The website www.nccc.ucsf.edu provides up-to-date HIV/AIDS information to pharmacists, physicians, and nurses and is staffed by pharmacists, physicians, and nurse practitioners.

Tuberculosis infection predominantly affects the lungs but can affect other organs, such as the bowel, brain, and lining of the heart, lungs, central nervous system (CNS), or integument. The CD4+ cell count is not a reliable predictor of increased risk for TB disease. Treatment for TB is discussed in Chapter 27.

Kaposi sarcoma causes dark blue lesions that can occur in a variety of locations, including the skin, mucous membranes, GI tract, lungs, or lymph nodes; they usually appear early in the course of HIV infection. Treatment depends on the symptoms and location, but chemotherapy is the preferred treatment for severe widespread disease.

Pneumocystis jiroveci pneumonia (PJP) is caused by a fungus that shares biologic characteristics with protozoa that infect the lungs. Symptoms include fever, dry cough, chest pain, and dyspnea. Even though PJP is classified as a fungal infection, it does not respond to antifungals. Trimethoprim-sulfamethoxazole (TMP-SMX), dapsone plus trimethoprim, pentamidine, or atovaquone are recommended treatment for persons with HIV and PJP.

Toxoplasmosis encephalitis caused by a protozoan can be found in uncooked meat and cat feces. Infection in the brain can cause headache, confusion, motor weakness, and fever. If left untreated, the disease progression results in seizures, stupor, and coma. Treatment includes pyrimethamine, sulfadiazine, and clindamycin. Leucovorin is added to decrease hematologic toxicities associated with pyrimethamine therapy.

Cryptosporidiosis is an infection caused by the protozoan parasite *Cryptosporidium,* usually in the bowel mucosa; in persons with low CD4+ counts, *Cryptosporidium* may involve the biliary tract or respiratory tract. GI symptoms include profuse, nonbloody, watery diarrhea, often with nausea, vomiting, and lower abdominal cramping. In addition to symptomatic therapy, treatment includes nitazoxanide or paromomycin combined with azithromycin. Treatment may be only partially effective in the setting of a low CD4+ count.

Diseases common with a CD4+ count below 50 cells/mL include:

Mycobacterium avium complex (MAC) is a blood infection caused by bacteria related to *M. tuberculosis,* the pathogen in TB. MAC generally affects multiple organs with symptoms that include fever, night sweats, weight loss, fatigue, diarrhea, and abdominal pain. Localized syndromes include pneumonitis, osteomyelitis, skin or soft-tissue abscesses, or CNS infections. Treatment includes clarithromycin, azithromycin, ethambutol, amikacin, moxifloxacin, rifabutin, or rifampin.

Cytomegalovirus (CMV) infection is caused by a virus that infects the entire body, but it most commonly appears as retinitis, causing blurred vision that can lead to blindness. CMV can also affect other organs and can cause fever, diarrhea, nausea, pneumonia-like symptoms, and dementia. Treatment includes ganciclovir, valganciclovir, foscarnet, or cidofovir.

Antiretroviral Therapy in Pregnancy

Optimal drug therapy should be used for women of reproductive age and for those who are pregnant. When initiating ART for women of reproductive age, the criteria for starting therapy and the goals of treatment are identical to those for other adults and adolescents. Because of considerations related to the prevention of HIV transmission to the fetus during pregnancy, the timing of initiation of treatment and the selection of regimens for pregnant patients may differ from those nonpregnant adults or adolescents. Women of childbearing potential should undergo a pregnancy test prior to initiation of efavirenz (EFV). If the patient expresses interest in becoming pregnant, and EFV is considered as part of the ARV regimen, a risk-benefit discussion must take place regarding the risk of neural tube defects related to EFV use in the first 5 to 6 weeks of pregnancy. EFV can be continued in pregnant patients receiving an efavirenz-based regimen who present for antenatal care in the first trimester, provided the regimen produces virologic suppression.

A patient infected with HIV can transmit the virus during pregnancy, labor, and delivery and through breastfeeding. To prevent mother-to-child transmission of HIV, ART is recommended in all pregnant patients who test positive for HIV infection, regardless of virologic, immunologic, or clinical parameters. Combination drug therapy is considered the standard of care for both treatment of maternal HIV infection and prophylaxis to reduce the risk for perinatal HIV transmission. The goal of ART is to achieve maximal and sustained viral suppression during pregnancy to prevent perinatal transmission of HIV. If viral load is greater than or equal to 400 copies/mL, IV zidovudine is recommended regardless of current ART. Prototype Drug Chart 29.1 presents the pharmacologic data for zidovudine.

Occupational HIV Exposure and Postexposure Prophylaxis

Treatment regimens after percutaneous exposure to HIV are called **postexposure prophylaxis (PEP)** regimens. Many PEP regimens are available, with varying degrees of tolerability and probability of patients completing 4 weeks of treatment. PEP management of potential HIV exposure should be initiated within 72 hours of the event and should be continued for 4 weeks. Health care workers who take PEP have reported adverse reactions, with the most common being nausea, malaise, and fatigue. More information from the Panel on the treatment of HIV/AIDS can be found at https://aidsinfo.nih.gov.

Critical Thinking Case Study

JP is a 35-year-old patient recently diagnosed with HIV. Other than a recent "case of the flu" approximately 1 month ago, she has been healthy. She has been divorced for 2 years and has a 3-year-old child from her previous marriage. JP tested HIV negative in the first trimester of her pregnancy and was not retested during the third trimester. She reports that the relationship with her husband was monogamous and that they did not use condoms. JP began a relationship with a new partner 1 year after her divorce. He claimed to be HIV negative, and they did not use condoms (JP takes oral contraceptives for pregnancy prevention). JP denies a history of intravenous drug use and other high-risk behaviors. Her baseline labs include a CD4+ count of 450 cells/mm^3 and a viral load of 75,000 copies/mL. Her genotypic resistance assay shows no baseline resistance. Her preference is for a once-a-day regimen. She may want to have another child but is not certain.

1. JP asks the nurse when she may have become infected with HIV. What are some of the responses that the nurse should include in a discussion with the patient? What else should the nurse discuss with the patient about HIV transmission?
2. Considering JP's preference for a daily antiretroviral regimen and in view of her history, which medication regimens could be considered? What, if any, risk-benefit discussion should occur with regard to choices?
3. JP is told she will begin therapy with a fixed-dose combination regimen containing three different ARVs. JP asks why she needs to be on more than one drug. What should be the explanation by the nurse for the multidrug regimen?
4. At her next routine visit, JP says that she missed two doses of her medications because she had an unplanned overnight stay during a trip. What counseling and interventions should the nurse include in her discussion with the patient?

NCLEX Study Questions

1. During routine prenatal testing, a patient is diagnosed with human immunodeficiency virus infection. To help prevent perinatal transmission of human immunodeficiency virus to the fetus, what is the nurse's best action?
   a. Provide the patient with contact information for an acquired immunodeficiency syndrome support group.
   b. Educate the patient about the risks of human immunodeficiency virus disease to the fetus.
   c. Notify the Centers for Disease Control and Prevention of the patient's diagnosis.
   d. Provide written and oral education about the use of antiretroviral therapy during pregnancy.
2. When a patient does not appear for a routine clinic visit, the nurse calls to ask about the missed visit. The patient says, "I don't need to come any longer. I'm so glad I no longer have human immunodeficiency virus." The nurse learns that recent laboratory results indicated an "undetectable" human immunodeficiency virus viral load and that the patient stopped his medication several weeks earlier. What is the nurse's best response?
   a. Inform the patient that he must be seen immediately because the undetectable viral load indicates that his medication stopped working.
   b. Have the patient reschedule his clinic visit.
   c. Congratulate the patient on his treatment success.
   d. Educate the patient about the continued need for his medications and ongoing laboratory monitoring.
3. The nurse advises human immunodeficiency virus–positive patients about blood draws to obtain a CD4+ count. What is the correct information to give them about when and how this laboratory blood work should be done?
   a. At the same laboratory at approximately the same time of day whenever possible
   b. After a 10-hour fast
   c. Approximately 1 hour after taking antiretroviral medications
   d. At any laboratory at any time of day
4. In collaboration with a patient on antiretroviral therapy, the nurse formulates a plan of care. Which items are appropriate to include in planning? (Select all that apply.)
   a. The patient's viral load will become and remain undetectable.
   b. The patient will not experience secondary infection.
   c. The patient will promptly report new onset of symptoms and side effects.
   d. Laboratory blood work will be within normal limits.
   e. The patient will adhere to the medication regimen and will report any difficulties related to adherence.
5. A patient is to start on efavirenz. Which points are important for the nurse to include in health teaching for this patient? (Select all that apply.)
   a. The dose is given at bedtime to minimize central nervous system adverse effects.
   b. Alcohol should be avoided because of adverse effects to the liver.
   c. The dose should be taken after breakfast to minimize central nervous system adverse effects.
   d. High-fat meals can increase absorption of the medication.
   e. Hyperglycemia, jaundice, and diabetes mellitus are side effects.

Answers: 1, d; 2, d; 3, a; 4, a, b, c, e; 5, a, b, d.

Transplant Drugs

OUTLINE

Organ Transplantation
- Principles of Immunosuppression
- Immunosuppressant Drugs
- Drugs for Transplant Rejection
- Drugs for Infection

Promoting Adherence
- Nursing Process: Patient-Centered Collaborative Care—Organ Transplants: Immunosuppression

Critical Thinking Case Study

NCLEX Study Questions

OBJECTIVES

- Describe the mechanism of action of the six maintenance therapy drugs and relate the processes to the principles of immunosuppression.
- Differentiate the three drugs used in the treatment of transplant rejection.
- Calculate the absolute neutrophil count of a patient on immunosuppressive drugs and relate it to neutropenic precautions.
- Describe the issues surrounding nonadherence in transplant recipients.
- Describe the nurse's role in promoting adherence to the therapeutic drug regimen.

KEY TERMS

cadaveric transplantation, p. 421
cytokine release syndrome, p. 422
immunosuppression, p. 421
induction therapy, p. 421
living-donor transplantation, p. 421
transplant rejection, p. 427

http://evolve.elsevier.com/McCuistion/pharmacology/

Organ Transplantation

Organ transplantation is a life-saving procedure. In **cadaveric transplantation**, a healthy organ donated at the time of a person's death is transplanted into the body of a patient with end-stage organ failure. In **living-donor transplantation**, a kidney or a portion of liver donated by a living person is transplanted into the body of a patient with end-stage kidney or liver disease. Organ transplant is an acceptable treatment option when organs fail (e.g., kidney, heart, liver, and lung). More than 122,000 people are currently waiting for an organ transplant. Every 10 minutes, another person is added to the wait list, and over 8000 people die each year while waiting for a donor organ.

Principles of Immunosuppression

The immune system remains the biggest barrier to transplantation as a routine medical treatment because it has effective mechanisms to fight off foreign organisms. These same mechanisms are involved in the rejection of transplanted organs, which are recognized as foreign by the recipient's immune system. The underlying premise of **immunosuppression** is to use multiple drugs that alter different aspects of the immune system (Fig. 30.1), thereby reducing the chances of transplant rejection and enabling the use of lower doses of individual drugs, which reduces the likelihood of drug toxicity. Transplantation has revolutionized care for patients with end-stage organ failure, yet significant problems remain with treatments designed to promote transplant survival and prevent rejection. Immunosuppressant drugs are not always effective; in addition, they are expensive and must be taken daily, and they are associated with toxic effects.

Immunosuppressant Drugs

Induction Therapy

Induction therapy provides intense immunosuppression with drugs designed to diminish antigen presentation and T-cell response, thus reducing the risk for acute rejection during the initial transplant period.

Basiliximab is a monoclonal antibody that inhibits interleukin 2 (IL-2)–mediated activation of lymphocytes, a critical component of the cellular immune response involved in transplant rejection. By inhibiting activation of lymphocytes, it prevents the body from mounting an immune response against the transplanted organ. Basiliximab has been approved for induction therapy in kidney transplants. Complete pharmacokinetic data are not available, but drug half-life is known to be 7.2 days in adults and 9.5 days in children.

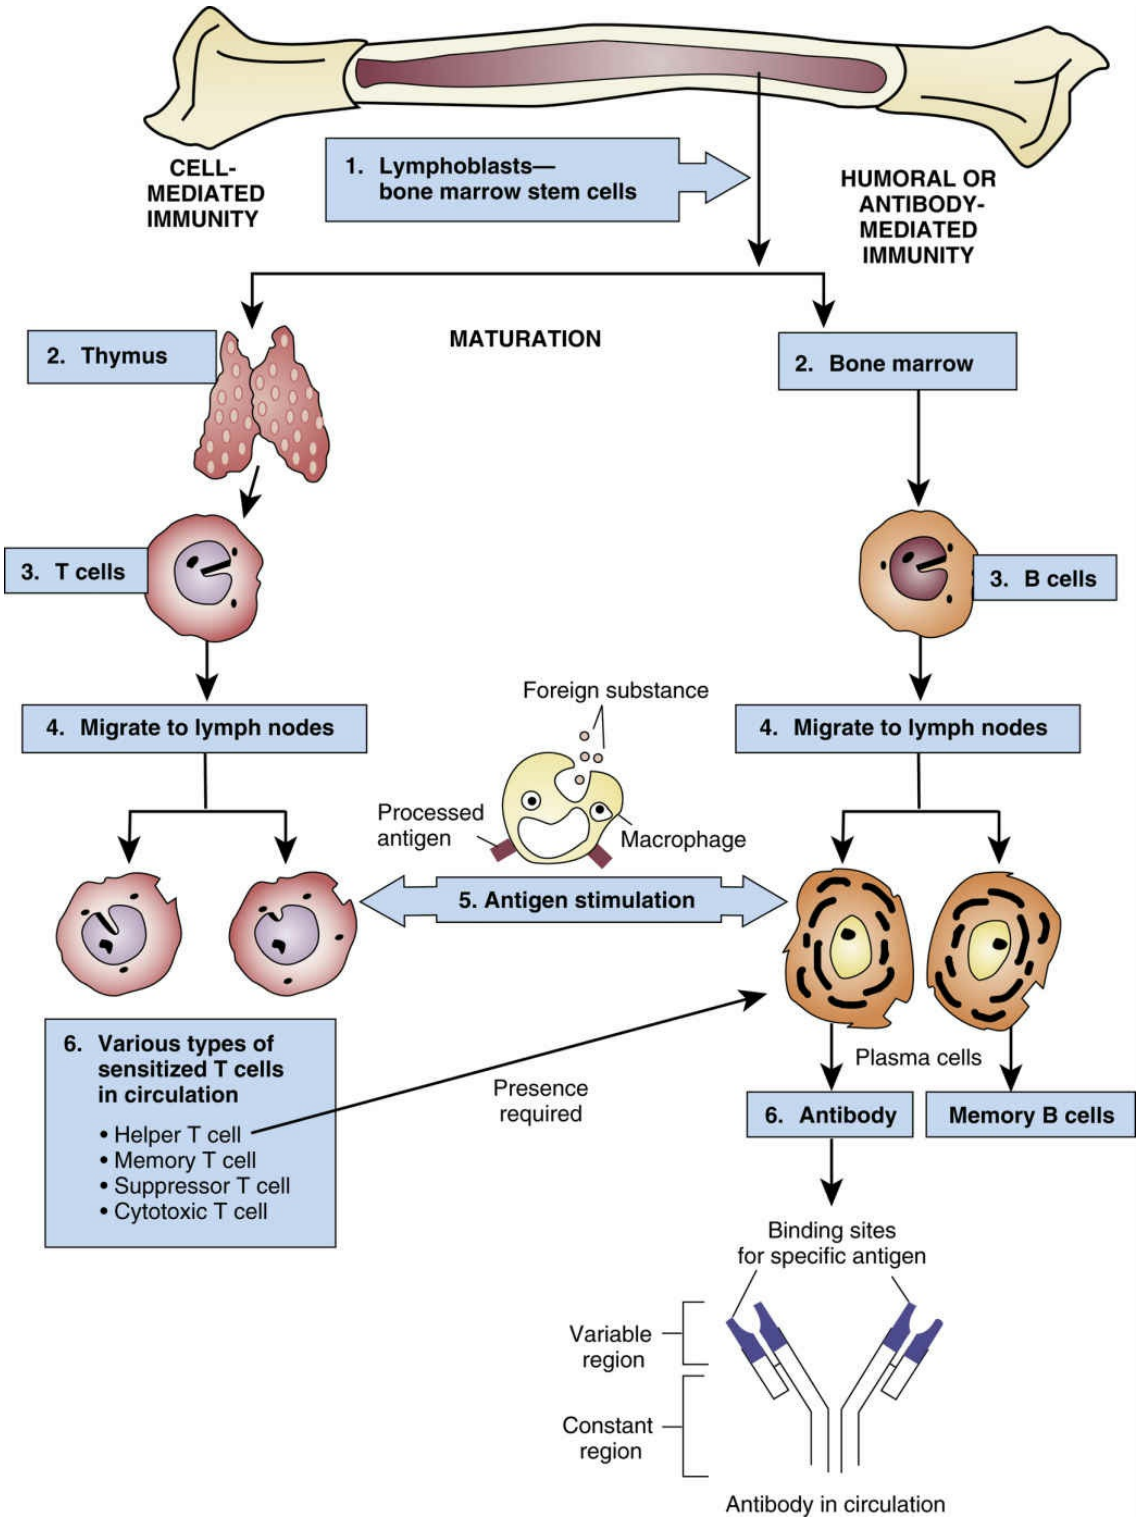

FIG. 30.1 The Immune Response.
From Gould, B., & Dyer, R. (2011). *Pathophysiology for the health professions* (4th ed.). St Louis: Saunders.

Basiliximab is administered intravenously (IV), 20 mg within 2 hours before transplant surgery, followed by a second 20-mg dose 4 days after transplantation. The second dose should be withheld if complications occur (including severe hypersensitivity reactions or loss of the transplanted organ). Children under 35 kg should receive 10 mg IV within 2 hours before transplant surgery, followed by a second 10-mg dose 4 days after transplantation; the second dose should be withheld if complications occur (including severe hypersensitivity reactions or loss of the transplanted

organ); children over 35 kg should receive the adult dose.

Side effects of basiliximab include abdominal and back pain, coughing, dizziness, fever or chills, fatigue, weakness, dysuria, dyspnea, sore throat, edema, tremor, nausea and vomiting, and anemia. Serious reactions include sepsis, opportunistic infections, malignancy, lymphoproliferative disorders, thrombocytopenia, leukopenia, diabetes mellitus, anaphylaxis, capillary leak syndrome, and **cytokine release syndrome** (Box 30.1).

BOX 30.1 Cytokine Release Syndrome

Cytokine release syndrome is a symptom complex associated with the use of anti-T–cell antibody infusions, such as antithymocyte globulin (rabbit) and muromonab-CD3. Commonly referred to as an *infusion reaction,* cytokine release syndrome results from the release of cytokines from cells targeted by the antibody. When cytokines are released into the circulation, systemic symptoms such as fever, nausea, chills, hypotension, tachycardia, asthenia, headache, rash, scratchy throat, and dyspnea can result. In most patients, the symptoms are mild to moderate in severity and are managed easily. Premedication with corticosteroids or acetaminophen plus an antihistamine have been reported to be effective in reducing the severity of symptoms caused by cytokine release. Other management measures include reduction of the infusion rate. However, some patients may experience life-threatening reactions, therefore nurses must closely monitor patients receiving anti-T–cell antibody infusions. Patients with asthma, autoimmune disease, history of drug allergies, and previous exposure to the drug are at increased risk of developing cytokine release syndrome. During infusions, nurses must assess the patient frequently, monitoring vital signs and watching for any signs or symptoms of a reaction. Reactions are most likely to occur in the first hour, but a reaction could occur at any time. Any delay in recognition of the signs of anaphylaxis can compromise the patient's outcome.

From Vogel, W. H. (2010). Infusion reactions: Diagnosis, assessment and management. *Clinical Journal of Oncology Nursing, 14*(2), E10-E21. Retrieved from http://chemotherapy.vc.ons.org/file_depot/0-10000000/0-10000/3365/folder/87592/Infusion+Reactions+(Vogel+2010).pdf

Transplant recipients who receive basiliximab should not receive live vaccines because they may produce an inadequate immune response and are at risk for disseminated infection resulting from the live virus. Caution is advised when basiliximab is administered with other drugs that lower the immune response because of the increased risk of serious infection.

Basiliximab was designated pregnancy category B; no adequate and well-controlled studies have been done on the drug's use in pregnant women, therefore women of childbearing potential should use effective contraceptive measures before beginning treatment, during treatment, and for 4 months after completion of therapy. It is not known whether basiliximab is excreted in breast milk. Because of the potential for adverse drug reactions, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Maintenance Therapy

Calcineurin Inhibitors

The calcineurin inhibitors (CNIs) suppress the immune system by binding to cytoplasmic proteins that inhibit calcineurin phosphatase, resulting in a reduction in cytokine synthesis and inhibition of T-lymphocyte proliferation. There are two CNIs, cyclosporine and tacrolimus; the prototype CNI is cyclosporine. The drug became available in 1983 and was modified to improve bioavailability in 1994. Cyclosporine oral solution USP modified and cyclosporine oral solution USP *are not* bioequivalent and *cannot* be used interchangeably.

After oral administration, absorption of cyclosporine is incomplete and varies widely from patient to patient. Drug distribution is concentration dependent; cyclosporine is 90% protein bound. The drug is extensively metabolized by the cytochrome P450 (CYP450) 3A enzyme system in the liver. Elimination is primarily biliary with only 6% excreted in urine. The average drug half-life is 8.4 hours.

Initial dosing of cyclosporine is 7 to 9 mg/kg orally per day in two divided doses; the first dose is given 4 to 12 hours before the transplant or postoperatively in both adult and pediatric patients.

Adjustments to drug dosing are based on therapeutic drug monitoring (TDM), with the desired level between 100 and 500 ng/mL, depending on the organ transplanted and the length of time posttransplant.

The daily dose of cyclosporine oral solution USP *modified* should *always* be given in two divided doses and on a consistent schedule with regard to time of day and relation to meals. Grapefruit and grapefruit juice affect drug metabolism, increasing blood concentration of cyclosporine; for this reason, grapefruit should be avoided. To make cyclosporine oral solution USP modified more palatable, it should be diluted with room-temperature orange or apple juice; patients should avoid switching diluents frequently. When mixed with juice, the cyclosporine solution may appear cloudy. Cyclosporine is also available as immediate-release capsules (25 mg and 100 mg) and as an IV solution (250 mg/5 mL).

Common side effects of cyclosporine include elevated blood urea nitrogen (BUN) and creatinine, hypertension, hirsutism, infection, tremor, gingival hyperplasia, headache, hypertriglyceridemia, nausea and vomiting, diarrhea, hyperuricemia, hyperglycemia, arthralgia, edema, acne, hypomagnesemia, and hyperkalemia. Serious reactions include opportunistic infections, nephropathy and nephrotoxicity, diabetes mellitus, leukopenia, thrombocytopenia, hemolytic anemia, malignancy, and seizures.

Transplant recipients taking cyclosporine should not receive live vaccines because they may have inadequate immune response and are at risk for disseminated infection resulting from the live virus.

Multiple antibiotics, melphalan (an antineoplastic drug), antifungals, antiinflammatory drugs, cimetidine and ranitidine (histamine 2–receptor blockers), tacrolimus (an immunosuppressant), fibric acid derivatives, and methotrexate may potentiate kidney dysfunction when administered with cyclosporine. Calcium channel blockers, azole antifungals, macrolide antibiotics, and glucocorticoids can increase cyclosporine concentrations, as can allopurinol, amiodarone, bromocriptine, colchicine, danazol, imatinib, metoclopramide, nefazodone, and oral contraceptives. Other drugs—nafcillin, rifampin, anticonvulsants, bosentan, octreotide, orlistat, sulfinpyrazone, terbinafine, ticlopidine—and St. John's wort can decrease cyclosporine concentrations.

Concomitant administration of cyclosporine with 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors (e.g., lovastatin, simvastatin, pravastatin, fluvastatin, and atorvastatin) may increase the risk for rhabdomyolysis. The dosage of HMG-CoA reductase inhibitors should be reduced.

In addition to TDM (drug levels should be drawn just prior to the dose), patients taking cyclosporine should have frequent monitoring of BUN, creatinine, potassium, and magnesium levels in addition to liver function tests (LFTs) and lipid profiles.

Cyclosporine was designated pregnancy category C; it does not appear to be a major human teratogen; however, it may be associated with increased rates of prematurity. Cyclosporine is present in breast milk. Because of the potential for serious adverse drug reactions in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Tacrolimus

Approved by the FDA in 1994, tacrolimus is the second calcineurin inhibitor approved for prophylaxis of rejection in heart, liver and kidney transplants. It carries a boxed warning for malignancies and serious infections. Patients taking this drug are at increased risk for developing lymphoma and other malignancies. Additionally, patients taking tacrolimus are at risk for developing bacterial, viral, fungal, and protozoal infections.

Dosing for heart transplant recipients begins no sooner than 6 hours posttransplant with a continuous infusion at 0.01 mg/kg/day IV. When oral dosing begins, it should be at a dose of 0.075 mg/kg/day orally divided every 12 hours. For patients with a liver transplant, tacrolimus is administered with a continuous infusion at 0.03 to 0.05 mg/kg/day IV. When oral dosing begins, it should be dosed 0.1 to 0.15mg/kg/day orally divided every two hours. Kidney transplant recipients should begin tacrolimus within 24 hours of receiving the transplanted organ. Dosing ranges from 0.1 to 0.2 mg/kg/day orally divided every 12 hours, and may vary based on drugs used for induction.

For all transplant recipients, dosing is adjusted based on serum drug levels with trough levels ranging between 5 and 20 ng/mL, depending on organ transplanted and length of time since

transplant.

The drug is highly nephrotoxic and should be administered at the lowest recommended dose for those with renal impairment. For those with postoperative oliguria, use of tacrolimus may be delayed until kidney function is adequate. All patients on tacrolimus should have their kidney function monitored periodically during therapy.

Tacrolimus may prolong the QT/QTc interval and may cause Torsade de Pointes. Avoid Tacrolimus in patients with congenital long QT syndrome. In patients with congestive heart failure, bradyarrhythmias, those taking certain antiarrhythmic medications or other medicinal products that lead to QT prolongation, and those with electrolyte disturbances such as hypokalemia, hypocalcemia, or hypomagnesemia, consider obtaining electrocardiograms and monitoring electrolytes (magnesium, potassium, calcium) periodically during treatment.

Tacrolimus is slowly absorbed in the GI tract. Bioavailability averages 25% and peak serum concentration is reached in 3 hours. Food, especially food high in fat, slows absorption and reduces bioavailability. It is metabolized extensively in the liver and is over 90% excreted in the feces, with the remaining excreted in the urine. Genetic variations in activity of the CYP3A5 protein can affect serum concentrations of tacrolimus. Its half-life is variable depending on organ transplanted (3.5 to 40.6 hours).

Tacrolimus has multiple common side effects, including tremor, diarrhea, headache, hypertension, nephrotoxicity, infection, insomnia, electrolyte, metabolic and lipid abnormalities, constipation, edema, fever, anemia, hyperglycemia, hepatotoxicity, anorexia, dyspepsia, dyspnea, pruritus, dizziness, cough, leukopenia, and photosensitivity. Serious reactions include malignancy, posttransplant lymphoproliferative disorder, severe infections, Stevens-Johnson syndrome, toxic epidermal necrolysis, anaphylaxis, neurotoxicity, seizures, myocardial hypertrophy, QT prolongation, torsades de pointes, pericardial effusion, diabetes, myelosuppression, DIC, thrombocytopenic purpura, and hemolytic anemia.

Persons receiving tracrolimus have absolute contraindication for live vaccines, mifepristone, pimozide, quinidine, saquinavir, streptozocin, talimogene laherparepvec (a genetically modified oncolytic viral therapy used in patients with recurrent melanoma), and ziprasidone. Multiple other drugs should be used with caution. Protease inhibitors may increase serum drug levels, as can antifungal agents, calcium channel blockers, gastric acid suppressors/antacids, and antibacterials. Anticonvulsants can decrease serum drug levels, as can St. John's wort. Patients receiving tacrolimus should avoid grapefruit juice, as it too, may increase serum drug levels.

Costimulation Blockers

Belatacept is a first-in-class selective T-cell costimulation blocking agent indicated for use in combination with basiliximab induction, mycophenolate mofetil, and corticosteroids to prevent kidney transplant rejection. It inhibits T-cell CD28 activation and proliferation by binding costimulatory ligands (CD80, CD86) of antigen-presenting cells, thereby inhibiting T-lymphocyte proliferation and the production of the cytokines IL-2 and IL-4, interferon-alfa, and tumor necrosis factor alpha (TNF-α), which are involved in systemic inflammation. Metabolism and excretion of belatacept are unknown, but half-life is 8.2 to 9.8 days.

The prescribed dose must be divisible by 12.5 to accurately prepare the dose from the reconstituted solution. Initial dosing is 10 mg/kg IV prior to surgery on the day of transplant; the dose is repeated on day 5 and at the end of weeks 2, 4, 8, and 12 after transplantation. Maintenance dosing is 5 mg/kg IV at the end of week 16 after transplantation and then every 4 weeks thereafter. Belatacept is not approved for pediatric use.

This drug carries a boxed warning for increased risk of developing posttransplant lymphoproliferative disorder (PTLD), predominantly involving the central nervous system (CNS). Additionally, recipients without immunity to EBV are at a particularly increased risk, therefore belatacept is for use in EBV-seropositive patients only.

Common side effects of belatacept include infection, anemia, diarrhea, peripheral edema, hypertension, constipation, fever, cough, nausea and vomiting, altered potassium levels, headache, leukopenia, abdominal pain, dyslipidemia, hypophosphatemia, arthralgia, hyperglycemia, proteinuria, increased creatinine, insomnia, hypocalcemia, back pain, dysuria, and anxiety. Serious reactions include PTLD, malignancy, serious infections, progressive multifocal leukoencephalopathy (PML), neutropenia, acute renal failure, nephropathy, and diabetes mellitus.

Transplant recipients receiving belatacept should not receive live vaccines because their immune

response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when belatacept is administered with other drugs that lower the immune response because of the increased risk of serious infection.

Belatacept was designated pregnancy category C, and adverse events have been observed in animal studies. According to the manufacturer, belatacept should not be used in pregnancy unless the potential benefit to the mother outweighs the potential risk to the fetus. A pregnancy registry has been established to monitor outcomes of women exposed to belatacept during pregnancy (1-877-955-6877). Safety during breastfeeding is unknown, therefore a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Mammalian Target of Rapamycin Inhibitors

There are two mammalian target of rapamycin (mTOR) inhibitors approved for the prevention of organ rejection in kidney transplant recipients aged 13 years and older: sirolimus and everolimus. Sirolimus is the prototype drug: it inhibits T-lymphocyte activation and proliferation and inhibits antibody production by binding to the FK binding protein, thereby inhibiting IL-2–mediated signal transduction. This results in cell-cycle arrest in the G1-S phase (growth phase and DNA replication), blocking T- and B-cell activation by cytokines. Time to peak concentration is 1 to 3 hours for sirolimus solution and 1 to 6 hours for tablets. Systemic bioavailability is 14% for solution and 47% for tablets. Sirolimus is extensively protein bound (92%) and is extensively metabolized in the intestine and liver. Excretion is 91% in the feces and 2.2% in the urine, and drug half-life is 2.5 days.

There are two boxed warnings for sirolimus: use of sirolimus increases susceptibility to infection and the possible development of lymphoma and other malignancies, and the safety and efficacy has not been established in liver or lung transplant patients, therefore use is not advised in liver or lung transplant patients due to increased morbidity and mortality.

For patients who weigh less than 40 kg, the loading dose should be 3 mg/m^2 once orally as soon as possible after transplantation; maintenance dosing should be adjusted based on body surface area (BSA) to 1 mg/m^2 per day orally. In patients who weigh more than 40 kg, the loading dose is 6 mg once orally as soon as possible after transplantation, and maintenance dosing is 2 mg/day orally.

It is recommended that the maintenance dose of sirolimus tablets be reduced by approximately one third in patients with mild or moderate hepatic impairment and by half in patients with severe hepatic impairment. Dosing should not exceed 40 mg/day.

TDM is recommended for all patients. Target whole-blood trough levels should range between 16 and 24 ng/mL for the first year following transplantation; thereafter, trough levels should range between 12 and 20 ng/mL. Sirolimus tablets are to be administered orally once daily, consistently with or without food. Tablets should not be crushed, chewed, or split. It is recommended that sirolimus tablets be taken 4 hours after administration of cyclosporine.

The most common side effects of sirolimus are peripheral edema, hypertriglyceridemia, hypertension, hypercholesterolemia, increased creatinine, constipation, abdominal pain, diarrhea, headache, fever, urinary tract infection, anemia, nausea, arthralgia, pain, and thrombocytopenia. Serious reactions include malignancy, lymphoma, severe infection, PML, nephropathy, hemolytic uremic syndrome, thrombotic microangiopathy, venous thromboembolism, myelosuppression, exfoliative dermatitis, pericardial effusion, ascites, interstitial lung disease, hepatotoxicity, and osteonecrosis.

Concurrent administration of sirolimus with ketoconazole, mifepristone, or voriconazole is contraindicated due to increased serum drug levels secondary to reduced metabolism of sirolimus.

Transplant recipients taking sirolimus should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when sirolimus is administered with other drugs that lower the immune response because of the increased risk of serious infection.

Sirolimus was designated pregnancy category C; no adequate and well-controlled studies have been done in pregnant women, therefore effective contraception must be initiated before sirolimus therapy, and it should continue during sirolimus therapy and for 12 weeks after therapy has been stopped. Sirolimus should be used during pregnancy only if the potential benefit outweighs the potential risk. Whether sirolimus is excreted in breast milk is unknown, therefore a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Purine Antimetabolites

Azathioprine, a purine antimetabolite, is converted into 6-mercaptopurine in the body, where it blocks purine metabolism and DNA synthesis, thereby suppressing T- and B-lymphocyte proliferation. It is indicated for the prevention of kidney transplant rejection. Azathioprine is well absorbed following oral administration. Both azathioprine and the metabolite 6-mercaptopurine are moderately bound to serum proteins (30%) and undergo extensive metabolism in the liver; both are primarily excreted in bile, and drug half-life is 5 hours.

Azathioprine has a boxed warning that chronic immunosuppression with azathioprine increases risk of malignancy in humans.

Dosing ranges from 1 to 3 mg/kg per day orally (an IV form is not currently available in the United States). In the setting of kidney dysfunction, the dose should be reduced by 25% for a creatinine clearance (CrCl) between 10 and 50 mL/min; if CrCl is less than 10 mL/min, the dose should be reduced by 50%.

Common side effects include leukopenia, thrombocytopenia, anemia, infection, nausea and vomiting, anorexia, diarrhea, elevated LFTs, malaise, myalgia, fever, and rash. Serious side effects include myelosuppression, PML, pancreatitis, hepatotoxicity, lymphomas, and other malignancies.

Transplant recipients taking azathioprine should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when azathioprine is administered with other drugs that lower the immune response because of an increased risk of serious infection. Combining azathioprine with antihypertensive drugs increases the risk of leukopenia.

Patients who receive azathioprine should have a complete blood count (CBC), including a platelet count, taken weekly during the first month, twice monthly for the second and third months of treatment, then monthly. Creatinine and LFTs should be monitored.

Azathioprine was designated pregnancy category D because it can cause fetal harm when given to pregnant women and should be avoided; however, maternal benefit may outweigh fetal risk in serious or life-threatening situations. Azathioprine is found in breast milk and is possibly unsafe during breastfeeding, therefore a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Inosine Monophosphate Dehydrogenase Inhibitors

Mycophenolate mofetil blocks synthesis of purine nucleotides by inhibition of the enzyme inosine monophosphate dehydrogenase (IMPDH), thereby preventing the proliferation of T cells and lymphocytes and preventing the formation of antibodies from B cells; it also may inhibit recruitment of leukocytes to inflammatory sites. Mycophenolate mofetil is rapidly absorbed following oral administration with 94% bioavailability, and it is 98% protein bound. It is a prodrug that is metabolized in the liver to mycophenolic acid (MPA); it is excreted in the urine (93%) and in feces (6%). Drug half-life for the oral formulation is 17.9 hours; the half-life for the IV formulation is 16.6 hours.

Recommended dosing for kidney transplant recipients is 1 g orally twice daily; for heart and liver transplant recipients, the dosage is 1.5 g orally twice daily. Kidney function should be monitored; for a CrCl less than 25 mL/min, the maximum dosage is 1 g twice daily. In pediatric transplant recipients, the recommended dose of mycophenolate mofetil oral suspension is 600 mg/m^2 twice daily, up to a maximum of 1 g twice daily.

The dose of mycophenolate mofetil should be reduced or interrupted for an absolute neutrophil count (ANC) of less than 1300. To calculate the ANC, the following formula is used (*WBC* is white blood cell count):

$$\text{WBC} \times \text{total neutrophils (segmented neutrophils \%} + \text{segmented bands \%)} \times 10 = \text{ANC}$$

A normal ANC is over 1500. An ANC of 500 to 1500 is considered neutropenic, and an ANC less than 500 indicates severe neutropenia and significantly increases a person's risk for infection (Box

30.2).

Common side effects of mycophenolate mofetil include hypertension, infection, diarrhea, edema, anemia, abdominal pain, constipation, headache, nausea and vomiting, dyspnea and cough, hypercholesterolemia, tremor, hypokalemia, acne, and insomnia. Serious reactions include thrombocytopenia, leukopenia, neutropenia, severe infection, viral reactivation, nephropathy, PML, lymphoma, lymphoproliferative disorders, malignancy, gastrointestinal (GI) bleeding, acute renal failure, and interstitial lung disease.

Transplant recipients taking mycophenolate mofetil should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when mycophenolate mofetil is administered with other drugs that lower the immune response because of the increased risk of serious infection. Combining mycophenolate mofetil with nonsteroidal antiinflammatory drugs (NSAIDs) increases the risk of GI bleeding.

BOX 30.2 Neutropenic Precautions

In addition to receiving treatment from your doctor, the following suggestions can help prevent infections:

- Clean your hands frequently.
- Try to avoid crowded places and contact with people who are sick.
- Do not share food, drink cups, utensils, or other personal items, such as toothbrushes.
- Shower or bathe daily and use an unscented lotion to prevent your skin from becoming dry and cracked.
- Cook meat and eggs all the way through to kill any germs.
- Carefully wash raw fruits and vegetables.
- Protect your skin from direct contact with pet bodily waste (urine or feces) by wearing vinyl or household cleaning gloves when cleaning up after your pet. Wash your hands immediately afterwards.
- Use gloves for gardening.
- Clean your teeth and gums with a soft toothbrush, and if your doctor or nurse recommends one, use a mouthwash to prevent mouth sores.
- Try and keep all your household surfaces clean.
- Get the seasonal flu shot as soon as it is available.
- If you go to the emergency room, you should not sit in the waiting room for a long time; when you check in, tell them right away you are receiving immunosuppressant drugs.
- Know the signs and symptoms of an infection:
  - Fever that is 100.4°F (38°C) or higher for more than one hour, or a one-time temperature of 101°F or higher.
  - Chills and sweats.
  - Change in cough or new cough.
  - Sore throat or new mouth sore.
  - Shortness of breath.
  - Nasal congestion.
  - Stiff neck.
  - Burning or pain with urination.
  - Unusual vaginal discharge or irritation.
  - Increased urination.
  - Redness, soreness, or swelling in any area, including surgical wounds.
  - Diarrhea.
  - Vomiting.
  - Pain in the abdomen or rectum.
  - New onset of pain.
  - Changes in skin, urination, or mental status.

From: Retrieved 12/23/16 from https://www.cdc.gov/cancer/preventinfections/pdf/neutropenia.pdf

Patients taking mycophenolate mofetil should have a baseline creatinine level drawn and should have CBCs done weekly during the first month, twice monthly for the second and third months of

treatment, then monthly throughout the first year.

Mycophenolate mofetil was designated pregnancy category D; it is associated with an increased risk of first-trimester pregnancy loss and an increased risk of congenital malformations. Females of reproductive potential must be made aware of the increased risk of first-trimester pregnancy loss and congenital malformations and must be counseled regarding pregnancy prevention and planning. It is unknown whether mycophenolate mofetil is found in breast milk, therefore a decision should be made whether to discontinue breastfeeding or to discontinue the drug, taking into account the importance of the drug to the mother.

Corticosteroids

Prednisone, a corticosteroid, is a glucocorticoid receptor agonist. It decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability; it suppresses the immune system by reducing the activity and volume of the lymphatic system; prednisone suppresses adrenal function at high doses and is readily absorbed from the GI tract (up to 90%). Plasma protein binding is less than 50% but is concentration dependent. Prednisone is metabolized by the liver to its active metabolite, prednisolone. It is excreted in the urine as sulfate and glucuronide conjugates. Prednisone has a plasma half-life of 2 to 4 hours and should be administered after meals or with food or milk to decrease GI upset.

In addition to their use in maintenance therapy, corticosteroids are used in high doses for the treatment of acute transplant rejection. The drug, methylprednisolone sodium succinate, is administered IV in doses that range from 250 mg to 500 mg daily for 3 to 5 days.

Common side effects of corticosteroid use include sodium retention, edema, hypokalemia, hypertension, diaphoresis, muscle atrophy, nausea and vomiting, dyspepsia, petechiae and ecchymosis, facial erythema, acne, rash, headache, dizziness and vertigo, insomnia, emotional lability, depression, anxiety, glucose intolerance, menstrual irregularities, hirsutism, appetite changes, and weight gain. Serious reactions include anaphylaxis, adrenal insufficiency, steroid psychosis, infection, diabetes mellitus, seizures, heart failure, peptic ulcer disease and GI bleeding, osteonecrosis, and tendon rupture. Long-term use may lead to impaired wound healing, skin atrophy, Cushing syndrome, glaucoma and cataracts, Kaposi sarcoma, and growth suppression in children. Cessation of corticosteroids may lead to withdrawal symptoms with high doses or long-term use.

Transplant recipients taking corticosteroids should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when corticosteroids are administered with other drugs that lower the immune response because of the increased risk of serious infection. Combining corticosteroids with certain antibiotics increases the risk of QT prolongation and arrhythmias; combining corticosteroids with diuretics increases the risk of hypokalemia.

Transplant recipients taking corticosteroids should have periodic monitoring of their electrolytes, blood pressure, weight, and glucose levels. Pediatric patients should have their height monitored. Chest x-rays and ophthalmic examinations are indicated with long-term use.

Caution is advised during pregnancy, especially in the first trimester or with long-term use, because of the possible risk of low birthweight and premature birth. Corticosteroids are probably safe during breastfeeding.

Drugs for Transplant Rejection

Transplant rejection occurs when the immune system of the transplant recipient attacks the transplanted organ. This happens because the immune system recognizes foreign tissues and attempts to destroy them, just as it attempts to destroy infecting organisms, such as bacteria and viruses. Treatment of rejection with an anti–T-cell antibody is used when corticosteroids have failed to reverse rejection or for treatment of a recurrent rejection.

Antithymocyte globulin (rabbit), or *ATG rabbit*, is a polyclonal (depleting) antibody that blocks T-cell membrane proteins CD2, CD3, and CD45; this causes altered T-cell function and lysis and prolonged T-cell depletion, which begins within 24 hours. Complete pharmacokinetic data are not available, but drug half-life is 2 to 3 days.

Dosing is 1.5 mg/kg IV each day for 7 to 14 days in adults. This drug is not approved for use in children. Dosage should be decreased by 50% if the white blood cell (WBC) count decreases to 2000

to 3000 or the platelet count is 50,000 to 75,000. Treatments should be discontinued if the WBC count falls to less than 2000 or the platelet count falls to less than 50,000.

Common side effects of ATG rabbit include high fever, chills, nausea and vomiting, headache, diarrhea, malaise, shortness of breath, leukopenia, thrombocytopenia, peripheral edema, and increased risk for infection. Serious side effects include anaphylaxis, severe infusion reaction, cytokine release syndrome, serum sickness, sepsis, cytomegalovirus (CMV), malignancy, and lymphoproliferative disorders. Premedication with corticosteroids and antihistamines decreases the incidence and severity of adverse reactions. Close supervision of the patient is required during and after IV infusion, to include frequent vital signs and assessment of the site for signs of extravasation.

Transplant recipients receiving ATG rabbit should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when ATG rabbit is administered with other drugs that lower the immune response because of the increased risk of serious infection.

Patients should have WBC and platelets monitored frequently during treatment. ATG rabbit was designated pregnancy category C, and there are no adequate and well-controlled studies in pregnant women. Inadequate information is available to assess the risk of ATG rabbit when breastfeeding, therefore a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Muromonab-CD3 is a monoclonal antibody that binds specifically to the CD3 complex on the surface of T lymphocytes; the CD3 complex is involved in antigen recognition and cell stimulation. Immediately after administration, CD3-positive T lymphocytes are abruptly removed from circulation. Complete pharmacokinetic data are not available, but drug half-life is 18 hours.

Dosing is 5 mg IV push daily for 10 to 14 days in adults. In pediatric patients under 30 kg, dosage is 2.5 mg IV push daily for 10 to 14 days; pediatric patients over 30 kg are dosed the same as adults.

Muromonab-CD3 carries a boxed warning for the risk of anaphylactic reactions occurring with any dose and life-threatening or lethal systemic, cardiovascular, and CNS reactions.

Common side effects of muromonab-CD3 include fever, chills, nausea and vomiting, diarrhea, headache, tachycardia, hypotension, dyspnea, tremor, rash, edema, fatigue, diaphoresis, dyspepsia, arthralgia, pruritus, leukopenia, and increased risk of infection. Serious reactions include anaphylaxis, Stevens-Johnson syndrome, cytokine release syndrome, cardiorespiratory arrest, seizures, encephalopathy, aseptic meningitis, opportunistic infection, malignancy, lymphoproliferative disorders, thrombosis, thrombocytopenia, anemia, neutropenia, and leukopenia.

Transplant recipients receiving muromonab-CD3 should not receive live vaccines because their immune response may be inadequate, and they are at risk for disseminated infection resulting from the live virus. Caution is advised when muromonab-CD3 is administered with other drugs that lower the immune response because of the increased risk of serious infection.

Transplant recipients receiving muromonab-CD3 should have BUN, creatinine, LFTs, and a CBC with differential drawn at baseline.

Muromonab-CD3 was designated pregnancy category C, and there are no adequate and well-controlled studies in pregnant women; however, potential benefits may warrant use of the drug in pregnant women despite potential risks. The drug is unsafe during breastfeeding.

Drugs for Infection

Bacterial

Pneumocystis jiroveci pneumonia (PJP) is a life-threatening illness in immunocompromised patients. Routine prophylaxis with trimethoprim-sulfamethoxazole (TMP-SMZ) has significantly reduced the morbidity and mortality of PJP following transplantation. TMP-SMZ is dosed once every morning or one tablet three times a week (Monday, Wednesday, and Friday). TMP-SMZ can make the skin more sensitive to sunlight, therefore patients should be instructed to use a lotion with a minimum sun protection factor (SPF) of 25 when in the sun. See Chapter 26 for further information regarding antibacterial drugs.

Fungal

Transplant recipients use nystatin to prevent or treat thrush in the mouth and esophagus. This is

usually given when the patient is on a high-dose immunosuppression regimen and is stopped when the steroid dose is reduced below 20 mg per day. Nurses must instruct the transplant recipient in proper administration of nystatin liquid:

- Shake the preparation well before measuring the dose.
- Swish the dose around in the mouth for at least 2 minutes before swallowing.
- Allow the nystatin to coat the mouth for as long as possible.
- Do not eat or drink anything for 30 minutes after taking the medication.

See Chapter 27 for further information regarding antifungal drugs.

Viral

One common virus that patients develop after transplantation is CMV. It may present as a viral syndrome or as invasive disease, and it plays a role in organ rejection. Transplant recipients receive antiviral prophylaxis with oral ganciclovir or valganciclovir for 3 to 6 months following surgery. If untreated, CMV can cause serious complications, particularly in the liver, intestine, kidneys, heart, lungs and eyes. See Chapter 27 for further information regarding antiviral drugs.

Promoting Adherence

On discharge from the hospital, transplant recipients begin a lifelong journey of close medical supervision that includes frequent visits to their health care provider, monitoring of blood work, and maintenance of a complex drug regimen. The 1-year survival rates are over 80% for liver transplants and over 90% for kidney transplants; most recipients experience an improved quality of life. However, long-term adherence is a problem, with reports of nonadherence ranging from a low of 2% to as high as 68%. Nonadherence to the posttransplant regimen (e.g., drug regimen, exercise and health promotion) is one of the top three reasons for transplant failure. Factors that affect adherence include episodes of rejection, comorbid illness and disease, side effects of drugs, and health care costs. Nurses play a key role in promoting adherence by incorporating education, motivational strategies, and coping skills into an individually tailored posttransplant plan of care.

Nursing Process: Patient-Centered Collaborative Care

Organ Transplants: Immunosuppression

Assessment

- Assess for clinical signs of rejection including malaise, fever, edema, pain over the transplant site, and increased weight.
- Assess for presence of risk factors for infection, including drugs, travel, and exposure to individuals with active infections.
- Assess for signs and symptoms of infection, including redness, swelling, pain, and elevated temperature.
- Assess immunization status.
- Assess nutritional status, including weight and history of weight loss.

Nursing Diagnosis

- Protection, Ineffective related to the possibility of transplant rejection
- Infection, Risk for

Planning

- Infection is recognized early to allow prompt treatment.
- The transplant recipient and family members will verbalize understanding of early signs and symptoms of rejection.
- The transplant recipient will remain free of infection.

Nursing Interventions

- Instruct the transplant recipient on the benefits of a balanced and healthy diet accompanied by exercise.
- Instruct the transplant recipient on proper adherence to the drug regimen.
- Patients should be instructed to avoid anyone with an active infection and to be careful not to injure themselves, which may increase the chance of acquiring a wound infection. They should stay away from anyone who has a cold, mumps, measles, chickenpox, or other communicable diseases.
- Promote health education with patients and families in order to recognize and minimize the risk of complications and rejection and to facilitate optimum quality of life.
- Teach the transplant recipient the signs and symptoms of rejection and infection, and instruct them on when to call their health care provider.
- Teach the transplant recipient to self-monitor vital signs, daily weights, and blood glucose (if appropriate); ensure the recipient knows when to call the health care provider.
- Transplant recipients and their families should be taught to wash hands properly, especially after toileting, before meals, and before administering drugs.

Evaluation

- Evaluate effectiveness of the plan, including adherence to the immunosuppressive drug

regimen and freedom from infection and transplant rejection.

Critical Thinking Case Study

EM is a 24-year-old female kidney transplant recipient 6 months out from surgery. She is experiencing an episode of acute rejection. In addition to cyclosporine oral solution, mycophenolate mofetil, and prednisone, she is now receiving antithymocyte globulin (rabbit), having failed high-dose steroid treatment for the rejection. EM has had a CBC with differential drawn and her WBC counts are $2.0 \times 10^3/\mu L$, segmented neutrophils are 14.8%, and the segmented bands are 5%.

1. What would be your primary nursing diagnosis? Why?
2. Why is EM prescribed multiple immunosuppressant drugs?
3. When questioning EM about her drug regimen, she states she mixes her cyclosporine in orange juice. She has also been drinking a small glass of grapefruit juice at night because she's heard it helps to lower lipid levels, and she knows cyclosporine can cause elevated lipids. How would you respond to EM?
4. Calculate the ANC. What precautions are necessary if the ANC is less than 500?

NCLEX Study Questions

1. All transplant drugs have the same advisory, to use caution when administering them with another immunosuppressant drug because of the increased risk for:
   a. Nausea and vomiting
   b. Edema
   c. Anemia
   d. Infection
2. Which virus has been associated with posttransplant lymphoproliferative disorder?
   a. Cytomegalovirus
   b. Herpes simplex virus
   c. Epstein-Barr virus
   d. Human immunodeficiency virus
3. Nurses are key to promoting adherence in transplant recipients. What factors influence whether a recipient adheres to a drug regimen? (Select all that apply.)
   a. Drug side effects
   b. Episodes of rejection
   c. Cost
   d. Other health care issues
4. Your patient is receiving basiliximab and develops cytokine release syndrome. You would expect to see:
   a. Coughing
   b. Chills
   c. Tremors
   d. Weakness
5. Your patient taking belatacept becomes pregnant. After discussion with her partner, you, and her health care provider, she decides the best thing to do is continue taking the drug while pregnant. In addition to making this informed decision, what else should she do?
   a. Discontinue all other drugs
   b. Contact the pregnancy registry
   c. Ensure her blood level stays between 16 and 24 ng/mL
   d. Decrease her dose by 50%

Answers: 1, d; 2, c; 3, a, b, c, d; 4, b; 5, b.

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Describe active and passive immunity as both relate to the action of vaccines used in immunizations.
- Differentiate between active natural and active acquired immunity as it relates to the human immune system.
- Identify the diseases that can be prevented with vaccines.
- Review the recommended immunization schedule for children and teens.
- Correlate the manifestations and administration routes for adult vaccines.
- Discuss contraindications to the administration of recommended immunizations.
- Apply the nursing process to include teaching for patients receiving vaccines.

Over the years, immunizations have prevented global epidemics, such as smallpox in 1977 and the eradication of polio in the United States in 1979. The U.S. National Immunization Survey (NIS; www.cdc.gov/vaccines) tracks vaccination coverage of children 19 to 35 months and teens 13 to 17 years. In 2014, vaccine coverage was high (at 90%) for 19- to 35-month-old children who received the recommended doses of diphtheria, tetanus, acellular pertussis (DTaP; for children <7 years old); *Haemophilus influenzae* type B (Hib); measles, mumps, and rubella (MMR); polio; hepatitis B (HepB); pneumococcal conjugate vaccine (PCV); varicella; rotavirus (RV); and hepatitis A (HepA). The survey also estimated that 0.8% of children below the federal poverty level had lower coverage for all vaccinations compared with children at or above the poverty level.

The 2014 national coverage also indicated that the Healthy People 2020 target goal of 90% was met for children aged 19 to 35 months who received the recommended doses of DTaP, polio, MMR, Hib, HepB, PCV, and varicella vaccines.

The NIS estimated that from 2013 to 2014, vaccination coverage among teens aged 13 to 17 years increased from 84.7% to 87.6% for tetanus, diphtheria, and acellular pertussis (Tdap; for individuals >11 years old), and from 76.6% to 79.3% for meningococcus 4-valent conjugate (MenACWY). Although human papillomavirus (HPV) vaccination increased for females (from 56.7% to 60%) and males (from 33.6% to 41.7%), vaccination coverage remained low. These results indicate an increase in all vaccinations for teens, with a need to improve HPV coverage.

Immunity

Active Immunity

The body can obtain immunity in different ways. **Active immunity** occurs when the body's **immune response** is stimulated by an **antigen** or when a **pathogen** enters the body. The body recognizes this pathogen as a foreign substance and produces **antibodies**, also called *immunoglobulins,* which defend the body against pathogens. The immune response is slow, taking several days or weeks to develop immunity. Yet the immunity is often long lasting. During this process, the immune system retains memory of the pathogen then produces antibodies to defend against the disease. **Natural acquired active immunity** occurs from exposure to a pathogen or disease. **Active acquired artificial immunity** occurs when a weakened antigen or immunoglobulin (Ig) is injected into an individual as a vaccination, which then stimulates an immune response.

Passive Immunity

When an individual is unable to make antibodies and memory cells, antibodies are given from another source to provide passive immunity. These antibodies may be produced using recombinant deoxyribonucleic acid (DNA) technology or pooled antigens from several human or animal sources that have been exposed to disease-causing pathogens.

Passive immunity can be natural, in which case the body produces its own antibodies, or it can be acquired—that is, the body receives antibodies from an outside source. Either way the immunity is immediate and short lived, lasting no more than several weeks to a few months; the recipient does not induce his or her own immune response. One example of natural immunity passively acquired is in infants, who are unable to protect against disease because of immature immune systems but instead require antibodies from an outside source, such as the mother's placenta and breast milk. Another example is receiving an Ig to provide antibodies against a specific disease. Passive acquired immunity is essential when (1) time does not permit active vaccination alone, (2) the exposed individual is at high risk for complications of the disease, or (3) the individual suffers from an immune system deficiency that renders that person unable to produce an effective immune response.

Community Immunity

Community immunity, also known as *herd immunity*, occurs when most of the community is immunized against contagious diseases, allowing protection of those not immunized. In contrast, when most of the community is *not* immunized, there is an increased risk for the spread of contagious disease within the community (Fig. 31.1). For more information, see www.vaccines.gov/basics/protection/.

Vaccines

Vaccination involves the administration of a small amount of antigen, which although capable of stimulating an immune response does not typically produce the disease. Different types of vaccines are available, but the type used in vaccinations depends on the person's immune response. The antigen in vaccines may be produced in several ways. Traditional vaccines contain the whole or components of an inactivated (killed) microorganism. Other vaccines are **attenuated viruses** composed of live, attenuated (weakened) microorganisms. Persons who are immunocompromised because of illness or who take medication that causes immunosuppression should avoid live vaccines. **Toxoids** are inactivated toxins that can no longer produce harmful diseases but do stimulate formation of antitoxins, which produces active immunity (e.g., tetanus toxoid).

Newer vaccines, called **conjugate vaccines**, require a protein or toxoid from an unrelated organism to link to the outer coating of the disease-causing microorganism. This linkage creates a substance that can be recognized by the immature immune system of young infants. One example is *H. influenzae* type B.

Recombinant subunit vaccines involve the insertion of some of the genetic material (e.g., DNA) of a pathogen into another cell or organism, where the antigen is then produced in massive quantities. These antigens are then used as a vaccine in place of the whole pathogen. The HepB vaccine is an example of this type of vaccine.

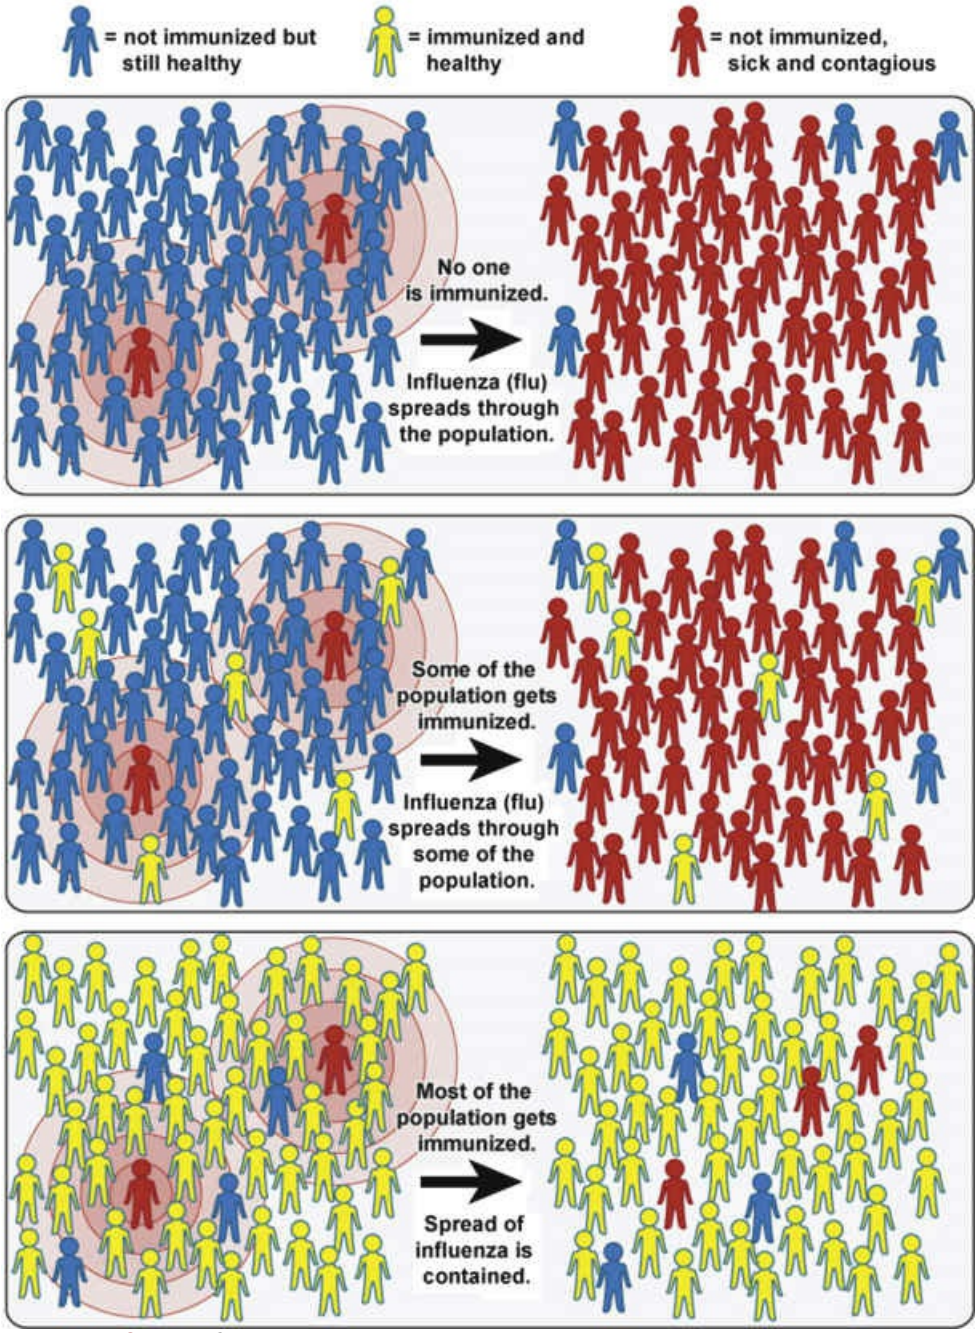

FIG. 31.1 Community immunity. Courtesy National Institute of Allergy and Infectious Diseases.

An **adjuvant**—often an aluminum salt such as aluminum hydroxide, aluminum phosphate, or aluminum potassium sulfate—is a substance added to a vaccine to increase the body's immune response to the vaccine. One value of adding adjuvant to a vaccine is to reduce the amount of antigen needed to produce a dose of vaccine. Vaccines with adjuvants are rigorously tested for safety before being licensed. In the United States, vaccines against measles, mumps, rubella, chickenpox, rotavirus, polio, and seasonal influenza do *not* contain adjuvants.

Regardless of the composition of the vaccine, each vaccine is designed to stimulate an immune response against a specific pathogen. Some vaccines require booster doses to maintain sufficient immunity. The immune system's memory responds rapidly to prevent disease when exposed to a booster, which provides an active albeit artificially acquired immunity.

Vaccine-Preventable Diseases

Vaccinations maintain health by preventing disease. In the United States, more than 20 infectious diseases may be prevented by active vaccination. Many of these vaccines are routinely administered to healthy children and adults. Others are reserved for special populations such as health care providers, military personnel, immigrants, adults with special health needs, the chronically ill, and travelers to certain foreign countries. Table 31.1 provides an overview of the disease manifestations and vaccine information, including route of administration and storage temperature. Vaccine-preventable diseases for children, adolescents, and adults include—but are not limited to—anthrax, diphtheria, *H. influenzae* type B, hepatitis A and B, human papillomavirus, influenza (flu), Japanese encephalitis, measles, meningococcal disease, mumps, pertussis, pneumococcal disease, poliomyelitis, rabies, rotavirus, rubella, smallpox, tetanus, tuberculosis (TB), typhoid, varicella, yellow fever, and herpes zoster.

Vaccination Recommendations

Immunization schedules are approved by the Advisory Committee on Immunizations (ACIP). Each schedule identifies recommended vaccinations, ages to vaccinate, dosage, and route for children, adolescents, and adults. For the most current information on childhood immunizations, consult the Centers for Disease Control and Prevention (CDC) website at www.cdc.gov/vaccines. A vaccine information statement (VIS) is also produced by the CDC for each vaccine, and provides information on the (1) route of administration, (2) schedule for routine vaccine administration, (3) minimum dosing intervals, (4) contraindications, and (5) standing orders for administering vaccines.

The childhood immunization schedule from birth to 6 years recommends HepB, RV, DTaP, Hib, PCV, inactivated polio virus (IPV), MMR, varicella, and HepA. Before immunizations are administered, screen for medical conditions that put the child at risk, use of prescription and over-the-counter (OTC) drugs to include herbal preparations, and any food or drug allergies (Complementary and Alternative Therapies 31.1).

The adolescent immunization schedule from ages 7 to 18 years recommends Tdap, influenza, HPV, and meningococcal vaccinations. Adolescents may also need to catch up on any vaccines missed, such as MMR, HepA, HepB, IPV, and varicella (chickenpox).

A catch-up immunization schedule is available for those up to 18 years of age who fall behind or start late with immunizations. Childhood and adolescent immunization schedules are also available as a combined schedule (birth to 18 years).

Adult (19 years and older) vaccination rates remain low, which indicates a need to improve. One way is to increase awareness that routine vaccines for adults are important for well-being, to provide information on how vaccines protect from diseases, and to assess immunization status during clinical visits. Adult vaccines are based on factors such as age and health status and include Tdap, tetanus-diphtheria (Td) booster, influenza, pneumococcal polysaccharide vaccine (PPSV23), HPV, MMR, varicella vaccine (chickenpox), and zoster vaccine (shingles). In certain situations, adults may also be immunized with certain additional vaccines, including HepA, HepB, smallpox (2016 update: routine for lab personnel handling vaccine cultures), and meningococcal vaccine. Current recommendations for adult immunization can be found at www.cdc.gov/vaccines/schedules/.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 31.1 Vaccines

Although patients should always be asked about their use of prescription drugs, OTC drugs, and complementary and alternative therapies, there are no known interactions between vaccinations and herbal preparations.

Patient Safety

Do not confuse…

- Hepatitis A, inactivated/hepatitis B (recombinant) vaccine provides active immunity against both hepititis A virus (HAV) and hepititis B virus (HBV) for adults >18 years of age who are at high risk for HAV and HBV.
- There are different types of **meningococcal vaccine**: MCV4 or MenACWY (conjugate; administered to pre-teens 11 to 12 years old), MenB (serogroup B; administered to teens and young adults ages 16 to 23), and MPSV4 (polysaccharide; for adults ≥56 who require a single dose [traveling or at risk due to community outbreak]).
- HepA and HepB vaccines are *dosed differently* for children, adolescents, and adults.
- Do not confuse HepB *vaccine* and HepB *immunoglobulin*.
- **Zoster vaccine,** a vaccine administered to adults to prevent shingles, and **varicella vaccine,** which prevents chickenpox and is approved for use in susceptible children and adults.
- **DTaP**, for active immunization in children 6 weeks to 6 years, and **Tdap,** the active booster

for those aged 10 years and older; antigens in both are the same, but the amount of antigen component varies.

TABLE 31.1
Vaccine-Preventable Diseases

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Anthrax, subcut 2°-8°C Do not freeze Pregnancy category: D*	*Cutaneous:* An itchy sore that may blister and form a black ulcer (eschar). The sore is usually painless but may have surrounding edema. *Gastrointestinal:* Abdominal pain, vomiting, mouth sores, bloody diarrhea, toxemia, shock, and possibly death *Inhaled,* wool sorter's disease or associated with the use of biologic warfare: Fever, malaise, headache, cough, shortness of breath, and chest pain (due to bleeding and swelling in chest cavity) are often followed by shock within 36 hours of symptom onset due to bacteremia.	Routine vaccinations are not recommended but are administered to specific groups: laboratory workers who work with anthrax; people who handle animals or animal products, such as some veterinarians; some members of the U.S. military. These persons sould receive 5 shots over 18 months with annual boosters. When used as postexposure prophylaxis, the vaccine is given as a three-dose series, administered at 0, 2, and 4 weeks after exposure, along with 60 days of antibiotic therapy (ciprofloxacin and doxycycline).
Diphtheria, IM (diphtheria toxoids) 35°-46°F (2°-8°C) Do not freeze Pregnancy category: C*	Respiratory infection, blocked airway, myocardial damage, nerve damage, sore throat, weakness, swollen glands	Toxoid A single-antigen toxoid is not available. Currently combined as DTaP, Tdap, DT, and Td. DTaP is used for active immunity in those 6 wk to 6 y. Tdap (active booster) is given as a single dose for those 10 years and older.
Haemophilus influenzae type B (Hib), IM 35°-46°F (2°-8°C) Do not freeze Pregnancy category: C*	Sepsis, arthritis, skin and throat infections, meningitis, intellectual disability, epiglottitis, pneumonia, and death Increased severity is seen in those younger than 5 y and older than 65 y.	Bacterial conjugate is contained in Hib vaccine. There are different types of influenza; Hib is specific to influenza B. Not all influenza bacteria have vaccines.
Hepatitis A virus (HAV), IM 36°-46°F (2°-8°C) Do not freeze Pregnancy category: C*	Fever; can cause liver damage or failure, malaise, jaundice, anorexia, nausea, arthralgia, kidney, pancreatic, and blood disorders This acute, self-limited illness is highly contagious.	Inactivated viral antigen is available as HepA vaccine and in HepA/HepB. Routinely administered to children 12-23 mo, high-risk populations, close contacts to persons with HAV, and persons traveling to certain countries. Because it is inactivated, the vaccine can be given to immunocompromised persons.

Table Continued

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Hepatitis B virus (HBV), IM 35°-46°F (2°-8°C) Do not freeze Pregnancy category: C*	Fever, headache, malaise, anorexia, arthralgia, arthritis, jaundice Chronic infection can occur, leading to liver cirrhosis, liver cancer, and death.	Recombinant viral antigen is available as HepB and HepA/HepB vaccines. Vaccines are recommended for at-risk infants, health care personnel, those who share injectable/IV drug needles and equipment, men who have sex with men, those whose sex partners are HBV positive, and those not in a monogamous relationship. HepB vaccine is available as a single dose and as a combined vaccine. Administer monovalent HepB to all infants at birth. Combination HepA-HepB is recommended only for those 18 y and older and for at-risk infants.
Human papillomavirus (HPV; various disease strains), IM 35°-46°F (2°-8°C) Protect from light, and shake well before administering Pregnancy: Administer only if needed	Sexually transmitted and seen as cervical, vaginal, anal, and oropharyngeal cancers and genital warts	The HPV vaccine is recommended for preteen boys and girls at age 11 or 12 so they are protected before ever being exposed to the virus. Women and men can receive the HPV vaccine through age 26.
Influenza, IM/ID/IN Inactivated influenza vaccine (IIV) 35°-46°F (2°-8°C): Administer IM/ID Live attenuated influenza vaccine (LAIV) ≤5°F (–15°C): Administer IN Pregnancy category: C*	Fever, chills, headaches, malaise, myalgias, nasal congestion, and cough Can cause pneumonia.	*Trivalent flu vaccine* (influenza A [H1N1 and an H3N2] and influenza B). *Quadravalent flu vaccine* (2 influenza A and 2 influenza B). Everyone 6 months and older should have the flu vaccine annually, particularly those at high risk. Those who should NOT receive the flu shot include infants <6 months old, those with allergies to the flu vaccine or any of its components, those with allergies to eggs, and those with or who have recovered from Guillain-Barré syndrome. The IN flu vaccine should not be administered to children <2 y or adults >50 y, or children >2 or <17 y receiving aspirin-containing therapy or with asthma.
Japanese encephalitis, subcut Keep at 35°-46°F (2°-8°C) before and after reconstitution Pregnancy category: B*	Headache, vomiting, fever, myalgias, confusion, encephalitis, and possible death	Inactivated virus is given to travelers going to some Asian locations.

Table Continued

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Measles, subcut (rubeola) 35°-46°F (2°-8°C) or colder; may be frozen Protect from light, and discard after 8 hours Pregnancy category: C*	Rash, fever, cough, nasal congestion, conjunctivitis, pneumonia Occasionally results in encephalitis	Live virus is contained in measles, MMR and MMRV vaccines. ❗ Contraindicated in pregnancy
Meningococcal disease, subcut/IM 35°-46°F (2°-8°C) Groups A, C, W, Y Meningococcal *Haemophilus influenzae* type b conjugate vaccine Pregnancy category: C*	Fever, sepsis, rash, meningitis	Meningococcal conjugate vaccines MenACWY: quadrivalent (protects against serogroups A, C, W, and Y). Recommended for children 2 mo to 10 y who are at increased risk and children/adolescents 11-18 y. First dose is recommended between 11 and 12 y with booster at 16 y. Also for adults following splenectomy, persons working with the pathogen, college freshmen, and military recruits. Meningococcal polysaccharide vaccine (MPSV4): quadrivalent (protects against serogroups A, C, W, and Y) meningococcal vaccine. For adults following splenectomy, persons working with the pathogen, college freshmen, and military recruits. Serogroup B meningococcal vaccine (MenB): monovalent (protects against serogroup B) meningococcal vaccine. Recommended for children/adolescents 10-18 y who are at increased risk.
Mumps, subcut 35°-46°F (2°-8°C), but may be frozen Pregnancy category: C*	Swelling of salivary glands, fever, headache, fatigue, and myalgia Can cause meningitis, encephalitis, inflammation of testicles or ovaries, deafness	Live attenuated virus is contained in MMR and MMRV. ❗ Contraindicated in pregnancy

Table Continued

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Pertussis ("whooping cough"), IM 35°-46°F (2°-8°C) Pregnancy category: C*	Highly contagious Severe coughing spasms; can cause pneumonia, seizures, encephalitis, and death Symptoms are more severe in infants and young children.	Antigenic components of inactivated bacteria (acellular) are contained in the two vaccines that are available, DTap and Tdap.
Pneumococcal disease, IM/subcut 35°-46°F (2°-8°C) Pregnancy category: B*	Ear infections, sinus infections, pneumonia; can cause sepsis, meningitis, and death	Pneumococcal polysaccharide vaccine (PPSV23) protects against 23 types of pneumococcal bacteria (IM/subcut). PPSV23 is recommended for all adults ≥65 y. Immunocompromised patients ≥2 but ≤64 y should also receive PPSV23. Pneumococcal conjugate vaccine (PCV13) protects against 13 types of pneumococcal bacteria (IM). PCV13 is recommended for all children <5 y as a series of 4 injections starting at 2 mo, then 4 mo, 6 mo, and between 12 and 15 mo; adults ≥65 y, and people ≥6 y with certain chronic illnesses should also receive the vaccine.
Poliomyelitis, subcut/IM 35°-46°F (2°-8°C) Pregnancy category: C*	Invades brain and spinal cord; the milder form causes fever, sore throat, nausea, and headaches; the severe form causes paralysis and death.	Children should receive a series of 4 inactive polio vaccine (IPV) injections starting at 2 mo, then at 4 mo, 6-18 mo, and a booster at 4-6 y.
Rabies, IM 35°-46°F (2°-8°C) Pregnancy category: C*	Anxiety, difficulty swallowing, seizures; almost always progresses to death	Administer killed virus to high-risk groups (e.g., veterinarians, animal handlers) and to persons traveling to areas where rabies is common. The pre-exposure schedule for rabies vaccination is three doses, given on the following schedule: 1st dose: prior to potential exposure 2nd dose: 7 days after the first dose 3rd dose: 21 days or 28 days after the second dose
Rotavirus, PO 35°-46°F (2°-8°C) Pregnancy category: C*	Acute gastroenteritis; contagious and may be particularly severe in infants and young children but mild in adults	Two vaccines are available: RV5 is given in 3 doses at ages 2 mo, 4 mo, and 6 mo RV1 is given in 2 doses at ages 2 mo and 4 mo Due to the small increase in cases of intussusception from rotavirus vaccination, health care providers should weigh the potential risks and benefits of administering rotavirus vaccine to infants with a previous history of intussusception.

Table Continued

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Rubella ("German measles"), subcut 35°-46°F (2°-8°C) May be frozen Pregnancy category: C*	Rash, fever, swollen lymph nodes Birth defects occur if rubella is acquired by a pregnant patient.	The rubella vaccine is a live attenuated virus. Recommended vaccination schedule: 1st dose: 12 through 15 mo 2nd dose: 4 through 6 y Contraindicated in pregnancy
Smallpox, percutaneous skin prick of 15 jabs using a steel bifurcated needle 35°-46°F (2°-8°C) Protect from light and use within 6-8 hours after reconstitution, then discard Pregnancy category: C*	High fever, severe headache, backache, abdominal pain, and lethargy that lasts 2-5 days; then an extensive rash develops that begins as macules and progresses to papules; then firm vesicles form; and finally, deep-seated, hard pustules form that cause significant scarring.	Smallpox vaccine (live vaccinia virus) is stockpiled in case of an outbreak and emergency. Immunization program for at-risk lab personnel and health care providers, emergency personnel, military personnel Vaccinate only if exposed to smallpox. Contraindicated in pregnancy; can cause stillbirth. Can cause myocarditis and pericarditis.
Tetanus ("lockjaw"), IM 35°-46°F (2°-8°C) Pregnancy category: C*	Stiffness in neck and abdominal muscles, difficulty swallowing, muscle spasms, fever; can cause broken bones, breathing difficulty, and death	Toxoid conjugate contained in tetanus, DTaP, DT, Tdap, and Td vaccines. Children should receive a series of 5 doses of DTaP vaccine, beginning at 2 mo; then at 4 and 6 mo; then between 15 and 18 mo; and between 4 and 6 y. The Td booster should be given every 10 y.

Table Continued

Disease, Route of Administration, Storage, Pregnancy Category	Manifestations	Vaccine
Tuberculosis (TB), ID (preferred)/subcut 35°-46°F (2°-8°C) Pregnancy category: C*	Highly contagious respiratory infection Symptoms include cough lasting 3 wk or longer, pleuritic chest pain, coughing up blood or sputum, weakness or fatigue, weight loss, anorexia, fever and night sweats. May also cause meningitis and bone, joint, and skin infections	Live attenuated bacteria Called bacille Calmette-Guérin (BCG) Not routinely administered in the United States, it prevents severe disease but does not prevent infection with the bacterium. Should only be considered for children who have a negative tuberculin skin test and who are continually exposed, or for select health care workers.
Typhoid, subcut/PO 35°-46°F (2°-8°C) Pregnancy category: C*	Sustained high fever, headache, anorexia, abdominal pain, enlarged liver and spleen, constipation, and later, diarrhea	Vaccine given in exposure to *Salmonella paratyphi* and *S. typhi B* is available as live attenuated bacteria (Ty21a; PO) or inactivated components of the typhoid bacterial capsule (Vi; subcut). Routine vaccinations are not required in the United States but are recommended for travelers to certain foreign countries.
Varicella (chickenpox), subcut ≤5°F (−15°C) Contraindicated in pregnancy	Fever and rash, consisting of a few to hundreds of itchy, blisterlike lesions; symptoms are more severe in older children and adults. Complications may include encephalitis, bacterial skin infections, pneumonia, Reye syndrome, and death.	Varicella vaccine, live, is recommended as a two-dose series, first at 12-15 mo, then again between 4 and 6 y. Contraindicated in pregnancy
Yellow fever, subcut 35°-46°F (2°-8°C) Pregnancy category: C*	Fever, jaundice, and gastrointestinal hemorrhage	Yellow fever vaccine, live A single primary dose is recommended for persons ≥9 mo traveling to, or living in, areas at risk for yellow fever virus transmission (e.g., South America and Africa). The vaccine is required by international regulations for travel to and from certain countries.
Herpes zoster (shingles), subcut ≤5°F (−15°C) Contraindicated in pregnancy	A painful, blisterlike rash in a dermatomal distribution occurs due to reactivation of varicella virus. Following resolution of the rash, prolonged severe pain (postherpetic neuralgia) may occur.	Herpes zoster vaccine approved by the FDA for people ≥50 y.

DT, Diphtheria-tetanus; *DTaP,* Diphtheria-tetanus–acellular pertussis; FDA, U.S. Food and Drug Administration; *HepA,* hepatitis A; *HepB,* hepatitis B; *ID,* intradermal; *IM,* intramuscular; *IN,* intranasal; *IV,* intravenous; *MMR,* measles-mumps-rubella; *MMRV,* measles-mumps-rubella-varicella; *mo,* months; *PO,* by mouth; *subcut*, subcutaneous; *Td,* tetanus-diphtheria; *Tdap,* tetanus-diphtheria–acellular pertussis; *wk,* weeks; *y,* years; >, greater than; ≥, greater than or equal to; <, less than; ≤, less than or equal to.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Immunization Before International Travel

International travel warrants the updating of routine vaccines based on age and immunization history, and travelers to some areas should consider additional vaccines. For example, the CDC currently recommends U.S. travelers 6 months and older to have an updated MMR vaccine based on the travel destination.

Travelers may need to consider vaccination against typhoid and yellow fever. Typhoid fever is caused by a bacterium, *Salmonella typhi,* which is generally spread via contaminated food and water (see Table 31.1). Risk of contracting this infection is greatest for travelers to India, Pakistan, Mexico, Bangladesh, the Philippines, and Haiti. Even stays of less than 2 weeks pose significant risk. Two forms of typhoid vaccine are available for use in the United States. Typhoid vaccine live oral contains the Ty21a strain of *S. typhi*, and is a live attenuated vaccine, which can be administered to persons 6 years of age and older and consists of four capsules, one taken every 48 hours, with the series completed 1 week before potential exposure. A booster dose consisting of the same four-capsule regimen is recommended every 5 years. The other vaccine, parenteral typhoid Vi polysaccharide vaccine, is an inactivated vaccine that contains purified cell surface polysaccharide antigens extracted from *S. typhi* of the Ty2 strain, and may be administered to travelers 2 years of age and older. It is administered at least 2 weeks before expected exposure as a single, intramuscular (IM) injection. A booster dose is recommended every 2 years for those who remain at risk.

Yellow fever is a mosquito-borne viral illness endemic to sub-Saharan Africa and tropical South America. The vaccine is administered as a single injection for persons older than 9 months. Boosters are no longer recommended (ACIP and World Health Organization [WHO], 2016) except for persons at risk. In the United States, the vaccine is administered only at authorized vaccine centers throughout the country. Other vaccines needed for travel may include those for meningococcus, rabies, hepatitis A and B, and Japanese encephalitis. Current vaccine recommendations and related travel information, such as with the Zika virus and cholera, are available from the CDC at 1-800-CDC-INFO or www.cdc.gov/travel.

Vaccine Safety: Reporting Diseases and Adverse Reactions

Vaccines are generally safe, although mild reactions include swelling at the injection site and low-grade fever. Awareness of the contraindications for use of vaccines decreases the incidence of serious adverse reactions. Contraindications include moderate or severe illness or **anaphylaxis**, a serious, life-threatening allergic reaction to a specific vaccine or vaccine component. Therefore it is important to review vaccine-specific contraindications prior to administering any vaccine. In general, vaccines may be given in cases of mild acute illness or the convalescent phase of illness, antimicrobial therapy, exposure to infectious disease, or premature birth.

Health care providers are responsible for reporting cases of vaccine-preventable diseases and adverse reactions following immunizations. These data identify whether an outbreak is occurring and assess the impact of immunization policies and procedures. Providers must report adverse reactions to the Vaccine Adverse Events Reporting System (VAERS). Information and forms are available at http://vaers.hhs.gov/index. VAERS is a surveillance system that receives and acts on reports of adverse events. The National Childhood Vaccine Injury Act of 1986 initiated the National Vaccine Injury Compensation Program (NVICP), which provides compensation for injury or death caused by a vaccination. More information is available at www.hrsa.gov/vaccinecompensation. To provide safety through communication, the NVICP requires providers to distribute a VIS before vaccines are administered. Federal law requires health care providers to provide information to those receiving vaccines. These information statements include indications, age recommendations, schedule of doses, side effects, special circumstances, and resources to notify if an adverse reaction occurs. For more information, visit www.cdc.gov/vaccines/hcp/vis.

Varicella Vaccine

Prior to the development of the varicella vaccine in 1995, about 4 million people came down with varicella zoster virus (VZV), resulting in 10,600 hospitalizations and close to 150 deaths per year. Since implementation of the varicella vaccine, cases of VZV have declined over 75%, hospitalizations have declined over 90%, and deaths from VZV have been reduced by 85% or more.

Prototype Drug Chart 31.1 provides the pharmacologic data for varicella vaccine.

Pharmacokinetics

Biologic products such as vaccines do not undergo the pharmacokinetic processes associated with other drug therapy.

Pharmacodynamics

Seroconversion is the acquisition of detectable levels of antibodies in the bloodstream. In the case of varicella vaccine, seroconversion occurs in more than 98% of 12-month-old to 12-year-old recipients approximately 6 weeks after receiving a single dose of vaccine. Susceptible persons 13 years of age and older who receive two doses of varicella vaccine 4 to 8 weeks apart show a seroconversion rate of approximately 75% 4 weeks after the first dose and 99% 4 weeks after the second dose. Despite the high rate of initial seroconversion among children 12 months to 12 years of age, clinical trials have shown that over a 10-year period, the vaccine's effectiveness in preventing disease was 94% for children who received one dose of vaccine and 98% for those who received two doses. Therefore, beginning in 2007, a second dose of varicella vaccine was recommended for all susceptible individuals, including children.

Contraindications

Varicella vaccine should be avoided in patients with a history of previous anaphylaxis to this vaccine or to any of its components, including gelatin and neomycin. It is also contraindicated in the presence of moderate to severe acute illness or active untreated tuberculosis.

PROTOTYPE DRUG CHART 31.1 Varicella Vaccine

Drug Class	Dosage
Vaccine Pregnancy category: C*	0.5 mL subcut × 2 doses First dose: 12-15 mo; second dose: 4-6 y Catch-up initiated any time after 12-15 mo <13 y, space doses at least 3 mo apart ≥13 y, space doses 4-8 wk apart *For varicella prophylaxis for outbreak control of local epidemics of wild-type varicella virus in susceptible persons following varicella exposure,* consult the current recommendations of the CDC (www.cdc.gov/chickenpox/outbreaks.html)
Contraindications	**Drug-Lab-Food Interactions**
Previous anaphylaxis to this vaccine or to any of its components; pregnancy or possibility of pregnancy within 1 mo; immunocompromised vaccine recipient; presence of moderate to severe acute illness; active untreated tuberculosis	Drug: Separate from other live virus vaccines (e.g., MMR, intranasal flu) by 4 wk if not given on the same day; delay VV for up to 11 mo after blood transfusion or Ig; delay Ig for 2 mo after VV, high-dose immunosuppressant medications; avoid salicylates for 6 wk after VV.
Pharmacokinetics	**Pharmacodynamics**
Not applicable	Seroconversion rates: 12 mo-12 y: >98% at 4-6 wk after vaccination ≥13 y: ~75% 4 wk after first dose and 99% 4 wk after second dose
Therapeutic Effects/Uses	
For prevention of chickenpox; when administered to susceptible individuals, vaccine results in complete protection from chickenpox for the majority of persons. For the minority in whom breakthrough chickenpox develops after vaccination, the disease is typically very mild. The vaccine may also provide prophylaxis protection if administered within 3-5 d of exposure to chickenpox. Mode of Action: Stimulates active immunity against natural disease	
Side Effects	**Adverse Reactions**
Pain and redness at injection site, fever, chickenpox-like rash (generalized or confined to area surrounding injection site)	Anaphylaxis, thrombocytopenia, encephalitis, Stevens-Johnson syndrome

CDC, Centers for Disease Control and Prevention; *d*, day; *Ig*, immunoglobulin; *MMR*, measles-mumps-rubella; *mo*, month; *subcut*, subcutaneous; *VV*, varicella vaccine; *wk*, week; *y*, year; <, less than; >, greater than; ≥, greater than or equal to; ~, approximately.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Although varicella infection can cause fetal harm, the possible effects of the vaccine on fetal development are currently unknown. Therefore varicella vaccine is contraindicated during pregnancy. Pregnancy should also be avoided for at least 1 month after each dose of the vaccine. It

is important to note that this recommendation differs from the product package insert, which suggests a 3-month delay in pregnancy.

Patients who are immunocompromised because of malignancies, high-dose systemic steroids, or other immunosuppressive therapy should avoid varicella vaccine. Likewise, the vaccine is generally contraindicated in the presence of primary or acquired immunodeficiencies. However, vaccination may be considered in children with certain classes of human immunodeficiency virus (HIV) infection.

Drug Interactions

Frequently a patient is eligible for several immunizations at a visit. A patient receiving varicella vaccine may receive all other vaccines concurrently as long as each is administered at a separate site. If the MMR or other live virus vaccine is not given the same day as the varicella vaccine, administration of the two vaccines should be separated by at least 4 weeks.

If a patient has received a transfusion of blood or blood products, including Ig, administration of the varicella vaccine will need to be deferred for as long as 11 months. Likewise, such blood products should be avoided for at least 2 months after vaccination if possible. Blood products and Ig interfere with the body's production of antibodies specific to chickenpox, thereby decreasing the likelihood that active immunity will develop.

Reye syndrome has occasionally occurred in children following natural chickenpox infection. The majority of these children were also receiving salicylate medications (e.g., aspirin). Therefore, it is generally recommended that patients avoid salicylates for 6 weeks after vaccination.

Future Developments in Vaccines

A small outbreak of anthrax cases in the United States in 2001 increased the level of awareness of the anthrax vaccine. Anthrax is caused by the bacteria *Bacillus anthracis*. A serious disease, cutaneous anthrax is the most common form (95% of cases). Anthrax can also occur in the gastrointestinal (GI) tract and lungs. As a biologic weapon, anthrax is highly lethal. It is easily produced, stored, and spread over large areas. Proper vaccination is an essential part of protection against this disease. Approved by the Food and Drug Administration (FDA) in 1970, anthrax vaccine adsorbed (AVA) has been routinely and safely administered to laboratory and military personnel, livestock farmers, and veterinarians. The vaccine requires 5 injections over 18 months with annual boosters. No serious side effects have been reported, but the vaccination is contraindicated during pregnancy. In the event of a bioterrorism attack, persons exposed to anthrax should receive 3 doses of vaccine over 4 weeks and be given ciprofloxacin and doxycycline for 60 days to prevent anthrax. Additional information is available at www.cdc.gov/anthrax/medical-care/prevention.html.

Smallpox, caused by the variola virus, is transmitted through human body fluids or contaminated materials. Smallpox was eradicated in the United States by 1972 and worldwide by 1977; therefore the United States discontinued routine childhood immunization against smallpox in 1972.The vaccine is no longer in use, except in persons who have a high risk of exposure. When the vaccine is administered, most people usually have a mild reaction, such as a sore arm, fever, and body aches. However, persons with a weakened immune system may experience more serious side effects, including death. Since the events of September 2001, concern has arisen that smallpox could be used as a bioterrorist weapon. A smallpox immunization response plan is available for outbreaks or emergencies (http://emergency.cdc.gov/agent/smallpox/vaccination/index.asp).

It has long been known that immunity to pertussis, or "whooping cough," weakens over time and that adolescents and adults are often responsible for transmitting this infection to vulnerable, incompletely immunized infants and young children. Although a relatively benign illness in the older population, pertussis in infants is associated with significant morbidity and mortality. Tdap contains tetanus and diphtheria toxoids along with acellular pertussis; these are licensed for use in older children and adults. Tdap may be used as an active booster for people 11 to 64 years of age, and DTaP is approved for use in children 6 weeks to 6 years. Each vaccine contains the same antigens, but the quantities of diphtheria and acellular pertussis vary. It is recommended that for booster immunization, adolescents and adults receive a one-time dose of Tdap in lieu of the Td vaccine.

Herpes zoster, commonly known as *shingles* or *zoster*, occurs as the result of reactivation of the varicella virus. Following a primary varicella infection (chickenpox), the virus persists but becomes dormant in the body, usually settling in a dorsal root ganglion. Zoster often occurs decades after the primary varicella infection. It appears that development of zoster may be related to a decline in immunity to the VZV. Zoster is characterized by a painful rash that presents in a dermatomal distribution. Especially in older adults, resolution of the rash may be followed by a chronic, severe, sometimes debilitating pain, referred to as *postherpetic neuralgia*. A live attenuated vaccine (zoster vaccine, live) is licensed for use as a one-time injection in adults 50 years of age and older. The vaccine has been shown to boost VZV immunity among vaccine recipients. In clinical trials, zoster vaccine prevented zoster in about 50% of people who received the vaccine. Effectiveness appears to decrease with increasing age of the vaccine recipient. In those who received the vaccine yet went on to develop zoster, the duration of pain was reduced.

Rotavirus is a leading cause of severe acute gastroenteritis in infants and young children. Rotavirus vaccine, live oral, containing five strains of rotavirus, is effective in protecting against severe gastroenteritis and significantly reduces the need for hospitalization among infected children. The vaccine is administered as a three-dose series at 2, 4, and 6 months of age. It is recommended that the third dose be administered before 8 months.

HPV is a sexually transmitted virus that causes cancer of the cervix, vagina, vulva, and penis and can cause genital warts. It also causes anal and oropharyngeal cancers in both men and women. There are over 100 different types of this disease. Two vaccines are approved as routine prophylaxis to prevent HPV disease: human papillomavirus quadrivalent vaccine (recombinant) and human papillomavirus 9-valent vaccine (recombinant). HPV quadrivalent vaccine prevents cervical, vulvar

vaginal, and anal cancer caused by HPV types 16 and 18; genital warts caused by HPV types 6 and 11; and precancerous/dysplastic lesions of the cervix, vagina, vulva, and anus caused by HPV types 6, 11, 16, and 18.

HPV 9-valent vaccine (recombinant) is used for prevention of cervical, vaginal, vulvar, and anal cancer caused by HPV types 16, 18, 31, 33, 45, 52 and 58; genital warts caused by HPV types 6 and 11, and precancerous/dysplastic lesions of the cervix, vagina, vulva, and anus caused by HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58.

Both HPV vaccines are administered as a three-dose series to 9- to 26-year-old males and females. The HPV vaccine is contraindicated in pregnancy. The FDA denied Merck's request for expanded use in women 27 to 45 years of age. Because HPV is sexually transmitted, the vaccine is most effective if administered before initiation of sexual intercourse.

The pneumococcal vaccine provides protection against multiple strains of *Streptococcus pneumoniae* (pneumococcus). Pneumococcal disease includes serious infections of the blood, brain, and lungs. Each year in the United States, around 22,000 persons (both children and adults) die from this vaccine-preventable disease. Two forms of the vaccine are available: pneumococcal 23-valent polysaccharide vaccine (PPV) targeting 23 of the most common serotypes, and pneumococcal 13-valent conjugate vaccine (PCV13) targeting 13 serotypes. PPV is indicated in high-risk persons between the ages of 2 and 65 years (e.g., those undergoing splenectomy, cochlear implant, or immunosuppression) and in all persons older than 65 years. PPV should be repeated after 5 years. PCV13 is recommended for all high-risk persons and for all persons older than 65 years. Since initiation of pneumococcal vaccination, the incidence of antibiotic-resistant disease has dropped significantly.

Bacterial meningitis is a potentially life-threatening infection. Annually, over 1000 cases occur in the United States; 10% to 15% of patients die and 1 out of 5 who live have permanent disability, including brain damage, hearing loss, amputations, or loss of kidney function. ACIP recommends routine vaccination to prevent meningococcal infection for those aged 2 to 55 years. The quadrivalent meningococcal conjugate vaccine (MCV4) and meningococcal polysaccharide vaccine (MPSV4) are approved in the United States. MCV4 is preferred for those between the ages of 2 and 55 years; MPSV4 should be used for those over 55 years of age. For those receiving MCV4, the first dose should be given at 11 or 12 years, with a booster at 16 years. For those who receive the first dose between 13 and 15 years, a one-time booster should be given between 16 and 18 years. If the first dose of MCV4 is given after 16 years, a booster is not needed unless the individual remains at high risk (e.g., microbiologists exposed to *Neisseria meningitidis*, military recruits, those traveling outside the U.S., or those with asplenia).

Nursing Process: Patient-Centered Collaborative Care

Vaccines

Assessment

- Identify benefits and barriers to timely and complete immunization (e.g., beliefs that vaccine-preventable diseases no longer exist, misunderstanding of true contraindications to immunization, concerns regarding vaccine safety and efficacy, fear of multiple injections, cost).
- Obtain a medical history, including history of malignancy or other immune deficiency.
- Determine history of pregnancy or possible pregnancy within the next month. Many vaccines are contraindicated during pregnancy.
- Obtain a drug history that includes high-dose immunosuppressants, blood transfusions, and Ig.
- Obtain a list of complementary and alternative therapies used, and in the case of a breastfed infant, include herbal products used by the mother.
- Determine a complete allergy history that includes drugs, vaccines, food, and environmental allergies.
- Assess for adverse reactions (other than allergic) to previous doses of vaccine or any vaccine component.
- Assess for symptoms of moderate to severe acute illness with or without fever.
- Screen for unvaccinated or immunocompromised household contacts at every visit.
- Obtain an immunization history and a history of vaccine-preventable diseases to determine

current vaccine needs. For example, a person with a reliable history of chickenpox or herpes zoster (shingles) does not need the varicella vaccine; natural immunity is assumed.

Nursing Diagnoses

- Knowledge, Deficient about vaccination risks and benefits
- Health Maintenance, Ineffective in adhering to the recommended immunization schedule
- Injury, Risk for due to adverse reactions to immunizations
- Knowledge, Readiness for Enhanced regarding immunization information

Planning

- The patient or the patient's parent or guardian will possess knowledge of vaccine-preventable diseases and risks and benefits of vaccination.
- The patient or the patient's parent or guardian will adhere to the recommended immunization schedule for vaccine-preventable diseases unless contraindications exist.
- The patient will be free of adverse reactions.

Nursing Interventions

- Strictly adhere to individual vaccine storage requirements to ensure potency of the product.
- Upon preparation, including reconstitution of a given vaccine, administer within the time limits stated in the package insert to ensure potency.
- Administer at separate sites all vaccines for which a patient is eligible at the time of the visit. Do *not* mix vaccines in the same syringe.
- Document in a patient's record the vaccination date, route, and site of administration; the vaccine type, manufacturer, lot number, and expiration date; and the name, business address, and title of the person administering the vaccine.
- Observe the patient for signs and symptoms of adverse reactions to vaccines.
- Keep epinephrine readily available for immediate use in case of an anaphylactic reaction.
- Provide the patient with a record of immunizations administered.

Patient Teaching

General

- Discuss vaccine-preventable diseases with the patient and/or the patient's family, including manifestations and risk of contracting the disease.
- Answer all questions regarding vaccine safety, effectiveness, and risk factors in clear, understandable language.
- Advise female patients of childbearing age to avoid pregnancy for 1 month, depending on the vaccines administered.
- Advise patients to avoid contact with immunocompromised persons, depending on the vaccines to be administered.
- Provide the patient or the patient's family with a current VIS, available from the CDC, for each vaccine before its administration as required by federal law.
- Remind the patient or the patient's family to maintain a vaccine immunization record and to bring it to all visits.
- Provide the patient or the patient's family with a return date for the next vaccination(s) based on assessment of the immunization history.

Side Effects

- Discuss common side effects of vaccines, such as injection site soreness, fever, and side effects specific to individual vaccines.
- Offer suggestions for management of common side effects (e.g., cold compresses for injection site soreness, acetaminophen for soreness or fever).
- Advise the patient or the patient's family to contact the health care provider if signs of a serious reaction are noted.

Cultural Considerations

- Modify communications to meet the cultural needs of the patient and the patient's family.
- Use a professional interpreter when necessary.
- Provide the patient and the patient's family with a VIS in the patient's preferred language (available at www.immunize.org).

Evaluation

- Evaluate patient and family understanding of rationale for immunizations.
- Evaluate patient adherence to the recommended immunization schedule.
- Evaluate whether the patient is free from adverse reactions.

Patient Safety

Don't Wait! Vaccinate!

Use the SHARE method (see https://www.cdc.gov/vaccines/hcp/adults/downloads/standards-immz-practice-recommendation.pdf):
Share reasons why the vaccine is right for the patient.
Highlight positive experiences.
Address the patient's questions about the vaccine.
Remind the patient that vaccines protect against diseases.
Explain the costs and consequences of getting the disease.

Critical Thinking Case Study

RR, a 22-year-old college student, is in the wellness clinic with her 3-month-old daughter and her 13-year-old sister. They live with RR's grandmother, who is 68 years old. RR requests immunizations for her daughter and asks if there are any immunizations she and her sister need.
1. RR says her daughter needs her "regular shots." The infant received her first hepatitis B vaccine while in the newborn nursery but has not had any shots since coming home. Against what vaccine-preventable illnesses should the nurse plan to vaccinate this infant today?
2. RR is worried that she will need to start her immunizations over because "she's so far behind." How should the nurse respond to her concern? When would her infant be due for another series of immunizations?
3. Which vaccines is RR's daughter due for today?
4. RR reports she is afraid the baby will have a reaction. Compare the mild side effects with the more severe allergic reactions. What is the best way of allaying RR's fears?
5. The nurse asks RR about her vaccine history. RR says she had her "baby shots" a long time ago but did not keep her personal vaccine record; however, she remembers receiving a flu shot 2 years ago. What immunizations will she need at this point? How can she best keep track of her immunizations?
6. RR informs the nurse that she is a college freshman and just received an email informing her that there is a campus-wide meningitis outbreak. She doesn't live on campus and asks the nurse if she needs a meningitis shot anyway. Identify the manifestations of this vaccine-preventable disease.
7. After administering RR's meningitis vaccine, RR's 13-year-old sister mentions that she heard that high school students should get a vaccination for human papillomavirus (HPV). She wants to know if she should get one or if it is too late. Who is eligible to receive the HPV vaccine, and what assessment questions would the nurse ask? What type and dosage of vaccine would the nurse administer?
8. RR appears relaxed and comfortable during the visit. However, she states that she is worried about her grandmother's health because her grandmother has diabetes and high blood pressure. RR wants to know if her grandmother should get any immunizations or if those would just make her sick. Identify which vaccine-preventable diseases and vaccines should be given.
9. After the visit, how does the nurse ensure that the vaccines were safely administered?

NCLEX Study Questions

1. The father of a 4-month-old infant calls in to the clinic reporting that his child is having a reaction to immunizations. What is the most important piece of information the nurse should elicit?
   a. The time the immunization was received
   b. Whether the father has given the infant any acetaminophen
   c. The signs and symptoms the infant is experiencing
   d. The sites used to administer the immunizations
2. The nurse is preparing to administer varicella vaccine to a young woman. Which of the following findings has the greatest implication for this young woman's care?
   a. The patient tells the nurse she is "deathly afraid of needles."
   b. The medical record indicates that the patient is allergic to eggs.
   c. The medical history indicates that the patient had leukemia as a young child.
   d. The patient appears to be pregnant.
3. A 38-year-old migrant farm worker is seen in the clinic with a cut to his arm from an old metal drum. The patient has sutures placed, and a tetanus, diphtheria, and acellular pertussis vaccine is given. What is the nurse's most important action after the vaccine has been administered?
   a. The nurse provides the patient with a vaccine information statement about the tetanus, diphtheria, and acellular pertussis vaccine in the patient's primary language.
   b. The nurse determines the exact date of the patient's last tetanus booster.
   c. The nurse documents that the patient did not experience any side effects immediately following immunization.
   d. The nurse provides the patient with a record of the immunization administered at the visit.
4. The nurse is preparing to administer routine, recommended immunizations to an immunocompromised 1-year-old child. What is the most important information to know prior to administering a vaccination?
   a. The type of vaccine to be administered to the child
   b. The child presents with a temperature of 99.8°F.
   c. The child's vaccine report shows immunizations were received on time.
   d. The child did not experience adverse reactions to prior immunizations.
5. A 14-year-old girl requests a vaccination for human papillomavirus. After the nurse administers the first dose, which of the following is important to include in the patient's teaching?
   a. Human papillomavirus prevents all sexually transmitted diseases.
   b. Pap smears are no longer needed after the human papillomavirus vaccination.
   c. The patient needs to notify the health care provider about pain at the injection site.
   d. The date the patient needs to return to the clinic for the next human papillomavirus dose
6. An 18-month-old child is accompanied to the clinic by her grandmother, the child's legal guardian. The grandmother reports that the child is due for her fourth diphtheria, tetanus, and acellular pertussis vaccination. The nurse determines that the child should *not* receive the diphtheria, tetanus, and acellular pertussis vaccine that day for which reason?
   a. The child received a varicella vaccine 2 weeks ago.
   b. The grandmother is receiving chemotherapy.
   c. The third diphtheria, tetanus, and acellular pertussis dose was administered 4 months ago.
   d. The nurse sees that the child has a runny nose during the visit.
7. Which of the following patients would be eligible to receive the influenza vaccine?
   a. The patient who is taking care of her son with human immunodeficiency virus
   b. The patient who is pregnant
   c. The patient with an egg allergy

d. The child who is 18 months old

8. With the help of an interpreter, the nurse has just immunized a 35-year-old woman with the tetanus, diphtheria, and acellular pertussis vaccine and the vaccine against measles, mumps, and rubella. It is essential that the nurse proceed with which action(s)? (Select all that apply.)

a. Provide a vaccine information statement in the patient's preferred language for each vaccine received.

b. Document in the patient's record the date; site and route of administration; vaccine type, manufacturer, lot number, and expiration date; and the name, business address, and title of the person administering the vaccine.

c. Administer a dose of ibuprofen to prevent postimmunization fever.

d. Instruct the patient to call about any injection site soreness.

Answers: 1, c; 2, d; 3, a; 4, a; 5, d; 6, c; 7, d; 8, a, b.

UNIT X
Antineoplastics and Biologic Response Modifiers

OUTLINE

Introduction
32. Anticancer Drugs
33. Targeted Therapies to Treat Cancer
34. Biologic Response Modifiers

Introduction

The development of cancer is a multistep process that is influenced by the environment (e.g., chemicals, radiation); genetics (e.g., genetic mutations); lifestyle factors (e.g., smoking, alcohol use); diet (e.g., high fat); infection (e.g., Epstein-Barr virus, *Helicobacter pylori,* human papillomavirus [HPV]); and the immune system (e.g., human immunodeficiency virus [HIV] infection, immunosuppressive drugs). It must be remembered that *tumor* and *cancer* are not synonyms. Tumors are a collection of unstructured new cells and are benign—that is, they have no known physiologic function—and they will not invade other unrelated tissues or organs. Cancer, or malignant cells, has the potential to invade or spread to other parts of the body (metastasis); and is further characterized by unregulated growth and poor differentiation.

The Cell Cycle

All cells progress through a distinct cycle that consists of five phases, four of which are directed toward cell replication and a fifth phase in which the cell stops dividing. The first phase of the cell cycle is called *gap 1* (G_1), and it is the presynthesis phase that produces ribonucleic acid (RNA), protein, and the enzymes necessary to synthesize deoxyribonucleic acid (DNA). The second phase is the *synthesis* (S) phase, in which DNA synthesis and replication occur. Next is the *gap 2* (G_2), the postsynthesis phase, in which the cell continues to grow and prepares for mitosis. Cell division (cytokinesis) of daughter cells occurs in the fourth, or *mitosis* (M), phase. The last phase, *gap 0* (G_0), is a dormant phase.

Most cells in the human body are in the G_0 stage. Exceptions include metabolically active cells (e.g., granulocytes) and epithelial cells. As each cell moves through the cell cycle, it must pass a number of checkpoints before it can progress to the next phase. At these **checkpoints**, cells deemed defective undergo **apoptosis** (self-destruction). The cell cycle is illustrated in Fig. X.1. The cell cycles of normal cells are similar to those of cancer cells with the exception that cancer cells ignore signals at the various checkpoints of the cell cycle to stop dividing, to specialize, or to undergo apoptosis.

Growth Rate

Growth rate, also called *doubling time,* is defined as the time it takes for a tumor to double in size. **Growth fraction,** the percent of actively dividing cells, decreases as the tumor enlarges, and doubling time increases. Growth rate depends on several factors, including the cell-cycle activity of the proliferating cells in the tumor mass, the number of cells proliferating within the tumor (*growth fraction*), and the rate of cell loss from the tumor. In general, anticancer drugs are more effective against cancer cells that have a high growth fraction. Anticancer drugs interfere with cell replication and thereby interfere with the growth of cancer cells. Malignant tumors that have prolonged cell cycles and a slower growth rate are more likely to be locally confined and therefore are more amenable to surgical excision.

Anticancer Therapy

Chemotherapy is the use of chemicals to kill cancer cells. Research has led to the use of new anticancer drugs and to the development of standard treatment protocols (drug, dose, and schedule) to guide therapy. Nurses play a vital role in managing the treatment of patients with cancer. This includes the administration of chemotherapy in health care facilities (inpatient treatment) and in the homes of clients (outpatient treatment). To provide the best possible care, nurses should understand the chemotherapy regimen, contraindications, drug interactions, therapeutic effects, side effects, and adverse reactions of the chemotherapy that clients receive.

Chapter 32 provides information on selected anticancer drugs and how they inhibit cellular replication or prevent cellular reproduction. The anticancer drugs are divided into major classes that include alkylating drugs, antimetabolites, antitumor antibiotics, plant alkaloids, immunomodulators, liposomal drugs, and hormonal drugs.

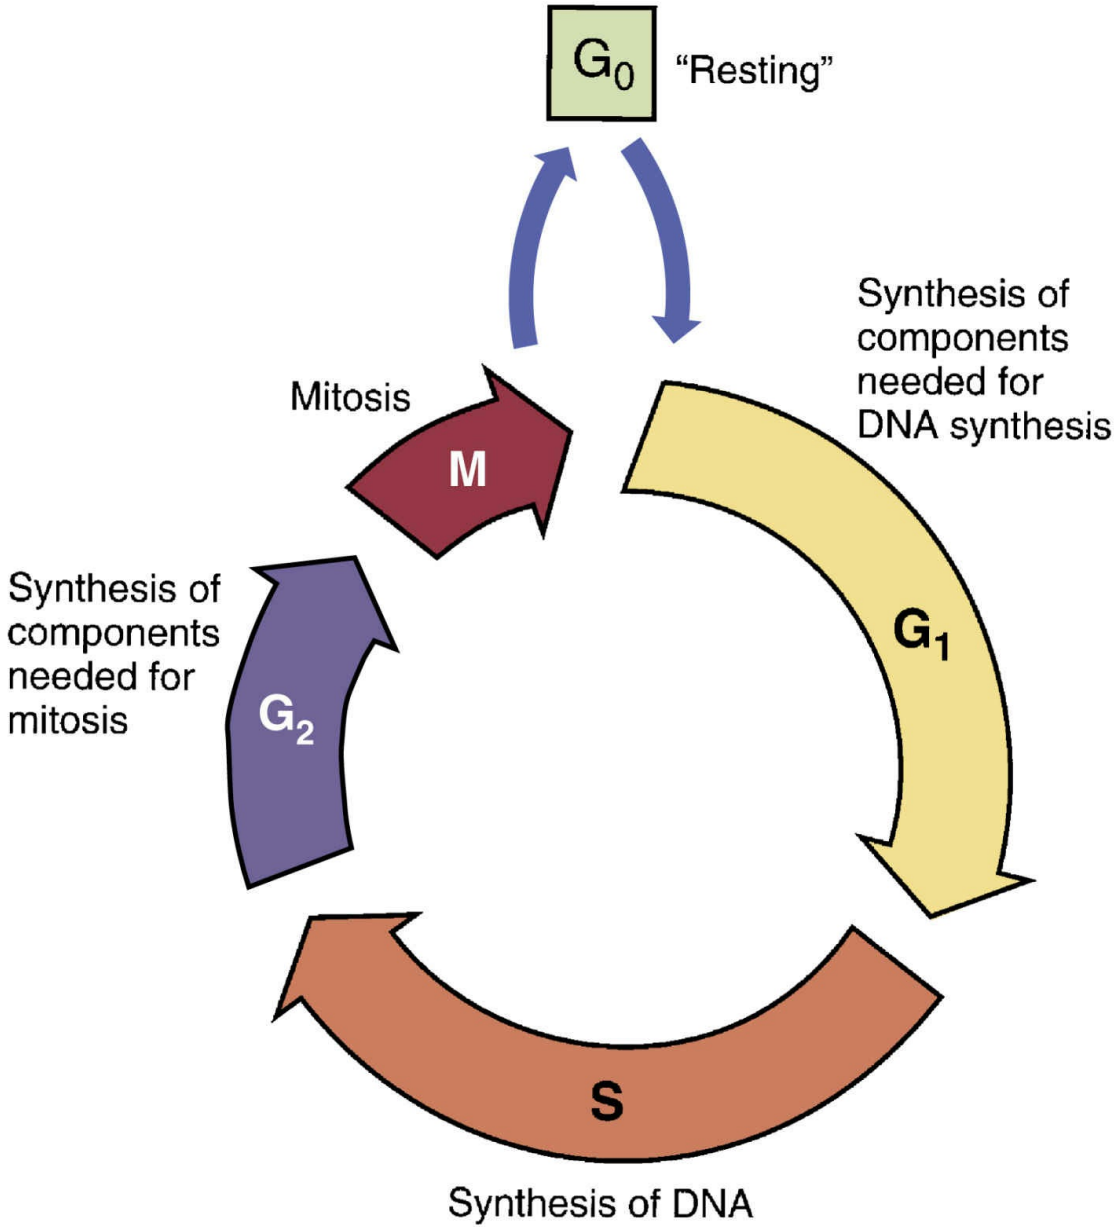

FIG. X.1 Cell cycle *G1 phase* (postmitotic gap): Production of RNA, protein, and enzymes for DNA synthesis; the G_1 phase lasts 15 to 18 hours. *S phase* (synthesis): All the components of DNA are synthesized, and the cells have doubled; the S phase lasts 10 to 20 hours. *G2 phase* (premitotic gap): The cell continues to grow and ensures it is not defective; the G_2 phase lasts approximately 3 hours. *M phase* (mitosis): Cell growth has stopped, and the cell divides into two identical (daughter) cells; the M phase lasts approximately 1 hour. *G0 phase* (resting): Cells remain in this phase and leave the cell cycle or return to the cell cycle for cell replication. Cells in this phase are not as sensitive to many antineoplastic drugs. The cells must pass through a series of checkpoints to continue through the cycle. Defective cells undergo apoptosis (self-destruction). From Burcham, J., & Rosenthal, L. (2016). *Lehne's pharmacology for nursing care* (9th ed.). St Louis: Elsevier.

Some chemotherapy agents negatively affect cancer cells when they are actively dividing. These are called *cell cycle–specific (CCS)* drugs. *Cell cycle–nonspecific (CCNS)* drugs work in any phase of the cell cycle, including in the G_0 (resting) phase. Chemotherapy usually targets RNA or DNA in cancer cells to prevent mitosis or to induce apoptosis. The specific drugs are selected based on the cancer cell type, the rate at which cancer cells divide, and the point in the cell cycle at which the drugs will be most effective. In general, chemotherapy is most effective in destroying cells that are rapidly dividing.

Chapter 33 explores targeted therapies to treat cancer. This modality targets malignant cells, and targeted therapies work by interfering with cancer cell growth and division in different ways and at

various points in its development, growth, and spread.

Chapter 34 describes the evolving state of biologic response modifiers (BRMs) that work to (1) enhance host immunologic function, (2) destroy or interfere with tumor activities, and (3) promote differentiation of stem cells.

Critical Thinking Case Study
NCLEX Study Questions

OBJECTIVES

- Discuss ways the nurse can avoid exposure to anticancer drugs.
- Differentiate between cell cycle–specific and cell cycle–nonspecific anticancer drugs.
- Compare the uses and considerations for alkylating compounds, antimetabolites, antitumor antibiotics, hormones, and biotherapy agents.
- Prioritize appropriate nursing interventions to use while patients receive anticancer drugs.
- Develop a focused teaching plan on the uses and side effects of anticancer drugs.

KEY TERMS

adjuvant therapy, p. 447
alkylating drugs, p. 450
anthracycline, p. 459
antimetabolites, p. 454

Cancer-related deaths rank second only to heart disease in the United States. Even though cancer-related mortality has decreased since the early 1990s, approximately 1 in 3 women and 1 in 2 men are projected to develop cancer over their lifetime. Excluding basal and squamous cell skin cancers, the highest incidence rates in men are prostate, lung, and colorectal cancer. In women, breast, lung, and colorectal cancers occur with the highest frequency. Lung cancer remains the leading cause of cancer-related death regardless of gender.

The incidences and mortality rates of cancer differ by ethnicity. Non-Hispanic blacks (henceforth "African Americans") have higher incidences (except breast cancer) and higher death rates from cancer (except breast and lung) than any racial or ethnic group. African American women have lower incidences of breast cancer but higher mortality rates than Caucasian women do. Hispanics have the lowest incidences and mortality rates of lung cancer. Incidences and mortality rates for liver and stomach cancers due to hepatitis B virus (HBV) and *Helicobacter pylori* (*H. pylori*) are the highest among Asians and Pacific Islanders. Incidences of cancer increase among all immigrants as they adopt a more westernized lifestyle.

Cancer is a group of diseases in which abnormal cells grow out of control and can spread to other areas of the body. DNA is the genetic substance in the body cells that transfers information necessary for the production of enzymes and protein synthesis. In most cases, cancer is caused by damage to the DNA within the cell. Although some cancers are inherited, most develop when genes in a normal cell become damaged or lost. More than one mutation is required before a malignancy can develop, therefore the development of cancer is a multistep process that may take years to complete.

Pharmaceuticals are often used to destroy cancer cells and are called by different names, including *anticancer drugs, cancer chemotherapeutic agents,* **antineoplastic drugs**, or **cytotoxic therapy**. In the 1970s, **combination chemotherapy**—the use of two or more chemotherapy agents to treat cancer—was adopted and led to improved response rates and increased survival times. Chemotherapy may be used as the only treatment of cancer, or it may be used in conjunction with other modalities such as radiation, surgery, and biologic response modifiers. Combination chemotherapy increases the chance for months to years of cancer remission. If cancer can no longer be controlled, palliative treatment with chemotherapy may be used to relieve disease-related symptoms and improve quality of life.

Genetic, Inflammatory, Infective, Environmental, and Dietary Influences

Cancer can be influenced by genetic mutations, inflammation, infectious organisms, environment, and an unhealthy diet. Box 32.1 gives examples of environmental substances, viruses, and foods that have a carcinogenic effect in humans. Genes provide the instructions for the production and function of cellular proteins essential for normal cellular activities. Genetic defects may occur in a variety of ways, including deletion, translocation, duplication, inversion, or insertion of genetic material. When defects cannot be effectively repaired, cells exhibit abnormal characteristics and unregulated growth. More than 2000 genes have been causally implicated in the formation of cancer. Cancers with a proven genetic influence include breast, ovarian, prostate, endometrial, colon, pancreatic, and lung cancers; retinoblastoma; and malignant melanoma, to name a few. Many more genetic influences are expected to be found as cancer research continues.

Genes can cause cells to become cancerous in several ways. **Proto-oncogenes** are normal genes involved in cell differentiation and division, and they regulate cell death, also known as **apoptosis**. These processes are necessary for healthy tissues and organs. An **oncogene** is a mutation in a proto-oncogene that affects cellular growth-control proteins and triggers unregulated cell division. Some genes, called **antioncogenes**, protect others. One such gene is the tumor-suppressor (TS) genes that signal a cell to cease multiplying and stop the action of oncogenes. Uncontrollable cell growth can occur if TS genes become lost or dysfunctional. Other genes repair damage to DNA. If these DNA-repair genes are damaged, mutations are not corrected and are subsequently passed on to the next generation of daughter cells. These and other gene mutations can take place over a long time before cancer develops. As a result, cancers more commonly occur in older individuals.

Inflammation is a normal physiologic process to heal injured tissues. Chronic inflammation, such as chronic inflammatory bowel disease, is an ongoing inflammatory process. The continued inflammation can lead to DNA damage and can result in cancer.

A number of viruses are associated with the development of cancer. The human papillomavirus (HPV) has been found in most women with invasive cervical cancer. Individuals with human immunodeficiency virus (HIV) may develop lymphomas and rectal or genital cancers. The Epstein-Barr virus (EBV) is found in almost all people with Burkitt lymphoma in central Africa and has been implicated in the development of nasopharyngeal cancer. Hepatocellular carcinoma (liver cancer) is linked to hepatitis B and C viruses. Other viruses linked to cancer include human T-cell lymphotropic virus (HTLV) and Kaposi sarcoma–associated herpesvirus.

Bacteria can play a role in the development of cancer. The presence of *H. pylori* in the stomach is associated with an increased risk of gastric cancer. Some reports have indicated a link between certain bacteria and cancer of the gallbladder, colon, and lung. However, no clear evidence supports a link between bacterial infection and other cancers.

BOX 32.1 Environmental, Infective, and Dietary Influences on Cancer Development

Environmental

Tobacco
Gastric cancers and cancer of the bladder, cervix, colon, esophagus, head and neck, kidney and ureter, liver, lung, pancreas, trachea and bronchus, and acute myeloid leukemia

Asbestos
Lung cancer

Benzene
Acute myelogenous leukemia

Formaldehyde
Cancer of the nose, throat, and trachea

Vinyl Chloride
Sarcoma, leukemia

Arsenic
Cancer of the lung and skin, sarcoma

Ionizing Radiation
Leukemia; cancer of the thyroid, breast

Ultraviolet Rays
Skin cancer

Aflatoxin
Liver cancer

Infective

Herpes Simplex 2 Virus (Genital Herpes)
Cervical and penile cancer

Hepatitis B and C Viruses
Cancer of the liver

Epstein-Barr Virus
Non-Hodgkin lymphoma, Hodgkin disease, nasopharyngeal cancers

Human Papillomavirus (HPV)
Cancer of the cervix, vulva, vagina, anus, penis, head and neck

Human Immunodeficiency Virus (HIV)
Kaposi sarcoma, non-Hodgkin lymphoma, cervical cancer

Human T-Cell Lymphotropic Virus
T-cell leukemia

Helicobacter pylori
Cancer of the stomach, gastric mucosa-associated lymphoid tissue (MALT) lymphoma

Diet

Animal Fat
Cancer of the colon, rectum, breast, uterus, prostate, ovary

Heterocyclic Amines (found in some smoked meats)
Cancer of the stomach, colon, rectum, pancreas, breast

Alcohol
Cancer of the mouth, throat, esophagus, liver, breast

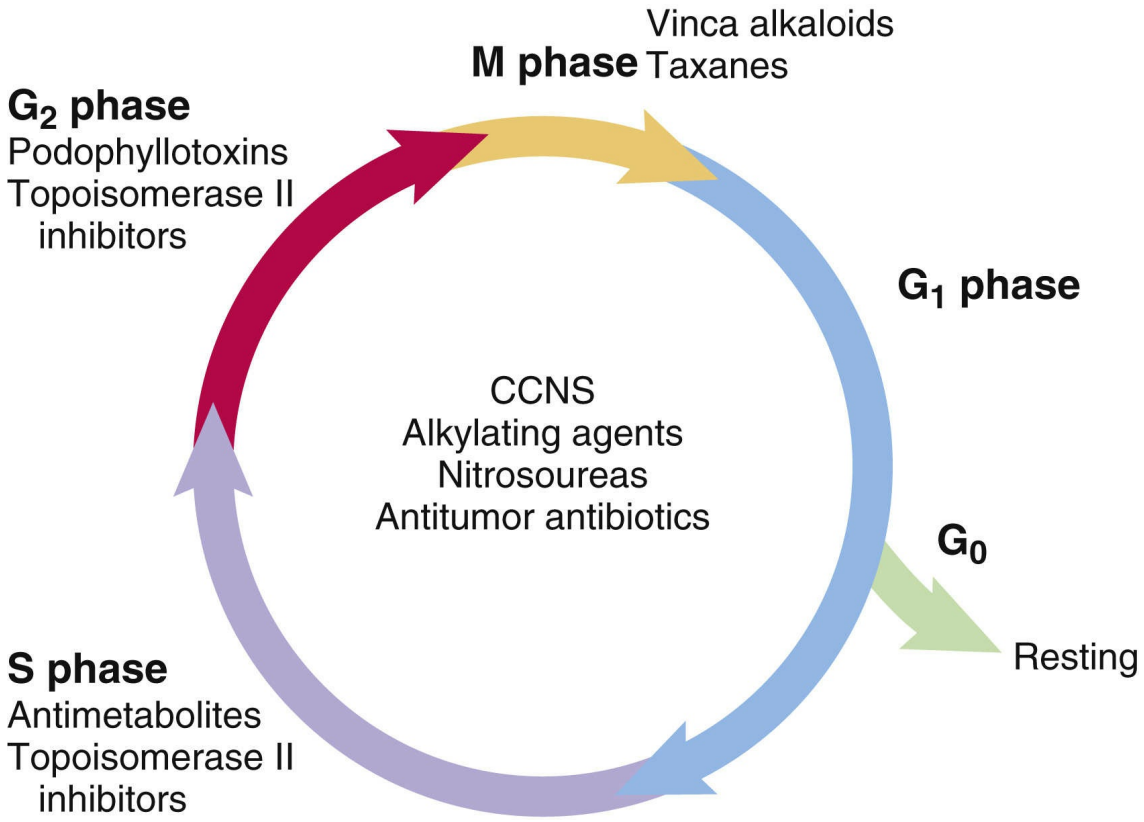

FIG. 32.1 Selected anticancer drugs and the phases of the cell cycle in which they are most effective. *CCNS*, cell cycle nonspecific.

Environmental factors associated with the development of cancer include tobacco use, poor diet, decreased physical activity, chemicals, and excessive sun and radiation exposures. According to the Centers for Disease Control and Prevention (CDC), 90% of lung cancers in men and 80% in women occur due to smoking. Other cancer-causing environmental agents include alcohol consumption on a regular basis, which raises the risk of mouth, larynx, and throat cancers; being overweight or obese, which increases the risk of uterine, breast, prostate, and colorectal cancers; and excessive exposure to sun and other forms of ultraviolet (UV) rays, which promotes skin cancers. Many of these cancers can be prevented. According to the American Cancer Society (ACS), about 43,840 people were expected to succumb to cancer during the year 2015.

Cell Cycle–Nonspecific and Cell Cycle–Specific Anticancer Drugs

The cell cycle for normal and cancer cells and the growth fraction and doubling time are discussed in the opening pages for Unit X (see Fig. 32.1).

Anticancer drugs stop or slow the growth of cancer cells by interfering with cell replication and are classified according to their action. **Cell cycle–nonspecific (CCNS) drugs** act during any phase of the cell cycle, including the G_0 phase. CCNS drugs include most alkylating drugs, antitumor antibiotics, and hormones. **Cell cycle–specific (CCS) drugs** exert their influence during a specific phase of the cell cycle and are most effective against rapidly growing cancer cells. The CCS drugs include antimetabolites, some alkylating agents, and vinca alkaloids. Fig. 32.1 shows selected categories of anticancer drugs and the phase of the cell cycle in which they are most effective.

Growth fraction and **doubling time** are two factors that play a major role in how the cancer cells respond to anticancer drugs. Anticancer drugs are more effective against neoplastic cells that have a high growth fraction. Leukemia and some lymphomas have high growth fractions and thus respond well to anticancer drug therapy.

Solid tumors have a large percentage of their cell mass in the G_0 phase, thus they generally have a low growth fraction and are less sensitive to anticancer drugs. As the tumor grows, the blood supply decreases, thereby slowing the growth rate. High-dose chemotherapy results in better tumor-killing (tumoricidal) effects. Depending on the type of cancer, malignant cell growth is usually faster in the earlier stages of tumor development. Adequate vascularization is needed for the anticancer drugs to be effective. Anticancer drugs are more effective against small, fast-growing tumors with sufficient blood supply. The vascularization in solid tumors can be inconsistent. Some areas of tumor may have an adequate blood supply, whereas other areas are poorly perfused. This characteristic may make some large tumors resistant to anticancer drugs and therefore difficult to treat.

Cancer Chemotherapy

Anticancer drugs do not affect just cancer cells; instead, the drugs affect both cancer and normal cells. The side effects of chemotherapy are largely related to the toxic effects on normal cells. Normal cells are able to repair themselves and continue to grow, thus the side effects of chemotherapeutic agents are often temporary. Chemotherapy is usually administered systemically for cancer that has spread to other parts of the body, for cancers in multiple sites, or for cancers too large to be removed by other means (e.g., surgery). The most common route of chemotherapy administration is through intravenous (IV) infusion, although other routes may be used and include oral, intramuscular, subcutaneous, intraperitoneal, intraventricular (intrathecal), intrapleural, intravesicular, intraarterial, and topical routes.

Some types of cancer can be cured with chemotherapy (e.g., Hodgkin disease, Burkitt lymphoma, and testicular cancer). Other types of cancer (e.g., breast and colon cancer) may be treated with surgery first, followed by chemotherapy to eliminate any residual cancer cells (microscopic metastases) that may remain in the body. This is referred to as **adjuvant therapy**. Sometimes **neoadjuvant chemotherapy** may be given first to help shrink a large tumor, so that it can be surgically removed. **Palliative chemotherapy**, used to relieve symptoms associated with advanced disease (e.g., pain and shortness of breath), can improve quality of life.

Chemotherapy administration is guided by specific **protocols** based on the results of controlled research studies. The length of treatment is determined by the type and extent of the malignancy, the type of chemotherapy given, expected side effects of the drugs, and the amount of time that normal cells need to recover. Chemotherapy is usually given in cycles to improve the likelihood that cancer cells will be destroyed and that normal cells can recover. The duration, frequency, and number of chemotherapy cycles are based on the cancer type and size, the spread of the disease to other areas of the body (**metastasis**), and the condition of the patient. Chemotherapy treatment may consist of one drug or a combination of drugs. Combination chemotherapy may be administered in one day or may be spread out over several days. The duration of treatment is based on the protocol being followed; it can vary from minutes to days and may be repeated weekly, biweekly, or monthly. Selected anticancer drugs are listed in Box 32.2 according to classification.

Combination Chemotherapy

Single-agent drug therapy is not usually used to treat cancer because combination therapy with two or more anticancer drugs has demonstrated more effective tumoricidal activity. Combination therapy increases the likelihood of affecting cancer cells in all phases of the cell cycle.

BOX 32.2 Anticancer Drugs by Classification*

Alkylating Agents

Nitrogen Mustard Gas Derivatives

Bendamustine
- Chlorambucil
- Cyclophosphamide
- Estramustine
- Ifosfamide
- Mechlorethamine hydrochloride
- Melphalan

Nitrosoureas

Carmustine (bis-chloroethylnitrosourea [BCNU])
- Lomustine (1-[2-chloroethyl]-3-cyclohexyl-1-nitrosourea [CCNU])
- Streptozocin

Alkyl Sulfonates

Busulfan

Alkylating-Like Agents
Altretamine
- Carboplatin
- Cisplatin
- Dacarbazine
- Oxaliplatin

Antimetabolites

Folic Acid Antagonists
Methotrexate
- Pemetrexed disodium

Pyrimidine Analogues
Azacitidine
- Capecitabine
- Cytarabine
- Floxuridine
- Fluorouracil injection (5-Fluorouracil [5-FU])
- Gemcitabine hydrochloride

Purine Analogues
Cladribine
- Clofarabine
- Fludarabine
- Mercaptopurine (6-MP)
- Nelarabine
- Pentostatin
- Thioguanine (6-TG)

Ribonucleotide Reductase Inhibitors (Enzyme Inhibitors)
Hydroxyurea

Antitumorals

Anthracyclines
Daunorubicin hydrochloride
- Daunorubicin liposomal
- Doxorubicin
- Epirubicin
- Idarubicin
- Mitoxantrone
- Valrubicin

Other Antitumor Antibiotics
Bleomycin sulfate
- Dactinomycin
- Doxorubicin liposomal
- Mitomycin

Plant Alkaloids

Antimicrotubules and Taxanes
Docetaxel
- Paclitaxel

Camptothecin Analogues
Irinotecan
- Topotecan

Epipodophyllotoxins
Etoposide
- Teniposide

Immunomodulators

Alemtuzumab
- Interleukin 2 (IL-2)
- Rituximab
- Thalidomide

Retinoids

Bexarotene

Vinca Alkaloids

Vinblastine sulfate
- Vincristine sulfate
- Vincristine, liposomal
- Vinorelbine

Sex Hormones, Hormonal Agonists and Antagonists, Selective Estrogen Receptor Modulators, Luteinizing Hormone–Releasing Hormone Agonists, Aromatase Inhibitors, Enzymes, and Vaccines

Androgens

Fluoxymesterone

Hormonal Agonists and Antagonists

Abiraterone
- Anastrozole
- Bicalutamide
- Enzalutamide
- Exemestane
- Flutamide
- Fulvestrant
- Goserelin acetate
- Histrelin acetate implant
- Letrozole
- Leuprolide acetate
- Medroxyprogesterone
- Megestrol acetate
- Mitotane
- Nilutamide
- Raloxifene
- Tamoxifen citrate
- Toremifene citrate

Enzymes

Asparaginase *Erwinia chrysanthemi*
- Pegaspargase

Vaccines

Hepatitis B
- Quadrivalent human papillomavirus subtypes 6, 11, 16, and 18
- Human papillomavirus bivalent vaccine

High-Alert Medications

All chemotherapeutic agents are categorized as high-alert medications for all routes of drug delivery.

---

* See Chapter 33 for monoclonal antibodies and targeted therapies and Chapter 34 for biologic therapies.

To maximize cell death, CCNS and CCS drugs are often combined to increase synergistic effects. Each individual drug used in combination therapy should have a proven tumoricidal activity, a

different mode of action, and different dose-limiting toxicities. A combination of antineoplastic drugs has the advantage of decreasing drug resistance while increasing cancer cell destruction. Table 32.1 presents some of the combined anticancer drugs.

General Side Effects and Adverse Reactions

Anticancer drugs exert adverse effects on rapidly growing normal cells, such as skin and hair. These drugs can also affect cells in the gastrointestinal (GI) tract, mucous membranes, bone marrow, and reproductive system. **Myelosuppression** can occur when there is a significant decrease in the bone marrow activity that results in decreased white blood cells, platelets, and red blood cells. Following chemotherapy administration, the **nadir**—the time at which the blood count is at the lowest—typically occurs 7 to 10 days after treatment. Table 32.2 lists the general adverse effects anticancer drugs exert on the fast-growing cells of the body. Selected nursing measures and considerations are included. Because of the toxic effects of chemotherapy, care in handling of such drugs must be considered, and protective gear that includes gloves specific for handling chemotherapy drugs must be used.

Anticancer Therapy in Outpatient Settings

The administration of anticancer drugs in outpatient settings, such as in homes and oncology clinics, is both cost-effective and convenient. Although chemotherapy regimens have become increasingly aggressive, most patients are not hospitalized unless they require close monitoring or become very ill. Patients receiving highly potent drugs will need to be closely monitored for severe adverse effects. When a chemotherapy drug is given, a health care provider qualified to administer anticancer drugs follows the policies provided by the oncologist and the health care agency. To reduce the nurse's exposure to hazardous chemotherapy drugs during administration, certain precautions should be followed to minimize occupational exposure:

TABLE 32.1

Selected Combinations of Anticancer Drugs

Generic	Acronym*	Selected Uses
Cytarabine, daunorubicin, etoposide	ADE	Acute myelogenous leukemia
Fluorouracil, doxorubicin, cyclophosphamide	FAC	Breast cancer
Fluorouracil, epirubicin, cyclophosphamide	FEC	
Leucovorin, fluorouracil, irinotecan	FOLFIRI	Colorectal cancer
Leucovorin, fluorouracil, oxaliplatin	FOLFOX	
Capecitabine, irinotecan	XELIRI	Esophageal cancer, gastric cancer
Bortezomib (PS-341), doxorubicin, dexamethasone	PAD	Multiple myeloma
Carboplatin, paclitaxel	CARBOPLATIN-TAXOL	Non–small cell lung cancer
Cyclophosphamide, doxorubicin, vincristine, prednisone	CHOP	Non-Hodgkin lymphoma
Rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone	R-CHOP	
Gemcitabine, cisplatin	(None)	Pancreatic cancer
Gemcitabine, fluorouracil, leucovorin	OFF	
Bleomycin, etoposide, cisplatin	BEP	Testicular cancer
Vinblastine, ifosfamide, cisplatin	VIP	

* Acronyms are based on the generic or trade name of the chemotherapy drugs used in a specific protocol (e.g., ABVD [Adriamycin, bleomycin, vinblastine, dacarbazine], FAC [fluorouracil, Adriamycin, cyclophosphamide]). Not all acronyms for combination chemotherapy treatments are listed.

TABLE 32.2

General Adverse Reactions to Anticancer Drugs

Adverse Reactions	Nursing Measures and Considerations
Bone Marrow Suppression, Myelosuppression	
Low RBC count (anemia)	Assess for fatigue, shortness of breath, low blood pressure, increased heart rate, increased respiratory rate, and oliguria. Assess for cyanosis. Plan rest periods. Administer oxygen as prescribed. Elevate the head of the bed to facilitate breathing. Provide pain mediation if pain is increasing oxygen consumption. Provide assistance with activities. Monitor for mental status changes. Anemia may be treated with ferrous sulfate or infusions of RBCs. EPO may be administered to stimulate RBC production. Monitor RBCs, hemoglobin, and hematocrit.
Low WBC count (leukopenia)	Susceptibility to infection increases as WBCs decrease. Patients should avoid people with infections and report fever, chills, URIs, or sore throat to their HCP. Hand hygiene before and after contact with the patient is important. Monitor for changes in body temperature; elevated temperature is considered a sign of infection. Avoid medications that may mask fever. Immediately report temperatures of 101°F (38.3°C) or above to the HCP. Appropriate cultures (e.g., blood, urine, sputum) are collected before antibiotics are started if applicable, and an antibiotic regimen is initiated. Assess for localized infections. Auscultate breath sounds. Colony-stimulating factors (e.g., filgrastim) may be administered to stimulate WBC production. Monitor WBCs, especially ANCs.
Low platelet count (thrombocytopenia)	Petechiae, bruising, bleeding of gums, and nosebleeds are signs of a low platelet count; report these signs to a HCP. Assess for bleeding, petechiae, and ecchymosis. Assess for occult bleeding in urine, feces, and emesis. Apply pressure to injection sites until bleeding has stopped. Platelet transfusions may be needed. Avoid medications that may promote bleeding (aspirin, heparin). Avoid invasive procedures (injections, indwelling urinary catheters, rectal temperature, and suppositories). Monitor platelet counts and bleeding time.

Gastrointestinal Disturbances	
Anorexia	Loss of appetite may be related to anemia, pain, fatigue, or altered taste caused by chemotherapy drugs. Provide small, frequent meals that are high in calories and protein. Plan rest periods. Address issues of pain control. Hard candy or ice chips may help relieve bitter taste.
Nausea and vomiting	Antineoplastic drugs often stimulate the CTZ, leading to nausea and vomiting, which can be caused by irritation of the GI tract; effects of radiation to chest, abdomen, or brain; anxiety; constipation; pain; electrolyte imbalances; or other medications. Grading scales are useful to assess severity. Provide antiemetics before, during, and after chemotherapy. Assess for GI upset, and medicate appropriately. Minimize noise, stimulation, and odors. Frequent mouth care is recommended. Monitor fluid balance and serum electrolytes.
Diarrhea	Diarrhea may be one of three types: *osmotic* (absorption defects), *secretory* (bacterial infection or neoplasm), or *exudative* (secondary to chemotherapy). Chemotherapeutic drugs most commonly associated with diarrhea are alkylating agents, antitumor antibiotics, and antimetabolites. Treatment (e.g., medications, diet changes) will depend on cause and severity.
Table Continued	

Gastrointestinal Disturbances	
	Diarrhea may be caused by other medications, such as antibiotics; comorbid conditions (e.g., Crohn disease); or enteral (tube) feedings. Assess normal bowel habits, and monitor for electrolyte imbalances and dehydration. Administer appropriate antidiarrheal medications (antibiotics, anticholinergics, antispasmodics, psyllium, kaolin and pectin, or octreotide acetate). Teach patients to eat small, frequent meals; follow a low-residue diet; limit spicy, fatty foods; limit intake of salty foods, whole grains, fresh fruits and vegetables, and caffeinated and carbonated drinks; and avoid very hot or very cold foods (may stimulate peristalsis). Monitor intake and output.
Mucositis (stomatitis)	Many antineoplastic drugs cause changes in oral mucosa that generally occur 2 to 14 days after initiation of therapy. Assess for taste changes, tissue swelling, redness, pain, dry mouth, white patches, or a white coating on the oral mucosa. Mucositis ranges from mild to severe. Symptomatic treatment may include frequent mouth rinses, topical anesthetics, antibiotics, antifungal medication, saliva substitutes, and pain medication. Patients should avoid commercial mouthwashes that contain alcohol. A soft toothbrush is recommended. Offer ice chips or ice pops to help relieve pain. Assess intake and output. Evaluate caloric needs. A grading scale may be useful to assess severity.

Other	
Alopecia	Not all chemotherapeutic drugs cause hair loss. Hair thinning, patchy baldness, or complete alopecia may occur, depending on the drug. Hair on all areas of the body is affected. Hair loss may be gradual, progressing with each cycle of chemotherapy, or rapid. Hair regrowth usually occurs once chemotherapy is completed, although the texture may be changed. Before therapy, discuss potential hair loss and ways to address the discomforts (e.g., baldness and scalp hypothermia) due to hair loss (wigs, scarves, hats, or turbans). Assess for body image changes and concerns.
Fatigue	Fatigue may be caused by chemotherapy, sleep disturbances, emotional distress, depression, bone marrow suppression, infection, pain, or electrolyte imbalances.
	Assess fatigue using a visual analog grading scale (0 = no fatigue; 10 = worst fatigue). Address conditions that might be contributing to fatigue (lack of sleep, pain, depression). Plan ways to help patients conserve energy. Plan a well-balanced diet, and encourage participation in regular (but not strenuous) exercise and stress-reduction measures, such as relaxation and guided imagery.
Infertility	If infertility occurs, it may be permanent. Pretreatment counseling is advised.

ANC, Absolute neutrophil count; *CTZ,* chemoreceptor trigger zone; *EPO,* erythropoietin; *GI,* gastrointestinal; *HCP,* health care provider; *RBC,* red blood cell; *URI,* upper respiratory infection; *WBC,* white blood cell.

The list above is not all inclusive. Some more serious reactions are discussed in the prototype drug charts.

- Use disposable powder-free gloves approved for handling chemotherapy, regardless of route of administration.
- Wear two pairs of gloves and change gloves every 30 minutes or when torn, punctured, or contaminated.
- Wear gowns with a front closure, long sleeves, and elastic or knit (closed) cuffs, and dispose of these after each use when administering IV chemotherapy.
- When there is a risk of aerosol exposure, follow the Occupational Safety and Health Administration (OSHA) respiratory protection standard. Surgical masks do *not* provide adequate respiratory protection.
- Use a face shield or a combination of a mask and face shield if there is a danger of splashing when administering chemotherapy or disposing of body fluids.

Cytotoxic drugs can be accidentally absorbed by inhalation, contact with skin or mucous membranes, or ingestion. For this reason, these guidelines should be followed:

1. Prepare chemotherapy in a separate work area. Use a plastic-backed absorbent pad to contain spills during preparation.
2. Wash hands before and after administration of chemotherapy.
3. Avoid hand-to-mouth or hand-to-eye contact while working with chemotherapy.
4. Refer to your agency's policy for priming IV tubing and disconnecting tubing after administration.
5. Wear gloves when disposing of body fluids (e.g., urine, feces, and emesis) of patients who have received chemotherapy in the previous 48 hours.
6. Refer to agency policy for disposal of used equipment.
7. Refer to agency policy for handling chemotherapy spills or exposure.

Alkylating Drugs

One of the largest groups of anticancer drugs is the alkylating compounds. **Alkylating drugs** damage the cell's DNA by cross-linkage of DNA strands, abnormal base pairing, or DNA strand breaks, thus preventing the reproduction of cancer cells. Drugs in this group belong to the CCNS category and kill cells in all phases of the cell cycle. They are used to treat many different types of cancer, including leukemia, lymphoma, multiple myeloma, sarcoma, and solid tumors such as those of the breast, ovary, uterus, lung, bladder, and stomach. Even though alkylating agents are effective in all phases of the cell cycle, they are most effective in the G_0 phase. Alkylating drugs are divided into five different classes: (1) nitrogen mustards, (2) nitrosoureas, (3) alkyl sulfonates, (4) triazines, and (5) ethylenimines. Table 32.3 lists some of the alkylating drugs, their uses, and considerations. Of the alkylating agents, nitrosoureas cross the blood-brain barrier, making them useful in the treatment of brain cancer. General adverse effects to anticancer drugs are discussed in Table 32.2. Additionally, alkylating agents given in high doses can cause long-term damage to the bone marrow, resulting in acute leukemia. The platinum (alkylating-like) drugs—cisplatin, carboplatin, and oxaliplatin—kill cells in a similar fashion but are less likely to cause leukemia later.

TABLE 32.3

Antineoplastics: Alkylating Drugs

Drug	Route and Dosage	Uses and Considerations
Nitrogen Mustards	Visually inspect parenteral products for particulate matter and discoloration prior to use. Observe and exercise precautions when handling, preparing, and administering cytotoxic drugs. The correct dose of chemotherapeutic drugs will vary from protocol to protocol. Consult appropriate references to verify doses.	
Bendamustine	CLL: A: IV: 100 mg/m^2 on days 1 and 2, repeated q28d for up to 6 cycles NHL: A: IV: 120 mg/m^2 on days 1 and 2, repeated q21d for up to 8 cycles	For CLL and NHL. Monitor for bone marrow depression. Assess for tumor lysis syndrome and skin reactions. Pregnancy category: D*; PB: 94%-96%; t½: 40 min
Chlorambucil	CLL: A: PO: 0.1-0.2 mg/kg/d (4-10 mg/d) for 3-6 wk Hodgkin disease: A/C: PO: 0.2 mg/kg/d NHL: A/C: PO: 0.1-0.2 mg/kg/d for 3-6 wk	For CLL, Hodgkin disease, and NHL. Monitor for bone marrow suppression or pancytopenia. Pregnancy category: D*; PB: 99%; t½: 1.5 h
Estramustine	A: PO: 14 mg/kg/d or 600 mg/m^2/d in 3-4 divided doses	For prostate cancer. Gynecomastia and impotence may occur. Pregnancy category: D*; PB: UK; t½: 20-24 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Ifosfamide	A: IV: 1.2-2 g/m^2/d for 5 d in combination with mesna; repeat every 3 wk after recovery from hematologic toxicity. Mesna is usually given concomitantly to prevent hemorrhagic cystitis.	For testicular cancer. Monitor for hemorrhagic cystitis. Pregnancy category: D*; PB: negligible; t½: 7-15 h
Mechlorethamine hydrochloride	Hodgkin disease: A: IV: 0.2 mg/kg or 6 mg/m^2 as single dose CLL: A: IV: 6 mg/m^2 q4wk CML: A: IV: 0.4 mg/kg or 6 mg/m^2 monthly Other dosing regimen and routes are available.	For Hodgkin disease, leukemias, solid tumors, and effusions caused by cancer. This drug is contraindicated in patients with active infections. Pregnancy category: D*; PB: UK; t½: Minutes
Melphalan	Multiple myeloma: A: PO: 6 mg daily for 2-3 wk Maint: 2 mg/d; adjust 1-3 mg/d based on hematologic response A: IV: 16 mg/m^2 q2wk for 4 doses Maint: 16 mg/m^2 q4wk Ovarian cancer: A: PO: 200 mcg/kg/d for 5 d; repeat q4-5wk based on hematologic response	For multiple myeloma and ovarian cancer. *Do not confuse Alkeran with Leukeran or Myleran.* Pregnancy category: D*; PB: 20%-30%; t½: 1.25-1.5 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Nitrosoureas		
Carmustine (BCNU)	Multiple myeloma and brain tumors: A: IV: 150-200 mg/m² single dose q6wk or 75-100 mg/m²/d for 2 days q6wk C: IV: 200-250 mg/m² q4-6wk Hodgkin disease or NHL: A: IV: 100 mg/m²/d q6wk	For Hodgkin disease, NHL, multiple myeloma, and brain tumors. Monitor for bone marrow suppression and pulmonary symptoms. Pregnancy category: D*; PB: UK; t½: 5-30 min
Lomustine (CCNU)	Hodgkin disease and malignant glioma: A/C: PO: 100-130 mg/m² q6wk	For Hodgkin disease and malignant gliomas. Monitor for bone marrow suppression and liver function. Pregnancy category: D*; PB: UK; t½: 16 h-2 d
Streptozocin	A/C: IV: 500 mg/m²/d for 5 d q4-6wk; doses above 500 mg/m² are not recommended	*Do not confuse with streptomycin.* For pancreatic cancer. Pregnancy category: C*; PB: UK; t½: 30-45 min
Alkyl Sulfonates		
Busulfan	A: PO: 4-8 mg/d C: PO: 0.06-0.12 mg/kg/d	For myelocytic leukemia. Monitor for seizures and cerebral hemorrhage. Pregnancy category: D*; PB: 32%; t½: 2.5 h
Alkylating-Like Drugs		
Altretamine	A: PO: 260 mg/m²/d in 4 divided doses after meals and at bedtime for 14 or 21 d in a 28-d cycle; drug holiday for ≥14 d then restart at 200 mg/m²/d	For ovarian cancer. Pregnancy category: D*; PB: Weakly; t½: 4.7-10.2 h
Table Continued		

Drug	Route and Dosage	Uses and Considerations
Carboplatin	New cancer: A: IV: 300 mg/m² in combination with cyclophosphamide q4wk for 6 cycles Recurrent cancer: A: IV: 360 mg/m² q4wk	For advanced ovarian cancer. Usually given as combination therapy. Pregnancy category: D*; PB: UK; t½: 1.5-2.5 h
Cisplatin	Bladder cancer: A: IV: 50-70 mg/m² q3-4wk Ovarian cancer: A: IV: 50-75 mg/m² q21d Testicular cancer: A/C: IV: 20 mg/m² for 5 d; repeat q3wk for 2 more cycles NSCLC: A: IV: 75 mg/m² q3wk	For bladder, ovarian, testicular, and NSCLC. Monitor for CNS function; reversible posterior leukoencephalopathy may occur. Pregnancy category: D*; PB: 90%; t½: 30-100 h, dose related
Dacarbazine	Melanoma: A: IV: 250 mg/m²/d for 5 d repeated q3wk Hodgkin disease: A/C: IV: 375 mg/m² days 1 and 15 q28d	For Hodgkin disease and malignant melanoma. Monitor hepatic function. Pregnancy category: C*; PB: Minimal; t½: 5 h
Oxaliplatin	A: IV: 85 mg/m² on day 1 q2wk for 12 cycles	For metastatic colorectal cancer. Used with 5-FU and leucovorin (FOLFOX4). Assess for pulmonary complications. Pregnancy category: D*; PB: >90%; t½: 391 h

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 11.

5-FU, 5-Fluorouracil; *A*, adult; *C*, child; *CLL*, chronic lymphocytic leukemia; *CML*, chronic myelogenous leukemia; *CNS*, central nervous system; *d*, day; *h*, hour; *IV*, intravenous; *maint*, maintenance; *min*, minute; *NHL*, non-Hodgkin lymphoma; *NSCLC*, non–small cell lung cancer; *PB*, protein binding; *PO*, by mouth; *q*, every; *t½*, half-life; *UK*, unknown; *wk*, week; >, greater than; ≥, greater than or equal to.

Cyclophosphamide

Cyclophosphamide, an alkylating agent, is an analogue of nitrogen mustard and has activity against many neoplastic diseases including Hodgkin and non-Hodgkin lymphoma (NHL), acute and chronic lymphocytic leukemia (CLL), multiple myeloma, breast and ovarian carcinoma, lung cancer, and retinoblastoma. The drug is also used for immunologic disorders such as lupus nephritis and has been shown to prevent progressive renal scarring, preserve renal function, induce renal remission, and decrease end-stage renal failure. This drug is a severe **vesicant** that causes tissue necrosis if it infiltrates into the tissues. Cyclophosphamide can be administered orally or intravenously. The patient should be well hydrated while taking cyclophosphamide to prevent hemorrhagic cystitis (bleeding due to severe bladder inflammation). Sodium 2-mercaptoethanesulfonate is a **chemoprotectant** drug often given with high-dose cyclophosphamide to inactivate urotoxic metabolites to reduce the incidence of hemorrhagic cystitis.

Patient Safety

Patients should be well hydrated before and during therapy.

Do not confuse…

- **Myleran** with **Alkeran**
- **Cisplatin** with **carboplatin**
- **Paraplatin,** with **Platinol**

- **Cyclophosphamide** with **cyclosporine**

Pharmacokinetics

Oral cyclophosphamide is well absorbed in the GI system. Cyclophosphamide is a prodrug that is activated and extensively metabolized by the liver. About 5% to 25% of the drug is eliminated by the kidney as unchanged drug, and its elimination half-life is 3 to 12 hours. Approximately 20% is bound to plasma protein, and this is not dose dependent. Some cyclophosphamide metabolites are greater than 60% protein bound. Less than 10%, most in the form of metabolites, are excreted in feces.

Pharmacodynamics

Cyclophosphamide is an early antineoplastic drug used alone or with other drugs to treat a variety of cancers. Average time to peak plasma concentration (T_{max}) is 1 hour. Several drug interactions can occur with cyclophosphamide. Patients should report all medications they are taking, including over-the-counter (OTC) medicines and herbal supplements. Anthracycline (e.g., doxorubicin) has been reported to induce cardiotoxicity when taken with cyclophosphamide, and it exacerbates hemorrhagic cystitis. Other serious drug interactions can occur when taking cyclophosphamide concomitantly with aspirin, allopurinol, phenobarbital, warfarin, thiazide diuretics, and some psychiatric medications. Complementary and Alternative Therapies 32.1 lists herbal supplements that may also interact with cyclophosphamide.

Side Effects and Adverse Reactions

The side effects of cyclophosphamide reflect those seen in the general class of antineoplastic drugs. (For the general side effects, see Table 32.2). Hemorrhagic cystitis is a serious problem that can arise when high doses of cyclophosphamide are given. Patients who receive a high dose should be assessed for cardiomyopathy and syndrome of inappropriate antidiuretic hormone (SIADH) during treatment with this drug. In addition, cyclophosphamide may increase pigmentation of the skin or nail beds. Prototype Drug Chart 32.1 details the pharmacologic behavior of cyclophosphamide.

Nursing Process: Patient-Centered Collaborative Care

Alkylating Drugs: Cyclophosphamide

Assessment

- To avoid drug-drug interactions, obtain a detailed medication history that includes prescriptions, OTC medicines, antacids, dietary supplements, vitamins, and herbal supplements.
- Obtain a list of the patient's drug and food allergies.
- Obtain baseline information about the patient's physical status. Include height, weight, vital signs, cardiopulmonary assessment, intake and output, skin assessment, nutritional status, and information on any underlying disease.
- Assess baseline laboratory values (complete blood count [CBC], uric acid, chemistry panel) for future comparisons.
- Assess baseline results of pulmonary function tests, chest radiographs, electrocardiography (ECG), and renal and liver function studies.
- Assess the patient's current level of comprehension.

Nursing Diagnoses

- Infection, Risk for
- Bleeding, Risk for
- Body Image, Risk for Disturbed body image
- Knowledge, Deficient related to chemotherapeutic protocol

Planning

- The patient/family member/caretaker will verbalize understanding of the signs and symptoms

of infection.
- The patient's white blood cell (WBC), red blood cell (RBC), and platelet counts will remain in the desired range.
- The patient will remain free from infection and hemorrhagic cystitis.
- The patient/family/caregiver will demonstrate understanding of protection from sun exposure.
- The patient/family/caregiver will demonstrate understanding of chemotherapeutic protocol (e.g., dose administration).

Nursing Interventions

- Monitor labs (CBC, blood urea nitrogen [BUN], creatinine, liver panel, and electrolytes) prior to drug administration and during treatment.
- Monitor the IV site frequently for irritation and phlebitis.
- Maintain strict medical asepsis during dressing changes and invasive procedures.
- Encourage small, frequent meals high in calories and protein.
- Monitor fluid intake and output and nutritional intake during therapy.
- Encourage patients to drink at least 2 L of fluid per day to promote excretion of cellular breakdown products and to reduce the risk of hemorrhagic cystitis.
- Assess the need for IV hydration.
- Maintain hydration before and during chemotherapy.
- Assess for signs and symptoms of hematuria, urinary frequency, or dysuria.
- Administer premedications as ordered 30 to 60 minutes before giving drugs.
- Provide drug information verbally and in print to the patient/family/caregiver.
- Encourage patients to use sunblock with a sun protection factor (SPF) of 50 or greater and to use other means to protect skin from sun exposure.

Patient Teaching

General

- Teach patients to take cyclophosphamide early in the day to prevent accumulation of drug in the bladder during the night.
- Remind patients to consult with a health care provider before administration of any vaccines.
- Advise patients to promptly report signs of infection (e.g., elevated temperature, fever, chills, sore throat, frequent urination or burning on urination, and redness/swelling/pain near a wound); bleeding (e.g., bleeding gums, petechiae, bruises, hematuria, blood in the stool); and anemia (e.g., increased fatigue, dyspnea, and orthostatic hypotension).
- Advise patients not to visit anyone who has a respiratory infection. A decreased WBC count puts patient at high risk for acquiring an infection.
- Emphasize protective precautions as necessary (e.g., hand washing and personal hygiene).
- Teach patients to empty their bladder every 2 to 3 hours.
- Teach methods of sun protection (e.g., sunblock with SPF 50 or greater, brimmed hats, and lightweight, long-sleeved shirts).

Side Effects

- Advise patients about good oral hygiene with a soft toothbrush for stomatitis; have patients use a soft toothbrush when the platelet count is less than 50,000/mm^3.
- Assess for use of alternative and complementary therapies that may interact with chemotherapy drugs.
- Advise patients to report any signs of bleeding.

Diet

- Advise patients to follow a diet low in purines—such as organ meats, beans, and peas—to alkalize urine.
- Advise patients to avoid citric acid.
- Offer patients food and fluids that may decrease nausea (e.g., cola, crackers, and ginger ale).
- Plan small, frequent meals.

Cultural Considerations

- Health care decisions are made by consensus in some cultures, and the family plays a key role in filtering the information given to a patient. Issues related to informed consent and full disclosure of medical information may cause distress in those who place the needs of the family above the needs of the individual. Interactions should be modified based on family structure,

religious values and beliefs, time orientation, cultural health practices, and verbal and nonverbal communication.
- Cultural assessment tools can provide general guidelines for health care providers.
- Cytochrome P450 system variance may prohibit the conversion of cyclophosphamide into its active form more among African Americans than among Caucasians.
- Renal function among African Americans is poorer than among Caucasians.
- Despite lowering the dosage, Asians may develop febrile neutropenia.

Evaluation

- The patient is free from infection.
- The patient maintains the target weight.
- The patient maintains nutritional status.
- The patient does not develop hemorrhagic cystitis.
- The patient/family/caregiver education needs are met.

Antimetabolites

Molecularly, **antimetabolites** resemble natural substances, building blocks that not only synthesize but also recycle and break down organic compounds used by the body. However, antimetabolites interfere with various substances needed for normal cell function. Most antimetabolites are classified as CCS, and they exert their effects during the S phase (DNA synthesis and metabolism) of the cell cycle. Few antimetabolites (e.g., 5-fluorouracil [5-FU], floxuridine) have cytotoxic effects in multiple phases of the cell cycle. Antimetabolites are classified according to the substances with which they interfere. Substances can include folate, pyrimidine, purine analogues, and ribonucleotide reductase inhibitors. Table 32.4 lists the antimetabolite drugs, uses, and considerations.

COMPLEMENTARY AND ALTERNATIVE THERAPIES 32.1

Cyclophosphamide

- Use cautiously with garlic (antiplatelet activity), ginkgo (increased antiplatelet effect), echinacea (decreased effects of immunosuppressive drugs), ginseng (altered bleeding time), St. John's wort (may interfere with chemotherapy), and kava kava (increased risk for bleeding). Toxicity and actions of both cyclophosphamide and vitamin A are altered if given together. *Do not use with mistletoe because it may promote cancer growth.*
- Astragalus (Huang-qi; milk vetch root) stimulates the immune system and may help speed recovery from immunosuppressive chemotherapy. Astragalus has blood clot–fighting properties and may increase risk of bleeding when given with cyclophosphamide.

Fluorouracil

- Use cautiously with ginseng and St. John's wort (may interfere with chemotherapy). *Do not use with mistletoe because it may promote cancer growth.*
- Astragalus stimulates the immune system and may help speed recovery from immunosuppressive chemotherapy. Astragalus has blood clot–fighting properties and may increase risk of bleeding when given with 5-fluorouracil (5-FU).

Doxorubicin

- St. John's wort is a potent cytochrome P450 inducer and moderate P-glycoprotein inducer that may decrease the concentration of doxorubicin.
- Grapefruit is a potent cytochrome P3A4 inhibitor that may increase the concentration and effect of doxorubicin.
- Black cohosh and Dong-quai should be avoided in estrogen-dependent tumors.
- Many complementary therapies—such as acupuncture, art therapy, and music therapy—have been utilized to improve patients' sense of well-being.

Vincristine

- St. John's wort and echinacea are cytochrome P450 inducers, which causes decreased levels of vincristine. Many complementary therapies—such as acupuncture, art therapy, and music therapy—have been utilized to improve patients' sense of well-being.

Methotrexate, a folate antimetabolite, is used to treat malignant and nonmalignant conditions (e.g., rheumatoid arthritis, psoriasis). Methotrexate affects cells that have high metabolic rates, such as neoplasms, hair follicles, endothelium, cells of the GI tract, fetal cells, and bone marrow; it is used to treat leukemias and cancers of the GI tract, head and neck, breast, and ovaries. Because methotrexate causes apoptosis to fetal cells, it can be used for ectopic pregnancies. Methotrexate inhibits the biosynthesis of a purine nucleotide, 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) transformylase, which provides antiinflammatory properties that result in metabolites; AICARs are immunotoxic. Leucovorin can be given 12 to 24 hours after methotrexate administration (not simultaneously) to reduce AICAR concentrations, thereby diminishing the adverse effects of methotrexate. Leucovorin should not be referred to as *folinic acid* because it can be

confused with *folic acid,* which can lead to severe methotrexate toxicity. Other interactions are seen with methotrexate. Nonsteroidal antiinflammatory drugs (NSAIDs) given just prior to, concomitantly with, or following intermediate or high doses of methotrexate have resulted in severe hematologic and GI toxicity. Furthermore, NSAIDs may mask fever, swelling, and other signs and symptoms of infection. Several corticosteroids can reduce the cytotoxicity of methotrexate. Protein-bound drugs such as salicylates (aspirin), sulfonylureas (glyburide), hydantoin (phenytoin) anticonvulsants, and sulfonamides can induce methotrexate toxicity. Penicillins, proton pump inhibitors, and probenecid, among other drugs, can cause methotrexate toxicity. Acidic food and drink can also cause elevated methotrexate concentrations.

PROTOTYPE DRUG CHART 32.1 Cyclophosphamide

Drug Class	Dosage
Alkylating drug: Nitrogen mustard Generic Name: Cyclophosphamide Pregnancy category: D*	Acute lymphocytic leukemia (ALL): A/C: IV: 300-1500 mg/m^2 A/C: PO: 1-5 mg/kg/d Breast cancer: A: IV: 500-1000 mg/m^2 q15d A: PO: 100-200 mg/m^2/d Various protocols exist, including combination therapy. Dosage varies based on indicated use and response. Adjust dose if bone marrow suppression (myelosuppression) occurs.
Contraindications	Drug-Lab-Food Interactions
Absolute contraindications: Hypersensitivity, severe urinary outflow obstruction, bladder obstruction *Caution:* Myelosuppression, tumor lysis syndrome, liver or kidney disease, hemorrhagic cystitis, or heart failure. Many other precautions are necessary when administering cyclophosphamide.	Drug: Doxorubicin may potentiate cardiac toxicity, and busulfan may potentiate lung toxicity. Other antineoplastic and immunosuppressive drugs may have an additive effect on immunosuppressive activity. Drugs metabolized via cytochrome P450 can increase toxic effects of cyclophosphamide. Doxorubicin decreases digoxin level and increases drug action of barbiturates, chloramphenicol half-life, and effects of anticoagulant drugs. Duration of leukopenia may be prolonged if given with thiazide diuretics. Actions and toxicities of allopurinol, probenecid, colchicine, phenothiazines, potassium iodide, imipramine, warfarin, and succinylcholine are altered if given with cyclophosphamide. Toxicity is increased if given with corticosteroids, phenytoin, or sulfonamides. Many other possible drug-drug interactions are not listed here.
	Lab: Suppresses positive reaction to uric acid, purified protein derivative, mumps, candida. Cyclophosphamide may cause Papanicolaou test (Pap smear) to be falsely positive.
Table Continued	

Pharmacokinetics	Pharmacodynamics
Absorption: PO: Well absorbed Distribution: PB: 20%, not dose dependent Metabolism: t½: 3-12 h	PO/IV:Onset: 7 d PO/IV: Peak: 7-15 d PO/IV: Duration: 21 d
Excretion: 5%-25% in urine unchanged; 4% in feces mostly as metabolites	
Therapeutic Effects/Uses	
Leukemias, breast and ovarian cancer, lymphomas, multiple myeloma, lung cancer, and retinoblastoma	
Mode of Action: Cell cycle–nonspecific alkylating drugs inhibit the protein synthesis by interfering with DNA replication by alkylation of DNA.	
Side Effects	Adverse Reactions
Nausea, vomiting, diarrhea, anorexia, leukopenia, febrile neutropenia, fever, weight loss, alopecia, amenorrhea, gonadal suppression, impaired wound healing, stomatitis, pain	Anaphylaxis, hematologic toxicity, pulmonary toxicity (pneumonitis, pulmonary fibrosis, pulmonary thrombosis), hemorrhagic cystitis, urotoxicity, nephrotoxicity, secondary neoplasm, cardiotoxicity, hepatotoxicity, tumor lysis syndrome

Note: Chemotherapy drug doses are based on body weight and are prescribed either as milligrams per kilogram (mg/kg) or milligrams per meter squared (mg/m^2). Doses will also vary based on drug protocol, type and stage of cancer, age, functional status, and comorbid conditions (e.g., heart disease).

A, Adult; *C,* child; *d,* day; *DNA,* deoxyribonucleic acid; *h,* hour; *IV,* intravenous; *q,* every; *PB,* protein binding; *PO,* by mouth; *t½,* half-life.

* Pregnancy categories have been revised. See http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Labeling/ucm093307.htm for more information.

Fluorouracil

Fluorouracil (5-FU), an antimetabolite agent similar to uracil with an addition of fluoride, is a component of chemotherapy for many cancers, including breast, colorectal, GI, and head and neck. 5-FU is administered intravenously to treat solid tumors and is applied topically for superficial basal cell carcinoma and actinic keratosis. A microsponge delivery system for a cream-based 5-FU was approved in 2000 to provide a sustained release formulation administered once daily. It is not administered orally because of the inconsistent bioavailability.

Patient Safety

Obtain a complete medication list that includes over-the-counter (OTC), herbal preparations, and other alternative therapies.

Do not confuse…

- **Hydroxyurea** with **hydroxychloroquine**

- **Xeloda** with **Xenical**

TABLE 32.4
Antineoplastics: Antimetabolites

Drug	Route and Dosage	Uses and Considerations
Folic acid antagonists		
Visually inspect parenteral products for particulate matter and discoloration prior to use. Observe and exercise precautions when handling, preparing, and administering cytotoxic drugs. Chemotherapeutic drug dosages will vary from protocol to protocol. Consult appropriate references to verify doses.		
Methotrexate	ALL: A/C: PO/IM/IV: 3.3 mg/m²/d for 4-6 wk followed by maintenance dosing NHL: A/C: IV: 200 mg/m² days 8 and 15 q21d in a combination regimen Head/Neck: A/C: IV: 40 mg/m² days 1 and 15 q21d A: PO: 25-50 mg/m² q7d C: PO: 7.5-30 mg/m² Osteogenic sarcoma: A/C: IV: 12 g/m² q2wk	For ALL, NHL, sarcomas, solid tumors, head and neck cancers, choriocarcinomas, lymphomas, and some autoimmune disorders. Older adults may be more sensitive to toxicity and adverse events. Pregnancy category: X*; PB: 50%-60%; t½: 10-12 h Leucovorin is used with high doses of methotrexate as rescue therapy to prevent fatal toxicity.
Pemetrexed	A: IV: 500 mg/m² day 1 of a 21-d cycle	For mesothelioma and non–small cell lung cancer. Folic acid and vitamin B12 IM injections are recommended to prevent hematologic and GI adverse reactions. Pregnancy category: D*; PB: 81%; t½: 3.5 h

Pyrimidine Analogues		
Azacitidine	A: IV/Subcut: 75 mg/m²/d for 7 d q4wk	For myelomonocytic syndrome (MDS). Absolutely contraindicated in those with mannitol hypersensitivity. Pregnancy category: D*; PB: UK; t½: 4 h
Capecitabine	Breast cancer: A: PO: 2500 mg/m²/d in 2 divided doses for 2 wk repeated q3wk Colorectal cancer: A: PO: 1250 mg/m²/d twice daily for 2 wk, repeated q3wk for a total of 8 cycles	For breast and colorectal cancer. Usually reserved for patients resistant to anthracyclines. Converted in tissue to 5-FU. Monitor for GI symptoms. Pregnancy category: D*; PB: <60%; t½: 0.75 h
