Lewis's Medical-Surgical Nursing

Assessment and Management of Clinical Problems

ELEVENTH EDITION

Mariann M. Harding, RN, PhD, FAADN, CNE

Professor of Nursing, Kent State University at Tuscarawas, New Philadelphia, Ohio

Section Editors

Jeffrey Kwong, RN, DNP, MPH, ANP-BC, FAAN, FAANP

Professor, Division of Advanced Nursing Practice, School of Nursing, Rutgers University, Newark, New Jersey

Dottie Roberts, RN, EdD, MSN, MACI, OCNS-C, CMSRN, CNE

Executive Director, Orthopaedic Nurses Certification Board, Chicago, Illinois

Debra Hagler, RN, PhD, ACNS-BC, CNE, CHSE, ANEF, FAAN

Clinical Professor, Edson College of Nursing and Health Innovation, Arizona State University, Phoenix, Arizona

Courtney Reinisch, RN, DNP, FNP-BC

Undergraduate Program Director, Associate Professor, School of Nursing, Montclair State University, Montclair, New Jersey

Dedication

Preface

Concepts Exemplars

Special Features

Section One. Concepts in Nursing Practice

1. Professional Nursing

- Conceptual Focus
- Professional Nursing Practice
- Influences on Professional Nursing Practice
- Patient-Centered Care
- Teamwork and Collaboration
- Safety
- Quality Improvement
- Informatics
- Evidence-Based Practice

2. Health Equity and Culturally Competent Care

- Conceptual Focus
- Determinants of Health
- Health Disparities and Health Equity
- Culture
- Cultural Competence
- Cultural Diversity in the Health Care Workplace

Cultural Factors Affecting Health and Health Care

Nursing Management: Promoting Health Equity and Increasing Cultural Competency

3. Health History and Physical Examination

Conceptual Focus

Data Collection

Nursing History: Subjective Data

Physical Examination: Objective Data

Types of Assessment

Problem Identification

4. Patient and Caregiver Teaching

Conceptual Focus

Role of Patient and Caregiver Teaching

Teaching-Learning Process

Process of Patient Teaching

5. Chronic Illness and Older Adults

Conceptual Focus

Chronic Illness

Nursing Management: Chronic Illness

Older Adults

Attitudes Toward Aging

Biologic Aging

Age-Related Physiologic Changes

Special Older Adult Populations

Social Support for Older Adults

Social Services for Older Adults

Medicare and Medicaid

Care Alternatives for Older Adults

Legal and Ethical Issues

Nursing Management: Older Adults

Section Two. Problems Related to Comfort and Coping

---

6. Stress Management

Conceptual Focus

What is Stress?

Physiologic Response to Stress

Mind-Body-Spirit Connection

Effects of Stress on Health

Coping Strategies

Relaxation Strategies

Nursing Management: Stress

7. Sleep and Sleep Disorders

Conceptual Focus

Sleep

Physiologic Sleep Mechanisms

Insufficient Sleep and Sleep Disturbances

Sleep Disturbances in the Hospital

Sleep Disorders

Nursing Management: Insomnia

Obstructive Sleep Apnea

Nursing and Interprofessional Management: Sleep Apnea

Periodic Limb Movement Disorder

Circadian Rhythm Disorders

Narcolepsy

Parasomnias

Special Sleep Needs of Nurses

8. Pain

Conceptual Focus

Magnitude of Pain Problem

Definitions and Dimensions of Pain

Classification of Pain

Pain Assessment

Pain Treatment

Nursing and Interprofessional Management: Pain

Institutionalizing Pain Education and Management

Ethical Issues in Pain Management

Managing Pain in Special Populations

9. Palliative and End-of-Life Care

Conceptual Focus

Palliative Care

Hospice Care

Death

End-of-Life Care

Legal and Ethical Issues Affecting End-of-Life Care

Nursing Management: End of Life

Special Needs of Caregivers and Nurses in End-of-Life Care

10. Substance Use Disorders

Conceptual Focus

Drugs Associated with Substance Use Disorder

Nursing and Interprofessional Management: Tobacco Use Disorder

Alcohol

Nursing and Interprofessional Management: Alcohol Use Disorder

Use of Other Substances

Nursing and Interprofessional Management: Stimulant Use

Depressants

Nursing and Interprofessional Management: Depressant Use

Inhalants

Cannabis

Caffeine

Nursing Management: Substance Use

Section Three. Problems Related to Homeostasis and Protection

11. Inflammation and Healing

- Conceptual Focus
- Inflammatory Response
- Nursing and Interprofessional Management: Inflammation
- Healing Process
- Nursing and Interprofessional Management: Wound Healing
- Pressure Injuries
- Nursing and Interprofessional Management: Pressure Injuries

12. Genetics

- Conceptual Focus
- Genetics and Genomics
- Genetic Disorders
- Genetic Screening and Testing
- Pharmacogenomics and Pharmacogenetics
- Gene Therapy
- Stem Cell Therapy
- Nursing Management: Genetics and Genomics

13. Immune Responses and Transplantation

- Conceptual Focus

Normal Immune Response

Altered Immune Response

Allergic Disorders

Nursing Management: Immunotherapy

Nursing and Interprofessional Management: Latex Allergies

Autoimmunity

Immunodeficiency Disorders

Human Leukocyte Antigen System

Organ Transplantation

Graft-Versus-Host Disease

14. Infection

Conceptual Focus

Infections

Types of Pathogens

Emerging Infections

Health Care–Associated Infections

Infection Prevention and Control

Human Immunodeficiency Virus Infection

Nursing Management: HIV Infection

15. Cancer

- Conceptual Focus
- Biology of Cancer
- Benign Versus Malignant Neoplasms
- Classification of Cancer
- Prevention and Early Detection of Cancer
- Interprofessional Care
- Surgical Therapy
- Chemotherapy
- Radiation Therapy
- Nursing Management: Chemotherapy and Radiation Therapy
- Late Effects of Radiation and Chemotherapy
- Immunotherapy and Targeted Therapy
- Nursing Management: Immunotherapy and Targeted Therapy
- Hormone Therapy
- Hematopoietic Growth Factors
- Hematopoietic Stem Cell Transplantation
- Gene Therapy
- Complications of Cancer
- Nutritional Problems

Infection

Oncologic Emergencies

Cancer Pain

Coping with Cancer and Treatment

Cancer Survivorship

16. Fluid, Electrolyte, and Acid-Base Imbalances

Conceptual Focus

Homeostasis

Water Content of the Body

Electrolytes

Mechanisms Controlling Fluid and Electrolyte Movement

Fluid Movement in Capillaries

Fluid Spacing

Regulation of Water Balance

Fluid Volume Imbalances

Fluid Volume Deficit

Fluid Volume Excess

Nursing Management: Fluid Volume Imbalances

Sodium Imbalances

Hypernatremia

Nursing and Interprofessional Management: Hypernatremia

Hyponatremia

Nursing and Interprofessional Management: Hyponatremia

Potassium Imbalances

Hyperkalemia

Nursing and Interprofessional Management: Hyperkalemia

Hypokalemia

Nursing and Interprofessional Management: Hypokalemia

Calcium Imbalances

Hypercalcemia

Nursing and Interprofessional Management: Hypercalcemia

Hypocalcemia

Nursing and Interprofessional Management: Hypocalcemia

Phosphate Imbalances

Hyperphosphatemia

Hypophosphatemia

Magnesium Imbalances

Hypermagnesemia

Hypomagnesemia

Acid-Base Imbalances

pH And Hydrogen ION Concentration

Acid-Base Regulation

Alterations in Acid-Base Balance

Clinical Manifestations of Acid-Base Imbalances

Assessment of Fluid, Electrolyte, and Acid-Base Imbalances

Oral Fluid and Electrolyte Replacement

IV. Fluid and Electrolyte Replacement

Central Venous Access Devices

Nursing Management: Central Venous Access Devices

Section Four. Perioperative Care

---

17. Preoperative Care

Conceptual Focus

Surgical Settings

Patient Interview

Nursing Assessment of Preoperative Patient

Nursing Management: Preoperative Patient

18. Intraoperative Care

Conceptual Focus

Physical Environment of the Operating Room

Surgical Team

Nursing Management: Patient Before Surgery

Nursing Management: Patient During Surgery

Nursing Management: Patient After Surgery

Anesthesia

Anesthesia Techniques

Perioperative Crisis Events

19. Postoperative Care

Conceptual Focus

Postoperative Care of Surgical Patient

Respiratory Problems

Nursing Management: Respiratory Problems

Cardiovascular Problems

Nursing Management: Cardiovascular Problems

Neurologic and Psychologic Problems

Nursing Management: Neurologic and Psychologic Problems

Pain and Discomfort

Nursing Management: Pain

Temperature Changes

Nursing Management: Temperature Changes

Gastrointestinal Problems

Nursing Management: Gastrointestinal Problems

Urinary Problems

Nursing Management: Urinary Problems

Integumentary Problems

Nursing Management: Surgical Wounds

Discharge from The Pacu

Ambulatory Surgery

Section Five. Problems Related to Altered Sensory Input

---

20. Assessment and Management: Visual Problems

Conceptual Focus

Visual System

Structures and Functions of Visual System

Visual Pathway

Assessment of Visual System

Diagnostic Studies of Visual System

Visual Problems

Visual Impairment

Nursing Management: Visual Impairment

Eye Trauma

Extraocular Disorders

Nursing Management: Inflammation and Infection

Dry Eye Disorders

Strabismus

Corneal Disorders

Intraocular Disorders

Nursing Management: Cataracts

Retinopathy

Retinal Detachment

Age-Related Macular Degeneration

Glaucoma

Nursing Management: Glaucoma

Intraocular Inflammation and Infection

Ocular Tumors

Enucleation

Ocular Manifestations of Systemic Diseases

21. Assessment and Management: Auditory Problems

Conceptual Focus

Auditory System

Structures and Functions of Auditory System

Assessment of Auditory System

Diagnostic Studies of Auditory System

Auditory Problems: External Ear and Canal

Nursing and Interprofessional Management: External Otitis

Cerumen and Foreign Bodies in External Ear Canal

Trauma

Malignancy of External Ear

Middle Ear and Mastoid

Nursing and Interprofessional Management: Chronic Otitis Media

Otosclerosis

Inner Ear Problems

Ménière’s Disease

Nursing and Interprofessional Management: Ménière's Disease

Benign Paroxysmal Positional Vertigo

Acoustic Neuroma

Hearing Loss and Deafness

Nursing and Interprofessional Management: Hearing Loss and Deafness

22. Assessment: Integumentary System

Conceptual Focus

Structures and Functions of Skin and Appendages

Assessment of Integumentary System

Diagnostic Studies of Integumentary System

23. Integumentary Problems

Conceptual Focus

Environmental Hazards

Skin Cancer

Nonmelanoma Skin Cancer

Melanoma

Skin Infections and Infestations

Allergic Skin Problems

Benign Skin Problems

Interprofessional Care: Skin Problems

Nursing Management: Skin Problems

Cosmetic Procedures

Nursing Management: Cosmetic Surgery

Skin Grafts

24. Burns

Conceptual Focus

Types of Burn Injury

Classification of Burn Injury

Prehospital and Emergency Care

Phases of Burn Management

Emergent Phase

Nursing and Interprofessional Management: Emergent Phase

Acute Phase

Nursing and Interprofessional Management: Acute Phase

Rehabilitation Phase

Nursing and Interprofessional Management: Rehabilitation Phase

Emotional/Psychologic Needs of Patients and Caregivers

Special Needs of Nurses

Section Six. Problems of Oxygenation: Ventilation

---

25. Assessment: Respiratory System

Conceptual Focus

Structures and Functions of Respiratory System

Assessment of Respiratory System

Diagnostic Studies of Respiratory System

26. Upper Respiratory Problems

Conceptual Focus

Problems Of Nose And Paranasal Sinuses

Nasal Fracture

Rhinoplasty

Nursing Management: Nasal Surgery

Epistaxis

Allergic Rhinitis

Acute Viral Rhinopharyngitis

Influenza

Sinusitis

Obstruction of Nose and Sinuses

Problems of Pharynx

Peritonsillar Abscess

Problems of Larynx and Trachea

Acute Laryngitis

Airway Obstruction

Tracheostomy

Nursing Management: Tracheostomy

Head and Neck Cancer

Nursing Management: Head and Neck Cancer

27. Lower Respiratory Problems

Conceptual Focus

Lower Respiratory Tract Infections

Acute Bronchitis

Pertussis

Pneumonia

Nursing Management: Pneumonia

Tuberculosis

Nursing Management: Tuberculosis

Atypical Mycobacteria

Pulmonary Fungal Infections

Lung Abscess

Environmental Lung Diseases

Lung Cancer

Nursing Management: Lung Cancer

Other Types of Lung Tumors

Chest Trauma and Thoracic Injuries

Fractured Ribs

Flail Chest

Pneumothorax

Chest Tubes and Pleural Drainage

Nursing Management: Chest Drainage

Chest Surgery

Restrictive Respiratory Disorders

Atelectasis

Pleurisy

Pleural Effusion

Interstitial Lung Diseases

Idiopathic Pulmonary Fibrosis

Sarcoidosis

Vascular Lung Disorders

Pulmonary Embolism

Nursing Management: Pulmonary Embolism

Pulmonary Hypertension

Idiopathic Pulmonary Arterial Hypertension

Secondary Pulmonary Arterial Hypertension

Cor Pulmonale

Lung Transplantation

28. Obstructive Pulmonary Diseases

Cenceptual Focus

Asthma

Nursing Management: Asthma

Chronic Obstructive Pulmonary Disease

Nursing Management: COPD

Cystic Fibrosis

Nursing Management: Cystic Fibrosis

Bronchiectasis

Interprofessional and Nursing Management: Bronchiectasis

Section Seven. Problems of Oxygenation: Transport

---

29. Assessment: Hematologic System

Conceptual Focus

Structures and Functions of Hematologic System

Assessment of Hematologic System

Diagnostic Studies of Hematologic System

30. Hematologic Problems

Conceptual Focus

Anemia

Nursing and Interprofessional Management: Anemia

Anemia Caused by Decreased Erythrocyte Production

Iron-Deficiency Anemia

Thalassemia

Megaloblastic Anemias

Anemia of Chronic Disease

Aplastic Anemia

Anemia Caused by Blood Loss

Acute Blood Loss

Chronic Blood Loss

Anemia Caused by Increased Erythrocyte Destruction

Sickle Cell Disease

Acquired Hemolytic Anemia

Other Red Blood Cell Disorders

Polycythemia

Problems Of Hemostasis

Thrombocytopenia

Nursing Management: Thrombocytopenia

Hemophilia and Von Willebrand Disease

Nursing Management: Hemophilia

Disseminated Intravascular Coagulation

Nursing Management: Disseminated Intravascular Coagulation

Neutropenia

Myelodysplastic Syndrome

Leukemia

Nursing Management: Leukemia

Lymphomas

Hodgkin’s Lymphoma

Non-Hodgkin’s Lymphoma

Multiple Myeloma

Disorders of the Spleen

Blood Component Therapy

Section Eight. Problems of Oxygenation: Perfusion

---

31. Assessment: Cardiovascular System

Conceptual Focus

Structures and Functions of Cardiovascular System

Assessment of Cardiovascular System

Diagnostic Studies of Cardiovascular System

32. Hypertension

Conceptual Focus

Normal Regulation of Blood Pressure

Hypertension

Nursing Management: Primary Hypertension

Hypertensive Crisis

33. Coronary Artery Disease and Acute Coronary Syndrome

Conceptual Focus

Coronary Artery Disease

Interprofessional and Nursing Care: Coronary Artery Disease

Chronic Stable Angina

Interprofessional and Nursing Care: Chronic Stable Angina

Acute Coronary Syndrome

Unstable Angina

Myocardial Infarction: St-Elevation and Non–St-Elevation Myocardial Infarction

Diagnostic Studies: Acute Coronary Syndrome

Interprofessional Care: Acute Coronary Syndrome

Nursing Management: Acute Coronary Syndrome

Sudden Cardiac Death

34. Heart Failure

Conceptual Focus

Heart Failure

Nursing Management: Heart Failure

Heart Transplantation

35. Dysrhythmias

Conceptual Focus

Rhythm Identification and Treatment

Syncope

36. Inflammatory and Structural Heart Disorders

Conceptual Focus

Inflammatory Disorders of Heart

Nursing Management: Infective Endocarditis

Acute Pericarditis

Nursing Management: Acute Pericarditis

Chronic Constrictive Pericarditis

Myocarditis

Nursing Management: Myocarditis

Rheumatic Fever and Rheumatic Heart Disease

Nursing Management: Rheumatic Fever and Rheumatic Heart Disease

Valvular Heart Disease

Mitral Valve Stenosis

Mitral Valve Regurgitation

Mitral Valve Prolapse

Aortic Valve Stenosis

Aortic Valve Regurgitation

Tricuspid and Pulmonic Valve Disease

Diagnostic Studies: Valvular Heart Disease

Interprofessional Care: Valvular Heart Disease

Nursing Management: Valvular Disorders

Cardiomyopathy

Dilated Cardiomyopathy

Hypertrophic Cardiomyopathy

Restrictive Cardiomyopathy

37. Vascular Disorders

Conceptual Focus

Peripheral Artery Disease

Peripheral Artery Disease of The Lower Extremities

Nursing Management: Lower Extremity Peripheral Artery Disease

Acute Arterial Ischemic Disorders

Thromboangiitis Obliterans

Raynaud's Phenomenon

Aortic Aneurysms

Nursing Management: Aortic Aneurysms

Aortic Dissection

Nursing Management: Aortic Dissection

Acute and Chronic Venous Disorders

Venous Thrombosis

Nursing Management: Venous Thromboembolism

Varicose Veins

Nursing Management: Varicose Veins

Chronic Venous Insufficiency and Venous Leg Ulcers

Section Nine. Problems of Ingestion, Digestion, Absorption, and Elimination

---

38. Assessment: Gastrointestinal System

Conceptual Focus

Structures and Functions of Gastrointestinal System

Assessment of Gastrointestinal System

Diagnostic Studies of Gastrointestinal System

39. Nutritional Problems

Conceptual Focus

Nutritional Problems

Normal Nutrition

Vegetarian Diet

Malnutrition

Nursing and Interprofessional Management: Malnutrition

Specialized Nutritional Support

Nursing Management: Parenteral Nutrition

Eating Disorders

Bulimia Nervosa

40. Obesity

Conceptual Focus

Obesity

Health Risks Associated with Obesity

Nursing and Interprofessional Management: Obesity

Bariatric Surgical Therapy

Nursing Management: Perioperative Care of The Obese Patient

Cosmetic Surgical Therapy

Metabolic Syndrome

Nursing and Interprofessional Management: Metabolic Syndrome

41. Upper Gastrointestinal Problems

Conceptual Focus

Nausea and Vomiting

Nursing Management: Nausea and Vomiting

Oral Inflammation and Infections

Oral Cancer

Nursing Management: Oral Cancer

Esophageal Disorders

Nursing and Interprofessional Management: GERD

Hiatal Hernia

Nursing and Interprofessional Management: Hiatal Hernia

Esophageal Cancer

Nursing Management: Esophageal Cancer

Other Esophageal Disorders

Disorders of the Stomach and Upper Small Intestine

Nursing Management: Peptic Ulcer Disease

Stomach Cancer

Nursing Management: Stomach Cancer

Gastric Surgery

Nursing Management: Gastric Surgery

Gastritis

Nursing and Interprofessional Management: Gastritis

Upper Gastrointestinal Bleeding

Nursing Management: Upper Gastrointestinal Bleeding

Foodborne Illness

42. Lower Gastrointestinal Problems

Conceptual Focus

Diarrhea

Nursing Management: Acute Infectious Diarrhea

Fecal Incontinence

Nursing Management: Fecal Incontinence

Constipation

Nursing Management: Constipation

Acute Abdominal Pain and Laparotomy

Nursing Management: Acute Abdominal Pain

Abdominal Trauma

Chronic Abdominal Pain

Irritable Bowel Syndrome

Inflammatory Disorders

Nursing Management: Appendicitis

Peritonitis

Nursing Management: Peritonitis

Gastroenteritis

Inflammatory Bowel Disease

Nursing Management: Inflammatory Bowel Disease

Intestinal Obstruction

Nursing Management: Intestinal Obstruction

Polyps of Large Intestine

Colorectal Cancer

Nursing Management: Colorectal Cancer

Bowel Resection and Ostomy Surgery

Nursing Management: Bowel Resection and Ostomy Surgery

Diverticulosis and Diverticulitis

Fistulas

Hernias

Malabsorption Syndrome

Celiac Disease

Lactase Deficiency

Short Bowel Syndrome

Gastrointestinal Stromal Tumors

Anorectal Problems

Nursing Management: Hemorrhoids

Anal Fissure

Anorectal Abscess

Anal Fistula

Anal Cancer

Pilonidal Sinus

43. Liver, Biliary Tract, and Pancreas Problems

Conceptual Focus

Disorders of The Liver

Nursing Management: Viral Hepatitis

Drug- and Chemical-Induced Liver Diseases

Autoimmune, Genetic, and Metabolic Liver Diseases

Cirrhosis

Nursing Management: Cirrhosis

Acute Liver Failure

Liver Cancer

Liver Transplantation

Disorders of The Pancreas

Nursing Management: Acute Pancreatitis

Chronic Pancreatitis

Pancreatic Cancer

Nursing Management: Pancreatic Cancer

Disorders of The Biliary Tract

Nursing Management: Gallbladder Disease

Gallbladder Cancer

Section Ten. Problems of Urinary Function

---

44. Assessment: Urinary System

Conceptual Focus

Structures and Functions of Urinary System

Assessment of Urinary System

Diagnostic Studies of Urinary System

45. Renal and Urologic Problems

Infectious and Inflammatory Disorders of Urinary System

Nursing Management: Urinary Tract Infection

Acute Pyelonephritis

Nursing Management: Acute Pyelonephritis

Chronic Pyelonephritis

Urethritis

Urethral Diverticula

Interstitial Cystitis/Painful Bladder Syndrome

Nursing Management: Interstitial Cystitis/Painful Bladder Syndrome

Genitourinary Tuberculosis

Immunologic Disorders of Kidney

Nursing and Interprofessional Management: Acute Poststreptococcal Glomerulonephritis

Nephrotic Syndrome

Obstructive Uropathies

Urinary Tract Calculi

Nursing Management: Urinary Tract Calculi

Strictures

Renal Trauma

Renal Vascular Problems

Nephrosclerosis

Renal Artery Stenosis

Renal Vein Thrombosis

Hereditary Kidney Diseases

Polycystic Kidney Disease

Medullary Cystic Disease

Alport Syndrome

Urinary Tract Tumors

Bladder Cancer

Nursing and Interprofessional Management: Bladder Cancer

Bladder Dysfunction

Nursing Management: Urinary Incontinence

Urinary Retention

Nursing Management: Urinary Retention

Catheterization

Catheter Construction

Types of Catheters

Surgery of the Urinary Tract

Urinary Diversion

Nursing Management: Urinary Diversion

46. Acute Kidney Injury and Chronic Kidney Disease

Conceptual Focus

Acute Kidney Injury

Nursing Management: Acute Kidney Injury

Chronic Kidney Disease

Nursing Management: Chronic Kidney Disease

Dialysis

Peritoneal Dialysis

Hemodialysis

Continuous Renal Replacement Therapy

Wearable Artificial Kidney

Kidney Transplantation

Nursing Management: Kidney Transplant Recipient

Section Eleven. Problems Related to Regulatory and Reproductive Mechanisms

47. Assessment: Endocrine System

Conceptual Focus

Structures and Functions of Endocrine System

Assessment of Endocrine System

Diagnostic Studies of Endocrine System

48. Diabetes Mellitus

Conceptual Focus

Diabetes Mellitus

Nursing Management: Diabetes

Acute Complications of Diabetes

Diabetic Ketoacidosis

Hyperosmolar Hyperglycemia Syndrome

Nursing Management: Diabetes-Related Ketoacidosis and Hyperosmolar Hyperglycemia Syndrome

Hypoglycemia

Nursing and Interprofessional Management: Hypoglycemia

Chronic Complications Associated with Diabetes

Retinopathy

Nephropathy

Neuropathy

Complications of Feet and Lower Extremities

Skin Complications

Infection

Psychologic Considerations

49. Endocrine Problems

Disorders of Anterior Pituitary Gland

Acromegaly

Interprofessional and Nursing Care

Excesses of Other Tropic Hormones

Hypofunction of Pituitary Gland

Interprofessional and Nursing Care

Pituitary Surgery

Nursing Management: Pituitary Surgery

Disorders of Posterior Pituitary Gland

Syndrome of Inappropriate Antidiuretic Hormone

Interprofessional and Nursing Care

Diabetes Insipidus

Interprofessional and Nursing Care

Disorders of Thyroid Gland

Goiter

Thyroiditis

Hyperthyroidism

Nursing Management: Hyperthyroidism

Hypothyroidism

Nursing Management: Hypothyroidism

Thyroid Nodules and Cancer

Interprofessional and Nursing Care

Multiple Endocrine Neoplasia

Disorders of Parathyroid Glands

Nursing Management: Hyperparathyroidism

Hypoparathyroidism

Interprofessional and Nursing Care

Disorders of Adrenal Cortex

Cushing Syndrome

Nursing Management: Cushing Syndrome

Adrenocortical Insufficiency

Interprofessional and Nursing Care

Corticosteroid Therapy

Hyperaldosteronism

Interprofessional and Nursing Care

Disorders of Adrenal Medulla

Interprofessional and Nursing Care

50. Assessment: Reproductive System

Conceptual Focus

Structures and Functions of Male and Female Reproductive Systems

Assessment of Male and Female Reproductive Systems

Diagnostic Studies of Reproductive Systems

51. Breast Disorders

Conceptual Focus

Assessment of Breast Disorders

Benign Breast Disorders

Breast Infections

Fibrocystic Changes

Fibroadenoma

Nipple Discharge

Atypical Hyperplasia

Intraductal Papilloma

Ductal Ectasia

Male Gynecomastia

Breast Cancer

Nursing Management: Breast Cancer

Mammoplasty

Nursing Management: Breast Augmentation and Reduction

52. Sexually Transmitted Infections

Conceptual Focus

Factors Affecting Incidence of Stis

STIs Characterized by Discharge, Cervicitis, or Urethritis

Gonococcal Infections

Trichomoniasis

STIs Characterized by Genital Lesions or Ulcers

Genital Warts

Syphilis

Nursing Management: STIs

53. Female Reproductive Problems

Conceptual Focus

Infertility

Early Pregnancy Loss

Problems Related to Menstruation

Premenstrual Syndrome

Nursing Management: Premenstrual Syndrome

Dysmenorrhea

Abnormal Uterine Bleeding

Nursing Management: Abnormal Uterine Bleeding

Ectopic Pregnancy

Perimenopause and Postmenopause

Nursing Management: Perimenopause and Postmenopause

Infections of Lower Genital Tract

Nursing Management: Infections of Lower Genital Tract

Pelvic Inflammatory Disease (Pid)

Nursing Management: Pelvic Inflammatory Disease

Chronic Pelvic Pain

Endometriosis

Benign Tumors of the Female Reproductive System

Ovarian Cysts

Cervical Polyps

Cancers of the Female Reproductive System

Endometrial Cancer

Ovarian Cancer

Vaginal Cancer

Vulvar Cancer

Nursing and Interprofessional Management: Cancers of Female Reproductive System

Pelvic Organ Prolapse

Uterine Prolapse

Cystocele and Rectocele

Nursing and Interprofessional Management: Pelvic Organ Prolapse

Fistula

Sexual Assault

Nursing Management: Sexual Assault

54. Male Reproductive Problems

Conceptual Focus

Problems of the Prostate Gland

Nursing Management: Benign Prostatic Hyperplasia

Prostate Cancer

Nursing Management: Prostate Cancer

Prostatitis

Problems of the Penis

Congenital Problems

Problems of Prepuce

Problems of Erectile Mechanism

Cancer of Penis

Problems of Scrotum and Testes

Inflammatory and Infectious Problems

Congenital Problems

Acquired Problems

Testicular Cancer

Sexual Function

Erectile Dysfunction

Hypogonadism

Infertility

Section Twelve. Problems Related to Movement and Coordination

---

55. Assessment: Nervous System

Conceptual Focus

Structures and Functions of Nervous System

Assessment of Nervous System

Diagnostic Studies of Nervous System

56. Acute Intracranial Problems

Conceptual Focus

Intracranial Regulation

Increased Intracranial Pressure

Nursing Management: Increased Intracranial Pressure

Head Injury

Nursing Management: Head Injury

Brain Tumors

Nursing Management: Brain Tumors

Cranial Surgery

Nursing Management: Cranial Surgery

Inflammatory Conditions of the Brain

Bacterial Meningitis

Nursing Management: Bacterial Meningitis

Viral Meningitis

Brain Abscess

Encephalitis

57. Stroke

Conceptual Focus

Pathophysiology of Stroke

Risk Factors for Stroke

Types of Stroke

Clinical Manifestations of Stroke

Diagnostic Studies for Stroke

Interprofessional Care for Stroke

Nursing Management: Stroke

58. Chronic Neurologic Problems

Conceptual Focus

Headaches

Tension-Type Headache

Migraine Headache

Cluster Headache

Other Types of Headaches

Interprofessional Care for Headaches

Nursing Management: Headaches

Chronic Neurologic Disorders

Nursing Management: Seizure Disorder

Restless Legs Syndrome

Interprofessional and Nursing Care

Degenerative Neurologic Disorders

Nursing Management: Multiple Sclerosis

Parkinson’s Disease

Nursing Management: Parkinson’s Disease

Myasthenia Gravis

Nursing Management: Myasthenia Gravis

Amyotrophic Lateral Sclerosis

Huntington’s Disease

59. Dementia and Delirium

Conceptual Focus

Dementia

Alzheimer’s Disease

Nursing Management: Alzheimer’s Disease

Delirium

Nursing and Interprofessional Management: Delirium

60. Spinal Cord and Peripheral Nerve Problems

Conceptual Focus

Spinal Cord Problems

Nursing Management: Spinal Cord Injury

Spinal Cord Tumors

Cranial Nerve Disorders

Trigeminal Neuralgia

Nursing Management: Trigeminal Neuralgia

Bell's Palsy

Nursing Management: Bell's Palsy

Polyneuropathies

Chronic Inflammatory Demyelinating Polyneuropathy

Tetanus

Botulism

61. Assessment: Musculoskeletal System

Conceptual Focus

Structures and Functions of Musculoskeletal System

Assessment of Musculoskeletal System

Diagnostic Studies of Musculoskeletal System

62. Musculoskeletal Trauma and Orthopedic Surgery

Conceptual Focus

Health Promotion

Soft Tissue Injuries

Sprains and Strains

Nursing Management: Sprains and Strains

Dislocation and Subluxation

Repetitive Strain Injury

Carpal Tunnel Syndrome

Rotator Cuff Injury

Meniscus Injury

Anterior Cruciate Ligament Injury

Bursitis

Fractures

Nursing Management: Fractures

Complications of Fractures

Types of Fractures

Humeral Shaft Fracture

Pelvic Fracture

Hip Fracture

Nursing Management: Hip Fracture

Femoral Shaft Fracture

Tibial Fracture

Stable Vertebral Fracture

Facial Fracture

Mandibular Fracture

Nursing Management: Mandibular Fracture

Amputation

Nursing Management: Amputation

Common Joint Surgical Procedures

Types of Joint Surgeries

Nursing and Interprofessional Management: Joint Surgery

63. Musculoskeletal Problems

Conceptual Focus

Osteomyelitis

Nursing Management: Osteomyelitis

Bone Tumors

Benign Bone Tumors

Malignant Bone Tumors

Nursing Management: Bone Cancer

Muscular Dystrophy

Low Back Pain

Acute Low Back Pain

Nursing and Interprofessional Management: Acute Low Back Pain

Chronic Low Back Pain

Intervertebral Disc Disease

Nursing Management: Vertebral Disc Surgery

Neck Pain

Foot Disorders

Nursing Management: Foot Disorders

Metabolic Bone Diseases

Osteomalacia

Osteoporosis

Nursing and Interprofessional Management: Osteoporosis

Paget's Disease

64. Arthritis and Connective Tissue Diseases

Conceptual Focus

Arthritis

Osteoarthritis

Nursing Management: Osteoarthritis

Rheumatoid Arthritis

Nursing Management: Rheumatoid Arthritis

Gout

Interprofessional and Nursing Management: Gout

Lyme Disease

Septic Arthritis

Spondyloarthropathies

Ankylosing Spondylitis

Psoriatic Arthritis

Reactive Arthritis

Systemic Lupus Erythematosus

Nursing Management: Systemic Lupus Erythematosus

Scleroderma

Nursing Management: Scleroderma

Polymyositis and Dermatomyositis

Interprofessional and Nursing Care

Mixed Connective Tissue Disease

Sjögren’s Syndrome

Myofascial Pain Syndrome

Fibromyalgia

Systemic Exertion Intolerance Disease (SEID)

Section Thirteen. Care in Specialized Settings

65. Critical Care

Conceptual Focus

Critical Care Nursing

Hemodynamic Monitoring

Nursing Management: Hemodynamic Monitoring

Circulatory Assist Devices

Nursing and Interprofessional Management: Circulatory Assist Devices

Noninvasive Ventilation

Artificial Airways

Nursing and Interprofessional Management: Artificial Airway

Mechanical Ventilation

Other Critical Care Content

66. Shock, Sepsis, and Multiple Organ Dysfunction Syndrome

Conceptual Focus

Shock

Nursing Management: Shock

Systemic Inflammatory Response Syndrome and Multiple Organ Dysfunction Syndrome

Nursing and Interprofessional Management: Sirs and Mods

67. Acute Respiratory Failure and Acute Respiratory Distress Syndrome

Conceptual Focus

Acute Respiratory Failure

Nursing and Interprofessional Management: Acute Respiratory Failure

Acute Respiratory Distress Syndrome

Nursing and Interprofessional Management: ARDS

68. Emergency and Disaster Nursing

Conceptual Focus

Care of Emergency Patient

Environmental Emergencies

Heat-Related Emergencies

Cold-Related Emergencies

Submersion Injuries

Stings and Bites

Poisonings

Violence

Agents of Terrorism

Penetrating Trauma

Emergency and Mass Casualty Incident Preparedness

Appendixes

Appendix A. Basic Life Support for Health Care Providers

Appendix B. Nursing Diagnoses

Appendix C. Laboratory Reference Intervals

About the Authors

Mariann M. Harding, RN, PhD, FAADN, CNE

Mariann Harding is a Professor of Nursing at Kent State University Tuscarawas, New Philadelphia, Ohio, where she has been on the faculty since 2005. She received her diploma in nursing from Mt. Carmel School of Nursing in Columbus, Ohio; her Bachelor of Science in nursing from Ohio University in Athens, Ohio; her Master of Science in Nursing as an adult nurse practitioner from the Catholic University of America in Washington, DC; and her doctorate in nursing from West Virginia University in Morgantown, West Virginia. Her 29 years of nursing experience have primarily been in critical care nursing and teaching in licensed practical, associate, and baccalaureate nursing programs. She currently teaches medical-surgical nursing, health care policy, and evidence-based practice. Her research has focused on promoting student success and health promotion among individuals with gout and facing cancer.

Jeffrey Kwong, RN, DNP, MPH, ANP-BC, FAAN, FAANP

Jeffrey Kwong is a Professor at the School of Nursing at Rutgers, the State University of New Jersey. He has worked for over 20 years in the area of adult primary care with a special focus on HIV. He received his undergraduate degree from the University of California—Berkeley, his nurse practitioner degree from the University of California—San Francisco, and completed his doctoral training at the University of Colorado—Denver. He also has a Master of Science Degree in public health with a focus on health education and behavioral sciences from the University of California—Los Angeles, and he was appointed a Hartford Geriatric Interprofessional Scholar while completing his gerontology education at New York University. In addition to teaching, Dr. Kwong maintains a clinical practice at Gotham Medical Group in New York City. He is a Fellow in the American Association of Nurse Practitioners.

Dottie Roberts, RN, EdD, MSN, MACI, CMSRN, OCNS-C, CNE

Dottie Roberts received her Bachelor of Science in nursing from Beth-El College of Nursing, Colorado Springs, Colorado; her Master of Science in adult health nursing from Beth-El College of Nursing and Health Sciences; her Master of Arts in curriculum and instruction from Colorado Christian University, Colorado Springs, Colorado; and her EdD in healthcare education from Nova Southeastern University, Ft. Lauderdale, Florida. She has over 25 years of experience in medical-surgical and orthopaedic nursing and holds certifications in both specialties. She has also taught in two baccalaureate programs in the Southeast and is certified as a nurse educator. She currently serves as contributing faculty for the RN-BSN program at Walden University. For her dissertation, Dottie completed a phenomenological study on facilitation of critical-thinking skills by clinical faculty in a baccalaureate nursing program. She has been Executive Director of the Orthopaedic Nurses Certification Board since 2005 and editor of *MEDSURG Nursing*, official journal of the Academy of Medical-Surgical Nurses, since 2003. Her free time is spent traveling, reading, and cross-stitching.

Debra Hagler, RN, PhD, ACNS-BC, CNE, CHSE, ANEF, FAAN

Debbie Hagler is a Clinical Professor in the Edson College of Nursing and Health Innovation at Arizona State University in Phoenix. She is Deputy Editor of *The Journal of Continuing Education in Nursing.* She received her Practical Certificate in Nursing, Associate Degree in Nursing, and Bachelor of Science in Nursing from New Mexico State University. She earned a Master of Science from the University of Arizona and a doctorate in Learning and Instructional Technology from Arizona State University. Her clinical background is in adult health and critical care nursing. Her current role focuses on supporting students through the Barrett Honors program and helping faculty members develop their scholarly writing for publication.

Courtney Reinisch, RN, DNP, FNP-BC

Courtney Reinisch is the Undergraduate Program Director and Associate Professor for the School of Nursing at Montclair State University. She earned her Bachelor of Arts in biology and psychology from Immaculata University. She received her Bachelor of Science in nursing and Masters of Science in family practice nurse practitioner degree from the University of Delaware. She completed her Doctor of Nursing Practice degree at Columbia University School of Nursing. Courtney's nursing career has focused on providing care for underserved populations in primary care and emergency settings. She has taught in undergraduate and graduate nursing programs in New York and New Jersey. Courtney enjoys playing tennis, snowboarding, reading, and spending time with her family and dogs. She is the biggest fan for her nieces and nephews at their soccer games, cross-country events, and track meets. She is an active volunteer in the Parents Association of her son's school and advocates for the needs of students with learning differences and the LGBTQ community.

Dedication

To the Profession of Nursing and to the Important People in Our Lives

Mariann

My husband Jeff, our daughters Kate and Sarah, and my parents, Mick and Mary.

Jeff

My parents, Raymond and Virginia, thank you for believing in me and providing me the opportunity to become a nurse.

Dottie

My husband Steve and my children Megan, E.J., Jessica, and Matthew, who have supported me through four college degrees and countless writing projects; and to my son-in-law Al, our grandsons Oscar and Stephen, and my new daughter-in-law Melissa.

Debbie

My husband James, our children Matthew, Andrew, Amanda, and Diana, and our granddaughter Emma.

Courtney

To future nurses and the advancement of health care globally.

Preface

The eleventh edition of *Lewis's Medical-Surgical Nursing: Assessment and Management of Clinical Problems* incorporates the most current medical-surgical nursing information in an easy-to-use format. This textbook is a comprehensive resource containing the essential information that students need to prepare for class, examinations, clinical assignments, and safe and comprehensive patient care. The text and accompanying resources include many features to help students learn key medical-surgical nursing content, including patient and caregiver teaching, gerontology, interprofessional care, cultural and ethnic considerations, patient safety, genetics, nutrition and drug therapy, evidence-based practice, and much more.

To address the rapidly changing practice environment, all efforts were directed toward building on the strengths of the previous editions while delivering this more effective new edition. To help students and faculty members focus on the most important concepts in patient care, most chapters open with a conceptual focus that introduces students to the common concepts shared by patients experiencing the main exemplars discussed in the chapter. This edition features more body maps and has many new illustrations. Lengthy diagnostic tables in the assessment chapters have been separated into specific categories, including radiologic studies and serology studies. The previously combined visual and auditory content is now in separate chapters focusing on the assessment and management of vision and hearing disorders. New Promoting Population Health boxes address strategies to improve health outcomes.

For a text to be effective, it must be understandable. In this edition,

great effort has been put into improving the readability and lowering the reading level. Students will find more clear and easier-to-read language, with an engaging conversational style. The narrative addresses the reader, helping make the text more personal and an active learning tool. The language is more positive. For example, particular side effects and complications are referred to as *common,* as opposed to *not uncommon.*

International Classification for Nursing Practice (ICNP) nursing diagnoses, one of the terminologies recognized by the American Nurses Association, are used throughout the text and ancillary materials. The language is similar to that of NANDA-I. ICNP nursing diagnoses are used in many facilities worldwide to document nursing care in electronic health records. By introducing students to the ICNP nursing diagnoses, students will learn a more shared vocabulary. This should translate into the more accurate use of diagnostic language in clinical practice across healthcare settings.

Contributors were selected for their expertise in specific content areas; one or more specialists in a given subject area have thoroughly reviewed each chapter to increase accuracy. The editors have undertaken final rewriting and editing to achieve internal consistency. The comprehensive and timely content, special features, attractive layout, full-color illustrations, and student-friendly writing style combine to make this the textbook used in more nursing schools than any other medical-surgical nursing textbook.

Organization

Content is organized into 2 major divisions. The first division, Sections 1 through 3 (Chapters 1 through 16), discusses general concepts related to the care of adult patients. The second division, Sections 4 through 13 (Chapters 17 through 68), presents nursing assessment and nursing management of medical-surgical problems. At the beginning of each chapter, the Conceptual Focus helps students focus on the key concepts and integrate concepts with exemplars affecting different

body systems. Learning Outcomes and Key Terms assist students in identifying the key content for that chapter.

The various body systems are grouped to reflect their interrelated functions. Each section is organized around 2 central themes: assessment and management. Chapters dealing with assessment of a body system include a discussion of the following:

1. A brief review of anatomy and physiology, focusing on information that will promote understanding of nursing care
2. Health history and noninvasive physical assessment skills to expand the knowledge base on which treatment decisions are made
3. Common diagnostic studies, expected results, and related nursing responsibilities to provide easily accessible information

Management chapters focus on the pathophysiology, clinical manifestations, diagnostic studies, interprofessional care, and nursing management of various diseases and disorders. The nursing management sections are presented in a consistent format, organized into assessment, nursing diagnoses, planning, implementation, and evaluation. To emphasize the importance of patient care in and across various clinical settings, nursing implementation of all major health problems is organized by the following levels of care:

1. Health Promotion
2. Acute Care
3. Ambulatory Care

Special Features

The 6 competencies for registered nursing practice identified by QSEN serve as the foundation of the text and are highlighted in the core content, case studies, and nursing care plans.

- *New!* **Nursing Management** tables and boxes focus on the actions nurses need to take to deliver safe, quality, effective patient care.
- *New!* **Diagnostic Studies** tables focus on the specific type of study, such as interventional, serologic, or radiologic, with more detailed information on interpreting results and associated nursing care.
- **Cultural and ethnic health disparities** content and boxes in the text highlight risk factors and important issues related to the nursing care of various ethnic groups. A special Culturally Competent Care heading denotes cultural and ethnic content related to diseases and disorders. Chapter 2 (Health Equity and Culturally Competent Care) discusses health status differences among groups of people related to access to care, economic aspects of health care, gender and cultural issues, and the nurse's role in promoting health equity.
- **Interprofessional care** is highlighted in special Interprofessional Care sections in all management chapters and Interprofessional Care tables throughout the text.
- **Focused Assessment boxes** in all assessment chapters provide brief checklists that help students do a more practical "assessment on the run" or bedside approach to assessment. They can be used to evaluate the status of previously identified health problems and monitor for signs of new problems.
- **Safety Alert boxes** highlight important patient safety issues and focus on the National Patient Safety Goals.
- **Pathophysiology Maps** outline complex concepts related to diseases in a flowchart format, making them easier to understand.
- **Patient and caregiver teaching** is an ongoing theme throughout the text. Chapter 4 (Patient and Caregiver Teaching) emphasizes the increasing importance and prevalence of patient management of chronic illnesses and conditions and the role of the caregiver in patient care.

- *New!* **Conceptual Focus** at the beginning of each chapter helps students focus on the key concepts and integrate concepts with exemplars affecting different body systems.
- **Gerontology and chronic illness** are discussed in Chapter 5 (Chronic Illness and Older Adults) and included throughout the text under Gerontologic Considerations headings and in Gerontologic Differences in Assessment tables.
- **Nutrition** is highlighted throughout the textbook. Nutritional Therapy tables summarize nutritional interventions and promote healthy lifestyles in patients with various health problems.
- *New!* **Promoting Population Health boxes** present health care goals and interventions as they relate to specific disorders, such as diabetes and cancer, and to health promotion, such as preserving hearing and maintaining a healthy weight.
- **Extensive drug therapy** content includes Drug Therapy tables and concise Drug Alerts highlighting important safety considerations for key drugs.
- **Genetics content** includes:
    - Genetics in Clinical Practice boxes that summarize the genetic basis, genetic testing, and clinical implications for genetic disorders that affect adults
    - A genetics chapter that focuses on practical application of nursing care as it relates to this important topic
    - Genetic Risk Alerts in the assessment chapters, which call attention to important genetic risks
    - Genetic Link headings in the management chapters, which highlight the specific genetic bases of many disorders
- **Gender Differences** boxes discuss how women and men are affected differently by conditions such as pain and hypertension.
- **Check Your Practice boxes** challenge students to think critically, analyze patient assessment data, and implement the

appropriate intervention. Scenarios and discussion questions are provided to promote active learning.

- **Complementary & Alternative Therapies boxes** expand on this information and summarize what nurses need to know about therapies such as herbal remedies, acupuncture, and yoga.
- **Ethical/Legal Dilemmas boxes** promote critical thinking for timely and sensitive issues that nursing students may deal with in clinical practice—topics such as informed consent, advance directives, and confidentiality.
- **Emergency Management tables** outline the emergency treatment of health problems most likely to require emergency intervention.
- **Nursing care plans** on the Evolve website focus on common disorders or exemplars. These care plans incorporate ICNP nursing diagnoses, Nursing Interventions Classification (NIC), and Nursing Outcomes Classification (NOC) in a way that clearly shows the linkages among NIC, NOC, and nursing diagnoses and applies them to nursing practice.
- Coverage on delegation and prioritization includes:
    - Specific topics and skills related to delegation and the nurse's role in working with members of the interprofessional team, which are detailed in Nursing Management tables.
    - Delegation and prioritization questions in case studies and Bridge to NCLEX Examination Questions.
    - Nursing interventions throughout the text, listed in order of priority.
    - Nursing diagnoses in the nursing care plans, listed in order of priority.
- **Assessment Abnormalities tables** in assessment chapters alert the nurse to commonly encountered abnormalities and their possible etiologies.
- **Nursing Assessment tables** summarize the key subjective and

objective data related to common diseases. Subjective data are organized by functional health patterns.
- **Health History tables** in assessment chapters present key questions to ask patients related to a specific disease or disorder.
- **Evidence-based practice** is covered in Applying the Evidence boxes and evidence-based practice-focused questions in the case studies. Applying the Evidence boxes use a case study approach to help students learn to use evidence in making patient care decisions.
- **Informatics boxes and content** in Chapter 4 (Patient and Caregiver Teaching) reflect the current use and importance of technology as it relates to patient self-management.
- **Bridge to NCLEX® Examination Questions** at the end of each chapter are matched to the Learning Outcomes and help students learn the important points in the chapter. Answers are provided just below the questions for immediate feedback, and rationales are provided on the Evolve website.
- **Case Studies** with photos bring patients to life. Management chapters have case studies at the end of the chapters. These cases help students learn how to prioritize care and manage patients in the clinical setting. Unfolding case studies are included in each assessment chapter, and case studies that focus on managing care of multiple patients are included at the end of each section. Discussion questions with a focus on prioritization, delegation, and evidence-based practice are included in all case studies. Answer guidelines are provided on the Evolve website.

Learning Supplements for Students

- The handy **Clinical Companion** presents approximately 200 common medical-surgical conditions and procedures in a concise, alphabetical format for quick clinical reference.

Designed for portability, this popular reference includes the essential, need-to-know information for treatments and procedures in which nurses play a major role. An attractive and functional four-color design highlights key information for quick, easy reference.

- An exceptionally thorough **Study Guide** contains over 500 pages of review material that reflect the content found in the textbook. It features a wide variety of clinically relevant exercises and activities, including NCLEX-format multiple choice and alternate format questions, case studies, anatomy review, critical thinking activities, and much more. It features an attractive four-color design and many alternate-item format questions to better prepare students for the NCLEX examination. An answer key is included to provide students with immediate feedback as they study.
- The **Evolve Student Resources** are available online at *http://evolve.elsevier.com/Lewis/medsurg* and include the following valuable learning aids organized by chapter:
    - Printable **Key Points** summaries for each chapter.
    - 1000 NCLEX examination **Review Questions.**
    - **Answer Guidelines** to the case studies in the textbook.
    - **Rationales for the Bridge to NCLEX® Examination Questions** in the textbook.
    - 55 **Interactive Case Studies** with state-of-the-art animations and a variety of learning activities, which provide students with immediate feedback. Ten of the case studies are enhanced with photos and narration of the clinical scenarios.
    - Customizable **Nursing Care Plans** for over 60 common disorder or exemplars.
    - **Conceptual Care Map Creator.**
    - **Audio glossary** of key terms, available as comprehensive alphabetical glossary and organized by chapter.

        - **Fluids and Electrolytes Tutorial.**
        - **Content Updates.**
- More than just words on a screen, **Elsevier eBooks** come with a wealth of built-in study tools and interactive functionality to help students better connect with the course material and their instructors. In addition, with the ability to fit an entire library on one portable device, students have the ability to study when, where, and how they want.

Teaching Supplements for Instructors

- The **Evolve Instructor Resources** (available online at *http://evolve.elsevier.com/Lewis/medsurg*) remain the most comprehensive set of instructor's materials available, containing the following:
    - **TEACH for Nurses Lesson Plans** with electronic resources organized by chapter to help instructors develop and manage the course curriculum. This exciting resource includes:
        - Objectives
        - Pre-class activities
        - Nursing curriculum standards
        - Student and instructor chapter resource listings
        - Teaching strategies, with learning activities and assessment methods tied to learning outcomes
        - **Case studies** with answer guidelines
    - The **Test Bank** features over 2000 NCLEX examination test questions with text page references and answers coded for NCLEX Client Needs category, nursing process, and cognitive level. The test bank includes hundreds of prioritization, delegation, and multiple patient questions. All

alternate-item format questions are included. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by NCLEX category, cognitive level, nursing process step, and question type; and administer and grade online tests.

- The **Image Collection** contains more than 800 full-color images from the text for use in lectures.
- An extensive collection of **PowerPoint Presentations** includes over 125 different presentations focused on the most common diseases and disorders. The presentations have been thoroughly revised to include helpful instructor notes/teaching tips, unfolding case studies, illustrations and photos not found in the book, new animations, and updated audience response questions for use with iClicker and other audience response systems.
- Course management system.
- Access to all student resources listed above.

- The **Simulation Learning System (SLS)** is an online toolkit that helps instructors and facilitators effectively incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The SLS provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each scenario in the SLS complements the textbook content and helps bridge the gap between lecture and clinical. The SLS provides the perfect environment for students to practice what they are learning in the text for a true-to-life, hands-on learning experience.

Acknowledgments

The editors are especially grateful to many people at Elsevier who assisted with this revision effort. In particular, we wish to thank the team of Jamie Blum, Rebecca Leenhouts, Denise Roslonski, Clay Broeker, and Julie Eddy. In addition, we want to thank Kristin Oyirifi in marketing. We also wish to thank our contributors and reviewers for their assistance with the revision process.

We are particularly indebted to the faculty, nurses, and student nurses who have put their faith in our textbook to assist them on their path to excellence. The increasing use of this book throughout the United States, Canada, Australia, and other parts of the world has been gratifying. We appreciate the many users who have shared their comments and suggestions on the previous editions.

We sincerely hope that this book will assist both students and clinicians in practicing truly professional nursing.

Special Features

Assessment Abnormalities Tables

Auditory System, 21, p. 382

Breast, 50, p. 1184

Cardiovascular System, 31, p. 665

Endocrine System, 47, p. 1100

Female Reproductive System, 50, p. 1184

Fluid and Electrolyte Imbalances, 16, p. 290

Gastrointestinal System, 38, p. 841

Hematologic System, 29, p. 595

Integumentary System, 22, p. 404

Male Reproductive System, 50, p. 1185

Musculoskeletal System, 61, p. 1439

Nervous System, 55, p. 1294

Respiratory System, 25, p. 468

Urinary System, 44, p. 1016

Vascular Skin Lesions, 29, p. 597

Visual System, 20, p. 356

Case Studies

End-of-Chapter Case Studies

Acute Respiratory Distress Syndrome, 67, p. 1603

Alzheimer's Disease, 59, p. 1400

Benign Prostatic Hyperplasia With Acute Urinary Retention, 54, p. 1276

Breast Cancer, 51, p. 1209

Burn Injury, 24, p. 451

Chronic Kidney Disease, 46, p. 1085

Chronic Obstructive Pulmonary Disease, 28, p. 581

Cirrhosis of the Liver, 43, p. 1003

Colorectal Cancer, 42, p. 966

Critical Care and Mechanical Ventilation, 65, p. 1563

Diabetic-Related Ketoacidosis, 48, p. 1141

Dysrhythmia and Cardiac Arrest, 35, p. 775

Fluid and Electrolyte Imbalance, 16, p. 295

Glaucoma and Diabetic Retinopathy, 20, p. 373

Gonococcal and Chlamydial Infection, 52, p. 1226

Graves' Disease, 49, p. 1169

Health Disparities, 2, p. 31

Heart Failure, 34, p. 752

HIV Infection, 14, p. 229

Inflammation and Infection, 11, p. 172

Insomnia, 7, p. 100

Intraoperative Patient, 18, p. 326

Laryngeal Cancer, 26, p. 499

Leukemia, 30, p. 652
Melanoma and Dysplastic Nevi, 23, p. 429
Ménière's Disease, 21, p. 393
Metastatic Bone Tumor/Pathologic Fracture, 63, p. 1496
Myocardial Infarction, 33, p. 731
Obesity, 40, p. 886
Older Adults, 5, p. 74
Pain, 8, p. 125
Painful Bladder and Frequent Urination, 45, p. 1057
Patient and Caregiver Teaching, 4, p. 56
Peptic Ulcer Disease, 41, p. 921
Peripheral Artery Disease, 37, p. 824
Periprosthetic Hip Fracture and Revision Arthroplasty, 62, p. 1475
Pneumonia and Lung Cancer, 27, p. 538
Postoperative Patient, 19, p. 345
Preoperative Patient, 17, p. 311
Primary Hypertension, 32, p. 696
Rheumatoid Arthritis, 64, p. 1529
Seizure Disorder With Headache, 58, p. 1380
Shock, 66, p. 1586
Spinal Cord Injury, 60, p. 1426
Spiritual Distress at End of Life, 9, p. 140
Stress-Induced Illness, 6, p. 86
Stroke, 57, p. 1350
Substance Use Disorder, 10, p. 153

Trauma, 68, p. 1621

Traumatic Brain Injury, 56, p. 1327

Undernutrition, 39, p. 867

Uterine Fibroids and Endometrial Cancer, 53, p. 1251

Valvular Heart Disease, 36, p. 797

Managing Care of Multiple Patients Case Studies

Care in Specialized Settings, Section 13, p. 1623

Perioperative Care, Section 4, p. 347

Problems of Ingestion, Digestion, Absorption, and Elimination, Section 9, p. 1006

Problems of Oxygenation: Perfusion, Section 8, p. 827

Problems of Oxygenation: Transport, Section 7, p. 655

Problems of Oxygenation: Ventilation, Section 6, p. 584

Problems of Urinary Function, Section 10, p. 1088

Problems Related to Altered Sensory Input, Section 5, p. 454

Problems Related to Comfort and Coping, Section 2, p. 155

Problems Related to Homeostsis and Protection, Section 3, p. 298

Problems Related to Movement and Coordination, Section 12, p. 1532

Problems Related to Regulatory and Reproductive Mechanisms, Section 11, p. 1278

Assessment Case Studies

SECTION ONE

Concepts in Nursing Practice

OUTLINE

1. Professional Nursing
2. Health Equity and Culturally Competent Care
3. Health History and Physical Examination
4. Patient and Caregiver Teaching
5. Chronic Illness and Older Adults

1

Professional Nursing

Mariann M. Harding

LEARNING OUTCOMES

1. Describe professional nursing practice in terms of domain, definitions, and recipients of care.
2. Compare the different scopes of practice available to professional nurses.
3. Describe the role of critical thinking skills and using the nursing process to provide patient-centered care.
4. Apply the SBAR procedure and effective communication techniques in the clinical setting.
5. Explore the role of the professional nurse in delegating care to licensed practical/vocational nurses and unlicensed assistive personnel.
6. Discuss the role of integrating safety and quality improvement processes into nursing practice.
7. Evaluate the role of informatics and technology in nursing practice.
8. Apply concepts of evidence-based practice to nursing practice.

Conceptual Focus

Care Competencies
Leadership
Professional Identity

Caring is the essence of nursing.

Jean Watson

http://evolve.elsevier.com/Lewis/medsurg/

This chapter presents an overview of professional nursing practice, discussing the wide variety of roles and responsibilities that nurses fulfill to meet society's health care needs. This overview includes several key concepts that are part of competent nursing practice.

These include safety, quality, informatics, and collaboration.

Professional Nursing Practice

Domain of Nursing Practice

Nursing practice today consists of a wide variety of roles and responsibilities necessary to meet society's health care needs. As a nurse, you are the frontline professional of health care (Fig. 1.1). You can practice in virtually all health care settings and communities. You have never been more important to health care than you are today. As a nurse, you (1) offer skilled care to those recuperating from illness or injury, (2) advocate for patients' rights, (3) teach patients to manage their health, (4) support patients and their caregivers at critical times, and (5) help them navigate the complex health care system. Although many nurses work in acute care facilities, nurses also practice in long-term care, home care, community health, public health centers, schools, and ambulatory or outpatient clinics. Wherever you practice, recipients of your care include individuals, families, groups, or communities.

The American Nurses Association (ANA) states that the authority for nursing practice is based on a contract with society that acknowledges professional rights and responsibilities, as well as mechanisms for public accountability.[1] The knowledge and skills that make up nursing practice are based on society's expectations and needs. Nursing practice continues to evolve according to society's health care needs and as knowledge and technology expand. This chapter introduces concepts and factors that affect professional nursing practice.

FIG. 1.1 Nurses are frontline professionals of health care. (© Michael Jung/iStock/Thinkstock.)

Definitions of Nursing

Well-known definitions of nursing show that the basic themes of health, illness, and caring have existed since Florence Nightingale described nursing. Following are 2 such examples:

- Nursing is putting the patient in the best condition for nature to act (Nightingale).[2]
- The nurse's unique function is to aid patients, sick or well, in performing those activities contributing to health or its recovery (or to peaceful death) that they would perform unaided if they had the necessary strength, will, or knowledge —and to do this in such a way as to help them gain independence as rapidly as possible (Henderson).[3]

In 1980 the ANA defined **nursing** as "the diagnosis and treatment of human responses to actual and potential health problems."[1] In this context, your care of a person with a fractured hip would focus on the patient's response to impaired mobility, pain, and loss of independence. The 2010 edition of the ANA's *Nursing: A Social Policy Statement* provided a new definition of nursing that reflects the continuing evolution of nursing practice:

> ***Nursing*** *is the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations.*[1]

Nursing's View of Humanity

A person has physiologic (or biophysical), psychologic (or emotional), sociocultural (or interpersonal), spiritual, and environmental components or dimensions. In this book, we consider a person to be in constant interaction with a changing environment. A person is composed of interrelated dimensions and not separate entities. Thus a problem in 1 dimension may affect 1 or more of the other dimensions. A person's behavior is meaningful and oriented toward fulfilling needs, coping with stress, and developing one's self. However, at times a person needs help to meet these needs, cope successfully, or develop his or her unique potential.

Scope of Nursing Practice

The essential core of nursing practice is to deliver holistic, patient-centered care. It includes assessment and evaluation, giving a variety of interventions, patient and family teaching, and being a member of the interprofessional health care team.

The extent that nurses engage in their scope of practice depends on their educational preparation, experience, role, and state law. To enter practice, a nurse must complete an accredited program and pass an examination verifying that the nurse has the knowledge necessary to provide safe care. Entry-level nurses with associate or baccalaureate degrees are prepared to function as generalists. At this level, nurses provide direct health care and focus on ensuring coordinated and comprehensive care to patients in a variety of settings. Nurses work collaboratively with other health care providers to manage the needs of persons and groups.

With experience and continued study, nurses may specialize in a specific practice area. Certification is a formal way for nurses to obtain professional recognition for having expertise in a specialty area. A variety of nursing organizations offer certification in nursing specialties.[4] Certification usually requires a certain amount of clinical experience and successful completion of an examination. Recertification usually requires ongoing clinical experience and continuing education. Common nursing specialties include critical care, women's health, geriatric, medical-surgical, perinatal, emergency, psychiatric/mental health, and community health nursing.

Additional formal education and experience can prepare nurses for advanced practice. An **advanced practice registered nurse (APRN)** is a nurse educated at the master's or doctoral level, with advanced education in pathophysiology, pharmacology, and health assessment and expertise in a specialized area of practice. APRNs include clinical nurse specialists, nurse practitioners, nurse midwives, and nurse anesthetists. APRNs play a vital role in the health care delivery system. In addition to managing and delivering direct patient care, APRNs have roles in leadership, quality improvement, evidence-based practice, and informatics.

The doctor of nursing practice (DNP) degree is a practice-focused terminal nursing degree. With raising the educational preparation for APRNs to the doctoral level, nursing is at the same level as other health professions that offer practice doctorates (e.g., pharmacy [PharmD], physical therapy [DPT]). Nurses with a research-focused doctorate (PhD) typically are used in health care settings as nurse faculty, clinical experts, researchers, and health care system executives.

Standards of Professional Nursing Practice

To guide nurses in how to perform professionally, the ANA defined Standards of Professional Nursing Practice. There are 2 parts, Standards of Practice and Standards of Professional Performance.[5] The Standards of Practice describe a competent level of nursing care, based on the nursing process. The Standards of Professional Performance describe behavioral competencies expected of a nurse. You are following the performance standards when you practice ethically and use evidence-based practice. Communicating effectively and staying competent in practice are important. You must be able to work in collaboration with other interprofessional team members, patients, and caregivers.

Influences on Professional Nursing Practice

Expanding Knowledge and Technology

Ever-changing technology and rapidly expanding clinical knowledge add to the complexity of health care. The increased treatment, diagnostic, and care options available are changing care delivery and extending patients' lives. Discoveries in genetics are changing the way we think about diseases such as cancer and heart disease. For example, genetic information guides breast cancer screening. If a woman has cancer, this information allows for treatment and drug

therapy based on her genetic makeup. Ethical dilemmas and controversies arise about the use of new scientific knowledge and the disparities that exist in patients' access to technologically advanced health care. Throughout this book, genetics, informatics, and ethical/legal boxes highlight expanding knowledge and technology's impact on nursing practice.

Diverse Populations

Patient populations are more diverse than ever. Americans are living longer, with the number of people with chronic illnesses and multiple co-morbidities increasing. Unlike those who receive acute, episodic care, patients with chronic illnesses have complex needs. They see different health care providers in various settings over an extended period. With care shifting from hospitals and nursing homes to managed care in the community, you need to be able to manage and coordinate care when patients are transitioning among different settings.

At the same time, you will be caring for a more culturally and ethnically diverse population. When delivering care, you must consider the patient's and caregiver's cultural beliefs and values. Immigrants, particularly undocumented immigrants, often lack the resources necessary to access health care. Inability to pay for health care is related to a tendency to delay seeking care, resulting in illnesses that are more serious at the time of diagnosis. Boxes throughout this book emphasize the influence of such factors as gender, culture, and ethnicity on nursing practice.

Consumerism

Health care is a consumer-focused business, and patients today are more involved in their health care. They want more control over their health care and expect high-quality, coordinated, and financially reasonable care. Health information is readily available. Many patients are very knowledgeable about their health and seek information about health problems and health care from media and

Internet sources. They gather information so that they can have a voice in making decisions about their health care. As a nurse, you must be able to help patients access, interpret, and use safe health care information (Fig. 1.2).

Health Care Financing

High health care costs are a growing problem. There are many reasons for the continued increase in costs. These include the rising use of prescription medications, administrative costs, and new medical innovations and treatments.[6] Many changes in health care systems that influence nursing care delivery are started by the government, employers, insurance companies, and regulating agencies. They are usually in effort to contain spending and provide more cost-effective health care. Historically, the most notable event related to reimbursement was the establishment of prospective payment systems in the Medicare program. With this system, payment for hospital services for Medicare patients are based on flat fees determined by the diseases and problems treated during the admission. For example, if a patient had a total knee replacement, the hospital receives a set sum of money, such as $45,000, for the patient's care.

FIG. 1.2 The patient, family, and nurse collaborate as part of coordinating high-quality care. (© monkeybusinessimages/iStock/Thinkstock.)

Other health care systems followed by introducing managed care systems that use prospective payment as a means of offering cost-effective health care delivery. In health maintenance organizations (HMOs) and preferred provider organizations (PPOs), charges are negotiated before the delivery of care using fixed reimbursement rates or capitation fees for medical care, hospitalization, and other health care services.

Now, quality and performance initiatives are driving further changes in health care financing. Value-based purchasing programs base reimbursement to health care providers on their performance on certain quality measures. These quality measures include clinical outcomes, patient safety, patient satisfaction, and the provider's adherence to evidence-based practice. Those who provide quality care at a lower cost may receive more payment.

As part of value-based purchasing, payment for care can be withheld if a patient experiences events such as developing a pressure injury during a hospital stay or having something happen that is considered preventable (e.g., a fall-related injury, having wrong-site surgery).[7] This type of event is considered a *serious reportable event (SRE).* SREs are discussed later in this chapter on p. 10.

Health Policy

Legislation has serious implications for health care delivery and nursing practice. The 2010 Patient Protection and Affordable Care Act (ACA) was the most important health care legislation since the creation of Medicare in 1965. The ACA triggered changes throughout the health care system. The ACA's main goal was to increase access to health care. The ACA created new health care delivery and payment models that emphasized teamwork, care coordination, and quality care.

The ACA encourages the creation of accountable care organizations (ACOs). ACOs are groups of physicians, hospitals, and other health care providers who unite to coordinate care for Medicare patients. The goal of an ACO is to ensure that patients, especially the chronically ill, get the right care at the right time, while avoiding duplicate services and preventing errors. As a nurse, you must take a leadership role in creating health care systems that provide safe, quality, patient-centered care.

Professional Nursing Organizations

The ANA is the primary professional nursing organization. There are many professional specialty organizations, such as the American Association of Critical-Care Nurses (AACN), National Association of Orthopedic Nurses (NAON), and Oncology Nursing Society (ONS). Professional organizations play a role in promoting quality patient care and professional nursing practice. These roles include developing standards of practice and codes of ethics, supporting research, and lobbying for legislation and regulations. Major nursing organizations

promote research into the causes of errors, develop strategies to prevent future errors, and address nursing issues that affect the nurse's ability to deliver patient care safely. Nurses join a professional organization to keep current in their practice and network with others who are interested in a specific practice area.

A program that supports nurses is the American Nurses Credentialing Center's Magnet Recognition Program. The Magnet program "recognizes health care organizations for quality patient care, nursing excellence and innovations in professional nursing practice."[8] Magnet designation shows a high quality of nursing care and achievement of a positive practice environment for nurses. Nurses who work in Magnet facilities have low turnover and burnout rates and more opportunities for professional and personal growth. This leads to better patient outcomes and greater career satisfaction.

Nursing Core Competencies

Several high-profile reports over the past 20 years have highlighted problems with the quality of health care. One of these reports, *The Future of Nursing: Leading Change, Advancing Health,* acknowledged the link between professional nursing practice and health care delivery. The report discussed how health care providers, including nurses, were not being adequately prepared to provide the highest quality care possible. It recommended making changes so that nurses will have the skills to advance health care and play leadership roles in the health care system[9] (Table 1.1).

To address nursing's role in solving these problems, the Robert Wood Johnson Foundation funded the *Quality and Safety Education for Nurses (QSEN) Institute.* QSEN has made a major contribution to nursing by defining specific competencies that nurses need to have to practice safely and effectively in today's complex health care system. The rest of this chapter describes each of the 6 QSEN nursing core competencies and the knowledge, skills, and attitudes (KSAs) necessary in each area: (1) patient-centered care, (2) teamwork and collaboration, (3) safety, (4) quality improvement, (5) informatics, and

(6) evidence-based practice[10] (Table 1.2). When you are licensed as a registered nurse, you accept responsibility to base your practice on these core competencies.

TABLE 1.1 Key Messages for the Future of Nursing

- Nurses should practice to the full extent of their education and training.
- Nurses should achieve high education and training through an improved education system that promotes seamless academic progression.
- Nurses should be full partners with physicians and other health professionals in redesigning health care.
- Effective workforce planning and policy making require better data collection and information infrastructure.

Source: IOM (now HMD) recommendations. Retrieved from www.thefutureofnursing.org/recommendations.

Patient-Centered Care

Nurses have long shown that they deliver patient-centered care based on each patient's unique needs and understanding of the patient's preferences, values, and beliefs. Patient-centered care is interrelated with quality and safety. In a patient-centered care model, patients and caregivers seek and receive care from competent and knowledgeable health care professionals. In addition, patients and caregivers are involved in making decisions and coordinating care.

Nursing Process

Nurses provide patient-centered care using an organizing framework called the *nursing process*. The **nursing process** is a problem-solving approach to the identification and treatment of patient problems that

is the foundation of nursing practice. The nursing process framework provides a structure for delivering nursing care and the knowledge, judgments, and actions that nurses use to achieve best patient outcomes. Once started, the nursing process is continuous and cyclic.

The nursing process consists of 5 phases: assessment, diagnosis, planning, implementation, and evaluation (Fig. 1.3). There is a basic order to the nursing process, beginning with assessment. *Assessment* is the collection of subjective and objective patient information on which you will base your plan of care. *Diagnosing* is the act of analyzing the assessment data and making a judgment about the nature of the data. It includes your identifying nursing diagnoses or problems and collaborative problems. During *planning,* you use nursing diagnoses and problems to develop patient outcomes or goals and identify nursing interventions to accomplish the outcomes. *Implementation* is the activation of the plan with the use of nursing interventions. *Evaluation* is a continual activity. During evaluation you decide whether the patient outcomes have been met because of the nursing interventions. If the outcomes were not met, a review of the steps of the process is necessary to figure out why not. You may need to revise the assessment (data collection), nursing diagnoses, planning (determining patient outcomes), or implementation (nursing interventions).

Standard Nursing Terminologies

The demands of the health care system challenge nursing to define its contribution to health care. The nursing profession can describe its unique role by answering questions such as: What do nurses do? How do they do it? How does it make a measurable difference in the health of those for whom they care? How are nursing's contributions different from those of medicine?

In response to these questions, nursing uses standard terminologies (also called *classification systems* or *taxonomies*) to define and evaluate nursing care. This promotes continuity of patient care and gives data showing nursing's impact on patient outcomes. Instead of using a variety of words to describe the same patient problems and nursing

interventions, nurses use a common language to improve communication.

TABLE 1.2 QSEN Competencies

Competency	Knowledge, Skills, and Attitudes
Patient-Centered Care	
Recognize the patient and caregiver as full partners in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs	• Provide care with sensitivity and respect, taking into consideration the patient's perspectives, beliefs, and cultural background • Assess level of comfort and treat appropriately • Engage the patient in an active partnership that promotes health, well-being, and self-care management • Facilitate patient's informed consent for care
Teamwork and Collaboration	
Function effectively within nursing and interprofessional teams	• Value the expertise of each interprofessional member • Initiate appropriate referrals • Follow communication practices that minimize risks associated with hand-offs and transitions in care • Take part in interprofessional rounds
Safety	
Minimize risk of harm to patients and providers	• Follow recommendations from national safety campaigns • Appropriately communicate concerns related to hazards and errors • Contribute to designing systems to improve safety
Quality Improvement	
Use data to monitor the outcomes of care and to improve the quality and safety of health care systems	• Use quality measures to understand performance • Identify gaps between local and best practices • Take part in investigating the circumstances surrounding a sentinel event (never event) or serious reportable event (SRE)
Informatics	
Use information and technology to communicate, manage knowledge, reduce errors, and support decision making	• Protect confidentiality of patient's protected health information • Document appropriately in electronic health records • Use communication technologies to coordinate patient care • Respond correctly to clinical decision-making alerts
Evidence-Based Practice	
Integrate best current evidence with clinical expertise and the patient/family preferences and values for delivery of optimal health care	• Read research, clinical practice guidelines, and evidence reports related to area of practice • Base patient care plan on patient's values, clinical expertise, and evidence • Continuously improve clinical practice based on new knowledge

Source: QSEN competencies. Retrieved from www.qsen.org/competencies.

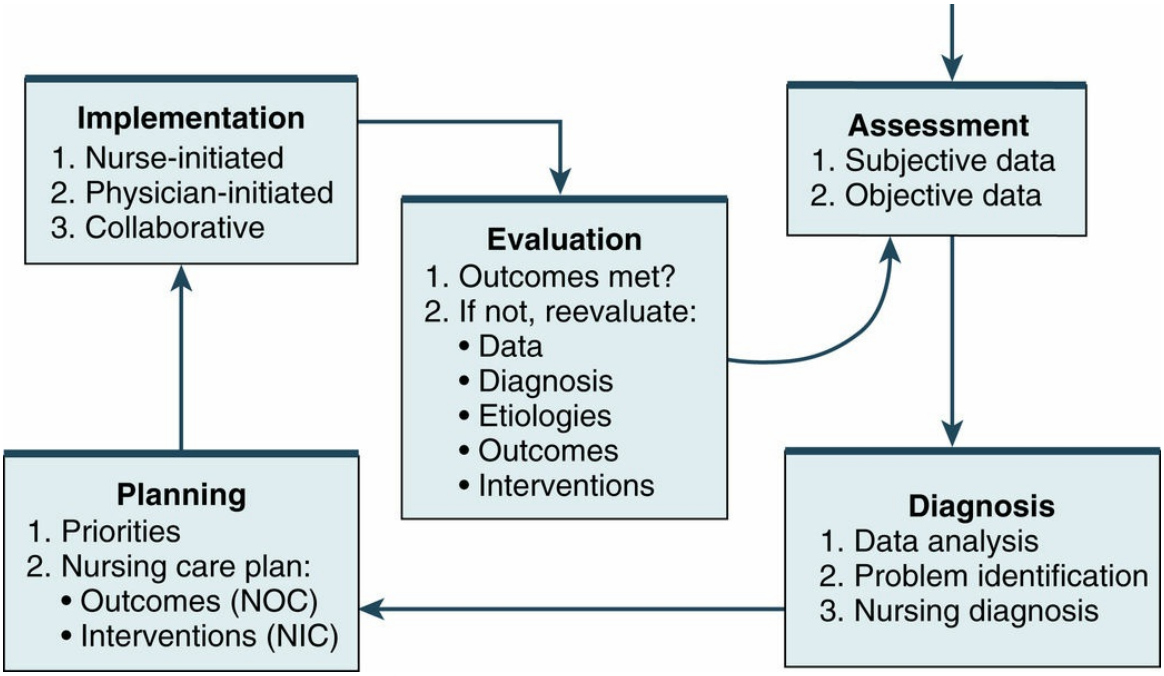

FIG. 1.3 Nursing process.

Standard languages are essential in exchanging information between different electronic records systems. The need for quality care makes it necessary to be able to share information in a meaningful way across care settings. Using the same language reduces ambiguity and confusion. For example, do the patient problems of pressure injury and skin breakdown mean the same thing? Does turning the patient every 2 hours mean the same thing as repositioning the patient every 2 hours? If you turn or reposition the patient every 2 hours, what is the result? Does placing the patient on a pressure-relieving mattress or a standard mattress change the results? When you use a standard language, each nurse reading and documenting in the electronic record understands the diagnosis, can provide the interventions, and can measure the outcome.

The ANA recognizes several nursing and multidisciplinary languages. Three nursing languages focus on specific phases of the nursing process: (1) NANDA International (NANDA-I): Nursing Diagnoses, Definitions, and Classification; (2) the Nursing Outcomes Classification (NOC); and (3) the Nursing Interventions Classification (NIC). Two other nursing languages, each with their own nursing diagnoses, outcomes, and interventions, include the International

Classification of Nursing Practice (ICNP) and the Clinical Care Classification (CCC).

Nursing Diagnoses

The ANA defines a nursing diagnosis as the nurse's clinical judgment about the patient's response to actual or potential health conditions or needs.[11] You determine nursing diagnoses based on your analysis of the assessment data. Delivering care based on accurately identified nursing diagnoses results in more effective and safer patient care. They are the basis for selecting nursing interventions to achieve patient outcomes for which nursing is accountable. This book uses the ICNP nursing diagnosis terminology (see Appendix B).

Outcome Identification

The next step is to create the framework for delivering care by identifying outcomes and goal indicators. After choosing an outcome, you need to identify short- and/or long-term measurable goals and then list the behaviors or observations you will use to determine if the goal was attained. By identifying the right outcomes and goals, you can measure and evaluate the impact of the interventions you provide as part of your nursing practice. They also guide the interprofessional team so that we are all working to achieve the same outcomes. The outcomes achieved by patients are the most important indicator of quality in health care.[12]

Nursing Interventions

An intervention is "a single nursing action, treatment, procedure, activity, or service designed to achieve an outcome of a nursing or medical diagnosis for which the nurse is accountable."[13] This includes treatments that you perform in all settings and includes direct and indirect care. The ICNP includes more than 1100 interventions. That many interventions may seem overwhelming. You will discover the interventions you will use most often with your patient population. When planning care for a patient, choose specific interventions for the

patient based on the nursing diagnosis and desired patient outcomes. You make the crucial decision of when and which interventions to use for a specific patient and situation based on your knowledge of the patient and the patient's condition.

Nursing Care Plans

In any clinical setting, you are responsible for providing a custom plan of care that includes nursing diagnoses, outcomes, and interventions. In clinical practice, electronic care plans often follow a standard format that has been adapted for that specific setting. These plans are guides for routine nursing care. You customize each to your patient's unique needs and problems.

In nursing education, the nursing process is often documented differently from clinical practice. The nursing process is often recorded in nursing care plans similar to those found on the website for this book (http://evolve.elsevier.com/Lewis/medsurg). These nursing care plans are teaching and learning tools. You practice and learn the nursing process by collecting assessment data, identifying nursing diagnoses, and selecting patient outcomes and nursing interventions. You usually should give rationales for the selected interventions.;

Nursing Care Plan 1.1

Patient With Heart Failure*

Nursing Diagnosis†*
Impaired Gas Exchange

Etiology: Increased preload, alveolar-capillary membrane changes
Supporting data: Abnormal O_2 saturation, hypoxemia, dyspnea, tachypnea, tachycardia, restlessness, patient's statement, "I am

so short of breath”

Patient Goal

Maintains adequate O_2/CO_2 exchange at the alveolar-capillary membrane to meet O_2 needs of the body

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Respiratory Status: Gas Exchange • **O_2 saturation __** • **Arterial pH __** • **PaO_2 __** • **$PaCO_2$ __** • **Chest x-ray findings __** **Measurement Scale** **1 = Severe deviation from normal range** **2 = Substantial deviation from normal range** **3 = Moderate deviation from normal range** **4 = Mild deviation from normal range** **5 = No deviation from normal range** • **Dyspnea with exertion __** • **Dyspnea at rest __** • **Restlessness __** • **Impaired cognition __** **Measurement Scale** **1 = Severe** **2 = Substantial** **3 = Moderate** **4 = Mild** **5 = None**	**Respiratory Monitoring** • Monitor pulse oximetry, respiratory rate, rhythm, depth, and effort of respirations *to detect changes in respiratory status.* • Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds *to detect presence of pulmonary edema.* • Monitor for increased restlessness, anxiety, and work of breathing *to detect increasing hypoxemia.* **Oxygen Therapy** • Administer supplemental O_2 or other noninvasive ventilator support (e.g., bilevel positive airway pressure [BiPAP]) as needed *to maintain adequate O_2 levels.* • Monitor the O_2 liter flow rate and placement of O_2 delivery device *to ensure O_2 is adequately delivered.* • Change O_2 delivery device from mask to nasal prongs during meals as tolerated *to sustain O_2 levels while eating.* • Monitor the effectiveness of O_2 therapy *to identify hypoxemia and establish range of O_2 saturation.* **Positioning** • Position patient to alleviate dyspnea (e.g., semi-Fowler's position), as appropriate, to improve ventilation by decreasing venous return to the heart and increasing thoracic capacity.

* This example presents 1 nursing diagnosis for heart failure. The complete nursing care plan for heart failure is available on http://evolve.elsevier.com/Lewis/medsurg.

† Nursing diagnoses are listed in order of priority.

The nursing care plans associated with this book list nursing diagnoses, in order of priority, based on the ICNP, along with outcomes and interventions (NCP 1.1). When you use these care

plans, you will need to customize the plan for your specific patient. You must use critical thinking to continually evaluate the situation and revise the nursing diagnoses, outcomes, and interventions to fit each patient's unique care needs.

Collaborative problems are certain physiologic complications that nurses must monitor to detect the onset of or changes in patient status.[14] Nurses manage collaborative problems using physician and nurse prescribed interventions to prevent morbidity and mortality. You identify these risks during the diagnosis phase of the nursing process. Identifying collaborative problems requires knowledge of pathophysiology and possible complications of medical treatment. Collaborative problem statements are usually written as "potential complication: _____" or "PC: _____" without a *related to* statement. An example is "PC: pulmonary embolism."

A *concept map* is another method of recording a nursing care plan. A concept map records the nursing process in a visual diagram. The map displays patient problems and interventions and shows relationships among clinical data. Nurse educators use concept mapping to teach nursing process and care planning. There are various formats for concept maps.

Conceptual care maps blend a concept map and a nursing care plan. On a conceptual care map, assessment data used to identify the patient's primary health concern are centrally positioned. Diagnostic test data, treatments, and medications surround the assessment data. Positioned below are nursing diagnoses or problems that represent the patient's responses to the health state. Listed with those are the supporting assessment data, outcomes, nursing interventions with rationales, and evaluation. After completing the map, you draw connections between identified relationships and concepts. A conceptual care map creator is available online on the website for this book. Concept maps for select case studies at the end of management chapters are available on the website at http://evolve.elsevier.com/Lewis/medsurg.

Continuum of Patient Care

Nursing is part of health care at all points along the patient care continuum. Depending on their health status, patients often move among a multitude of different health care settings. For example, a young man is in a trauma unit of an acute care hospital following a motor vehicle crash. After he is stable, he is transferred to a general medical-surgical unit and then to an acute rehabilitation facility. After rehabilitation is complete, he is discharged home to continue with outpatient rehabilitation, with follow-up by home health care nurses and care in an ambulatory clinic.

Decisions about the best setting for obtaining health care often depend on the cost of care and the patient's health care insurance plan and personal finances. Although the hospital is the mainstay for acute care interventions, community-based settings offer patients the opportunity to live or recover in settings that maximize their independence and preserve human dignity.

Community-based health care settings include ambulatory care, transitional care, and long-term care. *Transitional care* settings provide care in between the acute care and the home or long-term care setting. Patients may receive transitional care at an acute rehabilitation facility after head trauma or a spinal cord injury. *Long-term care* refers to the care of patients for a period longer than 30 days. It may be needed for those who are severely developmentally disabled, who are mentally impaired, or who have physical deficits requiring continuous medical and nursing care (e.g., patients who are ventilator dependent or have Alzheimer's disease). Long-term care facilities include skilled nursing facilities, assisted living facilities, and residential care facilities.

There is a new emphasis on care coordination when patients transition between care settings. *Transitions of care* refer to patients moving among health care practitioners, settings, and home as their condition and care needs change.[15] As a nurse, you are an essential part of care coordination by stressing actions that meet patients' needs and facilitate safe, quality care. Collaborating with other members of the interprofessional team is critical. A lack of communication can result in an ineffective care transition, leading to drug errors and higher hospital readmission rates. For example, you are a nurse in

acute care admitting a long-term care patient who has been receiving propranolol 20 mg/5 mL twice a day. The admitting orders read "propranolol 20 mg/mL, give 5 mL twice a day." You avert a potential drug error by using communication techniques to reconcile the difference.

Delivery of Nursing Care

Nurses deliver patient-centered care in collaboration with the interprofessional health care team and within the framework of a care delivery model. A care delivery model outlines how responsibilities and authority are structured to carry out patient care.[16] More positive care outcomes occur when the number and type of care providers match patient needs and there is a designated care coordinator.

In acute care settings, 2 basic models are used: team care and total patient care. *Team care* models involve a group of providers who work together to deliver care. A professional nurse is usually the team leader. As team leader, you manage and coordinate care with others, such as licensed practical/vocational nurses (LPN/VNs) and unlicensed assistive personnel (UAP). You have accountability for the quality of care delivered by team members during a work period. In total patient care models, you are responsible for planning and providing all care.

Other care models include case management and telehealth. **Case management** is "a collaborative process of assessment, planning, facilitation, care coordination, evaluation, and advocacy for options and services to meet an individual's and family's comprehensive health needs through communication and available resources to promote quality, cost-effective outcomes."[17] Although health care agencies implement case management in various ways, it involves managing the patient's care with other interprofessional team members across multiple care settings and levels of care.

A professional nurse often serves as the case manager. In this role, the nurse assesses the needs of patients and/or caregivers, coordinates services for them, makes appropriate referrals, and evaluates the

progress toward meeting care goals. For example, a nurse case manager in an outpatient clinic has been working for 3 months with an older male patient who has multiple co-morbidities, including severe coronary artery disease, diabetes, and osteoarthritis. After he is scheduled for a coronary artery bypass, the nurse manager coordinates his care with other members of the interprofessional team. She arranges his preoperative appointments and informs the other team members so that all health care providers understand the patient's unique needs. After the patient has surgery, he develops a deep venous thrombosis in his leg. The case manager then works with the interprofessional team to evaluate the patient's discharge needs and decide whether rehabilitation or home health care is necessary for the patient. With the patient and caregiver, the team decides to discharge the patient to a rehabilitation facility. The case manager helps with the transition, again coordinating care so that the providers at the rehabilitation facility are aware of the patient's needs.

Telehealth nursing is the delivery of health care and information through telecommunication technologies, including high-speed Internet, wireless, satellite, and video communications.[18] Among the many uses of telehealth are triaging patients, monitoring patients with chronic or critical conditions, helping patients manage symptoms, providing patient and caregiver education and emotional support, and providing follow-up care. Telehealth can increase access to care. The nurse engaged in telehealth can assess the patient's health status, deliver interventions, and evaluate the outcomes of nursing care while separated geographically from the patient (Fig. 1.4).

Critical Thinking

Complex health care environments require that you use critical thinking and clinical reasoning skills to make decisions that lead to the best patient outcomes. **Critical thinking**, your ability to focus your thinking to get the results you need in various situations, has been described as knowing how to learn, be creative, generate ideas, make decisions, and solve problems.[19]

FIG. 1.4 An older adult performing remote blood pressure monitoring. From Cooper K, Gosnell K: *Foundations of nursing,* St Louis, 2015, Elsevier.

Critical thinking is not memorizing a list of facts or the steps of a procedure. Instead, it is the ability to make judgments and solve problems by making sense of information. Learning and using critical thinking is a continual process that occurs inside and outside of the clinical setting.

Clinical reasoning is using critical thinking to examine and analyze patient care issues.[19] It involves understanding the medical and nursing implications of a patient's situation when making decisions about patient care. You use clinical reasoning when you identify a change in a patient's status, consider the context and concerns of the patient and caregiver, and decide what to do about it.

Given the complexity of patient care today, nurses need to learn and implement critical thinking and clinical reasoning skills before they gain those skills through experience in professional practice. Various experiences in nursing school offer opportunities for you to learn and make decisions about patient care. Various education activities,

including interactive case studies and simulation exercises, promote practice in critical thinking and clinical reasoning. Throughout this book, select boxes, case studies, and review questions promote your use of critical thinking and clinical reasoning skills.

Teamwork and Collaboration

Interprofessional Team

To deliver high-quality care, you need to have effective working relationships with members of the health care team. The **interprofessional team** is made up of providers from various disciplines, working together and sharing their expertise to provide customized care. It may consist of physicians, nurses, pharmacists, occupational and physical therapists, and others (Table 1.3). To be competent in interprofessional practice, you must collaborate in many ways by exchanging knowledge, sharing responsibility for problem solving, and making patient care decisions. You may be responsible for coordinating care among the team members, taking part in interprofessional team meetings or rounds, and making referrals when you need expertise in specialized areas to help the patient. To do so, you must be aware of the knowledge and skills of other team members and be able to communicate effectively with them.

TABLE 1.3 Interprofessional Team Members

Team Member	Description of Services Provided
Dentist	Provides preventive and restorative treatments for problems affecting the teeth and mouth
Dietitian	Provides general nutrition services, including dietary consultation about health promotion or specialized diets
Occupational therapist (OT)	May help patient with fine motor coordination, performing activities of daily living, cognitive-perceptual skills, sensory testing, and the construction or use of assistive or adaptive equipment

Pastoral care	Offers spiritual support and guidance to patients and caregivers
Pharmacist	Prepares medications and infusion products
Physical therapist (PT)	Works with patients on improving strength and endurance, gait training, transfer training, and developing a patient education program
Physician (medical doctor [MD])	Practices medicine and treats illness and injury by prescribing medication, performing diagnostic tests and evaluations, performing surgery, and providing other medical services and advice
Physician assistant	Conducts physical exams, diagnoses and treats illnesses, and counsels on preventive health care in collaboration with a physician
Respiratory therapist	May provide oxygen therapy in the home, give specialized respiratory treatments, and teach the patient or caregiver about the proper use of respiratory equipment
Social worker	Assists patients with developing coping skills, meeting caregiver concerns, securing adequate financial resources or housing, or making referrals to social service or volunteer agencies
Speech pathologist	Focuses on treatment of speech defects and disorders, especially by using physical exercises to strengthen muscles used in speech, speech drills, and audiovisual aids that develop new speech habits

TABLE 1.4 Guidelines for Communicating Using SBAR

Purpose: SBAR is a model for effective transfer of information by providing a standard structure for concise factual communications from nurse-to-nurse, nurse-to-physician, or nurse-to–other health professionals.	
Steps to Use: Before speaking with a physician or other health care professional about a patient problem, assess the patient yourself, read the most recent physician progress and nursing notes, and have the patient's chart available.	
S **Situation**	• What is the situation you want to discuss? What is happening right now? • Identify self, unit. State: I am calling about: *patient, room number.* • Briefly state the problem: what it is, when it happened or started, and how severe it is. State: I have just assessed the patient and am concerned about: *describe why you are concerned.*
B **Background**	• What is the background or circumstances leading up to the situation? State pertinent background information related to the situation that may include: • Admitting diagnosis and date of admission • List of current medications, allergies, IV fluids • Most recent vital signs • Date and time of any laboratory testing and results of previous tests for comparison • Synopsis of treatment to date • Code status
A **Assessment**	• What do you think the problem is? What is your assessment of the situation? State what you think the problem is: • Changes from prior assessments • Patient condition unstable or worsening
R **Recommendation/Request**	• What should we do to correct the problem? What is your recommendation or request? State your request. • Specific treatments • Tests needed • Patient needs to be seen now

Source: Institute for Health Care Improvement: SBAR technique for communication: A situational briefing model. Retrieved from www.ihi.org/resources/Pages/Tools/SBARTechniqueforCommunicatio

To help you develop the competencies necessary to practice within an interprofessional clinical environment, you may take part in education activities with students from other disciplines. Throughout this book, case studies and review questions discuss the roles others have in managing patient care.

Coordinating Care

Communication

Effective communication is key to fostering teamwork and coordinating care. To provide safe, effective care, everyone involved in a patient's care should understand the patient's condition and needs. Unfortunately, many issues result from a breakdown in communication. Miscommunication often occurs during transitions of care. One structured model used to improve communication is the **SBAR (Situation-Background-Assessment-Recommendation)** technique (Table 1.4). This technique offers a way to talk about a patient's condition among members of the health care team in a predictable, structured manner. Other ways to enhance communication during transitions include using bedside rounds, having standard processes for patient hand-offs, and conducting interprofessional rounds to identify risks and develop a plan for delivering care.

Clinical Pathways

Clinical pathways, also known as care maps, are interprofessional care plans that outline the care and desired outcomes for a specific time period for patients with a specific diagnosis. Think of a clinical pathway as a road map the patient and health care team should follow. As the patient progresses along the road, the patient should receive specific care and accomplish specific goals. If a patient's

progress differs from the planned path, a variance has occurred. A negative variance occurs when specific goals are not met. The nurse usually identifies when a negative variance is present and works with the interprofessional team to create a plan to address the issue.[16]

The exact content and format of clinical pathways vary among agencies and settings. Each agency usually develops its own pathways based on evidence-based practice guidelines. Common components include assessment guidelines, laboratory and diagnostic testing, medications, activity, diet, and teaching. In acute care, clinical pathways often describe which patient care components are needed at specific times (Fig. 1.5). The case types selected for this type of pathway are usually those that are high volume or high risk and predictable, such as myocardial infarction and surgical procedures (e.g., endoscopy, cholecystectomy, cataract surgery).

Delegation and Assignment

As a registered nurse (RN), you will delegate nursing care and supervise those who are qualified to deliver care. **Delegation** allows a care provider to perform a specific nursing activity, skill, or procedure that is beyond their usual role.[20] Delegating and assigning nursing activities is a process that, when used appropriately, results in safe, effective, and efficient patient care. Delegating can allow you more time to focus on complex patient care needs. Delegating care and supervising others will be one of your essential roles as a professional nurse.

Delegation usually involves tasks and procedures that licensed practical/vocational nurses (LPN/VNs) and unlicensed assistive personnel (UAP) perform. Nursing interventions that require independent nursing knowledge, skill, or judgment (e.g., initial assessment, patient teaching, evaluating care) are your responsibility and cannot be delegated. State nurse practice acts and agency policies identify activities that you can delegate to LPN/VNs and UAP. You will use professional judgment to select which activities to delegate. Your decision will be based on the patient's needs, the LPN/VN's and UAP's education and training, and the amount of supervision needed.

The most common delegated nursing actions occur during the implementation phase of the nursing process. For example, you can delegate measuring oral intake and urine output to UAP, but you use your nursing judgment to decide if the intake and output are adequate.

The general guideline for LPN/VN practice is that they can function independently in a stable, routine situation. However, they must work under the direct supervision of a professional nurse in acute, unstable situations in which a patient's condition can rapidly change. In most states, LPN/VNs may give medications, perform sterile procedures, and perform a wide variety of interventions planned by the RN. The procedure itself is not the issue when an RN is determining what to delegate. Rather, the stability of the patient determines whether it is appropriate for an RN to delegate a procedure to an LPN/VN. For example, the LPN/VN can change a dressing on an abdominal surgical wound, but the RN should do the first dressing change and wound assessment.

Patient Name _____ Date _____

DRG# _____ Expected LOS <23 hours

	Preprocedure	Preoperative	Intraoperative	Postoperative Phase I PACU	Postoperative PHASE II PACU	Discharge	Postoperative PHASE II PACU
Medication	Review medical history	Start IV	Administer meperidine, propofol, midazolam	Administer naloxone, flumazenil pm	Pain med prn	Start on Rx omeprazole	Continue medications
Diagnostic tests	H-&-P chest x-ray, ECG, blood work	Review tests	Endoscopy procedure	None, unless complications	None	None	None
Diet	Regular	NPO	NPO	NPO	Clear liquids & progress	Regular	Regular
Activity	Not restricted	Ambulate	None	Turn, cough, and deep breathe	Increase activity to ambulation	Normal ambulation	Not restricted
Nursing action	Assessment	Vital signs	Vital signs, O_2 saturation	Vital signs, level of consciousness, O_2 saturation	Monitor as before	Prepare for discharge	Follow-up evaluation via phone
Teaching/ discharge planning	Phone call	Patient education about procedure	Transport to PACU	Discharge when Aldrete criteria I met	Discharge when Aldrete criteria II met	Instructions reviewed	Phone call for follow-up

FIG. 1.5 Clinical pathway for endoscopy.
From Arnold EC, Boggs KU: *Interpersonal relationships,* ed 6, St Louis, 2011, Mosby.

UAP hold many titles, including nurse aides, certified medication aides, nursing assistants, patient care assistants, or technicians. The activities UAP perform typically include obtaining routine vital signs on stable patients, feeding and helping patients at mealtimes, ambulating stable patients, and helping patients with bathing and hygiene.

Delegation can occur among professional nurses. For example, if 1 RN has accountability for an outcome and asks another RN to perform a specific intervention related to that outcome, that is delegation. This type of delegation typically occurs when 1 RN leaves the unit/work area for a meal break.

Assignment is different from delegation. The term *assign* is used when you direct an LPN/VN or UAP to do an activity or procedure that is part of their everyday job.[20] An assignment must be within the authorized scope of practice of the LPN/VN or part of the routine function of the UAP. For example, you can assign an LPN/VN to give

medications to a patient, because this is within the LPN/VN's scope of practice. You cannot assign an LPN/VN to a patient who needs an admission assessment because an RN must perform the initial patient assessment.

Whether you delegate or are working with staff to whom you assign tasks, you are responsible for the patient's total care during your work period. You need to decide what patient care tasks must be carried out during the given period, identify who will do them, and prioritize the order in which the tasks must be completed. You are responsible for supervising UAP or LPN/VNs. Clearly communicate the tasks that must be done and give necessary guidance. Because you are accountable for ensuring that delegated tasks are completed in a competent manner, evaluate the care given, follow up as needed, and make sure no care was missed.

Delegation is a skill that is learned, and you must practice to be proficient in managing patient care. You need to use critical thinking and professional judgment to ensure that you follow the 5 Rights of Delegation (Table 1.5). To help you, information on delegation is presented in the nursing management tables and case study questions at the end of the management chapters.

Safety

It is estimated that about 250,000 patients each year die because of preventable medical errors.[21] Several groups are addressing this issue by outlining safety goals for health care organizations and identifying safety competencies for health professionals. By implementing various procedures and systems that improve patient safety, health care systems are working to attain a culture that minimizes the risk of harm to the patient. Because of your closeness to patients, you are in a unique position to promote patient safety.

Serious Reportable Events

The National Quality Forum (NQF) uses the term **serious reportable**

event (SRE), also called a *never event*, to describe serious, largely preventable, and harmful clinical events.[22] The current list of SREs consists of 29 events. These events include such things as a patient acquiring a stage III or greater pressure injury while hospitalized and death or disability from a fall or hypoglycemia.

TABLE 1.5 5 Rights of Delegation

The 5 Rights of Delegation		
The registered nurse uses critical thinking and professional judgment to be sure that the delegation or assignment is: 1. The right task 2. Under the right circumstances 3. To the right person 4. With the right directions and communication 5. Under the right supervision and evaluation		
Rights of Delegation	Description	Questions to Ask
Right Task	One that can be delegated for a specific patient	Is it appropriate to delegate based on legal and agency factors? Has the person been trained and evaluated in performing the task? Is the person able and willing to do this specific task?
Right Circumstances	Appropriate patient setting, available resources, and considering relevant factors, including patient stability	What are the patient's needs right now? Is staffing such that the circumstances support delegation strategies?
Right Person	Right person is delegating the right task to the right person to be performed on the right person	Is the prospective delegatee a willing and able employee? Are the patient needs a "fit" with the delegatee?
Right Directions and Communication	Clear, concise description of task, including its objective, limits, and expectations	Have you given clear communication about the task? With directions, limits, and expected outcomes? Does the delegatee know what and when to report? Does the delegatee understand what needs to be done?
Right Supervision and Evaluation	Appropriate monitoring, evaluation, intervention, and feedback	Do you know how and when you will interact about patient care with the delegatee? How often do you need to directly observe? Will you be able to give feedback to the staff member if needed?

Source: National Guidelines for Nursing Delegation. Retrieved from www.ncsbn.org/1625.htm.

To reduce the occurrence of SREs, the NQF has a list of effective *Safe Practices* that health care settings should use to provide safe patient care *(www.qualityforum.org).* You are implementing NQF practices when you perform a time-out before a surgical procedure, reconcile medication records, and implement interventions to prevent hospital-acquired infections, pressure injuries and falls.

National Patient Safety Goals

The Joint Commission (TJC), the accrediting agency for health care organizations, gathers and reports data on serious errors they call sentinel events. A *sentinel event* is a patient safety event not related to the patient's illness or underlying condition that reaches a patient and results in death, permanent harm, or severe temporary harm.[23] Events are "sentinel" because they signal the need for immediate investigation and response. Many sentinel events are also serious reportable events. If the patient undergoes a wrong-site or wrong-procedure surgery, experiences an assault in the health care setting, or receives an incompatible blood product, the occurrence is both a sentinel event, reportable to TJC, and a serious reportable event, reportable to NQF.

To address specific patient safety concerns, TJC issues National Patient Safety Goals (NPSGs).[24] NPSGs promote patient safety by offering evidence-based solutions to common safety problems. The 2017 NPSGs are listed in Table 1.6.

The latest safety goal, focusing on improving the safety of clinical alarm systems, greatly affects nursing. Patient monitoring systems provide vital information. Alarms that work well improve patient safety and care by telling you when a patient needs your attention. However, so many alarms can go off that *alarm fatigue* occurs, and nurses can become desensitized to the sounds. By better managing alarms, we reduce alarm fatigue and improve patient safety.

Because you have the greatest amount of interaction with patients, you play a key role in promoting safety. Many describe nurses as the patient's last line of defense. Every nurse has the responsibility to ensure the patient receives care in a manner that prevents errors and promotes patient safety. Throughout this book, safety alerts highlighting patient care issues and NPSGs will help you in learning to apply safety principles.

Quality Improvement

Quality care and safety are related: the higher the culture of safety, the better the quality of care. Health care systems focused on quality outcomes use practice standards and protocols based on best evidence while considering the patient's unique preferences and needs. Your role is to coordinate the complex aspects of patient care, including the care delivered by others, and identify and correct issues associated with poor quality and unsafe care.

Quality improvement (QI) programs involve systematic actions that monitor, assess, and improve health care quality. QI is an interprofessional team effort that is required by accrediting agencies. As part of professional nursing practice, you need to be able to collect data using QI tools, implement interventions to improve quality of care, and monitor patient outcomes. Several public and private groups focusing on improving health care quality have developed standard QI measures. These performance measures assess how well the health care team cares for a patient with a certain condition or receives a specific treatment. They describe what data the team must collect and monitor. Fig 1.6 shows an example of a QI system for adult patients with asthma. In this example, you would review patient medical records to decide if the rate of flu vaccine administration exceeds 90%. You would share the results with the team and, if the identified standard was not met, work as a team to implement measures to correct the deficiency.

TABLE 1.6 National Patient Safety Goals

Safety Goal	Examples
Identify patients correctly	• Use at least 2 ways to identify patients (e.g., have them state full name and date of birth). • Give the correct patient the correct blood with every blood transfusion.
Improve communication among the health care team	• Get critical test results to the right person on time.
Use medicines safely	• Before a procedure, label all medicines. Discard any found unlabeled. • Use proper precautions with patients who take anticoagulants. • Find out what medicines each patient is taking. Make certain that it is safe for the patient to take any new medicines with his or her current ones. • Give a medication list to the patient and the caregiver before discharge. Explain the list.
Use alarm systems safely	• Respond to alarms promptly. • Do not turn alarms off.
Prevent health care–associated infections	• Use soap, water, and hand sanitizer before and after every patient contact. • Use evidence-based practices to prevent infections related to central lines, indwelling urinary catheters, and multidrug-resistant organisms
Identify patient safety risks	• Assess patients at risk for suicide. • Assess any risks, such as fires, for patients who are getting home oxygen therapy.
Prevent mistakes in surgery	• Conduct a time-out before the start of any surgery. • Confirm correct patient, procedure, and site.

National Database of Nursing Quality Indicators

The National Database of Nursing Quality Indicators (NDNQI) provides data on nursing-sensitive measures to evaluate the impact of nursing care on patient outcomes. Patient outcomes are nursing sensitive if they improve with a greater quantity or quality of nursing care. NDNQI outcomes are unique because they identify how nursing workforce factors, including nurse staffing and skill mix, directly influence patient outcomes. NDNQI data show the incidence of falls and health care–associated pressure injuries and infections decreases with adequate staffing and increased nurse education and satisfaction with the work environment. Table 1.7 lists the current NDNQI.

Informatics

Nursing is an information-intense profession. Advances in informatics and technology have changed the way nurses plan, deliver, document, and evaluate care. All nurses, regardless of their setting or role, use informatics and technology every day in practice. Informatics has changed how you obtain and review diagnostic information, make clinical decisions, communicate with patients and health care team members, document, and provide care.

Technology advances have increased the efficiency of nursing care, improving the work environment and the care nurses provide. Computers and mobile devices allow you to document at the time you deliver care and give you quick and easy access to information, including clinical decision-making tools, patient education materials, and references. Texting, video chat, and e-mail enhance communication among health care team members and help you deliver the right message to the right person at the right time.

Technology plays a key role in providing safe, quality patient care. Medication administration applications improve patient safety by flagging potential errors, such as look-alike and sound-alike medications and adverse drug interactions, before they can occur. Computerized provider order entry (CPOE) systems can reduce errors caused by misreading or misinterpreting handwritten orders. Sensor technology can decrease the number of falls in high-risk patients. Care

reminder systems give cues that decrease the amount of missed nursing care.

TABLE 1.7 National Database of Nursing Quality Indicators

- Structure indicators
    - RN turnover rate
    - Nursing hours per patient day
    - RN education and certification
    - Staff mix: RNs, LPN/VNs, UAP, agency staff
- Process and outcome indicators
    - Patient falls and falls with injury
    - Pressure injury rate
    - RN surveys on job satisfaction and practice environment scale
- Outcome indicators
    - Physical/sexual assault rate
    - Restraint use
- Health care–associated infections (HAI) rate

Source: National Database of Nursing Quality Indicators. Retrieved from www.nursingquality.org.

Being able to use technology skills to communicate and access information is now an essential part of your professional nursing practice. You must be able to use word processing software, communicate by e-mail and book messaging, access information, and follow security and confidentiality rules. You need to have the ability to safely use patient care technologies and navigate electronic documentation systems.

Protected health information (PHI) is highly sensitive. *The Health*

Insurance Portability and Accountability Act (HIPAA) is part of federal legislation that addresses actions for how PHI is used and disclosed. With the increased use of informatics and

Ethical/Legal Dilemmas

Social Networking: HIPAA Violation

Situation

You log into a closed group on a social networking site and read a posting from a fellow nursing student. The posting describes in detail the complex care the student gave to an older patient in a local hospital the previous day. The student comments on how stressful the day was and asks for advice on how to deal with similar patients in the future.

Ethical/Legal Points for Consideration

- Protecting and maintaining patient privacy and confidentiality are basic obligations defined in the Code of Ethics for Nurses, which nurses and nursing students should uphold.[1]
- As outlined in the Health Insurance Portability and Accountability Act (HIPAA), a patient's private health information is any information that relates to the person's past, present, or future physical or mental health. This includes not only specific details such as a patient's name or picture but also information that gives enough details that someone may be able to identify that person.
- You may unintentionally breach privacy or confidentiality by posting patient information (diagnosis, condition, situation) on a social networking site. Using privacy settings or being in a closed group does not guarantee the secrecy of posted information. Others can copy and share any post without your knowledge.
- Potential consequences for improperly using social networking

vary based on the situation. These may include (1) disciplinary action by the state board of nursing; (2) being disciplined, suspended, or fired by an employer; (3) dismissal from a nursing program; and (4) civil and/or criminal charges.

- A student nurse who experienced a stressful day and is looking for advice and support from peers (e.g., "Today my patient died. I wanted to cry.") could share the experience by clearly limiting the posts to the student's personal perspective and not sharing any identifying information. This is 1 area in which it is safest to err on the side of caution to avoid the appearance of impropriety.

Discussion Questions

1. How would you deal with the situation involving the fellow nursing student?
2. How would you handle a situation in which you saw a staff member who violated HIPAA?

Reference

1. Code of Ethics for Nurses. Retrieved from *www.nursingworld.org/DocumentVault/Ethics-1/Code-of-Ethics-for-Nurses.html*.

technology come new concerns on how to comply with HIPAA regulations and maintain a patient's privacy. Wireless technologies, increased use of e-mail and computer networking, and the ongoing threat of computer viruses increase the need for properly protecting a patient's privacy. We must assure patients of their privacy and that only those with a right to know are accessing protected information.

FIG. 1.7 Members of the interprofessional team review a patient's electronic health record.
From Arnold EC, Boggs KU: *Interpersonal relationships,* ed 6, St Louis, 2011, Mosby.

As a nurse, you have an obligation to ensure the privacy of your patient's health information. To do so, you need to understand your agency's policies about the use of technology. You need to know the rules about accessing patient records and releasing PHI, what to do if information is accidentally or intentionally released, and how to protect any passwords you use. If you are using social networking, you must be careful not to place any individually identifiable PHI online. Throughout this book, Informatics in Practice boxes offer suggestions on how to use informatics in your practice.

Electronic Health Records

The largest use of informatics is **electronic health records (EHRs)**, also called *electronic medical records.* An EHR is a computerized record of patient information. It is shared among all health care team members

involved in a patient's care and moves with the patient—to other providers and across care settings. The ideal EHR provides a single place for team members to review and update a patient's health record, document care given, and enter patient care orders, including medications, procedures, diets, and diagnostic and laboratory tests (Fig. 1.7).

Several obstacles are still in the way of fully implementing EHRs. Systems are technologically complex, requiring many resources and training to implement and maintain. Communication is still lacking among computer systems and software applications. Finally, perceived challenges in the use of EHRs, including increased workload and the need for workarounds, affect implementation.

Evidence-Based Practice

Evidence-based practice (EBP) is a problem-solving approach to clinical decision making. Using the best available evidence (e.g., research findings, QI data), combined with your expertise and the patient's unique circumstances and preferences, leads to better clinical decisions and improved patient outcomes. EBP closes the gap between research and practice, providing more reliable and predictable care than that based on tradition, opinion, and trial and error.

TABLE 1.8 Steps of Evidence-Based Practice (EBP) Process

1. Ask the clinical question using the **PICOT** format:
   Patients/population
   Intervention
   Comparison or comparison group
   Outcome(s)
   Time (as applicable)

2. Search for the best evidence based on the clinical question.
3. Critically appraise and synthesize the evidence.
4. Implement the evidence in practice.
5. Evaluate the practice decision or change.
6. Share the outcomes of the decision or change.

EBP does not mean that you conduct a research study. Instead, EBP depends on you to take an active role in using the best available evidence when delivering care. You need to have an ongoing curiosity about what are the best nursing practices and routinely ask questions about your patient's care. Recognize when you need more information. When you base your practice on valid evidence, you are solving problems and supporting best patient outcomes.

Steps of EBP Process

The EBP process has 6 steps (Table 1.8).

Step 1

Step 1 is asking a clinical question in the PICOT format. Developing the clinical question is the key step in the EBP process.[25] A good clinical question sets the context for integrating evidence, clinical judgment, and patient preferences. In addition, the question guides the literature search for the best evidence to influence practice.

An example of a clinical question in PICOT format is, "In adult abdominal surgery patients (**P** = patients/population) is splinting with an elasticized abdominal binder (**I** = intervention) or a pillow (**C** = comparison) more effective in reducing pain associated with ambulation (**O** = outcome) on the first postoperative day (**T** = time period)?" A clinical question may not have all components of PICOT. Some only include 4 components. The (T) timing or (C) comparison components are not appropriate for every question. The (C) component of PICOT may include a comparison with a specific intervention, the usual standard of care, or no intervention at all.

Step 2

Step 2 is searching for the best evidence that applies to the clinical question. Technology provides you with ready access to data. You can easily search several online resources and collect large amounts of clinical information and evidence. It is important to evaluate all data sources for their credibility and reliability. Not all evidence is equal. Fig. 1.8 presents the hierarchy of evidence. As you go down the pyramid, the strength of the evidence becomes weaker. Systematic reviews and evidence-based clinical practice guidelines save time and effort in the EBP process. However, they are available for only a limited number of clinical topics and may not suit all types of clinical questions. When insufficient research exists to guide practice, recommendations from expert panels and authority figures may be the best evidence available.

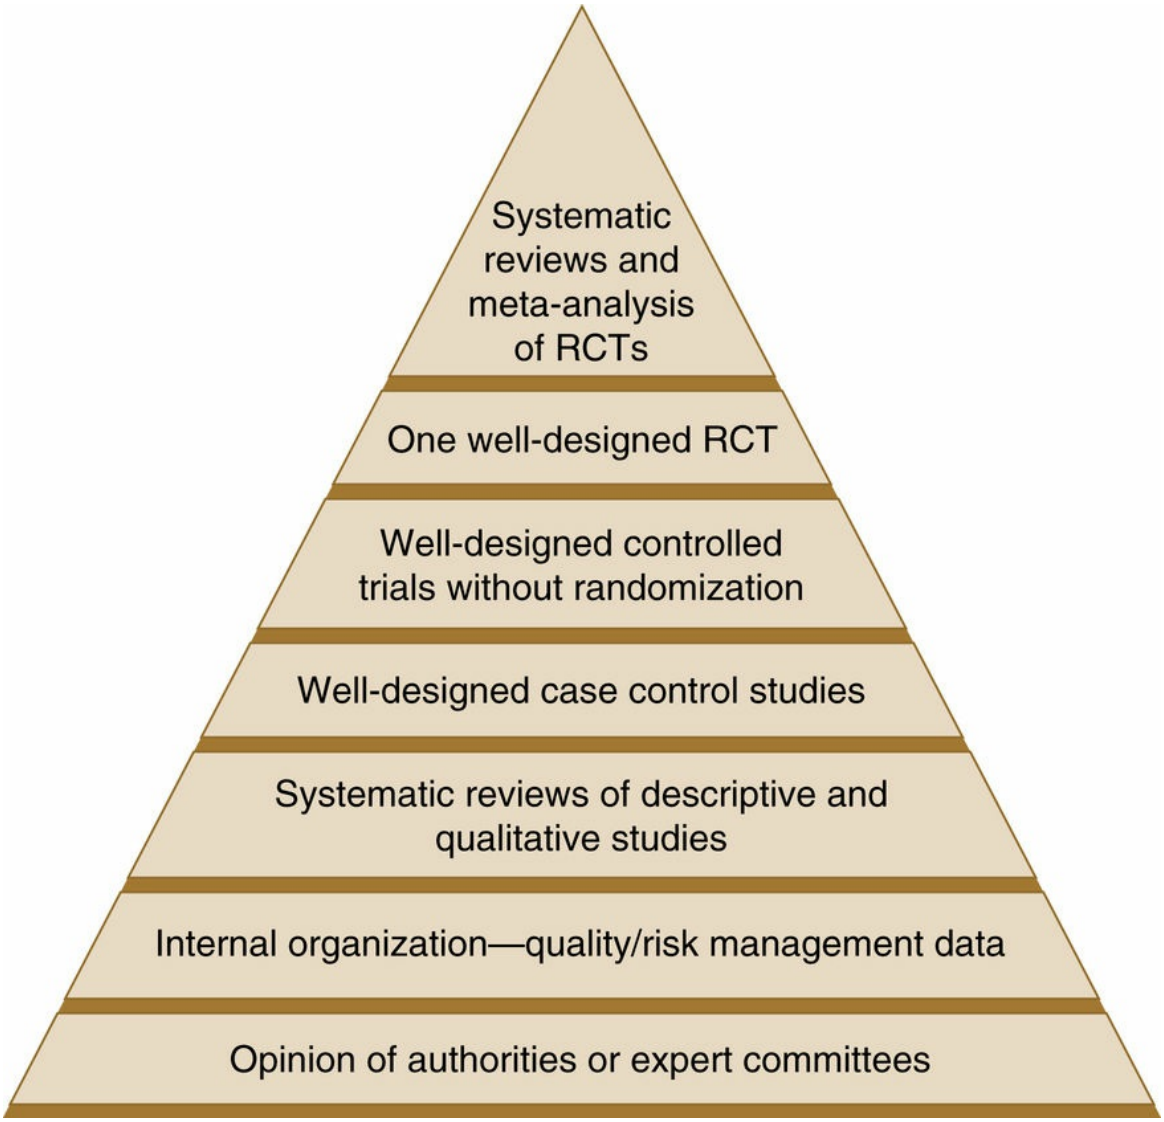

FIG. 1.8 Hierarchy of evidence.
Modified from Melnyk BM, Fineout-Overholt E: *Evidence-based practice in nursing and healthcare: A guide to best practice,* ed 3, Philadelphia, 2014, Lippincott Williams & Wilkins.

Step 3

Step 3 is to critically appraise the evidence you found. A successful critical appraisal process focuses on 3 essential questions: (1) What are the results? (2) Are the results reliable and valid? and (3) Will the results help me in caring for my patients? You decide the strength of the evidence and synthesize the findings related to the clinical question to conclude what is the best practice. For example, you find

strong evidence supporting effectiveness of elasticized binders and pillows in reducing pain associated with ambulation. However, the binder appears to be more effective if the patient is obese or has had prior abdominal surgery.

Step 4

Step 4 involves implementing the evidence in practice. The decision to implement change is made by combining the evidence, clinical judgment, and preferences and values of patients and caregivers. You may be part of an interprofessional team charged with implementing a practice change or applying evidence in a specific patient care situation. This may include developing clinical practice guidelines, policies and procedures, or new assessment, teaching, or documentation tools. For example, you may be part of a team implementing a new postoperative protocol focused on using elasticized abdominal binders with patients who are obese or had prior abdominal surgery.

Step 5

Step 5 is evaluating the outcome of the practice change. After implementing the change for a specific period, you should monitor outcomes to determine whether the change has improved patient outcomes. Accrediting bodies require documentation of outcome measures to show that the organization is using evidence to improve patient care.

Step 6

Step 6 is sharing the results of the EBP change. If you do not share the outcomes of EBP, then other health care providers and patients cannot benefit from what you learned from your experience. You can share information locally using unit- or hospital-based newsletters and posters and regionally and nationally through journal publications and presentations at conferences.

Implementing EBP

To implement EBP, you must develop the skills to be able to seek and incorporate into practice scientific evidence that supports best patient outcomes. Throughout this book, Evidence-Based Practice boxes provide an opportunity for you to practice your critical thinking skills in applying EBP to patient scenarios. To help you identify the use of evidence in this book, an asterisk (*) in the reference list at the end of each chapter indicates evidence-based information for clinical practice.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An example of a nursing activity that best reflects the American Nurses Association's definition of nursing is
   a. treating dysrhythmias that occur in a patient in the coronary care unit.
   b. diagnosing a patient with a feeding tube as being at risk for aspiration.
   c. setting up protocols for treating patients in the emergency department.
   d. offering antianxiety drugs to a patient with a disturbed sleep pattern.
2. A nurse working on the medical-surgical unit at an urban hospital would like to become certified in medical-surgical nursing. The nurse knows that this process would most likely require
   a. a bachelor's degree in nursing.
   b. formal education in advanced nursing practice.

c. experience for a specific period in medical-surgical nursing.

d. membership in a medical-surgical nursing specialty organization.

3. The nurse is assigned to care for a newly admitted patient. Number in order the steps for using the nursing process to prioritize care. (Number 1 is the first step, and number 5 is the last step.)

___ Evaluate whether the plan was effective.

___ Identify any health problems.

___ Collect patient information.

___ Carry out the plan.

___ Decide a plan of action.

4. Using the SBAR format, number in order the steps for how the nurse would communicate information with the provider. (Number 1 is the first step, and number 4 is the last step.)

____ "I would like you to order an IV medication and come evaluate the patient as soon as possible."

____ "This is Nurse M.H. I am calling from the unit because your patient, D.R., has a new onset of atrial fibrillation."

____ "The atrial fibrillation started about 10 minutes ago. The heart rate is 124; BP 90/60. The patient is experiencing dizziness."

____ "D.R., who is 2 days postoperative for a bowel resection for diverticulitis, has a history of mitral valve disease."

5. The nurse is caring for a diabetic patient in the ambulatory surgical unit who has undergone wound debridement. Which task is appropriate for the nurse to delegate to unlicensed assistive personnel (UAP)?
   a. Check the patient's vital signs.
   b. Assess the patient's pain level.
   c. Palpate the patient's pedal pulses.
   d. Monitor the patient's IV catheter site.
6. The nurse's role in addressing the National Patient Safety Goals established by The Joint Commission includes *(select all that apply)*
   a. answering all patient monitoring alarms promptly.
   b. memorizing all the rules published by The Joint Commission.
   c. obtaining a correct list of the patient's medications on admission.
   d. encouraging patients to be actively involved in their own health care.
   e. using side rails and alarm systems as necessary to prevent patient falls.
7. Advantages of using informatics in health care delivery are *(select all that apply)*
   a. reduced need for nurses in acute care.
   b. increased patient anonymity and confidentiality.
   c. the ability to achieve and maintain high standards of care.
   d. access to standard plans of care for many health problems.

e. improved communication of the patient's health status to the health care team.

8. When using evidence-based practice, the nurse
   a. must use clinical practice guidelines developed by national health agencies.
   b. should use findings from randomized controlled trials to plan care for all patient problems.
   c. uses clinical decision making and judgment to decide what evidence is appropriate for a specific clinical situation.
   d. analyzes the relationship of nursing interventions to patient outcomes to discover evidence for patient interventions.

1. b, 2. c, 3. 5, 2, 1, 4, 3, 4. 4, 1, 3, 2, 5. a, 6. a, c, e, 7. c, d, e, 8. c.

Health Equity and Culturally Competent Care

Andrew Scanlon

LEARNING OUTCOMES

1. Identify the key determinants of health and equity.
2. Describe the factors that contribute to health disparities and health equity.
3. Define the terms *culture, values, acculturation, ethnicity, race, stereotyping, ethnocentrism, cultural imposition, cultural competency,* and *culture-bound syndrome.*
4. Explain how culture and ethnicity may affect a person's physical and psychologic health.
5. Apply strategies for incorporating cultural information in the nursing process with all patients.
6. Describe the role of nursing in promoting health equity.
7. Examine ways that your own cultural background may influence nursing care.
8. Describe strategies for successfully communicating with a person who speaks a language that you do not understand.

KEY TERMS

acculturation, p. 21
cultural competence, p. 22
culture, p. 20
culture-bound syndromes, p. 27
determinants of health, p. 17
ethnicity, p. 18
ethnocentrism, p. 21
folk healers, p. 23
health disparities, p. 18
health equity, p. 18
health status, p. 17

Conceptual Focus

Culture
Health Disparities

We may have different religions, different languages, different colored skin, but we all belong to one human race. We all share the same basic values.

Kofi Annan

http://evolve.elsevier.com/Lewis/medsurg/

This chapter discusses health disparities and culture. Health is a cultural concept because culture frames and shapes our experiences. Cultural beliefs influence health promotion practices and attitudes about seeking health care. Cultural differences can lead to problems that decrease the chance of receiving equitable health care. Nurses play a key role in recognizing and reducing health disparities. Understanding the concept of culture is important in your ability to provide patient-centered care.

Determinants of Health

Why are there differences in people's health status? How do these differences occur? The **determinants of health** are factors that (1) influence the health of individuals and groups and (2) help explain why some people experience poorer health than others.[1] Where people are born, grow up, live, work, and age helps determine their health status, behaviors, and care.

Health status is a holistic concept that is more than the presence or absence of disease. It encompasses life expectancy as well as self-assessment of health. As such, many measures make up the concept of health status. For individuals, this means the sum of their current health problems plus their coping resources (e.g., family, financial resources). For a community, health status is the combination of health measures for all people living in the community. Community health measures include birth and death rates, life expectancy, access to care, and morbidity and mortality rates related to disease and injury.

Factors in a person's social and physical environment, including personal relationships, workplace, housing, transportation, and neighborhood violence, contribute to health status.[1] For example, the risk of youth homicide is much higher in neighborhoods with gang activity and high crime rates. The physical environment in which one

lives, works, and plays may expose a person to such risks as environmental hazards (workplace injuries), toxic agents (chemical spills, industrial pollution), unsafe traffic patterns (lack of sidewalks), or absence of fresh and healthy food choices.

A person's behavior is influenced by his or her environment, education, and economic status. Behaviors such as tobacco and illicit drug use are strongly linked to many health conditions (e.g., lung cancer, liver disease). A person's biologic makeup, such as genetics and family history of disease (e.g., heart disease), can increase the risk for specific diseases.

The availability of health care also contributes to a person's health. Though government initiatives are striving to reduce the number of uninsured Americans, millions remain uninsured and have limited access to care. This affects both individual and community health.

Health Disparities and Health Equity

Health disparities are differences in the incidence, prevalence, mortality rate, and burden of diseases that exist among specific population groups. In the United States this is because of social, economic, or environmental disadvantages. Health disparities can affect population groups based on gender, age, ethnicity, socioeconomic status, education, location, sexual orientation, or disability status.[2] **Health equity** is achieved when every person has the opportunity to attain his or her health potential, and no one is disadvantaged.

Ethical/Legal Dilemmas

Health Disparities

Situation

E.M., a 47-yr-old Mexican American woman living with type 2 diabetes mellitus, comes to the clinic to have her blood glucose

measured. It has been 12 months since her last visit. At that time, the nurse asked that she bring along her glucometer and strips to show how she checks her blood glucose because her glucose values were high at her previous visits.

When you check E.M.'s equipment and glucose strips, you find that the strips are for a different machine and they expired more than 2 years ago. When you inquire about the situation, E.M. explains that she cannot afford to come to the clinic or to buy new equipment and supplies to check her blood glucose level. During the day, E.M. cares for her 3 grandchildren so her daughter can work. E.M. spends most of her income on food for her family, so she has little money left for her health care.

Ethical/Legal Points for Consideration

- Ethnic minorities and other vulnerable or disadvantaged groups experience certain chronic illnesses at higher rates. Limited access to high-quality, accessible, and affordable health care services is associated with an increased incidence of illness and complications, as well as a reduced life span.
- People with certain health problems such as diabetes may have difficulty obtaining health care insurance. Consider these issues in the broader context of social justice.
- In many states, the legal definition of the role of the professional nurse includes patient advocacy. Advocacy includes the obligation to provide adequate follow-up care for all patients, especially those who are experiencing health care disparities.
- A nurse who observes disparities must consider the possibility of discrimination and abuse. Professional nurses are legally and ethically responsible for patient advocacy. The nurse may incur legal liability if failure to fulfill this obligation results in patient harm.

Discussion Questions

1. How would you work with E.M. to help her obtain the necessary resources and knowledge to care for her diabetes?
2. What can you do to begin working on the problems of health disparities in your community?

Factors and Conditions Leading to Health Disparities

Many factors and conditions can lead to the development of health disparities (Table 2.1). Awareness of these factors will help you provide optimal care for your patients.

Ethnicity and Race

The terms **ethnicity** and **race** are subjective and based on self-report. These terms are used interchangeably in conversation and are not defined by genetic markers. Social context and lived experiences influence people's decision about the ethnic and race category to which they identify or are assigned. For example, ethnic and race categories may differ on a person's birth certificate and death certificate.

People often identify their own ethnicity and race for health data collection (e.g., health plans, birth certificates). Collection of health data based on self-reported ethnic and race categories is important for research, to inform policy, and to understand and eliminate disparities. People identify their race using 1 or more categories. Law requires federal agencies to list a minimum of 5 race categories: white, black, American Indian or Alaska Native, Asian, and Native Hawaiian or other Pacific Islander. Federal agencies must also list a minimum of 2 ethnicities for people who self-identify as either *Hispanic or Latino* and *Not Hispanic or Latino.* A Hispanic or Latino is typically a person of Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish descent, regardless of race. In this book, we use the terms *ethnicity* and *race* interchangeably or together.

Although dramatic improvements in treatments have prolonged life and improved quality of life for many, racial and ethnic minorities

have benefited far less from these advances. Disparities are generally determined by comparing population groups. In the United States, minority groups include Hispanics/Latinos (17.8% of the U.S. population), blacks (13.3%), Asian Americans (5.7%), Native Hawaiians and other Pacific Islanders (0.2%), Native Americans and Native Alaskans (1.3%), and 2 or more races (2.6%) population.[3] The number for most of these groups is expected to increase in the coming decades.

Obesity and chronic illness rates for diabetes, hypertension, chronic obstructive pulmonary diseases, cancer, and stroke are higher among minority people. Racial, ethnic, and cultural differences exist in health services, treatments provided, and access to health care providers (HCPs). Race and ethnicity also influence disease risk and outcomes. For example, after myocardial infarction, minority patients are at greater risk of rehospitalization and death but are less likely than nonminority patients to receive potentially beneficial treatments.[4] Native Americans have a higher incidence of several types of cancers and are often diagnosed at later stages of disease, resulting in a poorer prognosis.[5] Numerous strategies are being developed to promote health equity and reduce disparities.

TABLE 2.1 Factors and Conditions Leading to Health Disparities

- Age
- Disability status
- Education
- Ethnicity and race
- Gender
- Health care provider attitudes/biases
- Health literacy
- Income status

- Lack of health care services access
- Language barrier
- Occupation or unemployment
- Place
- Sexual orientation

Place

Place refers to the geographic and environmental location where a person is born, grows, lives, works, and ages. Place affects the use of health services, health status, and health behaviors.

About 20% of Americans live in nonurban or rural areas.[6] Differences in access to health care services between rural and urban settings can create geographic health disparities. For example, rural populations and Native Americans living on reservations may need to travel long distances to receive health care. This can result in inadequate or less-frequent access to health care services. Some parts of the rural United States are "medically underserved" because of decreased numbers of HCPs per population.

People living in rural areas have higher rates of cancer, heart disease, diabetes, depression, and injury-related deaths than people living in urban areas. For example, in rural Appalachia the rates of lung, colon, cervical, and colorectal cancer are higher than the national average. Rural populations tend to be older than urban populations. Many rural areas have higher rates of obesity and chronic disease. The impact of social and physical environment on health choices can be illustrated by the problem of intimate partner violence in rural communities.[7] The decision to seek help is affected by geographic isolation, traditional gender roles, patriarchal attitudes, fear of lack of confidentiality, and economic factors that exist in some small rural communities.

Living in urban centers may also predispose a person to health disparities. Concerns about personal safety (e.g., clinics located in high-crime neighborhoods) can make patients reluctant to visit HCPs. High rates of chronic health problems and premature deaths occur in

neighborhoods with social inequalities, including high poverty rates and residential segregation.

Among the most obvious health behaviors affected by place are physical activity and nutrition. Safe, walkable neighborhoods with playgrounds and sources of healthy foods promote physical activity and healthy eating. Social support positively affects coping with illness. Social networks are more likely to be found in communities where neighbors interact and rely on one another.

Income, Education, and Occupation

People of lower income, education, or occupational status experience worse health. In addition, they die at a younger age than those who are more affluent. Adults without a high school diploma or equivalent are 3 times more likely to die before age 65 than those with a college degree. Health care costs are 1 of the key factors that contribute to health disparities. People who have no insurance, are underinsured, or lack financial resources to pay for treatment of diseases may forgo health care visits, screenings, and treatments. Patients who lack the knowledge and/or access to apply for government assistance programs (e.g., Medicaid) are also at risk. Hazardous work environments and high-risk occupations of laborers increase health risk and contribute to higher rates of illness, injury, and death.

Health Literacy

Health literacy is defined as the degree to which a person has the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions. This includes the ability to (1) read, understand, and analyze information; (2) understand instructions; (3) weigh risks and benefits; and (4) make decisions and take action. Low health literacy is associated with more hospitalizations, greater use of emergency department care, decreased use of cancer screening and influenza vaccine, decreased ability to use medications correctly, and higher mortality rates among older adults.

On a daily basis, patients need to self-manage conditions such as diabetes and asthma. For example, patients with diabetes may not be

able to maintain adequate blood glucose levels if they cannot read or understand the numbers on the home glucose monitoring system. The inability to read and understand medication labels can result in taking medications at the wrong time or in the wrong dose. See Chapter 4 for more about health literacy.

Gender

Health disparities exist between men and women. Adult women use health care services more than men. Women may not receive the same quality of care (Fig. 2.1). For example, women are less likely than men to receive procedures (e.g., coronary angiography) for cardiovascular disease.[8] When gender is combined with racial and ethnic differences, the disparities are even greater. Gender Differences boxes throughout this book highlight gender differences in disease risk, manifestations, and treatment.

FIG. 2.1 Older Asian women are especially at risk for health disparities.

© szefei/iStock/Thinkstock.

Age

Older adults are at risk for experiencing health disparities in the number of diagnostic tests done and aggressiveness of treatments used. Biases toward older adults that affect their care, or ageism, are discussed in Chapter 5. Older people of low socioeconomic status experience greater disability, more limitations in activities of daily living, and more frequent and rapid cognitive decline. Black and Latino older adults, in particular, are disproportionately affected by chronic illnesses, disability, depression, and substandard quality of life.[9]

Sexual Orientation

Sexuality is defined as a person's romantic, emotional, or sexual attraction to another person.

Lesbian, Gay, Bisexual, Transgender, and Queer or Questioning

Lesbian, gay, bisexual, transgender, and queer or questioning (LGBTQ) is a term that refers to the sexual orientation of these groups of people. LGBTQ persons encompass all races and ethnicities, religions, and social classes. Being LGBTQ places a person at risk for health disparities resulting from social, economic, or environmental disadvantages. Personal, family, and social acceptance of sexual orientation and gender identity affects the mental health and personal safety of LGBTQ persons. Discrimination against LGBTQ people has been associated with high rates of psychiatric disorders, substance abuse, and suicide.

LGBTQ people are more likely to be obese when compared with their heterosexual counterparts. Lesbian and bisexual women have higher rates of breast cancer and increased risk factors for cardiovascular disease. Gay and bisexual men have higher rates of human immunodeficiency virus and hepatitis infections than other

groups.[10] Older LGBTQ persons may face added barriers to health because of isolation and a lack of social services and culturally competent providers.[9]

Understanding the cause of disparities among LGBTQ persons is essential to providing safe and high-quality care. One of the barriers to accessing high-quality health care by LGBTQ adults is the current lack of HCPs who are knowledgeable about their health needs. LGBTQ people may also experience fear of discrimination in health care settings.

Some health care settings are addressing the negative stereotypes that health care professionals may have, but of which they may not be aware. The Joint Commission (TJC) requires that patients be allowed the presence of a support person of their choice. In addition, hospitals must adopt policies that bar discrimination based on factors such as sexual orientation and gender identification and expression.

Promoting Population Health

Improving the Health and Well-Being of LGBTQ Persons

- Provide supportive social services to reduce suicide among young LGBTQ persons.
- Inquire about and be supportive of a patient's sexual orientation to enhance the patient-provider interaction and patient's regular use of care.
- Implement antibullying policies in schools.
- Provide health care professionals with knowledge of the health needs of the LGBTQ community and training on LGBT mental health issues.
- Continue efforts to expand domestic partner health insurance coverage.
- Establish community advisory boards and LGBTQ health centers.

- Disseminate effective HIV and sexually transmitted infections interventions.

Health Care Provider Attitudes

Certain behaviors and biases of the HCP can contribute to health disparities. Factors such as bias and prejudice can affect health care-seeking behavior in minority populations. The health care system may also contribute to the problem of health disparities. For example, a clinic located in an area with a large population of Vietnamese immigrants that does not provide interpreters or educational materials and financial forms in Vietnamese may limit these families' ability to understand how to access health care.

Discrimination and *bias* based on a patient's race, ethnicity, gender, age, body size, sexual orientation, or ability to pay are likely to result in less aggressive or negative treatment practices. Discrimination can result in the delay of a proper diagnosis due to assumptions made about the patient. Sometimes discrimination is hard to recognize, especially when it occurs at the institutional level.

Because an HCP's overt discriminatory behavior may not be clear to the patient or yourself, it may be difficult to confront. Even well-intentioned providers who try to eliminate bias in their care can show their prior beliefs or prejudices through nonverbal communication. Many policies are in place to eliminate discrimination, but it still exists.

Culture

Culture is a way of life for a group of people. It includes the behaviors, beliefs, values, traditions, and symbols that the group accepts, generally without thinking about them. This way of life is passed along by communication and imitation from 1 generation to the next. You can also think of culture as cultivated behavior that one acquires through social learning. It is the totality of a person's learned, accumulated experience that is socially transmitted. The 4 classic

characteristics of culture are described in Table 2.2.

Values are the sets of rules by which persons, families, groups, and communities live. They are the principles and standards that serve as the basis for beliefs, attitudes, and behaviors. Although all cultures have values, the types and expressions of those values differ from 1 culture to another. These cultural values develop over time, guide decision making and actions, and may affect a person's self-esteem. Cultural values often unconsciously develop early in life as a child learns about acceptable and unacceptable behaviors. The extent to which a person's cultural values are internalized influences that person's tendency toward judging other cultures, while usually using his or her own culture as the accepted standard. Table 2.3 provides some examples of cultural characteristics of different ethnic groups in the United States.

Although persons within a cultural group may have many similarities through their shared values, beliefs, and practices, there is also diversity within groups (Fig. 2.2). Each person is culturally unique. Such diversity may result from different perspectives and interpretations of situations. These differences may be based on age, gender, marital status, family structure, income, education level, religious views, and life experiences. Within any cultural group, there are smaller groups that may not hold all the values of the dominant culture. These smaller cultural groups have experiences that differ from those of the dominant group. These differences may be related to ethnic background, residence, religion, occupation, health, age, gender, education, or other factors that unite the group. Members of a subculture share certain aspects of culture that are different from those of the overall cultural group. For example, among Hispanics some seek professional health care right away when symptoms appear. Other Hispanics rely first on folk healers. Others first seek the opinion of family and friends before seeking formal health care.

TABLE 2.2 Basic Characteristics of Culture

- *Dynamic* and ever-changing
- *Not always shared* by all members of a cultural group
- *Adapted* to specific conditions such as environmental factors
- *Learned* through oral and written histories, as well as socialization

TABLE 2.3 Cultural Characteristics of Different Ethnic Groups

Asian American

- Cultural foods
- Family loyalty
- Folk healing
- Harmonious relationships
- Harmony and balance within body vital for preservation of life energy
- Respect for elders
- Respect for one's parents and ancestors

Black

- Cultural foods
- Family networks
- Folk healing
- Importance of religion
- Interdependence within ethnic group
- Music and physical activities valued

European American

- Equal rights of genders
- Independence and freedom
- Individualistic and competitive
- Materialistic
- Self-reliance valued
- Youth and beauty valued

Hispanic/Latino

- Cultural foods
- Folk healing
- Extended family valued
- Interdependence and collectivism
- Involvement of family in social activities
- Religion and spirituality highly valued
- Respect for elders and authority

Native American

- Doing the honorable thing
- Folk healing
- Living in harmony with people and nature
- Respect for tribal elders and children
- Respect for all things living
- Return what is taken from nature
- Spiritual guidance

Pacific Islander American

- Collective concern and involvement

- Kinship alliance among nuclear and extended family
- Knowledge is collective; belongs to group, not a person
- Natural order and balanced relationships

Adapted from Andrews MM, Boyle JS: *Transcultural concepts in nursing care,* ed 7, Philadelphia, 2016, Lippincott Williams & Wilkins; and Giger JN, Davidhizar RE: *Transcultural nursing: Assessment and intervention*, ed 7, St Louis, 2016, Mosby.

Cultural beliefs about symptom tolerance and health care–seeking behavior can contribute to health disparities. Some cultures consider pain something to be endured or ignored, and as a result, the patient does not seek help. Some cultures may view diseases or problems fatalistically; that is, people see no reason to seek treatment because they believe it is unlikely to have any benefit. Some cultures view the signs and symptoms of an illness as "God's will" or as a punishment for some prior behavior. In some cultures, it may not be acceptable to see an HCP who is not of the same gender or ethnic group. Such beliefs can result in delays in seeking health care or inadequate treatment.

FIG. 2.2 Members of this family share a common heritage.

Acculturation is the lifelong process of incorporating cultural aspects of the contexts in which a person grows, lives, works, and ages.[11] Acculturation is often bidirectional. In other words, the context changes as a person's culture influences it. Change may be in attitudes, behaviors, and values. For example, a sedentary person who loves to cook may change his or her attitude toward exercise when living with athletic roommates, who in turn also change as they begin to appreciate cooking. Behaviors change when an immigrant child learns the local language while influencing the conduct of classmates. A deeply held value such as self-sufficiency may change for a person exposed to a culture in which reliance on others dominates.

Newcomers may adopt both the strengths and limitations of the dominant culture. This is relevant when considering health behaviors and the quality of health care delivered by professionals. For example, an immigrant may be negatively influenced by a dominant cultural context in which unhealthy eating habits prevail.[12]

The result of acculturation may be new cultural variations in attitudes, behaviors, and values. All people take part in this process over their lives. People who move to a new cultural context are more aware of the acculturation experience than people who are not exposed to new experiences. Exposure to new cultural contexts increases a nurse's cultural competency.

Stereotyping refers to an overgeneralized viewpoint that members of a specific culture, race, or ethnic group are alike and share the same values and beliefs. This oversimplified approach does not consider the individual differences that exist within a culture. Being a member of a particular cultural, ethnic, or racial group does not make the person an expert on other members of that same group. Such stereotyping can lead to false assumptions and affect a patient's care. For example, it would be inappropriate for you to assume that just because a nurse is Mexican American, he would know how a Mexican American patient's beliefs may affect that patient's health care practices. As another example, a young Mexican American nurse born and raised in a large city has experienced a different culture than the older patient who was born and raised in a rural area of Mexico.

Ethnocentrism refers to the belief that one's own culture and worldview are superior to those of others from different cultural, ethnic, or racial backgrounds.[11] Comparing others' ways to your own can lead to seeing others as different or inferior. HCP's ethnocentrism can result in poor communication, patient alienation, and potentially inadequate treatment. To avoid ethnocentrism, you need to remain open to a variety of perspectives and maintain a nonjudgmental view of the values, beliefs, and practices of others. Failure to do this can result in ethnic stereotyping or cultural imposition.

Cultural imposition occurs when we impose our own cultural beliefs and practices on another person or group of people. In health care, it can result in disregarding or trivializing a patient's health care beliefs or practices. Cultural imposition may happen when an HCP is unaware of the patient's cultural beliefs and plans and implements care without taking them into account.

Cultural safety describes care and advocacy for a person of another

culture determined by that person or family. Care that is culturally safe prevents cultural imposition. Culturally safe practice requires cultural competency and action to ensure that cultural histories, experiences, and traditions of patients, their families, and communities are valued and shape health care approaches and policies.[13]

Madeleine Leininger coined the term **transcultural nursing** in the 1950s. Transcultural nursing is a specialty that focuses on the comparative study and analysis of cultures and subcultures. The goal of transcultural nursing is the discovery of culturally relevant facts that can guide the nurse in providing culturally appropriate care.[11]

Cultural Competence

Cultural competence is the ability to understand, appreciate, and work with people from cultures other than your own. It involves an awareness and acceptance of cultural differences, self-awareness, knowledge of the patient's culture, and adaptation of skills to meet the patient's needs. The 4 components of cultural competence are (1) cultural awareness, (2) cultural knowledge, (3) cultural skill, and (4) cultural encounter (Table 2.4).

We present specific information throughout this book to help you develop an awareness of cultural differences and learning assessment skills for different cultural groups. Table 2.8 (later in this chapter) presents a cultural assessment guide. It may be helpful to review general cultural characteristics associated with a cultural group when preparing to interview a patient. However, recognize that the patient may not identify with the assumed cultural group and the provider's own biases and stereotypes may affect the patient and result in more patient-provider barriers.

Providing culturally competent care may increase patient satisfaction, promote health equity, increase patient safety, and prevent misunderstandings between you and your patients.[14] It also involves integrating cultural practices into Western medicine. For example, before some diagnostic procedures and interventions, it is

typical to have patients remove personal objects they are wearing on the body. Ask patients whether they wear personal objects and the significance of their removal, since they may have cultural or spiritual significance. You should know whether wearing these objects will compromise patient safety, test results, or outcomes of the intervention.

Cultural Diversity in the Health Care Workplace

Poorer health outcomes for minorities are linked to the shortage of culturally and ethnically diverse HCPs, who have historically been underrepresented in the health professions. A diversity gap exists between the ethnic composition of the interprofessional health care team and the overall population in the United States (Fig. 2.3). For example, the diversity of nurses in the United States is increasing but still lags that of the overall population. Blacks, Hispanic/Latino Americans, and Native Americans make up more than 35% of the population but only 24% of the nation's nurses.[3,15] Biased behaviors against nurses of diverse cultural and ethnic backgrounds by patients and health care professionals may contribute to their underrepresentation.

TABLE 2.4 How to Develop Cultural Competence

Description	Role of Nurse
Cultural Awareness	
• **Ability to understand patients' unique cultural needs**	• Understand your own cultural background, values, and beliefs, especially as related to health and health care. • Examine your own cultural biases toward people whose cultures differ from your own culture.
Cultural Knowledge	
• **Process of learning key aspects of a group's culture, especially as it relates to health and health care practices** • **Patients are best source of information about their culture**	• Learn basic general information about predominant cultural groups in your geographic area. Cultural pocket guides can be a good resource. • Assess patients for presence or absence of cultural traits based on an understanding of generalizations about a cultural group. • Do not make assumptions based on cultural background because the degree of acculturation varies among persons. • Read research studies that describe cultural differences. • Read ethnic newspaper articles and books. • View documentaries about cultural groups.
Cultural Skill	
• **Ability to collect relevant cultural data** • **Performance of a cultural assessment**	• Be alert for unexpected responses with patients, especially as related to cultural issues. • Become aware of cultural differences in predominant ethnic groups. • Develop assessment skills to do a competent cultural assessment for any patient (see Table 2.8). • Learn assessment skills for different cultural groups, including cultural beliefs and practices.
Cultural Encounter	
• **Direct cross-cultural interactions between people from culturally diverse backgrounds** • **Extended contact with a cultural group to enhance understanding of its values and beliefs**	• Create opportunities to interact with predominant cultural groups. • Attend cultural events, such as religious ceremonies, significant life passage rituals, social events, and demonstrations of cultural practices. • Visit markets and restaurants in ethnic neighborhoods. • Explore ethnic neighborhoods, listen to different types of ethnic music, and learn games of various ethnic groups. • Visit or volunteer at health fairs in local ethnic neighborhoods. • Learn about prominent cultural beliefs and practices and incorporate this knowledge into planning nursing care.

FIG. 2.3 Interprofessional team working together in a multicultural health care environment.
© Thinkstock/Stockbyte/Thinkstock.

Cultural differences exist in how well patients think they can communicate with their HCP. In the United States, minority patients are more likely to have difficulty communicating with their HCP.[16] Communication issues include not understanding the HCP, feeling that they are not listened to, and having questions but not asking them. As more internationally educated nurses join the workforce, sufficient training and transitional support must be in place to ensure communication and quality of care.

When HCPs from different cultures work together as members of the health care team, opportunities for miscommunication and conflict can occur. This is termed *cultural conflict.* The cultural origins of miscommunication and conflict in the workplace are often

interconnected with cultural beliefs, values, and etiquette. Seeking clarification about misperceptions and misunderstandings is a communication strategy to foster effective teamwork among a multicultural health care team. To ensure the recruitment and retention of nurses from minority populations, all members of the health care team and leadership must create an environment that promotes effective cross-cultural communication and reduces bias and discrimination.

Cultural Factors Affecting Health and Health Care

Many cultural factors affect the patient's health and health care. Several potential factors are outlined in Table 2.5.

Folk Healers and Traditions

Many cultures have **folk healers**, who are also known as *traditional healers*. Most folk healers speak the person's native language and cost less than conventional HCPs. Among the many folk healers found worldwide, Hispanics, particularly from regions in Mexico and Central and South America, may choose to use a *curandero* (or *curandera*); blacks may visit a *hougan;* Native Americans may seek help from a medicine man or *shaman;* and Asian Americans may use folk healers such as a Chinese herbal therapist. In addition to folk healers, some cultures involve lay midwives (e.g., *parteras* for Hispanic women) in the care of pregnant women.

TABLE 2.5 Cultural Factors Affecting Health and Health Care

Beliefs and Practices

- Care provided in established health care programs may not be perceived as culturally relevant.
- Religious reasons, beliefs, or practices may affect a person's decision to seek (or not seek) health care.
- Patients may delay seeking health care because of fear or dependence on folk medicine and herbal remedies.
- Patients may stop treatment or visits for health care because the symptoms are no longer present and they think that further care is not needed.
- Some patients associate hospitals and extended care facilities with death.
- The patient may have had a previous negative experience with culturally incompetent HCPs or discriminatory practices.
- Some people mistrust the majority population and institutions dominated by them.
- Some patients may feel apprehensive about unfamiliar diagnostic procedures and treatment options.

Communication and Language

- Patients may not speak English and may not be able to communicate with the HCP.
- It may be hard to communicate, even with interpreters.

Economic Factors

- Patients may not get health care because they cannot pay for it or because of the costs associated with travel for health care.
- Refugee or undocumented immigrant status may deter some patients from using the health care system.
- Immigrant women who are heads of households or single mothers may not seek health care for themselves because of child

care costs.
- Patients may lack health insurance.

Health Care System

- Patients may not make or keep appointments because of the time lag between the onset of an illness and an available appointment.
- Hours of operation of health care facilities may not accommodate patients' need to work or use public transportation.
- Requirements to access some types of care may discourage some patients from taking the steps to qualify for health care or health care payment assistance.
- Some patients have a general distrust of HCPs and health care systems.
- Lack of ethnic-specific health care programs may deter some people from seeking health care.
- Transportation may be a problem for patients who must travel long distances for health care.
- Adequate interpreter services may be unavailable.
- Patients may not have a primary HCP and may use emergency departments or urgent care centers for health care.
- Shortages of HCPs from specific ethnic groups may deter some people from seeking health care.
- Patients may lack knowledge about the availability of existing health care resources.
- Facility policies may not be culturally competent (e.g., hospital policy may limit the number of visitors, which is problematic for cultures that value having many family members present).

Time Orientation

- For some cultures, it is more important to attend to a social role

than to arrive on time for an appointment with an HCP.
- Some cultures are future oriented; others are past or present oriented.

TABLE 2.6 Health-Related Beliefs and Practices of Selected Religious Groups

Amish

- Prohibit drinking alcoholic beverages
- Prohibit abortion, artificial insemination, and stem cell use
- Seldom buy commercial health insurance
- Prohibit drugs unless prescribed by HCPs

Buddhism

- Prohibit drinking alcoholic beverages and using illicit drugs
- Practice moderation in diet and avoidance of extremes
- Central tenets are maintaining right views, intentions, speech, actions, livelihood, effort, mindfulness, and concentration

Catholicism

- Fast and abstain from meat and meat products on Ash Wednesday and the Fridays of Lent
- Prohibit artificial contraception and direct abortion
- Indirect abortion (e.g., treatment of uterine cancer in a pregnant woman) may be morally justified
- Sacrament of the Sick includes anointing of sick with oil, blessing by a priest, and communion (unleavened wafer made of flour and water)

Church of Jesus Christ of Latter-Day Saints (Mormons)

- Strict dietary code called Word of Wisdom prohibits all alcoholic beverages, hot drinks (nonherbal teas and coffee), tobacco, and recreational drugs
- Fast for a 24-hour period each month on "Fast Sunday"
- During hospitalization or serious illness, an elder anoints the ill person with oil while a second elder seals the anointing with a prayer and blessing (laying on of hands)
- Prohibit abortion except when the mother's life is in danger

Hinduism

- Prohibit eating meat because it involves harming a living creature
- Cremation is the usual form of body disposal, but fetuses or newborns are sometimes buried

Islam

- Fasting during daytime hours occurs during a month-long period called Ramadan
- Perform a ritual cleansing with water before eating and before prayer
- Prohibit eating pork or taking medicines with pork derivatives
- Prohibit drinking alcoholic beverages
- Artificial insemination is permissible only if from the husband to his own wife

Jehovah's Witness

- Prohibit transfusions of blood in any form or agents in which blood is an ingredient
- Blood volume expanders are acceptable if they are not derivatives of blood
- Prohibit transplants that involve bodily mutilation
- Prohibit artificial insemination and therapeutic and on-demand abortions

Judaism

- Prohibit eating pork, shellfish, or predatory fowl or mixing milk dishes and meat dishes when preparing foods
- Certain foods and drinks are designated as kosher, which means "proper." All animals must be ritually slaughtered
- On the eighth day after birth, boys are circumcised in a ritual called Brit Milah. Girls are given a dedication ceremony involving prayers and blessings
- Prohibit abortion except when the mother's life is in danger
- Organized support system for the sick includes a visit from the rabbi. The rabbi may pray with the sick person alone or in a minyan, a group of 10 adults over age 13
- If an autopsy is done, all body parts must be returned for burial

Seventh-Day Adventism

- Encourage a vegetarian diet
- Nonvegetarian members do not eat foods derived from any animal having a cloven hoof that chews its cud (e.g., pigs, goats).
- Prohibit eating shellfish; eating fish with fins and scales is acceptable
- Prohibit drinking alcoholic beverages
- Healthy church members practice voluntary fasting

Data from Andrews MM, Boyle JS: *Transcultural concepts in nursing care*, ed 7, Philadelphia, 2016, Lippincott Williams & Wilkins.

Folk medicine and traditions are culturally based forms of prevention and treatment. They traditionally rely on oral transmission of healing techniques from 1 generation to the next. The patient may not use the term *folk medicine* but thinks of these as cultural home remedies or treatment practices. A patient can be practicing folk medicine at home without using a folk healer. It is important to assess whether the patient is practicing traditional or folk healing.

Some traditions that are practiced as a rite of passage in some cultures are considered harmful in the dominant culture in the United States. For example, female genital cutting is a tradition that is illegal in most countries yet still practiced in many countries in Africa and the Middle East. It results in physical and emotional trauma and may affect childbirth. Nurses can advocate for immigrant women who have experienced this trauma and to prevent return of young girls to their country of origin for the procedure.

Spirituality and Religion

Spirituality and religion are aspects of culture that may affect a person's beliefs about health, illness, and end-of-life care. They may also play a role in nutrition and decisions related to health, wellness, and how to respond to or treat an illness.

Spirituality refers to a person's effort to find purpose and meaning in life. It is influenced by a person's unique life experiences and reflects one's personal understanding of life's mysteries. Spirituality relates to the soul or spirit more than to the body, and it may provide hope and strength for a person during an illness.

Religion is a more formal and organized system of beliefs, including belief in or worship of God or gods. Religious beliefs include the cause, nature, and purpose of the universe and involve prayer and rituals. Religion is based on beliefs about life, death, good, and evil. You can use several interventions to meet a patient's religious and

spiritual needs, including prayer, scripture reading, listening, and referral to a chaplain, rabbi, or priest.

Many patients find that rituals help them during times of illness. Rituals help a person make sense of life experiences and may take the form of prayer, meditation, or other rituals that the patient may create. You should include spiritual questions in your patient assessment and plan care accordingly. Table 9.5 has a spiritual assessment guide that may be used with patients. Table 2.6 summarizes health-related beliefs and practices of selected religious groups.

Cross-Cultural Communication

Communication refers to an organized, patterned system of behavior that may be verbal or nonverbal (Fig. 2.4). *Verbal communication* includes not only one's language or dialect, but also voice tone, volume, timing, and ability to share thoughts and feelings. More than 45 million people in the United States speak a language other than English in their home, with Spanish being the most common. Hispanic people who do not speak English at home are less likely to receive a variety of health care services even if they are comfortable speaking English.

FIG. 2.4 Co-workers from different cultures communicate with verbal and nonverbal cues.
© BananaStock/Thinkstock.

Nonverbal communication may take the form of writing, gestures, body movements, posture, facial expressions, and personal dress in some cultures. It also includes eye contact, use of touch, body language, style of greeting, and spatial distancing. Eye contact varies greatly among cultural groups. Patients who are Asian, Arab, or Native American may avoid direct eye contact and consider it disrespectful or aggressive. Hispanic patients may expect you to look directly at them but may not return that direct gaze. Other variables to consider include the role of gender, age, acculturation, status, or appropriate eye contact. For example, Muslim-Arab women exhibit modesty when avoiding eye contact with men other than their husbands and when in public situations.

Silence has many meanings. It is important to understand the meaning of silence for different cultural groups. Some people are comfortable with silence. Others become uncomfortable and may speak to decrease the amount of silent time. It is important to clarify what silence means in an interaction with a patient. Patients sometimes nod their head or say "yes" as if agreeing with you or to show they understand. Actually, they may be doing this because it is a culturally acceptable manner of showing respect, not because they understand or agree.

Many Native Americans are comfortable with silence and interpret silence as essential for thinking and carefully considering a response. In these interactions, silence shows respect for the other person and shows the importance of the remarks. In traditional Japanese and Chinese cultures, the speaker may stop talking and leave a period of silence for the listener to think about what was said before continuing. Silence may show respect for the speaker's privacy. In some cultures (e.g., French, Spanish, and Russian) the person may interpret silence as meaning agreement. Asian Americans may use silence to show respect for elders. Blacks may use silence as a response to what they perceive to be an inappropriate question.

Racism and microaggression affect communication. *Racism* is a belief that differences among the various racial/ethnic groups determine cultural or individual achievement. It usually involves the idea that one's own race/ethnicity is superior and has the right to dominate others or that a particular racial/ethnic group is inferior to the others.

FIG. 2.5 Family roles and relationships differ from 1 culture to another.
© Jupiterimages/Photos.com/Thinkstock.

Microaggression is social exchanges in which a person says or does something that can either intentionally or unintentionally belittle or alienate a person, especially someone of a different racial/ethnic

group. It is imperative that nurses seek to understand racism and microaggression through education, self-awareness, and open dialogue with peers.[17]

Family Roles and Relationships

Family roles differ from 1 culture to another (Fig. 2.5). It is important for you to determine who should be involved in communication and decision making related to health care. Some cultural groups emphasize interdependence rather than independence. In the United States, many in the mainstream culture have strong beliefs related to autonomy. We expect a patient to sign consent forms when receiving health care. In some cultural groups, the patient may expect a family member to make health care decisions. When you encounter a patient who values interdependence over independence, the health care system may have difficulty with how the patient makes decisions. We may have to delay treatment while the patient waits for family members to arrive before giving consent for a procedure or treatment. In other instances, the patient may make a decision that is best for the family despite adverse outcomes for the patient. Being aware of such values will better prepare you to advocate for the patient.

Some cultural differences relate to expectations of family members in providing care. In some cultures, family members expect to provide care for the patient even in the hospital. The patient may expect that the family, along with the HCPs, will provide all care. This view is the opposite of the predominant Western expectation that the patient will assume self-care as quickly as possible.

Ask about culturally relevant gender relationships. For example, in some cultures, such as many Arab groups, it is not appropriate for a man to be alone with a woman other than his wife. Nor is it appropriate for a woman other than a man's wife to provide physical care for him. The clinical implication of this cultural belief is that for many patients from Arab cultures, nurses cannot provide direct physical care for patients of the opposite gender. In some instances, patients may only receive procedures or treatments from providers of

the opposite gender if a third party is present.

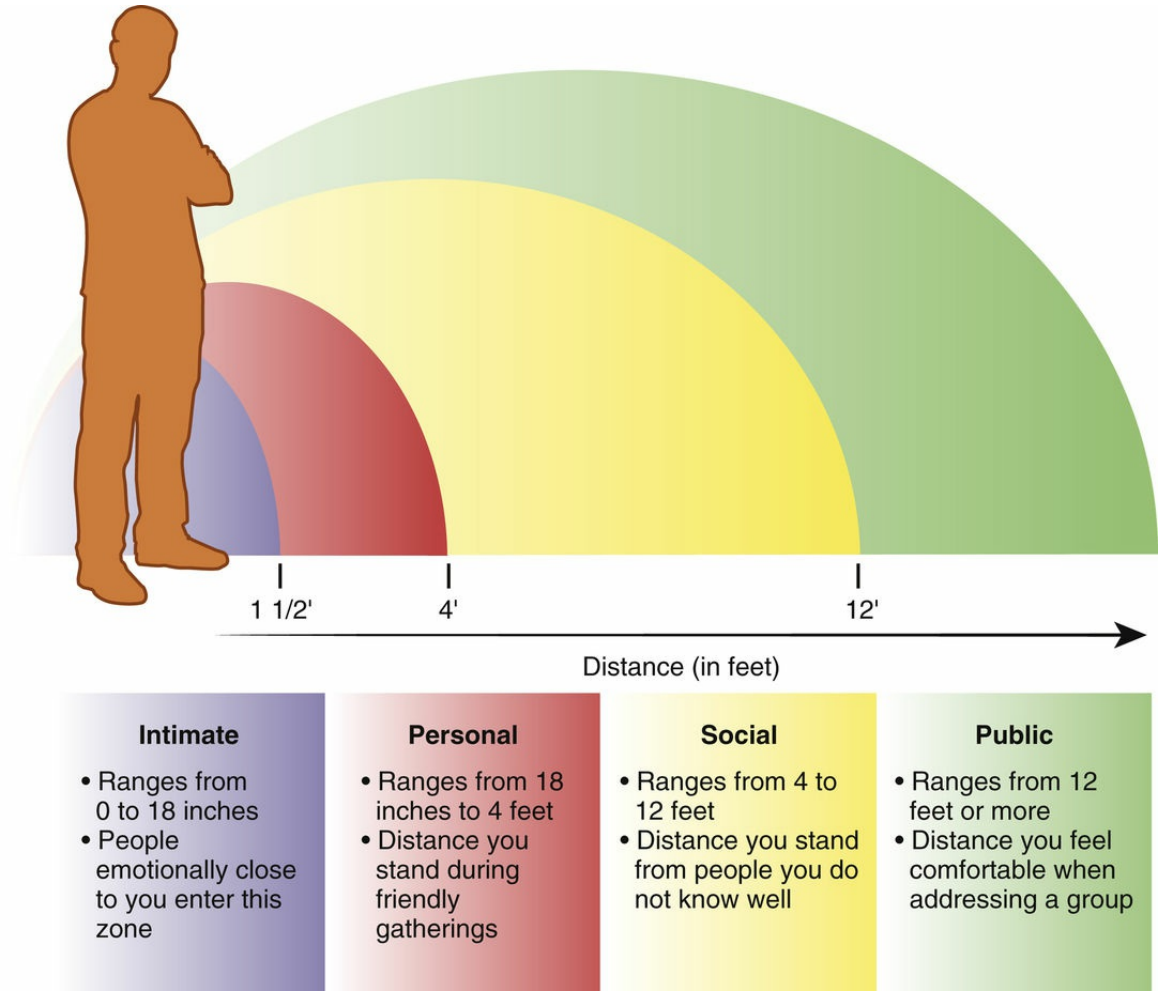

FIG. 2.6 Personal space zones.

Personal Space

Personal space zones are the variable and subjective distance at which 1 person feels comfortable talking to another. A representative example of personal space zones for European Americans is shown in Fig. 2.6. Personal space distances vary from culture to culture, as well as within a culture. As a nurse, you often interact with patients in the intimate or personal distance, which may be uncomfortable for the patient.

Cultural groups have wide variations in their perception of appropriate distances. An American nurse of European descent may be comfortable with a certain distance. A person from a Hispanic or

Middle Eastern background may believe that the distance is too far and will move closer, perhaps causing you to feel uncomfortable. If you then move away to a more comfortable distance, this may cause the other person to think that you are unfriendly or the person may be offended.

Touch

Physical contact with patients conveys various meanings depending on the culture. Performing a comprehensive assessment requires touching a patient. Many people of Asian and Hispanic heritage believe that touching a person's head is a sign of disrespect because the head is the source of one's strength and/or soul. Many people in the world believe in the evil eye, or *mal ojo.* In this culture-bound syndrome, the illness—usually in a child or a woman—resulted from excessive admiration by another person. In some cultures, the proper way to ward off the evil eye is to touch the area of admiration. For example, if the person admires the hair, the top of the head may be touched. It is important for you to ask permission before touching anyone, particularly if it is necessary to touch the person's head.

Nutrition

An important part of cultural practices is food, including both the foods that are eaten and rituals and practices associated with food. Muslims fast during the daytime during the Islamic month of Ramadan. Such practices may affect when and how patients take medications. Patients may need to make major changes in their diets because of health problems. A person may use food to cope with life changes such as homesickness. Specific foods may be considered essential to good health during pregnancy or other life stages. The HCP should consider food-related cultural beliefs, practices, and habits when discussing nutrition with patients and planning their diets.

When people immigrate to an area that is very different from their country of origin, they may experience unfamiliar foods, food-storage

systems, and food-buying habits. They may come from countries that have limited food supplies because of poverty, wars, and poor sanitation. They may arrive with conditions such as malnutrition, diarrhea, and dental caries. Other problems may develop after the person arrives in the new country. For example, second-generation Hispanic immigrants have a greater chance of becoming overweight than their first-generation counterparts. The increase in weight is related to the degree of acculturation experienced by the immigrant.

Immigrants and Immigration

Several conditions drive migration, such as overcrowding, natural disasters, geopolitical conflict, persecution, and economic forces. Because of these migrations, a rich diversity of cultures exists in many communities and countries today (Fig. 2.7).

Recent immigrants may be at risk for physical and mental health problems for many reasons. Conditions in their countries of origin (e.g., malnutrition, poor sanitation, civil war) may have resulted in chronic health problems. In addition, recent immigrants are at increased risk for health problems after arriving in a new area. Relocation is associated with many losses and can cause economic hardship, physical stress, and mental distress.

As new immigrants go through the acculturation process, many have cultural stress as they adjust to their new environment, especially if they have left relatives behind or are unable to return to their home country. Older immigrants are especially affected by changes in role and social position. This may result in depression. Immigrants who have survived wars and violence may have posttraumatic stress disorder. Immigrants may face barriers to social acceptance, such as prejudice or discrimination, and experience a lack of ethnic and cultural resources. For some, it may mean loss of the social status that they experienced in their countries of origin.

Another potential problem is tuberculosis (TB). Two-thirds of the TB cases in the United States occur in people born outside the country.[18] Those who have recently immigrated from areas that have

a high endemic rate of TB are more likely to have TB. Foreign-born Hispanics and Asians combined account for 48% of the nation's TB cases. The top 5 countries of the origin of foreign-born people with TB are Mexico, Philippines, Vietnam, India, and China. The *Refugee Health Guidelines* from the Centers for Disease Control and Prevention supports early identification and treatment.[19]

During the past 45 years, the migration pattern of North America has shifted. Once most immigrants came from Europe. Now, most originate from Asia, Latin America, and Africa. Additionally, an increased number of first- and second-generation immigrants enter the United States after visiting friends and relatives. They have a higher risk for malaria, typhoid fever, cholera, and hepatitis A than people born in the United States. Many immigrants lack health insurance and may primarily obtain their health care in emergency departments and urgent care clinics. Therefore nurses in all settings need to be aware of refugee health screening, treatment recommendations, and resources for access to health care and social services.

Drugs

Genetic differences among people from diverse ethnic or racial groups may explain differences in drug choice, dosage, or administration. For example, some drugs are more effective in certain ethnic groups than others. Side effects may vary among persons from diverse backgrounds.

Genetic variations can affect how the body processes a drug and the overall effect of selected drugs on the body. Although race and ethnicity are imprecise indicators of genetic differences, they can be helpful in predicting variations in the response to drugs. For example, European Americans respond better to angiotensin-converting enzyme (ACE) inhibitors and β-blockers than blacks. Genetics and drug metabolism are discussed in Chapter 12.

FIG. 2.7 Recently arrived immigrants join a neighbor for a barbecue, a common American tradition.
© Jack Hollingsworth/Photodisc/Thinkstock.

Regardless of their cultural origins, many people use cultural remedies and prescription drugs to treat illness. Problems can result from interactions of these substances. For example, some Mexican Americans may treat gastrointestinal problems with preparations that contain lead. Some people may self-treat their depression with St. John's wort, which can result in adverse effects if taken with prescription antidepressants.

Patients may avoid standard Western medicine until herbs and other remedies become ineffective or the illness becomes acute. The

challenge for you is to try to accommodate the patient's desire for traditional aspects of care while using evidence-based approaches that are appropriate and acceptable to the patient. Evaluate the safety and appropriateness of the patient's traditional cultural healing therapies.

Develop a collaborative, trusting relationship with patients and encourage them to discuss their traditional approaches to healing. Seek out information on potential drug and herbal product interaction from the pharmacist. Honor the patient's choices, if safe and effective, since this will enhance collaboration and may have a positive impact on health outcomes.

Psychologic Factors

Symptoms are interpreted through a person's cultural norms and may vary from the recognized interpretations of Western medicine. All symptoms have meaning, and the meanings may vary from 1 culture to another. For example, the degree of depression following a cardiac diagnosis is mediated by cultural views. It is important to ask patients what their illness means to them, what they believe is the cause, and what they think is the best treatment.

Culture-bound syndromes are illnesses or afflictions that are recognized only within a cultural group (Table 2.7). The symptoms, course of the illness, and people's reactions to the illness are limited to specific cultures. Culture-bound syndromes are expressed through psychologic or physical symptoms.

TABLE 2.7 Culture-Bound Syndromes

Syndrome	Description
Blacks	
Brain Fag	Term describing brain "fatigue" caused by the challenges of school. Symptoms include difficulties concentrating, remembering, and thinking.
Thin Blood	Affects older adults, women, and children. Weakens a person and increases susceptibility to illness.
Cambodians	
Koucharang or Kit Chroeun	Translates as "thinking too much," brought about by having seen or experienced a horrific trauma. Characterized by physical and emotional exhaustion, immobilization, and constant preoccupation with past suffering and loss.
Caribbean and Southern United States	
Falling Out	Characterized by a sudden collapse, which may sometimes be preceded by dizziness or "swimming" in the head. The person can hear but is unable to move.
Chinese	
Shenjing Shuairuo	Characterized by physical and mental fatigue, headaches and other pains, dizziness, sleep disturbances, and concentration difficulties.
Hispanics/Latinos	
Bilis or Colera	Caused by strong anger or rage. Anger results in excess bile that gets into the systemic circulation. Symptoms include acute nervous tension, headache, trembling, screaming, stomach disturbances, and, in severe cases, loss of consciousness.
Ataque de Nervios	Brought on by a stressful family event (e.g., death, divorce). Symptoms may include uncontrollable shouting, crying, trembling, and verbal or physical aggression.
Empacho	The perception that an undigested food bolus is "stuck" somewhere in the gastrointestinal tract, causing nausea, pain, and diarrhea.
Susto	Sometimes referred to as "fright sickness" or "soul loss." A traumatic anxiety-depressive state that may result from a frightening experience, such as a loud sound or some threat. Can cause anxiety, insomnia, listlessness, loss of appetite, and social withdrawal. One treatment is to have the affected person lie on the floor. The healer then sweeps indigenous herbs over the person's body while praying to release the evil wind.
Koreans	
Hwa-Byung	Ailment characterized by resentment that is brought about by bitterness and discontent.
Native Americans	
Ghost Sickness	Condition sometimes associated with witchcraft and a preoccupation with death. Symptoms include general weakness, loss of appetite, a feeling of suffocation, recurring nightmares, and a pervasive feeling of terror

Nursing Management: Promoting Health Equity and Increasing Cultural Competency

Nurse's Self-Assessment

The first step in promoting health equity and providing culturally competent care is for you to assess your own cultural background, values, and beliefs, especially those that are related to health and health care. Many tools are available to help you with this process (http://nccc.georgetown.edu).

Table 2.4 suggests ways for you to improve your cultural competence. This information can help you better understand patients and provide culturally competent care. It is important to understand that cultures evolve and change over time. Culturally competent care requires continual learning and self-reflection. Many other important

aspects of culture related to health care are included in the Culturally Competent Care sections throughout this book.

In today's increasingly multicultural environment, you will meet patients, families, significant others, and members of the health care team from many different cultures. You will find yourself in patient care situations that require an understanding of the patient's cultural beliefs and practices. Even when you provide care for patients from your own cultural background, you may be from a different subculture than the patient. For example, there are more than 550 federally recognized Native American tribes in the United States. It would be inappropriate for you to assume that a Native American nurse can give culturally appropriate care to a Native American patient when the nurse may be from a different tribe. A white nurse from an urban upbringing may find cultural differences with a white patient from a rural community. Cultural competence is a lifelong process that involves self-reflection and continual learning.[20]

Patient Assessment

HCPs play a key role in promoting health equity. However, the causes of health disparities are not always easy to identify. Assess patients for their risk for reduced health care services because of limited access, inadequate resources, age, or low health literacy.

A cultural assessment should be included in the nursing process.[21] Table 2.8 lists important components of the assessment. Determine the patient's (1) health beliefs and health care practices and (2) perspective of the meaning, cause, and preferred treatment of illness. Ask questions that you are comfortable with based on your own culture.

How can you be aware of the differences among ethnic groups? Using guides for cultural assessment will facilitate the nursing process when working with patients, families, or other groups who are from different cultures. Although guides can help in this process, you need to be careful not to stereotype or assume that common cultural characteristics pertain to each patient. Use guides to explore the

degree to which patients share commonalities with the traits attributed to their cultural group. You need to know about traditional characteristics of cultural groups while recognizing that culture is constantly evolving and unique for each person.

Nursing Implementation

Although the issues associated with health disparities can seem overwhelming, several strategies are available to reduce and eliminate health disparities. Table 2.9 presents nursing interventions to promote health equity.

Advocacy

The solutions to reduce health disparities often rest with the policymakers. Economic issues often determine health care delivery. Access and public policy decisions determine who is eligible for federal and state health insurance coverage. You, along with the social worker, can help by identifying key resources in the community, including transportation services, reduced-fee screening programs, and appropriate federal and state offices for Medicaid and Medicare.

TABLE 2.8 Cultural Assessment

A cultural assessment should include the following:

- Brief history of the cultural group with which person identifies
- Communication
- Cultural sanctions and restrictions
- Educational background
- Health-related beliefs and practices
- Nutrition
- Organizations providing cultural support
- Religious affiliation

- Socioeconomic considerations
- Spiritual considerations
- Values orientation

Adapted from Jarvis C: *Physical examination and health assessment,* ed 7, Philadelphia, 2016, Saunders.

TABLE 2.9 Nursing Management

Interventions to Promote Health Equity

- Treat all patients equally.
- Be aware of your own biases or prejudices and work toward eliminating them.
- Learn about services and programs that focus on specific cultural/ethnic groups.
- Inform patients about health care services available for their specific cultural/ethnic group.
- Make sure the same standards of care are followed for all patients regardless of culture or ethnicity.
- Recognize health care practices and cultural practices that are important to cultural and ethnic identity.
- Take part in research focused on understanding and improving care to culturally and ethnically diverse populations.
- Identify stereotypic attitudes toward a culture/ethnic group that may interfere with getting appropriate health care.
- Support patients who are fearful about traveling outside the accepted neighborhood for health care services.
- Advocate for patients of specific cultural/ethnic groups to receive health care services that pay special attention to English-language

limitations and cultural health practices.

- Learn advocacy and interpersonal strategies from leaders of specific cultural/ethnic groups. For example, blacks may respond to themes such as "do it for your loved ones." Asian Americans may respond to fear of dependency themes.
- Ensure availability of culturally appropriate patient educational resources.

You can be an advocate in your health care setting by helping to create a community advisory group. Such a group can be very helpful when setting up health programs within a community. This can increase the distribution of culturally sensitive information. Another powerful strategy is to increase the number of underrepresented populations in the health care professions (Fig. 2.8).

Standardized Guidelines

The use of standardized, evidence-based care guidelines can reduce disparities in diagnosis and treatments. For example, the management of hypertension should be based on guidelines and the patient's BP, symptoms, history, and laboratory values rather than other characteristics such as gender, age, or culture. Following the guidelines reduces racial or cultural differences in outcomes. In addition, recommendations related to cultural competency will guide you in your learning and practice.

FIG. 2.8 A Navajo nurse teaching a Navajo patient.
From Giger JN: *Transcultural nursing,* ed 7, St Louis, 2016, Mosby.

The National Standards for Culturally and Linguistically Appropriate Services in Health Care (CLAS standards) are guidelines that improve the quality of health care.[22] The CLAS standards provide practical guidance for care of people with limited English proficiency and of diverse cultural backgrounds.

Communication

Improving interpersonal skills is an important first step in providing culturally competent care. To show respect for the patient, consider the patient's usual communication style. For instance, conduct a health history in an unhurried manner and in a way that is appropriate for the culture. In some cultures, it is best to start with general rather than direct questions. For some cultures, it is most effective to engage in "small talk," with the discussion including

answers that may seem to be unrelated to the questions. If you appear to be "too busy," communication may be impaired.

When meeting patients or family members, introduce yourself and indicate how you would like them to address you—whether they should use first names; Mr., Ms., or Mrs.; or a title, such as Nurse. Ask the patient how he or she prefers to be addressed. This shows respect and will help you begin the relationship in a culturally appropriate manner.

If you need to gather personal information, it is important to understand the most effective approach to use. For instance, when talking with people from some cultural groups, it is imperative that you take time to establish trust and listen to the patient's responses to questions. There may be long silences as the person thinks about the question, showing respect by giving the question proper consideration before answering. Take time to listen and help establish trust.

Consider how the patient's age may affect his or her views and communication. For example, black older adults with mental health concerns may struggle with shame, uncertainty, and lack of trust in the system.

Do not try to serve as an interpreter if your patient does not understand English, because this could lead to misunderstandings. Get the help of a person who is qualified to do medical interpretation when you cannot speak the patient's primary language (Table 2.10). Interpreters are available by phone anywhere in the United States through a fee-based service. Use them rather than a family member. Table 2.11 offers guidelines for communicating when no interpreter is available.

TABLE 2.10 Using a Medical Interpreter

Choosing an Interpreter

- Use an agency interpreter if possible.
- Use a trained medical interpreter who knows how to interpret,

has a health care background, understands patients' rights, and can help with advice about the cultural relevance or appropriateness of the health care plan and instructions.

- Use a family member only if necessary. Be aware of limitations if the family member does not understand medical terms, is younger or a different gender from the patient, or is not aware of the health care procedures or medical ethics.
- Interpreter should be able to do the following:
    - Interpret the patient's nonverbal as well as verbal communication.
    - Translate the message into understandable terms.
    - Act as a patient advocate to represent the patient's needs to the health care team.
    - Be culturally competent and understand how to give teaching instructions.

Strategies for Working With an Interpreter

- If possible, have the interpreter meet with the patient ahead of time to establish rapport before the interpreting begins.
- Speak slowly.
- Maintain eye contact with the patient.
- Talk to the patient, not the interpreter.
- Use simple language with as few medical terms as possible.
- Speak 1 or 2 sentences at a time to allow for easier interpretation.
- Avoid raising your voice during the interaction.
- Obtain feedback to be certain the patient understands.
- Plan to take twice as long to complete the interaction.

Informatics in Practice

Use of Translation Applications

- Communication barriers can negatively affect the type of care received by non–English-speaking patients.
- Use a language translation app to help you translate 1 language into another language.
- Some apps allow you to speak critical phrases and the translation is immediately spoken back to you or the patient in a natural human voice with the proper accent.
- Check the policy of the health care institution on the use of medical interpreters or translators, including the use of translation apps.

A dictionary that translates from both your language and the patient's language (e.g., Spanish-English/English-Spanish dictionary) is useful. Patients may find it helpful if you have a list of questions and potential answers in several languages prepared by using these types of dictionaries. Many websites and applications translate words and documents from 1 language into another (see Informatics in Practice box). It is helpful to have resources for persons from cultural groups who often use the health care facility. This is especially beneficial when a qualified medical interpreter is not readily available, and you need to learn important phrases in another language.

TABLE 2.11 Overcoming Language Barriers

1. Be polite and formal.
2. Pronounce name correctly. If unsure, ask about the correct pronunciation of the name. Use proper titles of respect, such as "Mr.," "Mrs.," "Ms.," "Dr." Greet the person using the last or complete name.
3. Gesture to yourself and say your name.

4. Offer a handshake or nod. Smile.
5. Proceed in an unhurried manner. Pay attention to any effort by the patient or family to communicate.
6. Speak in a low, moderate voice and avoid excess hand gestures. Remember that there is a tendency to raise the volume and pitch of your voice when the listener appears not to understand. The listener may perceive that you are shouting or angry.
7. Use any words that you might know in the person's language. This shows that you are aware of and respect his or her culture.
8. Use simple words such as "pain" instead of "discomfort." Avoid medical jargon, idioms, and slang. Avoid using contractions (e.g., don't, can't, won't). Use nouns repeatedly instead of pronouns. *Example:*
   Do not say: "He has been taking his medicine, hasn't he?"
   Do say: "Does Juan take medicine?"
9. Pantomime words and simple actions while you say them.
10. Give instructions in the proper sequence. *Example:*
    Do not say: "Before you rinse the bottle, sterilize it."
    Do say: "First, wash the bottle. Second, rinse the bottle."
11. Discuss 1 topic at a time. Avoid using conjunctions. *Example:*
    Do not say: "Are you cold and in pain?"
    Do say: "Are you cold [while pantomiming]? Are you in pain?"
12. Validate whether the person understands by having him or her repeat instructions, demonstrate the procedure, or act out the meaning.
13. Write out several short sentences in English and determine the person's ability to read them.
14. Try a third language. Many Indochinese people speak French. Europeans often know 2 or more languages. Try Latin words or phrases. Use English words that have Latin roots (e.g., use precipitation instead of rain).
15. Ask the person's family and friends who could serve as an interpreter.

16. Use websites that translate words from 1 language to another. Some of them also have audio to help you know how to say the word correctly.
17. Obtain phrase books from a library or bookstore, make or purchase flash cards, contact hospitals for a list of interpreters, and use both a formal and an informal network to find a suitable interpreter.

Case Study

Health Disparities

© Luevanos/iStock/Thinkstock.

Patient Profile

M.S. is an 81-yr-old woman who came to the United States from India 4 years ago with her son and daughter-in-law and their 4 children. She has several health problems, including coronary artery disease,

hypertension, osteoarthritis in her right hip, and diabetes. Her daughter-in-law is the primary caregiver and often brings her to the urban community health clinic for a variety of health-related problems. Recently, M.S. has been having memory problems.

The entire family comes to the health clinic with M.S. Because English is a second language (Hindustani is their first language) for all the adult family members, the staff relies on the oldest granddaughter to interpret.

At this clinic visit, M.S. is presenting with shortness of breath. Through her granddaughter's interpretation, she tells the nurse that she is having trouble walking up the stairs in the apartment building. The nurse does the history and assessment, checks her blood glucose (which is within normal limits), and tells her that she should get more exercise. Given M.S.'s memory problems and limited English, the nurse does not complete a 24-hour dietary recall or teach her or the family about diabetes management. M.S. is scheduled for an appointment with the cardiologist for an evaluation of her hypertension and heart disease. Two weeks later, when she sees the cardiologist, her shortness of breath is much worse, and she is having chest pain. She is hospitalized immediately.

Meanwhile, the clinic supervisor is completing a chart audit for the clinic's quality review program. She is reviewing M.S.'s chart and notices that, although she has been a patient in the clinic for 3 years, she has never received instructions on blood glucose monitoring or general diabetes management. The clinic has a nurse diabetes educator who teaches individual patients and groups of patients with diabetes. The clinic manager reviews these findings with the nurse and asks why she has not recommended that M.S. see the diabetes educator. The nurse states that with M.S.'s memory problems and the language barrier, she assumed that M.S. and her family would not benefit from the consultation.

Discussion Questions

1. What type of health disparity has M.S. experienced?
2. What factors led to her not receiving the standard of care?

3. What other assessment should have been done at the initial visit?
4. ***Patient-Centered Care*:** What strategies may have worked to enhance patient education?
5. ***Patient-Centered Care*:** How would you assess M.S.'s religious and spiritual needs?
6. ***Quality Improvement*:** If you were the clinic manager, how would you recommend that the nurse improve her practice?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. What are the *leading* determinants of a patient's health *(select all that apply)*?
   a. Genetics
   b. Health behaviors
   c. Family history of disease
   d. Social and physical environment
   e. Type and quality of medical care received
2. In identifying patients at the *greatest* risk for health disparities, the nurse would note that
   a. patients who live in urban areas have readily available access to health care services.
   b. cultural differences exist in patients' ability to communicate with their health care provider.
   c. a patient receiving care from a health care provider of a different culture will have decreased quality of care.

d. men are more likely than women to have their cardiovascular disease symptoms ignored by a health care provider.

3. Forcing one's own cultural beliefs and practices on another person is an example of
   a. stereotyping.
   b. ethnocentrism.
   c. cultural relativity.
   d. cultural imposition.

4. Which statement *most* accurately describes cultural factors that may affect health?
   a. Diabetes and cancer rates differ by cultural/ethnic groups.
   b. There are limited ethnic variations in physiologic responses to drugs.
   c. Most patients find that religious rituals help them during times of illness.
   d. Silence during a nurse-patient interaction means the patient understands the instructions.

5. As part of the nursing process, cultural assessment is *best* accomplished by
   a. judging the patient's cultural values based on observations.
   b. using a cultural assessment guide as part of the nursing process.
   c. seeking guidance from a nurse from the patient's cultural background.
   d. relying on the nurse's previous experience with patients

from that cultural group.

6. Nurses play a key role in promoting health equity. An important mechanism to do this is to
   a. discourage use of evidence-based practice guidelines.
   b. insist that patients adhere to established clinical guidelines.
   c. teach patients to use the Internet to find resources related to their health.
   d. engage in active listening and establish relationships with patients and families.
7. What is the *first* step in developing cultural competence?
   a. Create opportunities to interact with a variety of cultural groups.
   b. Examine the nurse's own cultural background, values, and beliefs about health and health care.
   c. Learn about a multitude of folk medicines and herbal substances that different cultures use for self-care.
   d. Learn assessment skills for different cultural groups, including cultural beliefs and practices and physical assessments.
8. When communicating with a patient who speaks a language that the nurse does not understand, it is important to *first* attempt to
   a. have a family member interpret.
   b. use a trained medical interpreter.
   c. use specific medical terminology so there will be no mistakes.
   d. focus on the translation rather than nonverbal

communication.

1. a, b, d, 2. b, 3. d, 4. a, 5. b, 6. d, 7. b, 8. b

Health History and Physical Examination

Courtney Reinisch

LEARNING OUTCOMES

1. Explain the purpose, components, and techniques of a patient's health history and physical examination.
2. Obtain a nursing history using a functional health pattern format.
3. Select appropriate techniques of inspection, palpation, percussion, and auscultation for physical examination of a patient.
4. Distinguish among emergency, comprehensive, and focused types of assessment in terms of indications, purposes, and components.

KEY TERMS

auscultation, p. 38

database, p. 33

functional health patterns, p. 35

inspection, p. 38

nursing history, p. 34

objective data, p. 34
palpation, p. 38
percussion, p. 38
subjective data, p. 34

We make a living by what we get, but we make a life by what we give.

Conceptual Focus

Clinical Judgment
Collaboration
Communication

During the assessment phase of the nursing process, you will obtain a patient's health history and perform a physical examination. This serves as part of the interprofessional team evaluation. The interprofessional team, also known as an interdisciplinary, transdisciplinary, or multidisciplinary team, is made up of a number of health care professionals who provide care to a patient. The findings of your nursing assessment (1) contribute to a database that identifies the patient's current and past health status and (2) provide a baseline against which future changes can be evaluated. The purpose of the nursing assessment is to enable you to make clinical judgments about your patient's health status.[1] Assessment is the first step of the nursing process. It is performed continually throughout the nursing process to validate nursing diagnoses, evaluate nursing interventions, and determine whether patient outcomes and goals have been met.

The language of assessment is complex, with many overlapping and confusing terms. In this text, *assessment* describes a hands-on data

collection process and a *database* identifies a specific list of information (data) to collect.

Data Collection

The **database** is all the health information about a patient. It includes (1) nursing history and physical examination, (2) the medical history and physical examination, and (3) laboratory and diagnostic test results. A nurse and health care provider (HCP) perform a patient history and a physical examination using formats and data based on each discipline's focus.

Medical Focus

A *medical history* is designed to collect data to be used primarily by the HCP to determine risk for disease and diagnose medical conditions. The medical history is usually collected by a member of the health care team (e.g., physician, advanced practice nurse [APN], resident, physician's assistant, medical student). The HCP's physical examination and diagnostic tests aid in establishing medical diagnoses and implementing and monitoring the medical treatment plan. The information collected and reported by the HCP is used by nurses and other health care team members (e.g., pharmacist, physical therapist, dietitian, social worker) based on the focus of their care. For example, the abnormal results of a neurologic examination by an APN may aid in diagnosing a stroke. You may use the same results to identify a priority nursing diagnosis of fall risk. A physical therapist may use this information to plan therapy involving range-of-motion exercises.

Nursing Focus

The focus of nursing care is the diagnosis and treatment of human responses to actual or potential health problems or life processes. The information obtained from the **nursing history** and physical

examination is used to determine the patient's strengths and responses to a health problem. For example, a patient with a diagnosis of diabetes may respond with anxiety or a lack of knowledge about self-managing the condition. This patient may experience the physical response of fluid volume deficit because of the abnormal fluid loss caused by hyperglycemia. These human responses to the condition of diabetes are diagnosed and treated by nurses. During the nursing history interview and physical examination, you will obtain and record the data to support the identification of nursing diagnoses (Fig. 3.1).

Types of Data

The database includes subjective and objective data. **Subjective data**, also known as *symptoms,* are collected by interviewing the patient and/or caregiver during the nursing history. This type of data includes information that can be described or verified only by the patient or caregiver. It is what the person tells you either spontaneously or in response to a direct question.

Objective data, also known as *signs,* are data that can be observed or measured. You obtain this type of data using inspection, palpation, percussion, and auscultation during the physical examination. Objective data are also acquired by diagnostic testing. Patients often provide subjective data while you are performing the physical examination. You will observe objective signs while interviewing the patient. All the findings related to a specific problem, whether subjective or objective, are known as *clinical manifestations* of that problem.

Interview Considerations

The purpose of the patient interview is to obtain a health history (i.e., subjective data) about the patient's past and present health state. Effective communication is needed in the interview process. Creating a climate of trust and respect is critical to establishing a therapeutic relationship.[2] You need to communicate acceptance of the patient as a

person by using an open, responsive, nonjudgmental approach. You communicate through spoken language, as well as in your manner of dress, gestures, and body language. Culture influences the words, gestures, and postures one uses and the information that is shared with others (see Chapter 2).

FIG. 3.1 Conducting a nursing focused interview.
Courtesy Linda Bucher, RN, PhD, CEN, CNE, Staff Nurse, Virtua Memorial Hospital, Mt. Holly, N.J.

In addition to understanding the principles of effective communication, you will develop a personal style of relating to patients. One style of communication does not fit all. The wording of questions can increase the likelihood of obtaining the needed information. The ease of asking questions, particularly those related to sensitive areas such as sexual functioning, comes with training and experience.

The amount of time you need to complete a nursing history varies with the format used and your experience. The nursing history may

be completed in 1 or several sessions, depending on the setting and patient. For example, an older adult patient with a low energy level may need a few brief interviews to allow time for the patient to give the needed information. You must make a judgment about the amount of information to collect on initial contact with the patient. In interviews with patients with chronic disease, patients in pain, and patients in emergency situations, ask only those questions that are pertinent to a specific problem. You can complete the health history interview at a more appropriate time.

Judge the reliability of the patient as a historian. An older adult may give a false impression about his or her mental status because of a prolonged response time or visual and hearing impairments. The complexity and long duration of health problems may make it hard for an older adult or a chronically ill younger patient to be an accurate historian.

It is important for you to determine the patient's priority concerns and expectations, since your priorities may be different from the patient's. For example, your priority may be to complete the health history, while the patient is interested only in relief from symptoms. Until the patient's priority need is met, you will probably be unsuccessful in obtaining complete and accurate data.

Nursing Management

Assessment and Data Collection

In acute care, a registered nurse (RN) must complete the initial (admission) nursing assessment within the timeframe determined by the agency. Ongoing data collection is expected of all members of the health care team.

- On admission, complete a comprehensive assessment (Table 3.4).
- Obtain patient's health history by interviewing patient and/or caregiver.

- Perform physical examination using inspection, palpation, percussion, and auscultation as appropriate.
- Document findings from the health history and physical examination in the patient's record.
- Organize patient data into functional health patterns (Table 3.2).
- Develop and prioritize nursing and collaborative problems for the patient.
- Throughout hospitalization, perform focused assessments based on patient's history or clinical manifestations (Table 3.7).
- Oversee aspects of data collection by UAP.
- Vital signs, including oxygen saturation
- Height and weight, oral intake, and output
- Per agency policy, point-of-care testing (e.g., glucose)

Symptom Investigation

At any time during the assessment the patient may report a symptom such as pain, fatigue, or weakness. Because we do not observe symptoms patients experience, the symptoms must be explored. Table 3.1 shows a mnemonic (PQRST) to help you remember the areas to explore when a symptom is reported. The information you receive may help determine the cause of the symptom. A common symptom that you will assess is pain (see Chapter 8). For example, if a patient states that he has "pain in his leg," you would assess and record the data using PQRST.

Has right midcalf pain that usually occurs at work when climbing stairs after lunch (P). Pain is alleviated by stopping and resting for 2 to 3 minutes. Patient states he has been "eating a banana every day for extra potassium" but "it hasn't helped" (P). Pain is described as "stabbing" and is non-radiating (Q, R). Pain is so severe (rating 9 on 0-10 scale) that patient cannot continue activity (S). Onset is abrupt, occurring once or twice daily. It last occurred yesterday while cutting the lawn (T).

Data Organization

You must systematically obtain and organize assessment data so you can readily analyze and make judgments about the patient's health status and any health problems. Some assessment forms are organized using body systems. Although helpful, these types of forms may be incomplete because they may omit areas such as health promotion behaviors, sleep, coping, and values.

Functional health patterns, developed by Gordon,[3] provide the framework used throughout this book for obtaining a nursing history. This format includes an initial collection of important health information followed by assessment of 11 areas of health status or function (Table 3.2). Data organized in this format allow for the identification of areas of wellness (or positive function) and health problems.[2]

Culturally Competent Care: Assessment

The process of obtaining a health history and performing a physical examination is an intimate experience for you and the patient. Culture influences patterns of communication and the information one shares with others. During the interview and physical examination, be sensitive to issues of eye contact, space, modesty, and touching, as discussed in Chapter 2. Knowing the cultural norms related to male-female relationships is especially important during the physical examination. To avoid violating any culturally based practices, ask the patient about cultural values. Determine if the patient would like to have someone present during the history or physical examination or someone of the same gender to perform the history and physical examination.[1]

Nursing History: Subjective Data

Important Health Information

Important health information offers an overview of past and present

medical conditions and treatments. Past health history, medications, allergies, and surgery or other treatments are included in this part of the history.

Past Health History

The past health history provides information about the patient's prior state of health. Ask the patient about major childhood and adult illnesses, injuries, hospitalizations, and surgeries. Specific questions are more effective than simply asking whether the patient has had any illness or health problems in the past. For example, asking "Do you have a history of diabetes?" elicits better information than asking "Do you have any chronic health problems?"

Medications

Ask the patient for specific details related to past and current medications, including prescription and illicit drugs, over-the-counter (OTC) drugs, vitamins, herbs, and dietary supplements. Patients often do not consider herbs and dietary supplements as drugs. It is important to specifically ask about their use because they can interact adversely with existing or newly prescribed medications (see the Complementary & Alternative Therapies box).

Complementary & Alternative Therapies

Assessment of Use of Herbs and Dietary Supplements

Why Assessment Is Important

- Herbs and dietary supplements may have side effects or may interact adversely with prescription or OTC drugs.
- Patients at high risk for drug-herb interactions include those taking anticoagulant, antihypertensive, antidepressant, or immune-regulating therapy and patients undergoing anesthesia.

Most herbs must be stopped 2 to 3 weeks before surgery.

- Many patients do not tell HCPs that they are using herbs and dietary supplements. They may fear HCPs will disapprove of their use.
- Many herbal preparations have a variety of ingredients. Ask the patient or caregiver to bring labeled containers to the health care site to determine product composition.

Nurse's Role

- Patients typically share information about the use of herbs and dietary supplements with you if you ask them.
- Create an accepting and nonjudgmental attitude when assessing use or interest in herbs or dietary supplements.
- Use open-ended questions such as, "What types of herbs, vitamins, or supplements do you take?" and "What effects have you noticed from using them?"
- Document the use of any herb(s) or dietary supplements in the patient record, including the name, amount, frequency of use, and any side effects.
- Inform patients of the following:
    - Risks and benefits associated with herbal use, including drug-herb interactions
    - Health food store employees are not licensed HCPs
    - Importance of carefully reading the labels of herbal therapies and dietary supplements and taking only the recommended amount
    - Moisture, sunlight, and heat may change the components of herbs
    - Many herbal therapies have side effects. Report these to the HCP at once.

Question older adult and chronically ill patients about medication

routines. Look for issues related to medication cost and polypharmacy. Changes in absorption, metabolism, and elimination of drugs can pose serious potential problems for these patients.[4]

Allergies

Explore the patient's history of allergies to drugs, latex, contrast media, food, and the environment (e.g., pollen). Include a detailed description of any allergic reaction(s) reported by the patient.

Surgery or Other Treatments

Record all surgeries, along with the date, reason for the surgery, and outcome. The outcome includes whether the problem was resolved or has residual effects. Ask about and record any blood products the patient has received.

Table 3.1 Investigation of Patient-Reported Symptom

	Factor	Questions for Patient and Caregiver	Record
P	Precipitating and Palliative	Were there any events that came before the symptom? What makes it better? Worse? What have you done for the symptom? Did this help?	Influence of physical and emotional activities. Patient's attempts to alleviate (or treat) the symptom
Q	Quality	Tell me what the symptom feels like (e.g., aching, dull, pressure, burning, stabbing).	Patient's own words (e.g., "Like a pinch or stabbing feeling")
R	Radiation	Where do you feel the symptom? Does it move to other areas?	Region of body. Local or radiating, superficial or deep
S	Severity	On a scale of 0–10, with 0 meaning no pain and 10 being the worst pain you could imagine, what number would you give your symptom?	Pain rating number (e.g., 5/10)
T	Timing	When did the symptom start? Was it sudden or gradual? Any particular time of day, week, month, or year? Has the symptom changed over time? Has the symptom happened before? What are you doing when the symptom occurs?	Time of onset, duration, periodicity, and frequency. Course of symptoms. Where patient is and what patient is doing when the symptom occurs

Functional Health Patterns

Assess the patient's functional health patterns to identify effective, dysfunctional, and potential dysfunctional health patterns. *Dysfunctional health patterns* occur with disease. *Potential dysfunctional*

patterns identify risk conditions for problems. You may identify patients with effective health function who want a higher level of wellness. Table 3.2 gives examples of possible questions to ask the patient related to functional health patterns.

Health Perception–Health Management Pattern

This pattern focuses on the patient's perceived level of health and well-being and on personal practices for maintaining health. Ask the patient to describe his or her personal health and any concerns about it. Explore the patient's feelings of effectiveness at staying healthy by asking what helps and what hinders his or her well-being. Ask the patient to rate his or her health as excellent, good, fair, or poor. When possible, record this information in the patient's own words.

Next, ask about the type of HCP the patient uses. For example, if the patient is Native American, a medicine man may be considered the primary HCP. If the patient is of Hispanic origin, a *curandero,* a Hispanic healer who uses folk medicine and herbs to treat patients, may be the primary HCP (see Chapter 2).

Other questions seek to identify risk factors by obtaining a thorough family history (e.g., heart disease, cancer, genetic disorders), history of personal health habits (e.g., tobacco, alcohol, drug use), and history of exposure to environmental hazards (e.g., asbestos). If the patient is hospitalized, ask about the expectations for this experience. Have the patient describe his or her understanding of the current health problem, including its onset, course, and treatment. These questions obtain information about a patient's knowledge of the health problem and ability to use appropriate resources to manage the problem.

Nutritional-Metabolic Pattern

This pattern assesses the processes of ingestion, digestion, absorption, and metabolism. Obtain a 24-hour diet recall from the patient to evaluate the quantity and quality of foods and fluids consumed. If a problem is found, ask the patient to keep a 3-day food diary for a more careful analysis of dietary intake. Assess the impact of psychologic factors such as depression, anxiety, stress, and self-

concept on nutrition. Evaluate socioeconomic and cultural factors such as food budget, who prepares the meals, and food preferences. Determine whether the patient's present condition has interfered with eating and appetite by exploring any symptoms of nausea, intestinal gas, or pain. Food allergies should be distinguished from food intolerances, such as lactose or gluten intolerance.

Elimination Pattern

This pattern involves bowel, bladder, and skin function. Ask the patient about the frequency of bowel and bladder activity. Ask about urgency, incontinence, and diuretic use. Inquire about stool consistency, color, and laxative use. Assess the skin in the elimination pattern in terms of its excretory function.

Activity-Exercise Pattern

Assessing this pattern looks at the patient's usual pattern of exercise, work activity, leisure, and recreation. Question the patient about his or her ability to perform activities of daily living (ADLs) and note any specific problems. Table 3.2 includes a scale for rating the functional levels of common activities.

Sleep-Rest Pattern

This pattern describes the patient's perception of his or her pattern of sleep, rest, and relaxation in a 24-hour period. Elicit this information by asking, "Do you feel rested when you wake up?"

Cognitive-Perceptual Pattern

Assessing this pattern involves a description of all the senses and cognitive functions. Assess pain as a sensory perception (see pain assessment in Chapter 8). Ask the patient about any sensory deficits that affect the ability to perform ADLs. Record ways in which the patient compensates for any sensory-perceptual problems. Ask the patient how he or she learns best and in what language. Ask what he or she understands about the illness and treatment plan. Plan patient

teaching according to identified needs and preferences (see Chapter 4 for details on patient teaching).

Self-Perception–Self-Concept Pattern

This pattern describes the patient's self-concept, which is critical in determining the way the person interacts with others. Included are attitudes about self, perception of personal abilities, body image, and general sense of worth. Ask the patient for a self-description and about how his or her health condition affects self-concept. Patients' expressions of hopelessness or loss of control often reflect an inability to care for one's self.

TABLE 3.2 Health History*Functional Health Pattern Format*

Demographic Data

Name, address, age, occupation, gender

Race, ethnicity, culture, spirituality

Important Health Information

Past health history

Medications, supplements

Allergies

Surgery or other treatments

Health Perception–Health Management Pattern

1. **Reason for visit?**
2. **General state of health?**
3. **Most important things done to keep healthy? Testicular self-examination? Colorectal cancer, hypertension, and heart disease risk screening? Papanicolaou (Pap) test? Immunizations such as tetanus, pneumonia, hepatitis, and flu vaccines?**
4. **Who is your primary health care provider?**
5. **Health adherence problems?**
6. **Cause of illness? Action taken? Results?**
7. **Things important to you while here?**
8. **Family health history (e.g., cardiovascular disease, hypertension, cancer, diabetes, psychiatric illness, genetic disorders)?**
9. **Illness and injury risk factors (e.g., sexual abuse, intimate partner abuse, violence, use of tobacco or alcohol, substance abuse)?**

Nutritional-Metabolic Pattern

1. **Typical daily food intake (describe)? Supplements?**
2. **Typical daily fluid intake (describe)?**
3. **Weight loss or gain (amount, time span, intentional)?**
4. **Desired weight?**
5. **Appetite?**
6. **Food or eating: Discomfort? Diet restrictions?**
7. **Change in appetite with anxiety?**
8. **Heal well or poorly?**
9. **Skin problems: Lesions? Dryness?**
10. **Dentition: Dental problems? Well-fitting dentures?**
11. **Food preferences?**
12. **Food allergies?**

Elimination Pattern

1. **Bowel elimination pattern (describe): Frequency? Character? Discomfort? Laxatives? Enemas?**
2. **Urinary elimination pattern (describe): Frequency? Problem in control? Diuretics?**
3. **Any external devices?**
4. **Excess perspiration? Odor problems? Itching?**

Activity-Exercise Pattern

1. **Sufficient energy for desired or required activities?**
2. **Exercise pattern? Type? Regularity?**
3. **Spare time (leisure) activities?**
4. **Dyspnea? Chest pain? Palpitations? Stiffness? Aching? At rest? With activity?**
5. **Perceived ability for (rate Functional Level 0–III for each):**

   Eating _ Cooking _ Grooming _

   Transfer (e.g., bed to chair) _ Toileting _

   Bathing _Dressing _ Shopping _ General mobility _

Functional Levels

Level 0: Full self-care

Level I: Requires use of equipment or device

Level II: Needs help or supervision from another person

Level III: Is dependent and does not participate

Sleep-Rest Pattern

1. Generally rested and ready for daily activities after sleep?
2. Sleep onset problems? Aids (e.g., drugs, CPAP)? Dreams (nightmares)? Early awakening?
3. Usual sleep rituals?
4. Usual sleep pattern?

Cognitive-Perceptual Pattern

1. Hearing impairment? Hearing aids?
2. Vision? Wear glasses? Wear contact lens? Last checked?
3. Any change in taste? Any change in smell?
4. Any recent change in memory?
5. Easiest way to learn things?
6. Any discomfort? Pain (rating on scale of 0–10)? How managed?
7. Ability to communicate (e.g., primary language)?
8. Understanding of illness?
9. Understanding of treatments?

Self-Perception–Self-Concept Pattern

1. Self-description? Self-perception?
2. Effect of illness on self-image?

Role-Relationship Pattern

1. Live alone? Family/caregiver? Family structure?
2. Family problems?
3. Family problem solving?
4. Family dependence on you for things? How managing?
5. Family's and others' feelings about illness or hospitalization?*
6. Problems with children? Hard to handle?*
7. Belong to social groups? Have close friends? Feel lonely (frequency)?
8. Work (school) satisfaction? Income sufficient for needs?*
9. Feel part of or isolated from neighborhood where living?

Sexuality-Reproductive Pattern

1. Any changes or problems in sexual relations?*
2. Effect of illness?
3. Use of contraceptives? Problems?
4. When menstruation started? Last menstrual period? Menstrual problems? Gravida? Para?†
5. Effect of present condition or treatment on sexuality?
6. Sexually transmitted infections?

Coping–Stress Tolerance Pattern

1. Tense a lot of the time? What helps? Use any drugs, alcohol?
2. Have someone to confide in? Available to you now?
3. Recent life changes?
4. Problem-solving techniques? Effective?

Value-Belief Pattern

1. Satisfied with life?
2. Religion important in your life?
3. Conflict between treatment and beliefs?

CPAP, Continuous positive airway pressure.

* If appropriate.

† For women.

Modified from Gordon M: *Manual of nursing diagnosis,* ed 13, Boston, 2014, Jones & Bartlett.

Role-Relationship Pattern

This pattern reveals the patient's roles and relationships, including major responsibilities. Ask the patient to describe family, social, and work roles and relationships and to rate his or her performance of the expected behaviors related to these. Determine whether patterns in these roles and relationships are satisfactory or whether strain is evident. Note the patient's feelings about how the present condition affects his or her roles and relationships.

Sexuality-Reproductive Pattern

This pattern describes satisfaction or dissatisfaction with personal sexuality and describes reproductive issues. Assessing this pattern is important because many illnesses, surgical procedures, and drugs affect sexual function. A patient's sexual and reproductive concerns may be expressed. Teaching needs may be identified through information obtained in this pattern.

You may feel uncomfortable obtaining information related to sexuality. However, it is important to take a health history and screen for sexual function and dysfunction in a nonjudgmental way. Provide appropriate information or refer the patient to a more experienced HCP.

Coping–Stress Tolerance Pattern

This pattern describes the patient's general coping and the effectiveness of the coping mechanisms. Assessing this pattern involves analyzing the specific stressors or problems that confront the patient, the patient's perception of the stressors, and the patient's response to the stressors. Document any major losses or stressors

experienced by the patient in the previous year. Note strategies used by the patient to deal with stressors and relieve tension. Ask about persons and groups that make up the patient's social support networks.

Value-Belief Pattern

This pattern describes the values, goals, and beliefs (including spiritual) that guide health-related choices. Document the patient's ethnic background and effects of culture and beliefs on health practices. Note and respect the patient's wishes about continuation of religious or spiritual practices and the use of religious articles.

Physical Examination: Objective Data

General Survey

After the nursing history, make a *general survey statement.* This is your general impression of a patient, including behavioral observations. The initial survey begins with your first encounter with the patient and continues during the health history interview.

The major areas included in the general survey statement are (1) body features, (2) mental state, (3) speech, (4) body movements, (5) obvious physical signs, (6) nutritional status, and (7) behavior. Vital signs and body mass index (BMI) (calculated from height and weight [kg/m^2]) may be included. The following is a sample of a general survey statement:

A.H. is a 34-yr-old Hispanic woman, BP 130/84, P 88, R 18. No distinguishing body features. Alert but anxious. Speech rapid with trailing thoughts. Wringing hands and shuffling feet during interview. Skin flushed, hands clammy. Overweight relative to height (BMI = 28.3 kg/m^2). Sits with eyes downcast, shoulders slumped, and avoids eye contact.

Physical Examination

The *physical examination* is the systematic assessment of a patient's physical status. Explore any positive findings using the same criteria used when investigating a symptom in the nursing history (Table 3.1). A *positive finding* shows that the patient has or has had the particular problem or sign under discussion (e.g., if the patient with jaundice has an enlarged liver, it is a positive finding). Relevant information about this problem should then be gathered.

Negative findings may be significant. A pertinent *negative finding* is the absence of a sign or symptom usually associated with a problem. For example, peripheral edema is common with advanced liver disease. If edema is not present in a patient with advanced liver disease, specifically note this as "no peripheral edema."

Techniques

Four major techniques are used in performing the physical examination: inspection, palpation, percussion, and auscultation. The techniques are usually performed in this sequence: inspection, palpation, percussion, and auscultation. The abdominal examination is an exception. Inspection is first, followed by auscultation, percussion, and palpation. Performing percussion and palpation before auscultation can alter bowel sounds and produce false findings. Not every assessment area requires the use of all 4 assessment techniques (e.g., musculoskeletal system requires only inspection and palpation).

Inspection

Inspection is the visual examination of a part or region of the body to assess normal conditions or deviations. Inspection is more than just looking. This technique is deliberate, systematic, and focused. Compare what is seen with the known, generally visible characteristics of the body part that you are inspecting. For example, most 30-yr-old men have hair on their legs. Absence of hair may indicate a vascular problem and the need for further investigation, or it may be normal for a patient of a particular ethnicity (e.g., Filipino men have little body hair). Always compare 1 side of the patient's

body to the other to assess bilaterally for any abnormal findings.

Palpation

Palpation is the examination of the body using touch. Using light and deep palpation can yield information related to masses, pulsations, organ enlargement, tenderness or pain, swelling, muscular spasm or rigidity, elasticity, vibration of voice sounds, crepitus, moisture, and texture. Different parts of the hand are more sensitive for specific assessments. For example, use the palmar surface (base of fingers) to feel vibrations, the dorsa (backs) of your hands and fingers to assess skin temperature, and tips of your fingers to palpate the abdomen[1] (Fig. 3.2).

Percussion

Percussion is a technique that produces a sound and vibration to obtain information about the underlying area (Fig. 3.3). The sounds and vibrations are relative to the underlying structures. A change from an expected sound may indicate a problem. For example, dullness in the right lower quadrant instead of the normal sound of tympany should be explored. Specific percussion sounds of various body parts and regions are discussed in the appropriate assessment chapters.

Auscultation

Auscultation involves listening to sounds produced by the body with a stethoscope to assess normal and abnormal conditions. This technique is useful in evaluating sounds from the heart, lungs, abdomen, and vascular system. The bell of the stethoscope is more sensitive to low-pitched sounds (e.g., heart murmurs). The diaphragm of the stethoscope is more sensitive to high-pitched sounds (e.g., bowel sounds). Some stethoscopes have only a diaphragm, designed to transmit low- and high-pitched sounds. To listen for low-pitched sounds, hold the diaphragm lightly on the skin. For high-pitched sounds, press the diaphragm firmly on the skin (Fig. 3.4).[1] Specific

sounds and auscultation techniques are discussed in the appropriate assessment chapters.

FIG. 3.2 Palpation is the examination of the body using touch.
From Jarvis C: *Physical examination and health assessment,* ed 7, St Louis, 2015, Saunders.

FIG. 3.3 Percussion is tapping of the patient's skin with the middle finger or striking finger of the dominant hand. Hyperextend the middle finger of the nondominant hand and place its distal joint and tip firmly on the patient's skin. Normal percussion sounds: *resonant*—lung tissue; *tympany*—air-filled viscus (e.g., intestines); *dull*—dense organs (e.g., liver); *flat*—no air present (e.g., bone, muscle).
Adapted from Jarvis C: *Physical examination and health assessment,* ed 7, St Louis, 2015, Saunders.

Equipment

Collect the equipment needed for the physical examination before you begin (Table 3.3). This saves time and energy for you and the patient. It promotes trust by showing a level of professionalism. The use of specific equipment is discussed in the appropriate assessment chapters.

Organization of Examination

Perform the physical examination systematically and efficiently. Give explanations to the patient as the examination proceeds and consider the patient's comfort, safety, and privacy. Follow the same sequence every time to avoid omitting a procedure, a step in the sequence, or a part of the body. Table 3.4 presents a comprehensive, organized physical examination outline.

FIG. 3.4 Auscultation is listening to sounds produced by the body to assess normal conditions and deviations from normal.

Courtesy Linda Bucher, RN, PhD, CEN, CNE, Staff Nurse, Virtua Memorial Hospital, Mt. Holly, N.J.

TABLE 3.3 Common Physical Examination Equipment

- Alcohol swabs
- Blood pressure cuff
- Cotton balls
- Examining table or bed
- Eye chart (e.g., Snellen eye chart)
- Paper cup with water
- Patient gown
- Pocket flashlight
- Reflex hammer
- Stethoscope (with bell and diaphragm or a dual-purpose diaphragm; tubing 15–18 inches [38–46 cm])
- Tongue blades
- Watch (with second hand or digital)

Adapting the physical examination is often useful for the older adult patient, who may have age-related problems such as decreased mobility, limited energy, and perceptual changes.[5] An outline listing some useful adaptations is found in Table 3.5.

A nurse with appropriate education can perform advanced techniques. A retinal reflex examination would be done with an eye examination. Speculum and bimanual examination of women and the prostate gland examination of men would be performed after inspecting the genitalia.

Recording Physical Examination

At the end of the examination, record the normal and abnormal findings in the patient's health record. See Table 3.6 for an example of

how to record findings of a normal physical examination of a healthy adult. See Table 5.5 to find age-related assessment findings in the book.

Types of Assessment

Different types of assessment are used to obtain information about a patient. These approaches are divided into 3 types: emergency, comprehensive, and focused (Table 3.7). Decide what type of assessment to perform based on the clinical situation. Sometimes the health care agency provides guidelines, and other times it is a nursing judgment.

Emergency Assessment

An *emergency assessment* may be done in an emergency or life-threatening situation. This involves a rapid history and examination of a patient while supporting vital functions.

TABLE 3.4 Physical Examination Outline

1. General Survey

Observe general state of health (patient is seated).

- Body features
- Mental state and level of orientation
- Speech
- Body movements
- Physical appearance
- Nutritional status
- Behavior

2. Vital Signs

Record vital signs.

- Blood pressure—both arms for comparison
- Apical/radial pulse
- Respiration
- Temperature
- Oxygen saturation

Record height and weight; calculate body mass index (BMI).

3. Integument

Inspect and palpate skin for the following:

- Color
- Integrity (e.g., lacerations, lesions, breakdown)
- Scars, tattoos, piercings
- Bruises, rash
- Edema
- Moisture
- Texture
- Temperature
- Turgor
- Vascularity

Inspect and palpate nails for the following:

- Color
- Lesions
- Size
- Shape
- Angle

- Capillary refill time

4. Head and Neck

Inspect and palpate head for the following:

- Shape and symmetry of skull
- Masses
- Tenderness
- Condition of hair and scalp
- Temporal arteries
- Temporomandibular joint
- Sensory (CN V, light touch, pain)
- Motor (CN VII, shows teeth, purses lips, raises eyebrows)
- Looks up, wrinkles forehead (CN VII)
- Raises shoulders against resistance (CN XI)

Inspect and palpate (occasionally auscultate) neck for the following:

- Skin (vascularity and visible pulsations)
- Symmetry
- Range of motion
- Pulses and bruits (carotid)
- Midline structure (trachea, thyroid gland, cartilage)
- Lymph nodes (preauricular, postauricular, occipital, mandibular, tonsillar, submental, anterior and posterior cervical, infraclavicular, supraclavicular)

Test visual acuity.
Inspect and lightly palpate eyes/eyebrows for the following:

- Position and movement of eyelids (CN VII)

- Visual fields (CN II)
- Extraocular movements (CN III, IV, VI)
- Cornea, sclera, conjunctiva
- Pupillary response (CN III)
- Red reflex

Inspect and palpate nose and sinuses for the following:

- External nose: Shape, blockage
- Internal nose: Patency of nasal passages, shape, turbinates or polyps, discharge
- Frontal and maxillary sinuses

Inspect and palpate ears for the following:

- Placement
- Pinna
- Auditory acuity (whispered voice, ticking watch) (CN VIII)
- Mastoid process
- Auditory canal
- Tympanic membrane

Inspect and palpate mouth for the following:

- Lips (symmetry, lesions, color)
- Buccal mucosa (Stensen's and Wharton's ducts)
- Teeth (absence, state of repair, color)
- Gums (color, receding from teeth)
- Tongue for strength (asymmetry, ability to stick out tongue, side to side, fasciculations) (CN XII)
- Palates

- Tonsils and pillars
- Uvular elevation (CN IX)
- Posterior pharynx
- Gag reflex (CN IX and X)
- Jaw strength (CN V)
- Moisture
- Color
- Floor of mouth

5. Extremities

Observe size and shape, symmetry and deformity, involuntary movements. Inspect and palpate arms, fingers, wrists, elbows, shoulders for the following:

- Strength
- Range of motion
- Joint pain
- Swelling
- Pulses (radial, brachial)
- Sensation (light touch, pain, temperature)
- Test reflexes: Triceps, biceps, brachioradialis

Inspect and palpate legs for the following:

- Strength
- Range of motion
- Joint pain
- Swelling, edema
- Hair distribution
- Sensation (light touch, pain, temperature)
- Pulses (dorsalis pedis, posterior tibialis)
- Test reflexes: Patellar, Achilles, plantar

6. Posterior Thorax

Inspect for muscular development, scoliosis, respiratory movement, approximation of AP diameter.

- Palpate for symmetry of respiratory movement, tenderness of CVA, spinous processes, tumors or swelling, tactile fremitus
- Percuss for pulmonary resonance
- Auscultate for breath sounds
- Auscultate for egophony, bronchophony, whispered pectoriloquy

7. Anterior Thorax

- Assess breasts for configuration, symmetry, dimpling of skin
- Assess nipples for rash, direction, inversion, retraction
- Inspect for apical impulse, other precordial pulsations
- Palpate the apical impulse and the precordium for thrills, lifts, heaves, tenderness
- Inspect neck for venous distention, pulsations, waves
- Palpate lymph nodes in the subclavian, axillary, brachial areas
- Palpate breasts
- Auscultate for rate and rhythm; character of S_1 and S_2 in the aortic, pulmonic, Erb's point, tricuspid, mitral areas; bruits at carotid, epigastrium

8. Abdomen

- Inspect for scars, shape, symmetry, bulging, muscular position and condition of umbilicus, movements (respiratory, pulsations, presence of peristaltic waves)
- Auscultate for peristalsis (i.e., bowel sounds), bruits
- Percuss then palpate to confirm positive findings; check liver

(size, tenderness), spleen, kidney (size, tenderness), urinary bladder (distention)
- Palpate femoral pulses, inguinofemoral nodes, abdominal aorta

9. Neurologic

Observe motor status:

- Gait
- Toe walk
- Heel walk
- Drift

Observe coordination:

- Finger to nose
- Romberg sign
- Heel to opposite shin

Observe the following:

- Proprioception (position sense of great toe)

10. Genitalia

Male External Genitalia

- Inspect penis, noting hair distribution, prepuce, glans, urethral meatus, scars, ulcers, eruptions, structural changes, discharge
- Inspect epidermis of perineum, rectum
- Inspect skin of scrotum; palpate for descended testes, masses, pain

Female External Genitalia

- Inspect hair distribution; mons pubis, labia (minora and majora); urethral meatus; Bartholin's, urethral, Skene's glands (may be palpated, if indicated); introitus; any discharge
- Assess for presence of cystocele, prolapse
- Inspect perineum, rectum

AP, Anteroposterior; *CN,* cranial nerve; *CVA,* costovertebral angle.

TABLE 3.5 Gerontologic Assessment Differences*Adaptations in Physical Assessment Techniques*

General Approach

Keep patient warm and comfortable because loss of subcutaneous fat decreases ability to stay warm. Adapt positioning to physical limitations. Avoid unnecessary changes in position. Perform as many activities as possible in the position of comfort for the patient.

Skin

Handle with care because of fragility and loss of subcutaneous fat.

Head and Neck

Provide a quiet environment free from distraction because of possible sensory impairments (e.g., decreased vision, hearing).

Extremities

Use gentle movements and reinforcement techniques. Avoid having patient hop on 1 foot or perform deep knee bends if patient has limited range of motion of the extremities, decreased reflexes, or diminished sense of balance.

Thorax

Adapt examination for changes related to decreased force of

expiration, weakened cough reflex, and shortness of breath.

Abdomen

Use caution in palpating patient's liver because it is readily accessible because of a thinner, softer abdominal wall. The older adult patient may have diminished pain perception in the abdominal wall.

Comprehensive Assessment

A *comprehensive assessment* includes a detailed health history and physical examination of all body systems. This is typically done on admission to the hospital or onset of care in a primary care setting.

Focused Assessment

A *focused assessment* is an abbreviated health history and examination. It is used to evaluate the status of previously identified problems and monitor for signs and symptoms of new problems. It can be done when a specific problem (e.g., pneumonia) is identified. The patient's clinical manifestations guide a focused assessment. For example, abdominal pain signals the need for a focused assessment of the abdomen. Some problems need a focused assessment of more than 1 body system. A patient with a headache may need musculoskeletal, neurologic, and head and neck examinations. Examples of focused assessments for the various body systems are found in each assessment chapter of this book.

Using Assessment Approaches

Assessment in an inpatient, acute care hospital setting is different from assessment in other settings. Focused assessment of the hospitalized patient is frequent and performed by many different HCPs. A team approach demands a high degree of consistency among HCPs from a variety of disciplines.

As you gain experience, you will be able to form a mental image of a patient's status from a few basic details, such as "85-yr-old Hispanic

woman admitted for COPD exacerbation." Details from a complete verbal report, including length of stay, laboratory results, physical findings, and vital signs will help you make a clearer picture. Next, perform your own assessment using a focused approach. During your assessment, you will confirm or revise the findings that you read in the medical record and what you heard from other HCPs.

Remember, the process does not end once you have done your first assessment on a patient during rounds. Continue to gather information about all your patients throughout your shift. Everything you learned previously about each patient is considered in light of new information. For example, when you are doing a respiratory assessment on your patient with COPD, you hear crackles in her lungs. This finding should lead you to do a cardiovascular assessment because heart problems (e.g., heart failure) can also cause crackles. As you gain experience, the importance of new findings will be more obvious to you. Assessment case studies integrated into all the assessment chapters will help you develop your assessment skills and knowledge.

TABLE 3.6 Findings From a Physical Examination of a Healthy Adult*Example*

General Status

Well-nourished, well-hydrated, well-developed white (woman) or (man) in NAD, appears stated age, speech clear and evenly paced; is alert and oriented ×3; cooperative, calm; BMI 23.8

Skin

Clear s̄ lesions, warm and dry, trunk warmer than extremities, normal skin turgor, no ↑ vascularity, no varicose veins

Nails

Well-groomed, round 160-degree angle s lesions, nail beds pink, capillary refill <2 sec

Hair

Thick, brown, shiny, normal (male, female) distribution

Head

Normocephalic, nontender

Eyes

Visual fields intact on gross confrontation

Visual acuity:	Right eye	20/20
	Left eye	20/20
	Both eyes	20/20
	glasses	

EOM: Intact on all gazes s ptosis, nystagmus
Pupils: PERRLA, negative cover and uncover tests

Ears

Pinna intact, in proper alignment; external canal patent; small amount of cerumen present bilaterally; TMs intact; pearly gray LM, LR visible, not bulging; whisper heard at 3 ft bilaterally

Nose

Patent bilaterally; turbinates pink, no swelling
Sinuses nontender

Mouth

Moist and pink, soft and hard palates intact, uvula rises midline on "ahh," 24 teeth present and in good repair

Throat

Tonsils surgically removed, no redness

Tongue

Moist, pink, size appropriate for mouth, no lesions

Neck

Supple, s̄ masses, s̄ bruits, lymph nodes nonpalpable and nontender
Thyroid: Palpable, smooth, not enlarged
ROM: Full, intact strong
Trachea: Midline, nontender

Breasts

Soft, nonpendulous, s̄ venous pattern, s̄ dimpling, puckering
Nipples: s̄ inversion, point in same direction, areola dark and symmetric, no discharge, no masses, nontender

Axilla

Hair present, no lesions, no palpable lymph nodes

Thorax and Lungs

Respiratory rate 18, regular rhythm, oxygen saturation 98% on room air; AP < transverse diameter, no ↑ in tactile fremitus, no tenderness, lungs resonant throughout, diaphragmatic

excursion 4 cm bilaterally, chest expansion symmetric, lung fields clear throughout

Heart

Rate 82, regular rate and rhythm; blood pressure: RA: 122/76, LA: 120/78; no lifts, heaves

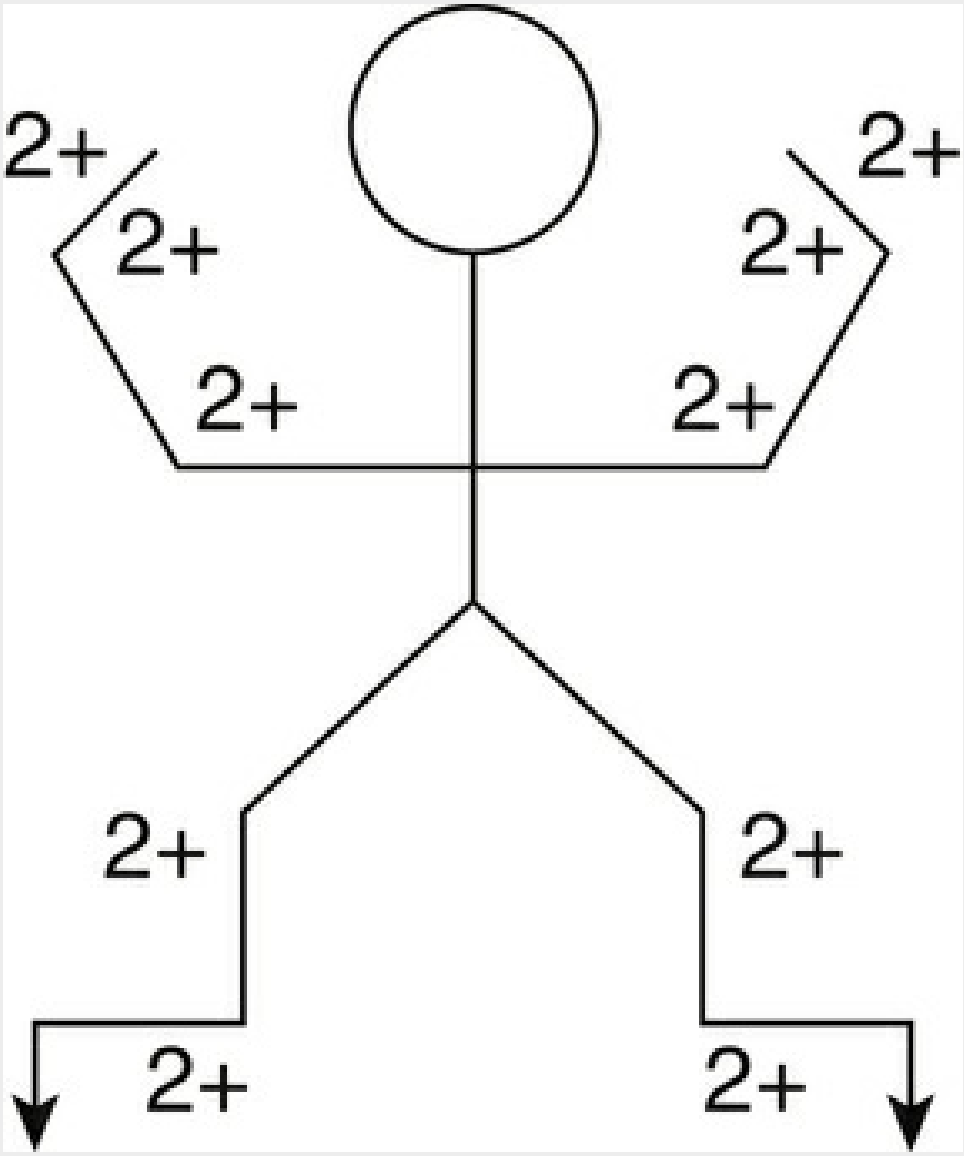
Apical impulse: 5th ICS at MCL; no palpable thrills; S_1, S_2 louder, softer in appropriate locations; no S_3, S_4; no murmurs, rubs, clicks

Carotid, femoral, pedal, and radial pulses present; equal, 2+ bilaterally

Abdomen

No pulsations visible, rounded, positive bowel sounds in 4 quadrants, no bruits or CVA tenderness, no palpable masses

Liver



Lower border percussed at costal margin, smooth, nontender; approx. 9-cm span

Spleen

Nonpalpable, nontender

Neurologic System

Cranial nerves I–XII intact
Motor (drift, toe stand) intact
Coordination (FN, Romberg) intact
Reflexes: See diagram

Grading Scale

0 No response
1+ Diminished
2+ Normal
3+ Increased
4+ Hyperactive
Sensation (touch, vibration, proprioception) normal bilaterally, upper and lower extremities

Musculoskeletal System

Well developed, no muscle wasting; ō crepitus, nodules, swelling; no scoliosis
ROM: Full and equal bilaterally, upper and lower extremities
Strength: Equal, strong 5/5 bilaterally, upper and lower extremities
Gait: Walks erect 2-foot steps, arms swinging at side ō staggering

Female Genitalia*

External genitalia: No swelling, redness, tenderness in BUS; normal hair distribution, no cysts
Vagina: No lesions, discharge; bulging, pink
Cervix: Os closed; pink, no lesions, erosions, nontender
Uterus: Small, firm, nontender
Adnexa: No enlargement; nontender
Rectovaginal: Sphincter intact; confirms above findings

Male Genitalia*

Normal male hair distribution, negative inguinal hernia
Penis: Urethral opening patent; no redness, swelling, discharge; no lesions, structural changes
Scrotum: Testes descended; no redness, masses, tenderness
Rectal: No lesions, redness; sphincter intact; prostate small, nontender

AP, Anterior-posterior; *BMI,* body mass index; *BUS,* Bartholin's gland, urethral meatus, Skene's duct; *CVA,* costovertebral angle; *EOM,* extraocular movements; *FN,* finger to nose; *ICS,* intercostal space; *LA,* left arm; *LM,* landmarks; *LR,* light reflex; *MCL,* midclavicular line; *NAD,* no acute distress; *PERRLA,* pupils equal,

round, reactive to light and accommodation; *RA,* right arm; *ROM,* range of motion; s̄, without; S_1, S_2, S_3, and S_4, heart sounds; *TM,* tympanic membrane.

---

* Some data would be obtained only if the nurse has the appropriate education.

TABLE 3.7 Types of Assessment

The following describes types of assessment that you may use in various situations.

Description	When and Where Performed	Where to Find in Book
Emergency		
• **Limited to assessing life-threatening conditions (e.g., inhalation injuries, anaphylaxis, myocardial infarction, shock, stroke)** • **Conducted to ensure survival. Focuses on elements in primary survey (e.g., airway, breathing, circulation, disability)** • **After life-saving interventions are started, perform brief systematic assessment to identify other injuries or problems**	• Performed in any setting when signs or symptoms of a life-threatening condition appear (e.g., emergency department, critical care unit, surgical setting)	• Chapter 68, Table 68.3 and Table 68.5 • Emergency management tables throughout the book and listed in Table 68.1
Comprehensive		
• **Detailed assessment of all body systems (head-to-toe assessment)**	• Onset of care in primary or ambulatory care setting • On admission to hospital, rehabilitation, or long-term care setting • On initial home care visit	• Assessment chapters for each body system • Physical examination outline (Table 3.4) • Findings from physical examination of a healthy adult (Table 3.6)
Focused		
• **Abbreviated assessment that focuses on 1 or more body systems that are the focus of care** • **Includes an assessment related to a specific problem (e.g., pneumonia, specific abnormal laboratory findings)** • **Monitors for signs and symptoms of new problems**	• Throughout hospital admission—at beginning of a shift and as needed throughout shift • Revisit in ambulatory care setting or home care setting	• Focused assessment boxes in each assessment chapter • Tables on nursing assessment of specific diseases throughout book

Table 3.8 shows how you perform different types of assessments based on a patient's progress through a given hospitalization. When a patient arrives at the emergency department with a life-threatening condition, you will perform an emergency assessment based on the

elements of a primary survey (e.g., airway, breathing, circulation, disability) (see Table 68.3). Once the patient is stable, you can begin a focused assessment of related body systems. After the patient is admitted, a comprehensive assessment of all body systems is completed.

Problem Identification

After completing the history and physical examination, analyze the data to develop a list of nursing and collaborative problems. See Chapter 1 for a description of the nursing process, including the identification of nursing and collaborative problems.

TABLE 3.8 Clinical Applications for Types of Assessment

The following is an example of how different types of assessment would be used as a patient progresses from the emergency department to a clinical unit of a hospital.

Timeline	Type of Assessment
Emergency Department	
Patient arrives in acute respiratory distress. **Problem is found, and critical interventions are performed.** **Patient stabilizes.**	• Perform emergency assessment (see Table 68.3). • Conduct a focused assessment of the respiratory and related body systems (e.g., cardiovascular). • May begin comprehensive assessment of all body systems.
Clinical Unit	
Patient is admitted to a monitored clinical unit. **Beginning of each shift: Reassess per orders and more frequently as determined by the nurse.**	• Complete comprehensive assessment of all body systems within proper timeframe. • Perform focused assessment of respiratory system and other related body systems per agency protocol. • Perform focused assessment of appropriate body system(s) if new symptoms are reported.

Bridge To NCLEX Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The patient health history and physical examination provide the nurse with information primarily to
   a. diagnose a medical problem.
   b. investigate a patient's signs and symptoms.
   c. classify subjective and objective patient data.
   d. identify nursing diagnoses and collaborative problems.
2. The nurse would place information about the patient's concern that his illness is threatening his job security in which functional health pattern?
   a. Role-relationship
   b. Cognitive-perceptual
   c. Coping–stress tolerance
   d. Health perception–health management
3. The nurse is preparing to examine a patient's abdomen. Place in order the proper steps for an abdominal assessment, using the numbers 1–4, with 1 = the first technique and 4 = the last technique:
   ___ Inspection
   ___ Palpation
   ___ Percussion
   ___ Auscultation
4. Which situation would require the nurse to obtain a focused assessment *(select all that apply)*?
   a. A patient denies a current health problem.
   b. A patient reports a new symptom during rounds.
   c. A previously identified problem needs reassessment.
   d. A baseline health maintenance examination is needed.

e. A patient with an emergent problem needs immediate care.

1. d, 2. a, 3. 1, 4, 3, 2, 4. b, c.

Patient and Caregiver Teaching

Brenda C. Morris

LEARNING OUTCOMES

1. Apply the teaching-learning process to diverse patient populations.
2. Apply strategies to support patient learning.
3. Evaluate the role of the caregiver in patient teaching.
4. Relate the physical, psychologic, and sociocultural characteristics of the patient and caregiver to the teaching-learning process.
5. Prioritize patient teaching goals for patients and caregivers.
6. Choose appropriate teaching strategies for patients and their caregivers.
7. Choose appropriate methods to evaluate patient and caregiver teaching.

Conceptual Focus

Adherence
Communication
Health Promotion
Patient Education
Self-Management

This chapter describes the process of patient and caregiver teaching and strategies that contribute to successful teaching and learning experiences. The concept of patient and caregiver (family member or significant other) teaching is central to delivering quality patient care. It is a dynamic, interactive process that involves a change in a patient's knowledge, behavior, and/or attitude to maintain or improve health. You will find that teaching is 1 of your most challenging and rewarding roles. Teaching patients and caregivers is a key nursing intervention that makes a difference in their lives.

Role of Patient and Caregiver Teaching

The general goals of patient teaching include health promotion, disease prevention, management of illness, and appropriate choice and use of treatment options. In patients with acute and chronic health problems, teaching can prevent complications and promote recovery, self-care, and independence. Chronic diseases are responsible for 7 of 10 deaths each year in the United States.[1] Whether patients adequately manage their health problems and maintain quality of life depends on what they learn about their conditions and what they do with this knowledge. Patients who have the knowledge, skills, and desire to take responsibility for managing their health are less likely to visit the emergency department or be readmitted.[2]

Teaching may occur wherever you work. Although agencies may employ advanced practice nurses and patient educators to establish and oversee patient teaching programs, you are always responsible for patient and caregiver teaching.[3] It is a responsibility that cannot be delegated to unlicensed assistive personnel (UAP).

Every interaction with a patient and a caregiver is a potential *teachable moment*. On any given day, more informal opportunities to teach occur than formal opportunities. Take advantage of and document all these moments. For example, when you teach a patient with asthma how to use a peak flow meter, you do not need a formal teaching plan. However, when your patient has a specific learning need about health promotion or management of a health problem, you should develop a teaching plan. A **teaching plan** includes (1) assessment of the patient's ability and readiness to learn, (2) identification of teaching needs, (3) development of learning goals with the patient, (4) implementation of the teaching, and (5) evaluation of the patient's learning.

Teaching-Learning Process

Teaching is "a complex process intended to facilitate learning" (p. 75).[4] When a nurse is teaching a patient about health, the nurse becomes the teacher and the patient becomes the learner. Nurses often teach patients using various methods such as direct instruction,

coaching, counseling, and behavior modification. Teaching may be formal, such as giving a planned presentation to a group of patients and their caregivers, or informal such as teaching a patient about medications prior to giving them.

Learning is the act of a person acquiring knowledge, skills, or attitudes that may result in a permanent change.[4] Observation of this change is an indication that learning has occurred. However, learning may not result in any observable change. A patient who understands the instruction and is fully informed may choose not to change behavior.

Although learning may occur without teaching, a teacher helps to organize information and skills to make learning more efficient. In patient teaching, the teaching-learning process involves the patient, the patient's caregiver(s), and you.

Adult Learner

Adult Learning Principles

Understanding how and why adults learn is important for you to effectively teach patients and their caregivers. Many theories of adult learning have evolved from the work of Malcolm Knowles. He identified 6 principles of *andragogy* (adult learning) that are important for you to consider when teaching adults (Table 4.1).[5]

Models to Promote Health

Patients and their caregivers may progress through a series of steps before they are willing or able to accept a change in health behaviors. Prochaska and Velicer proposed 6 stages of change in their *Transtheoretical Model of Health Behavior Change* (Table 4.2).[6] This model is often used for planning to help patients stop smoking, manage diabetes, and lose weight.

Motivational interviewing uses nonconfrontational interpersonal communication techniques to motivate patients to change behavior.[7] This strategy includes interventions that enhance the patient's

motivation for change (Table 4.3). The techniques used in motivational interviewing are linked to the stages of change identified by Prochaska and Velicer.

During the process of change, relapse and recycling through the stages are expected. Sometimes patients do not change behaviors, or they return to previous behaviors after a period of change. This may mean that the interventions used did not consider the patient's stage of change. Identify the patient's current stage of readiness for change and the stage to which the patient is moving. Patients who are in the early stages of change need and use different kinds of motivational support than patients at later stages of change.

For example, a hospitalized patient who smokes cigarettes may be in the *precontemplation* or *contemplation* stage of change. In the precontemplation stage, patients are not concerned about their cigarette smoking and are not considering changing their behavior. During this stage, it is important to help the patient increase awareness of risks and problems related to smoking and create doubt about using cigarettes. Ask the patient what he or she thinks could happen if the behavior is continued. Give evidence of the problem (e.g., x-ray changes), and share facts about the risks of smoking. Although patients may not be ready to change behavior while experiencing an acute health problem, the seeds of doubt are sown. In other cases, such as when a patient has a life-threatening condition (e.g., heart attack), there may be an immediate awareness of the problem and motivation to change.

TABLE 4.1 Adult Learning Principles Applied to Patient and Caregiver Teaching

Principles	Teaching Implications for Nurse	Examples
Need to know	• Patients need to know why they should learn something, what they need to learn, and how it will help them. • Ask the patient questions such as, "What do you think you need to learn about this topic?"	Your patient and his caregiver ask what they need to know about exercise guidelines after a heart attack.
Readiness to learn	• Readiness and motivation to learn are high when facing new tasks. • Health crises provide opportunities for patients to learn and change behavior. • Stress and anxiety may interfere with learning, thus requiring frequent reinforcement of content.	While recovering from a transient ischemic attack, your patient tells you that she is ready to learn about the changes she needs to take to reduce her risk for stroke.
Prior experiences	• Motivation is increased when one already knows something about the subject from past experiences. • Identification of past knowledge and experiences can help find familiar ground to increase patients' confidence.	Your patient needs to begin injections of enoxaparin. She tells you that she gives her father insulin injections and is ready to learn how to give this medication.
Motivation to learn	• Patients prefer to apply learning at once. • Long-term goals may have less appeal than short-term goals. • Focus teaching on information that the patient views as needed right now.	Your patient is scheduled for discharge in the morning. Both she and her caregiver have received instruction on wound care and have watched the procedure. The caregiver tells you that he wants to perform the wound care today.
Orientation to learning	• Patients seek out various resources for specific learning and prefer choices. • When the patient does not recognize the relevancy of the teaching, offer explanations of the value of the learning. • Teaching should target the specific problem or circumstance.	Your patient, who is newly diagnosed with diabetes mellitus, tells you that he is worried about the diet changes he will need to make. Share several options with him to learn about diet changes (e.g., cooking classes, Web-based tutorials, mobile applications, individual sessions with the dietitian, brochures).
Self-concept	• Patients need control and self-direction (sense of autonomy) to maintain their sense of self-worth. • Patients do not learn when we treat them like children and tell them what they must do.	Your patient has a temporary colostomy. She says she is not ready to look at the stoma. Work out a schedule with her for learning colostomy care that meets her need for control and prepares her for self-care.

TABLE 4.2 Stages of Change in Transtheoretical Model

Stage	Patient Behavior	Nursing Implications
1. Precontemplation	Is not considering a change. Is not ready to learn	Provide support, increase awareness of condition. Describe benefits of change and risks of not changing
2. Contemplation	Thinks about a change. May	Introduce what is involved in changing the

	state recognition of need to change. Says "I know I should," but identifies barriers	behavior. Reinforce the stated need to change
3. Preparation	Starts planning the change, gathers information, sets a date to start change, shares decision to change with others	Reinforce the positive outcomes of change, give information and encouragement, develop a plan, help set priorities, and identify sources of support
4. Action	Begins to change behavior through practice. Tentative and may experience relapses	Reinforce behavior with reward, encourage self-reward, discuss choices to help minimize relapses and regain focus. Help patient plan to deal with potential relapses
5. Maintenance	Practices the behavior regularly. Able to sustain the change	Continue to reinforce behavior. Provide more teaching on the need to maintain change.
6. Termination	Change has become part of lifestyle. Behavior no longer considered a change	Evaluate effectiveness of the new behavior. No further intervention needed.

Adapted from Prochaska J, Velicer W: The transtheoretical model of health behavior change, *Am J Health Promot* 12:38, 1997. (Classic).

TABLE 4.3 Key Aspects of Motivational Interviewing

- Listen rather than tell.
- Adjust to, rather than oppose, patient resistance.
- Express empathy through reflective listening.
- Focus on the positive. Do not criticize the patient.
- Gently persuade with the understanding that change is up to the patient.
- Focus on the patient's strengths to support the hope needed to make changes.
- Avoid argument and direct confrontation, which can cause defensiveness and a power struggle.
- Help the patient recognize the "gap" between where he or she is and where he or she hopes to be.

A patient in the *contemplation* stage of change often is ambivalent. The patient understands that the behavior is a problem and that change is necessary. However, he or she believes that change is too hard or that the pleasures of the behavior are worth the risks. This is seen in the patient who says, "I know that I have to stop smoking. This heart attack really scared me. I know I need to lose weight and start exercising, but I can't change everything all at once. Smoking helps me control my eating; I can't stop until I lose some weight." During this stage of change, help the patient consider the positive and negative aspects of his or her behavior (e.g., tobacco use), gently trying to tip the balance in favor of positive behavior. Helping the patient discover internal motivators in addition to those external motivators (e.g., second heart attack, lung disease) that push the patient toward change can move the patient from contemplating change to preparation and action. Throughout this process, emphasize the patient's personal choices and responsibilities for change.

As the patient moves from contemplation to *preparation,* we can help strengthen the commitment to change by helping the patient develop **self-efficacy**. This is the belief that one can succeed in a given situation. In this case, it is the patient's belief that they can change tobacco-use behaviors. Support even the smallest effort to change. Movement through action and maintenance stages of change requires continued support to increase the patient's involvement and participation in treatment. You can find a comprehensive discussion of motivational interviewing in the Treatment Improvement Protocols available at *www.ncbi.nlm.nih.gov/books/NBK14856*.

The resolution of acute health problems or discharge from the hospital often occurs before the patient moves to the preparation and action stages of change. As the patient develops readiness in the contemplative stage of change, continue to support him or her with referral to appropriate community and outpatient resources.

Nurse as Teacher

Required Competencies

Knowledge of Subject Matter

Although it is impossible to be an expert in all subject areas, develop confidence as a teacher by becoming knowledgeable about the topic. For example, if you are teaching patients about managing hypertension, you must be able to explain what hypertension is and why treating it is important. Teach patients what they need to know about exercise, diet, medication side effects, monitoring BP, and situations that must be reported to the health care provider (HCP). Last, provide the patient with resources such as credible websites, brochures, and information about support organizations (e.g., American Heart Association).

Sometimes you will not be able to answer patients' or caregivers' questions. Clarify the questions to be sure of what they are asking. When you do not know the answer, tell this to the patient and caregiver. Seek help from co-workers, patient educators, and other reliable sources to answer the question.

Communication Skills

Patient teaching depends on effective communication between you and the patient or caregiver. Medical jargon can be intimidating and frightening. Introduce medical words and define their meanings. Limit the use of acronyms (e.g., CABG for coronary artery bypass graft) and abbreviations (e.g., IV) when talking with patients. Have the patient and caregiver clarify their understandings of the disease process. Ask them to explain what they know in their own words. For example, if we tell a patient he has leukopenia, define this term in words that mean something to him. Explain that *leuko-* refers to a leukocyte, a white blood cell that fights infections, and that *penia* refers to a shortage. To enhance learning, use a brief explanation such as, "You have a shortage of white blood cells, the cells that fight infection."

Nonverbal communication is critical when teaching. Cultural practices often guide nonverbal communication. For example, in Western culture, sitting in an open, relaxed position facing the patient with eyes at the same level delivers a positive nonverbal message (Fig. 4.1).

Raise the patient's bed or sit in a chair at the bedside. Open body gestures communicate interest and a willingness to share. Patients from Eastern cultures may prefer that you avoid direct eye contact and give health information to a family spokesperson rather than directly to the patient.

Develop the art of *active listening* by paying attention to what the patient says, observing the patient's nonverbal cues, and not interrupting. Nod in response to the patient's statements and restate what the patient is saying to help clarify communication.

Empathy is the courage to enter the world of another in a manner that does not judge or correct but tries to understand. Empathy means putting aside your own self and stepping into the patient's shoes. Active listening, combined with empathy, is a powerful way to communicate caring and prepare the patient to learn.

Challenges to Nurse-Teacher Effectiveness

Teaching patients and caregivers has many challenges, including (1) lack of time, (2) your own feelings as a teacher, (3) nurse-patient differences in learning goals, and (4) rapid or early discharge from the health care system.

Lack of time can be a barrier to effective teaching. For example, the patient's physical needs may compete for time that you could use for teaching. To make the most of limited time, it is critical to set learning priorities with the patient. Tell the patient at the beginning of the interaction how much time you can devote to the session. Deliver or reinforce teaching during every contact with the patient or caregiver. For example, when giving medications, explain the purpose and side effects of each. Reinforcing small pieces of information over time is an effective teaching strategy, especially if information is new or complex.

Other barriers are your *own feelings as a teacher* and insecurity about your own knowledge and skill. Teaching is a skill that will take time to master. Become familiar with the resources for patient teaching available at your agency. Consult with nurse educators or experienced co-workers for further help with developing your teaching skills.

Sometimes disagreements arise among the patient, the caregiver, and you about the expectations or outcomes of teaching. Having realistic discussions about discharge plans, timelines, and home care options can emphasize the need for learning. For example, after a diagnosis of heart failure due to aortic valve insufficiency and subsequent emergent valve surgery, the patient and caregiver may reject teaching efforts until they realize and accept the seriousness of the patient's health problem.

FIG. 4.1 Open, relaxed positioning of patient, spouse, and nurse at eye level promotes communication in teaching and learning.
© Jupiterimages/Photos.com/Thinkstock.

Another important challenge to patient teaching relates to patients having early and quick discharges from the health care system. Shortened lengths of hospital stays have resulted in patients having only basic teaching plans implemented; thus it is important to begin teaching patients soon after admission to the health care system.

Caregiver Support in the Teaching-Learning Process

The teaching and learning process applies to the caregiver as well as the patient. **Caregivers** are people who care for those who cannot care for themselves. Most caregivers are family members or significant others who (1) give or help with direct patient care; (2) provide emotional, social, spiritual, and possibly financial support for the patient; and (3) manage and coordinate health care services.

About 1 in 4 American adults serves as a caregiver to a person with a long-term disability or illness.[8] We often categorize caregivers by their relationship to the patient. The most common caregivers are spouses, adult children, parents, grandparents, and life partners. Identify the key caregiver(s) and assess their roles and relationships to the patient. Because the patient's health problem affects family roles and functions, it is important to identify the needs of caregivers. If the caregiver's needs are unmet, this may interfere with the ability to assist the patient (Table 4.4).

Consider cultural differences when assessing the caregiver. In some cultures, a male family member may be the designated spokesperson to receive and communicate information among family members and the patient. In this type of situation, the caregivers who will actually provide care for the patient and the family spokesperson should be included in discharge planning (see Chapter 2 for more information on culturally competent care).

When possible, teach the caregiver along with the patient. Explain the goals of the teaching plan. Caregivers may need help to learn the physical and technical requirements of care, find resources for home care, find equipment and supplies, and rearrange the home to accommodate the patient. Sources of support for the transition from hospital to home include community-based agencies, Medicare and Medicaid offices, and case managers at the hospital and insurance companies.

TABLE 4.4 Assessment of Caregiver Needs

Ask caregivers the following questions:

1. How are you coping with your caregiver role?
2. Do you have any problems performing your caregiver responsibilities?
3. How much support do you get from outside sources (e.g., other family members, friends)?
4. Are you aware of and do you use community resources (e.g., disease-specific professional organizations [such as Alzheimer's Association, American Heart Association], adult day care centers, church, synagogue)?
5. Do you know about resources that are available for respite (someone caring for your loved one while you have time to yourself)?
6. What kind of help or services do you need now and in the near future?
7. How can I or other health care providers help you in your caregiving role?

Patients and caregivers may have different teaching needs. For example, the priority of an older patient with a diabetic leg ulcer may be to learn how to transfer from a bed to a chair in the least painful manner. On the other hand, the caregiver may be most concerned about learning the technique for dressing changes. Both the patient's and caregiver's learning needs are important. The patient and caregiver may also have differing or conflicting views of the illness and treatment options. Developing a successful teaching plan requires you to view the patient's needs within the context of the caregiver's needs. For instance, you may teach a patient with right-sided *paresis* (weakness) self-feeding techniques with special tools, but at a home visit you find the caregiver feeding the patient. On questioning, the caregiver reveals that it is too hard to watch the patient struggle with feeding, it takes too long, and it is messy. As a result, the caregiver decided that it is easier to feed the patient. This is an example of a

situation in which the patient and caregiver need more teaching about goals for self-care.

Discuss the potential that support groups, family and friends, and community resources have for providing ongoing resources. Support groups help by people sharing experiences and information, offering understanding and acceptance, and suggesting solutions to common problems and concerns.

Regulatory Mandates for Patient Teaching

Several important agencies have specific mandates related to teaching hospitalized patients. The Joint Commission's (TJC's) accreditation standards, National Patient Safety Goals,[9] and the American Hospital Association's Patient Care Partnership[10] state that patients have a fundamental right to receive information about their care. This information includes their diagnosis, treatment, and prognosis in terms that they can understand. For example, this means that written materials must be at the patient's reading level. One program started by TJC, Speak Up, was developed to encourage patients to become more involved and informed about their plan of care (Table 4.5).[11] Another program implemented by the Institute for Healthcare Improvement's National Patient Safety Foundation is Ask Me 3.[12] Both programs encourage patients to ask specific questions about their care.

TABLE 4.5 The Joint Commission's Speak Up Initiative

Speak up if you have questions or concerns. If you still do not understand, ask again. It is your body and you have a right to know.

Pay attention to the care you get. Always make sure you are getting the right treatments and medicines by the right health

care professionals. Do not assume anything.

Educate yourself about your illness. Learn about the medical tests you get and your treatment plan.

Ask a trusted family member or friend to be your advocate (advisor or supporter).

Know what medicines you take and why you take them. Medicine errors are the most common health care mistakes.

Use a hospital, clinic, surgery center, or other type of health care organization that has been carefully checked out.

Participate in all decisions about your treatment. You are the center of the health care team.

Source: The Joint Commission: To prevent health care errors, patients are urged to Speak Up (poster). Retrieved from *www.jointcommission.org/assets/1/18/SpeakUp_Poster.pdf*.

Process of Patient Teaching

We use many different approaches in the process of patient teaching. However, the approach used most often by nurses parallels the nursing process. The **teaching process** and the nursing process involve the development of a plan that includes assessment, goal setting, implementation, and evaluation. The teaching process, like the nursing process, may not always flow in linear order, but the steps serve as checkpoints.

Assessment

During the general nursing assessment, gather data to determine if the patient has learning needs. For example, what does the patient know about the health problem? How does he or she perceive the problem? If you identify a learning need, you need a more detailed assessment, and address that problem with the teaching plan. Include caregivers in the assessment as you determine their role and ability to care for the patient at home. Key questions to use in the assessment are

outlined in Table 4.6.

Physical Factors

The patient's age is a factor to consider in the teaching plan. Age affects the patient's experiences and rate of learning. Some effects of increased age on learning may be obvious, but the inexperience of younger people can also affect learning. For example, a man in his twenties who has never thought about his own mortality may be unable to accept the long-term health implications of diabetes mellitus.

Sensory impairments (e.g., hearing or vision loss) decrease sensory input and can alter learning. Cognition may be affected by disorders of the nervous system (e.g., stroke, head trauma) and by other diseases (e.g., liver impairment, heart failure). Patients with altered cognition may have a hard time learning and need more caregiver involvement in the teaching process. You need manual dexterity to perform skills such as giving injections or BP monitoring.

Pain, fatigue, and certain drugs influence the patient's ability to learn. No one can learn effectively when in pain. Provide teaching after the patient's pain is controlled. A tired, weak patient cannot learn effectively because of the inability to concentrate. Sleep disruption is common during hospitalization, and patients are often sleep deprived at the time of discharge. Drugs that cause central nervous system depression, such as opioids and sedatives, decrease mental alertness and can affect the patient's ability to learn new information. Adjust the teaching plan by setting high-priority goals based on need-to-know information and realistic expectations. Patients often need a referral for follow-up so that teaching continues and learning is confirmed after discharge.

TABLE 4.6 Assessment of Factors Affecting Patient TeachingKey Factors and Questions

Physical

- What is the patient's age?
- Is the patient acutely ill?
- Is the patient fatigued or in pain?
- What is the primary diagnosis?
- Are there other medical problems?
- What is the patient's current mental status?
- What is the patient's hearing ability? Visual ability? Motor ability?
- What drugs does the patient take that may affect learning?

Psychologic

- Does the patient appear anxious, afraid, depressed, defensive?
- Is the patient in a state of denial?
- What is the patient's level of motivation? Self-efficacy?

Sociocultural

- What are the patient's beliefs about his or her illness or treatment?
- Is the proposed teaching consistent with the patient's cultural values?
- What is the patient's educational experience, reading ability, primary language?
- What is the patient's present or past occupation?
- How does the patient describe his or her financial status?
- What is the patient's living arrangement?
- Does the patient have family or close friends?

Learner

- What does the patient already know about his or her health problem?
- What does the patient think is most important to learn?
- What prior learning experiences could act as a frame of reference for current learning needs?
- Is the patient ready to learn? Change behavior?
- How does the patient learn best (e.g., reading, listening, looking at pictures, doing, playing games)?
- In what kind of environment does the patient learn best? Formal classroom? Computer/Web-based setting? Informal setting, such as home? Alone or in a group?
- In what way should the caregiver(s) be involved in patient teaching?

Psychologic Factors

Psychologic factors have a major influence on the patient's ability to learn. Anxiety and depression are common reactions to illness. Although mild anxiety increases the learner's perceptual and learning abilities, moderate or severe anxiety limits learning. Anxiety and depression can negatively affect the patient's motivation and readiness to learn. For instance, the patient newly diagnosed with diabetes who is depressed about the diagnosis may not listen or respond to instructions about glucose testing. Discussions with the patient about these concerns or referrals to an appropriate support group may help the patient to learn that management of diabetes is possible.

Patients respond to the stress of illness with a variety of defense mechanisms, such as denial, rationalization, or even humor. A patient who denies having cancer will not be receptive to information related to treatment options. Similarly, a caregiver may have a hard time accepting a terminal diagnosis. A patient using rationalization will imagine any number of reasons for avoiding change or for rejecting teaching. For example, a patient with heart disease who does not want to change dietary habits will relate stories of people who have eaten

bacon and eggs every day and lived to be 100. Some patients use humor to filter reality or decrease anxiety. They may use laughter to escape from the experience of facing threatening situations. Humor in the teaching process is important and useful but notice when humor is used excessively or inappropriately to avoid reality.

One important factor in successful adoption of new behaviors is the patient's sense of self-efficacy. There is a strong relationship between self-efficacy and outcomes of illness management. Self-efficacy increases when a person gains new skills in managing a threatening situation. It decreases if the person has repeated failure, especially early in the course of events. Plan easily achievable goals early in the teaching sessions. Proceed from simple to more complex content to support a feeling of success.

Sociocultural Factors

Health Literacy

Literacy is the ability to use printed and written information to function in society. **Health literacy** is the degree to which a person can obtain and understand basic health information needed to make appropriate health decisions.[13] As many as 50% of U.S. adults have limited literacy skills, and almost 90% have limited health literacy skills.[14]

Improving health literacy will advance population health. Currently, only 64% of adults report receiving easy-to-understand instructions from their HCPs and only 24% report that a HCP asked them to describe how they will follow the instructions provided.[15] Patients with low levels of health literacy have trouble understanding and acting on health information, placing them at greater risk for hospital readmissions.[16] Even patients with high levels of health literacy may have a hard time understanding complex health information if they are sick or stressed. Health illiteracy results in poor patient outcomes, not following treatment plans, limited self-management skills, and increased health disparities.[16]

It is challenging to assess health literacy, because patients may be embarrassed to admit that they are having trouble understanding health information. Health professionals often over-estimate the health literacy of patients, so it is important to routinely assess health literacy level. Easy-to-use assessment tools are available. The Single-Item Literacy Screener (SILS) uses 1 question to identify adults who need help with reading.[17] The question is, "How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy?"

Another approach is to implement health literacy universal precautions. These are the steps to take when we assume that all patients may have difficulty understanding important health information and accessing health services. These include using simple communications about health information and verifying patient understanding.[14]

FIG. 4.2 Nurse communicating with a non–English-speaking patient using a translation phone service.
Courtesy Linda Bucher, RN, PhD, CEN, CNE, Staff Nurse, Virtua Memorial Hospital, Mt. Holly, N.J.

TJC states that we must tailor patient teaching to the patient's literacy needs. For example, teach patients and give them written materials in their primary language. Teaching materials are available in multiple languages. It is preferable to use medical interpreters instead of family members or friends, to protect patient privacy (Fig. 4.2). Medical interpreters are discussed in Chapter 2 in Table 2.10. Choose patient teaching materials written at the fifth-grade or lower reading level. Other interventions to help patients with low levels of health literacy include using the teach-back method, highlighting key text, and teaching content in small increments.

Cultural Considerations

The wider culture to which a patient belongs influences learning.

Cultural traditions influence our health practices, beliefs, and behavior. These traditions, which can affect patient teaching, can be identified in a cultural assessment (see Table 2.3). TJC requires that patient teaching be tailored to the patient's cultural needs.[18] Ask patients to describe their beliefs about health and illness.

One cultural element that specifically affects the teaching-learning process is a conflict between the patient's cultural beliefs and values and the behaviors promoted by the health care team. For example, you can teach a patient who values a trim figure to use diet and exercise to keep that figure while at the same time improving BP control. However, being heavier may be valued in another patient's culture. This patient may have more difficulty accepting the need for diet and exercise in BP control.

Assess the patient's use of cultural remedies and healing practices (see the Complementary & Alternative Therapies Box: Assessment of Use of Herbs and Dietary Supplements in Chapter 3, p. 35). Consider the cultural remedies that may interfere with or are contraindicated by the treatment plan.

Last, it is important to know who has authority in the patient's culture. The patient may defer to the authority, such as an elder or a spiritual leader, for decisions. In this case, identify and work with the patient and the decision makers in the patient's cultural group. See Chapter 2 for more information on cultural competence.

Socioeconomic Considerations

Consider a variety of socioeconomic factors when preparing to teach patients. Knowing the patient's present or past occupation may help you determine the vocabulary to use during teaching. For example, an auto mechanic may understand the volume overload associated with heart failure as flooding an engine. An engineer may understand the principles of physics associated with gravity and pressures when discussing vascular problems.

Ask the patient about living arrangements. Whether the patient lives alone, with friends, or with family influences who you include in the teaching process. You may need to change the teaching plan if the

patient does not have access to electricity or phones. If the patient has unmet learning needs by the time of discharge, arrange for ongoing teaching after discharge.

Learner Factors

Last, assess learner factors, including the patient's learning needs, readiness to learn, and learning style.

Learning Needs

Learning needs are the new knowledge and skills that a person must have to meet a goal. The assessment of learning needs determines what the patient already knows and any past experiences with health problems. Patients with long-standing health problems may have different learning needs from those patients with newly diagnosed health problems.

What patients should learn about managing an illness or what behaviors promote health may seem obvious to you. However, what you think is important may be different from what patients want to know. Remember, adults learn best when the teaching gives information that they view as being needed at once (Table 4.1). Ask patients to prioritize what they see as the most critical information. Start by giving the patient a list of the recommended topics and then ask the patient to identify other topics not on the list. Having patients prioritize their own learning needs lets you begin with the patient's most important needs. Explain why critical information is "need to know."

Readiness to Learn

Readiness to learn and motivation depend on multiple factors, such as perceived need, attitudes, and beliefs. When teaching adults, identify what information the person values. Readiness to learn is increased if the patient perceives a need for information, has a belief that a behavior change has value, or perceives the learning activities as new and stimulating.[5]

Before implementing the teaching plan, determine where the patient is in the stages of change (Table 4.2). If the patient is in the precontemplation stage, provide support and increase the patient's awareness of the problem until the patient is ready to consider a change in behavior. Nurses in outpatient settings and home health care can continue to assess the patient's readiness to learn and implement the teaching plan as the patient moves through the stages of change. Reinforcement throughout the change process is a strong motivational factor for achieving a desired behavior. **Positive reinforcement** involves rewarding the target behavior with positive feedback or other rewards to maintain the behavior.[6]

Learning Style

Each person has a distinct style of learning. The 3 general learning styles are (1) *visual* (reading, pictures), (2) *auditory* (listening), and (3) *physical* (doing things). People often use more than 1 learning style to gain new knowledge or skills. To assess a patient's preferred learning style, ask how the patient likes to learn and has learned effectively in the past. When assessing the patient's learning style, identify the patient who does not read or who has low health literacy. For example, the patient may tell you that he or she does not read much but likes to learn from television. In addition, assess the patient's *ehealth literacy*. This refers to the degree that patients use digital information (e.g., webinars, online health management tools) and communication technologies (e.g., online communication with HCP, online support groups) to improve their health (Fig. 4.3).[19] When possible, use the patient's or caregiver's preferred learning style.

FIG. 4.3 Older couple accessing the Web for health information.
© monkeybusinessimages/iStock/Thinkstock.

Planning

Prioritize the patient's learning needs and agree on learning goals. If the patient's physical or psychologic condition interferes with participation, involve the patient's caregiver(s) in the planning phase.

Setting Goals

It is important to have clear and measurable learning goals or outcomes (Table 4.7). Learning goals relate to the intended outcome of the learning process, guide the choice of teaching strategies, and help evaluate the patient's progress. Learning goals are parallel to patient outcomes in the nursing care plan (NCP). Most settings have standardized NCPs with preset goals and interventions for specific learning needs. You will modify these NCPs based on the patient's unique sociocultural and learner characteristics.

Choosing Teaching Strategies

Three factors that influence the choice of teaching strategies are (1) patient characteristics (e.g., learning style, educational background, culture, language skills), (2) subject matter, and (3) available resources. Table 4.8 summarizes learner characteristics and recommends teaching approaches based on the generation of the patient or caregiver.

Consider various strategies (Table 4.9) in the teaching plan. We often use multiple teaching strategies to improve learning (Fig. 4.4). Discussion is the most common type of interaction used in teaching patients and caregivers. A type of group teaching involves *peer teaching,* as occurs in support groups. Patients dealing with common problems such as cancer, alcoholism, and eating disorders can receive help from peer teaching.

Adapt your teaching methods when teaching patients with a disability how to care for themselves or how to take part in their own care. It is essential to know how to modify teaching methods to meet the needs of patients with cognitive impairment, hearing loss, limited manual dexterity, or vision loss. Magnifying glasses, bright lighting, and materials printed in a large font may help the patient with impaired vision read teaching materials. More visual stimuli can help people with hearing loss. Using adaptive equipment may help those with problems performing manual skills. Table 4.10 presents strategies for teaching patients with disabilities.

TABLE 4.7 Writing Learning Goals

Elements of Learning Goals

Learning goals (also called outcomes or objectives) are written statements that define exactly how patients demonstrate their knowledge of the content. Goals address the following 4 questions:

1. Who Will Perform the Activity or Acquire the Desired Behavior?

Examples:

I(the patient) will
I(the caregiver) will
We (patient's family/caregivers) will

2. What Is the Actual Behavior That the Learner Will Exhibit to Show Mastery of the Goal?

Examples:

List the symptoms.
Self-administer an insulin injection.
Choose from a hospital menu.

3. What Are the Conditions Under Which the Behavior Is to Be Demonstrated?

Examples:

In front of the nurse
From a random list
Using sterile technique

4. What Are the Specific Criteria That Will Be Used to Measure the Patient's Success, Such as Time and Degree of Accuracy?

Examples:

With 100% accuracy
Over the next week
Before discharge

Verbs in Learning Goals

Avoid vague, ambiguous verbs that are hard to measure:	*Use verbs that have precise descriptions with few interpretations:*
• **Appreciate** • **Learn** • **Understand** • **Enjoy** • **Feel** • **Value**	• Identify • List • Describe • Demonstrate • Perform • Choose

Poorly and Well-Written Learning Goals

Example of Poorly Written Learning Goal	**Examples of Well-Written Learning Goals**
• **The patient will understand the importance of managing his own colostomy.** ***Analysis*: It is not clear how the patient will show that he "understands" the importance of managing his colostomy, when and to whom he will demonstrate this behavior, or what criteria will be used to determine whether the goal has been met.**	• The patient will describe to the nurse the basic steps for changing the colostomy pouch and skin barrier by 2/14/21. • Using correct technique, the patient will empty his colostomy pouch when one-third full. • The patient's caregiver will perform colostomy care, including changing the pouch and skin barrier. • Given a list of signs and symptoms related to complications of a colostomy, the patient and caregiver will identify signs and symptoms to report to a health care provider before discharge. *Analysis*: When learning goals are clear and specific and documented in the patient's record, all members of the health care team can work together to achieve the same outcomes.

TABLE 4.8 Learner Characteristics and Teaching Strategies by Generation

Birth Year	Learner Characteristics	Recommended Teaching Strategies
Millennials (Generation Y, Yers, Nexters, Digital Natives)		
1981–2000	• Multitaskers • Prefer interactive and virtual environments • Technologically focused • Need flexibility • Short attention span • Team players • Prefer more structured learning compared to Xers • Accustomed to learning whatever, wherever, whenever	• Integrate technology and media in teaching • Discuss reliable health-related mobile apps and websites • Download health information to smart phones, tablets, or similar devices • Consider group teaching • Consider active learning approaches
Generation X (Xers, Digital Natives)		
1965–1980	• Self-directed or self-paced learning • Self-reliant • Consumers of education • Short attention span	• Integrate technology and media in teaching • Discuss reliable websites • Consider health-related mobile applications • Give Web-based education materials • Provide education materials that are brief and easy to read • Encourage questions
Baby Boomers (Digital Immigrants)		
1946–1964	• Emphasis on self-knowledge • Solve problems by action • Acquisition of knowledge from authoritative sources • Receptive to feedback • Prefer text over graphics • Process (step-by-step) oriented	• Assess ehealth literacy and consider strategies as appropriate • Consider lecture or lecture-discussion (e.g., PowerPoint presentation) • Use patient education TV channels • Provide printed materials
Veterans (Traditionalists, Digital Immigrants)		
Born before 1946	• Emphasis on rote learning • Memorization of knowledge • Follow rules	• Assess ehealth literacy and consider strategies as appropriate • Consider lecture or lecture-discussion • Use pictures and printed materials such as books

Compiled from Bradshaw M, Lowenstein A: *Innovative teaching strategies in nursing*, ed 7, Burlington, Mass, 2017, Jones & Bartlett Learning; and Hart S: Today's learners and educators: bridging the generational gaps, *Teach Learn Nurs* 12:253, 2017.

Learning Materials

Use learning materials in multiple formats. Learn what resources are available in your agency and from support services and professional groups. The use of CDs/DVDs and online videos is helpful, particularly when teaching visual content such as the steps of a procedure (e.g., suctioning a tracheostomy). The health care agency's television system may show high-quality, professionally produced patient teaching programs on demand or on a rotating schedule (Fig. 4.4).

Printed materials are useful for teaching patients and caregivers, especially for those whose preferred learning style is reading. Some health-related organizations, such as the American Cancer Society and the American Heart Association provide quality patient education

materials free of charge. Some governmental organizations, such as the National Institutes of Health and the Centers for Disease Control and Prevention, have learning materials for patients and caregivers. These materials can be used in combination with other teaching strategies. For instance, after a discussion on the effects of smoking on health, you may use material from the American Cancer Society to reinforce the information.

When writing teaching materials, use several techniques to keep the reading level at a fifth-grade level. These include (1) organize the content logically; (2) highlight or place key information in bold or italics; (3) use short, common words of 1 or 2 syllables; (4) define medical words in simple language; (5) keep sentences short, between 10 and 15 words; (6) use pictures or drawings; and (7) use active voice in the same manner in which you would normally speak.[20] Whenever possible, appraise written materials for readability level using word processing (e.g., Microsoft Word) or Web-based (e.g., *www.wordscount.info*) programs.

Using Technology

Patients may use the Internet and other digital technology (e.g., smart phones) to obtain information and manage their health. Patients can quickly do a Web search or open a software application for access to information about diseases, drugs, treatments, and surgeries. Your job is to help patients sift through the information and determine if it is valid, reliable, and usable. Encourage patients to use websites established by the government, universities, or reputable health-related organizations (e.g., American Diabetes Association, American Heart Association, National Institutes of Health, U.S. Food and Drug Administration). Understanding the principles of Web searching for health information and teaching patients how to find valid information are critical skills. The presence of Internet connections in many patient rooms provides an opportunity for you to teach patients about their illness and how to use the Web to find related information.

Overall, the digital health divide for older adults has narrowed. However, adults older than 75 years of age, those with less than a

high school education, and those with very low income are less likely to access the Internet for health-related Internet use.[21] Organizations dedicated to improving the quality of life for older adults promote the development of user-friendly websites (e.g., *www.nlm.nih.gov/pubs/checklist.pdf*) and publish guides to help evaluate Web-based health information (e.g., *www.mlanet.org/resources/userguide.html*).

The quantity and complexity of digital health care technology available to you and your patients will continue to increase. *Telehealth,* a broad term that refers to the delivery of health-related services and information via telecommunications technologies, allows for (1) remote HCP-patient consultations *(telemedicine);* (2) monitoring of vital signs, weight, heart rhythm, blood glucose, etc.; and (3) ongoing patient teaching. Learn about these technologies and determine how useful they may be when teaching patients.

TABLE 4.9 Comparison of Teaching Strategies

Description	Advantages	Limitations
Discussion ("Teach Back")		
• **Purpose is to exchange points of view about a topic or to arrive at a decision or conclusion** • **Can be done with patient, with patient and caregiver, or with group** • ***Example:*** **Weight loss**	• Allows for an active exchange of information and previous experiences among participants • Good choice when patients have previous experience with subject and have information to share • Nonthreatening format • Can use peers (patients with common problems) to teach	• May need more time depending on topic and number of participants
Lecture-Discussion		
• **Useful when group of patients and caregivers can benefit from basic information** • **Lecture portion is short (i.e., 15–20 min)** • **Discussion ("teach back") follows lecture** • ***Example:*** **Basic principles of cardiac rehabilitation (e.g., exercise, nutrition)**	• Combines short lecture to present basic information with time for discussion • Provision of printed material related to lecture content is useful and recommended	• Need to limit number of lecture topics to 3 to 5 • May need more time depending on topic and number of participants
Demonstration/Return Demonstration ("Show Back")		
• **Purpose is to teach patient and caregiver to perform a skill** • **Return demonstration ("show back") can show patient's ability to perform skill (see Fig. 4.5)** • ***Examples:*** **Dressing change, injection**	• Provides for learning and practice of physical skills • Dividing skill into series of smaller steps helps mastery and provides reinforcement	• May need more time for practice needed to master skill • Patients with limited manual dexterity may have difficulty
Use of Teaching Resources		
• **Audiovisual aids to supplement teaching** • **Printed materials (e.g., brochures)** • **CDs/DVDs** • **Hospital-based TV (see Fig. 4.4)** • **Digital and communication technologies (e.g., mobile applications, Web-based patient education programs, game-based education, online support groups)** • **Telehealth**	• Enhances the presentation through visual and/or auditory stimulation • Best used in combination with other teaching strategies • Use of digital and communication technologies for health information is the preferred choice for many • Web access in patient rooms is standard in most health care agencies • Health information can be given and reinforced to patients remotely	• Review materials for accuracy, reading level, completeness, etc., before using • Evaluate websites, games, applications, programs, etc., for validity of information • May not be appropriate for all learners (e.g., lack of interest, decreased mental capacity) • Finances (e.g., equipment purchase, Internet service) may be a limiting factor to using digital technology

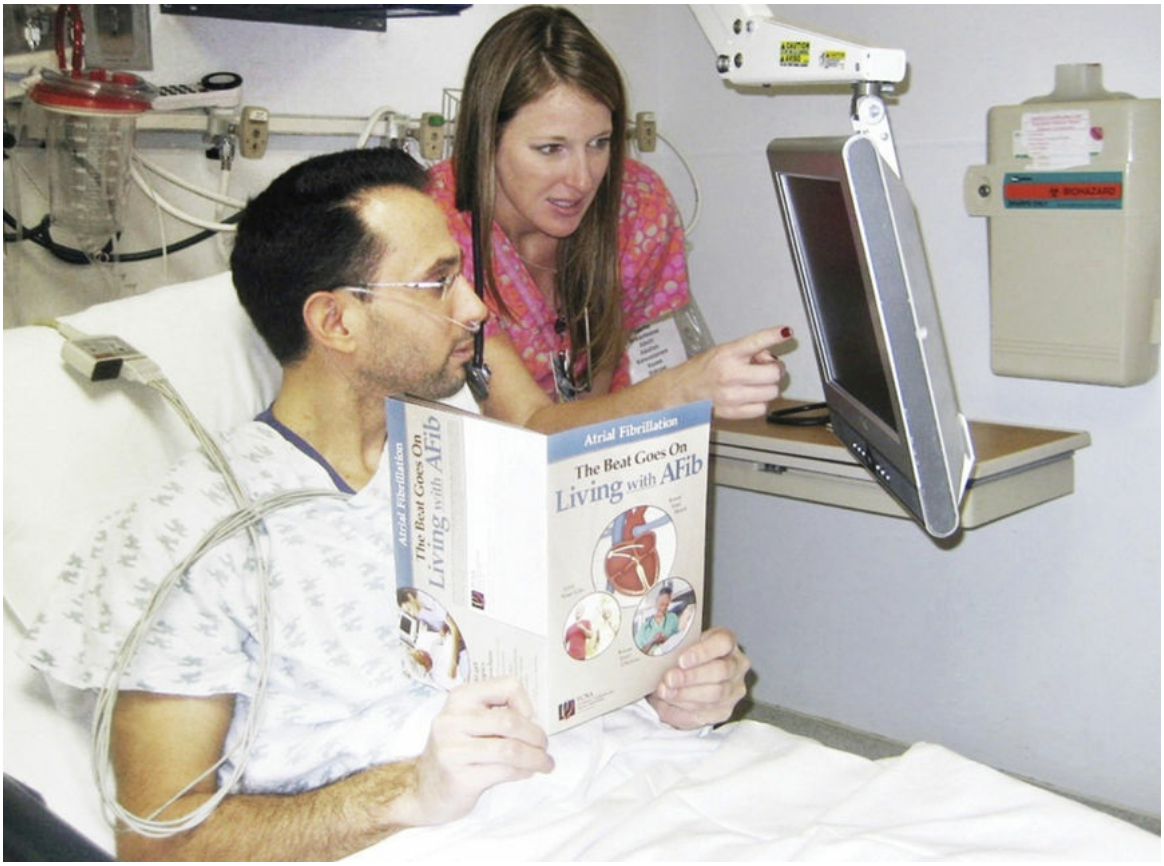

FIG. 4.4 Effective teaching using a variety of strategies (written materials, computer-based patient education programs). Courtesy Linda Bucher, RN, PhD, CEN, CNE, Staff Nurse, Virtua Memorial Hospital, Mt. Holly, N.J.

Implementation

During the implementation phase, use the planned strategies to present information and teach new skills (Table 4.10). Incorporate verbal and nonverbal communication skills, active listening, and empathy into the process. Based on the assessment of the patient's physical, psychologic, sociocultural, and learner characteristics, determine how much the patient can participate. Whenever possible and appropriate, involve the patient's caregiver(s) in the teaching-learning process.

Remember the principles and characteristics of the adult learner. Although reinforcement and reward are important, phrases such as, "Aren't you doing well!" in a tone one would use with a child can be

condescending to adult learners.

Evaluation

Evaluation, the last step in the learning process, is a measure of the degree to which the patient has achieved the learning goals. You can use various evaluation techniques (Table 4.11). Use techniques such as "teach back" to determine the knowledge and skill levels of the patient and/or caregiver throughout the teaching and learning process (Fig. 4.5). If goals are not reached, reassess the patient and revise the teaching plan as needed.

TABLE 4.10 Teaching Patients With Disabilities

Hearing Loss[22]

- Sit in front of the patient at eye level with the light shining on your face
- Use assistive listening devices to amplify sound
- Speak slowly and clearly, using short, simple sentences
- Create a quiet environment that eliminates or minimizes background noises
- Assess patient's preferred communication method (sign language or lip reading)
- If patient prefers to use sign language:
    - Leave as much freedom as possible for their dominant hand to allow for signing
    - Use a sign language interpreter to preserve patient privacy and confidentiality
    - If using a sign language interpreter, speak to the patient, not the interpreter
- If the patient prefers lip-reading:
    - Make sure the patient can see your lips

- Face the patient and maintain eye contact
- Ensure there is good lighting on your lips
- Speak in a normal rhythm and tone
- Use facial expressions to help convey meaning

Limited Manual Dexterity

- Provide assistive (ease of use) devices to help the patient perform necessary tasks to perform a skill

Mild Cognitive Impairment[23]

- Explain what you will be doing
- Use simple wording
- Present 1 instruction at a time
- Ask yes/no questions
- Avoid open-ended questions
- Be patient
- Answer repeated questions as if it were the first time the question was asked
- Reinforce instructions often
- Create a quiet environment and minimize distractions

Vision Loss[24,25]

- Use low-vision aids, such as magnifiers, high-power reading glasses, or handheld or mounted telescopes
- Use technology, such as screen readers that read text on the computer screen using a speech synthesizer or convert text to braille
- Use electronic tablets or smart phones with adjustable text size

- Use large print publications
- Ensure that there is good lighting in the environment
- Minimize distractions and eliminate background noise
- Give educational materials available in braille
- Provide verbal or tactile instruction instead of written instruction

The patient may not have been giving himself enough insulin for some time. The patient's vision had declined, and he now needs special equipment to correctly draw up the insulin. The lesson here is that assumptions about a patient's knowledge and skills are dangerous. Confirm prior knowledge even as you are teaching new skills.

Long-term evaluation of learning goals often requires follow-up after discharge. Provide a written schedule of visits and other appropriate referrals before the patient leaves the hospital or clinic. It is important to share this information with the patient's caregiver(s) so that everyone involved in the patient's long-term progress has the same information.

TABLE 4.11 Evaluating Patient and Caregiver Learning

Technique	Strategy and Examples

Observe patient or caregiver directly	• Ask person to show you how to change the dressing
	• Return demonstration ("show back") determines whether:
	  • Skill has been mastered
	  • Further instruction is needed
	  • Patient and caregiver are ready for new or more content

Observe verbal and nonverbal cues	• Teaching may have to be delayed, more teaching needed, or different strategy used if patient or caregiver:
	  • Asks you to repeat instructions
	  • Loses eye contact
	  • Begins to doze in chair or bed
	  • Becomes restless or fidgety
	  • Does not speak English

Ask open-ended questions ("teach back")	• Open-ended questions provide more information about understanding than closed-ended questions, which need only a "yes" or "no"
	• Ask questions such as:
	  • "How often do you need to change the dressing?"
	  • "What will you do if you develop chest pain at home?"

Talk with caregiver ("teach back")	• Involve caregiver in the evaluation process
	• Ask questions such as:
	  • "What medications is she taking?"
	  • "When does he use his oxygen?"

Seek the patient's self-evaluation of progress	• Ask patient's opinion about his or her progress • Assess what evidence the patient has that the goals are being met • Assess if the patient is ready to learn new material

Documentation is an essential part in the teaching-learning process. Record everything from the assessment through plans for evaluation and follow-up. Because members of the health care team use these records in different settings and for various reasons, the teaching goals, strategies, and evaluation results need to be clear, complete, and available to the team members.

Check Your Practice

Your patient is a 53-yr-old man with type 1 diabetes who entered the hospital with a blood glucose level of 550 mg/dL (30.53 mmol/L). He is now stable and soon will be discharged.

You prepare his insulin and plan to give him the syringe to let him do his own injection. Before you go to his room, your preceptor suggests that you observe his technique of preparing the insulin as well as the injection. This comment puzzles you because he has had diabetes for 32 years and should know how to do it.

When you go to his room, you ask him to prepare the insulin injection ("show back"). You notice that he filled the syringe with 30

units of insulin and 10 units of air, instead of 40 units of insulin. After correcting the dose and questioning the patient more fully ("teach back"), you wonder what happened.

What are possible reasons that he did not draw up the correct amount of insulin?

Case Study

Patient and Caregiver Teaching

Patient Profile

©azndc/iStock/Thinkstock.

M.L., a 60-yr-old Asian woman, is admitted to the hospital with a diagnosis of exacerbation of chronic obstructive pulmonary disease (COPD).

Subjective Data

- History of COPD for 10 years. Admitted twice in the past 8 months for exacerbations of COPD. Reports a chronic cough but denies any recent change in sputum color. States: "I stopped smoking last year, but my son-in-law smokes in the house."
- Past medical history: Gastroesophageal reflux disease; macular degeneration in right eye.
- Social history: Widowed 5 years ago. Lives with daughter and son-in-law, who work full time. Cares for 2 young grandchildren after school. English is M.L.'s second language.

Objective Data
Physical Examination

- Alert, cognitively intact, anxious, thin woman with dyspnea on minimal exertion. Speaks in short phrases. States: "I have no energy."
- Oxygen via nasal cannula at 2 L/min
- Weight 100 lb, height 5 ft 2 in

Diagnostic Studies

- Chest x-ray negative for acute infection
- Arterial blood gases on room air: pH 7.35, $PaCO_2$ 47 mm Hg, PaO_2 75 mm Hg, HCO_3^- 30 mEq/L
- O_2 saturation (via pulse oximetry) during 6-minute walk test on room air = 83%

- Forced expiratory volume in 1 second of expiration (FEV_1) = 60% of predicted

Interprofessional Care

- Medications: bronchodilator therapy (inpatient nebulizer therapy, inhalers at home), oral corticosteroids
- Continuous home O_2 therapy 2 L/min via nasal cannula
- Pulmonary rehabilitation: inpatient and outpatient

Discussion Questions

1. **Priority Decision:** What are M.L.'s priority learning needs?
2. ***Patient-Centered Care:*** What factors (e.g., sociocultural, physical, psychologic) noted in the assessment may influence M.L.'s response to teaching?
3. ***Patient-Centered Care:*** What potential challenges might you expect when planning to teach M.L.? How would you manage them?
4. ***Priority Decision:*** Choose 2 of M.L.'s priority learning needs. Develop a teaching plan for M.L. for each of these needs.

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

FIG. 4.5 Teaching using discussion ("teach back") and demonstration/return demonstration ("show back") increases successful learning by the patient.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which technique is *most* appropriate when using motivational interviewing with a patient who tells you that he is ready to start a weight-loss program?
   a. Confirm that the patient is serious about losing weight.
   b. Insist that the patient consider an organized group

weight-loss program.

c. Focus on the patient's strengths to support his optimism that he can successfully lose weight.

d. Ask a prescribed set of questions to increase the patient's awareness of his dietary behaviors.

2. Which is the *priority* patient teaching strategy when limited time is available?

a. Setting realistic goals that have high priority for the patient

b. Referring the patient to a nurse educator in private practice

c. Observing more experienced nurse-teachers to learn how to teach faster and more efficiently

d. Providing reading materials for the patient instead of discussing information the patient needs to learn

3. The nurse needs to include caregivers in patient teaching primarily because *(select all that apply)*

a. caregivers provide all the care for patients after discharge.

b. they might feel rejected if they are not included in the teaching.

c. patients have better outcomes when their caregivers are involved.

d. the patient may be too ill or too stressed to fully understand the teaching.

e. caregivers are responsible for the overall management of the patient's care.

4. Which patient characteristic enhances the teaching-

learning process?

a. Moderate anxiety

b. High self-efficacy

c. Being in the precontemplative stage of change

d. Being able to laugh about the current health problem

5. What would be the *priority* teaching goal for a middle-aged Hispanic woman about methods to relieve symptoms of menopause?

a. Prevent the development of future disease.

b. Maintain the patient's current state of health.

c. Provide information on possible treatment options.

d. Change the patient's beliefs about herbal supplements.

6. A patient tells the nurse that she enjoys talking with others and sharing experiences but often falls asleep when reading. Which teaching strategy would be *most* effective with this patient?

a. Formal lecture

b. Journal writing

c. Web-based program

d. Small group discussion

7. The nurse has taught a family caregiver how to administer insulin. Evaluation of the caregiver's learning would include

a. monitoring the patient's glucose readings.

b. arranging for follow-up with a home care nurse.

c. asking the caregiver to "show back" the ability to administer insulin.

d. asking the caregiver what was helpful about the teaching experience.

Chronic Illness and Older Adults

Sherry A. Greenberg

LEARNING OUTCOMES

1. Describe the prevention and major causes of chronic illness.
2. Explain the characteristics of a chronic illness.
3. Describe the demographics of aging.
4. Explain the needs of special populations of older adults.
5. Describe nursing interventions to assist older adults with chronic illnesses.
6. Describe common problems of older adults related to hospitalization and acute illness and the nurse's role in assisting them.
7. Differentiate among care alternatives to meet needs of older adults.
8. Describe the nurse's role in health promotion and managing the special needs of older adults.

Conceptual Focus

Cognition
Family Dynamics
Functional Ability
Mobility
Nutrition
Sensory Perception

This chapter discusses issues related to chronic illness and aging. The population of older adults is growing rapidly. You need to consider their multiple, complex health care conditions and needs when planning and providing comprehensive nursing care. Functional ability in those with chronic illness and older adults is interrelated with several concepts, including mobility, perfusion, nutrition, cognition, and sensory perception. Family dynamics and caregiving shape the care provided to those who need help to meet their needs.

Chronic Illness

Illness can be categorized as either acute or chronic (Table 5.1). The U.S. health care system faces a growing burden of chronic illness as the population ages. Chronic illnesses account for 70% of all deaths in the United States. Chronic illness results in limitations in physical functioning, work productivity, and quality of life for nearly 1 out of 10 Americans. Many older adults live with more than 1 chronic illness, some live with 6 or more. A sizable portion of U.S. health care dollars goes toward treating chronic illnesses.[1] Managing a chronic illness greatly affects the lives of the older adult, family, and caregiver. Table 5.2 presents the impact of some chronic illnesses.

In addition to people living longer, other societal changes have contributed to the increase in chronic illnesses. These include insufficient physical activity, lack of access to fresh fruits and vegetables, and tobacco and alcohol use.[1]

Trajectory of Chronic Illness

The person with a chronic illness can move from a level of optimum functioning, with the illness well controlled, to a period of physical instability. Corbin and Strauss proposed a view of chronic illness as a trajectory (Fig. 5.1) with overlapping phases[2] (Table 5.3). This trajectory characterizes the common course of most chronic conditions. In addition, Corbin and Strauss identified the 7 tasks of those who are chronically ill (Table 5.4). These tasks are discussed in the following sections.

Preventing and Managing a Crisis

Most chronic illnesses have the potential for an acute exacerbation of symptoms, which may result in further disability or death. Examples include the patient with heart disease who has another myocardial infarction or the patient with asthma who has a severe attack. A major task for the patient and caregiver is to learn to prevent or manage the crisis. First, the patient and caregiver need to understand the potential for the crisis to occur. Second, they need to know ways to prevent or

modify the threat. This often involves adhering to a prescribed medical plan. Patients need to know the signs and symptoms of the onset of a crisis or exacerbation. Depending on the chronic illness, signs and symptoms may occur suddenly (e.g., bleeding in a patient with inflammatory bowel disease) or slowly (e.g., heart failure in a person with untreated hypertension). It is important for the patient and caregiver to develop a plan to manage a crisis that is likely to occur.

TABLE 5.1 Characteristics of Acute and Chronic Illness

Description	Characteristics
Acute Illness	
Diseases that have a rapid onset and short duration ***Examples:* colds, influenza, acute gastroenteritis**	• Usually self-limiting • Responds readily to treatment • Complications infrequent • After illness, return to previous level of functioning
Chronic Illness	
Diseases that are prolonged, do not resolve spontaneously, and are rarely cured completely ***Examples:* Table 5.2**	• Permanent impairments or deviations from normal • Irreversible pathologic changes • Residual disability • Special rehabilitation needed • Need for long-term medical and/or nursing management

Carrying Out Prescribed Treatment Plan

Treatment plans vary in degree of difficulty and the impact they have on the person's lifestyle. Treatment plans may be challenging or time consuming, such as changing a dressing multiple times a day or following a toileting program. However, they generally save time and prevent complications.

Controlling Symptoms

An important task for those with chronic illnesses is to learn to control symptoms so that they can continue desired activities. Some redesign their lifestyle by learning to plan ahead. People with heart failure

adjust the time they take diuretics when going out for the day to avoid needing to rush to a bathroom. Encourage independence in decision making and collaborating with the health care provider (HCP) about treatment plans to avoid an exacerbation of the illness. Others may redesign their living space. Patients and their families and/or caregivers need to learn about the pattern of symptoms, such as typical onset, duration, and severity, so that lifestyle may be changed accordingly, while maintaining safety.

Reordering Time

People with chronic illness often report having too much or too little time. Treatment plans that require large amounts of time for the person, as well as caregivers, may require changing schedules or eliminating other activities. For example, the patient with a new ileostomy needs to plan for increased time in the bathroom to change the drainage bag.

TABLE 5.2 Impact of Chronic Illnesses

Chronic Illness	Impact	Content in Book	
		Chapter	Page
Alzheimer's disease	• Affects 5.5 million people • Sixth leading cause of death among all adults; fifth leading cause of death among those age 65 and above	59	1386
Arthritis	• Affects 1 in 5 people • One of most common chronic illnesses • Leading cause of disability	64	1499
Cancer	• Second leading cause of death • Risk increases with age	15	232
Cardiovascular disease, including heart disease and stroke	• Affects about 17 million adults • Account for 31% of U.S. deaths annually • Heart disease is leading cause of death in United States • Heart failure is a common cause of hospitalization and rehospitalization • Stroke is fifth leading cause of death • Stroke is a common cause of serious disability	33	698
Chronic obstructive pulmonary disease (COPD)	• Affects many older adults • Third leading cause of death	28	560
Diabetes	• Affects >29 million Americans • 25% of adults in United States do not know they have diabetes • Seventh leading cause of death	48	1108
Human immunodeficiency virus (HIV)	• 45% of those living with HIV in the United States are over 50 years old • Older adults more likely to receive diagnosis of HIV infection later in course of disease	14	216
Obesity	• Affects about 1 in 3 adults • Major contributor to other health problems and chronic diseases	40	869

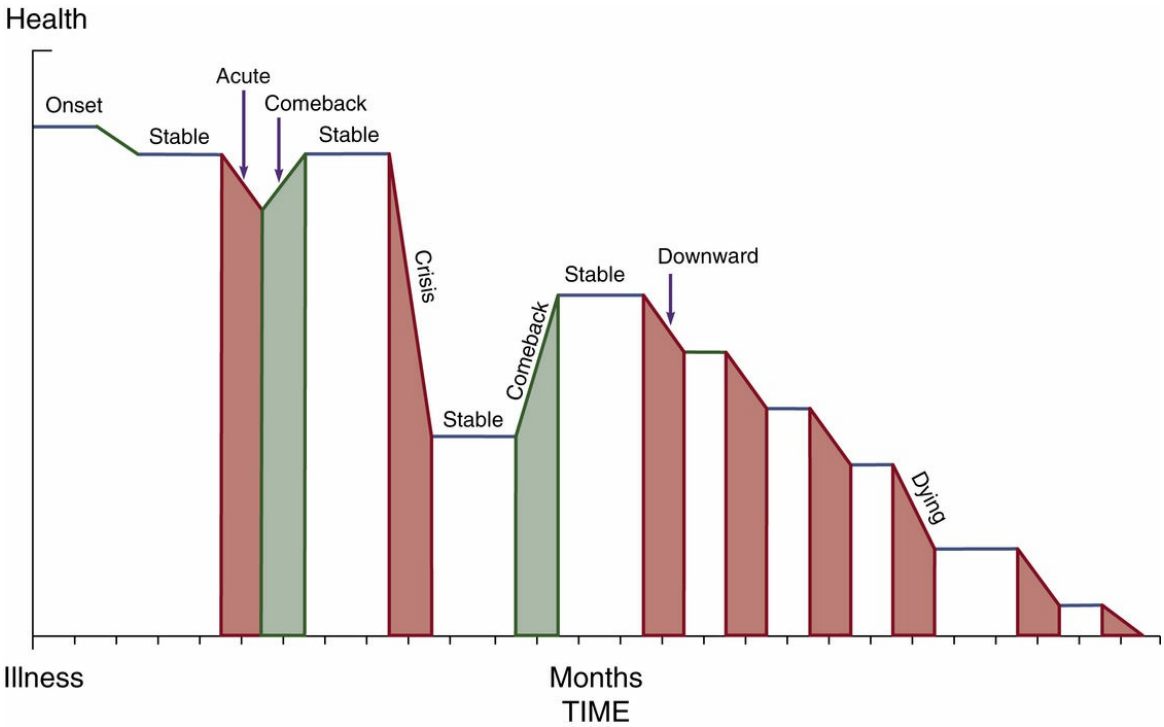

FIG. 5.1 The Chronic Illness Trajectory is a theoretical model of chronic illness. The trajectory model of chronic illness recognizes that chronic illness will have many phases (Table 5.3).
From Woog P: *The chronic illness trajectory framework: The Corbin and Strauss nursing model*, New York, 1992, Springer.

TABLE 5.3 Chronic Illness Trajectory

Phases	Description
Onset	• Signs and symptoms are present • Disease diagnosed
Stable	• Illness course and symptoms controlled by treatment plan • Person maintains everyday activities
Acute	• Active illness with severe and unrelieved symptoms or complications • Hospitalization may be needed for management
Comeback	• Gradual return to an acceptable way of life
Crisis	• Life-threatening situation occurs • Emergency services are necessary
Unstable	• Unable to keep symptoms or disease course under control • Life becomes disrupted while patient works to regain stability • Hospitalization not required
Downward	• Gradual and progressive deterioration in physical or mental status • Accompanied by increasing disability and symptoms • Continuous changes in everyday life activities
Dying	• Patient has to relinquish everyday life interests and activities, let go, and die peacefully • Immediate weeks, days, hours preceding death

Source: Woog P: *The chronic illness trajectory framework: The Corbin and Strauss nursing model*, New York, 1992, Springer.

TABLE 5.4 7 Tasks of People With Chronic Illness

1. Prevent and manage a crisis
2. Carry out prescribed treatment plan
3. Control symptoms
4. Reorder time
5. Adjust to changes in course of disease
6. Prevent social isolation
7. Attempt to normalize interactions with others

Source: Corbin JM, Strauss A: A nursing model for chronic illness management based upon the trajectory framework, *Sch Inq Nurs Pract* 5:155, 1991.

Adjusting to Changes in the Course of Disease

Some diseases, such as multiple sclerosis, have unpredictable courses that make planning activities difficult. Part of the person's task is to develop a personal identity that includes the chronic illness and to adjust to the necessary lifestyle changes. For example, a person taking warfarin due to a mechanical heart valve may need to avoid extreme physical sports that have a high potential for injury.

Preventing Social Isolation

Social isolation may occur with chronic illness. The person may choose to withdraw from social activities or others withdraw from the chronically ill person. For example, a woman who has aphasia secondary to a stroke may not want to go out in public because of embarrassment related to communication issues.

Attempting to Normalize Interactions With Others

Most persons with chronic illness try to manage symptoms so that they can hide their disabilities or disfigurement. This may involve wearing a prosthesis or showing that they can function the same as a person without a disability or chronic illness. An example of this is the woman with heart failure who stops walking to catch her breath but appears to be inspecting a plant or looking in a store window.

Prevention of Chronic Illness

Chronic illnesses are often preventable. *Primary prevention* refers to measures such as eating a healthy diet, getting proper exercise, and receiving immunizations that prevent a specific disease. Appropriate immunizations for older adults include influenza, pneumococcal, herpes zoster, tetanus/diphtheria/pertussis (Td/Tdap), and hepatitis A and B. *Secondary prevention* refers to actions aimed at health screening and early detection of disease. This can lead to interventions to prevent disease progression, such as colon cancer screening or breast cancer screening. *Tertiary prevention* refers to activities that limit disease progression such as rehabilitation.

Nursing Management: Chronic Illness

Diagnosis and treatment of the acute phase or acute exacerbations of a chronic illness sometimes take place in a hospital. Other phases of a chronic illness are regularly assessed and managed in an ambulatory care setting, at home, in an assisted living facility, or in a skilled nursing facility.

An assessment of health status, at least annually, includes a person's level of daily functioning and his or her perception of relative health, function, and/or illness. Health assessment includes activities of daily living (ADLs), such as bathing, dressing, eating, toileting, and transferring. It also includes instrumental ADLs (IADLs), such as using a phone, shopping, preparing food, housekeeping, doing laundry, arranging transportation, taking medications, and handling

finances.[3]

Because most chronic illnesses are treated in an ambulatory care setting, it is important for patients and caregivers to understand and manage their own health. The term *self-management* refers to the person's ability to manage his or her health, especially in response to living with a chronic illness. It includes the ability to manage symptoms, medications and treatment plan, physical and psychosocial consequences, and lifestyle changes.[4] Self-management is in conjunction with the family and HCP.

You play a key role in managing patients with chronic illness. This includes conducting a comprehensive history and physical assessment, teaching the patient and caregiver about the treatment plan, implementing strategies for symptom management, and evaluating patient outcomes.

Family caregivers (e.g., spouses, partners, adult children) often have important roles in the life of the chronically ill person. The ideal situation is 1 in which family caregivers work together with the patient to manage the chronic condition(s). This collaboration begins under the direction of the health care team at the time of diagnosis. When the caregiver is a spouse or partner who is also older, he or she may have a chronic illness or multiple chronic conditions as well. This may add a level of complexity to the coordination of care.[5]

Older Adults

Demographics Of Aging

The older adult population (those 65 years of age and older) continues to outpace the rest of the population. Nearly 1 in 7 U.S. residents, more than 47.8 million people, or 14.9% of the population, were age 65 or older in 2016.[6] This is projected to more than double to 98 million in 2060. The U.S. Census Bureau predicts life expectancy to continue to increase for both men and women. Those reaching 65 years have an average life expectancy of an added 19.4 years, specifically 20.6 years for females and 18 years for males.[6] Whether this gender difference is

due to differences in health behaviors (e.g., smoking, alcohol use) or occupation is not known.

The fastest-growing segment of older Americans is people ages 85 or older. The 85 and older population is projected to increase from 6.3 million in 2015 to 14.6 million in 2040.[6] The increase in life span is due to declining infant mortality, new drug therapies, mechanical devices, and improved surgical interventions. A greater emphasis on health promotion, disease prevention, and earlier detection as well as better care management has led to more Americans living past 85 years.

In 2016, 22% of the U.S. population age 65 years or older were of racial or ethnic minority populations, including 9% black; 4% Asian or Pacific Islanders; and 0.5% Native American. People of Hispanic ethnicity (who may be of any race) represented 8% of the older population.[6] The number of older adults of racial or ethnicity populations in the United States is projected to increase from 10.6 million in 2015 (22% of older adults) to 21.1 million in 2030 (28% of older adults).[6]

Gender Differences

Older Adults

Men

- More likely to be married and living with spouse or partner
- More likely to have health insurance
- Higher income after retirement
- Less likely to be involved in caregiving activities
- Overall have fewer chronic health conditions

Women

- More likely to live alone
- More likely to be widowed
- Less likely to have health insurance
- More likely to live in poverty
- Poverty rates highest among minority women
- More likely to lack formal work experience, leading to lower income
- More likely to rely on Social Security as major source of income
- More likely to be caregiver of ill spouse or partner
- Have a higher incidence of chronic health conditions such as arthritis, hypertension, stroke, and diabetes

Upcoming cohorts of older adults will likely have increased access to higher education, employment, technology, and resources than previous cohorts. Between 1970 and 2015, the percent of older adults who had completed high school rose from 28% to 85%.[6] In 2016, about 28% of the population 65 and older have earned a bachelor's degree or higher.[6]

The terms **young-old adult** (65–74 years of age) and **old-old adult** (85 years of age and older) describe 2 groups of older adults with distinct characteristics, needs, and living arrangements. The number of older adults age 65 living in nursing homes increases with age; 1% of those age 65 to 74, 3% of those age 75 to 84, and 9% of those 85 and older live in nursing homes. The old-old adult is often a widowed, divorced, or single woman dependent on family for support or care. Many old-old adults have outlived children, spouses or partners, and siblings.

The **frail older adult** is usually over age 75 with multiple physical, cognitive, and/or mental conditions. These often interfere with self-management and the ability to perform daily activities independently. Frail older adults are discussed later in this chapter on page 64.

Attitudes Toward Aging

Who is old? The answer to this question often depends on the respondent's age and attitude. Your "real" age is set by a date in time. Many factors influence how "old" you feel. These include emotional and physical health, developmental stage, socioeconomic status, culture, and ethnicity. We all age. As we do, we are exposed to new and different life experiences. The accumulation of these differences makes older adults more diverse than any other age-group.

As you assess older adults, consider and value their diversity and life history. Assess their feelings of what it means to be an older adult. Most older adults report having good-to-excellent health despite having a chronic condition. However, those with poor health often report a higher perceived age and lower sense of well-being when compared with healthy older adults. Age is important, but it may not be the most relevant factor in determining the appropriate care of an individual older adult.

Myths and stereotypes about aging are often supported by media reports of older adults who are "problematic." These misconceptions may lead to omissions or errors in assessment and unnecessary limitations or interventions. For example, if you think that all older people are rigid in their thinking, you may not present new ideas to a patient.[7]

Ageism is a negative attitude based on age. Ageism leads to discrimination and disparities in the care given to older adults. If you have negative attitudes, it may be because you fear your own aging process. Or, you are not knowledgeable about aging and the health care needs of the older adult.

Biologic Aging

From a biologic view, *aging* reflects the changes that occur over time. Biologic aging is a multifactorial process involving genetics, diet, and environment.[8] In part, we view biologic aging as a balance of positive and negative factors (Fig. 5.2). Research is directed at increasing the average life span, functional status, and quality of life of older adults. The hope is that we can develop new antiaging therapies to slow

down or reverse age-related changes that result in chronic illness and disability.

Age-Related Physiologic Changes

Age-related changes affect every body system. These changes are normal and occur as people age. However, the age at which specific changes occur differs from person to person and within the same person. For instance, a person who has gray hair at age 45 may have relatively unwrinkled skin at age 80. As a nurse, you will assess for age-related changes. Table 5.5 shows where you can find tables outlining specific age-related assessment findings throughout the book.

Special Older Adult Populations

Chronically Ill Older Adults

Daily living with chronic illness is a reality for many older adults. The incidence of chronic illness triples after age 45. Most people 65 years of age and older have at least 1 chronic condition, and many have multiple conditions.[1] The most common chronic conditions in older adults are hypertension, heart failure, coronary artery disease, chronic obstructive pulmonary disease (COPD), cancer, diabetes, and osteoarthritis. Other common chronic conditions include Alzheimer's disease, vision and hearing deficits, osteoporosis, stroke, Parkinson's disease, and depression.

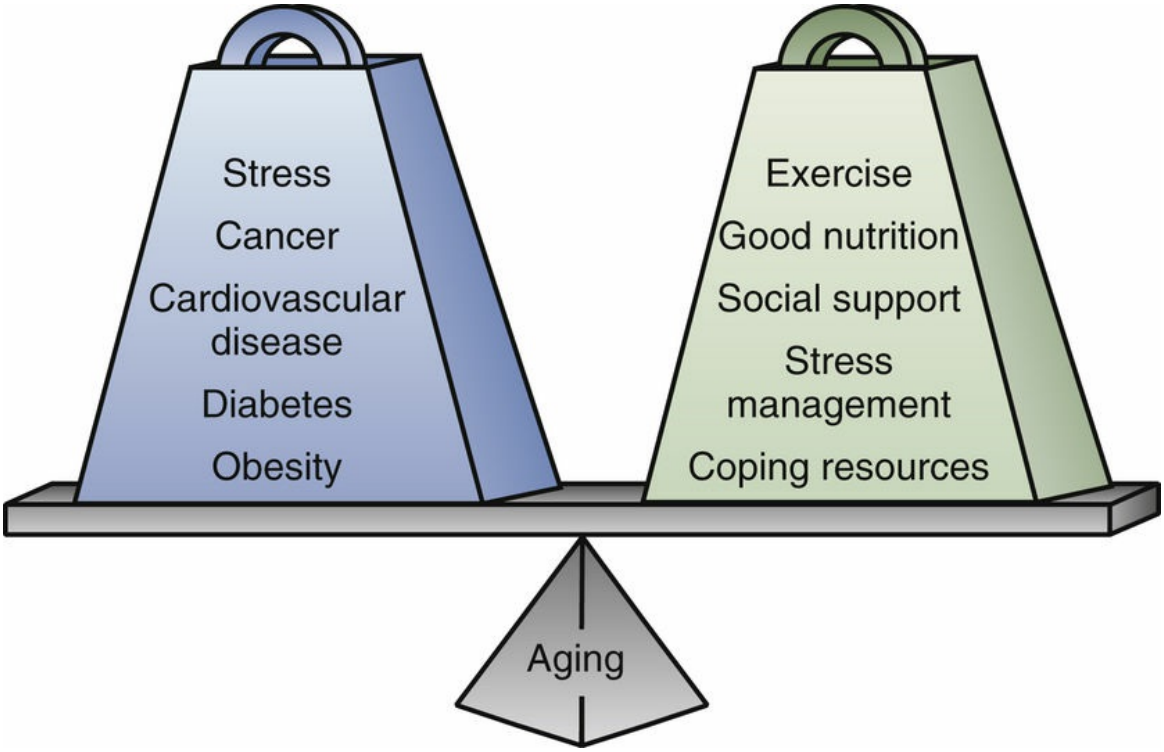

FIG. 5.2 The aging process can be viewed as a balance between negative and positive factors.

Cognitively Impaired Older Adults

Most healthy older adults have no noticeable decline in cognitive abilities (Table 5.6). Older adults may have a mild decline in memory and may need more time to recall events or new information. This differs from cognitive impairment. New learning may be slower. Refer older adults with memory loss to their HCP for an evaluation. Teach them to use memory aids, attempt recall in a calm and quiet environment, and actively engage in enhancing memory. Memory aids include clocks, calendars, notes, marked pillboxes, safety alarms on stoves, and identification necklaces or bracelets. Memory techniques include word association, mental imaging, and mnemonics.

Dementia, delirium, and depression can occur and may coexist in older adults. Declining physical health and acute illness are important factors that may influence cognition. For example, an older adult who

undergoes surgery may have an acute change in mental status known as *delirium*.[9] Delirium superimposed on dementia may signify an acute or emergent condition such as heart failure. Hence, it is important to distinguish signs and symptoms of each. Cognitive impairment, delirium, and dementia are discussed in Chapter 59.

TABLE 5.5 Gerontologic Assessment DifferencesSummary of Tables

Body System	Table Number	Page
Visual	20-1	352
Auditory	21-1	378
Integumentary	22-1	398
Respiratory	25-2	460
Hematologic	29-3	591
Cardiovascular	31-1	661
Gastrointestinal	38-5	835
Urinary	44-2	1012
Endocrine	47-3	1095
Reproductive	50-3	1178
Nervous	55-2	1287
Musculoskeletal	61-1	1434

TABLE 5.6 Gerontologic Assessment DifferencesCognitive Function

Effect of Aging	Cognitive Function
Improves with aging	• Vocabulary and verbal reasoning • Crystallized intelligence (ability to use skills, knowledge, and experience)
Declines during middle age	• Mental performance speed • Synthesis of new information • Fluid intelligence (ability to think logically and solve problems in new situations)
Declines during old age	• Short-term recall memory
Constant (no changes with aging)	• Long-term recall memory

Rural Older Adults

Key barriers to health care access for rural older adults are transportation, limited supply of health care workers and facilities, lack of quality health care, social isolation, and financial limitations. Particularly vulnerable are older adults of racial or ethnic minority living in rural areas, who have even less access to HCPs. Older adults who live in rural areas may be less likely to engage in health-promoting activities.

When you work with older adults in rural areas, recognize lifestyle values and practices of rural life (Fig. 5.3). In planning care, be aware that transportation is the number 1 barrier to health care for rural older adults. Alternative service approaches such as computer-based Internet sources, DVDs, radio, community centers, and church social events may be used to promote healthy practices or to conduct health screening (Fig. 5.4).

The use of telehealth devices for monitoring patients in their home environments has enhanced the ability to provide care, including to those more isolated.[10] We must continue to develop innovative models of nursing practice to help the rural older adult. Older adults are increasingly using technology in their daily lives. Most older adults use the Internet and own a cell phone.[10]

Informatics In Practice

Older Adults and Internet Use

- Sixty-seven percent of older adults use the Internet, as of 2016.
- Older adults may use the Internet to look for health information.
- Many track their weight, diet, and exercise using apps.
- Older adults are more likely to accept as true what they read on the Internet.
- Teach those who use the Internet as a source of information how to assess the credibility of a website.
- Suggest the use of websites and apps that include senior-friendly design elements.

Source: *www.pewinternet.org/2017/05/17/technology-use-among-seniors/*.

Homeless Older Adults

The number of older adults who are homeless is increasing. Key factors associated with homelessness include (1) having a low income, (2) having reduced cognitive capacity, (3) living alone, and (4) living in a community that lacks affordable housing. Homeless older adults may be chronically homeless or recently homeless because of a crisis in either health, economic, or social status.

Mortality rates for homeless older adults are higher than for older adults who have housing. Older homeless adults are at higher risk for more health problems because many aging network services are not designed to reach out to homeless people. They are less likely to use shelters or meal site services than younger homeless people. This may be due to fear of institutionalization. Care for homeless older adults requires an interprofessional approach (including nurses, physicians, social workers, clerical workers, and transporters) that links shelters with outreach, primary care clinics, Medicare and Medicaid offices, pharmacies, senior centers, and Area Agencies on Aging. Long-term care placement is often an alternative to homelessness, especially when the person is cognitively impaired.

FIG. 5.3 Older adults living in rural areas often enjoy outside activities, such as gardening.

Frail Older Adults

Frailty is a common clinical syndrome seen in older adults. Manifestations of frailty include older adults with 3 or more of the following criteria: (1) unintentional weight loss (10 pounds or more in a year); (2) self-reported exhaustion; (3) weakness (measured by grip strength); (4) slow walking speed; and (5) low level of physical activity.[11] Risk factors include disability, multiple chronic conditions, and dementia. People are more likely to become frail if they smoke, have a history of depression or long-term medical health problems, or are underweight. The old-old adult is most at risk for frailty, although many in this age-group are healthy and robust.

Older frail adults experience declining function and decreasing daily energy. When stressful life events (e.g., death of a close friend) and daily strain (e.g., caring for an ill spouse) occur, frail older adults often have ineffective coping mechanisms and, as a result, may become ill. Common health problems of frail older adults include mobility limitations, sensory impairment, cognitive decline, and falls.

TABLE 5.7 SCALES: Nutritional Assessment of Older Adults

The acronym SCALES can remind you to assess important nutritional indicators:

Sadness, or mood change
Cholesterol, high
Albumin, low
Loss or gain of weight
Eating problems (e.g., mechanical problems, such as impaired swallowing, poor dentition)
Shopping and food preparation problems

Frail older adults may tire easily, have little physical reserve, and are at risk for physical dependence and institutionalization. They are especially at risk for malnutrition and dehydration. These are related

to factors such as living alone, depression, and low socioeconomic status. Other factors, such as dementia, inadequate dental care, sensory deficits, fatigue, and limited mobility increase the risk for malnutrition and dehydration. Monitor frail older adults for adequate calorie, protein, iron, calcium, vitamin D, and fluid intake. Use the *SCALES* tool to assess the risk factors for poor nutritional status in older adults (Table 5.7). Once you identify an older adult's nutritional needs, common interventions include home-delivered meals, dietary supplements, Supplemental Nutrition Assistance Program (SNAP), dental referrals, and vitamin supplements.[12] Because medications may affect appetite or interact with nutrients, perform a thorough medication review, including prescription drugs, over-the-counter (OTC) drugs, vitamins, minerals, supplements, herbs, and cultural remedies. Nutrition is discussed in Chapter 39.

Culturally Competent Care: Older Adults

The term **ethnogeriatric** describes the specialty area of providing culturally competent care to older adults.[13] As American society changes, ethnic institutions and neighborhoods may also change. For the older adult with strong ethnic and cultural roots, there may be a loss of friends who speak the native language, a loss of the religious institution that supports social ethnic activities, and a loss of stores that carry desired ethnic foods. This sense of loss is increased when children and others deny or ignore ethnic and cultural practices. Support for older adults of racial or ethnic minority is most often found in the family, religious practices, and isolated geographic or community ethnic clusters.

Ethnic populations of older adults face unique situations. Older adults may live in neighborhoods where physical security and personal safety related to crime may be a concern. Those who identify with particular ethnic groups often have disproportionately lower incomes and may not be able to afford Medicare deductibles or drugs needed to treat chronic illnesses. Older adults from minority populations such as Hispanics use health care services less often when

compared to nonminority groups.[13]

Assess each older adult's ethnic and cultural background. Assume that ethnicity and culture are important and of value to older adults and their families unless they tell you otherwise during an assessment. For you to be effective with the ethnic older adult, a sense of respect and clear communication are critical. Nursing interventions to help meet the needs of ethnic populations are described in Table 2.9.[14] Culturally competent care is discussed in Chapter 2.

Social Support for Older Adults

Social support for older adults occurs at 3 levels. First, family members are the primary and preferred providers of social support. Second, semiformal support is found in clubs, religious (faith-based) organizations, neighborhoods, adult day care, and senior centers. Third, older adults may be linked to formal systems of social welfare agencies, health facilities, and government support. Generally, you, as a nurse, are part of the formal support system.

Family Caregivers

Many older adults need caregiving by family members. This includes those with multiple chronic conditions, those needing help with ADLs and IADLs, and older adults with dementia. The most common caregivers are spouses, adult children, parents, grandparents, and life partners. Older adult women, age 65 or older, are the most common family caregivers.[15] Other examples include husbands who care for wives with Alzheimer's disease, adult children who care for a parent with a stroke, grandparents who care for a grandchild with a developmental disorder, and parents who care for an adult child with a spinal cord injury. Many family caregivers are caring for themselves, their aging parents, and their children and grandchildren.

The caregiver usually takes on responsibilities gradually. For example, a caregiver may initially need only to adjust work schedules to accommodate a patient's health care appointments. Later, as the

patient's needs become greater, the caregiver may have to reduce work hours and provide more help with ADLs.

Caregiving is an experience for which most people are not prepared. It is common for caregivers to become physically, emotionally, and economically overwhelmed by the responsibilities and demands of caring for a loved one. The stress of caregiving may lead to emotional problems such as depression, anger, and resentment. Signs of caregiver stress include irritability, inability to concentrate, fatigue, and sleeplessness. The caregiver often experiences decreased social interactions and may be at risk for social isolation. Multiple commitments, fatigue, and, at times, the patient's socially inappropriate behaviors contribute to the caregiver's social isolation. Stress can progress to burnout and result in negligence and abuse of the patient by the caregiver. Consider collaborating with a social worker if caregiver stress or strain is present and caregivers need respite.

Encourage caregivers to take care of themselves. Suggest journaling or joining a support group to help them share feelings that may be hard to express. Remind caregivers that getting regular exercise and sleep and eating balanced meals will enhance their well-being. Encourage contact with others to give emotional support. Finally, humor is important. Sometimes its use by caregivers can provide distraction and relieve stress-filled situations.

Elder Mistreatment

Elder mistreatment (EM) describes intentional acts of omission or commission by a caregiver or "trusted other" that cause harm or serious risk for harm to a vulnerable older adult. EM may occur in community (home or assisted living facility) or long-term care (institutional) settings.

Between 2 and 10% of community-dwelling older adults in the United States are abused, neglected, or exploited by trusted others.[16] The prevalence of EM in institutional settings is unknown, but it is thought to be widespread. Although EM rates are similar in women

and men, most victims are women because of the predominance of women in older age cohorts. Victims of EM have a mortality risk that is 3 times higher than that of nonmistreated peers. The higher mortality risk is not due to the abuse or neglect itself but may be due to stress-related illnesses associated with prolonged mistreatment.[16]

EM is a hidden problem. For every reported case in the community setting, more than 5 cases go unreported. Underreporting may be higher based on immigration status, ethnic background, or sexual orientation. Victims are unlikely to report mistreatment by "trusted others" because of isolation; impaired cognitive or physical function; feelings of shame, guilt, or self-blame; fear of reprisal; pressure from family members; fear of long-term care; or cultural norms. HCPs also underreport EM, possibly from a failure to suspect or recognize EM, perceived inability to successfully intervene, desire to avoid responsibility for further action, or ageism.

Family members are responsible for up to 90% of domestic EM.[16] Adult children who abuse, neglect, or exploit their parents are usually dependent on their parent(s) for housing and financial support, have a history of violence, are unemployed, and/or are disabled from substance use or mental illness. Abusive spouses or partners may either begin intimate partner violence in older age or continue a lifelong pattern of abuse.

Many factors put community-dwelling older adults at risk for domestic EM. These include (1) physical or cognitive dysfunction that leads to an inability to perform ADLs (and therefore produces dependence on others for care), (2) any psychiatric diagnoses, including dementia and depression, (3) alcohol misuse and abuse, (4) decreased social support; (5) living with a large number of household members other than a spouse and (6) low income.[17] In long-term care settings the same factors that lead to institutionalization are risk factors for mistreatment by staff, visitors, and others. These include dependence on others for care because of physical or cognitive limitations.

Types of EM, characteristics, and manifestations are shown in Table 5.8. In institutional settings, EM includes the types described in Table

5.8 as well as failure to follow the plan of care, unauthorized use of physical or chemical restraints, overuse or underuse of medication, or isolation as punishment.

Follow your organization's protocols for EM screening and interventions. Perform a thorough history and physical examination that includes screening for mistreatment. It is important that you interview people alone. If mistreatment is occurring, they may not disclose it in the presence of the person who is with them, especially if that person is the abuser. Be especially attentive to explanations about injuries that are not consistent with what you observe, contradictory explanations between the patient and the caregiver, or behavioral clues that suggest the patient is being threatened or intimidated. Other nursing assessments and interventions are listed in Table 5.9. In most states, health care workers are among those mandated to report suspected or actual EM to Adult Protective Services (APS) and/or law enforcement. Know your legal responsibilities by checking the laws in your state.

Self-Neglect

Most referrals made to APS are for self-neglect. Older adults who self-neglect are often unable to meet their basic needs and refuse help; have multiple, untreated medical or psychiatric conditions; and live alone and often in squalor. Older community-dwelling adults who self-neglect face a higher risk for mortality than peers who do not self-neglect.[18] Nursing interventions include assessment for possible self-neglect, referrals for long-term interprofessional case management, and referral to APS.

TABLE 5.8 Types of Elder Mistreatment

Characteristics	Manifestations
Abandonment	
Desertion of an older person by a person who has assumed responsibility for providing care or by a person with physical custody.	Older adult's reports of being abandoned; deserting an older adult at a hospital or skilled nursing facility, shopping center, or other public place.
Financial Abuse	
Denying access to personal resources, stealing money or possessions. Coercing to sign contracts or durable power of attorney. Making changes in will or trust.	Living situation below level of personal resources. Sudden change in personal finances, sudden transfer of assets.
Neglect	
Failure or refusal to provide basic life needs, including food, water, medications, clothing, hygiene. Failure to provide physical aids such as dentures, eyeglasses, hearing aid. Failure to ensure safety.	Older adult's report of being neglected. Untreated or infected pressure injuries on sacral area, heels. Weight loss, malnutrition. Laboratory values showing dehydration. Poor personal hygiene. Lack of adherence with medical treatment.
Failure to provide social stimulation. Leaving alone for long periods. Failure to provide companionship.	Depression, withdrawn behavior, agitation. Ambivalent attitude toward caregiver or family member.
Physical Abuse	
Slapping, striking, restraining, incorrect positioning. Oversedation with medications.	Bruises, bilateral injuries (upper arms, ankles, wrists), repeated injuries in various stages of healing, burn marks, oversedation. Use of several emergency departments.
Psychologic Abuse	
Berating verbally, harassment, intimidation, threats of punishment, or deprivation. Childlike treatment, isolation.	Depression, withdrawn behavior, agitation. Ambivalent attitude toward caregiver or family member.
Sexual Abuse	
Nonconsensual sexual contact, including touching inappropriately. Forced sexual contact.	Older adult's report of sexual abuse. Unexplained vaginal or anal bleeding, bruised breasts, unexplained sexually transmitted or genital infections.
Violation of Personal Rights	
Denying right to privacy or right to make decisions about health care or living environment. Forcible eviction.	Sudden inexplicable changes in living situation, confusion.

Social Services for Older Adults

A network of services supports older adults in the community and health care facilities. In the United States, most older adults are the beneficiaries of at least 1 social or governmental service. To understand the older adult's situation, learn about government structures that fund and regulate programs for older adults. The Administration on Aging (AoA), which is part of the Department of Health and Human Services, is the federal agency responsible for many older adult programs. Funding from the AoA is given to state and local Area Agencies on Aging (AAAs).

TABLE 5.9 Nursing ManagementElder Mistreatment

When elder mistreatment is suspected, it is important to do the following:

- Screen for possible elder mistreatment, including domestic violence.
- Conduct a thorough history and head-to-toe physical assessment. Document your findings, including any statements made by the older adult or accompanying adult.
- If the older adult appears to be in immediate danger, develop and implement a safety plan in collaboration with the interprofessional team involved in the person's care.
- Identify, collect, and preserve physical evidence (e.g., dirty or bloody clothing dressing sheets).
- After obtaining consent, take photographs to document physical findings of suspected abuse or neglect. If possible and appropriate, do this before treating or bathing the alleged victim.
- If you suspect that mistreatment is occurring, report your findings to the state agency and/or law enforcement as mandated by the laws in your state.
- Initiate appropriate consultations with social work, forensic nursing, and adult protective services.

Medicare and Medicaid

Medicare is a federally funded health insurance program for people ages 65 years or older. It also covers people under age 65 with certain disabilities and people of any age with end-stage renal disease (ESRD) requiring dialysis or a kidney transplant.

Medicare has 4 options for coverage: A, B, C, and D. Part A covers inpatient hospital care and partially covers skilled nursing facility care, hospice, and home health care. Part A coverage is "free" because workers support Medicare through payroll taxes. Medicare Part B partially covers outpatient care, physicians' or primary care providers' services, and home health care. It also covers some preventive services, such as mammograms. Medicare Part B is voluntary and has a monthly premium and an annual deductible before payment begins. Medicare Advantage Plans, sometimes called "Part C" or "MA Plans,"

are offered by private companies approved by Medicare to provide Part A and Part B benefits. Part D is available to Medicare enrollees and provides a prescription drug benefit. Members pay a yearly deductible, monthly premium, and copayment. People with lower incomes and limited assets may qualify for extra help to pay for prescriptions.

Medicare does not cover long-term care, custodial ADLs or IADLs care, dental care or dentures, hearing aids, or eyeglasses. (More information is available at *www.medicare.gov*.) Out-of-pocket expenditures for people on Medicare continue to rise. The costs increase with age, functional disabilities, number of chronic conditions, and number of hospitalizations.[19]

Medicaid is a state-administered, needs-based program to help eligible low-income people, including Medicare beneficiaries, with certain medical expenses. Those who qualify for both Medicare and Medicaid are referred to as *dual-eligible.* Eligibility and coverage vary by state. For qualified Medicare beneficiaries, Medicaid pays Medicare premiums, deductibles, and co-insurance, as well as long-term care and home health expenses. In the United States most long-term care is paid for by Medicaid or private pay. (More information is available at *www.medicaid.gov*.)

FIG. 5.5 Senior centers offer places for older adults who live independently to meet and gather with friends.

Care Alternatives for Older Adults

Older adults with special care needs include people who are homeless, in need of help with ADLs, cognitively impaired, homebound, or no longer able to live at home. Older adults may be served by adult day care, adult day health care, home health care, and long-term care. Continuing care retirement communities, congregate housing, and assisted living facilities are housing options for older adults.

Adult Day Care and Adult Day Health Care

Adult day care centers provide social, recreational, and health-related services to people in a safe, community-based environment (Fig. 5.5). This includes daily supervision, social activities, opportunities for social interaction, and ADLs help for 2 groups of adults: (1) those who are cognitively impaired and (2) those who have problems independently performing ADLs. Adult day care programs provide individualized services based on need. Programs designed for adults who are cognitively impaired offer therapeutic recreation, support for family, family counseling, and social involvement.

Adult day health care centers are like adult day care but provide care to meet the needs of older adults and people with disabilities who need a higher level of care. This might include health monitoring, therapeutic activities, 1-on-1 ADLs training, and personal services.

Adult day care centers and adult day health care centers may offer respite to allow continued employment for the caregiver and delay institutionalization of older adults. States set standards and regulate centers. Medicare does not cover costs. Adult day health care is tax deductible as dependent care. Appropriate placement in adult care programs that match participants' needs is important. You can help by knowing the available centers in your area and assessing the needs of older adults and their families. You will then be able to help them make good decisions about their care.

Home Health Care

Home health care (HHC) can be a cost-effective care alternative for older adults who are homebound, have health needs that are intermittent or acute, and have supportive caregiver involvement. HHC is not an alternative for adults in need of 24-hour help with ADLs or continuous safety supervision. Private duty care may be an alternative in these situations. HHC services require physician orders and skilled nursing care for Medicare reimbursement. Unless one meets these requirements, Medicare will not pay for home health aides for ADLs management or a homemaker for IADLs management.

In addition to HHC, caregivers often seek homemaker services and respite and personal care through organizations that provide nonmedical assistance. These services help older adults stay at home.

Long-Term Care Facilities

Three factors appear to precipitate placement in a long-term care facility: (1) rapid patient deterioration, (2) caregiver inability to continue care because of stress and burnout, and (3) a change in or loss of the family support system. Progressive dementia, urinary incontinence, or a major health event (e.g., stroke) can hasten long-term care placement.

The conflicts and fears faced by older adults and their families make placement a difficult transition. Common caregiver concerns include: (1) Will the older adult resist the admission process? (2) Will the level of care given by staff be insufficient? (3) Will the resident be lonely? and (4) Will nursing care be affordable?

The physical relocation of the older adult may lead to adverse health effects. *Relocation stress syndrome* is associated with the disruption, confusion, and challenges that older adults face when moving to a new environment. Older adults may have anxiety, depression, and disorientation. Appropriate interventions can reduce the effects of relocation. Whenever possible, involve older adults in the decision to move and fully inform them about the location. Caregivers can share information, pictures, or a video recording of the new location. Staff members at the institution can send a welcome message. On arrival, they can greet new residents and provide orientation. To bridge the relocation, new residents can be "buddied" with seasoned residents (Fig. 5.6).

Programs for All-Inclusive Care for the Elderly (PACE)

Programs for All-Inclusive Care for the Elderly (PACE) provide care for adults age 55 and older. PACE services include primary care

including prescription medications and wound care; physical, occupational, recreational, and speech therapy; adult day care; dental; podiatry; social services; and home health care. Respite care, hospitalization, short-term rehabilitation, and long-term care are provided as needed.[20]

FIG. 5.6 Social interaction and acceptance are important for older adults.
©Hemera/Thinkstock.

A person who has Medicaid will not have to pay a monthly premium for the long-term portion of the PACE benefit. A person who does not qualify for Medicaid but has Medicare must pay a monthly premium to cover the long-term care portion.

Legal and Ethical Issues

Legal guidance and assistance is needed by many older adults. Legal

issues include advance directives, estate planning, taxation issues, appeals for denied services (e.g., disability), financial decisions, or exploitation by strangers or "trusted others."

Advance directives are written statements of a person's wishes about medical care. A health care proxy may be appointed to make medical decisions if a person is unable to make his or her own medical decisions. These documents allow people to direct their own care at end of life. Advance directives are discussed in detail in Chapter 9 and Table 9.6.

When working with older adults, you may find several ethical issues that influence practice, such as the assessment of older adults' ability to make decisions. Other ethical issues related to end-of-life care include decisions about resuscitation, treatment of infections, nutrition and hydration, and transfer to more intensive treatment units and the hospital. These situations are often complex, especially during emotionally difficult times. You can assist the older adult, family, and other health care workers by (1) keeping current on the ethical issues, (2) acknowledging when an ethical dilemma is present, and (3) advocating for an institutional ethics committee to help provide guidance in the decision-making process and assist when differences of opinion occur.

Nursing Management: Older Adults

Gerontologic nursing is the care of older adults based on the specialty body of knowledge of gerontology and nursing. These specialty nurses provide care for older adults using a whole-person (physical, psychologic, functional, developmental, socioeconomic, cultural) perspective. Care of older adults is complex and presents challenges that require skilled assessment and creative nursing interventions tailored to this population.

Diseases and conditions in older adults may be hard to accurately assess and diagnose. Older adults may underreport symptoms and try to manage these symptoms by changing their functional status. For example, a woman having loss of feeling in her feet because of

neuropathy may start using a walker to get around, while not reporting the symptom to her HCP. The older adult may attribute a new symptom to "aging" and ignore it. The older adult may eat less, sleep more, or "wait it out."

In older adults, disease symptoms are often atypical. For example, confusion may be a sign of an infection. A patient being treated for a urinary tract infection may be diagnosed with asymptomatic heart disease. Pathologic conditions with similar symptoms can be confused. For example, depression may be misdiagnosed and treated as dementia. The most common atypical illness presentations are "delirium" or "acute change in mental status" and change in functional status. A caregiver may say that a relative "is acting differently," "doesn't appear as him/herself," or is no longer taking part in usual activities or self-care.

In older adults a *cascade disease pattern* may occur. For example, a person who has insomnia treats the condition with a sleeping medication becomes lethargic and delirious and falls, sustaining a hip fracture. This decreases activity and mobility, leading to pneumonia and/or pressure injuries. Nurses play a vital role in preventing this downward trajectory.

For older adults, the stress of an illness may lead to fear and anxiety. They may view health care personnel as helpful but perceive institutions as negative and potentially harmful places. Communicate a sense of concern and care by use of direct and simple statements, appropriate eye contact, direct touch, and gentle humor. These actions help the older adult relax in this stressful situation.

Nursing Assessment

Prior to assessment, attend to the person's primary needs. For example, ensure that older adults are comfortable and ask if they need to use the bathroom. If older adults normally use eyeglasses and hearing aids, ask them to use these during the assessment. Place all assistive devices, such as walkers, within reach. Assess your patient's level of fatigue and pause the interview if necessary. Allow adequate time to offer information and time for the person to respond to

questions. Interview both the older adult and his or her family or caregivers. You can do this separately, unless the patient is cognitively impaired or specifically requests the caregiver's presence. Although the health history may be lengthy, it is important to obtain. Review medical records and determine what information is most relevant or needs more detail.

The focus of a comprehensive geriatric assessment is to determine appropriate interventions to support and enhance the health, quality of life, function, and independence of older adults. At a minimum, it includes the medical history, functional assessment, medication review, cognitive and mood evaluation, social resources, and physical examination followed by recommended diagnostic tests. Comprehensive geriatric assessment is often conducted by an interprofessional geriatric assessment team. This team minimally includes a staff nurse, an HCP such as a physician or adult-geriatric nurse practitioner, and a social worker. It may also include a physical and/or occupational therapist, dietitian, podiatrist, ophthalmologist, dentist, and pastoral care representative. After the assessment is complete, the interprofessional team meets with the patient and family to present the team's findings and recommendations.

Specific elements in a comprehensive nursing assessment include a thorough history, mood assessment, functional assessment including ADLs and IADLs, mental status evaluation, social-environmental assessment, and physical assessment. Evaluation of mental status is particularly important for older adults because these results often determine the potential for independent living. *SPICES,* an effective tool for obtaining assessment data in older adults, may be used as an initial nursing assessment in any setting (Fig. 5.7). Multiple evidence-based geriatric assessment tools and best practice approaches to nursing care for older adults are available from the *Try This* Series at the Hartford Institute for Geriatric Nursing (available at *www.consultgeri.org/tools*).

A comprehensive geriatric assessment includes fall risk, fear of falling, cause(s) of past falls, and post-fall assessment. Those at increased risk for falls have a history of falls or a fear of falling. Many

factors increase the risk for falls, including prescription and nonprescription medications; infection; orthostatic hypotension; dehydration; electrolyte imbalance or other laboratory abnormalities; arthritis; changes in gait, balance, and mobility; neurologic impairment (e.g., stroke, Parkinson's disease); decreased muscle strength; and decreased visual acuity. Assess for symptoms of dizziness or lightheadedness upon standing. Other risk factors include environmental hazards, feet abnormalities, poor footwear, clutter, throw rugs, incorrect use of an assistive device such as a walker or cane, shiny or waxy floors, slippery floors, poor lighting, bed in an incorrect position such as too high, and uneven pavement.

Evaluation of the results of a comprehensive nursing assessment helps determine the service and potential long-term placement needs of older adults. Collect data about community resources that will help older adults and their caregivers in supporting maximal function. The goal is to plan and implement actions that help older adults stay as functionally independent as possible and to promote their quality of life.

Planning

When setting goals with older adults, identify their strengths and abilities. Include caregivers in planning. Priority goals may include gaining a sense of control, feeling safe, and reducing stress.

Nursing Implementation

When carrying out a plan of action for older adults, adjust your approach and actions based on their physical, functional, and mental status. The small body size common in frail older adults may require the use of pediatric equipment (e.g., BP cuff). Safety is a primary concern when caring for an older adult. Those with bone and joint changes often need transfer assistance, altered positioning, and use of gait belts and lift devices. Older adults with declining energy reserves may need extra time to complete tasks. A slower approach and the use of other adaptive equipment may be needed. Cognitive impairment, if

present, requires that you offer careful explanations and a calm approach to avoid producing anxiety and resistance. Depression can result in apathy and poor cooperation with the treatment plan.

Health Promotion

Health promotion and prevention of health problems for older adults focus on 3 areas: (1) increased participation in health promotion and disease prevention activities (Fig. 5.8), (2) reduction in diseases and health-related issues, and (3) increased use of services that reduce health hazards. Programs exist for screening for chronic health conditions, tobacco cessation, geriatric foot care, vision and hearing screening, stress reduction, exercise programs, fall prevention programs, drug usage, crime prevention, elder mistreatment, and home safety assessment.[3] Teach older adults about the need for specific preventive services and available programs.

Promoting Population Health

Promoting Health in Older Adults

- Get influenza, pneumococcal, shingles, and tetanus vaccines as needed.
- Create a living environment free of hazards to reduce the risk for falling.
- Drink plenty of liquids. Limit drinks with lots of added sugar or salt.
- Be physically active 3 to 5 days each week.
- Maintain an appropriate weight based on a nutrient-rich diet.

- Use medications, herbs, and supplements according to your HCP's direction.

Include health promotion and disease prevention in nursing interventions and plans at any setting or level of care in which nurses and older adults interact. You can use health promotion activities to increase personal responsibility for health and independent functioning. Teaching and reinforcement are important tools for you to use to enhance self-care practices by older adults. Patient teaching is discussed in Chapter 4.

Acute and Ambulatory Care

The hospital may be the first point of contact for older adults with the health care system. Conditions that often result in hospitalization include falls, dysrhythmias, heart failure, stroke, fluid and electrolyte imbalances (e.g., hyponatremia, dehydration), pneumonia, urosepsis, and hip fractures. Hospitalized older adults often have multiple problems.

When older adults are being cared for in the acute care setting, both patients and caregivers need help with a variety of functions (Table 5.10). The outcome of hospitalization for older adults varies. Of special concern are patients undergoing high-risk surgical procedures (e.g., hip replacement) and those who have delirium while hospitalized.

Care Transitions

The time of a care transition to another setting (e.g., acute care hospital to rehabilitation) is challenging for many older adults. While in the hospital, patients and caregivers are counseled on how to prepare for posthospital care. Those with multiple health conditions have a particularly high risk for rehospitalization.

Medicare regulations require a registered nurse, social worker, or qualified person to develop a care transition plan for patient discharge. Safe and effective care transitions are most likely to occur when interprofessional team members work together with the patient and family to coordinate care.

TABLE 5.10 Nursing ManagementCare of the Hospitalized Older Adult

Give special consideration to the following nursing interventions when caring for hospitalized older adult:

- Identify older adults at risk for consequences of medical and/or surgical treatments).
- Consider discharge and postacute needs early in the hospital stay, especially assistance with activities of daily living and medications.
- Encourage the development and use of interprofessional teams, special care units, and providers who focus on the special needs of older patients.
- Implement standard protocols to screen for at-risk conditions common in the hospitalized older adult, such as urinary tract infection and delirium.
- Implement mobility and exercise programs to prevent functional decline.
- Monitor for and prevent skin integrity changes.
- Implement measures focused on safety (e.g., fall prevention).
- Refer patients to the appropriate community-based services.

The Transitional Care Model (TCM) is an evidence-based, innovative approach to care coordination and management of the complex needs of older adults.[21] In this model a transitional care nurse delivers and coordinates care by nurses and other team members throughout potential and acute episodes of illness. Those most likely to benefit from transitional care nursing include those of older age and those with functional deficits, behavioral or psychiatric issues, multiple chronic conditions, polypharmacy, a recent hospitalization, lack of a support system, low health literacy, and history of non-adherence to treatment.[21]

Rehabilitation

The goal of rehabilitation is to help older adults adapt to or recover from disability or an acute functional decline. Rehabilitation may occur in acute inpatient rehabilitation, subacute rehabilitation, or long-term care settings. With proper training, assistive equipment, and attendant personal care, people with functional deficits may live independently. Older adults, primarily through Medicare reimbursement, can receive rehabilitative assistance through acute inpatient rehabilitation (limited days) and home health care programs (Fig. 5.9).

Older adults with chronic conditions, such as arthritis, have increased risk for functional decline. Decreased function or disabilities lead to increased self-care deficits, increased rates of institutionalization, decreased quality of life, and higher mortality rates.

Several factors influence the rehabilitation of older adults. First, preexisting conditions associated with decreased reaction time, visual acuity, fine motor ability, physical strength, and cognitive function affect the short- and long-term rehabilitation potential. Older adults may have anxiety, fear, or concern about falling. Poor nutrition and financial issues may limit the rehabilitation process. Encouragement, support, and acceptance from the interdisciplinary team members as well as their caregivers can help older adults remain motivated for potentially physically challenging rehabilitation.

Second, older adults often lose function because of inactivity and immobility. This deconditioning can occur because of unstable acute medical conditions, lack of assistive devices, and a lack of motivation to stay fit. The effect of inactivity leads to “use it or lose it” consequences. Older adults can improve flexibility, strength, and aerobic capacity even into very old age. Passive and active range-of-motion exercises are used with all older adults to preserve muscle tone and strength and prevent deconditioning and subsequent functional decline.

FIG. 5.9 The nurse assists a patient in a geriatric rehabilitation facility.
© KeithBrofsky/Photodisc/Thinkstock.

Last, the goal of rehabilitation is to strive for maximal function and physical capabilities considering the person's current health and functional status. For example, on admission to an acute or long-term care facility and home health services, assess for fall risk as well as the person's fear of falling. Initiate appropriate fall prevention interventions and assess for ongoing risk. Conduct comprehensive foot and peripheral vascular assessments for all older adults, especially those with diabetes, and arrange appropriate follow-up care.

Assistive Devices

Consider the use of assistive devices as interventions for older adults. Using appropriate assistive devices such as dentures, glasses, hearing aids, walkers, wheelchairs, adaptive utensils, elevated toilet seats, and skin protective devices can increase function. Include these tools and devices in the older adult's care plan when needed and teach the

proper use of the devices. For example, using a cane correctly may decrease fall risk.

Technology can help with rehabilitation and living with functional impairments. For example, we can use electronic monitoring equipment to monitor heart rhythm and BP. Monitoring can locate a person with dementia who has wandered away from home or a long-term care facility. Computerized assistive devices may help patients with speech difficulties after a stroke. Small electronic devices can serve as memory aids.

Safety

Safety is crucial in the health maintenance of older adults. When compared to younger adults, older adults are at higher risk for accidents due to normal sensory changes, slowed reaction time, decreased thermal and pain sensitivity, changes in gait and balance, and medication effects. Most accidents occur in or around the home. Falls, motor vehicle accidents, and fires are common causes of accidental death in older adults. Declining thermoregulation impairs the older person's ability to adapt to extremes in environmental temperatures. The bodies of older adults can neither conserve nor dissipate heat as efficiently as those of younger adults. Therefore both hypothermia and hyperthermia occur more readily. The older adult age-group accounts for most deaths during severe cold spells and heat waves.

You can review environmental changes that can improve safety for older adults. Measures such as colored step strips, tub and toilet grab bars, and stairway handrails can be effective in "safety-proofing" the living spaces of older adults. Uncluttered floor space (e.g., removal of throw rugs), railings, and increased lighting and night-lights are some of the easiest and most practical adaptations. Social workers may help older adults implement these environmental changes. You can advocate for home fire and security alarms.

Other interventions to decrease the risk for falling include exercise, physical therapy, and management of foot and footwear issues. Encourage the patient's use of glasses and hearing aids as ordered.

Fear of falling can affect the older adults' decisions about the activities that they engage in and how active they remain.

Older adults who are new to inpatient or long-term care settings need a thorough orientation to the environment. Reassure the older adult that he or she is safe. Answer all questions and refer to interprofessional team members and specialists as needed. Foster orientation by displaying large-print clocks, keeping wall designs simple, clearly designating doors and exits, and using simple bed and nurse or family-call controls. Provide diffuse lighting while avoiding glare.

Medication Use

Medication use in older adults requires thorough and regular assessment, care planning, and evaluation. Nonadherence to medication plans by older adults is common. Many older adults are unable to read prescription drug labels and understand the health information that we provide them.

Age-related changes alter the pharmacodynamics and pharmacokinetics of drugs. Drug-drug, drug-nutrient, and drug-disease interactions influence the absorption, distribution, metabolism, and excretion of drugs. The most dramatic changes with aging are related to drug metabolism (Fig. 5.10). Hepatic blood flow and the enzymes responsible for drug metabolism decrease markedly with aging. These increase drug half-life in older adults and lead to greater risk for drug toxicity and adverse drug events. Overall, by age 75 to 80, there is a 50% decline in the renal clearance of drugs. Older adults with altered renal function may need a lower dose and/or decreased frequency of administration of a drug excreted by the kidney. When drug level monitoring is available (e.g., digoxin), identify toxic levels by serum monitoring at regular intervals, especially when there is a change of dose and/or frequency of administration.

Older adults may have difficulty managing medication due to cognitive impairment, altered sensory perception, and limited hand mobility or dexterity. Table 5.11 lists common reasons for drug errors

made by older adults.

Polypharmacy (the use of multiple medications by a person who has more than 1 health problem), overdose, and addiction to prescription drugs are major causes of illness in older adults.[22] Potential medication errors include the (1) taking both brand and generic medications, (2) refilling medications too soon or too late (resulting in taking the medication incorrectly), and (3) drug-drug interactions. These errors can be prevented by having a pharmacist review medications regularly. Suggest the use of 1 pharmacy for filling all prescription medications.

The effects of medications in older adults with multiple health problems are particularly challenging to assess and manage. As 1 disease is treated, another may be affected. For example, the use of a drug such as oxybutynin, which is given to treat overactive bladder, may cause confusion. To accurately assess medication knowledge and use, ask older adults to bring all medications (OTC drugs, prescription drugs, vitamins and supplements, laxatives, sleep aids, and herbal remedies) that they take regularly or occasionally to their health care appointment. You will then be able to accurately assess all medications that the patient is taking, including drugs that the person may have omitted or thought unimportant. The American Geriatrics Society (AGS) Beers Criteria are designed to reduce problems with medications in older adults.[22] Table 5.12 describes other nursing interventions to help older adults follow a safe medication routine.

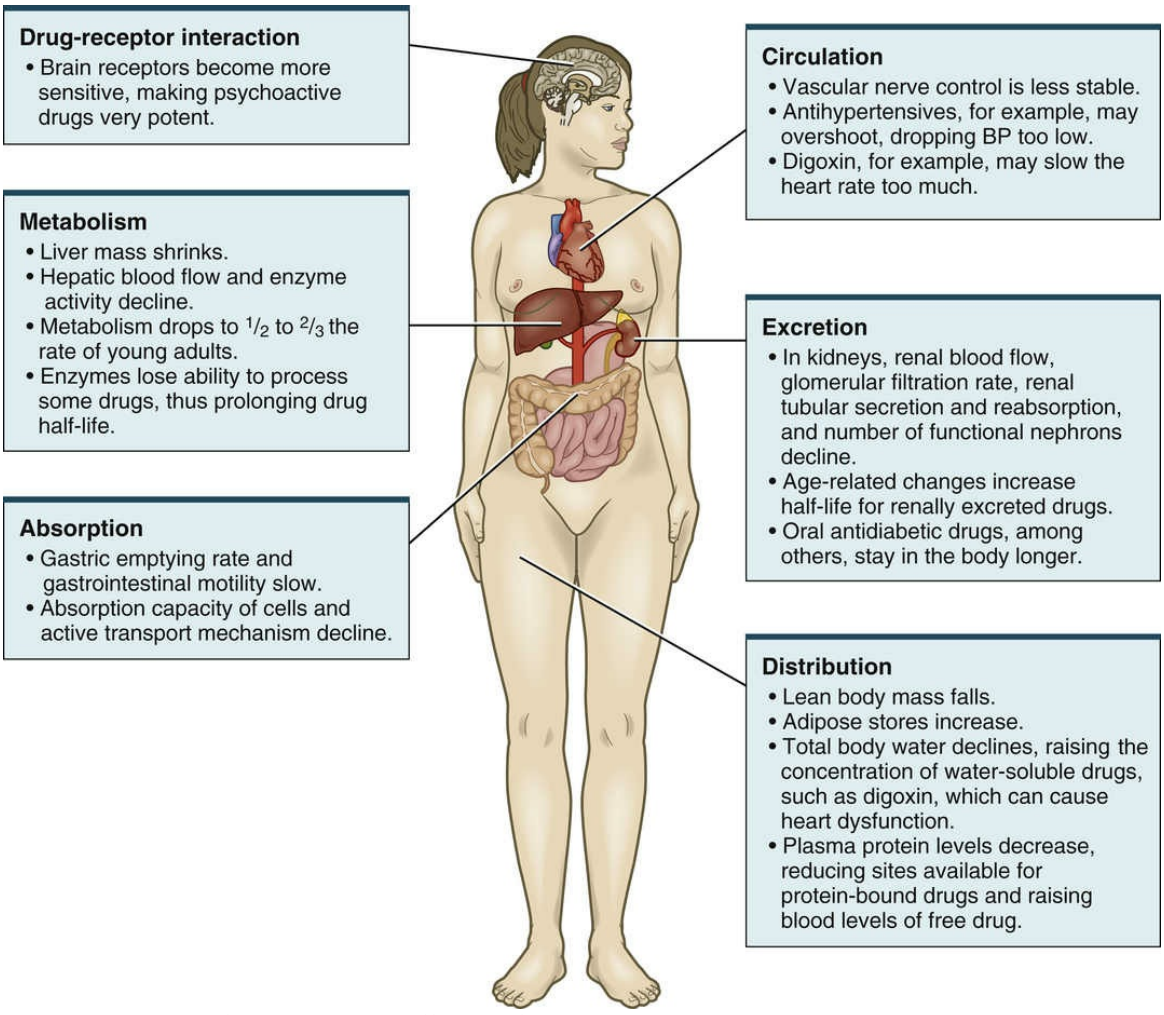

FIG. 5.10 The effects of aging on drug metabolism.

TABLE 5.11 Drug TherapyCauses of Medication Errors by Older Adults

- Decreased vision
- Forgetting to take drugs
- Use of nonprescription over-the-counter drugs
- Use of medications prescribed for someone else
- Lack of financial resources to obtain prescribed medication
- Refusal to take medication because of undesirable side effects

- Failure to understand instructions or importance of drug treatment

Depression

Depression is not a normal part of aging. However, it is often an underrecognized problem in older adults. Around 15% of older adults living in their homes have manifestations of depression. Rates of depressive symptoms in older adults in institutional settings are higher. The second highest rate of suicide occurs in those over 75.

Depression is associated with female gender, being divorced or separated, low socioeconomic status, poor social support, and a recent adverse and unexpected event. Depression in older adults tends to arise from a loss of self-esteem and may be related to life situations, such as retirement or loss of a spouse or partner. Problems such as pain, insomnia, lethargy, agitation, weight loss, and dementia are associated with depression.

TABLE 5.12 Drug TherapySafe Medication Use by Older Adults

When older adults are using medications, it is important to take the following measures to prevent medication errors:

- Assess cognitive function and monitor for changes.
- Try to reduce medication use that is not essential by consulting the HCP and pharmacist.
- Assess ability to self-administer medication and overall medication use, including prescription drugs; OTC drugs; pain treatments; antihistamines; cough syrups; vitamins, minerals, and supplements; sleep remedies; and herbal remedies.
- Assess alcohol and illicit drug use.
- Encourage the use of written or electronic medication-reminder systems.

- Encourage the use of 1 pharmacy.
- Work with HCPs and pharmacists to set up routine drug profiles on all older adult patients.
- Advocate for low-income prescription support services.

Late-life depression often occurs together with medical conditions, such as heart disease, stroke, diabetes, and cancer. Depression can worsen medical conditions by affecting adherence to diet, exercise, or drug regimens. It is important that your assessment include physical examination and interpretation of laboratory results for physical disorders that may have symptoms similar to those of depression (e.g., thyroid disorders, vitamin deficiencies).

Encourage older adults who have depressive symptoms to seek treatment. Because older adults with depression may feel unworthy, withdrawn, and isolated, the support of the family or others in encouraging older adults to seek treatment is important. Assist older adult caregivers who have depressive symptoms to seek medical attention, and help them in secure respite services and support for their caregiving role.

Restraint Use

Physical restraints are devices, materials, and equipment that physically prevent persons from moving freely, such as walking, standing, lying, transferring, or sitting. *Chemical restraints* are drugs used to restrict a patient's freedom of movement or in some cases to sedate a patient. The current standard is to provide safe care without using restraints of any form, whether physical or chemical. Restraints are a last resort in the care of older adults. Only use restraints to ensure the person's safety or the safety of others.

Before considering the use of any restraint, completely assess the perceived need for the restraint and document the assessment. Behavioral symptoms, such as crying and shouting, may arise from co-morbidities, pain, medication effects, unmet needs, and/or environmental factors. When behavioral manifestations are present, ask the following questions to better understand the patient's

behavior: Is the person able to say what she or he needs and wants? People with dementia may respond by speaking, gesturing, nodding, or making eye contact. Questions that use "yes" or "no" answers are better than open-ended questions for gathering assessment information. Ask family, friends, or staff members from previous care settings about the patient's (1) history; (2) usual communication style and cues to indicate pain, fatigue, hunger, or a need to urinate or defecate; (3) abilities in ADLs; and (4) daily routines (e.g., "Is he often awake at night or an early riser?" "Does she prefer breakfast before dressing? Take an afternoon nap? Have a routine for dressing?").

Evaluate whether disruptive behaviors signal unmet physiologic or psychosocial needs. For example, a patient who tries to get out of bed without help may be trying to reach the toilet. A toileting schedule will help to curtail such attempts and prevent incontinence.

Long-term care regulations and The Joint Commission set standards for restraint use. These include time limit, observation and care, mandating use of least restrictive measures (e.g., mittens), and alternatives to restraint use. Restraint alternatives include low beds, body props, and electronic devices (such as bed and chair alarm signaling). Such approaches support the development of a "restraint-free," safe environment. Alternatives to restraints require vigilant, creative, and sensitive nursing care.

All restraints require an order from an HCP. Carefully document restraint use and the reason for use. It is not appropriate to use restraints to prevent falls, avoid interference with medical devices, or reduce irritating behaviors, such as calling out. Frequent scheduled reviews of the ongoing need for the restraint are done with consideration of when to discontinue the restraint.

Sleep

Adequacy of sleep is often a concern for older adults because of altered sleep patterns. Older people have a marked decrease in deep sleep and are easily aroused. Many older adults report difficulty going to sleep and staying sleep. They may feel "unrefreshed" after sleep. See Chapter 7 for more about the sleep problems of older adults.

Evaluation

The evaluation phase of the nursing process is similar for all patients. The results of evaluation direct you to continue the plan of care or revise as needed. When evaluating nursing care with older adults, focus on functional improvement and quality of life. Useful questions to consider when evaluating the plan of care for older adults are outlined in Table 5.13.

TABLE 5.13 Evaluating Nursing Care for Older Adults

Use the following questions to evaluate the effectiveness of care for older adults:

- Is there an identifiable change in function, mental status, or signs and symptoms of exacerbation of chronic condition(s)?
- Does the person consider his or her health state to be improved?
- Does the person think the plan is helpful?
- Do the person and caregiver think the care is worth the time and cost?
- Can you document positive changes that support the interventions?

Case Study

Older Adults

©azndc/iStock/Thinkstock.

Patient Profile

C.L., a 73-yr-old Taiwanese woman, was admitted through the emergency department with shortness of breath. She was diagnosed with community-acquired pneumonia. Her medical history includes COPD, hypertension, diabetes, mild cognitive impairment, depression, macular degeneration, and significant hearing loss.

Subjective Data

- A stroke 5 years ago and has right-sided weakness
- A 100 pack-year history of tobacco use but quit smoking after her stroke
- Not seen primary care physician in 1 year
- In past year has had an unplanned weight loss of 15 pounds
- Spends her days either in bed or in a recliner watching television
- Shortness of breath for past 5 days

Psychosocial Data

- Came to the United States 15 years ago from Taiwan
- Speaks Mandarin Chinese with limited English proficiency
- Lives with her unemployed adult son who provides help with ADLs and IADLs
- Has 3 daughters who live within a 2-hour drive
- Limited financial resources but has Medicare and Medicaid benefits
- Daughters raise concerns about their mother's care and safety at home, given their brother's history of anger issues and a gambling addiction
- When daughters ask their brother about how he is caring for his mother, he says, "I'm doing the best I can. She refuses help. She refuses to go to the doctor. What do you want me to do? She's old. She's crazy. She's going to die anyway!"
- Daughters state their mother does not want to go to a nursing home

Objective Data
Physical Examination

- Unwashed, matted hair, poor oral hygiene, overgrown toenails
- 2 Stage 3 sacral pressure injuries
- Unstageable right heel pressure injury
- Multiple small bruises on her forearms and shins
- 5- × 10-cm bruise in the middle of her back

Diagnostic Tests

- Serum albumin 2.4 g/dL
- X-ray reveals consolidation in lower left and right lung lobes

Discussion Questions

1. What other information do you need to assess C.L.'s condition? How should you address questions about potential elder mistreatment?
2. Define ageism, and explain how it may be manifested in this case.
3. Identify the stage of Corbin and Strauss chronic illness trajectory that describe C.L.'s current status. Which stage is the goal of your nursing care?
4. ***Patient-Centered Care:*** What is your assessment of C.L.'s ability to manage her chronic illnesses? What will you include in your care planning to optimize her self-care ability?
5. ***Priority Decision:*** Based on your assessment of C.L., what are the priority nursing diagnoses?
6. ***Safety:*** To ensure C.L.'s safety, what nursing interventions are necessary during her hospitalization?
7. ***Collaboration:*** How would you use unlicensed assistive personnel (UAP) on the hospital unit to carry out the priorities that you identified in question 4?
8. What risk factors does C.L. have for developing frailty? Which factors are modifiable?

9. Based on your knowledge of care alternatives for older adults, what setting would be most appropriate for C.L. upon hospital discharge?
10. ***Collaboration:*** Because she has an expressed desire to return home, what referrals would be indicated if this were the plan?
11. What risk factors does C.L. have for becoming a victim of elder mistreatment? List and provide the rationale for nursing interventions and legal and ethical responsibilities in this case.

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to NCLEX Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Examples of primary prevention strategies include
   a. colonoscopy at age 50.
   b. avoidance of tobacco products.
   c. teaching the importance of exercise to a patient with hypertension.
   d. intake of a diet low in saturated fat in a patient with high cholesterol.
2. A characteristic of a chronic illness is that it *(select all that apply)*
   a. has reversible pathologic changes.
   b. has a consistent, predictable clinical course.
   c. results in permanent deviation from normal.
   d. is associated with many stable and unstable phases.
   e. always starts with an acute illness and then progresses

slowly.

3. Among older Americans in the United States
   a. more than 30% live in nursing homes.
   b. women are less likely to live in poverty.
   c. the number of those who completed college is lower than in previous decades.
   d. those 85 years or older account for the fastest growing segment of the population.
4. An ethnic older adult may feel a loss of self-worth when the nurse (*select all that apply)*
   a. prohibits visits from a faith healer.
   b. informs the patient about ethnic support services.
   c. allows a patient to rely on ethnic health beliefs and practices.
   d. emphasizes that a therapeutic diet does not allow ethnic foods.
   e. uses a medical interpreter to provide explanations and teaching.
5. An important nursing action to help a chronically ill older adult is to
   a. avoid discussing future lifestyle changes.
   b. ensure the patient that the condition is stable.
   c. treat the patient as a competent manager of the disease.
   d. encourage the patient to "fight" the disease as long as possible.
6. Older adults who become ill are more likely than younger adults to

a. report symptoms to their health care providers.

b. refuse to carry out lifestyle changes to promote recovery.

c. seek medical attention because of limitations on their lifestyle.

d. alter their daily living activities to accommodate new symptoms.

7. An appropriate care choice for an older adult who lives with an employed daughter but needs help with activities of daily living is

a. adult day care.

b. long-term care.

c. a retirement center.

d. an assisted living facility.

8. Nursing interventions directed at health promotion in the older adult are primarily focused on

a. disease management.

b. controlling symptoms of illness.

c. teaching positive health behaviors.

d. teaching about nutrition to enhance longevity.

1. b, 2. c, d, 3. d, 4. a, d, 5. c, 6. d, 7. a, 8. c.

Stress Management

Margaret R. Rateau

LEARNING OUTCOMES

1. Distinguish between the terms *stressor* and *stress.*
2. Describe the role of the nervous and endocrine systems in the stress process.
3. Describe the effects of stress on the immune system.
4. Discuss the effects of stress on health.
5. Explain the role of coping in managing stress.
6. Select coping and relaxation strategies that you, a patient, or a caregiver experiencing stress can use.
7. Describe the nursing assessment and management of a patient experiencing stress.

Conceptual Focus

Coping
Stress

All people experience stress. Stress has a powerful effect on the mind and therefore a significant effect on one's health and well-being. The concept of stress directly relates to multiple other concepts. Chronic stress is a major factor in causing and worsening chronic health conditions. This in turn is a major driver of escalating health care costs.

High levels of stress are common among patients and caregivers. How they deal with their stress is critical to their well-being. As a nurse, you play a key role in helping them recognize stress and manage stressful events. This chapter focuses on how stress can affect the mind, body, and spirit and how a person can effectively cope with

stress.

What is Stress?

Stress is the inability to cope with perceived (real or imagined) demands or threats to one's mental, emotional, or spiritual well-being.[1] What 1 person perceives as stressful may not be perceived as stressful to someone else. Responses to the same stressor vary greatly. Stress might be more prevalent in women than men, although it may be that women are more willing to admit they are experiencing stress.[2] *Perception* of the potential stressor influences the way a person responds to that stressor. This is shown in the following examples:

- B.J., a 43-yr-old woman, becomes depressed after a laparoscopic hysterectomy for fibroids. She is unwilling to take part in normal self-care activities. You are surprised by her response. You think she had a simple surgery and should get on with her life. After further assessment, you discover that removing her uterus is a great psychologic stressor because she perceives it as a loss of her womanhood and femininity.
- K.R., a 52-yr-old woman, has just been told by her health care provider (HCP) of her new diagnosis of type 2 diabetes. After the HCP's visit with her, you are prepared to provide emotional support. However, you are puzzled when she is smiling and feeling relieved. You think that this diagnosis should be stressful. However, K.R. tells you that she is so relieved because for weeks she was worried that her symptoms were caused by cancer.

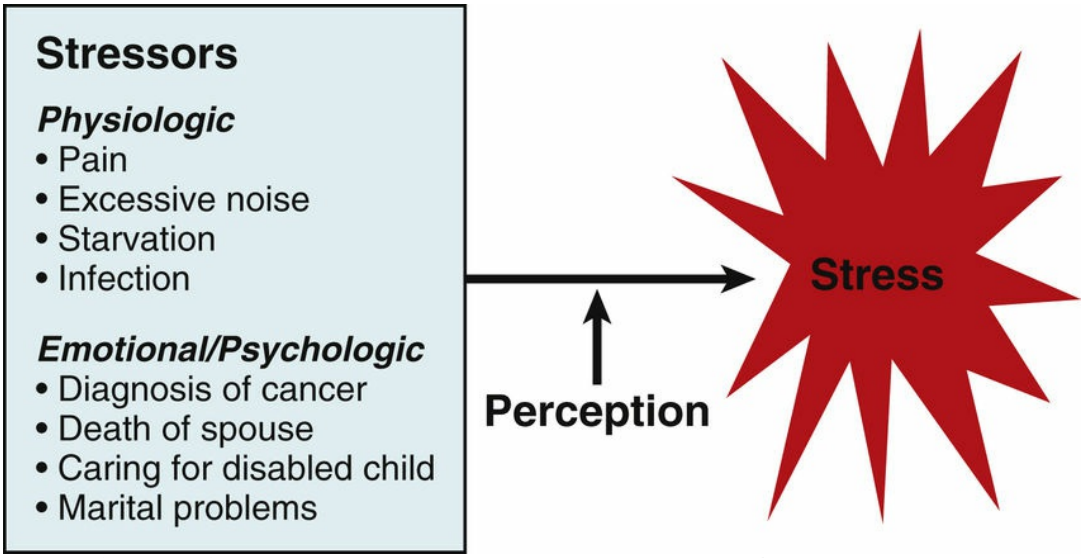

FIG. 6.1 Stressors can be physiologic or emotional/psychologic. Your perception of these stressors will determine whether they cause stress. Events or circumstances become stressful when you perceive them to be.

Many different events or factors can be **stressors**. They can be physiologic or emotional/psychologic (Fig. 6.1). The emotional/psychologic stressors can be positive or negative. For example, the birth of a baby is usually a positive stressor. Marital discord is a negative stressor.

Is Stress Bad or Good?

We tend to think of stress as bad or a threat. Actually, any event or situation that is out of the ordinary can be a stressor. This includes events that we normally consider happy or enjoyable (e.g., getting married, going on a vacation).

Stress can be helpful. A little stress can motivate you. Stress can actually inspire you to achieve a goal and become more confident or stronger physically.

The body does not distinguish between bad stress and good stress or real or imaginary stress. It responds to the stressor with the same stress response. This stress response is the way our bodies react both physically and emotionally to any change, be it good, bad, real, or

imagined.

For you as a nursing student, a test can be a stressful situation. A little bit of stress related to the upcoming test makes you study and become better prepared. If you feel mildly stressed during the test, it may help your test performance as a little stress heightens your awareness and increases your mental acuity. However, if you are overly stressed, it causes mental blocks, lack of concentration, and inability to remember things.

Stress is a key for survival, but too much stress can be detrimental. That is why it is important for you and your patients to learn to cope more effectively with the stressors in life.

Factors Affecting Response to Stress

Why do people respond so differently to stress? Why do some people cope better with stress than others? Interestingly, some people experience significant adverse life events but do not succumb to the effects of stress.

Differences in the responses to a stressor can be based on the duration of a stressor (acute or chronic) and intensity of a stressor (mild, moderate, or severe). For example, a person dealing with the chronic stress of caring for a loved one may be exposed to many acute stressors (e.g., car accident, influenza). The type, duration, and intensity of a stressor are important variables that can influence a person's response (Fig. 6.2).

FIG. 6.2 During stressful situations, the demands seem to exceed the resources.

TABLE 6.1 Factors Affecting Response to Stress

Internal

- Age
- Attitude
- Genetic background
- Hardiness
- Health status
- Nutritional status
- Optimistic outlook
- Personality characteristics
- Previous experience with stressors

- Resilience
- Sleep status

External

- Cultural and ethnic influences
- Number of stressors already experiencing
- Religious or spiritual influences
- Socioeconomic status
- Social support
- Timing of stressors

Factors that affect a person's response to stress include internal and external influences (Table 6.1). These factors show the importance of using a holistic approach when assessing the impact of stress on a person. Key personal characteristics that buffer the effects of stress are attitude, hardiness, being optimistic, and resilience.

Resilience is being resourceful and flexible and having good problem-solving skills. People who have a high degree of resilience are not as likely to perceive an event as stressful.

Hardiness is a combination of 3 characteristics: commitment, control, and openness to change. Together they give the courage and motivation needed to turn stressful circumstances from potential calamities into opportunities for personal growth.[3]

Attitude can influence the effect of stress on a person. People with positive attitudes view situations differently from those with negative attitudes. A person's attitude also influences how he or she manages stress. To some extent, positive emotional attitudes can prevent disease and prolong life.[4]

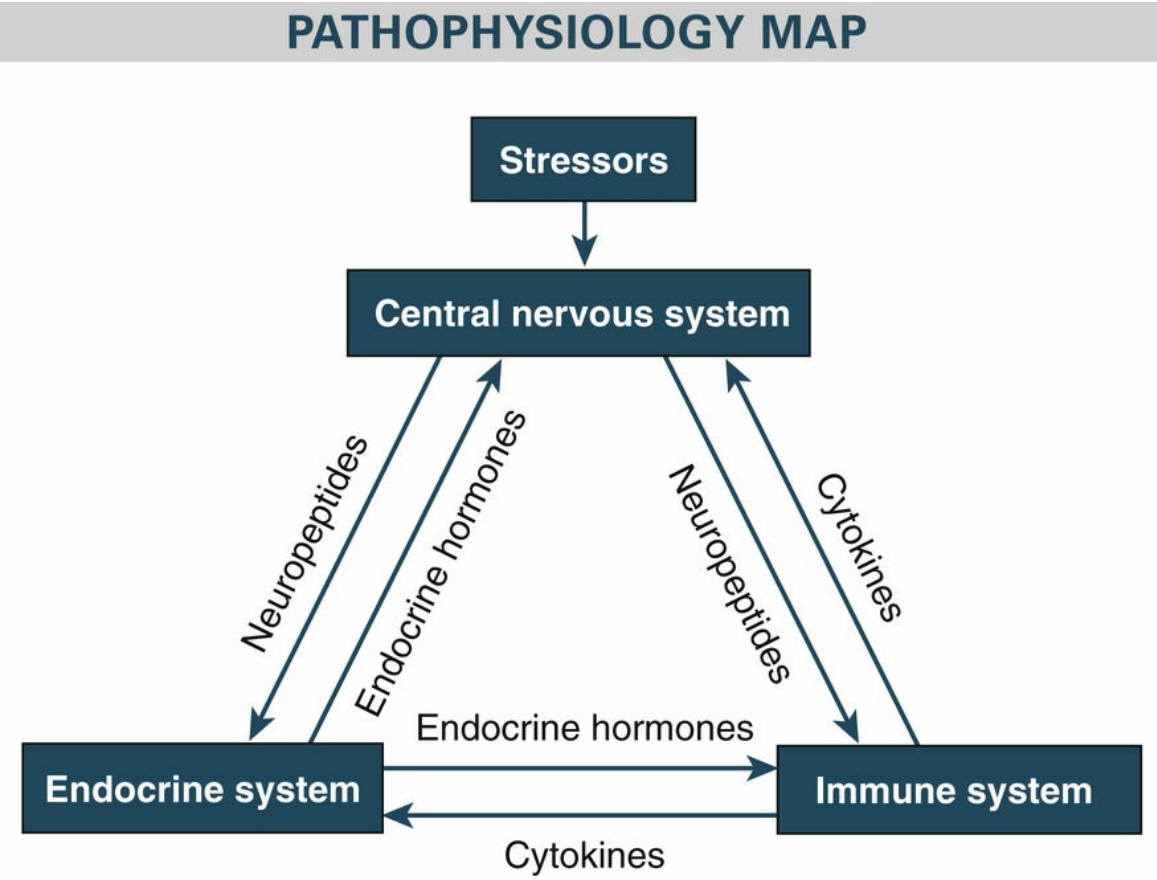

FIG. 6.3 Neurochemical links among the nervous, endocrine, and immune systems. The communication among the systems is bidirectional.

Being optimistic can help you cope more effectively with stress. Optimism also reduces a person's chances of developing stress-related illnesses. When optimistic people do become ill, they tend to recover more quickly. Pessimists are likely to deny the problem, distance themselves from the stressful event, focus on stressful feelings, or allow the stressor to interfere with achieving a goal. People with a more pessimistic attitude tend to report poorer health than people with optimistic attitudes.[4]

In addition to personal characteristics, external factors play a vital role in one's ability to cope with stress. Being surrounded by a strong social support system and receiving positive support from friends and family have a large impact on a person's ability to cope with stressors.

Physiologic Response to Stress

The nervous, endocrine, and immune systems are primarily involved in the stress response. These systems are interrelated, and that interrelationship is reflected in a person's physiologic response to stress (Fig. 6.3). Further, stress activation of these systems affects other body systems, such as the cardiovascular, respiratory, gastrointestinal, renal, and reproductive systems. A person's response to a stressor (real or imagined and physiologic or emotional/psychologic) determines the impact that stress will have on the body.

Nervous System

Cerebral Cortex

The areas of the cerebral cortex, or cerebrum, involved in the control of cognition, affect, and movement influence how we perceive stressors. We evaluate the stressor in light of past experiences and future consequences. This gives us some control over our response to stress. The motor areas also send signals to the adrenal medulla that directly relate to how stressors are managed.[5]

Limbic System

The *limbic system* lies in the inner midportion of the brain near the base of the brain. The limbic system is an important mediator of emotions and behavior. When the limbic system is stimulated, emotions, feelings, and behaviors can occur that ensure survival and self-preservation.

Reticular Formation

The *reticular formation* is located between the lower end of the brainstem and thalamus. It contains the *reticular activating system* (RAS), which sends impulses contributing to alertness to the limbic system and cerebral cortex. When the RAS is stimulated, it increases its output of impulses, leading to wakefulness. Stress usually increases the degree of wakefulness and can lead to sleep disturbances.

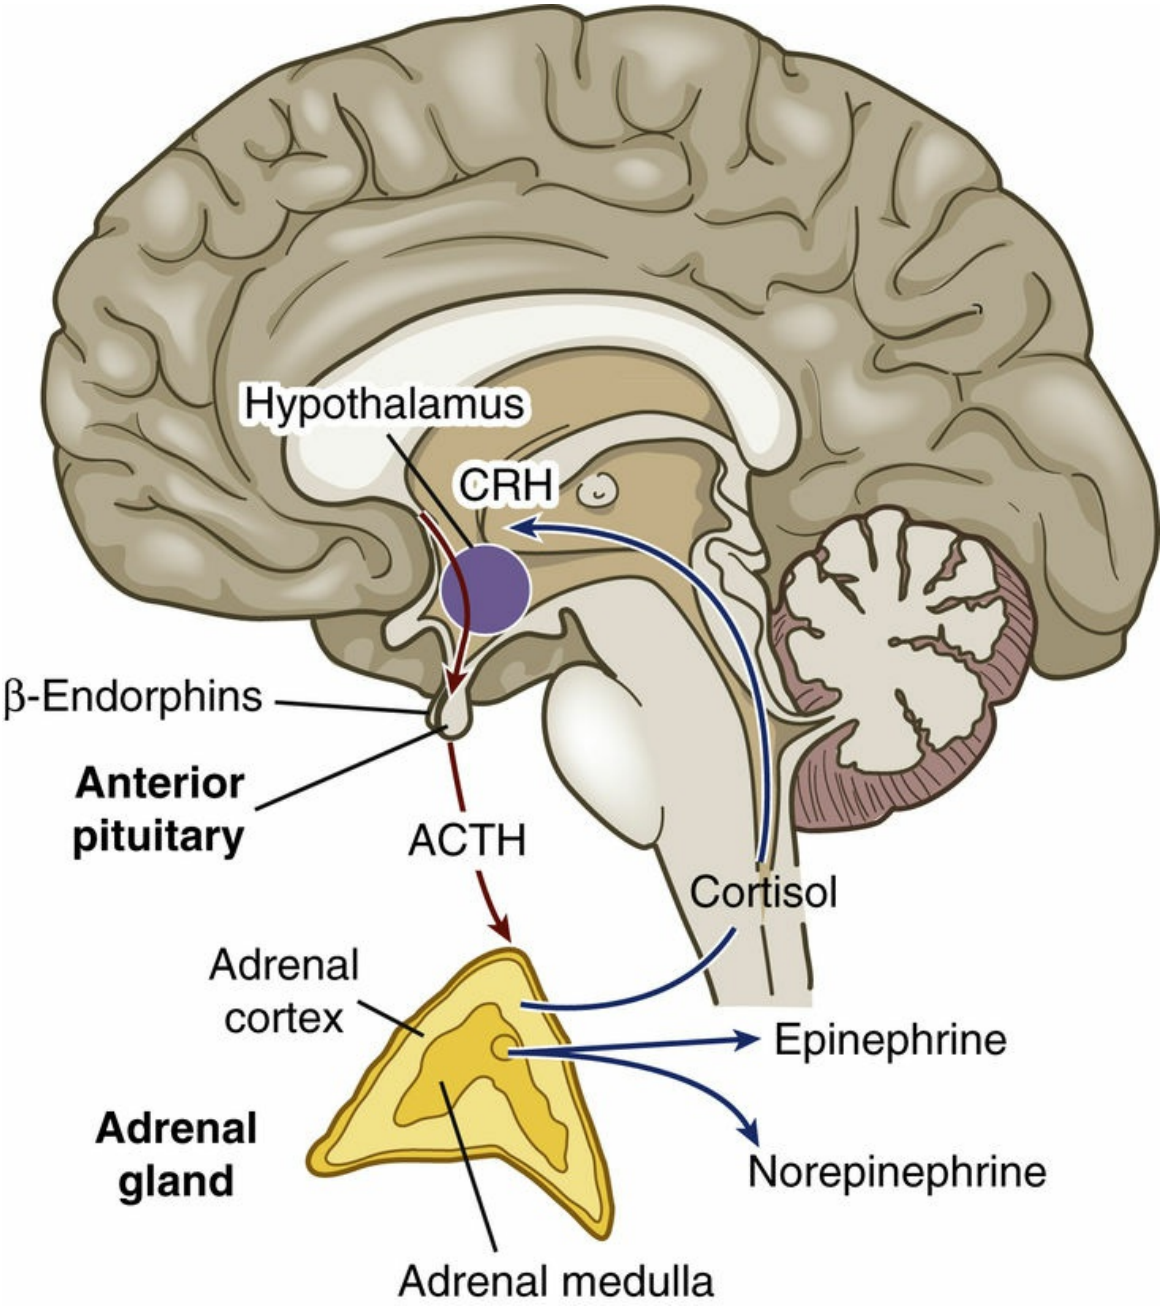

FIG. 6.4 Hypothalamic-pituitary-adrenal axis. *ACTH,* Adrenocorticotropic hormone; *CRH,* corticotropin-releasing hormone.

Hypothalamus

The hypothalamus, which lies at the base of the brain just above the pituitary gland, has many functions that aid in adaptation to stress. Stress activates the limbic system, which in turn stimulates the

hypothalamus. Because the hypothalamus secretes neuropeptides that regulate the release of hormones by the anterior pituitary, it is central to the connection between the nervous and endocrine systems in responding to stress (Fig. 6.4).

The hypothalamus plays a primary role in the stress response by regulating the function of both the sympathetic and parasympathetic branches of the autonomic nervous system. When a person perceives a stressor, the hypothalamus sends signals that initiate both the nervous and endocrine responses to the stressor. It does this primarily by sending signals via nerve fibers to stimulate the sympathetic nervous system (SNS) and by releasing corticotropin-releasing hormone (CRH), which stimulates the pituitary to release adrenocorticotropic hormone (ACTH) (see Chapter 47).

Endocrine System

Once the hypothalamus is activated in response to stress, the endocrine system becomes involved. The SNS stimulates the adrenal medulla to release epinephrine and norepinephrine (catecholamines). The effect of catecholamines and the activation of the SNS, including the response of the adrenal medulla, is referred to as the *sympathoadrenal response.* Epinephrine and norepinephrine prepare the body for the *fight-or-flight response* (Fig. 6.5).

Stress activates the hypothalamic-pituitary-adrenal (HPA) axis. In response to stress, the hypothalamus releases CRH, which stimulates the anterior pituitary to release proopiomelanocortin (POMC). Both ACTH (a hormone) and β-endorphin (a neuropeptide) are derived from POMC. Endorphins have analgesic-like effects and blunt pain perception during stress situations involving pain stimuli. ACTH in turn stimulates the adrenal cortex to synthesize and secrete corticosteroids (e.g., cortisol) and, to a lesser degree, aldosterone.

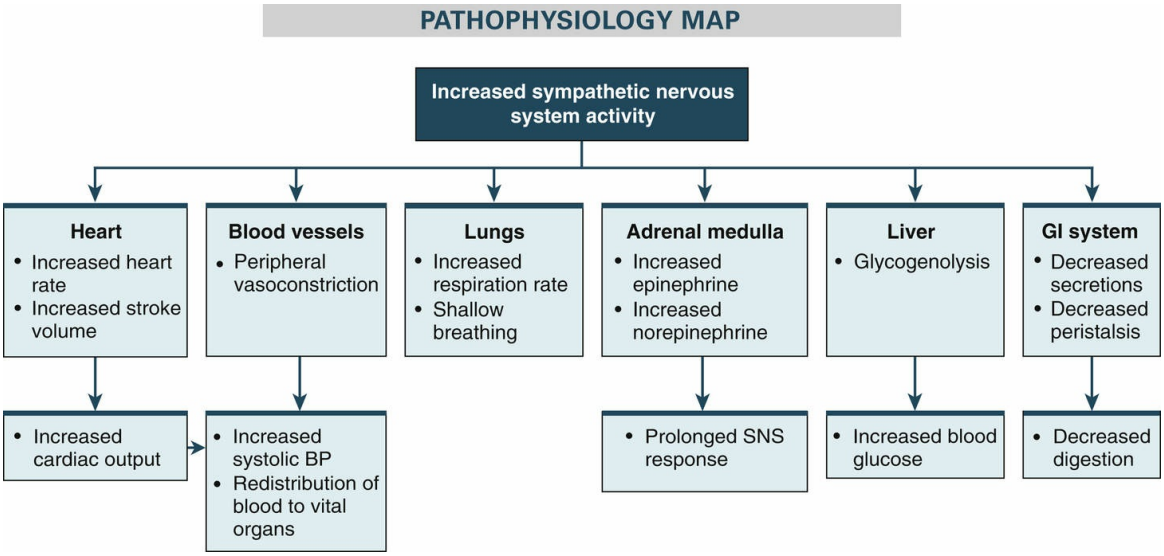

FIG. 6.5 "Fight-or-flight" reaction. Alarm reaction responses resulting from increased sympathetic nervous system *(SNS)* activity.

Corticosteroids are essential for the stress response. Cortisol produces several physiologic effects, such as increasing blood glucose levels, intensifying the action of catecholamines on blood vessels, and inhibiting the inflammatory response. Corticosteroids play an important role in "turning off" or blunting the stress response, which, if uncontrolled, can become self-destructive. This is shown by their ability to suppress the release of proinflammatory mediators, such as the cytokines tumor necrosis factor (TNF) and interleukin-1 (IL-1). The persistent release of such mediators is believed to initiate organ dysfunction in conditions such as sepsis or autoimmune disease. Thus corticosteroids act not only to support the body's adaptive response to a stressor but also to suppress an overzealous and potentially self-destructive response.

The stress response involves increases in (1) cardiac output (resulting from the increased heart rate and increased stroke volume), (2) blood glucose levels, (3) oxygen consumption, and (4) metabolic rate (Fig. 6.5). In addition, dilation of skeletal muscle blood vessels increases blood supply to the large muscles and supports quick movement. Increased cerebral blood flow increases mental alertness. For example, in the case of stressful situations (e.g., blood loss from trauma), the increased blood volume (from increased extracellular

fluid and the shunting of blood away from the gastrointestinal system) helps to maintain adequate circulation to vital organs.

Summary of Stress Response

In summary, the fight-or-flight response is an important and necessary adaptive mechanism of the body to acute stress. We activate this response to stressors whether they are physiologic (e.g., acute pain) or emotional/psychologic (e.g., death of a child, loss of a home through fire, fear).

Acute stress leads to physiologic changes that are important to a person's survival. This is your "alarm system." It puts you on high alert. The acute stress response is a state of physiologic and psychologic arousal characterized by increased SNS activity that leads to increased heart and respiratory rate, increased BP, increased muscle tension, increased brain activity, and decreased skin temperature.

Immune System

Stress has an impact on the immune system. **Psychoneuro-immunology (PNI)** is an interdisciplinary science that studies the interactions among psychologic, neurologic, and immune responses. Because neuroanatomic and neuroendocrine pathways connect the brain to the immune system, stressors have the potential to lead to changes in immune function (Fig. 6.6).

Nerve fibers extend from the nervous system and synapse on cells and tissues of the immune system (i.e., spleen, lymph nodes). In turn, the cells of the immune system have receptors for many neuropeptides and hormones. This allows them to respond to nervous and neuroendocrine signals. As a result, the mediation of stress by the central nervous system leads to corresponding changes in immune cell activity.

Both acute and chronic stress can cause immunosuppression. Stress affects immune function by (1) decreasing the number and function of natural killer cells; (2) decreasing lymphocyte proliferation; (3) altering production of *cytokines* (soluble factors secreted by white

blood cells and other cells, e.g., interferon, interleukins); and (4) decreasing phagocytosis by neutrophils and monocytes. This stress-induced immunosuppression may worsen or increase the risk for progression of immune-related diseases such as multiple sclerosis, asthma, rheumatoid arthritis, and cancer.[6] Natural killer cells, lymphocytes, and cytokines are discussed in Chapter 13.

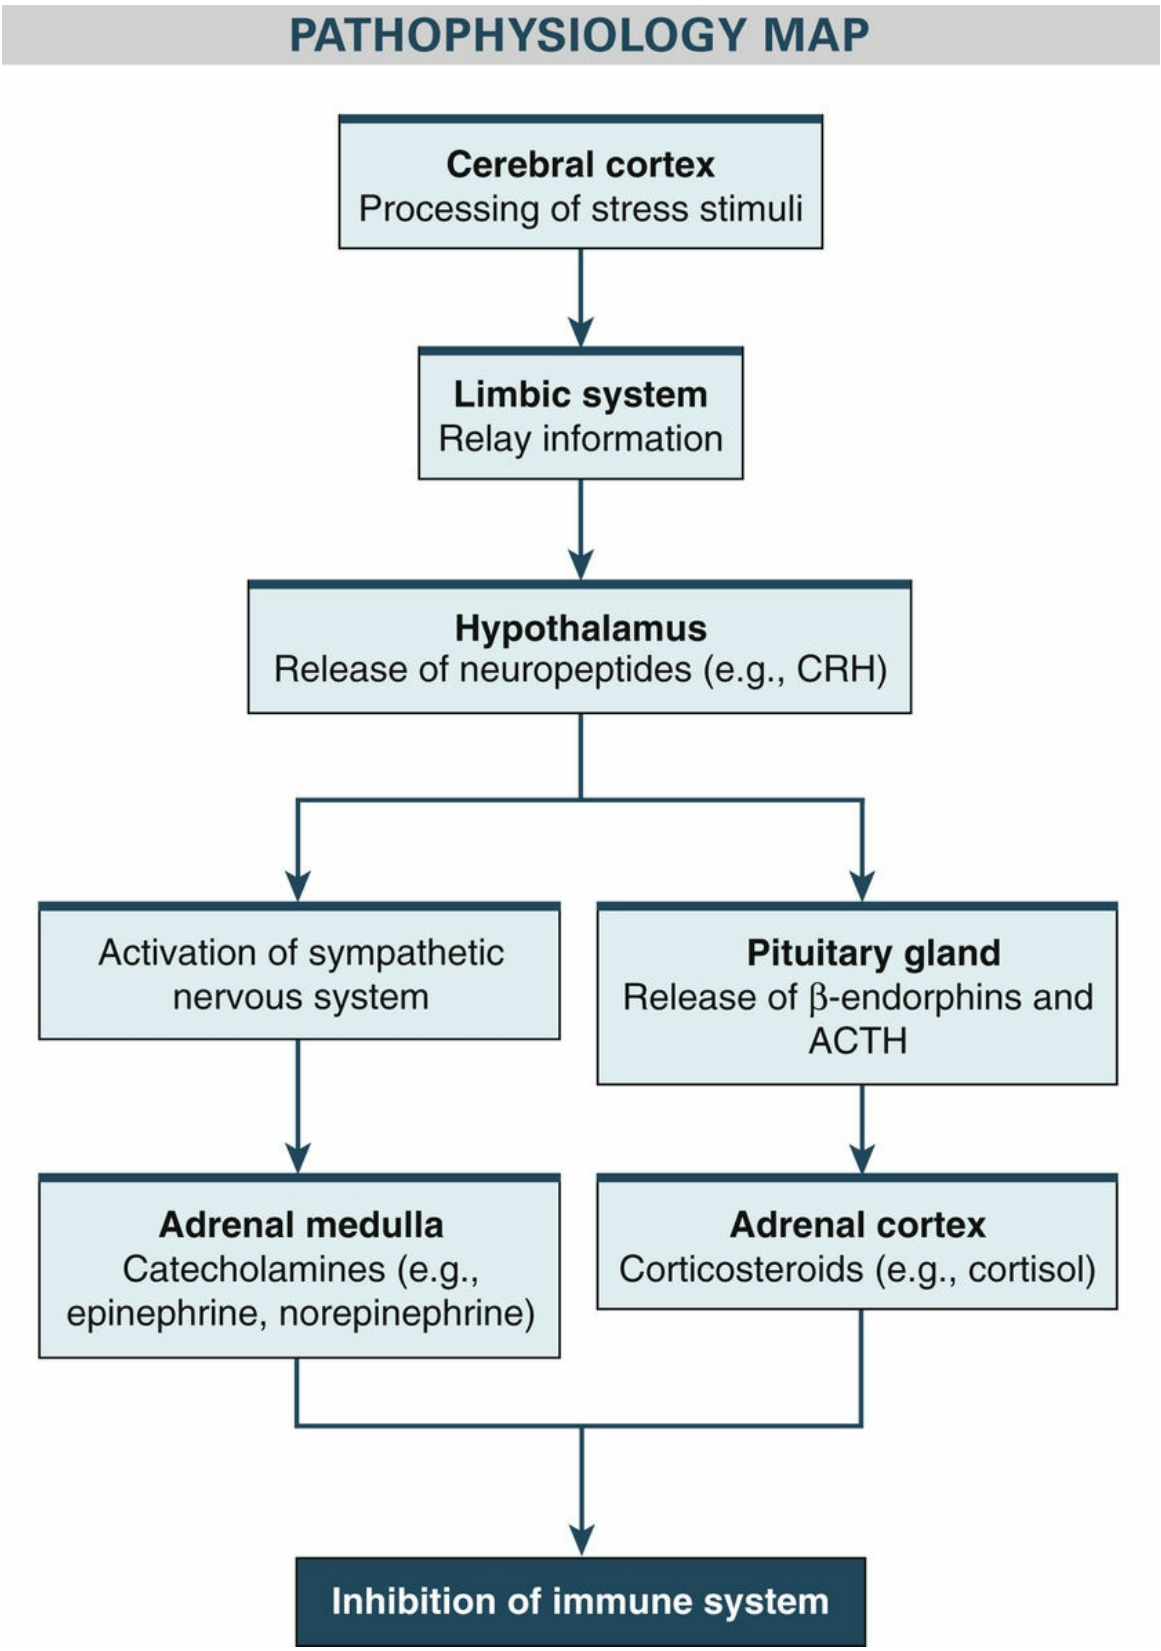

FIG. 6.6 The cerebral cortex processes stressful stimuli and relays the information via the limbic system to the hypothalamus.

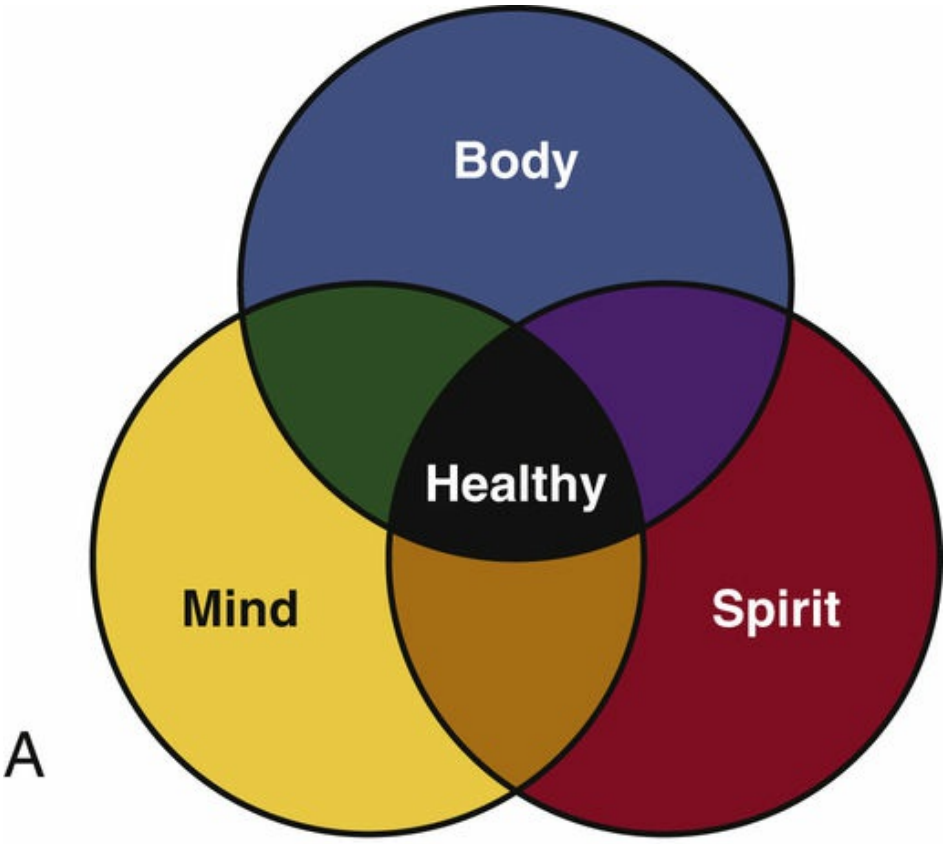
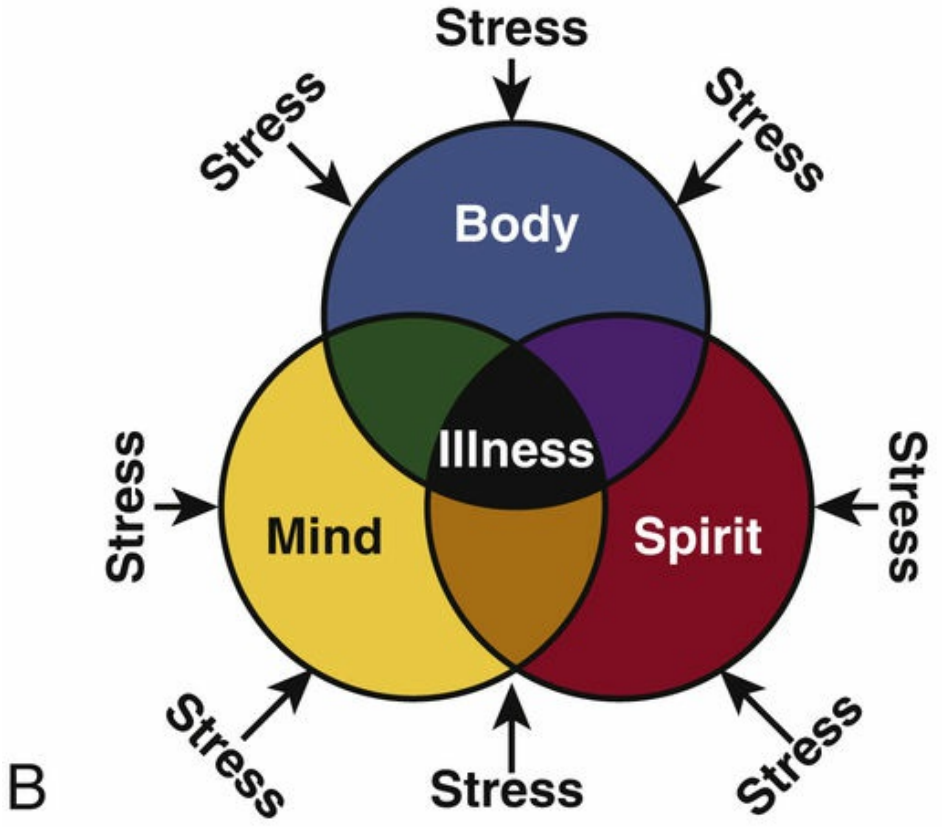


Corticotropin-releasing hormone *(CRH)* stimulates the release of adrenocorticotropic hormone *(ACTH)* from the pituitary gland. ACTH stimulates the adrenal cortex to release corticosteroids. Sympathetic nervous system stimulation results in the release of epinephrine and norepinephrine from the adrenal medulla. The result is the inhibition of the immune system.

Importantly, the network that links the brain and immune system is bidirectional (Fig. 6.3). Signals from these systems travel back and forth, allowing for communication among these systems. Consequently, not only do emotions influence the immune response, but products of immune cells send signals back to the brain and alter its activity. Many of the communication signals sent from the immune system to the brain are mediated by cytokines, which are central to the coordination of the immune response. For example, IL-1 (a cytokine made by monocytes) acts on the temperature regulatory center of the hypothalamus and initiates the febrile response to infectious pathogens (see Fig. 11.4).



Many questions about stress and the immune response are unanswered. For example, it is not known how much stress (intensity or chronicity) is needed to cause changes or how much of a change in the immune system is necessary before disease susceptibility occurs.

Mind-Body-Spirit Connection

The **mind-body-spirit connection** shows the relationship and interconnectedness among the parts that make up a person: mind, body, and spirit (Fig. 6.7). All 3 parts are important in your life and in determining who you are. What goes on in your mind influences every part of the body. Your mind is 1 of the most powerful weapons you have to deal with and conquer stress. You have a choice in how you respond to a crisis or a difficult time. Even if the outcome of the situation is not what a person desired, one can emerge with a winning attitude.

Body
Healthy
Mind
Spirit

A

Stress
Stress
Stress
Body
Illness
Mind
Spirit
Stress
Stress
Stress
Stress
Stress

B

FIG. 6.7 The connections among the mind, body, and spirit can lead to a person being healthy **(A)** or the effects of stress on the mind, body, and spirit connections can lead to illness **(B)**.

How you deal with difficult situations or stressful times greatly influences your overall well-being: your mind, body, and spirit. When your mind is healthy, your body can resist illness better. When your body is healthy, your feelings are more positive. Your spirit is renewed and energized.

As a nurse, stress can have a significant effect on you. A primary source of stress for a nurse can be the work environment, which includes extreme physical demands and the potential for violence.[7] The mind-body-spirit connection also influences your ability to provide nursing care. Your ability to maintain the mind-body-spirit balance is important in providing proper care to your patients and in maintaining a healthy and meaningful life for yourself.

Effects of Stress on Health

As previously mentioned, the acute stress response is your alarm system and puts you on alert. However, your body was not meant to be on high alert all the time. If stress is excessive or prolonged, these same "helpful" physiologic responses can lead to harm and disease. When a person sustains chronic, unrelieved stress, the body's defenses can no longer keep up with the demands. Therefore stress plays a role in the development and/or progression of diseases of adaptation, or stress-related illnesses (Table 6.2).

TABLE 6.2 Common Disorders With a Stress Component

- Depression
- Dyspepsia

- Eating disorders
- Erectile dysfunction
- Fatigue
- Fibromyalgia
- Headaches
- Hypertension
- Insomnia
- Irritable bowel syndrome
- Low back pain
- Menstrual irregularities
- Peptic ulcer disease
- Sexual dysfunction

Stress is linked to leading causes of death, including cancer, accidents, and suicides. Stress can have effects on cognitive function, including poor concentration, memory problems, distressing dreams, sleep disturbances, and impaired decision making. It can also cause a wide variety of changes in behavior. These include people withdrawing from others, becoming quiet or unusually talkative, changing eating habits, drinking alcohol excessively, or becoming irritable.[8] Long-term exposure to catecholamines resulting from excessive SNS activation may increase the risk for cardiovascular diseases such as atherosclerosis and hypertension.[9] Other conditions that are precipitated or worsened by stress include migraine headaches, irritable bowel syndrome, and peptic ulcers.[10] Stress affects the control of metabolic conditions, such as diabetes mellitus. Behavioral interventions aimed at stress reduction and relaxation have helped manage these diseases in conjunction with standard medical therapy.[11]

Stressful life events can make a person more susceptible to infection. For example, psychologic stress may increase one's risk for developing the common cold. In a landmark study, researchers intranasally inoculated healthy people with low doses of upper

respiratory tract viruses. The people underwent psychologic testing to measure the occurrence of stressful events in their lives and their reactions to such stresses. The results showed that the rates of both viral infection and clinical colds increased with the degree of psychologic stress. In this study, social support buffered the harmful effects of stress.[12]

At the cellular level, stress may promote earlier onset of age-related diseases. There is a link between stress and telomere length. Telomeres are the protective end caps on chromosomes. Their diminishing size is a sign of age. Telomeres are highly susceptible to stress and depression. Telomeres are shorter in people who are stressed and depressed than in healthy people. Thus chronic stress can have a long-term effect on our overall health by changing our DNA and accelerating the rate at which our cells age.[13]

Coping Strategies

Coping is a person's efforts to manage stressors.[14] *Coping strategies* are what you do (your behaviors and actions) to help deal with stress. Coping can be either positive or negative. Positive coping includes activities such as exercise and spending time with friends and family. Healthy coping helps you handle your stressors so that they do not overwhelm you. Negative coping may include substance use and denial.

Unfortunately, some coping strategies make the stress worse. Sometimes coping strategies temporarily relieve the stress, but in the long run they increase the stress. For example, you may really enjoy watching a favorite TV show as a form of coping. However, if you become fixated on several reality shows, then TV becomes an addiction and an escape from dealing with your real stressors.

You cannot always choose your destiny in life, but you can choose how you cope with it.

Norman Vincent Peale

We can use a number of coping strategies to cope with stress. Table 6.3 has examples of coping strategies that you can use in your life and teach to your patients and caregivers. Coping strategies can be divided into 2 broad categories: emotion-focused coping and problem-focused coping. **Emotion-focused coping** involves managing the emotions that a person feels when a stressful event occurs. When a situation is unchangeable or uncontrollable, emotion-focused coping may predominate. The primary purpose of emotion-focused coping is to help decrease negative emotions and create a feeling of well-being. Examples include discussing feelings with a friend or taking a hot bath.

Problem-focused coping involves attempts to resolve the problems causing the stress. If you can change or control a problem, this strategy is the most helpful. Problem-focused coping strategies allow a person to look at a challenge objectively, act to address the problem, and thereby reduce the stress. Setting priorities, collecting information, and seeking advice are examples of problem-focused coping.

We often use a combination of strategies to cope with the same stressor. Table 6.4 gives examples of emotion- and problem-focused coping when applied to the same stressful situation.

Relaxation Strategies

The *relaxation response* is a state of physiologic and psychologic rest. It is opposite of the stress response. The relaxation response is characterized by decreased SNS activity, which leads to decreased heart and respiratory rate, decreased BP, decreased muscle tension, decreased brain activity, and increased skin temperature.

We can use a variety of relaxation strategies to elicit the relaxation response (Table 6.5). Regular elicitation of the relaxation response is an effective treatment for a wide range of stress-related disorders, including chronic pain, insomnia, and hypertension. People who

regularly engage in relaxation strategies better cope with their stressors, increase their sense of control over stressors, and reduce their tension.[15]

Relaxation Breathing

The way one breathes affects every aspect of one's life. When a person is stressed, muscles tense and breathing becomes shallow and rapid. Therefore 1 of the simplest and most effective ways to stop the stress response is to breathe deeply and slowly. It is hard to stay tense when breathing in a slow, deep, and relaxed pattern. **Relaxation breathing** forms the basis for most relaxation strategies. It is especially useful during a stressful or anxious situation to reduce stress. You can do relaxation breathing while sitting, standing, or lying down. It is natural for newborns and sleeping adults.

TABLE 6.3 Coping Strategies

Strategy	Description	How to Implement
Aromatherapy	• Use of essential oils (fragrant molecules from plants) for inhalation or topical application • Variety of essential oils, including lavender, peppermint, rosemary, eucalyptus, sandalwood, etc.	• Place 5–8 drops in a full bath and agitate water before bathing. • Place a few drops on a tissue or in diffuser or vaporizer.
Art therapy	• Allows a person to nonverbally express and communicate feelings, emotions, and thoughts • Can reduce stress, promote relaxation, and help process experiences • Based on the belief that the creative process is healing and life enhancing	• Close your eyes and draw a line on a piece of paper. Open your eyes. Continue to build on that line and draw whatever comes to mind. • Get a piece of paper and doodle. Do not edit. • Get a coloring book and crayons and just start coloring.
Exercise	• Any form of movement, especially aerobic movement • Can be viewed as meditation in motion	• Walk, swim, garden, bicycle, dance, climb stairs, take part in group exercises.
Humor	• Can take the form of laughter, cartoons, funny movies, videos, riddles, comic books, and joke books	• Keep a "tickler" scrapbook with funny photos, cartoons, etc. • Humor carts can be set up in many clinical settings for patient and family use.
Journaling	• Allows a person to express self in writing • Enhances personal development and awareness through self-reflection	• Use a journaling notebook or computer to write down thoughts, feelings, memories, and perceptions.
Pet therapy (animal-assisted therapy) (Fig. 6.8)	• Use of animals as a form of treatment • Improves a patient's social, emotional, or cognitive functioning	• Pet therapist or family member or friend brings a pet with which patient can socialize.
Social support	• Relationships with family and friends • Self-help groups and professional help	• Get together with family and friends on a regular basis. • Join a support group that specifically helps to meet needs (e.g., grief support group).

Complementary & Alternative Therapies

Yoga

Yoga is an ancient system of relaxation, exercise, and healing with origins in Indian philosophy. The goal of yoga is physical and mental well-being achieved using stretching, postures, breathing practices, and meditation.

Scientific Evidence

Yoga can be used to treat hypertension and reduce stress and anxiety in cancer patients.[16]

Nursing Implications

- Deep abdominal relaxation breathing is a main component of all types of yoga. It helps one to focus on the inner self and promote the relaxation response.
- Yoga is used to promote relaxation, decrease stress, improve flexibility, and enhance overall health.
- Yoga is considered safe. Patients with certain medical conditions or illnesses should avoid some postures.

TABLE 6.4 Problem- and Emotion-Focused Coping

Stressor	Problem-Focused Coping	Emotion-Focused Coping
Failing an examination	Obtaining a tutor	Going for a run
Being diagnosed with diabetes	Attending education classes about diabetes	Getting a massage
Receiving questionable mammogram results	Scheduling follow-up testing for ultrasound	Expressing feelings of anxiety to friends and nurse

TABLE 6.5 Common Relaxation Strategies

- Qigong
- Relaxing breathing
- Tai Chi
- Yoga

FIG. 6.8 Pet therapy can be used in a variety of settings including rehabilitation.
© RonChappleStudios/Hemera/Thinkstock.

Before practicing relaxation breathing, it is important to assess one's normal breathing pattern (Table 6.6). Chest breathing, which involves the upper chest and shoulders, is inefficient. We often use it during times of anxiety and distress.

Relaxation breathing is a more efficient type of breathing. It involves the primary use of the diaphragm and less use of the upper chest and shoulders to help in each breath. In this type of breathing, the abdomen gently moves in and out during exhalation and inhalation. The breaths should be slow, steady, and deep.

One basic technique for relaxation breathing is as follows: (1) Inhale slowly and deeply, pushing the abdomen out. Think about breathing in peace. (2) Exhale slowly, letting the abdomen come in and all the muscles relax. Think about breathing out tension. (3) Repeat these

deep breaths 10 times without interruption. As with any breathing exercise, if a light-headed feeling arises, stop for 30 seconds, and then start again.

Other methods used to teach relaxation breathing are the 4 × 4 technique and relaxation sigh. Breathing techniques are discussed in the Stress-Busting Kit for Nursing Students available on the website for this book.

Initially, relaxation breathing may feel unusual. With practice it becomes easier, and its relaxing benefits are soon obvious. You should personally learn to use relaxation breathing before teaching it to patients and their caregivers. Once learned, you can easily teach relaxation breathing to patients in a variety of settings, particularly when they are undergoing stressful and painful procedures.

Biofeedback

Biofeedback helps a person become more aware of involuntary body responses such as breathing, heart rate, and muscle activity. Electrodes attached to the skin or, in some cases, hand-held sensors measure these processes and display them on a monitor. This feedback allows the person to learn to control their responses. This gives a person the power to use thoughts to control the body, often to improve a health condition or physical performance.[15]

TABLE 6.6 Relaxation Breathing TechniquesBreathing Assessment

1. Begin by placing 1 hand gently on your abdomen below your waistline.
2. Place the other hand on the center of your chest on the sternum.
3. Without changing the normal breathing pattern, take several breaths. During inhalation notice which hand rises the most.
4. When relaxation breathing is done properly, the hand on the

abdomen should rise more than the hand on the chest.

4 × 4 Technique

1. Sit up straight with your back flush to the support of the chair and your feet flat on the floor.
2. Rest your arms on your lap, thighs, or arms of the chair.
3. Take in a deep breath through your nose to a count of 4 (1 … 2 … 3 … 4).
4. Hold your breath to a count of 4 (1 … 2 … 3 … 4).
5. Release your breath through your mouth to a count of 4 (1 … 2 … 3 … 4).
6. Rest for a count of 4 (1 … 2 … 3 … 4).
7. Repeat the cycle 4 times.

Relaxing Sigh

1. Sit up straight with your back against the support of the chair and your feet flat on floor.
2. Inhale a natural breath and then sigh deeply. Let out a sound of relief as the air rushes out of your lungs.
3. Do not think about inhaling at the end of the sigh; just let the air come in naturally as you breathe deeply.
4. Repeat this sigh about 4 to 6 times very slowly.
5. You can repeat this exercise whenever you need it.

Meditation

Meditation is a practice of concentrated focus on a sound, object, visualization, the breath, or movement. The purpose of meditation is to increase awareness, reduce stress, promote relaxation, and enhance personal and spiritual growth.

It is best to practice meditation in a quiet place, free of distractions. Table 6.7 gives some basic guidelines on how to meditate. Meditation

is often practiced while seated, and it is important to maintain a comfortable posture. Meditation can be done while walking and focusing on a single action such as the movement of the feet. In the beginning, you typically start with just 5 to 10 minutes of meditation at a time. Increase the time as the practice becomes more comfortable. Meditation exercises are available in the Stress-Busting Kit for Nursing Students on the website for this book.

Imagery

Imagery is the use of one's mind to generate images that have a calming effect on the body. It involves focusing the mind and incorporates all the senses to create physiologic and emotional changes. It is a simple relaxation technique that needs no equipment other than an active imagination. *Guided imagery* is a variation of imagery in which another person (either live or through technology) suggests the images to you.

You can use imagery in your own life or use guided imagery with your patients. One of the uses of imagery is to create a special place for a mental retreat. Table 6.8 describes the steps involved in creating a special place. More imagery exercises are available in the Stress-Busting Kit for Nursing Students on the website for this book.

TABLE 6.7 Guide to Meditation

You can teach yourself the basics of meditation by following a few simple steps:

1. Find a quiet place.
2. Make sure there are no distractions.
3. Sit in a comfortable position.
4. Close your eyes.
5. Shut out the world so that your brain can stop processing information coming from your senses.

6. Pick a focus word, short phrase, song verse (melody), or prayer that is firmly rooted in your belief system, such as *one, peace, The Lord is my shepherd, Hail Mary full of grace,* or *shalom.*
7. Breathe slowly and practice relaxation breathing. Say your focus word, short phrase, song verse, or prayer silently to yourself as you exhale.
8. Say the word or phrase again and again.
9. Try saying the word or phrase silently to yourself with every exhalation. The monotony will help you focus.
10. Relax your muscles, progressing from your feet to your calves, thighs, abdomen, shoulders, head, and neck.
11. Do not be concerned when other thoughts come to mind. Just acknowledge them and return calmly to your word or phrase.
12. Continue for 10 to 20 minutes, but even 5 minutes can leave you feeling calm and refreshed. Rise slowly.
13. Practice once or twice daily.

TABLE 6.8 ImageryCreating Your Special Place

1. Begin by closing your eyes and taking several slow, deep breaths.
2. Imagine a place where you feel completely comfortable and peaceful. It may be a real place or 1 you imagine: 1 from your past or a place you have always wanted to go.
3. Allow this special place to take form, slowly. As it takes form, look around to your left, to your right. Enjoy the scenery: the colors, the texture, the shapes.
4. Listen carefully to the sounds of your place. What do you hear?
5. Is there a gentle breeze or sunshine warming your face? Pick up or touch some favorite objects from your special place.
6. Take in a deep breath through your nose and notice the rich smells around you. Perhaps your favorite flower is in bloom, or you smell the scents of the ocean.

7. Take another deep breath and relax. Enjoy the peace, comfort, and safety of your special place.
8. This is your special place. You relax and feel thankful that you are here, in your special place.
9. You can return to this place any time that you wish.

It is best to perform imagery in a comfortable position. Take slow, deep breaths. Focus should involve all senses (sight, hearing, touch, smell). For example, you can use an image, such as Fig. 6.9, engaging all the senses as you focus on the image.

Imagery can be used in many clinical settings for stress reduction and pain relief. Benefits of imagery include anxiety reduction, decreased muscle tension, improved comfort during medical procedures, enhanced immune function, decreased recovery time after surgery, and reduction in sleeping problems. It can specifically target a disease, problem, or stressor. Table 6.9 describes some suggestions for using imagery in specific diseases or disorders.

A person can use imagery to enhance performance or process stressful or difficult tasks. For example, an athlete or musician can use imagery to achieve greater success. Imagery allows one to mentally rehearse the difficult or challenging situation. Imagery can help a fearful nurse start an IV line or perform a difficult procedure. It can be used with a patient who is afraid to have a stressful or painful procedure (e.g., bone marrow biopsy).

FIG. 6.9 In imagery, special places are created involving all the senses, such as a place where one can hear rustling water, smell flowers, feel the wind, and see a colorful landscape.
© iStockphoto/Thinkstock.

TABLE 6.9 Examples of Imagery

Imagery can be used to relieve stress and promote health and healing in conjunction with regular medical care. Special images can be created to ease symptoms or treat diseases or disorders. The image should be strong and vivid for the person, using many senses to create the image. Below are some examples that some people have found useful.

Disease or Disorder	Images
Asthma	• Tiny elastic rubber bands that constrict the airways pop open
Cancer	• Shark gobbles up cancer cells • Radiation or chemotherapy treatments enter the body like healing rays of light; they destroy cancer cells
Coronary artery disease	• Water flows freely through a wide, open river
Depression	• Attach troubles and feelings of sadness to big colorful helium balloons that float off into a clear blue sky
Infection	• White blood cells with flashing red sirens arrest and imprison harmful germs
Pain	• Wash away pain by a cool calm river flowing through the entire body
Weakened immune system	• White blood cells rapidly multiply like millions of seeds bursting from a ripe seed pod

Adapted from Sobel DS, Ornstein R: *Healthy mind, healthy body,* New York, 1996, Patient Education Materials, Time Life.

Massage

Massage includes a range of techniques that manipulate the soft tissues and joints of the body. Involving touch and movement, massage is typically delivered with the hands. It reduces muscle tension and positively affects mental and emotional states.

Massage is an important form of touch. It is a form of caring, communication, and comfort. Your role related to massage differs from that of the registered massage therapist. A massage therapist can provide more comprehensive massage therapies. As a nurse, you can use specific massage techniques as part of nursing care. For example, you can give a back massage to help promote sleep. For a bedridden patient, gentle massage can stimulate circulation and help prevent skin breakdown. A simple hand massage can have a calming and relaxing effect, especially for patients who are anxious or agitated. During end-of-life care, hospice nurses may include massage into their nursing care as the massaging touch can lessen pain and restlessness.

When you identify that massage may be useful, first assess the patient's preference about touch and massage. Consider cultural and social beliefs and discuss potential benefits with the patient. You can teach family members to massage their loved one, giving a way for family members to take part in patient care. This can be therapeutic for the patient and family, even when the loved one is cognitively impaired or unresponsive.

Music

Music can help achieve relaxation and bring about healthy changes in emotional or physical states. Listening to relaxing music can divert one's focus from a stressful situation.

Music can be used in many clinical settings. It is noninvasive, safe, inexpensive, and easy to use. Music decreases anxiety and elicits the relaxation response. Music helps people with insomnia go to sleep. It can decrease muscle tension, pain sensation, and emotional stress.[17]

Each person considers different types of music to be relaxing. Music that has 60 to 80 beats/min is considered soothing. Many find low-pitched tones and music without words best for relaxation. Mozart's music is popular for relaxation. On the other hand, fast-tempo music can stimulate and uplift a person. Assess each patient's interest and preference in music, and find music that best matches the person's needs and circumstance. Create a listening environment by helping the patient find a comfortable position and minimizing interruptions. Evaluate patients' responses to the music, asking them how it sounds and how it makes them feel.

Prayer

Prayer can be a form of meditation. It is a spiritual communion with God or an object of worship. Many people find deep comfort in their faith. Religious services, conversations with clergy, and personal worship and prayer may help to ease a person's stress and give 1 greater perspective, strength, and inspiration.

Nursing Management: Stress

Nursing Assessment

Patients and caregivers face many potential stressors that can have health consequences. As a nurse, you are in a key position to (1) assess stress in patients and their caregivers, (2) help them identify high-risk periods for stress, and (3) implement stress management strategies

that can prevent the negative consequences of stress on their health (Fig. 6.10).

The first step in managing stress is to become aware of its presence. This includes identifying what the stressors are and the person's response to them. Be aware of situations that are likely to result in stress. Assess the number of stressors, duration of these stressors, and prior experience with similar demands. Assess the personal meaning attached to the stressful situation to provide useful insight for planning stress management strategies with the patient.

FIG. 6.10 As a nurse, you have a key role in helping patients deal with stress.
© AlexRaths/iStock/Thinkstock.

Be specific with your questions: Have you experienced this stressor before? How did you handle it? What worked well and what did not? Although the manifestations of stress may vary from person to person, assess the patient for the signs and symptoms of the stress response, including an increased heart rate and BP, hyperventilation,

sweating, headache, musculoskeletal pain, gastrointestinal upset, loss of appetite, insomnia, and fatigue. In addition, the patient may show stress-related illness (Table 6.2).

Behavioral manifestations of stress may include an inability to concentrate, accident proneness, impaired speech, anxiety, crying, frustration, and irritability. Work-related responses to stress may include absenteeism or tardiness at work, decreased productivity, and job dissatisfaction. Cognitive responses include self-reports about the inability to make decisions and forgetfulness. Some of these responses may be apparent to significant others.

Consider the caregivers' responses to the stressors. A patient's illness often causes stress for the caregiver and other family members. Assess what aspects of the illness are the most stressful for the patient and caregiver. These may include the patient's physical health, job responsibilities, finances, and children. This information is valuable because it helps you to understand the patient's perspective of the stressors. Knowledge of stressors, the feelings these stressors evoke, and the psychologic effects they can produce will help you recognize potential and actual sources of stress and their effect on the patient.

Nursing Implementation

Your role is to facilitate and enhance the patient's coping and adaptation. Nursing interventions depend on the severity of the stress experience. For example, a patient with multiple trauma expends energy to physically survive. As a nurse, you direct efforts toward life-supporting interventions and approaches aimed at reducing added stressors for the patient. The patient is much less likely to adapt or recover if faced with more stressors, such as sleep deprivation or an infection. You can assume a primary role in implementing stress management strategies. Some personal tips for handling stress are shown in Table 6.10. These tips will help you personally and enhance your own level of health and wellness. It is essential that you first care for yourself before you can help the patients who need your care. Many professional organizations, such as the American Nurses Association, offer resources to help you manage stress

(www.nursingworld.org). Once you included these strategies into your life, you can share them with patients and caregivers.

TABLE 6.10 Personal Tips for Handling Stress

- Do not try to be superhuman.
- Learn to "let go" of things that are outside of your control.
- Learn acceptance of yourself.
- Exercise regularly.
- Share your feelings.
- Keep a sense of humor; laugh often.
- Learn relaxation breathing.
- Use imagery.
- Meditate or pray.
- Get adequate sleep.
- Live a healthy lifestyle.
- Try to look at change as a positive challenge, not as a threat.
- Solve the little problems, since this can help you gain a feeling of control.
- Work to resolve conflicts with other people.
- If needed, get professional counseling.

TABLE 6.11 How to Implement Stress Management in Practice

1. Learn relaxation breathing. It is the easiest method of relaxation to use.
2. Practice teaching relaxation breathing with peers, then patients.
3. Pick coping strategies (Table 6.4) and relaxation strategies that

are appropriate for your clinical area.
4. Practice using the strategy yourself. It becomes easier with time.
5. Take advantage of opportunities to teach coping and relaxation strategies to patients.
6. If you have setbacks, think about what went wrong. Do NOT quit!
7. Attend seminars and workshops on stress management to learn more.

Ideas for how to include stress management strategies into nursing practice are described in Table 6.11. Although some require additional training, many stress management strategies are within the scope of nursing practice. These include relaxation breathing, imagery, music, exercise, massage, meditation, art therapy, and journaling. More resources are in the Stress-Busting Kit for Nursing Students on the website for this book.

Coping strategies used should be helpful and not a source of added stress for the patient. You can teach most coping and relaxation strategies to patients in 10 to 15 minutes. Choose a coping or relaxation strategy to best suit the patient and situation. Effective stress management provides a sense of control of the stressful situation. As stress management practices become part of daily activities, the person can increase his or her confidence and self-reliance and limit the emotional response to the stressful circumstances. Having a sense of control can prevent the harmful effects of a stress response.

As a nurse, you are in an ideal situation to integrate stress management in clinical practice. You are well equipped to develop and test the effectiveness of new ways to manage stress and promote positive health outcomes. However, it is very important to recognize when you need to refer the patient or caregiver to a professional with advanced training in counseling.

Case Study

Stress-Induced Illness

© JackF/iStock/Thinkstock.

Patient Profile

K.F., a 48-yr-old woman, recently moved to the United States from

Romania with her 2 teenage children. She has no family in the country and was recently divorced. She has taken a job as a waitress in a hectic restaurant and works as a seamstress out of her home in the evenings.

She has developed some unusual symptoms and comes to see the nurse practitioner at a community clinic. Although she says that she was in good healthwhen she left Romania, she now presents with fatigue, inability to sleep, and aches all over her body. Even when she gets some extra sleep, she still feels exhausted. Her co-worker told her she has fibromyalgia.

Discussion Questions

1. Consider K.F.'s situation and describe the stressors with which she is dealing. Describe the possible effects of these stressors on her health.
2. ***Priority Decision:*** What are the priority coping strategies that you should include in K.F.'s plan of care?
3. What limitations should you consider when discussing specific coping strategies?
4. ***Patient-Centered Care:*** What cultural considerations should you include in the plan of care?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to NCLEX Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Determination of whether an event is a stressor is based on a person's
   a. tolerance.
   b. perception.

c. adaptation.

d. stubbornness.

2. The nurse would expect which finding in a patient because of the physiologic effect of stress on the reticular formation?

   a. An episode of diarrhea while awaiting painful dressing changes

   b. Refusal to communicate with nurses while awaiting a cardiac catheterization

   c. Inability to sleep the night before beginning to self-administer insulin injections

   d. Increased blood pressure, decreased urine output, and hyperglycemia after a car accident

3. The nurse uses knowledge of the effects of stress on the immune system by encouraging patients to

   a. sleep for 10 to 12 hours per day.

   b. avoid exposure to upper respiratory tract infections.

   c. receive regular immunizations when they are stressed.

   d. use emotion-focused rather than problem-focused coping strategies.

4. The nurse recognizes that a person who has chronic stress could be at higher risk for *(select all that apply)*

   a. osteoporosis.

   b. fibromyalgia.

   c. colds and flu.

   d. high blood pressure.

   e. high serum cholesterol.

5. The nurse recognizes that a patient with newly diagnosed breast cancer is using an emotion-focused coping process when she
   a. joins a support group for women with breast cancer.
   b. considers the pros and cons of the various treatment options.
   c. delays treatment until her family can take a weekend trip together.
   d. tells the nurse that she has a good prognosis because the tumor is small.
6. During a stressful circumstance that is unchangeable, which type of coping strategy is the *most* effective?
   a. Avoidance
   b. Coping flexibility
   c. Emotion-focused coping
   d. Problem-focused coping
7. An appropriate nursing intervention for a hospitalized patient who says she cannot cope with her illness is
   a. controlling the environment to prevent sensory overload and promote sleep.
   b. encouraging the patient's family to offer emotional support by frequent visiting.
   c. arranging for the patient to phone family and friends to maintain emotional bonds.
   d. asking the patient to describe previous stressful situations and how she managed to resolve them.

1. b, 2. c, 3. b, 4. b, c, d, 5. a, 6. c, 7. d.

Sleep and Sleep Disorders

Diana Taibi Buchanan

LEARNING OUTCOMES

1. Define sleep.
2. Describe the stages of sleep.
3. Explain the relationship of various diseases/disorders and sleep disorders.
4. Describe the etiology, clinical manifestations, and interprofessional and nursing management of insomnia.
5. Describe the etiology, clinical manifestations, and interprofessional and nursing management of obstructive sleep apnea.
6. Describe clinical manifestations and interprofessional management of narcolepsy, parasomnias, and circadian rhythm disorders.
7. Select strategies for managing sleep problems associated with shift work sleep disorder.

KEY TERMS

circadian rhythms, p. 89

continuous positive airway pressure (CPAP), p. 96
insomnia, p. 91
jet lag disorder, p. 97
narcolepsy, p. 98
obstructive sleep apnea (OSA), p. 95
parasomnias, p. 98
periodic limb movement disorder (PLMD), p. 97
shift work sleep disorder, p. 99
sleep, p. 88
sleep-disordered breathing (SDB), p. 95
sleep disorders, p. 88
sleep disturbance, p. 88
sleep hygiene, p. 92
wake behavior, p. 89

Conceptual Focus

Functional Ability
Mood and Affect
Sleep

I slept and dreamt that life was joy. I awoke and saw that life was service. I acted and behold, service was joy.

Rabindranath Tagore

http://evolve.elsevier.com/Lewis/medsurg/

Sleep

Sleep is a state in which a person lacks conscious awareness of environmental surroundings but can be easily aroused. Sleep is distinct from unconscious states such as coma, in which the person cannot be aroused. Sleep is a basic, dynamic, highly organized, and complex behavior that is essential for healthy functioning and survival. Over a life span of 80 years, a person who sleeps 7 hours each night will spend around 24 years sleeping. Sleep influences mood, behavior, and physical functioning. Some physical functions affected by sleep are memory, mood, hormone secretion, glucose metabolism, immune function, and body temperature.

Most adults need 7 to 8 hours of sleep within a 24-hour period.[1] Adequate sleep is defined as the amount of sleep one needs to be fully awake and alert the next day. *Insufficient sleep* means getting less than the recommended amount of sleep. *Fragmented sleep* means a person wakes up or almost wakes (called an arousal), interrupting continuous sleep. *Nonrestorative sleep* means that a person sleeps the recommended amount but does not feel refreshed and alert the next day.

Sleep disturbance is a broad term that refers to poor sleep quality from various causes. Sleep disturbance may be related to environmental factors such as noise or light. It can be caused by health-related factors such as pain or by **sleep disorders**, which are problems unique to sleep. Sleep disorders discussed in this chapter include insomnia, obstructive sleep apnea syndrome, periodic limb movement disorder, circadian sleep disorders, narcolepsy, and parasomnias.

Sleep disturbances and sleep disorders can result in insufficient sleep. Many people get insufficient sleep because they simply are not in bed long enough to allow for an adequate amount of sleep. About 35% of Americans get less than the recommended 7 hours of sleep per night. An estimated 50 to 70 million people in the United States have a sleep disorder.[2] Many are unaware that they have a problem (Fig. 7.1). People with chronic illnesses have the greatest risk for sleep disturbances.

Untreated sleep disorders cause considerable health, safety, and

economic consequences. Daytime sleepiness can be so severe that it interferes with work and social functioning. Driving while drowsy is related to 100,000 accidents and 1500 traffic fatalities per year.[3] Sleep disorders, sleep loss, and excessive daytime sleepiness cost the United States billions of dollars each year from the cost of health care, work-related accidents, and lost productivity.[4] Opportunities to address sleep problems are often missed because health care providers (HCPs) do not ask and patients do not readily talk about them.

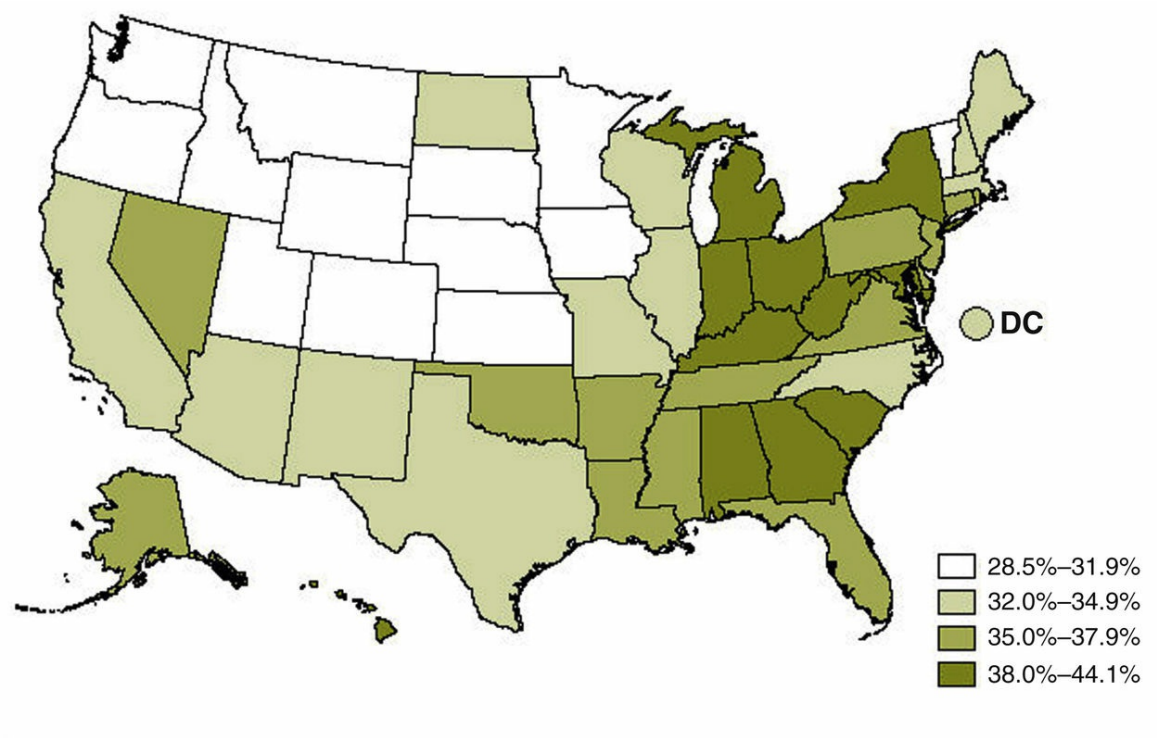

FIG. 7.1 Prevalence among U.S. adults of obtaining less than 7 hours of sleep each night.
Modified from *www.cdc.gov/sleep/data_statistics.html*.

Physiologic Sleep Mechanisms

Sleep-Wake Cycle

The brain controls the cyclic changes between sleep and waking.

Complex networks in the areas of the forebrain (cerebral cortex, hypothalamus, thalamus) and brainstem interact to regulate the sleep-wake cycle.

Wake Behavior

Wake behavior is maintained by an integrated network of arousal systems from the brainstem and forebrain. A cluster of neuron structures in the brainstem, called the *ascending reticular activating system (ARAS),* promote general activation of the cerebral cortex, which is responsible for higher brain functions. This activation gives rise to typical wake behaviors such as alertness and attention. Various neurotransmitters (glutamate, acetylcholine, norepinephrine, dopamine, histamine, serotonin) promote wake behavior.[5]

People with Alzheimer's disease lose cholinergic neurons in the forebrain, which results in sleep disturbances. In Parkinson's disease, dopamine neurons in the ARAS degenerate, which causes excessive daytime sleepiness. Histamine neurons in the hypothalamus stimulate cortical activation and wake behavior.[6] The sedating properties of many over-the-counter (OTC) medications (e.g., diphenhydramine) result from inhibiting histamine-related arousal systems.[7]

Orexin (also called hypocretin) is a neuropeptide found in the hypothalamus. Orexin is involved in regulating the sleep-wake cycle. It plays an important role in keeping people awake. Decreased levels of orexin or its receptors lead to difficulties staying awake, which is a syndrome called *narcolepsy*.[8] Narcolepsy is discussed later in this chapter on p. 98.

Sleep Behavior

An area in the hypothalamus just above the optic chiasm contains many sleep-promoting neurons. These neurons inhibit the ARAS and promote sleep.[5] Sleep is stimulated by a variety of sleep-promoting neurotransmitters and peptides, including γ-aminobutyric acid (GABA), galanin, melatonin, adenosine, somatostatin, growth hormone–releasing hormone (GHRH), delta-sleep–inducing peptide,

prostaglandins, and proinflammatory cytokines. When a person has an infection, proinflammatory cytokines (interleukin-1, tumor necrosis factor, interleukin-6) contribute to sleepiness and lethargy. Peptides released by the gastrointestinal tract after food ingestion (e.g., cholecystokinin) may mediate sleepiness after eating (called *postprandial sleepiness*).

Melatonin is a hormone made by the pineal gland in the brain. Melatonin secretion is linked to the environmental light-dark cycle. Release of the hormone signals the time for sleep by "turning off" the mechanisms that promote wakefulness. Under normal day-night conditions, we release melatonin in the evening as it gets dark. Light exposure at night can suppress melatonin secretion.[7]

Circadian Rhythms

Many biologic rhythms of behavior and physiology fluctuate within a 24-hour period. These 24-hour patterns are called **circadian** (*circadian*, about a day) **rhythms**. The suprachiasmatic nucleus (SCN) in the hypothalamus is the master clock of the body. The SCN synchronizes the genetic clocks within individual cells and regulates the 24-hour sleep-wake cycle. Circadian rhythm timing is synchronized to the environmental light and dark periods through specific light detectors in the retina. Pathways from the retina reach the SCN, and pathways from the SCN innervate brain regions controlling wake and sleep behavior.[7]

Light is the strongest time cue for the sleep-wake rhythm. Thus we can use light as a therapy to shift the timing of the sleep-wake rhythm. For example, bright light used early in the morning will cause the sleep-wake rhythm to move to an earlier time; bright light used in the evening will cause the sleep-wake rhythm to move to a later time. For some people, being outside in daylight (without sunglasses) may be helpful. Others need light therapy, which is given through a device that makes very bright light.

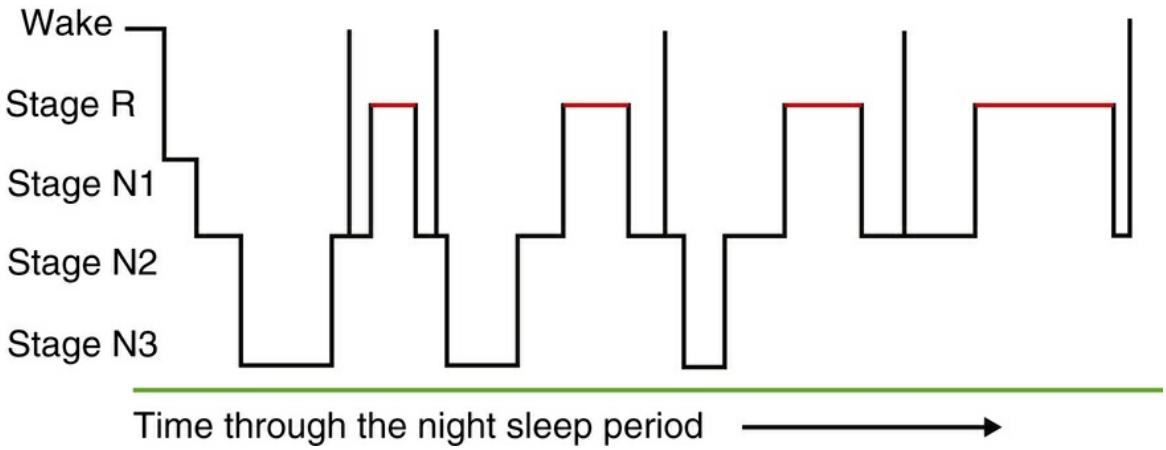

FIG. 7.2 Sleep stages graphed across a complete sleep cycle. From Goldman L, Schafer AI: *Goldman's Cecil medicine*, ed 25, Philadelphia, 2016, Saunders.

Sleep Architecture

Sleep architecture refers to the pattern of nighttime sleep recorded from physiologic measures of brain waves, eye movements, and muscle tone called *polysomnography* (PSG). Sleep consists of 2 basic states: *rapid eye movement (REM) sleep* and *non–rapid eye movement (NREM) sleep*. During sleep, the body cycles between NREM and REM sleep. Once asleep, a person goes through 4 to 6 NREM and REM sleep cycles, each cycle lasting 60 to 110 minutes (Fig. 7.2).

NREM Sleep

Healthy adults spend about 75% to 80% of sleep time in NREM sleep. NREM sleep is subdivided into 3 stages.[9] However, you may see the older version of sleep staging that used 4 stages. The newer, 3-stage approach combines the old stages 3 and 4 into N3.

N1 is the stage that occurs at the beginning of sleep. It is characterized by slow eye movements and is a transition phase from wakefulness to sleep. During this period the person can be easily awakened.

N2 is the stage that takes up most of the night's sleep. The heart

rate slows down and body temperature drops. N2 is associated with specific brain wave forms measured by electroencephalograph (EEG) that represent sleep-maintaining neural activity.

N3 is the deepest stage of sleep. It is called slow-wave sleep (SWS) because large, low-frequency EEG waves are characteristic. N3 is associated with large EEG waveforms, called delta waves. They are a measure of sleep intensity. SWS declines as people age. Most adults over 60 years of age have little NREM stage 3 sleep.

REM Sleep

REM sleep accounts for 20% to 25% of sleep. REM sleep follows NREM sleep in a sleep cycle. In this stage, brain waves resemble wakefulness and postural muscles are inhibited, leading to greatly reduced skeletal muscle tone. During REM sleep a person cannot initiate muscle movement (e.g., cannot stand up). REM sleep is the period when the most vivid dreaming occurs.

Insufficient Sleep and Sleep Disturbances

Insufficient sleep is associated with changes in body function (Fig. 7.3) and health problems (Table 7.1). Impaired cognitive function and impaired performance on simple behavioral tasks occur within 24 hours of sleep loss. The effects of sleep loss are cumulative.[10] Those who report less than 6 hours of sleep a night are more likely to be obese. The risk for developing glucose intolerance and diabetes is higher in those with a history of insufficient sleep. Chronic loss of sleep places people at risk for depression, impaired daytime functioning, social isolation, and overall reduction in quality of life.[11]

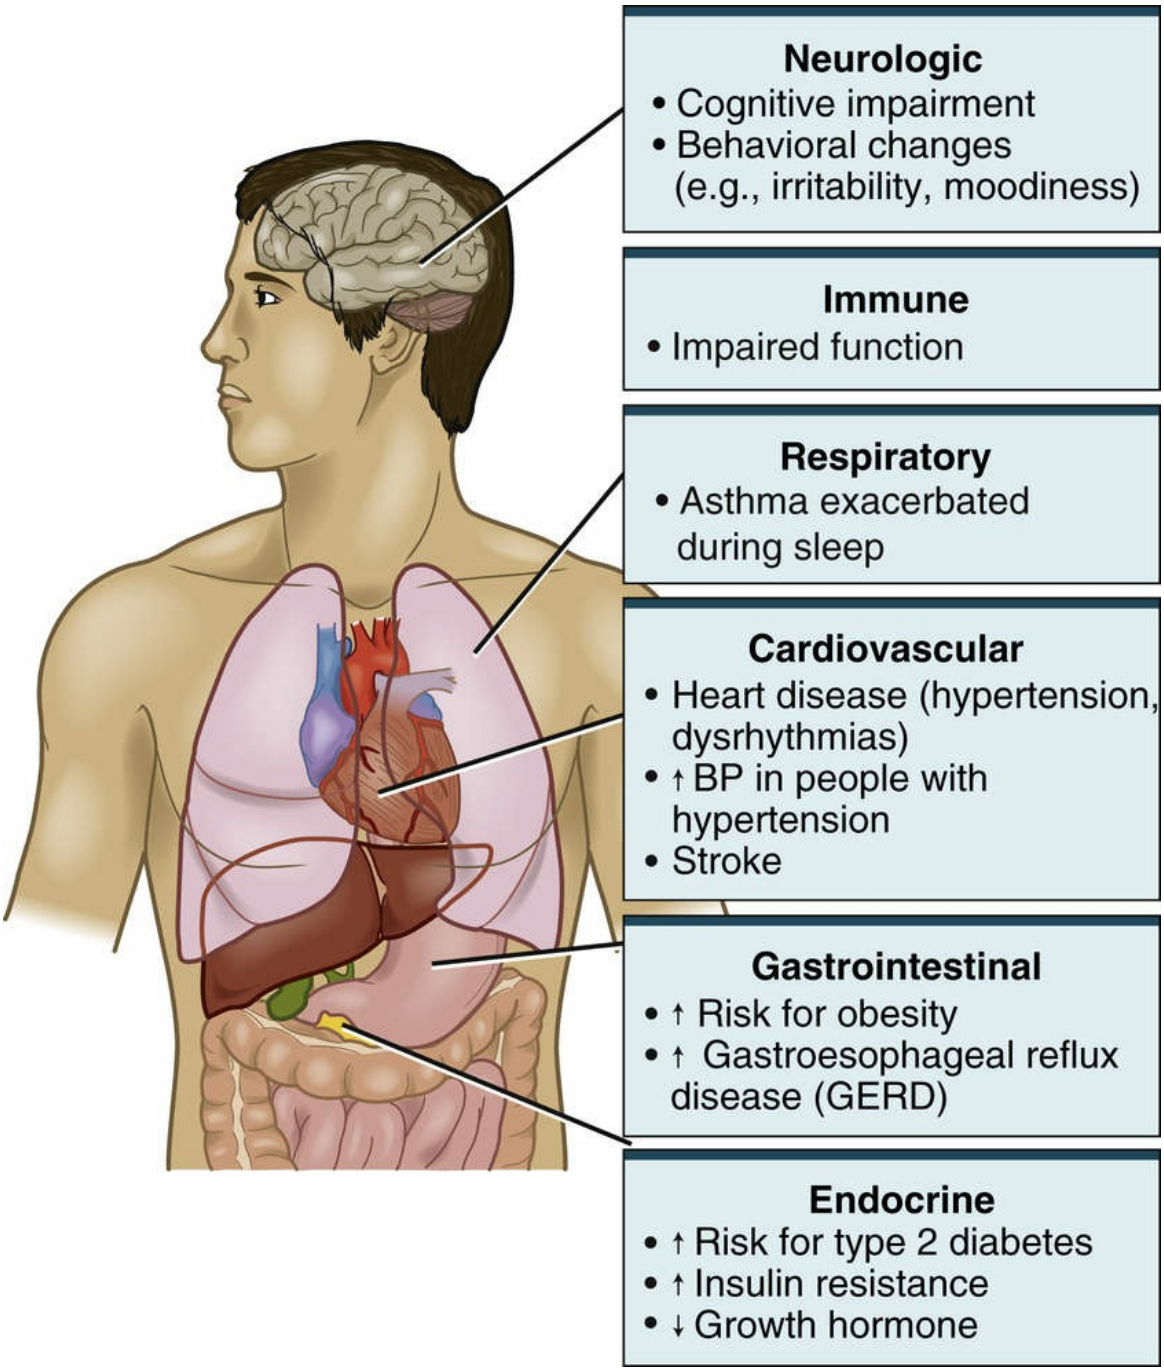

FIG. 7.3 Effects of sleep deprivation and sleep disorders on the body.

Sleep Disturbances in the Hospital

Hospitalized patients, especially in the intensive care unit (ICU), may have decreased total sleep time, disrupted normal sleep stages, and

disrupted circadian rhythms.[12] In the hospital, environmental sleep-disruptive factors, psychoactive medications, and acute and critical illness contribute to poor sleep. Contributing environmental factors include around-the-clock noise, light, and patient care activities. Hospital and ICU noise often persists both day and night from sources such as staff paging system, ventilator alarms, bedside monitors, infusion alarms, and staff conversations near patients (e.g., in hallways). Bright lights during the night disrupt sleep and reduce melatonin levels. Patient care activities including dressing changes, blood draws, vital sign monitoring, and medication administration often disrupt patients' ability to get sound, continuous sleep. This includes when we provide care to a patient's roommate in a shared room. Inactivity, boredom, and napping during the day and evening that can affect nighttime sleep. Patient symptoms, including pain, dyspnea, and nausea, can contribute to sleep loss in the acutely ill patient. Commonly used medications can further contribute to sleep loss. Preexisting sleep disorders may be worsened or triggered in those who are hospitalized.

Decreased sleep duration and sleep loss cause patients to be more sensitive to pain and less able to tolerate pain.[13] Adequate pain management may improve total sleep time, but many medications used to relieve pain, especially opioids, alter sleep quality and place a person at risk for sleep-disordered breathing.

You play a key role in creating an environment conducive to sleep. This includes the scheduling of medications and procedures, including those performed by unlicensed assistive personnel (UAP). Reducing light and noise levels can promote opportunities for sleep. Hypnotic sleep-aid medications are often available on an as-needed basis or can be discussed with the HCP.

TABLE 7.1 Relationship of Sleep Disturbances to Diseases and Disorders

Disease or Disorder	Sleep Disturbance
Cardiovascular (CV)	
Coronary artery disease	• People with sleep apnea or sleep disorders are at increased risk for CV disorders, including hypertension, dysrhythmias, and coronary artery disease
Heart failure (HF)	• Sleep problems (insomnia, PLMD, SDB) are common • Cheyne-Stokes breathing and central apnea are signs of HF exacerbation related to fluid overload
Hypertension	• Inadequate sleep in people with hypertension can lead to further elevations in BP
Endocrine	
Diabetes	• Insufficient sleep linked to increased risk for type 2 diabetes • Sleep deprivation in healthy people increases insulin resistance
Gastrointestinal	
Obesity	• Short sleep duration may result in metabolic changes that are linked to obesity • Higher body mass index (BMI) in those who sleep <6 hours compared with those who sleep >8 hours • Risk factor for SDB
Gastroesophageal reflux disease (GERD)	• Reflux of gastric contents into the esophagus occurs during sleep because of incompetent lower esophageal sphincter • Swallowing is depressed during sleep
Liver disease	• Associated with excessive sleepiness, nocturnal arousal, and RLS
Immune Disorders	
Human immunodeficiency virus (HIV)	• Sleep problems and fatigue highly prevalent and associated with increased morbidity and mortality
Musculoskeletal	
Arthritis	• Increased rates of RLS and SDB • Disease activity linked to sleep complaints
Fibromyalgia	• Co-morbid insomnia, especially complaint of nonrestorative sleep • Increased rates of PLMD and RLS • Lower levels of sleep-dependent hormones (growth hormone, prolactin)
Systemic exertion intolerance disease (chronic fatigue syndrome)	• Co-morbid insomnia • Increased rates of SDB
Neurologic	
Alzheimer's disease	• Many have SDB (frequently sleep apnea) • Circadian rhythm changes with nocturnal wandering, daytime sleepiness, and sleep disruption and awakening
Cancer	• Higher rates of insomnia • Chemotherapy for cancer treatment associated with fragmented sleep and fatigue
Pain (acute and chronic)	• Decreases quantity and quality of sleep • Poor sleep can intensify pain
Parkinson's disease	• Associated with difficulty initiating or maintaining sleep, parasomnias, and excessive daytime sleepiness
Renal	
End-stage renal disease (ESRD)	• Disrupted nocturnal sleep with excessive daytime sleepiness • Patients on dialysis have a high incidence of SDB and RLS, which are both significant predictors of mortality
Respiratory	
Asthma	• Worse during sleep
Chronic obstructive pulmonary disease (COPD)	• Associated with poor sleep quality, nocturnal oxygen desaturation, and coexisting sleep apnea
Obstructive sleep apnea (OSA)	• Linked with heart disease (hypertension, stroke, heart failure, coronary artery disease, dysrhythmias) • Results in impaired glucose control like that which occurs in type 2 diabetes

PLMD, Periodic limb movement disorder; *RLS,* restless legs syndrome; *SDB,* sleep-disordered breathing.

Sleep Disorders

Insomnia

The most common sleep disorder is insomnia. It affects 1 in 3 adults. **Insomnia** is characterized by difficulty falling asleep, difficulty staying asleep, waking up too early, or waking up feeling unrefreshed. The main problem people with insomnia report is overall dissatisfaction with sleep quality and quantity.

Acute insomnia refers to difficulties falling or remaining asleep at least 3 nights per week for less than a month. *Chronic insomnia* is defined by the same symptoms and a daytime problem related to poor sleep (e.g., fatigue, poor concentration, interference with social or family activities) that persist for 3 months or longer. Chronic insomnia occurs in 10% to 15% of Americans. It is more common in women than men. Insomnia is more common in people who are divorced, widowed, and separated than in those who are married. It is more prevalent in people with low socioeconomic status and less education.[14]

Etiology and Pathophysiology

Behaviors, lifestyle, diet, physical and mental conditions, and medications may contribute to insomnia. Insomnia is worsened or perpetuated by behaviors such as keeping irregular sleep-wake schedules (varying one's bedtime and rise time), taking long naps in the afternoon, spending time awake in bed trying to sleep, sleeping late in the morning, and exercising near bedtime. Lifestyle factors can contribute to insomnia. Although the sedative effects of alcohol help people fall asleep, it suppresses REM sleep and causes restlessness and awakenings later in the night. Use of various stimulants, including nicotine in tobacco products, caffeine, or methamphetamine, can cause restlessness and sleep disruption, worsening insomnia. Insomnia is a common side effect of many medications (e.g., antidepressants, antihypertensives, corticosteroids, psychostimulants, analgesics).

The physiologic and psychologic causes of chronic insomnia may be related to varied factors. Often people report that the onset occurred after a stressful life event, such as losing a job or the death of a loved one. In other cases, psychiatric illnesses, medical conditions, medications, or substance use may precipitate insomnia. Patients with psychiatric or medical conditions are more likely to have insomnia than those without these conditions. Once insomnia becomes chronic, symptoms are likely to persist over time.

Clinical Manifestations

Manifestations of insomnia include 1 or more of the following symptoms: (1) difficulty falling asleep *(long sleep latency),* (2) frequent awakenings *(fragmented sleep),* (3) prolonged nighttime awakenings or awakening too early and not being able to fall back to sleep *(difficulty maintaining sleep),* and (4) awakening feeling unrefreshed *(nonrestorative sleep).*[14] Daytime or functional consequences of insomnia include fatigue, having trouble concentrating at work or school, and having an altered mood. Behavioral manifestations of poor sleep include irritability, sleepiness during the day, forgetfulness, and attention and concentration problems.

Diagnostic Studies

Self-Report

The diagnosis of insomnia is made based on subjective complaints and an evaluation of a 1- or 2-week sleep diary completed by the patient. A diary or log usually includes the number and times of naps, times of going to bed, awakening, and getting up, number of awakenings, and overall sleep quality ratings.

In ambulatory care settings, the evaluation of insomnia requires a comprehensive sleep history. This establishes the type of insomnia and screens for possible psychiatric, medical, or other sleep disorders that would require specific treatment. Questionnaires, such as Pittsburgh Quality Sleep Index, Insomnia Severity Index, and Epworth Daytime Sleepiness, are often used to assess sleep quality

and negative daytime symptoms related to insomnia.

Actigraphy

Actigraphy is a relatively noninvasive method of monitoring rest and activity cycles. An actigraph is a device that measures overall motor activity. It is worn on the wrist like commercially available activity monitors. Actigraphs used for sleep medicine and research are more accurate and sensitive than consumer-based devices. The unit continuously records the patient's movements, producing data that are downloaded to a computer and analyzed. Activity corresponds to time spent awake, and continuous inactivity corresponds to time spent asleep. Actigraphy is not necessary for diagnosing insomnia, but it is useful for confirming patient's sleep self-reports and monitoring the effects of treatments.

- Melatonin-receptor agonist
- Antidepressants

Complementary and Alternative Therapy

- Melatonin

Polysomnography

A polysomnography (PSG) study is not recommended to diagnose insomnia. A PSG study is done only if there are symptoms or signs of another sleep disorder, such as sleep-disordered breathing (discussed later in the chapter). In a PSG study, electrodes simultaneously record physiologic measures that define the main stages of sleep and wakefulness. These measures include (1) muscle tone recorded using an electromyogram (EMG), (2) eye movements recorded with an electrooculogram (EOG), and (3) brain activity recorded through EEG. To determine additional characteristics of specific sleep disorders, other measures made during PSG include airflow at the nose and mouth, respiratory effort around the chest and abdomen, heart rate, noninvasive oxygen saturation, and EMG of the anterior tibialis muscles (used to detect periodic leg movements). Finally, cameras and microphones continuously monitor a patient's gross body movements.

Interprofessional Care

Insomnia treatments are directed toward changing behaviors that perpetuate insomnia and managing symptoms (Table 7.2). The goal is to (1) prevent acute insomnia from becoming chronic and (2) treat

chronic insomnia. An important first step is to provide teaching about sleep along with behavioral strategies. **Sleep hygiene** is a variety of different practices that are important to have normal, quality nighttime sleep and daytime alertness (Table 7.3). Patients often have some familiarity with sleep hygiene principles, but they may still benefit from coaching on how to use these principles effectively.

Cognitive-Behavioral Therapy for Insomnia

Although teaching about sleep hygiene practices is useful, those with chronic insomnia need more in-depth *cognitive-behavioral therapy for insomnia (CBT-I)*.[14] CBT-I is based on structured treatment plans that include cognitive and behavioral components. The cognitive part of CBT-I may include stress management techniques (e.g., relaxation breathing, imagery) or cognitive strategies to address misconceptions about sleep. The specific approach used varies based on the patient's need. The behavioral part of CBT-I includes instructions to (1) limit the amount of time a person can stay in bed, (2) set a scheduled time to get up in the morning, (3) go to bed only when feeling sleepy, and (4) get out of bed when unable to sleep. CBT-I includes focused teaching and coaching on how to effectively use sleep hygiene practices (Table 7.3). CBT-I requires people to change behavior, which can be hard.

TABLE 7.3 Patient Teaching

Sleep Hygiene

Include the following instructions when teaching a patient who has a sleep disturbance or disorder.

- Do not go to bed unless you are sleepy.
- If you are not asleep after 20 minutes, get out of bed and do a nonstimulating activity. Return to bed only when you are sleepy.

- Adopt a regular pattern in terms of bedtime and awakening.
- Begin rituals (e.g., warm bath, light snack, reading) that help you relax each night before bed.
- Get a full night's sleep on a regular basis.
- Make your bedroom quiet, dark, and a little bit cool.
- Do not read, write, eat, watch TV, talk on the phone, or use technologies such as smart phones and tablet computers in bed.
- Avoid caffeine, nicotine, and alcohol at least 4–6 hours before bedtime.
- Do not go to bed hungry, but do not eat a big meal near bedtime either.
- Avoid strenuous exercise within 6 hours of your bedtime.
- Avoid sleeping pills, or use them cautiously.
- Practice relaxation techniques (e.g., relaxation breathing) to help you cope with stress.

Adapted from American Academy of Sleep Medicine: Healthy sleep habits, 2017. Retrieved from *www.sleepeducation.org/treatment-therapy/healthy-sleep-habits/*.

Although full CBT-I treatment should be delivered by trained HCPs, you can apply many of the principles to help patients. Teach the person with insomnia to avoid naps. Older adults may have difficulty fully avoiding naps. You can teach them that naps are less likely to affect nighttime sleep if they are limited to 15 to 20 minutes, once per day, and scheduled no later than 7 to 9 hours after waking in the morning. Regular exercise may enhance sleep quality but should not be done within several hours of bedtime.

Drug Therapy

Most medications for insomnia work by producing sleepiness to promote the onset or maintenance of sleep. Based on the characteristics (onset, half-life, and mechanism of action), certain

medications may be recommended for specific patterns of insomnia but not for others. They can treat problems falling asleep (sleep onset), waking during the night and having trouble falling back asleep (sleep maintenance), or both. Medications that treat insomnia can cause next-day drowsiness and impair driving and other activities that require alertness. People can be impaired even when they feel fully awake. Many people become used to taking OTC or prescription medications to treat insomnia and risk becoming dependent on them, psychologically and physically. *Rebound insomnia* is worsening of sleep that may occur when one abruptly stops certain sleep medications.

Medications are generally recommended for short-term treatment of insomnia. There is little evidence to support the use of medications for chronic insomnia. In 2017 the American Academy of Sleep Medicine (AASM) published new guidelines for pharmacologic treatment of chronic insomnia.[15] Drug classes used to treat insomnia include benzodiazepines, benzodiazepine-receptor agonists, orexin-receptor antagonist, melatonin-receptor agonist, antidepressants, and antihistamines (Table 7.4).[16] Use of hypnotic medications in older adults is controversial due to side effects and safety concerns, such as fall risk.[17]

Benzodiazepine Hypnotics

Benzodiazepines activate GABA receptors to promote sleep. These agents are no longer recommended as first-line therapy for insomnia. Only 2 benzodiazepines are included in the 2017 AASM guidelines: triazolam (Halcion) is recommended for sleep onset insomnia, and temazepam (Restoril) is recommended for both sleep onset and sleep maintenance insomnia.[15] Some benzodiazepines are recommended for treating anxiety but not insomnia (e.g., diazepam, alprazolam). However, you may still encounter patients who are prescribed these medications for insomnia. Other benzodiazepines (estazolam, flurazepam, oxazepam) lack enough research to support clinical

recommendations. The prolonged half-life of some of these drugs can result in daytime sleepiness, amnesia, dizziness, and rebound insomnia. Tolerance develops, and there is a risk for dependence and the potential for misuse. They should be used for only 2 to 3 weeks. In addition, they interact with alcohol and other central nervous system (CNS) depressants.

Non-Benzodiazepine Hypnotics

Non-benzodiazepine hypnotics act at GABA receptors but have more selective action than benzodiazepines, resulting in better safety.[16] These agents are considered first-line for pharmacologic treatment of insomnia. The 2017 AASM guidelines recommend zaleplon (Sonata) for sleep onset insomnia and zolpidem (Ambien) and eszopiclone (Lunesta) for sleep onset and sleep maintenance insomnia.[15] These drugs are effective and safe for use from 3 months to a year.[16] Food has the potential to delay onset of action and should not be taken with these agents. These agents have short half-lives, making their duration of action short and reducing the risk for daytime sedation. Newer formulations have improved specific therapeutic uses. A controlled-release formulation of zolpidem (Ambien CR) lengthens the action of the medication, improving its use for sleep maintenance insomnia. Zolpidem (Intermezzo) is available in a quick-acting sublingual tablet that may be taken for middle-of-the-night awakenings. A dissolvable tablet form of zolpidem (Edluar) and an oral spray formulation (ZolpiMist) may be used with those who have difficulty swallowing pills or are on restricted oral fluid intake.

Orexin-Receptor Antagonist

Suvorexant (Belsomra) is the first approved orexin-receptor antagonist. It promotes sleep by blocking the effects of orexin. Suvorexant should be taken no more than once per night, within 30 minutes of going to bed, with at least 7 hours remaining before the planned time of waking. It is recommended only for sleep maintenance insomnia.[15] The most common side effect is drowsiness.

Melatonin-Receptor Agonist

Ramelteon (Rozerem) is a melatonin-receptor agonist. It has a rapid onset that is effective for sleep onset. Ramelteon does not cause tolerance, but it is not always effective in improving sleep quality. Ramelteon is recommended for insomnia with sleep onset difficulty, not for sleep maintenance problems.[15]

Antidepressants

Certain tricyclic antidepressants (e.g., doxepin, amitriptyline) are used as sleep aids due to their side effects of sedation. The insomnia dose is much lower than the antidepressant dose. The AASM recommends doxepin for sleep maintenance insomnia.[15] Doxepin improves sleep without next-day drowsiness in older and middle-aged adults with chronic primary insomnia.

Trazodone, an atypical antidepressant, is 1 of the most common agents prescribed to treat insomnia, especially in older adults. Giving this drug to older adults is controversial. Daytime sleepiness is a common side effect. Tolerance can develop within a few weeks. The AASM recommends against using trazodone because there is not enough research to determine if the benefit outweighs risks for side effects.[15]

Antihistamines

Many people self-medicate with OTC sleep aids. These include doxylamine (Unisom) and several agents that contain diphenhydramine. Diphenhydramine is in many "nighttime" pain medicines. The AASM guidelines do not recommend diphenhydramine for insomnia because research does not show that it effectively improves sleep. It should not be used by older adults. Antihistamines have anticholinergic side effects, including daytime sleepiness, impaired cognitive function, blurred vision, urinary retention, constipation, and risk for increased intraocular pressure. The AASM guidelines do not mention doxylamine.[15]

Complementary and Alternative Therapy

Many types of complementary and alternative therapies are used as sleep aids (see Complementary & Alternative Therapies: Melatonin box). Melatonin is not recommended for treatment of insomnia,[15] but it may be effective for improving sleep disturbance associated with jet lag.[18] It also helps night shift workers sleep during the daytime. Valerian is an herb that has been used for many years as a sleep aid and to relieve anxiety. Although valerian is safe, it is not effective in treating insomnia. Other sleep aids include white noise devices or relaxation strategies.

Complementary & Alternative Therapies

Melatonin

Scientific Evidence

Overall, the scientific evidence suggests melatonin may help people who take it for jet lag. It may also decrease the time it takes to fall asleep (sleep latency).

Nursing Implications

- Regarded as safe in recommended doses for short-term use.
- Avoid in patients using warfarin (Coumadin).
- Avoid in patients using central nervous system depressants.
- Common side effects are headache, nausea, dizziness, and drowsiness.

TABLE 7.5 Nursing Assessment

Sleep

Use the following questions to do an initial sleep assessment.

1. What time do you normally go to bed at night? What time do you normally wake up in the morning?
2. Do you often have trouble falling asleep at night?
3. About how many times do you wake up at night?
4. If you do wake up during the night, do you usually have trouble falling back asleep?
5. Does your bed partner say or are you aware that you frequently snore, gasp for air, or stop breathing?
6. Does your bed partner say or are you aware that you kick or thrash about while asleep?
7. Are you aware that you ever walk, eat, punch, kick, or scream during sleep?
8. Are you sleepy or tired during much of the day?
9. Do you usually take 1 or more naps during the day?
10. Do you usually doze off without planning to during the day?
11. How much sleep do you need to feel alert and function well?
12. Are you currently taking any type of medication or other preparation to help you sleep?

Nursing Management: Insomnia

Nursing Assessment

As a nurse, you are in a key position to assess sleep problems in patients and their caregivers. Sleep assessment is important in helping patients identify personal habits and environmental factors that contribute to poor sleep. Family caregivers may have sleep disruptions from the need to provide care to patients in the home. These sleep disruptions can increase the burden of caregiving.

Self-report and objective data are used to assess sleep duration and quality. Many patients do not tell their HCP about their sleep problems. Make sure to ask patients about their sleep and problems with sleep. A sleep history includes characteristics of sleep such as sleep duration, the pattern of sleep, and daytime alertness (Table 7.5). Healthy adults should have 7 to 8 hours of sleep a night. Occasional difficulty getting to sleep or awakening during the night is not unusual. However, sleep disturbances longer than 1 month are problematic. Assess the diet and caffeine intake.

Ask the patient about sleep aids. This includes OTC and prescription medications. Note the drug dose, frequency of use, and any side effects (e.g., daytime drowsiness, dry mouth). Ask about alcohol consumption and whether it is used as a sleep aid. Many people consume herbal or dietary supplements that they believe will improve sleep. Common supplements include valerian, melatonin, hops, passion flower, kava, and skullcap. Tell the patient that many of these products are sold as dietary supplements and do not have U.S. Food and Drug Administration (FDA) approval or regulatory oversight. The exact components and concentrations of herbs and supplements often are unknown. Patients may have adverse effects or herb-drug interactions. Certain agents such as kava are associated with liver toxicity.

Encourage the patient to keep a sleep diary for 1 to 2 weeks. A free sleep diary is available from the National Sleep Foundation (*www.sleepfoundation.org/sites/default/files/SleepDiaryv6.pdf*). You can help the patient choose 1 of the many sleep diary smartphone applications that track information about sleep. Commercially available activity monitors can track sleep, but these vary in accuracy. Encourage people with sleep problems to share this information with their HCP to help identify sleep patterns.

The patient's medical history can provide important information about factors that contribute to poor sleep. For example, a man with benign prostatic hyperplasia may report frequent awakenings during the night for voiding. Psychiatric problems (e.g., depression, anxiety, posttraumatic stress disorder [PTSD], drug use) are associated with

sleep disturbances. Some patients being seen for sleep problems may complete short questionnaires to screen for mood disturbances. Sleep disturbances often develop as a result or complication of a chronic or terminal condition (e.g., heart disease, dementia, cancer). Painful conditions such as arthritis may contribute to nighttime awakenings.

Ask about work schedules and cross-country and international travel. Shift work contributes to reduced or poor-quality sleep. Work-related behaviors resulting from poor sleep may include poor performance, decreased productivity, and job absenteeism.

Nursing Diagnoses

Nursing diagnoses related to sleep include sleep deprivation and impaired sleep pattern.

Nursing Implementation

Nursing care depends on the severity and duration of the sleep problem. Although teaching about sleep hygiene practices (Table 7.3) is beneficial, patients with chronic insomnia need more in-depth intervention using CBT-I strategies. An important part of sleep hygiene is reducing dietary intake of caffeine-containing substances (Table 7.6). Caffeine has a half-life of about 6 hours and possibly as long as 9 hours in older adults. Patients should avoid consuming caffeinated beverages after 12 noon.

Suggest and implement changes in home and institutional environments to enhance sleep. Reducing light and noise levels enhances sleep. Awareness of time passing and watching the clock adds to anxiety about not falling asleep or returning to sleep. Keeping the bedroom dark and cool is conducive to good sleep.

Teach patients about sleeping medications. With the benzodiazepines, non-benzodiazepine hypnotics, and melatonin-receptor agonists, teach the patient to take the drug right before bedtime and be prepared to get a full night's sleep of at least 6 to 8 hours. Tell patients not to plan activities the next morning that require highly skilled psychomotor coordination. Advise patients not to take

these medications with high-fat food (delays absorption), alcohol, or other CNS depressants. Patient follow-up about medications is important. Ask about daytime sleepiness, nightmares, and any difficulties in activities of daily living.

Obstructive Sleep Apnea

The term **sleep-disordered breathing (SDB)** describes abnormal respiratory patterns associated with sleep. These include snoring, apnea (temporary cessation of respiration), and hypopnea (temporary restriction of respiration without full cessation) with increased respiratory effort leading to frequent arousals. SDB results in frequent sleep disruptions and changes in sleep stages. Obstructive sleep apnea is the most commonly diagnosed SDB problem.

Obstructive sleep apnea (OSA), also called *obstructive sleep apnea–hypopnea syndrome* (OSAHS), is characterized by partial or complete upper airway obstruction during sleep. *Apnea* is the cessation of respiratory airflow (90% or greater reduction) lasting longer than 10 seconds. *Hypopnea* is a condition characterized by shallow respirations (30%–90% reduction in airflow).[9] Airflow obstruction in OSA occurs because of (1) narrowing of the air passages with relaxation of muscle tone during sleep and/or (2) the tongue and soft palate falling backward to partially or completely obstruct the pharynx (Fig. 7.4). Each obstruction may last from 10 to 90 seconds. During the apneic period the patient can have *hypoxemia* (decreased PaO_2 or SpO_2) and *hypercapnia* (increased $PaCO_2$). These changes are ventilatory stimulants and cause brief arousals, but the patient may not fully awaken.

TABLE 7.6 Caffeine Content of Select Beverages

Food or Beverage	Caffeine (mg)

Coffee, brewed (8 oz)	95–165
Coffee, instant (8 oz)	7.63
Coffee, espresso (1 oz)	47.64
Coffee, decaffeinated	2–5
Cola (8 oz)	24–46
Energy drink (8 oz)	27.164
Energy shot (1 oz)	40–100
Hot chocolate (8 oz)	5
Root beer, most brands (8 oz)	0
Sprite, 7up (12 oz)	0
Tea, black (8 oz)	25–48
Tea, green (8 oz)	25–297

Source: Mayo Clinic: Caffeine content for coffee, tea, soda and more, 2017. Retrieved from *www.mayoclinic.org/healthy-lifestyle/nutrition-and-healthy-eating/in-depth/caffeine/art-20049372*.

The patient has a generalized startle response, snorts, and gasps, which cause the tongue and soft palate to move forward and the airway to open. Apnea and arousal cycles occur repeatedly throughout the night. Apneic episodes occur most often during REM sleep, when airway muscle tone is lowest.

There is no single cause for OSA. The condition is related to multiple factors that influence airway patency and the tone of airway musculature. Risk factors include obesity (body mass index [BMI] greater than 30 kg/m^2), age older than 65 years, neck circumference greater than 17 inches, craniofacial abnormalities that affect the upper airway, and acromegaly (acromegaly is discussed in Chapter 49). Smokers are more likely to have OSA. OSA is more common in men than in women until after menopause, when the prevalence of the disorder is equal.[19] Women with OSA have higher mortality rates than men with OSA. OSA patients with excessive daytime sleepiness

have increased mortality.

Clinical Manifestations

Clinical manifestations of sleep apnea include frequent arousals during sleep, insomnia, excessive daytime sleepiness, and witnessed apneic episodes. The patient's bed partner may complain about the patient's loud snoring. Other symptoms include morning headaches (from hypercapnia or increased BP that causes vasodilation of cerebral blood vessels), personality changes, and irritability.

A major risk of OSA is cardiovascular complications. Apnea during sleep causes hypoxia, nocturnal arousals, and increased pressure in the thoracic cavity. These events can lead to negative physiologic consequences, including overactivation of the sympathetic nervous system, increased vascular resistance, and reduced oxygenation of the heart muscle. Long-term effects include hypertension, cardiac dysrhythmias, arteriosclerosis, heart failure, and cardiovascular-related mortality.[20]

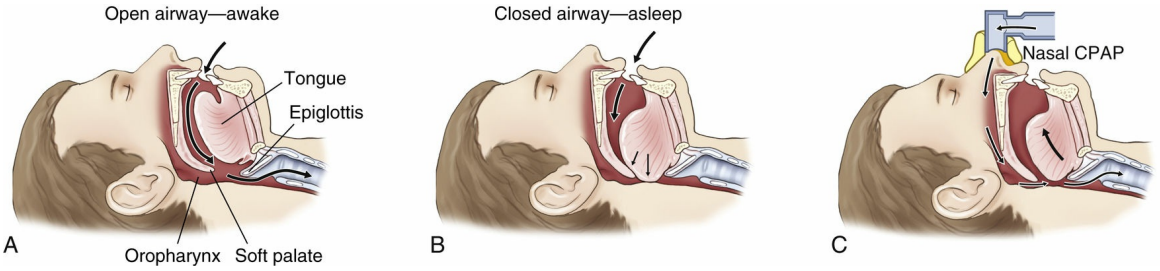

FIG. 7.4 How sleep apnea occurs. **A,** The patient predisposed to obstructive sleep apnea (OSA) has a small pharyngeal airway. **B,** During sleep, the pharyngeal muscles relax, allowing the airway to close. Lack of airflow results in repeated apneic episodes. **C,** Continuous positive airway pressure *(CPAP)* splints the airway open, preventing airflow obstruction.
Modified from LaFleur Brooks M: *Exploring medical language: A student-directed approach*, ed 8, St Louis, 2012, Mosby.

Chronic sleep loss predisposes the person to diminished ability to concentrate, impaired memory, failure to complete daily tasks, and interpersonal difficulties. Men may have impotence. Hypercapnia and

arousals contribute to daytime sleepiness in people with OSA. Driving accidents may occur due to excessive daytime sleepiness. Family life and the patient's ability to maintain employment are often compromised. As a result, the patient may become depressed. Cessation of breathing reported by the bed partner is usually a source of great anxiety because of the fear that breathing may not resume.

Diagnostic Studies

Assessment of the patient with OSA includes a thorough sleep and medical history. Tools used to screen for OSA are the Berlin questionnaire and the STOP-BANG questionnaire, which assesses for clinical manifestations highly suspicious of OSA.[19]

Typically, OSA is diagnosed by PSG done in a clinical sleep laboratory. The patient's chest and abdominal movement, oral and nasal airflow, SpO_2, eye movement, and heart rate and rhythm are monitored. In some instances, portable sleep studies are done in the home setting. Overnight pulse oximetry assessment may be done to determine whether nocturnal oxygen supplementation is needed.

A diagnosis of sleep apnea requires documentation of apneic events or hypopneas of at least 10 seconds' duration. OSA is defined as more than 5 apnea/hypopnea events per hour with a 3% to 4% decrease in oxygen saturation. Severe apnea can be associated with apneic events of more than 30 to 50 per hour of sleep.[9]

Informatics in Practice

Sleep Apnea Diagnosis and Monitoring

- Home respiratory monitoring is a cost-effective alternative to diagnose and manage SDB that allows patients the convenience of sleeping in their own home.
- It is used as part of a comprehensive sleep evaluation and in

patients likely to have moderate to severe OSA but without heart failure, obstructive lung disease, or neuromuscular disease.

- Home respiratory monitoring is used to monitor the effectiveness of non-CPAP therapies for patients with sleep-related breathing disorders.
- Wireless monitors can detect changes in vital signs and pulse oximetry, raising an alarm if values fall outside of set parameters.

Nursing and Interprofessional Management: Sleep Apnea

Conservative Treatment

Mild sleep apnea (5–10 apnea/hypopnea events per hour) may respond to simple measures. Conservative treatment at home begins with sleeping on one's side rather than on the back (called *positional therapy*), which reduces the effects of gravity on the airway. Elevating the head of the bed may eliminate OSA in some patients.

Medications that relax airway muscle tone often make OSA worse. Teach the patient to avoid taking sedatives or consuming alcoholic beverages for 3 to 4 hours before sleep. Sleep medications often make OSA worse. Excess weight worsens sleep apnea as the pressure of adipose tissue in the neck and on the chest restricts ventilation. Referral to a weight loss program may be needed. Bariatric surgery may also reduce OSA.[19] Teach the patient the dangers of driving or using heavy equipment due to the profound sleepiness that is common in people with OSA. Insomnia is common in people with OSA. They may need specific treatment for the insomnia (such as CBT-I).

Symptoms may resolve in up to half of patients with OSA who use a special mouth guard, also called an oral appliance, during sleep to prevent airflow obstruction. Oral appliances bring the mandible and tongue forward to enlarge the airway space, thereby preventing airway occlusion.[19] Some find a support group helpful, because they

can express concerns and feelings and discuss strategies for resolving problems.

In patients with more severe symptoms (>15 apnea/hypopnea events/hour), **continuous positive airway pressure (CPAP)** by mask is the treatment of choice. With CPAP, the patient applies a nasal mask that is attached to a high-flow blower (Fig. 7.5). The blower is adjusted to maintain enough positive pressure (5–25 cm H_2O) in the airway during inspiration and expiration to prevent airway collapse.

Some patients cannot adjust to wearing a mask over the nose or mouth or to exhaling against the high pressure. A technologically more sophisticated therapy, bilevel positive airway pressure (BiPAP), can deliver a higher inspiration pressure and a lower pressure during expiration. With BiPAP, the apnea can be relieved with a lower mean pressure and may be better tolerated.

CPAP reduces apnea episodes, daytime sleepiness, and fatigue. It improves quality of life ratings and returns cognitive functioning to normal. Benefits of CPAP are dose-dependent based on how long the device is used during the night. It must be used a minimum of 4 hours each night to reduce/reverse the negative cardiovascular effects of OSA.[20] Although CPAP is a highly effective treatment, patients have problems with using it every day. About two-thirds of those using CPAP report side effects such as nasal stuffiness.

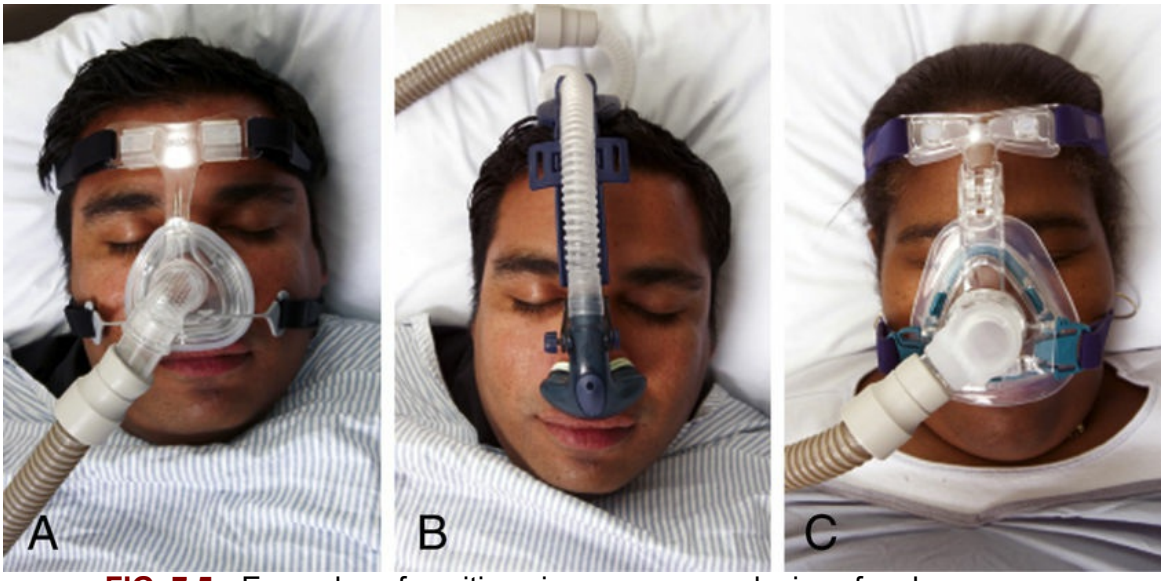

FIG. 7.5 Examples of positive airway pressure devices for sleep apnea. **A,** Patient wearing a nasal mask and headgear (positive pressure only through nose). **B,** Patient wearing nasal pillows (positive pressure only through nose). **C,** Patient wearing a full face mask (positive pressure to nose and mouth).
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

First, assess the patient's knowledge about OSA and CPAP. Involve the bed partner in teaching. Assess the patient for nasal resistance. To ensure successful adherence to CPAP treatment, patients need to be involved in choosing the mask and device before the start of therapy. Patient-centered care may improve patient outcomes given that OSA treatment requires behavioral and lifestyle changes. You can facilitate goal-setting discussions between patients and HCPs to arrive at treatment plans that are feasible and mutually agreed upon.

When patients with a history of OSA are hospitalized, be aware that giving opioid analgesics and sedating medications (benzodiazepines, hypnotics) may worsen OSA symptoms by depressing respirations. Check with the HCP in charge of the patient's care to determine if a patient who uses home CPAP or BiPAP should continue this therapy in the hospital. If so, it is important for these patients to wear the device when resting or sleeping. Many patients can use their own equipment but check hospital policy to be certain it can be used.

Surgical Treatment

If other measures fail, OSA can be managed surgically. The goal of OSA surgery is to reduce collapsibility and increase patency of the upper airway, including oral, nasal, and pharyngeal passages. The most common procedures are uvulopalatopharyngoplasty (UPPP or UP3) and genioglossal advancement and hyoid myotomy (GAHM). UPPP involves excision of the tonsillar pillars, uvula, and posterior soft palate to remove the obstructing tissue. GAHM involves advancing the attachment of the muscular part of the tongue on the mandible. When GAHM is performed, UPPP is generally done as well. Depending on the site of the obstruction, symptoms are relieved in up to 80% of patients.

Radiofrequency ablation (RFA) of obstructive tissues alone or in combination with other surgical techniques is also used. RFA is the least invasive surgical intervention. New treatments involve surgically implanted neurostimulators. One type stimulates the hypoglossal nerve to increase the tone of airway muscles. This treatment for OSA is still being tested for effectiveness and safety.[19]

After surgery, complications of airway obstruction or hemorrhage occur most often in the immediate postoperative period. Patients are usually discharged home within 1 day after the procedure. Before going home, teach the patient what to expect during the postoperative recovery period. Tell patients that their throat will be sore. They may have a foul breath odor that may be reduced by rinsing with diluted mouthwash and then salt water for several days. Snoring may persist until the inflammation has subsided. Follow-up after surgery is important. A repeat PSG is done 3 to 4 months after surgery.

Periodic Limb Movement Disorder

Periodic limb movement disorder (PLMD) is characterized by *periodic limb movements in sleep* (PLMS): involuntary, repetitive movement of the limbs that affects people only during sleep.[21] PLMD usually involves the legs and rarely involves the arms. Sometimes

abdominal, oral, and nasal movement accompanies PLMD. Movements typically occur for 0.5 to 10 seconds, in intervals separated by 5 to 90 seconds. PLMD causes poor-quality sleep and excessive daytime sleepiness. The causes of PLMD are not fully understood. Iron deficiency and dopamine dysfunction in the CNS have been implicated.[21]

PLMS can occur with medical disorders (e.g., sleep apnea, narcolepsy) and certain medications. For a diagnosis of PLMD, the occurrence of PLMS must not be due to another disorder. PLMS affects many people with restless legs syndrome (RLS). RLS is discussed in Chapter 58.

PLMD is diagnosed using a detailed history from the patient and/or bed partner and doing PSG. PLMD is treated by medications aimed at reducing or eliminating the limb movements or the arousals. Clonazepam, a benzodiazepine, is used to treat PLMD. It likely helps patients by improving sleep quality rather than reducing limb movements. Other medications shown to be effective are valproic acid, an antiseizure drug that reduces muscle activity, and selegiline, a dopaminergic agent. Dopamine agonists (pramipexole, ropinirole) are used to treat RLS, but there is little research on their efficacy for PLMD. However, it is common practice for HCPs to prescribe these drugs treat PLMD.

Circadian Rhythm Disorders

Circadian rhythm disorders can occur when the circadian time-keeping system loses synchrony with the environment. Lack of synchrony between the circadian time-keeping system and environment disrupts the sleep-wake cycle and affects the patient's ability to have quality sleep. The common symptoms are insomnia and excessive sleepiness. Jet lag disorder and shift work sleep disorder (see Special Sleep Needs of Nurses section on p. 99) are the most common types of circadian rhythm disorders.

Jet lag disorder occurs when a person travels across multiple time zones. The result is your body's time is not synchronized with

environmental time. Most persons crossing at least 3 time zones get jet lag. The number of time zones crossed affects the severity of symptoms and the time it takes to recover. Resynchronization of the body's clock occurs at a rate of about 1 hr/day when traveling eastward and 1.5 hr/day when traveling westward. Melatonin and exposure to daylight help to synchronize the body's rhythm.

Several strategies may help to reduce the risk for developing jet lag. Before travel the person can start to get in harmony with the time schedule of the destination. When time at destination is brief (i.e., 2 days or less), keeping home-based sleep hours rather than adopting destination sleep hours may reduce sleepiness and jet lag symptoms.

Narcolepsy

Narcolepsy is a chronic neurologic disorder caused by the brain's inability to regulate sleep-wake cycles normally. At various times throughout the day, people with narcolepsy have uncontrollable urges to sleep. Patients with narcolepsy often go directly into REM sleep from wakefulness.[21] This does not occur in normal sleep and is a unique feature of narcolepsy. Patients with narcolepsy also have fragmented and disturbed nighttime sleep. There are 2 types of narcolepsy: with cataplexy (type 1) and without cataplexy (type 2).[21] Cataplexy is a brief and sudden loss of skeletal muscle tone. It can manifest as a brief episode of muscle weakness or complete postural collapse and falling. Laughter, anger, or surprise often triggers episodes.

The onset of narcolepsy typically occurs in adolescence or early in the third decade. Head trauma, a sudden change in sleep-wake habits, and infection may trigger the onset of narcolepsy symptoms. The cause of narcolepsy is unknown. It is associated with destruction of neurons that make orexin. The resulting deficiency of orexin causes instability of wake and transitions from wake to sleep that occur unpredictably. The loss of neurons may be due to an autoimmune process.[22]

Narcolepsy is diagnosed based on a history of sleepiness, PSG, and

daytime *multiple sleep latency tests* (MSLTs).[21] For the MSLT, patients undergo an overnight PSG evaluation followed by 4 or 5 naps scheduled every 2 hours during the next day. Short sleep latencies and onset of REM sleep in more than 2 MSLTs are diagnostic signs of narcolepsy.

Narcolepsy cannot be cured. Management is focused management of common symptoms: excessive daytime sleepiness, nighttime sleep disturbance, and cataplexy (Table 7.3). Provide teaching about sleep and sleep hygiene. Advise the patient to take 3 or more short (15-minute) naps throughout the day and to avoid large or heavy meals and alcohol.[22] You can play a key role in ensuring patient safety by teaching safety behaviors and encouraging adherence to the prescribed medication regimen. Safety precautions, especially when driving, are critically important for patients with narcolepsy. The behavioral therapies for insomnia are also used to address the sleep disturbances. Stimulants are used to counter daytime sleepiness.

Modafinil (Provigil) and armodafinil (Nuvigil) are nonamphetamine wake-promotion drugs that are considered a first-line drug therapy. Sodium oxybate (Xyrem), a metabolite of GABA, is another wake-promoting medication that is effective for treating both daytime sleepiness and cataplexy. Antidepressants are used to treat cataplexy. Tricyclic antidepressants used to be commonly used, but selective serotonin reuptake inhibitors (SSRIs) (e.g., fluoxetine [Prozac], venlafaxine) are becoming favored for the management of cataplexy.[22]

Parasomnias

Parasomnias are unusual and often undesirable behaviors that occur while falling asleep, transitioning between sleep stages, or arousing from sleep.[21] They are due to CNS activation and often involve complex behaviors. The parasomnia is generally goal directed, although the person is not aware or conscious of the act. Parasomnias may result in fragmented sleep and fatigue.

Sleepwalking and sleep terrors are arousal parasomnias that occur

during NREM sleep. *Sleepwalking* behaviors can range from sitting up in bed, moving objects, and walking around the room to driving a car. During a sleepwalking event the person may not speak and may have limited or no awareness of the event. On awakening, the person does not remember the event. In the ICU, a parasomnia may be misinterpreted as ICU psychosis. Sedated ICU patients can have manifestations of a parasomnia.

Sleep terrors (night terrors) are characterized by a sudden awakening from sleep along with a loud cry and signs of panic. The person has marked increases in heart rate and respiration and diaphoresis. Factors in the ICU such as sleep disruption and deprivation, fever, stress, and exposure to noise and light can contribute to sleep terrors.

Nightmares are a parasomnia characterized by recurrent awakening with recall of a frightful or disturbing dream. These normally occur during REM sleep during the final third of sleep. In critically ill patients, nightmares are common and likely due to medications. Drug classes most likely to cause nightmares are sedative-hypnotics, β-adrenergic antagonists, dopamine agonists, and amphetamines.

Gerontologic Considerations: Sleep

Older age is associated with overall shorter total sleep time, decreased sleep efficiency, and more awakenings (Fig. 7.6). A common misconception is that older people need less sleep than younger people. In fact, the amount of sleep needed as a person ages stays relatively constant. Other sleep disorders (e.g., sleep-disordered breathing) increase with age and may manifest with symptoms of insomnia. Some older adults have a shift in their circadian sleep timing so that they get sleepy earlier in the evening and awaken early in the morning.[23]

Multiple factors impair older adults' ability to obtain quality sleep. Insomnia symptoms in older adults often occur with depression, cardiovascular disease, pain, and cognitive problems. Chronic conditions that are common in older adults (chronic obstructive pulmonary disease [COPD], diabetes, dementia, chronic pain, cancer)

can affect sleep quality. Medications used to treat these conditions can contribute to sleep problems. OTC medications can lead to sleep problems. Stimulating OTC medications include cough and cold medications, especially those containing pseudoephedrine; caffeine-containing drugs; and drugs containing nicotine (e.g., nicotine gum, transdermal patches).

Awakening and getting out of bed during the night (e.g., to use the bathroom) increase the risk for falls. Older adults may use OTC medications or alcohol as a sleep aid. This practice can further increase the risk for falls at night. Chronic disturbed sleep in older adults can result in disorientation, delirium, impaired intellect, disturbed cognition, and increased risk for accidents and injury.

FIG. 7.6 Many older people have sleep problems.
© Studio-Annika/iStock/Thinkstock.

Because older adults may attribute their disturbed sleep to normal aging, they may fail to report symptoms of sleep disorders to their HCPs. Use a sleeping assessment (Table 7.5) to detect sleep disturbances in older adults.

Sleep medications should be used with great caution in older adults. Diphenhydramine, alone or in combination with other drugs, is sedating with anticholinergic effects. Any OTC medication labeled

"PM" probably has diphenhydramine and should be used cautiously by older adults. Metabolism of most hypnotic drugs decreases with aging. Older adults have increased sensitivity to hypnotic and sedative medications. Thus drug therapies for sleep disturbances are started at lower doses and monitored carefully.[17] Whenever possible, long-acting benzodiazepines should be avoided. Older adults receiving benzodiazepines are at increased risk of daytime sedation, falls, and cognitive and psychomotor impairment.

Special Sleep Needs of Nurses

Nursing is 1 of several professions that needs night shift and rotating shift schedules. In many settings, nurses work a variety of day and night shifts, often alternating and rotating them. Unfortunately, nurses who do shift work often report less job satisfaction and more job-related stress.[24]

Nurses on permanent night or rapidly rotating shifts are at increased risk for experiencing **shift work sleep disorder**. It is characterized by insomnia, sleepiness, and fatigue. Nurses on rotating shifts get the least amount of sleep. With repeated periods of inadequate sleep, the sleep debt grows. Chronic fatigue in nurses doing shift work poses challenges for the individual nurse's health and for patient safety (Fig. 7.7).[24]

FIG. 7.7 Sleep disturbances are common among nurses.
© iStock.com/kupicoo.

Shift work alters the synchrony between circadian rhythms and the environment, leading to sleep disruption. Nurses working the night shift are often too sleepy to be fully alert at work and too alert to sleep soundly the next day. Sustained changes in circadian rhythms such as those imposed by rotating shift work are linked to increased morbidity and mortality risks associated with cardiovascular problems. Mood disorders such as anxiety are higher in nurses who work rotating shifts.

From a safety perspective, disturbed sleep and subsequent fatigue can result in errors and accidents for nurses as well as for their patients. Fatigue diminishes or distorts perceptual skills, judgment, and decision-making capabilities. Lack of sleep reduces the ability to cope and handle stress and may result in physical, mental, and emotional exhaustion.

The problem of sleep disruption is critically important to nursing. Several strategies may help reduce the distress associated with rotating shift work. These include brief periods of on-site napping.

Maintaining a consistent sleep-wake schedule even on days off is best but somewhat unrealistic. For night shift work, scheduling the sleep period just before going to work increases alertness and vigilance, improves reaction times, and decreases accidents during night shift work. Nurses who have control over their work schedules appear to have less sleep disruption than those whose schedule is imposed. As a nurse, you need to manage the impact of sleep disruption by using sleep hygiene practices.

Case Study

Insomnia

Patient Profile

G.P., a 49-yr-old black woman, is seen in the primary care clinic for chronic fatigue and disturbed sleep. She is postmenopausal based on self-report. In the past year, since the end of her periods, she has had daily hot flashes and sleep problems. She denies any other health problems. On a usual workday she drinks 2 cups of hot tea in the morning and a can of diet cola in the late afternoon. Currently she is

taking OTC diphenhydramine for sleep. Her partner, who has accompanied her to the clinic, states that her snoring has gotten worse, and it is interfering with his sleep.

Subjective Data

- Reports hot flashes and nighttime sweating
- Reports daytime tiredness and fatigue
- States she has trouble getting to sleep and staying asleep

Objective Data
Physical Examination

- Laboratory evaluations within normal limits
- Height 5′6″
- Weight 190 lb

Diagnostic Studies

- Nighttime PSG study reveals episodes of obstructive sleep apnea

Interprofessional Care

- CPAP nightly
- Referred for weight reduction counseling
- Education about sleep hygiene

Discussion Questions

1. What are G.P.’s risk factors for sleep apnea?
2. What are the major health risks for G.P. from sleep apnea?
3. ***Priority Decision:*** Based on the assessment data provided, what

are the priority nursing diagnoses?
4. How does CPAP work?
5. ***Priority Decision:*** Based on your assessment of G.P., what are the priority nursing interventions for her?
6. ***Collaboration:*** For the interventions that you identified in the previous question, which can you delegate to unlicensed assistive personnel (UAP)?
7. ***Patient-Centered Care:*** What specific sleep hygiene practices could G.P. use to improve the quality of her sleep?
8. ***Collaboration:*** What referrals may be indicated for G.P.?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Sleep is *best* described as a
   a. loosely organized state similar to coma.
   b. quiet state in which there is little brain activity.
   c. state in which a person has reduced sensitivity to pain.
   d. state in which a person lacks conscious awareness of the environment.
2. Which statements are true about rapid eye movement (REM) sleep (*select all that apply*)?
   a. The EEG pattern is quiescent.
   b. Muscle tone is greatly reduced.
   c. It occurs only once in the night.
   d. It is physiologically similar to NREM sleep.
   e. The most vivid dreaming occurs during this phase.

3. Insufficient sleep is associated with *(select all that apply)*
   a. increased body mass index.
   b. increased insulin resistance.
   c. impaired cognitive functioning.
   d. improved immune responsiveness.
   e. increased daytime body temperature.
4. When teaching the patient with primary insomnia about sleep hygiene, the nurse should emphasize
   a. the importance of daytime naps.
   b. the need for long-term use of hypnotics.
   c. the need to exercise about 1 hour before bedtime.
   d. the importance of avoiding caffeine 6 to 9 hours before bedtime.
5. An overweight patient with sleep apnea would like to avoid using a nasal CPAP device. To help him reach this goal, the nurse suggests that the patient
   a. lose excess weight.
   b. take a nap during the day.
   c. eat a high-protein snack at bedtime.
   d. use mild sedatives or alcohol at bedtime.
6. While caring for a patient with a history of narcolepsy with cataplexy, the nurse can delegate which activity to the unlicensed assistive personnel (UAP)?
   a. Teaching about the timing of medications
   b. Walking the patient to and from the bathroom
   c. Developing a plan of care with a family member
   d. Planning an appropriate diet that avoids caffeine-

containing foods

7. Strategies to reduce sleepiness during nighttime working include
   a. exercising before work.
   b. taking melatonin before working the night shift.
   c. sleeping for at least 2 hours immediately before work time.
   d. walking for 10 minutes every 4 hours during the night shift.

1. d, 2. b, e, 3. a, b, c, 4. d, 5. a, 6. b, 7. c

Pain

Debra Miller-Saultz

LEARNING OUTCOMES

1. Define pain.
2. Describe the neural mechanisms of pain and pain modulation.
3. Distinguish between nociceptive and neuropathic types of pain.
4. Explain the physical and psychologic effects of unrelieved pain.
5. Interpret the subjective and objective data that are obtained from a comprehensive pain assessment.
6. Describe effective interprofessional pain management techniques.
7. Describe drug and nondrug methods of pain relief.
8. Explain your role and responsibility in pain management.
9. Discuss ethical and legal issues related to pain and pain management.
10. Evaluate the influence of one's own knowledge, beliefs, and attitudes about pain assessment and management.

Pain

One word frees us of all the weight and pain of life. That word is love.

Sophocles

http://evolve.elsevier.com/Lewis/medsurg/

Pain is a complex, multidimensional experience that can cause

suffering and decreased quality of life. Pain is 1 of the major reasons that people seek health care. To effectively assess and manage patients with pain, you need to understand the physiologic and psychosocial dimensions of pain. Pain is interrelated with many concepts. Culture and spirituality influence the expression of pain. Acute pain adversely affects mobility and sleep, leading to fatigue. Having pain is a stressor that can lead to depression. Those with severe or chronic pain are more likely to describe their health as poor and have increased mortality. This chapter presents evidence-based information to help you assess and safely manage pain in collaboration with other interprofessional team members.

Magnitude of Pain Problem

Millions of people suffer from pain. Each year in the United States, at least 25 million people have acute pain because of injury or surgery. Common chronic pain conditions, such as arthritis, migraine headache, and back pain, affect more than 1 million American adults.[1] Of the 1.7 million people diagnosed with cancer each year, about 60% have pain during treatment.[2] Despite the high prevalence and costs of acute and chronic pain, inadequate pain management occurs. Consequences of unrelieved acute pain are shown in Table 8.1.

Definitions and Dimensions of Pain

In 1968 Margo McCaffery, a nurse and pioneer in pain management, defined **pain** as "whatever the person experiencing the pain says it is, existing whenever the person says it does."[3] The International Association for the Study of Pain (IASP) defines *pain* as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage."[1]

TABLE 8.1 Negative Consequences of Unrelieved Acute Pain

Response	Possible Consequences
Cardiovascular	
↑ Heart rate ↑ Cardiac output ↑ Peripheral vascular resistance ↑ Myocardial oxygen consumption ↑ Coagulation	Hypertension Unstable angina Myocardial infarction Deep vein thrombosis
Endocrine and Metabolic	
↑ Adrenocorticotropic hormone (ACTH) ↑ Cortisol ↑ Antidiuretic hormone (ADH) ↑ Epinephrine and norepinephrine ↑ Renin, ↑ aldosterone ↓ Insulin Gluconeogenesis Glycogenolysis Muscle protein catabolism	Weight loss (from ↑ catabolism) ↑ Respiratory rate ↑ Heart rate Shock Glucose intolerance Hyperglycemia Fluid overload Hypertension Urinary retention, ↓ urine output
Gastrointestinal	
↓ Gastric and intestinal motility	Constipation Anorexia Paralytic ileus
Immunologic	
↓ Immune response	Infection
Musculoskeletal	
Muscle spasm Impaired muscle function	Immobility Weakness and fatigue
Neurologic	
Impaired cognitive function	Confusion Impaired ability to think, reason, and make decisions
Renal and Urologic	
↓ Urine output Urinary retention	Fluid imbalance Electrolyte disturbance
Respiratory	
↓ Tidal volume Hypoxemia ↓ Cough, sputum retention	Atelectasis Pneumonia

These definitions emphasize the subjective nature of pain, in which the patient's self-report is the most valid means of assessment. Although understanding the patient's experience and relying on his or her self-report is essential, this view is problematic for many patients. For example, patients who are comatose or who have dementia, patients who are mentally disabled or challenged, and patients with expressive aphasia have varying abilities to report pain. In these instances, you must include nonverbal information, such as observed

behaviors, into your pain assessment.

The emotional distress of pain can cause *suffering,* which is the state of distress associated with loss. Suffering can result in a sense of insecurity, lack of control, and spiritual distress. It is important to assess the ways in which a person's spirituality influences and is influenced by pain.[4]

The meaning of the pain to the person is important. For example, a woman in labor may have severe pain but can manage it without analgesics because for her it is associated with a joyful event. Moreover, she may feel control over her pain because of the training she received in prenatal classes and the knowledge that the pain is time-limited. In contrast, a woman with chronic, undefined musculoskeletal pain may be stressed

TABLE 8.2 Dimensions of Pain

Dimension	Description
Affective	• Emotional responses to pain include anger, fear, depression, and anxiety • Negative emotions impair patient's quality of life
Behavioral	• Observable actions (e.g., grimacing, irritability, coping skills) are used to express or control pain • People unable to communicate may have behavioral changes (e.g., agitation, combativeness)
Cognitive	• Beliefs, attitudes, memories, and meaning attributed to pain influence the ways in which a person responds to pain
Physiologic	• Genetic, anatomic, and physical determinants of pain influence how painful stimuli are processed, recognized, and described
Sociocultural	• Age and gender influence nociceptive processes and responses to opioids • Families and caregivers influence patient's response to pain through their beliefs, behaviors, and support • Culture affects pain expression, medication use, pain-related beliefs, and coping methods

Gender Differences

Pain

Men

- Are less likely to report pain than women

- Report more control over pain
- Are less likely to use alternative treatments for pain

Women

- More often have migraine headache, back pain, arthritis, fibromyalgia, irritable bowel syndrome, neuropathic pain, abdominal pain, and foot ache
- Are more likely to be diagnosed with a nonspecific, somatic disorder
- Are less likely to receive analgesics for symptoms of chest and abdominal pain

by thoughts that her pain is "not real," is uncontrollable, or is caused by her own actions. Perceptions influence the ways in which a person responds to pain and must be included in a comprehensive treatment plan.

Some people cope with pain by distracting themselves. Others convince themselves that the pain is permanent, untreatable, and overwhelming. People who believe their pain is uncontrollable and overwhelming are more likely to have poor outcomes.[5] The biopsychosocial model of pain includes the physiologic, affective, cognitive, behavioral, and sociocultural dimensions of pain (Table 8.2).

Families and caregivers influence the patient's response to pain through their beliefs and behaviors. For example, families may discourage the patient from taking opioids because they have preconceived notions and fears that the patient may become addicted. Understanding these beliefs helps you address them through patient and family teaching.

Pain Mechanisms

Nociception is the physiologic process by which information about

tissue damage is communicated to the central nervous system (CNS). It involves 4 processes: (1) transduction, (2) transmission, (3) perception, and (4) modulation (Fig. 8.1).

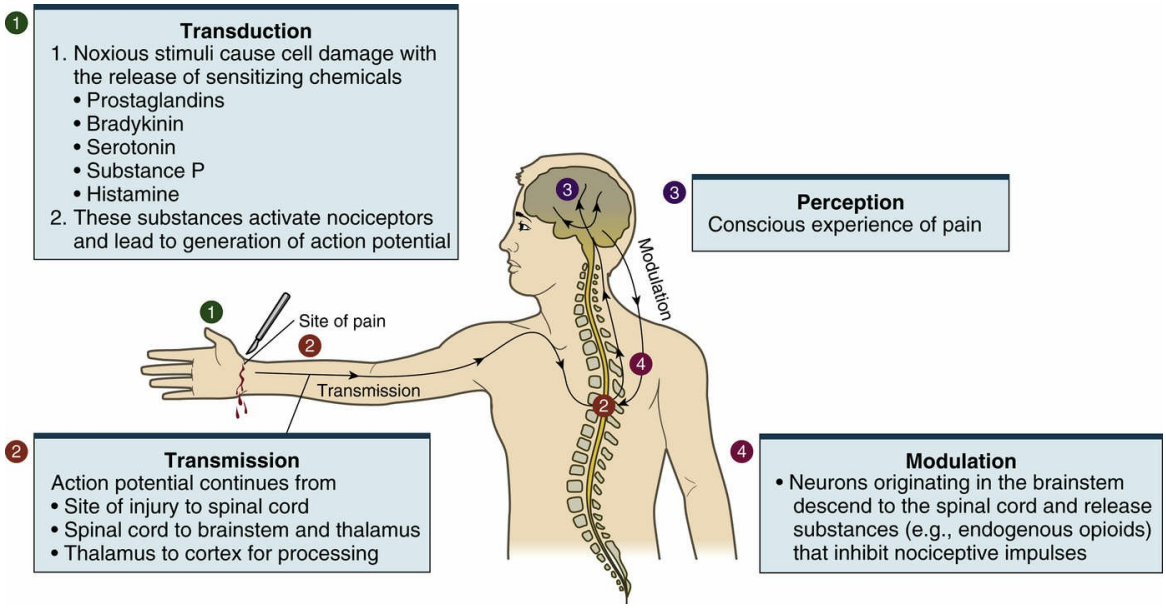

FIG. 8.1 Nociceptive pain originates when the tissue is injured. *1,* Transduction occurs when there is release of chemical mediators. *2,* Transmission involves the conduct of the action potential from the periphery (injury site) to the spinal cord and then to the brainstem, thalamus, and cerebral cortex. *3,* Perception is the conscious awareness of pain. *4,* Modulation involves signals from the brain going back down the spinal cord to modify incoming impulses. Developed by McCaffery M, Pasero C, Paice JA. Modified from McCaffery M, Pasero C: *Pain: Clinical manual,* ed 2, St Louis, 1999, Mosby.

Transduction

Transduction involves the conversion of a noxious mechanical, thermal, or chemical stimulus into an electrical signal called an action potential. Noxious (tissue-damaging) stimuli, including thermal (e.g., sunburn), mechanical (e.g., surgical incision), or chemical (e.g., toxic substances) stimuli, cause the release of chemicals, such as substance P and adenosine triphosphate (ATP), into the damaged tissues. Other chemicals are released from mast cells (e.g., serotonin, histamine,

prostaglandins) and macrophages (e.g., cytokines). These chemicals activate nociceptors, which are specialized receptors, or free nerve endings, which respond to painful stimuli. Activation of nociceptors results in an action potential that is carried from the nociceptors to the spinal cord primarily by small, rapidly conducting, myelinated A-delta fibers and slowly conducting unmyelinated C fibers.

In addition to stimulating nociceptors, inflammation and the subsequent release of chemical mediators lower nociceptor thresholds. As a result, nociceptors may fire in response to stimuli that previously were insufficient to elicit a response. They may also fire in response to non-noxious stimuli, such as light touch. We call this increased susceptibility to nociceptor activation **peripheral sensitization**. Leukotrienes, prostaglandins, cytokines, and substance P are involved in peripheral sensitization. Cyclooxygenase (COX), produced in the inflammatory response, also plays a key role in peripheral sensitization. A clinical example of this process is sunburn. This thermal injury causes inflammation that results in a sensation of pain when the affected skin is lightly touched. Peripheral sensitization amplifies signal transmission, which in turn contributes to central sensitization (discussed under Dorsal Horn Processing). The pain from activation of peripheral nociceptors is called nociceptive pain (described later in the chapter on p. 106).

Therapies that change either the local environment or sensitivity of the peripheral nociceptors can prevent transduction and initiation of an action potential. Decreasing the effects of chemicals released at the periphery is the basis of several drug approaches to pain relief. For example, nonsteroidal antiinflammatory drugs (NSAIDs), such as ibuprofen (Advil), exert their analgesic effects by blocking the action of COX (see Fig. 11.4).

Transmission

Transmission is the process by which pain signals are relayed from the periphery to the spinal cord and then to the brain. Nerves that carry pain impulses from the periphery to the spinal cord are called *primary afferent fibers*. These include A-delta and C fibers. Each is

responsible for a different pain sensation. A-delta fibers conduct pain rapidly and are responsible for the initial, sharp pain that accompanies tissue injury. C fibers transmit painful stimuli more slowly and produce pain that is typically aching or throbbing. Primary afferent fibers end in the dorsal horn of the spinal cord. Activity in the dorsal horn integrates and modulates pain inputs from the periphery.

The movement of pain impulses from the site of transduction to the brain is shown in Fig. 8.1. Three segments are involved in nociceptive signal transmission: (1) transmission along the peripheral nerve fibers to the spinal cord, (2) dorsal horn processing, and (3) transmission to the thalamus and cerebral cortex.

Drugs that stabilize the neuronal membrane act on peripheral sodium channels to inhibit movement of nerve impulses. These medications include local anesthetics (e.g., injectable or topical lidocaine, bupivacaine [Sensorcaine]) and antiseizure drugs (e.g., gabapentin [Neurontin]).

Transmission to Spinal Cord

The *first-order neuron* extends the entire distance from the periphery to the dorsal horn with no synapses. For example, an afferent fiber from the great toe travels from the toe through the fifth lumbar nerve root into the spinal cord; it is 1 cell. Once generated, an action potential travels all the way to the spinal cord unless it is blocked by a sodium channel inhibitor (e.g., local anesthetic) or disrupted by a lesion, such as a dorsal root entry zone lesion.

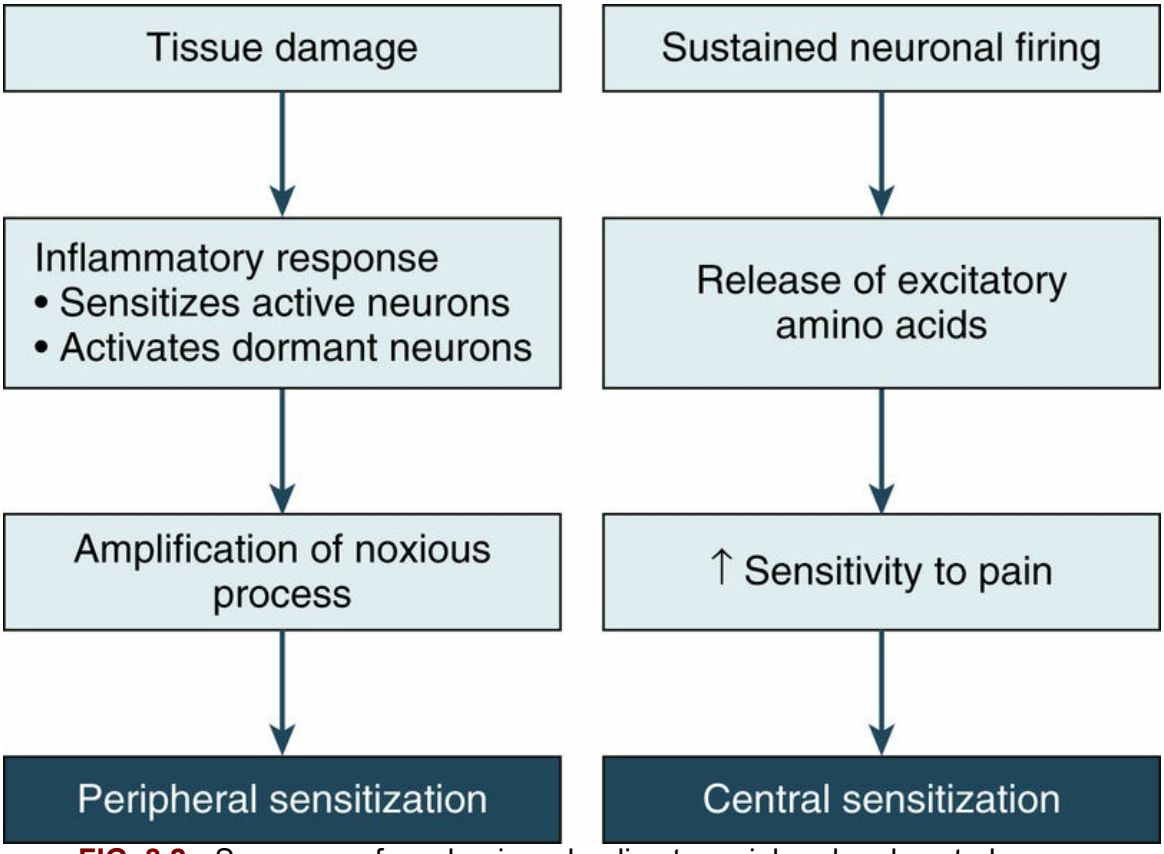

FIG. 8.2 Sequence of mechanisms leading to peripheral and central sensitization. Increased susceptibility to nociceptor activation is called *peripheral sensitization.* Increased sensitivity and hyperexcitability of neurons in the CNS is called *central sensitization.*

The way nerve fibers enter the spinal cord is central to the notion of spinal dermatomes. *Dermatomes* are areas on the skin that are innervated primarily by a single spinal cord segment. The distinct pattern of the rash caused by herpes zoster (shingles) across the back and trunk is determined by dermatomes (see Fig. 23.7). Different dermatomes and their innervations are shown in Fig. 55.7.

Dorsal Horn Processing

Once a nociceptive signal arrives in the spinal cord, it is processed within the dorsal horn. Neurotransmitters released from the afferent fiber bind to receptors on nearby cells. Some of these neurotransmitters (e.g., glutamate, substance P) produce activation. Others (e.g., γ-aminobutyric acid [GABA], serotonin) inhibit activation of nearby cells. In this area, exogenous and endogenous

opioids (e.g., encephalin, β-endorphin) play a vital role by binding to opioid receptors and blocking the release of neurotransmitters, especially substance P. They produce analgesic effects similar to those of exogenous opioids, such as morphine. The neurons that project to the thalamus are called *second-order neurons*.

Increased sensitivity and hyperexcitability of neurons in the CNS is called **central sensitization**. With central sensitization, the central processing circuits are altered. Peripheral tissue damage or nerve injury can cause central sensitization. Continued nociceptive input from the periphery maintains it (Fig. 8.2). In some cases, central sensitization can be long-lasting due to multiple changes that occur in the periphery and CNS.[6]

Because of the increased excitability of CNS neurons, normal sensory inputs cause abnormal sensing and responses to painful and other stimuli. This explains why some people have significant pain from touch or tactile stimulation in and around the areas of tissue or nerve injury. We call this *allodynia,* pain from a stimulus that is not typically painful. It also explains why some people have *hyperalgesia,* an exaggerated or increased pain response to noxious stimuli.

With ongoing stimulation of slowly conducting unmyelinated C-fiber nociceptors, firing of specialized dorsal horn neurons gradually increases. These inputs can lead to the sprouting of wide dynamic range (WDR) neuron dendrites and the induction of glutamate-dependent *N*-methyl-D-aspartate (NMDA) receptors. This results in an increased capacity to transmit a broader range of stimuli-producing signals, which are then passed up the spinal cord and to the brain. This process is known as *wind-up.*[7] Activation of NMDA receptors also plays a role in wind-up. NMDA receptor antagonists, such as ketamine (Ketalar), potentially interrupt or block mechanisms that lead to or sustain central sensitization. Wind-up is like central sensitization and hyperalgesia in that it occurs in response to C-fiber inputs. Wind-up is different, however, in that it can be short-lasting, while central sensitization and hyperalgesia persist over time.

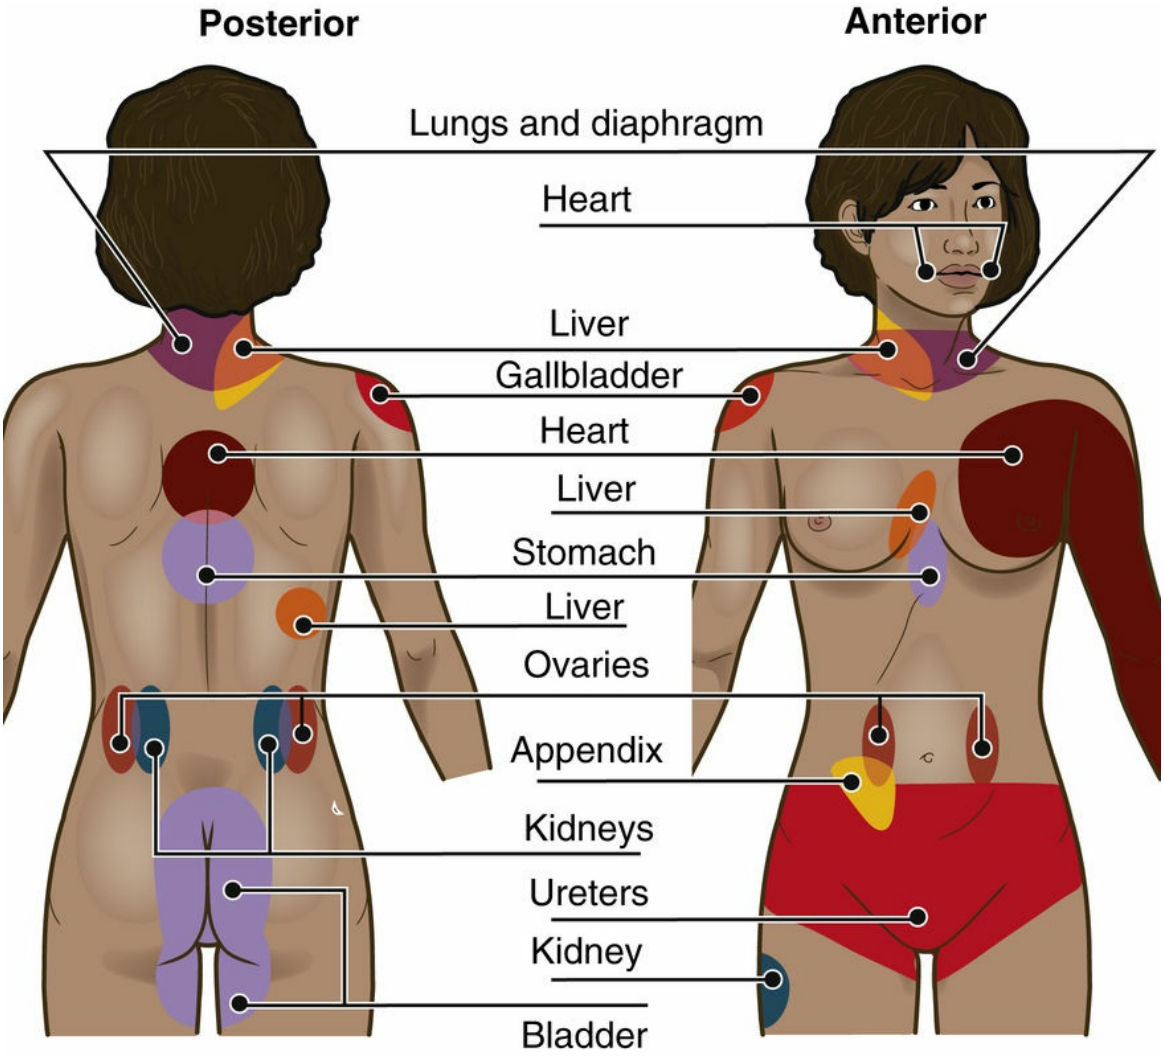

FIG. 8.3 Typical areas of referred pain.

It is important for you to understand that acute, unrelieved pain leads to chronic pain through central sensitization. Even brief intervals of acute pain can induce long-term neuronal remodeling and sensitization *(plasticity)*, chronic pain, and lasting psychologic distress.

Neuroplasticity refers to processes that allow neurons in the brain to compensate for injury and adjust their responses to new situations or changes in their environment.[8] Neuroplasticity contributes to adaptive mechanisms for reducing pain but can result in maladaptive mechanisms that enhance pain sensitivity.

Genetic variability may play a key role in changes that occur in the CNS and the response to different analgesic therapies to treat pain.

Understanding this phenomenon helps explain individual differences in response to pain and why some patients develop chronic pain conditions and others do not.[9] *Referred pain* must be considered when interpreting the location of pain reported by the person with an injury or a disease involving visceral organs. The location of a stimulus may be distant from the pain location reported by the patient (Fig. 8.3). For example, pain from liver disease often occurs in the right upper abdominal quadrant. It also can be referred to the anterior and posterior neck region, shoulder area, and posterior flank area. If we do not consider referred pain when evaluating a pain location report, diagnostic tests and therapy could be misdirected.

TABLE 8.3 Comparison of Nociceptive and Neuropathic Pain

	Nociceptive Pain	Neuropathic Pain*
Definition	Normal processing of stimulus that damages normal tissue or has the potential to do so if prolonged	Abnormal processing of sensory input by the peripheral or central nervous system
Treatment	Usually responsive to nonopioid and/or opioid drugs	Usually includes adjuvant analgesics
Types	**Superficial Somatic Pain** Pain arising from skin, mucous membranes, subcutaneous tissue. Tends to be well localized *Examples:* Sunburn, skin contusions **Deep Somatic Pain** Pain arising from muscles, fasciae, bones, tendons. Localized or diffuse and radiating *Examples:* Arthritis, tendonitis, myofascial pain **Visceral Pain** Pain arising from visceral organs, such as the GI tract and bladder. Well or poorly localized. Often referred to cutaneous sites *Examples:* Appendicitis, pancreatitis, cancer affecting internal organs, irritable bowel and bladder syndromes	**Central Pain** Caused by primary lesion or dysfunction in the CNS *Examples:* Poststroke pain, pain associated with multiple sclerosis **Peripheral Neuropathies** Pain felt along the distribution of 1 or many peripheral nerves caused by damage to the nerve *Examples:* Diabetic neuropathy, alcohol-nutritional neuropathy, trigeminal neuralgia, postherpetic neuralgia **Deafferentation Pain** Pain resulting from a loss of or altered afferent input *Examples:* Phantom limb pain, postmastectomy pain, spinal cord injury pain **Sympathetically Maintained Pain** Pain that persists secondary to autonomic nervous system dysfunction *Examples:* Phantom limb pain, complex regional pain syndrome

* Some types of neuropathic pain (e.g., postherpetic neuralgia) are caused by more than 1 neuropathologic mechanism.

Transmission to Thalamus and Cortex

From the dorsal horn, nociceptive stimuli are communicated to the *third-order neuron,* primarily in the thalamus. Fibers of dorsal horn

projection cells enter the brain through several pathways, including the spinothalamic tract and spinoreticular tract. Distinct thalamic nuclei receive nociceptive input from the spinal cord and have projections to several regions in the cerebral cortex, where the perception of pain is presumed to occur.

Therapeutic approaches that target pain transmission include opioid analgesics that bind to opioid receptors on primary afferent and dorsal horn neurons. These agents mimic the inhibitory effects of endogenous opioids. Another medication, baclofen (Lioresal), inhibits pain transmission by binding to GABA receptors, thus mimicking the inhibitory effects of GABA.

Perception

Perception occurs when pain is recognized, defined, and assigned meaning by the person experiencing the pain. In the brain, nociceptive input is perceived as pain. There is no single, precise location where pain perception occurs. Instead, pain perception involves several brain structures. For example, it is thought that the reticular activating system is responsible for warning the person to attend to the pain stimulus; the somatosensory system is responsible for localization and characterization of pain; and the limbic system is responsible for the emotional and behavioral responses to pain.

Cortical structures are crucial to constructing the meaning of the pain. Therefore behavioral strategies, such as distraction and relaxation, are effective pain-reducing therapies for many people. Meditation and imagery can affect pain perception. By directing attention away from the pain sensation, patients can reduce the sensory and affective components of pain.

Modulation

Modulation involves the activation of descending pathways that exert inhibitory or facilitatory effects on the transmission of pain (Fig. 8.1). Depending on the type and degree of modulation, nociceptive stimuli may or may not be perceived as pain. Modulation of pain signals can occur at the level of the periphery, spinal cord, brainstem, and

cerebral cortex. Descending modulatory fibers release chemicals, such as serotonin, norepinephrine, GABA, and endogenous opioids, which can inhibit pain transmission.

Several antidepressants exert their effects through the modulatory systems. For example, tricyclic antidepressants (e.g., amitriptyline) and serotonin norepinephrine reuptake inhibitors (SNRIs) (e.g., venlafaxine) are used to manage chronic noncancer and cancer pain. These agents interfere with the reuptake of serotonin and norepinephrine, thereby increasing their availability to inhibit noxious stimuli.

Classification of Pain

We categorize pain in several ways. Most often, pain is categorized as nociceptive or neuropathic based on underlying pathology (Table 8.3). Another useful scheme is to classify pain as acute or chronic (Table 8.4).

Nociceptive Pain

Nociceptive pain is caused by damage to somatic or visceral tissue. *Somatic pain* often is further categorized as superficial or deep. *Superficial pain* arises from skin, mucous membranes, and subcutaneous tissues. It is often described as sharp, burning, or prickly. *Deep pain* is often described as aching or throbbing. It originates in bone, joint, muscle, skin, or connective tissue.

Visceral pain comes from the activation of nociceptors in the internal organs and lining of the body cavities, such as the thoracic and abdominal cavities. Visceral nociceptors respond to inflammation, stretching, and ischemia. Stretching of hollow viscera in the intestines and bladder that occurs from tumor involvement or obstruction can produce intense cramping pain. Examples of visceral nociceptive pain include pain from a surgical incision, pancreatitis, and inflammatory bowel disease.

Neuropathic Pain

Neuropathic pain is caused by damage to peripheral nerves or structures in the CNS. Although neuropathic pain is often associated with diabetic neuropathy and other neuropathic pain syndromes, around 8% of the general population has pain with neuropathic characteristics.[9] Typically described as numbing, hot, burning, shooting, stabbing, sharp, or electric shock–like, neuropathic pain can be sudden, intense, short lived, or lingering. Paroxysmal firing of injured nerves is responsible for shooting and electric shock-like sensations. Common causes of neuropathic pain include trauma, inflammation, metabolic diseases (e.g., diabetes), alcoholism, nervous system infections (e.g., herpes zoster, human immunodeficiency virus), tumors, toxins, and neurologic diseases (e.g., multiple sclerosis). Examples of neuropathic pain conditions include phantom limb sensation, diabetic neuropathy, and trigeminal neuralgia. No single sign or symptom is diagnostic for neuropathic pain.

TABLE 8.4 Differences Between Acute and Chronic Pain

	Acute Pain	Chronic Pain
Onset	Sudden	Gradual or sudden
Duration	<3 mo or as long as it takes for normal healing to occur	>3 mo. May start as acute injury or event but continues past the normal time for recovery
Severity	Mild to severe	Mild to severe
Cause of pain	Usually can identify a precipitating event (e.g., illness, surgery)	May not be known. Original cause of pain may differ from mechanisms that maintain the pain.
Course of pain	Decreases over time and goes away as recovery occurs	Typically pain does not go away Characterized by periods of increasing and decreasing pain
Typical physical and behavioral manifestations	Manifestations vary but can reflect sympathetic nervous system activation: • ↑ Heart rate, respiratory rate, BP • Diaphoresis, pallor • Anxiety, agitation, confusion • Urine retention	Common behavioral manifestations: • Flat affect • ↓ Physical activity • Fatigue • Withdrawal from social interaction
Usual goals of treatment	Pain control with ability to take part in recovery activities Minimize side effects of treatment	Pain control to the extent possible Focus on enhancing function and quality of life

CNS lesions or dysfunction cause *central pain*. *Deafferentation pain* results from loss of or altered afferent input secondary to either peripheral nerve injury (e.g., amputation) or CNS damage, including a spinal cord injury. Painful peripheral polyneuropathies (pain felt along the distribution of multiple peripheral nerves) and painful mononeuropathies (pain felt along the distribution of a damaged nerve) arise from damage to peripheral nerves. They generate pain that people may describe as burning, paroxysmal, or shock-like. The patient may have positive or negative motor and sensory signs, including numbness, allodynia, or change in reflexes and motor strength.

Sympathetically maintained pain is associated with a group of conditions that have a degree of changes in autonomic nervous system. One particularly debilitating type is **complex regional pain syndrome (CRPS)**. Typical features include dramatic changes in the color and temperature of the skin over the affected limb or body part, accompanied by intense burning pain, skin sensitivity, sweating, and swelling. CRPS type I is often triggered by tissue injury, surgery, or a vascular event, such as stroke.[10] CRPS type II includes all these features and a peripheral nerve lesion.

Neuropathic pain is often not well controlled by opioid analgesics alone. Treatment often requires a multimodal approach combining various adjuvant analgesics from different drug classes. These include tricyclic antidepressants (e.g., amitriptyline), SNRIs (e.g., bupropion [Wellbutrin, Zyban]), antiseizure drugs (e.g., pregabalin [Lyrica]), transdermal lidocaine, and α_2-adrenergic agonists (e.g., clonidine). NMDA receptor antagonists, such as ketamine, have shown promise in alleviating neuropathic pain refractory to other drugs.

Acute and Chronic Pain

Acute pain and chronic pain differ in their cause, course, manifestations, and treatment (Table 8.4). Examples of *acute pain* include postoperative pain, labor pain, pain from trauma (e.g., lacerations, fractures, sprains), pain from infection (e.g., dysuria from

cystitis), and pain from acute ischemia. For acute pain, treatment includes analgesics for symptom control and treatment of the underlying cause (e.g., splinting for a fracture, antibiotic therapy for an infection). Normally, acute pain decreases over time as healing occurs. However, acute pain that persists can lead to disabling chronic pain states. For example, pain associated with herpes zoster subsides as the acute infection resolves, usually within a month. However, sometimes the pain persists and develops into a chronic pain state called *postherpetic neuralgia.* Because of the connection between inadequately treated acute pain and chronic pain, it is important to treat acute pain aggressively.

Chronic pain, or *persistent pain,* lasts for longer periods, often defined as longer than 3 months or past the time when an expected acute pain or acute injury should subside. The severity and functional impact of chronic pain often are disproportionate to objective findings because of changes in the nervous system not detectable with standard tests. Although acute pain functions as a signal, warning the person of potential or actual tissue damage, chronic pain does not appear to have an adaptive role. Chronic pain can be disabling and often is accompanied by anxiety and depression.

Pain Assessment

Assessment is an essential, although often overlooked, step in pain management. Regularly screen all patients for pain and, when present, perform a more thorough pain assessment. The key to accurate and effective pain assessment is to consider the principles of pain assessment (Table 8.5).

The goals of a nursing pain assessment are to (1) describe the patient's pain experience to identify and implement appropriate pain management techniques and (2) identify the patient's goal for therapy and resources for self-management.

Elements of a Pain Assessment

Most components of a pain assessment involve direct interview or observation of the patient. Diagnostic studies and physical examination findings complete the initial assessment. Although the assessment differs according to the clinical setting, patient population, and point of care (i.e., whether the assessment is part of an initial workup or a reassessment of pain following therapy), the evaluation of pain should always be multidimensional (Table 8.6).

Before beginning any assessment, recognize that patients may use words other than "pain." For example, older adults may deny that they have pain but respond positively when asked if they have soreness or aching. Document the specific words that the patient uses to describe pain. Then consistently ask the patient about pain using those words.

TABLE 8.5 Principles of Pain Assessment

Principles	Nursing Implications
1. Patients have the right to appropriate assessment and management of pain.	• Assess pain in *all* patients.
2. Pain is always subjective.	• Patient's self-report of pain is the single most reliable indicator of pain. • Accept and respect this self-report unless there are clear reasons for doubt.
3. Physiologic and behavioral signs of pain (e.g., tachycardia, grimacing) are not reliable or specific for pain.	• Do not rely primarily on observations and objective signs of pain unless the patient is unable to self-report pain.
4. Pain is an unpleasant sensory and emotional experience.	• Address physical and psychologic aspects of pain when assessing pain.
5. Assessment approaches, including tools, must be appropriate for the patient population.	• Special considerations are needed for assessing pain in patients with difficulty communicating. • Include family members in the assessment process (when appropriate).
6. Pain can exist even when no physical cause can be found.	• Do not attribute pain that does not have an identifiable cause to psychologic causes.
7. Different patients have different levels of pain in response to comparable stimuli.	• A uniform pain threshold does not exist.
8. Patients with chronic pain may be more sensitive to pain and other stimuli.	• Pain tolerance varies among and within persons depending on several factors (e.g., genetics, energy level, coping skills, prior experience with pain).
9. Unrelieved pain has adverse consequences. Acute pain that is not adequately controlled can result in physiologic changes that increase the chance of developing persistent pain.	• Encourage patients to report pain, especially patients who are reluctant to discuss pain, deny pain when it is probably present, or fail to follow through on prescribed treatments.

Pain Pattern

Assessing pain *onset* involves determining when the pain started. Patients with acute pain resulting from injury, acute illness, or

treatment (e.g., surgery) typically know exactly when their pain began. Those with chronic pain may be less able to relate when the pain started. Establish the *duration* of the pain (how long it has lasted). This information helps to determine whether the pain is acute or chronic and helps identify the cause of the pain. For example, a patient with advanced cancer who has chronic low back pain from spinal stenosis reports a sudden, severe pain in the back that began 2 days ago. Knowing the onset and duration can lead to a diagnostic workup that may reveal new metastatic disease in the spine.

The pain pattern gives clues about the cause of the pain and directs its treatment. Many types of chronic pain (e.g., arthritis pain) can increase and decrease over time. A patient may have pain all the time (around-the-clock pain), as well as discrete periods of intermittent pain.

Breakthrough pain (BTP) is transient, moderate to severe pain that occurs in patients whose baseline persistent pain is otherwise mild to moderate and fairly well controlled. The average peak of BTP can be 3 to 5 minutes and can last up to 30 minutes or even longer. BTP can be either predictable or unpredictable. Patients can have 1 to many episodes per day. Several transmucosal fentanyl products are used specifically to treat BTP.

End-of-dose failure is pain that occurs before the expected duration of a specific analgesic. It should not be confused with BTP. Pain that occurs at the end of the duration of an analgesic often leads to a prolonged increase in the baseline persistent pain. For example, in a patient on transdermal fentanyl (Duragesic patches) the typical duration of action is 72 hours. An increase in pain after 48 hours on the drug would be an end-of-dose failure. End-of-dose failure signals the need for changes in the dose or scheduling of the analgesic. Episodic, procedural, or *incident pain* is a transient increase in pain that is caused by a specific activity or event that precipitates pain. Examples include dressing changes, movement, position changes, and procedures, such as catheterization.

TABLE 8.6 Nursing Assessment

Pain

Subjective Data

Important Health Information

Health history: Pain history includes onset, location, intensity, quality, patterns, aggravating and alleviating factors, and expression of pain. Coping strategies. Past treatments and their effectiveness. Review health care use related to the pain problem (e.g., emergency department visits, treatment at pain clinics, visits to primary HCPs and specialists)

Medications: Use of any prescription or over-the-counter, illicit, or herbal products for pain relief. Alcohol use

Nondrug measures: Use of therapies, such as massage, heat or ice, Reiki, aromatherapy, acupuncture, hypnosis, yoga, or meditation

Functional Health Patterns

Health perception–health management: Social and work history, mental health history, smoking history. Effects of pain on emotions, relationships, sleep, and activities. Interviews with family members. Records from psychologic/psychiatric treatment related to the pain

Elimination: Constipation related to opioid drug use, other medication use, or pain related to elimination

Activity-exercise: Fatigue, limitations in ability to perform activities of daily living (ADLs), instrumental activities of daily living (IADLs), and pain related to use of muscles

Sexuality-reproductive: Decreased libido

Coping–stress tolerance: Psychologic evaluation using standardized measures to examine coping style, depression,

anxiety

Objective Data

Physical examination, including evaluation of functional limitations
Psychosocial evaluation, including mood

Location

Determining the *location* of pain helps us identify possible causes and treatment. Some patients may be able to specify the precise location(s) of their pain. Others may describe general areas or comment that they "hurt all over." The location of the pain may be referred from its origin to another site (Fig. 8.3). For example, myocardial infarction can result in pain in the left shoulder. Pain can radiate from its origin to another site. For example, angina pectoris can radiate from the chest to the jaw or down the left arm. We refer to this as radiating pain. *Sciatica* is pain that follows the course of the sciatic nerve. It may originate from joints or muscles around the back or from compression or damage to the sciatic nerve. The pain is projected along the course of the peripheral nerve, causing painful shooting sensations down the back of the thigh and inside of the leg to the foot.

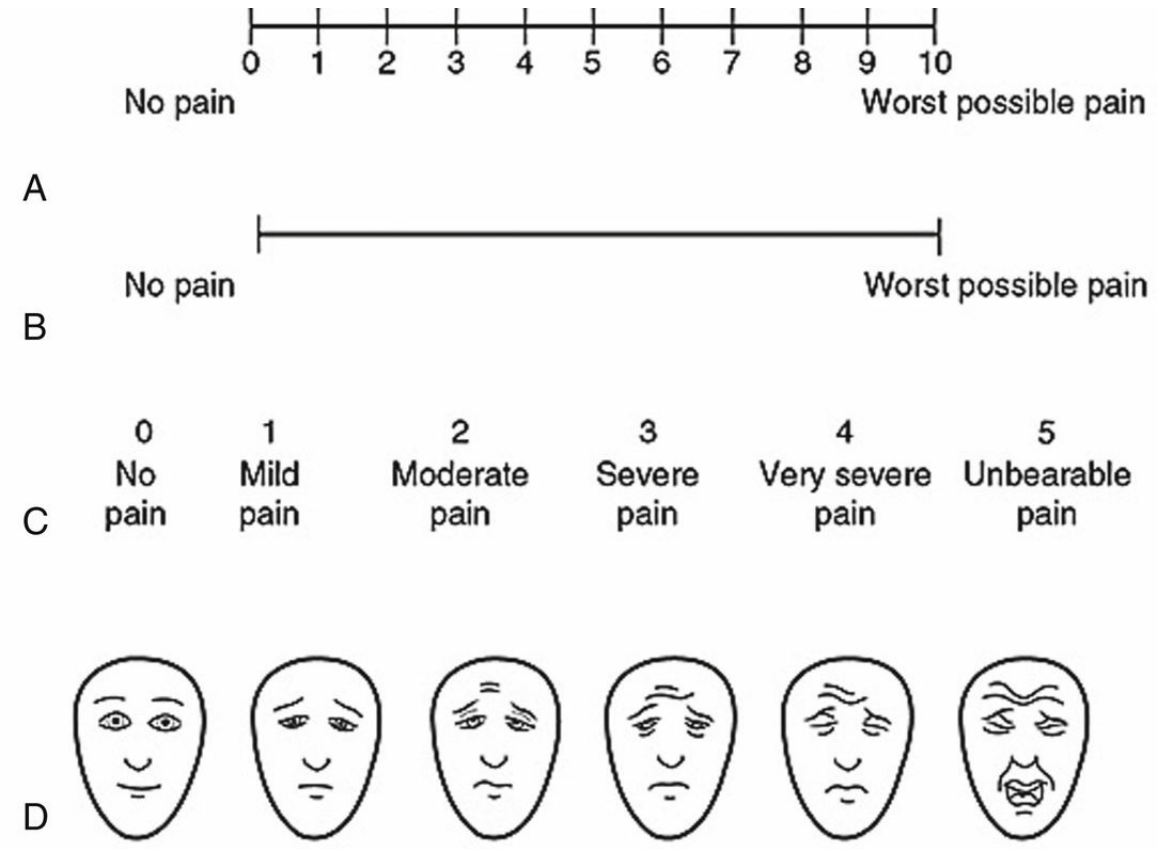

FIG. 8.4 Pain intensity scales. **A,** 0 to 10 numeric scale. **B,** Visual analog scale. **C,** Descriptive scale. **D,** Faces Pain Scale. Modified from Baird M: *Manual of critical care nursing: Nursing interventions and collaborative management,* ed 2, St Louis, 2015, Elsevier.

Obtain information about the location of pain by asking the patient to (1) describe the site(s) of pain, (2) point to painful areas on the body, or (3) mark painful areas on a pain map. Because many patients have more than 1 site of pain, make certain that the patient describes every location.

Intensity

Assessing the severity, or *intensity,* of pain provides a reliable measure to determine the type of treatment and its effectiveness. Pain scales help the patient communicate pain intensity. Base your choice of a scale on the patient's developmental needs and cognitive status (Fig. 8.4). Most adults can rate the intensity of their pain using a numeric rating scale (e.g., 0 = no pain, 10 = the worst pain). Patients who wish

to have word choices to quantify pain may prefer a verbal descriptor scale (e.g., none, mild, moderate, severe). For those oriented to vertical representations, the Pain Thermometer Scale is an option. Other visual pain measures, such as the Wong-Baker FACES pain tool, are useful for patients with cognitive or language barriers to describe their pain.[11] Pain assessment measures for cognitively impaired adults and nonverbal adults are addressed later in this chapter.

Although intensity is an important factor in determining analgesic approaches, do not dose patients with opioids solely based on reported pain scores.[12] Opioid "dosing by numbers" without considering a patient's sedation level and respiratory status can lead to unsafe practices and serious adverse events. Safer analgesic administration can be achieved by balancing an amount of pain relief with analgesic side effects and using a multimodal approach. (Multimodal approach is described later in this chapter.) Adjustments in therapy can be made to promote better pain control and minimize adverse outcomes.

Quality

The pain *quality* refers to the nature or characteristics of the pain. For example, patients often describe neuropathic pain as burning, numbing, shooting, stabbing, electric shock–like, or itchy. Nociceptive pain may be described as sharp, aching, throbbing, dull, and cramping. Since the quality of pain relates to a degree to the classification of pain (e.g., neuropathic, nociceptive), these descriptors can help to guide treatment options that best address the specific mechanism of pain.

Associated Symptoms

Associated symptoms, such as anxiety, fatigue, and depression, may worsen or be worsened by pain. Patients with pain often report poor sleep and subsequent daytime sleepiness. Poor sleep can further increase pain perception. Ask about aggravating factors that increase pain as well as activities and situations that alleviate pain. For example, musculoskeletal pain may be increased or decreased with

movement and ambulation. Resting or immobilizing a painful body part can decrease pain. Knowing what makes pain better or worse can help characterize the type of pain and be helpful in selecting treatments.

Management Strategies

As people experience and live with pain, they may cope differently and be more or less willing to try different strategies to manage it. Some strategies are successful, while others are not. To maximize the effectiveness of the pain treatment plan, ask patients what they are using now to control pain, what they have used in the past, and the outcomes of these methods. Strategies include prescription and nonprescription drugs and nondrug therapies, such as hot and cold applications, complementary and alternative therapies (e.g., acupuncture), and relaxation strategies (e.g., imagery). It is important to document both those that work and those that are ineffective.

Impact of Pain

Pain can have a profound influence on a patient's quality of life and functioning. Assess the effect of the pain on the patient's ability to sleep, enjoy life, interact with others, perform work and household duties, and engage in physical and social activities. Assess the impact of pain on the patient's mood.

In an acute care setting, time limitations may dictate a shortened assessment. At a minimum, assess the effects of the pain on the patient's sleep and daily activities, relationships with others, physical activity, and emotional well-being. Include the ways in which the patient describes the pain and strategies used to cope with and control the pain.

Patient's Beliefs, Expectations, and Goals

Patient and family beliefs, attitudes, and expectations influence responses to pain and pain treatment. Assess for attitudes and beliefs that may hinder effective treatment (e.g., belief that opioid use will

result in addiction). Ask about expectations and goals for pain management.

Documentation

Document the pain assessment, since this is critical to ensure safe, effective communication among interprofessional team members. Many health care facilities have adopted specific tools to record an initial pain assessment, treatment, and reassessment. There also are many multidimensional pain assessment tools, such as the Brief Pain Inventory, the McGill Pain Questionnaire, and the Neuropathic Pain Scale.

Reassessment

It is critical for you to reassess pain at appropriate intervals. The frequency and scope of reassessment are guided by factors such as pain severity, physical and psychosocial condition, type of intervention and risks for adverse effects, and institutional policy. For example, reassessment of a postoperative patient may be done frequently, such as at the time of peak effect for each analgesic dose. In a long-term care facility, residents with chronic pain are reassessed at least quarterly or with a change in condition or functional status.

Pain Treatment

Basic Principles

All pain treatment plans are based on the following 10 principles and practice standards:

1. *Follow the principles of pain assessment* (Table 8.5). Remember that pain is a subjective experience. The patient is not only the best judge of his or her own pain but also the expert on the effectiveness of each pain treatment.

2. *Use a holistic approach to pain management.* The pain experience affects all aspects of a person's life. Thus a holistic approach to assessment, treatment, and evaluation is required.
3. *Every patient deserves adequate pain management.* Many patient populations, including ethnic minorities, cognitively impaired adults, and people with past or current substance abuse, are at risk for inadequate pain management. Be aware of your own biases and ensure that all patients are treated respectfully.
4. *Base the treatment plan on the patient's goals.* Discuss with the patient realistic goals for pain relief during the initial pain assessment. Although goals can be described in terms of pain intensity (e.g., the desire for average pain to decrease from "8/10" to "3/10"), with chronic pain conditions, encourage functional goal setting (e.g., a goal of performing certain daily activities, such as socializing and recreational activities). Encourage functional activities for the patient with acute pain as well. For example, the pain must be at a level that allows the patient to use the incentive spirometer, get out of bed, and ambulate. Over time, reassess these goals and progress made toward meeting them. The patient, in collaboration with the interprofessional team, determines new goals. If the patient has unrealistic goals for therapy, such as wanting to be completely rid of all chronic arthritis pain or be completely pain free after a major surgery, work with the patient to establish a more realistic goal.
5. *Use both drug and nondrug therapies.* Although drugs are considered the mainstay of therapy, include self-care activities and nondrug therapies to increase the overall effectiveness of therapy and to allow for the reduction of drug dosages to minimize adverse drug effects.
6. *When appropriate, use a multimodal approach to analgesic therapy.* **Multimodal analgesia** employs the use of 2 or more classes of analgesic agents to take advantage of the various mechanisms of action. For acute, postoperative pain, a multimodal approach may include the use of an opioid

(morphine), nonopioid (nonsteroidal antiinflammatory drug), and/or antiseizure drug (e.g., gabapentin). Regional anesthesia and continuous peripheral neural blockade can be used with local anesthetics as part of multimodal regimens.[13] Factors such as age, type of surgery, risk for developing chronic pain, and coexisting conditions are all considered when designing a multimodal analgesic regimen. Multimodal analgesia is used to treat chronic or persistent pain. Similar to the strategies for acute postoperative pain, the goal is to combine classes of analgesics for the maximum benefit of relieving pain with minimum doses to achieve relief and reduce adverse events from analgesics. Multimodal regimens achieve superior pain relief, enhance patient satisfaction, and decrease adverse effects of individual drugs.[14]

7. *Address pain using an interprofessional approach.* The expertise and perspectives of an interprofessional team are often necessary to provide effective assessment and therapies for patients with both acute and chronic pain. For hospitalized patients or those with complex acute or chronic pain issues, anesthesiology-based pain services may be available to manage patients with technology-supported pain care (e.g., patient-controlled analgesia or regional analgesia). Team members for these services can include pain management nurses, nurse practitioners, clinical nurse specialists, anesthesiologists, and clinical pharmacists. These teams help to establish realistic goals with patients and families to facilitate recovery and discharge. Many outpatient pain management centers or clinics are available. Some provide comprehensive pain care and employ multiple providers, including anesthesiologists, rehabilitation physicians, nurses, psychologists, physical and occupational therapists, and social workers. Services may focus on medication management, pain interventional therapies, psychologic counseling, cognitive and behavioral therapies, rehabilitative therapies (physical and occupational therapy), and social services. Specialized pain

treatment centers may also offer more holistic therapies, such as massage, music and art therapy, and acupuncture. Advise patients seeking specialized pain care from outpatient treatment centers to check about services that are provided.

8. *Evaluate the effectiveness of all therapies to ensure that they are meeting the patient's goals.* Achievement of an effective treatment plan often requires trial and error. Adjustments in drug, dosage, or route are common to achieve maximal benefits while minimizing adverse effects. This trial-and-error process can become frustrating for the patient and caregivers. Reassure them that pain relief, if not pain cessation, is possible and that the interprofessional team will continue to work with them to achieve adequate pain relief.

TABLE 8.7 Drug Therapy

Managing Side Effects of Pain Medications

Side effects can be managed by 1 or more of the following methods:

- Decreasing the dose of analgesic by 10% to 15%
- Changing to a different medication in the same class
- Adding a drug to counteract the adverse effect of the analgesic (e.g., using a stool softener for patients experiencing opioid-induced constipation)
- Using an administration route that

minimizes drug concentrations (e.g., intraspinal administration of opioids used to minimize high drug levels that produce sedation, nausea, and vomiting)

9. *Prevent and/or manage medication side effects.* Side effects or adverse events are a major reason for treatment failure and nonadherence. Side effects are managed in 1 of several ways, as described in Table 8.7. You play a key role in monitoring for and treating side effects and in teaching patients and caregivers how to minimize these effects.
10. *Include patient and caregiver teaching throughout assessment and treatment.* Content should include information about the causes of the pain, pain assessment methods, treatment goals and options, expectations of pain management, proper use of drugs, side effect management, and nondrug and self-help pain relief measures. Document the teaching and include evaluation of patient and caregiver comprehension.

Drug Therapy for Pain

Pain medications generally are divided into 3 categories: nonopioids, opioids, and adjuvant drugs. Patient-centered treatment regimens may include medications from 1 or more of these groups. Mild pain often can be relieved using nonopioids alone. Moderate to severe pain usually requires an opioid. Certain types of pain, such as neuropathic pain, typically require adjuvant drug therapy alone or in combination with an opioid or another class of analgesics. Pain caused by cancer may be treated with chemotherapy or radiation therapy, as well as pain medications.

Nonopioids

Nonopioid analgesics include acetaminophen, aspirin and other salicylates, and NSAIDs (Table 8.8). These agents are characterized by (1) their analgesic properties have an **analgesic ceiling**; that is, increasing the dose beyond an upper limit provides no greater analgesia; (2) they do not produce tolerance or physical dependence; and (3) many are available without a prescription. To provide safe care, monitor over-the-counter (OTC) analgesic use to avoid serious problems related to drug interactions, side effects, and overdose.

Nonopioids are effective for mild to moderate pain. They are often used in conjunction with opioids because they allow for effective pain relief using lower opioid doses (thereby causing fewer opioid side effects). This phenomenon is called the *opioid-sparing effect*.

Aspirin is effective for mild pain, but its use is limited by its common side effects, including increased risk for bleeding, especially gastrointestinal (GI) bleeding. Other salicylates, such as choline magnesium trisalicylate (Trilisate), cause fewer GI problems and bleeding abnormalities. Similar to aspirin, acetaminophen (Tylenol) has analgesic and antipyretic effects. Unlike aspirin, it has no antiplatelet or antiinflammatory effects. Acetaminophen is well tolerated. It is metabolized by the liver. Hepatotoxicity may result from chronic dosing of more than 3 g/day, acute overdose, or use by patients with severe preexisting liver disease.[15] Adding acetaminophen to opioid therapy produces an opioid-sparing effect, lower pain scores, and fewer side effects. This is the reason for opioid-acetaminophen combinations.

TABLE 8.8 Drug Therapy

Selected Nonopioid Analgesics

Drug	Nursing Considerations
Nonsalicylate acetaminophen (Tylenol)	• Chronic overdose: Liver toxicity • Sustained release, rectal suppository, and injectable forms (OFIRMEV) available • Maximum daily dose of 3 g • Oral doses of >3 g may cause hepatotoxicity • Acute overdose: Acute liver failure • Chronic overdose: Liver toxicity • Maximum daily IV dose should not exceed 4 g/day for adults ≥50 kg
Nonsteroidal Antiinflammatory Drugs (NSAIDs)	
celecoxib (Celebrex)	• Causes fewer GI side effects (e.g., bleeding) than other NSAIDs, but risk still present • More costly than other NSAIDs • May increase risk for serious cardiovascular thrombotic events, myocardial infarction, and stroke • Risks may increase with duration of use, preexisting cardiovascular disease, or risk factors for cardiovascular disease
diclofenac K	• Use lowest effective dose for shortest possible duration • Available in oral, ophthalmic, topical preparations
ibuprofen (Advil)	• Use lowest effective dose for shortest possible duration • Increased risk for serious GI adverse events (bleeding, ulceration, perforation), especially in older adults • May increase risk for serious cardiovascular thrombotic events, myocardial infarction, and stroke • May increase risk for hypertension and renal insufficiency
ketorolac	• Limit treatment to 5 days • May precipitate renal failure in dehydrated patients
naproxen (Naprosyn, Aleve)	• Use lowest effective dose for shortest possible duration • Increased risk for serious GI adverse events (bleeding, ulceration, perforation), especially in older adults • Contraindicated for the treatment of perioperative pain in setting of coronary artery bypass graft (CABG) surgery
Salicylates	
aspirin	• Rectal suppository and sustained-release preparations available • Chance of upper GI bleeding • Used more often in low doses as a cardioprotective measure than for its analgesic properties
choline magnesium trisalicylate (Trilisate)	• Unlike aspirin and NSAIDs, does not increase bleeding time

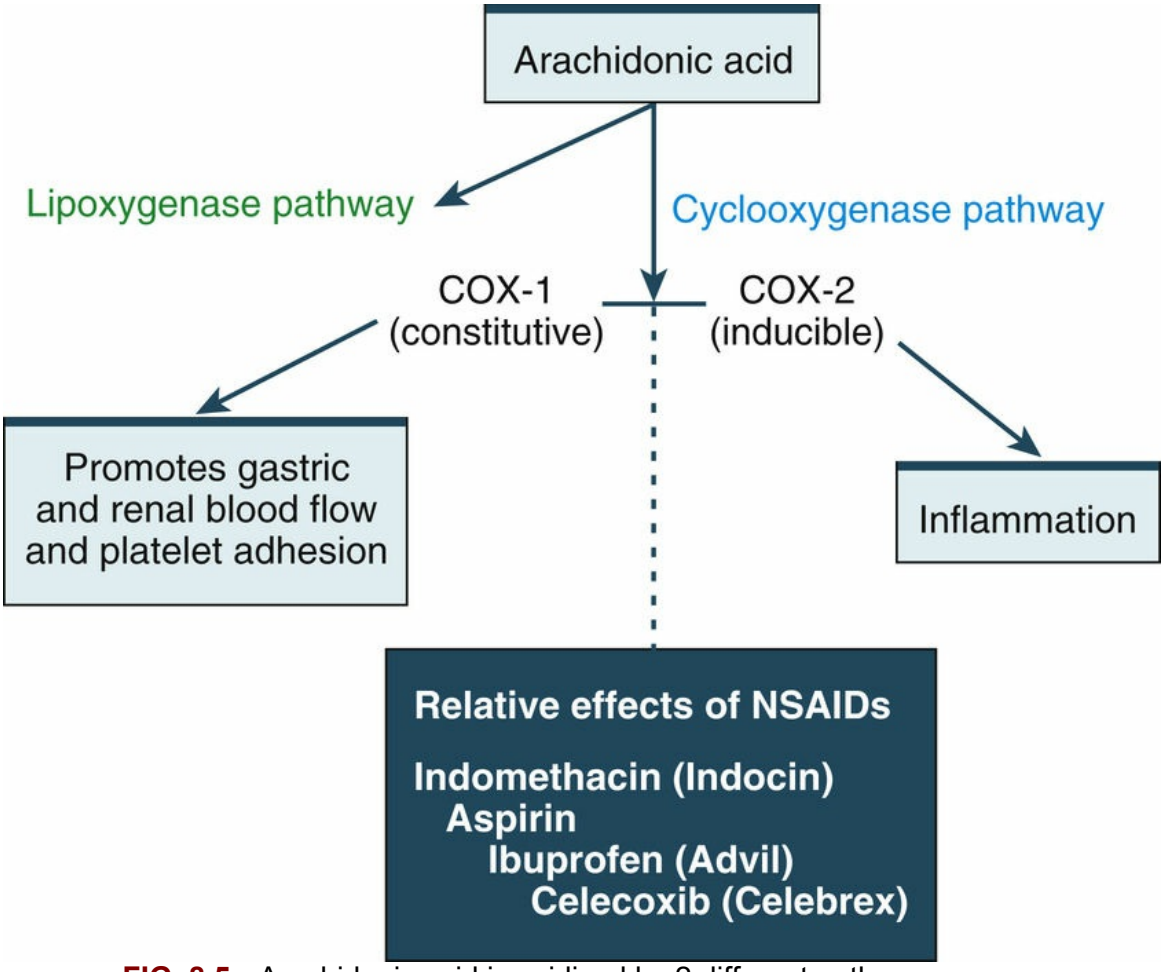

FIG. 8.5 Arachidonic acid is oxidized by 2 different pathways: lipoxygenase and cyclooxygenase. The cyclooxygenase pathway leads to 2 forms of the enzyme cyclooxygenase: COX-1 and COX-2. COX-1 is known as *constitutive* (always present), and COX-2 is known as *inducible* (its expression varies markedly depending on the stimulus). Nonsteroidal antiinflammatory drugs (NSAIDs) differ in their actions, with some having more effects on COX-1 and others more on COX-2. Indomethacin acts primarily on COX-1. Ibuprofen is equipotent on COX-1 and COX-2. Celecoxib primarily inhibits COX-2.

IV acetaminophen (Ofirmev) is used alone for the treatment of acute mild to moderate pain and as an adjunct to opioid analgesics or part of a multimodal analgesic regimen for moderate to severe pain. It must be given over 15 minutes and has a short duration of action. The daily dose should not exceed 4 g/day.

NSAIDs represent a broad class of drugs with varying efficacy and side effects. All NSAIDs inhibit COX, the enzyme that converts arachidonic acid into prostaglandins and related compounds. The

enzyme has 2 forms: COX-1 and COX-2. COX-1 is found in almost all tissues. It is responsible for several protective physiologic functions. In contrast, COX-2 is made mainly at the sites of tissue injury, where it mediates inflammation (Fig. 8.5). Inhibition of COX-1 causes many of the untoward effects of NSAIDs, such as impairment of renal function, bleeding tendencies, GI irritation, and ulceration. COX-2 inhibition is associated with the therapeutic, antiinflammatory effects of NSAIDs. (Celecoxib [Celebrex] is a COX-2 inhibitor.) Older NSAIDs, such as ibuprofen, inhibit both forms of COX. We refer to them as nonselective NSAIDs.

Patients vary greatly in their responses to a specific NSAID. So, when 1 NSAID does not provide relief, another should be tried. NSAIDs are associated with many side effects, including GI problems ranging from dyspepsia to life-threatening ulceration and hemorrhage. NSAIDs can cause cognitive impairment and hypersensitivity reactions with asthma-like symptoms.

Patients at risk for NSAID-associated GI toxicity include those who have a recent history of peptic ulcer disease, patients who are older than 65, and those concurrently using corticosteroids or anticoagulants. If NSAIDs are used in patients at risk for GI bleeding, they should have concomitant therapy with misoprostol (Cytotec) or a proton pump inhibitor, such as omeprazole. NSAIDs should not be given concurrently with aspirin since this increases the risk for GI bleeding.

Drug Alert

Nonsteroidal Antiinflammatory Drugs (NSAIDs)

- NSAIDs, except aspirin, have been linked to a higher risk for cardiovascular events, such as myocardial infarction, stroke, and heart failure.
- Patients who have just had heart surgery should not take

NSAIDs.

Opioids

Opioids (Table 8.9) produce their effects by binding to receptors in the CNS. This results in (1) inhibition of the transmission of nociceptive input from the periphery to the spinal cord, (2) altered limbic system activity, and (3) activation of the descending inhibitory pathways that modulate transmission in the spinal cord. Thus opioids act on several nociceptive processes.

Types of Opioids

Opioids are categorized according to their physiologic action (i.e., agonist, antagonist) and binding at specific opioid receptors (e.g., mu, kappa, delta). The most commonly given subclass of opioids is the pure opioid agonists, or morphine-like opioids, which bind to mu receptors.

Opioid agonists are used for acute and chronic pain. Although nociceptive pain seems to be more responsive to opioids than neuropathic pain, opioids may be used to treat both types of pain. In the treatment of neuropathic pain, antineuropathic pain drugs, such as antidepressants and antiseizure drugs, are recommended as first-line agents. Pure opioid agonists include morphine, oxycodone (OxyContin), hydrocodone, codeine, methadone, hydromorphone (Dilaudid), and levorphanol (Table 8.9). These drugs are effective for moderate to severe pain because they are potent, theoretically have no analgesic ceiling, and can be given by several routes. When opioids are prescribed for moderate pain, they are usually combined with a nonopioid analgesic, such as acetaminophen with codeine or hydrocodone plus acetaminophen or ibuprofen. Adding acetaminophen limits the total daily dose that we can give.

Drug Alert

Morphine

- Morphine may cause respiratory depression.
- If respirations are 12 or fewer breaths per minute, withhold medication and contact the health care provider (HCP).

Methadone has a unique mechanism of action as an NMDA receptor antagonist and mu opioid receptor agonist. It is used primarily in the treatment of chronic pain but can be used for acute pain. It produces analgesic effects independent of its action as an opioid.[16]

Drug Alert

Methadone (Dolophine)

- Methadone may cause respiratory depression.
- Methadone can cause cardiac toxicity, specifically QT prolongation.

Mixed agonist-antagonists (e.g., pentazocine [Talwin], butorphanol) bind as agonists on kappa receptors and as weak antagonists or partial agonists on mu receptors. Because of this difference in binding, mixed agonist-antagonists produce less respiratory depression than drugs that act only at mu receptors. These drugs cause more dysphoria and agitation. In addition, opioid agonist-antagonists have an analgesic ceiling and can precipitate withdrawal if used by a patient who is physically dependent on mu agonist drugs. Partial opioid agonists (e.g., buprenorphine [Buprenex]) can produce some pain relief but bind tightly to mu receptors and can block the effect of other drugs. Agonist-antagonists and partial agonists currently have limited clinical application in pain management.

TABLE 8.9 Drug Therapy

Opioid Analgesics

Drug	Routes of Administration	Nursing Considerations
Mu Agonists		
codeine oral (with acetaminophen [Tylenol #3]), codeine injectable	PO, subcutaneous	• Associated with higher incidence of nausea and constipation than other mu agonists • Many codeine preparations are combined with acetaminophen • 5%–10% of European Americans lack the enzyme to metabolize codeine to morphine
fentanyl (Sublimaze [IV]), Duragesic [transdermal], Actiq [transmucosal], Fentora [buccal tablet], Abstral [sublingual], Lazanda [nasal spray]	IV, epidural, intrathecal, transmucosal, transdermal	• Immediate onset after IV route, 7–8 min after IM route, 5–15 min after transmucosal route, up to 6 hr after transdermal route • For procedures, IV fentanyl often combined with benzodiazepines for analgesia and sedation • Very potent; dosage is in micrograms (mcg) • Transdermal fentanyl used only for chronic pain and should not be given to opioid-naive patients
hydrocodone with acetaminophen (Norco), hydrocodone with bitartrate (Hysingla, Zohydro ER), hydrocodone with ibuprofen (Reprexain)	PO (short-acting and long-acting)	• Used for moderate or moderately severe pain • For short-term management of acute pain (e.g., trauma, musculoskeletal)
hydromorphone (Dilaudid)	PO (short-acting and long-acting forms), rectal, IV, subcutaneous, epidural, intrathecal	• Slightly shorter duration than morphine • For moderate to severe pain • Tablets for sustained-release preparations are to be swallowed whole and must not be broken, chewed, dissolved, or crushed • Preparations for neuraxial administration must be preservative free
levorphanol	PO, IV, IM, subcutaneous	• Accumulates with repeated dosing
methadone (Dolophine)	PO, IV, IM	• High oral and rectal bioavailability • Accumulates with repeated dosing • Use with caution in older adults • Risk for QT interval prolongation
morphine (MS Contin, Kadian, Duramorph, Embeda)	PO (short-acting and sustained-release forms), rectal, IV, subcutaneous, epidural, intrathecal, sublingual, intranasal	• Standard of comparison for opioid analgesics (Table 8.12) • For moderate to severe pain • Can stimulate histamine release, leading to pruritus, with systemic administration • Tablets for sustained-release preparations are to be swallowed whole and must not be broken, chewed, dissolved, or crushed • Preparations for neuraxial administration must be preservative free
oxycodone (Roxicodone) **oxycodone extended-release (OxyContin)** **oxycodone plus acetaminophen (Percocet)** **oxycodone plus aspirin (Percodan)**	PO (short-acting and extended-release forms)	• Available as single entity and in combination with a nonopioid • Used similarly to oral morphine for moderate to severe pain • Often combined with a nonopioid for acute, moderate pain • Extended-release indicated for chronic pain
tapentadol (Nucynta)	PO (short-acting and extended release)	• Dual mechanism of action: Mu opioid agonist and blocks reuptake of norepinephrine and serotonin
tramadol (Ultram)	PO (short-acting and extended release)	• Dual mechanism of action: Mu opioid agonist and blocks reuptake of norepinephrine and serotonin • Used for moderate pain
Mu Mixed Agonist-Antagonists		
butorphanol	Nasal spray, injectable form Not available orally	• Psychotomimetic effects lower than with pentazocine • May precipitate withdrawal in opioid-dependent patients • Injectable used for acute pain • Nasal spray given for migraine headaches
pentazocine (Talwin)	IM, IV, subcutaneous	• May cause psychotomimetic effects (e.g., hallucinations) and may precipitate withdrawal in opioid-dependent patients • Not recommended for treatment of chronic pain and rarely for acute pain
Partial Agonists		

Drug	Routes of Administration	Nursing Considerations
buprenorphine	Sublingual, injectable, implant	• Sublingual form should not be chewed or swallowed • Lower abuse potential than morphine • Does not produce psychotomimetic effects • May precipitate withdrawal in opioid-dependent patients. Not readily reversed by naloxone • Buprenorphine plus naloxone used as a sublingual preparation to treat opioid dependence for easier withdrawal when necessary to taper from opioids
buprenorphine plus naloxone sublingual (Suboxone)		

Dual-Mechanism Agents

Some analgesics have 2 distinct actions, or dual mechanisms. Tramadol (Ultram) is a weak mu agonist and inhibits the reuptake of norepinephrine and serotonin. It is effective in low back pain, osteoarthritis, fibromyalgia, diabetic peripheral neuropathic pain, polyneuropathy, and postherpetic neuralgia. The most common side effects are like those of other opioids, including nausea, constipation, dizziness, and sedation. As with other medications that increase serotonin and norepinephrine, avoid this drug in patients with a history of seizures because it lowers seizure threshold.

Tapentadol (Nucynta) is a centrally acting analgesic that works at mu receptors and inhibits norepinephrine reuptake. It is approved for management of moderate to severe acute pain. For chronic moderate to severe pain, an extended-release formula is available. The side effects are like those of conventional opioids, except that this drug is associated with less nausea and constipation.

Opioids to Avoid

Some opioids should be avoided for pain relief because of limited efficacy and/or toxicities. Meperidine (Demerol), or pethidine, is associated with neurotoxicity (e.g., seizures) caused by accumulation of its metabolite, normeperidine. Its use is limited for very short-term (i.e., less than 48 hours) treatment of acute pain when other opioid agonists are contraindicated.

Drug Alert

Meperidine (Demerol)

The American Pain Society does not recommend the use of meperidine as an analgesic.

Side Effects of Opioids

Common side effects of opioids include constipation, nausea and vomiting, sedation, respiratory depression, and pruritus. With continued use, many side effects diminish; the exception is constipation. Less common side effects include urinary retention, myoclonus, dizziness, confusion, and hallucinations. *Constipation* is the most common side effect of opioids. Left untreated, it may increase the person's pain and can lead to fecal impaction and paralytic ileus.

Because tolerance to opioid-induced constipation does not develop, a bowel regimen should be started at the beginning of opioid therapy and continued for as long as the person takes opioids. Although dietary fiber, fluids, and exercise should be encouraged, these measures alone may not be enough. Most patients should use a gentle stimulant laxative (e.g., senna) plus a stool softener (e.g., docusate sodium [Colace]). Other agents (e.g., Milk of Magnesia, bisacodyl, polyethylene glycol, lactulose) can be added if needed. Methylnaltrexone (Relistor), naldemedine (Symproic), and naloxegol (Movantik) are peripheral opioid receptor antagonists used for opioid-induced constipation when the response to traditional laxative and stool softener therapy is insufficient.

Nausea is often a problem in opioid-naive patients. The use of an antiemetic, such as ondansetron (Zofran), metoclopramide (Reglan), transdermal scopolamine, or hydroxyzine (Vistaril), can prevent or minimize nausea and vomiting until tolerance develops, usually within 1 week. Opioids delay gastric emptying (patient relates gastric fullness). Metoclopramide can reduce this effect. If nausea and vomiting are severe and persistent, changing to a different opioid may be needed.

Sedation is usually seen in opioid-naive patients being treated for

acute pain. Regularly monitor patients receiving opioid analgesics for acute pain, especially in the first few days (e.g., after surgery). Be aware that the risk for unintended sedation in postoperative patients is greatest within 4 hours after leaving the postanesthesia care unit. Opioid-induced sedation resolves with the development of tolerance. Persistent sedation with chronic opioid use can be effectively treated with psychostimulants, such as caffeine, dextroamphetamine (Dexedrine), methylphenidate (Ritalin), or the anticataleptic drug modafinil (Provigil).

The risk for *respiratory depression* is higher in opioid-naive, hospitalized patients who are treated for acute pain. Clinically significant respiratory depression is rare in opioid-tolerant patients and when opioids are titrated to analgesic effect. Patients most at risk for respiratory depression include those who are age 65 or older, have a history of snoring or witnessed apneic episodes, report excessive daytime sleepiness, have underlying heart or lung disease, are obese (body mass index greater than 30 kg/m^2), have a history of smoking (more than 20 pack-years), or are receiving other CNS depressants (e.g., sedatives, benzodiazepines, antihistamines). For postoperative patients the greatest risk for opioid-related respiratory adverse events is within the first 24 hours after surgery. Clinically significant respiratory depression cannot occur in patients who are fully awake.

Check Your Practice

A 74-yr-old male patient returned to the clinical unit after surgery for a hip replacement. You are having difficulty arousing him with either verbal or physical stimulation. His wife tells you to just let him sleep. His respiratory rate ranges from 8 to 10 breaths/min.

- What should you do?

Frequently monitor both the sedation level and respiratory rate in patients receiving opioid analgesics.[17] A sedation scale can be used for

monitoring and providing appropriate interventions based on the level of sedation (Table 8.10).

Safety Alert

Sedation and Respiratory Depression

- If the patient's respiratory rate falls below 8 or 10 breaths/min and the sedation level is 3 or greater, you should vigorously stimulate the patient and try to keep the patient awake.
- If the patient becomes oversedated, apply oxygen.
- In this situation, the opioid dose should be reduced.

For patients who are excessively sedated or unresponsive, we can give naloxone, an opioid antagonist that rapidly reverses the effects of opioids. Naloxone can be given IV, subcutaneously, or intranasally. Evzio (hand-held autoinjector containing naloxone) can be used by a caregiver or family member to treat a person known or suspected to have had an opioid overdose.

If the patient has been taking opioids regularly for more than a few days, use naloxone carefully because it can precipitate severe, agonizing pain; profound withdrawal symptoms; hypertension; and pulmonary edema. Because naloxone's half-life is shorter than that of most opioids, frequently monitor the patient.

Pruritus (itching) is another common side effect of opioids. It occurs most often when opioids are given by neuraxial (i.e., epidural, intrathecal) routes. Managing opioid-induced pruritus in noncancer patients may include low-dose infusions of naloxone.

TABLE 8.10 Pasero Opioid-Induced Sedation Scale (POSS) With Interventions

Level of Sedation	Nursing Intervention
S = Sleep, easy to arouse	• Acceptable • No action necessary • May increase opioid dose if needed
1. Awake and alert	• Acceptable • No action necessary • May increase opioid dose if needed
2. Slightly drowsy, easily aroused	• Acceptable • No action necessary • May increase opioid dose if needed
3. Frequently drowsy, arousable, drifts off to sleep during conversation	• Unacceptable • Monitor respiratory status and sedation level closely until sedation level is stable at <3 and respiratory status is satisfactory • Decrease opioid dose 25%–50% or notify HCP or anesthesiologist for orders • Consider giving a nonsedating, opioid-sparing nonopioid, such as acetaminophen or an NSAID, if not contraindicated
4. Somnolent, minimal or no response to verbal or physical stimulation	• Unacceptable • Stop opioid • Consider giving naloxone • Notify HCP or anesthesiologist • Monitor respiratory status and sedation level closely until sedation level is stable at <3 and respiratory status is satisfactory

Adapted from Pasero C: Assessment of sedation during opioid administration for pain management, *J PeriAnesthesia Nurs* 24:186, 2009.

A rare but concerning problem with long-term and even short-term use of high-dose opioids is *opioid-induced hyperalgesia* (OIH). OIH is a state of nociceptive sensitization caused by exposure to opioids. It is characterized by a paradoxical response in which patients become more sensitive to certain painful stimuli and report increased pain with opioid use. The exact mechanism is not clearly understood, but it may be due to neuroplasticity changes. This may explain why opioids tend to lose their effectiveness in certain patients over time.

Adjuvant Analgesic Therapy

Analgesic adjuvants are drugs that can be used alone or in conjunction with opioid and nonopioid analgesics (Table 8.11). Generally, these agents were developed for other purposes (e.g., antiseizure drugs, antidepressants) and found to be effective for treating pain.

α_2-Adrenergic Agonists

We think clonidine and tizanidine (Zanaflex), the most widely used

α_2-adrenergic agonists, work on the central inhibitory α-adrenergic receptors. These agents may also decrease norepinephrine release peripherally. They are given for chronic headache and neuropathic pain.

Antidepressants

Tricyclic antidepressants (TCAs) enhance the descending inhibitory system by preventing the cellular reuptake of serotonin and norepinephrine. Higher levels of serotonin and norepinephrine in the synapse inhibit the transmission of nociceptive signals in the CNS. Other potential beneficial actions of TCAs include sodium channel modulation, α_1-adrenergic antagonist effects, and a weak NMDA receptor modulation. They are effective for a variety of pain syndromes, especially neuropathic pain syndromes. However, side effects, such as sedation, dry mouth, blurred vision, and weight gain, limit their usefulness. Antidepressants that selectively inhibit reuptake of serotonin and norepinephrine (SNRIs) are effective for many neuropathic pain syndromes and have fewer side effects than the TCAs. These agents include venlafaxine, desvenlafaxine (Pristiq), milnacipran (Savella), and bupropion.

Antiseizure Drugs

Antiseizure drugs affect peripheral nerves and the CNS in several ways, including sodium channel modulation, central calcium channel modulation, and changes in excitatory amino acids and other receptors. Agents such as gabapentin, lamotrigine, and pregabalin are valuable adjuvant agents in chronic pain therapy and are being used more in the treatment of acute pain.

GABA-Receptor Agonist

Baclofen, an agonist at GABA receptors, can interfere with the transmission of nociceptive impulses. It is used for muscle spasms and neuropathic pain. It crosses the blood-brain barrier poorly and is much more effective for spasticity when delivered intrathecally.

Corticosteroids

Corticosteroids include dexamethasone, prednisone, and methylprednisolone (Medrol). They are used for managing acute and chronic cancer pain, pain secondary to spinal cord compression, and inflammatory joint pain syndromes. Mechanisms of action may be related to the ability of corticosteroids to decrease edema and inflammation.

Corticosteroids have many side effects, especially when given chronically in high doses. These include hyperglycemia, fluid retention, dyspepsia and GI bleeding, impaired healing, muscle wasting, osteoporosis, adrenal suppression, and susceptibility to infection. Because they act through the same final pathway as NSAIDs, do not give corticosteroids at the same time as NSAIDs.

Local Anesthetics

For acute pain from surgery or trauma, local anesthetics, such as bupivacaine and ropivacaine, can be given epidurally by continuous infusion or by intermittent or continuous infusion with regional nerve blocks. Systemic lidocaine given in an IV infusion is sometimes used for neuropathic and postoperative visceral pain. Topical applications are used to interrupt transmission of pain signals to the brain. For example, 5% lidocaine patch (Lidoderm) is a first-line agent for the treatment of several types of neuropathic pain. In the treatment of chronic severe neuropathic pain that is refractory to other analgesics, oral therapy with mexiletine (Mexitil) may be tried.

Cannabinoids

Cannabinoid-derived medications show promise in the treatment of neuropathic pain, certain pain syndromes, and some symptoms. However, these preparations have sparked considerable controversy and confusion, mostly because cannabinoids are related to the cannabis plant, also known as marijuana. Synthetic cannabinoids (e.g., dronabinol [Marinol]) have been approved for medical use. Smoking marijuana or cannabis rapidly increases plasma levels of tetrahydrocannabinol (THC). The increase depends on composition of

the marijuana cigarette and inhalation technique. As a result, this form of use is associated with variable pain relief. With commercially available oral preparations, the absorption and bioavailability are more reliable and predictable.

Cannabinoids exert their analgesic effects primarily through the cannabinoid-l (CB1) and CB2 receptors. Activation of cannabinoid receptors modulates neurotransmission in the serotoninergic, dopaminergic, and glutamatergic systems, as well as other systems. Cannabinoids also enhance the endogenous opioid system. Other beneficial effects include alleviating nausea and increased appetite. They may have opioid-sparing effects, possibly reducing opioid tolerance and symptoms of opioid withdrawal.[18]

TABLE 8.11 Drug Therapy

Adjuvant Drugs Used for Pain

Drug	Specific Indication	Nursing Considerations
α_2-Adrenergic Agonists		
clonidine (Duraclon) **tizanidine (Zanaflex)**	Particularly useful for neuropathic pain when given intrathecally	• Side effects include sedation, orthostatic hypotension, dry mouth • Often combined with anesthetics (e.g., bupivacaine)
Anesthetics: Local		
capsaicin (active compound of chili peppers)	Pain associated with arthritis, postherpetic neuralgia, diabetic neuropathy	• Apply very sparingly onto affected area. • Use gloves or wash hands with soap and water after application • Monitor for side effects: Skin irritation (burning, stinging) at application site and cough when inhaled
lidocaine (L-M-X)	Topical local anesthetic cream applied to intact skin before venipuncture or lumbar puncture. May be effective for postherpetic neuralgia	• Apply bubble layer to intact skin and wait at least 20–30 min before wiping and performing painful procedure • Duration is around 60 min after wiped from skin • Available without prescription
lidocaine 2.5% + prilocaine 2.5% (topical eutectic mixture of local anesthetics [EMLA])	Longer time to take effect than L-M-X	• Apply under an occlusive dressing (e.g., Tegaderm, DuoDerm) or on an anesthetic disk • Side effects include mild erythema, edema, skin blanching
Anesthetics: Oral or Systemic		
5% lidocaine-impregnated transdermal patch (Lidoderm patch)	Postherpetic neuralgia	• Local skin reactions (e.g., change in color, colored spots, irritation, itching, rash, burning) occur at the site of application; typically mild
mexiletine	Diabetic neuropathy Neuropathic pain	• Monitor for side effects: High incidence of nausea, dizziness, perioral numbness, paresthesias, tremor, seizures (at high doses), dysrhythmias, and myocardial depression • Avoid in patients with preexisting heart disease
Antidepressants		
Tricyclic Antidepressants		
amitriptyline **desipramine (Norpramin)** **doxepin** **imipramine (Tofranil)** **nortriptyline (Pamelor)**	Neuropathic pain	• Side-effect profile differs for each agent and is often dose-dependent • Common side effects include anticholinergic effects (e.g., dry mouth) and sedation • Monitor for anticholinergic side effects • Titrate slowly over days to weeks to reach optimal therapeutic doses
Serotonin Norepinephrine Reuptake Inhibitor (SNRI) Antidepressants		
duloxetine (Cymbalta) **milnacipran (Savella)** **venlafaxine (Effexor)**	Neuropathic pain Multimodal therapy for acute pain (venlafaxine) Fibromyalgia (duloxetine, milnacipran)	• Side effects vary with each agent • Decreased arousal and desire for sex
Other Antidepressants		
bupropion (Wellbutrin)	Neuropathic pain Headaches	• Low risk for sexual problems and sedation • Distinguished from TCAs and SNRIs as an inhibitor of norepinephrine and dopamine uptake
Antiseizure Drugs		
First generation: carbamazepine (Tegretol) **phenytoin (Dilantin)** **Second generation: gabapentin (Neurontin)** **lamotrigine (Lamictal)** **pregabalin (Lyrica)**	Neuropathic pain Multimodal therapy for acute pain (gabapentin, pregabalin) Fibromyalgia (pregabalin)	• Start with low doses, increase slowly • Side effects vary with each agent
Cannabinoids		
dronabinol (Marinol)	Neuropathic pain Certain pain syndromes	• May relieve nausea and increase appetite • May have opioid-sparing effects, possibly reducing opioid tolerance and symptoms of opioid withdrawal
Corticosteroids		
dexamethasone (Decadron)	Inflammation	• Avoid high doses for long-term use
GABA-Receptor Agonist		
baclofen (Lioresal)	Neuropathic pain Muscle spasms	• Monitor for weakness, urinary dysfunction • Avoid abrupt discontinuation because of CNS irritability

2011, Mosby.

Administration

Scheduling

Appropriate analgesic scheduling focuses on preventing or controlling pain, rather than providing analgesics only after the patient's pain has become severe. Premedicate a patient before procedures and activities that will likely produce pain. Similarly, a patient with constant pain should receive analgesics around the clock rather than on an "as needed" (PRN) basis. These strategies control pain before it starts and usually result in lower analgesic requirements. Use fast-acting drugs for incident or breakthrough pain, while long-acting analgesics are more effective for constant pain. Examples of fast-acting and sustained-release analgesics are described later in this section.

Titration

Analgesic titration is dose adjustment based on assessment of the adequacy of analgesic effect versus the side effects produced. The amount of analgesic needed to manage pain varies widely, and titration is an important strategy in addressing this variability. An analgesic can be titrated upward or downward, depending on the situation. For example, in a postoperative patient the dose of analgesic decreases over time as the acute pain resolves. On the other hand, opioids for chronic, severe cancer pain may be titrated upward many times over the course of therapy to maintain adequate pain control. The goal of titration is to use the smallest dose of analgesic that provides effective pain control with the fewest side effects.

Equianalgesic Dosing

The term **equianalgesic dose** refers to a dose of 1 analgesic that is equivalent in pain-relieving effects to a given dose of another analgesic (Table 8.12). This equivalence helps guide opioid dosing

when changing routes or opioids when a specific drug is ineffective or causes intolerable side effects. Equianalgesic charts and conversion programs are widely available in clinical guidelines, in health care facility pain protocols, and on the Internet. They are useful tools, but you need to understand their limitations since these doses are estimates. To ensure safety, all changes in opioid therapy must be carefully monitored and adjusted for the individual patient.

Administration Routes

We can deliver opioids and other analgesic agents by many routes. This flexibility allows the HCP to (1) target a particular anatomic source of the pain, (2) achieve therapeutic blood levels rapidly when necessary, (3) avoid certain side effects through localized administration, and (4) provide analgesia when patients are unable to swallow. The following discussion highlights the uses and nursing considerations for analgesic agents delivered through a variety of routes.

TABLE 8.12 Opioid Equianalgesic Doses*

Drug	Dose Equal to Parenteral Morphine 10 mg	
	Oral (mg)	Parenteral (IM, IV, Subcutaneous) (mg)
Codeine	200	120–130
Fentanyl	NA	0.1 (100 mcg)
Hydrocodone	30	NA
Hydromorphone	7.5	1.5
Levorphanol	4	2
Meperidine	300	75
Morphine	30	10
Oxycodone	15–30	NA

* All equivalencies are approximations. These amounts can be affected by many factors, including interpatient variability, type of pain, and tolerance. Monitor patients for effectiveness and adverse reactions and adjust the dose accordingly.

Oral

Generally, oral administration is the route of choice for the person with a functioning GI system. Most pain medications are available in oral preparations, such as liquid and tablet. For opioids, larger oral doses are needed to achieve the equivalent analgesia of doses given IM or IV (Table 8.12). For example, 10 mg of parenteral morphine is equivalent to around 30 mg of oral morphine. The reason larger doses are needed is related to the *first-pass effect* of hepatic metabolism. This means that oral opioids are absorbed from the GI tract into the portal circulation and shunted to the liver. Partial metabolism in the liver occurs before the drug enters the systemic circulation and becomes available to peripheral receptors or can cross the blood-brain barrier and access CNS opioid receptors, which is needed to produce analgesia. Oral opioids are as effective as parenteral opioids if the dose is large enough to compensate for the first-pass metabolism.

Many opioids are available in short-acting (immediate-release) and long-acting (sustained-release or extended-release) oral preparations. Immediate-release products are effective in providing rapid, short-term pain relief. Sustained-release or extended-release preparations generally are given every 8 to 12 hours, although some preparations (e.g., Kadian, Exalgo) may be dosed every 24 hours.

Safety Alert

Sustained-Release or Extended-Release Preparations

- These should not be crushed, broken, dissolved, or chewed. These drugs are to be swallowed whole.
- If all the medicine is released into a person at once, serious side effects can occur, including death from overdose.

Transmucosal and buccal routes

Although morphine has historically been given sublingually to people with cancer pain who have difficulty swallowing, little of the drug is

absorbed from the sublingual tissue. Instead, most of the drug dissolves in saliva and is swallowed, making its absorption similar to that of oral morphine.

Several transmucosal fentanyl products are used for the treatment of breakthrough pain. These include (1) oral transmucosal fentanyl citrate (OTFC) (Actiq), with the fentanyl embedded in a flavored lozenge on a stick that is absorbed by the buccal mucosa after being rubbed actively over it when given as the lozenge (not sucked as a lollipop); (2) fentanyl buccal tablet (FBT) (Fentora) in the form of a buccal tablet that disintegrates; and (3) fentanyl sublingual (Abstral). Transmucosal absorption allows the drug to enter the bloodstream and travel directly to the CNS. Pain relief typically occurs 5 to 7 minutes after administration. These formulations should be used only for patients who are already receiving and are tolerant to opioid therapy.[19]

Intranasal route

Intranasal administration allows delivery of medication to highly vascular mucosa and avoids the first-pass effect. Butorphanol is given for acute headache and other intense, recurrent types of pain. A transmucosal fentanyl nasal spray (Lazanda) is available for the treatment of breakthrough pain.

Rectal

The rectal route is often overlooked but is particularly useful when the patient cannot take an analgesic by mouth, such as with severe nausea and vomiting. Analgesics that are available as rectal suppositories include hydromorphone, oxymorphone, morphine, and acetaminophen. If rectal preparations are not available, many oral formulations can be given rectally if the patient is unable to take medications by mouth.

Transdermal route

Transdermal patches are designed for systemic drug delivery (e.g., Duragesic) or for topical or local delivery (e.g., Lidoderm). Fentanyl

(Duragesic) is useful for the patient who cannot tolerate oral analgesic drugs. Absorption from the patch is slow. It takes 12 to 17 hours to reach full effect with the first application. Therefore transdermal fentanyl is not suitable for rapid dose titration but can be effective if the patient's pain is stable and the dose needed to control it is known. Patches may have to be changed every 48 hours rather than the recommended 72 hours based on individual patient responses. Patches are applied to intact, nonhairy skin. Rashes caused by the patch's adhesive may be reduced by preparing the skin 1 hour before placement with a weak corticosteroid cream. Bioocclusive dressings are available if the patch keeps falling off because of sweating. A transdermal patient-controlled analgesia (PCA) system (iontophoretic transdermal system [ITS]) is available.

Drug Alert

Fentanyl Patches

- Fentanyl patches (Duragesic) may cause death from overdose.
- Signs of overdose include trouble breathing or shallow respirations; tiredness, extreme sleepiness, or sedation; inability to think, talk, or walk normally; and faintness, dizziness, or confusion.

A 5% lidocaine-impregnated transdermal patch (Lidoderm patch) is used for postherpetic neuralgia. The patch is placed directly on the intact, nonhairy skin in the area of postherpetic pain and left in place for up to 12 hours. There are few systemic side effects, even with chronic use.

Creams and lotions containing 10% trolamine salicylate (Aspercreme, Myoflex Creme) are available for joint and muscle pain. This aspirin-like substance is absorbed locally. This route avoids GI irritation but not the other side effects of high-dose salicylates. Topical

diclofenac solution and a diclofenac patch (Flector) are effective for osteoarthritic pain of the knee.

Other topical analgesic agents, such as capsaicin (e.g., Zostrix) and lidocaine (L-M-X cream), also provide analgesia. Derived from red chili pepper, capsaicin acts on C-fiber heat receptors. If used 3 or 4 times a day for 4 to 6 weeks, it will cause the C nociceptor fibers to become inactive. The result is neuronal resistance to painful stimuli. Capsaicin may control pain associated with diabetic neuropathy, arthritis, and postherpetic neuralgia. L-M-X cream is useful for control of pain associated with venipunctures. Cover the targeted area of intact skin with a layer of L-M-X for at least 20 to 30 minutes, then wipe it off prior to beginning a painful procedure.

Parenteral routes

The parenteral routes include IV and subcutaneous administration. Single, repeated, or continuous dosing (IV or subcutaneous) is possible with parenteral routes. IV administration is the best route when immediate analgesia and rapid titration are needed. Continuous IV infusions provide excellent steady-state analgesia through stable blood levels.

Onset of analgesia after subcutaneous administration is slow, and thus the subcutaneous route is rarely used for acute pain management. However, continuous subcutaneous infusions are effective for pain management at the end of life. This route is especially helpful for people with abnormal GI function and limited venous access.

The IM route is not recommended because injections cause significant pain and result in unreliable absorption. With chronic use, IM injections can result in abscesses and fibrosis.

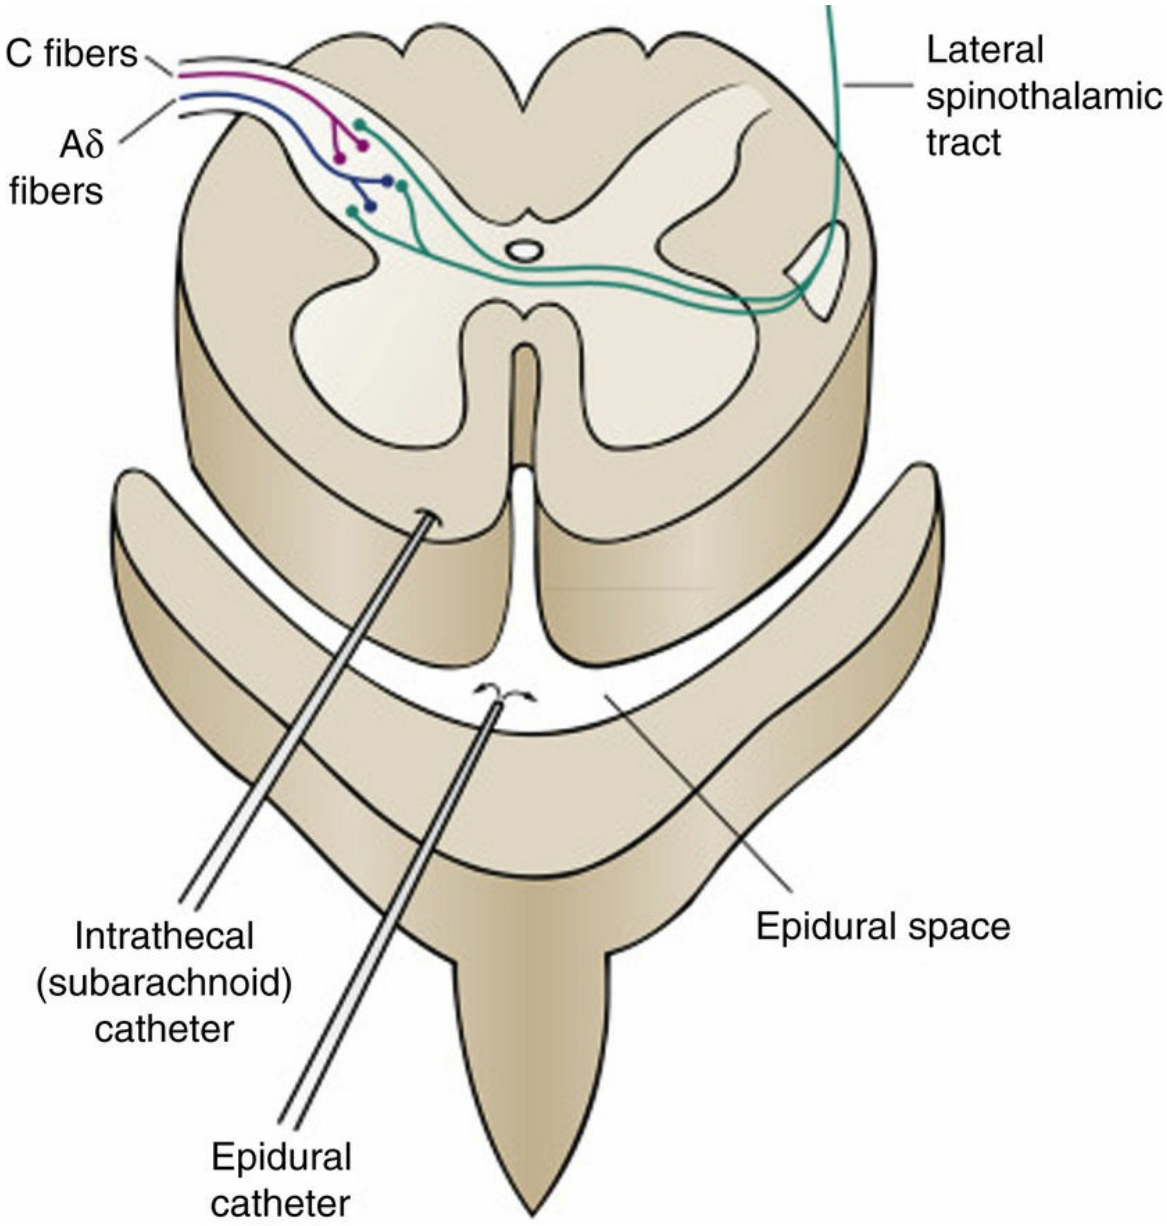

FIG. 8.6 Cross section of spinal cord with placement of catheters into the subarachnoid space (intrathecal delivery) and the epidural space (epidural delivery).
From Urden LD, Stacy KM, Lough ME: *Critical care nursing: Diagnosis and management*, ed 8, St Louis, 2018, Elsevier.

Intraspinal delivery

Intraspinal or neuraxial opioid therapy involves inserting a catheter into the subarachnoid space *(intrathecal delivery)* or the epidural space *(epidural delivery)* (Fig. 8.6). Analgesics are injected either by

intermittent bolus doses or continuous infusion.

Percutaneously placed temporary catheters are used for short-term therapy (2 to 4 days), and surgically implanted catheters are used for long-term therapy. Although the lumbar region is the most common site of placement, epidural catheters may be placed at any point along the spinal column (cervical, thoracic, lumbar, or caudal). The tip of the epidural catheter is placed as close to the nerve supplying the painful dermatome as possible. For example, a thoracic catheter is placed for upper abdominal surgery, and a high lumbar catheter is used for lower abdominal surgery. Fluoroscopy ensures correct placement of the catheter.

Intraspinal analgesics are highly potent because they are delivered close to the receptors in the spinal cord dorsal horn. Smaller doses of analgesics are needed than with other routes, including IV. For example, 1 mg of intrathecal morphine equals 10 mg of epidural morphine, 100 mg of IV morphine, and 300 mg of oral morphine. Drugs delivered intraspinally include morphine, fentanyl, sufentanil (Sufenta), alfentanil (Alfenta), hydromorphone, clonidine, and ziconotide, a calcium channel receptor modulator for use in neuropathic pain syndromes. Nausea, itching, and urinary retention are common side effects of intraspinal opioids.

Complications of intraspinal analgesia include catheter displacement and migration, accidental infusions of neurotoxic agents, epidural hematomas, and infection. Clinical manifestations of catheter displacement or migration depend on catheter location and the drug being infused. A catheter that migrates out of the intrathecal or epidural space causes a decrease in pain relief with no improvement with more boluses or increases in the infusion rate. If an epidural catheter migrates into the subarachnoid space, increased side effects become quickly apparent. Somnolence, confusion, and increased anesthesia (if the infusate contains an anesthetic) occur. Check with institutional policy before aspirating cerebrospinal fluid to determine intrathecal catheter placement. Migration of a catheter into a blood vessel may cause an increase in side effects because of systemic drug distribution.

Many drugs and chemicals are highly neurotoxic when given intraspinally. These include antibiotics, chemotherapy agents, potassium, parenteral nutrition, and many preservatives, such as alcohol and phenol. To avoid inadvertent injection of IV drugs into an intraspinal catheter, the catheter should be clearly marked as an intraspinal access device. Only preservative-free drugs should be used.

Infection is a rare but serious complication of intraspinal analgesia. Assess the skin around the exit site for inflammation, drainage, or pain. Manifestations of an intraspinal infection include diffuse back pain, pain or paresthesia during bolus injection, and unexplained sensory or motor deficits in the lower limbs. Fever may or may not be present. Acute bacterial infection (meningitis) is manifested by photophobia, neck stiffness, fever, headache, and altered mental status. Regular, meticulous wound care and using sterile technique when caring for the catheter and injecting drugs reduces infection risk.

Long-term epidural catheters may be placed for terminal cancer patients or patients with certain pain syndromes that are unresponsive to other treatments. If a long-term indwelling epidural catheter is used, bacterial filters are recommended.

Implantable pumps

Intraspinal catheters can be surgically implanted for long-term pain relief. The surgical placement of an intrathecal catheter to a subcutaneously placed pump and reservoir allows for the delivery of drugs directly into the intrathecal space. The pump, which is normally placed in a pocket made in the subcutaneous tissue of the abdomen, may be programmable or fixed.

We make changes reprogramming the pump, changing the mixture, or concentration of drug in the reservoir. The pump is refilled every 30 to 90 days depending on flow rate, mixture, and reservoir size.

Patient-controlled analgesia

Patient-controlled analgesia (PCA) (demand analgesia) is a method

that allows the patient to self-administer preset doses of an analgesic within a prescribed time period by activating an infusion pump. Routes of administration include oral, IV, epidural, inhaled, nasal, and transcutaneous. In acute care, PCA often refers to an electronically controlled infusion pump that delivers the medication by an IV or epidural route (**patient-controlled epidural analgesia [PCEA]**). PCEA often combines an opioid and local anesthetic. PCA also can be adapted for oral administration. With PCA/PCEA, a dose of opioid is delivered when the patient decides a dose is needed. PCA/PCEA uses an infusion system in which the patient pushes a button to receive a bolus infusion of an analgesic. PCA/PCEA is used widely for the management of acute pain, including postoperative pain and cancer pain.

Opioids, such as morphine and hydromorphone, are often given via PCA therapy for acute and chronic pain. Sometimes IV PCA is given with a continuous or background infusion called a *basal rate*, depending on the patient's opioid requirement. Adding a basal rate in opioid-naive patients and those at risk for adverse respiratory outcomes (e.g., older age, obstructive sleep apnea, lung disease) may lead to serious respiratory events. Basal rates are often used with epidural catheter pain management. Because the medication is delivered directly into the epidural space, the amount of opioid is 10 times less than is needed by IV route. This lessens the risk for respiratory depression but does not eliminate it.

Patient teaching is very important with the use of PCA/PCEA. Help the patient understand the mechanics of getting a drug dose and how to titrate the drug to achieve good pain relief. Teach the patient to self-administer the analgesic before pain is severe. Assure the patient that he or she cannot "overdose" because the pump is programmed to deliver a maximum number of doses per hour. The patient will not receive more analgesic once the maximum dose has been reached. If the maximum dose is inadequate to relieve pain, the pump can be reprogrammed to increase the amount or frequency of dosing. In addition, you can give bolus doses if they are part of the HCP's orders. To make a smooth transition from infusion PCA to oral drugs,

the patient should receive increasing doses of oral drug as the PCA analgesic is tapered.

Patient-controlled delivery systems are intended for use by the patient. An *authorized agent controlled analgesia (AACA)* is a method of delivery performed by a consistently available and competent person for patients who are unable to independently activate PCA devices.[20] This authorized agent must be carefully selected, taught the principles of PCA, and capable of recognizing pain and the appropriate times to give medication via the PCA device. Understand your institution's policies about PCA and AACA.

Interventional Therapy

Therapeutic Nerve Blocks

Nerve blocks involve 1-time or continuous infusion of local anesthetics into a particular area to produce pain relief. These techniques are also called *regional anesthesia.* Nerve blocks interrupt all afferent and efferent transmission to the area and thus are not specific to nociceptive pathways. They include local infiltration of anesthetics into a surgical area (e.g., chest incisions, inguinal hernia) and injection of anesthetic into a specific nerve (e.g., occipital, pudendal nerve) or nerve plexus (e.g., brachial, celiac plexus). Nerve blocks can be used during and after surgery to manage pain. For longer term relief of chronic pain syndromes, local anesthetics can be given by a continuous infusion.

Adverse effects of nerve blocks are similar to those for local anesthetics delivered by other systemic routes. Effects include systemic toxicity resulting in dysrhythmias, confusion, nausea and vomiting, blurred vision, tinnitus, and metallic taste. Temporary nerve blocks affect motor function and sensation and typically last 2 to 24 hours, depending on the agent and the site of injection. Motor ability generally returns before sensation.

Neuroablative Techniques

Neuroablative interventions are done for severe pain that is

unresponsive to all other therapies. They involve destroying nerves, thereby interrupting pain transmission. Destruction is by surgical resection or thermocoagulation, including radiofrequency coagulation. Neuroablative interventions that destroy the sensory division of a peripheral or spinal nerve are classified as *neurectomies, rhizotomies,* and *sympathectomies.* Neurosurgical procedures that ablate the lateral spinothalamic tract are classified as *cordotomies* if the tract is interrupted in the spinal cord or *tractotomies* if the interruption is in the medulla or midbrain of the brainstem (Fig. 8.7). Cordotomy and tractotomy can be done with the aid of local anesthesia by a percutaneous technique under fluoroscopy.

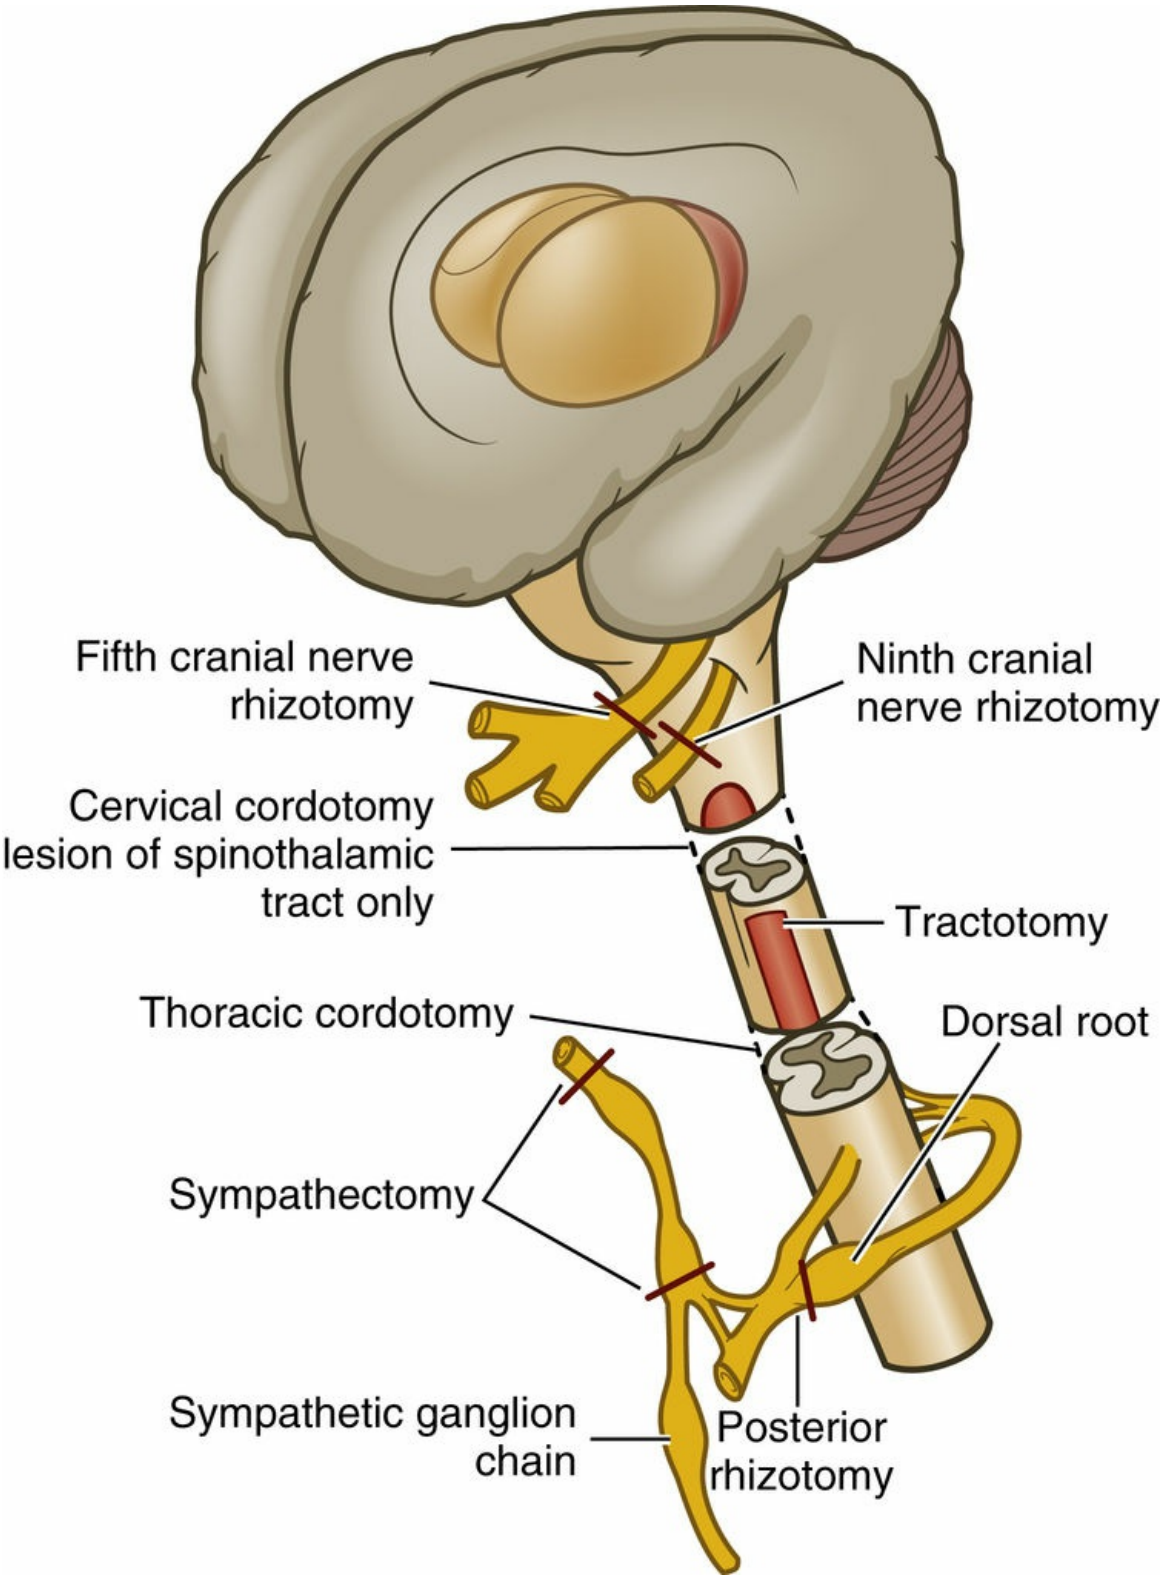

FIG. 8.7 Sites of neurosurgical procedures for pain relief.

Neuroaugmentation

Neuroaugmentation involves electrical stimulation of the brain and spinal cord. Spinal cord stimulation (SCS) is done much more often than brain stimulation. The most common use of SCS is for chronic back pain secondary to nerve damage that is unresponsive to other therapies. Other uses include CRPS, spinal cord injury pain, and interstitial cystitis. Potential complications include those related to the surgery (bleeding and infection), migration of the generator (which usually is implanted in the subcutaneous tissues of the upper gluteal or pectoralis area), and nerve damage.

Nondrug Therapies for Pain

Nondrug strategies play an important role in pain management (Table 8.13). They can reduce the dose of an analgesic needed to relieve pain and thereby minimize side effects of drug therapy. Moreover, they increase the patient's sense of personal control about managing pain and increase coping skills. Some strategies are thought to alter ascending nociceptive input or stimulate descending pain modulation mechanisms. These nondrug therapies are useful for both acute and chronic pain.

Physical Pain Relief Strategies

Massage

Massage is useful for acute and chronic pain. Many different massage techniques exist, including moving the hands or fingers over the skin slowly or briskly with long strokes or in circles (superficial massage) or applying firm pressure to the skin to maintain contact while massaging the underlying tissues (deep massage). Another type is trigger point massage. A **trigger point** is a circumscribed hypersensitive area within a tight band of muscle. It is caused by acute or chronic muscle strain. It feels like a tight knot under the skin. Trigger point massage is done by applying strong, sustained digital pressure; deep massage; or gentler massage with ice followed by

muscle heating. Massage is discussed in Chapter 6.

Exercise

Exercise is an essential part of the treatment plan for patients with chronic pain, particularly those with musculoskeletal pain. Many patients become physically deconditioned from their pain, which in turn leads to more pain. Exercise acts via many mechanisms to relieve pain. It enhances circulation and cardiovascular fitness, reduces edema, increases muscle strength and flexibility, and enhances physical and psychosocial functioning. Tailor an exercise program to the patient's physical needs and lifestyle. It may include aerobic exercise, stretching, and strengthening exercises. Trained personnel (e.g., physical therapist) should supervise the program.

Transcutaneous Electrical Nerve Stimulation

Transcutaneous electrical nerve stimulation (TENS) involves the delivery of an electric current through electrodes applied to the skin surface

over the painful region, at trigger points, or over a peripheral nerve. A TENS system consists of 2 or more electrodes connected by lead wires to a small, battery-operated stimulator (Fig. 8.8). Usually a physical therapist is responsible for delivering TENS therapy, although nurses can be trained in the technique.

TENS may be used for acute pain, including postoperative pain and pain associated with physical trauma. The effects of TENS on chronic pain are less clear, but it may be effective in these cases.[21]

TABLE 8.14 Patient & Caregiver Teaching

Heat and Cold Therapy

Include the following instructions when teaching the patient and caregiver about superficial heat or cold techniques:

Heat Therapy

- Do not use heat on an area that is being treated with radiation therapy, is bleeding, has decreased sensation, or has been injured in the past 24 hours.
- Do not use any menthol-containing products (e.g., Ben-Gay, Vicks, Icy Hot) with heat applications because this may cause burns.
- Cover the heat source with a towel or cloth before applying to the skin to prevent burns.

Cold Therapy

- Cover the cold source with a cloth or towel before applying to the skin to prevent tissue damage.
- Do not apply cold to areas that are being treated with radiation therapy, have open wounds, or have poor circulation.

- If it is not possible to apply the cold directly to the painful site, try applying it right above or below the painful site or on the opposite side of the body on the corresponding site (e.g., left elbow if the right elbow hurts).

Acupuncture

Acupuncture is a technique of Traditional Chinese Medicine in which very thin needles are inserted into the body at designated points. Acupuncture is used for many kinds of pain. Acupuncture is described in Chapter 6.

Heat Therapy

Heat therapy is the application of either moist or dry heat to the skin. Heat therapy can be either superficial or deep. We can apply superficial heat using an electric heating pad (dry or moist), a hot pack, hot moist compresses, warm wax (paraffin), or a hot water bottle. To expose large areas of the body, patients can immerse themselves in a hot bath, shower, or whirlpool. Physical therapy departments provide deep-heat therapy through techniques such as short-wave diathermy, microwave diathermy, and ultrasound therapy. Patient and caregiver teaching about heat therapy is described in Table 8.14.

Cold Therapy

Cold therapy involves the application of either moist or dry cold to the skin. Dry cold can be applied by using an ice bag, moist cold by using towels soaked in ice water, cold hydrocollator packs, or immersion in a bath or under running cold water. Icing with ice cubes or blocks of ice made to resemble Popsicles is another technique used for pain relief. Cold therapy is thought to be more effective than heat for a variety of painful conditions, including acute pain from trauma or surgery, acute flare-ups of arthritis, muscle spasms, and headache. Patient and caregiver teaching about cold therapy is described in Table 8.14.

Cognitive Therapies

Techniques to alter the affective, cognitive, and behavioral components of pain include a variety of cognitive strategies and behavioral approaches. For example, patients can identify and challenge negative pain-related thoughts and replace them with more positive coping thoughts. Some techniques need little training and often are adopted independently by the patient. For others, a trained therapist is needed.

Distraction

Distraction involves redirection of attention away from the pain and onto something else. It is a simple but powerful strategy to relieve pain. Distraction involves engaging the patient in any activity that can hold his or her attention (e.g., watching TV or a movie, conversing, listening to music). It is important to match the activity with the patient's energy level and ability to concentrate.

Hypnosis

Hypnotherapy is a structured technique that enables a patient to achieve a state of heightened awareness and focused concentration that can be used to alter the patient's pain perception. Hypnosis should be delivered and monitored only by specially trained clinicians.

Relaxation Strategies

Relaxation strategies reduce stress, decrease acute anxiety, distract from pain, ease muscle tension, combat fatigue, promote sleep, and enhance the effectiveness of other pain relief measures.[22] Relaxation strategies include relaxation breathing, music, imagery, meditation, muscle relaxation, and art (see Chapter 6).

Nursing and Interprofessional

Management: Pain

You are an important member of the interprofessional pain management team. You provide input into the assessment and reassessment of pain. You help in planning and implementing treatments, including teaching, advocacy, and support of the patient, caregiver, and family. Because patients in any care setting can have pain, you must be knowledgeable about current therapies and flexible in trying new approaches to pain management.

Together with the patient, develop a written agreement or treatment plan that describes the pain management. The plan should ensure that pain will be treated based on the patient's perception and report of pain. When appropriate, the plan outlines the gradual tapering of the analgesic dose, with eventual substitution of parenteral analgesics with long-acting oral preparations and possibly cessation of opioids.

Many nursing roles are described earlier in this chapter, including assessing pain, giving treatment, monitoring for side effects, and teaching patients and caregivers. However, the success of these actions depends on your ability to establish a trusting relationship with the patient and caregiver and to address their concerns about pain and its treatment.

Effective Communication

Because pain is a subjective experience, patients need to feel confident that their reporting of pain will be believed and will not be perceived as "complaining." The patient and caregiver need to know that you consider the pain significant and understand that pain may profoundly disrupt a person's life. Communicate concern and commit to helping the patient obtain pain relief and cope with any unrelieved pain. Support the patient and caregiver through the period of trial and error that may be necessary to implement an effective therapeutic plan. It is important to clarify responsibilities in pain relief. Help the patient understand the role of the interprofessional team members, as well as the patient's roles and expectations.

In addition to addressing specific aspects of pain assessment and treatment, evaluate the impact that the pain has on the lives of the patient and caregiver. Table 8.15 addresses teaching needs of patients and caregivers related to pain management.

Challenges to Effective Pain Management

Common challenges to effective pain management include misunderstandings about tolerance, physical dependence, and addiction. It is important for you to understand and be able to explain these concepts. Table 8.16 lists barriers to pain management and strategies to address them.

Nursing Management

Pain Management

- Assess pain characteristics (pattern and onset, area or location, intensity, quality, associated symptoms, and management strategies).
- Develop treatment plan for patient's pain (including drug and nondrug therapies).
- Give ordered pain medications.
- Evaluate whether current treatment plan is effective.
- Teach patient and caregiver about treatment plan.
- Implement discharge teaching about pain management.
- Provide effective supervision of UAP:
    - Help with screening for pain and notify RN if patient expresses pain.
    - Take and report vital signs before and after pain medications are given.
    - Note and report if patient is refusing to take part in ordered activities, such as ambulation (since this may

indicate inadequate pain management).

TABLE 8.15 Patient & Caregiver Teaching

Pain Management

Include the following information in the teaching plan for the patient with pain and caregiver:

- Self-management techniques
- Realistic goals for pain control
- Negative consequences of unrelieved pain
- Need to maintain a record of pain level and effectiveness of treatment
- Treat pain with drugs and/or nondrug therapies before it becomes severe
- Medication may stop working after it is taken for a period of time, and dosages may have to be adjusted
- Potential side effects and complications associated with pain therapies can include nausea and vomiting, constipation, sedation and drowsiness, itching, urinary retention, and sweating.
- Need to report when pain is not relieved to tolerable levels

Tolerance

Tolerance occurs with chronic exposure to a variety of drugs. In the case of opioids, tolerance to analgesia is characterized by the need for an increased opioid dose to maintain the same degree of analgesia. Although the development of tolerance to side effects (except constipation) is more predictable, the incidence of clinically significant analgesic opioid tolerance in chronic pain patients is unknown, since dosage needs may increase as the disease (e.g., cancer) progresses. It is

essential to assess for increased analgesic needs in patients on long-term therapy. The interprofessional team must evaluate and rule out other causes of increased analgesic needs, such as disease progression or infection.

If significant tolerance to opioids develops and the opioid is losing its effectiveness, or intolerable side effects are associated with escalation of doses, the practice of *opioid rotation* may be considered. This involves switching from 1 opioid to another, assuming that the new opioid will be more effective at lower equianalgesic doses. However, very high opioid doses can result in OIH rather than pain relief. This means that increases in the dose can lead to higher pain levels. (OIH is discussed on p. 115.)

Physical Dependence

Like tolerance, physical dependence is a normal physiologic response to ongoing exposure to drugs. It is manifested by a withdrawal syndrome when the drug is abruptly decreased. Manifestations of opioid withdrawal are listed in Table 8.17. When opioids are no longer needed to provide pain relief, a tapering schedule should be used in conjunction with careful monitoring. A typical tapering schedule may involve reducing the dose by 20% to 50% per day. The goal is to reduce the amount of medication and at the same time minimize adverse and withdrawal effects.

Pseudoaddiction

Inadequate treatment of pain can lead to a phenomenon called *pseudoaddiction*. This occurs when patients show behaviors associated with addiction (e.g., frequent requests for analgesic refills or higher dosages), but the behaviors resolve with adequate treatment of the patient's pain. These patients are often labeled as drug seeking, which can result in mistrust between the patient and HCP. This problem can be avoided by effective communication strategies and optimal pain management.

Addiction

Addiction is a complex neurobiologic condition characterized by aberrant behaviors arising from a drive to obtain and take substances for reasons other than the prescribed therapeutic value (see Chapter 10). Tolerance and physical dependence are not indicators of addiction. Rather, they are normal physiologic responses to chronic exposure to certain drugs, including opioids. Addiction rarely occurs in patients who receive opioids for pain control. If addiction is suspected, it must be investigated and appropriately diagnosed. It should not be implied without evidence because this interferes with pain management. The hallmarks of addiction include (1) compulsive use, (2) loss of control of use, and (3) continued use despite risk of harm.

Risk Monitoring

Several opioid risk assessments are available to help clinicians assess patients for abuse, misuse, and addiction. A controlled substance agreement for those at risk for addiction may be used. Addiction risk assessment tools, such as the Opioid Risk Tool (*www.drugabuse.gov/sites/default/files/files/OpioidRiskTool.pdf*) and the Screener and Opioid Assessment for Patient Pain (*www.nhms.org/sites/default/files/Pdfs/SOAPP-14.pdf*) are available. Patient monitoring with urine drug screens and access to state prescription monitoring programs to track prescriptions are effective in detecting misuse of drugs. The risk for addiction should not prevent HCPs from using opioids to effectively treat moderate to severe acute and chronic pain.

Institutionalizing Pain Education and Management

Besides patient and caregiver barriers, other barriers to effective and safe pain management include inadequate HCP education and lack of institutional support. Traditionally, medical and nursing school curricula have spent little time teaching future physicians and nurses

about pain and symptom management. The lack of emphasis on pain has contributed to inadequate training of HCPs.

We have made progress overcoming these barriers. Medical and nursing schools devote more time to addressing pain. Numerous professional organizations have published evidence-based guidelines for assessing and managing pain in many patient populations and clinical settings.

Institutional commitment and practices are changing clinical practice. One major step in institutionalizing pain management is the development and adoption of The Joint Commission (TJC) guideline on pain.[23] TJC is the accrediting body for most health care facilities (hospitals, nursing homes, and health care clinics). Under these standards, health care facilities are required to (1) recognize the patient's right to appropriate assessment and management of pain; (2) identify pain in patients during their initial assessment and as needed, during ongoing, periodic reassessments; (3) teach HCPs about pain assessment and management and ensure competency; and (4) teach patients and their families about pain management.

TABLE 8.16 Patient & Caregiver Teaching

Reducing Barriers to Pain Management

When teaching the patient and caregiver about pain management discuss the following barriers:	
Barrier	Nursing Considerations
Fear of addiction	• Explain that addiction is uncommon in patients taking opioids as directed by the HCP for pain.
Fear of tolerance	• Teach that tolerance is a normal physiologic response to chronic opioid therapy. If tolerance does develop, the drug may have to be changed (e.g., morphine in place of oxycodone). • Teach that there is no absolute upper limit to pure opioid agonists (e.g., morphine). Dosages can be increased, and patient should not save drugs for when the pain is worse. • Teach that tolerance develops more slowly to analgesic effects of opioids than to side effects (e.g., sedation, respiratory depression). Tolerance does not develop to constipation; thus a regular bowel program should be started early.
Concern about side effects	• Teach methods to prevent and to treat common side effects. • Stress that side effects, such as sedation and nausea, decrease with time. • Explain that different drugs have unique side effects, and other pain drugs can be tried to reduce the specific side effect.
Fear of injections	• Explain that oral medicines are preferred. • Stress that even if oral route becomes unusable, transdermal or indwelling parenteral routes can be used rather than injections.
Desire to be "good" patient	• Discuss that patients are partners in their care and that partnership requires open communication by both patient and nurse. • Stress to patients that they have a responsibility to keep you informed about their pain.
Desire to be stoic	• Explain that although stoicism is a valued behavior in many cultures, failure to report pain can result in undertreatment and severe, unrelieved pain.
Forgetting to take analgesic	• Provide and teach use of pill containers. • Provide methods of record keeping for drug use. • Recruit caregivers to help with the analgesic regimen.
Concern that pain indicates disease progression	• Explain that increased pain or the need for analgesics may reflect tolerance. • Stress that new pain may come from a non–life-threatening source (e.g., muscle spasm, urinary tract infection). • Use drug and nondrug strategies to reduce anxiety. • Ensure that patient and caregivers have current, accurate, comprehensive information about the disease and prognosis. • Provide psychologic support.
Sense of fatalism	• Explain that pain can be managed in most patients. • Explain that most therapies require a period of trial and error. • Stress that side effects can be managed.
Ineffective medication	• Teach that there are multiple options within each category of medication (e.g., opioids, NSAIDs), and another medication from the same category may provide better relief. • Discuss that finding the best treatment regimen may require trial and error. • Include nondrug approaches in treatment plan.

TABLE 8.17 Manifestations of Opioid Withdrawal Syndrome

	Early Response (6–12 hr)	Late Response (48–72 hr)
Psychosocial	• Anxiety	• Excitation
Secretions	• Lacrimation • Rhinorrhea • Diaphoresis	• Diarrhea
Other	• Yawning • Piloerection • Shaking, chills • Dilated pupils • Anorexia • Tremor	• Restlessness • Fever • Nausea and vomiting • Abdominal cramping pain • Hypertension • Tachycardia • Insomnia

Ethical Issues in Pain Management

Fear of Hastening Death by Giving Analgesics

A common concern of health care professionals and caregivers is that giving a sufficient amount of drug to relieve pain will hasten or precipitate death of a terminally ill person. However, there is no scientific evidence that opioids can hasten death, even among patients at the very end of life. Moreover, you have a moral obligation to provide comfort and pain relief at the end of life. Even if there is a concern about the possibility of hastening death, the rule of double effect provides ethical justification. This rule states that if an unwanted consequence (i.e., hastened death) occurs because of an action taken to achieve a moral good (i.e., pain relief), the action is justified if the nurse's intent is to relieve pain and not to hasten death.

Requests for Assisted Suicide

Unrelieved pain is 1 of the reasons that patients make requests for assisted suicide. Aggressive and adequate pain management may decrease the number of such requests. Assisted suicide is a complex issue that extends beyond pain and pain management. Physician-assisted suicide is legal in some states (e.g., Oregon, Washington). To address the legal and ethical issues about this situation, the International Association for Hospice and Palliative Care prepared a position paper on this topic.[24]

Use of Placebos in Pain Assessment and Treatment

Placebos are still sometimes used to assess and treat pain. Using a placebo involves deceiving patients by making them think they are receiving an analgesic when they are receiving an inert substance, such as saline. Many professional organizations condemn the use of

placebos to assess or treat pain.

Gerontologic Considerations: Pain

Persistent pain is a common problem in older adults and is often associated with physical disability and psychosocial problems. The prevalence of chronic pain among community-dwelling older adults exceeds 50% and among older nursing home patients is around 80%. The most common painful conditions among older adults are musculoskeletal conditions, such as osteoarthritis and low back pain. Chronic pain often results in depression, sleep problems, decreased mobility, increased health care use, and physical and social role dysfunction. Despite its high prevalence, pain in older adults is often inadequately assessed and treated.

Several barriers to pain assessment in the older patient exist. Older adults and their HCPs often believe that pain is a normal, inevitable part of aging and that nothing can be done to relieve the pain. Older adults may not report pain for fear of being a "burden" or a "complainer." They may fear taking opioids. In addition, older patients are more likely to use words such as "aching," "soreness," or "discomfort" rather than "pain." Be persistent in asking older adults about pain. Carry out the assessment in an unhurried, supportive manner.

Another barrier is the increased prevalence of cognitive, sensory-perceptual, and motor problems that interfere with a person's ability to process information and communicate. Examples include dementia and delirium, poststroke aphasia, and other communication barriers. Hearing and vision deficits may complicate assessment. Therefore pain assessment tools may have to be adapted for older adults. For example, you many need to use a large-print pain intensity scale. Most older adults, even those with mild to moderate cognitive impairment, can use quantitative scales accurately and reliably.

In older patients with chronic pain, perform a thorough physical examination and history to identify causes of pain, possible therapies, and potential problems. Assess for depression and functional impairments, because they are also common among older adults with

pain.

Treatment of pain in older adults is complicated by several factors. First, older adults metabolize drugs more slowly than younger people and thus are at greater risk for higher blood levels and adverse effects. The adage "start low and go slow" must be applied to analgesic therapy in this age group. Second, the use of NSAIDs in older adults is associated with a high frequency of GI bleeding. Third, older adults often are taking many drugs for 1 or more chronic conditions. The addition of analgesics can result in dangerous drug interactions and increased side effects. Fourth, cognitive impairment and ataxia can be worsened by analgesics, such as opioids, antidepressants, and antiseizure drugs. This requires that HCPs titrate drugs slowly and monitor carefully for side effects.

Treatment regimens for older adults must include nondrug modalities. Exercise and patient teaching are important nondrug interventions for older adults with chronic pain. Include family and caregivers in the treatment plan (Tables 8.15 and 8.16).

Managing Pain in Special Populations

Patients Unable to Self-Report Pain

Although the patient's self-report is the gold standard of pain assessment, many illnesses and conditions affect a patient's ability to report pain. These diagnoses and conditions include dementia and delirium. For these people, behavioral and physiologic changes may be the only indicators of pain. You must be astute at recognizing behavioral symptoms of pain.

TABLE 8.18 Assessing Pain in Nonverbal Patients

The following assessment techniques are recommended:

- Obtain a self-report when possible.

- Never assume a nonverbal person is unable to communicate pain; blinking, writing, hand gestures, or nodding can be ways to express pain or the absence of pain.
- Investigate potential causes of pain.
- Observe patient behaviors that indicate pain (e.g., grimacing, frowning, rubbing a painful area, groaning, restlessness).
- Obtain surrogate reports of pain from professional and family caregivers.
- Try to use analgesics and reassess the patient to observe for a decrease in pain-related behaviors.

Modified from Herr K, Coyne PJ, McCaffery M, et al: Position statement from the American Society for Pain Management Nursing (ASPMN): Pain assessment in the patient unable to self-report—Position statement with clinical practice recommendations, *Pain Manag Nurs* 12:230, 2011.

A guide for assessing pain in nonverbal patients is outlined in Table 8.18. Several scales are available to assess pain-related behaviors in nonverbal patients, particularly those with advanced dementia and the critically ill. Links to several pain assessment tools are available at the City of Hope Pain and Palliative Care Resource Center website (*http://prc.coh.org*).

Patients With Substance Use Problems

HCPs are often reluctant to give opioids to patients at risk for addiction or those with substance-abuse disorders for fear of promoting or worsening addictions. However, there is no evidence that providing opioid analgesia to these patients in any way worsens their addictive disease. In fact, the stress of unrelieved pain may contribute to relapse in the recovering patient or increased drug use in the patient who is actively abusing drugs.

Check Your Practice

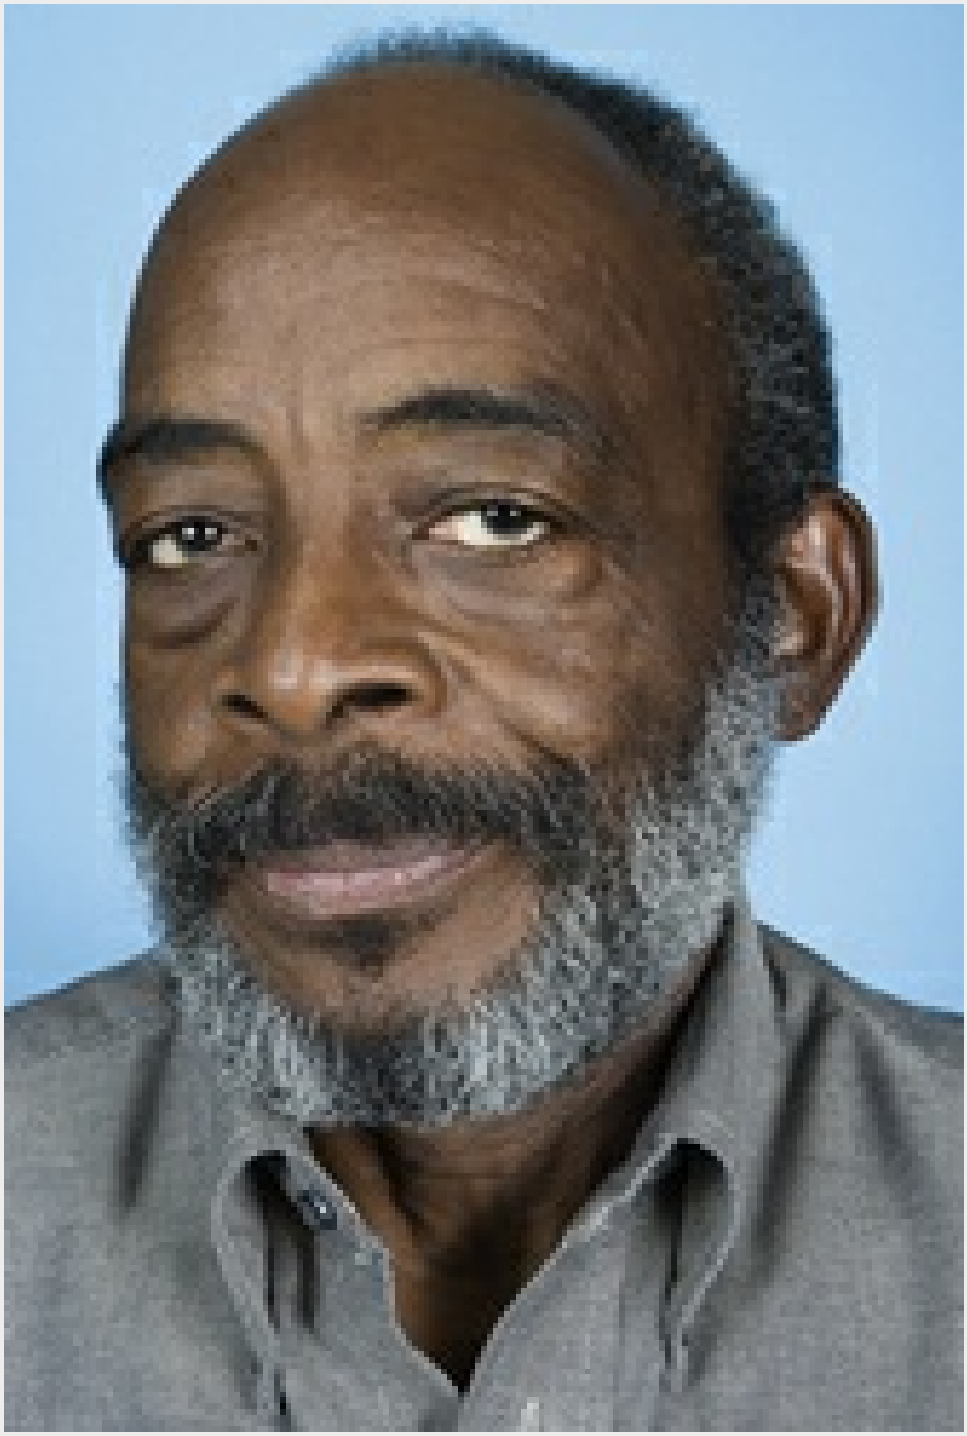
A 36-yr-old male patient is recovering from abdominal surgery to remove his spleen after an automobile accident. He is a known drug user. You are taking care of him, and he is very irritable because he is not getting enough pain medication. You are reluctant to give him his PRN morphine for fear that you will contribute to his addiction problem.

- What should you do?

Guidelines for pain management in patients with addictive disease have been established by the American Society for Pain Management Nursing (ASPMN). These guidelines reflect your role in a team approach in which patients with addictive disease and pain have the right to be treated with dignity, respect, and the same quality of pain assessment and management as all other patients.

If the patient acknowledges substance use, determine the types and amounts of drugs used. Avoid exposing the patient to the misused drug. Effective equianalgesic doses of other opioids may be determined if daily drug doses are known. If a history of drug use is unknown or if the patient does not acknowledge substance use, be suspect when normal doses of analgesics do not relieve the patient's pain.

Aggressive behavior patterns and signs of withdrawal may occur. Withdrawal symptoms can worsen pain and lead to drug-seeking behavior or illicit drug use. Toxicology screens may be helpful in determining recently used drugs. Discussing these findings with the patient may help gain the patient's cooperation in pain control.



Severe pain should be treated with opioids and at much higher doses than those used with drug-naive patients. The use of a single opioid is preferred. Avoid using a mixed opioid agonist-antagonist (e.g., butorphanol) or a partial agonist (e.g., buprenorphine) because these drugs may precipitate withdrawal symptoms. Nonopioid and

adjuvant analgesics and nondrug pain relief measures may be used as needed. To maintain opioid blood levels and prevent withdrawal symptoms, provide analgesics around the clock. Use supplemental doses to treat breakthrough pain. IV or PCA infusions may be considered for acute pain management.

Pain management for people with addiction is challenging and needs an interprofessional team approach. When possible, the team includes pain management and addiction specialists. Team members need to be aware of their own attitudes about people with substance use problems, which may result in undertreatment of pain.

Case Study

Pain

© iStock.com/XiXinXing.

Patient Profile

K.C. is a 280-lb (127-kg) 68-yr-old black man with diabetes, peripheral neuropathy, hypertension, and gout, who was admitted for an

incision and drainage of a right abdominal abscess. He is being discharged on his second postoperative day. His daughter will perform dressing changes at home.

Subjective Data

- Lives alone
- Desires 0 pain but will accept 1 or 2 on a scale of 0 to 10
- Reports incision area pain as a 2 or 3 between dressing changes and as a 6 during dressing changes
- States sharp pain persists 1 to 2 hours after dressing change
- Reports pain between dressing changes controlled by 2 oxycodone tablets
- Has history of peripheral neuropathy and describes chronic pain in his feet

Objective Data

- Needs dressing changes 4 times per day after discharge
- For discharge, oxycodone (2 tablets q4hr for pain PRN) is prescribed.

Discussion Questions

1. Describe the assessment data that are important for determining whether K.C. has adequate pain management.
2. ***Priority Decision:*** Based on the data presented, what are the priority nursing diagnoses? Are there any collaborative problems?
3. ***Priority Decision:*** What are the priority nursing interventions for K.C.?
4. How long should the daughter wait after the oxycodone is given to begin the dressing change?

5. ***Patient-Centered Care:*** What other pain therapies might you plan to help K.C. through the dressing change?
6. ***Safety:*** What side effects might he have because of his pain medication? How can these be safely managed?
7. ***Collaboration:*** To whom can you delegate teaching K.C. and his daughter the plan of care at home?
8. ***Evidence-Based Practice:*** K.C.'s daughter asks you if any other strategies could be used to help decrease her father's incisional pain and his peripheral neuropathy pain.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Pain is *best* described as
   a. a creation of a person's imagination.
   b. an unpleasant, subjective experience.
   c. a maladaptive response to a stimulus.
   d. a neurologic event resulting from activation of nociceptors.
2. A patient is receiving a PCA infusion after surgery to repair a hip fracture. She is sleeping soundly but awakens when the nurse speaks to her in a normal tone of voice. Her respirations are 8 breaths/min. The *most* appropriate nursing action in this situation is to
   a. stop the PCA infusion.
   b. obtain an oxygen saturation level.
   c. continue to closely monitor the patient.

d. administer naloxone and contact the provider.

3. Which words are *most* likely to be used to describe neuropathic pain *(select all that apply)*?
   a. Dull
   b. Itching
   c. Burning
   d. Shooting
   e. Shock-like

4. Unrelieved pain is
   a. not expected after major surgery.
   b. expected in a person with cancer.
   c. dangerous and can lead to many physical and psychologic complications.
   d. an annoying sensation, but it is not as important as other physical care needs.

5. A cancer patient who reports ongoing, constant moderate pain with short periods of severe pain during dressing changes is
   a. probably exaggerating his pain.
   b. in need of a referral for surgical treatment of his pain.
   c. best treated by receiving a long-acting and a short-acting opioid.
   d. best treated by regularly scheduled short-acting opioids plus acetaminophen.

6. An example of distraction to provide pain relief is
   a. TENS.
   b. music.

c. exercise.

d. biofeedback.

7. Appropriate nonopioid analgesics for mild pain include *(select all that apply)*

a. oxycodone.

b. ibuprofen (Advil).

c. lorazepam (Ativan).

d. acetaminophen (Tylenol).

e. codeine with acetaminophen (Tylenol #3).

8. An *important* nursing responsibility related to pain is to

a. leave the patient alone to rest.

b. help the patient appear to not be in pain.

c. believe what the patient says about the pain.

d. assume responsibility for eliminating the patient's pain.

9. Giving opioids to an actively dying patient who has moderate to severe pain

a. may cause addiction.

b. will likely be ineffective.

c. is an appropriate nursing action.

d. will likely hasten the person's death.

10. A nurse believes that patients with the same type of tissue injury should have the same amount of pain. This statement reflects

a. a belief that will contribute to appropriate pain management.

b. an accurate statement about pain mechanisms and

expected goals of pain therapy.

c. a belief that will not have any effect on the type of care provided to people in pain.

d. a lack of knowledge about pain mechanisms, which is likely to contribute to poor pain management.

1. b, 2. c, 3.b, c, d, e, 4. c, 5. c, 6. b, 7. b, d, 8. c, 9. c, 10. d.

Palliative and End-of-Life Care

Denise M. McEnroe-Petitte

LEARNING OUTCOMES

1. Distinguish the purpose of palliative care at the end of life and hospice care.
2. Describe the physical and psychologic manifestations at the end of life.
3. Explain the process of grief and bereavement at the end of life.
4. Examine the cultural and spiritual issues related to end-of-life care.
5. Discuss ethical and legal issues in end-of-life care.
6. Describe the nursing management of the dying patient.
7. Explore the special needs of family caregivers in end-of-life care.
8. Discuss the special needs of the nurse who cares for dying patients and their families.

Palliative Care

Palliative care is any form of care or treatment that focuses on reducing the severity of disease symptoms. The overall goals of palliative care are to (1) prevent and relieve suffering and (2) improve

quality of life for patients with serious life-limiting illnesses[1] (Fig. 9.1). Specific goals of palliative care are listed in Table 9.1.

Ideally, all patients receiving curative or restorative health care should receive palliative care at the same time. Palliative care extends into the period of end-of-life (EOL) care and offers patient and family support while planning for EOL needs.[2] Bereavement care follows the patient's death (Fig. 9.2).

Palliative care originated as EOL care in the 1960s. Initially, this care focused on providing symptom relief and emotional support to the patient, family, and significant others during the terminal phases of a serious life-limiting disease. We now call that phase of palliative care *palliative care at the end of life,* which is the focus of this chapter.

The role of palliative care at the EOL is increasing in our current health care environment. Demographic changes are increasing the demand for palliative care. A growing number of Baby Boomers are turning 65. Improvements in health care technology have led to longer life expectancies and an increased number of older adults. The growing number of people with conditions such as diabetes and heart disease contribute to the increased use of palliative care.[2]

Older adults often have multiple chronic illnesses resulting in increased health care use.[3] Palliative care has been shown to (1) improve quality of life for those with chronic illness, (2) decrease the associated economic costs for their health care, and (3) ease caregiver burden for those with chronic and terminal illnesses.

FIG. 9.1 One goal of palliative care is to improve the quality of the patient's remaining life.
Courtesy Kathleen A. Pollard, RN, MSN, CHPN, Phoenix, AZ.

TABLE 9.1 Goals of Palliative Care

- Regard dying as a normal process
- Provide relief from symptoms, including pain
- Affirm life and neither hasten nor postpone death
- Support holistic patient care and enhance quality of life
- Offer support to patients to live as actively as possible until death
- Offer support to the family during the patient's illness and in their own bereavement

Adapted from World Health Organization: WHO definition of

palliative care. Retrieved from *www.who.int/cancer/palliative/definition/en*.

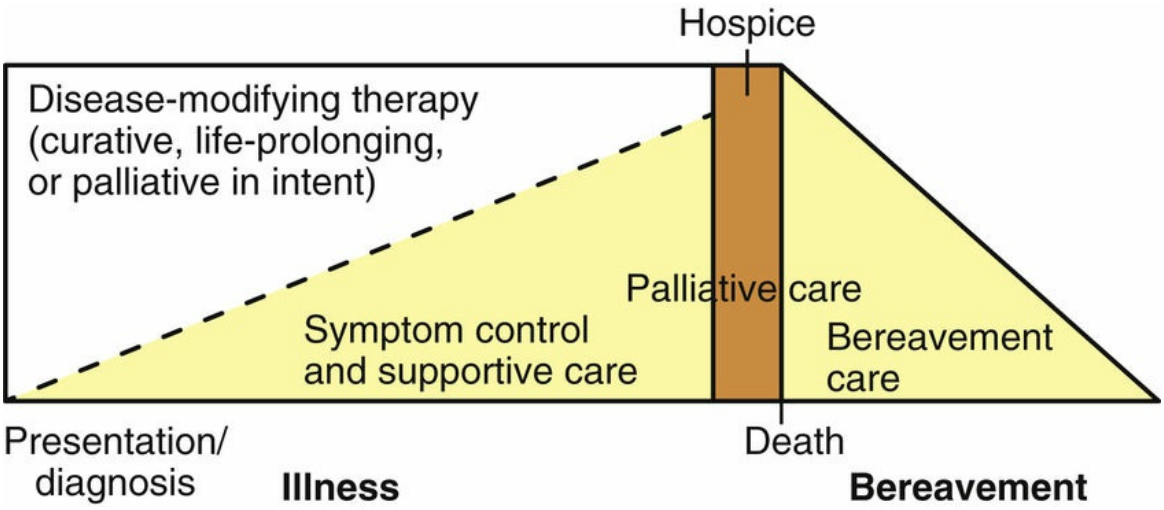

FIG. 9.2 Continuum-of-care model showing integration of curative care, palliative and end-of-life/hospice care, and bereavement care. Redrawn from Robert Wood Johnson Foundation: *The EPEC Project: Elements and models of end-of-life care*, 1999.

To optimize the benefits of palliative care, it should be started after a person receives a diagnosis of a life-limiting illness, such as cancer, heart failure, chronic obstructive pulmonary disease, dementia, or end-stage kidney disease. The palliative care team is an interprofessional collaboration involving physicians, nurses, social workers, pharmacists, chaplains, and other health care professionals. Communication among the patient, family, and interprofessional palliative team is important to provide optimal care.

Patients may receive palliative care services in multiple settings, including the home, long-term and acute care, mental health facilities, rehabilitation centers, and prisons. Many institutions have established interprofessional palliative and hospice care teams.[1]

Hospice Care

Palliative care often includes hospice care before or at the EOL (Fig.

9.3). **Hospice** is a concept of care that provides compassion, concern, and support for persons in the last phases of a terminal disease (Fig. 9.4). The main goals of hospice care are to assist the patient to live as fully and comfortably as possible while dying with dignity. Hospice programs provide care with an emphasis on symptom management, advance care planning, spiritual care, and family support.

FIG. 9.3 Relationship of palliative care and end-of-life care/hospice. From Rosenberg M, Lamba S, Misra S: Palliative medicine and geriatric emergency care: Challenges, opportunities, and basic principles, *Clin Geriatr Med* 29:1, 2013.

FIG. 9.4 Hospice care is designed to provide compassion, concern, and support for the dying.
From Rick Brady, Riva, MD.

The major difference between palliative care and hospice care is that palliative care allows a person to simultaneously receive curative and palliative treatments. Hospice care is an option when the physician determines a person has 6 months or less to live and that person or health care proxy decides to forgo curative treatments. Hospice is often underused, as many assume the person must be actively dying before hospice is necessary. On the contrary, it is important that the person be referred to hospice as soon as possible to ease the physical, emotional, and spiritual distress so common at the EOL.

Almost half of the patients who die in the United States are under the care of a hospice program.[4] More than three-quarters of persons in hospice programs are over the age of 65 years, and the majority are white. Most patients have cancer, dementia, stroke, or heart or respiratory conditions.[4]

Hospice programs are organized under a variety of models. Some are hospital-based programs, others are part of existing home health care agencies, and others are freestanding or community-based programs.

Like palliative care, hospice care is provided in a variety of

locations, including the home, inpatient settings, acute and long-term care facilities, and rehabilitation centers. Hospice services are available 24 hours a day, 7 days a week to help patients and families in their homes. Inpatient hospice settings often have a relaxed and homelike atmosphere (Fig. 9.5). Staff and volunteers are available for the patient and family.

FIG. 9.5 Inpatient hospice settings are designed to make the atmosphere as relaxed and homelike as possible.

© Photodisc/Thinkstock.

A medically supervised interprofessional team and volunteers provide holistic hospice services. The hospice nurse plays a pivotal role in coordination of the hospice team.[5] Hospice nurses work with other interprofessional team members to provide care and support to the patient and family. Hospice nurses focus on pain control and symptom management, spiritual assessment, and assessment and management of family needs. To meet patient and family needs, the hospice nurse needs excellent teaching skills, compassion, flexibility, cultural competence, and adaptability.

The decision to begin hospice care is hard for several reasons. Many patients, families, physicians, and other health care providers (HCPs) lack information about hospice care. Some cultural/ethnic groups may not use hospice because of a lack of awareness of hospice services, a desire to continue with potentially curative therapies, and concerns about lack of minority hospice workers. Physicians may be reluctant to give referrals because they sometimes view a patient's decline as their personal failure. Some patients or family members see hospice care as "giving up" or receiving second-rate care.

It is important to consider potential barriers to hospice care in vulnerable populations. These may include veterans, homeless, immigrants, impoverished, disabled, or institutionalized persons. In these populations, besides the hospice team, you may need to collaborate with community partners to facilitate support services to meet the needs of the patient and family.[5]

Medicare, Medicaid, and many private insurance agencies cover hospice services. Admission to a hospice program has 2 criteria. The first criterion is that the patient must want the services and agree in writing to use only hospice care, not curative care, to treat the terminal illness. The second criterion is that the patient must be medically eligible for hospice. Medicare, Medicaid, and other insurers require that 2 physicians certify that the patient's prognosis is terminal, with less than 6 months to live. After this initial certification, only 1 physician (e.g., the hospice medical director) is needed to

recertify the patient. It is important to realize that the physician who certified that a hospice patient is terminal does not "guarantee" death within 6 months. If a patient in hospice survives beyond 6 months, Medicare and other reimbursement organizations will continue to reimburse for an extended period if the patient still meets enrolment criteria.

Hospice patients can receive care for other health problems that are not related to the terminal illness. However, the hospice, Medicare, Medicaid, or patient's insurance company may not cover those services.[6] They can voluntarily withdraw from the program at any time. Occasionally, a patient's condition stabilizes, and the patient may be discharged from hospice care. This decision is made after review of the current treatment plan and input from members of the interprofessional hospice team.

Death

Death occurs when all vital organs and body systems cease to function. It is the irreversible cessation of cardiovascular, respiratory, and brain function.

Brain death is an irreversible loss of all brain functions, including those of the brainstem. Brain death is a clinical diagnosis. It occurs when the cerebral cortex stops functioning or is irreversibly destroyed.

With the growing use of technology that assists in supporting life, controversies have arisen over the exact definition of death. Questions and discussions have focused on whether brain death occurs when the whole brain (cortex and brainstem) ceases activity or when function of the cortex alone stops. The American Academy of Neurology developed the diagnostic criteria guidelines for clinical diagnosis of brain death. The criteria include coma or unresponsiveness, absence of brainstem reflexes, and apnea. Physicians must perform specific assessments to confirm each of the criteria.[7]

Currently, legal and medical standards require that all brain function must cease to be able to pronounce brain death and

disconnect life support. Diagnosing brain death is of special importance when organ donation is an option. In some states and under specific circumstances, a registered nurse is legally allowed to pronounce death. Policies and procedures may vary from state to state and among health care institutions.

End-of-Life Care

End of life generally refers to the final phase of a patient's illness when death is imminent. The time from diagnosis of a terminal illness to death varies depending on the patient's diagnosis and extent of disease.

The National Academy of Medicine defines *end of life* as the period during which a person copes with declining health from a terminal illness or from the frailties associated with advanced age, even if death is not clearly imminent.[8] In some cases it is obvious to HCPs that the patient is at the EOL. In other cases, they may be uncertain if the EOL is near. This uncertainty adds to the challenge of answering the common question asked by the patient and family, "How much time is left?"

End-of-life care (EOL care) is the term used for issues and services related to death and dying. EOL care focuses on physical and psychosocial needs for the patient and family. The goals for EOL care are to (1) provide comfort and supportive care during the dying process, (2) improve the quality of the patient's remaining life, (3) help ensure a dignified death, and (4) provide emotional support to the family.

TABLE 9.2 Physical Manifestations at End of Life

System	Manifestations
Cardiovascular system	• Increased heart rate; later slowing and weakening of pulse • Irregular rhythm • Decreased BP • Delayed absorption of drugs given IM or subcutaneously
Gastrointestinal system	• Slowing or cessation of GI function (may be enhanced by pain-relieving drugs) • Gas accumulation • Distention and nausea • Loss of sphincter control, producing incontinence • Bowel movement before imminent death or at time of death
Integumentary system	• Mottling on hands, feet, arms, and legs • Cold, clammy skin • Cyanosis of nose, nail beds, knees • "Waxlike" skin when very near death
Musculoskeletal system	• Gradual loss of ability to move • Sagging of jaw resulting from loss of facial muscle tone • Difficulty speaking • Swallowing becoming more difficult • Difficulty maintaining body posture and alignment • Loss of gag reflex • Jerking seen in patients on high doses of opioids
Respiratory system	• Increased respiratory rate • Cheyne-Stokes respiration • Inability to cough or clear secretions resulting in grunting, gurgling, or noisy congested breathing (death rattle or terminal secretions) • Irregular breathing, gradually slowing down to terminal gasps (may be described as guppy breathing)
Sensory system	
Hearing	• Usually last sense to disappear
Sight	• Blurring of vision • Sinking and glazing of eyes • Blink reflex absent • Eyelids stay half-open
Taste and smell	• Decreased with disease progression
Touch	• Decreased sensation • Decreased sense of pain and touch
Urinary system	• Gradual decrease in urine output • Incontinence of urine • Inability to urinate

Physical Manifestations at End of Life

As death approaches, metabolism reduces and the body gradually slows down until all functions end. Respiratory changes are common. Respirations may be rapid or slow, shallow, and irregular. Breath sounds may become wet and noisy, both audibly and on auscultation. Mouth breathing and accumulation of mucus in the airways cause noisy, wet-sounding respirations, termed the **death rattle** or terminal secretions. **Cheyne-Stokes respiration** is a pattern of breathing characterized by alternating periods of apnea and deep, rapid breathing. When respirations cease, the heart stops beating within a few minutes. The physical manifestations of approaching death are listed in Table 9.2.

Psychosocial Manifestations at End of Life

A variety of feelings and emotions can affect the dying patient and family at the EOL (Table 9.3). Most patients and families struggle with a terminal diagnosis and the realization that there is no cure. The patient and family may feel overwhelmed, fearful, powerless, and fatigued. The family's response depends in part on the type and length of the illness and their relationship with the person.

The patient's needs and wishes must be respected. Patients need time to think and express their feelings. Response time to questions may be sluggish because of fatigue, weakness, and confusion.

TABLE 9.3 Psychosocial Manifestations at End of Life

- Altered decision making
- Anxiety about unfinished business
- Decreased socialization
- Fear of loneliness
- Fear of meaninglessness of one's life
- Fear of pain
- Helplessness
- Life review
- Peacefulness
- Restlessness
- Saying goodbyes
- Unusual communication
- Vision-like experiences
- Withdrawal

Bereavement and Grief

Although we often use the terms interchangeably, *bereavement* refers to the state of loss and *grief* refers to the reaction to loss. **Bereavement** is the period after the death of a loved one during which we experience grief and mourning occurs. The time spent in bereavement depends on several factors, including how attached one was to the person who died and how much time one spent expecting the loss.

TABLE 9.4 Kübler-Ross Model of Grief

Stage	What Person May Say	Characteristics
Denial	No, not me. It cannot be true.	Denies the loss has taken place and may withdraw. This response may last minutes to months
Anger	Why me?	May be angry at the person who inflicted the hurt (even after death) or at the world for letting it happen. May be angry with self for letting an event (e.g., car accident) take place, even if nothing could have stopped it
Bargaining	Yes me, but . . .	May make bargains with God, asking, "If I do this, will you take away the loss?"
Depression	Yes me, and I am sad.	Feels numb, although anger and sadness may remain underneath
Acceptance	Yes me, but it is okay.	Anger, sadness, and mourning have tapered off. Accepts the reality of the loss

Adapted from Kübler-Ross E: *On death and dying*, New York, 1969, Macmillan. (Classic)

Grief is a normal reaction to loss. Grief occurs in response to the real loss of a loved one and the loss of what might have been. Grief is dynamic and includes both psychologic and physiologic responses after a loss. Psychologic responses include anger, guilt, anxiety, sadness, depression, and despair. Physiologic reactions include sleeping problems, changes in appetite, physical problems, and illness.

Grief is a powerful emotional state that affects all aspects of a person's life. It is a complex and intense emotional experience. In the Kübler-Ross model of grief, there are 5 stages[9] (Table 9.4). Not every person experiences all the stages of grieving, and they are not always progressive. It is common to reach a stage and then go backward. For example, a person may have reached the stage of bargaining and then revert to the denial or anger stage.

Another model of grief is the grief wheel (Fig. 9.6). After a person has a loss, he or she feels *shock* (numbness, denial, inability to think straight). Next is the *protest* stage, in which a person may have anger, guilt, sadness, fear, and searching. Then comes the *disorganization* stage, in which a person feels despair, apathy, anxiety, and confusion. The next stage is *reorganization,* in which a person gradually returns to normal functioning, but he or she feels different. The last stage is the *new normal*. Eventually the destabilization experienced in grief resolves and a normal state can begin. However, because of the loss, the normal state is different from before. The challenge is to accept the new normal. Trying to go back to the "old" normal (which is not there anymore) is what causes a great deal of anxiety and stress.

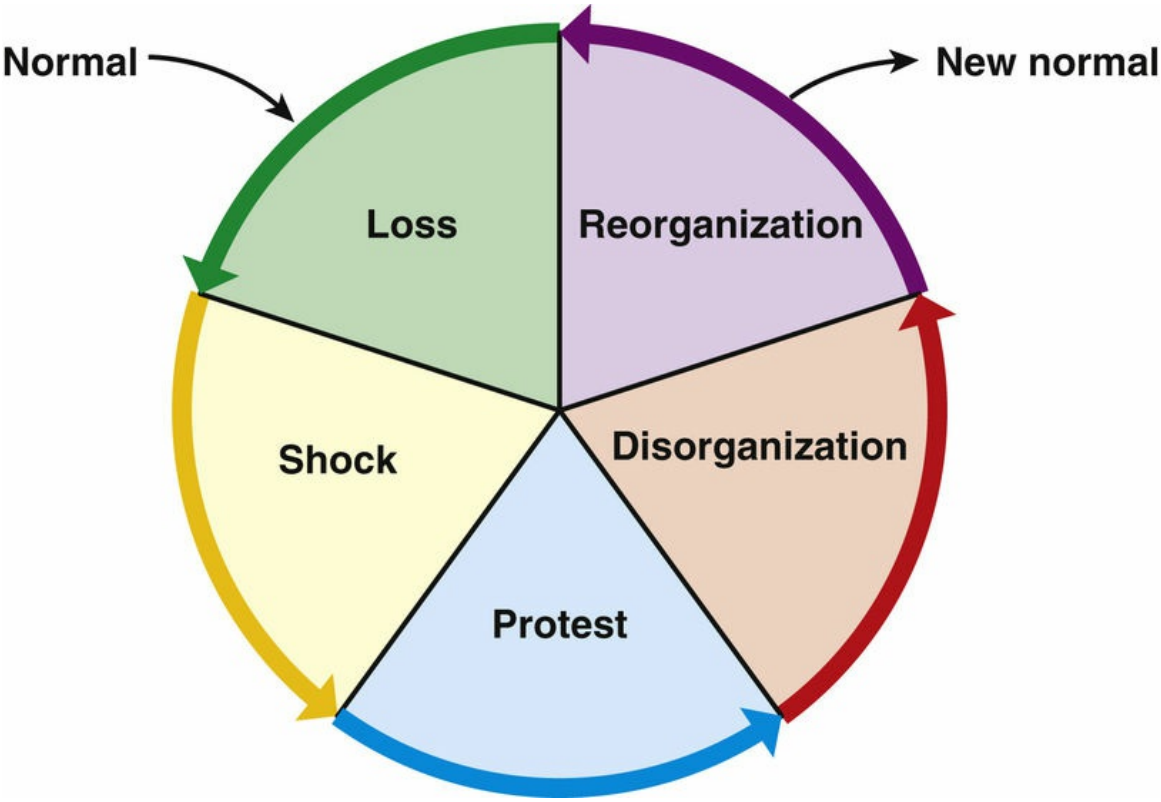

FIG. 9.6 The grief wheel model begins with the normal state at the bottom. After a person goes through the grief process, eventually the grief will resolve. However, because of the loss, the normal state is different from before. The challenge is to accept the "new normal."

The way a person grieves depends on factors such as the relationship with the person who has died (e.g., spouse, parent), physical and emotional coping resources, concurrent life stresses, cultural beliefs, and personality. Other factors that affect the grief response include mental and physical health, economic resources, religious influences or spiritual beliefs, family relationships, social support, and time spent preparing for the death. Issues that occurred before the death (e.g., marital problems) may affect the grief response.[10]

The grief experience for the caregiver of the patient with a chronic illness often begins long before the actual death event. This is called *anticipatory grief*. Patients at the EOL also can have anticipatory grief.

Working in a positive way through the grief process helps to adapt to the loss. Grief that helps the person accept the reality of death is called *adaptive grief.* It is a healthy response. It may be associated with

grieving before death occurs or when the inevitability of the death is known. Indicators of adaptive grief include the ability to see some good resulting from the death and positive memories of the deceased person.

Dysfunctional reactions to loss can occur, and the physical and psychologic impact of the loved one's death may persist for years. *Prolonged grief disorder,* formerly called *complicated grief,* is a term used to describe prolonged and intense mourning. Prolonged grief disorder can include symptoms such as recurrent and severe distressing emotions and intrusive thoughts related to the loss of a loved one, self-neglect, and denial of the loss for longer than 6 months. About 1 in 5 bereaved persons has prolonged grief disorder. Those with prolonged grief disorder have a higher risk for illness and may have work and social impairments.

Bereavement and grief counseling are core parts of patient- and family-centered palliative care. The goal of a bereavement program is to provide support and to help survivors in the transition to a life without the deceased person. Incorporate grief support into the plan of care for the family and significant others during the patient's illness and after the death.

TABLE 9.5 Spiritual Assessment

1. Who or what provides you strength and hope?
2. Do you use prayer in your life?
3. How do you express spirituality?
4. How would you describe your philosophy of life?
5. What type of spiritual or religious support do you wish?
6. What is the name of your clergy, minister, chaplain, pastor, rabbi?
7. What does suffering mean to you?
8. What does dying mean to you?
9. What are your spiritual goals?

10. Is there a role of a church, synagogue, mosque, or temple in your life?
11. Has belief in God been important in your life?
12. How does your faith help you cope with illness?
13. How do you keep going day after day?
14. What helps you get through this health care experience?
15. How has illness affected you and your family?

FIG. 9.7 Spiritual needs are an important consideration in end-of-life care.
© Photodisc/Thinkstock.

Priority interventions for grief focus on providing an environment that allows the patient and family to express their feelings, such as anger, fear, and guilt. Discussing feelings helps the patient and family work toward resolution of the grief process. Respect for the patient's privacy and need or desire to talk (or not to talk) is important.

Honesty in answering questions and giving information is essential.

Spiritual Needs

Assessment of spiritual needs in EOL care is a key consideration (Table 9.5). **Spirituality** is a broad concept that encompasses beliefs, values, and purpose that relate to the search for existential meaning and purpose.[11] Some define spirituality as a relationship with a supreme being that directs beliefs and practices. Spiritual needs do not necessarily equate to religion or belief in a higher power. A person may not be part of a particular religion but have a deep spirituality. Assess the patient's and family's preferences related to spiritual guidance or pastoral care services and make appropriate referrals.

Deep-seated spiritual beliefs may surface for some patients when they deal with their terminal diagnosis and related issues. Patients may question their beliefs about a higher power, their journey through life, religion, and an afterlife (Fig. 9.7). Spiritual distress may occur.[11] Characteristics of spiritual distress include anger toward God or a higher being, change in behavior and mood, desire for spiritual assistance, or displaced anger toward clergy.

Spirituality has been associated with decreased despair in patients at EOL. Some dying patients are secure in their faith about the future. It is common to see patients relinquish material possessions of life and focus on values that they believe will lead them on to another place. Many turn to religion because it gives order to the world even in the presence of physical decline, social losses, suffering, and impending death. Religion may offer an existential meaning that offers a sense of peace and recognition of one's place in the broader cosmic context.[11]

Culturally Competent Care: End of Life

Culture and ethnicity are important considerations for patients who are receiving palliative and EOL care and their families. Cultural beliefs affect a person's understanding of and reaction to death or loss. In some cultural/ethnic groups, death and dying are private matters

shared only with significant others. Often feelings are repressed or internalized. People who believe in "toughing it out" or "being strong" may not express themselves when they are experiencing a loss. Some cultural groups, such as blacks and Hispanic/Latinos, may easily express their feelings and emotions. Kinship tends to be strong in the Hispanic culture, and immediate and extended family provide support for one another. Expressing feelings of loss is encouraged and accepted easily.

Culture and ethnicity affect decision making about life support, withholding and withdrawing treatments, and using palliative or hospice care.[12] In some cultures, such as the Filipino American culture, it may be appropriate to first discuss a terminal diagnosis with the family before informing the patient. For Hispanics, often spouses and daughters are involved in decisions about palliative care and hospice. Blacks and Asian Americans use hospice care less often, with blacks being more likely to prefer aggressive treatment.

Rituals associated with dying are part of all cultures. In certain cultures, the family may want to keep constant vigil in the room of a dying patient or in the waiting area. For example, some Jewish Americans believe that the spirit should not be alone when it leaves the body at the time of death. Therefore someone who is terminally ill should never be alone. The Jewish culture believes all body tissues must be buried with the person. Once a death has occurred, some cultures, such as the Puerto Rican American culture, may want to kiss and touch the body to say goodbye. In the Islamic cultures, the traditional rites of washing, shrouding, funeral prayers, and burial are done as soon as possible.

Cultural variations exist in symptom expression (e.g., pain expression) and use of health care services. Providing culturally competent care requires assessment of nonverbal cues, such as grimaces, body position, and decreased or guarded movements. See Chapter 8 for issues related to pain assessment and management.

Many differences exist among cultural beliefs and values in relation to death and dying. Assess beliefs and preferences on an individual basis to avoid stereotyping patients with different cultural belief

systems. Assess and document the patient's cultural background, concerns, health practices, and attitudes about suffering. Ask the patient and family to describe their desires for care before death and care of the body after death. Use this assessment to guide the patient's plan of care and evaluation. You can suggest or plan grief and bereavement counseling for the family.

Make accommodations related to the patient's language, diet, and cultural beliefs and practices. Families with non–English-speaking members are at risk for receiving less information about their family member's critical illness and prognosis.[13] When appropriate, access medical interpreter services so that the patient's wishes are known. Culturally competent care is discussed in Chapter 2.

Legal and Ethical Issues Affecting End-of-Life Care

Patients and families struggle with many decisions during the terminal illness and dying experience. Many people decide that the outcomes related to their care should be based on their own wishes and values. It is important to provide information to help patients with these decisions. The decisions may involve the choice for (1) organ and tissue donations, (2) advance directives (e.g., medical power of attorney, living wills), (3) resuscitation, (4) mechanical ventilation, and (5) feeding tube placement.

Decisional capacity refers to the ability to consent to or refuse care. It means that the person has an understanding and appreciation of the information received and has the capacity to engage in the reasoning process.

Organ and Tissue Donation

Persons who are legally competent may choose organ donation. You can donate any body part or the entire body. The decision to donate organs or to provide anatomic gifts may be made by a person before

death or by immediate family after death. Family permission must be obtained at the time of donation.[14]

Some people carry donor cards. Some states mark organ donation wishes on drivers' licenses. The names of agencies that handle organ donation vary by state and community. Common names for such an agency may be the organ bank, organ-sharing network, and organ-sharing alliance. Organ and tissue donations follow specific legal guidelines. Follow those requirements and facility policies for organ or tissue donation. Notify the proper personnel at once when organ donation is intended, because some tissues must be used within hours after death.

Advance Care Planning and Advance Directives

Advance care planning is a process that involves having patients (1) think through their values and goals for treatment, (2) talk about their values and goals with others, and (3) document them. **Advance directives** are the written documents that provide information about the patient's wishes and his or her designated spokesperson (Table 9.6).

The first advance directive was known by laypersons as a *living will.* Most states have replaced the idea of living wills with *natural death acts,* which may include *directive to physicians* (DTPs), *durable power of attorney for health care* (DPAHC), *medical power of attorney* (MPOA), and *power of attorney for health care* (POAH). Under the natural death acts, a person can tell the HCP exactly what treatment is or is not desired. Each state has its own unique requirements. Patients often change their minds about desired treatments as their disease state progresses. It is important to reassess a patient's advance directives. For cognitively impaired older adults, consider the person's values and manner of life to make health care decisions consistent with decisions they made when they were cognitively intact.

People can get copies of state-specific forms from local medical associations and on the Internet. However, a person may write his or

her wishes without special forms. Verbal directives can be given to the attending physician in the presence of 2 witnesses. The physician may use a Physician Order for Life-Sustaining Treatment (POLST) or Medical Order for Life-Sustaining Treatment (MOLST) to outline current treatment options that honor the person's desire for treatment (Table 9.6).

The person should keep a copy of the order to use in case of an emergency in which the primary physician is not available for consultation. Attorneys and notaries may not be needed to develop these directives. If the person is not capable of communicating his or her wishes, the surrogate decision maker (most often family or significant other) decides the measures that will or will not be taken. In this case, the physician and nurse can discuss the available options with the family. Then it is important to document the family's decision. This is important because often nurses and other medical professionals do not know who can legally make EOL decisions for patients when they no longer have decisional capacity.

Resuscitation

Cardiopulmonary resuscitation (CPR) is common practice in health care. Patients who have respiratory or cardiac arrest receive CPR unless the physician gives a *do-not-resuscitate (DNR) order*. A DNR order is a written medical order that documents a patient's wishes about resuscitation and, more important, the patient's desire to avoid CPR.[15]

There are several types of CPR decisions. Complete and total heroic measures, which may include CPR, drugs, and mechanical ventilation, can be referred to as a *full code.* Some people choose variations of the full code. A *chemical code* involves the use of drugs for resuscitation without the use of CPR. A "no code," or a DNR order, allows the person to die with comfort measures only and without the interference of technology. Some states have implemented a form called *out-of-hospital DNR* for use by terminally ill patients who wish to have no heroic measures used to prolong life after they leave an

acute care facility.

Allow natural death (AND) is a term being used to replace "no code" or DNR. This term more accurately conveys our actions. It is sometimes referred to as *"comfort measures only"* status. The patient receives all comfort measures associated with pain control and symptom management, but the natural physiologic progression to death is not delayed or interrupted. The use of this type of language means that we do not withhold care, but care is supportive while allowing nature to take its course. It is meant to promote comfort and dignity at the EOL.

An advance directive includes whether to withhold or withdraw certain treatments. The directive must clearly state what is to be done and what is not to be done. The American Nurses Association (ANA) states that the decision to withhold artificial nutrition and hydration should be made by the patient or surrogate together with the interprofessional team. It is important we continue to provide expert nursing care for patients who are no longer receiving artificial nutrition and hydration.

You need to be aware of legal issues and have a primary role in supporting the patient's wishes. Advance directives and organ donor information should be in the medical record and identified on the patient's record and/or the nursing care plan. All caregivers responsible for the patient need to know the patient's wishes. Additionally, you need to be familiar with state, local, and agency procedures in EOL care documentation.

TABLE 9.6 Common Documents Used in End-of-Life Care

Document	Description	Special Considerations
Advance directive	General term used to describe documents that give instructions about future medical care and treatments and who should make the decisions in the event the person is unable to communicate	• Should adhere to guidelines established by state of residence
Allow natural death (AND)	Written order acknowledging that comfort measures only are being provided to patient. Used in many palliative care and hospice settings to indicate that patient wants to die naturally with dignity and comfort	• In many settings, may be used in conjunction with DNR terminology to ensure patient/family wishes for advance directives are followed (DNR/AND)
Directive to physicians (DTP)	Written document specifying the patient's wish to be allowed to die without heroic or extraordinary measures	• Indicates specific measures to be used or withheld
Do not resuscitate (DNR)	Written physician's order instructing HCPs not to attempt CPR. DNR order often requested by family	• Must indicate any specific measures to be used or withheld • Must be signed by a physician to be valid
Living will	Lay term used to describe any documents that give instructions about future medical care and treatments or the wish to be allowed to die without heroic or extraordinary measures should the patient be unable to communicate for self	• Must identify specific treatments that a person wants or does not want at end of life
Medical power of attorney (MPOA)	Term used by some states to describe a document used for listing the person(s) to make health care decisions should a patient become unable to make informed decisions for self	• May be the same as durable power of attorney for health care, health care proxy, or appointment of a health care agent or surrogate • Specifies measures to be used or withheld • Person appointed may be called a health care agent, surrogate, attorney-in-fact, or proxy
Physician Order for Life-Sustaining Treatment (POLST) or Medical Order for Life-Sustaining Treatment (MOLST)	A standardized physician order guided by the patient's medical condition and based upon personal preferences stated by patient or expressed in advance directive	• Only for those whose illness may limit life to <12 mo • Guides current treatments. Differs from advance directive, which guides future treatments • Physician completes form based on discussion with patient or authorized representative, or in review of advance directive • Signed by physician, patient, or patient representative • Printed on bright pink paper
Power of attorney for health care (POAH)	Term used by some states to describe a document used for listing the person(s) to make health care decisions should a patient become unable to make informed decisions for self	• May be the same as medical power of attorney • Indicates specific measures to be used or withheld

Euthanasia is the deliberate act of hastening death. The ANA statement on active euthanasia states that the nurse should not take part in active euthanasia, because such an act is in direct violation of the Code for Nurses, ethical traditions and goals of the profession, and its covenant with society.

Physician-assisted suicide is legal in some states. In this case, the physician provides the means and/or information about how the patient can commit suicide. As a nurse, you have an obligation to provide prompt, humane, comprehensive, and compassionate EOL care. Some confuse euthanasia with *palliative sedation,* which is the use of medications to intentionally produce sedation to relieve intractable symptoms and distress in a patient who is imminently dying. The intent of palliative sedation is to relieve pain and suffering and not to

shorten life or to hasten death, as is the case with euthanasia.

The use of opioids for symptom management at the EOL is often misunderstood and feared by patients, families, and HCPs. For this reason, many patients refuse to take opioids, which leads to physical and emotional suffering due to uncontrolled pain and symptoms. Your ethical obligation is to relieve suffering. This includes giving medications that have the potential of producing harm, such as with opioids. The *principle of double effect* refers to a principle that regards it morally permissible to give a medication that has the potential for harm if it is given with the intent of relieving pain and suffering and not intended to hasten death.

As a nurse, your role is to teach the patient and family about addiction and tolerance to and dependence on medications. The person with terminal illness should not be concerned with addiction when the goal of treatment is comfort. Pain management is discussed in Chapter 8.

Ethical/Legal Dilemmas

End-of-Life Care

Situation

A.P. is a terminally ill 50-yr-old woman with metastatic breast cancer who is hospitalized with severe bone pain. She moans at rest and shows severe pain with any movement to reposition her. The present dose of IV morphine is not controlling her pain. At the team conference, the nurses discuss the need for more effective pain control but are concerned that more pain medicine could hasten her death.

Ethical/Legal Points for Consideration

- Adequate pain relief is an important outcome for all patients, especially patients who are terminally ill.

- The *Code of Ethics for Nurses* addresses the responsibility of the nurse to relieve suffering and have conversations with patients and families about pain and symptom management.[1]
- The *principle of beneficence* means that we provide care to benefit patients. The goal of adequate pain control in the terminally ill to ease suffering is based on the *principle of nonmaleficence* (preventing or reducing harm to the patient). The secondary effect of hastening the patient's death is ethically justified and known as the *double effect.*
- Legally, the *standard of care* is used to define the nursing acts that are required for safe and competent nursing practice. When the actual nursing care falls below the standard of care, it is considered negligent and unsafe, and the nurse is at risk for being found incompetent.
- In a court of law, the standard of care in nursing is determined by nursing experts and evidence-based practices. The increasing use of technology to access the latest scientific findings is changing the standard of nursing care to a national, if not global, standard defined by research findings and nationally recognized expert testimony. Standards for providing expert nursing care and counseling at EOL are available.[1]
- In A.P.'s situation the standard of care is that the patient will have pain relief. Failure of the nurse to act assertively to achieve pain relief for the patient and failure to effectively use resources to obtain that pain relief will be considered below the standard of care and unsafe and incompetent practice.

Discussion Questions

1. What types of discussions need to occur among the health care team, patient, and family as the terminally ill patient approaches this phase of care?
2. Distinguish between promotion of comfort and relief of pain in dying patients and between assisted suicide and euthanasia.

Reference

1. ANA: Code of ethics for nursing. Retrieved from *www.nursingworld.org/DocumentVault/Ethics-1/Code-of-Ethics-for-Nurses.html*.

Nursing Management: End of Life

Nurses spend more time with patients near the EOL than any other health care professionals. Nursing care of terminally ill and dying patients is holistic and encompasses all psychosocial and physical needs. Respect, dignity, and comfort are important for the patient and family. Although there is no cure for the person's disease, the treatment plan still consists of assessment, planning, implementation, and evaluation. The main difference is that the focus of care is on the management of the symptoms of the disease, not necessarily the disease itself. Nurses who care for the dying need to recognize their own needs when dealing with grief and dying.

Nursing Assessment

Assessment of the terminally ill or dying patient varies with the patient's condition. Be sensitive and do not impose repeated, unnecessary assessments on the dying patient. When possible, use health history data that are available in the medical record rather than tiring the patient with an interview.

Document the specific event or change that brought the patient into the health care setting. Record the patient's medical diagnoses, medication profile, and allergies.

If the patient is alert, do a brief review of the body systems. Assess for discomfort, pain, nausea, and dyspnea so that you can implement interventions using evidence-based tools for symptom assessment. These include numeric scales or visual analog scales for pain rating. Evaluate and manage co-morbidities or acute episodes of problems, such as diabetes mellitus or headache. Elicit information about the

patient's abilities, food and fluid intake, patterns of sleep and rest, and response to the stress of terminal illness. Assess the patient's ability to cope with the diagnosis and prognosis of the illness. Determine the family's ability to manage the needed care and to cope with the illness and its consequences.

The physical assessment is abbreviated and focuses on changes that accompany terminal illness and the specific disease process. Pay attention to patients who are nonverbal for subtle changes in their condition.[16] The frequency of assessment depends on the patient's stability. Assessment is done at least every 8 hours in the institutional setting. For patients cared for in their homes by hospice programs, assessment may occur weekly. As changes occur, you may have to complete assessment and documentation more often. If the patient is in the final hours of life, we may limit the physical assessment to essential data.

Key elements of a social assessment include determining the relationships and patterns of communication among the family. If multiple family members are present, listen to concerns from different members. Differences in expectations and interpersonal conflict can produce disruptions during the dying process and after the death of the loved one. Social assessment also includes evaluating the goals of the patient and family.

As death approaches, monitor the patient for multiple systems that often are failing during the EOL period. This requires vigilance and attention to often subtle physical changes. Neurologic assessment is especially important and includes level of consciousness, presence of reflexes, and pupil responses. Evaluation of vital signs, skin color, and temperature shows changes in circulation. Monitor and describe respiratory status, character and pattern of respirations, and characteristics of breath sounds. Assess nutritional and fluid intake, urine output, and bowel function, since this gives data about renal and gastrointestinal functioning. Assess skin condition on an ongoing basis, because skin becomes fragile and may easily break down.

In the last hours of life, limit assessments to only those that you need to determine patient comfort. Assessment of pain and

respiratory status may be the most important during this time. It may be more peaceful and comforting to the patient and family to refrain from overstimulation that may occur from certain types of assessments, such as measuring BP or checking for pupillary response. As death approaches, your efforts may be better spent providing emotional support to the patient and family rather than performing tasks that will have no impact on the patient's physical care.

Planning

The patient and family need to be involved in planning and coordinating EOL care. In some cases, a family conference may be helpful to develop a coordinated plan of care.

Develop a comprehensive plan to support, teach, and evaluate patients and families. Nursing care goals during the last stages of life involve comfort and safety measures and care of the patient's emotional and physical needs. These goals may include determining where the patient would like to die and whether this is possible. For example, the patient may want to die at home, but the family may object. Many factors contribute to the patient and family's decision. Interprofessional EOL care that includes the physician, social worker, chaplain, and other members of the palliative and/or hospice care team is important. Advocate for the patient so that their wishes are met as much as possible.

The last hours or days of the patient experiencing brain death (e.g., from trauma) are often spent in the ICU. Planning for EOL care may be particularly challenging in the ICU environment. At this time, some families are approached about organ donation. Consultation from palliative care specialists may help the family plan and cope with EOL issues.

Nursing Implementation

Psychosocial care and physical care are interrelated for both the dying patient and family. Teaching them is an important part of EOL care.

Families need ongoing information on the disease, the dying process, and any care you will be providing. They need information on how to cope with the many issues during this period of their lives. Denial and grieving may be barriers to learning and understanding at the EOL for both the patient and family.

Psychosocial Care

As death approaches, respond appropriately to the patient's psychosocial manifestations at the EOL (Table 9.7).

Anxiety and Depression

Patients often show signs of anxiety and depression during the EOL period. Causes of anxiety and depression may include uncontrolled pain and dyspnea, psychosocial factors related to the disease process or impending death, altered physiologic states, and drugs used in high dosages. Anxiety is often related to fear. Encouragement, support, and teaching decrease some of the anxiety and depression. Management of anxiety and depression may include both medications and nonpharmacologic interventions. Relaxation strategies, such as relaxation breathing, muscle relaxation, music, and imagery, may be useful (see Chapter 6).

Anger

Anger is a common and normal response to grief. A grieving person cannot be forced to accept the loss. The surviving family members may be angry with the dying loved one who is leaving them. Encourage the expression of feelings, but at the same time realize how hard it is to come to terms with loss. As a nurse, you may be the target of the anger. You need to understand what is happening and not react on a personal level.

Hopelessness and Powerlessness

Feelings of hopelessness and powerlessness are common during the EOL period. Encourage realistic hope within the limits of the

situation. Allow the patient and family to deal with what is within their control and help them recognize what is beyond their control. When possible, support the patient's involvement in decision making about care to foster a sense of control and autonomy.

TABLE 9.7 Nursing Management

Psychosocial Care at End of Life

Manifestations	Nursing Management
Saying Goodbyes	
It is important for the patient and family to acknowledge their sadness, mutually forgive one another, and say goodbye.	Encourage the dying person and family to share their feelings of sadness, loss, forgiveness and to touch, hug, cry. Allow the patient and family privacy to express their feelings and comfort one another.
Spiritual Needs	
Patient or family may request spiritual support, such as the presence of a chaplain.	Assess spiritual needs. Allow patient to express his or her spiritual needs. Encourage visit by appropriate spiritual care service provider, chaplain, or family member.
Unusual Communication	
This may indicate that an unresolved issue is preventing the dying person from letting go. Patient may become restless and agitated or perform repetitive tasks (may also indicate terminal delirium).	Encourage the family to talk with and reassure the dying person.
Vision-Like Experiences	
Patient may talk to persons who are not there or see places and objects not visible. Vision-like experiences help the dying person in coming to terms with meaning in life and transition from it.	Affirm the dying person's experience as a part of transition from this life.
Withdrawal	
Patient near death may seem withdrawn from the physical environment, maintaining the ability to hear but unable to respond	Converse as though the patient were alert, using a soft voice and gentle touch.

Fear

Fear is a typical feeling associated with dying. Specific fears associated with dying are fear of pain, fear of shortness of breath, fear of loneliness and abandonment, and fear of meaninglessness.

Fear of pain

Many people assume that pain always accompanies death. Physiologically, there is no absolute indication that death is always painful. Psychologically, pain may occur based on the anxieties and

separations related to dying. Patients can take part in their own pain relief by discussing pain relief measures and their effects. Most patients want their pain relieved without the side effects of grogginess or sleepiness. Pain relief measures do not have to deprive the patient of the ability to interact with others.

Patients with physical pain should have pain-relieving drugs available. Assure the patient and family that drugs will be given promptly when needed and that side effects of drugs can and will be managed. As many EOL patients are unable to swallow, other routes, such as patches, sublingual, and rectal routes, may be used.[17] Consider alternative methods like massage, music, aromatherapy, and mindfulness.

Fear of shortness of breath

Respiratory distress and dyspnea are common near the EOL. The sensation of air hunger results in anxiety for the patient and family. Current therapies include opioids, bronchodilators, and oxygen, depending on the cause of the dyspnea. Anxiety-reducing agents (e.g., anxiolytics) may help produce relaxation.

FIG. 9.8 Dying patients typically want someone whom they know and trust to stay with them.
© iStockphoto/Thinkstock.

Fear of loneliness and abandonment

Most terminally ill and dying people fear loneliness and do not want to be alone. Many dying patients are afraid that loved ones who are unable to cope with the patient's imminent death will abandon them. Simply being present offers support and comfort (Fig. 9.8). Holding hands, touching, and listening are important nursing interventions. Providing companionship allows the dying person a sense of security.

Fear of meaninglessness

Fear of meaninglessness leads people to review their lives. They review their intentions during life, examining actions and expressing regrets about what might have been. *Life review* helps patients recognize the value of their lives. Assist patients and their families to identify the positive qualities of the patient's life. Practical ways of helping may include looking at photo albums or collections of

important mementos. Sharing thoughts and feelings may enhance spirituality and provide comfort. Respect and accept the practices and rituals associated with the patient's life review while staying nonjudgmental.

Communication

Communication among the interprofessional team, patient, and family is essential at the EOL. Empathy and active listening are essential parts of communication in care. *Empathy* is the identification with and understanding of another's situation, feelings, or motives. *Active listening* is paying attention to what is said, observing the patient's nonverbal cues, and not interrupting.

There may be silence. Often silence is related to the overwhelming feelings experienced at the EOL. Silence can also allow time to gather thoughts. Listening to the silence sends a message of acceptance and comfort. Communication must be respectful of the patient's ethnic, cultural, and religious backgrounds.

Patients and family members may have difficulties expressing themselves emotionally. Allow time for them to express their feelings and thoughts. Make time to listen and interact in a sensitive way to enhance the relationship among you, the patient, and the family. A family conference is 1 way to create a good environment for communication.

Prepare family members for changes in emotional and cognitive function that occur as death nears. Unusual communication by the patient may take place. The patient's speech may become confused, disoriented, or garbled. Patients may speak to or about family members or others who have predeceased them or give instructions to those who will survive them. Active, careful listening allows for the identification of specific patterns in the dying person's communication and decreases the risk for inappropriate labeling of behaviors.

Physical Care

Nursing management related to physical care at the EOL focuses on symptom management and comfort rather than treatment for curing a

disease or disorder (Table 9.8). The priority is meeting the patient's physiologic and safety needs. Physical care focuses on the needs for oxygen, nutrition, pain relief, mobility, elimination, and skin care. People who are dying deserve and require the same physical care as people who are expected to recover. If possible, it is important to discuss with the patient and family the goals of care before treatment begins. An advance directive should be completed so that the patient and family wishes are followed.

Postmortem Care

After the patient is pronounced dead, prepare or delegate preparing the patient's body for immediate viewing by the family with consideration for cultural customs and in accord with state law and agency policies and procedures (Table 9.9). In some cultures and in some types of death, it may be important to allow the family to prepare or help in caring for the patient's body. When the death is unexpected, preparing the patient's body for viewing or release to a funeral home depends on state law and agency policies and procedures.

Care of and discussion related to the person should continue to be respectful even after death. Allow the family privacy and as much time as they need with the deceased person. Never refer to the deceased person as "the body."

Special Needs of Caregivers and Nurses in End-of-Life Care

Special Needs of Family Caregivers

Family caregivers are important in meeting the patient's physical and psychosocial needs. Their role includes working and communicating with the patient and other family members, supporting the patient's concerns, and helping the patient resolve any unfinished business. Families often face emotional, physical, and economic consequences

from caring for a family member who is dying. The caregiver's responsibilities do not end when the patient is admitted to an acute care, inpatient hospice, or long-term care facility.[18]

An understanding of the grieving process as it affects both the patient and family is important. Being present during a family member's dying process can be highly stressful. Recognize signs and behaviors among family members who may be at risk for abnormal grief reactions and be prepared to intervene if needed. Warning signs may include dependency and negative feelings about the dying person, inability to express feelings, sleep disturbances, a history of depression, difficult reactions to previous losses, perceived lack of social or family support, low self-esteem, multiple previous bereavements, alcoholism, or substance abuse. Caregivers with concurrent life crises (e.g., divorce) are especially at risk.

Family caregivers and other family members need encouragement to continue their usual activities as much as possible. They need to discuss their activities and maintain some control over their lives. Inform caregivers about resources for support, including respite care. Community counseling and local support may help some people in working through their grief.

Encourage caregivers to build a support system of extended family, friends, faith community, and clergy. The caregivers should have people to call on at any time to express any feelings they are experiencing.

TABLE 9.8 Nursing Management

Physical Care at End of Life

Manifestation	Nursing Management
Anorexia, Nausea, and Vomiting	
• **May be caused by complications of disease process** • **Drugs contribute to nausea** • **Constipation, impaction, and bowel obstruction can cause anorexia, nausea, and vomiting**	• Assess the patient for nausea or vomiting • Assess possible contributing causes of nausea or vomiting • Provide antiemetics before meals if ordered • Offer and provide frequent meals with small portions of favorite foods • Offer culturally appropriate foods • Provide frequent mouth care, especially after vomiting • Ensure uninterrupted mealtimes • If ordered, give drugs (e.g., megestrol, corticosteroids) to increase appetite • Teach family that appetite naturally decreases at end of life and hunger is rare • Do not force the patient to eat
Bowel Patterns	
• **Immobility, opioid medication use, depression, lack of fiber in the diet, and dehydration can cause constipation** • **Diarrhea may occur as muscles relax or from a fecal impaction related to the use of opioids and immobility**	• Assess bowel function • Assess for and remove fecal impactions • Encourage movement and physical activities as tolerated • Encourage fiber in the diet if appropriate • Encourage fluids if appropriate • Use suppositories, stool softeners, laxatives, or enemas if ordered • Assess for confusion, agitation, restlessness, and pain, which may be signs of constipation
Candidiasis	
• **White, cottage cheese–like oral plaques** • **Fungal overgrowth in the mouth due to chemotherapy and/or immunosuppression**	• If ordered, give oral antifungal nystatin • Clean dentures and other dental appliances to prevent reinfection • Provide oral hygiene and use soft toothbrush
Dehydration	
• **May occur during the last days of life** • **Hunger and thirst are rare in the last days of life** • **As the end of life approaches, patients tend to take in less food and fluid**	• Assess mucous membranes often for dryness, which can lead to discomfort • Maintain complete, regular oral care to provide for comfort and hydration of mucous membranes • Encourage consumption of ice chips and sips of fluids or use moist cloths to provide moisture to the mouth • Use moist cloths and swabs for unconscious patients to avoid aspiration • Apply lubricant to the lips and oral mucous membranes as needed • Do not force the patient to drink • Teach family that thirst is rare in the last days of life • Reassure family that cessation of food and fluid intake is a natural part of the process of dying
Delirium	
• **A state characterized by confusion, disorientation, restlessness, clouding of consciousness, incoherence, fear, anxiety, excitement, and often hallucinations** • **May be misidentified as depression, psychosis, anger, or anxiety** • **May be caused by using opioids or corticosteroids** • **Underlying disease process may contribute to delirium** • **Considered a reversible process**	• Perform a thorough assessment for reversible causes of delirium, including pain, constipation, and urinary retention • Provide a room that is quiet, well lit, and familiar to reduce the effects of delirium • Reorient the dying person to person, place, and time with each encounter • Give ordered benzodiazepines and sedatives as needed • Stay physically close to frightened patient Reassure in a calm, soft voice with touch and slow strokes of the skin • Provide family with emotional support and encouragement in their efforts to cope with the behaviors associated with delirium
Dysphagia	
• **May occur because of extreme weakness and changes in level of consciousness** • **Difficulty swallowing** • **Aspiration of liquids and/or solids** • **Drooling/inability to swallow secretions**	• Identify the least invasive alternative routes of administering drugs needed for symptom management • Suction orally as needed • Modify diet as tolerated/desired • Hand feed small meals • Elevate the head for meals and at least 30 minutes after • If necessary, use alternative (rectal, buccal, transdermal) medication routes • Discontinue nonessential medications • Discuss risk for aspiration
Dyspnea	

Manifestation	Nursing Management
• **Subjective symptom** • **Accompanied by fear of suffocation and anxiety** • **Underlying disease process can worsen dyspnea** • **Coughing and expectorating secretions become difficult**	• Assess respiratory status regularly • Elevate the head and/or position patient on side to improve chest expansion • Use a fan or air conditioner to help movement of cool air • Teach and encourage the use of pursed-lip breathing • Give supplemental oxygen as ordered • Suction PRN to remove accumulation of mucus from the airways. Suction cautiously in the terminal phase • Give an expectorant as ordered

Table Continued

Manifestation	Nursing Management
Myoclonus	
• **Mild to severe jerking or twitching sometimes associated with use of high dose of opioids** • **Patient may have involuntary twitching of extremities**	• Assess for initial onset, duration, and any discomfort or distress • If myoclonus is distressing or becoming more severe, discuss possible drug therapy modifications with the HCP • Changes in opioid medication may decrease myoclonus
Pain	
• **May be a major symptom associated with terminal illness and the 1 most feared** • **Can be acute or chronic** • **Bone pain can be caused by metastases, fractures, arthritis, immobility** • **Physical and emotional stressors can worsen pain**	• Assess pain thoroughly and regularly to determine the quality, intensity, location, and contributing and alleviating factors • Minimize irritants, such as skin irritations from wetness, heat or cold, pressure • Give medications around the clock, in a timely manner, and on a regular basis to provide constant relief rather than waiting until the pain is unbearable and then trying to relieve it • Provide complementary and alternative therapies, such as guided imagery, massage, and relaxation techniques as needed (see Chapter 6) • Evaluate effectiveness of pain relief measures frequently to ensure that the patient is on a correct, adequate drug regimen • Do not delay or deny pain relief measures to a terminally ill patient
Restlessness	
• **May occur as death approaches and cerebral metabolism slows** • **May occur with tachypnea, dyspnea, sweating**	• Assess for previous anxiety disorder • Assess for spiritual distress and/or concerns related to death as causes of restlessness and agitation • Assess for urinary retention and stool impaction • Do not restrain • Use soothing music and slow, soft touch and voice • Limit the number of persons at the bedside
Skin Breakdown	
• **Skin integrity is hard to maintain at the end of life** • **Immobility, urinary and bowel incontinence, dry skin, nutritional deficits, anemia, friction, and shearing forces lead to a high risk for skin breakdown** • **Disease and other processes may impair skin integrity** • **As death approaches, circulation to the extremities decreases and they become cool, mottled, and cyanotic**	• Assess skin for signs of breakdown • Implement protocols to prevent skin breakdown by controlling drainage and odor and keeping the skin and any wound areas clean • Perform wound assessments as needed • Follow appropriate nursing management protocol for dressing wounds • Follow appropriate nursing management protocol for a patient who is immobile, but consider realistic outcomes of skin integrity vs. maintenance of comfort • Follow appropriate nursing management to prevent skin irritations and breakdown from urinary and bowel incontinence • Use blankets to cover for warmth. Never apply heat
Urinary Incontinence	
• **May result from disease progression or changes in the level of consciousness** • **As death becomes imminent, the perineal muscles relax**	• Assess urinary function • Use absorbent pads for urinary incontinence • Follow appropriate nursing protocol for the consideration and use of indwelling or external catheters • Follow appropriate nursing management to prevent skin irritations and breakdown from urinary incontinence
Weakness and Fatigue	
• **Expected at the end of life** • **Metabolic demands related to disease process contribute to weakness and fatigue**	• Assess the patient's tolerance for activities • Time nursing interventions to conserve energy • Help the patient identify and complete valued or desired activities • Provide support as needed to maintain positions in bed or chair • Give frequent rest periods

TABLE 9.9 Nursing Management

Postmortem Care

- Close the patient's eyes and jaw.
- Replace dentures; remove jewelry and eyeglasses.
- Wash the body as needed then apply a clean gown and bed linen.
- Place a waterproof pad or incontinence brief to absorb urine and feces.
- Comb and arrange the hair neatly.
- Remove tubes and dressings (if appropriate).
- Straighten the body, placing the arms at their sides or across the abdomen with palms down.
- Place a pillow under the head.

Special Needs of Nurses

Many nurses who care for dying patients do so because they are passionate about providing high-quality EOL care. Caring for patients and their families at the EOL is challenging and rewarding but also intense and emotionally charged. A bond or connection may develop between you and the patient or family. Be aware of how grief personally affects you. When you provide care for terminally ill or dying patients, you are not immune to feelings of loss. It is common to feel helpless and powerless when dealing with death. Express feelings of sorrow, guilt, and frustration. It is important to recognize your own values, attitudes, and feelings about death. Common ethical concerns include lack of adequate communication, lack of effective decision making, when to stop life-prolonging interventions, and concerns with symptom treatment, especially with use of opioids.

Interventions are available that may help ease your physical and emotional stress. Be aware of what you can and cannot control.

Recognizing personal feelings allows openness in exchanging feelings with the patient and family. Realizing that it is okay to cry with the patient or family during the EOL may be important for your well-being.

To meet your personal needs, focus on interventions that will help decrease your stress. Get involved in hobbies or other interests, schedule time for yourself, ensure time for sleep, maintain a peer support system, and develop a support system beyond the workplace. Many hospice agencies offer support groups and discussion sessions that can help you cope.

Case Study

Spiritual Distress at End of Life

© Mocker_bat/iStock/Thinkstock.

Patient Profile

G.M. is a 42-yr-old Orthodox Jewish man. He is being seen by the hospice nurse for increasing abdominal pain, nausea, vomiting, lack of appetite, and constipation. He was diagnosed 6 months ago with pancreatic cancer that has metastasized to the liver and lungs. He quit work 1 month later. Two weeks ago, he ended the drug trial he was on for 5 months and enrolled in hospice. Currently, he is taking oral opioids for pain, ondansetron for nausea and vomiting, sertraline for depression, and megestrol for appetite. His wife is worried that he will become addicted to the pain medication.

Subjective Data

- States that he is angry at God for giving him this illness
- Reports fatigue and lack of appetite
- Reports pain at 7 (0–10 point scale) not relieved by medication
- States he is worried about the loss of his health benefits and what will happen to his young family, including a son age 3, when he is gone

Objective Data
Physical Examination

- Underweight (20% less than ideal body weight for height)
- Skin is jaundiced
- Yellow sclera

Interprofessional Care

- Review pain medications for dosage adjustment.
- Hospice social worker to review medical benefits and disability application
- Ensure that advance directives are in place.

Discussion Questions

1. What are G.M.'s risk factors for spiritual distress?
2. Based on the data given, what are the major health problems for G.M.?
3. ***Patient-Centered Care:*** What specific palliative care needs does G.M. have?
4. ***Priority Decision:*** Based on your assessment of G.M., what are the priority nursing interventions for him?
5. ***Collaboration:*** For the interventions that you identified in the previous question, which personnel could be responsible for

implementing them: RN, LPN/VN, unlicensed assistive personnel (UAP)?

6. ***Collaboration:*** What referrals may be indicated?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An 80-yr-old female patient is receiving palliative care for heart failure. The *primary* purpose(s) of her receiving palliative care is (are) to (*select all that apply*)
   a. improve her quality of life.
   b. assess her coping ability with disease.
   c. have time to teach patient and family about disease.
   d. focus on reducing the severity of disease symptoms.
   e. provide care that the family is unwilling or unable to give.
2. A 67-yr-old woman was recently diagnosed with inoperable pancreatic cancer. Before the diagnosis, she was very active in her neighborhood association. Her husband is concerned because his wife is staying at home and missing her usual community activities. Which common EOL psychologic manifestation is she *most* likely demonstrating?
   a. Peacefulness
   b. Decreased socialization
   c. Decreased decision making

d. Anxiety about unfinished business

3. For the past 5 years, Tom has repeatedly asked his mother to donate his deceased father's belongings to charity, but his mother has refused. She sits in the bedroom closet, crying and talking to her long-dead husband. What type of grief is Tom's mother experiencing?
   a. Adaptive grief
   b. Disruptive grief
   c. Anticipatory grief
   d. Prolonged grief disorder
4. While caring for his dying wife, the husband states that his wife is a devout Roman Catholic, but he is a Baptist. Who is considered the *most* reliable source for spiritual preferences concerning EOL care for the dying wife?
   a. A priest
   b. Dying wife
   c. Hospice staff
   d. Husband of dying wife
5. The family attorney informed a patient's adult children and wife that the patient did not have an advance directive after he suffered a serious stroke. Who is responsible for making the decision about EOL measures when the patient cannot communicate his or her specific wishes?
   a. Notary and attorney
   b. Physician and family
   c. Wife and adult children
   d. Physician and nursing staff

6. The home health nurse visits a 40-yr-old patient with metastatic breast cancer who is receiving palliative care. The patient has pain at a level of 7 (0–10 point scale). In prioritizing activities for the visit, what should the nurse do *first*?

   a. Auscultate for breath sounds.

   b. Give as needed pain medication.

   c. Check pressure points for skin breakdown.

   d. Ask family about patient's food and fluid intake.

7. The children caregivers of an older patient whose death is imminent have not left the bedside for the past 36 hours. In the nurse's assessment of the family, what findings indicate the potential for an abnormal grief reaction to occur *(select all that apply)*?

   a. Family cannot express their feelings to one another.

   b. Dying patient is becoming more restless and agitated.

   c. A family member is going through a difficult divorce.

   d. Family talks with and reassures the patient at frequent intervals.

   e. Siblings who were estranged from each other have now reunited.

8. A nurse has been working full-time with terminally ill patients for 3 years. He has been experiencing irritability and mixed emotions when expressing sadness since 4 of his patients died on the same day. To optimize the quality of his nursing care, he should examine his own

   a. full-time work schedule.

   b. past feelings toward death.

c. patterns for dealing with grief.

d. demands for involvement in patient care.

1. a, d, 2. b, 3. d, 4. b, 5. c, 6. b, 7. a, c, 8. c.

Substance Use Disorders

Mariann M. Harding

LEARNING OUTCOMES

1. Relate the effects of substance use to its resulting major health complications.
2. Distinguish among the effects of the use of stimulants, depressants, and cannabis.
3. Explain your role in promoting the cessation of smoking and tobacco use.
4. Summarize the nursing and interprofessional management of patients who experience toxicity or withdrawal from stimulants and depressants.
5. Apply the Screening, Brief Intervention, and Referral to Treatment approach in clinical situations.
6. Describe the incidence and effects of substance use in the older adult.

KEY TERMS

acute alcohol toxicity, p. 147

alcohol use disorder (AUD), p. 145

alcohol withdrawal syndrome (AWS), p. 147

binge drinking, p. 145

electronic cigarettes, p. 143

Screening, Brief Intervention, and Referral to Treatment (SBIRT), p. 150

substance use disorder (SUD), Table 10.1, p. 143

tobacco use disorder (TUD), p. 142

Conceptual Focus

Addiction
Coping
Motivation

You can accomplish with kindness what you cannot by force.

Publilius Syrus

http://evolve.elsevier.com/Lewis/medsurg/

Substance use is a serious problem affecting society and the health care system. Substance-related disorders involve several types of substances, ranging from widely used and accepted tobacco and alcohol to illegal, brain-altering drugs such as heroin and cocaine. The *Diagnostic and Statistical Manual of Mental Disorders V (DSM-V)* outlines criteria used to identify the presence of substance use disorder (SUD)[1] (Table 10.1).

Whether SUD is mild, moderate, or severe depends on the person's pattern of use and the functional impact of use on the person's daily life. Knowing the severity of substance use allows the health care team to tailor treatment according to a patient's needs. For example, a person who binge drinks may not have alcohol SUD but is at increased risk for it. On the other hand, a person who uses heroin or

cocaine is likely to have severe SUD because these substances are highly addictive.

Many patients with substance use problems receive acute care for problems associated with substance use. SUD does not exist in isolation. There are many interrelated concepts depending on the patient situation. Every drug associated with SUD harms some tissue or organ. Substance use causes specific health problems, such as liver damage related to alcohol use or lung cancer related to smoking. Other problems result from injuries associated with substance use, such as falls or motor vehicle accidents. Common health problems related to substance use are outlined in Table 10.2.

This chapter focuses on the role of the medical-surgical nurse in identifying and managing the patient with SUD in the acute care setting. A hospitalized patient who uses substances can develop withdrawal when substance use abruptly stops. You need to be able to recognize substance use and its effects on health problems and manage withdrawal. The health care setting offers an opportunity for screening and providing teaching about substance use. It is your responsibility to motivate the patient to change behavior and refer the patient to programs that offer treatment.

Drugs Associated with Substance Use Disorder

Nicotine

You are most likely to encounter people with **tobacco use disorder (TUD)**. People with TUD are dependent on the drug nicotine due to using tobacco products. Several products contain nicotine, including smoked tobacco (cigarettes, cigars, pipes), smokeless tobacco (chew, snuff, dip), and some electronic cigarettes. Cigarette smoking is the main form of tobacco use in the United States.

TABLE 10.1 Criteria for Substance Use Disorder

The following criteria (clustered in 4 groups) can be used to identify **substance use disorder (SUD)**. The severity of SUD can be classified as mild (2-3 criteria), moderate (4-5 criteria), or severe (6 or more criteria).

Impaired Control

- Taking more or for longer than intended
- Not quitting use despite multiple times of trying to do so
- Spending a great deal of time obtaining, using, or recovering from use
- Craving the substance

Social Impairment

- Missing school, work, or other responsibilities due to use
- Continuing use despite problems caused or worsened by use
- Giving up or reducing important activities because of use

Risky Use

- Recurrent use in hazardous situations
- Continued use despite causing or worsening problems

Pharmacologic Dependence

- Physical tolerance to effects of the substance
- Presence of withdrawal symptoms when not using or using less

Source: American Psychiatric Association: *The diagnostic and statistical manual of mental disorders,* ed 5, Arlington, VA, 2013, The Association.

Effects of Use and Complications

Nicotine is a central nervous system stimulant. Within seconds of entering the body, nicotine reaches the brain, causing the release of adrenaline and creating feelings of a "high" or a "buzz." The effects last about 1 to 2 hours before withdrawal symptoms occur, leaving the person feeling tired, irritable, and anxious. The need to have the "high" or "buzz" feelings again makes the person crave more nicotine, leading to addiction.

Smoked tobacco is the most harmful method of nicotine use. Smoking harms nearly every organ in the body and reduces the general health of smokers. More than 14 million persons in the United States have a smoking related disease.[2] Smoking causes lung disease, cardiovascular disease, and lung and other cancers and is a major factor in many other conditions (Fig. 10.1).

Although those who use smokeless tobacco have less risk for lung disease, use can cause serious health problems. Holding tobacco in the mouth is associated with periodontal disease and cancer of the mouth, cheek, tongue, throat, and esophagus. Smokeless tobacco users experience the systemic effects of nicotine on the cardiovascular system, increasing the risk for heart attack and stroke.[3]

The use of **electronic cigarettes**, or e-cigs, continues to increase. E-cigs have a similar look and feel of traditional cigarettes. These battery-operated devices turn nicotine and other chemicals, including propylene glycol and flavorings, into an aerosol. Emerging information shows e-cigs can be harmful. E-cigs may affect the respiratory and immune systems. Those containing nicotine may increase the risk for cardiovascular problems and influence brain development in adolescents and pregnant users.[4] Other problems, such as poisonings and facial burns from device explosions, have occurred. Although some believe using an e-cig may aid in smoking cessation, no e-cigs are FDA approved. Do not recommend them as a smoking cessation aid.

TABLE 10.2 Health Problems Related to Substance Use

Health Problems*	
Substance	
Amphetamines	• Cardiac dysrhythmias, myocardial ischemia and infarction • Liver, lung, kidney damage • Mood disturbances, violent behavior, psychoses
Cannabis	• Bronchitis, chronic cough • Depression, anxiety, schizophrenia • Memory impairment
Cocaine	• Cardiac dysrhythmias, myocardial ischemia and infarction • Seizures, stroke • Psychosis
Inhalants	• Cognitive and motor impairment • Acute and chronic kidney injury
Opioids	• Sexual dysfunction • Gastric ulcers • Glomerulonephritis
Sedative-hypnotics	• Memory impairment • Personality changes, depression
Behaviors	
Injecting drugs	• Blood clots, phlebitis, skin infections • Hepatitis B and C • HIV/AIDS • Other infections: endocarditis, tuberculosis, pneumonia, meningitis, tetanus, bone and joint infections, lung abscesses
Personal neglect	• Malnutrition, impaired immunity • Accidental injuries
Risky sexual behavior	• HIV/AIDS • Hepatitis B and C • Sexually transmitted infections
Snorting drugs	• Nasal sores, septal necrosis or perforation • Chronic sinusitis

* Health problems related to SUD are discussed in the appropriate chapters throughout the text where they are identified as risk factors for these problems.

Adapted from National Institute on Drug Abuse: Medical consequence of drug abuse. Retrieved from *www.drugabuse.gov/related-topics/medical-consequences-drug-abuse*.

Nursing and Interprofessional Management: Tobacco Use Disorder

Tobacco Cessation

As a nurse, you have a professional responsibility to help people stop smoking or using tobacco. The Joint Commission mandates that every

health professional must identify tobacco users and provide them with information on ways to stop using tobacco. Patients who receive even brief advice and intervention from you are more likely to quit than those who receive no intervention.

With each patient encounter, encourage the patient to quit and offer specific smoking cessation interventions. The Agency for Healthcare Research and Quality has issued clinical practice guidelines for clinicians, including nurses, to use to motivate users to quit[5] (Tables 10.3 and 10.4). Use these brief clinical interventions, called the "5 *A*s," with each patient encounter. These interventions will help you identify tobacco users, encourage them to quit, determine their willingness to quit, assist them in quitting, and arrange for follow-up. A patient teaching guide (Table 10.5) expands on the fourth strategy, *Assist,* to help you aid the user willing to quit. If a tobacco user is unwilling to quit, using the "5 *R*s" may motivate the user to quit in the future.

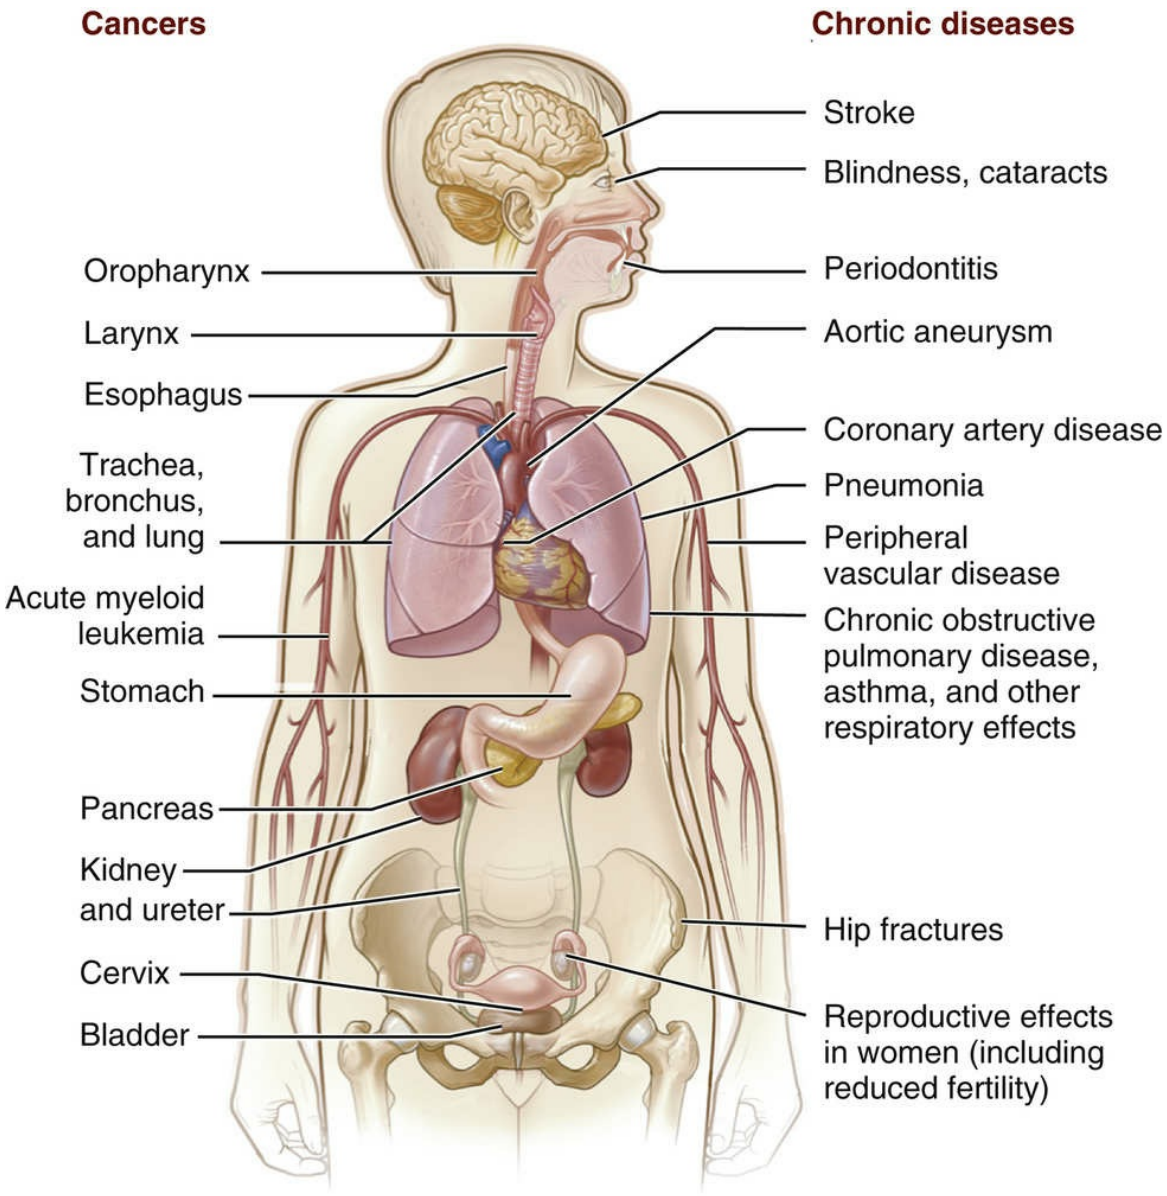

FIG 10.1 Health effects of smoking.
From Samet JM: Tobacco smoking, *Thorac Surg Clin* 23[2]:103, 2013.

TABLE 10.3 Clinical Practice Guideline

Treating Tobacco Use Disorder

The 5 *As* for Users Who Want to Quit	The 5 *Rs* for Users Unwilling to Quit
1. **Ask:** Identify all tobacco users at every contact. 2. **Advise:** Strongly urge all tobacco users to quit. 3. **Assess:** Determine willingness to make a quit attempt. 4. **Assist:** Develop a plan with the patient to help the patient quit (e.g., counseling, medication). 5. **Arrange:** Schedule follow-up contact.	1. **Relevance:** Ask the patient to say why quitting is personally relevant (e.g., health). 2. **Risks:** Ask the patient to identify his or her potential risks/consequences of tobacco use. 3. **Rewards:** Ask the patient to relate potential benefits of stopping tobacco use. 4. **Roadblocks:** Ask patient to identify barriers or impediments to quitting. 5. **Repetition:** Repeat process every clinic visit.

Source: Agency for Healthcare Research and Quality: *AHCPR supported clinical practice guideline: Treating tobacco use and dependence—2008 update,* Washington, DC, 2008, U.S. Public Health Service.

A variety of smoking cessation products are available to help support users in quitting. These include prescription medicines as well as over-the-counter (OTC) products such as skin patches, lozenges, and gum. Nicotine replacement products are 1 type of smoking cessation product. These products reduce the craving and withdrawal symptoms associated with cessation by supplying the body with smaller amounts of nicotine (Table 10.6).

TABLE 10.4 Inpatient Tobacco Cessation Interventions

Take the following steps for every hospitalized patient:

- Ask each patient on admission if he or she uses tobacco and document tobacco use status.
- For current tobacco users, list tobacco use status on the admission problem list and as a discharge diagnosis.
- Use counseling and medication to help all tobacco users stay abstinent and to treat withdrawal symptoms.
- Give advice and assistance on how to quit during hospitalization and stay abstinent after discharge.
- Arrange for follow-up about smoking status. Provide supportive contact for at least a month after discharge.

Source: Agency for Healthcare Research and Quality: *AHCPR supported clinical practice guideline: Treating tobacco use and dependence: 2008 update,* Washington, DC, 2008, U.S. Public Health Service.

Because most health care facilities are tobacco-free environments, admitted patients who are addicted to nicotine may experience withdrawal symptoms since they are unable to smoke. These symptoms are the same as for the person who stops using tobacco "cold turkey." Offering nicotine replacement therapy to every patient who wants to quit will help control withdrawal symptoms during hospitalization and promote continued cessation after discharge.

Non-nicotine products also play a role in helping users quit. Varenicline (Chantix) is a drug used to aid smoking cessation. Varenicline is unique in that it has both agonist and antagonist actions. Its agonist activity at 1 subtype of nicotinic receptors provides some nicotine effects to ease withdrawal symptoms. If the person does resume smoking, its antagonist action blocks the effects of nicotine at another subtype of nicotinic receptor, making smoking less enjoyable. Bupropion (Zyban), an antidepressant drug, reduces the urge to smoke, reduces some symptoms of withdrawal, and helps prevent weight gain associated with smoking cessation.

TABLE 10.5 Patient Teaching

Smoking and Tobacco Use Cessation

The following interventions are methods that work for quitting tobacco use. Tobacco users have the best chance of quitting if they use more than 1 method.

Develop a Quit Plan

- Set a quit date, ideally within 2 weeks.
- Talk to your HCP about getting help to quit.

- Tell family, friends, and co-workers about quitting and request understanding and support.
- Expect withdrawal symptoms and challenges when quitting.
- Before quitting, avoid smoking in places where you spend a lot of time (work, car, home).
- Throw away all tobacco products from your home, car, and work.
- Have support options in place by your quit date.

Use Approved Nicotine Replacement Systems

- Use a nicotine replacement agent unless you are a pregnant or nursing woman (Table 10.6).
- Do not use other forms of tobacco when using nicotine replacement systems.

Support and Encouragement

- Joining a quit-tobacco support group will increase your chances of stopping permanently.
- If you get the urge for tobacco, call someone to help talk you out of it—preferably an ex-user.
- Be proud every time you reach a quit milestone and reward yourself.
- Do not be afraid to talk about how you feel while quitting, especially fears of not being able to quit for good. Ask your spouse or partner, friends, and co-workers to support you. Self-help materials, mobile phone applications, and hot lines are available:
    - American Lung Association: 800-586-4872; *www.lung.org*
    - American Cancer Society: 800-227-2345; *www.cancer.org*
    - National Cancer Institute: LiveHelp; *www.smokefree.gov*

Dealing With Urges to Use Tobacco

- Identify situations that may cause you to want to smoke or use other tobacco, such as being around other smokers, being under time pressure, feeling sad or frustrated, and drinking alcohol.
- Avoid difficult situations while you are trying to quit. Try to lower your stress level.
- Exercise can help, such as walking, jogging, or bicycling.
- Distract yourself from thoughts of smoking and the urge to use tobacco by talking to someone, going to a movie, getting busy with a task, or having a game night with friends.
- Drink a lot of water.
- Keep your hands busy with a pen or toothpick.

Avoiding Relapse

Most relapses occur within the first 3 months after quitting. Do not be discouraged if you start using tobacco again. Remember, most people try several times before they finally quit. Explore different ways to break habits. You may have to deal with some of the following triggers that cause relapse.

- *Change your environment.* Get rid of cigarettes, tobacco (in any form), and ashtrays in your home, car, and place of work. Get rid of the smell of cigarettes in your car and home.
- *Alcohol.* Consider limiting or stopping alcohol use while you are quitting tobacco.
- *Other smokers at home.* Encourage housemates to quit with you. Work out a plan to cope with others who smoke and avoid being around them.
- *Weight gain.* Tackle 1 problem at a time. Work on quitting tobacco first. You will not necessarily gain weight, and increased appetite is often temporary. Eat healthy and exercise.
- *Negative mood or depression.* If these symptoms persist, talk to your

HCP. You may need treatment for depression.

- *Withdrawal symptoms.* Your body will go through many changes when you quit tobacco. You may have a dry mouth, cough, or scratchy throat, and you may feel irritable. The nicotine patch or gum may help with cravings (Table 10.6).
- *Focus on the benefits of quitting:*
    - Your BP and heart rate will lower almost at once.
    - Your risk for a heart attack declines within 24 hours. The blood will become less likely to clot, making dangerous blood clots less likely.
    - Within a few weeks, you will be less short of breath, cough less, and have more energy. Your ability to smell and taste should improve.
    - Your immune system will be stronger, so you will be less likely to be sick.
    - Quitting will improve your night vision and help preserve your overall vision.

Adapted from National Cancer Institute: 18 ways smoking affects your health. Retrieved from *www.smokefree.gov/health-effects*.

Drug Alert

Varenicline (Chantix) and Bupropion (Zyban)

- Serious neuropsychiatric symptoms such as changes in behavior, hostility, agitation, depressed mood, suicidal thoughts and behavior, and attempted suicide can occur.
- Tell patients to stop taking these drugs and contact the HCP at once if they have any of these manifestations.

Along with using a smoking cessation product, users who wish to quit are more likely to succeed if they take part in a tobacco cessation

program. You should be aware of available community resources. Cessation programs may involve hypnosis, acupuncture, behavioral interventions, aversion therapy, group support programs, individual therapy, and self-help options. Many of these programs teach users to avoid high-risk situations for smoking relapse (e.g., those that promote cue-induced craving) and help them develop coping skills, such as cigarette refusal skills, assertiveness, alternative activities, and peer support systems.

Alcohol

Of Americans ages 18 and older, 70% consume alcohol. Most people use alcohol in moderation.[6] *Risky drinking* is consuming more alcohol than the amounts in guidelines established by the National Institute on Alcohol Abuse and Alcoholism (Fig. 10.2). Risky drinking can have negative physical, emotional, and social consequences. **Alcohol use disorder (AUD)**, or alcoholism, affects about 6.2% of U.S. adults.[6] A higher percent engages in periodic excess alcohol use. **Binge drinking** is consuming 5 or more alcoholic drinks for males or 4 or more alcoholic drinks for females on the same occasion at least once per month.

TABLE 10.6 Drug Therapy

Smoking Cessation*

Agents	Common Side Effects	Considerations
Nicotine Replacement Agents		
Nicotine Gum (OTC) **Nicorette 2 mg, 4 mg** • **Use up to 12 wk** • **Use 1 piece q1–2hr for 6 wk then q2–4hr for 3 wk** • **Maximum dose: 24 pieces/day**	Hiccups, mouth/jaw pain, mouth ulcers, indigestion, throat irritation, nausea	Specific 30-min chewing regimen with periods of holding the gum between cheek and teeth. Take only water 15 min before and during use. Hard to use with dentures.
Nicotine Lozenge (OTC) **Commit 2 mg, 4 mg** • **Use 8–12 wk** • **Use 1 lozenge q1–2hr tapering to 1 lozenge q4–8hr in 12 wk**	Insomnia, nausea, sore throat, hiccups, cough, heartburn, headache	Dissolves in mouth in 20–30 min. Do not chew or swallow. Avoid food and drink during use. Occasionally rotate around the mouth.
Nicotine Patch (OTC) **NicoDerm CQ, Habitrol, Nicotine transdermal system** • **18- or 24-hr doses** • **Use ≥8 wk**	Local skin irritation, insomnia, nausea, headache	Provides steady level of nicotine and is easy to use. Cannot be used by those with adhesive allergies. Rotate site to diminish skin irritation.
Nicotine Nasal Spray **Nicotrol NS** • **1–2 doses (2 sprays)/hr** • **Use ≥6 mo**	Nose and throat irritation, sneezing, rhinitis, headache, cough	Requires a prescription. Provides fastest nicotine delivery. Do not sniff or inhale while dosing. Tilt head back slightly for best results.
Nicotine Inhaler **Nicotrol nicotine inhalation system** • **Use 1 cartridge q1–2hr** • **Use 3–6 mo**	Cough, mouth and throat irritation, headache, nausea, hiccups	Requires a prescription. Simulates smoking with mouthpiece and nicotine cartridge. May not be advisable for those with asthma or pulmonary disease
Non-Nicotine Agents		
bupropion (Zyban) • **150 mg/day for 3 days, then 150 mg bid** • **Use 12 wk; can use up to 6 mo**	Insomnia, dry mouth, irritability, rash, tremors, anorexia	Contraindicated with history of seizures or eating disorders. Promotes weight loss. First choice for smokers with depression
varenicline (Chantix)† • **0.5 mg/day for 3 days, 0.5 mg bid for 4 days, then 1 mg bid** • **Use 12 wk; additional 12 wk may be used in select patients**	Nausea, sleep disturbances, constipation, flatulence, vomiting, headache	If taken concurrently with nicotine replacement therapy, incidence of nausea, headache, vomiting, dizziness, dyspepsia, and fatigue is increased, but nicotine pharmacokinetics not affected.

* OTC nicotine replacement agents are also available in generic forms. More information and patient instructions are available from the American Lung Association at *www.lungusa.org.*

† See the Drug Alert for varenicline on p. 145.

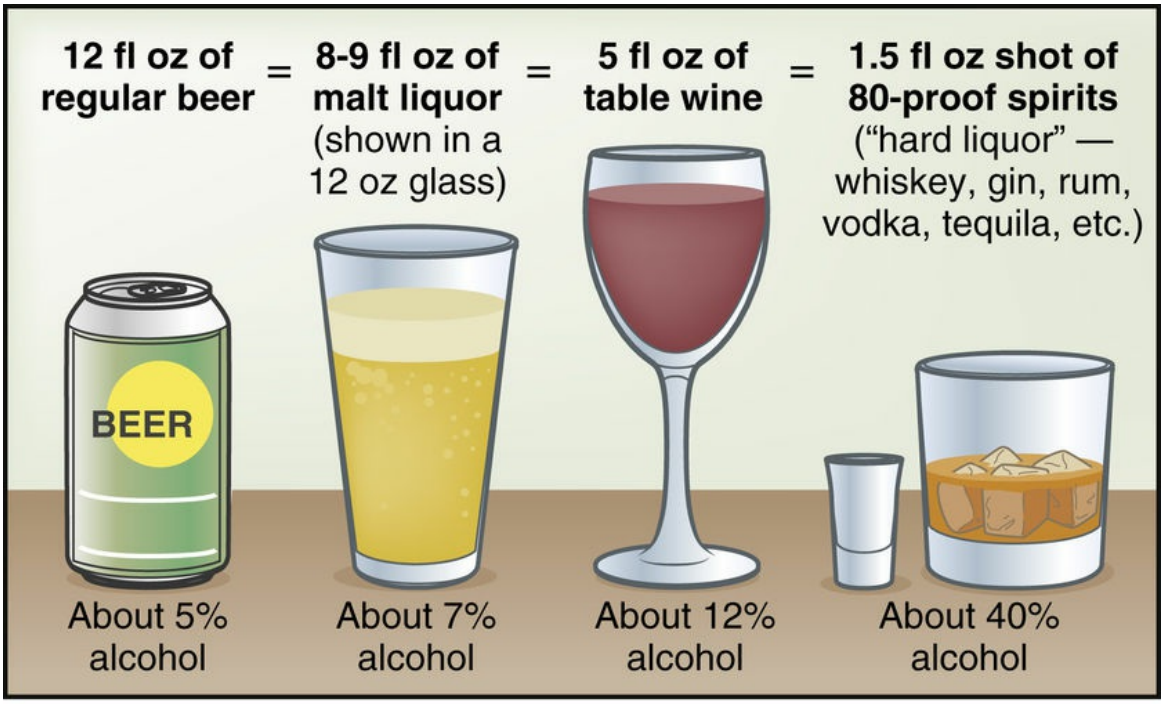

FIG 10.2 U.S. standard drink equivalents. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) guidelines for alcohol use state that healthy men younger than 65 should consume no more than 14 standard drinks per week or 4 drinks per drinking occasion. Healthy, nonpregnant women and adults older than 65 should consume no more than 7 standard drinks per week or 3 drinks per drinking occasion. From NIAAA: *What's a standard drink?* Retrieved from *www.niaaa.nih.gov*.

Effects of Use and Complications

Alcohol affects almost all cells of the body. It changes levels of neurotransmitters in the central nervous system (CNS), affecting all areas and functions of the CNS. These include centers that control our impulses, mood, and behavior; coordinate motor activity; and promote respiratory and cardiac function. The immediate effects of alcohol depend on a person's susceptibility to alcohol and the blood alcohol concentration (BAC).

For the person who is not dependent on alcohol, the BAC generally predicts alcohol's effects. The relationship between BAC and behavior

is different in a person who has developed tolerance to alcohol and its effects. The *tolerant person* is usually able to drink large amounts without obvious impairment and perform complex tasks without problems at BAC levels much higher than levels that would produce obvious impairment in the *nontolerant drinker*. Women have higher blood alcohol levels than men do after the same amount of alcohol intake.

Alcohol use is linked to many health problems (Table 10.7), which are often the reason that people seek health care. Long-term alcohol use can lead to hypertension, heart disease, stroke, liver disease, and digestive problems. Short-term, excess alcohol use increases the risk for injury from motor vehicle crashes, falls, firearms, assault, drowning, and burns. Patients with AUD undergoing surgery have increased in-hospital death rates and longer lengths of stay.

TABLE 10.7 Effects of Chronic Alcohol Use

Body System	Effects
Cardiac	Hypertension, atrial fibrillation, cardiomyopathy, stroke, coronary artery disease, sudden cardiac death
Gastrointestinal	Gastritis, gastroesophageal reflux disease (GERD), peptic ulcer, esophagitis, esophageal varices, gastrointestinal bleeding, pancreatitis, oropharyngeal cancer, colorectal cancer
Hematologic	Bone marrow depression, anemia, leukopenia, thrombocytopenia, blood clotting abnormalities
Hepatic	Alcoholic hepatitis, cirrhosis, liver cancer
Integumentary	Palmar erythema, spider angiomas, rosacea, rhinophyma
Musculoskeletal	Myopathy, osteoporosis, gout
Neurologic	Alcoholic dementia, Wernicke-Korsakoff syndrome, impaired cognitive function, psychomotor skills, abstract thinking, and memory. Depression, anxiety, attention deficit, labile moods, seizures, insomnia, peripheral neuropathy, chronic headache
Nutrition	Diabetes, anorexia, malnutrition, vitamin deficiencies (especially thiamine)
Reproductive	Breast cancer, testicular atrophy, decreased beard growth, decreased libido, decreased sperm count, gynecomastia
Urinary	Diuretic effect from inhibition of antidiuretic hormone

Complications may arise from the interaction of alcohol with commonly prescribed or OTC medications. Those that interact with alcohol in an additive manner include antihypertensives, antihistamines, and antianginals. Alcohol taken with aspirin may cause or worsen GI bleeding. Alcohol taken with acetaminophen may increase the risk for liver damage. Taking a CNS depressant with alcohol can increase, or potentiate, the effect of both. An alcohol-dependent person may have cross-tolerance, needing higher doses of CNS depressants to achieve the desired effect.

Nursing and Interprofessional Management: Alcohol Use Disorder

Alcohol Toxicity

Acute alcohol toxicity occurs when a person has a high level of alcohol in the blood, generally after ingesting a large amount of alcohol. This leads to behavior changes and alcohol-induced CNS depression, resulting in respiratory and circulatory failure. Unconsciousness, coma, and death can occur. Other common effects include hypokalemia, hypomagnesemia, and hypoglycemia.

Obtain as accurate a health history as possible and assess for injuries, diseases, and hypoglycemia. No antidote for alcohol is available. Implement supportive care measures to maintain airway, breathing, and circulation (the ABCs) until the alcohol metabolizes. Frequently monitor vital signs and level of consciousness. Treat alcohol-induced hypotension with IV fluids.

Patients with hypoglycemia may receive glucose-containing IV solutions. IV thiamine may be given before or with IV glucose solutions to prevent *Wernicke-Korsakoff syndrome,* which can cause seizures and brain damage.[7] Many patients have low serum magnesium levels and other signs of malnutrition, so HCPs often add multivitamins and magnesium to the IV fluids.

Agitation and anxiety are common. Stay with the patient as much as possible, orienting as necessary. Assess the patient for increasing

belligerence and a potential for violence. Since the patient is at risk for injury because of lack of coordination and impaired judgment, use protective measures.

Alcohol Withdrawal Syndrome

Alcohol withdrawal syndrome (AWS) can develop in a hospitalized patient when the use of alcohol abruptly stops. The onset of AWS is variable depending on the quantity, frequency, pattern, and duration of alcohol use. The early signs usually develop within a few hours after the last drink. They peak after 24 to 48 hours and then disappear unless the withdrawal progresses to alcohol withdrawal delirium.

Alcohol withdrawal delirium is a serious complication that can occur from 2 to 3 days after the last drink and last 2 to 3 days. The greater the patient's dependence on alcohol, the greater the risk for alcohol withdrawal delirium. Death may result from multiorgan dysfunction, dysrhythmias, or peripheral vascular collapse.[8]

Management begins with identifying at-risk persons. Use a symptom assessment tool, such as the Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar), to determine treatment[7] (Table 10.8). Table 10.9 presents the clinical manifestations and suggested treatment for AWS. A nursing care plan (eNursing Care Plan 10.1) for a patient with AWS is available on the website at *http://evolve.elsevier.com/Lewis/medsurg*.

Check Your Practice

A 34-yr-old male patient was admitted for multiple trauma following a car accident. His girlfriend tells you that he always drinks too much and she knew he would get in trouble someday.

- What signs and symptoms would alert you to the presence of AWS?
- What measures would you use to protect his safety?

- How would you involve members of the interprofessional team in planning patient care?

Use of Other Substances

Stimulants

Amphetamine-related stimulants are highly addictive substances. While the use of crack cocaine and methamphetamine is illegal, amphetamines have a role in treating narcolepsy, obesity, and attention deficit disorder. Though most people responsibly use prescribed stimulants, prescription stimulants are often misused. All stimulants increase cardiac activity and excite the CNS by increasing levels of norepinephrine, serotonin, and dopamine. People use these drugs to produce feelings of euphoria, increase alertness, and boost their energy. Health problems associated with using stimulants are outlined in Table 10.2.

TABLE 10.8 Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar)

CIWA-Ar Categories	Score Range in Each Category
Agitation	0–7
Anxiety	0–7
Auditory disturbances	0–7
Headache	0–7
Clouding of sensorium	0–4
Paroxysmal sweats	0–7
Tactile disturbances	0–7
Tremor	0–7
Visual disturbances	0–7

www.umem.org/files/uploads/1104212257_CIWA-Ar.pdf.

TABLE 10.9 Manifestations and Treatment of Alcohol Withdrawal

Manifestations	Interprofessional Care
Alcohol Withdrawal Syndrome	
• **Agitation** • **Anxiety** • **↑ Heart rate** • **↑ BP** • **Sweating** • **Nausea** • **Tremors** • **Insomnia** • **Hyperactivity**	• Benzodiazepines (e.g., lorazepam, diazepam) to prevent seizures and delirium • Thiamine to prevent Wernicke-Korsakoff syndrome • Multivitamins (e.g., folic acid, B vitamins) • Magnesium sulfate to treat low serum magnesium • IV glucose solution to treat hypoglycemia • β-Blockers (e.g., atenolol) or α_2-agonists (e.g., clonidine) to stabilize vital signs • Respiratory support
Alcohol Withdrawal Delirium	
• **Disorientation** • **Visual, tactile, or auditory hallucinations** • **Seizures**	• Continued use of benzodiazepines • Valproic acid or gabapentin to treat seizures • Antipsychotic agents (haloperidol [Haldol]) • Chlordiazepoxide if psychosis persists after benzodiazepine administration

Nursing and Interprofessional Management: Stimulant Use

Toxicity

Patients with stimulant toxicity present with *sympathetic overdrive* (increased stimulation of the sympathetic nervous system). The patient has restlessness, agitation, delirium, impaired judgment, and paranoia with psychotic symptoms. Physical effects include hypertension, tachycardia, fever, pupil dilation, seizures, confusion, and diaphoresis. Death may occur from stroke, dysrhythmias, or myocardial infarction.[1]

TABLE 10.10 Emergency Management

Stimulant Toxicity

Assessment Findings	Interventions
Cardiovascular • **Palpitations** • **Tachycardia** • **↑ BP** • **Dysrhythmias** • **Myocardial ischemia** • **Chest pain** **Central Nervous System** • **Agitation** • **Euphoria** • **Insomnia** • **Combativeness** • **Seizures** • **Hallucinations** • **Confusion** • **Paranoia** • **Fever**	• Ensure patent airway. • Establish IV access and start appropriate fluid replacement. • Obtain a 12-lead ECG and start ECG monitoring. • Treat ventricular dysrhythmias as needed. • Treat hypertension and chest pain with nitrates or calcium channel blockers. • Aspirin may be given to lower the risk for myocardial infarction. • Give IV diazepam or lorazepam for seizures. • Give IV antipsychotic drugs for psychosis and hallucinations. • Monitor vital signs and level of consciousness. • Begin cooling measures for hyperthermia. • Treat insomnia with trazodone, hydroxyzine, or diphenhydramine at bedtime. • Start gastric lavage in cases of recent ingestion.

The emergency management depends on the clinical manifestations at the time of treatment (Table 10.10). A specific antidote for stimulant toxicity is not available. Treatment focuses on supportive care measures.

Withdrawal

Stimulant withdrawal is usually not an emergency. Abrupt cessation can lead to a "crash." The patient may be depressed and experience fatigue, disturbed sleep, vivid dreams, general aching, irritability, increased appetite, and mood swings.[9] Craving for the drug is intense during the first hours to days of drug cessation and may continue for weeks. Supportive care includes providing a safe, quiet environment and allowing the patient to sleep and eat as desired. If a patient has severe depression, initiate suicide precautions and refer for further treatment.

Depressants

Commonly used depressants include sedative-hypnotics and opioids.

Depressants have a rapid development of tolerance and dependence. Their use is associated with many medical emergencies involving toxicity and withdrawal. The majority of drug overdose deaths involve an opioid, either alone or in combination with another depressant (e.g., opioid and benzodiazepine).[10] Common health problems resulting from depressant use are outlined in Table 10.2.

Sedative-Hypnotics

Common sedative-hypnotic agents include barbiturates, benzodiazepines, and barbiturate-like drugs. Sedative-hypnotic drugs depress the CNS, causing sedation at low doses and sleep at high doses. Their use produces a euphoria and intoxication that resembles that of alcohol. Tolerance develops rapidly to the effects of these drugs, requiring higher doses to achieve euphoria. However, tolerance may not develop to the brainstem-depressant effects. As a result, an increased dose may trigger hypotension and respiratory depression, resulting in death.

Opioids

Opioids include substances directly derived from the opium poppy (e.g., morphine), semisynthetics (e.g., heroin, hydromorphone), and synthetic compounds (e.g., fentanyl). Persons dependent on opioids include those who use illegal drugs sold on the street and those who misuse prescription opioids. Opioids act on opiate receptors and neurotransmitter systems in the CNS, causing sedation and analgesia. The person taking an opioid experiences euphoria, mood changes, mental clouding, drowsiness, and pain reduction. While this makes prescription opioids useful in treating a number of medical conditions, their pleasurable effects promote misuse. Misusing oxycodone or fentanyl can result in the same harmful consequences as abusing heroin.

Nursing and Interprofessional

Management: Depressant Use

Toxicity

Overdoses can occur when a person purposefully misuses a depressant or takes 1 prescribed for someone else. Unintentional overdose often occurs, especially when depressants are used with alcohol or other drugs. Depressant toxicity can cause death from respiratory and CNS depression. The priority of care is always the patient's ABCs. Supporting respiratory and cardiovascular function and continuous monitoring of neurologic status is critical until the patient is stable. The emergency management depends on the substance used and the clinical manifestations (Table 10.11).

TABLE 10.11 Emergency Management

Depressant Toxicity

Assessment Findings	Interventions
• Aggressive behavior • Agitation • Confusion • Lethargy • Stupor • Hallucinations • Depression • Slurred speech • Pinpoint pupils • Nystagmus • Seizures • Cold, clammy skin • Rapid, weak pulse • Slow or rapid shallow respirations • Decreased O_2 saturation • Hypotension • Dysrhythmias • ECG changes • Cardiac or respiratory arrest	• Ensure patent airway. • Expect intubation if respiratory distress present. • Establish IV access. • Obtain temperature. • Obtain 12-lead ECG and start continuous ECG monitoring. • Obtain information about substance (name, route, when taken, amount). • Obtain specific drug levels or comprehensive toxicology screen. • Obtain a health history, including drug use and allergies. • Give the right antidotes. • Perform gastric lavage if necessary. • Give activated charcoal and cathartics as needed. • Monitor vital signs, level of consciousness, and O_2 saturation.

Sedative-Hypnotics

On occasion, a patient with a benzodiazepine overdose may receive

flumazenil, a specific benzodiazepine antagonist. Because flumazenil may have a shorter duration of action than some benzodiazepines, repeated doses may be needed until the benzodiazepine is metabolized. Place the patient on safety precautions as flumazenil can cause seizures.

There are no antagonists for barbiturates or other sedative-hypnotic drugs. The patient receives supportive care, including passive rewarming, hydration, and vasopressors, along with treatments to promote drug elimination. If the airway can be maintained, activated charcoal is an option. Dialysis can be used in certain situations.

Opioids

Overdose in the inpatient setting may occur when a patient inadvertently receives an incorrect dose, or when opioids are aggressively dosed, given to patients with new kidney or liver impairment, or given with drugs that potentiate respiratory depression.[11] Treatment includes supporting respiratory function and giving the opioid antagonist naloxone. Naloxone reverses respiratory depression and other manifestations of toxicity. Monitor the patient closely because naloxone has a shorter duration of action than most opioids. Repeated doses or IV infusion of naloxone may be needed until the opioid is metabolized.

Overdose in the community setting can occur when a person deliberately misuses an illegal or prescription opioid, takes an opioid in combination with other depressants, or takes an opioid prescribed for someone else. In many areas, naloxone is publicly available. This allows police, first responders, family members, and friends to give someone naloxone in emergencies, thus reversing the effects of an overdose sooner. As a result, you may see more patients requiring postreversal care.

Withdrawal

Sedative-Hypnotics

Withdrawal from sedative-hypnotics can be life threatening. The

manifestations and treatment are similar to those of AWS. Early, the patient may have tremors, anxiety, insomnia, fever, orthostatic hypotension, and disorientation. Since the patient may experience delirium, seizures, and respiratory and cardiac arrest within 24 hours after the last dose, closely monitor the patient. Treatment consists of giving a long-acting benzodiazepine in a tapered dose. IV diazepam is an option for severe manifestations. Supportive care includes implementing patient safety and comfort measures, frequently assessing neurologic status and vital signs, and providing reassurance and orientation.

Opioids

Opioid withdrawal symptoms depend on the opioid used, route of administration, and duration of use. It is usually not life threatening but can be extremely uncomfortable. Manifestations include intense drug craving, diaphoresis, gastrointestinal distress, restlessness, fever, insomnia, watery eyes, tremors, muscle aches, runny nose, and anxiety.[1] With shorter acting drugs, withdrawal may begin 4 to 6 hours after the last dose, peak in 36 to 72 hours, and last 7 to 10 days. With longer acting drugs, manifestations may begin 24 to 48 hours after last dose and peak in 3 to 4 days.[11]

Treatment focuses on relieving symptoms and often requires drug therapy. Substituting a long-acting opioid (e.g., methadone, buprenorphine) at low doses or α_2-adrenergic agonists (e.g., clonidine) decreases withdrawal symptoms. Other therapies include medications for GI distress (e.g., loperamide, ondansetron), acetaminophen or nonsteroidal antiinflammatory agents for muscle aches and fever, and antihistamines for acute anxiety and sleep disturbances.

Inhalants

Persons with inhalant use disorder inhale hydrocarbon-based fumes, such as those found in glues or paints, to change their mental state.[1]

Inhalants are rapidly absorbed and reach the CNS quickly. Most are depressants with effects like those of alcohol. They cause a brief period of euphoria, followed by drowsiness and lightheadedness. Long-term use can result in neurologic problems, including damage to parts of the brain that control cognition, movement, vision, and hearing (Table 10.2).

The patient with inhalant toxicity may have lethargy, dizziness, slurred speech, blurry vision, tremors, and impaired coordination.[1] The effects usually resolve within minutes to a few hours. Inhalant toxicity is managed with supportive care. However, in some cases, users need emergency treatment for dysrhythmias, heart failure, or CNS hyperactivity (e.g., seizures). Using some inhalants (e.g., toluene) can result in nephrotoxicity; so, you must monitor renal function. Withdrawal is rare as most inhaled substances have a very short duration. Any manifestations that may occur require supportive care.

Cannabis

The use of cannabis, also called marijuana or weed, continues to increase in the United States. Cannabis is available in forms that can be smoked, vaporized, or ingested. The main ingredient is tetrahydrocannabinol (THC). At low to moderate doses, THC produces euphoria, reduced anxiety, and improved appetite. Adverse effects include impaired memory, impaired motor coordination, altered judgment, and, in high doses, paranoia and psychosis. Long-term use is associated with a wide range of effects, particularly on cardiopulmonary and mental health (Table 10.2).

Legalizing cannabis for recreational and medical use is controversial. Sales for recreational use continue to grow. More than half of the states have legalized its use for specific medical reasons. If an HCP in 1 of those states determines a patient has a disorder that qualifies for medical cannabis use, the HCP can give the patient an *authorization for use*. This form allows the patient to buy cannabis at special dispensaries or have a limited number of cannabis plants. THC-based medications, dronabinol (Marinol) and nabilone

(Cesamet), are available to control nausea and vomiting from cancer chemotherapy. Dronabinol is also used to stimulate appetite in patients with acquired immunodeficiency syndrome (AIDS). Illegal synthetic cannabinoid drugs (e.g., K2, Spice) have some of the same properties as THC. They contain varying amounts of different ingredients. The result is that these products have unpredictable effects and are more toxic. Sometimes, death has occurred with 1 use.

Patients with *acute marijuana toxicity* can present with acute psychotic episodes, especially if the patient used a synthetic derivative. Cannabis can induce tachycardia and hypertension, triggering dysrhythmias and myocardial infarction. Support the patient's ABCs. Panic and flashbacks are managed by maintaining a quiet environment and reassuring the patient. Benzodiazepines give symptom relief. [12]

Withdrawal can occur in a hospitalized patient who uses cannabis. The patient may have irritability, insomnia, anorexia, cramping, mild agitation, and nausea.[13] This peaks about 48 hours after cessation and may be more severe in women. There is no specific drug therapy for treating withdrawal. Supportive care includes measures to promote sleep, safety, and patient comfort, including analgesics and hydration.

Caffeine

Caffeine is the most widely used psychoactive substance in the world. It is very weak when compared with the other stimulants. Most people use it to promote wakefulness. Other uses include promoting motor activity and treating headaches. Its use is safe in most people. Problems from high doses of caffeine have occurred in association with specialized drinks. A large caffeine intake can cause cardiac dysrhythmias, hypertension, disturbed sleep, seizures, and anxiety. Treatment consists of seizure control with benzodiazepines and supportive care until the effects wear off. In a hospitalized patient, caffeine withdrawal can result in muscle pain or stiffness, drowsiness, irritability, and headaches after general anesthesia or during restrictions on usual caffeine intake.[1]

Nursing Management: Substance Use

Nursing Assessment

You need to be able to determine if patients use substances in a way that places them at risk or if SUD is present. Screening is a simple, effective way to identify patients who need further assessment. Use the **Screening, Brief Intervention, and Referral to Treatment (SBIRT)** approach (Fig. 10.3). SBIRT consists of 3 parts: (1) screening to quickly identify and assess the severity of any substance use problems, (2) providing a brief intervention or teaching patients about the consequences of substance use, and (3) referring those who screen positive for further treatment.[14]

Screening is the first part of SBIRT. Use screening tools to identify those who may have problems with substance use. As a baseline, ask every patient about the use of all substances, including prescribed medications, OTC medications, caffeine, tobacco, and recreational drugs. Use simple 1 or 2 question screening tests to detect alcohol, tobacco, and/or other substance use problems (Table 10.12). If a patient has a positive screen, follow up with a detailed assessment to identify specific problems. A screening tool for AUD, the Alcohol Use Disorders Identification Test, is shown in Table 10.13. A score of 8 points or more in men or 7 or more in women is concerning. Another useful tool is the Drug Abuse Screening Test (DAST-10), shown in Table 10.14.

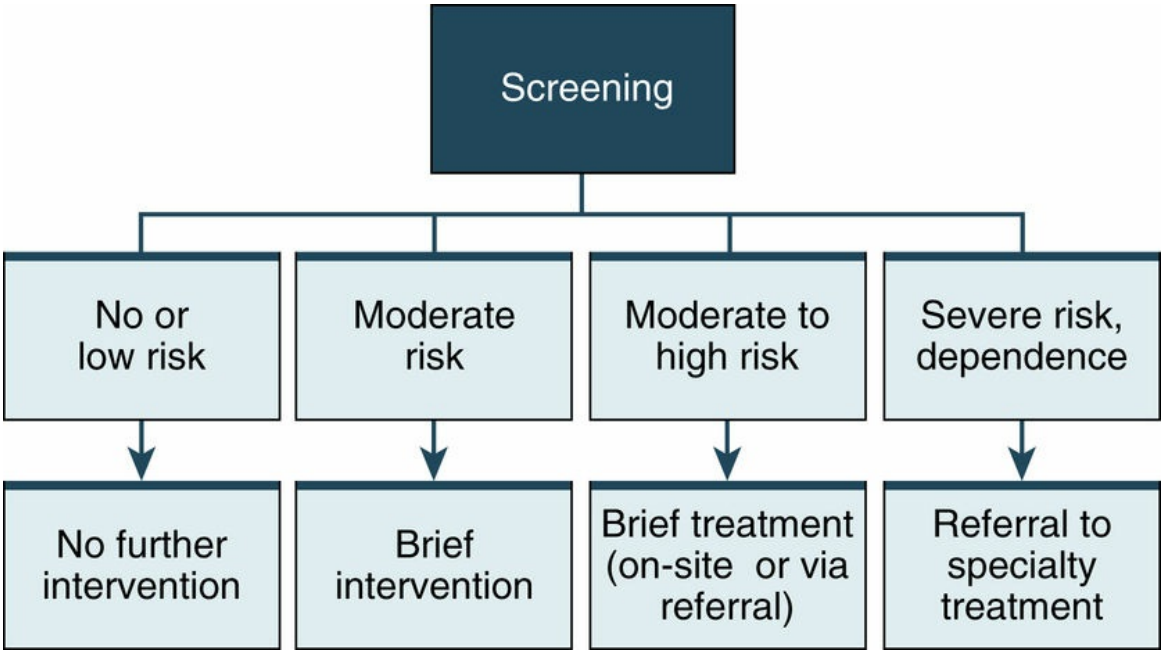

FIG 10.3 Screening, Brief Intervention, and Referral to Treatment approach.
From Substance Abuse and Mental Health Services Administration [SAMHSA]: Systems-level implementation of screening, brief intervention, and referral to treatment, Technical Assistance Publication [TAP] Series 33. HHS Publication No. 13-4741, Rockville, MD, 2013, SAMHSA. Retrieved from *www.integration.samhsa.gov/SBIRT/tap33.pdf*.

TABLE 10.12 Brief Screening Tools for Substance Use

Single Question Tests

Use 1 of the following questions to screen for the presence of alcohol, drug, or tobacco use.

- How often in the past year have you had 5 (men) or 4 (women) or more drinks in a day?
- How many times in the past year have you used illegal drugs or prescription medications for nonmedical reasons?
- In the past year, how often have you used tobacco products?

2-Question Tests

Use the following 2 questions to screen for alcohol or drug use.

- In the past year, have you ever drunk or used drugs more than you meant to?
- Have you felt you wanted or needed to cut down on your drinking or drug use in the past year?

Adapted from Strobbe S: Prevention and screening, brief intervention, and referral to treatment for substance use in primary care, *Prim Care Clin Office Pract* 41:185, 2014.

If there is any sign of substance use, figure out when the patient last used the substance. Knowing this information will let you know when to expect the onset of withdrawal and help you anticipate drug interactions. Assess for factors that influence the onset of withdrawal, including the substance used, dose taken, method of intake, and length of time the patient has used the substance. You may discover that the patient is dealing with *polysubstance use,* or the use of more than 1 substance. Alert the HCP as these patients need care tailored to the combination of substances used.

You may find problems associated with substance use during your physical assessment. Assess the patient's general appearance and nutritional status. Examine the abdomen, skin, and cardiovascular, respiratory, and neurologic systems. The presence of a mental health disorder, such as anxiety, bipolar disorder, or depression, increases the risk for SUD. Serum and urine drug screens can identify the type and amounts of drugs present in the body. A complete blood count, serum electrolytes, blood urea nitrogen, creatinine, and liver function tests evaluate for electrolyte imbalances and cardiac, kidney, or liver dysfunction.

During your assessment, look for patient behaviors such as denial, avoidance, underreporting or minimizing substance use, or giving inaccurate information. Behaviors and physical manifestations

suggesting substance use are outlined in Table 10.15. However, these behaviors are not all inclusive.

Nursing Diagnoses

Nursing diagnoses for the patient with substance use disorder include:

- Substance abuse, drug, alcohol and/or tobacco
- Risk for injury
- Acute confusion
- Altered perception

Planning

Nursing care focuses on the priority problems of reducing the risk for injury and managing acute confusion. The overall goals are that the patient with a substance use problem will (1) have normal physiologic functioning, (2) acknowledge a substance use problem, (3) explain the psychologic and physiologic effects of substance use, (4) abstain from substance use, and (5) cooperate with a proposed treatment plan.

Please answer each question by checking 1 of the circles in the second column.		
		Score
1. How often do you have a drink containing alcohol?	• Never	(0)
	• Monthly or less	(1)
	• 2 to 4 times per month	(2)
	• 2 to 4 times per week	(3)
	• 4+ times per week	(4)
2. How many drinks containing alcohol do you have on a typical day when you are drinking?	• 1 or 2	(0)
	• 3 or 4	(1)
	• 5 or 6	(2)
	• 7 to 9	(3)
	• 10 or more	(4)
3. How often do you have 6 or more drinks on 1 occasion?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
4. How often during the last year have you found that you were not able to stop drinking once you had started?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
5. How often in the last year have you failed to do what was normally expected of you because you were drinking?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
6. How often during the last year have you needed a first drink in the morning to get yourself going after a heavy drinking session?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
7. How often during the last year have you had a feeling of guilt or remorse about drinking?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
8. How often during the last year have you been unable to remember what happened the night before because you had been drinking?	• Never	(0)
	• Less than monthly	(1)
	• Monthly	(2)
	• Weekly	(3)
	• Daily or almost daily	(4)
9. Have you or someone else been injured as a result of your drinking?	• No	(0)
	• Yes, but not in the last year	(2)
	• Yes, during the last year	(4)
10. Has a relative, friend, or other health worker been concerned about your drinking or suggested that you cut down?	• No	(0)
	• Yes, but not in the last year	(2)
	• Yes, during the last year	(4)

Scoring for AUDIT: Questions 1 through 8 are scored 0, 1, 2, 3, or 4. Questions 9 and 10 are scored 0, 2, or 4 only. The minimum score (nondrinkers) is 0 and the maximum possible score is 40. A score of 9 or more indicates hazardous or harmful alcohol consumption.

TABLE 10.14 Drug Abuse Screening Test (DAST-10)

In the last 12 months:		
1. Have you used drugs other than those required for medical reasons?	No	Yes
2. Do you abuse more than 1 drug at a time?	No	Yes
3. Are you always able to stop using drugs when you want to?	No	Yes
4. Have you had "blackouts" or "flashbacks" as a result of drug use?	No	Yes
5. Do you ever feel bad or guilty about your drug use?	No	Yes
6. Does your spouse (or parents) ever complain about your involvement with drugs?	No	Yes
7. Have you neglected your family because of your use of drugs?	No	Yes
8. Have you engaged in illicit activities in order to obtain drugs?	No	Yes
9. Have you ever experienced withdrawal symptoms or felt sick when you stopped taking drugs?	No	Yes
10. Have you had medical problems as a result of your drug use?	No	Yes

TABLE 10.15 Findings Suggesting Substance Use

Physiologic

- Fatigue
- Insomnia
- Headaches
- Seizure disorder
- Changes in mood

- Anorexia, weight loss
- Vague physical complaints
- Appearing older than stated age, unkempt appearance
- Sexual dysfunction, decreased libido, erectile dysfunction
- Failure of standard doses of sedatives to have a therapeutic effect

Behavioral

- Overuse of mouthwash or toiletries
- Citations for driving while intoxicated or impaired
- Leisure activities that involve alcohol and/or other drugs
- Trauma secondary to falls, auto accidents, fights, or burns
- Financial problems, including those related to spending for substances
- Defensive or evasive answers to questions about substance use and its importance in the person's life
- Problems in areas of life function (e.g., frequent job changes; marital conflict, separation, or divorce; work-related accidents, tardiness, absenteeism; legal problems; social isolation, estranged from friends or family)

Nursing Implementation

Health Promotion

Your role in health promotion includes prevention and early detection of substance use. Prevention measures include abstaining from harmful substances and limiting alcohol use. These measures decrease the risk for substance-related injury or illness. You can help prevent substance use problems by (1) teaching about the effects and negative outcomes of substance use and (2) providing support. Through screening, you have an opportunity to prevent patients from becoming dependent on alcohol and drugs. You can do this by using brief interventional techniques and helping patients access

appropriate care through referral to treatment if they show risky behaviors or are already dependent.

Acute Intervention

The immediate result of overconsumption is acute toxicity or overdose. The patient may also present with trauma or injuries. The priority of care is supporting the patient's ABCs, especially respiratory status. In addition to treating injuries, provide supportive care until detoxification can occur. Nursing care includes frequently assessing neurologic status and vital signs, giving IV fluids to prevent dehydration, orienting to time and place, and implementing patient safety measures.

Sometimes, uncertainty exists as to what substances are involved. If the patient used multiple substances, a complex clinical picture can result. For example, a patient presents with toxicity and the health care team does not know what substances are involved. Although blood and urine tests will help identify the substances, treatment is started while waiting for the test results. The patient in this situation would usually receive naloxone. If the substance used is a barbiturate or another CNS depressant, naloxone will not help the patient, but it will not hurt the patient either. If the patient does not respond to a total dose of 10 mg of naloxone, it is unlikely opioids are involved.

Once acute health issues are resolved, provide a brief intervention to teach patients about the consequences of substance use and support behavioral change. When patients have a substance use problem, it is critical to motivate the patient to engage in long-term treatment. You are in a unique position to facilitate behavior change. When a patient seeks care for health problems related to substance use or when hospitalization interferes with the usual pattern of use, the patient's awareness of any substance use problem increases. Intervention at this time can promote behavior change. Take an active role in performing motivational interviewing and providing counseling aimed at cessation. (Motivational interviewing is discussed in Chapter 4.) Discuss the risks associated with substance use and provide feedback and advice. If the patient agrees, assist with referral to counseling or

behavioral therapy.

Gerontologic Considerations: Substance Use

Substance use in older adults is a fast-growing and often hard to recognize problem. Older adults do not fit the image of users. For example, older users are less likely to binge drink and use different substances than younger users. The effects of alcohol and drugs can be mistaken for medical conditions common among older adults (e.g., hypertension, dementia). So, we may attribute substance use problems to another cause and not offer treatment. Some use alcohol or drugs to cope with grief and loss issues, such as the death of a spouse.[15]

Because of the higher rate of coexisting medical problems, older adults are at greater risk for medical problems associated with substance use. Common problems include liver damage and cardiovascular, GI, and endocrine problems. Substance use may cause confusion, delirium, memory loss, and neuromuscular impairment. Physiologic changes may lead to toxicity at levels that may not have been a problem at a younger age. Withdrawal symptoms may be more severe than in younger persons.

FIG 10.4 Older adults are often unaware of their substance use problems.
© Ned White/iStock/Thinkstock.

It is important to screen older adults for substance use. Family members are important sources of information (Fig. 10.4). Other potential sources include friends, home health aides, meal delivery personnel, and staff members at senior citizen centers and long-term care facilities. It is important for you to discuss drug and alcohol use with older adult patients, including OTC and herbal drug use. Assess the patient's knowledge of currently used drugs. Common screening questionnaires may not identify an older adult with a substance use problem. The Short Michigan Alcoholism Screening Test–Geriatric version (SMAST-G) is a short-form alcoholism screening instrument for older adults *(www.consultgerirn.org)* that can identify older adults with potential AUD.

Smoking and other tobacco use is another issue. Those who have

smoked for decades may feel unable to stop or believe there is no benefit to stopping at an advanced age. However, smoking contributes to and worsens many chronic illnesses found in the older adult population. Smoking cessation at any age is beneficial. The information about smoking cessation discussed earlier is appropriate for helping older adults with smoking cessation (Tables 10.3 to 10.6).

Patient teaching for the older adult includes teaching about the desired effects, possible side effects, and proper use of prescribed and OTC drugs. When you suspect alcohol or substance use, refer the patient for treatment. It is a mistaken belief that older people have little to gain from alcohol and drug dependence treatment. The rewards of treatment can lead to greater quality and quantity of life for older adults.

Case Study

Substance Use Disorder

©JPC-PROD/iStock/Thinkstock.

Patient Profile

C.M., a 78-yr-old woman, is admitted to the emergency department after falling and injuring her right hip. She has been widowed for 4 years and lives alone. Recently her best friend died. Her only family is a daughter who lives out of town. When contacted by phone, the

daughter tells the nurse that her mother has appeared more disoriented and confused over the past few months when she has talked to her on the phone.

Subjective Data

- Describing severe pain in her right hip
- Admits she had some wine in the late afternoon to stimulate her appetite
- Has experienced several falls in the past 2 months
- Reports that she fell after taking a prescribed sleeping pill because she does not sleep well
- Speech is hesitant and slurred
- Says she smokes about a half pack of cigarettes a day

Objective Data
Physical Examination

- Oriented to person and place, but not time
- BP 162/94, pulse 92, respirations 24
- Severe pain and tenderness in the right hip region
- Bilateral hand tremors

Diagnostic Tests

- X-ray reveals a subtrochanteric fracture of the right femur requiring surgical repair
- Blood alcohol concentration (BAC) 120 mg/dL (0.12%)
- Complete blood count: Hemoglobin 10.6 g/dL, hematocrit 33%

Discussion Questions

1. What other information is needed to assess C.M.'s condition?
2. How should you address questions about these areas?
3. What factors may contribute to C.M.'s substance use?
4. ***Priority Decision:*** Based on the assessment data given, what are the priority nursing diagnoses? Are there any collaborative problems?
5. ***Priority Decision:*** What are the priority nursing interventions during C.M.'s preoperative period?
6. What possible complications and injury risks may occur during C.M.'s postoperative recovery?
7. ***Safety:*** To ensure C.M.'s safety, what nursing interventions are necessary after surgery?
8. ***Delegation Decision:*** How would you use the unlicensed assistive personnel (UAP) on the postoperative unit to carry out the interventions that you identified in question 5?
9. ***Collaboration:*** What referrals are indicated?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. When admitting a patient, the nurse must assess the patient for substance use based on the knowledge that long-term use of addictive substances leads to
   a. the development of coexisting psychiatric illnesses.
   b. a higher risk for complications from underlying health problems.
   c. potentiation of effects of similar drugs taken when the person is drug free.
   d. increased availability of dopamine, resulting in

decreased sleep requirements.

2. The nurse would suspect cocaine toxicity in the patient who is experiencing
   a. agitation, dysrhythmias, and seizures.
   b. blurred vision, restlessness, and irritability.
   c. diarrhea, nausea and vomiting, and confusion.
   d. slow, shallow respirations; bradycardia; and hypotension.
3. The *most* appropriate nursing intervention for a patient who is being treated for an acute exacerbation of chronic obstructive pulmonary disease who is not interested in quitting smoking is to
   a. accept the patient's decision and not intervene until the patient expresses a desire to quit.
   b. ask the patient to identify the risks and benefits of quitting and what barriers to quitting are present.
   c. realize that some smokers never quit, and trying to assist them increases the patient's frustration.
   d. motivate the patient to quit by describing how continued smoking will worsen the breathing problems.
4. While caring for a patient who is experiencing alcohol withdrawal, the nurse should *(select all that apply)*
   a. monitor neurologic status on a routine basis.
   b. provide a quiet, nonstimulating, dimly lit environment.
   c. pad the side rails and place suction equipment at the bedside.
   d. orient the patient to environment and person with each contact.

e. give antiseizure drugs and sedatives to relieve withdrawal symptoms.

5. A patient admitted for scheduled surgery has a positive brief screening test result for an alcohol use disorder. Which initial action is *most* appropriate?
   a. Notify the health care provider.
   b. Complete a detailed alcohol use assessment.
   c. Initiate a referral to a specialty treatment center.
   d. Provide patient teaching on postoperative health risks.
6. Substance use problems in older adults are usually related to
   a. use of drugs and alcohol as a social activity.
   b. continuing the use of illegal drugs started during middle age.
   c. misuse of prescribed and over-the-counter medications and alcohol.
   d. a pattern of binge drinking for weeks or months with periods of sobriety.

1. b, 2. a, 3. b, 4. a, c, d, e, 5. b, 6. c

Case Study

Managing Care of Multiple Patients

You are assigned to care for the following 5 patients on a medical-surgical unit. Your team consists of yourself, a new LPN still on orientation, and a UAP.

Patients

 © Luevanos/iStock/Thinkstock.	M.S. is an 81-yr-old woman who came to the United States from India 4 years ago with her daughter, son-in-law, and their 4 children. She speaks minimal English, relying on her oldest granddaughter to translate. M.S., who has a history of diabetes, was admitted to the hospital yesterday with a diagnosis of heart failure.
 © Thomas M Perkins/ Shutterstock.	M.L. is a 60-yr-old Asian woman who was admitted to the hospital with a diagnosis of exacerbation of chronic obstructive pulmonary disease (COPD). She is receiving O_2 at 2 L/min via nasal cannula. Her condition is currently stable.
 © azndc/iStock/ Thinkstock.	C.L. is a 73-yr-old Taiwanese woman who was brought to the ED by her son. Her chief complaint is shortness of breath. She has a history of COPD, hypertension, and diabetes. She was diagnosed with community-acquired pneumonia, which is being treated with IV antibiotics.
 © azndc/iStock/Thinkstock.	K.C. is a 280-lb (127-kg) 68-yr-old black man with diabetes who was admitted for incision and drainage of a right abdominal abscess. He is being discharged on his second postoperative day. His daughter will assist with dressing changes at home.
 © JPC-PROD/iStock/Thinkstock.	C.M. is a 78-yr-old woman who was admitted from the ED after falling and fracturing her right hip. She is in Buck's traction and is scheduled to undergo surgical repair later this morning. She has a history of substance use, and her blood alcohol content (BAC) was 120 mg/dL (0.12 %) on admission. The night nurse reports that she has been confused and restless overnight.

Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide rationale.

2. ***Collaboration*:** Which morning task(s) could you delegate to the LPN *(select all that apply)*?
   a. Obtain a capillary blood glucose reading on K.C.
   b. Assess C.L.'s IV site for signs of phlebitis or infiltration.
   c. Access the hospital's available translation services for M.S.
   d. Provide discharge teaching on wound care for K.C. and her daughter.
   e. Titrate M.L.'s O_2 to obtain a pulse oximetry reading of 95% (as ordered by the HCP).
3. ***Priority and Collaboration:*** When you and the LPN enter M.S.'s room, you find her sitting up in bed with labored respirations. Although you cannot understand what she is saying, you note that she is unable to say more than a few words without stopping for a breath. Which *initial* action would be the *most* appropriate?
   a. Give M.S.'s cardiac and respiratory medications and reassess her in 30 minutes.
   b. Ask the LPN to stay with M.S. while you go to the nurse's station to call the HCP.
   c. Have the LPN find M.S.'s granddaughter so that she can translate what M.S. is trying to tell you.
   d. Ask the LPN to obtain an O_2 saturation and vital signs while you perform a respiratory assessment.

Case Study Progression

M.S.'s assessment reveals bibasilar crackles, 2+ dependent pitting edema, BP 175/84, pulse 116, RR 32, temp 36.8°C, and pulse oximetry 88% on room air. You apply O_2 at 4 L/min via nasal cannula and obtain an order from M.S.'s HCP for furosemide 40 mg IV stat. After

giving the diuretic, M.S.'s granddaughter arrives and you discuss her grandmother's condition. She tells you that her grandmother asked her to bring in potato chips and soda yesterday. She did not think her grandmother should be eating salt, but M.S. insisted that the dietitian said that she could eat them.

4. On further investigation, the dietitian tells you that an interpreter (translator) was not available when she saw M.S. yesterday. Because the dietitian did not understand what the patient was saying, she could not respond to her questions. She planned to visit M.S. today when the granddaughter is present. Being a culturally competent nurse, you realize that M.S. most likely interpreted the dietitian's silence as
   a. agreement with what A.Z. was asking.
   b. demonstrating a lack of respect for A.Z.'s wishes.
   c. a lack of understanding by the dietitian as to what she was asking.
   d. a need for the dietitian to get more information before answering her questions.
5. Which assessment findings may suggest elder mistreatment by C.L.'s son with whom she lives *(select all that apply)*?
   a. 2 sacral ulcers
   b. Asking when her son is coming to visit
   c. Multiple small bruises on her forearms and shins
   d. Matted hair, poor oral hygiene, overgrown toenails
   e. C.L. becomes totally silent when her son comes to visit
6. Knowing that C.M.'s confusion and restlessness overnight may indicate acute alcohol withdrawal, you perform a

more thorough assessment. Your assessment reveals a score of 11 on the Clinical Institute Withdrawal Assessment for Alcohol Scale. To prevent alcohol delirium, you plan to give which medication per the HCP's order?

a. morphine

b. naloxone

c. lorazepam

d. IV thiamine

7. ***Priority Decision:*** You assess C.M. and find her trying to pull out the IV line and remove the Buck's traction. What action should you do *first*?

   a. Have the UAP stay with C.M.

   b. Ask C.M.'s daughter to stay with her.

   c. Obtain a restraint order from the HCP.

   d. Move C.M. to a room closer to the nurse's station.

8. ***Management Decision:*** The UAP informs you that the LPN is not following C.L.'s fall risk protocol. What is your *most* appropriate action?

   a. Notify the unit manager as soon as possible.

   b. Ask the UAP to explain hospital protocol to the LPN.

   c. Write up the LPN's actions so they will be included in her evaluation.

   d. Talk to the LPN about the importance of following protocol to prevent C.L. from sustaining a fall-related injury.

Inflammation and Healing

Catherine R. Ratliff

LEARNING OUTCOMES

1. Describe the inflammatory response, including vascular and cellular responses and exudate formation.
2. Explain local and systemic manifestations of inflammation and their physiologic bases.
3. Describe the drug therapy, nutrition therapy, and nursing management of inflammation.
4. Distinguish among healing by primary, secondary, and tertiary intention.
5. Describe the factors that delay wound healing and common complications of wound healing.
6. Describe the nursing and interprofessional management of wound healing.
7. Explain the etiology and clinical manifestations of pressure injuries.
8. Apply a patient risk assessment for pressure injuries to measures used to prevent the development of pressure injuries.
9. Discuss nursing and interprofessional management of a patient with pressure injuries.

Conceptual Focus

Health Promotion
Inflammation
Nutrition
Pain
Perfusion
Sensory Perception
Tissue Integrity

This chapter focuses on inflammation, wound healing, and pressure injury prevention and management. Maintaining skin and tissue

integrity is a key nursing role. Multiple concepts are closely related to tissue integrity. Adequate nutrition and perfusion are essential so that the body has the necessary factors to promote healing when injury occurs. Impaired mobility and sensory perception increase the risk for injury. When injury does occur, pain and problems regulating temperature and fluid and electrolyte balance are common.

Inflammatory Response

The **inflammatory response** is a sequential reaction to cell injury. It neutralizes and dilutes the inflammatory agent, removes necrotic materials, and establishes an environment suitable for healing and repair. The term *inflammation* is often incorrectly used as a synonym for *infection.* Inflammation is always present with infection, but infection is not always present with inflammation. However, a person who is neutropenic may not be able to mount an inflammatory response. An infection involves invasion of tissues or cells by microorganisms, such as bacteria, fungi, and viruses. In contrast, heat, radiation, trauma, chemicals, allergens, and an autoimmune reaction also can cause inflammation.

The mechanism of inflammation is basically the same regardless of the injuring agent. The intensity of the response depends on the extent and severity of injury and on the injured person's reactive capacity. The inflammatory response can be divided into a vascular response, cellular response, formation of exudate, and healing. Fig. 11.1 shows the vascular and cellular response to injury.

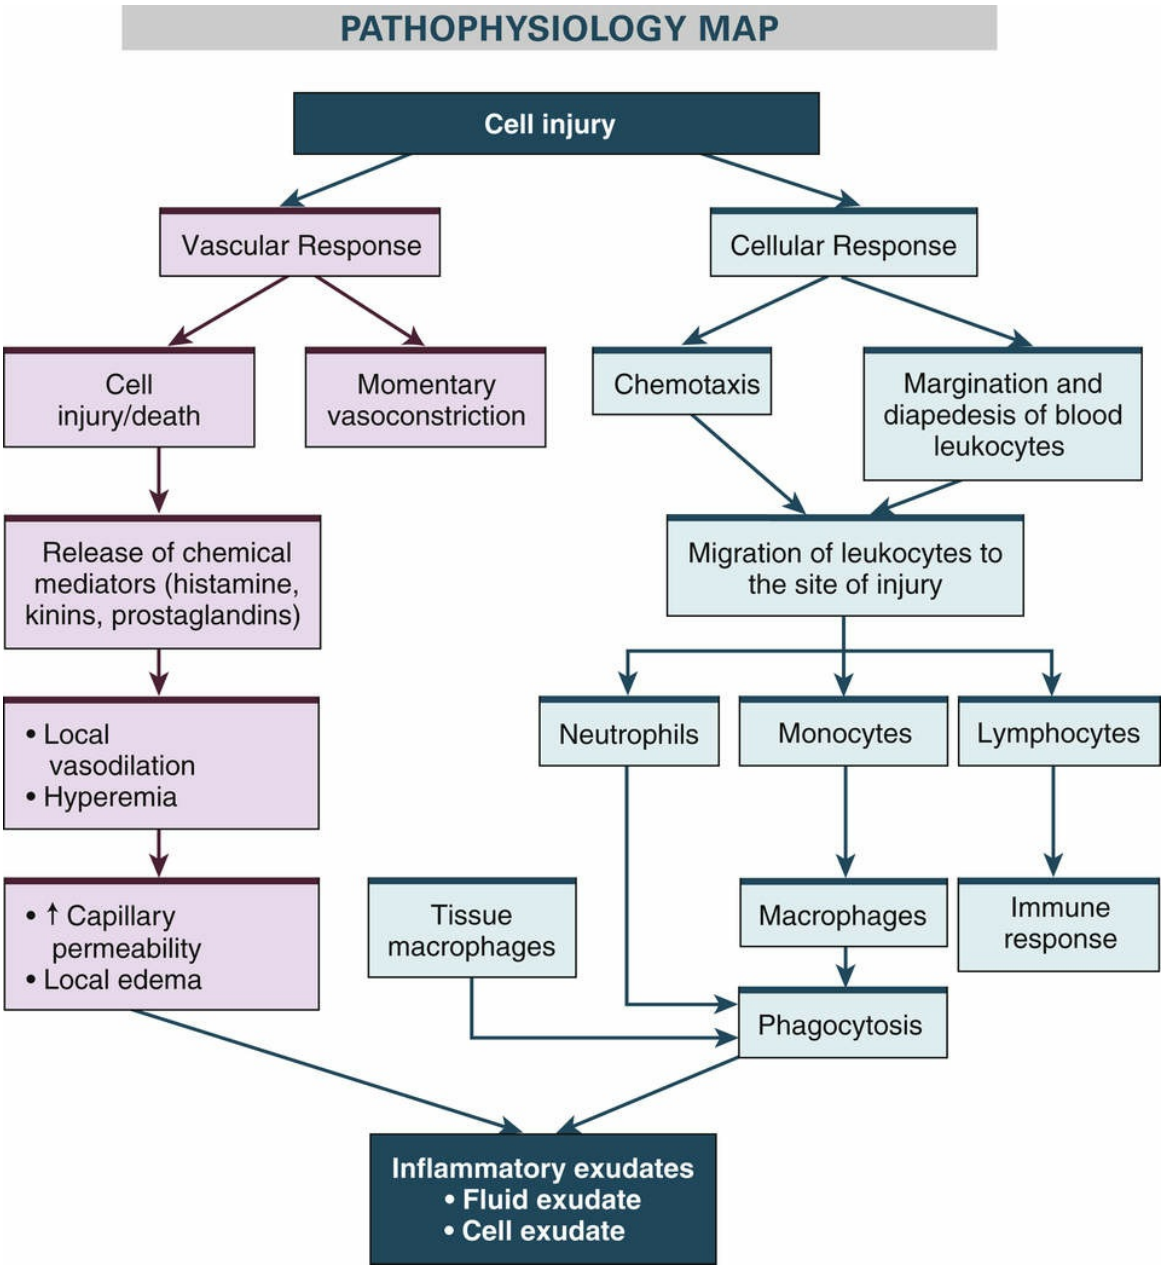

FIG 11.1 Vascular and cellular responses to tissue injury.

Vascular Response

After cell injury, local arterioles briefly undergo transient vasoconstriction. After release of histamine and other chemicals by the injured cells, the vessels dilate. Chemical mediators cause increased capillary permeability and facilitate fluid movement from capillaries into tissue spaces. At first this inflammatory exudate is made up of

serous fluid. Later, it contains plasma proteins, primarily albumin. These proteins exert oncotic pressure that further draws fluid from blood vessels. Both vasodilation and increased capillary permeability are responsible for redness, heat, and swelling at the site of injury and the surrounding area.

As the plasma protein fibrinogen leaves the blood, it is activated to fibrin by the products of the injured cells. Fibrin strengthens a blood clot formed by platelets. In tissues, the clot functions to trap bacteria, prevent their spread, and serve as a framework for the healing process. Platelets release growth factors that start the healing process.

Cellular Response

Neutrophils and monocytes move from circulation to the site of injury (Fig. 11.1). *Chemotaxis* is the directional migration of white blood cells (WBCs) to the site of injury, resulting in an accumulation of neutrophils and monocytes at the site.

Neutrophils

Neutrophils are the first WBCs to arrive at the injury site (usually within 6 to 12 hours). They phagocytize (engulf) bacteria, other foreign material, and damaged cells. With their short life span (24 to 48 hours), dead neutrophils soon accumulate. In time, a mixture of dead neutrophils, digested bacteria, and other cell debris accumulates as a creamy substance called *pus.*

To keep up with the demand for neutrophils, the bone marrow releases more neutrophils into circulation. This results in a high WBC count, especially the neutrophil count. Mature neutrophils are called *segmented neutrophils*. Sometimes the demand for neutrophils increases to the extent that the bone marrow releases immature forms of neutrophils *(bands)* into circulation. We call an increased number of band neutrophils in circulation a *shift to the left.* It is common in patients with acute bacterial infections. (See Chapter 29 for a discussion of neutrophils.)

Monocytes

Monocytes are the second type of phagocytic cells that migrate from circulating blood. They usually arrive at the site within 3 to 7 days after the onset of inflammation. On entering the tissue spaces, monocytes transform into macrophages. Together with the tissue macrophages, these newly arrived macrophages help in phagocytosis of the inflammatory debris. The macrophage role is important in cleaning the area before healing can occur. Macrophages have a long life span. They can multiply and may stay in the damaged tissues for weeks. These long-lived cells are important in orchestrating the healing process.

TABLE 11.1 Mediators of Inflammation

Mediator	Source	Mechanisms of Action
Complement components (C3a, C4a, C5a)	Anaphylatoxic agents generated from complement pathway activation	Stimulate histamine release and chemotaxis
Cytokines	See	
Histamine	Stored in granules of basophils, mast cells, platelets	Causes vasodilation and increased capillary permeability
Serotonin	Stored in platelets, mast cells, enterochromaffin cells of GI tract	Same as above. Stimulates smooth muscle contraction
Kinins (e.g., bradykinin)	Produced from precursor factor kininogen because of activation of Hageman factor (XII) of clotting system	Cause contraction of smooth muscle and vasodilation. Result in stimulation of pain
Prostaglandins (PGs) and leukotrienes (LTs)	Produced from arachidonic acid (Fig. 11.2)	PGs cause vasodilation. LTs stimulate chemotaxis

When particles are too large for a single macrophage, macrophages accumulate and fuse to form a *multinucleated giant cell.* Collagen encapsulates this giant cell, leading to the formation of a granuloma.

A classic example of this process occurs in tuberculosis of the lung. While the *Mycobacterium* bacillus is walled off, a chronic state of inflammation exists. The granuloma formed is a cavity of necrotic tissue.

Lymphocytes

Lymphocytes arrive later at the site of injury. Their primary role is related to humoral and cell-mediated immunity (see Chapter 13).

Chemical Mediators

Mediators of the inflammatory response are outlined in Table 11.1.

Complement System

The complement system is an enzyme cascade (C1 to C9) consisting of pathways to mediate inflammation and destroy invading pathogens. Major functions of the complement system are enhanced phagocytosis, increased vascular permeability, chemotaxis, and cellular lysis. All these activities are important mediators of the inflammatory response and healing.

Cell lysis occurs when the final components create holes in the cell membranes and cause targeted cell death by membrane rupture. In autoimmune disorders, complement activation and the resulting inflammatory response can damage healthy tissue. Examples of this include rheumatoid arthritis and systemic lupus erythematosus.

Prostaglandins and Leukotrienes

When cells are activated by injury, the arachidonic acid in the cell membrane is rapidly converted to produce prostaglandins (PGs), thromboxane, and leukotrienes (Fig. 11.2). PGs are considered proinflammatory. They are potent vasodilators contributing to increased blood flow and edema formation.

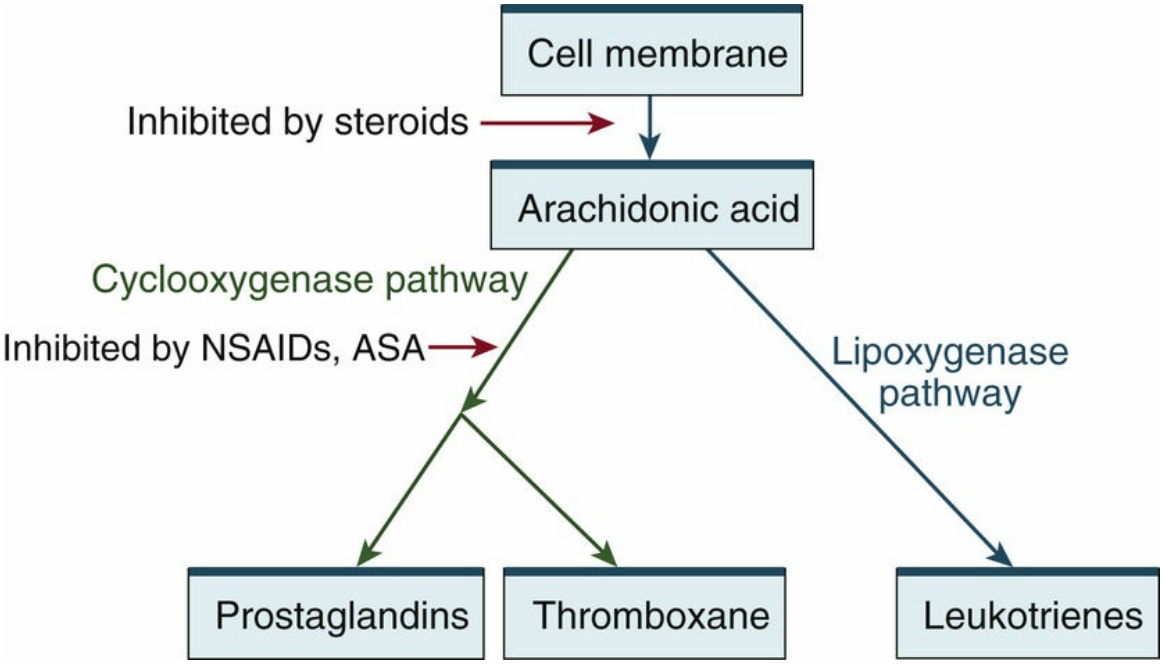

FIG 11.2 Pathway of generation of prostaglandins, thromboxane, and leukotrienes. Corticosteroids, nonsteroidal antiinflammatory drugs *(NSAIDs),* and acetylsalicylic acid *(ASA)* act to inhibit various steps in this pathway.

Some subtypes of PGs form when platelets are activated and can inhibit platelet and neutrophil aggregation. PGs have a significant role in sensitizing pain receptors to arousal by stimuli that would normally be painless. PGs have a pivotal role as pyrogens when stimulating the temperature-regulating area of the hypothalamus and producing a febrile response (see section on Fever on p. 158).

Thromboxane is a powerful vasoconstrictor and platelet-aggregating agent. It causes brief vasoconstriction and skin pallor at the injury site and promotes clot formation. It has a short half-life. The pallor soon gives way to vasodilation and redness, which is caused by PGs and histamine.

Leukotrienes form the slow-reacting substance of anaphylaxis (SRS-A). SRS-A constricts smooth muscles of the bronchi, causing narrowing of the airway, and increases capillary permeability, leading to airway edema.

Exudate Formation

Exudate consists of fluid and WBCs that move from the circulation to the site of injury. The nature and quantity of exudate depend on the type and severity of the injury and tissues involved (Table 11.2).

Clinical Manifestations

The *local* manifestations of inflammation include redness, heat, pain, swelling, and loss of function (Table 11.3 and Fig. 11.3). *Systemic* manifestations include an increased WBC count with a shift to the left, malaise, nausea and anorexia, increased pulse and respiratory rate, and fever.

Leukocytosis results from the increased release of WBCs from the bone marrow. The causes of other systemic manifestations may be related to complement activation and the release of *cytokines* (soluble factors secreted by WBCs and other types of cells that act as intercellular and intracellular messengers). Some cytokines (e.g., interleukins [ILs], tumor necrosis factor [TNF]) are important in causing fever and other systemic manifestations of inflammation. An increase in pulse and respiration follows the rise in metabolism because of an increase in body temperature. (Cytokines are discussed in Chapter 13.)

Fever

The release of cytokines triggers the onset of fever. Cytokines cause fever by initiating metabolic changes in the temperature-regulating center in the hypothalamus (Fig. 11.4). The synthesis of PGs is the most critical metabolic change. PGs act directly to increase the thermostatic set point. The hypothalamus then activates the autonomic nervous system to stimulate increased muscle tone and shivering and decreased perspiration and blood flow to the periphery. Epinephrine released from the adrenal medulla increases the metabolic rate. The net result is fever.

TABLE 11.2 Types of Inflammatory Exudate

Type	Description	Examples
Catarrhal	Found in tissues where cells produce mucus Inflammatory response accelerates mucus production	Runny nose associated with upper respiratory tract infection
Fibrinous	Occurs with increasing vascular permeability and fibrinogen leakage into interstitial spaces Excessive amounts of fibrin that coats tissue surfaces may cause them to adhere	Adhesions, gelatinous ribbons seen in surgical drain tubing Frequently covers fluid-exuding wounds, such as venous injuries
Hemorrhagic	Results from rupture or necrosis of blood vessel walls	Hematoma, bleeding after surgery or tissue trauma
Purulent (pus)	Consists of WBCs, microorganisms (dead and alive), liquefied dead cells, and other debris	Furuncle (boil), abscess, cellulitis (diffuse inflammation in connective tissue)
Serosanguinous	Found during the midpoint in healing after surgery or tissue injury Composed of RBCs and serous fluid, which is semiclear pink and may have red streaks	Surgical drain fluid
Serous	Results from outpouring of fluid. Seen in early stages of inflammation or when injury is mild	Skin blisters, pleural effusion

TABLE 11.3 Local Manifestations of Inflammation

Manifestations	Cause
Heat	Increased metabolism at inflammatory site
Loss of function	Swelling and pain
Pain	Change in pH. Nerve stimulation by chemicals (e.g., histamine, prostaglandins). Pressure from fluid exudate
Redness	Hyperemia from vasodilation
Swelling	Fluid shift to interstitial spaces. Fluid exudate accumulation

With the physiologic thermostat raised to a higher-than-normal temperature, the body increases heat production and conservation until the temperature reaches that new set point. At this point, the person feels chilled and shivers. The shivering response is the body's method of raising the body's temperature to the new set point.[1] This seeming paradox is dramatic: the body is hot, yet the person piles on blankets and may go to bed to get warm. When the body temperature reaches the set point, the chills and warmth-seeking behavior cease.

FIG 11.3 Inflammation secondary to postoperative deep wound infection after wrist surgery.
From Hayden RJ, Jebson PJL: Wrist arthrodesis, *Hand Clin* 21[4]:631, 2005.

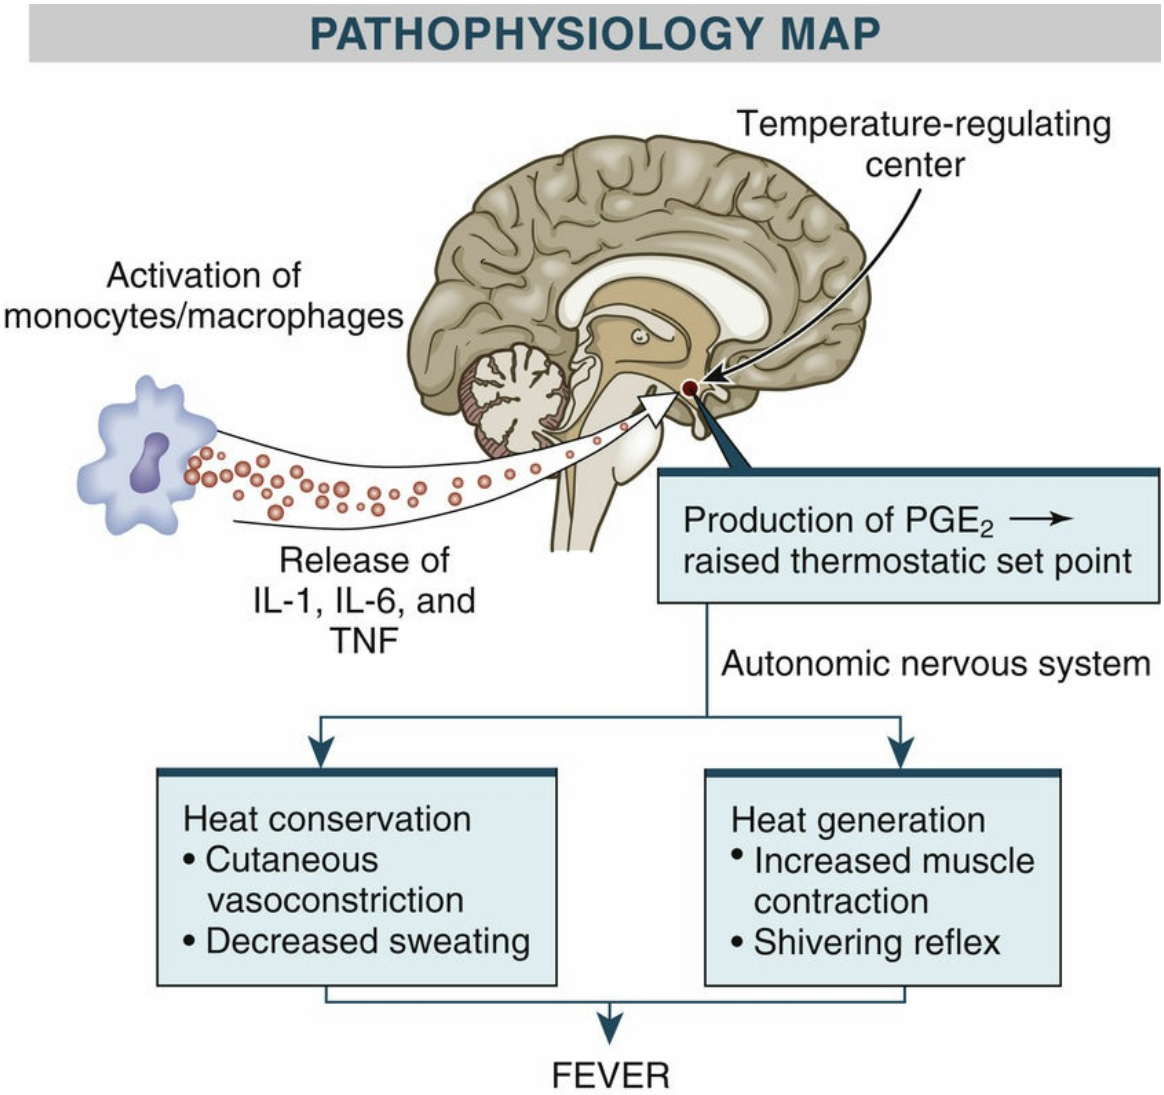

FIG 11.4 Production of fever. When monocytes/macrophages are activated, they secrete cytokines such as interleukin-1 *(IL-1),* interleukin-6 *(IL-6),* and tumor necrosis factor *(TNF),* which reach the hypothalamic temperature-regulating center. These cytokines promote the synthesis and secretion of prostaglandin E_2 *(PGE_2)* in the anterior hypothalamus. PGE_2 increases the thermostatic set point, and the autonomic nervous system is stimulated, resulting in shivering, muscle contraction, and peripheral vasoconstriction.

The released cytokines and the fever that they trigger activate the body's defense mechanisms. Beneficial aspects of fever include increased killing of microorganisms, increased phagocytosis by neutrophils, and increased proliferation of T cells. Higher body temperatures may enhance the activity of interferon, the body's natural virus-fighting substance (see Chapter 13).

Types of Inflammation

The basic types of inflammation are acute, subacute, and chronic. In *acute inflammation,* the healing occurs in 2 to 3 weeks and usually leaves no residual damage. Neutrophils are the predominant cell type at the site of inflammation. A *subacute inflammation* has the features of the acute process but lasts longer. For example, infective endocarditis is a smoldering infection with acute inflammation, but it lasts for weeks or months (see Chapter 36).

Chronic inflammation lasts for weeks, months, or even years. The injurious agent persists or repeatedly injures tissue. The predominant cell types present at the site of inflammation are lymphocytes and macrophages. Examples of chronic inflammation include rheumatoid arthritis and osteomyelitis. The prolongation and chronicity of any inflammation may be the result of an alteration in the immune response (e.g., autoimmune disease) and can lead to physical deterioration.

Nursing and Interprofessional Management: Inflammation

Nursing Implementation

Health Promotion

The best management of inflammation is the prevention of infection, trauma, surgery, and contact with potentially harmful agents. This is not always possible. A simple mosquito bite causes an inflammatory response. Because occasional injury is inevitable, concerted efforts to minimize inflammation and infection are needed.

Adequate nutrition is essential so that the body has the necessary factors to promote healing when injury occurs. A high fluid intake will replace fluid loss from perspiration. There is a 7% increase in metabolism for every 1°F increase in temperature above 100°F (37.8°C), or a 13% increase for every 1°C increase. The increased metabolic rate increases a patient's need for calories.

Early recognition of inflammation is essential so that appropriate treatment can begin. This may be rest, drug therapy, or specific treatment of the injured site. Immediate treatment may prevent the extension and complications of inflammation.

Acute Care

Observation and Vital Signs

The ability to recognize the manifestations of inflammation is important. In the immunosuppressed person (e.g., taking corticosteroids, receiving chemotherapy), the classic manifestations of inflammation may be masked. The early symptoms of inflammation may be malaise or "just not feeling well."

Vital signs are important to note with any inflammation, especially when an infectious process is present. With infection, the temperature may rise, and pulse and respiration rates may increase.

Fever

An important aspect of fever management is determining its cause. Although many regard fever as harmful, an increase in body temperature is an important host defense mechanism. In the seventeenth century, Thomas Sydenham noted that "fever is a mighty engine which nature brings into the world for the conquest of her enemies."[2]

Steps are often taken to lower body temperature to relieve anxiety of the patient and health care professionals. Because mild to moderate fever usually does little harm, imposes no great discomfort, and may help host defense mechanisms, antipyretic drugs are rarely essential to patient welfare. Moderate fevers (up to 103°F [39.4°C]) usually produce few problems in most patients. However, if the patient is very young or very old, is extremely uncomfortable, or has a significant medical problem (e.g., severe heart or lung disease, brain injury), antipyretic use should be considered. Fever in the immunosuppressed patient should be treated immediately with antibiotic therapy because infections can rapidly progress to

septicemia. (Neutropenia is discussed in Chapter 30 on pp. 631.)

Fever, especially if greater than 104°F (40°C), can damage body cells, and delirium and seizures can occur. At temperatures greater than 105.8°F (41°C), the hypothalamic temperature control center becomes impaired. Damage can occur to many cells, including those in the brain.

TABLE 11.4 Drug TherapyInflammation and Healing

Drug	Mechanism of Action
Antipyretic Drugs	
Acetaminophen (Tylenol)	Inhibits synthesis of prostaglandins (PGs). Lowers temperature by action on heat-regulating center in hypothalamus
NSAIDs (e.g., ibuprofen [Advil])	Inhibit synthesis of PGs
Salicylates (aspirin)	Inhibit synthesis of PGs (Fig. 11.2). Lower temperature by action on heat-regulating center in hypothalamus, resulting in peripheral vasodilation and heat loss
Antiinflammatory Drugs	
Corticosteroids (e.g., prednisone)	Interfere with tissue granulation, induce immunosuppressive effects (decreased lymphocyte synthesis), prevent liberation of lysosomes
NSAIDs (e.g., ibuprofen, piroxicam [Feldene])	Inhibit synthesis of PGs
Salicylates (aspirin)	Inhibit synthesis of PGs, reduce capillary permeability
Vitamins	
Vitamin A	Accelerates epithelialization
Vitamin B complex	Acts as coenzymes
Vitamin C	Aids in synthesis of collagen and new capillaries
Vitamin D	Facilitates calcium absorption

Older adults have a blunted febrile response to infection. The body temperature may not rise to the level expected for a younger adult, or there may be a delay in the onset of the rise. The blunted response can delay diagnosis and treatment. By the time fever (as defined for younger adults) is present, the illness may be more severe. Patients who are taking nonsteroidal antiinflammatory drugs (NSAIDs) on a regular basis (e.g., for rheumatoid arthritis) may have a blunted febrile response.

Although sponge baths increase evaporative heat loss, they may not decrease the body temperature unless the person received antipyretic

drugs to lower the set point. Otherwise, the body will initiate compensatory mechanisms (e.g., shivering) to restore body heat. The same principle applies to the use of cooling blankets. They are most effective in lowering body temperature after the set point has been lowered.

A nursing care plan for the patient with a fever (eNursing Care Plan 11.1) is available on the website for this chapter at *http://evolve.elsevier.com/Lewis/medsurg*.

Drug Therapy

Drugs can decrease the inflammatory response and lower the body temperature (Table 11.4). Aspirin blocks PG synthesis in the hypothalamus and elsewhere in the body. Acetaminophen acts on the heat-regulating center in the hypothalamus. Some NSAIDs (e.g., ibuprofen [Motrin, Advil]) have antipyretic effects. Corticosteroids are antipyretic through the dual actions of preventing cytokine production and PG synthesis. This results in dilation of superficial blood vessels, increased skin temperature, and sweating.

Check Your Practice

A 76-yr-old female patient has acute osteomyelitis after a fractured femur. You are checking her temperature every 2 hours and giving acetaminophen when it is higher than 102°F. However, you notice that her temperature is fluctuating from 96° to 103°F.

- What should you do?

Antipyretics cause a sharp decrease in temperature. They should be given around the clock to prevent acute swings in temperature. Giving them intermittently can induce or perpetuate chills. When the antipyretic wears off, the body may initiate a compensatory involuntary muscular contraction (i.e., chill) to raise the body temperature back up to its previous level. We can prevent this

unpleasant side effect by giving them regularly at 2- to 4-hour intervals.

Antihistamine drugs may be used to inhibit the action of histamine. Antihistamines are discussed in Chapters 13 and 26.

Rice

Rest, **i**ce, **c**ompression, and **e**levation (RICE) is a key concept in treating soft tissue injuries and related inflammation.

Rest

Rest helps the body use its nutrients and O_2 for the healing process. The repair process is facilitated by allowing fibrin and collagen to form across the wound edges with little disruption.

Cold and heat

Cold application is usually appropriate at the time of the initial trauma. Use promotes vasoconstriction and decreases swelling, pain, and congestion from increased metabolism in the area of inflammation. Heat may be used later (e.g., after 24 to 48 hours) to promote healing by increasing the circulation to the inflamed site and subsequent removal of debris. Heat is used to localize the inflammatory agents. Warm, moist heat may help debride the wound site if necrotic material is present.

Compression and immobilization

Compression counters the vasodilation effects and development of edema. Compression by direct pressure over a laceration occludes blood vessels and stops bleeding. Compression bandages support injured joints when tendons and muscles are unable to provide support on their own. Assess distal pulses and capillary refill before and after application of compression to evaluate whether compression has compromised circulation (e.g., pale color of skin, loss of feeling).

Immobilization of the inflamed or injured area promotes healing by decreasing the tissues' metabolic needs. Immobilization with a cast or splint supports fractured bones and prevents further tissue injury

from sharp bone fragments that could sever nerves or blood vessels, causing hemorrhage. As with compression, evaluate the patient's circulation after application and at regular intervals. Swelling can occur within the closed space of a cast and compromise circulation.

Elevation

Elevating the injured extremity above the level of the heart reduces the edema at the inflammatory site by increasing venous and lymphatic return. Elevation helps reduce pain associated with blood engorgement at the injury site. Elevation may be contraindicated in patients with significantly reduced arterial circulation.

TABLE 11.5 Regenerative Ability of Different Types of Tissues

Tissues	Cell Type	Description
Skin, lymphoid organs, bone marrow, and mucous membranes	Labile cells	Cells divide constantly. Injury to these organs is followed by rapid regeneration.
Liver, pancreas, kidney, and bone cells	Stable cells	Retain their ability to regenerate but do so only if the organ is injured. Regeneration is slow.
Neurons of the central nervous system (CNS) and skeletal and cardiac muscle cells	Permanent cells	Do not divide. Damage to CNS neurons or skeletal or heart muscle can lead to permanent loss. Healing of skeletal and cardiac muscle will occur by repair with scar tissue. If neurons in the CNS are destroyed, the tissue is generally replaced by glial cells. Neurogenesis may occur from stem cells (see Chapter 55).

Healing Process

The last phase of the inflammatory response is healing. Healing includes 2 major components: regeneration and repair.

Regeneration

Regeneration is the replacement of lost cells and tissues with cells of the same type. The ability of cells to regenerate depends on the cell type (Table 11.5).

Repair

Repair is healing, with connective tissue replacing lost cells. Repair is the more common type of healing and usually results in scar formation. Repair is a more complex process than regeneration. Most injuries heal by connective tissue repair. Repair healing occurs by primary, secondary, or tertiary intention (Fig. 11.5).

Primary Intention

Primary intention healing takes place when wound margins are neatly approximated, as in a surgical incision or a paper cut. A continuum of processes is associated with primary healing (Table 11.6). These processes include 3 phases.

Initial Phase

In the *initial* (inflammatory) phase, the edges of the incision are aligned and sutured (or stapled) in place. The incision area fills with blood from the cut blood vessels, blood clots form, and platelets release growth factors to begin the healing process. This forms a matrix for WBC migration. An acute inflammatory reaction occurs.

The area of injury is composed of fibrin clots, erythrocytes, neutrophils (dead and dying), and other debris. Macrophages ingest and digest cellular debris, fibrin fragments, and red blood cells (RBCs). Extracellular enzymes derived from macrophages and neutrophils help digest fibrin. As the wound debris is removed, the fibrin clot serves as a meshwork for future capillary growth and migration of epithelial cells.

Granulation Phase

The *granulation* phase is the second step. The components of granulation tissue include proliferating fibroblasts; proliferating capillary sprouts *(angioblasts);* various WBCs; exudate; and loose, semifluid, ground substance.

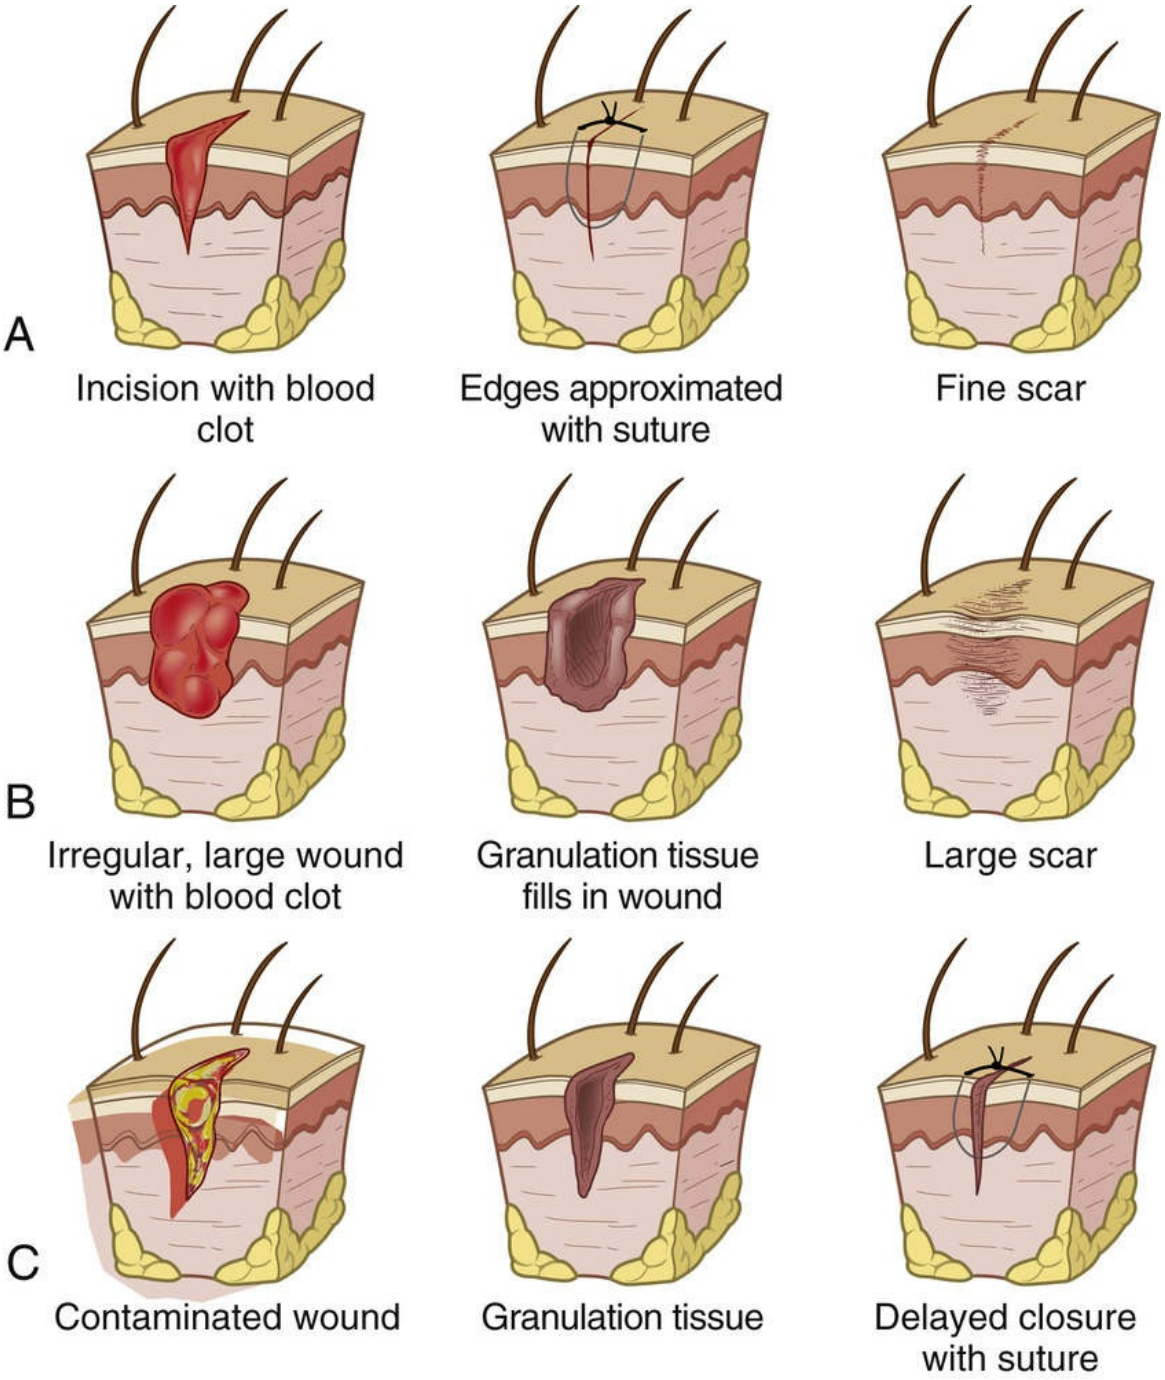

FIG 11.5 Types of wound healing. **A,** Primary intention. **B,** Secondary intention. **C,** Tertiary intention.

TABLE 11.6 Phases in Primary Intention Healing

Phase	Duration	Description
Initial	3 to 5 days	Approximation of incision edges. Migration of epithelial cells. Clot serving as meshwork for starting capillary growth
Granulation	5 days to 4 weeks	Migration of fibroblasts. Secretion of collagen. Abundance of capillary buds. Wound fragile
Maturation and scar contraction	7 days to several months	Remodeling of collagen. Strengthening of scar

Fibroblasts are immature connective tissue cells that migrate into the healing site and secrete collagen. In time, the collagen is organized and restructured to strengthen the healing site. At this stage, it is called *fibrous* or *scar tissue.*

During the granulation phase, the wound is pink and vascular. Numerous red granules (young budding capillaries) are present. At this point, the wound is friable, at risk for dehiscence (Fig. 11.6), and resistant to infection.

Surface epithelium at the wound edges begins to regenerate. In a few days, a thin layer of epithelium migrates across the wound surface in a 1-cell-thick layer until it contacts cells spreading from the opposite direction. The epithelium thickens and begins to mature, and the wound now closely resembles the adjacent skin. In a superficial wound, re-epithelialization may take 3 to 5 days.

FIG 11.6 Dehiscence after a cholecystectomy.
From Bale S, Jones V: *Wound care nursing: A patient-centered approach,* ed 2, St Louis, 2006, Mosby.

Maturation Phase and Scar Contraction

The *maturation* phase, during which scar contraction occurs, overlaps with the granulation phase. It may begin 7 days after the injury and continue for several months or years. This is the reason abdominal surgery discharge instructions limit lifting for up to 6 weeks.

Collagen fibers are further organized, and the remodeling process occurs. Fibroblasts disappear as the wound becomes stronger. The active movement of the myofibroblasts causes contraction of the healing area, helping to close the defect and bring the skin edges closer together. A mature scar is then formed. In contrast to granulation tissue, a mature scar is virtually avascular and pale. The scar may be more painful at this phase than in the granulation phase.

Secondary Intention

Wounds that occur from trauma, injury, and infection have large amounts of exudate and wide, irregular wound margins with extensive tissue loss. These wounds may have edges that cannot be *approximated* (brought together). The inflammatory reaction may be greater than in primary healing. This results in more debris, cells, and exudate. We may have to clear the debris away *(debride)* before healing can take place.

The process of healing by secondary intention is essentially the same as healing by primary intention. The major differences are the greater defect and the gaping wound edges. Healing and granulation take place from the edges inward and from the bottom of the wound upward until the wound is filled. There is more granulation tissue, and the result is a much larger scar.

Tertiary Intention

Tertiary intention (delayed primary intention) healing occurs with delayed suturing of a wound in which 2 layers of granulation tissue are sutured together. This occurs when a contaminated wound is left open and sutured closed after the infection is controlled. It also occurs when a primary wound becomes infected, is opened, allowed to granulate, and then sutured. Tertiary intention usually results in a larger and deeper scar than primary or secondary intention.

Wound Classification

A *wound* is a break or opening into the skin. Wounds often occur because of accidents or injuries. Types of wounds can range from minor scrapes to deep wounds involving bones, blood vessels, and nerves.

Identifying the cause of a wound is essential to classifying the wound properly. Wounds can be classified by their cause (surgical or nonsurgical; acute or chronic) or the depth of tissue affected (superficial, partial thickness, or full thickness). A *superficial wound* involves only the epidermis. *Partial-thickness* wounds extend into the

dermis. *Full-thickness* wounds have the deepest layer of tissue destruction. They involve the subcutaneous tissue and sometimes extend into the fascia and underlying structures, including muscle, tendon, or bone.

A *skin tear* is a wound caused by shear, friction, and/or blunt force resulting in separation of skin layers. A skin tear can be partial thickness or full thickness. This type of wound is common, especially in older adults and critically or chronically ill adults.[3]

Complications of Healing

Certain factors can interfere with wound healing and lead to complications (Table 11.7).

TABLE 11.7 Complications of Wound Healing

Adhesions

- Bands of scar tissue that form between or around organs
- May occur in the abdominal cavity or between the lungs and the pleura
- Those in the abdomen may cause an intestinal obstruction.

Contractions

- Wound contraction is a normal part of healing.
- Complications occur when excessive contraction results in deformity.
- Shortening of muscle or scar tissue, especially over joints, results from excessive fibrous tissue formation.

Dehiscence

- Separation and disruption of previously joined wound edges (Fig. 11.6)
- Usually occurs when a primary healing site bursts open
- May be caused by:
    - Infection causing an inflammatory process
    - Granulation tissue not strong enough to withstand forces imposed on wound
    - Obesity, because adipose tissue has less blood supply and may slow healing
    - Pocket of fluid (seroma, hematoma) developing between tissue layers and preventing the edges of the wound from coming together

Evisceration

- Occurs when wound edges separate to the extent that intestines protrude through wound
- Usually needs immediate surgical treatment

Excess Granulation Tissue ("Proud Flesh")

- Excess granulation tissue may protrude above surface of healing wound.
- If the tissue is cauterized or cut off, healing continues in normal manner.

Fistula Formation

- An abnormal passage between organs or a hollow organ and skin (abdominal or perianal fistula)

Infection (Fig. 11.3)

- ↑ Risk for infection when wound contains necrotic tissue or blood supply is ↓, patient's immune function is ↓ (e.g., from immunosuppressive drugs), undernutrition, multiple stressors, and hyperglycemia in diabetes.

Hemorrhage

- Abnormal internal or external blood loss may be caused by suture failure, clotting abnormalities, dislodged clot, infection, or erosion of a blood vessel by a foreign object (tubing, drains) or infection process.

Hypertrophic Scars

- Inappropriately large, raised red and hard scars (Fig. 11.7)
- Occur when an overabundance of collagen is made during healing

Keloid Formation

- Great protrusion of scar tissue that extends beyond wound edges and may form tumor-like masses of scar tissue (Fig. 11.8)
- Permanent without any tendency to subside
- Patients often have tenderness, pain, and hyperparesthesia, especially in early stages.
- Thought to be a hereditary condition occurring most often in dark-skinned people.

FIG 11.7 Hypertrophic scarring.

Nursing and Interprofessional Management: Wound Healing

Nursing Assessment

The first step in wound care is to carefully assess and document the characteristics of the wound and surrounding area. This includes the location, size (longest length and widest width), depth, undermining and tunneling, wound margin (e.g., normal, macerated, erythema), and wound base (e.g., eschar, slough, exudate). There are several ways to measure a wound. One way is shown in Fig. 11.9. Record the consistency, color, and odor of any drainage and report if abnormal for the situation. *Staphylococcus* and *Pseudomonas* are common organisms that cause purulent, draining wounds.

Thoroughly assess the wound on admission, or first clinic visit, and on a regular basis thereafter. In healthy people, wounds heal at a normal, predictable rate. Assess for factors that may delay wound healing and contribute to chronic nonhealing wounds (Table 11.8). If deterioration in the wound occurs, you need to assess and document changes more often.[4]

Chronic wounds are those that do not heal within the normal time (around 3 months). If a wound does not heal as expected, assess and identify factors that may delay healing. Refer the patient to an HCP specializing in wound management. Time does not heal all wounds. While caring for patients during the healing process, you need to continually assess for complications (e.g., infection) associated with healing (Table 11.7).

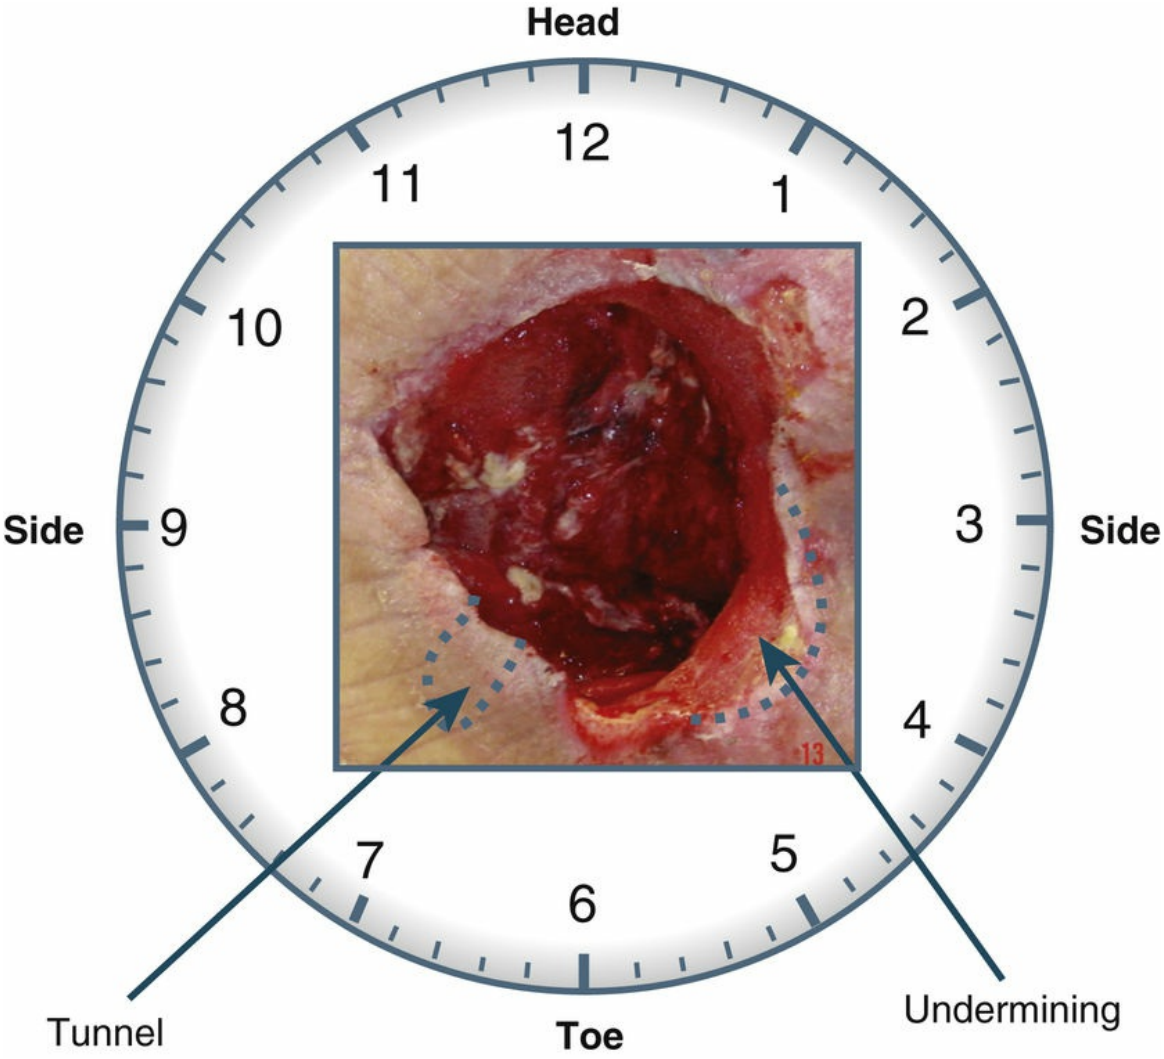

FIG 11.9 Wound measurements are made in centimeters. The first measurement is oriented from head to toe, the second is from side to side, and the third is the depth (if any). If there is any tunneling (when cotton-tipped applicator is placed in wound, there is movement) or undermining (when cotton-tipped applicator is placed in wound, there is a "lip" around the wound), this is charted in respect to a clock, with 12 o'clock being toward the patient's head. This wound would be charted as a full-thickness, red wound, 7 × 5 × 3 cm, with a 3-cm tunnel at 7 o'clock and 2 cm undermining from 3 o'clock to 5 o'clock. Courtesy Robert B. Babiak, RN, BSN, CWOCN, San Antonio, TX.

Nursing Implementation

The type of wound management and dressings needed depend on the type, extent, and characteristics of the wound and the phase of

healing. The purposes of wound management include (1) protecting a clean wound from trauma so that it can heal normally, (2) cleaning a wound to remove any dirt and debris from the wound bed, and (3) treating infection to prepare the wound for healing.

Clean Wounds

Superficial skin injuries may only need cleansing. Material used to close wounds include adhesive strips (e.g., Steri-Strips, butterflies), sutures (stitches), staples, and tissue adhesives (fibrin sealants). We use adhesive strips instead of *sutures* for some injuries because they decrease scarring and it is easier to care for them. Sutures are used to close wounds because suture material provides the mechanical support needed to sustain closure. A wide variety of suturing materials are available. Tissue adhesives are a biologic adhesive that can be applied alone or with sutures or tape.

A dressing material that keeps the wound surface clean and slightly moist is best to promote epithelialization. For wounds that heal by primary intention, it is common to cover the wound or incision with a dry, sterile dressing. It is removed as soon as the drainage stops or in 2 to 3 days. Medicated sprays that form a transparent film on the skin may be used for dressings on a clean incision or injury. Transparent film or adhesive semipermeable dressings (e.g., OpSite, Tegaderm) are occlusive dressings that are permeable to oxygen. The wound is then usually covered with a sterile dressing. Sometimes an HCP will leave a surgical wound uncovered or remove the dressing within 48 hours after surgery.[5] Examples of types of wound dressings are described in Table 11.9.

TABLE 11.8 Factors Delaying Wound Healing

Factor	Effect on Wound Healing
Advanced age	Slows collagen synthesis by fibroblasts, impairs circulation, needs longer time for epithelialization of skin, alters phagocytic and immune responses
Anemia	Supplies less O_2 at tissue level
Corticosteroid drugs	Impair phagocytosis by WBCs, inhibit fibroblast proliferation and function, depress formation of granulation tissue, inhibit wound contraction
Diabetes	Decreases collagen synthesis, delays capillary growth, impairs phagocytosis (result of hyperglycemia), reduces supply of O_2 and nutrients secondary to vascular disease
Inadequate blood supply	Decreases supply of nutrients to injured area, decreases removal of exudative debris, inhibits inflammatory response
Infection	Increases inflammatory response and tissue destruction
Mechanical friction on wound	Destroys granulation tissue, prevents apposition of wound edges
Nutritional deficiencies	
Vitamin C	Delays formation of collagen fibers and capillary development
Protein	Decreases supply of amino acids for tissue repair
Zinc	Impairs epithelialization
Obesity	Decreases blood supply in fatty tissue
Poor general health	Causes generalized absence of factors necessary to promote wound healing
Smoking	Nicotine, a potent vasoconstrictor, impedes blood flow to healing areas

TABLE 11.9 Types of Wound Dressings

Type of Dressing	Description	Uses	Examples
Alginates	Derived from processed seaweed or kelp. Form a nonstick gel on contact with draining wound. Highly absorbent. Easy to use over irregular-shaped wounds. Require a secondary dressing	Wounds with moderate to heavy exudates (e.g., pressure injuries, infected wounds)	Algisite, CalciCare, Kalginate, Melgisorb
Antimicrobials	Alter the wound bed bioburden. Often contain silver, iodine, chlorhexidine, honey, or polyhexamethylene biguanide (PHMB). Available as sponges, impregnated woven gauzes, film dressings, absorptive products, nylon fabric, nonadherent barriers, or a combination of materials		Aquacel, Acticoat, Curity AMD, Iodoflex, Medihoney, SilverSorb, Silvercel
Foams	Film-coated gel or polyurethane. Absorption of minimal to heavy exudate, nonadherent. May need to be affixed with a secondary dressing	Primary dressing for absorption, secondary dressing for wounds with packing. Used for prevention of sacral pressure injuries	Allevyn, Cutimed, Hydrocell, Lyofoam, Mepilex, PolyMem
Gauze	Made of woven or nonwoven material. Absorb exudates. Most often combined with another kind of dressing	Can be used on almost any kind of wound. Cleansing, packing, and covering a variety of wounds	Numerous products available (e.g., Curity, Kerlix)
Hydrocolloids	Gelatin, pectin, or carboxymethylcellulose bonded to a film or sheet. Produce a flat occlusive dressing that forms a gel on wound surface. Occlusion does not interfere with wound healing. Support autolytic debridement and prevent secondary infections	Wounds with light to moderate drainage	Bursamed, Comfeel, DuoDerm, Primacol
Hydrogels	Available in gels, gel-covered gauze, or sheets. Give moisture to a dry wound and maintain a moist environment. Can rehydrate wound tissue. Debridement (autolytic) because of moisturizing effects. Require a secondary dressing	Dry wounds. Wounds with minimal drainage. Necrotic wounds. May have a cooling effect to help decrease pain	Aquasite, Curasol, IntraSite, Purilon, Solosite
Nonadherent	Woven or nonwoven dressings. May be impregnated with saline, petrolatum, or antimicrobials. Minimally absorbent	Minor wounds or as a second dressing	Adaptic, Vaseline gauze, Xeroform
Transparent films	Generally composed of polyurethane. Transparency allows visualization of the wound. Minimally absorbent. Use with caution over superficial wounds. Can result in further tissue loss in fragile wounds (e.g., skin tears). In other wounds, can draw in moisture, increasing risk for infection	Dry, uninfected wounds or wounds with minimal drainage	Bioclusive, OpSite, Suresite, Tegaderm, Transeal

For more information, see www.woundsource.com/product-category/dressings.

Clean wounds that are granulating and re-epithelializing should be kept slightly moist and protected from further trauma until they heal naturally.[6] Do not let a wound that has the potential to heal dry out. Dryness is an enemy of wound healing. "Airing out" a wound is a great mistake. Wounds need a moist environment to heal. Unnecessary manipulation during dressing changes may destroy new granulation tissue and break down fibrin formation.

Topical antimicrobials and antibactericidals (e.g., povidone-iodine [Betadine], Dakin's solution [sodium hypochlorite]), should be used with caution in wound care because they can damage the new epithelium of healing tissue and delay healing. They should never be

used in a clean granulating wound.

Sometimes drains are inserted into the wound to help remove fluid. The Jackson-Pratt drain is a suction drainage device consisting of a flexible plastic bulb connected to an internal plastic drainage tube (Fig. 11.10).

Contaminated Wounds

If the wound is contaminated, it must be converted into a clean wound before healing can occur normally. Debridement of a wound that has debris or dead tissue may be needed. Another option is absorptive dressings. They can be used to absorb exudate and clean the wound surface. These dressings work by drawing excess drainage from the wound surface. The amount of wound secretions determines the number of dressing changes.

In hydrocolloid dressings, such as DuoDerm, the inner part of the dressing interacts with the exudate, forming a hydrated gel over the wound. When the dressing is removed, the gel separates and stays over the wound. The wound must be cleansed gently to prevent damage to newly formed tissue. We can leave these dressings in place for up to 7 days or until leakage occurs around the dressing.

Debridement is done to remove dead tissue.[7] The debridement method used depends on the amount of debris and the condition of the wound tissue (Table 11.10).

Negative-Pressure Wound Therapy

Negative-pressure wound therapy (NPWT) is used to treat acute and chronic wounds. A vacuum source creates continuous or intermittent negative pressure inside the wound to remove fluid, exudates, and infectious materials to prepare the wound for healing and closure. We do not know exactly how NPWT promotes healing. It is thought that NPWT pulls excess fluid from the wound, reduces bacterial load, and encourages blood flow into the wound base.

NPWT systems consist of a vacuum pump, drainage tubing, a foam or gauze wound dressing, and an adhesive film dressing

Nursing Management

Wound Care

In general, the registered nurse (RN) manages wound care for complex or nonhealing wounds. Wound, ostomy, and continence (WOC) nurses may treat and manage pressure injuries, traumatic and draining wounds, surgical incisions, and tubes and fistulas. State nurse practice acts vary in the wound care actions allowed by licensed practical/vocational nurses (LPNs/VNs). In general, the role of the RN includes:

- Assess all patients at risk for pressure injury at time of first hospital and/or home visit or whenever the patient's condition changes. Thereafter, assess at regular intervals based on care setting (every 24 hours for acute care or every visit in home care).
- Assess patients for factors that may delay wound healing and develop a plan of care to address these factors.
- Assess and document initial wound appearance, including wound size, depth, color, and drainage.
- Develop a plan of care to prevent the development of pressure injuries.
- Plan nursing actions to aid with wound healing, including wound care, positioning, and nutritional interventions.
- Choose dressings and therapies for wound treatment (in conjunction with the HCP and/or wound care specialist).
- Implement wound care for complex or new wounds, including negative-pressure wound therapy and hyperbaric O_2 therapy.
- Evaluate whether wound care is effective in promoting wound healing.
- Provide teaching to patient and caregivers about home wound care and pressure injury prevention.
- Oversee LPN/VN:

        - Perform sterile dressing changes on acute and chronic wounds.
        - Apply ordered topical antimicrobials and antibactericidals to wounds.
        - Apply prescribed dressings or medications for wound debridement.
        - Collect and record data about wound appearance.
    - Collaborate with dietitian to:
        - Assess and monitor patient's nutritional status.
        - Outline diet to support proper wound healing.

that covers and seals the wound.[8] In NPWT, the wound is cleansed and a gauze or foam dressing is cut to the dimensions of the wound. A large occlusive dressing is applied, with a small hole made over the gauze or foam dressing where the tubing is attached (Fig. 11.11). The tubing is connected to a pump, which creates a negative pressure in the wound bed.

FIG 11.10 Jackson-Pratt drainage device.
From Perry AG, Potter PA, Elkin MK: *Nursing interventions and clinical skills,* ed 5, St Louis, 2012, Mosby.

TABLE 11.10 Types of Debridement

Type	Description
Autolytic debridement	• Moisture-retentive semiocclusive or occlusive dressings (e.g., hydrocolloids, transparent films, hydrogels) (Table 11.9) that soften dry eschar by autolysis • Must assess area around wound for maceration
Biologic debridement (larval therapy)	• Application of sterile fly larvae to dead tissue
Conservative sharp	• Use of scalpels, curettes, scissors to remove nonviable tissue • Ensure adequate vascular blood supply
Enzymatic debridement	• Drug applied topically to dissolve necrotic tissue and then covered with moist dressing (e.g., saline-moistened gauze) • Process can be slow, and thick eschar may have to be scored with scalpel
Mechanical debridement	• Methods: • *Wet-to-dry dressings,* in which open-mesh gauze is moistened with normal saline, lightly packed into wound surface, and outer layer allowed to dry. Wound debris adheres to dressing and then dressing is removed • *Wound irrigation.* Make certain bacteria are not accidentally driven into wound with high irrigation pressure • Noncontact low-frequency ultrasound and ultrasonic mist
Surgical/sharp debridement	• Quick method of debridement to prevent, control, or remove infection • Used when large amounts of nonviable tissue are present • Prepares wound bed for healing, skin grafting, or flaps

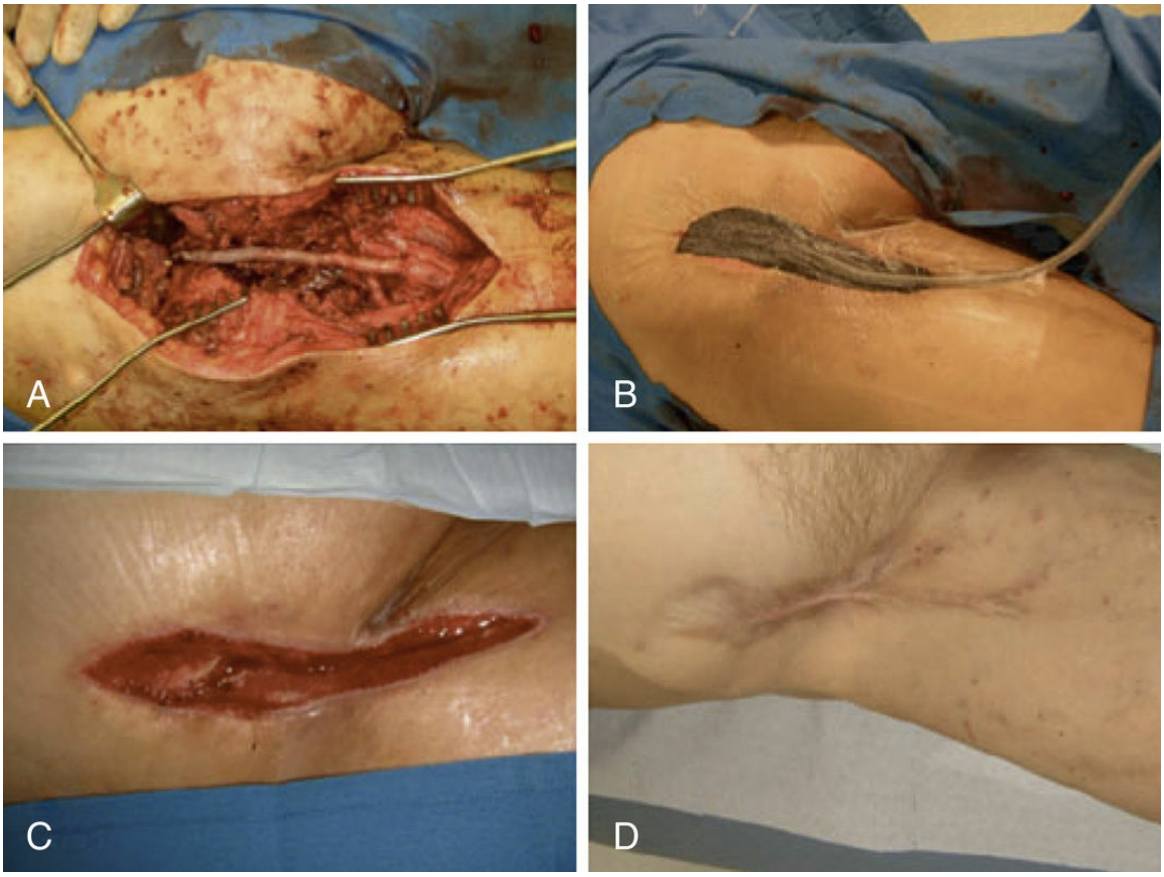

FIG 11.11 Negative-pressure wound therapy in woman with history of IV drug abuse. **A,** The completely destroyed femoral artery was reconstructed with a homograft. **B,** A black open-pore polyurethane foam was directly applied to the vascular reconstruction and negative pressure applied to wound. **C,** Wound site 16 days after surgery. **D,** Healed wound at 28 months without reinfection.
Reprinted from Mayer D, Hasse B, Koelliker J, et al: Long-term results of vascular graft and artery preserving treatment with negative pressure wound therapy in Szilagyi grade III infections justify a paradigm shift, *Ann Surg* 254:754, 2011. © Southeastern Surgical Congress.

Monitor the patient's serum protein levels and fluid and electrolyte balance because of losses from the wound. Also, monitor the patient's coagulation studies (platelet count, prothrombin time [PT], partial thromboplastin time [PTT]).

Hyperbaric Oxygen Therapy

Hyperbaric O_2 therapy (HBOT) is the delivery of O_2 at increased atmospheric pressures. It can be given topically by creating a chamber around the injured limb. It also can be given systemically with the

patient in an enclosed chamber, receiving 100% O_2 at 1.5 to 3 times the normal atmospheric pressure.

HBOT allows O_2 to diffuse into the serum, rather than RBCs, and be transported to the tissues. By increasing the O_2 content in the serum, HBOT moves the O_2 past narrowed arteries and capillaries where RBCs cannot go.

In addition, high O_2 levels stimulate *angiogenesis* (production of new blood vessels), kill anaerobic bacteria, and increase the killing power of WBCs and certain antibiotics (e.g., fluoroquinolones, aminoglycosides). HBOT accelerates granulation tissue formation and wound healing.

Most systemic treatments last from 90 to 120 minutes. The number of treatments is highly variable (from 10 to 60), depending on the condition being treated.

Drug Therapy

Platelet-derived growth factor is released from the platelets and stimulates cell proliferation and migration. Becaplermin (Regranex), a recombinant human platelet–derived growth factor gel, actively stimulates wound healing. It is used to treat foot injuries in patients with diabetes (see Chapter 48). Becaplermin should be used only when the wound is free of dead tissue and infection. It should not be used if cancer is suspected in the wound.

Nutritional Therapy

Special nutritional measures promote wound healing. A high fluid intake is needed to replace fluid loss from perspiration and exudate formation. An increased metabolic rate intensifies water loss. Persons at risk for wound healing problems are those with malabsorption problems (e.g., Crohn's disease, GI surgery, liver disease), deficient intake or high energy demands (e.g., cancer, major trauma or surgery, sepsis, fever), and diabetes.

Undernutrition puts a person at risk for poor healing. A diet high in protein, carbohydrate, and vitamins with moderate fat intake is

necessary to promote healing. Protein is needed to correct the negative nitrogen balance resulting from the increased metabolic rate. It is also needed for the synthesis of immune factors, WBCs, fibroblasts, and collagen, which are the building blocks for healing. Carbohydrates are needed to meet the increased metabolic energy required for healing. If there is a carbohydrate deficit, the body will break down protein for the needed energy. Fats help in the synthesis of fatty acids and triglycerides, which are part of the cellular membrane.[9]

Vitamin C is needed for capillary synthesis and collagen production by fibroblasts. The B-complex vitamins are necessary as coenzymes for many metabolic reactions. If a vitamin B deficiency develops, a disruption of protein, fat, and carbohydrate metabolism will occur. Vitamin A aids in epithelialization. It increases collagen synthesis and tensile strength of the healing wound.

If the patient is unable to eat, enteral feedings and supplements should be the first choice if the GI tract is functional. Parenteral nutrition is indicated when enteral feedings are contraindicated or not tolerated. (Enteral and parenteral nutrition are discussed in Chapter 39.)

Infection Prevention and Control

You and the patient must scrupulously follow aseptic procedures, including hand washing, for keeping the wound free from infection. Do not allow the patient to touch a recently injured area. The patient's environment should be as free as possible from contamination from items introduced by roommates and visitors. Some patients may receive prophylactic antibiotics.

If an infection develops, a culture and sensitivity test is done to determine the organism and the most effective antibiotic for that specific organism. Obtain the culture before the first dose of antibiotic is given. We can obtain cultures by needle aspiration, tissue culture, or swab technique. HCPs perform needle and tissue punch biopsies.

As a nurse, you can obtain cultures using the swab technique. This is done using Levine's technique, which involves rotating a culture swab over a cleansed 1-cm^2 area near the center of the wound. Use

enough pressure to extract wound fluid from deep tissue layers. Take a culture of the clean tissue because exudate and necrotic tissue will not provide an accurate sample.[10] The sample must be sent to the laboratory within 1 hour.

Psychologic Implications

The patient may be distressed at the thought or sight of an incision or wound because of fear of scarring or disfigurement. Drainage and odor from a wound often cause alarm. The patient needs to understand the healing process and normal changes that occur as the wound heals.

When changing a dressing, avoid inappropriate facial expressions that may alert the patient to problems with the wound or raise doubts about your ability to care for it. Wrinkling your nose may convey disgust to the patient. Be careful not to focus on the wound to the extent that you are not treating the patient as a total person.

Patient Teaching

Because patients are being discharged earlier after surgery and many have surgery as outpatients, it is important that the patient and caregiver know how to care for the wound and perform dressing changes. Wound healing may not be complete for 4 to 6 weeks or longer. Emphasize the importance of adequate rest and good nutrition throughout this time. Physical and emotional stress should be minimal. Observing the wound for complications, such as contractures, adhesions, and secondary infection, is important. Teach the patient and caregiver the signs and symptoms of infection. Have them note changes in the wound color and amount of drainage. Teach the patient to notify the HCP of any signs of abnormal wound healing.

Drugs may be given for a time after recovery from the acute infection. Review drug-specific side effects and adverse effects with the patient and caregiver, as well as methods to prevent side effects (e.g., taking with food). Teach the patient to contact the HCP if any of these effects occur. Discuss the need to complete the entire course of therapy. For example, a patient who needed to take an antibiotic for

10 days decides to stop taking the drug after 5 days because of absent symptoms. However, the organism was not entirely eliminated. It becomes resistant to the antibiotic, and the patient develops a more severe infection.

Pressure Injuries

Etiology and Pathophysiology

A **pressure injury** is localized damage to the skin and/or underlying soft tissue. It usually occurs over a bony prominence or is related to a medical or other device. The injury occurs because of intense and/or prolonged pressure or pressure in combination with shear. The most common site for pressure injuries is the sacrum, with heels being second.

TABLE 11.11 Risk Factors for Pressure Injuries

- Advanced age
- Anemia
- Contractures
- Critically ill, cared for in critical care setting
- Diabetes
- Fever
- Friction (rubbing of surfaces together)
- Hip fracture
- Immobility
- Incontinence
- Long and/or extensive surgical procedure
- Low diastolic blood pressure (<60 mm Hg)
- Major trauma

- Mental deterioration
- Neurologic disorders
- Pain
- Peripheral vascular disease
- Spinal cord injury

Factors that influence the development of pressure injuries include the amount of pressure (intensity), length of time the pressure is exerted on the skin (duration), and ability of the patient's tissue to tolerate the externally applied pressure. Other factors that contribute to pressure injury formation include **shear** (pressure exerted on the skin when it adheres to the bed and the skin layers slide in the direction of body movement [e.g., when pulling the patient up in bed]) and *excessive moisture* (increases risk for skin breakdown). The tolerance of soft tissue for pressure and shear are affected by microclimate, nutrition, perfusion, co-morbidities, and condition of the soft tissue.[11]

Factors that put a patient at risk for developing a pressure injury are outlined in Table 11.11. Patients at risk include those who are older, incontinent, unable to reposition or unaware of the need to reposition (e.g., spinal cord injury), and bed- or wheelchair-bound.

Clinical Manifestations

The manifestations of pressure injuries depend on the extent of the tissue involved. The injury can present as intact skin or an open injury and may be painful. We stage pressure injuries based on the visible or palpable tissue in the injury bed. Table 11.12 shows the pressure injury stages based on the National Pressure Injury Advisory Panel (NPUAP).[11]

If the pressure injury becomes infected, the patient may have signs of infection (e.g., leukocytosis, fever). The pressure injury may increase in size, odor, and drainage; have necrotic tissue; and be indurated, warm, and painful. Untreated pressure injuries may lead to

cellulitis (spreading of inflammation to subcutaneous or connective tissue), chronic infection, sepsis, and possibly death. The most common complication of a pressure injury is recurrence. Therefore it is important to note the location of previously healed pressure injuries on a patient's admission assessment.

Nursing and Interprofessional Management: Pressure Injuries

In 1859, Florence Nightingale wrote, "If he has a bedsore, it is generally not the fault of the disease, but of the nursing."[12] Her comment emphasizes the critical role that nurses have in prevention and treatment of pressure injuries.

TABLE 11.12 Pressure InjuriesPressure Injuries

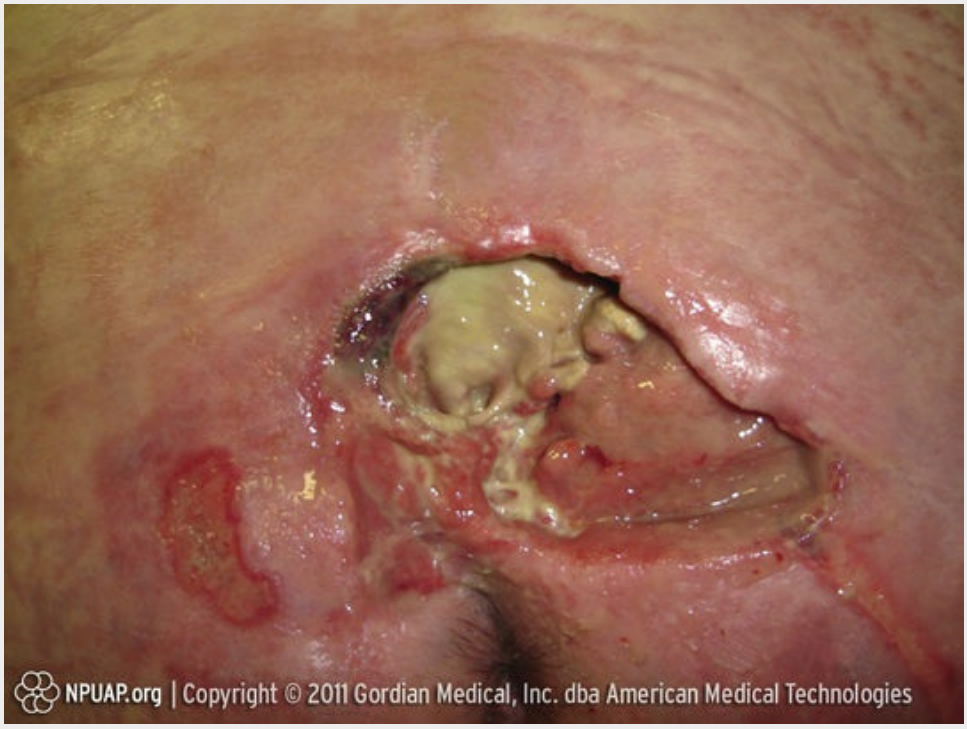
Stage 1 Pressure Injury: Non-Blanchable Erythema of Intact Skin
Intact skin with a localized area of non-blanchable erythema, which may appear differently in dark skin. Blanchable erythema or changes in sensation, temperature, or firmness may precede visual changes.

Stage 2 Pressure Injury: Partial-Thickness Skin Loss With Exposed Dermis

Partial-thickness loss of skin with exposed dermis. The wound bed is viable, pink or red, and moist. May present as an intact or ruptured serum-filled blister. Adipose and deeper tissues are not visible. Often result from adverse microclimate and shear in the skin over the pelvis and shear in the heel.

Stage 3 Pressure Injury: Full-Thickness Skin Loss

Full-thickness loss of skin, in which adipose is visible in the injury. Granulation tissue and epibole (rolled wound edges) are often present. Slough and/or eschar (types of dead tissue) may be visible. The depth of tissue damage varies by anatomical location; areas of significant adiposity can develop deep wounds. Undermining and tunneling may occur.



Stage 4 Pressure Injury: Full-Thickness Skin and Tissue Loss

Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone in the injury. Slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur. Depth varies by anatomical location.

Unstageable Pressure Injury: Obscured Full-Thickness Skin and Tissue Loss

Full-thickness skin and tissue loss in which the extent of tissue damage within the injury cannot be confirmed because it is obscured by slough or eschar. A Stage 3 or Stage 4 pressure injury is present after removing slough or eschar. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed.

Deep Tissue Pressure Injury (DTPI): Persistent Non-Blanchable Deep Red, Maroon, or Purple Discoloration

Intact or non-intact skin with localized area of persistent non-blanchable deep red, maroon, purple discoloration, or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes. Discoloration may appear differently in dark skin. Results from intense and/or prolonged pressure and shear forces at the bone-muscle interface. May evolve rapidly to reveal the actual extent of tissue injury or may resolve without tissue loss. Visible necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures indicates a full-thickness pressure injury (Unstageable, Stage 3 or Stage 4). Do not use DTPI to describe vascular, traumatic, neuropathic, or dermatologic conditions.

Medical Device–Related Pressure Injury

Results from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant injury generally conforms to the pattern or shape of the device. Stage the injury using the staging system.

Mucosal Membrane Pressure Injury

Found on mucous membranes with a history of a medical device in use at the site of the injury. These injuries cannot be staged due to the anatomic location.

Photos used with permission of the National Pressure Injury Advisory Panel. Retrieved from www.npuap.org/resources/educational-and-clinical-resources/pressure-injury-staging-illustrations/.

TABLE 11.13 Assessing Patients With Dark Skin

- Look for changes in skin color, such as skin that is darker

(purplish, brownish, bluish) than surrounding skin.

- Use natural or halogen light source to accurately assess the skin color. Fluorescent light casts blue color, which can make skin assessment difficult.
- Assess the area for the skin temperature using your hand. The area may feel initially warm, then cooler.
- Touch the skin to feel its consistency. Boggy or edematous feel may indicate a Stage 1 pressure injury.
- Ask the patient if he or she has any pain or itchy sensation.

Safety Alert

Pressure Injuries

- Stage 3 or 4 (full skin–thickness injury) pressure injury acquired after admission to a health care setting is considered a serious reportable event (SRE) (never event).[13] (SREs are discussed in Chapter 1.)

Nursing and interprofessional management are discussed together because the activities are interrelated. In addition to the nurse, other members of the health team, such as the wound care specialist, plastic surgeon, dietitian, physical therapist, and occupational therapist, can provide valuable input into the complex treatment necessary to prevent and treat pressure injuries.

Nursing Assessment

Assess patients for pressure injury risk initially on admission and at periodic intervals based on the patient's condition. Conduct a thorough head-to-toe assessment on admission to identify and document any pressure injuries. After admission, conduct periodic reassessments of the skin and wounds.

Safety Alert

Assessing for Pressure Injuries

- In acute care, reassess patients for pressure injuries every 24 hours.
- In long-term care, reassess residents weekly for the first 4 weeks after admission and then at least monthly or quarterly.
- In home care, reassess patients at every nurse visit.

To do a risk assessment, use a validated assessment tool, such as the Braden Scale (available at www.bradenscale.com). Knowing the level of risk can help determine how aggressive preventive measures should be.

Identification of skin changes may be hard in patients with dark skin. Table 11.13 presents techniques to help assess darker skin.

TABLE 11.14 Nursing AssessmentPressure Injuries

Subjective Data

Important Health Information

Past health history: Stroke, spinal cord injury; prolonged bed rest or immobility; circulatory impairment; poor nutrition; altered level of consciousness; prior history of pressure injury; immunologic abnormalities; advanced age; diabetes; anemia; trauma

Medications: Use of opioids, hypnotics, systemic corticosteroids

Surgery or other treatments: Recent surgery

Functional Health Patterns

Nutritional-metabolic: Obesity, emaciation; decreased fluid, calorie, or protein intake; vitamin or mineral deficiencies; clinically significant malnutrition as shown by low serum albumin, decreased total lymphocyte count, and decreased body weight (15% less than ideal body weight)
Elimination: Incontinence of urine, feces, or both
Activity-exercise: Weakness, debilitation, inability to turn and position body; contractures
Cognitive-perceptual: Pain or altered cutaneous sensation in pressure injury area; decreased awareness of pressure on body areas; capacity to follow treatment plan

Objective Data
General

Fever

Integumentary

Diaphoresis, edema, and discoloration, especially over bony areas, such as sacrum, hips, elbows, heels, knees, ankles, shoulders, and ear rims, progressing to increased tissue damage characteristic of injury stages

Possible Diagnostic Findings

Leukocytosis, positive cultures for microorganisms from pressure injury

Subjective and objective data that should be obtained from a person

with or at risk for a pressure injury are outlined in Table 11.14.

Nursing Diagnoses

Nursing diagnoses for the patient with a pressure injury may include:

- Impaired tissue integrity
- Risk for infection

Planning

The overall goals are that the patient with a pressure injury will (1) have no deterioration of the wound, (2) not develop an infection in the pressure injury, (3) have healing of pressure injuries, and (4) have no recurrence.

Nursing Implementation

Health Promotion

The primary nursing responsibilities are (1) identifying patients at risk for developing pressure injuries (Tables 11.11 and 11.14) and (2) implementing pressure injury prevention strategies for those who are at risk. Prevention is the best treatment for pressure injuries. Implementing evidence-based pressure injury prevention programs can reduce the occurrence of health care–acquired pressure injuries.[14,15]

Evidence-Based Practice

Repositioning and Pressure Injuries

You are doing discharge planning with L.H., an obese 76-yr-old woman with a history of diabetes, hypertension, and macular degeneration. L.H. has spent most of her time while hospitalized in a

bed or wheelchair and now has a stage 1 pressure injury on her sacrum. You explain the importance of skin care with her son, who is her primary caregiver.

Making Clinical Decisions

Best Available Evidence. Repositioning is the primary method of reducing the risk for pressure injury. Pressure relief schedules should be developed. Pressure-reducing devices (e.g., foam mattress, padded commode, wheelchair seats) may be used but are not be a substitute for repositioning. In addition, develop a nutrition care plan based on the patient's nutritional and hydration needs, feeding route, and care goals.

Clinician Expertise. You know patients with pressure injury should be repositioned at least every 2 hours while in bed and every hour when in a chair.

Caregiver Preferences and Values. L.H.'s caregiver states he will reposition his mother during the day and have the home health care aide reposition her more often at night.

Implications for Nursing Practice

1. In addition to repositioning, what information is important to discuss with L.H.'s son to prevent further skin injury?
2. What are the risk factors for L.H. to develop worsening pressure injury?
3. What is important for the home health care nurse to monitor on her visits to L.H. related to pressure injuries and healing?

References for Evidence

Edsberg L.E, Black J.M, Goldberg M, et al. Revised National Pressure Advisory Panel Pressure Injury Staging System. *J Wound Ostomy Continence Nurs*. 2016;43(585) National Pressure Injury Advisory Panel. Retrieved from. www.npuap.org/wp-

content/uploads/2014/08/Updated-10-16-14-Quick-Reference-Guide-DIGITAL-NPUAP-EPUAP-PPPIA-16Oct2014.pdf.

Safety Alert

Preventing Pressure Injuries

- Use devices to reduce pressure and shear (e.g., low-air-loss mattresses, foam mattresses, wheelchair cushions, padded commode seats, boots [foam, air], lift sheets) as appropriate. These devices do not replace the need for frequent repositioning.
- Reposition patients often to prevent pressure injuries.

In the past, the "standard" was to turn and reposition patients every 2 hours. However, this "policy" is not evidence-based. Individualize time schedules and frequency based on risk factors, patient's overall condition, and type of mattress and support surface. For example, some high-risk patients may need to be turned and repositioned every hour, while others at lower risk may need to be turned and repositioned only every 3 to 4 hours.[11,14]

Acute Care

Care of a patient with a pressure injury requires wound care and support measures of the whole person, including adequate nutrition, pain management, control of other medical conditions, and redistributing pressure. Both conservative and surgical strategies are used in the treatment of pressure injuries, depending on the stage and condition of the injury.

Once a pressure injury has developed, initiate interventions based on the injury characteristics (e.g., stage, size, location, amount of exudate, type of wound, presence of infection or pain) and the patient's general status (e.g., nutritional state, age, cardiovascular status, level of mobility). Carefully document the size of the pressure

injury. A wound-measuring card or tape can be used to note the injury's maximum length and width in centimeters. To find the depth of the injury, take a sterile cotton-tipped applicator and soak it with saline. Gently place it into the deepest part of the injury, and then measure the length of the part of the applicator that probed the injury. Documentation of the healing wound can be done using several available pressure injury healing tools, such as the NPUAP Pressure Injury Scale for Healing (PUSH) tool (available at www.npuap.org/wp-content/uploads/2012/03/push3.pdf).

Some agencies require that pictures of the pressure injury be taken initially and at regular intervals during treatment. The Informatics box has suggestions for digital imaging.

Informatics in Practice

Digital Images

To monitor wound progress, use digital photography. For the best images:

- Include a ruler with date, length, width, and depth of the wound in each photo.
- Position the patient the same way for each photo.
- Take the photo from the same angle each time. Pointing perpendicularly at the wound is best.
- Use natural light, without flash, whenever possible.
- Show the wound on a solid background, avoiding shiny underpads.
- Avoid patient identifiers, such as jewelry, tattoos, or visible family members.

Pressure injuries generally fall under the category of healing by secondary intention. Care may involve debridement, wound cleaning, application of a dressing, and offloading pressure. It is important to

choose the right pressure-redistributing techniques (e.g., mattress replacement, mattress overlay, integrated bed system, seat cushion, seat cushion overlay) to move pressure off areas of pressure injury. Whenever possible, do not turn the patient onto a body surface that has blanchable erythema. Massage is contraindicated in the presence of acute inflammation and where there is the possibility of damaged blood vessels or fragile skin.

Sliding down in bed causes shear. Encourage patients to reposition themselves by lifting rather than sliding and to use a trapeze if needed. Use lift sheets to move patients up in bed or to transfer them.

A pressure injury that has necrotic tissue or eschar (except for dry, stable necrotic feet or heels) should have the tissue removed by surgical, mechanical, enzymatic, or autolytic debridement methods. Once the pressure injury has been successfully debrided and has a clean granulating base, the goal is to provide a wound environment that supports moist wound healing and prevents disruption of the newly formed granulation tissue. Reconstruction of the pressure injury site by surgical repair, including skin grafting, skin flaps, musculocutaneous flaps, or free flaps, may be necessary.

Clean pressure injuries with noncytotoxic solutions (e.g., normal saline) that do not kill or damage cells, especially fibroblasts. Cytotoxicity is a concern when applying a topical agent to a pressure injury. However, if there is a delay in healing due to infection, then antimicrobial use (e.g., sodium hypochlorite [Dakin's solution], povidone-iodine, cadexomer iodine) overrides the toxicity concern. Hydrogen peroxide is cytotoxic and should not be used. It is important to use enough irrigation pressure (4 to 15 psi) to adequately clean the pressure injury without causing trauma or damage to the wound. You can achieve this pressure using a 30-mL syringe and a 19-gauge needle.

After the pressure injury has been cleansed, cover it with an appropriate dressing. Keep a pressure injury slightly moist, rather than dry, to enhance re-epithelialization. Some factors to consider when choosing a dressing are maintaining a moist environment, preventing the wound from drying out, ability to absorb the wound

drainage, location of the wound, amount of caregiver time required to change the dressing, cost of the dressing, presence of infection, clean versus sterile dressings, and care delivery setting. Dressings are described in Table 11.9.

Stages 2 through 4 pressure injuries are considered contaminated or colonized with bacteria. Remember that in people who have chronic wounds or are immunocompromised, the signs and symptoms of infection (purulent exudate, odor, erythema, warmth, tenderness, edema, pain, fever, high WBC count) may not be present even when the pressure injury is infected.

Maintaining adequate nutrition is an important nursing responsibility for the patient with a pressure injury. Often the patient is debilitated and has a poor appetite secondary to inactivity. Oral feedings must be adequate to meet the patient's nutritional requirements. The caloric intake needed to correct and maintain nutritional balance may be 30 to 35 calories/kg/day and 1.25 to 1.50 g of protein/kg/day.

Enteral feedings can supplement oral feedings. When oral and enteral feedings are inadequate, parenteral nutrition consisting of amino acid and glucose solutions is used. Parenteral and enteral nutrition are discussed in Chapter 39.

Ambulatory Care

Pressure injuries affect the quality of life of patients and their caregivers. Because pressure injuries often recur, teaching prevention techniques to the patient and caregiver is extremely important (Table 11.15). A sixth-grade level version of the patient guide to pressure injury prevention is available for use in patient teaching at www.npuap.org/wp-content/uploads/2016/04/Pressure-Injury-Prevention-Points-2016.pdf.

TABLE 11.15 Patient & Caregiver TeachingPressure Injury

When teaching the patient and caregiver to prevent and care for pressure injuries, do the following:

1. Identify and explain risk factors and cause of pressure injuries.
2. Teach the caregiver techniques for incontinence. If incontinence occurs, cleanse skin at time of soiling and use absorbent pads or briefs.
3. Demonstrate correct positioning to decrease risk for skin breakdown. NEVER position the patient directly on the pressure injury if possible.
4. Teach caregiver to reposition a bed-bound patient at least every 2 hours and a chair-bound patient every hour.
5. Review the available resources (i.e., caregiver's availability and skill, finances, equipment) of patients who need pressure injury care at home.
6. Teach patient and/or caregiver to place clean dressings over sterile dressings using "no touch" technique when changing dressings. Review the disposal of contaminated dressings.
7. Teach patient and caregiver to inspect skin daily. Tell them to report any significant changes to the HCP.
8. Teach patient and caregiver the importance of good nutrition to enhance injury healing.
9. Evaluate program effectiveness.

The caregiver needs to know the cause of pressure injuries, prevention techniques, early signs, nutritional support, and care techniques for actual pressure injuries. Because the patient with a pressure injury often needs extensive care for other health problems, it is important that the nurse support the caregiver with the added responsibility for pressure injury treatment. eNursing Care Plan 11.2 (available on the website for this chapter at http://evolve.elsevier.com/Lewis/medsurg) outlines the care for the patient with a pressure injury.

Evaluation

The expected outcomes are that the patient with a pressure injury will have

- Healing of pressure injury(s)
- Intact skin with no further breakdown

Case Study

Inflammation and Infection

© iStockphoto/Thinkstock.

Patient Profile

G.N., a 65-yr-old black man, was admitted to the hospital emergency department with partial-thickness burns that involved his face, neck, and upper trunk. He also had a lacerated right leg. His injuries occurred about 36 hours earlier when he fell out of a tree onto his lit gas grill while trimming tree branches.

Subjective Data

- Reports a slightly hoarse voice and irritated throat
- States that he tried to treat himself because he does not have health insurance
- Has been coughing up sooty sputum
- Describes severe pain in left hip

Objective Data

Physical Examination

- Leg wound is gaping and has drainage: temperature 101.1°F (38.4°C)
- X-rays reveal a fractured right tibia and fractured left hip

Laboratory Studies

- WBC count 26,400/μL (26.4×10^9/L) with 80% neutrophils (10% bands)

Interprofessional Care

- Surgery was done to repair the left hip.

Discussion Questions

1. What manifestations of inflammation did G.N. exhibit, and what are their pathophysiologic mechanisms?
2. What type of exudate formation did he develop?
3. What is the basis for the development of the temperature?
4. What is the significance of his WBC count and differential?
5. Because his wound was gaping, primary tissue healing was not possible. How would you expect healing to take place? What complications could he develop?
6. What risk factors does G.N. have to develop a pressure injury?
7. ***Priority Decision:*** Based on the assessment data provided, what are the priority nursing diagnoses? Are there any collaborative problems?
8. ***Collaboration:*** What nursing activities related to wound care can be delegated to unlicensed assistive personnel (UAP)?
9. ***Quality Improvement:*** What outcomes would indicate that interprofessional care was effective?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient 1 day postoperative after abdominal surgery has incisional pain, 99.5°F temperature, slight erythema at the incision margins, and 30 mL serosanguinous drainage in the Jackson-Pratt drain. Based on this assessment, what conclusion would the nurse make?

   a. The patient has a normal inflammatory response.

   b. The abdominal incision shows signs of an infection.

c. The abdominal incision shows signs of impending dehiscence.

d. The patient's health care provider must be notified about her condition.

2. The nurse assessing a patient with a chronic leg wound finds local signs of erythema, and the patient reports pain at the wound site. What would the nurse expect to be ordered to assess the patient's systemic response?

a. Serum protein analysis

b. WBC count and differential

c. Punch biopsy of center of wound

d. Culture and sensitivity of the wound

3. A patient in the unit has a 103.7°F temperature. Which intervention would be *most* effective in restoring normal body temperature?

a. Using a cooling blanket while the patient is febrile

b. Giving antipyretics on an around-the-clock schedule

c. Providing increased fluids and have the UAP give sponge baths

d. Giving prescribed antibiotics and placing warm blankets for comfort

4. A nurse is caring for a patient who has a pressure injury that is treated with debridement, irrigations, and moist gauze dressings. How would the nurse expect healing to occur?

a. Cell regeneration

b. Tertiary intention

c. Secondary intention

d. Remodeling of tissues

5. Which patient has the *greatest* risk for experiencing delayed wound healing?
   a. A 65-yr-old woman with stress incontinence
   b. A 52-yr-old obese woman with type 2 diabetes
   c. A 78-yr-old man who has a history of hypertension
   d. A 30-yr-old man who drinks 2 alcoholic beverages per day
6. Which order should a nurse question in the plan of care for an older adult, immobile stroke patient with a pink, clean stage 3 pressure injury?
   a. Pack the wound with foam dressing.
   b. Turn and position the patient every hour.
   c. Clean the wound every shift with Dakin's solution.
   d. Assess for pain and medicate before dressing change.
7. An 85-yr-old patient has a score of 16 on the Braden Scale. What should the nurse include in the plan of care?
   a. Implementing a 1-hour turning schedule with skin assessment.
   b. Elevating the head of bed to 90 degrees when the patient is supine.
   c. Continuing with weekly skin assessments with no special precautions.
   d. Placing a silicone foam dressing on the patient's sacrum to prevent breakdown.
8. Which patients are at *most* risk for pressure injuries? *Select all that apply.*

a. A patient with right sided-paralysis and fecal incontinence

b. An older adult who is alert and needs assistance to ambulate

c. A young adult patient with paraplegia after a gunshot wound

d. A morbidly obese patient who has an open abdominal wound

e. An ambulatory patient who has occasional stress incontinence

f. A young adult with a tibial fracture from a motor vehicle accident

9. An 82year-old man is being cared for at home by his family. A pressure injury on his right buttock measures 1 × 2 × 0.8 cm in depth, and pink subcutaneous tissue is completely visible on the wound bed. Which stage would the nurse document on the wound assessment form?

a. Stage 1

b. Stage 2

c. Stage 3

d. Stage 4

1. a, 2. b, 3. b, 4. c, 5. b, 6. c, 7. a, 8. a, c, d, 9. c

LEARNING OUTCOMES

1. Describe common terms related to genetics and genetic disorders: autosomal, carrier, heterozygous, homozygous, mutation, recessive, and X-linked gene.
2. Distinguish between the 2 common causes of genetic mutations.
3. Compare and contrast the 3 most common inheritance patterns of genetic disorders.
4. Describe the most common classifications of genetic disorders.
5. Explore the complex ethical and social implications of genetic testing.
6. Analyze the role of pharmacogenomics and pharmacogenetics in developing personalized drug therapy.
7. Discuss your role in assisting the patient and family in dealing with genetic and genomic issues.

Genetics and Genomics

Genes are the basic units of heredity. They are composed of sequences of DNA found along a person's chromosomes. Genes are passed from 1 generation to the next. The **genome** is the complete set of DNA. It includes all the organism's genes. An organism's genome has all the information it needs to build and maintain itself.[1]

Genetics is the study of genes and their role in inheritance. Genetics determines the way that certain traits or conditions are passed down through genes. A person's genes can have a profound impact on

health and disease. More than 4000 diseases are thought to be related to altered genes.

Genomics is the study of all a person's genes (the *genome*), including interactions of these genes with each other and with the person's environment. Genomics includes the study of complex diseases, such as heart disease, diabetes, and cancer, because these diseases are typically caused by a combination of genetic and environmental factors rather than by a single gene. Genomics may help us understand why some people who eat healthy diets and exercise regularly die at a young age of cancer, and some people eat unhealthy diets and never exercise and yet live to an old age. Common terms used in genetics and genomics are defined in Table 12.1.

Important advances in genetic and genomic research and technology have affected the delivery of health care services.[2] In response to these scientific developments, nursing organizations have established practice standards that provide a framework for applying the nursing process to the care of persons with genetic and genomic concerns. Other standards outline competencies and education in relation to professional practice and genetics.

The identification of a genetic basis for many diseases has the potential to strongly influence the care of patients at risk for or diagnosed with a disease that has a genetic link. You need to know the basic principles of genetics, be familiar with the impact that genetics and genomics have on health and disease and be prepared to aid the patient and family with genetic issues.

TABLE 12.1 Glossary of Genetic and Genomic Terms

Term	Definition
Allele	One of a series of alternative forms (genotypes) at a specific region (locus) of a chromosome

Autosome	A chromosome other than X or Y. The human genome has 44 autosomes (22 pairs of autosomes)
Carrier	A person who is heterozygous for a gene variant that causes autosomal recessive or X-linked recessive disease. Used to describe heterozygotes for risk alleles of complex traits with variable penetrance, regardless of inheritance type
Carrier rate	Frequency of carriers in a population
Carrier testing	Clinical method used to identify at-risk family members of populations, who are usually asymptomatic but may have a pathogenic variant for an autosomal recessive or X-linked disorder
Chromosome	Microscopic structures in the cell nucleus composed of chromatin, which contain genetic information. Each cell normally has 46 chromosomes in 23 pairs (22 autosome pairs and 2 sex chromosomes)
Codominance	Expression of each pair of alleles when present in the heterozygous state (e.g., AB blood type)
Congenital	Present at birth
Consanguineous	Reproduction between 2 persons from the same bloodline, such as first or second cousins. Consanguineous parentage increases the probability of a rare recessive disease
Dominant allele	Gene that is expressed in the phenotype of a heterozygous person
Familial disorder	A trait that appears with higher frequency among close relatives than in the general population
Gene	Functional unit of heredity. A gene is a unit of DNA sequence that encodes for a specific functional product, such as RNA
Genetic risk	Probability that a trait will occur or recur in a family, based on knowledge of its genetic pattern of transmission
Genetics	Study of genes and their role in inheritance
Genome	All the DNA contained in a person. A person's genetic constitution
Genome-wide association study (GWAS)	A type of genetic mapping study design that involves scanning complete sets of DNA (genomes) of many people to find genetic variations associated with a particular disease
Genomics	Study of how genes interact and influence people's biologic and physical characteristics
Genotype	Genetic identity of a person, comprised of the entire complex of genes inherited from both parents
Haploid	Cells or organisms that have 1 copy of each autosomal chromosome and 1 copy of each sex chromosome. Ova and sperm are haploid. Fertilization results in an embryo with 1 set of chromosomes from each parent (diploid embryo)
Hereditary	Transmission of a disease, condition, or trait from parent to children
Heterozygous	Having 2 different alleles for 1 given gene, 1 inherited from each parent
Homozygous	Having 2 identical alleles for 1 given gene, 1 inherited from each parent
Locus	Position of a gene on a chromosome
Mutation	A change in a gene that affects function. Types include nonsense, missense silent, and frameshift. A mutation associated with a disease is called a *pathogenic variant.* Sometimes mutations are passed from parent to children.
Oncogene	Gene that contributes to the conversion of normal cells to cancer cells.

	Usually dominant
Pedigree	A graphic representation that shows family relationships, gender, age, and presence of diseases for each family member
Pharmacogenetics	Study of variability of drug metabolism related to variations in single genes
Pharmacogenomics	Study of variability of drug metabolism in relation to variations in and interactions of multiple genes or the person's genome
Phenotype	Observable characteristics of a person. Can be measured categorically or quantitatively
Protooncogene	Genes that can be turned into oncogenes by a dominant activating mutation. Oncogenes synthesize structurally altered proteins that result in cancer
Recessive allele	Allele that has no noticeable effect on the phenotype in a heterozygous person
Trait	Physical characteristic that one inherits, such as hair or eye color
X-linked gene	Gene found on the X chromosome rather than an autosome. In general, sex-linked disorders are seen in males

Basic Principles of Genetics

Genes

We think there are around 30,000 genes in each person's genome. Genes carry the instructions (encode) for making proteins that direct the activities of cells. Genes control how a cell functions, including how quickly it grows, how often it divides, and how long it lives. To control these functions, genes make proteins that perform specific tasks and act as messengers for the cell. It is essential that each gene have the correct instructions, or "code," for making its protein so that the protein can perform the proper function for the cell.

Genes are arranged in a specific linear formation along a chromosome (Fig. 12.1). Each gene has a specific location on a chromosome, termed a *locus.* An *allele* is 1 of 2 or more alternative forms of a gene that occupy corresponding loci on *homologous chromosomes* (a pair of chromosomes having corresponding deoxyribonucleic acid [DNA] sequences, with 1 coming from the mother and the other from the father). Each allele codes for a specific inherited characteristic.

When there are 2 different alleles, the allele that is fully expressed is the *dominant allele.* The other allele that lacks the ability to express itself in the presence of a dominant allele is the *recessive allele.* The

actual genetic makeup of the person is called the *genotype.* Physical traits expressed by a person are called the *phenotype.*

Chromosomes

Chromosomes are found in the cell nucleus. They occur in pairs. Humans have 23 pairs of chromosomes. Twenty-two of the 23 pairs of chromosomes are *homologous* and are termed *autosomes.* Autosomes are the same in both males and females. The sex chromosomes make up the twenty-third pair of chromosomes. A female has 2 X chromosomes, and a male has 1 X and 1 Y chromosome. One chromosome of each pair is inherited from the mother and one from the father. Half of each child's chromosomes (and therefore the genetic makeup) comes from his or her father and half from his or her mother.

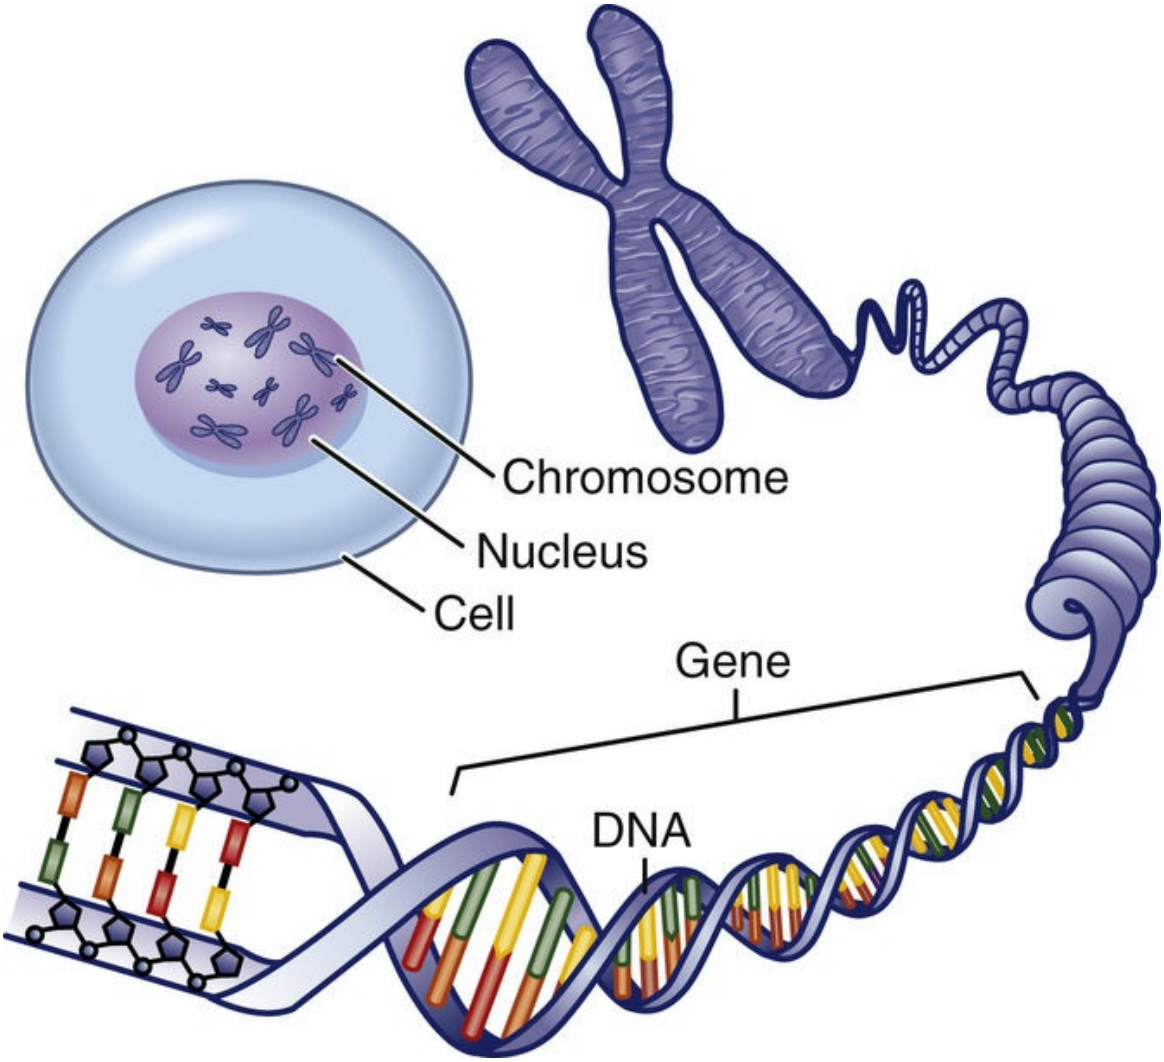

FIG. 12.1 The long, stringy DNA that makes up genes is spooled within chromosomes inside the nucleus of a cell. (Note that a gene would be a much longer stretch of DNA than what is shown here.) Adapted from *The new genetics ,* Bethesda, MD, 2010, National Institute of General Medical Science, National Institutes of Health, U.S. Department of Health and Human Services.

DNA

Genes are made up of a nucleic acid called *deoxyribonucleic acid* (DNA). DNA stores genetic information and encodes the instructions for synthesizing specific proteins needed to maintain life. DNA also dictates the rate at which proteins are made. Every somatic cell in a person's body has the same DNA.

The information in DNA is stored as a code made up of 4

nitrogenous bases: adenine (A), guanine (G), cytosine (C), and thymine (T). Human DNA consists of about 3 billion bases, and more than 99% of those bases are the same in all people. The order, or sequence, of these bases determines the information for building and maintaining an organism. This is similar to the way we use letters of the alphabet to create words and sentences.

DNA bases pair up with each other, A with T and C with G, to form units called *base pairs.* Each base is attached to a sugar molecule and a phosphate molecule (Fig. 12.2). Together, a base, sugar, and phosphate are called a *nucleotide.* Nucleotides are arranged in 2 long strands that form a spiral called a *double helix*. The structure of the double helix is like a ladder, with the base pairs forming the ladder's rungs and the sugar and phosphate molecules forming the ladder's vertical sidepieces.

DNA can *replicate* or make copies of itself. Each strand of DNA in the double helix can serve as a pattern for duplicating the sequence of bases. When cells divide, each new cell must have an exact copy of the DNA that was in the parent (original) cell.

If you uncoiled the chromosomes in a cell and placed it end to end, the DNA would be about 6 feet long. If all the DNA in your body were connected, it would stretch about 67 billion miles.[2]

S
C
Nucleotide

FIG. 12.2 DNA consists of 2 long, twisted chains made up of nucleotides. Each nucleotide contains a base, a phosphate molecule *(P),* and the sugar molecule deoxyribose *(S).* The bases in DNA nucleotides are adenine *(A),* thymine *(T),* cytosine *(C),* and guanine *(G).*
Adapted from *The new genetics,* Bethesda, MD, 2010, National Institute of General Medical Science, National Institutes of Health, U.S. Department of Health and Human Services.

RNA

Ribonucleic acid (RNA) is similar to DNA but with some significant differences. RNA contains the nitrogenous bases adenine, guanine, and cytosine, but it contains uracil instead of thymine. RNA is single, not double, stranded. It contains ribose instead of deoxyribose sugar. RNA transfers the genetic information obtained from DNA to the proper location for protein synthesis.

Protein Synthesis

Protein synthesis, or the making of proteins, occurs in 2 steps: *transcription* and *translation.* Transcription is the process by which messenger RNA (mRNA) is made from single-stranded DNA. The mRNA becomes attached to a ribosome, where translation occurs. At this point another specialized type of RNA, transfer RNA (tRNA), arranges the amino acids in the correct sequence to assemble the protein. Once the protein is complete, it is released from the ribosome and able to perform its specific function in the cell.

Mitosis

Mitosis is a type of cell division that results in the formation of genetically identical daughter cells. Before cell division, the chromosomes duplicate, and each new cell (called *daughter cells*) receives an exact replica of the chromosomes from the original cell (called the *parent cell*).

Meiosis

Meiosis occurs only in germline, or sexual reproductive, cells. Two

consecutive nuclear divisions, meiosis I and meiosis II, occur without chromosomes replicating in between. This results in the production of 4 haploid sex cells. Each has a single copy of each chromosome.

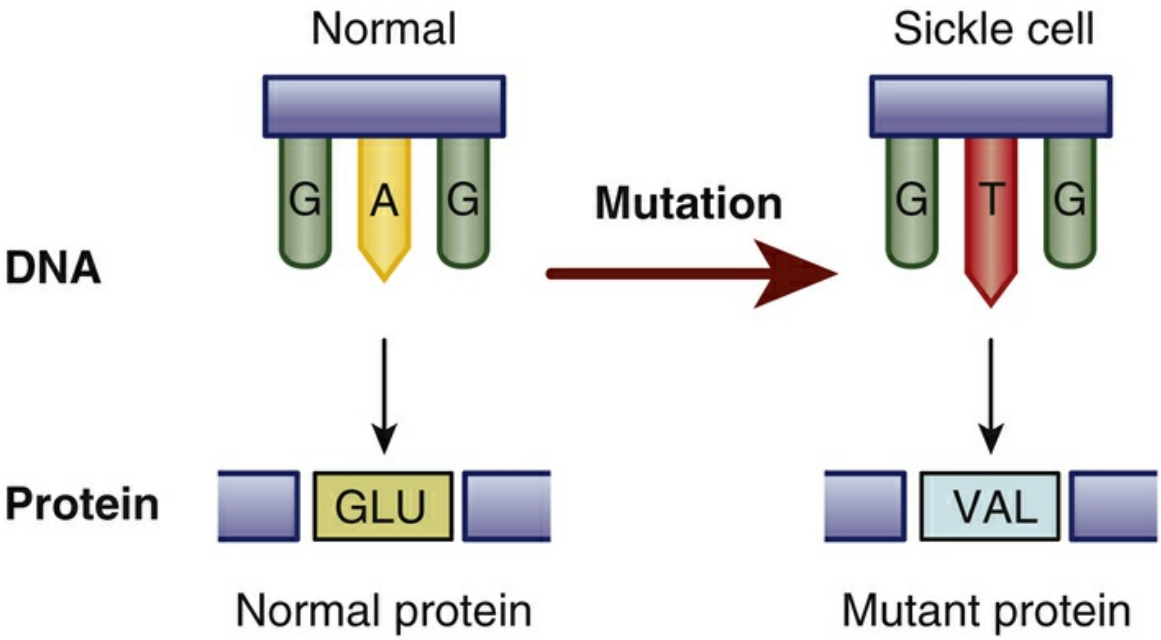

FIG. 12.3 In sickle cell disease, a single gene mutation leads to mutant (incorrect) protein. The substitution of valine *(VAL)* for glutamic acid on the β-globin chain of hemoglobin produces abnormal hemoglobin, hemoglobin S *(Hb S)*. In response to low O_2 levels, the erythrocytes with Hb S stiffen and elongate, taking on a sickle shape (see).

Genetic Mutations

A **mutation** is any change in the usual DNA sequence. Mutations range in size from a single DNA base (building block) to a large segment of a chromosome. The change in gene structure may change the type and/or amount of protein made. The protein may not work at all, or it may work incorrectly. In some cases, genetic mutations do not have an obvious effect on the people who have them. Some gene variations may result in disease or an increased risk for disease. For example, in people with sickle cell disease, a substitution of a single

base (adenine is replaced by thymine) in a single gene (β-globin gene) causes the disease (Fig. 12.3).

Types of Mutations

Genetic mutations occur in 2 ways. They can be inherited from a parent (germline mutation) or acquired (somatic mutation) during a person's lifetime.

Germline mutations are passed from parent to child. These mutations are present in the oocyte and sperm cells. This type of mutation is present throughout a person's life in virtually every cell in the body.

Acquired (somatic) mutations occur in the DNA of a cell at some time during a person's life. An acquired mutation is passed on to all cells that develop from that single cell. These mutations in somatic cells cannot be passed on to the next generation. Acquired mutations can occur if (1) a mistake is made as DNA replicates during cell division or (2) environmental factors alter the DNA.

Mutations can occur when a cell is dividing. During replication, occasionally mistakes, such as deletions, insertions, or duplication of DNA material, can occur. Although DNA repair enzymes can correct replication errors, mistakes can go uncorrected.

DNA damage can also occur from environmental factors. For example, ultraviolet (UV) radiation can cause DNA damage, leading to skin cancer. Toxins in cigarettes can lead to lung cancer. Many chemotherapy drugs used to treat cancer target the DNA of cancer cells and healthy cells. In the process, these drugs increase a person's risk for developing secondary cancers (see Chapter 15).

Cells have built-in mechanisms that catch and repair most of the changes that occur during DNA replication or from environmental damage. However, as we age, our DNA repair does not work as effectively and we accumulate changes in our DNA.

Inheritance Patterns

Genetic conditions can be inherited in several ways, including autosomal dominant, autosomal recessive, X- linked, and Y-linked

disorders. If the mutant gene is found on an autosome, the genetic disorder is called *autosomal.* If the mutant gene is on the X chromosome, the genetic disorder is called *X-linked.* These patterns are considered mendelian patterns of inheritance. They occur less often than multifactorial or complex traits and disorders. Table 12.2 compares characteristics of autosomal dominant, autosomal recessive, and X-linked recessive conditions. Family pedigrees for autosomal recessive and dominant disorders and X-linked recessive disorders are shown in Figs. 12.4 and 12.5. These diagrams will be discussed later in this chapter in the context of documenting a pedigree and family history.

TABLE 12.2 Comparison of Genetic Disorders

Characteristics	Examples
Autosomal Dominant	
• Males and females are affected, or have the disease, equally • More common than recessive disorders and usually less severe • Affected persons show variable expression • Affected persons may have an affected parent • Children of a heterozygous (affected) parent have a 50% chance of being affected • Persons are affected in successive generations	• Breast and ovarian cancer related to *BRCA* genes • Familial hypercholesterolemia • Hereditary nonpolyposis colorectal cancer • Huntington's disease • Neurofibromatosis • Marfan's syndrome
Autosomal Recessive	
• Males and females are affected equally • Heterozygotes are carriers and usually asymptomatic • Affected persons may have unaffected parents who are heterozygous for trait • Children of 2 heterozygous parents have a 25% chance of being affected and a 50% chance of being carriers (Fig. 12.9) • Often no family history of disease	• Cystic fibrosis • Phenylketonuria • Sickle cell disease • Tay-Sachs disease • Thalassemia
X-Linked Recessive	
• Most affected persons have unaffected parents • Affected persons are usually male • Daughters of affected males are carriers • Sons of affected males are unaffected (unless mother is a carrier)	• Duchenne muscular dystrophy • Hemophilia • Wiskott-Aldrich syndrome

Autosomal dominant disorders are caused by a mutation of a single gene pair (heterozygous) on a chromosome. A dominant allele prevails over a normal allele. *Penetrance* describes the chance that a carrier of a dominant mutation will show signs of the disorder. *Incomplete penetrance* occurs when a person with a genetic mutation

does not have signs of the disorder. It explains why a parent who has a genetic disorder may not have signs of the disorder, but the child does. Autosomal dominant disorders show variable expressivity. *Expressivity* describes the way the phenotype manifests. This accounts for how symptoms of a disorder vary from person to person, even though they have the same mutated gene. Symptoms are also influenced by other, usually unknown, genetic factors, gene-environment interactions, and chance events.

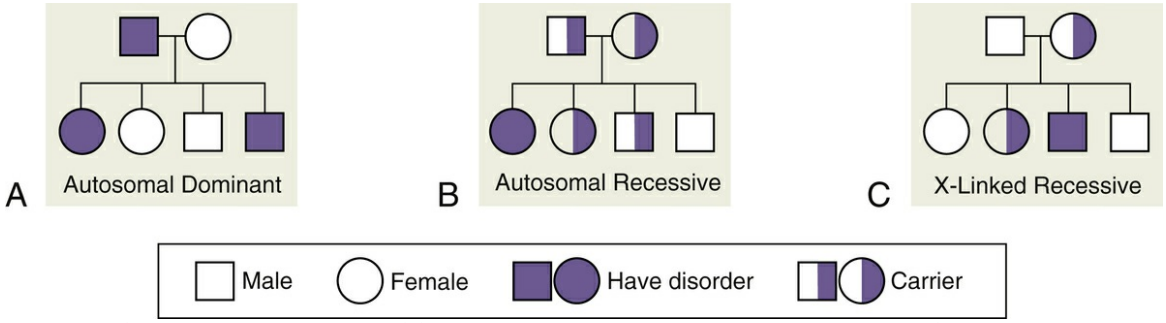

FIG. 12.4 Examples of family pedigrees showing inheritance of **(A)** autosomal dominant, **(B)** autosomal recessive, and **(C)** X-linked recessive disorders.

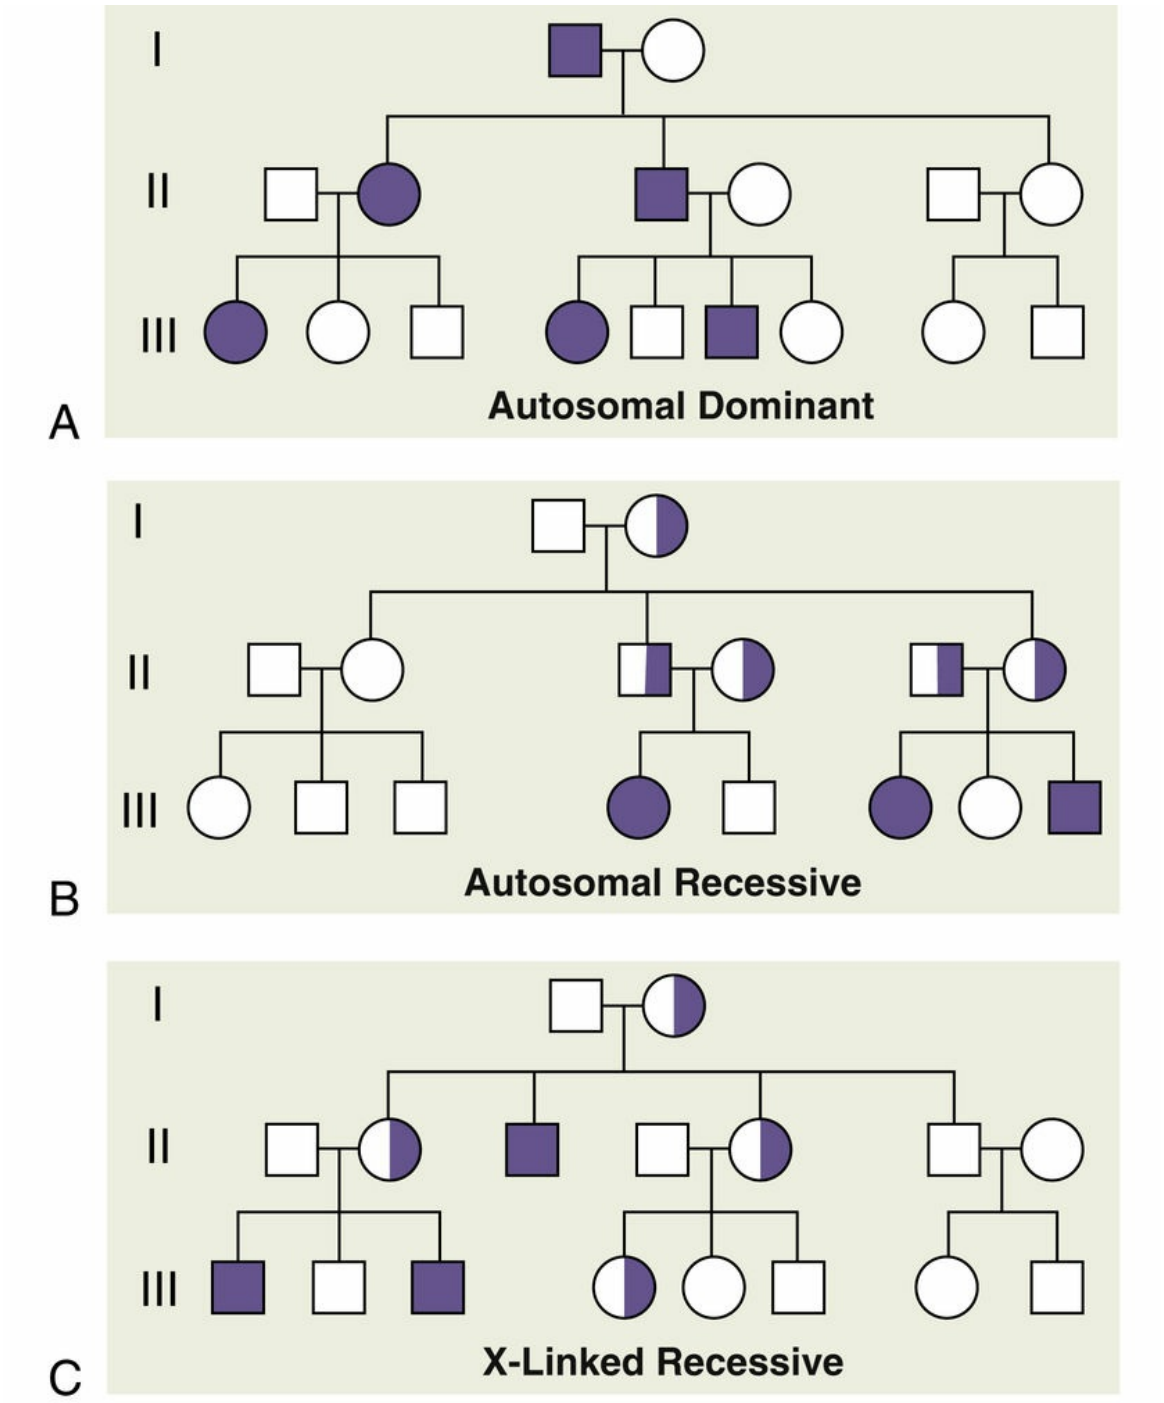

FIG. 12.5 Family pedigrees showing 3 generations. **A,** Family pedigree suggestive of an autosomal dominant disorder. **B,** Family pedigree suggestive of an autosomal recessive disorder. **C,** Family

pedigree suggestive of an X-linked recessive disorder.

Autosomal recessive disorders are caused by mutations of 2 gene pairs (homozygous) on a chromosome. A person who inherits 1 copy of the recessive allele does not develop the disease because the normal allele predominates.[3] However, this person is a *carrier.* Several children of 1 couple may be affected. Males and females are affected with equal frequency and severity. These disorders occur in 1 generation and more often among children of parents who are blood relatives, such as first cousins.

X-linked recessive disorders are caused by a mutation on the X chromosome. Men can be severely affected because they have only 1 X chromosome. Women who carry the mutated gene on 1 X chromosome have another X chromosome to compensate for the mutation. Women who carry the mutated gene can transmit it to their offspring.

Y chromosomal inheritance occurs for genes that are only on the Y chromosome. An affected father transmits the disorder to all his sons. Only men are affected.

Human Genome Project

The Human Genome Project (HGP), which was completed in 2003, mapped the entire human genome.[4] Analysis of the data will continue for many years. The knowledge gained through the HGP will (1) help improve the diagnosis of diseases, (2) allow for earlier detection of genetic predisposition to diseases, and (3) play a critical role in determining risk assessment for genetic-related diseases. In addition, the results of the HGP help match organ donors with transplant recipients.

Genetic Disorders

A *genetic disorder* is caused in whole or in part by a change in the DNA sequence. They can be inherited (person born with altered genetic

code) or they can be acquired (e.g., replication errors, damage to DNA from toxins).[3] Genetic disorders can be caused by (1) a mutation in 1 gene (single gene disorder); (2) mutations in multiple genes (multifactorial inheritance disorder), which are often related to environmental factors; or (3) damage to chromosomes (changes in the number or structure of chromosomes).

Classification of Genetic Disorders

Single Gene Disorders

Some genetic disorders result from a single gene mutation (Fig. 12.6, *A*). Examples include cystic fibrosis, sickle cell disease, and polycystic kidney disease. The pattern of inheritance for single gene disorders can be autosomal dominant, autosomal recessive, or X-linked. Single gene disorders are relatively rare compared with more commonly occurring multifactorial genetic disorders.

Multifactorial Inherited Conditions

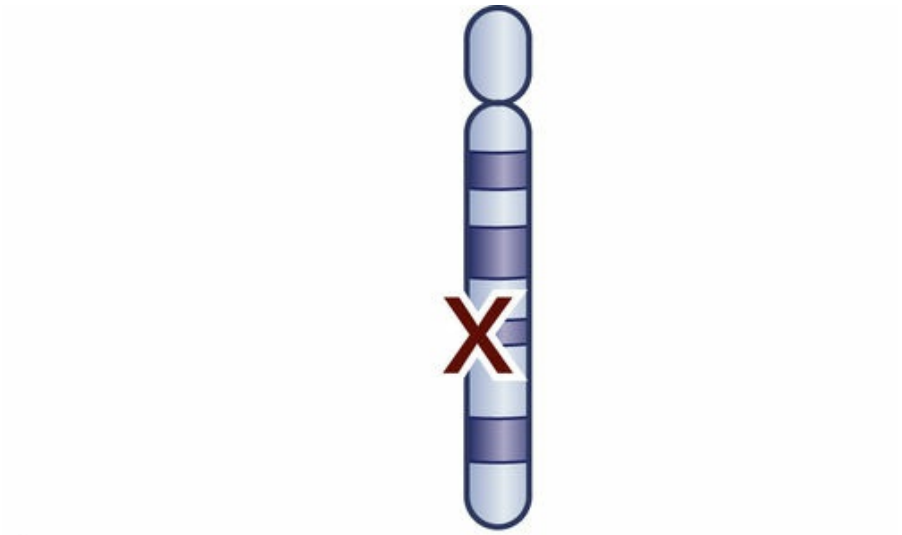
Multifactorial inherited conditions are complex diseases that result from inherited variations in genes acting together with environmental factors (Fig. 12.6, *B*). These disorders run in families but do not show the same inherited characteristics as the single gene mutation conditions. Heart disease, diabetes, and most cancers are examples of such disorders.[5]

Many diseases can also be caused by rare hereditary mutations in a single gene. In these cases, genetic mutations that cause or strongly predispose a person to these diseases run in a family. These mutations can significantly increase each family member's risk for developing the disease. One example is breast cancer, in which inheritance of a mutated *BRCA1* or *BRCA2* gene confers significant risk for developing the disease.

Epigenetics

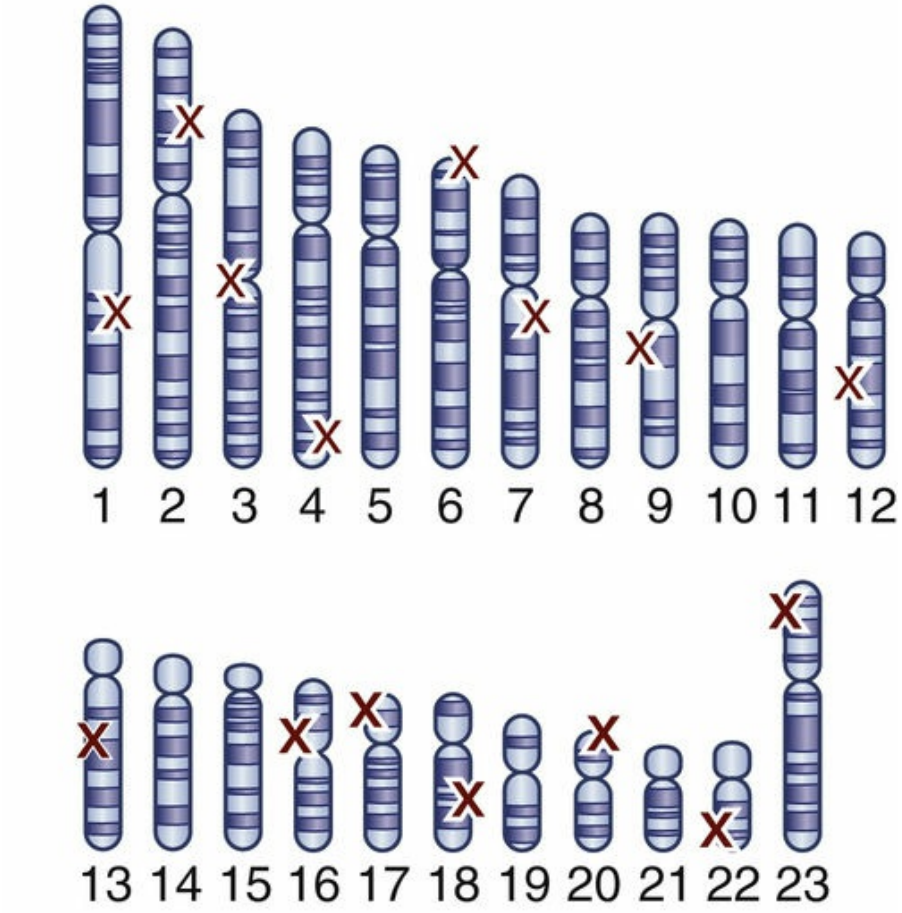
Epigenetics is the study of inheritable changes in gene expression that

do not involve changes in the DNA sequence. There is a change in phenotype without a change in genotype. Epigenetic modifications define how the information in genes is expressed and used by cells.



Epigenetics influences the way cells terminally differentiate to become different types of cells (e.g., skin, liver) or result in disease. Epigenetic changes occur regularly and can be influenced by age, the environment, exercise, diet, and disease. Identical twins, who have the same genetic makeup, do not always develop the same diseases or at the same rate. Twins share the same genes, but their environments become different as they age. This unique aspect of twins makes them an excellent model for understanding how genes and the environment contribute to certain traits, especially complex behaviors and diseases.[6]

Chromosome Disorders



Chromosome disorders are caused by structural changes within chromosomes or by an excess or deficiency of the genes that are found on chromosomes. For example, an extra copy of chromosome 21 causes Down syndrome (called *trisomy 21*), so there are 3 copies of this chromosome instead of 2. In Down syndrome, there is no individual abnormal gene on the chromosome.

Chronic myelocytic leukemia can be caused by a chromosomal translocation, in which portions of 2 chromosomes (chromosomes 9 and 22) are exchanged. This translocation is called the *Philadelphia chromosome*.

Throughout the book, genetic disorders are highlighted in Genetics in Clinical Practice boxes, Genetic Risk Alert boxes (in the assessment chapters), and Genetic Links content (in the management chapters).

A **Mutation in a single gene**

B **Mutations in multiple genes**

FIG. 12.6 **A,** Genetic disorders can be caused by a mutation in a single gene (e.g., sickle cell disease, cystic fibrosis, hemophilia). **B,** Most genetic disorders are multifactorial genetic disorders caused by a combination of mutations in multiple genes, often interacting with environmental factors. Examples include cancer, diabetes, obesity, and hypertension.

Genetics In Clinical Practice

Types 1 and 2 Diabetes and MODY	48	1110

Genetic Screening and Testing

Genetic screening is the first level of detection. It is offered to general or targeted populations who are at risk for a disorder but do not have symptoms or have a family history of the disorder. An example is screening for α-fetoprotein, which is offered to pregnant women to detect fetal anomalies. Community groups, hospitals, or governmental agencies may offer screenings.

Genetic testing is focused on persons and families for a specific reason. Symptoms or family history may show there is increased risk for a specific condition. Testing procedures analyze chromosomes, genes, or any gene product that can determine whether a mutation or predisposition to a condition exists. A person's blood, skin, hair, or saliva can be used to obtain samples for genetic testing. Tissues and cells can be obtained prenatally. In most cases, insurance companies do not cover the cost of genetic testing.

Genetic testing has been very useful in health care (Table 12.3). Genetic tests have been developed for more than 2000 diseases. Most tests assess single genes and are used to diagnose genetic disorders, such as cystic fibrosis or Duchenne muscular dystrophy.[7] Some genetic tests look at rare inherited mutations of otherwise protective genes, such as *BRCA1* and *BRCA2,* which are responsible for some types of hereditary breast and ovarian cancers.[8]

Test results are used to assess risk or diagnose a disorder, an important step in providing ongoing care for the person and family. It is important to identify people at high risk for conditions that may be preventable. For example, persons who have inherited a gene for familial adenomatous polyposis (FAP) need ongoing monitoring.[8] FAP is discussed in Chapter 42 on p. 948.

Genetic testing may raise ethical questions. People considering genetic testing should receive counseling about the various issues. They should be aware that test results in their medical records might not be private and there is the potential for discrimination by employers and insurance companies. To protect people from discrimination by employers and health insurance companies, the federal government passed the Genetic Information Nondiscrimination Act (GINA) in 2008.

Genetics in Clinical Practice

Genetic Information Nondiscrimination Act (GINA)

The Genetic Information Nondiscrimination Act (GINA) is a federal law that prohibits discrimination in health care coverage and employment based on genetic information. Genetic information is any data about a person's genetic tests, family members' genetic tests, and family history of a genetic disease or disorder.

- Addresses concerns about discrimination that might prevent people from seeking genetic tests
- Enables people to take part in research studies without fear that their DNA information may be used against them in the workplace or prevent them from getting health insurance
- Prevents health insurers from denying health insurance coverage and discriminating against a person based solely on genetic or family history information
- Prevents health insurers from asking that a person have a genetic test
- Prohibits most employers from using genetic information for hiring, firing, or promotion decisions and for any decisions about terms of employment
- Protection does not extend to life insurance, disability insurance, and long-term care insurance

For more information see:

- www.genome.gov/Pages/PolicyEthics/GeneticDiscrimination/GIN
- Frequently Asked Questions about GINA at *www.dol.gov/sites/default/files/ebsa/about-ebsa/our-activities/resource-center/faqs/gina.pdf*.

If a person has genetic testing, it may uncover information that may affect a family member who was not tested. These persons may not have taken part in the decision-making process to undergo testing. Similarly, if a whole family is tested, the results may show that a biologic relationship is not what the family believed it to be. For more information about genetic testing, see www.cdc.gov/genomics/gtesting/index.htm.

Interpreting Genetic Test Results

The results of genetic tests are not always straightforward, which often makes them challenging to interpret and explain. When interpreting test results, HCPs need to consider the reason the test was done, pretest counseling provided, the person's medical history, the family history, and the type of genetic test.[8]

A *positive test* result means that the laboratory found a change in a particular gene, chromosome, or protein that was being tested. Depending on the purpose of the test, this result may confirm a diagnosis (e.g., Huntington's disease), show that a person is a carrier of a particular genetic mutation (e.g., cystic fibrosis), identify an increased risk for developing a disease (e.g., breast cancer), or suggest a need for further testing. A positive result of a predictive or presymptomatic genetic test usually cannot establish the absolute risk for developing a disorder. A positive test also cannot predict the course or severity of a condition.

In some situations, it is difficult to interpret a positive result because some people who have the genetic mutation never develop the disease. For example, having the *apolipoprotein E-4 (Apo E-4)* allele increases the risk for developing Alzheimer's disease. However, many people who test positive for *Apo E-4* never develop Alzheimer's disease (see Chapter 59).

A *negative test* result means that the laboratory did not find an altered form of the gene, chromosome, or protein under consideration. This result generally means a person is not affected by a particular disorder, is not a carrier of a specific genetic mutation, or does not

have increased risk for developing a certain disease. It is possible that the test missed a disease-causing genetic alteration. Many tests cannot detect all the genetic changes that cause a particular disorder. Further testing may be needed to confirm a negative result.

Direct-to-Consumer Genetic Tests

Direct-to-consumer genetic tests are marketed directly to people (consumers) via television, print advertisements, or the Internet. The test kit is mailed to the person instead of being ordered through an HCP's office. The test typically involves collecting a DNA sample at home, often by swabbing the inside of the cheek, and mailing the sample back to the laboratory. In some cases, the person must visit a health clinic to have blood drawn. People are notified of their results by mail, over the telephone, or online. In some cases, a genetics counselor or other HCP is available to explain the results and answer questions.

Ethical/Legal Dilemmas

Genetic Testing

Situation

A 30-yr-old woman informs you that she is 3 months pregnant. She has 2 children with her current husband. This pregnancy was unplanned, and her youngest child has cystic fibrosis (CF). She expresses concern about the chance of having another child with CF. She mentions that she would like to have genetic testing on her fetus. Her husband asks you what the chance is of having another child with CF.

Ethical/Legal Points for Consideration

- With genetic testing, the patient and her family can find out whether their child will have CF. The woman and her husband

can then make an informed decision.

- Genetic counseling is recommended before and after genetic testing because of the complexity of the information and the emotional issues involved with implications and options.
- Knowing that CF is an autosomal recessive condition, you can use Punnett squares (Fig. 12.9) or a family pedigree (Figs. 12.4 and 12.5) to show the woman and her husband the probability of having another child with CF.
- Be mindful of the privacy and confidentiality of genetic information and the potential conflict between 1 person's right to privacy and another person's right to information.

Discussion Questions

1. What information would you give the patient and her husband about genetic testing for them to make an informed decision?
2. What options are available for this couple?
3. How would you help this couple as they are considering ending the pregnancy if the results of the genetic testing reveal that the fetus will have CF?

TABLE 12.3 Use of Genetic Tests

Type of Test	Description	Examples
Carrier screening	• Can be used to identify unaffected persons who carry 1 copy of a gene • Offered to persons who have a family history of a genetic disorder and to those in ethnic groups with an increased risk for specific genetic conditions • If both parents are tested, the test can provide information about a couple's risk for having a child with a genetic condition	• Cystic fibrosis • Sickle cell disease • Hemophilia
Diagnostic testing	• Used to diagnose, rule out, or confirm a specific genetic or chromosomal condition • Used to confirm findings when patient's signs and symptoms suggest a genetic disorder • Can be done at any time during a person's life but is not available for all genes or all genetic conditions	• Cystic fibrosis • Sickle cell disease • Polycystic kidney disease • Hemophilia • Familial hypercholesterolemia
Forensic testing	• Done to identify a person for legal purposes	• Identify crime or victims in catastrophic situations • Rule out or implicate a crime suspect
Newborn screening	• Most widespread use of genetic testing • Early intervention to treat these disorders can eliminate or reduce symptoms that may otherwise cause a lifetime of disability	• Phenylketonuria • Congenital hypothyroidism • Cystic fibrosis
Parental testing	• Establish biologic relationships between people	• Paternity testing
Pharmacogenomic testing	• Identifies genetic variations that influence a person's response to drugs • Results provide information to help choose drug therapy that is best for the person	• Warfarin (Coumadin) dose
Predictive testing	• Can identify mutations that increase a person's risk for developing disorders • If results are positive, person can have prophylactic measures (e.g., mastectomy, oophorectomy) to prevent development of cancer	• Breast cancer • Ovarian cancer
Preimplantation genetic diagnosis (PGD)	• Fertilized embryos tested before implantation and pregnancy • Allows embryos free of particular disorders to be placed into the uterus • Embryos that test positive for genetic disorders can be destroyed	• For persons known to have or be a carrier for a genetic mutation (e.g., Huntington's disease)
Prenatal diagnostic testing	• Fluid obtained from amniocentesis or tissue from chorionic villus used to obtain fetal cells. Can obtain fetal samples from mother's blood • Used to detect changes in genes or chromosomes of fetus before birth • Type of testing offered to a couple with an increased risk for having a baby with a genetic or chromosomal disorder • Can decrease a couple's uncertainty or help them decide whether to end a pregnancy	• Down syndrome • Other genetic alterations in fetuses
Presymptomatic testing	• Used to detect genetic mutations associated with disorders that appear later in life • Can be helpful to people who have a family member with a genetic disorder but who have no features of the disorder themselves at the time of testing • Results can provide information about a person's risk for developing a specific disorder and help with making decisions about treatment	• Huntington's disease • Adult polycystic kidney disease • Hemochromatosis • Familial adenomatous polyposis • Hereditary nonpolyposis colorectal cancer syndrome

Direct-to-consumer genetic tests have significant risks and limitations. People may want their genetic information, but they may not understand what it means. They are vulnerable to being misled by the results of unproven or invalid tests. Without guidance from an HCP, they may make important decisions about disease treatment or prevention based on inaccurate, incomplete, or misunderstood information about their health. People may experience an invasion of genetic privacy if testing companies use their genetic information in an unauthorized way. When people are considering using these kinds of genetic tests, nurses should provide education and suggest they discuss the issue with their HCP or a genetics counselor. Teaching related to genetic testing is outlined in Table 12.4.

Genetic Technology

DNA Fingerprinting

DNA (genetic) fingerprinting begins by extracting DNA from the cells in a sample of blood, saliva, semen, or other appropriate fluid or tissue. *Polymerase chain reaction* (*PCR)* is a quick, easy method to provide unlimited copies of a DNA or RNA sequence using only a small amount of sample. PCR involves the artificial replication of a DNA or RNA sequence. The DNA or RNA strands can be separated to form new templates that are used for replication.

PCR is a key element in *genetic fingerprinting.* It is an essential technique to finding mutations in genes. It is used in forensic medicine to identify the DNA of criminal suspects by using samples from blood, hair, saliva, and semen. It has been used to free persons who are wrongly incarcerated. PCR is used in paternity testing and as a confirmatory test in human immunodeficiency virus (HIV) testing. This is especially important when an infant of a mother who is HIV-antibody positive tests HIV positive. In this situation, PCR will determine if the baby is infected with HIV or if the antibodies are from the mother.

DNA Microarray (DNA Chip)

Although all a person's somatic cells have identical genetic material, the same genes are not active in every cell. Studying which genes are active and which are inactive in different cell types helps to understand (1) how these cells function normally and (2) how they are affected when various genes do not perform properly.

TABLE 12.4 Patient & Family TeachingGenetic Testing

Genetic Counselors

- People who are considering genetic testing should meet with a genetics counselor who is specially trained in medical genetics and counseling.
- Counseling is advised to help you understand the purpose of genetic testing, considerations before testing, and the emotional and medical impact of the test results.
- Genetics counseling can help you understand the pros and cons of genetic testing before making a decision to undergo a genetic test.

General Information

The following includes some important general information about genetic testing:

- Genetic testing can be expensive and may not be included in your medical insurance policy.
- Genetic testing may determine whether you are predisposed to developing an inherited disease.
- A particular genetic test will only tell you whether there is a specific genetic variant or mutation. Positive tests do not mean you will develop that disease or disorder. Neither can the results tell you when you will develop the disease.
- If a genetic test shows a genetic predisposition to an inherited disorder, the news can be depressing.
- Knowledge of a genetic predisposition to a disease may give you the motivation to take preventive measures (e.g., taking drugs for familial hypercholesterolemia) or make lifestyle changes to lower the risk for a disease (e.g., exercising to decrease the risk for type 2 diabetes).
- If a genetic test reveals you are at risk for a specific genetic disorder, there is the chance that other family members may be at risk.
- If a genetic test reveals you are at risk for developing an inherited

disease, whether you decide to share that information with family members is a personal and an ethical decision that you will have to make.

- Genetic testing may provide important information that you can use when making decisions about having children.

Gene expression profiling uses a technology called *DNA microarrays* (DNA chips). DNA chips can identify changes in gene sequences or if certain genes are turned off in cells and tissues. It can serve as a diagnostic test or determine if certain medications might have a better therapeutic effect for certain people. The chip is a small glass plate enclosed in plastic. The surface of each chip has thousands of short, synthetic, single-stranded DNA sequences. Together they represent the normal gene, as well as known variations of the gene.

To determine if a mutation is present for a specific disease, a sample of DNA from the blood of the person with suspected disease and a control sample, which does not have a mutation in the gene, are obtained. The DNA in the samples is separated into single-stranded molecules and then cut into small fragments. The fragments are labeled using fluorescent dye. Different colors are used to identify the control and test samples. Both sets are inserted into the chip, where they bind to the synthetic DNA on the chip. If the person does not have a mutation for the gene, both samples will bind to the normal sequences on the chip. If a mutation is present, the person's DNA will bind to the sequence on the chip that represents the mutated DNA.

Genome-Wide Association Study (GWAS)

Genome-wide association study (GWAS) is an approach that involves rapidly scanning complete sets of DNA, or genomes, of many people to find genetic variations associated with the development or progression of a particular disease.

Until recently, researchers looked at single genes and the proteins that they encoded. With GWAS, researchers study large numbers of genes and proteins, including how they act and interact. This gives a

more complete picture of what goes on in a person. After the genetic associations are found, researchers may be able to learn how to stop or jump-start genes on demand, change the course of a disease, or prevent it from ever happening. GWAS is particularly useful in finding genetic variations that contribute to multifactorial inherited disorders, such as cancer and heart disease.

To carry out a GWAS, researchers use 2 groups of people: those with the disease and similar people without the disease. Each person's complete set of DNA, or genome, is purified from the blood or cells, placed on tiny chips, and scanned on automated laboratory machines. The machines quickly survey each person's genome for strategically selected markers of genetic variation.

If certain genetic variations are significantly more common in people with the disease compared to people without the disease, the variations are said to be "associated" with the disease. The associated genetic variations can serve as powerful pointers to the region of the human genome where the disease-causing problem exists.

The potential impact of GWAS is substantial, since it lays the groundwork for personalized medicine. This changes the "1-size-fits-all" approach to health care. It provides a mechanism for providing more individualized plans of care. The information will help the HCP tailor prevention programs.

Pharmacogenomics and Pharmacogenetics

Patients vary widely in their response to drugs. Although the reasons for this are complex, genetic factors may account for a large percentage of individual variability. **Pharmacogenomics** looks at how drugs affect and interact with the genome and output expression. Pharmacogenomics allows for the identification of variations in multiple genes that affect drug response. **Pharmacogenetics** is the study of variable drug responses, including adverse events from differences in inheritable genes. These terms are often used

interchangeably when describing the relationship between pharmacology and genetic variability in determining a person's response to drugs. Pharmacogenetics has a narrower focus than pharmacogenomics.[9]

Pharmacogenetic and pharmacogenomic studies could lead to the development of drugs that can be tailor-made or adapted to each person's particular genetic makeup. This will make it possible to have personalized medicine by choosing the right drug and the right dose for the right person.[8] HCPs are starting to use pharmacogenomic information to prescribe drugs. Examples are shown in Table 12.5.

One important area of study has focused on the hepatic cytochrome P450 (CYP450) enzyme system, which is responsible for oxidizing many drugs and chemicals.[8] The enzymes in this system share certain amino acid sequences. Each is coded by a separate gene. People with a less active form of the enzyme (who metabolize the drug slowly) may get too much of the drug. People with a more active form of the enzyme (who metabolize the drug quickly) may get too little of the drug. It may appear that the medication is not effective. These persons may need more frequent dosing. So, pharmacogenomic testing can help HCPs in prescribing the right dose of medicine based on a patient's particular genetic makeup (Fig. 12.7).

TABLE 12.5 Examples of Pharmacogenetics

Drug	Role of Pharmacogenetics
abacavir (Ziagen)	• Some people are at greater risk for serious allergic reactions when first starting treatment with this drug. • Genetic testing for *HLA-B∗5701* before taking the drug can identify those who carry a genetic marker that is associated with life-threatening hypersensitivity reactions.
clopidogrel (Plavix)	• For clopidogrel to work, cytochrome P450 enzymes in the liver (particularly CYP2C19) must convert the drug to its active form. • About 2% to 14% of the population are poor metabolizers of the drug. These patients may not receive the full benefits of the drug. • Genetic tests are available to identify genetic differences in CYP2C19 function.
crizotinib (Xalkori)	• Used to treat patients with late-stage, non–small cell lung cancers (NSCLCs) who express the abnormal anaplastic lymphoma kinase *(ALK)* gene. • *ALK* gene abnormality causes cancer development and growth. • Blocks certain proteins called *kinases*, including the protein made by the abnormal *ALK* gene. • Drug was approved for use with a companion genetic diagnostic test that determines whether a patient with NSCLC has the abnormal *ALK* gene.
trastuzumab (Herceptin)	• In breast cancer, drug works only for women whose tumors have genes that lead to the overproduction of a protein called HER-2. • Drug is a monoclonal antibody to HER-2. After the antibody attaches to the antigen, it kills the cells. • Genetic testing provides information on which women are good candidates for treatment with drug. • Drug does not work for women whose tumor genes do not express HER-2.
vemurafenib (Zelboraf)	• Approved for patients with late-stage (metastatic) or unresectable melanoma. • Indicated for the treatment of patients with melanoma whose tumors express a gene mutation called *BRAF V600E*. • To be considered for treatment, patients must first have genetic testing to determine whether melanoma cells have the *BRAF V600E* mutation.
warfarin (Coumadin) (see Fig. 12.7)	• Genetic variants in the genes *VKORC1* and cytochrome P450 2C9 *(CYP2C9)* have a significant impact on people's sensitivity to warfarin (Fig. 12.7). • Persons with particular variations in these genes need a lower warfarin dose to maintain therapeutic levels of anticoagulation. • Persons with other variations need higher doses. • Together, these genetic variations explain about 50% of the required dose difference between persons. • Testing for *CYP2C9* and *VKORC1* genotype information can assist in choosing the starting dose.

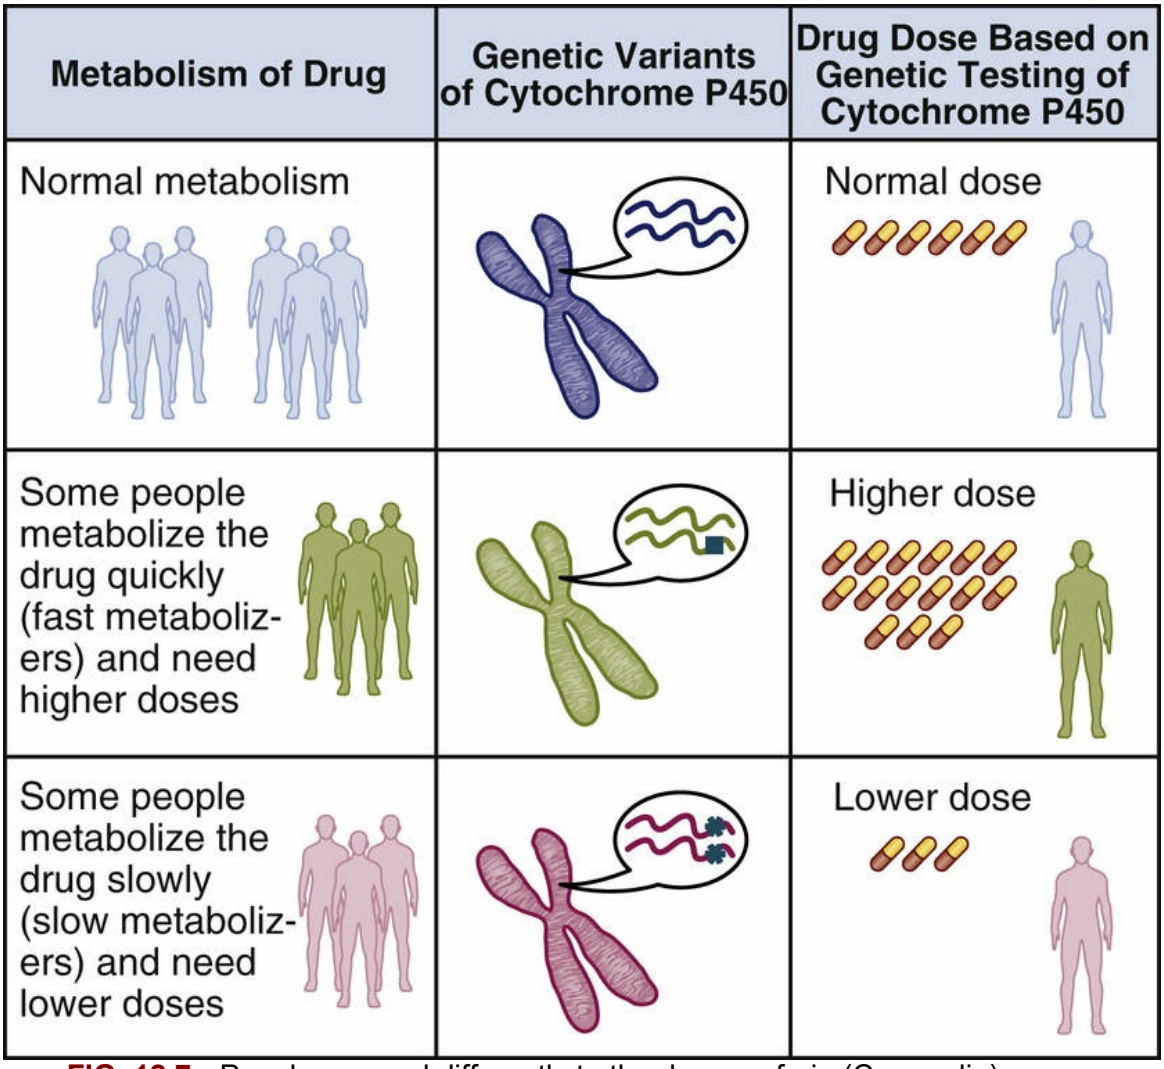

FIG. 12.7 People respond differently to the drug warfarin (Coumadin). The diversity of responses is partially due to genetic variants in 1 of the cytochrome *P450* genes.

Gene Therapy

Gene therapy is an investigational technique used to treat the underlying cause of a disease. Gene therapy may be used to supply a missing gene, avoid the missing gene's role, or enhance treatment of a disease. The goal is to provide a normally functioning gene to a person with a pathogenic gene variant. A carrier molecule called a *vector* must be used to deliver the therapeutic gene to the person's target cells.[10] Currently, the most common vector is a virus that has

been genetically altered to carry normal human DNA.[11] The vector can be injected or given intravenously directly into specific tissue. The vector unloads its genetic material containing the therapeutic human gene into the target cell. If the treatment is successful, the new gene will make a functional protein and restore the target cell to a normal state. A diagram of gene therapy is shown in Fig. 12.8.

Although gene therapy is a promising treatment for a number of diseases (including inherited disorders, some types of cancer, certain viral infections), the technique is still under study. In 2017 the FDA approved the first 2 gene therapies. Tisagenlecleucel (Kymriah) is used to treat certain pediatric and young adult patients with a form of acute lymphoblastic leukemia. The other gene therapy treats vision loss from a congenital retinal degenerative disorder. The cost of that 1-time gene therapy is currently $850,000.[12]

Stem Cell Therapy

Stem cells are the subject of much discussion because they may offer treatment for many diseases.[8] The use of stem cells may allow for the regeneration of lost tissue and restoration of function in various diseases.

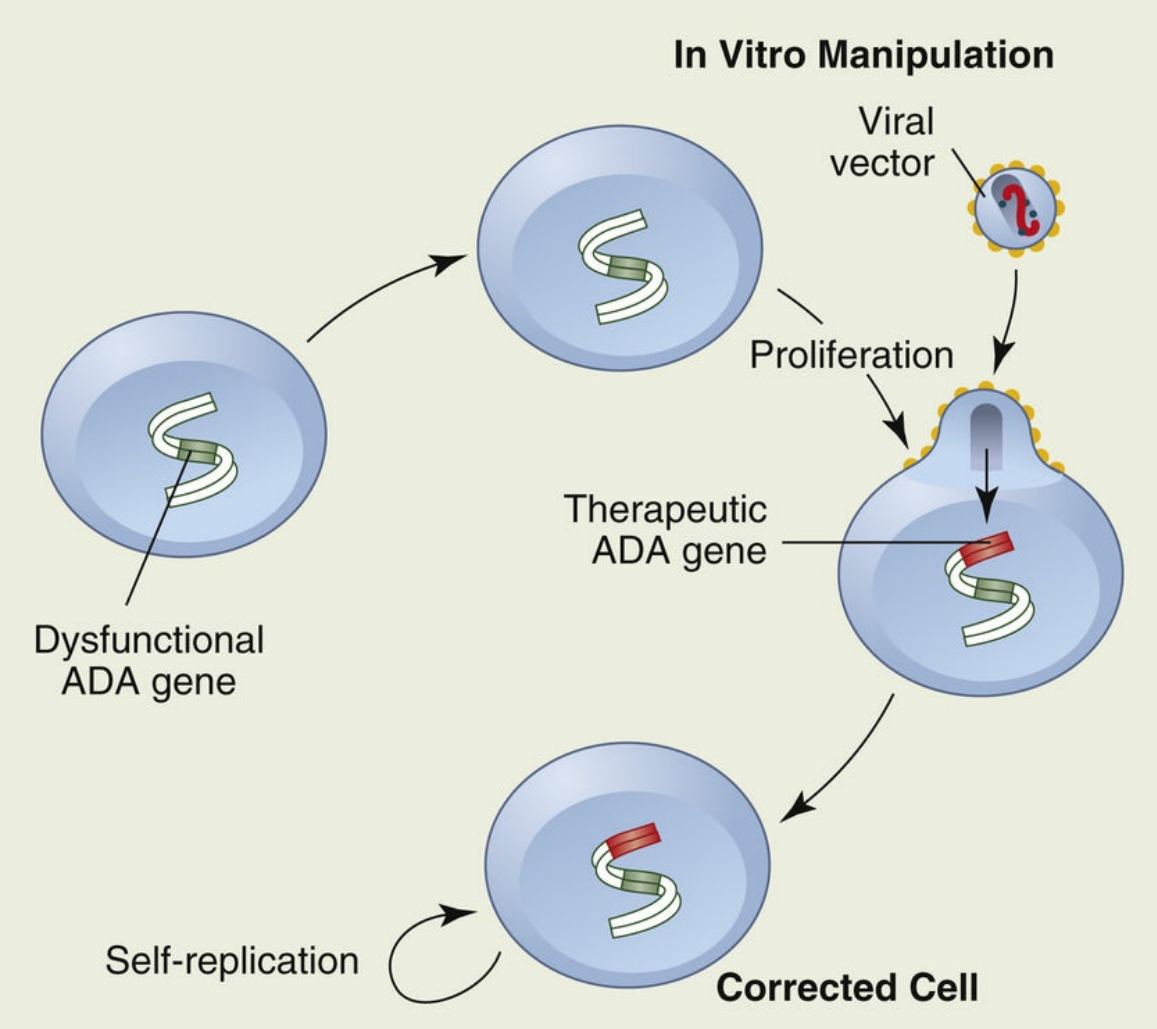

FIG. 12.8 Gene therapy for adenosine deaminase *(ADA)* deficiency tries to correct this immunodeficiency state. The viral vector containing the therapeutic ADA gene is inserted into the patient's lymphocytes. These cells can then make the ADA enzyme.

Stem cells are unspecialized cells in the body that have the ability to (1) remain in their unspecialized state and divide or (2) differentiate and develop into specialized cells. Stem cells can be derived from human embryos or adult somatic tissues. Stem cells can be totipotent, pluripotent, multipotent, or unipotent. Totipotent cells can produce all the cell types of the developing organism. Pluripotent cells can make any body cell because they make all cells of the embryo. Multipotent cells only make cells within a specific germ layer. Unipotent cells make a single cell type.

Adult stem cells are undifferentiated cells that are found in small

numbers in many organs and tissues, including brain, bone marrow, peripheral blood, blood vessels, skeletal muscle, skin, teeth, heart, GI tract, liver, ovarian epithelium, and testes. The primary roles of adult stem cells are to maintain and repair the tissues in which they are found. They are usually thought of as multipotent cells, giving rise to a closely related family of cells within the tissue. For example, skin stem cells produce new skin cells. Hematopoietic stem cells found within the bone marrow can form all the various blood cells. These cells are prolific by design.

Stems cells are used to treat persons with many different disorders, including severe burns and orthopedic conditions that require bone grafting. For the past 20 years, hematopoietic stem cell transplantation has been a standard for treatment for hematologic cancers and bone marrow failure (see Chapter 15). Medical researchers are investigating the use of stem cells to repair or replace damaged body tissues, similar to whole organ transplants.

Nursing Management: Genetics and Genomics

You need to understand genetics and genomics to assist persons and families seeking information and making decisions related to genetic issues.[13] By understanding the profound influence that genetics has on health and illness, you can aid the patient and family in making critical decisions related to genetic issues, such as genetic testing. You can facilitate access to resources and provide education in response to questions.

You will collaborate with other health care team members, including genetics nurses and genetics counselors. A genetics nurse is a licensed professional nurse with specialized education and training in genetics. Nurses with *GCN* after their names are baccalaureate-prepared licensed registered nurses who have received specialty credentialing as a Genetic Clinical Nurse (GCN). Nurses with *APNG* after their names are registered nurses with a master's degree who

have received specialty credentialing as an Advanced Practice Nurse in Genetics (APNG).

The specialized knowledge and counseling skills of a genetics nurse or genetics counselor are often important when genetic testing is considered. Genetic testing may raise many emotional issues. Knowledge of carrier status of a genetic disorder may influence a person's career, marriage, and childbearing decisions. It may also affect family members, as they contemplate potentially serious life and health care issues.

For example, how should a wife deal with a husband who has tested positive for Huntington's disease and shows early signs of cognitive impairment? Should their children be tested for the disease? Consider the situation of a woman who has a family history of breast cancer and is now diagnosed with breast cancer. She asks whether she and her teenage daughters should have *BRCA* testing. What do you tell her?

Genetic testing raises ethical questions. Who should know the results of a genetic test? Who should protect the privacy of test results and prevent persons from discrimination? People may be reluctant to share or disclose information about family history or genetic test results. They fear they are vulnerable to discrimination based on their DNA. As a nurse, you need to understand how different health care policies relate to genetic testing. Discuss how the Genetic Information Nondiscrimination Act (GINA) protects persons from discrimination by employers and health care insurance companies (see Genetics in Clinical Practice Box on p. 181).[14]

Nursing Assessment: Family History

As a nurse, it is very important that you ask persons about their family history and identify and assess inheritance patterns by constructing a family pedigree (Figs. 12.4 and 12.5). The family health history is a written or graphic record of the diseases and health conditions present in one's family (see Chapter 3). A pedigree is a graphic representation of the family history. The family history and

pedigree should include a minimum of 3 generations.

To help people record information about their family history, the Centers for Disease Control and Prevention (CDC) has collaborated with the U.S. Surgeon General and other federal agencies to develop a Web-based tool called My Family Health Portrait (*https://phgkb.cdc.gov/FHH/html/index.html*). Other Web-based programs are available to help create pedigree diagrams based on the information entered. Or, you can draw a pedigree by hand.

When constructing the pedigree, start with the proband, or person being interviewed. Identify that person with an arrow. For each family member, document date of birth, any medical illnesses or health conditions and the age when diagnosed, and age and cause of death, if the person is deceased. Comment on ancestors' racial and ethnic information, information that is unknown, and presence of consanguinity. After recording the family history or pedigree, review the information to identify key features that may increase a person's risk for genetic-related diseases. These include:

- Disease in more than 1 close relative
- Disease that does not usually affect a certain gender (e.g., breast cancer in a male)
- Disease that occurs at an earlier age than expected (e.g., myocardial infarction before age 35)
- Certain combinations of diseases within a family (e.g., breast and ovarian cancer, heart disease, and diabetes)

If 1 or more of these features are identified, the family history may hold important clues about a person's risk for a genetic disease. These persons may benefit from further clinical investigation, screening, and diagnostic testing. As a nurse, you may refer these persons to a specialist for information about the benefits and risks of genetic screening and testing.

Genetic Risk Alert boxes in the assessment chapters of this book highlight persons' risks related to genetic diseases and disorders. You can use the information in these boxes to assess the family history.

As a nurse, you can support the person and family by providing education and reinforcing the information they receive throughout the process. You can use the family history, pedigree, and Punnett squares (Fig. 12.9) to explain the risk for inheritable disease. When a diagnosis is confirmed, you can discuss health promotion activities. People with multifactorial disorders may benefit from lifestyle modification that addresses unhealthy behaviors (e.g., smoking, poor eating habits). You can help the person and family understand how evidence-based guidelines are used for monitoring, screening, and ongoing follow-up. For example, it is important to monitor cholesterol levels in a person with a family history of familial hypercholesterolemia. Throughout this process, maintain the person's confidentiality and respect his or her values and beliefs.

Autosomal Recessive (e.g., cystic fibrosis)

A

Father \ Mother	C	c
C	CC Normal	Cc Normal
c	Cc Normal	cc Affected with cystic fibrosis

X-Linked Recessive (e.g., hemophilia)

B

Father \ Mother	X_h	X
X	XX_h Female carrier	XX Normal female
Y	X_hY Male with hemophilia	XY Normal male

Autosomal Dominant (e.g., Huntington's disease)

C

Father \ Mother	H	H
H	HH Normal	HH Normal
h	Hh Affected	Hh Affected

FIG. 12.9 Punnett squares illustrate inheritance possibilities. **A,** If the mother and father are both carriers for cystic fibrosis, there is a 25% chance that offspring will have cystic fibrosis. **B,** If the mother is a carrier for the hemophilia gene and the father has a normal genotype, there is a 50% chance that any male offspring will have hemophilia. There is a 50% chance that any female offspring will be a carrier. **C,** If the mother has a normal genotype and the father has Huntington's disease, there is a 50% chance that offspring will have the disease.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. If a person is heterozygous for a given gene, it means that the person
   a. is a carrier for a genetic disorder.
   b. is affected by the genetic disorder.
   c. has 2 identical alleles for the gene.
   d. has 2 different alleles for the gene.
2. Common causes of genetic mutations include *(select all that apply)*
   a. DNA damage from toxins.
   b. DNA damage from UV radiation.
   c. inheritance of altered genes from father.
   d. inheritance of altered genes from mother.
   e. inheritance of somatic mutations from either parent.
3. A father who has an X-linked recessive disorder and a wife with a normal genotype will
   a. pass the carrier state to all his children.
   b. pass the carrier state to his male children.

c. pass the carrier state to his female children.

d. not pass on the genetic mutation to any of his children.

4. What characterizes multifactorial genetic disorders?

a. Often caused by single gene alterations

b. Genetic testing available for most disorders

c. Many family members report having the disorder

d. Caused by complex interactions of genetic and environmental factors

5. If a person tests positive for a genetic mutation, it means *(select all that apply)*

a. the laboratory found an alteration in a gene.

b. the person is predisposed to develop a genetic disease.

c. there is the chance other family members may be at risk.

d. the person will develop the disease at some point in time.

e. the person should not have any children or any more children.

6. What role does pharmacogenomics have in health care?

a. It can assess individual variability to many drugs.

b. It can be used to assess the effectiveness of a drug.

c. It provides important assessment data for gene therapy.

d. It can assess the variability of drug responses due to single genes.

7. A couple who recently had a son with hemophilia A is consulting with a nurse. They want to know if their next child will have hemophilia A. The nurse can tell the parents that if their child is a

a. boy, he will have hemophilia A.

b. boy, he will be a carrier of hemophilia A.

c. girl, she will be a carrier of hemophilia A.

d. girl, there is a 50% chance she will be a carrier of hemophilia A.

1. d, 2. a, b, c, d, 3. c, 4. d, 5. a, c, 6. d, 7. d

Immune Responses and Transplantation

Haley Hoy, and Yeow Chye Ng

LEARNING OUTCOMES

1. Describe the components and functions of the immune system.
2. Characterize the 5 types of immunoglobulins.
3. Distinguish among the 4 types of hypersensitivity reactions in terms of immunologic mechanisms and resulting alterations.
4. Outline the clinical manifestations and emergency management of a systemic anaphylactic reaction.
5. Describe the assessment and interprofessional care of a patient with chronic allergies.
6. Describe the etiologic factors, clinical manifestations, and treatment modalities of autoimmune diseases.
7. Describe the etiologic factors and categories of immunodeficiency disorders.
8. Explain the relationship between the human leukocyte antigen system and certain diseases.
9. Distinguish among the types of rejections after transplantation.
10. Identify the types and side effects of immunosuppressive therapy.

Conceptual Focus

Functional Ability
Immunity
Infection
Inflammation
Tissue Integrity

Compassion is the ultimate expression of your highest self.

Russell Simmons

Our bodies have several defense mechanisms for protecting ourselves. One of the most complex is the immune response. Immune processes must be functioning properly for the body to defend itself against the presence of foreign substances. This response is critical to

maintaining health. Thus many problems occur when the immune response is altered. These problems are closely related to the concepts of inflammation, infection, and tissue integrity. You will find that the care of patients with immune disorders discussed in this chapter will be similar to the care of patients with inflammation (Chapter 11), neutropenia (Chapter 30), and general infection (Chapter 14).

Normal Immune Response

Immunity is the body's ability to resist disease. Immune responses serve the following 3 functions:

1. *Defense:* The body protects against invasions by microorganisms and prevents the development of infection by attacking foreign antigens and pathogens.
2. *Homeostasis:* Damaged cellular substances are digested and removed. Through this mechanism, the body's different cell types stay uniform and unchanged.
3. *Surveillance:* Mutations continually arise but are recognized as foreign cells and destroyed.

TABLE 13.1 Types of Acquired Specific Immunity

Type	Natural	Artificial
Active	Natural contact with antigen through actual infection (e.g., chickenpox, measles, mumps)	Immunization with antigen (e.g., vaccines for chickenpox, measles, mumps)
Passive	Transplacental and colostrum transfer from mother to child (e.g., maternal immunoglobulins passed to baby)	Injection of serum with antibodies from 1 person (e.g., injection of hepatitis B immune globulin) to another person who does not have antibodies

Antigens

An antigen is a substance that elicits an immune response. Most antigens are composed of protein. However, other substances such as large polysaccharides, lipoproteins, and nucleic acids can act as antigens. All the body's cells have antigens on their surface that are unique to that person and enable the body to recognize itself. The immune system normally becomes "tolerant" to the body's own molecules. Therefore it is nonresponsive to "self" antigens.

Types of Immunity

We classify immunity as innate or acquired.

Innate Immunity

Innate immunity is present at birth. Its primary role is first-line defense against pathogens. This type of immunity involves a nonspecific response, and neutrophils and monocytes are the primary white blood cells (WBCs) involved. Innate immunity is not antigen specific. So, it can respond within minutes to an invading microorganism without prior exposure to that organism.

Acquired Immunity

Acquired immunity is the development of immunity, either actively or passively (Table 13.1).

Active Acquired Immunity

Active acquired immunity results from the invasion of the body by foreign substances such as microorganisms and the subsequent development of antibodies and sensitized lymphocytes. With each reinvasion of the microorganisms, the body responds more rapidly and vigorously to fight off the invader. Active acquired immunity may result naturally from a disease or artificially through immunization. Because the body makes antibodies, immunity takes time to develop but is long lasting.

Passive Acquired Immunity

In *passive acquired immunity,* the host receives antibodies to an antigen rather than making them. This may take place naturally through the transfer of immunoglobulins across the placental membrane from mother to fetus. Artificial passive acquired immunity occurs through injection with gamma globulin (serum antibodies). The benefit of this immunity is its immediate effect. Unfortunately, passive immunity is short lived because the person does not make the antibodies and memory cells for the antigen.

Lymphoid Organs

The lymphoid system is composed of central (or primary) and peripheral lymphoid organs. The *central lymphoid organs* are the thymus gland and bone marrow. The *peripheral lymphoid organs* are the lymph nodes; tonsils; spleen; and gut-, genital-, bronchial-, and skin-associated lymphoid tissues (Fig. 13.1).

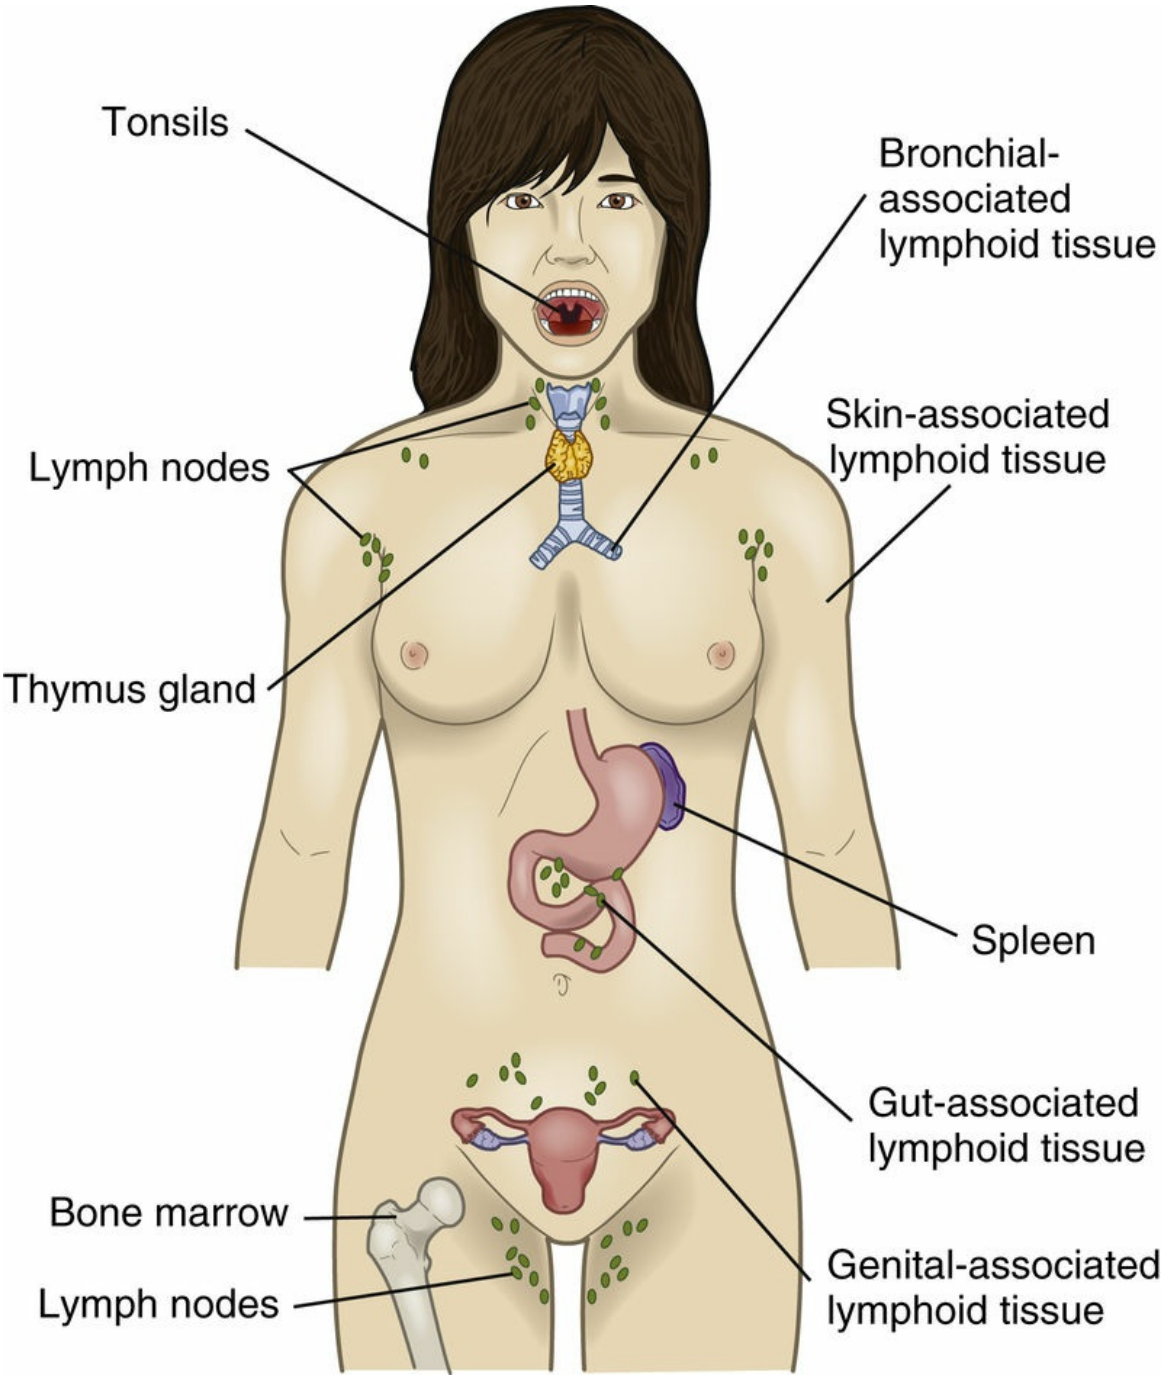

FIG. 13.1 Organs of the immune system.

Lymphocytes are made in the bone marrow. They eventually migrate to the peripheral organs. The thymus is involved in the differentiation and maturation of T lymphocytes and is therefore essential for a cell-mediated immune response. The thymus is its largest during childhood. After puberty, the thymus starts to slowly

shrink and become replaced by fat. By age 75, the thymus is little more than fatty tissue and produces few T lymphocytes.

When antigens enter the body, they may be carried by the bloodstream or lymph channels to regional lymph nodes. The antigens interact with B and T lymphocytes and macrophages in the lymph nodes. The 2 major functions of lymph nodes are (1) filtration of foreign material brought to the site and (2) circulation of lymphocytes.

The tonsils are an example of lymphoid tissue. The spleen, a peripheral lymph organ, is important as the primary site for filtering foreign antigens from the blood. Lymphoid tissue is found in the submucosa of the GI (gut-associated), genitourinary (genital-associated), and respiratory (bronchial-associated) tracts. This tissue protects the body from external microorganisms.

The skin-associated lymph tissue consists primarily of lymphocytes and Langerhans' cells (type of dendritic cell) found in the epidermis of skin. When Langerhans' cells are depleted, the skin cannot initiate an immune response. Therefore a delayed hypersensitivity reaction (as determined by skin testing with injected antigens) does not occur.

Cells Involved in Immune Response

Mononuclear Phagocytes

The *mononuclear phagocyte system* includes monocytes in the blood and macrophages found throughout the body. Mononuclear phagocytes have a critical role in the immune system. They are responsible for capturing, processing, and presenting the antigen to the lymphocytes. This stimulates a humoral or cell-mediated immune response. Capturing is accomplished through phagocytosis. The macrophage-bound antigen, which is highly immunogenic, is presented to circulating T or B lymphocytes and thus triggers an immune response (Fig. 13.2).

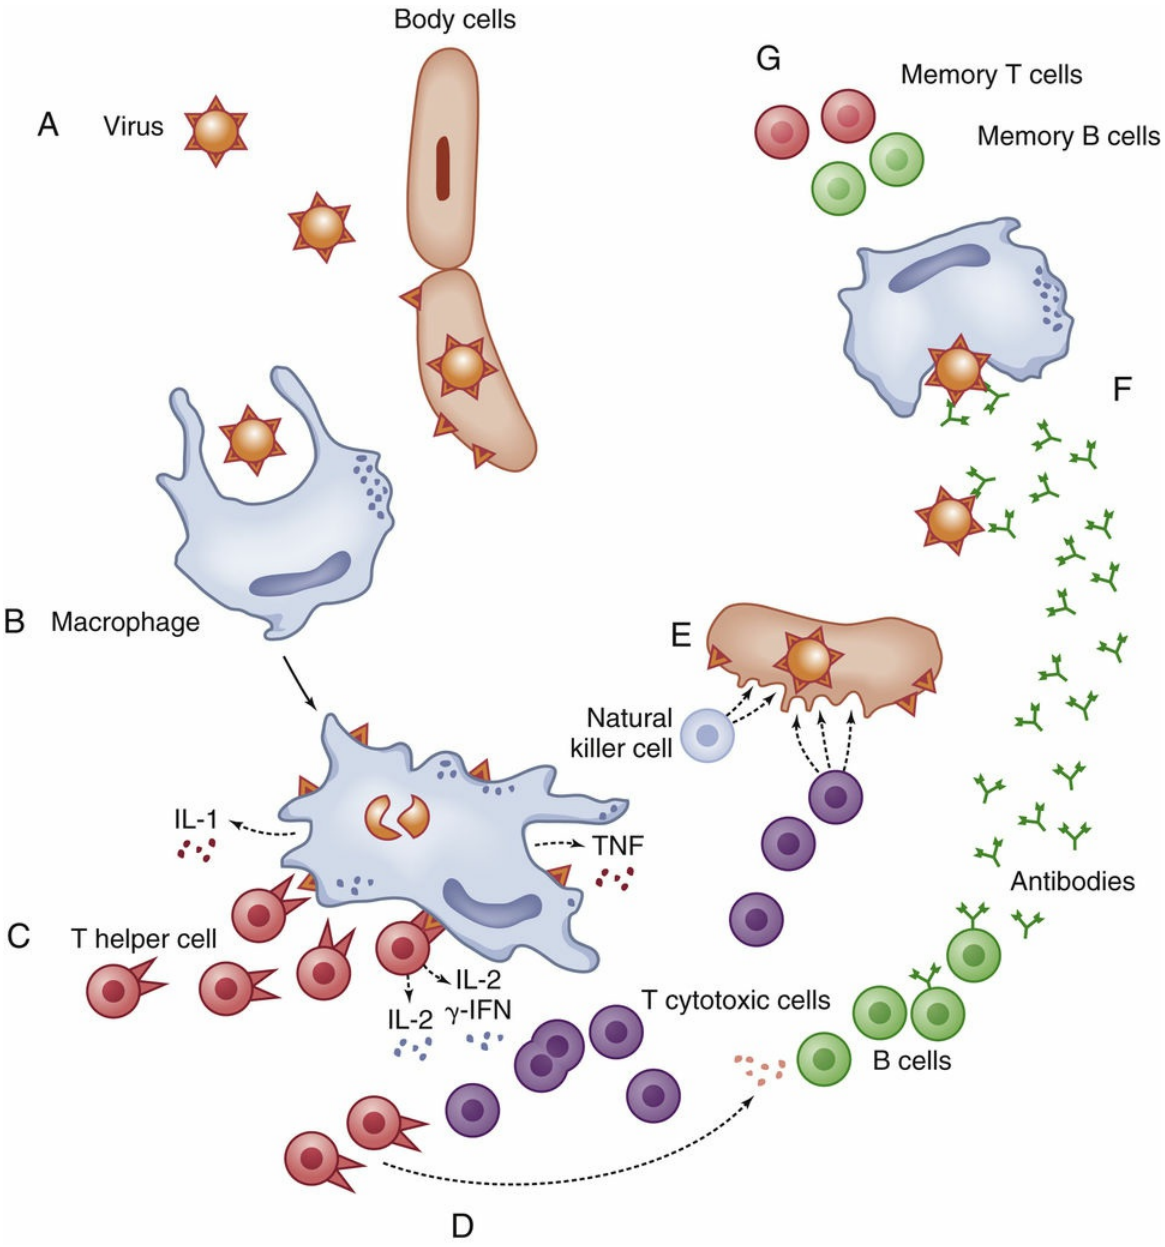

FIG. 13.2 The immune response to a virus. **A,** A virus invades the body through a break in the skin or another portal of entry. The virus must make its way inside a cell to replicate itself. **B,** A macrophage recognizes the antigens on the surface of the virus. The macrophage digests the virus and displays pieces of the virus (antigens) on its surface. **C,** T helper cell recognizes the antigen displayed and binds to the macrophage. This binding stimulates the production of cytokines (interleukin-1 *[IL-1]* and tumor necrosis factor *[TNF]*) by the macrophage and interleukin-2 *(IL-2)* and γ-interferon *(γ-IFN)* by the T cell. These cytokines are intracellular messengers that provide communication among the cells. **D,** IL-2 instructs other T helper cells and T cytotoxic cells to proliferate (multiply). T helper cells release cytokines, causing B cells to multiply and make antibodies. **E,** T cytotoxic cells and natural killer cells destroy infected body cells. **F,** The

antibodies bind to the virus and mark it for macrophage destruction. **G,** Memory B and T cells stay behind to respond quickly if the same virus attacks again.

Lymphocytes

Lymphocytes are made in the bone marrow (Fig. 13.3). They then differentiate into B and T lymphocytes.

B Lymphocytes

In the early research on *B lymphocytes* (bursa-equivalent lymphocytes) in birds, we discovered that they mature under the influence of the bursa of Fabricius, hence the name *B cells.* However, this lymphoid organ does not exist in humans. The bursa-equivalent tissue in humans is the bone marrow. B cells differentiate into *plasma cells* when activated. Plasma cells make antibodies (immunoglobulins) (Table 13.2).

T Lymphocytes

Cells that migrate from the bone marrow to the thymus differentiate into *T lymphocytes* (thymus-dependent cells). The thymus secretes hormones, including thymosin, that stimulate the maturation and differentiation of T lymphocytes. T cells make up 70% to 80% of the circulating lymphocytes. They are primarily responsible for immunity to intracellular viruses, tumor cells, and fungi. T cells can live from a few months to the life span of a person. They account for long-term immunity.

T lymphocytes can be categorized into T cytotoxic and T helper cells. Antigenic characteristics of WBCs can be classified using monoclonal antibodies. These antigens are classified as *clusters of differentiation,* or *CD antigens.* We refer to many types of WBCs, especially lymphocytes, by their CD designations. All mature T cells have the CD3 antigen.

T cytotoxic cells

T cytotoxic (CD8) cells are involved in attacking antigens on the cell membrane of foreign pathogens and releasing cytolytic substances that destroy the pathogen. These cells have antigen specificity and are sensitized by exposure to the antigen. Much like B cells, some sensitized T cells do not attack the antigen but remain as memory T cells. As in the humoral immune response, a second exposure to the antigen results in a more intense and rapid cell-mediated immune response.

T helper cells

T helper (CD4) cells are involved in the regulation of cell-mediated immunity and the humoral antibody response. T helper cells differentiate into subsets of cells that make distinct types of cytokines (discussed in a later section). These subsets are called T_H1 cells and T_H2 cells. T_H1 cells stimulate phagocyte-mediated ingestion and killing of microbes, the key component of cell-mediated immunity. T_H2 cells stimulate eosinophil-mediated immunity, which is effective against parasites and is involved in allergic responses.

Natural Killer Cells

Natural killer (NK) cells are involved in cell-mediated immunity. These cells are not T or B cells but are large lymphocytes with many granules in the cytoplasm. NK cells do not need prior sensitization for their generation. These cells are involved in recognition and killing of virus-infected cells, tumor cells, and transplanted grafts. NK cells have a vital role in immune surveillance for malignant cell changes. We do not fully understand the mechanism of recognition.

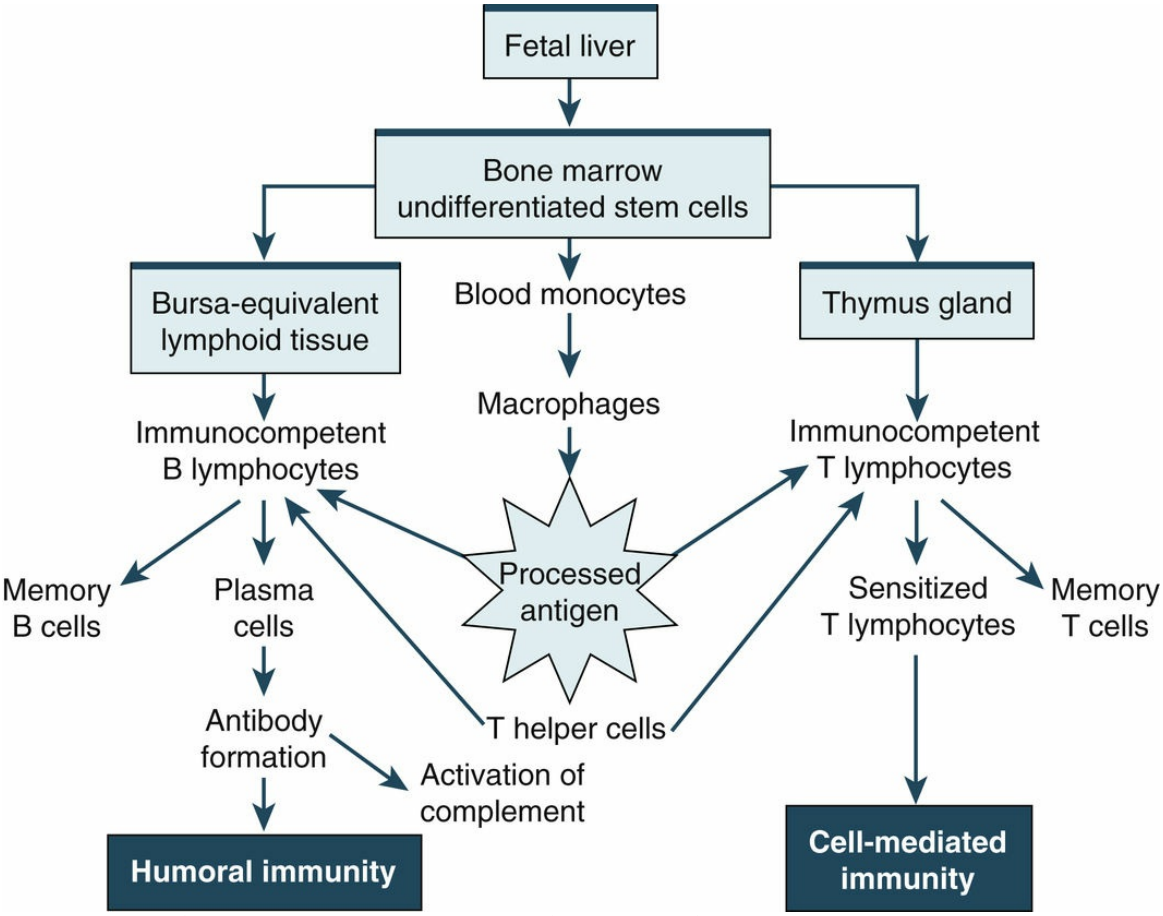

FIG. 13.3 Relationships and functions of macrophages, B lymphocytes, and T lymphocytes in an immune response.

TABLE 13.2 Characteristics of Immunoglobulins

Class	Serum Concentration (%)	Location	Characteristics
IgG	76	Plasma, interstitial fluid	Only immunoglobulin that crosses placenta Responsible for secondary immune response
IgA	15	Body secretions, including tears, saliva, breast milk, colostrum	Lines mucous membranes and protects body surfaces
IgM	8	Plasma	Responsible for primary immune response Forms antibodies to ABO blood antigens
IgD	1	Plasma	Present on lymphocyte surface Aids in the differentiation of B lymphocytes
IgE	0.002	Plasma, interstitial fluids	Causes symptoms of allergic reactions Fixes to mast cells and basophils Aids in defense against parasitic infections

T Dendritic Cells

Dendritic cells make up a system of cells that is important to the immune system, especially the cell-mediated immune response. They have an atypical shape with extensive dendritic processes that form and retract. They are found in many places in the body, including the skin (where they are called *Langerhans' cells*) and the lining of the nose, lungs, stomach, and intestine. There are many immature dendritic cells in the blood.[1]

Dendritic cells function primarily to capture antigens at sites of contact with the external environment (e.g., skin, mucous membranes) and then transport the antigen until it meets a T cell with specificity for that antigen. In this role, they have an important function in activating the immune response.

Cytokines

The immune response involves complex interactions of T cells, B cells, monocytes, and neutrophils. These interactions depend on **cytokines** (soluble factors secreted by WBCs and a variety of other cells in the body) that act as messengers among the cell types. Cytokines instruct cells to alter their proliferation, differentiation, secretion, or activity.

Currently, we know of more than 100 different cytokines. They can be classified into distinct categories. Some of these cytokines are listed in Table 13.3. In general, the interleukins (ILs) act as immunomodulatory factors. Colony-stimulating factors act as growth-regulating factors for hematopoietic cells. Interferons are antiviral and immunomodulatory.

The net effect of an inflammatory response is determined by a balance between proinflammatory and antiinflammatory mediators. We can sometimes classify cytokines as proinflammatory or antiinflammatory. However, it is not that clear-cut, since many other factors (e.g., target cells, environment) influence the inflammatory response to a given injury or insult.

Cytokines have a beneficial role in hematopoiesis and immune function. They can have detrimental effects such as those seen in

chronic inflammation, autoimmune diseases, and sepsis. Cytokines such as colony-stimulating factors, interferons, and IL-2 have clinical uses (Table 13.4).

Interferon helps the body's natural defenses attack tumors and viruses. We know of 3 types of interferon (Table 13.3). Interferon is not directly antiviral but produces an antiviral effect in cells by reacting with them and inducing the formation of a second protein termed *antiviral protein* (Fig. 13.4). This protein mediates the antiviral action of interferon by changing the cell's protein synthesis and preventing new viruses from becoming assembled.

TABLE 13.3 Types and Functions of Cytokines

Type	Primary Functions
Colony-Stimulating Factors (CSFs)	
Granulocyte colony-stimulating factor (G-CSF)	Stimulates proliferation and differentiation of neutrophils, enhances functional activity of mature PMNs
Granulocyte-macrophage colony-stimulating factor (GM-CSF)	Stimulates proliferation and differentiation of PMNs and monocytes
Macrophage colony-stimulating factor (M-CSF)	Promotes proliferation, differentiation, and activation of monocytes and macrophages
Erythropoietin	Stimulates erythroid progenitor cells in bone marrow to make red blood cells
Interferons (IFNs)	
α-IFN **β-IFN**	Inhibits viral replication, activates NK cells and macrophages, antiproliferative effects on tumor cells
γ-IFN	Proinflammatory mediator. Activates macrophages, neutrophils, and NK cells. Promotes B cell differentiation. Inhibits viral replication
Interleukins (ILs)	
IL-1	Proinflammatory mediator. Promotes proliferation of B cells. Activates T cells, NK cells, and macrophages
IL-2	Activates T cells, NK cells, and macrophages. Stimulates release of other cytokines (α-IFN, TNF, IL-1, IL-6)
IL-3	Hematopoietic growth factor for hematopoietic precursor cells
IL-4	Antiinflammatory mediator. B cell growth and differentiation. Induces differentiation into T_H2 cells. Stimulates growth of mast cells
IL-5	B-cell growth and differentiation. Promotes growth and differentiation of eosinophils
IL-6	Proinflammatory mediator. T- and B-cell growth factor, promotes differentiation of B cells into plasma cells and stimulates antibody secretion. Induces fever. Synergistic effects with IL-1 and TNF
Tumor Necrosis Factor (TNF)	Proinflammatory mediator. Activates macrophages and granulocytes. Promotes immune and inflammatory responses. Kills tumor cells. Responsible for weight loss associated with chronic inflammation and cancer

NK, Natural killer; *PMNs,* polymorphonuclear neutrophils.

TABLE 13.4 Clinical Uses of Cytokines

Cytokine	Clinical Uses
Colony-Stimulating Factors	
G-CSFfilgrastim (Neupogen) pegfilgrastim (Neulasta)	Chemotherapy-induced neutropenia
GM-CSFsargramostim (Leukine)	Neutropenia, myeloid recovery after bone marrow transplantation
Erythropoietin epoetin alfa (Epogen, Procrit), darbepoetin alfa (Aranesp)	Anemia related to chronic kidney disease, cancer, and chemotherapy
IL-1 Receptor Antagonist anakinra (Kineret)	Rheumatoid arthritis
Interferons	
α-Interferon (Roferon-A, Intron A)	Hairy cell leukemia, chronic myelogenous leukemia, malignant melanoma, renal cell cancer, ovarian cancer, multiple myeloma, Kaposi sarcoma, hepatitis B and C
β-Interferon (Betaseron, Avonex, Rebif)	Multiple sclerosis
Interleukins	
Interleukin-2aldesleukin (Proleukin)	Metastatic renal cell cancer, metastatic melanoma
Interleukin 11 (platelet growth factor) oprelvekin (Neumega)	Thrombocytopenia related to chemotherapy
Soluble TNF Receptoretanercept (Enbrel)	Rheumatoid arthritis

G-CSF, Granulocyte colony-stimulating factor; *GM-CSF,* granulocyte-macrophage colony-stimulating factor; *TNF,* tumor necrosis factor.

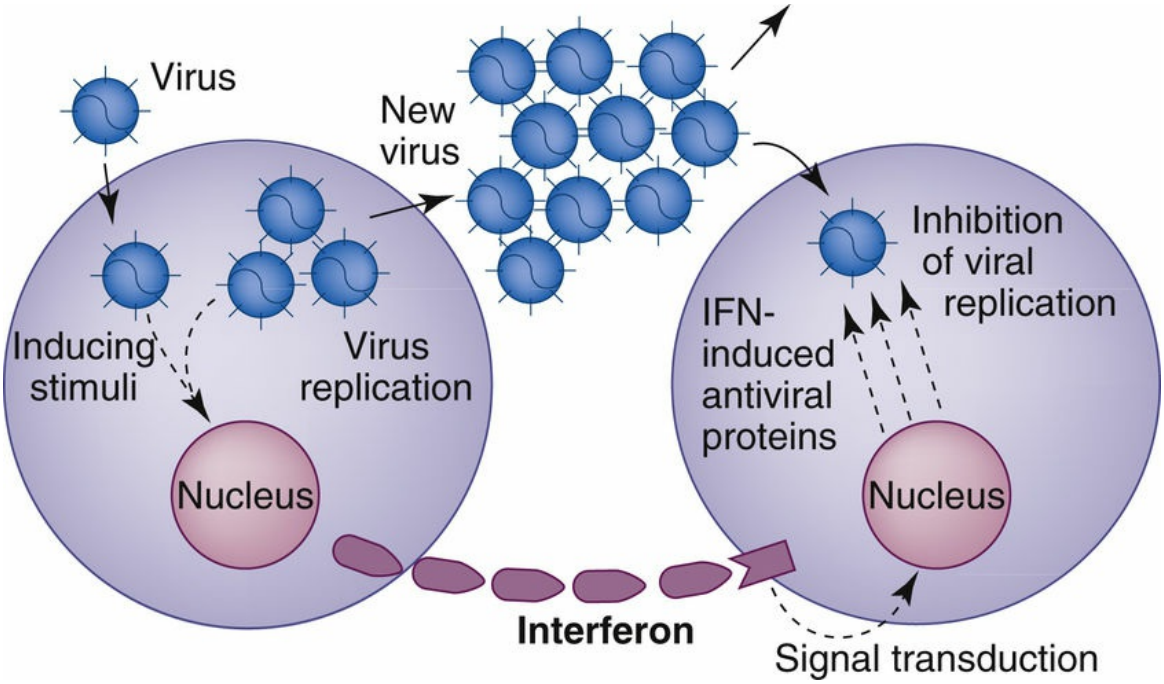

FIG. 13.4 Mechanism of action of interferon *(IFN).* When a virus attacks a cell, the cell begins to make viral DNA and IFN. IFN serves as an intercellular messenger and induces the production of antiviral proteins. Then the virus is not able to replicate in the cell.

Comparison of Humoral and Cell-Mediated Immunity

Humans need both humoral and cell-mediated immunity to remain healthy. Each type of immunity has unique properties, different methods of action, and reactions against particular antigens. Table 13.5 compares humoral and cell-mediated immunity.

TABLE 13.5 Comparison of Humoral and Cell-Mediated Immunity

Characteristics	Humoral Immunity	Cell-Mediated Immunity
Cells involved	B lymphocytes	T lymphocytes, macrophages
Products	Antibodies	Sensitized T cells, cytokines
Memory cells	Present	Present
Protection	Bacteria Viruses (extracellular) Respiratory and GI pathogens	Fungus Viruses (intracellular) Chronic infectious agents Tumor cells
Examples	Anaphylactic shock Atopic diseases Transfusion reaction Bacterial infections	Tuberculosis Fungal infections Contact dermatitis Graft rejection Destruction of cancer cells

Humoral Immunity

Humoral immunity consists of antibody-mediated immunity. The term *humoral* comes from the Greek word *humor*, which means body fluid. Since antibodies are made by plasma cells (differentiated B cells) and found in plasma, the term *humoral immunity* is used. Antibody production is an essential part of the humoral immune response. Each of the 5 classes of immunoglobulins (Igs) (IgG, IgA, IgM, IgD, IgE) has specific characteristics (Table 13.2).

When a pathogen (especially bacteria) enters the body, it may encounter a B cell that is specific for antigens found on that bacterial

cell wall. In addition, a monocyte or macrophage may phagocytize the bacteria and present its antigens to a B cell. The B cell recognizes the antigen because it has receptors on its cell surface specific for that antigen. When the antigen comes in contact with the cell surface receptor, the B cell becomes activated, and most B cells differentiate into plasma cells (Fig. 13.3). The mature plasma cell secretes immunoglobulins. Some stimulated B cells remain as memory cells.

The primary immune response becomes evident 4 to 8 days after the first exposure to the antigen (Fig. 13.5). IgM is the first type of antibody formed. Because of the large size of the IgM molecule, IgM is confined to the intravascular space. As the immune response progresses, we make IgG. IgG can move from intravascular to extravascular spaces.

When a person is exposed to the antigen the second time, a secondary antibody response occurs. This response occurs faster (1 to 3 days), is stronger, and lasts for a longer time than a primary response. Memory cells account for the memory of the first exposure to the antigen and the more rapid production of antibodies. IgG is the primary antibody found in a secondary immune response.

IgG crosses the placental membrane. It provides the newborn with passive acquired immunity for at least 3 months. Infants may get some passive immunity from IgA in breast milk and colostrum.

Cell-Mediated Immunity

Immune responses that are initiated through specific antigen recognition by T cells are termed cell-mediated immunity. Several cell types and factors are involved in cell-mediated immunity. These include T cells, macrophages, and NK cells. Cell-mediated immunity is of primary importance in (1) immunity against pathogens that survive inside of cells, including viruses and some bacteria (e.g., mycobacteria); (2) fungal infections; (3) rejection of transplanted tissues; (4) contact hypersensitivity reactions; and (5) tumor immunity.

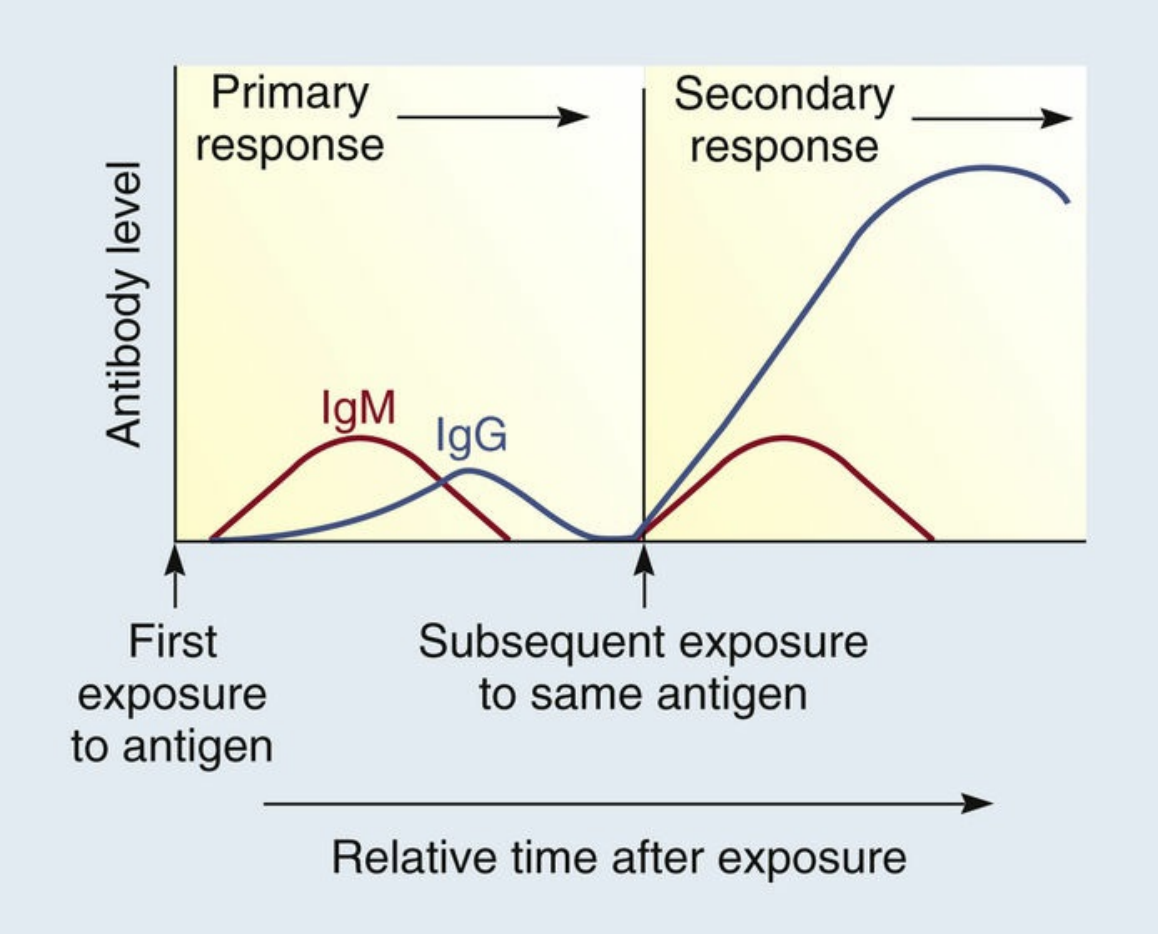

FIG. 13.5 Primary and secondary immune responses. The introduction of antigen induces a response dominated by 2 classes of immunoglobulins, IgM and IgG. IgM predominates in the primary response, with some IgG appearing later. After the host's immune system is primed, another challenge with the same antigen induces the secondary response, in which some IgM and large amounts of IgG are made.

Gerontologic Considerations: Effects of Aging on the Immune System

With advancing age, there is a decline in the function of the immune response (Table 13.6). The main evidence of *immunosenescence* is the high incidence of cancer in older adults. Older people are also more susceptible to infections (e.g., influenza, pneumonia) from pathogens that they were more immunocompetent against earlier in life. Bacterial pneumonia is the leading cause of death from infections in

older adults. The antibody response to immunizations (e.g., flu vaccine) in older adults is considerably lower than in younger adults.[1]

The bone marrow is unaffected by increasing age. Immunoglobulin levels decrease with age, leading to a suppressed humoral immune response in older adults. The thymus shrinks with age, along with decreased numbers of T cells. These changes in the thymus gland are a primary cause of immunosenescence. Both T and B cells show deficiencies in activation, transit time through the cell cycle, and subsequent differentiation. However, the most significant changes involve T cells. As thymic output of T cells diminishes, the differentiation of T cells increases. Consequently, there is an accumulation of memory cells rather than new precursor cells responsive to previously unencountered antigens.

The delayed hypersensitivity reaction, as determined by skin testing with injected antigens, is often decreased or absent in older adults. This altered response reflects **anergy** (an immunodeficient condition characterized by lack of or diminished reaction to an antigen or a group of antigens).

Altered Immune Response

Immunocompetence exists when the body's immune system can identify and inactivate or destroy foreign substances. When the immune system is incompetent or underresponsive, severe infections, cancers, and immunodeficiency diseases may occur. When the immune system overreacts, hypersensitivity disorders such as allergies and autoimmune diseases may develop.

Hypersensitivity Reactions

Sometimes the immune response is overreactive against foreign antigens or reacts against its own tissue, resulting in tissue damage. These responses are termed hypersensitivity reactions. *Autoimmune disease,* a type of hypersensitivity response, occurs when the body does not recognize self-proteins and reacts against self-antigens.

We can classify hypersensitivity reactions by the source of the antigen, time sequence (immediate or delayed), or immunologic mechanisms causing the injury. Four types of hypersensitivity reactions exist (Table 13.7). Types I, II, and III are immediate and are examples of humoral immunity. Type IV is a delayed hypersensitivity reaction and is related to cell-mediated immunity.

TABLE 13.6 Gerontologic Assessment DifferencesEffects of Aging on the Immune System

- ↓ Primary and secondary antibody responses
- ↑ Autoantibodies

IL, Interleukin.

Type I: IgE-Mediated Reactions

Anaphylactic reactions are type I reactions that occur only in susceptible people who are highly sensitized to specific allergens. IgE antibodies, made in response to the allergen, have a characteristic property of attaching to mast cells and basophils (Fig. 13.6; see). Within these cells are granules containing potent chemical mediators (histamine, serotonin, leukotrienes, eosinophil chemotactic factor of anaphylaxis [ECF-A], kinins, and bradykinin). Chemical mediators of inflammation are discussed in Chapter 11 and Table 11.1.

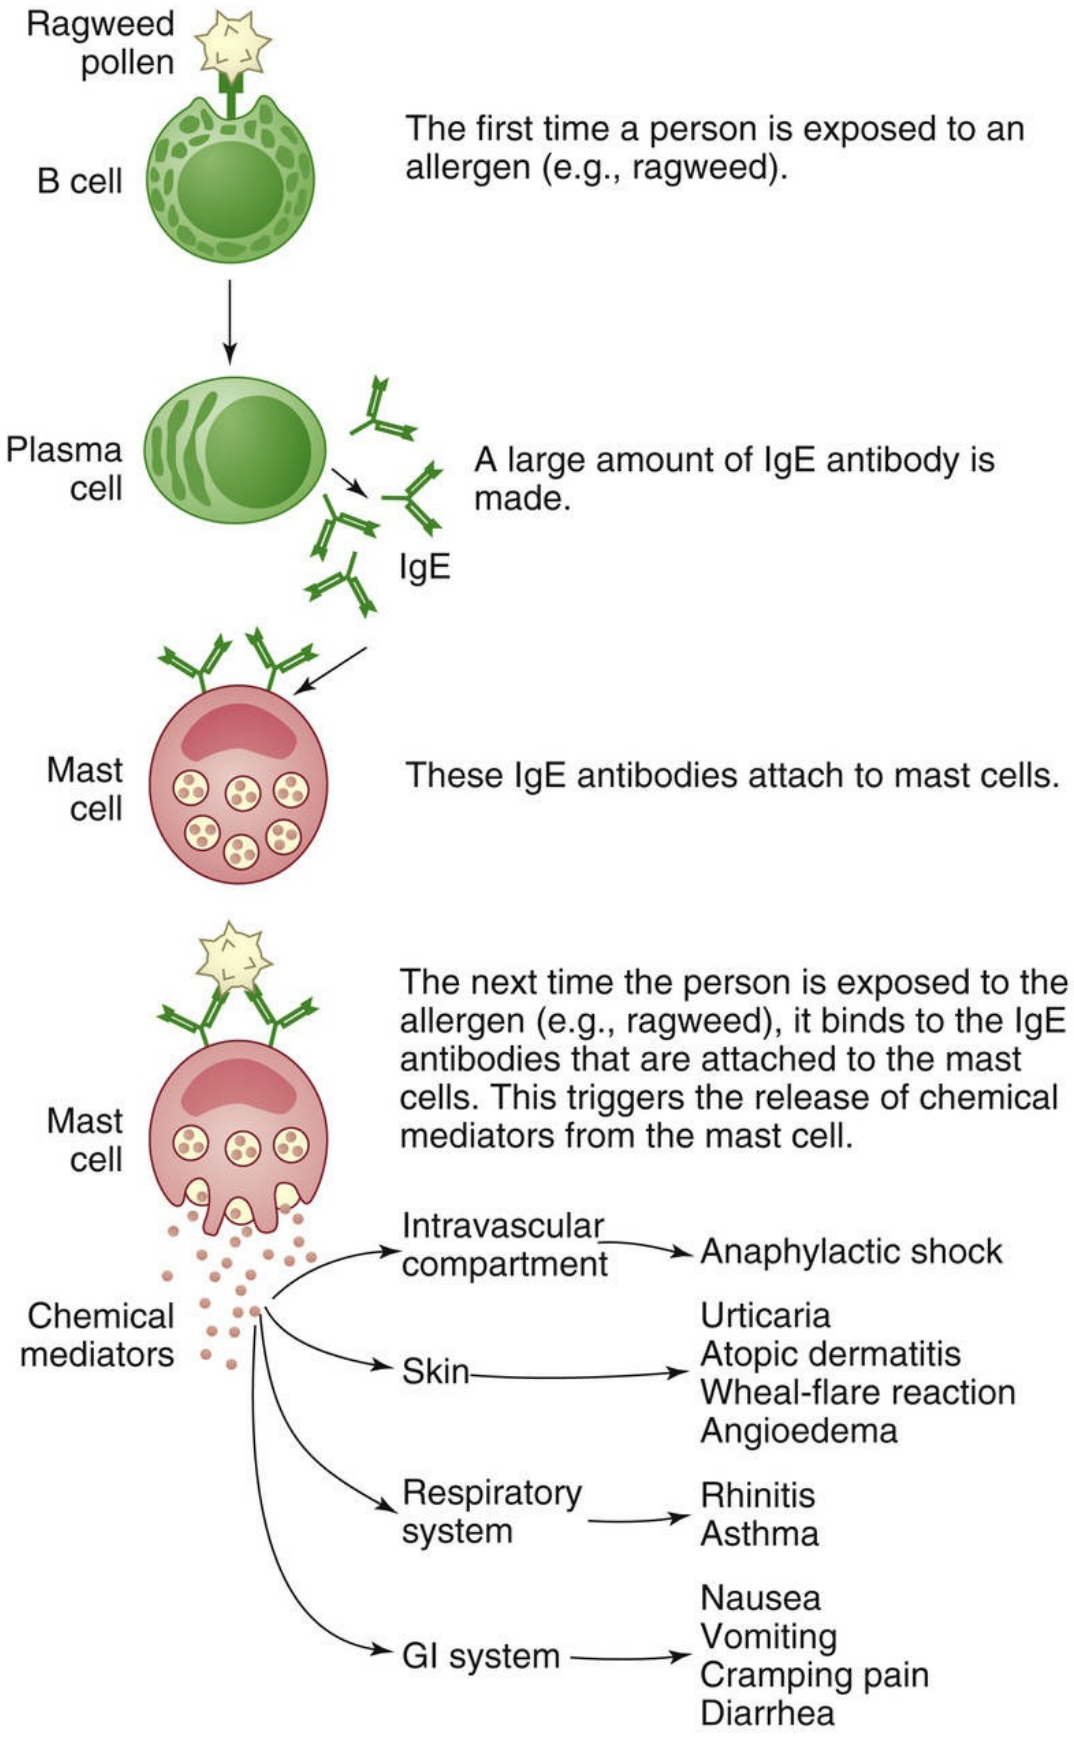
On the first exposure to the allergen, IgE antibodies are made and bind to mast cells and basophils. On any subsequent exposures, the allergen links with the IgE bound to mast cells or basophils and triggers degranulation of the cells and the release of chemical mediators from the granules. In this process, the mediators that are released attack target tissues, causing clinical symptoms of an allergic response. These effects include smooth muscle contraction, increased vascular permeability, vasodilation, hypotension, increased secretion of mucus, and itching. Fortunately, the mediators are short acting and their effects are reversible. The mediators are listed in Table 13.8.

A genetic predisposition to the development of allergic diseases exists. The capacity to become sensitized to an allergen, rather than the specific allergic disorder, appears to be the inherited trait. For example, a father with asthma may have a son who has allergic rhinitis.

The manifestations of an anaphylactic reaction depend on whether the mediators remain localized or become systemic or whether they affect specific organs. When the mediators are localized, a cutaneous response termed the *wheal-and-flare reaction* occurs. This reaction is characterized by a pale wheal containing edematous fluid surrounded by a red flare from the hyperemia. The reaction occurs in minutes or hours and is usually not dangerous. A classic example of a wheal-and-flare reaction is the mosquito bite. The wheal-and-flare reaction serves a diagnostic purpose as a means of showing allergic reactions to specific allergens during skin tests.

TABLE 13.7 Types of Hypersensitivity Reactions

Type I: IgE-Mediated	Type II: Cytotoxic	Type III: Immune-Complex	Type IV: Delayed Hypersensitivity
Antigen			
Pollen, food, drugs, dust	Cell surface of RBCs Cell basement membrane	Extracellular fungal, viral, bacterial	Intracellular or extracellular
Rate of Development			
Immediate	Minutes to hours	Hours to days	Several days
Complement Involved			
No	Yes	Yes	No
Mediators of Injury			
Histamine **Mast cells** **Leukotrienes** **Prostaglandins**	Complement lysis Macrophages in tissues	Neutrophils Complement lysis Monocytes, macrophages Lysosomal enzymes	Cytokines T cytotoxic cells
Examples			
Allergic rhinitis **Asthma** **Atopic dermatitis** **Urticaria** **Angioedema**	Transfusion reaction Goodpasture syndrome Immune thrombocytopenic purpura Graves' disease	SLE Rheumatoid arthritis Acute glomerulonephritis	Contact dermatitis (e.g., to poison ivy)
Skin Test			
Wheal and flare	None	Erythema and edema in 3–8 hr	Erythema and edema in 24–48 hr (e.g., TB test)



Ragweed pollen
B cell
The first time a person is exposed to an allergen (e.g., ragweed).
Plasma cell
A large amount of IgE antibody is made.
IgE
Mast cell
These IgE antibodies attach to mast cells.
Mast cell
The next time the person is exposed to the allergen (e.g., ragweed), it binds to the IgE antibodies that are attached to the mast cells. This triggers the release of chemical mediators from the mast cell.
Chemical mediators
Intravascular compartment
Anaphylactic shock
Skin
Urticaria
Atopic dermatitis
Wheal-flare reaction
Angioedema

Diarrhea

FIG. 13.6 Steps in a type I allergic reaction.

TABLE 13.8 Mediators of Allergic Response

- Anaphylatoxins (C3a, C4a, C5a from complement activation)
- Histamine
- Kinins
- Leukotrienes
- Platelet-activating factor
- Prostaglandins
- Serotonin

Common allergic reactions include anaphylaxis and atopic reactions.

Anaphylaxis

Anaphylaxis can occur when mediators are released systemically (e.g., after injection of a drug, after an insect sting). The reaction occurs within minutes and can be life threatening because of bronchial constriction and subsequent airway obstruction and vascular collapse. The target organs affected are shown in Fig. 13.7. Initial symptoms include edema and itching at the site of exposure to the allergen. Shock can occur rapidly and is manifested by rapid, weak pulse; hypotension; dilated pupils; dyspnea; and possibly cyanosis. Bronchial edema and angioedema can compound shock. Death will occur without emergency treatment. Some of the important allergens that can cause anaphylactic shock in hypersensitive people are listed in Table 13.9. Drugs are the leading cause of anaphylaxis-related deaths.[2]

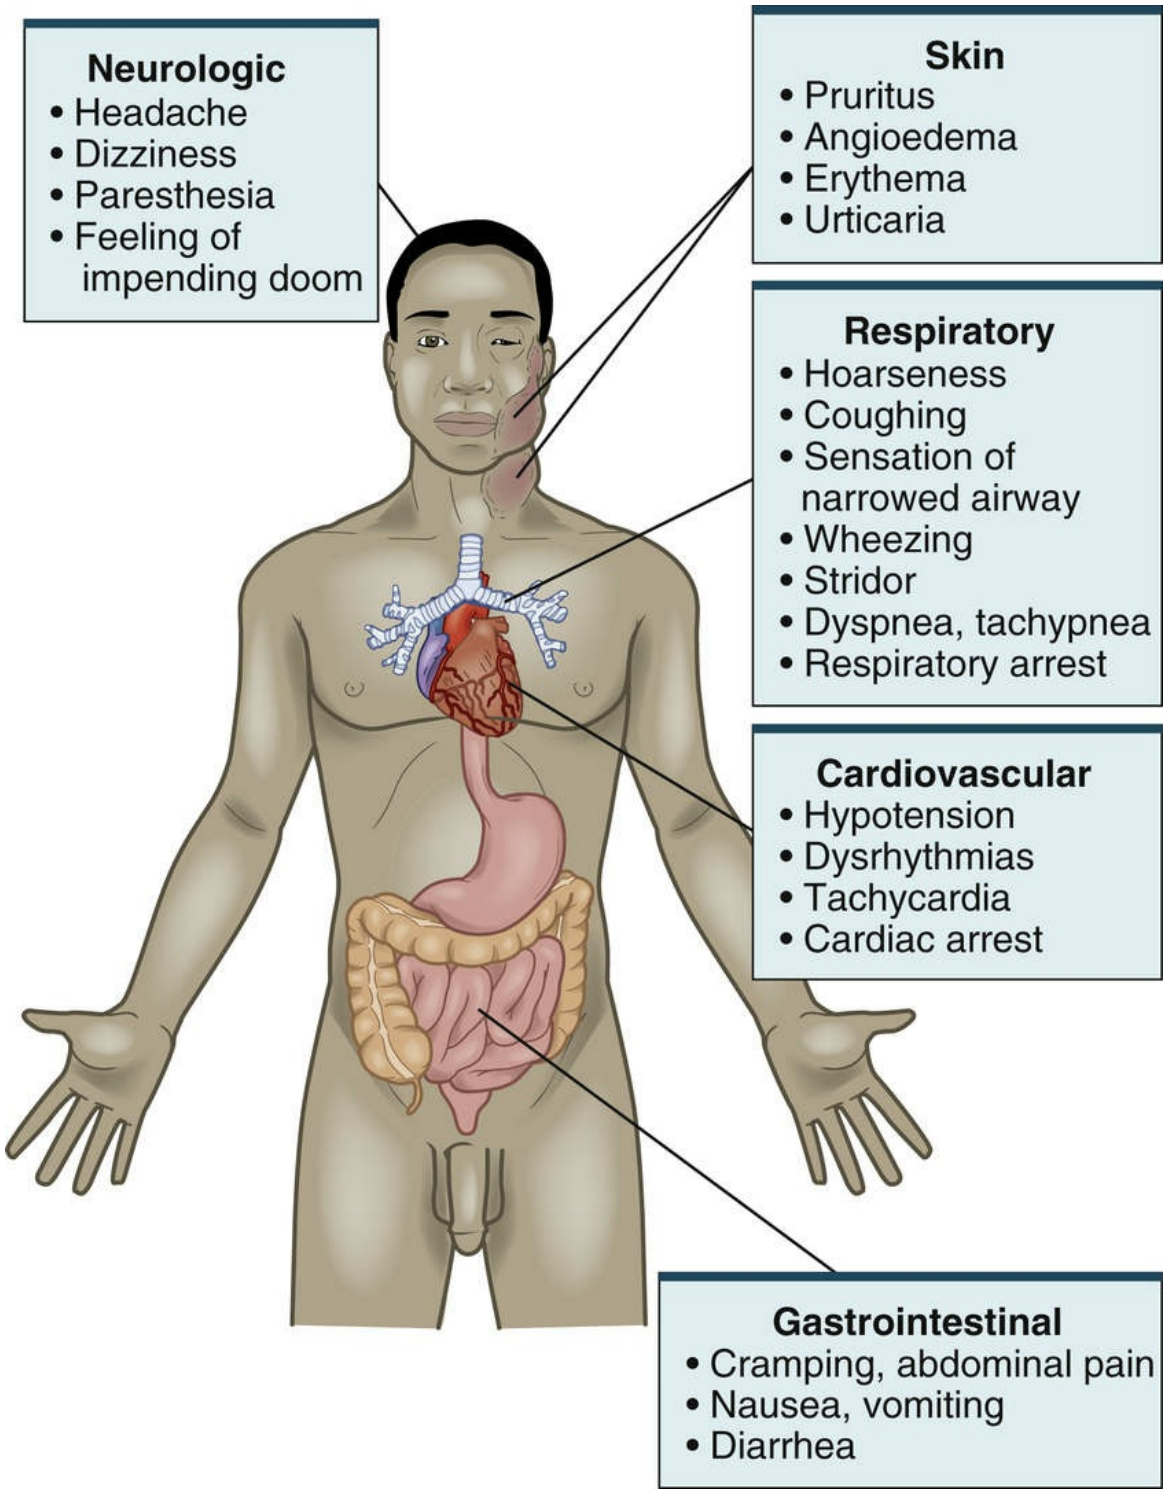

FIG. 13.7 Manifestations of a systemic anaphylactic reaction.

Atopic Reactions

Around 20% of the population is *atopic,* having an inherited tendency

to become sensitive to environmental allergens. The atopic diseases that can result are allergic rhinitis, asthma, atopic dermatitis, urticaria, and angioedema.

Allergic rhinitis, or hay fever, is the most common type I hypersensitivity reaction. It may occur year-round (perennial allergic rhinitis), or it may be seasonal (seasonal allergic rhinitis). Airborne substances such as pollens, dust, and molds are the primary causes of allergic rhinitis. Dust, molds, and animal dander often cause perennial allergic rhinitis. Seasonal allergic rhinitis is often caused by pollens from trees, weeds, or grasses. The target areas affected are the conjunctiva of the eyes and the mucosa of the upper respiratory tract. Symptoms include nasal discharge; sneezing; tearing; mucosal swelling with airway obstruction; and pruritus around the eyes, nose, throat, and mouth. Treatment of allergic rhinitis is discussed in Chapter 26 on p. 480.

Many patients with *asthma* have an allergic component to their disease. These patients often have a history of atopic disorders (e.g., infantile eczema, allergic rhinitis, food intolerances). Inflammatory mediators produce bronchial smooth muscle constriction, excess secretion of thick mucus, edema of the mucous membranes of the bronchi, and decreased lung compliance. Because of these physiologic changes, patients have dyspnea, wheezing, coughing, tightness in the chest, and thick sputum. Asthma is discussed in depth in Chapter 28.

TABLE 13.9 Allergens Causing Anaphylactic Shock

Drugs
• Aspirin • Cephalosporins • Chemotherapy drugs • Insulins

- Local anesthetics
- Nonsteroidal antiinflammatory drugs
- Penicillins
- Sulfonamides
- Tetracycline

Foods

- Eggs, milk, nuts, peanuts, shellfish, fish, chocolate, strawberries

Treatment Measures

- Allergenic extracts used in immunotherapy
- Blood products (whole blood and components)
- Iodine-contrast media for CT scan or other radiologic procedures

Insect Venoms

- Wasps, hornets, yellow jackets, bumblebees, ants

Animal Sera

- Diphtheria antitoxin
- Rabies antitoxin
- Snake venom antitoxin
- Tetanus antitoxin

Atopic dermatitis is a chronic, inherited skin disorder characterized by exacerbations and remissions. It is caused by several environmental allergens that are often hard to identify. Although patients with atopic dermatitis have high IgE levels and positive skin

tests, the histopathologic features do not represent the typical, localized wheal-and-flare type I reactions. The skin lesions are more generalized and involve vasodilation of blood vessels, resulting in interstitial edema with vesicle formation (Fig. 13.8). Dermatitis is discussed in Chapter 23.

Urticaria (hives) is a cutaneous reaction against systemic allergens occurring in atopic people. It is characterized by transient wheals (pink, raised, edematous, pruritic areas) that vary in size and shape and may occur all over the body. Urticaria develops rapidly after exposure to an allergen and may last minutes or hours. Histamine causes localized vasodilation (erythema), transudation of fluid (wheal), and flaring. Flaring is due to dilated blood vessels on the edge of the wheal. Histamine is responsible for the pruritus associated with the lesions. Urticaria is discussed in Chapter 23.

Angioedema is a localized cutaneous lesion similar to urticaria but involving deeper layers of the skin and submucosa. The principal areas of involvement include the eyelids, lips, tongue, larynx, hands, feet, GI tract, and genitalia (Fig. 13.9). Swelling usually begins in the face and then progresses to the airways and other parts of the body. Dilation and engorgement of the capillaries secondary to the release of histamine cause the diffuse swelling. Welts are not present as in urticaria. The outer skin appears normal or has a reddish hue. The lesions may burn, sting, or itch and can cause acute abdominal pain if in the GI tract. The swelling may occur suddenly or over several hours and usually lasts for 24 hours.

Type II: Cytotoxic and Cytolytic Reactions

Cytotoxic and cytolytic reactions are type II hypersensitivity reactions involving the direct binding of IgG or IgM antibodies to an antigen on the cell surface. Antigen-antibody complexes activate the complement system, which mediates the reaction. Cellular tissue is destroyed by either (1) activation of the complement system resulting in cytolysis or (2) enhanced phagocytosis.

FIG. 13.8 Atopic dermatitis of the hands.
From James W, Berger TG: *Andrews' diseases of the skin,* ed 12, St Louis, 2016, Elsevier.

FIG. 13.9 Allergic reaction with angioedema of the lip.
From Habif TP: *Clinical dermatology*, ed 6, Philadelphia, 2016, Saunders.

Target cells often destroyed in type II reactions are erythrocytes, platelets, and leukocytes. The tissue damage usually occurs rapidly. Some of the antigens involved are the ABO blood group, Rh factor, and drugs. Pathophysiologic disorders characteristic of type II reactions include ABO incompatibility transfusion reaction, Rh incompatibility transfusion reaction, autoimmune and drug-related hemolytic anemias, leukopenias, thrombocytopenias, erythroblastosis fetalis (hemolytic disease of the newborn), and Goodpasture syndrome.

Hemolytic Transfusion Reactions

A classic type II reaction occurs when a recipient receives ABO-incompatible blood from a donor. Naturally acquired antibodies to antigens of the ABO blood group are in the recipient's serum but are not present on the erythrocyte membranes (see). For example, a person with type A blood has anti-B antibodies, a person with type B blood has anti-A antibodies, a person with type AB blood has no antibodies, and a person with type O blood has anti-A and anti-B antibodies.

If the recipient is transfused with incompatible blood, antibodies immediately coat the foreign erythrocytes, causing *agglutination* (clumping). The clumping of cells blocks small blood vessels in the body, uses existing clotting factors, and depletes them, leading to bleeding. Within hours, neutrophils and macrophages phagocytize the agglutinated cells. The complement system is activated. Cell lysis occurs, which causes the release of hemoglobin into the urine and plasma. Acute kidney injury can result from the hemoglobinuria. Blood transfusions are discussed in Chapter 30.

Goodpasture Syndrome

Goodpasture syndrome is a disorder involving the lungs and kidneys. An antibody-mediated autoimmune reaction occurs involving the

glomerular and alveolar basement membranes. The circulating antibodies combine with tissue antigen to activate the complement system, which causes deposits of IgG to form along the cell basement membranes of the lungs or kidneys. This reaction may result in pulmonary hemorrhage and glomerulonephritis. Goodpasture syndrome is discussed in Chapter 45.

Type III: Immune-Complex Reactions

Tissue damage in immune-complex reactions, which are type III reactions, occurs secondary to antigen-antibody complexes. Soluble antigens combine with IgG and IgM to form complexes that are too small to be effectively removed by the mononuclear phagocyte system. Therefore the complexes deposit in tissue or small blood vessels. They cause activation of the complement system and release of chemotactic factors that lead to inflammation and destruction of the involved tissue.

Type III reactions may be local or systemic and immediate or delayed. The manifestations depend on the number of complexes and the location in the body. Common sites for deposit are the kidneys, skin, joints, blood vessels, and lungs. Severe type III reactions are associated with autoimmune disorders such as systemic lupus erythematosus (SLE), acute glomerulonephritis, and rheumatoid arthritis. SLE and rheumatoid arthritis are discussed in Chapter 64. Acute glomerulonephritis is discussed in Chapter 45.

Type IV: Delayed Hypersensitivity Reactions

A *delayed hypersensitivity reaction*—a type IV reaction—is a *cell-mediated immune response.* Although cell-mediated responses are usually protective mechanisms, tissue damage occurs in delayed hypersensitivity reactions.

The tissue damage in a type IV reaction does not occur in the presence of antibodies or complement. Rather, sensitized T cells attack antigens or release cytokines. Some of these cytokines attract macrophages into the area. The macrophages and enzymes released by them are responsible for most of the tissue destruction. In the

delayed hypersensitivity reaction, it takes 24 to 48 hours for a response to occur.

Examples of delayed hypersensitivity reactions include contact dermatitis (Fig. 13.10); hypersensitivity reactions to bacterial, fungal, and viral infections; and transplant rejections. Some drug sensitivity reactions also fit this category.

Contact Dermatitis

Allergic contact dermatitis is an example of a delayed hypersensitivity reaction involving the skin. The reaction occurs when the skin is exposed to substances that easily penetrate the skin to combine with epidermal proteins. The substance then becomes antigenic. Over a period of 7 to 14 days, memory cells form to the antigen. On subsequent exposure to the substance, a sensitized person develops eczematous skin lesions within 48 hours. The most common antigenic substances are metal compounds (e.g., those containing nickel or mercury); rubber compounds; poison ivy, poison oak, and poison sumac; cosmetics; and some dyes.

In acute contact dermatitis, the skin lesions appear erythematous and edematous and are covered with papules, vesicles, and bullae. The involved area is pruritic but may burn or sting. When contact dermatitis becomes chronic, the lesions resemble atopic dermatitis because they are thickened, scaly, and lichenified. The main difference between contact dermatitis and atopic dermatitis is that contact dermatitis is localized and restricted to the area exposed to the allergens. Atopic dermatitis is usually widespread.

FIG. 13.10 Contact dermatitis to rubber.
From Morison MJ: *Nursing management of chronic wounds,* Edinburgh, 2001, Mosby.

Microbial Hypersensitivity Reactions

The classic example of a microbial cell-mediated immune reaction is the body's defense against the tubercle bacillus. Tuberculosis results from invasion of lung tissue by the highly resistant tubercle bacillus. The organism itself does not directly damage the lung tissue. However, antigenic material released from the tubercle bacilli reacts with T cells, initiating a cell-mediated immune response. The resulting response causes extensive caseous necrosis of the lung.

After the first cell-mediated reaction, memory cells persist, so subsequent contact with the tubercle bacillus or an extract of purified protein from the organism causes a delayed hypersensitivity reaction. This is the basis for the purified protein derivative (PPD) tuberculosis skin test, which we read 48 to 72 hours after injecting the PPD intradermally. Tuberculosis is discussed in Chapter 27.

Allergic Disorders

Assessment

For a thorough assessment of a patient with allergies, obtain a complete history and perform a comprehensive physical examination, diagnostic workup, and skin testing for allergens. Obtain information from the patient about family allergies, past and present allergies, and social and environmental factors.

Family history, including information about atopic reactions in relatives, is especially important in identifying at-risk patients. Note past and present allergies. Obtain information about the manifestations and course of allergic reaction. The time of year when an allergic reaction occurs can be a clue to a seasonal allergen. Ask about any over-the-counter or prescription medications used to treat the allergies.

Social and environmental factors, especially the physical environment, are important. Ask about pets, trees and plants on the property, pollutants in the air, floor coverings, houseplants, and cooling and heating systems in the home and workplace. Note any reactions to medication. A daily or weekly food diary with a description of any untoward reactions may be useful.[3] Ask about the patient's lifestyle and stress level in connection with the allergic symptoms.

TABLE 13.10 Nursing AssessmentAllergies

Subjective Data
Important Health Information

Past health history: Recurrent respiratory problems, seasonal exacerbations. Unusual reactions to insect bites or stings; past and present allergies

Medications: Unusual reactions to any medications; use of over-

the-counter drugs or medications for allergies

Functional Health Patterns

Health perception–health management: Family history of allergies; malaise
Nutritional-metabolic: Food intolerances, vomiting
Elimination: Abdominal cramps, diarrhea
Activity-exercise: Fatigue; hoarseness, cough, dyspnea
Cognitive-perceptual: Itching, burning, stinging of eyes, nose, throat, or skin; chest tightness
Role-relationship: Altered home and work environment, presence of pets

Objective Data
Integumentary

Rashes, including urticaria, wheal and flare, papules, vesicles, bullae; dryness, scaliness, scratches, irritation

Eyes, Ears, Nose, and Throat

Eyes: Conjunctivitis, lacrimation, rubbing or excessive blinking, dark circles under the eyes (“allergic shiner”)
Ears: Diminished hearing, immobile or scarred tympanic membranes, recurrent ear infections
Nose: Nasal polyps, nasal voice, nose twitching, itchy nose, rhinitis; pale, boggy mucous membranes; sniffling, repeated sneezing; swollen nasal passages; recurrent, unexplained nosebleeds; crease across the bridge of nose (“allergic salute”)
Throat: Continual throat clearing, swollen lips or tongue, red throat, palpable neck lymph nodes

Respiratory

Wheezing, stridor; thick sputum

Possible Diagnostic Findings

Eosinophilia of serum, sputum, or nasal and bronchial secretions; increased serum IgE levels; positive skin tests; abnormal chest and sinus x-rays

Table 13.10 outlines subjective and objective data to obtain. During the physical examination, focus attention on the site of the allergic manifestations.

Diagnostic Studies

Various immunologic techniques are used to detect abnormalities of lymphocytes, eosinophils, and immunoglobulins. A complete blood count (CBC) with WBC differential is done, with an absolute lymphocyte count and eosinophil count. Immunodeficiency is diagnosed if the lymphocyte count is below 1200/μL (1.2×10^9/L). T cell and B cell quantification is used to diagnose specific immunodeficiency syndromes. The eosinophil count is high in type I hypersensitivity reactions involving IgE. The serum IgE level is also generally high in type I hypersensitivity reactions and serves as a diagnostic indicator of atopic diseases.

We can test sputum and nasal and bronchial secretions for the presence of eosinophils. Pulmonary function tests, especially for forced expiratory volume, are helpful for patients with asthma.

Skin testing for allergens is the preferred method. Sometimes skin testing is contraindicated and blood allergy testing is used. Allergy blood testing is recommended if a person (1) is using a drug that interferes with skin test results (e.g., antihistamines, corticosteroids) and cannot stop taking it for a few days, (2) cannot tolerate the many

needle scratches needed for skin testing, or (3) has a skin disorder (e.g., severe eczema, dermatitis, psoriasis).

Skin Tests

Skin testing is used to identify the specific allergens that are causing the allergy symptoms. With the use of empiric allergy medications as the treatment of choice for most allergic rhinitis, it has become common practice to omit skin testing for specific allergens in these patients. However, diagnosing an allergy to a specific antigen allows the patient to avoid an allergen and makes him or her a candidate for immunotherapy. Unfortunately, we cannot do skin testing on patients who cannot stop taking drugs that suppress the histamine response or patients with food allergies.

Procedure

We can do skin testing by 3 different methods: (1) a scratch or prick test, (2) an intradermal test, or (3) a patch test. The areas of the body usually used in skin testing are the arms and back. Allergen extracts are applied to the skin in rows with a corresponding control site opposite the test site. Saline or another diluent is applied to the control site. In the *scratch test* a drop of allergen is placed on the skin, and then a pricking device is used so that the allergen can enter the skin. In the *intradermal test* the allergen extract is injected under the skin, similar to a PPD test for TB. In the *patch test* an allergen is applied to a patch that is placed on the skin.

Results

In the scratch and intradermal tests, the reaction occurs in 5 to 10 minutes. In the patch test the patches must be worn for 48 to 72 hours. If the person is hypersensitive to the allergen, a positive reaction will occur within minutes after insertion in the skin and may last for 8 to 12 hours. We will see a local wheal-and-flare response with a positive reaction.

The size of the positive reaction does not always correlate with the

severity of allergy symptoms. False-positive and false-negative results may occur. Negative results from skin testing do not always mean the person does not have an allergic disorder. Positive results do not always mean that the allergen was causing the manifestations. Positive results imply that the person is sensitized to that allergen. Therefore correlating skin test results with the patient's history is important.

Precautions

A highly sensitive person is always at risk for developing an anaphylactic reaction to skin tests. Therefore never leave a patient during the testing period. If a severe reaction does occur with a skin test, the extract is immediately removed and antiinflammatory topical cream is applied to the site. For intradermal testing, the arm is best so that a tourniquet can be applied during a severe reaction. A subcutaneous injection of epinephrine may be needed.

Interprofessional and Nursing Management

After an allergic disorder is diagnosed, treatment is aimed at reducing exposure to the offending allergen, treating the symptoms, and, if needed, desensitizing the person through immunotherapy.

TABLE 13.11 Emergency Management Anaphylactic Shock

Etiology

- Injection of, inhalation of, ingestion of, or topical exposure to substance that produces profound allergic response (Table 13.9)

Assessment Findings

- See Fig. 13.7

Interventions
Initial

- Ensure patent airway. Intubation if evidence of impending obstruction
- Remove insect stinger if present
- Establish IV access
- Epinephrine (1 mg/mL preparation): Give 0.3–0.5 mg IM preferably in the mid-outer thigh. Can repeat every 5–15 min.
- Give high-flow O_2 (8–10 L/min) via face mask. Can give up to 100% as needed
- Nebulized albuterol for bronchospasm resistant to epinephrine
- Diphenhydramine IV for urticaria and itching
- Corticosteroids: Methylprednisolone IV

Hypotension

- Place recumbent and elevate legs
- IV normal saline rapid bolus of 1–2 L
- Maintain BP with fluids, volume expanders, vasopressors (e.g., dopamine)

Ongoing Monitoring

- Monitor vital signs, respiratory effort, O_2 saturation, level of consciousness, cardiac rhythm, and urine output
- Anticipate intubation with severe respiratory distress
- Anticipate cricothyrotomy or tracheostomy with severe laryngeal edema

Anaphylaxis

Anaphylactic reactions occur suddenly in hypersensitive patients after exposure to the offending allergen. They may occur after parenteral injection of drugs (especially antibiotics) or blood products and after insect stings. The cardinal principle in management is speed in (1) recognizing signs and symptoms of an anaphylactic reaction, (2) maintaining a patent airway, (3) giving drugs, and (4) treating for shock. Table 13.11 outlines the emergency treatment of anaphylactic shock.

Epinephrine is the drug of choice to treat an anaphylactic reaction. It must be given parenterally (IM, IV). Patients receiving β-blockers may be resistant to treatment with epinephrine and can develop refractory hypotension and bradycardia. Glucagon should be given to these patients because it has inotropic and chronotropic effects that are not mediated through β-receptors. Severe cases of anaphylaxis may result in hypovolemic shock because of the loss of intravascular fluid into interstitial spaces that occurs due to increased capillary permeability.[4] Peripheral vasoconstriction and stimulation of the sympathetic nervous system occur to compensate for the fluid shift. However, unless shock is treated early, the body will no longer be able to compensate and irreversible tissue damage will occur, leading to death. (Hypovolemic shock is discussed in Chapter 66.)

Check Your Practice

You are caring for a patient who has been receiving IV antibiotic therapy for 2 days. Several minutes after starting the latest infusion, the patient states that his chest feels tight and begins coughing. You take his BP and it is 100/64 and his pulse is 124.

- What should you do?

All health care workers must be prepared for the rare but life-threatening anaphylactic reaction, which requires immediate medical

and nursing interventions. It is extremely important to list all the patient's allergies on the chart, nursing care plan, and medication record.

Chronic Allergies

Most allergic reactions are chronic. They are characterized by remissions and exacerbations of symptoms. Treatment focuses on identification and control of allergens, relief of symptoms through drug therapy, and hyposensitization of a patient to an offending allergen.

Allergen Recognition and Control

You play a key role in helping the patient make lifestyle adjustments so that there is minimal exposure to offending allergens. Reinforce that, even with drug therapy and immunotherapy, the patient will never be totally desensitized or completely symptom free. Help the patient use various preventive measures to control the allergic symptoms.

Of primary importance is the need to identify the offending allergen. Sometimes this is done through skin testing. In the case of food allergies an elimination diet is sometimes valuable. If an allergic reaction occurs, all foods eaten shortly before the reaction should be eliminated and gradually reintroduced 1 at a time until the offending food is detected.

Many allergic reactions, especially asthma and urticaria, may be worsened by fatigue and emotional stress. Help the patient plan a stress management program. Have the patient practice relaxation techniques when coming in for frequent immunotherapy treatments.

Sometimes control of allergic symptoms requires environmental control, including changing an occupation, moving to a different climate, or giving up a favorite pet. In the case of airborne allergens, sleeping in an air-conditioned room, damp dusting daily, covering mattresses and pillows with hypoallergenic covers, and wearing a mask outdoors may be helpful.

If the allergen is a drug, have the patient avoid the drug. The

patient has the responsibility to make any drug allergies known to all health care team members. The patient should wear a Medic Alert bracelet listing the drug allergy and have the drug allergy listed on all medical and dental records.

For a patient allergic to insect stings, commercial kits containing automatic injectable epinephrine are available. Teach the patient and family how to use the injector and have them practice assembling and using the non–drug containing training device (Table 13.12). This patient should wear a Medic Alert bracelet and carry an insect-sting kit whenever going outdoors.

Drug Therapy

The major categories of drugs used for symptomatic relief of chronic allergic disorders include antihistamines, sympathomimetic/decongestant drugs, corticosteroids, antipruritic drugs, and mast cell–stabilizing drugs. Many of these drugs can be bought OTC and are often misused by patients.

TABLE 13.12 Patient and Caregiver TeachingAutomatic Epinephrine Injectors

Include the following information when teaching the patient and caregiver how to use an automatic epinephrine injector.

1. Fill the prescription at once and keep at least 2 doses available.
2. Always keep at least 1 autoinjector with you.
3. Keep an autoinjector in a place where others can easily find it in case of an emergency. Tell family and friends where it is stored.
4. Keep the autoinjector in the original case, at room temperature, away from extremes of cold and heat.
5. Mark on your calendar when the autoinjector expires, although an expired autoinjector may be used if there is no alternative. Replace solutions that are discolored or contain particles.
6. Use the device if you have any sign of anaphylaxis, such as

trouble breathing or feeling tightness in the throat or lightheaded.

7. When needed:
    - Inject the drug into the top of the thigh, slightly to the outside, at a 90-degree angle. Hold in place for at least 2 to 3 seconds.
    - You can inject the drug through clothes. Avoid pockets and seams where the fabric is thick.
    - After use, call 911 and get to the nearest hospital for monitoring. Take the autoinjector with you.

Antihistamines

Antihistamines are the best drugs for treatment of allergic rhinitis and urticaria (see Chapter 26,). They are less effective for severe allergic reactions. They act by competing with histamine for H_1-receptor sites, thus blocking the effect of histamine. Results are best if they are taken as soon as allergy symptoms appear. Antihistamines can be used effectively to treat edema and pruritus. They are ineffective in preventing bronchoconstriction. With seasonal rhinitis, antihistamines should be taken during peak pollen seasons.

Sympathomimetic/Decongestant Drugs

The major sympathomimetic drug is epinephrine (Adrenalin). Epinephrine is made by the adrenal medulla and stimulates α- and β-adrenergic receptors. Stimulation of the α-adrenergic receptors causes vasoconstriction of peripheral blood vessels. β-Receptor stimulation relaxes bronchial smooth muscles. Epinephrine also acts directly on mast cells to stabilize them against further degranulation. The action of epinephrine lasts only a few minutes.

Minor sympathomimetic drugs differ from epinephrine because they are taken orally or nasally and last for several hours. Included in this category are drugs containing phenylephrine and pseudoephedrine. The minor sympathomimetic drugs are used mainly to treat allergic rhinitis (see Chapter 26 and).

Corticosteroids

Nasal corticosteroid sprays are effective in relieving the symptoms of allergic rhinitis (see Chapter 26 and). Occasionally patients have such severe manifestations of allergies that they are truly incapacitated. In these situations, a brief course of oral corticosteroids can be used.

Antipruritic Drugs

Topically applied antipruritic drugs are most effective when the skin is intact. These drugs protect the skin and provide relief from itching. Common OTC drugs include calamine lotion, coal tar solutions, and camphor. Menthol and phenol may be added to other lotions to produce an antipruritic effect.

Mast Cell–Stabilizing Drugs

Cromolyn is a mast cell–stabilizing agent that inhibits the release of histamines, leukotrienes, and other agents from the mast cell after antigen-IgE interaction. It is available as an inhalant nebulizer solution or a nasal spray. Cromolyn is used in the management of allergic rhinitis (see Chapter 26).

Leukotriene Receptor Antagonists

Leukotriene receptor antagonists (LTRAs) block leukotriene, 1 of the major mediators of the allergic inflammatory process (see). These medications can be taken orally. They are used to treat allergic rhinitis and asthma.

Immunotherapy

Immunotherapy is the recommended treatment for control of allergic symptoms when the allergen cannot be avoided and drug therapy is not effective. Few patients with allergies have symptoms so intolerable that they need allergy immunotherapy. Immunotherapy is definitively indicated for those with anaphylactic reactions to insect venom.

Immunotherapy involves giving small titers of an allergen extract in

increasing strengths until hyposensitivity to the specific allergen is achieved. For best results, teach the patient to avoid the offending allergen whenever possible because complete desensitization is impossible. Unfortunately, not all allergy-related conditions respond to immunotherapy. Food allergies cannot be safely treated with this therapy. Eczema may worsen with immunotherapy.

Mechanism of Action

The IgE level is high in atopic people. When IgE combines with an allergen in a hypersensitive person, a reaction occurs, releasing histamine in various body tissues. Allergens more readily combine with IgG than with other immunoglobulins. Therefore immunotherapy involves injecting allergen extracts that will stimulate increased IgG levels. The goal of long-term immunotherapy is to keep "blocking" IgG levels high. By increasing IgG levels, IgE is blocked from binding to the allergen. This prevents mast cell degranulation. In addition, allergen-specific T suppressor cells develop in those receiving immunotherapy.

Method of Administration

The allergens included in immunotherapy are chosen based on the results of skin testing with a panel of allergens. Results are best when immunotherapy is given throughout the year.

Subcutaneous immunotherapy

Subcutaneous immunotherapy (SCIT) involves the subcutaneous injection of titrated amounts of allergen extracts biweekly or weekly. The dose is small at first and then increased slowly until a maintenance dosage is reached. Generally, it takes 1 to 2 years of immunotherapy to reach the maximal therapeutic effect. Therapy may continue for about 5 years. After that, some patients may stop therapy. Many have a sustained decrease in symptoms after the treatment is stopped. Those with severe allergies or sensitivity to insect stings may continue maintenance therapy indefinitely.

Sublingual immunotherapy

Sublingual immunotherapy (SLIT) involves allergen extracts taken under the tongue. SLIT has been used in Europe for decades. Recently the first sublingual products have become available in the United States. These include a 5-grass pollen tablet (Oralair), a single grass pollen tablet (Grastek), and a ragweed pollen tablet (Ragwitek).[5]

Patients usually take SLIT once daily at home. The first dose is usually given under medical supervision. Some patients have local application site reactions (e.g., oral pruritus, throat irritation, tongue swelling). Local reactions subside in many patients within a few days to a week. Systemic allergic reactions are markedly fewer than with SCIT.

SLIT has the advantage of being a convenient, self-administered oral therapy. Its primary disadvantage is that the patient must consistently adhere to the therapy.[6]

Nursing Management: Immunotherapy

You will often be the person responsible for giving SCIT. Immunotherapy always carries the risk for a severe anaphylactic reaction. Therefore an HCP, emergency equipment, and essential drugs should be available whenever injections are given. Always anticipate adverse reactions, especially when using a new dose strength, after a previous reaction, or after a missed dose. Early manifestations of a systemic reaction include pruritus, urticaria, sneezing, laryngeal edema, and hypotension. If these occur, initiate emergency measures for anaphylactic shock at once.

Describe any local reaction according to the degree of redness and swelling at the injection site. If the area is greater than the size of a quarter in an adult, report the reaction to the HCP so that the allergen dosage may be decreased.

Record keeping must be accurate and can help prevent an adverse reaction to the allergen extract. Before giving an injection, check the patient's name against the name on the vial. Next, determine the vial strength, amount of last dose, date of last dose, and any reaction

information.

Always give the allergen extract in an extremity away from a joint so that a tourniquet can be applied for a severe reaction. Rotate the site for each injection. After giving the injection, carefully observe the patient for 20 to 30 minutes, since systemic reactions are most likely to occur immediately. However, warn the patient that a delayed reaction can occur as long as 24 hours later.

Latex Allergies

Allergies to latex products have become an increasing problem, affecting patients and health care workers. The increase in allergic reactions has coincided with the sharp increase in glove use. The more frequent and prolonged the exposure to latex, the greater the risk for developing a latex allergy.[7]

Besides gloves, we use many other latex-containing products in health care. These include BP cuffs, stethoscopes, tourniquets, IV tubing, syringes, electrode pads, O_2 masks, tracheal tubes, colostomy and ileostomy pouches, urinary catheters, anesthetic masks, and adhesive tape. Latex proteins can become aerosolized through powder on gloves and can result in serious reactions when inhaled by sensitized persons. All health care facilities should use powder-free gloves to avoid respiratory exposure to latex proteins.[8]

Types of Latex Allergies

Two types of latex allergies can occur: type IV allergic contact dermatitis and type I allergic reactions. *Type IV contact dermatitis* is caused by the chemicals used in the manufacturing process of latex gloves. It is a delayed reaction that occurs within 6 to 48 hours. Typically, the person first has dryness, pruritus, fissuring, and cracking of the skin, followed by redness, swelling, and crusting at 24 to 48 hours. Chronic exposure can lead to lichenification, scaling, and hyperpigmentation. The dermatitis may extend beyond the area of physical contact with the allergen.

A *type I allergic reaction* is a response to the natural rubber latex

proteins and occurs within minutes of contact with the proteins. The manifestations of type I reactions can vary from skin redness, urticaria, rhinitis, conjunctivitis, or asthma to full-blown anaphylactic shock. Systemic reactions to latex may result from exposure to latex protein via various routes, including the skin, mucous membranes, inhalation, and blood.

Latex-Food Syndrome

Because some proteins in rubber are similar to food proteins, some foods may cause an allergic reaction in people who are allergic to latex. This is called *latex-food syndrome*. The most common of these foods are banana, avocado, chestnut, kiwi, tomato, water chestnut, guava, hazelnut, potato, peach, grape, and apricot. Most people with latex allergy have a positive allergy test to at least 1 related food.

TABLE 13.13 Guidelines for Preventing Allergic Latex Reactions

- Use nonlatex gloves for activities that are not likely to involve contact with infectious materials (e.g., food preparation, housekeeping).
- Use appropriate barrier protection when handling infectious materials.
- If you choose latex gloves, use powder-free gloves with reduced protein content.
- Do not use oil-based hand creams or lotions when wearing latex gloves.
- Frequently clean work areas that are contaminated with latex-containing dust (e.g., carpets, ventilation ducts).
- Learn to recognize the symptoms of latex allergy: Skin rash; hives; flushing; itching; nasal, eye, or sinus symptoms; asthma; and shock.

- If symptoms of latex allergy develop, avoid direct contact with latex gloves and products.
- Wear a Medic Alert bracelet and carry an epinephrine pen (e.g., EpiPen, Symjepi).

Source: National Institute for Occupational Safety and Health (NIOSH). Retrieved from *www.cdc.gov/niosh*.

Nursing and Interprofessional Management: Latex Allergies

Identifying patients and health care workers sensitive to latex is crucial to prevent adverse reactions. Obtain a thorough health history and history of any allergies, especially for patients with any history of latex contact symptoms. We cannot identify all latex-sensitive people, even with a careful and thorough history. The greatest risk factor is long-term multiple exposures to latex products (e.g., health care personnel, those who have had multiple surgeries, rubber industry workers). Other risk factors include a patient history of allergic rhinitis, asthma, and allergies to certain foods (listed earlier).

Use latex precaution protocols for those patients with a positive latex allergy test or a history of signs and symptoms related to latex exposure. Many health care facilities have created latex-free product carts to use with patients with latex allergies. The National Institute for Occupational Safety and Health (NIOSH) has published recommendations for preventing allergic reactions to latex in the workplace (Table 13.13).

Because of the potential for severe symptoms of food allergy, teach patients to avoid those foods. Other recommendations for people with latex and food allergies include wearing a Medic Alert bracelet or necklace and carrying an injectable epinephrine pen.

Multiple Chemical Sensitivity

Multiple chemical sensitivity (MCS) is a subjective illness marked by recurrent, vague, nonspecific symptoms attributed to low levels of chemical, biologic, or physical agents.

Commonly accused substances include smoke, pesticides, plastics, synthetic fabrics, scented products, petroleum products, and paint fumes. Women between the ages of 30 and 50 are more likely to develop the symptoms. MCS is a controversial diagnosis. It is not recognized as an illness by the American Medical Association or other authorities.[9]

The symptoms that people report are wide-ranging and not specific. They include headache, fatigue, dizziness, nausea, congestion, itching, sneezing, sore throat, chest pain, breathing problems, muscle pain or stiffness, skin rash, diarrhea, bloating, gas, confusion, difficulty concentrating, memory problems, and mood changes. These symptoms are usually subjective, with no evidence of a pathologic condition or physiologic dysfunction.

Diagnosis is usually made based on a patient's health history. There is no established test to diagnose MCS. The most effective treatment for MCS is to avoid the chemicals that may trigger the symptoms and create a chemical-free and odor-free home and workplace.

Psychotherapy is the recommended treatment. In patients who are unwilling to undergo psychotherapy but willing to accept medications, antidepressants, including selective serotonin reuptake inhibitors (SSRIs) (e.g., citalopram [Celexa]), are options. Drugs for anxiety and sleep also have been used.

Autoimmunity

Autoimmunity is an immune response against self in which the immune system no longer differentiates self from nonself. For some unknown reason, immune cells that are normally unresponsive (tolerant to self-antigens) are activated. In autoimmunity, autoantibodies and autosensitized T cells cause pathophysiologic tissue damage.

The cause of autoimmune diseases is still unknown. Age may play

some role because the number of circulating autoantibodies increases in people over age 50. However, the principal factors in the development of autoimmunity are (1) the inheritance of susceptibility genes, which may contribute to the failure of self-tolerance, and (2) initiation of autoreactivity by triggers, such as infections, which may activate self-reactive lymphocytes.

Autoimmune diseases tend to cluster. A given person may have more than 1 autoimmune disease (e.g., rheumatoid arthritis, Addison's disease), or the same or related autoimmune diseases may be found in other members of the same family. This observation has led to the concept of genetic predisposition to autoimmune disease. Most of the genetic research in this area correlates certain human leukocyte antigen (HLA) types with an autoimmune condition. (HLAs and disease association are discussed later in this chapter on p. 204.)

Even in a genetically predisposed person, some trigger is needed to initiate autoreactivity. This may include infectious agents such as a virus. Viral infections can change cells or tissues that are not normally antigenic. The virally induced changes make the cells or tissues antigenic. Viruses may be involved in the development of diseases such as type 1 diabetes. Rheumatic fever and rheumatic heart disease are autoimmune responses triggered by streptococcal infection and mediated by antibodies against group A β-hemolytic streptococci that cross-react with heart muscles and valves and synovial membranes.

Drugs can be precipitating factors in autoimmune disease. Hemolytic anemia can result from methyldopa administration. Procainamide can induce the formation of antinuclear antibodies and cause a lupus-like syndrome.

Gender and hormones have a role in autoimmune disease. More women than men have autoimmune disease. During pregnancy, many autoimmune diseases get better. After delivery, the woman with an autoimmune disease often has an exacerbation.

Autoimmune Diseases

Generally, autoimmune diseases are grouped according to organ-specific and systemic diseases (Table 13.14). SLE is a classic example

of a systemic autoimmune disease characterized by damage to multiple organs. The cause is unknown, but there appears to be a loss of self-tolerance for the body's own DNA antigens.

TABLE 13.14 Examples of Autoimmune Diseases

Systemic Diseases

- Rheumatoid arthritis
- Scleroderma (systemic sclerosis)
- Systemic lupus erythematosus

Organ-Specific Diseases

Blood

- Primary biliary cirrhosis

Muscle

- Myasthenia gravis

In SLE, tissue injury appears to be the result of the formation of antinuclear antibodies. For some reason (possibly a viral infection), the cell membrane is damaged and DNA is released into the systemic circulation, where it is viewed as nonself. This DNA is normally sequestered inside the nucleus of cells. On release into the circulation, the DNA antigen reacts with an antibody. Some antibodies are involved in immune complex formation, and others may cause damage directly. Once the complexes are deposited, the complement system is activated and further damages the tissue, especially the renal glomerulus. SLE is discussed in Chapter 64.

Apheresis

Apheresis is a procedure to separate components of the blood followed by the removal of 1 or more of these components. It is an effective treatment for several autoimmune diseases and other diseases and disorders. Compound words are often used to describe a specific apheresis procedure, depending on the blood components being collected. *Plateletpheresis* is the removal of platelets, usually for collection from normal persons to infuse into patients with low platelet counts (e.g., patients taking chemotherapy who develop thrombocytopenia). *Leukocytapheresis* is a general term indicating the removal of WBCs. It is used in chronic myelogenous leukemia to remove high numbers of leukemic cells.

Apheresis is used in hematopoietic stem cell transplantation to collect stem cells from peripheral blood. These stem cells can then be used to repopulate a person's bone marrow after high-dose chemotherapy (see Chapter 15 for more on hematopoietic stem cell transplants).

Plasmapheresis

Plasmapheresis is the removal of plasma containing components causing or thought to cause disease. It can be used to get plasma from healthy donors to give to patients as replacement therapy.

Plasmapheresis involves the removal of whole blood through an IV

device, and then the blood circulates through the apheresis machine. Inside the machine the blood is divided into plasma and its cellular components by centrifugation or membrane filtration. The plasma is generally replaced with normal saline, lactated Ringer's solution, fresh-frozen plasma, plasma protein fractions, or albumin. When we manually remove blood, we can only take 500 mL at 1 time. However, with the use of apheresis procedures, more than 4 L of plasma can be pheresed in 2 to 3 hours.

Plasmapheresis has been used to treat autoimmune diseases such as SLE, glomerulonephritis, Goodpasture syndrome, myasthenia gravis, rheumatoid arthritis, and Guillain-Barré syndrome. Many of these disorders have circulating autoantibodies (usually of the IgG class) and antigen-antibody complexes. The reason for performing therapeutic plasmapheresis in autoimmune disorders is to remove pathologic substances present in plasma. Immunosuppressive therapy has been used to prevent recovery of IgG production, and plasmapheresis to prevent antibody rebound.

Plasmapheresis may remove inflammatory mediators (e.g., complement) that are responsible for tissue damage. In the treatment of SLE, plasmapheresis is usually reserved for the patient having an acute attack who is unresponsive to conventional therapy.

You need to be aware of side effects associated with plasmapheresis. The most common complications are hypotension and citrate toxicity. Hypotension is usually the result of a vasovagal reaction or transient volume changes. Citrate, used as an anticoagulant, may cause hypocalcemia, which may cause headache, paresthesias, and dizziness.

Immunodeficiency Disorders

When the immune system does not adequately protect the body, immunodeficiency exists. Immunodeficiency disorders involve an impairment of 1 or more immune mechanisms, which include (1) phagocytosis, (2) humoral response, (3) cell-mediated response, (4) complement, and (5) a combined humoral and cell-mediated

deficiency. Immunodeficiency disorders are *primary* if the immune cells are improperly developed or absent and *secondary* if an illness or treatment causes the deficiency. Primary immunodeficiency disorders are rare and often serious. Secondary disorders are more common and less severe.

Primary Immunodeficiency Disorders

The basic categories of primary immunodeficiency disorders are (1) phagocytic defects, (2) B-cell deficiency, (3) T-cell deficiency, and (4) a combined B-cell and T-cell deficiency (Table 13.15).

Secondary Immunodeficiency Disorders

Key factors that may cause secondary immunodeficiency disorders are listed in Table 13.16. Drug-induced immunosuppression is the most common. Immunosuppressive therapy is prescribed for patients to treat autoimmune disorders and to prevent transplant rejection. Immunosuppression is a serious side effect of drugs used in cancer chemotherapy. Generalized leukopenia often results, leading to a decreased humoral and cell-mediated response. Therefore secondary infections are common in immunosuppressed patients.

Malnutrition alters cell-mediated immune responses. When protein is deficient over a prolonged period, the thymus gland atrophies and lymphoid tissue decreases. In addition, an increased susceptibility to infections always exists.

TABLE 13.15 Primary Immunodeficiency Disorders

Disorder	Affected Cells	Genetic Basis
Ataxia-telangiectasia	B, T	Autosomal recessive
Bruton's X-linked agammaglobulinemia	B	X-linked

Chronic granulomatous disease	PMNs, monocytes	X-linked
Common variable hypogammaglobulinemia	B	—
DiGeorge syndrome (thymic hypoplasia)	T	—
Graft-versus-host disease	B, T	—
Job syndrome	PMNs, monocytes	—
Severe combined immunodeficiency disease	Stem, B, T	X-linked or autosomal recessive
Selective IgA, IgM, or IgG deficiency	B	Some X-linked
Wiskott-Aldrich syndrome	B, T	X-linked

Ig, Immunoglobulin; *PMNs*, Polymorphonuclear neutrophils.

Therapies

- Anesthesia
- Radiation
- Surgery

Hodgkin's lymphoma impairs the cell-mediated immune response, and patients may die from severe viral or fungal infections (see Chapter 30). Viruses, especially rubella, may cause immunodeficiency by direct cytotoxic damage to lymphoid cells. Systemic infections can place such a demand on the immune system that resistance to a secondary or another infection is impaired.

Radiation can destroy lymphocytes either directly or through depletion of stem cells. As the radiation dose is increased, more bone

marrow atrophies, leading to severe pancytopenia and suppression of immune function. Splenectomy in children is especially dangerous. They may develop sepsis from a simple respiratory tract infection.

Stress may alter the immune response. This response involves interrelationships among the nervous, endocrine, and immune systems (see Chapter 6).

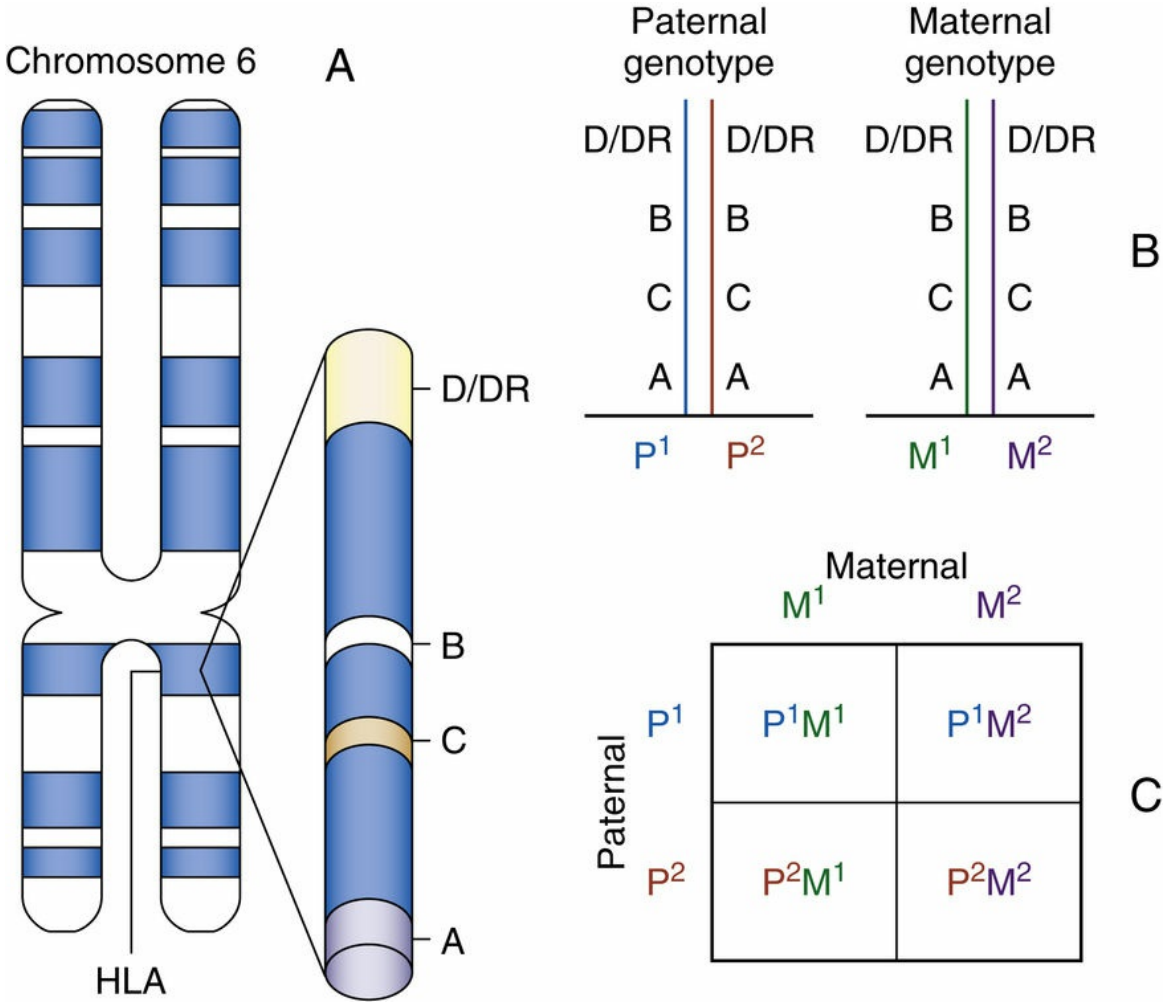

FIG. 13.11 Patterns of human leukocyte antigen (HLA) inheritance. **A,** HLA genes are found on chromosome 6. **B,** The 2 haplotypes of the father are labeled P^1 and P^2, and the haplotypes of the mother are labeled M^1 and M^2. Each child inherits 2 haplotypes, one from each parent. **C,** Therefore only 4 combinations—P^1M^1, P^1M^2, P^2M^1, and P^2M^2—are possible, and 25% of the offspring will have identical HLA haplotypes.

Human Leukocyte Antigen System

The antigens responsible for rejection of genetically unlike tissues are called the *major histocompatibility antigens.* These antigens are products of histocompatibility genes. In humans, they are called the **human leukocyte antigen (HLA)** system. The genes for the HLA antigens are linked and occur together on the sixth chromosome. HLAs are present on all nucleated cells and platelets. We primarily use the HLA system in matching organs and tissues for transplantation.

An important characteristic of HLA genes is that they are highly *polymorphic* (variable). Each HLA locus can have many different possible alleles, and thus many combinations exist. Each person has 2 alleles for each locus, 1 inherited from each parent. Both alleles of a locus are expressed independently (i.e., they are codominant). The proteins encoded by certain genes are known as *antigens*.

The entire set of A, B, C, D, and DR genes (the HLA genes) on 1 chromosome is termed a *haplotype*. A complete set is inherited as a unit (haplotype). One haplotype is inherited from each parent (Fig. 13.11). This means that a person has HLA genes that are half identical to those of each parent. The HLA genes of 1 person have a 25% chance of being identical to the HLA genes of a sibling.

In organ transplantation A, B, and DR are primarily used for compatibility matching. The specific allele at each locus is identified by a number. For example, a person could have an HLA of A2, A6, B7, B27, DR4, and DR7. Currently more than 8000 HLA alleles have been identified for the various HLA genes.

Human Leukocyte Antigen and Disease Associations

The early interest in HLAs was stimulated by the role of HLAs in matching donors and recipients of organ transplants. Since that time, the interest in the association between HLAs and disease has grown. Several diseases show significant associations with specific HLA alleles. People who have these alleles are much more likely to develop

the associated disease than those who do not have the alleles. However, having a particular HLA allele does not mean that the person will necessarily develop the associated disease—only that the relative risk is greater than in the general population.

Most of the HLA-associated diseases are classified as autoimmune disorders. Examples of HLA types and disease associations include (1) HLA-B27 and ankylosing spondylitis; (2) HLA-DR2, HLA-DR3, and SLE; (3) HLA-DR3, HLA-DR4, and diabetes; and (4) HLA-DR2 and narcolepsy.

The discovery of HLA associations with certain diseases was a major breakthrough in understanding the genetic bases of these diseases. It is now known that at least part of the genetic bases of HLA-associated diseases lies in the HLA region, but the actual mechanisms involved in these associations are still unknown. However, most people who inherit a specific HLA type (e.g., HLA-DR3) that is associated with a disease will never develop that disease.

Currently the association between HLAs and certain diseases is of minimal practical clinical importance. Nevertheless, there is promise for the development of clinical applications in the future. For example, with certain autoimmune diseases, it may be possible to identify members of a family at greatest risk for developing the same or a related autoimmune disease. These people would need close medical supervision, implementation of preventive measures (if possible), and early diagnosis and treatment to prevent chronic complications.

Organ Transplantation

Transplantation success has improved with advances in surgical technique, advances in histocompatibility testing, and more effective immunosuppressant drugs. Common tissue transplants include corneas, skin, bone marrow, heart valves, bone, and connective tissues (Fig. 13.12). Cornea transplants can prevent or correct blindness. Skin grafts are used in managing burn patients. Donated bone marrow can help patients with leukemias and other cancers.

Transplanted organs currently come from many different body

systems. These organs include the heart, lung, liver, kidney, pancreas, and intestine. Multiple organs can be transplanted together, such as kidney and pancreas, kidney and liver, kidney and heart, or the complete intestinal tract. For example, some patients with diabetes who receive a pancreas transplant also receive a kidney transplant because the diabetes has not only impaired the pancreas but also led to renal failure.

Some organs can be transplanted in parts or segments instead of transplanting an entire organ. Liver and lung lobes (rather than the whole organ) may be transplanted, or an intestine may be used in segments, thus allowing for 1 person's organ donation to help many recipients. This technique enables living donors to donate part of an organ or 1 of their organs, in the case of kidneys.

Organ donations come from either deceased (cadaver) or living donors. Most organs and tissues currently come from deceased donors. However, because of the shortage of organs from deceased donors, the use of related and living unrelated donor organs is increasing.

FIG. 13.12 Tissues and organs that can be transplanted.

People can indicate their wish to become a donor when they sign a donor card or driver's license or join a donor registry (depending on the state). However, on their death or imminent death, the person's legal next of kin may need to consent to the donation. Legal requirements and the facility's policy for a donor's legal next of kin to consent regardless of whether the donor's wishes varies from state to state and from facility to facility.

Currently more than 116,000 people are on the organ procurement and transplantation network's national waiting list. This list is maintained by the United Network for Organ Sharing (UNOS). However, fewer than 35,000 people receive transplants annually. The organs in highest demand are kidneys, hearts, and livers. These are also the most often transplanted organs.[10] The Uniform Anatomical Gift Act regulates organ and tissue donations to allow for fair and consistent transplantation laws among all states.[11] Patients are matched to available donors based on a number of factors: ABO blood and HLA typing, medical urgency, time on the waiting list, and geographic location.

Tissue Typing

The recipient usually receives a transplant from an ABO blood group–compatible donor (see). The donor and recipient do not need to share the same Rh factor.

HLA Typing

HLA typing is done on potential donors and recipients. Currently we think only the A, B, and DR antigens are clinically significant for transplantation. Because each locus has 2 alleles that encode for antigens, a total of 6 antigens is identified. In transplantation we try to match as many antigens as possible between the HLA-A, HLA-B, and HLA-DR loci. Antigen matches of 5 and 6 antigens and some 4-antigen matches have better clinical outcomes (i.e., the patient is less

likely to reject the transplanted organ), especially in kidney and bone marrow transplants.

The degree of HLA matching needed or suitable for successful solid organ transplantation depends on the type of organ and degree of acceptable risk. Certain organ and tissue transplants need a closer histocompatibility match than other organs. For example, a cornea transplant can be accepted by nearly anyone because corneas are avascular and therefore no antibodies reach the cornea to cause rejection. In kidney and bone marrow transplantation, HLA matching is very important, since these transplants are at high risk for graft rejection. On the other hand, for liver transplants, HLA mismatches have little impact on graft survival. Heart and lung transplants fall somewhere in between but minimizing HLA mismatches significantly improves survival. For liver, lung, and heart transplants, few donors are available and it is hard to get good HLA matches.

Transporting and storing donated organs can take time. The "best" match may live many miles from the "ideal" recipient. The need to have the "best" matches must be balanced against the time it takes to procure and transport a donated organ and then transplant it.

Panel of Reactive Antibodies

A *panel of reactive antibodies (PRA)* shows the recipient's sensitivity to various HLAs before receiving a transplant. To detect preformed antibodies to HLA, the recipient's serum is mixed with a randomly selected panel of donor lymphocytes to determine reactivity. The potential recipient may have been exposed to HLA antigens by previous blood transfusions, pregnancy, or a previous organ transplant.

PRA allows for the determination of whether a recipient is of high or low reactivity to potential donors. The results for the PRA are calculated in percentages. A high PRA indicates that the person has a large number of cytotoxic antibodies and is highly sensitized, which means there is a poor chance of finding a crossmatch-negative donor. In patients awaiting transplantation, a PRA panel is usually done on a regular basis. In highly sensitized patients (high PRA),

plasmapheresis and IV immunoglobulin (IVIG) can be used to lower the number of antibodies.

Crossmatch

A crossmatch is done to determine the existence of antibodies against the potential donor. A crossmatch uses serum from the recipient mixed with donor lymphocytes to test for any preformed anti-HLA antibodies to the potential donor organ. The crossmatch can be used as a screening test when possible living donors are being considered or once a cadaver donor is chosen.

A negative crossmatch means that no preformed antibodies are present, and it is safe to go ahead with transplantation. A positive crossmatch means that the recipient has cytotoxic antibodies to the donor, which is an absolute contraindication in living donor transplants. Live donor transplants may be done for patients with a positive crossmatch if no other live donors (with a negative crossmatch) exist. In this situation, plasmapheresis or IVIG can be done to remove antibodies.

It is not always possible to complete a crossmatch prior to transplantation. If a retrospective crossmatch is done, the results will have implications for immunosuppression protocols after the transplant. A prospective crossmatch is especially important for kidney transplants. It may not be done for lung, liver, and heart transplants.

Transplant Rejection

Rejection is 1 of the major problems after organ transplantation. Organ rejection occurs as a normal immune response to foreign tissue. The risk for rejection is reduced by using immunosuppression therapy, performing ABO and HLA matching, and ensuring that the crossmatch is negative. Unfortunately, many different HLAs exist. A perfect match is nearly impossible unless the tissue is from one's self, an identical twin, or in some cases a sibling. Rejection can be hyperacute, acute, or chronic. Prevention, early diagnosis, and

treatment of rejection are essential for long-term graft function.

Hyperacute Rejection

Hyperacute rejection occurs within 24 hours after transplantation because the blood vessels are rapidly destroyed. It occurs because the person had preexisting antibodies against the transplanted tissue or organ. There is no treatment for hyperacute rejection, and we must remove the transplanted organ. Fortunately, hyperacute rejection is a rare event because of improved immunosuppression medications and because the final testing prior to transplantation usually determines whether the recipient is sensitized to any of the donor HLAs.

Acute Rejection

Acute rejection most often occurs in the first 6 months after transplantation. This type of rejection is usually a cell-mediated immune response by the recipient's lymphocytes, which have been activated against the donated (foreign) tissue or organ (Fig. 13.13). In addition to cell-mediated rejection, another type of acute rejection occurs when the recipient develops antibodies to the transplanted organ (humoral rejection).

It is common to have at least 1 rejection episode, especially with organs from deceased donors. These episodes are usually reversible with additional immunosuppressive therapy. This may include increased corticosteroid doses or polyclonal or monoclonal antibodies. Unfortunately, immunosuppressants increase the risk for infection. To combat acute rejection, all patients with transplants need long-term use of immunosuppressants, putting them at a high risk for infection, especially in the first few months after transplant when the immunosuppressive doses are highest.

Chronic Rejection

Chronic rejection is a process that occurs over months or years and is irreversible. Chronic rejection can occur for unknown reasons or from repeated episodes of acute rejection. Large numbers of T and B cells

infiltrate the transplanted organ, indicating ongoing, low-grade, immune-mediated injury. Chronic rejection results in fibrosis and scarring. In heart transplants it manifests as accelerated coronary artery disease. In lung transplants it manifests as bronchiolitis obliterans. In liver transplants, we see a loss of bile ducts. In kidney transplants it manifests as fibrosis and glomerulopathy.

There is no definitive therapy for this type of rejection. Treatment is primarily supportive. This type of rejection is hard to manage and is not associated with the optimistic prognosis of acute rejection.

Immunosuppressive Therapy

Immunosuppressive therapy requires a lifelong balance between rejection and infection. On 1 hand, the immune response must be suppressed to prevent rejection of the transplanted organ. On the other hand, an adequate immune response must be maintained to prevent overwhelming infection and the development of cancers.[12]

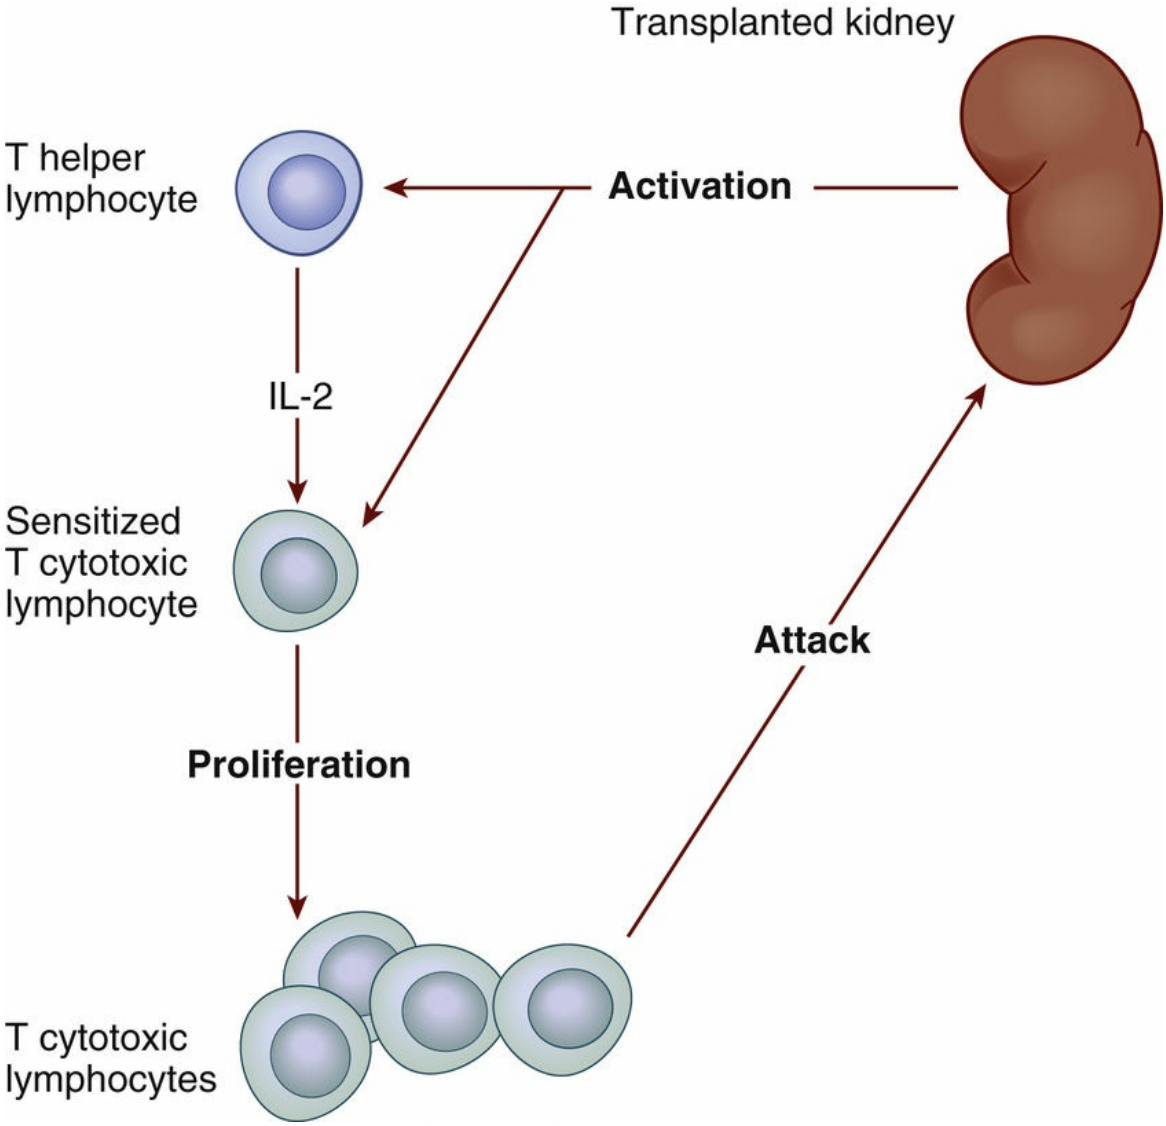

FIG. 13.13 Mechanism of action of T cytotoxic lymphocyte activation and attack of transplanted tissue. The transplanted organ (e.g., kidney) is recognized as foreign and activates the immune system. T helper cells are activated to make interleukin-2 *(IL-2),* and T cytotoxic lymphocytes are sensitized. After the T cytotoxic cells proliferate, they attack the transplanted organ.

Many of the drugs used to achieve immunosuppression have significant side effects. Because transplant recipients must take immunosuppressants for life, the risk for toxicity continues for the rest of their lives.

Immunosuppressant drugs are listed in Table 13.17. With the use of a combination of agents that work during different phases of the immune response (Fig. 13.13), we can give lower doses of each drug to

produce effective immunosuppression while minimizing side effects.

The major immunosuppressive agents are (1) calcineurin inhibitors; (2) corticosteroids (prednisone, methylprednisolone); (3) purine synthesis antagonists, including mycophenolate mofetil (CellCept, Myfortic) and azathioprine (Imuran); and (4) sirolimus. Muromonab-CD3 (Orthoclone OKT3) and either horse antithymocyte globulin (Atgam) or rabbit antithymocyte globulin (ATG) are IV medications used for short periods to prevent early rejection or reverse acute rejection.

Immunosuppression protocols are highly variable among transplant centers, with different combinations of medications being used. Most patients are initially on triple therapy. The standard triple therapy usually includes a calcineurin inhibitor, a corticosteroid, and mycophenolate mofetil.

The doses of immunosuppressant drugs are reduced over time after the transplant. The trend in many transplant centers is to follow an immunosuppression protocol that uses minimal corticosteroids because of their many side effects. Patients taking corticosteroids may be weaned off after a few years.

Calcineurin Inhibitors

This group of drugs, including tacrolimus (Prograf) and cyclosporine (Sandimmune), is the foundation of most immunosuppression regimens. As the most effective immunosuppressants, these drugs prevent a cell-mediated attack against the transplanted organ (Fig. 13.14). They are generally used in combination with corticosteroids, mycophenolate mofetil, and sirolimus. Tacrolimus is the most widely used calcineurin inhibitor. Cyclosporine is being used less often.

Table 13.17 Drug TherapyImmunosuppressive Therapy

Agent	Route	Mechanism of Action	Side Effects
Calcineurin Inhibitors			
cyclosporine (Sandimmune, Neoral, Gengraf)	PO, IV	Acts on T helper cells to prevent production and release of IL-2 Inhibits proliferation of T and B cells	Nephrotoxicity, ↑ risk for infection, neurotoxicity (tremors, seizures), hepatotoxicity, lymphoma, hypertension, tremors, hirsutism, leukopenia, gingival hyperplasia
tacrolimus (Prograf)	PO, IV	Same as cyclosporine but more effective	Same as cyclosporine
Corticosteroids			
prednisone, methylprednisolone	PO, IV	Suppress inflammatory response Inhibit cytokine production (IL-1, IL-6, TNF) and T-cell activation and proliferation	Peptic ulcers, hypertension, osteoporosis, Na^+ and H_2O retention, muscle weakness, easy bruising, delayed healing, hyperglycemia, ↑ risk for infection
Cytotoxic (Antiproliferative) Drugs			
azathioprine (Imuran)	PO, IV	Inhibits purine synthesis Suppresses proliferation of T and B cells	Bone marrow suppression (neutropenia, anemia, thrombocytopenia)
cyclophosphamide	PO, IV	Cross-links DNA, leading to cell injury and death. Results in decrease in number and activity of T and B cells	Neutropenia, hemorrhagic cystitis
everolimus (Zortress)	PO	Binds to mechanistic target of rapamycin (mTOR), thereby suppressing T-cell activation and proliferation	Peripheral edema, constipation, hypertension, nausea, anemia, urinary tract infection, hyperlipidemia
mycophenolate mofetil (CellCept, Myfortic)	PO, IV	Inhibits purine synthesis Suppresses proliferation of T and B cells	Diarrhea, nausea and vomiting, neutropenia, thrombocytopenia, ↑ risk for infection, ↑ incidence of cancer
sirolimus (Rapamune)	PO	Same as everolimus	↑ Risk for infection, leukopenia, anemia, thrombocytopenia, hyperlipidemia, hypercholesterolemia, arthralgias, diarrhea. ↑ incidence of cancer
Monoclonal Antibodies			
alemtuzumab (Campath)	IV	Monoclonal antibody that targets the CD52 antigen on T and B cells, monocytes, and macrophages Causes prolonged T cell depletion	Fever, chills, dyspnea, chest pain, nausea, vomiting. Neutropenia, anemia, thrombocytopenia Increased risk for opportunistic infections
basiliximab (Simulect)	IV	Monoclonal antibody that targets IL-2 receptor and inhibits T cell activation and proliferation	Can cause acute hypersensitivity reaction, including anaphylaxis
daclizumab (Zenapax)	IV	Same as basiliximab	Same as basiliximab
muromonab-CD3 (Orthoclone OKT3)	IV push	Monoclonal antibody that binds to CD3 receptors on T cells, causing cell lysis. Inhibits function of T cells	Fever, chills, dyspnea, chest pain, nausea, vomiting Anaphylactic reactions include pulmonary edema, cardiac or respiratory arrest
Other			
belatacept (Nulojix)	IV	Prevents the activation of T cells	Anemia, diarrhea, constipation, urinary tract infection, peripheral edema
Polyclonal Antibodies			
Horse antithymocyte globulin (Atgam) **Rabbit antithymocyte globulin (Thymoglobulin, ATG)**	IV	Prepared by immunizing horse or rabbit with human thymocytes or T cells. Polyclonal antibodies directed against T cells, thus depleting them	Fever, chills, dyspnea, myalgia, chest pain, nausea and vomiting, anaphylaxis, leukopenia, thrombocytopenia, rash, ↑ risk for infection

They do not cause bone marrow suppression or change the normal inflammatory response. Many of the side effects are dose related. These drugs are potentially nephrotoxic. We monitor drug levels closely to prevent toxicity.

Drug Alert

Tacrolimus and Cyclosporine

- A substance in grapefruit and grapefruit juice prevents metabolism of these drugs.
- Consuming grapefruit or grapefruit juice while using these drugs can increase their toxicity.

Mycophenolate Mofetil

Mycophenolate mofetil inhibits purine synthesis with suppressive effects on T and B cells. The major limitation of this drug is GI toxicity, including nausea, vomiting, and diarrhea. In many cases the side effects can be lessened by lowering the dose or giving smaller doses more often.

Drug Alert

Mycophenolate Mofetil

- When given IV, it can only be reconstituted in D_5W.
- Do not give as IV bolus. Give over 2 or more hours.

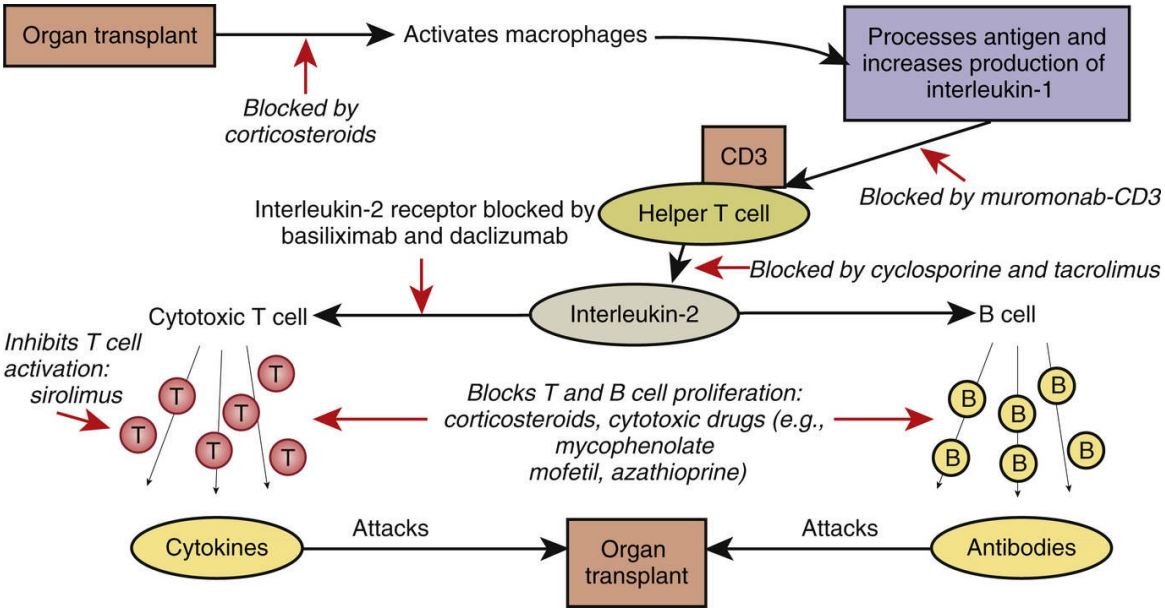

FIG. 13.14 Sites of action for immunosuppressive agents.
Adapted from McKenry L, Tessier E, Hogan M: *Mosby's pharmacology in nursing,* St Louis, 2006, Mosby.

Sirolimus

Sirolimus (Rapamune) suppresses T-cell activation and proliferation. It is used in combination with corticosteroids, cyclosporine, and/or tacrolimus.

Monoclonal Antibodies

Monoclonal antibodies are used to prevent and treat acute rejection episodes. Muromonab-CD3 was the first of these monoclonal antibodies to be used in clinical transplantation. It is a mouse monoclonal antibody that binds with the CD3 antigen found on the surface of human thymocytes and mature T cells. It interferes with the function of T cells, the pivotal cells involved in rejection. All T cells are affected, rather than just the subset active in graft rejection. It is given by IV bolus. Within minutes after the first infusion of muromonab-CD3, the number of circulating T cells decreases significantly.

A flu-like syndrome occurs during the first few days of treatment because of cytokine release. Side effects include fever, rigors, headache, myalgias, and various GI disturbances. To reduce the

expected side effects of muromonab-CD3, give patients acetaminophen, diphenhydramine, and IV methylprednisolone beforehand.

Newer generation monoclonal antibodies are a hybrid of mouse and human antibodies and have fewer side effects than muromonab-CD3 because they have been "humanized." These include daclizumab (Zenapax) and basiliximab (Simulect), which target the IL-2 receptor and impair lymphocyte proliferation. Another monoclonal antibody is alemtuzumab (Campath), which targets the CD52 antigen found on T and B cells, monocytes, and macrophages. It can cause prolonged T-cell depletion.

Polyclonal Antibodies

Polyclonal antibodies to T cells include horse antithymocyte globulin (Atgam) and rabbit antithymocyte globulin (thymoglobulin, ATG). These agents are derived by injecting animals (rabbit or horse) with human lymphoid cells, then procuring and purifying the resultant antibody. They are often used for induction immunosuppression and treatment of acute rejection.

Allergic reactions to the foreign proteins from the host animal, manifested by fever, arthralgias, and tachycardia, are common but usually not severe enough to prevent use. These side effects can be decreased by giving the preparation slowly, over 4 to 6 hours, and premedicating patients with acetaminophen, diphenhydramine, and methylprednisolone. The main toxicities of polyclonal antibodies are leukopenia and thrombocytopenia. They are caused by antibody contaminants that are not completely removed during preparation of the antibodies.

Graft-Versus-Host Disease

Graft-versus-host disease (GVHD) occurs when an immunoincompetent (immunodeficient) patient receives immunocompetent cells. A GVHD response is most common in hematopoietic stem cell transplants. In most transplantation situations, the biggest concern is the patient's

(host's) rejection of the organ or transplant. However, in GVHD disease, the graft (donated tissue) rejects the host (recipient) tissue.[12]

The GVHD response may begin 7 to 30 days after transplantation. Once the reaction is started, little can be done to change its course. The exact mechanism involved in this reaction is not completely understood. However, it involves donor T cells attacking and destroying vulnerable host (recipient) cells.

The target organs for the GVHD phenomenon are the skin, liver, and GI tract. The skin disease may be a maculopapular rash, which may be pruritic or painful. It initially involves the palms and soles of the feet but can progress to a generalized erythema with bullous formation and desquamation (shedding of the outer layer of skin). The liver disease may range from mild jaundice with high liver enzymes to hepatic coma. GI manifestations may include mild to severe diarrhea, severe abdominal pain, GI bleeding, and malabsorption.

The biggest problem with GVHD is infection, with different types of infections seen in different periods. Bacterial and fungal infections predominate right after transplantation when granulocytopenia exists. The development of interstitial pneumonitis is the primary concern later.

There is no adequate treatment of GVHD once it is established. Although corticosteroids are often used, they enhance the susceptibility to infection. The use of immunosuppressive agents (e.g., methotrexate, cyclosporine) has been most effective as a preventive rather than a treatment measure. Radiating blood products before they are given is another way to prevent T-cell replication. Ibrutinib (Imbruvica), a kinase inhibitor that is used to treat several forms of leukemia and lymphoma, is an option for some patients with chronic GVHD.[13]

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The function of monocytes in immunity is related to their ability to
   a. stimulate the production of T and B lymphocytes.
   b. make antibodies after exposure to foreign substances.
   c. bind antigens and stimulate natural killer cell activation.
   d. capture antigens by phagocytosis and present them to lymphocytes.
2. The reason newborns are protected for the first 3 months of life from bacterial infections is because of the maternal transmission of
   a. IgA.
   b. IgE.
   c. IgG.
   d. IgM.
3. In a type I hypersensitivity reaction the primary immunologic disorder appears to be
   a. binding of IgG to an antigen on a cell surface.
   b. deposit of antigen-antibody complexes in small vessels.
   c. release of cytokines used to interact with specific antigens.
   d. release of chemical mediators from IgE-bound mast cells and basophils.
4. The nurse is alerted to possible anaphylactic shock immediately after a patient has received IM penicillin by the development of
   a. edema and itching at the injection site.
   b. sneezing and itching of the nose and eyes.

c. a wheal-and-flare reaction at the injection site.

d. chest tightness and production of thick sputum.

5. The nurse tells a friend who asks him to administer his allergy shots that

a. it is illegal for nurses to administer injections outside of a medical setting.

b. he is qualified to do it if the friend has epinephrine in an injectable syringe provided with his extract.

c. avoiding the allergens is a more effective way of controlling allergies, and allergy shots are not usually effective.

d. immunotherapy should only be administered in a setting where emergency equipment and drugs are available.

6. A patient is undergoing plasmapheresis for treatment of systemic lupus erythematosus. The nurse explains that plasmapheresis is used in treatment to

a. remove T lymphocytes in her blood that are producing antinuclear antibodies.

b. remove normal particles in her blood that are being damaged by autoantibodies.

c. exchange her plasma that contains antinuclear antibodies with a substitute fluid.

d. replace viral-damaged cellular components of her blood with replacement whole blood.

7. The *most* common cause of secondary immunodeficiencies is

a. drugs.

b. stress.

c. malnutrition.

d. human immunodeficiency virus.

8. Association between HLA antigens and diseases is *most* commonly found in what disease conditions?

a. Cancers

b. Infectious diseases

c. Neurologic diseases

d. Autoimmune disorders

9. What accurately describes rejection after transplantation?

a. Hyperacute rejection can be treated with OKT3.

b. Acute rejection can be treated with sirolimus or tacrolimus.

c. Chronic rejection can be treated with tacrolimus or cyclosporine.

d. Hyperacute reaction can be avoided if crossmatching is done before transplantation.

10. In a person having an acute rejection of a transplanted kidney, what would help the nurse understand the course of events *(select all that apply)*?

a. A new transplant should be considered.

b. Acute rejection can be treated with OKT3.

c. Repeated episodes of acute rejection can lead to chronic rejection.

d. Corticosteroids are the most successful drugs used to treat acute rejection.

e. Acute rejection is common after a transplant and can be

treated with drug therapy.

1. d, 2. c, 3. d, 4. a, 5. d, 6. c, 7. a, 8. d, 9. d, 10. b, c, e

Infection

Jeffrey Kwong

LEARNING OUTCOMES

1. Evaluate the impact of emerging and reemerging infections on health care.
2. Identify interventions to reduce health care–associated infections.
3. Explain the transmission of human immunodeficiency virus (HIV) and factors that affect transmission.
4. Describe the pathophysiology of HIV infection.
5. Apply the diagnostic criteria for acquired immunodeficiency syndrome (AIDS).
6. Describe methods used to test for HIV infection.
7. Discuss the role of HIV antiretroviral therapy.
8. Summarize the characteristics of opportunistic diseases associated with AIDS.
9. Describe the potential complications associated with long-term treatment of HIV infection.
10. Compare and contrast HIV prevention methods.
11. Describe the nursing management of HIV-infected patients and HIV-at-risk patients.

KEY TERMS

acquired immunodeficiency syndrome (AIDS), p. 219
antiretroviral therapy (ART), p. 217

Conceptual Focus

Adherence
Coping
Fatigue
Functional Ability
Immunity
Infection
Inflammation
Nutrition

This chapter presents a brief overview of the concept of emerging and health care–associated infections (HAIs). This includes identifying persons most at risk, recognizing signs and symptoms of infection, and understanding ways to treat or manage infection. Infection, immunity, and inflammation are closely related. Infection stimulates an inflammatory response and affects thermoregulation. The patient may have fatigue and pain. Maintaining adequate nutrition and rest is important to combating infection and supporting immune function. The chapter closes with a comprehensive discussion of human immunodeficiency virus (HIV) infection, focusing on transmission, pathophysiology, and interprofessional and nursing management.

Infections

Infections, such as lower respiratory tract infections, malaria, HIV, and tuberculosis (TB), are responsible for a significant number of deaths worldwide. Infection occurs when a *pathogen* (a microorganism that causes disease) invades the body, multiplies, and produces disease, usually causing harm to the host. The signs and symptoms of infection are a result of specific pathogen activity, which triggers inflammation and other immune responses.

We categorize infections as localized, disseminated, or systemic. A *localized* infection is limited to a small area. A *disseminated* infection has spread to areas of the body beyond the initial site of infection. *Systemic* infections have spread extensively throughout the body, often via the blood.

Types of Pathogens

The many kinds of pathogens are classified into several groups, including bacteria, viruses, fungi, protozoa, and prions. *Bacteria* are one-celled organisms that are common throughout nature. Many bacteria are normal flora. They live harmoniously in or on the human body without causing disease under normal circumstances. Normal flora protect the human body by preventing the overgrowth of other

microorganisms. For example, *Escherichia coli* is part of the normal flora in the large intestine.

Bacteria cause disease in 2 ways: by entering the body and growing inside human cells (e.g., TB) or by secreting toxins that damage cells (e.g., *Staphylococcus aureus*). Bacteria are classified based on the shape of their cells. *Cocci,* such as streptococci and staphylococci, are round. *Bacilli* are rod shaped and include tetanus and TB. *Curved rods* include *Vibrio* bacteria, one of which causes cholera. *Spirochetes* are spiral shaped. They include the organisms that cause leprosy and syphilis. Table 14.1 lists common bacteria that cause disease.

Viruses, unlike bacteria, do not have a cellular structure. They are simple infectious particles that consist of a small amount of genetic material (either ribonucleic acid [RNA] or deoxyribonucleic acid [DNA]) and a protein envelope. Viruses can reproduce only after releasing their genetic material into the cell of another living organism. Examples of diseases caused by viruses are shown in Table 14.2.

TABLE 14.1 Disease-Causing Bacteria

Bacteria	Diseases Caused
Chlamydia trachomatis	Chlamydia, lymphogranuloma venereum
Clostridia	
• *Clostridium botulinum*	Food poisoning with progressive muscle paralysis
• *Clostridium tetani*	Tetanus (lockjaw)
Corynebacterium diphtheriae	Diphtheria
Escherichia coli	UTIs, peritonitis, hemolytic-uremic syndrome
Haemophilus	
• *Haemophilus influenzae*	Nasopharyngitis, meningitis, pneumonia
• *Haemophilus pertussis*	Pertussis (whooping cough)
Helicobacter pylori	Peptic ulcers, gastritis
Klebsiella-Enterobacter organisms	UTIs, peritonitis, pneumonia
Legionella pneumophila	Pneumonia (Legionnaires' disease)
Mycobacteria	
• *Mycobacterium leprae*	Hansen's disease (leprosy)
• *Mycobacterium tuberculosis*	Tuberculosis
Neisseriae	
• *Neisseria gonorrhoeae*	Gonorrhea, pelvic inflammatory disease, proctitis
• *Neisseria meningitidis*	Meningococcemia, meningitis
Proteus species	UTIs, peritonitis
Pseudomonas aeruginosa	UTIs, meningitis
Salmonella	
• *Salmonella typhi*	Typhoid fever
• Other *Salmonella* organisms	Food poisoning, gastroenteritis
Shigella	Shigellosis; diarrhea, abdominal pain, and fever (dysentery)
Staphylococcus aureus	Skin infections, pneumonia, UTIs, acute osteomyelitis, toxic shock syndrome
Streptococci	
• *Streptococcus faecalis*	Genitourinary infection, infection of surgical wounds
• *Streptococcus pneumoniae*	Pneumococcal pneumonia
• *Streptococcus pyogenes* (group A β-hemolytic streptococci)	Pharyngitis, scarlet fever, rheumatic fever, acute glomerulonephritis, erysipelas, pneumonia
• *S. pyogenes* (group B β-hemolytic streptococci)	UTIs
• *Streptococcus viridans*	Bacterial endocarditis
Treponema pallidum	Syphilis

Fungi are organisms similar to plants, but they lack chlorophyll. *Mycosis* is any disease caused by a fungus. Pathogenic fungi cause infections that are usually localized but can become disseminated in an immunocompromised person. Tinea pedis (athlete's foot) and tinea corporis (ringworm) are common mycotic infections. Some fungi are normal flora in the body, but when overgrowth occurs, disease can result. Overgrowth of *Candida albicans,* for example, can cause candidiasis in the mouth (thrush), esophagus, intestines, and vagina. Table 14.3 lists other fungi and their respective mycotic infections.

Protozoa are single-cell, animal-like microorganisms. Protozoa normally live in soil and bodies of water. When introduced into the

human body, they can cause infection. Protozoal parasites cause amoebic dysentery and giardiasis. A sporozoan called *Plasmodium malariae* causes malaria.

TABLE 14.2 Disease-Causing Viruses

Virus	Diseases Caused
Adenoviruses	Upper respiratory tract infection, pneumonia
Arbovirus	Syndrome of fever, malaise, headache, myalgia; aseptic meningitis; encephalitis
Coronavirus	Upper respiratory tract infection
Coxsackieviruses A and B	Upper respiratory tract infection, gastroenteritis, acute myocarditis, aseptic meningitis
Ebola	Hemorrhagic fever
Echoviruses	Upper respiratory tract infection, gastroenteritis, aseptic meningitis
Hepatitis A, B, C	Viral hepatitis
Herpesviruses	
• Cytomegalovirus CMV)	Gastroenteritis; pneumonia and retinal damage in immunosuppressed persons, infectious mononucleosis-like syndrome
• Epstein-Barr	Mononucleosis, Burkitt's lymphoma (possibly)
• Herpes simplex type 1	Herpes labialis ("fever blisters"), genital herpes infection
• Herpes simplex type 2	Genital herpes infection
• Varicella-zoster	Chickenpox, shingles
Human immunodeficiency virus (HIV)	HIV infection, AIDS
Influenza A and B	Upper respiratory tract infection, H1N1 (swine) flu, H5N1 avian (bird) flu
Mumps	Parotitis, orchitis in postpubertal males
Papillomavirus	Genital warts, cervical and anal cancer
Parainfluenza 1-4	Upper respiratory tract infection
Parvovirus	Gastroenteritis
Poliovirus	Poliomyelitis
Pox viruses	Smallpox, Molluscum contagiosum
Reoviruses 1, 2, 3	Upper respiratory tract infection
Respiratory syncytial virus	Gastroenteritis, respiratory tract infection
Rhabdovirus	Rabies
Rhinovirus	Upper respiratory tract infection, pneumonia
Rotaviruses	Gastroenteritis
Rubella	German measles
Rubeola	Measles
West Nile virus	Flu-like symptoms, meningitis, encephalitis
Zika virus	Flu-like symptoms, fetal microcephaly

TABLE 14.3 Disease-Causing Fungi

Fungi	Diseases Caused	Organs Affected
Aspergillus fumigatus	Aspergillosis	Lungs*
	Otomycosis	Ears
Blastomyces dermatitidis	Blastomycosis	Lungs,* various organs
Candida albicans	Candidiasis	Intestines
	Vaginitis	Vagina
	Thrush	Skin,† mouth
Coccidioides immitis	Coccidioidomycosis	Lungs*
Epidermophyton	Tinea corporis	Skin†
Microsporum	Tinea capitis	Skin†
Pneumocystis jiroveci	Pneumocystis pneumonia (PCP)	Lungs*
Sporothrix schenckii	Sporotrichosis	Skin, lymph vessels
Trichophyton	Tinea pedis	Skin†

* See Table 27.14: Fungal Infections of the Lung.

† See Table 23.8, Common Fungal Infections of the Skin.

Prions are infectious particles that have abnormally shaped proteins. Not all prions cause disease. Those that do typically affect the nervous system. They can cause a group of illnesses called *transmissible spongiform encephalopathies (TSEs).* Examples of TSEs are Creutzfeldt-Jakob disease and bovine spongiform encephalopathy in cattle (also known as mad cow disease).

Emerging Infections

An **emerging infection** is an infectious disease that has recently increased in incidence or that threatens to increase in the immediate future.[1] Table 14.4 lists examples of emerging infections. Emerging infectious diseases can originate from unknown sources or from contact with animals, changes in known diseases, or biologic warfare. For example, severe acute respiratory syndrome (SARS) and the Ebola virus come from animal sources. Others emerged when a previously treatable organism developed resistance to antibiotics.

The battle against infection is not new, but modern technologies have changed the rules of the game. Global travel, population density, encroachment into new environments, misuse of antibiotics, and bioterrorism have increased the risk for widespread distribution of emerging infections.

Additionally, some diseases thought to be under control, such as TB, measles, and pertussis, have reemerged. Newer infections include Middle Eastern respiratory syndrome (MERS), severe acute respiratory syndrome (SARS), Zika virus, and zoonotic influenza viruses (e.g., H1N1, H5N1).

Studies in *zoonosis* (science of transmission of diseases from animals to humans) have shown that many known infectious diseases come from animal and insect vectors. The SARS outbreak in China in 2003, for instance, was linked to the civet cat, a small carnivorous mammal found throughout much of Asia and Africa. SARS is discussed in Chapter 67.

West Nile virus is carried and transmitted by mosquitoes. Mosquitoes acquire the virus as they draw blood from infected animals and humans. The virus does not cause illness in the mosquito. The mosquito transfers the virus to uninfected animals and humans when it feeds. Bird deaths are an early warning sign of a West Nile virus outbreak, which can spread quickly if action is not taken promptly. West Nile virus is discussed in Chapter 56.

TABLE 14.4 Emerging Infections

Microorganism	Related Disease
Bacteria	
Borrelia burgdorferi	Lyme disease
Campylobacter jejuni	Diarrhea
***Escherichia coli* O157:H7**	Hemorrhagic colitis, hemolytic-uremic syndrome
Helicobacter pylori	Peptic ulcer disease
Legionella pneumophila	Pneumonia (Legionnaires' disease)
***Vibrio cholerae* 0139**	New strain associated with epidemic cholera
Virus	
Chikungunya	Fever, muscle aches, rash
Ebola virus	Ebola hemorrhagic fever
H1N1	H1N1 (swine) flu
Hantavirus	Hemorrhagic fever associated with severe pulmonary syndrome
Hepatitis C virus	Parenterally transmitted hepatitis
Hepatitis E virus	Enterically transmitted hepatitis
Human immunodeficiency virus (HIV)	HIV infection and AIDS
Human herpesvirus 6 (HHV-6)	Roseola subitum
Human herpesvirus 8 (HHV-8)	Associated with Kaposi sarcoma in immunosuppressed patients, including people with HIV infection
West Nile virus	West Nile fever
Zika virus	Fever, rash, muscle aches; microcephaly in children born to infected mothers
Parasite	
Cryptosporidium parvum	Acute and chronic diarrhea

Influenza viruses are examples of how disease can spread between animals and humans. Variants of influenza A viruses are responsible for many influenza epidemics. We traced the 2009 influenza A (H1N1) outbreak back to pigs, hence the name *swine flu.* In 1997 and 2003, outbreaks of the influenza A (H5N1) strain of avian flu resulted from transmission of influenza virus from chickens to humans.

Ebola virus has been an ongoing public health challenge since it was first seen in 1976. In 2014, rates of Ebola increased significantly in East Africa and the first cases of Ebola occurred in the United States. These initial cases were primarily from travelers or medical aid workers who were working in Africa. Ebola virus can cause severe hemorrhagic fever and is usually lethal. Therapeutic and preventive measures are limited. The natural reservoir and path of transmission are unknown, which makes it impossible to effectively combat Ebola virus and the disease it causes.

Reemerging Infections

Advances in the development of medications and vaccines has led to

the near eradication of some infections (e.g., smallpox, polio), but infective agents can reemerge under the right conditions. Table 14.5 presents some diseases that have shown resurgence in recent decades. For example, infections such as measles and pertussis have had sporadic resurgences.[2] This is in part due to people not receiving recommended vaccines.

TABLE 14.5 Reemerging Infections

Microorganism	Infection	Description
Bacteria		
Corynebacterium diphtheriae	Diphtheria	Localized infection of mucous membranes or skin
Bordetella pertussis	Pertussis	Acute, highly contagious respiratory disease characterized by loud whooping inspiration. Also known as whooping cough
Mycobacterium tuberculosis	Tuberculosis	Chronic infection transmitted by inhalation of infected droplets (see Chapter 27)
Virus		
Dengue viruses (flaviviruses)	Dengue fever	Acute infection transmitted by mosquitoes. Occurs mainly in tropical and subtropical regions
Rubeola	Measles	Fever, malaise, cough, and maculopapular rash
Parasite		
Giardia	Giardiasis	Diarrheal illness that usually originates in water contaminated with fecal matter. Also known as traveler's diarrhea

International travel has created a new obstacle for the local eradication of diseases. For example, measles is no longer endemic in the United States but is still a leading cause of death in developing countries. Domestic outbreaks have typically occurred in areas with low vaccination rates. Some cases occurred in people who have recently traveled to measles-endemic areas outside the United States.[3]

Antimicrobial-Resistant Organisms

Resistance occurs when pathogenic organisms change in ways that decrease the ability of a drug (or a family of drugs) to treat disease.[4] Microorganisms can become resistant to classic treatments (e.g., penicillin) as well as to newer antibiotics and antiviral agents. Microorganisms are highly adaptable. They have evolved genetic and biochemical mechanisms to defend against antimicrobials. Genetic

mechanisms include mutation and acquisition of new DNA or RNA. Biochemically, bacteria can resist antibiotics by producing enzymes that destroy or inactivate the drugs. Drug target sites are then altered so that the antibiotic cannot bind to or enter the bacteria. If the drug cannot enter the cell, it cannot kill the bacteria. Table 14.6 describes common antibiotic-resistant bacteria.

Methicillin-resistant *S. aureus* (MRSA), vancomycin-resistant enterococci (VRE), vancomycin-resistant *S. aureus* (VRSA), carbapenem-resistant Enterobacteriaceae (CRE), and penicillin-resistant *Streptococcus pneumoniae* are examples of emerging strains of antibiotic-resistant organisms. These drug-resistant bacteria were first seen in health care settings but are becoming more prevalent in the community. For example, we initially considered MRSA, a form of *S. aureus* that does not respond to methicillin- or penicillin-based therapies, a health care–associated infection (HA-MRSA). However, a variant strain of MRSA that is primarily acquired in the community (community-acquired MRSA [CA-MRSA]) has emerged.[5] This strain of MRSA is more *virulent* (able to cause disease or infection) compared with HA-MRSA. CA-MRSA can cause rapidly forming skin infections and systemic diseases, including pneumonia and sepsis. VRE infection is another concern for patients and health care workers. VRE are more virulent than MRSA and can survive on environmental surfaces for weeks. Although antibiotic-resistant bacteria can infect anyone, hospitalized patients and those with a suppressed immune system are more likely to be exposed to these bacteria and to develop infection.

TABLE 14.6 Common Antibiotic-Resistant Organisms and Treatment

Bacteria	Resistant to	Preferred Treatment
Enterococcus faecalis	vancomycin streptomycin gentamicin	daptomycin (Cubicin) linezolid (Zyvox) oritavancin (Orbactiv) tigecycline (Tygacil)
Enterococcus faecium	vancomycin streptomycin gentamicin	daptomycin (Cubicin) linezolid (Zyvox) tigecycline (Tygacil)
Klebsiella pneumoniae	carbapenems (e.g., imipenem, meropenem)	ceftazidime and avibactam (Avycaz)
Staphylococcus aureus	methicillin*	vancomycin
Staphylococcus epidermidis	methicillin*	vancomycin
Streptococcus pneumoniae	penicillin G	ceftriaxone cefotaxime

* This drug is no longer available in the United States.

HCPs have contributed to the development of drug-resistant microorganisms by (1) giving antibiotics for viral infections, (2) succumbing to patient pressure to prescribe unnecessary antibiotic therapy, (3) using inadequate drug regimens to treat infections, or (4) using broad-spectrum or combination agents for infections that should be treated with first-line medications.

Patients can contribute to resistance development by (1) skipping doses, (2) not taking antibiotics for the full duration of prescribed therapy, or (3) saving unused antibiotics "in case I need them later." In addition, limited resources and access to medications make it hard for some patients to get adequate treatment for infections. Teaching patients and their families the proper use of antibiotics (Table 14.7) is crucial to treatment success and prevention of drug-resistant pathogens. The Centers for Disease Control and Prevention (CDC), the Infectious Diseases Society of America (IDSA), and many health care organizations campaign for greater vigilance in minimizing the misuse of antibiotics in reaction to this growing concern.

Although antibiotics are a class of drugs that we typically think of when discussing drug-resistant organisms, any organism (virus, fungi, parasite) can develop drug resistance to agents typically used to treat them. Hence, we now use the term *antimicrobial resistance* to describe the phenomena of resistance across different classes of organisms.

Health Care–Associated Infections

Health care–associated infections (HAIs) are infections that are acquired because of exposure to microorganisms in a health care setting.[6] About 722,000 HAIs occur annually, and nearly 1 in every 25 hospitalized patients has at least 1 HAI. Improvements in infection control have resulted in fewer infections in recent years.[7] We have seen decreases in several of the major types of HAIs, including central line–associated bloodstream infections, surgical site infections, *Clostridium difficile* infections, and methicillin-resistant *S. aureus* bacteremia. Any organism can cause HAIs, but certain bacteria, including *E. coli, S. aureus, Enterobacter aerogenes,* and various types of streptococci, are the more common culprits. Some bacteria that do not normally cause disease can cause infections in high-risk patients because of illness or treatment of illness. Surgical and immunocompromised patients are at highest risk.

TABLE 14.7 Patient & Caregiver TeachingDecrease Risk for Antibiotic-Resistant Infection

Include the following instructions when teaching patients or their caregivers how to decrease the risk for antibiotic-resistant infection.

1. Only Take Antibiotics Prescribed for You

- This decreases your risk for developing resistant infection.
- You may need antibiotics before certain surgeries and dental work or in the presence of immune dysfunction.

2. Wash Your Hands Frequently

- Hand washing is the single most important thing you can do to prevent infection.

3. Follow Directions When Taking Antibiotics

- Not taking your antibiotic as prescribed or skipping doses can allow antibiotic-resistant bacteria to develop.

4. Do Not Request an Antibiotic for Flu or Colds

- If your HCP says that you do not need an antibiotic, chances are you do not.
- Antibiotics are effective against bacterial infections but not viruses, which cause colds and flu.

5. Finish Your Antibiotic

- Do not stop taking your antibiotic when you feel better.
- If you stop taking your antibiotic early, the hardiest bacteria survive and multiply.
- Eventually you could develop an infection resistant to any antibiotics. You should never have leftover antibiotics.

6. Do Not Take Leftover Antibiotics

- Do not save unfinished antibiotics for later use or borrow leftover drugs from family or friends.
- This is dangerous because (1) the leftover antibiotic may not be appropriate for you, (2) your illness may not be a bacterial infection, (3) old antibiotics can lose their effectiveness and, in some cases, can be fatal, and (4) there will not be enough doses in a leftover bottle to provide full treatment.

Around one-third of HAIs are preventable. HCPs often transmit HAIs from patient to patient through direct contact. First lines of

defense to prevent the spread of HAIs include hand washing (or using an alcohol-based hand sanitizer) before and after patient contact or procedures, appropriate use of personal protective equipment such as gloves, and decontamination of equipment used for patient care.[8] Isolated infections also can be caused when bacteria that normally stay in one area of the body are introduced into another area. Therefore you must take care to change gloves and wash hands when moving from one task to another, even when working with the same patient. Most facilities have developed and implemented guidelines on reducing and controlling the spread of disease in health care settings, especially of antimicrobial-resistant organisms (Table 14.8).[9] Nurses and all HCPs have the responsibility of using appropriate measures, including transmission-based precautions, to help protect patients from HAIs.

TABLE 14.8 OSHA Requirements for Personal Protective Equipment

The following equipment minimizes exposure to blood-borne pathogens.

Equipment	Indications for Use
Gloves	• Must be used when the employee can reasonably expect having contact with blood or other potentially infectious materials, when performing vascular access procedures, and when handling or touching contaminated items or surfaces. • Gloves must be replaced if torn, punctured, or contaminated or their ability to function as a barrier is compromised.
Clothing (gowns, aprons, caps, boots)	• Must be used when occupational exposure is expected. • The type and characteristics depend on the task and degree of exposure expected.
Face protection (mask and glasses with solid side shields or a chin-length face shield)	• Must be used when splashes, sprays, spatters, or droplets of blood or other potentially infectious materials pose a hazard to the eyes, nose, or mouth.

Source: Occupational Safety and Health Administration (OSHA): Bloodborne pathogens and needlestick prevention. Retrieved from *www.osha.gov/SLTC/bloodbornepathogens*.

Gerontologic Considerations: Infections in Older Adults

For older adults, the rate of HAIs is 2 to 3 times higher compared to younger patients. Persons in long-term care facilities are at higher risk for HAI. Age-related changes (e.g., impaired immune function) and co-morbidities, such as diabetes and physical disabilities, contribute to higher infection rates in older adults.[10]

Infections common in older adults include pneumonia, urinary tract infections (UTIs), skin infections, and TB. UTIs are more common in those who live in long-term care facilities. Patients with indwelling catheters are at particular risk.

Check Your Practice

You are working in a long-term care facility. One of your residents, a 76-yr-old man who is recovering from a stroke, seems very confused today. You discuss your concerns with the unlicensed assistive personnel (UAP). You explain that he seemed so alert yesterday and wonder if he may have an infection, such as pneumonia or a UTI. The UAP says, "I just took his temperature and it is normal. I don't think he has an infection."

- How should you follow up with the resident and the UAP?

Infections in older adults often have atypical manifestations, such as cognitive and behavioral changes, before the emergence of fever, pain, or changes in laboratory values. Do not rely on the presence of fever to indicate infection in older adults because many have lower core body temperatures and decreased immune responses. Suspicion of disease should typically begin if a patient shows changes in the ability to perform daily activities or in cognitive function. In addition, underlying diseases, increased frequency of drug reactions, and institutionalization can complicate the management of an older adult with infection.

Infection Prevention and Control

Occupational Safety and Health Administration (OSHA) Guidelines

OSHA is a federal agency that protects workers from injury and illness in places of employment and supports activities that minimize or eliminate exposure to infectious materials in the workplace. OSHA mandates that any employer whose employees could be exposed to potentially infectious materials implement standard policies and procedures to protect those employees. Employees must be provided with appropriate personal protective equipment (PPE) and safety equipment at no cost to the employee.[11] These include gloves, gowns, facial protection, and disposal systems for sharps (Table 14.8). PPE also must be provided in the right sizes. Hypoallergenic gloves or similar alternatives must be made available to those who have an allergic sensitivity to gloves. Appropriate PPE varies depending on the situation. You need to use sound judgment when deciding when and how to use protective equipment.

Infection Precautions

The CDC has established guidelines with 2 levels of precautions: (1) **standard precautions**, designed for the care of all patients in hospitals and health care facilities and (2) **transmission-based precautions**, designed for specific diseases.[12] The purpose of these precautions is to prevent the transmission of organisms from patients to HCPs, from HCPs to patients, from patients to other patients, and from health care personnel and patients to people outside of the hospital (Table 14.9).

The *standard precautions* system applies to (1) blood; (2) all body fluids, secretions, and excretions; (3) non-intact skin; and (4) mucous membranes. Standard precautions are designed to reduce the risk for transmission of microorganisms in hospitals. Standard precautions should be applied to *all* patients regardless of diagnosis or presumed infection status. The CDC's standard precautions incorporate all the

OSHA blood-borne pathogens standard requirements.

TABLE 14.9 Types of Isolation Precautions Used in Health Care Settings

Type	Examples
Standard Precautions	
• **Used for care of all patients, regardless of their diagnosis or presumed infection status**	Includes the use of hand washing and appropriate personal protective equipment
Transmission-Based Precautions	
• **Recommended to provide additional precautions beyond standard precautions to prevent transmission of pathogens** • **Can be used for patients known or suspected to be infected or colonized with pathogens that can be transmitted by airborne or droplet transmission, or by contact with dry skin or contaminated surfaces** • **These precautions should be used in addition to standard precautions**	**Airborne precautions:** Used for infections spread in small particles in the air, such as chickenpox (varicella), measles, and TB **Droplet precautions:** Used for infections spread in large droplets by coughing, talking, or sneezing, such as influenza and bacterial meningitis **Contact precautions:** Used for infections spread by skin-to-skin contact or contact with other surfaces, such as *C. difficile*, MRSA, and VRE

Transmission-based precautions are used for patients known to be or suspected of being infected with highly transmissible or epidemiologically important pathogens that require additional precautions to interrupt transmission and prevent infection. Transmission-based precautions include airborne precautions, droplet precautions, and contact precautions. *Airborne precautions* are used if the organism can cause infection over long distances when suspended in the air (e.g., TB, rubeola). *Droplet precautions* minimize contact with pathogens that spread through the air at close contact and that affect the respiratory system or mucous membranes (e.g., influenza, pertussis). *Contact precaution*s minimize the spread of pathogens that are acquired from direct or indirect contact, especially multidrug-resistant organisms (e.g., MRSA, VRE, CRE). Transmission-based precautions may be combined for diseases that have multiple routes of transmission. Whether used alone or in combination, transmission-based precautions should always be used in conjunction with standard precautions.

Human Immunodeficiency Virus Infection

Human immunodeficiency virus (HIV) is a retrovirus that causes immunosuppression. Persons with HIV are more susceptible to infections that people normally control through immune responses. The terms *HIV disease* and *HIV infection* are used interchangeably. With advances in treatment, we view HIV as a chronic disease since people with the disease are living longer.

More than 1 million people are currently living with HIV in the United States, with about 37,600 new infections occurring each year.[13] With the availability of effective HIV treatment, there has been a dramatic drop in the number of deaths attributable to HIV. In North America HIV is most prevalent among men who have sex with men (MSM).

Transmission of HIV

HIV can be transmitted through contact with infected blood, semen, vaginal secretions, or breast milk.[14] HIV transmission occurs through sexual intercourse with an infected partner; exposure to HIV-infected blood or blood products; and perinatal transmission during pregnancy, at delivery, or through breastfeeding. HIV is not spread casually. The virus cannot be transmitted through hugging, dry kissing, shaking hands, sharing eating utensils, using toilet seats, or casual encounters in any setting. It is not spread by tears, saliva, urine, emesis, sputum, feces, sweat, respiratory droplets, or enteric routes. Health care personnel have a low risk for acquiring HIV at work, even after a needle-stick injury.[15]

Sexual Transmission

The most common mode of HIV transmission is unprotected sexual contact with an HIV-infected partner. Sexual activity involves contact with semen, vaginal secretions, and/or blood, all of which have

lymphocytes that may contain HIV. During any form of sexual intercourse (anal, vaginal, oral), the risk for infection is greater for the partner who receives the semen. This is because the receiver has prolonged contact with infected fluids. It helps explain why it is easier to infect women than men during heterosexual intercourse. Sexual activities that cause trauma to local tissues can increase the risk for transmission. In addition, genital lesions from other sexually transmitted infections (e.g., herpes, syphilis) significantly increase the chance of transmission.

Contact With Blood and Blood Products

HIV can be transmitted from exposure to blood when sharing drug-using paraphernalia. Needles, syringes, straws, and other equipment may be contaminated with HIV or other blood-borne organisms. Sharing this equipment can result in disease transmission.

Routine screening of blood donors to identify at-risk persons and testing donated blood for the presence of HIV have improved the safety of the blood supply. In countries that routinely test donated blood, HIV infection because of blood transfusions or hemophilia clotting factors is unlikely.

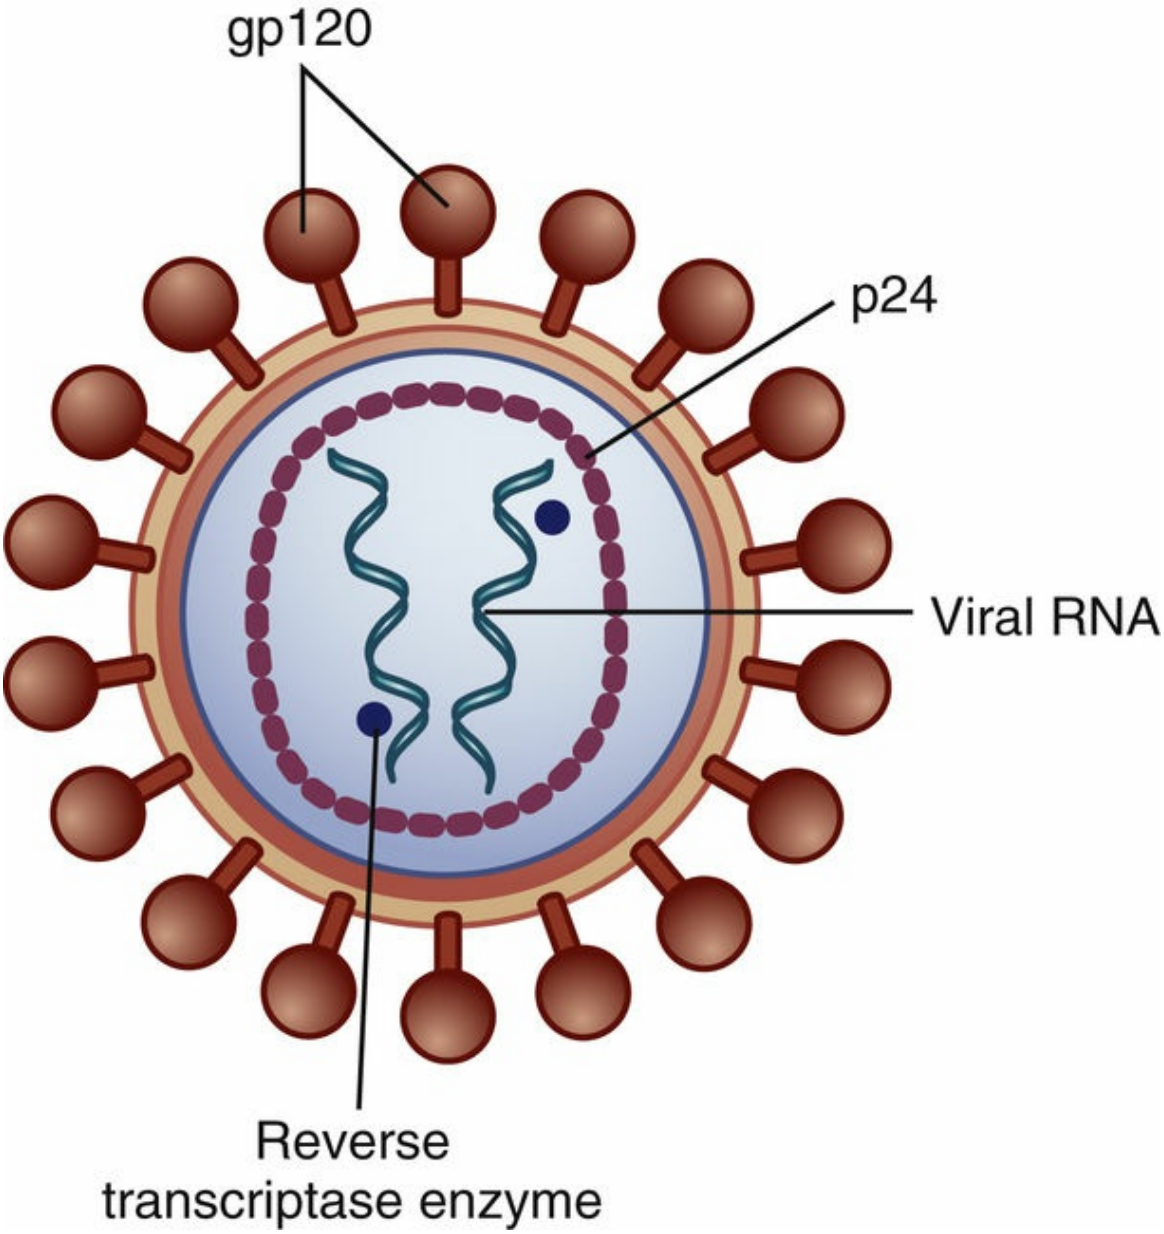

FIG. 14.1 HIV is surrounded by an envelope made up of proteins (including gp120) and a core of viral RNA and proteins.

Puncture wounds are the most common means of work-related HIV transmission. The risk for infection after a needle-stick exposure to HIV-infected blood is 0.3% to 0.4% (or 3 or 4 out of 1000).[15] The risk is higher if the exposure involves blood from a patient with a high level of circulating HIV, a deep puncture wound, a needle with a hollow bore and visible blood, or a device used for venous or arterial access. Splash exposures of blood on skin with an open lesion present some

risk, but it is much lower than from a puncture wound.

Perinatal Transmission

Perinatal transmission from an HIV-infected mother to her infant can occur during pregnancy, delivery, or breastfeeding. On average, 25% of infants born to women with untreated HIV infection are born with HIV. Fortunately, the risk for transmission is less than 2% in settings in which pregnant women are routinely tested for HIV infection and, if found to be infected, treated with **antiretroviral therapy (ART)**, a combination of medications used to control and suppress HIV replication.[16]

Pathophysiology

HIV is an RNA virus. RNA viruses are called *retroviruses* because they replicate in a "backward" manner (going from RNA to DNA). Like all viruses, HIV cannot replicate unless it is inside a living cell.[17] The *$CD4^+$ T cell (CD4 cell),* a type of lymphocyte, is the target cell for HIV. HIV enters the CD4 cell by binding to protein receptors on the outside of the cell (Fig. 14.1). This process is known as *fusion* (Fig. 14.2).

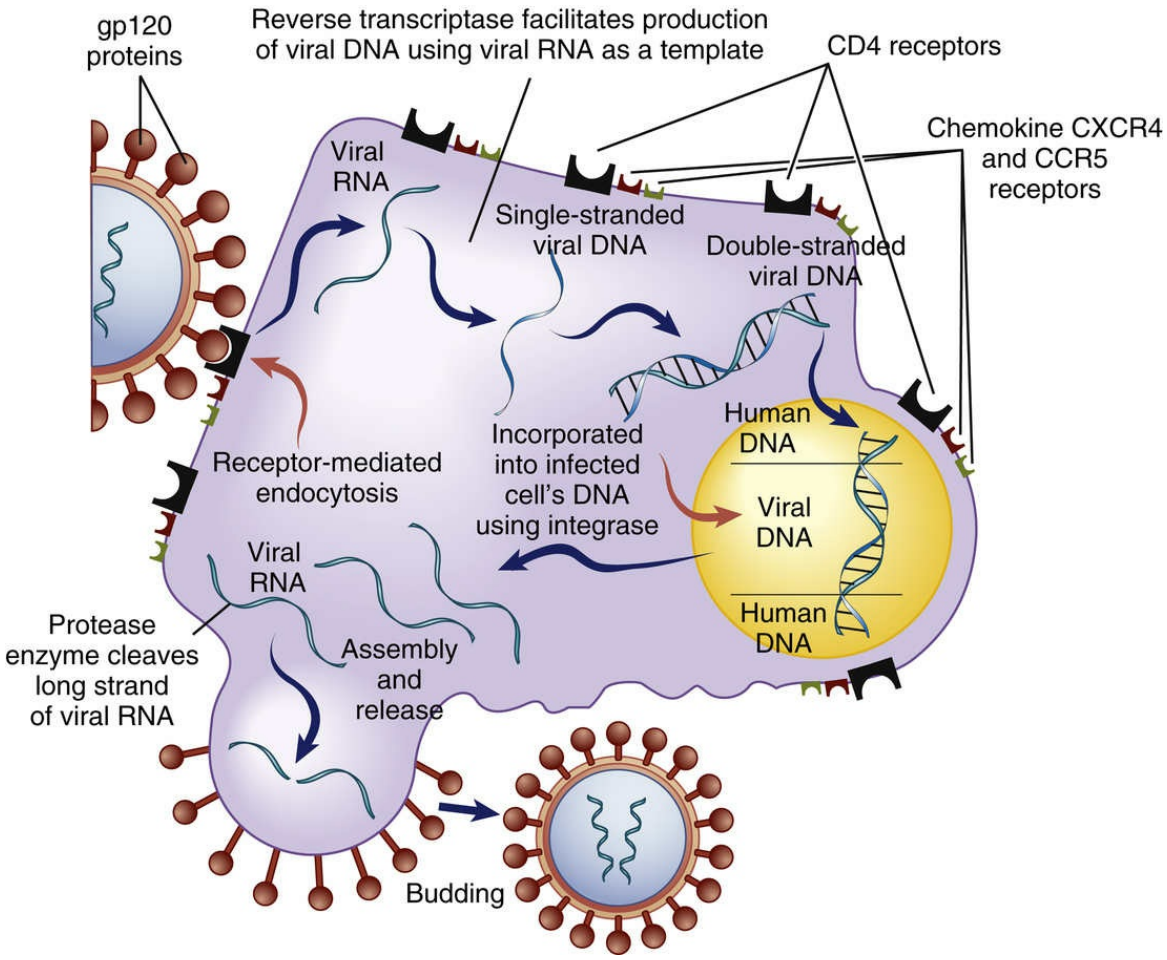

FIG. 14.2 HIV has gp120 glycoproteins that attach to CD4 and chemokine CXCR4 and CCR5 receptors on the surface of CD4 cells. Viral RNA then enters the cell, produces viral DNA in the presence of reverse transcriptase, and incorporates itself into the cellular genome in the presence of integrase, causing permanent cellular infection and the production of new virions. New viral RNA develops initially in long strands that are cut in the presence of protease and leave the cell through a budding process that contributes to cellular destruction.

Once HIV is attached and fused with the CD4 cell, HIV RNA enters the CD4 cell. This triggers the release of *reverse transcriptase,* an enzyme that transforms HIV RNA into a single strand of DNA. This strand copies itself, becoming double-stranded viral DNA. Another enzyme, called *integrase,* allows the newly formed double-stranded DNA to integrate itself into the host' genetic structure. This action has 2 consequences: (1) because all genetic material is replicated during cell division, all daughter cells are infected and (2) viral DNA in the genome directs the cell to make new HIV.

Protease, another enzyme involved in the replication process, cleaves the newly formed strands of HIV genetic material into smaller pieces. New HIV virions are then formed and released. The CD4 cell is then destroyed after the HIV virions are released.[17]

HIV destroys about 1 billion CD4 cells every day. For many years, the body can make new CD4 cells to replace the destroyed cells. However, over time the ability of HIV to destroy CD4 cells exceeds the body's ability to replace the cells. The decline in the CD4 cell count impairs immune function. Generally, the immune system remains healthy with more than 500 CD4 cells/μL. Immune problems begin to occur when the count drops below 500 CD4 cells/μL. Severe problems develop with fewer than 200 CD4 cells/μL.

With HIV, a point is eventually reached at which so many CD4 cells have been destroyed that not enough are left to regulate immune responses (Fig. 14.3). This allows **opportunistic diseases** (infections and cancers that occur in immunosuppressed patients) to develop. Opportunistic diseases are the main cause of disease, disability, and death in patients with HIV infection.

Clinical Manifestations and Complications

The typical course of untreated HIV infection follows the pattern shown in Fig. 14.4. It is important to remember that (1) disease progression is highly individualized, (2) treatment can significantly alter this pattern, and (3) a person's prognosis is unpredictable.

Acute Infection

About 2 to 4 weeks after someone becomes newly infected with HIV, the person typically develops *acute HIV infection.* During this period, the person can have a mononucleosis-like syndrome of fever, swollen lymph nodes, sore throat, headache, malaise, nausea, muscle and joint pain, diarrhea, and/or a diffuse rash. Some people have neurologic complications, such as aseptic meningitis, peripheral neuropathy, facial palsy, or Guillain-Barré syndrome.[18] During this time, there is a high **viral load**, the amount of HIV circulating in the blood. CD4 cell

counts fall temporarily but quickly return to baseline or near-baseline levels (Fig. 14.3). Many people, including HCPs, mistake acute HIV symptoms for a bad case of the flu. People are most infectious during the acute infection stage because of the high amounts of circulating HIV.

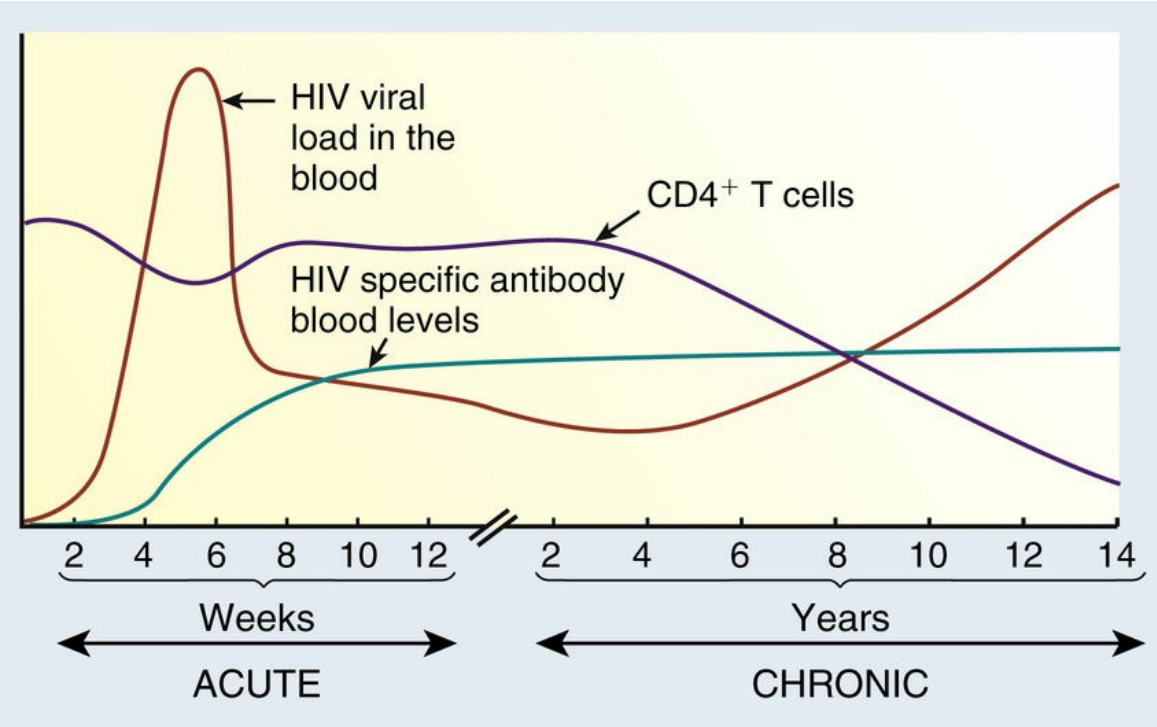

FIG. 14.3 Viral load in the blood in relationship to number of CD4 cells over the spectrum of untreated HIV infection.

Chronic HIV Infection

Asymptomatic Infection

The time between initial HIV infection and a diagnosis of AIDS is about 10 years in untreated infection. During the first several years after initial infection, people are typically asymptomatic and have no symptoms or limited signs of infection.

Because most symptoms during early infection are vague and nonspecific for HIV, people may not be aware that they are infected.

During this time, infected people continue their usual activities, which may include high-risk sexual and drug-using behaviors. This is a public health problem because infected persons can transmit HIV to others even though they have no symptoms.[19] Personal health is also affected because people who do not know that they are infected have little reason to seek treatment and are less likely to make behavior changes that could improve the quality and length of their lives.

Symptomatic Infection

As the CD4 cell count declines closer to 200 cells/μL and the viral load increases, HIV advances to a more active stage. Symptoms such as persistent fever, frequent night sweats, chronic diarrhea, recurrent headaches, and severe fatigue may develop.

One of the more common infections associated with this phase of HIV infection is oropharyngeal candidiasis (thrush) (Fig. 14.5). *Candida* organisms rarely cause problems in healthy adults but are more common in HIV-infected people. Other infections that can occur at this time include shingles (caused by the varicella-zoster virus); persistent vaginal candidal infections; outbreaks of oral or genital herpes; bacterial infections; and Kaposi sarcoma (KS), caused by human herpesvirus 8 (Fig. 14.6). *Oral hairy leukoplakia,* an Epstein-Barr virus infection that causes painless, white, raised lesions on the lateral aspect of the tongue (Fig. 14.7), is another sign of disease progression.

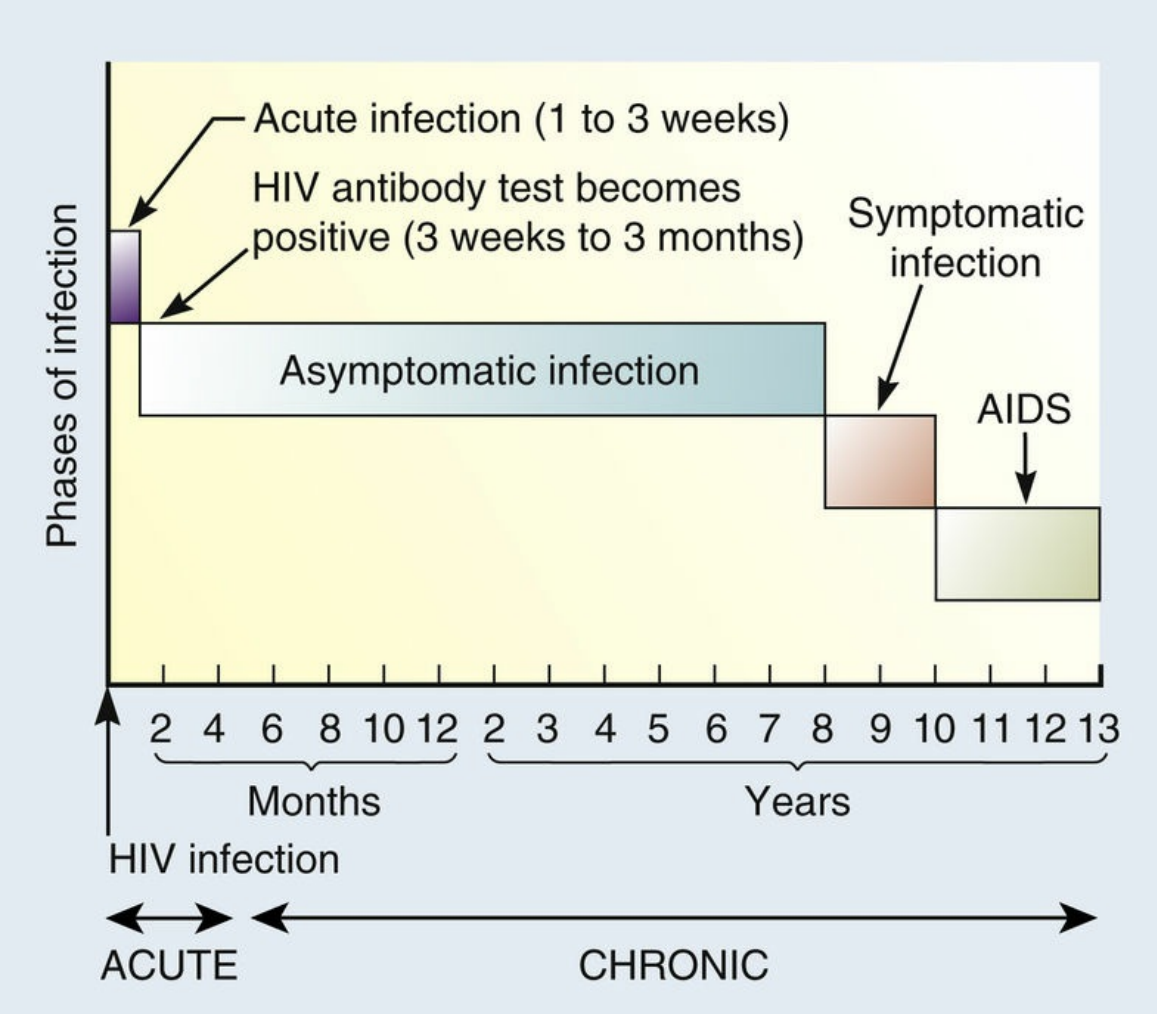

FIG. 14.4 Timeline for the spectrum of untreated HIV infection. The timeline represents the course of untreated illness from the time of infection to clinical manifestations of disease.

AIDS

A diagnosis of **acquired immunodeficiency syndrome (AIDS)** is made when an HIV-infected patient meets criteria established by the CDC.[20] This occurs when the immune system becomes severely compromised (Table 14.10). Opportunistic diseases generally do not occur in the presence of a functioning immune system. Many infections, a variety of cancers, wasting, and HIV-related cognitive changes can occur in patients with immune impairment (Table 14.11). Organisms that do not cause severe disease in people with functioning immune systems can cause debilitating, life-threatening infections

during this stage. Several opportunistic diseases may occur at the same time, increasing the difficulties of diagnosis and treatment. Advances in HIV treatment have decreased the occurrence of opportunistic diseases.

FIG. 14.7 Oral hairy leukoplakia on the lateral aspect of the tongue. Set of slides published in 1992 by Jon Fuller, MD, and Howard Libman, MD, at Boston University School of Medicine, Boston, MA.

Diagnostic Studies

Diagnosis of HIV Infection

Diagnosis of HIV infection is made by testing for HIV antibodies and/or antigens.[21] HIV screening tests can be done using blood or saliva. Typically it takes several weeks after infection before a screening test can detect evidence of HIV (Fig. 14.3). This delay is known as the **window period**. The typical window period for most tests to detect HIV infection is about 3 weeks (Table 14.12). If a newly infected person is tested during the window period, the test may not be able to detect infection and they will have a false negative result.

Laboratory Studies in HIV Infection

Two laboratory tests are used for monitoring HIV progression: CD4 cell count and viral load. The CD4 cell count is a marker of immune function. As the disease progresses, the number of CD4 cells usually decreases (Fig. 14.3). The normal range for CD4 cells is 800 to 1200 cells/μL. Laboratory tests that measure viral levels provide an assessment of disease progression. The lower the viral load, the less active the disease. In HIV, viral loads are reported as real numbers (e.g., 1260 copies/μL). The goal of treatment is to suppress the viral load to the lowest level possible, which is below the level of detection on a commercial assay. This is often referred to as "undetectable." "Undetectable" does *not* mean that the virus has been eliminated from the body or that the person can no longer transmit HIV to others. Rather, it refers to the fact that the amount of circulating HIV in the blood is below the level of detection of the test.

TABLE 14.10 Diagnostic Criteria for AIDS

AIDS is diagnosed when a person with HIV develops at least one of the following conditions:

1. $CD4^+$ T cell count drops below 200 cells/μL.
2. One of the following opportunistic infections (OIs):
    - *Bacterial: Mycobacterium tuberculosis* (any site); any disseminated or extrapulmonary mycobacteria, including *Mycobacterium avium* complex (MAC) or *Mycobacterium kansasii;* recurrent pneumonia; recurrent *Salmonella* septicemia
    - *Fungal:* Candidiasis of bronchi, trachea, lungs, or esophagus; *Pneumocystis jiroveci* pneumonia (PCP); disseminated or extrapulmonary coccidioidomycosis; disseminated or extrapulmonary histoplasmosis
    - *Protozoal:* Toxoplasmosis of the brain, chronic intestinal isosporiasis, chronic intestinal

cryptosporidiosis
- *Viral:* Cytomegalovirus (CMV) disease other than liver, spleen, or nodes; CMV retinitis (with loss of vision); herpes simplex with chronic ulcer(s) or bronchitis, pneumonitis, or esophagitis; progressive multifocal leukoencephalopathy (PML); extrapulmonary cryptococcosis

3. One of the following opportunistic cancers:
   - Burkitt's lymphoma
   - Immunoblastic lymphoma
   - Invasive cervical cancer
   - Kaposi sarcoma (KS)
   - Primary lymphoma of the brain
4. Wasting syndrome. *Wasting* is defined as a loss of 10% or more of ideal body mass.

Modified from Centers for Disease Control and Prevention: 1993 Revised classification system for HIV infection and expanded surveillance case definition for AIDS among adolescents and adults, 1993. Retrieved from *www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a1.htm?s_cid=rr5710a1_e*.

TABLE 14.11 Common Opportunistic Diseases Associated With HIV Infection

Organism or Disease	Clinical Manifestations
Candida albicans	Thrush (Fig. 14.5), esophagitis, vaginitis. Whitish yellow patches in mouth, esophagus, GI tract, vagina
Coccidioides immitis	Pneumonia and fever, weight loss, cough
CNS lymphoma	Cognitive dysfunction, motor impairment, aphasia, seizures, personality changes, headache
Cryptococcus neoformans	Meningitis, cognitive impairment, motor dysfunction, fever, seizures, headache
Cryptosporidium muris	Gastroenteritis, watery diarrhea, abdominal pain, weight loss
Cytomegalovirus (CMV)	*Retinitis:* retinal lesions, blurred vision, loss of vision *Esophagitis, stomatitis:* difficulty swallowing, colitis or gastritis: bloody diarrhea, pain, weight loss *Pneumonitis:* respiratory symptoms *Neurologic disease:* central nervous system (CNS) manifestations
Hepatitis B virus (HBV)	Jaundice, fatigue, abdominal pain, loss of appetite, nausea, vomiting, joint pain. Some have no signs or symptoms
Hepatitis C virus (HCV)	Jaundice, fatigue, abdominal pain, loss of appetite, nausea, vomiting, dark urine. Many have no signs or symptoms
Herpes simplex virus (HSV)	*HSV-1 (type 1):* orolabial and mucocutaneous vesicular and ulcerative lesions. Keratitis, visual changes, encephalitis, CNS manifestations *HSV-2 (type 2):* genital and perianal vesicular and ulcerative lesions
Histoplasma capsulatum	*Pneumonia:* fever, cough, weight loss *Meningitis:* CNS manifestations, disseminated disease
JC papovavirus	Progressive multifocal leukoencephalopathy (PML), CNS manifestations, mental and motor declines
Kaposi sarcoma (KS) caused by human herpesvirus 8 (HHV-8)	Vascular lesions on the skin (Fig. 14.6), mucous membranes, and viscera with wide range of presentation: firm, flat, raised, or nodular; pinpoint to several cm in size; hyperpigmented, multicentric. Can cause lymphedema and disfigurement. Usually not serious unless occurring in the respiratory or GI system
***Mycobacterium avium* complex (MAC)**	Gastroenteritis, watery diarrhea, weight loss
Mycobacterium tuberculosis (MTB, TB)	Respiratory and disseminated disease. Productive cough, fever, night sweats, weight loss
***Pneumocystis jiroveci* pneumonia (PCP)**	Pneumonia, nonproductive cough, hypoxemia, progressive shortness of breath, fever, night sweats, fatigue
Toxoplasma gondii	Encephalitis, cognitive dysfunction, motor impairment, fever, altered mental status, headache, seizures, sensory abnormalities
Varicella-zoster virus (VZV)	*Shingles:* erythematous maculopapular rash along dermatomal planes, pain, pruritus *Ocular:* progressive outer retinal necrosis (PORN)

TABLE 14.12 HIV Testing*HIV-Antibody/Antigen Testing*

A highly sensitive test detects antibodies and antigens associated with HIV. Blood samples that are negative for HIV infection are reported as negative. The antigen/antibody testing algorithm includes confirmation with HIV viral load testing for any indeterminate results.

- If the patient has a negative HIV antibody/antigen test, but reports recent risky behaviors, encourage retesting in 4 to 6 weeks. Persons at ongoing risk should be assessed or counseled for risk reduction interventions, including preexposure prophylaxis (PrEP).
- If the results are positive and consistent with HIV infection, assist

the patient in getting appropriate counseling, support, and follow-up HIV primary care.

Rapid HIV-Antibody Testing

1. The Centers for Disease Control and Prevention strongly recommends rapid testing. Results are highly accurate. It can be done in a variety of settings (mobile health units, HCP offices, privacy of a person's home). Results are typically available within 20 minutes.
2. In-home HIV test kits are available. Testing is done on saliva.
3. Follow a negative rapid test with a risk assessment to determine the need for repeat tests.
4. Positive rapid tests can be disclosed to the patient but must be confirmed with a standard HIV assay. This step necessitates a blood draw and a return appointment to get results.

Abnormal blood test results are common in HIV infection. They may be caused by HIV, opportunistic diseases, or complications of therapy. Decreased white blood cell (WBC) counts, especially below-normal numbers of lymphocytes (lymphopenia) and neutrophils (neutropenia), often occur. HIV, antiplatelet antibodies, or drug therapy can cause low platelet counts (thrombocytopenia). Anemia is associated with the chronic disease process and adverse effects of ART. Altered liver function, caused by HIV infection, drug therapy, or co-infection with a hepatitis virus, is common. Early identification of co-infection with hepatitis B virus (HBV) or hepatitis C virus (HCV) is extremely important. These infections have a more serious course in patients with HIV, may limit options for ART, and can cause liver-related morbidity and mortality.[22]

Resistance tests can determine if a patient's HIV is resistant to drugs used for ART. *Genotype* and *phenotype* assays help HCPs know which medications can best control a patient's infection. These tests are similar to culture and sensitivity testing used for antibiotic selection.

Interprofessional Care

Interprofessional care of the HIV-infected patient focuses on (1) monitoring HIV disease progression and immune function, (2) initiating and monitoring ART, (3) preventing the development of opportunistic diseases, (4) detecting and treating opportunistic diseases, (5) managing symptoms, (6) preventing or decreasing complications of treatment, and (7) preventing further transmission of HIV. To achieve these goals, ongoing assessment, clinician-patient interactions, and patient teaching and support are needed.

TABLE 14.13 Drug TherapyHIV Infection

Drug Classification	Mechanism of Action	Drug Names
Attachment Inhibitors	Interrupts the ability of HIV to attach to the CD4 cell.	ibalizumab-uiyk (Trogarzo)
Entry Inhibitors	Prevent binding of HIV to cells, thus preventing entry of HIV into cells where replication would occur	enfuvirtide (Fuzeon) maraviroc (Selzentry)
Integrase Inhibitors	Bind with integrase enzyme and prevent HIV from incorporating its genetic material into the host cell	bictegravir* dolutegravir (Tivicay) elvitegravir* raltegravir (Isentress)
Protease Inhibitors (PIs)	Prevent the protease enzyme from cutting HIV proteins into the proper lengths needed to allow viable virions to assemble and bud out from the cell membrane	atazanavir (Reyataz) darunavir (Prezista) fosamprenavir (Lexiva) indinavir (Crixivan) lopinavir + ritonavir (Kaletra) nelfinavir (Viracept) ritonavir (Norvir)† saquinavir (Fortovase, Invirase) tipranavir (Aptivus)
Reverse Transcriptase Inhibitors		
Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)	Inhibit the action of reverse transcriptase	efavirenz (Sustiva) etravirine (Intelence) delavirdine (Rescriptor) nevirapine (Viramune XR) rilpivirine (Edurant)
Nucleoside Reverse Transcriptase Inhibitors (NRTIs)	Insert a piece of DNA into the developing HIV DNA chain, blocking further development of the chain and leaving the production of the new strand of HIV DNA incomplete	abacavir (Ziagen) didanosine (Videx, Videx-EC) doravarine (Pifeltro) emtricitabine (Emtriva) lamivudine (Epivir) stavudine (Zerit) zidovudine (Retrovir)
Nucleotide Reverse Transcriptase Inhibitor (NtRTI)	Combines with reverse transcriptase enzyme to block the process needed to convert HIV RNA into HIV DNA	tenofovir (Viread)

* Elvitegravir and bictegravir are integrase inhibitors that are available only in fixed-dose combinations with tenofovir AF and emtricitabine (Table 14.14).

† Most often used in low doses with other PIs to boost effect.

The first patient visit provides an opportunity to gather baseline data and start establishing rapport. A complete history and physical examination, including an immunization history and psychosocial and dietary evaluations, should be done. Findings from the history, assessment, and laboratory tests help determine patient needs. This is a good time to complete the case reports required by the state health department. Initiate patient teaching about the spectrum of HIV disease, treatment, prevention of transmission to others, improvements in health, and family planning at this meeting. Use patient input to develop a plan of care and determine the need for referrals. Remember that a newly diagnosed patient may not be able to retain or understand information. Be prepared to repeat and clarify information over the course of several months.

Drug Therapy for HIV Infection

The goals of drug therapy in HIV infection are to (1) decrease the viral load, (2) maintain or increase CD4 cell counts, (3) prevent HIV-related symptoms and opportunistic diseases, (4) delay disease progression, and (5) prevent HIV transmission. HIV cannot be cured, but ART can delay disease progression by decreasing viral replication.[23] When taken consistently and correctly, ART can reduce viral loads by 90% to 99%. This makes adherence to treatment regimens extremely important.

Drugs used to treat HIV work at various points in the HIV replication cycle (Tables 14.13 and 14.14). The major advantage of using drugs from different classes is that combination therapy can inhibit viral replication in different ways. This makes it more difficult for the virus to recover and decreases the chance of drug resistance. A major problem with most drugs used in ART is that resistance develops rapidly when they are used alone *(monotherapy)* or taken in inadequate doses. This is why patients receive combinations of 3 or more drugs.

Safety Alert

Interaction of ART With Other Drugs

- Significant interactions with ARTs occur with over-the-counter (OTC) drugs, including antacids, proton pump inhibitors, and certain supplements.
- Many ARTs have interactions with other commonly used drugs and herbal therapies (e.g., St. John's wort).
- Be sure to ask patients about prescribed and OTC drugs as well as herbal products and supplements.

TABLE 14.14 Fixed-Dose Drug Combination Products>*HIV Infection*

Mechanism of Action
More than one drug combined into a single tablet. Drugs may be from the same or different classes.

Examples
Atripla (tenofovir DF + emtricitabine + efavirenz)
Biktarvy (tenofovir AF + emtricitabine + bictegravir)
Combivir (lamivudine + zidovudine)
Complera (tenofovir DF + emtricitabine + rilpivirine)
Delstrigo (tenofovir DF + lamivudine + doravarine)
Descovy (tenofovir AF + emtricitabine)
Epzicom (abacavir + lamivudine)
Evotaz (atazanavir + cobicistat†)
Genvoya (tenofovir AF + emtricitabine + elvitegravir + cobicistat†)
Juluca (dolutegravir + rilpivirine)
Odefsey (tenofovir AF + emtricitabine + rilpivirine)
Prezcobix (darunavir + cobicistat†)
Temixys (tenofovir DF + lamivudine)
Triumeq (abacavir + lamivudine + dolutegravir)
Trizivir (abacavir + lamivudine + zidovudine)
Truvada (tenofovir DF + emtricitabine)
Stribild (tenofovir DF + emtricitabine + elvitegravir + cobicistat†)
Symtuza (tenofovir AF + emtricitabine + darunavir + cobicistat†)

AF, Alafenamide. *DF,* disoproxil fumarate.
† Cobicistat is a pharmacologic booster that enhances the potency of some HIV antiretrovirals. It has no direct effects against HIV.

Drug Therapy for Opportunistic Diseases

Management of HIV is complicated by the many opportunistic diseases that can develop as the immune system deteriorates (Table 14.11). Prevention is the preferred approach to opportunistic diseases. Several opportunistic diseases associated with HIV can be delayed or prevented with adequate ART, vaccines (including hepatitis B, influenza, pneumococcal), and disease-specific prevention measures.[24] Although it is usually not possible to eradicate opportunistic diseases once they occur, prophylactic medications can significantly decrease morbidity and mortality rates. Advances in the prevention, diagnosis, and treatment of opportunistic diseases have contributed significantly to increased life expectancy.

Preventing Transmission of HIV

Preexposure prophylaxis (PrEP) is a comprehensive HIV prevention strategy to reduce the risk for sexually acquired HIV infection in adults at high risk.[25] PrEP should be used in conjunction with other proven prevention interventions such as condoms, risk reduction counseling, and regular HIV testing.

Currently, certain antiretrovirals are approved for both treatment of HIV in persons living with HIV, as well as prevention of HIV infection in persons without HIV infection. Various formulations have been studied for PrEP. The first medications approved for PrEP were tenofovir disoproxil fumarate (Tenofovir DF) in combination with emtricitabine. Other medications, including injectable options, will soon be available. As PrEP, these medications reduce the risk for HIV infection in uninfected people who are at significant risk for acquiring HIV. Tenofovir and emtricitabine are also used in combination with other antiretroviral agents for the treatment of HIV-infected people.

Nursing Management: HIV Infection

Nursing Assessment

Nursing assessment of people not known to have HIV infection should focus on behaviors that put the person at risk for HIV and other sexually transmitted and blood-borne infections. Assess patients for risky behaviors on a regular basis. Do not assume that someone is without risk because he or she is too old, too young, heterosexual, or married.

Assess risk by asking some basic questions: (1) Have you ever had a blood transfusion or used clotting factors? If so, was it before 1985? (2) Have you ever shared drug-using equipment with another person? (3) Have you ever had a sexual experience in which your penis, vagina, rectum, or mouth came into contact with another person's penis, vagina, rectum, or mouth? (4) Have you ever had a sexually transmitted infection? (5) Have you ever had sexual contact with someone known to have HIV? These questions provide the minimum information needed to initiate a risk assessment. Follow up a positive response to any of these questions with an in-depth exploration of issues related to the identified risk.

A person who has HIV infection needs specific, ongoing assessment. Subjective and objective data are outlined in Table 14.15. Repeated nursing assessments over time are essential because people's circumstances change. Early recognition and treatment can slow the progression of HIV infection and prevent new infections. A complete history and thorough systems review can help identify and address problems in a timely manner.

Nursing Diagnoses

Nursing diagnoses for the patient with HIV disease may include:

- Risk for infection
- Lack of knowledge
- Difficulty coping

- Impaired nutritional status

Planning

Nursing interventions can help the patient (1) adhere to drug regimens; (2) adopt a healthy lifestyle that includes avoiding exposure to other sexually transmitted infections and blood-borne diseases; (3) protect others from HIV; (4) maintain or develop healthy and supportive relationships; (5) maintain activities and productivity; (6) explore spiritual issues; (7) come to terms with issues related to disease, disability, and death; and (8) cope with symptoms caused by HIV and its treatments.

Nursing Implementation

The complexity of HIV disease is related to its chronic nature. As with most chronic and infectious diseases, primary prevention and health promotion are the most effective health care strategies. When prevention fails, disease results. Table 14.15 shows a summary of nursing goals, assessments, and interventions throughout the course of HIV infection.

Health Promotion

Even with recent successes in HIV treatment, prevention is key in controlling the epidemic. In addition, health promotion encourages early detection of the disease so that, if primary prevention has failed, early intervention can be initiated.

TABLE 14.15 Nursing AssessmentHIV-Infected Patient

Subjective Data

Important Health Information

Past health history: Route of infection. Hepatitis, other sexually transmitted infections, tuberculosis. Frequent viral, fungal, and/or bacterial infections

Medications: Use of immunosuppressive drugs

Functional Health Patterns

Health perception–health management: Perception of illness. Alcohol and drug use. Malaise

Nutritional-metabolic: Weight loss, anorexia, nausea, vomiting. Lesions, bleeding, or ulcerations of lips, mouth, gums, tongue, or throat. Sensitivity to acidic, salty, or spicy foods. Difficulty swallowing, abdominal cramping. Skin rashes, lesions, or color changes

Elimination: Persistent diarrhea, change in character of stools. Painful urination, low back pain

Activity-exercise: Chronic fatigue, muscle weakness, difficulty walking. Cough, shortness of breath

Sleep-rest: Insomnia, night sweats, fatigue

Cognitive-perceptual: Headaches, stiff neck, chest pain, rectal pain, retrosternal pain. Blurred vision, photophobia, diplopia, loss of vision. Hearing impairment. Confusion, forgetfulness, attention deficit, changes in mental status, memory loss, personality changes. Paresthesias, hypersensitivity in feet, pruritus

Role-relationship: Support system(s), career or job, financial resources

Sexuality-reproductive: Lesions on genitalia or anus (internal or external), pruritus or burning in vagina, penis, or anus. Painful sexual intercourse, rectal pain or bleeding, changes in menstruation, vaginal or penile discharge. Use of birth control measures, pregnancies, desire for future children

Coping–stress tolerance: Stress levels, previous losses, coping patterns, self-concept; social withdrawal

Objective Data

General

Lethargy, persistent fever, lymphadenopathy, peripheral wasting, fat deposits in truncal areas and upper back

Eyes

Presence of exudates, retinal lesions or hemorrhage, papilledema

Integumentary

Decreased skin turgor, dry skin, diaphoresis. Pallor, cyanosis. Lesions, eruptions, discolorations, bruises of skin or mucous membranes. Vaginal or perianal excoriation. Alopecia. Delayed wound healing

Respiratory

Tachypnea, dyspnea, intercostal retractions. Crackles, wheezing, productive or nonproductive cough

Cardiovascular

Pericardial friction rub, murmur, bradycardia, tachycardia

Gastrointestinal

Mouth lesions, including blisters (HSV), white-gray patches (*Candida* infection), painless white lesions on the side of the tongue (hairy leukoplakia), discolorations (Kaposi sarcoma).

Gingivitis, tooth decay or loosening. Redness or white patchy lesions of throat. Vomiting, diarrhea, incontinence, rectal lesions, hyperactive bowel sounds, abdominal masses, hepatosplenomegaly

Musculoskeletal

Muscle wasting, weakness

Neurologic

Ataxia, tremors, lack of coordination. Sensory loss, slurred speech, aphasia. Memory loss, peripheral neuropathy, apathy, agitation, depression, inappropriate behavior. Decreasing levels of consciousness, seizures, paralysis, coma

Reproductive

Genital lesions or discharge, abdominal tenderness secondary to pelvic inflammatory disease (PID)

Possible Diagnostic Findings

Positive HIV antibody/antigen assay. Detectable viral load. ↓ CD4 cell count, ↓ WBC count, lymphopenia, anemia, thrombocytopenia. Electrolyte imbalances, abnormal liver function tests. ↑ cholesterol, triglycerides, and blood glucose

Ethical/Legal Dilemmas

Individual vs. Public Health Protection

Situation

A nurse in a community clinic is having a follow-up visit with V.T., a 38-yr-old woman who was diagnosed with HIV infection during her annual examination 2 weeks ago. During the visit, V.T. discloses that her partner verbally and physically abuses her. V.T. says she had not yet told her partner about the HIV diagnosis because she is afraid that he will hurt her. She has not used any protection during sex with him since she learned of her test results because she suspects he infected her.

Ethical/Legal Points for Consideration

- You face a conflict between preventing further harm to V.T. (possible increase in intimate partner violence), providing care to her partner (his need for an HIV test, diagnosis, and treatment), and protecting the public health (potential spread of HIV infection to her partner or from her partner to others in the community). Patient teaching and support are essential because your primary obligation is to the patient.
- Because relevant law varies from state to state, your first step is to be familiar with your state law concerning mandated reporting for domestic partner abuse and infectious diseases.
- Federal laws about protection of privacy in HIV testing apply everywhere.
- In many states, reporting domestic abuse is mandatory only when the reporter actually witnesses the abuse or when the immediate effects of the abuse (e.g., wounds, contusions, broken bones) are witnessed.[1]
- You should be familiar with crisis counseling services for V.T. and offer her the following advice: Collect and stash a set of car keys or taxi money in a safe place, keep a bag packed and hidden or even stored in a locker somewhere accessible, develop a code phrase to use with a friend or family member to call for help, keep a cell phone charged, and have money hidden in a safe place.

Discussion Questions

1. Within the parameters of your state's requirements for reportable conditions, how can you protect the patient's confidentiality to prevent further intimate partner violence?
2. What services does your state offer to notify a partner without disclosing the source patient's name? How would V.T. access those services in your state?
3. How can you protect the partner from possible infection while also protecting V.T. from further violence?
4. How can you best address the issue of intimate partner violence? What resources would V.T. have in your community?
5. Discuss the benefits of universal, voluntary testing in light of V.T.'s case.

Prevention of HIV Infection

HIV infection is preventable. Avoiding or modifying risky behaviors is the most effective prevention tool. Nursing interventions to prevent disease transmission are based on an assessment of the person's risk behaviors. Provide culturally sensitive, language-appropriate, and age-specific teaching and behavior change counseling. Nurses who are comfortable with and know how to talk about sensitive topics such as sexuality and drug use are best prepared to provide prevention education.

Promoting Population Health

Prevention and Early Detection of HIV

- Increase safer sexual practices, including condom use
- Decrease equipment sharing among IV drug users
- Increase clinician skills to assess for risk factors for HIV infection, recommend HIV testing, and provide counseling for behavior change
- Make voluntary HIV testing a routine part of health care
- Increase access to new HIV testing technologies, especially rapid testing
- Increase access to HIV testing facilities in traditional health care settings and alternative sites, such as drug and alcohol treatment facilities and community-based organizations
- Increase risk assessment and individualized behavior change messages to people with HIV to prevent new infections
- Decrease perinatal HIV infection by offering voluntary HIV testing as a part of routine prenatal care
- Provide counseling and appropriate HIV therapy to those who are infected

A wide variety of activities can reduce the risk for HIV infection.[26] Help people choose the methods that best fit their needs and circumstances. Prevention techniques are divided into *safe sexual activities* (those that eliminate risk) and *risk-reducing sexual activities* (those that decrease, but do not eliminate, risk).

The goal is to develop safer, healthier, and less risky behaviors. The more consistently and correctly one uses prevention methods, the more effective they are in preventing HIV infection. It is a good idea to use a combination of prevention methods (e.g., using condoms, decreasing the number of sex partners) to increase the prevention effect.

Decreasing risks related to sexual intercourse

Safe sexual activities eliminate the risk for exposure to HIV in semen and vaginal secretions. Abstaining from all sexual activity is an effective way to achieve this goal, but there are safe options for those who cannot or do not wish to abstain. Limiting sexual behavior to activities in which the mouth, penis, vagina, or rectum does not come into contact with a partner's mouth, penis, vagina, or rectum eliminates contact with blood, semen, or vaginal secretions. Safe activities include masturbation, mutual masturbation ("hand job"), and other activities that meet the "no contact" requirements. *Insertive sex* between partners who are not infected with HIV and not at risk of becoming infected with HIV is considered safe.

Risk-reducing sexual activities decrease the risk of contact with HIV through the use of barriers. Barriers should be used when engaging in insertive sexual activity (oral, vaginal, anal) with a partner who has HIV or whose HIV status is not known. The most commonly used barrier is the male condom. Male condoms offer protection during anal, vaginal, and oral intercourse. Female condoms are an alternative to male condoms. Squares of latex (known as dental dams) can be used as a barrier during oral sexual activity.

Decreasing risks related to drug use

Drug use, including alcohol and tobacco, can cause immunosuppression, poor nutrition, and a host of psychosocial problems. However, drug use does not cause HIV infection. The major risk for HIV related to using drugs involves sharing equipment or having unsafe sexual experiences while under the influence of drugs. Basic risk reduction rules are (1) do not use drugs; (2) if you use drugs, do not share equipment; and (3) do not have sexual intercourse when under the influence of any drug, including alcohol, that impairs decision making.[27]

The safest method is to abstain from drugs, but this may not be a practical option for users who are not prepared to quit or have no access to drug treatment services. The risk for HIV infection for these persons is eliminated if they do not share equipment. Injecting equipment ("works") includes needles, syringes, cookers (spoons or

bottle caps used to mix the drug), cotton, and rinse water. Blood can contaminate equipment used to snort (straws) or smoke (pipes) drugs and should not be shared.

Evidence-Based Practice

Condom Use and HIV

As a nurse in an HIV clinic, you are counseling M.J., a 27-yr-old gay man and his partner. M.J. is on antiretroviral therapy (ART). His viral load is very low, and his CD4 cell count is normal. He tells you that since the drugs are working, he and his partner (who is HIV-negative) are considering not using condoms in the future.

Making Clinical Decisions

Best Available Evidence. One of the best ways to prevent HIV transmission from an infected person to an uninfected person continues to be the consistent and correct use of latex condoms. Those with HIV who take ART and get and keep an undetectable viral load (<200 copies/mL) have effectively no risk for transmitting HIV to their HIV-negative sexual partners. Behavior change programs provided by HCPs, peers, and others can significantly reduce risk behaviors among those with HIV and the transmission of the virus to others.

Clinician Expertise. You know that risk-reducing sexual activities in this situation include the continued use of condoms. However, you also know that although an undetectable viral load decreases the risk for HIV transmission, the risk may not be completely eliminated.

Patient Preferences and Values. M.J. tells you that he and his partner are in a committed relationship, have no other partners, and do not like using condoms.

Implications for Practice

1. What information would you discuss with M.J. related to HIV transmission, ART and viral load, and the risks of unprotected sexual activity?
2. What measures besides condom use would you discuss with M.J. to reduce the risk for HIV transmission?

References for Evidence

Centers for Diseases Control and Prevention. Evidence of HIV treatment and viral suppression in preventing the sexual transmission of HIV. Retrieved from *www.cdc.gov/hiv/pdf/risk/art/cdc-hiv-art-viral-suppression.pdf*.

Centers for Diseases Control and Prevention. Proven HIV prevention methods. Retrieved from *www.cdc.gov/nchhstp/newsroom/docs/factsheets/hiv-proven-prevention-methods-508.pdf*.

Access to sterile equipment is an important risk elimination tactic. Some communities have needle and syringe exchange programs (NSEPs) that provide sterile equipment in exchange for used equipment. Opposition to these programs is related to the fear that access to injecting supplies will increase drug use. However, studies have shown that in communities with NSEPs, drug use does not increase, rates of HIV and other blood-borne infections are controlled, and an overall cost benefit results.[28] Appropriately cleaning equipment before use can reduce risk by decreasing the chance of blood contact.

Providing support for patients with substance use and referring them to professionals who can assist with managing the psychologic aspects of substance use is important. Other self-help programs (e.g., Narcotics Anonymous, Alcoholics Anonymous) may be helpful.

Decreasing risks of perinatal transmission

The best way to prevent HIV infection in infants is to prevent HIV infection in women. Women infected with HIV should be asked about their reproductive desires. Those who choose not to have children need to have family planning methods discussed in detail. Should they become pregnant, we need to discuss their options, including the possibility of maintaining the pregnancy and using ART to decrease the risk for transmission or having an abortion.

If HIV-infected pregnant women are appropriately treated during pregnancy, the rate of perinatal transmission decreases from 25% to less than 2%. ART has significantly decreased the risk for infants born to HIV-infected women, and more of these women are now becoming mothers. The current standard of care is for all women who are pregnant or contemplating pregnancy to receive HIV counseling, be offered access to voluntary HIV-antibody testing, and, if infected, offered optimal ART.[29]

Decreasing risks at work

The risk for infection from occupational exposure to HIV is small but real. OSHA requires employers to protect workers from exposure to blood and other potentially infectious materials (Table 14.8). Precautions and safety devices decrease the risk for direct contact with blood and body fluids. Should exposure to HIV-infected fluids occur, **postexposure prophylaxis (PEP)** with combination ART can significantly decrease the risk for infection.[15] The need for timely treatment and counseling makes it critical for nurses to report all blood exposures.

HIV Testing

An estimated 14% of people living with HIV in the United States are not aware that they are infected. People who do not know they are infected are more likely to transmit the infection to others. Current guidelines recommend universal, voluntary testing as part of routine medical care.[30,31] The goal is to normalize the test, decrease the stigma related to HIV testing, find hidden cases, get infected persons into

care, and prevent new cases of infection.

Acute Care

Early Intervention

Early intervention after detection of HIV infection can promote health and limit disability. The nursing assessment in HIV disease should focus on early detection of symptoms, opportunistic diseases, and psychosocial problems (Table 14.16).

Initial response to diagnosis of HIV

Reactions to an HIV diagnosis are similar to the reactions of people who are diagnosed with any life-threatening, debilitating, or chronic illness. These reactions include anxiety, panic, fear, depression, denial, hopelessness, anger, and guilt.[32] Unfortunately, all these emotions are overlaid with the stigma and discrimination that continue to infuse societal reactions to HIV. The patient's family members, friends, and caregivers experience many of the same reactions. As time passes, patients and their loved ones will be confronted with complex treatment decisions; feelings of loss, anger, powerlessness, depression, and grief; social isolation; the possibility of death; and/or thoughts of suicide.

Antiretroviral therapy

ART can significantly slow the progression of HIV. However, treatment regimens can be complex, the drugs have side effects, ART does not work for everyone, and it is expensive. These factors can contribute to problems with adherence to treatment, a dangerous situation because of the high risk for developing drug resistance.

Check Your Practice

You are working in an outpatient HIV clinic, and one of the patients, a 34-yr-old single parent with HIV infection, tells you, "I've been

feeling well lately. I've been so busy taking care of my kids and working, I have not been taking my HIV meds."

- How would you respond to this patient?

Interventions include teaching about (1) advantages and disadvantages of new treatments, (2) dangers of poor adherence to therapeutic regimens, (3) how and when to take each drug, (4) drug interactions to avoid, and (5) side effects to report to the HCP. Table 14.17 outlines patient and caregiver teaching on HIV treatment and initial follow-up.

Clinical guidelines provide information on initial drug regimens.[23] However, one of the most important considerations for initiating therapy is patient readiness for treatment. Adherence to ART is a critical part of successful drug therapy for people with HIV infection. Nurses are uniquely prepared to provide assistance with adherence to the drug regimen (Table 14.18). Taking drugs as prescribed (right dose and time) is important for all drug therapy, but with HIV infection, missing even a few doses can lead to drug resistance. We can help patients adhere to difficult treatment regimens with electronic reminders, beepers, timers on pillboxes, and calendars. Group support and individual counseling can help. The best approach is to learn about the patient's life and assist with problem solving related to taking medications within the confines of that life.

Informatics in Practice

Use of Internet and Mobile Devices to Manage HIV

- The Internet offers resources and support for patients that can help them cope with their illness and teach them about signs and symptoms of serious illness.
- By monitoring their health and quickly spotting warning signs of

serious illnesses, patients are able to alert their HCPs and receive earlier treatment.

- These systems can help the patient manage antiretroviral therapy by sending medication reminders by text or e-mail.

Delaying disease progression

Promoting a healthy im-mune system, whether the patient chooses to take ART or not, may delay the progression of HIV disease. Useful interventions for HIV-infected patients include (1) getting nutritional support to maintain lean body mass and ensure appropriate levels of vitamins and micronutrients; (2) moderating or eliminating alcohol, tobacco, and drug use; (3) keeping up to date with recommended vaccines; (4) getting adequate rest and exercise; (5) reducing stress; (6) avoiding exposure to new infectious agents; (7) accessing counseling; (8) getting involved in support groups and community activities; and (9) developing a consistent relationship with HCPs, including attending regular appointments.

TABLE 14.16 Nursing ManagementHIV Infection

Nursing Care and Goals	Assessment	Interventions
Health Promotion		
Prevent HIV infection	*Risk factors:* What behaviors or social, physical, emotional, pathogenic, or immune factors place the patient at risk?	• Education, including knowledge, attitudes, and behaviors, with emphasis on risk reduction to the following: • *General population:* Cover general information • *Pregnant women:* General information and information specific to HIV infection and pregnancy • *Individual patient:* Specific to assessed need • Empower patients to take control of prevention measures.
Detect HIV infection early	Does the patient need to be tested for HIV?	• Provide HIV antibody/antigen testing with appropriate counseling.
Acute Care		
Promote health and limit disability	*Physical health:* Is the patient experiencing problems? *Mental health:* How is the patient coping? *Resources:* Does the patient have family or social support? Is the patient accessing community services? Is money or insurance a problem? Does the patient have access to spiritual support as desired?	• Provide case management or refer to interprofessional team, including social work. • Teach about HIV, the spectrum of infection, options for care, signs and symptoms to report, treatment options, immune enhancement, risk reduction, and ways to adhere to treatment regimens. • Establish long-term, trusting relationship with patient, family, and significant others. • Provide emotional and spiritual support. • Develop resources for legal needs: discrimination prevention, wills and advance directives, child care wishes. • Empower the patient to identify needs, direct care, and seek services.
Manage problems caused by HIV infection	*Physical health:* Has the patient had an acute exacerbation of problems related to immunodeficiency, opportunistic disease, or risk factors (e.g., substance use)? *Mental health status:* Has the patient's ability to cope with psychosocial issues deteriorated?	• Provide care during acute exacerbations: recognition of life-threatening developments, life support, rapid intervention with treatments and drugs, comfort, and hygiene needs. • Support patient and family during crisis. • Assist the patient with mental health issues and provide referral to mental health specialist as needed.
Ambulatory Care		
Maximize quality of life	*Physical health:* Are new symptoms developing? Is the patient experiencing drug side effects or interactions?	• Continue case management. • Teach about changing treatment options and continued adherence. • Empower patient to continue to direct care and to make desires known to family members and significant others.
Resolve life and death issues	*Mental health:* How is the patient coping? What adjustments have been made? *Finances:* Can the patient maintain health care and basic standards of living? *Family, social, and community support:* Are these available? Is the patient using support in an effective manner? Do family or significant others need teaching, encouragement, or stress relief? *Spirituality issues:* Does the patient desire support from a religious organization or spiritual counselor? What assistance does the patient desire?	• Continue physical care for chronic disease process: treatments, drugs, comfort, and hygiene needs. • Encourage health promotion measures (as above). • Refer the patient to resources to support finances. • Support patient and family or significant others in a trusting relationship. • Assist with end-of-life issues: resuscitation orders, comfort measures, funeral plans, estate planning, child care, etc. • Assess desires and refer to resources that will help in meeting spiritual needs.

Teach patients to recognize symptoms that may indicate disease progression and/or drug side effects so that prompt medical care can be initiated. Table 14.19 gives an overview of symptoms that patients should report.

Acute Exacerbations

Acute exacerbations of recurring problems characterize chronic disease. This is especially true in HIV disease in which infections,

cancers, debility, and psychosocial or economic issues may interact to overwhelm the patient's ability to cope. Nursing care becomes more complex as the patient's immune system declines and new problems arise to compound existing difficulties. When opportunistic diseases or difficult treatment side effects develop, the patient needs symptom management, teaching, and emotional support.

Nursing care can help prevent the many opportunistic diseases associated with HIV infection. The best way to prevent opportunistic disease is to ensure that the patient is adhering to an effective ART regimen and, if appropriate, taking prophylactic medications for opportunistic infections. Should an opportunistic disease occur, nursing care is an essential part of helping the patient adhere to medications and providing supportive care specific to the opportunistic disease. For example, if the patient has *Pneumocystis jiroveci* pneumonia (PCP) (Fig. 14.8), nursing interventions can ensure adequate oxygenation. If the patient has cryptococcal meningitis, an important nursing concern is maintaining a safe environment for a confused patient.

TABLE 14.17 Patient & Caregiver TeachingAntiretroviral Drugs

Resistance to antiretroviral drugs is a major problem in treating HIV infection. Include the following instructions when teaching the patient and/or caregiver to decrease the risk for developing resistance.

1. Discuss options with your HCP to find the best regimen for you.
2. Know the drugs you are taking and how to take them (some have to be taken with food, some must be taken on an empty stomach, some cannot be taken together). If you do not understand, ask. Have your nurse write the instructions for you.
3. Take the full dose prescribed and take it on schedule. If you cannot take the drug because of side effects or other problems,

report it to your HCP immediately.

4. Take all your medications as prescribed. Do not quit taking one drug while continuing the others. If you cannot tolerate even one of your drugs, talk to your HCP, who will recommend a way to deal with the side effects or a new set of drugs.
5. Many antiretroviral drugs interact with other drugs, including many common drugs you can buy without a prescription. Be sure your HCP and pharmacist know all the drugs that you are taking. Do not take any new drugs without checking for possible interactions.
6. The goals of antiretroviral therapy are to decrease the amount of virus in your blood (your viral load) and to keep your CD4 cell count high. The best results reduce your viral load below detectable levels and keep your CD4 cell count high. Most HCPs do routine laboratory work every 3 to 6 months whether you are taking antiretroviral drugs or not.
7. At 2 to 4 weeks after you start on drug therapy or change your therapy, your HCP will test your viral load to find out how the drugs are working.
    - Your viral load is reported in absolute numbers. All you need to know is that you want to see the viral load drop.
    - Your CD4 cell count is reported in absolute numbers or percentages. It is best for your CD4 cell count to be above 500 cells/μL. If reported in percentages, you would like your CD4 cell value to be above 14%.
8. An undetectable viral load means that the amount of virus is extremely low, and HIV cannot be found in the blood using current testing technology. It does not mean that the virus is gone because the virus can be in lymph nodes and organs that blood tests cannot detect. It also does not mean that you are no longer able to transmit HIV to others. You will need to continue protecting all your sexual and drug-using partners from HIV.

TABLE 14.18 Patient & Caregiver TeachingImproving Adherence to Antiretroviral Therapy

The following are strategies that you can use to improve a patient's adherence to using antiretroviral therapy:

1. Determine whether the patient understands the importance of adherence and is ready to start therapy.
2. Provide teaching on medication dosing.
3. Review potential side effects of drugs.
4. Assure the patient that side effects can be treated. If not, medication regimens can be changed.
5. Use teaching and memory aids, including pictures, pillboxes, and calendars.
6. Engage family and friends in the teaching process. Solicit their support to help the patient take treatment.
7. Simplify regimens, dosing, and food requirements as much as possible.
8. Use a team of nurses, HCPs, pharmacists, case managers, and mental health and peer counselors to support the patient.
9. Help the patient integrate the medication regimen into his or her typical life activities and work schedules.

Modified from Centers for Disease Control and Prevention: Guidelines for the use of antiretroviral agents in HIV-1-infected adults and adolescents, 2015. Retrieved from *www.aidsinfo.nih.gov*.

TABLE 14.19 Patient & Caregiver TeachingSigns and Symptoms HIV-Infected Patients Need to Report

Teach the patient with HIV infection and the caregiver to report the following signs and symptoms.

Report Immediately

- Any change in level of consciousness: lethargic, hard to arouse, unable to be aroused, unresponsive, unconscious
- Headache accompanied by nausea and vomiting, changes in vision, changes in ability to perform coordinated activities, or after any head trauma
- Vision changes: blurry or black areas in vision field, new floaters, double vision
- Persistent shortness of breath related to activity and not relieved by a short rest period
- Nausea and vomiting accompanied by abdominal pain
- Vomiting blood
- Dehydration: unable to eat or drink because of nausea or mouth lesions; severe diarrhea or vomiting; dizziness when standing
- Yellow discoloration of the skin
- Any bleeding from the rectum that is not related to hemorrhoids or trauma (e.g., from anal sexual intercourse)
- Pain in the flank with fever and inability to urinate for more than 6 hours
- Blood in the urine
- New onset of weakness in any part of the body, new onset of numbness that is not obviously related to pressure, new onset of difficulty speaking
- Chest pain not obviously related to cough
- Seizures
- New rash accompanied by fever
- New oral lesions accompanied by fever
- Severe depression, anxiety, hallucinations, delusions, or thoughts of causing danger to self or others

Report the Following Signs and Symptoms Within

24 Hours

- New or different headache; constant headache not relieved by over-the-counter medication
- Headache accompanied by fever, nasal congestion, or cough
- Burning, itching, or discharge from the eyes
- New or productive cough
- Vomiting 2 or 3 times a day
- Vomiting accompanied by fever
- New, significant, or watery diarrhea (more than 6 times a day)
- Painful urination, bloody urine, urethral discharge
- Significant new rash (widespread; painful; or following a path down the leg or arm, around the chest, or on the face)
- Difficulty eating or drinking because of mouth lesions
- Vaginal discharge, pain, or itching

Ambulatory Care

HIV infection has no cure, continues for life, causes physical disability, and contributes to impaired health. In many cases it can lead to death. HIV infection affects the entire range of a person's life from physical health to social, emotional, economic, and spiritual well-being. As a nurse, you are often the person who works most closely with patients who are trying to cope with living with HIV.

Stigma of HIV

HIV-infected patients share problems experienced by all those with chronic diseases, but these problems are worsened by negative social attitudes and beliefs surrounding HIV. HIV-infected people may be thought to lack control over urges to have sex or use IV drugs. Some people conclude that people with HIV brought the disease on themselves and deserve to be sick. Some view behaviors associated with HIV infection as immoral (e.g., homosexuality, promiscuity).

Other behaviors are sometimes illegal (e.g., using drugs, sex work). The fact that infected people can transmit HIV to others creates fear, which leads to stigma and discrimination in all areas of life.[33]

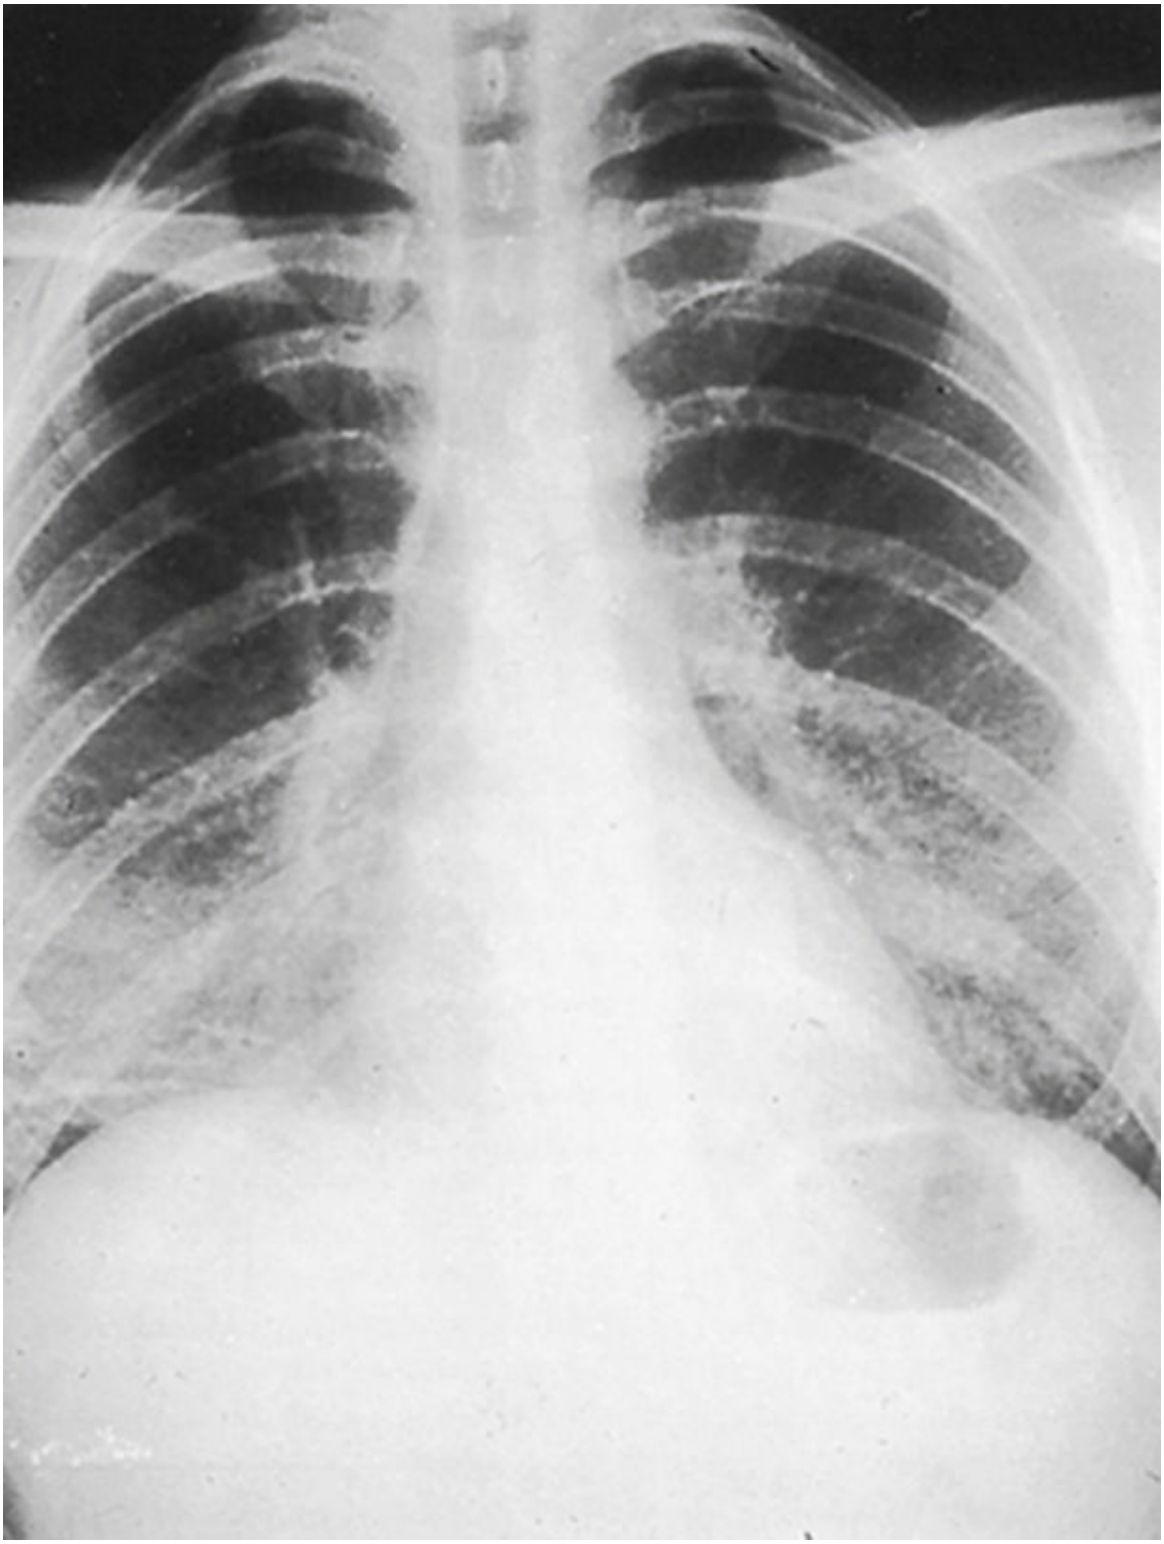

FIG. 14.8 Chest x-ray showing interstitial infiltrates as the result of *Pneumocystis jiroveci* pneumonia.
From the Centers for Disease Control and Prevention. Courtesy Jonathan W. M. Gold, MD, New York, NY.

In the United States, HIV-infected people have lost jobs, homes, and insurance, although the Americans with Disabilities Act (ADA) prohibits these forms of discrimination. HIV-related stigma is a global problem that is often more severe for women. Discrimination can lead to social isolation, dependence, frustration, low self-image, loss of control, and economic pressures.

Disease and Drug Side Effects

Physical problems related to HIV or its treatment can interfere with the patient's ability to maintain a desired lifestyle. HIV-infected patients often have anxiety, fear, depression, diarrhea, peripheral neuropathy, pain, nausea, vomiting, and fatigue. Nursing interventions for these symptoms are similar to what they would be for the patient who does not have HIV infection. For example, nursing management of diarrhea includes helping patients collect specimens, recommending diet changes, encouraging fluid and electrolyte replacement, teaching the patient about skin care, and managing skin breakdown around the perianal area. Nursing approaches for fatigue in HIV include teaching patients to assess fatigue patterns; determine contributing factors; set activity priorities; conserve energy; schedule rest periods; exercise regularly; and avoid substances such as caffeine, nicotine, alcohol, and other drugs that may disturb sleep.

Some HIV-infected patients, especially those who have been infected and on ART for a long time, may develop a set of metabolic disorders. These include (1) lipodystrophy (changes in body shape caused by a redistribution of fat in the abdomen, upper back, and breasts along with fat loss in the arms, legs, and face) (Fig. 14.9); (2) hyperlipidemia (high triglycerides, high low-density lipoproteins, and decreased high-density lipoproteins); (3) insulin resistance; (4) hyperglycemia; (5) bone disease (osteoporosis, osteopenia, avascular necrosis); (6) lactic acidosis; (7) renal disease; and (8) cardiovascular disease.[34]

FIG. 14.9 Lipodystrophy manifestations.
From James WD, Berger T, Elston D: *Andrews' diseases of the skin: Clinical dermatology,* ed 11, St Louis, 2011, Saunders.

It is still not clear why these disorders develop, but it is likely a combination of factors such as long-term infection with HIV, side effects of ART, genetic predisposition, and chronic stress. Management of metabolic disorders focuses on detecting problems early, dealing with symptoms, and helping the patient cope with emerging problems and changes to treatment regimens. It is

important to recognize and treat these problems early, especially because cardiovascular disease and lactic acidosis are potentially fatal complications.

A frequent first intervention is to change ART medications because some drugs are more often associated with these disorders. Lipid abnormalities are generally treated with lipid-lowering drugs (see Table 33.6), diet changes, and exercise. Insulin resistance is treated with hypoglycemic drugs and weight loss. Exercise, diet changes, and calcium and vitamin D supplements may improve bone disease.

End-of-Life Care

Despite new developments in the treatment of HIV infection, many patients eventually have disease progression, disability, and death. Sometimes these occur because treatments do not work for the patient. Sometimes the patient's HIV becomes resistant to all available drug therapies. In addition, ART is now allowing people living with HIV to live longer and to develop diseases of aging, such as cardiovascular and endocrine problems that lead to death.

Nursing care during the terminal phase of any disease should focus on keeping the patient comfortable, facilitating emotional and spiritual acceptance of the finite nature of life, helping the patient's significant others deal with grief and loss, and maintaining a safe environment.[35] As a nurse, you are the pivotal care provider during this phase of illness, whether at home, through hospice, or in a health care facility. End-of-life care is discussed in Chapter 9.

Evaluation

The expected outcomes are that the patient at risk for HIV infection will:

- Develop and implement a personal plan to decrease personal risk factors
- Have testing for HIV

The expected outcomes are that the patient with HIV infection will:

- Adhere to treatment for HIV disease
- Work with the health care team to achieve optimal health
- Prevent transmission of HIV to others

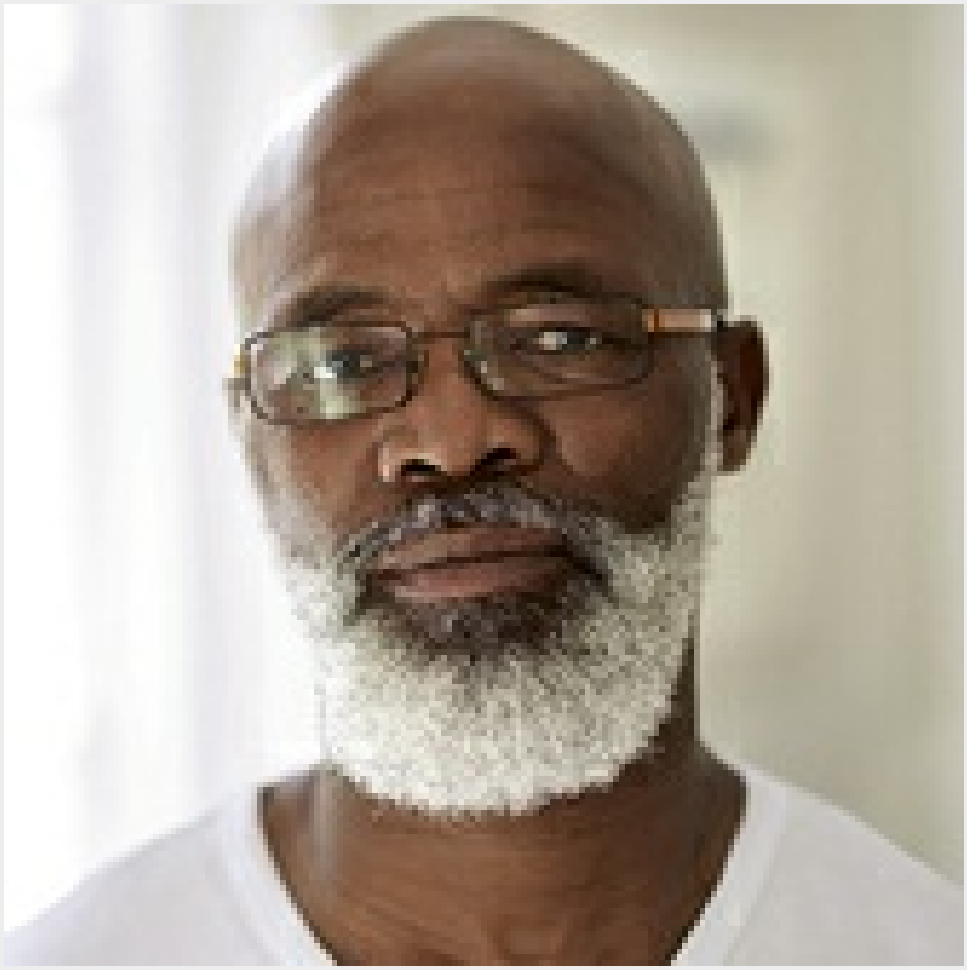
Gerontologic Considerations: HIV Infection

The number of older adults who have HIV disease is increasing because (1) HIV treatment has been effective in reducing the number of deaths from HIV-related opportunistic infections and (2) people 60 and older are being infected at increasing rates. The number of people over the age of 60 living with HIV is expected to grow.

Remember that older people living with HIV are susceptible to the same diseases as non–HIV-infected older people. These include heart disease, cancer, diabetes, bone disease, arthritis, hypertension, kidney disease, and cognitive impairment. However, people with HIV infection may develop these diseases at an earlier age (compared with non–HIV-infected people) and be at higher risk for co-morbidities related to ART.[36] For example, some HIV medications are associated with increased lipids and altered insulin metabolism. Focusing nursing care on early identification of these complications, and helping patients reduce their risk for heart disease, diabetes, or other chronic disease, are critical aspects of caring for the older HIV patient.

Check Your Practice

You are receiving report on a patient newly admitted to the rehabilitation unit. He is a 68-yr-old male patient who had a hip replacement 3 days ago. The nurse giving the report casually mentions, “Oh, by the way, he has AIDS. Can you believe that an old man like that has HIV?”



- How would you respond?

The impact of polypharmacy is another consideration with the aging HIV population. In general, older adults take multiple medications to manage various chronic diseases. Some medications may interact with or be potentiated by HIV medications. Therefore careful monitoring and assessment of possible drug interactions is important when providing care to this population.

Older adults may be ashamed and hesitate to tell anyone that they have an HIV infection. This may make it hard for them to get the appropriate health care and support. As a nurse, you need to recognize that HIV will affect an increasing number of older adults and be prepared to help the older person who is living with HIV infection.

Case Study

HIV Infection

© iStock.com/Cecilie_Arcurs.

Patient Profile

J.N., a 69-yr-old black male with HIV, chronic hepatitis B, and hypertension, was admitted 2 days ago with *Pneumocystis jiroveci* pneumonia (PCP).

Subjective Data

- Diagnosed with HIV infection at age 56 after his male partner was diagnosed with Kaposi's sarcoma
- Has had issues taking ART consistently, "Too many side effects"
- Has fatigue and frequent oral candidiasis outbreaks
- Expresses concern about his future, "I don't know who will take care of me. I don't have any family around"

Objective Data
Physical Examination

- 5 ft 10 in tall, 150 lb, temperature 100.4° F (38° C), O_2 saturation 92% on 3 L of O_2 via nasal cannula

Laboratory Studies

- CD4 cell count 185 cells/μL
- Viral load 155,328 copies/μL

Interprofessional Care

- Trimethoprim/sulfamethoxazole
- Combination antiretroviral therapy: tenofovir alafenamide and emtricitabine (Descovy), with dolutegravir (Tivicay)

Discussion Questions

1. Why was trimethoprim/sulfamethoxazole ordered, and what are its common side effects?
2. ***Priority Decision:*** What priority teaching needs should be covered before J.N. is discharged from the hospital to return home?
3. How can J.N. be helped to adhere to his medication schedule?
4. ***Priority Decision:*** What are the priority nursing interventions? What nursing care will he need after discharge?
5. ***Collaboration:*** Older lesbian, gay, bisexual, transgender (LGBT) adults often lack familial social support as they age. What barriers could this cause for J.N.'s treatment? How could the interprofessional team assist in addressing these issues? What referrals may be made?

6. ***Safety:*** The nurse needs to start an IV for fluid replacement on J.N. Before inserting the IV what type of personal protective equipment is recommended for this situation?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Emerging and reemerging infections affect health care by *(select all that apply)*
   a. reevaluating vaccine practices.
   b. revealing antimicrobial resistance.
   c. limiting antibiotics to those with life-threatening infection.
   d. challenging researchers to discover new antimicrobial therapies.
2. Interventions to prevent health care–associated infections include (*select all that apply*)
   a. following hand-washing protocols.
   b. limiting visitors to persons over age 18.
   c. placing high-risk patients in private rooms.
   d. decontaminating equipment used for patient care.
   e. appropriately using personal protective equipment.
3. Transmission of HIV from an infected person to another most often occurs because of
   a. unprotected anal or vaginal sexual intercourse.

b. low levels of virus in the blood and high levels of $CD4^+$ T cells.

c. transmission from mother to infant during labor and delivery and breastfeeding.

d. sharing eating utensils, dry kissing, hugging, using toilet seats, or shaking hands.

4. During HIV infection

a. reverse transcriptase helps HIV fuse with the $CD4^+$ T cell.

b. HIV RNA uses the $CD4^+$ T cell's mitochondria to replicate.

c. the immune system is impaired predominantly by the eventual widespread destruction of $CD4^+$ T cells.

d. a long period of dormancy develops during which HIV cannot be found in the blood and there is little viral replication.

5. A diagnosis of AIDS is made when an HIV-infected patient has

a. a $CD4^+$ T cell count below 200/μL.

b. a high level of HIV in the blood and saliva.

c. lipodystrophy with metabolic abnormalities.

d. oral hairy leukoplakia, an infection caused by Epstein-Barr virus.

6. Screening for HIV infection generally involves

a. detecting $CD8^+$ cytotoxic T cells in saliva.

b. laboratory analysis of saliva to detect $CD4^+$ T cells.

c. analysis of lymph tissues for the presence of HIV RNA.

d. laboratory analysis of blood to detect HIV antigen and/or antibody.

7. HIV antiretroviral drugs are used to
   a. cure acute HIV infection.
   b. decrease viral RNA levels.
   c. treat opportunistic diseases.
   d. decrease symptoms in terminal disease.

8. Opportunistic diseases in HIV infection
   a. are usually benign.
   b. are generally slow to develop and progress.
   c. occur in the presence of immunosuppression.
   d. are curable with appropriate drug interventions.

9. Which statements about metabolic side effects of ART are true (*select all that apply*)?
   a. These are annoying symptoms that are ultimately harmless.
   b. ART-related body changes include fat redistribution and peripheral wasting.
   c. Lipid problems include increases in triglycerides and decreases in high-density cholesterol.
   d. Insulin resistance and hyperlipidemia can be treated with drugs to control glucose and cholesterol.
   e. Compared to uninfected people, insulin resistance and hyperlipidemia are harder to treat in HIV-infected patients.

10. Which strategy can the nurse teach the patient to eliminate the risk for HIV transmission?

a. Using sterile equipment to inject drugs

b. Cleaning equipment used to inject drugs

c. Taking lamivudine (Epivir) during pregnancy

d. Using latex or polyurethane barriers to cover genitalia during sexual contact

11. What is the *most* appropriate nursing intervention to help an HIV-infected patient adhere to a treatment regimen?

a. Set up a drug pillbox for the patient every week.

b. Give the patient a video and a brochure to view and read at home.

c. Tell the patient that side effects of ART are bad but that they go away.

d. Assess the patient's routines and find adherence cues that fit into the patient's life circumstances.

1. a, b, d, 2. a, d, e, 3. a, 4. c, 5. a, 6. d, 7. b, 8. c, 9. b, c, d, 10. a, 11. d

Cancer

Marisa Cortese

LEARNING OUTCOMES

1. Describe the incidence, survival, and mortality rates of cancer in the United States.
2. Describe the processes involved in the biology of cancer.
3. Outline the stages of cancer development.
4. Describe the role of the immune system related to cancer.
5. Discuss the role of the nurse in the prevention, detection, and diagnosis of cancer.
6. Explain the use of surgery, chemotherapy, radiation therapy, immunotherapy, targeted therapy, and hormone therapy in the treatment of cancer.
7. Identify the classifications of chemotherapy agents and methods of administration.
8. Distinguish between external beam radiation and brachytherapy.
9. Describe the effects of radiation therapy and chemotherapy on normal tissues.
10. Identify the types and effects of immunotherapy and targeted therapy.
11. Describe the nursing management of patients receiving chemotherapy, radiation therapy, immunotherapy, and targeted therapy.

12. Describe nutritional therapy for patients with cancer.
13. Identify complications associated with advanced cancer.
14. Describe support interventions for cancer patients, cancer survivors, and their caregivers.

Conceptual Focus

Cellular Regulation
Coping
Health Promotion

Cancer is a group of diseases characterized by uncontrolled and unregulated growth of cells. The resulting problems may be directly related to the cancer, a consequence of treating the cancer, or a combination of both. The combined physiologic, psychologic, and social impact of cancer on patients and their caregivers is considerable. Despite advances in treatment and care, a great deal of anxiety and fear continue to be associated with a diagnosis of cancer.

Educating health care professionals and the public is essential to promote realistic attitudes about cancer and cancer treatment. You are in a strategic position to lead efforts for changing attitudes about cancer. You can (1) help people decrease their risk for cancer development, (2) increase rates of cancer screening, (3) help patients adhere to cancer management plans, and (4) support patients and caregivers as they cope with the effects of cancer and related treatment. You need to be knowledgeable about specific types of cancer, treatment options, management of side effects of therapy, and supportive therapies for cancer.

Cancer is often considered a disease of aging, with most cases diagnosed in those over age 55 years. However, it occurs in people of all ages. An estimated 1.7 million people in the United States are diagnosed annually with invasive cancer (excluding basal and squamous cell skin cancers).[1]

Overall both the incidence and mortality rates of cancer have been declining.[2] The incidence of many cancers, such as colorectal, lung,

breast, and oropharyngeal cancers, have declined largely because of preventive efforts. However, the incidence of other types of cancers, such as kidney, thyroid, pancreas, liver, uterus, skin melanoma, multiple myeloma, and non-Hodgkin's lymphoma, is increasing.[3]

Overall cancer incidence is higher in men than women. Gender differences in incidence and death rates for specific cancers are shown in the Gender Differences box and Tables 15.1 and 15.2.

Gender Differences

Cancer

Men

- More men than women die from cancer-related deaths each year.
- Mortality rate from lung cancer is higher in men.
- Cancer with the highest incidence among men is prostate cancer.
- Men are more likely to develop liver cancer.
- Head and neck cancers occur more often in men.

Women

- Cancer with the highest death rate among women is lung cancer.
- Cancer with the highest incidence among women is breast cancer.
- Thyroid cancer is more prevalent in women.
- Women are less likely to have colon cancer screenings.

TABLE 15.1 Cancer Incidence by Site and Gender*

Although mortality rates from all cancers combined are on the decline, it is still the second most common cause of death in the United States. Cancer is the leading cause of death of people 40 to 79 years of age. Each year about 609,640 Americans are expected to die because of cancer, which is more than 1600 people per day.[1,2]

Considerable progress has been made in controlling cancer for long periods. More than 15.5 million Americans are alive today who have a history of cancer. This includes those who have cancer and are undergoing treatment, are disease free, or are in remission.[2] Cancer survivors are discussed later on pp. 264-265.

Biology of Cancer

Two major dysfunctions present in the process of cancer development are defective cell proliferation (growth) and defective cell differentiation.

Defect in Cell Proliferation

Normally, most tissues have a population of undifferentiated cells known as stem cells. These stem cells ultimately differentiate and become mature, functioning cells of a specific tissue.

Cell proliferation starts in the stem cell and begins when the stem cell enters the cell cycle (Fig. 15.1). The time from when a cell enters the cell cycle to when the cell divides into 2 identical cells is called the *generation time* of the cell. A mature cell continues to function until it degenerates and dies.

All the body's cells are controlled by an intracellular mechanism that determines when cell proliferation is necessary. Under normal conditions, there is a state of dynamic equilibrium. This means cell proliferation equals cell degeneration or death. Normally, the process of cell division and proliferation is activated only in the presence of cell degeneration or death *(apoptosis).* Cell proliferation also occurs if the body has a physiologic need for more cells. For example, a normal increase in white blood cell (WBC) count occurs with infection.

Another means of proliferation control in normal cells is *contact inhibition*. Normal cells respect the boundaries and territory of the cells surrounding them. They will not invade a territory that is not their own. We think the neighboring cells inhibit cell growth through the physical contact of the surrounding cell membranes. Cancer cells

grown in tissue culture have a loss of contact inhibition. They have no regard for cell boundaries and grow on top of one another and on top of or between normal cells.

The rate of normal cell proliferation (from the time of cell birth to the time of cell death) differs in each body tissue. In some tissues, such as bone marrow, hair follicles, and epithelial lining of the gastrointestinal (GI) tract, the rate of cell proliferation is rapid. In other tissues, such as myocardium and cartilage, cell proliferation does not occur or is slow.

Cancer cells proliferate at the same rate as the normal cells of the tissue from which they arise. However, cancer cells respond differently from normal cells to the intracellular signals that regulate cell proliferation and death. The result is that the proliferation of the cancer cells is indiscriminate and continuous. Sometimes they produce more than 2 cells at the time of mitosis. In this way, there is continuous growth of a tumor mass: 1 × 2 × 4 × 8 × 16 and so on. This is termed the *pyramid effect.* The time needed for a tumor mass to double in size is known as its *doubling time.*

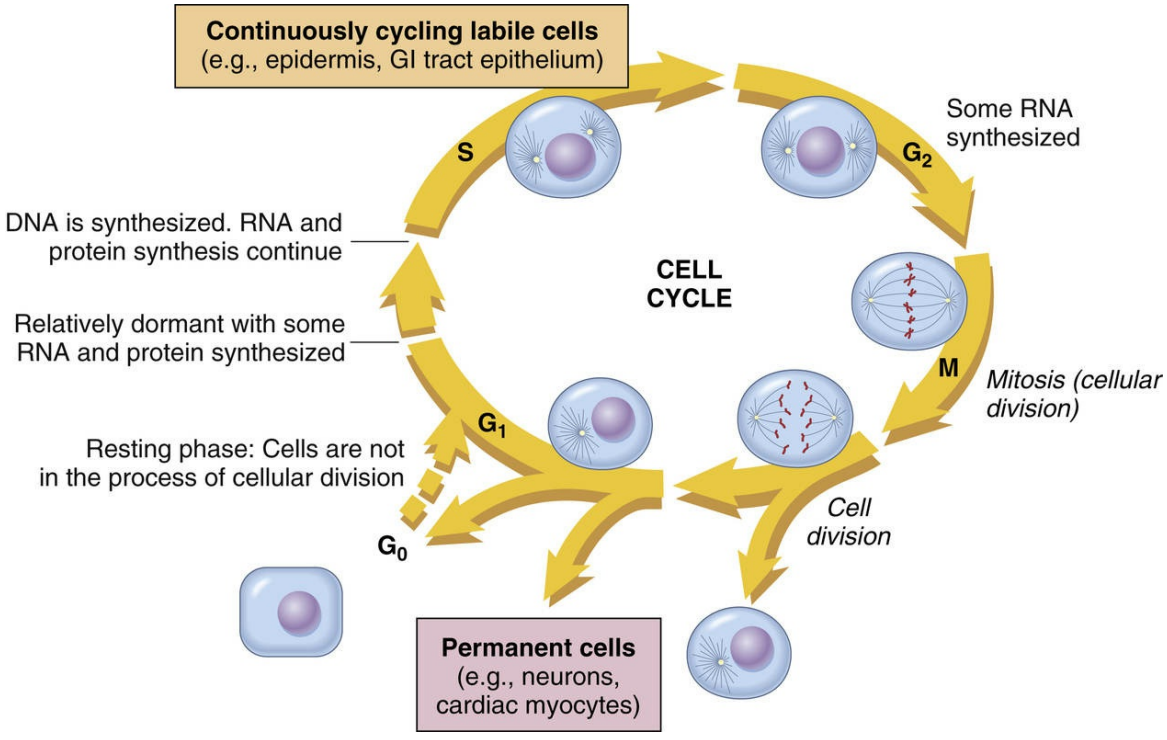

FIG. 15.1 Cell life cycle and metabolic activity. Generation time is the period from *M* phase to *M* phase. Cells not in the cycle but capable of division are in the resting phase *(G_0).*

Adapted from Kumar V, Abbas AK, Fausto N, et al: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.

Defect in Cell Differentiation

Cell differentiation is normally an orderly process that progresses from a state of immaturity to a state of maturity. Because all body cells are derived from the fertilized ova, all cells have the potential to perform all body functions. As cells differentiate, this potential is repressed, and the mature cell can perform only specific functions. With cell differentiation, there is a stable and orderly phasing out of cell potential. Under normal conditions, the differentiated cell is stable and will not *dedifferentiate,* or return to its previous undifferentiated state.

Genetic Link

Cancer involves the malfunction of genes that control differentiation and proliferation. Two types of normal genes that can be affected by mutation are *protooncogenes* and *tumor suppressor genes*.
Protooncogenes are normal cell genes that are important regulators of normal cell processes. Protooncogenes promote growth. Tumor suppressor genes suppress growth. Mutations that change the expression of protooncogenes can cause them to function as **oncogenes** (tumor-inducing genes).

The protooncogene has been described as the genetic lock that keeps the cell in its mature functioning state. When this lock is "unlocked," as may occur through exposure to *carcinogens* (agents that cause cancer) or oncogenic viruses, genetic alterations and mutations occur. The abilities and properties that the cell had in fetal development are again expressed. Oncogenes can change a normal cell to a malignant one. This cell regains a fetal appearance and

function. For example, some cancer cells make new proteins characteristic of the embryonic and fetal periods of life. These proteins, found on the cell membrane, include carcinoembryonic antigen (CEA) and α-fetoprotein (AFP). They can be found in the blood by laboratory studies. Other cancer cells, such as small cell cancer of the lung, make hormones that are usually made by cells arising from the same embryonic cells as the tumor cells. See Complications of Cancer later in this chapter on pp. 260-263.

Tumor suppressor genes regulate cell growth. They prevent cells from going through the cell cycle. Mutations can change tumor suppressor genes and make them inactive. This results in a loss of their tumor-suppressing action. Examples of tumor suppressor genes are *BRCA1* and *BRCA2.* Alterations in these genes increase a person's risk for breast and ovarian cancer. Another tumor suppressor gene is the *APC* gene. Mutations in this gene increase a person's risk for familial adenomatous polyposis, a precursor for colorectal cancer (see Chapter 42). Mutations in the *p53* tumor suppressor gene have been found in many cancers, including bladder, breast, colorectal, esophageal, liver, lung, and ovarian cancers.

Development of Cancer

The following is a theoretical model of cancer development. The cause and development of each type of cancer are likely to be multifactorial. A common misbelief is that cancer development is a rapid, haphazard event. However, cancer is usually an orderly process that occurs over time. It has 3 stages: initiation, promotion, and progression (Fig. 15.2).

Initiation

Cancer cells arise from normal cells because of changes in genes. The first stage, *initiation*, involves a mutation in the cell's genetic structure. A *mutation* is any change in the usual DNA sequence.

Genetic Link

Gene mutations can occur in 2 ways: *inherited* from a parent (passed from one generation to the next) or *acquired* during a person's lifetime. (Mutations are discussed in Chapter 12.)

The genetic predisposition to cancer is thought to play a role in about 5 to 10% of all cancers. These genetic alterations lead to a high risk for developing a specific type of cancer. However, most cancers do not result from inherited genes. They are acquired from damage to genes occurring during one's lifetime. An acquired mutation is passed on to all cells that develop from that single cell. The damaged cell may die or repair itself. However, if cell death or repair does not occur before cell division, the cell will replicate into daughter cells, each with the same genetic alteration.

Evidence of regional spread and metastasis

FIG. 15.2 Process of cancer development.

Carcinogens

Many **carcinogens** (cancer-causing agents capable of producing cell alterations) are detoxified by protective enzymes and harmlessly excreted. If this protective mechanism fails, carcinogens can enter the cell's nucleus and alter deoxyribonucleic acid (DNA). Carcinogens may be chemical, radiation, or viral.

Chemical carcinogens

Chemicals were identified as cancer-causing agents in the latter part of the 18th century. Percival Pott noted that chimney sweeps had a higher incidence of cancer of the scrotum associated with exposure to soot residue in chimneys. As the years passed, we have found many chemicals that are carcinogens (e.g., benzene, arsenic, formaldehyde). People exposed to these chemicals over time have a greater incidence of certain cancers than others. The long latency period from the time of exposure to the development of cancer makes it hard to identify cancer-causing chemicals.

Radiation

Radiation can cause cancer in almost any body tissue. When cells are exposed to a source of radiation, damage occurs to DNA. Certain cancers are correlated with radiation as a carcinogenic agent:

- The incidence of leukemia, lymphoma, and thyroid cancer increased in the general population of Hiroshima and Nagasaki after the atomic bomb explosions.
- A higher incidence of bone cancer occurs in people exposed to radiation in certain occupations, such as radiologists, radiation chemists, and uranium miners.

Ultraviolet (UV) radiation has long been associated with melanoma and squamous and basal cell skin cancers. Skin cancer is the most

common type of cancer among whites in the United States. Sunlight exposure is the main source of UV exposure, giving off UVA and UVB rays. UV radiation from tanning beds also causes skin cancer.[4]

Viral carcinogens

Certain DNA and ribonucleic acid (RNA) viruses, termed *oncogenic,* can alter the cells they infect and induce malignant transformation. These viruses have been identified as causative agents of cancer in animals and humans. Burkitt's lymphoma is associated with Epstein-Barr virus (EBV).[5] People with acquired immunodeficiency syndrome (AIDS), which is caused by human immunodeficiency virus (HIV), have a high incidence of Kaposi sarcoma (see Chapter 14). Other viruses linked to cancer development include hepatitis B virus, which is associated with hepatocellular cancer, and human papillomavirus (HPV). HPV is thought to cause lesions that progress to squamous cell cancers, such as cervical, anal, and head and neck cancers.

Promotion

A single alteration of the genetic structure of the cell is not enough to cause cancer. However, the odds of cancer development are increased with the presence of promoting agents. *Promotion,* the second stage in cancer development, is characterized by the reversible proliferation of the altered cells. An increase in the altered cell population further increases the likelihood of more mutations.

An important distinction between initiation and promotion is that the activity of promoters is reversible. This is a key concept in cancer prevention. Promoting factors include agents such as dietary fat, obesity, cigarette smoking, and alcohol use. Changing a person's lifestyle to modify these risk factors can reduce the chance of cancer development. Around one third of cancer-related deaths in the United States are related to tobacco use, unhealthy diet, physical inactivity, and obesity.[1]

Several promoting agents have activity against specific types of body tissues. So, these agents tend to promote specific kinds of cancer. For example, cigarette smoke is a promoting agent in lung cancer. In

conjunction with alcohol use, it promotes esophageal and bladder cancers.

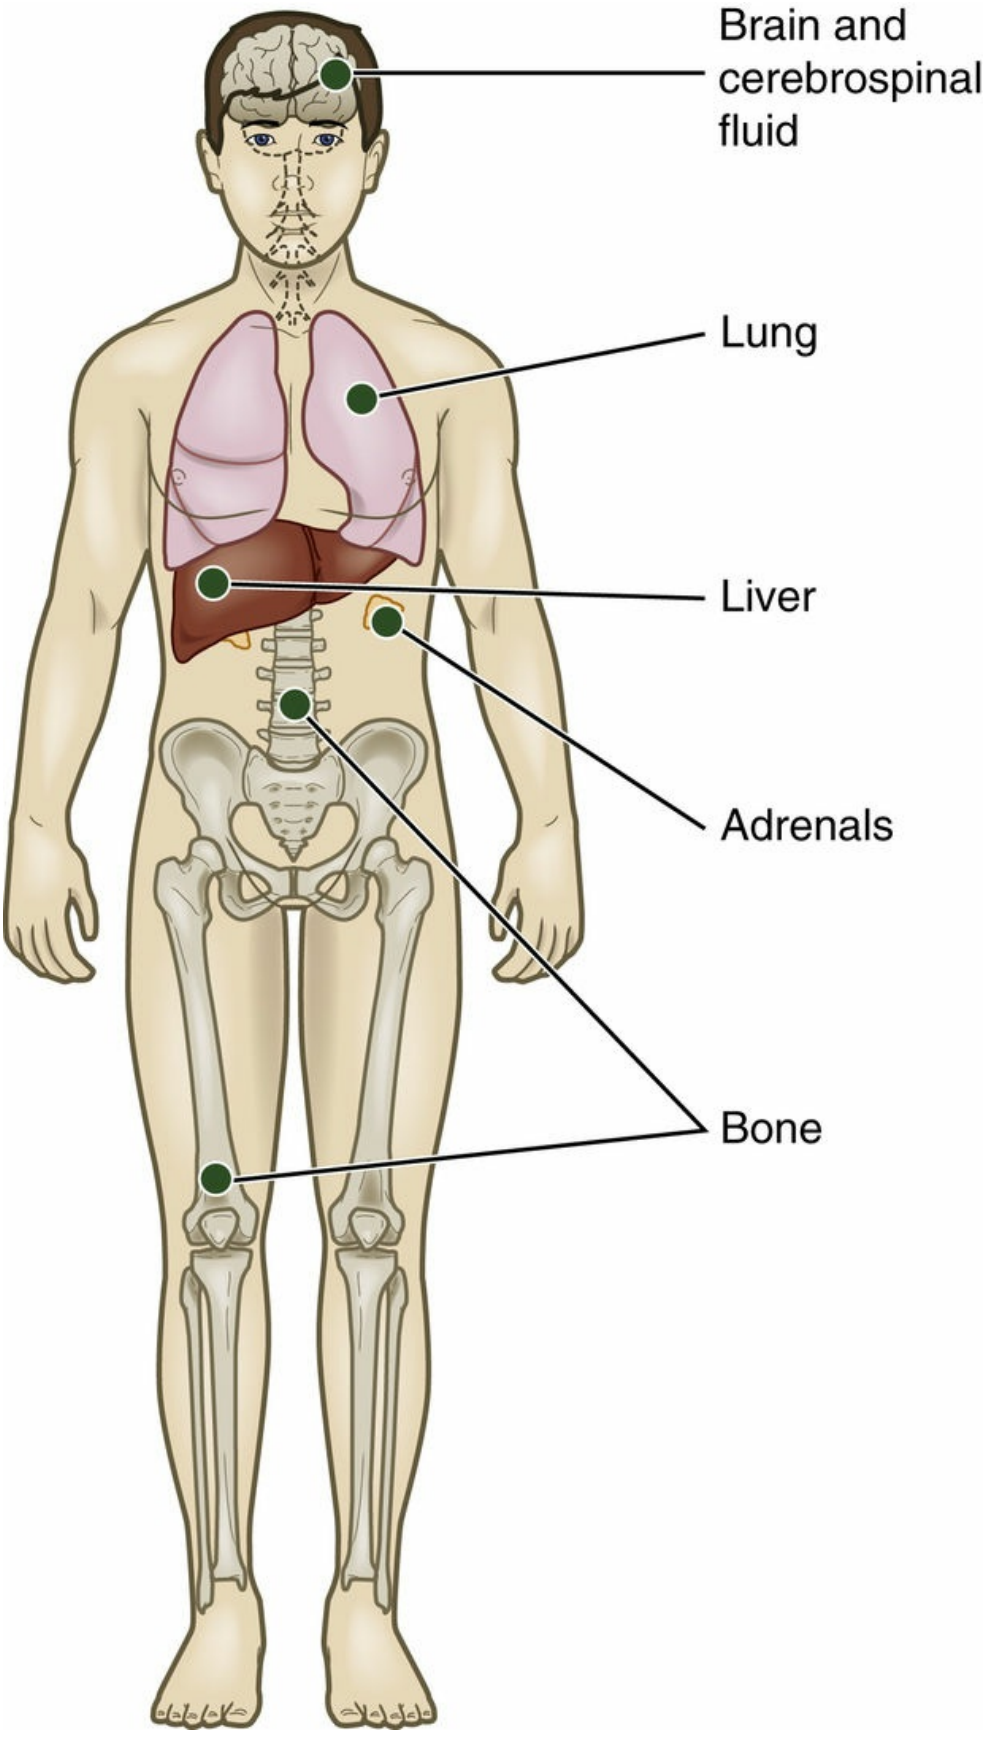
Some carcinogens, termed *complete carcinogens*, are capable of both initiating and promoting cancer development. Cigarette smoke is an example of a complete carcinogen.

A period of time elapses between the first genetic alteration and the actual clinical evidence of cancer. This period, called the *latent* period, includes both the initiation and promotion stages in the natural history of cancer. The variation in the length of time that elapses before the cancer becomes clinically evident is related to the mitotic rate of the tissue of origin and environmental factors. In most cancers, this process is years or even decades in length.

For the disease process to become clinically evident, the cells must reach a critical mass. A tumor that is 1.0 cm (0.4 inch) (the size usually detectable by palpation) has 1 billion cancer cells. A 0.5-cm tumor is the smallest that can be detected by current diagnostic measures, such as MRI.

Progression

Progression is the last stage in the natural history of a cancer. This stage is characterized by increased growth rate of the tumor, increased invasiveness, and **metastasis** (spread of the cancer to a distant site). Certain cancers have an affinity for a particular tissue or organ as a site of metastasis (e.g., colon cancer often spreads to the liver). Other cancers (e.g., melanoma) are unpredictable in their pattern of metastasis. The most common sites of metastasis are lungs, liver, bone, brain, and adrenal glands (Fig. 15.3).



Brain and cerebrospinal fluid

Liver
Adrenals
Bone

FIG. 15.3 Main sites of metastasis.
Adapted from Stevens A, Lowe J: *Pathology: An illustrated review in colour,* ed 2, London, 2000, Mosby.

Metastasis is a multistep process. It begins with the rapid growth of the primary tumor (Fig. 15.4). As the tumor increases in size, developing its own blood supply is critical to its survival and growth. The process of the formation of blood vessels within the tumor itself is termed **tumor angiogenesis**. It is facilitated by tumor angiogenesis factors made by the cancer cells.

Tumor cells can detach from the primary tumor, invade the tissue surrounding the tumor, and penetrate the walls of lymph or vascular vessels for metastasis to a distant site. Once free from the primary tumor, metastatic tumor cells often travel to distant organ sites by hematogenous or lymphatic routes.

Hematogenous metastasis involves several steps beginning with primary tumor cells penetrating blood vessels. These tumor cells then enter the circulation, travel through the body, and adhere to and penetrate small blood vessels of distant organs. Most tumor cells do not survive this process and are destroyed by mechanical mechanisms (e.g., turbulence of blood flow) and cells of the immune system. The formation of a combination of tumor cells, platelets, and fibrin deposits may protect some tumor cells from destruction in blood vessels.

In the lymphatic system, tumor cells may be "trapped" in the first lymph node confronted and likely to spread from a tumor. This lymph node is referred to as the *sentinel lymph node.* A sentinel lymph node biopsy (SLNB) can be done to help determine the extent of the cancer. A positive SLNB means cancer is present in the sentinel node and may have spread to other lymph nodes and organs. Sometimes, the tumor cells may bypass local lymph nodes and travel to distant lymph nodes, a phenomenon termed *skip metastasis.*

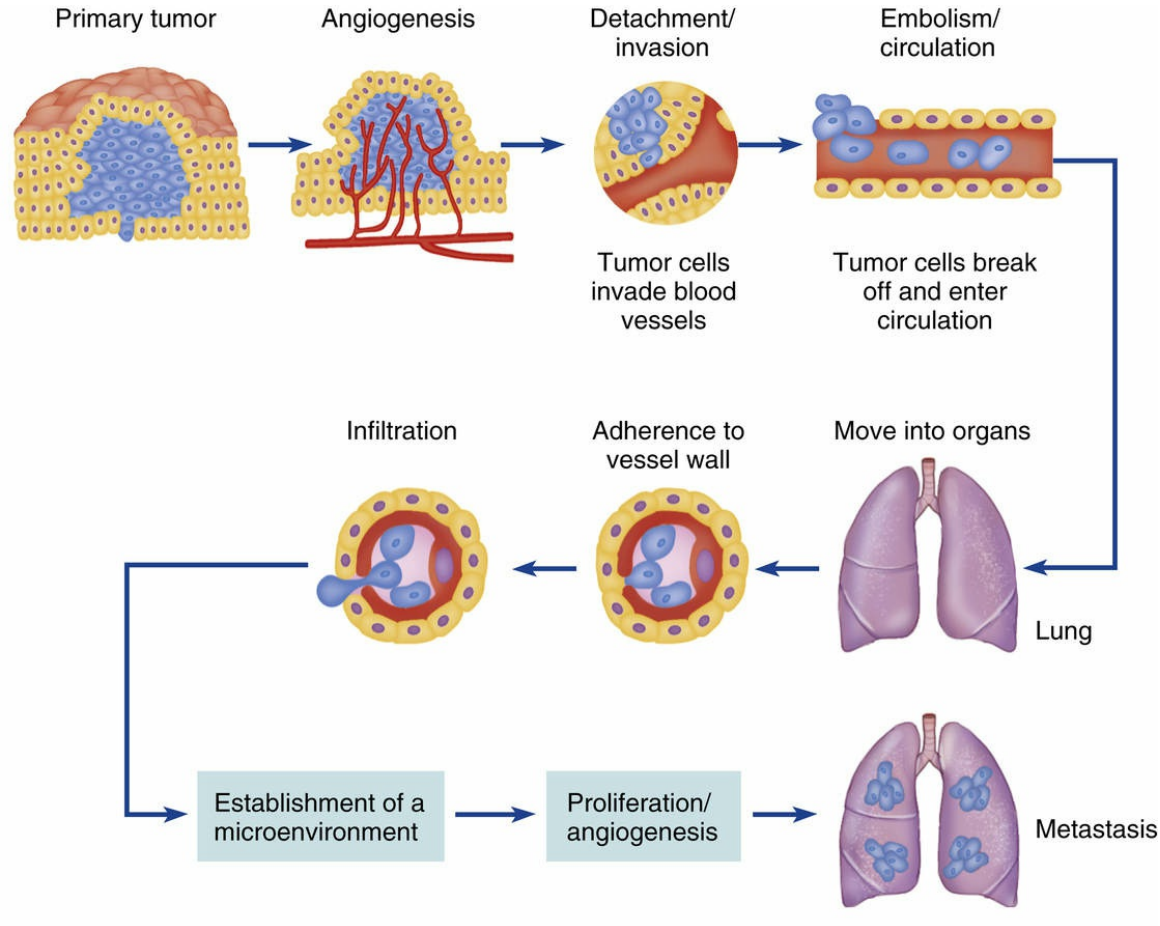

FIG. 15.4 The pathogenesis of cancer metastasis. To produce metastases, tumor cells must detach from the primary tumor and enter the circulation, survive in the circulation to rest in the capillary bed, adhere to capillary basement membrane, gain entrance into the organ parenchyma, respond to growth factors, proliferate, induce angiogenesis, and evade host defenses.
Adapted from Fidler IT: The pathogenesis of cancer metastasis: The "seed and soil" hypothesis revisited, *Nat Rev Cancer* 3:453, 2003.

Tumor cells that survive the process of metastasis must create an environment in the distant organ site that promotes their growth and development. Growth and development are facilitated by the tumor cells' ability to evade cells of the immune system and produce a vascular supply within the metastatic site like that of the primary tumor site. Vascularization is critical to the supply of nutrients to the metastatic tumor and the removal of waste products.

Role of the Immune System

This section is limited to a discussion of the role of the immune system in the recognition and destruction of tumor cells. For a detailed discussion of immune system function, see Chapter 13.

The immune system has the potential to tell normal (self) cells from abnormal (nonself) cells. For example, cells of transplanted organs can be recognized by the immune system as *nonself* and thus elicit an immune response. This response can result in organ rejection. Similarly, cancer cells can be perceived as nonself. This can elicit an immune response, resulting in their rejection and destruction. However, unlike transplanted cells, cancer cells arise from normal human cells and, although they are mutated and thus different, the immune response that is mounted against cancer cells may be inadequate to effectively kill them.

Cancer cells may have altered cell-surface antigens because of malignant transformation. These antigens are termed *tumor-associated antigens (TAAs)* (Fig. 15.5). We think that the immune system responds to TAAs through a process termed **immunologic surveillance**. In this process, lymphocytes continuously check cell-surface antigens. They detect and destroy cells with abnormal or altered antigenic determinants. Under most circumstances, immune surveillance prevents transformed cells from developing into clinically detectable tumors.

Immune response to cancer cells involves cytotoxic T cells, natural killer (NK) cells, macrophages, and B cells. *Cytotoxic T cells* play a dominant role in resisting tumor growth. These cells can kill tumor cells. T cells are important in the production of cytokines (e.g., interleukin-2 [IL-2], γ-interferon), which stimulate T cells, NK cells, B cells, and macrophages.

Natural killer (NK) cells can directly lyse tumor cells spontaneously without any prior sensitization. γ-Interferon (made by T cells) and IL-2 (released from T cells) stimulate NK cells, resulting in increased cytotoxic activity.

Monocytes and *macrophages* have several important roles in tumor immunity. γ-Interferon can activate macrophages to become nonspecifically lytic for tumor cells. Macrophages secrete cytokines,

including IL-1, tumor necrosis factor (TNF), and colony-stimulating factors (CSFs). The release of IL-1, coupled with the presentation of the processed antigen, stimulates T-cell activation and production. α-Interferon augments the killing ability of NK cells. TNF causes hemorrhagic necrosis of tumors and exerts cytocidal or cytostatic actions against tumor cells. CSFs regulate the production of various blood cells in the bone marrow and stimulate the function of various WBCs.

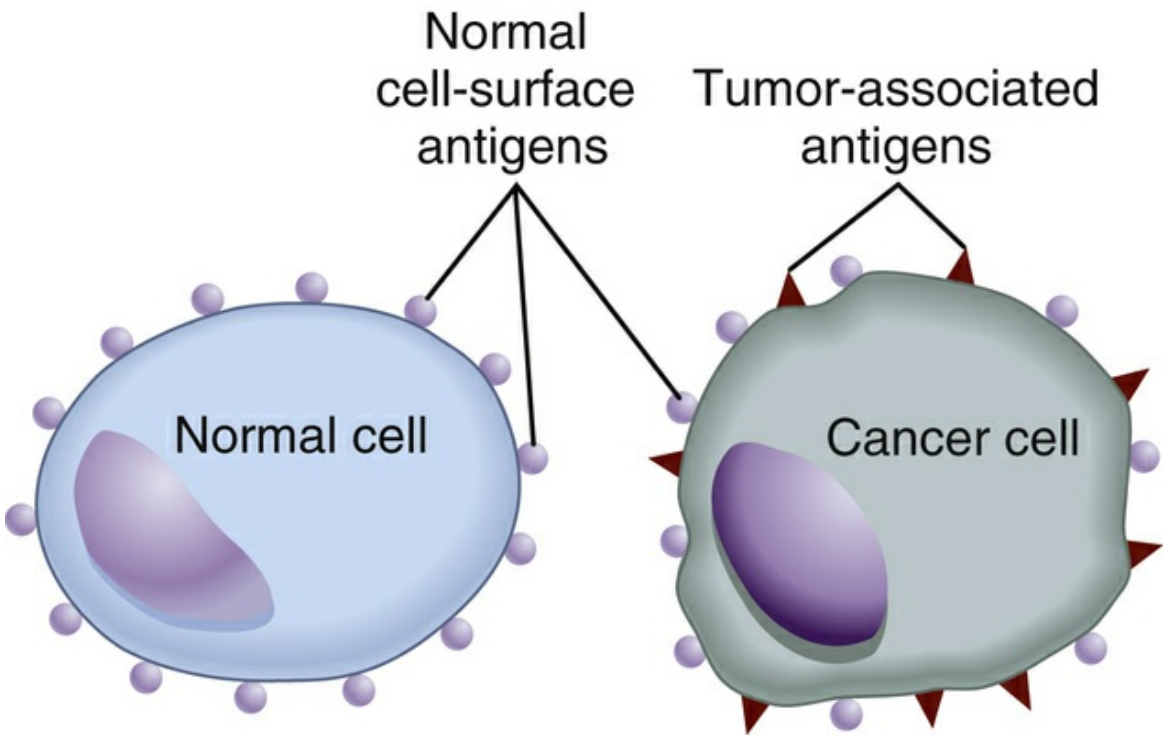

FIG. 15.5 Tumor-associated antigens appear on the cell surface of cancer cells.

B cells can make specific antibodies that bind to tumor cells. These antibodies are often detectable in the patient's serum and saliva.

Escape Mechanisms From Immunologic Surveillance

The process by which cancer cells evade the immune system is termed *immunologic escape*. Possible mechanisms by which cancer cells escape immunologic surveillance include (1) suppression of factors that

stimulate T cells to react to cancer cells; (2) weak surface antigens allowing cancer cells to "sneak through" immunologic surveillance; (3) development of tolerance of the immune system to some tumor antigens; (4) suppression of the immune response by products secreted by cancer cells; (5) induction of suppressor T cells by the tumor; and (6) blocking antibodies that bind TAAs, thus preventing their recognition by T cells (Fig. 15.6).

Oncofetal Antigens and Tumor Markers

Oncofetal antigens are a type of tumor antigen. They are found on the surfaces and the inside of cancer cells and fetal cells. These antigens are an expression of the shift of cancerous cells to a more immature metabolic pathway. This expression is usually associated with embryonic or fetal periods of life. The reappearance of fetal antigens in cancer is not well understood. We think it is the result of the cell regaining its embryonic capability to differentiate into many different cell types.

Examples of oncofetal antigens are CEA and AFP. CEA is found on the surfaces of cancer cells from the GI tract and normal cells from the fetal gut, liver, and pancreas. Normally, CEA disappears during the last 3 months of fetal life. CEA was originally isolated from colorectal cancer cells. However, high CEA levels can be found in nonmalignant conditions (e.g., cirrhosis of the liver, ulcerative colitis, heavy smoking).

Oncofetal antigens can be used as *tumor markers* that may be clinically useful to monitor the effect of therapy and indicate tumor recurrence. However, they are not 100% specific for tumor recurrence. Tumor markers are affected by various factors that must be accounted for when reviewing these results. For example, the persistence of high preoperative CEA titers after surgery means that the tumor is not completely removed. A rise in CEA levels after chemotherapy may mean recurrence or spread of the cancer. Or, it may be due to chronic lung disease and smoking.

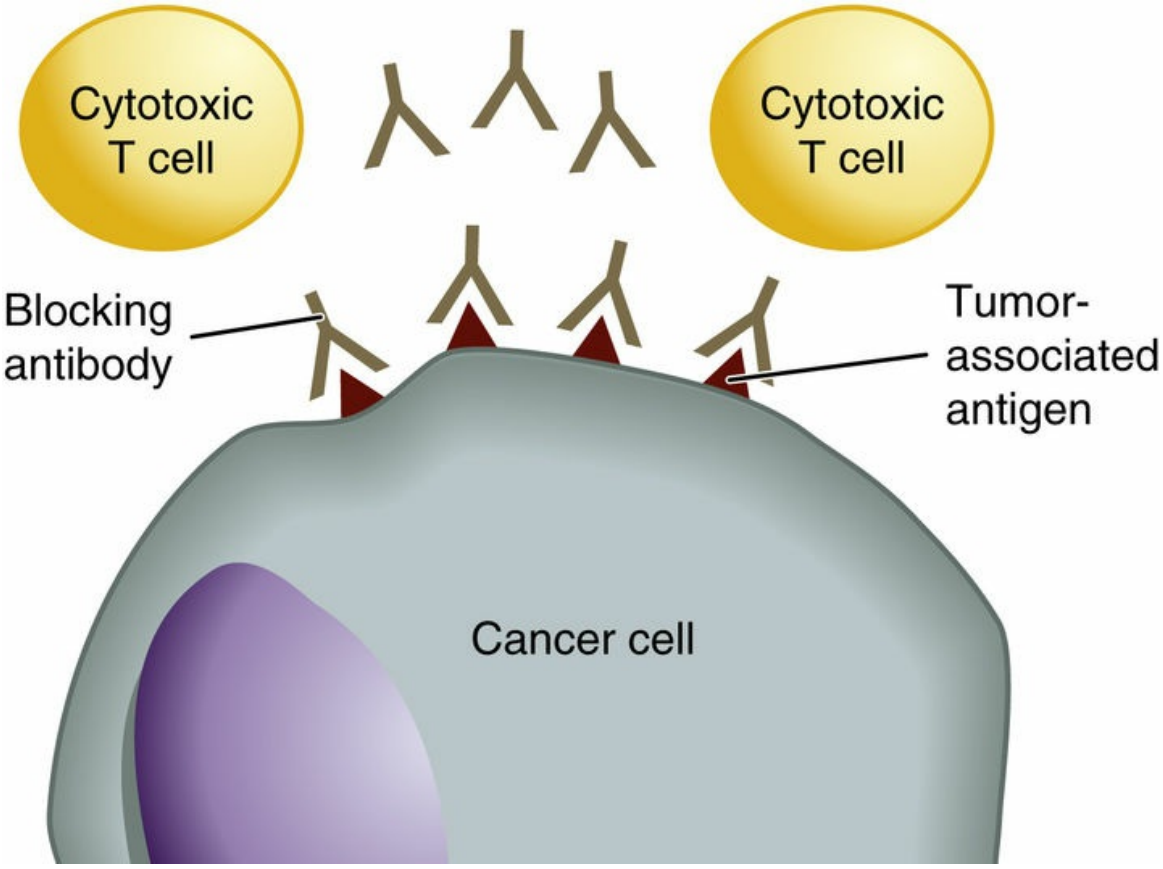

FIG. 15.6 Blocking antibodies prevent T cells from interacting with tumor-associated antigens and from destroying the cancer cell.

AFP is made by malignant liver cells and fetal liver cells. AFP has diagnostic value in primary liver cancer (hepatocellular cancer). It is also made when metastatic liver growth occurs. This makes AFP valuable in tumor detection and determination of tumor progression. AFP levels are also high in some cases of testicular cancer and viral hepatitis.

Other examples of oncofetal antigens are CA-125 (ovarian cancer), CA-19-9 (pancreatic and gallbladder cancer), prostate-specific antigen (PSA) (prostate cancer), and CA-15.3 and CA-27-29 (breast cancer). Molecular markers for specific tumors include kRAS (expression of oncogene in colon cancer), epidermal growth factor receptor (EGFR) often overexpressed in lung cancer, and human epidermal growth factor receptor-2 (HER-2) expression in breast cancer.

Benign Versus Malignant Neoplasms

Tumors can be classified as benign or malignant. In general, *benign neoplasms* are well differentiated. **Malignant neoplasms** range from well differentiated to undifferentiated. The ability of malignant tumor cells to invade and metastasize is the major difference between benign and malignant neoplasms. Other differences are outlined in Table 15.3.

Classification of Cancer

Tumors can be classified according to anatomic site, histology (grading), and extent of disease (staging). Tumor classification systems provide a standardized way to (1) communicate the status of the cancer to all members of the interprofessional care team, (2) assist in determining the most effective treatment plan, (3) evaluate the treatment plan, (4) predict prognosis, and (5) compare groups for statistical purposes.

Anatomic Site Classification

In the *anatomic classification* of tumors, the tumor is identified by the tissue of origin, anatomic site, and behavior of the tumor (e.g., benign or malignant) (Table 15.4). *Carcinomas* originate from embryonal *ectoderm* (skin and glands) and *endoderm* (mucous membrane linings of the respiratory tract, GI tract, and genitourinary [GU] tract). *Sarcomas* originate from embryonal *mesoderm* (connective tissue, muscle, bone, and fat). Lymphomas and leukemias originate from the hematopoietic system.

TABLE 15.3 Comparison of Benign and Malignant Neoplasms

Characteristic	Benign	Malignant
Encapsulated	Usually	Rarely
Differentiated	Normally	Poorly
Metastasis	Absent	Capable
Recurrence	Rare	Possible
Vascularity	Slight	Moderate to marked
Mode of growth	Expansive	Infiltrative and expansive
Cell characteristics	Fairly normal, like parent cells	Cells abnormal, become more unlike parent cells

Histologic Classification

In **histologic grading** of tumors, the appearance of cells and degree of differentiation are evaluated pathologically. For many tumor types, 4 grades are used to evaluate abnormal cells based on the degree to which the cells resemble the tissue of origin. Tumors that are poorly differentiated (undifferentiated) have a poorer prognosis than those that are closer in appearance to the normal tissue of origin (well differentiated):

Grade I: Cells differ slightly from normal cells (mild dysplasia) and are well differentiated (low grade).
Grade II: Cells are more abnormal (moderate dysplasia) and moderately differentiated (intermediate grade).
Grade III: Cells are very abnormal (severe dysplasia) and poorly differentiated (high grade).
Grade IV: Cells are immature, primitive *(anaplasia),* and undifferentiated; cell of origin is hard to determine (high grade).
Grade X: Grade cannot be assessed.

Extent of Disease Classification

Classifying the extent and spread of disease is termed **staging**. Staging is based on the anatomic extent of disease. Although there are

similarities in the staging of various cancers, there are many differences for specific types of cancer.

Clinical Staging

The clinical staging classification system determines the anatomic extent of the malignant disease process by stages:

Stage 0: Cancer in situ
Stage I: Tumor limited to the tissue of origin; localized tumor growth
Stage II: Limited local spread
Stage III: Extensive local and regional spread
Stage IV: Metastasis

Clinical staging has been used as a basis for staging a variety of tumor types, including colorectal cancer (see Fig. 42.7) and Hodgkin's lymphoma (see Fig. 30.15). Other cancers (e.g., leukemia) do not use this staging approach.

TABLE 15.4 Anatomic Classification of Tumors

Site	Benign	Malignant
Epithelial Tissue Tumors*	**-oma**	**-carcinoma**
Surface epithelium	Papilloma	Carcinoma
Glandular epithelium	Adenoma	Adenocarcinoma
Connective Tissue Tumors†	**-oma**	**-sarcoma**
Fibrous tissue	Fibroma	Fibrosarcoma
Cartilage	Chondroma	Chondrosarcoma
Striated muscle	Rhabdomyoma	Rhabdomyosarcoma
Bone	Osteoma	Osteosarcoma
Nervous Tissue Tumors	**-oma**	**-oma**
Meninges	Meningioma	Meningeal sarcoma
Nerve cells	Ganglioneuroma	Neuroblastoma
Hematopoietic Tissue Tumors		
Lymphoid tissue	—	Hodgkin's lymphoma, non-Hodgkin's lymphoma
Plasma cells	—	Multiple myeloma
Bone marrow	—	Lymphocytic and myelogenous leukemia

* Body surfaces, lining of body cavities, and glandular structures.

† Supporting tissue, fibrotic tissue, and blood vessels.

TNM Classification System

The *TNM classification system* (Table 15.5) is used to determine the anatomic extent of the disease involvement according to 3 parameters: tumor size and invasiveness (T), presence or absence of regional spread to the lymph nodes (N), and metastasis to distant organ sites (M). Examples of the TNM classification system can be found in Tables 27.17 and 51.6. TNM staging cannot be applied to all cancers. For example, leukemias are not solid tumors and cannot be staged using these guidelines.

The latest cancer staging guidelines for some cancers add nonanatomic factors when making the final determination of stage. Staging is still based on the TNM classification, but it now adds grade and hormone receptor expression. When appropriate, it also includes genomic profile results (e.g., Oncotype DX, Mammaprint). This information should allow a more accurate determination of prognosis and better guide therapy.

Carcinoma in situ (CIS) refers to a cancer whose cells are localized and show no tendency to invade or metastasize to other tissues. CIS has its own designation in the system (T_{is}) because it has all the histologic characteristics of cancer except invasion—a key feature of the TNM staging system.

Staging of the disease can be done initially and at several points. Clinical staging is done at the completion of the diagnostic workup to guide treatment selection. Examples of diagnostic studies that may be done to assess for extent of disease include bone and liver scans, ultrasonography, and CT, MRI, and positron emission tomography (PET) scans.

Surgical staging refers to the extent of the disease as determined by surgical excision, exploration, and/or lymph node sampling. For example, a laparotomy and splenectomy may be done to stage Hodgkin's lymphoma. During a staging laparotomy, lymph node

biopsies may be done, and margins of any masses may be marked with metal clips for use during radiation therapy. Exploratory surgical staging is being used less often as noninvasive diagnostic technology becomes more sophisticated.

After the extent of the disease is determined, the stage classification is set. The original description of the extent of the tumor stays part of the record. If more treatment is needed, or if treatment fails, retreatment staging is done to determine the extent of the disease before retreatment. "Restaging" classification (rTNM) is differentiated from the stage at diagnosis, since the clinical significance may be different. Staging can never decrease, but the stage can increase. For example, a patient may initially be a stage 3. After treatment failure, the tumor metastasizes, and now the patient is a stage 4.

TABLE 15.5 TNM Classification System

Primary Tumor (T)	
T_0	No evidence of primary tumor
T_{is}	Carcinoma in situ
T_{1-4}	Ascending degrees of increase in tumor size and involvement
T_x	Tumor cannot be measured or found
Regional Lymph Nodes (N)	
N_0	No evidence of disease in lymph nodes
N_{1-4}	Ascending degrees of nodal involvement
N_x	Regional lymph nodes unable to be assessed clinically
Distant Metastases (M)	
M_0	No evidence of distant metastases
M_{1-4}	Ascending degrees of metastatic involvement, including distant nodes
M_x	Cannot be determined

In addition to tumor classification systems, other rating scales can be used to describe and document the status of patients with cancer at the time of diagnosis, treatment, and retreatment and at each follow-up examination. For example, the Karnofsky Performance Scale and Katz Index of Independence in Activities of Daily Living describe patient's functional performance.

Prevention and Early Detection of Cancer

We can reduce the incidence of cancer through a stronger emphasis on prevention through promoting healthy lifestyles. As a nurse, you have an essential role in the prevention and early detection of cancer. Reducing risk factors reduces the incidence of cancer. For example, rates of smoking-related cancers (e.g., lung and head and neck cancers) have declined with a reduction in smoking rates.[1]

Early detection and prompt treatment are responsible for increased survival rates in patients with cancer. Colonoscopy is important in reducing colon cancer mortality both by early detection of colon cancers and prevention (e.g., excision of adenomatous polyps).

The goals of public education are to (1) motivate people to recognize and change behaviors that may negatively affect health and (2) encourage awareness of and participation in health-promoting behaviors. When you teach about cancer, try to minimize the fear that surrounds the diagnosis.

Teach people to be familiar with their bodies. Review how to perform self-examinations and the 7 warning signs of cancer (Table 15.6). Encourage them to seek immediate medical care if they notice a change in what is normal for them or if cancer is suspected. Following recommended cancer screening guidelines for breast, colon, cervical, and prostate cancer from the American Cancer Society (ACS) is important.[6]

Promoting Population Health

Prevention and Early Detection of Cancer

Teach patients and the public about cancer prevention and early detection, including:

- Limit alcohol use.

- Get regular physical activity (e.g., 30 minutes or more of moderate physical activity 5 times weekly).
- Maintain a normal body weight.
- Have regular physical examinations.
- Obtain regular colorectal screenings.
- Avoid cigarette smoking and other tobacco use.
- Get regular mammography screening and Pap tests.
- Be familiar with your own family history and risk factors for cancer.
- Obtain adequate, consistent periods of rest (at least 6 to 8 hours per night).
- Use sunscreen with a sun protection factor of 15 or higher. Avoid the use of tanning beds.
- Eliminate, reduce, or change the perception of stressors and enhance the ability to effectively cope with stress (see Chapter 6).
- Eat a balanced diet that includes vegetables and fresh fruits, whole grains, and adequate amounts of fiber. Reduce dietary fat and preservatives, including smoked and salt-cured meats with high nitrite concentrations.

Diagnosis of Cancer

When a patient has a possible diagnosis of cancer, it is a stressful time for the patient and caregivers. Patients may undergo several days to weeks of diagnostic studies. During this time, fear of the unknown may be more stressful than the actual diagnosis of cancer. Patients may be overwhelmed or confused by the need for multiple diagnostic studies and consultations. Help coordinate care between multiple specialists. Explain the purpose of required tests and any special preparation needed for them.

Some facilities have comprehensive oncology teams and services that are all housed in the same building to help coordinate care among the cancer specialists. These centers combine appointments to make the experience convenient and comfortable for patients and their

caregivers.

While patients are waiting for the results of diagnostic studies, be available to actively listen to their concerns. Their anxiety may arise from myths and misconceptions about cancer (e.g., cancer is a "death sentence," cancer treatment is worse than the illness). Correcting those misconceptions can help to minimize their anxiety.

Learn to recognize your own discomfort during difficult conversations. Avoid communication patterns that may hinder exploration of feelings and meaning. These include providing false reassurances (e.g., "It's probably nothing"), redirecting the discussion (e.g., "Let's discuss that later"), generalizing (e.g., "Everyone feels this way"), and using overly technical language. These self-protective strategies deny patients the opportunity to share the meaning of their experience. They can jeopardize your ability to build a trusting relationship with your patients.

During this time of high anxiety, the patient may need repeated explanations of the diagnostic workup. Include as much information as needed by the patient and caregivers. Give clear, understandable explanations and reinforce them as needed. Written information is helpful to reinforce verbal information.

A diagnostic plan for the person suspected of having cancer includes the health history (including a history of present illness), identifying risk factors, the physical examination, and specific diagnostic studies. For many people, cancer is diagnosed after the findings of an abnormal screening test (e.g., mass on mammogram). For others, they are alerted to the presence of cancer by a presenting symptom or cluster of symptoms (e.g., cough and hemoptysis, anorexia and weight loss).

Concentrate on risk factors for cancer. Obtain information about any family and personal history of cancer and any exposure to or use of known carcinogens (e.g., cigarette smoking, occupational pollutants or chemicals, radiation exposure). Review the medical history for diseases characterized by chronic inflammation or immunosuppression (e.g., ulcerative colitis) and treatments (e.g., hormone therapy, previous anticancer therapies). Assess factors that

may call for additional supportive care during therapy, including alcohol or drug use, living situation, social support, and coping strategies for perceived stressors.

TABLE 15.6 7 Warning Signs of Cancer

Change in bowel or bladder habits **A** sore that does not heal **U**nusual bleeding or discharge from any body orifice **T**hickening or a lump in the breast or elsewhere **I**ndigestion or difficulty in swallowing **O**bvious change in a wart or mole **N**agging cough or hoarseness

Diagnostic studies depend on the suspected primary or metastatic site(s) of the cancer. (Specific procedures as they relate to each body system are discussed in the respective assessment chapters.) Examples of diagnostic studies include:

- Cytology studies (e.g., Pap test, bronchial washings)
- Tissue biopsy
- Chest x-ray
- Complete blood count (CBC), chemistry profile
- Liver function studies (e.g., aspartate aminotransferase [AST])
- Endoscopic examination: upper GI, sigmoidoscopy, or colonoscopy (including guaiac test for occult blood)
- Radiographic studies (e.g., mammography, ultrasound, CT scan, MRI)
- Radioisotope scans (e.g., bone, lung, liver, brain)
- PET scan (Fig. 15.7)
- Tumor markers (e.g., CEA, AFP, PSA, CA-125)
- Genetic markers (e.g., *BRCA1, BRCA2*)

- Molecular receptor status (e.g., estrogen and progesterone receptors)
- Bone marrow examination (if a hematolymphoid malignancy is suspected or to document metastatic disease)

Biopsy

A *biopsy* is the removal of a tissue sample for pathologic analysis. Various methods are used to obtain a biopsy depending on the location and size of the suspected tumor. *Percutaneous biopsy* is often done for tissue that can be safely reached through the skin. *Endoscopic biopsy* may be used for lung or other intraluminal lesions (esophageal, colon, bladder). When a tumor is not easily accessible, a *surgical procedure* (laparotomy, thoracotomy, craniotomy) is often needed to obtain a piece of the tumor tissue. Many radiographic techniques may be used in conjunction with the biopsy procedure (e.g., CT, MRI, ultrasound-guided biopsy, stereotactic biopsy) to improve tissue localization.

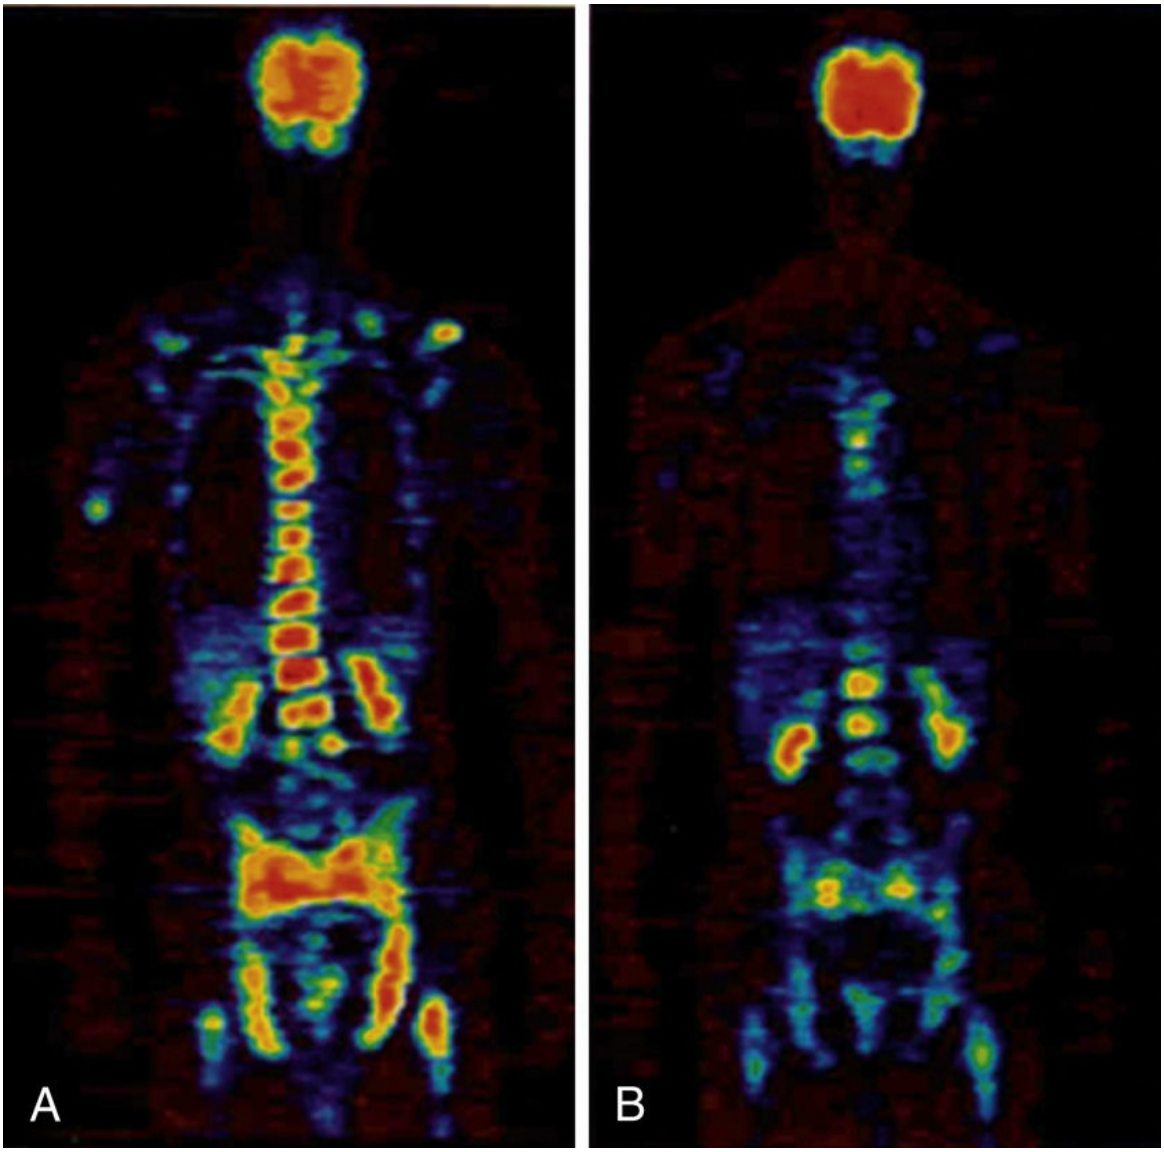

FIG. 15.7 PET scan before treatment **(A)** showing metastasis throughout the body. PET scan after treatment **(B)** shows the effects of therapy. More radioactive material accumulates in areas that have higher levels of activity. This often corresponds to areas of disease and shows up as brighter spots on the PET scan.
From Shimizu N, Masuda H, Yamanaka H, et al: Fluorodeoxyglucose PET scan of prostate cancer bone metastases with flare reaction after endocrine therapy, *J Urol* 151:609, 1999.

Various types and sizes of biopsy needles are available and chosen according to the type of tissue to be sampled. *Fine-needle aspiration* (FNA) may be done with a small-gauge aspiration needle that provides cells from the mass for cytologic examination. *Large-core biopsy* cutting needles deliver an actual piece of tissue (core) that can

be analyzed. An advantage is that it preserves the histologic architecture of the tissue specimen. *Excisional biopsy* involves the surgical removal of the entire lesion, lymph node, nodule, or mass. So, it is therapeutic as well as diagnostic. If an excisional biopsy is not feasible, an *incisional biopsy* (partial excision) may be done with a scalpel or dermal punch.

Pathologic evaluation of a tissue sample is the only definitive way to diagnose cancer. The pathologist examines the tissue to determine (1) whether it is benign or malignant, (2) the anatomic tissue from which the tumor arises *(histology),* and (3) the degree of cell differentiation *(histologic grade).* Other information that can be obtained includes the extent of malignant involvement (size of tumor and depth), evidence of invasiveness (extracapsular, lymphatic), adequacy of surgical excision (positive or negative surgical margin status), and nuclear grade (mitotic rate). Special staining techniques may give insight into responsiveness of the tumor to treatment or disease behavior (receptor status, tumor markers).

Interprofessional Care

Treatment Goals

The goals of cancer treatment are cure, control, and palliation (Fig. 15.8). When caring for the patient with cancer, knowing the treatment goals will help you appropriately communicate with, teach, and support the patient. The main factors that determine what therapy is used are the tumor histology and staging outcomes. Other crucial factors are the patient's physiologic status (e.g., presence of co-morbid illnesses), psychologic status, and personal desires (e.g., active treatment versus palliation).

These factors influence (1) the modalities chosen for treatment (e.g., surgery, radiation therapy, chemotherapy, immunotherapy, targeted therapy, hormone therapy), (2) how therapies are sequenced, and (3) the length of time the treatment is prescribed. Each type of therapy can be used alone or in any combination during initial treatment, as

maintenance therapy, and in retreatment if the disease does not respond or recurs after remission.

For many cancers, 2 or more of the treatment modalities (known as *multimodality therapy* or *combined modality therapy*) are used to achieve the goal of cure or control for a long time. Multimodality therapy has the benefit of being more effective (because it takes advantage of more than one mechanism of action), but often at the expense of greater toxicity.

Cure

When *cure* is the goal, treatment is expected to have the greatest chance of eradicating the cancer. Curative cancer therapy differs according to the cancer being treated. It may involve local therapies (e.g., surgery or radiation) alone or in combination, with or without periods of adjunctive systemic therapy (e.g., chemotherapy).

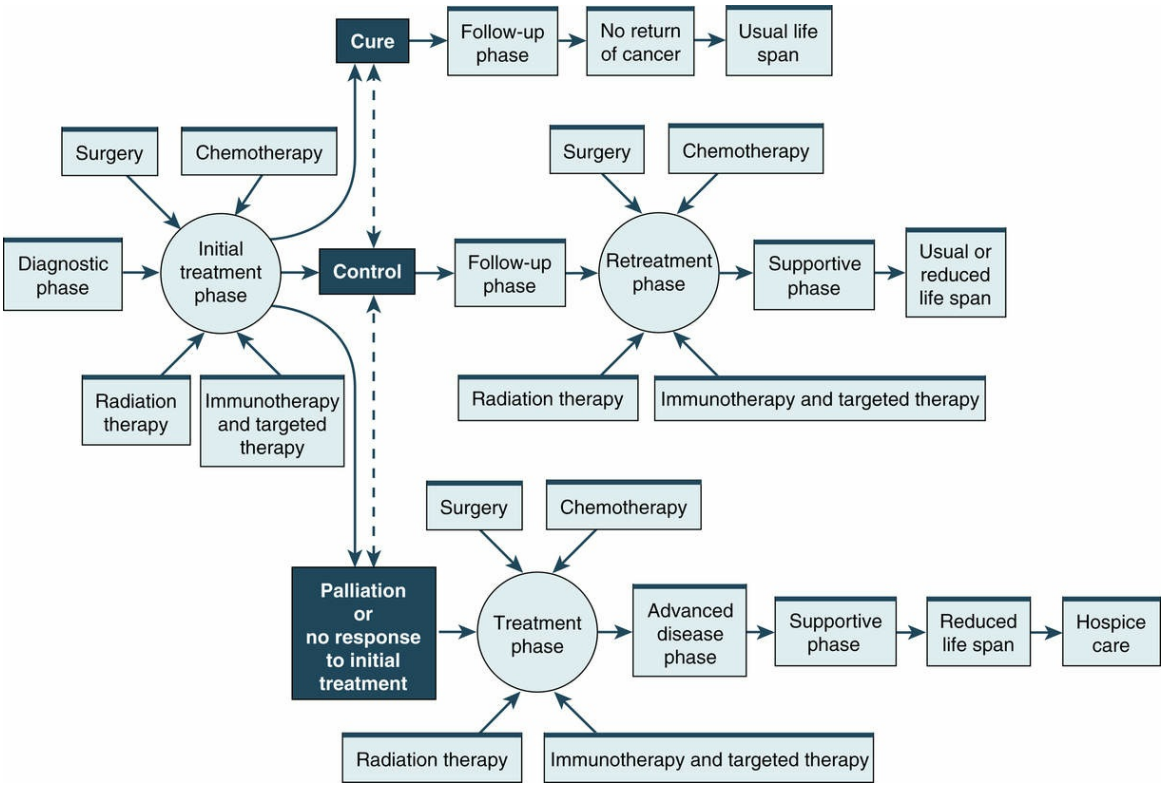

FIG. 15.8 Goals of cancer treatment.

For example, basal cell skin cancer is usually cured by surgical removal of the lesion and several weeks of radiation therapy. In the treatment plan for acute promyelocytic leukemia (which has curative potential), several chemotherapy drugs are given on a scheduled basis over many months to several years. Testicular cancer can be cured with a combination of surgery, chemotherapy, and radiation.

There is no benchmark that ensures "cure" for most cancers. In general, the risk for recurrent disease is highest after treatment completion. It gradually decreases the longer the patient is disease free after treatment. Cancers with a higher mitotic rate (e.g., testicular cancer) are more likely to recur than cancers with slower mitotic rates (e.g., postmenopausal breast cancer). So, the timeframe to consider a person "cured" may differ according to the tumor and its characteristics.

Control

Control is the goal of treatment for cancers that cannot be completely eradicated but are responsive to anticancer therapies. As with other chronic illnesses (e.g., diabetes, heart failure), cancer can be controlled for long periods with therapy. Examples include multiple myeloma and chronic lymphocytic leukemia (see Chapter 30). Patients may undergo an initial course of treatment followed by maintenance therapy for as long as the disease is responding. Patients are monitored closely for early signs and symptoms of disease recurrence or progression and the cumulative effects of therapy. Evidence of tumor resistance (e.g., disease progression) may call for changing to a different therapy.

Palliation

Palliation is the goal of treatment when the goals are the relief or control of symptoms and maintaining a satisfactory quality of life. Palliative care and treatment are not mutually exclusive and can take place concurrently. An example of treatment in which palliation is the goal includes using radiation therapy to reduce tumor size and relieve subsequent symptoms, like the pain of bone metastasis.

Personalized Cancer Medicine

Personalized medicine is an emerging trend in cancer treatment. It involves using the patient's genetic information to guide decisions about prevention, diagnosis, and treatment of cancer. Many diagnostic studies (tumor markers, genetic markers, molecular receptor status) are useful in determining treatment options.

Before personalized medicine, most patients with a specific type and stage of cancer received the same treatment. However, some treatments worked well for some patients and not as well for others. With increasing research, we have found that genetic differences in people and their tumors explain many of these different responses to treatment. By performing genetic tests and analysis, treatments can now be personalized.[7]

Next-generation sequencing, also known as massive parallel sequencing, can sequence millions of DNA fragments. This technology can determine if a patient's cancer is caused by a hereditary cancer syndrome or if it is sporadic. Results guide which specific drugs target a patient's mutation and help identify clinical trials specific to the genetic mutation.[8]

Targeted therapy (Table 15.13) targets a cancer's specific genes or proteins that contribute to cancer growth and survival. Treatment with a targeted therapy depends on assessing whether the tumor has the specific target. This is usually done by testing a sample of the tumor obtained through a biopsy.

Pharmacogenomics and *pharmacogenetics* is the study of genomic variation associated with drug responses.[9] Examples of how the results of genetic testing can be applied to the use of cancer drugs are shown in Table 12.5. For example, vemurafenib (Zelboraf) is used to treat patients with metastatic melanoma. However, it is indicated only for the treatment of patients with melanoma whose tumors express a gene mutation called *BRAF V600E.*

Despite the promises of personalized cancer treatments, not all types of cancer have personalized treatment options. Genetic testing may be costly and time consuming. Many insurance plans do not

cover the costs of these tests. Some personalized treatments, such as targeted treatments, can be expensive.[7]

Surgical Therapy

Surgery is the oldest form of cancer treatment. The treatment of choice for many years was to remove the cancer and as much of the surrounding normal tissue as possible. What this approach did not fully consider was the ability of cancer cells to travel from the original tumor site to other locations, making surgical cure possible only when the tumor was localized and relatively small. Today surgery is used to meet a variety of goals (Fig. 15.9). The trend is toward less radical surgeries.

Prevention

Surgical intervention can be used to eliminate or reduce the risk for cancer development. Prophylactic removal of nonvital organs has been successful in reducing the risk for some cancers. For example, patients who have adenomatous familial polyposis may benefit from a total colostomy to prevent colorectal cancer (see Chapter 42). Those who have genetic mutations of *BRCA1* or *BRCA2* and have a strong family history of early-onset breast cancer may consider having a prophylactic mastectomy (see Chapter 51).

Cure or Control

When the goal is cure or control, the objective is to remove all or as much resectable tumor as possible while sparing normal tissue. Examples of surgical procedures used for cure or control of cancer include radical neck dissection, mastectomy, thyroidectomy, nephrectomy, hysterectomy, and/or oophorectomy.

A *debulking* or *cytoreductive procedure* may be used if the tumor cannot be completely removed (e.g., a tumor attached to a vital organ). When this occurs, as much tumor as possible is removed and

the patient is given chemotherapy and/or radiation therapy. This type of surgical procedure can make chemotherapy or radiation therapy more effective, since the tumor mass is reduced before treatment is started. Other times, a patient may need to receive *neoadjuvant* (treatment before surgery) chemotherapy and/or radiation therapy to reduce tumor size and improve the surgical outcome.

Supportive and Palliative Care

When cure or control of cancer is no longer possible, the focus shifts to supportive care and palliation of symptoms. Surgical procedures may be used to provide supportive care that maximizes bodily function or facilitates cancer treatment. Examples of supportive surgical procedures include:

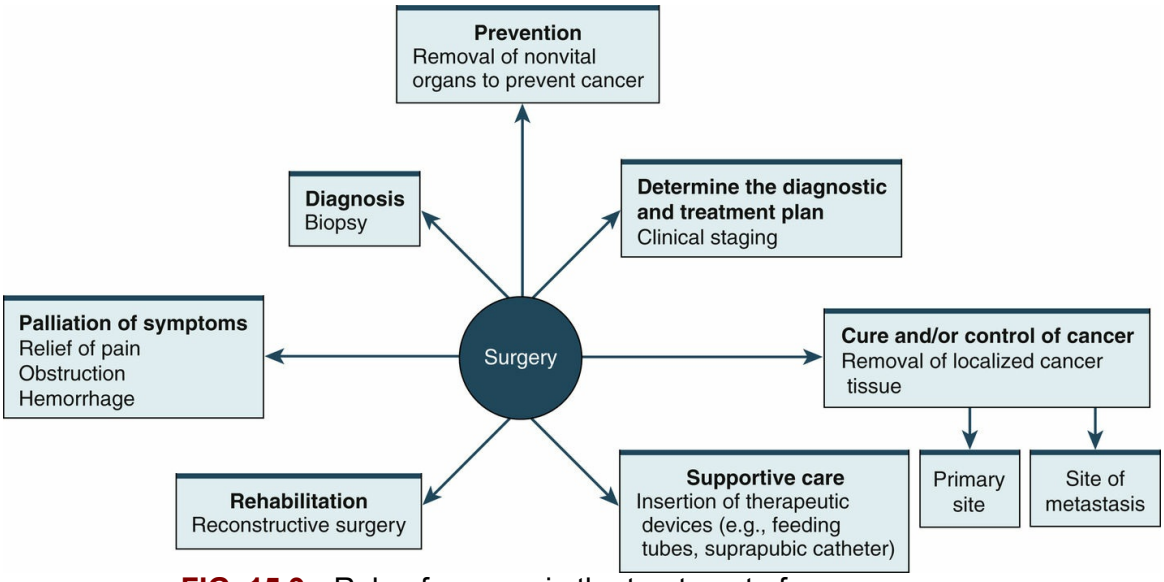

FIG. 15.9 Role of surgery in the treatment of cancer.

- Insertion of a feeding tube to maintain nutrition during head and neck cancer treatment
- Placement of a central venous access device to deliver chemotherapy agents

- Prophylactic surgical fixation of bones at risk for pathologic fracture

Effects of treatment or symptoms from metastatic cancer may require surgical intervention for palliation. Examples include (1) tumor debulking to relieve pain or pressure, (2) colostomy for the relief of a bowel obstruction (see Chapter 42), and (3) laminectomy for the relief of a spinal cord compression (see Chapter 60).

Chemotherapy

Chemotherapy (antineoplastic therapy) is the use of chemicals as a systemic therapy for cancer. In the 1970s, chemotherapy was proven an effective treatment for cancer. Chemotherapy is now a mainstay of cancer treatment for most solid tumors and hematologic cancers (e.g., leukemias, lymphomas). Chemotherapy can offer cure for some cancers, control other cancers for long periods, and in some cases, offer palliative relief of symptoms when cure or control is no longer possible (Fig. 15.10).

Effect on Cells

The goal of chemotherapy is to eliminate or reduce the number of cancer cells in the primary and metastatic tumor site(s). All cells (cancer cells and normal cells) enter the cell cycle for replication and proliferation (Fig. 15.1). The effects of the chemotherapy drugs are described in relation to the cell cycle.

The 2 major categories of chemotherapy drugs are cell cycle phase–nonspecific and cell cycle phase–specific drugs. *Cell cycle phase–nonspecific chemotherapy drugs* have their effect on the cells during all phases of the cell cycle. This includes the process of cell replication and proliferation and the resting phase (G_0). *Cell cycle phase–specific chemotherapy drugs* have their greatest effects during specific phases of the cell cycle (e.g., when cells are in the process of replication or proliferation during G_1, S, G_2, or M). Cell cycle phase–

specific and cell cycle phase–nonspecific agents are often given together to maximize effectiveness by using agents that function in different ways and throughout the cell cycle.

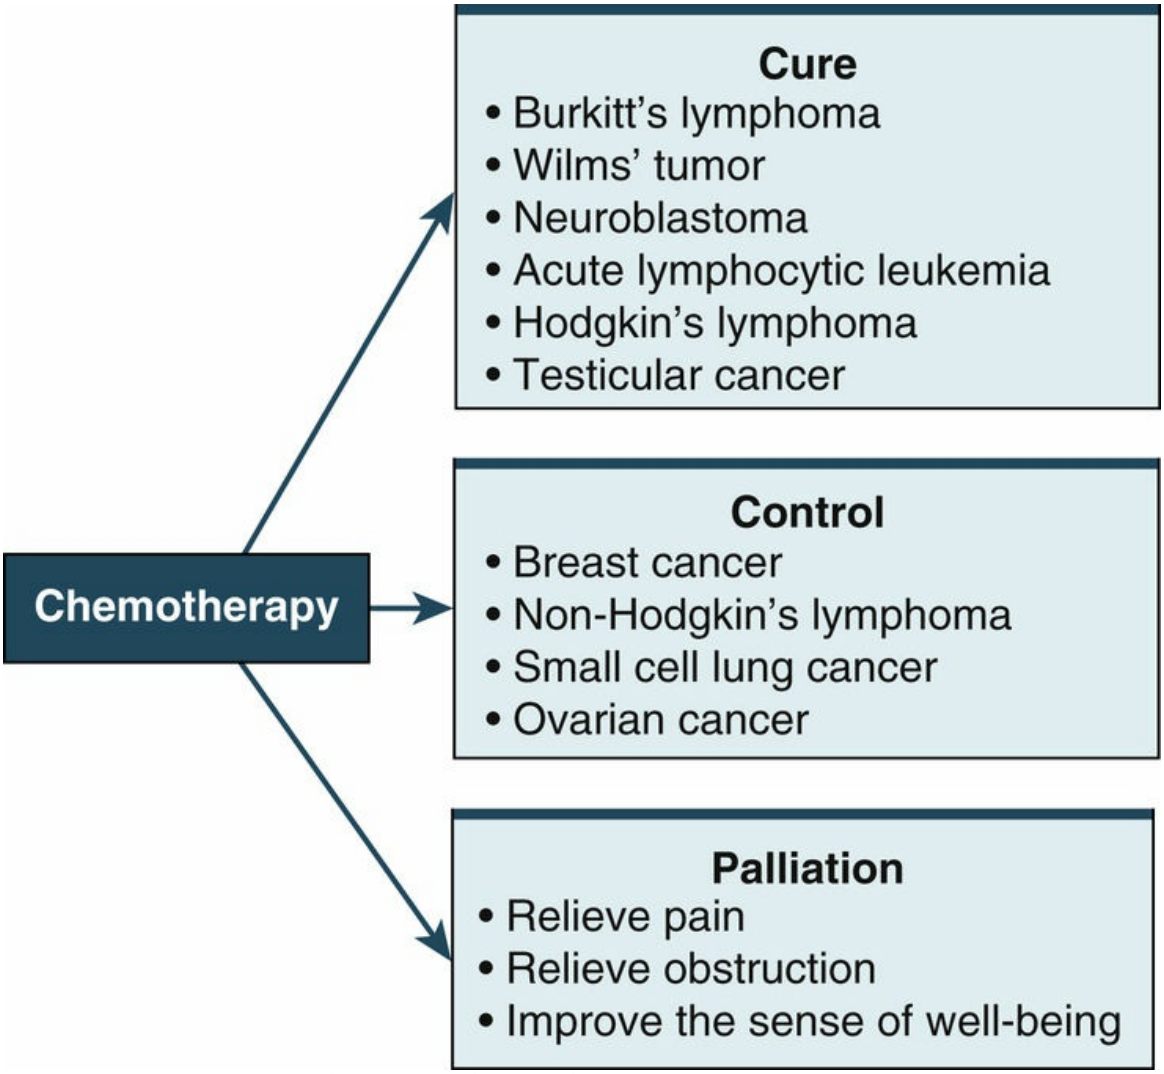

FIG. 15.10 Goals of chemotherapy.

When cancer first begins to develop, most of the cells are actively dividing. As the tumor increases in size, more cells become inactive and convert to a resting state (G_0). Because most chemotherapy agents are effective against dividing cells, cells can escape death by staying in the G_0 phase. A major challenge is to overcome the effect of resistant resting and noncycling cells.

Classification of Chemotherapy Drugs

Chemotherapy drugs are classified in general groups according to their molecular structure and mechanisms of action (Table 15.7). Each drug in a particular class has many similarities. However, there are major differences in how the drugs work and the unique side effects associated with drugs in each class.

TABLE 15.7 Drug TherapyChemotherapy

Mechanisms of Action	Examples
Alkylating Agents	
Cell Cycle Phase–Nonspecific Agents	
Damage DNA by causing breaks in the double-stranded helix. If repair does not occur, cells will die immediately (cytocidal) or when they try to divide (cytostatic).	bendamustine (Treanda), busulfan (Myleran), chlorambucil (Leukeran), cyclophosphamide, dacarbazine, ifosfamide (Ifex), mechlorethamine (Mustargen), melphalan, temozolomide (Temodar), thiotepa
Antimetabolites	
Cell Cycle Phase–Specific Agents	
Mimic naturally occurring substances, thus interfering with enzyme function or DNA synthesis. Primarily act during S phase. Purine and pyrimidine are building blocks of nucleic acids needed for DNA and RNA synthesis.	
• Interfere with purine metabolism	cladribine, clofarabine (Clolar), fludarabine, mercaptopurine (Purixan), nelarabine (Arranon), pentostatin (Nipent), thioguanine
• Interfere with pyrimidine metabolism	capecitabine (Xeloda); cytarabine, floxuridine, fluorouracil, gemcitabine (Gemzar)
• Interfere with folic acid metabolism	methotrexate (Trexall), pemetrexed (Alimta)
• Interfere with DNA synthesis	hydroxyurea (Hydrea, Droxia)
Antitumor Antibiotics	
Cell Cycle Phase–Nonspecific Agents	
Bind directly to DNA, thus inhibiting the synthesis of DNA and interfering with transcription of RNA.	bleomycin, dactinomycin (Cosmegen), daunorubicin, doxorubicin (Doxil), epirubicin (Ellence), idarubicin, mitomycin, mitoxantrone, valrubicin (Valstar)
Mitotic Inhibitors	
Cell Cycle Phase–Specific Agents	
Taxanes	albumin-bound paclitaxel (Abraxane), docetaxel (Taxotere), paclitaxel (Taxol)
Antimicrotubule agents that interfere with mitosis. Act during the late G_2 phase and mitosis to stabilize microtubules, thus inhibiting cell division.	
Vinca Alkaloids	vinblastine, vincristine, vinorelbine (Navelbine)
Act in M phase to inhibit mitosis.	
Others	estramustine (Emcyt), ixabepilone (Ixempra), eribulin (Halaven)
Microtubular inhibitors.	
Nitrosoureas	
Cell Cycle Phase–Nonspecific Agents	
Like alkylating agents, break DNA helix, interfering with DNA replication. Cross blood-brain barrier.	carmustine (BiCNU, Gliadel), lomustine (Gleostine), streptozocin (Zanosar)
Platinum Drugs	
Cell Cycle Phase–Nonspecific Agents	
Bind to DNA and RNA, miscoding information and/or inhibiting DNA replication, and cells die.	carboplatin, cisplatin, oxaliplatin
Topoisomerase Inhibitors	
Cell Cycle Phase–Specific Agents	
Inhibit topoisomerases (normal enzymes) that function to make reversible breaks and repairs in DNA that allow for flexibility of DNA in replication.	etoposide, irinotecan (Camptosar), topotecan (Hycamtin)

Preparation of Chemotherapy

Only persons specifically trained in chemotherapy handling techniques should be involved with the preparation and administration of cancer drugs.[10] They may pose an occupational hazard to health care professionals who do not follow safe handling guidelines. A person preparing, transporting, or giving chemotherapy

may absorb the drug through inhalation of particles when reconstituting a powder or through skin contact from exposure to droplets or powder. There may be some risk in handling the body fluids and excretions of people during the first 48 hours after they receive chemotherapy. Guidelines for the safe handling of chemotherapy agents have been developed by the National Institute for Occupational Safety and Health (OSHA) and the Oncology Nursing Society (ONS).[11]

Methods of Administration

Chemotherapy can be given by multiple routes (Table 15.8). With advances in drug formulation techniques, more oral chemotherapy agents are available. With oral agents, the patient will need to be taught about storage and side effects.

The IV route is the most common method of giving chemotherapy. Major concerns associated with IV chemotherapy administration include venous access problems, device- or catheter-related infection, and *extravasation*.[10] It is the infiltration of drugs into tissues surrounding the infusion site, causing local tissue damage (Fig. 15.11).

TABLE 15.8 Drug Therapy Methods of Chemotherapy Administration

Method	Examples
Oral	cyclophosphamide, capecitabine (Xeloda), temozolomide (Temodar)
Intramuscular	bleomycin
Intravenous	doxorubicin, vincristine, cisplatin, fluorouracil, paclitaxel (Taxol)
Intraarterial	dacarbazine, fluorouracil, methotrexate
Intracavitary (pleural, peritoneal)	Radioisotopes, alkylating agents, methotrexate
Intrathecal	methotrexate (preservative free), cytarabine

Perfusion	Alkylating agents
Subcutaneous	cytarabine, bortezomib
Topical	fluorouracil

FIG. 15.11 Extravasation injury from infiltration of chemotherapy drug.
From Weinzweig N, Weinzweig J: *The mutilated hand,* Philadelphia, 2005, Mosby.

Many chemotherapy drugs are either irritants or vesicants. *Irritants* will damage the intima of the vein, causing phlebitis and sclerosis and limiting future peripheral venous access. They will not cause tissue damage if infiltrated. However, **vesicants**, if inadvertently infiltrated into the skin, may cause severe local tissue breakdown and necrosis. It is extremely important to monitor for and promptly take action if extravasation of a vesicant occurs. To minimize discomfort, emotional distress, and risks of infection and infiltration, IV chemotherapy can be given through a *central venous access device* (CVAD). CVADs are placed in large blood vessels and allow frequent, continuous, or intermittent administration of chemotherapy, immunotherapy, and targeted therapy, and other products, thus avoiding multiple venipunctures for vascular access. (CVADs are discussed in Chapter

16.)

Regional Chemotherapy Administration

Regional treatment with chemotherapy involves delivery of the drug directly to the tumor site. The advantage of this method is that higher concentrations of the drug can be delivered to the tumor with less systemic toxicity. Several regional delivery methods have been developed. These include intraarterial, intraperitoneal, intrathecal, intraventricular, and intravesical bladder chemotherapy.

Intraarterial Chemotherapy

Intraarterial chemotherapy delivers the drug to the tumor through the arteries supplying the tumor. This method has been used for the treatment of osteogenic sarcoma; cancers of the head and neck, bladder, and cervix; melanoma; primary liver cancer; and metastatic liver disease. One method of intraarterial drug delivery involves the surgical placement of a catheter that is connected to an external or implanted infusion pump for infusion of the chemotherapy agent.

Intraperitoneal Chemotherapy

Intraperitoneal chemotherapy involves the delivery of chemotherapy to the peritoneal cavity. It is a treatment for peritoneal metastases from primary colorectal and ovarian cancers and malignant ascites. Temporary Silastic catheters (Tenckhoff, Hickman, Groshong) are percutaneously or surgically placed into the peritoneal cavity for short-term administration of chemotherapy. An implanted port also can be used to give chemotherapy intraperitoneally. Chemotherapy is generally infused into the peritoneum in 1 to 2 L of fluid and allowed to *dwell* in the peritoneum for 1 to 4 hours. After the *dwell time,* the fluid is drained from the peritoneum.

Intrathecal or Intraventricular Chemotherapy

Cancers that metastasize to the central nervous system (CNS) are hard to treat because the blood-brain barrier often prevents distribution of

chemotherapy to this area. One method used to treat metastasis to the CNS is intrathecal chemotherapy. This method involves a lumbar puncture and injection of chemotherapy into the subarachnoid space. To reduce the need for repeated lumbar punctures, patients may have an Ommaya reservoir inserted. An Ommaya reservoir is a Silastic, dome-shaped disk with an extension catheter that is surgically implanted through the cranium into a lateral ventricle.

Intravesical Bladder Chemotherapy

Intravesical bladder chemotherapy involves instilling chemotherapy into the bladder. This is done through a urinary catheter. The solution is retained for 1 to 3 hours.

Effects of Chemotherapy on Normal Tissues

Chemotherapy agents cannot selectively distinguish between normal cells and cancer cells. Chemotherapy-induced side effects are the result of the destruction of normal cells, especially those that are rapidly proliferating. These include those in the bone marrow, lining of the GI system, and integument (skin, hair, nails) (Table 15.9). The general and drug-specific adverse effects of these drugs are classified as acute, delayed, or chronic.

Acute toxicity occurs during and right after drug administration. It includes anaphylactic and hypersensitivity reactions, extravasation or a flare reaction, anticipatory nausea and vomiting, and dysrhythmias.

Delayed effects are numerous. They include delayed nausea and vomiting, mucositis, alopecia, skin rashes, bone marrow suppression, altered bowel function (diarrhea, constipation), and a variety of cumulative neurotoxicities.

Chronic toxicities involve damage to organs, such as the heart, liver, kidneys, and lungs. Chronic toxicities can be either long-term effects that develop during or right after treatment and persist or late effects that are absent during treatment and manifest later.

Some side effects fall into more than 1 category. For example, nausea and vomiting can be both acute and delayed.

Treatment Plan

Although single-drug chemotherapy is sometimes prescribed, the most common modality is combining agents in multidrug regimens. Multidrug treatment targets more than one signaling pathway and is more effective in managing most cancers. The regimens involve drugs with different mechanisms of action and varying toxicity profiles. However, when chemotherapy agents are used in combination, patients can have an increase in toxicities.

TABLE 15.9 Cells With Rapid Rate of Proliferation

Cells	Generation Time	Effect of Cell Destruction
Bone marrow stem cell	6–24 hr	Myelosuppression (infection, bleeding, anemia)
Epithelial cells lining the GI tract	12–24 hr	Anorexia, mucositis (including stomatitis, esophagitis), nausea, vomiting, diarrhea
Hair follicle cells	24 hr	Alopecia
Neutrophils	12 hr	Leukopenia, infection
Ova or testes	24–36 hr	Reproductive problems

Drug regimens are chosen based on evidence supporting their use in specific cancers. Sometimes they are customized to meet the needs of an individual patient. Chemotherapy is most effective when the tumor burden is low, therapy is not interrupted, and the patient receives the intended dose. The dose of each drug is based on the person's body weight and height using the body surface area calculation.

Mutation of cancer cells within the tumor can result in cells that are resistant to chemotherapy. With multiple drugs working at different

places in the cell cycle, cancer cells can be more effectively killed. Thus mutation and resistance of cancer cells can be decreased.

Informatics in Practice

Managing Cancer Patients' Symptoms

- Patients arriving at some clinics are handed a tablet computer. While in the waiting room or chemotherapy infusion unit, with the touch of a finger they select the symptoms that they are having.
- Health care team members can review the information and provide care aimed at managing the patient's specific symptoms.
- After the visit, the notes are stored in the patient's electronic health record. This system can help determine if standards of care were followed.

Radiation Therapy

Along with surgery, radiation therapy is one of the oldest methods of cancer treatment. It was first used to treat a woman with breast cancer in 1896. Although the patient responded locally, she died later of metastatic disease. It was not until the 1960s that advances in equipment and treatment planning facilitated the delivery of adequate radiation doses to tumors and tolerable doses to normal tissues. Today many cancer patients receive radiation therapy at some point in their treatment.

Effects of Radiation

Radiation is energy that is emitted from a source and travels through space or some material. Delivery of high-energy beams, when absorbed into tissue, produces ionization of atomic particles. The

energy in ionizing radiation acts to break the chemical bonds in DNA. The DNA is damaged, causing cell death.

Different types of ionizing radiation are used to treat cancer, including *electromagnetic radiation* (e.g., x-rays, gamma rays) and *particulate radiation* (e.g., alpha particles, electrons, neutrons, protons). High-energy x-rays (photons) are generated by an electric machine, such as a linear accelerator.

Technologic advances have expanded and refined the sources and methods of delivering radiation therapy. This allows for more accurate and less invasive treatment options. Most radiation centers in the United States use megavoltage linear accelerator technology. Larger facilities may offer a combination of machines that give patients more options at that site.

Principles of Radiobiology

As the radiation beam passes through the treatment field, energy is deposited. *Low-energy beams* (e.g., electrons) expend energy quickly on impact with matter, so they penetrate only a short distance. They are clinically useful in treating superficial skin lesions. *High-energy beams* (e.g., photons) have greater depth of penetration, not reaching full intensity until they reach a certain depth. This makes them suitable for delivering optimal doses to internal targets while sparing the skin.

Technically, all cancer cells could be killed with radiation given in high enough doses. However, to avoid serious toxicity and long-term complications of treatment, radiation to surrounding healthy tissue must be limited to the *maximal tolerated dose* for that specific tissue. Advances in planning and in delivery technology (e.g., *intensity-modulated radiation therapy [IMRT]* and *image-guided radiation therapy [IGRT]*) have greatly improved the ability to deliver maximal doses while sparing critical structures (e.g., spinal cord, carotid arteries, optic chiasm) as much as possible.

Historically, the radiation dose was expressed in units called *rads* (radiation absorbed doses). Now we use *gray* (Gy) or centigray (cGy). A *centigray* is equal to 1 rad; 100 centigray equals 1 gray. Once the total dose to be delivered is determined, that dose is divided into daily

fractions. Doses between 180 and 200 cGy/day are considered *standard fractionation*. They are typically delivered once a day Monday through Friday for a period of 2 to 8 weeks, depending on the desired total dose.

Certain cancers are more responsive to the effects of radiation than others (Table 15.10). Radiosensitivity is the relative responsiveness of cells and tissues to the effects of radiation. In highly responsive tumors (such as lymphomas), even a large tumor is affected by radiation therapy. In less responsive tumors, there may be a slower or incomplete response. Localized prostate cancer responds very slowly to radiation (several months after treatment is completed).

Simulation and Treatment Planning

Simulation is a process by which the radiation treatment fields are defined, filmed, and marked out on the skin. The radiation oncologist specifies the dose and volume of area to be treated. Treatment volumes include the (1) *gross target v*olume (GTV), which is the gross extent of the tumor identified by examination or imaging; (2) the *clinical target* volume (CTV), which is the GTV plus additional margin to encompass any potential microscopic or subclinical disease; and (3) the *planning target* volume (PTV), which is the GTV/CTV plus additional margin to allow for organ motion or variance in daily set-up position.

During the simulation, the patient is positioned on a simulator. It is a diagnostic x-ray machine that re-creates the actions of the linear accelerator. The radiation fields are marked on the patient's skin. Immobilization devices (e.g., casts, bite blocks, thermoplastic face masks) are typically used to help the patient keep a stable position (Fig. 15.12).

TABLE 15.10 Tumor Radiosensitivity

High Radiosensitivity

- Hodgkin's lymphoma
- Neuroblastoma
- Non-Hodgkin's lymphoma
- Ovarian dysgerminoma
- Testicular seminoma
- Wilms' tumor

Moderate Radiosensitivity

- Bladder carcinoma
- Breast adenocarcinoma
- Esophageal carcinoma
- Oropharyngeal carcinoma
- Prostate carcinoma
- Uterine and cervical carcinoma

Mild Radiosensitivity

- Colon adenocarcinoma
- Gastric adenocarcinoma
- Renal adenocarcinoma
- Soft tissue sarcomas (e.g., chondrosarcoma)

Poor Radiosensitivity

- Osteosarcoma
- Malignant glioma
- Melanoma
- Testicular nonseminoma

The target is defined using a variety of imaging techniques (e.g., x-rays; CT, MRI, PET scans), physical examination, and surgical reports. Small tattoos may be placed to ensure the patient position is precisely reproduced each treatment.

Treatment

Radiation is used to treat a carefully defined area of the body. Since radiation affects only tissues within the treatment field, it is not appropriate as the main treatment for systemic disease. However, radiation may be used by itself, in combination with chemotherapy or surgery to treat primary tumors, or for palliation of metastatic lesions.

External Radiation

Radiation can be delivered externally *(external beam radiation therapy)*

or internally *(brachytherapy).* **External beam radiation** is the most common form of radiation treatment delivery. With this technique, the patient is exposed to radiation from a megavoltage treatment machine. The beam passes through the external tissues to reach the internal target. A linear accelerator, which generates ionizing radiation from electricity and can have multiple energies, is the most commonly used machine for delivering external beam radiation (Fig. 15.13). *Gamma knife technology* (used to deliver highly accurate stereotactic treatment to a localized treatment volume) uses a cobalt source.

Internal Radiation

Radiation can be delivered as **brachytherapy**, which means "close" or internal radiation treatment. It consists of the implantation or insertion of radioactive materials directly into the tumor (interstitial) or near the tumor (intracavitary or intraluminal). This allows for direct delivery of radiation to the target with minimal exposure to surrounding healthy tissues. It is often used in combination with external radiation as a supplemental "boost" treatment. It may be a primary or adjuvant therapy.

FIG. 15.12 Immobilization device. A head holder and an immobilization mask may be used to ensure accurate positioning for daily treatment of head and neck cancer.
Courtesy Jormain Cady, Virginia Mason Medical Center, Seattle, WA.

FIG. 15.13 Linear accelerator. Varian Clinac EX linear accelerator with multiple photon and electron energies available for use according to the treatment plan. Patient is positioned on radiation treatment table for treatment of head and neck cancer.
Courtesy Jormain Cady, Virginia Mason Medical Center, Seattle, WA.

Sources of radiation for brachytherapy include temporary sealed sources (e.g., iridium-192, cesium-137) and permanent sealed sources (e.g., iodine-125, gold-198, palladium-103). These are supplied in the form of seeds or ribbons. With a temporary implant, the source may be placed into a special catheter or metal tube that has been inserted into the tumor area. It is left in place until the prescribed dose of radiation has been reached in the calculated number of hours.

Brachytherapy may be delivered as high-dose-rate (HDR) treatment (e.g., several doses given at varying intervals over a few minutes each time) or low-dose-rate (LDR) treatment (e.g., continuous treatment over several hours or days). A remote "afterloading" technique (e.g.,

the source is inserted after the applicator is in place) is designed to enhance HCP and patient safety. It is used for HDR brachytherapy with iridium-192. These methods are often used for head and neck, lung, breast, and gynecologic cancers.

Permanent implants, such as for prostate brachytherapy, involve the insertion of radioactive seeds directly into the tumor tissue, where they stay permanently. As interstitial seeds used for treatment emit low energies with limited tissue penetration, patients are not considered radioactive. However, some initial radiation precautions may be recommended because of a small risk of seed dislodgement. Over time, the isotopes that are used decay and are no longer radioactive. The timeframe for side effects induced by treatment can be predicted based on the rate of decay for the specific isotope used.

Radioactive drugs, or radiopharmaceuticals, are used to treat some cancers systemically. They may be given orally as a capsule or drink (e.g., iodine-131 for thyroid cancer), or IV as with yttrium-90 given for resistant lymphomas or samarium-153 used to treat bone metastases. The drug is sometimes bound to monoclonal antibodies. The antibodies attach to the cancer cell, directly delivering the radiation. This may minimize the effects of the radiation on healthy cells.

Caring for the person undergoing brachytherapy or receiving radioactive drugs requires that you be aware when the patient is emitting radioactivity. Patients with temporary implants are radioactive only while the source is in place. In those with permanent implants, because the sources have short half-lives and are weak emitters, the radioactive exposure to the outside and to others is low. These patients may be discharged with minimal precautions.

The principles of *ALARA (as low as reasonably achievable)* and *time, distance,* and *shielding* are vital to our safety when caring for the person with a source of internal radiation. Organize care to limit the time spent in direct contact with the patient. To minimize anxiety and confusion, tell the patient the reason for time and distance limitations before the procedure.

The radiation safety officer will say how much time at a specific distance can be spent with the patient. This is determined by the dose

delivered by the implant. Because the source is nonpenetrating, small differences in distance are critical. Only care that must be delivered near the source, such as checking placement of the implant, is done in close proximity. Use shielding, if available. Do not deliver care without wearing a film badge (dosimeter) showing cumulative radiation exposure. Do not share the film badge. Do not wear it anywhere but at work and return it according to the agency's protocol.

Nursing Management: Chemotherapy and Radiation Therapy

You play a key role in helping patients deal with the side effects of chemotherapy and radiation therapy. Before starting teaching, assess the patient's ability to process information. Customize teaching to meet the patient's and caregiver's learning needs.

Common side effects of chemotherapy and radiation are outlined in Table 15.11. Bone marrow suppression, fatigue, GI disturbances, skin and mucosal reactions, and pulmonary and reproductive effects are discussed in this section.

Nursing Implementation

Bone Marrow Suppression

Myelosuppression is one of the most common effects of chemotherapy. To a lesser extent, it can occur with radiation. Treatment-induced myelosuppression can result in life-threatening and distressing effects. These include infection, hemorrhage, and overwhelming fatigue. The major difference in manifestations between radiation therapy and chemotherapy is that radiation (a local therapy) only affects bone marrow within the treatment field. Chemotherapy (a systemic therapy) affects bone marrow function throughout the body. When the therapies are combined, the risk for myelosuppression greatly increases.

In general, the onset of bone marrow suppression is related to the life span of the type of blood cell. WBCs (especially neutrophils) are affected first (within 1 to 2 weeks), platelets in 2 to 3 weeks, and red blood cells (RBCs), with a longer life span of 120 days, later. The severity of myelosuppression depends on the chemotherapy drugs used, drug dosages, and the radiation treatment field. Radiation to large marrow-containing regions of the body produces the most clinically significant myelosuppression. In the adult, most of the active marrow is in the pelvis and thoracic and lumbar vertebrae.

Monitor the CBC, especially the neutrophil, platelet, and RBC counts, in patients receiving chemotherapy or radiation. Patients often have the lowest blood cell counts (called the *nadir*) between 7 and 10 days after starting therapy. However, the exact onset depends on the drug regimen.

Neutropenia is more common in patients receiving chemotherapy than radiation therapy. It is a serious risk factor for life-threatening infection and sepsis. Significant neutropenia will prompt treatment delay or adjustments (e.g., lower dosages). Take every measure to prevent infections in these patients. Hand hygiene is the mainstay of patient protection. Patients and their contacts, including health care team members, should follow hand-washing guidelines.

Monitor temperature routinely. Any sign of infection should be treated promptly, since fever in the presence of neutropenia is a medical emergency. WBC growth factors (e.g., filgrastim [Neupogen], pegfilgrastim [Neulasta]) are routinely used to reduce the duration of chemotherapy-induced neutropenia. They are used as a prophylactic measure to prevent neutropenia when highly myelosuppressive chemotherapy drugs are used.[12] (Neutropenia is discussed in Chapter 30. See the patient teaching guide in Table 30.23 and eNursing Care Plan 30.3 on the website for that chapter.)

Thrombocytopenia can result in spontaneous bleeding or major hemorrhage. Avoid invasive procedures. Teach patients to avoid activities that place them at risk for injury or bleeding (including excessive straining). Risk for serious bleeding is generally not present until the platelet count falls below 50,000/μL. Platelet transfusions

may be necessary and are usually given when platelet counts fall below 20,000/μL. (Thrombocytopenia is discussed in Chapter 30. See the patient teaching guide in Table 30.15 and eNursing Care Plan 30.2 on the website for that chapter.)

Anemia is common in patients undergoing either radiation therapy or chemotherapy. It generally has a later onset (about 3 to 4 months after starting treatment). For patients with low hemoglobin levels, RBC growth factors (e.g., darbepoetin [Aranesp], epoetin [Procrit]) may be given according to clinical guidelines. In extreme circumstances (e.g., symptomatic anemia), RBC transfusions may be needed. However, in general, RBC transfusions are avoided. (Hematopoietic growth factors are discussed later in this chapter and in Table 15.15.)

Fatigue

Fatigue is the persistent subjective sense of tiredness that interferes with usual day-to-day functioning. Fatigue is a nearly universal symptom affecting most patients with cancer. It is often reported by patients as the most distressful of treatment-related side effects. Fatigue may persist long after treatment has ended.

TABLE 15.11 Nursing ManagementProblems Caused by Chemotherapy and Radiation Therapy

Etiology	Nursing Management
Biochemical	
Hyperuricemia	
Increased uric acid levels due to chemotherapy-induced cell destruction. **Can cause secondary gout and obstructive uropathy.**	• Monitor uric acid levels. • Allopurinol may be given as a prophylactic measure. • Maintain increased fluid intake.
Cardiovascular	
Cardiotoxicity	
Some chemotherapy drugs (e.g., anthracyclines, taxanes) can cause ECG changes and rapidly progressive heart failure.	• Monitor heart with ECG and cardiac ejection fractions. • Drug therapy may need to be changed for symptoms or deteriorating cardiac function studies. • Administer antidysrhythmic drugs as ordered.
Pericarditis and Myocarditis	
Inflammation from radiation injury. **Complication from chest wall radiation.** **May occur up to 1 year after treatment.** **Side effect of some chemotherapy drugs.**	• Monitor for manifestations of these disorders (e.g., dyspnea).
Comfort	
Fatigue	
Anabolic processes result in accumulation of metabolites from cell breakdown.	• Assess for reversible causes of fatigue and address them as indicated. • Reassure patient that fatigue is a common side effect of therapy. • Encourage patient to rest when fatigued, to maintain usual lifestyle patterns, as much as possible, and to pace activities in accordance with energy level. • Encourage moderate exercise as tolerated.
Gastrointestinal System	
Anorexia	
Release of TNF and IL-1 from macrophages has appetite-suppressant effect. **Therapy-induced GI effects (mucositis, nausea, vomiting, bowel problems) and anxiety reduce appetite.**	• Monitor weight. • Encourage patient to eat small, frequent meals of high-protein, high-calorie foods. • Gently encourage patient to eat, but do not nag. • Recommend keeping a food diary to track daily calories and fluids. • Serve food in pleasant environment.
Constipation	
Autonomic nervous system dysfunction decreases intestinal motility. **Caused by neurotoxic effects of plant alkaloids (vincristine, vinblastine).**	• Teach patients to take stool softeners as needed, eat high-fiber foods, and increase fluid intake. • Teach patients to increase activity (e.g., walking) if tolerated.
Diarrhea	
From denuding of epithelial lining of intestines. **Side effect of chemotherapy.** **Follows radiation to abdomen, pelvis, lumbosacral areas.**	• Give antidiarrheal drugs as needed. • Encourage low-fiber, low-residue diet. • Encourage fluid intake of at least 3 L/day.
Hepatotoxicity	
Toxic effects from chemotherapy drugs (usually transient and resolve when drug is stopped).	• Monitor liver function tests.
Nausea and Vomiting	
Release of intracellular breakdown products stimulates vomiting center in brain. **Drugs stimulate vomiting center in brain (see Fig. 41.1).** **Radiation and chemotherapy destroy lining of GI tract.**	• Encourage patient to eat and drink when not nauseated. • Give prophylactic antiemetics before chemotherapy and on as-needed basis. • Teach patients to take antiemetics on a scheduled basis for 2–3 days after highly emetogenic chemotherapy. • Use diversional activities (if appropriate).

Table Continued

Etiology	Nursing Management
Stomatitis, Mucositis, and Esophagitis	
Epithelial cells are destroyed by chemotherapy or radiation treatment when located in field (e.g., head and neck, stomach, esophagus). **Rapid cell destruction causes inflammation and ulceration.**	• Assess oral mucosa daily and teach patient to do this. • Encourage nutritional supplements (e.g., Ensure, Carnation Instant Breakfast) if intake is decreasing. • Be aware that eating, swallowing, and talking may be difficult and patient may need analgesics. • Teach avoidance of irritating spicy or acidic foods or too hot or too cold food (extremes in temperature). • Teach how to choose moist, bland, and softer foods. • Encourage patient to keep oral cavity clean and moist by frequent oral rinses with saline or salt and soda solution. • Encourage patient to use artificial saliva to manage dryness (radiation). • Discourage use of irritants, such as tobacco and alcohol. • Apply topical anesthetics (e.g., viscous lidocaine, oxethazaine).
Genitourinary Tract	
Hemorrhagic Cystitis	
Chemotherapy (e.g., cyclophosphamide, ifosfamide) destroys cells lining the bladder **Side effect of radiation when in the treatment field.**	• Encourage increased fluid intake 24–72 hr after treatment as tolerated. • Monitor for urgency, frequency, and hematuria. • Give cytoprotectant agent (mesna [Mesnex]) and hydration. • Give supportive care agents to manage symptoms (e.g., flavoxate).
Nephrotoxicity	
Exposure to nephrotoxic agents (cisplatin and high-dose methotrexate) directly damages renal cells. **Precipitation of metabolites of cell breakdown (tumor lysis syndrome [TLS]).**	• Monitor BUN and serum creatinine levels. • Avoid potentiating drugs. • Alkalinize the urine by adding sodium bicarbonate to IV infusion • Give allopurinol or rasburicase for TLS prevention.
Reproductive Problems	
Therapy damages cells of testes or ova.	• Discuss possibility with patients before treatment initiation. • Offer opportunity for sperm and ova banking before treatment for patients of childbearing age.
Hematologic System	
Anemia	
Therapy causes bone marrow depression. **Malignant infiltration of bone marrow by cancer.**	• Monitor hemoglobin and hematocrit levels. • Give iron supplements and erythropoietin. • Encourage intake of foods that promote RBC production (see Table 30.5).
Leukopenia	
Chemotherapy or radiation therapy causes bone marrow depression. **Infection most frequent cause of morbidity and death in cancer patients.** **Respiratory and genitourinary system are usual sites of infection.**	• Monitor WBC count, especially neutrophils. • Tell patient to report temperature elevation and any other manifestations of infection. • Teach patient to avoid large crowds and people with infections. • Give WBC growth factors (Table 15.15). • For patient teaching, see Table 30.23.
Thrombocytopenia	
Chemotherapy causes bone marrow depression. **Malignant infiltration of bone marrow crowds out normal marrow.** **Spontaneous bleeding can occur with platelet counts ≤ 20,000/μL.**	• Observe for signs of bleeding (e.g., petechiae, ecchymosis). • Monitor platelet counts. • For patient teaching, see Table 30.15.
Integumentary System	
Alopecia	
Chemotherapy or radiation to scalp destroys hair follicles. **Hair loss usually is temporary with chemotherapy, but usually permanent in response to radiation.**	• Suggest ways to cope with hair loss (e.g., hair pieces, scarves, wigs). • Cut long hair before therapy. • Avoid excessive shampooing, brushing, and combing of hair. • Avoid use of electric hair dryers, curlers, and curling rods. • Discuss impact of hair loss on self-image.

Table Continued

Etiology	Nursing Management
Chemotherapy-Induced Skin Changes	
Acneiform eruptions. **Acral erythema.** **Hyperpigmentation.** **Photosensitivity.** **Telangiectasia.**	• Alert patient to potential skin changes. • Encourage patient to avoid sun exposure. • Implement symptomatic management as needed depending on specific skin effect (e.g., application of lotions, corticosteroid creams).
Radiation Skin Changes (dry to moist desquamation)	
Radiation damages skin.	• See Table 15.12 for patient management details.
Nervous System	
Cognitive Changes ("chemo brain")	
Occur during and after treatment (especially with chemotherapy). **Problems with concentration, memory lapses, trouble remembering details, taking longer to finish tasks.** **May happen quickly and last a short time. Some people have mild long-term effects.**	• Teach patients to: • Use detailed daily planner. • Get enough sleep and rest. • Exercise brain (learn something new, do word puzzles). • Focus on one thing (no multitasking).
Intracranial Pressure	
May result from radiation edema in central nervous system.	• Monitor neurologic status. • May be controlled with corticosteroids.
Peripheral Neuropathy	
Paresthesias, areflexia, skeletal muscle weakness, and smooth muscle dysfunction can occur as a side effect of plant alkaloids, taxanes, and cisplatin.	• Monitor for manifestations in patients on these drugs. • Consider temporary chemotherapy dose interruption or reduction until symptoms improve. • Antiseizure drugs (e.g., gabapentin [Neurontin]) may be considered.
Respiratory System	
Pneumonitis	
Radiation pneumonitis develops 2–3 mo after start of treatment. **After 6–12 mo, fibrosis occurs and is evident on x-ray.** **Side effect of some chemotherapy and immunotherapy drugs.**	• Monitor for dry, hacking cough; fever; and dyspnea with exertion. • Encourage activity and respiratory exercises.

Anemia is one cause of fatigue. Other causes may be related to the (1) accumulation of toxic substances that are left in the body after cells are killed by cancer treatment, (2) need for extra energy to repair and heal body tissue damaged by treatment, and (3) lack of sleep caused by some chemotherapy drugs. Assess for reversible causes of fatigue, such as anemia, hypothyroidism, depression, anxiety, insomnia, dehydration, or infection.

Help patients recognize that fatigue is a common side effect of therapy. Teach them energy conservation strategies. Help patients identify days or times during the day when they typically feel better. Encourage them to be more active during that period.

Resting before activity and having others help with work or home tasks may be necessary. Ignoring the fatigue or overstressing the body when fatigue is tolerable may lead to an increase in symptoms. Maintaining exercise and activity within tolerable limits is often helpful in managing fatigue. Walking programs are a way for most

patients to keep active without overtaxing themselves. Staying active helps improve mood and avoid the debilitating cycle of fatigue-depression-fatigue that can occur in patients with cancer. Guidelines for the evaluation and management of cancer-related fatigue are available.[13]

Check Your Practice

Your 56-yr-old female patient with breast cancer has just completed 4 cycles of a chemotherapy regimen of CAF (cyclophosphamide, doxorubicin, fluorouracil). At her clinic visit today, she reports being so tired that she "can barely get out of bed." She then becomes tearful, sharing "who knows what my future holds, and now I am missing so many things with my grandchildren."

- How would you respond?

Gastrointestinal Effects

The cells of the mucosal lining of the GI tract are highly proliferative. The epithelial cells are replaced every 2 to 6 days. The intestinal mucosa is one of the most sensitive tissues to radiation and chemotherapy. The cause of GI reactions is related to a variety of mechanisms. These include (1) the release of serotonin from the GI tract, which then stimulates the chemoreceptor trigger zone (CTZ) and the vomiting center in the brain and (2) cell death and resulting damage to GI mucosa. Radiation to treatment fields that contain GI structures (e.g., abdominopelvic, lumbosacral, lower thoracic areas) and selected chemotherapy agents cause direct injury to GI epithelial cells. These injuries cause a variety of GI effects, including nausea and vomiting, diarrhea, mucositis, and anorexia. These problems can significantly affect the patient's hydration and nutritional status and sense of well-being.

Nausea and Vomiting

Nausea and vomiting are common effects of chemotherapy and sometimes radiation therapy. Chemotherapy-induced nausea and vomiting (CINV) may occur within 1 hour of chemotherapy administration. Vomiting may start a few hours after radiation therapy to the chest or abdomen. It may persist for 24 hours or more. Several antiemetic drugs are available (see Table 41.1).

Serotonin (5-HT_3) receptor antagonists (ondansetron [Zofran], granisetron, palonosetron [Aloxi]) and neurokinin-1 receptor antagonists (NK_1RA), (e.g., aprepitant [Emend], netupitant, rolapitant [Varubi]) can reduce CINV. Dexamethasone is given with other antiemetics to manage acute and delayed CINV. Akynzeo is a fixed combination of palonosetron (a 5-HT_3 receptor antagonist) and netupitant (a NK_1RA antagonist).

Anticipatory nausea and vomiting can develop if a patient has poorly controlled nausea and vomiting after chemotherapy administration. In this phenomenon, encountering the cues even without receiving treatment may precipitate nausea and vomiting. Aggressive emesis control, including giving prophylactic antiemetic and antianxiety medication 1 hour before treatment, is recommended. The patient may find that eating a light meal of nonirritating food before treatment is helpful.

Delayed nausea and vomiting can develop 24 hours to a week after treatment. Assess patients who have nausea and vomiting for signs and symptoms of dehydration and metabolic alkalosis. Nausea and vomiting can be successfully managed with antiemetic drugs, diet adjustments, and other nondrug interventions (e.g., relaxation breathing).

Diarrhea

Diarrhea is a reaction of the bowel mucosa to radiation and some chemotherapy drugs. It is characterized by an increase in frequency and liquidity of stool. The small bowel is extremely sensitive and does not tolerate significant radiation doses. With pelvic radiation, patients

may be treated with a full bladder. This moves the small bowel out of the treatment field. Both radiation- and chemotherapy-induced diarrhea are best managed with diet adjustments, antidiarrheals, antimotility agents, and antispasmodics (see Table 42.2).

Recommend a diet low in fiber and residue before chemotherapy known to cause diarrhea. This includes limiting foods high in roughage (e.g., fresh fruits, vegetables, seeds, nuts). To prevent diarrhea, other foods to avoid include fried, fatty, or highly seasoned foods and foods that are gas producing. Bowel mucosal injury from radiation may cause temporary lactose intolerance. So, avoiding milk products is helpful for some patients during and right after treatment.

Depending on the severity of the diarrhea, hydration and electrolyte supplementation are recommended. Lukewarm sitz baths may ease discomfort and cleanse the rectal area if significant rectal irritation has developed. The rectal area must be kept clean and dry to maintain skin integrity. Inspect the perianal area for evidence of skin breakdown. Systemic analgesia may be used for painful skin irritations. Note the number, volume, consistency, and character of stools per day. Have patients keep a diary or log to record episodes and aggravating and alleviating factors.

Mucositis

Mucositis is irritation, inflammation, and/or ulceration of the mucosa. Chemotherapy or radiation therapy can cause mucositis. Patients diagnosed with head and neck cancer who receive radiation are at high risk. Like the bowel mucosa, the mucosal linings of the oral cavity, oropharynx, and esophagus are extremely sensitive to the effects of radiation and chemotherapy.

Certain factors can compound the problem. For example, patients undergoing head and neck radiation may face the added challenge of radiation-induced parotid gland dysfunction. This may result in decreased salivary flow, causing acute or chronic *xerostomia* (dry mouth). Dryness or thick saliva compromises the protective salivary functions of assisting with cleansing teeth, moistening food, and swallowing. Meticulous oral care during and for a long time after

treatment reduces the risk for cavities, which may occur due to decreased saliva. Teach patients to continue regular dental follow-up every 6 months. They should use fluoride supplements as recommended by their dentist. Saliva substitutes may be offered to patients with xerostomia. Many patients find that drinking small amounts of water frequently has a similar effect.

Dysgeusia (taste loss) may develop during therapy. By the end of treatment, patients often report that all food has lost its flavor. Ultimately, nutritional status may be compromised. *Dysphagia* (difficulty swallowing), which marks pharyngeal and/or esophageal involvement, further impedes eating. Patients may report feeling that they have a "lump" as they swallow and that "foods get stuck." The patient with *odynophagia* (painful swallowing) caused by oropharyngeal or esophageal irritation and ulceration may need analgesics before meals.

Oral assessment and meticulous intervention to keep the oral cavity moist, clean, and free of debris are essential to prevent infection and promote nutritional intake. Implementing standard oral care protocols that address prevention and management of mucositis promotes routine assessment, patient and caregiver teaching, and intervention.

Routinely assess the oral cavity, mucous membranes, characteristics of saliva, and ability to swallow. Having a dentist perform all necessary dental work before starting treatment is recommended. Teach the patient to self-examine the oral cavity and how to perform oral care. Oral care should be done at least before and after each meal, at bedtime, and as needed through the day. A saline solution of 1 tsp of salt in 1 L of water is an effective cleansing agent; 1 tsp of sodium bicarbonate may be added to the oral care solution to decrease odor, ease pain, and dissolve mucin. Have the patient use a soft bristled toothbrush.

Mucositis or pain in the throat can be eased by systemic and/or topical analgesics and antibiotics if infection is present. Monitor and get prompt treatment for oral candidiasis (which often occurs with mucositis). Frequent cleansing with saline and water and topical application of anesthetic gels directly to the lesions are standard care.

Anorexia

Anorexia (loss of appetite) is a common occurrence in patients with cancer. It is a side effect of the cancer as well as of cancer treatment. Anorexia may be related to an inflamed mouth or esophagus, which creates difficulty chewing or swallowing, or to emotions, such as anxiety or depression. It is important to have a dietitian involved in patient care before cancer treatment starts.

Patients with nausea and vomiting, bowel problems, mucositis, and taste changes typically have little desire to eat. Anorexia seems to peak at about 4 weeks of treatment. It resolves more quickly than fatigue when treatment ends.

Monitor patients with anorexia during and after treatment to ensure that weight loss does not become excessive. Observe for dehydration. Small, frequent meals of high-protein, high-calorie foods are better tolerated than large meals. Nutritional supplements can be helpful, too. Enteral or parenteral nutrition may be needed if the patient is severely malnourished, if symptoms are expected to interfere with nutrition for a time, or if the bowel is being rested. Monitor for and manage other symptoms that may interfere with appetite (e.g., nausea, vomiting, pain, depression).

Skin Reactions

Radiation Skin Changes

With radiation therapy, skin effects are local, occurring only in the treatment field. Radiation-induced skin changes can be acute or chronic depending on the area irradiated, dosage, and technique. The skin-sparing ability of modern radiation equipment limits the severity of these reactions.

Erythema may develop 1 to 24 hours after a single treatment. It generally occurs progressively as the treatment dose accumulates. It is an acute response followed by dry desquamation (Fig. 15.14). If the rate of cell sloughing is faster than the ability of the new epidermal cells to replace dead cells, a wet desquamation occurs with exposure of the dermis and weeping of serous fluid (Fig. 15.15). Skin reactions

are especially evident in areas of skinfolds or where skin is subjected to pressure. This includes behind the ear; in gluteal folds; on the perineum, breast, or collar line; and bony prominences.

Although skin care protocols vary, basic skin care principles apply. The goal is to prevent infection and promote wound healing. Protect radiated skin from temperature extremes. Do not use heating pads, ice packs, and hot water bottles in the treatment field. Avoid constricting garments, rubbing, harsh chemicals, and deodorants, since they may traumatize the skin. Dry reactions are uncomfortable and result in pruritus. Lubricate dry skin with a nonirritating lotion emollient that contains no metal, alcohol, perfume, or additives. These can be irritating. Calendula ointment and topical hyaluronic acid cream are effective for managing radiation dermatitis. Aloe vera gel is useful for preventing skin problems.

FIG. 15.14 Dry desquamation.

FIG. 15.15 Wet desquamation.

Wet desquamation of tissues generally causes pain, drainage, and increased risk for infection. Skin care to manage moist desquamation includes keeping tissues clean with normal saline compresses or modified Burow's solution soaks. Protect the skin from further damage with moisture vapor–permeable dressings or Vaseline petrolatum gauze. Because protocols vary widely, you should verify the guidelines in Table 15.12 with your agency' s radiation oncology department.

Chemotherapy Skin Changes

Chemotherapy causes a wide range of skin toxicities. These can range from mild erythema and hyperpigmentation to more distressing effects, such as acral erythema and *erythrodysesthesia syndrome* (also called palmar-plantar erythrodysesthesia or hand-foot syndrome).

TABLE 15.12 Patient & Caregiver TeachingRadiation Skin Reactions

Include the following instructions when teaching the patient and caregiver to clean and protect the skin in a radiation treatment area:

1. Gently cleanse the skin in the treatment field using a mild soap (Ivory, Dove), tepid water, a soft cloth, and a gentle patting motion. Rinse thoroughly and pat dry.

2. Apply nonmedicated, nonperfumed, moisturizing lotion or cream, such as calendula ointment, aloe gel, Aquaphor, or Biafine cream, to alleviate dry skin. Some substances must be gently cleansed from the treatment field before each treatment and reapplied. Over-the-counter hydrocortisone cream 1% may reduce itching.

3. Rinse the area with saline solution. Expose the area to air as often as possible. If copious drainage is present, use astringent compresses (such as Domeboro solution) and nonadhesive absorbent dressings. Change dressings as soon as they become wet.

4. Observe the area daily for signs of infection.

5. Avoid wearing tight-fitting clothing, including brassieres and belts, over the treatment field.

6. Avoid wearing harsh fabrics, such as wool and corduroy. A lightweight cotton garment is best. If possible, expose the treatment field to air.

7. Use gentle detergents (e.g., Dreft, Ivory Snow) to wash clothing that will come in contact with the treatment field.

8. Avoid direct exposure to the sun. If the treatment field is in an area that is exposed to the sun, wear protective clothing, such as a wide-brimmed hat, when out in the sun and apply sunscreen lotion.

9. Avoid all sources of excessive heat (hot water bottles, heating pads, sunlamps) on the treatment field.

10. Avoid exposing the treatment field to cold temperatures (ice bags or cold weather).

11. Avoid swimming in saltwater or in chlorinated pools during the time of treatment.

12. Avoid the use of potential irritants (e.g., perfumes, powders, or cosmetics) on the skin in the treatment field. Review the use of other topical medications or lotions with your HCP during treatment. Avoid tape, dressings, and adhesive bandages unless allowed by the radiation therapist.

12. Continue to protect sensitive skin after the treatment is completed. Do the following:

    - Avoid direct exposure to the sun. A sunscreen agent and protective clothing must be worn if the potential of exposure to the sun is present.
    - Use an electric razor if shaving is needed in the treatment field.

Erythrodysesthesia syndrome can cause mild symptoms of redness and tingling of the palms of the hands and soles of the feet. It may also cause severe symptoms of painful moist desquamation, ulceration, blistering, and pain.

Alopecia is an easily recognizable effect of cancer treatment. Hair loss associated with radiation is local. Chemotherapy affects hair throughout the body. The degree and duration of hair loss depends on the type and dose of the chemotherapy agent. Scalp cooling during chemotherapy may reduce alopecia. Cold caps are placed on the head before, during, and after chemotherapy treatment. Common side effects are headache and cold sensation.[14]

Alopecia caused by chemotherapy agents is usually reversible. Usually the hair does not grow back until 3 to 4 weeks after the end of therapy. Often the new hair is a different color and texture than the hair that was lost.

Patients have a range of emotions at the prospect of losing their hair and when hair loss occurs. These may include anger, grief, embarrassment, or fear. Hair loss is a visible reminder of their cancer and the challenges of treatment. For some people, the hair loss is one of the most stressful events experienced during treatment. The ACS's "Look Good, Feel Better" program is an excellent support and resource for people with hair loss and body image changes.

Pulmonary Effects

Both chemotherapy and radiation have the potential to cause irreversible and progressive lung damage. Distinguishing between the complications of treatment and those related to disease is challenging. The effects of radiation on the lung include both acute and late reactions. Acute effects can be alarming to patients because they may mimic symptoms (e.g., cough, dyspnea) that precipitated the cancer diagnosis.

Pneumonitis is a delayed acute inflammatory reaction that may occur within 1 to 3 months after completing thoracic radiation. This

reaction is often asymptomatic, although an increase in cough, fever, and night sweats may occur. Some patients may develop pulmonary fibrosis (with or without prior pneumonitis), which is a late effect of therapy.

The most common toxicities associated with chemotherapy include pulmonary edema (noncardiogenic) related to capillary leak syndrome or fluid retention, hypersensitivity pneumonitis, interstitial fibrosis, and pneumonitis due to an inflammatory reaction or destruction of alveolar-capillary endothelium.

Cardiovascular Effects

Radiation to the thorax can damage the pericardium, myocardium, valves, and coronary blood vessels. The pericardium is most often involved. Pericardial effusion and pericarditis are key problems. Patients with preexisting coronary artery disease are especially at risk.

Anthracyclines (e.g., doxorubicin, daunorubicin) cause cardiotoxicity. Acute cardiotoxicities may cause electrocardiographic (ECG) changes. Late effects cause left ventricular dysfunction and heart failure. Baseline and periodic echocardiograms to monitor left ventricular function during treatment are usually done.

Cognitive Effects

Cognitive effects can happen at any time during cancer, especially after treatment. This change in mental function, often described by patients as mental cloudiness or fog, is commonly called *chemo brain.*[15] Patients can have thinking and memory problems. Although the brain will usually recover over time, the effects can last a short time or for years. The effects can be so severe that patients may be unable to be involved in any activities that need mental effort, including school, work, or social activities.

Reproductive Effects

Reproductive problems from radiation and chemotherapy vary according to the radiation treatment field and dosage, the

chemotherapy agent and dosage, and host factors (e.g., age). Treatment can cause temporary or permanent gonadal failure. Reproductive problems occur most often when reproductive organs are included in the radiation treatment field and when alkylating agents are used.

The testes are highly sensitive to radiation. They should be protected with a testicular shield whenever possible. Pretreatment status may be a significant factor. A low sperm count and loss of motility are seen in those with testicular cancer and Hodgkin's lymphoma before any therapy is begun. Combined modality treatment or prior chemotherapy with alkylating agents enhances and prolongs the effects of radiation on the testes. When radiation is used alone with conventional doses and appropriate shielding, testicular recovery often occurs. Men may have erectile dysfunction after pelvic radiation.

The radiation dose that induces ovarian failure changes with age. Unlike the testes, there is no way to repair ovarian function. When radiation therapy is given, the ovaries are shielded whenever possible. Other factors that influence reproductive or sexual functioning in women include reactions in the cervix and endometrium. These tissues withstand a high radiation dose with minimal sequelae. This accounts for the ability to treat endometrial and cervical cancer with high external and brachytherapy doses. Acute reactions, such as tenderness, irritation, and loss of lubrication, compromise sexual activity. Late effects of combined internal and external radiation therapy include vaginal shortening related to fibrosis and loss of elasticity and lubrication.

The patient and partner need information about the expected effects of treatment related to reproductive and sexual issues. Fertility preservation should be addressed before starting cancer treatment. Pretreatment harvesting of sperm, ova, or ovarian tissue may be considered.[16]

Potential infertility can be a significant consequence, and counseling may be needed. However, in no case should the patient think that conception is not possible during treatment. Specific suggestions that

have an impact on sexual function include using a water-soluble vaginal lubricant and a vaginal dilator after pelvic irradiation. Encourage discussion of issues related to reproduction and sexuality, offer specific suggestions, and make referrals for ongoing counseling when needed.

Late Effects of Radiation and Chemotherapy

Cancer survivors are achieving long-term remission and survival with advancements in treatment modalities. However, therapy (especially radiation therapy and chemotherapy) may cause long-term effects *(late effects)* that occur months to years after therapy.[17] Every body system can be affected to some extent by radiation therapy or chemotherapy.

Acute radiation effects generally manifest as transient inflammatory changes in highly proliferative cells (e.g., epithelial tissues). In contrast, late radiation effects occur most often in post-mitotic cells (e.g., liver, kidney, lung, heart, muscle, bone, connective tissues). Once they occur, the late effects may be progressive and generally are permanent. Examples range from skin telangiectasias to strictures, fistulas, or radiation necrosis. Alteration of the lymphatic channels (e.g., axillary lymph node dissection) may contribute to lymphedema.

Long-term effects of chemotherapy include cardiac toxicity, cataracts, arthralgia, endocrine problems, renal insufficiency, hepatitis, osteoporosis, neurocognitive problems, or other effects depending on the agents. The additive effects of multiagent chemotherapy before, during, or after a course of radiation therapy can significantly increase the resulting late effects.

The cancer survivor may be at risk for secondary cancers, including leukemia, angiosarcoma, and skin cancer. Patients treated with alkylating agents and those treated with high-dose radiation have an increased risk. The potential risk for developing a secondary cancer does not contraindicate the use of cancer treatment.

Immunotherapy and Targeted Therapy

Immunotherapy uses the immune system, the body's main defense against infection and disease, to fight cancer. Some types of immunotherapy are called *biologic therapy*. Immunotherapy can (1) boost or manipulate the immune system and create an environment that is not conducive for cancer cells to grow or (2) attack cancer cells directly. Types of immunotherapy include cytokines, vaccines, and monoclonal antibodies (Table 15.13). Antibodies are proteins made by the immune system that bind to a target antigen on the cell surface. Monoclonal antibodies (drugs ending in -mab) are the most successful immunotherapy. Because each antibody is specific to an antigen, that mechanism is used to develop specific drugs to treat cancer. Many of the monoclonal antibodies are targeted therapies.

Targeted therapy interferes with cancer growth by targeting specific cell receptors and pathways that are important in tumor growth.[18,19] Targeted therapies work at sites that are on the cell surface, at the intracellular level, or in the extracellular domain (Fig. 15.16 and Table 15.13). Targeted therapies are more selective for specific molecular targets than chemotherapy drugs. Thus they act on specific targets that are associated with cancer. A major advantage of targeted therapy is that it does less damage to normal cells.

As we identify more oncogene targets, agents are being developed that target those specific oncogenes. Targeted therapies provide personalized treatment based on the biology of the tumor. Examples of some targeted therapies are discussed in the next few paragraphs.

A major class of targeted therapy is tyrosine kinase inhibitors (Table 15.13). Tyrosine kinases are enzymes responsible for activating many proteins by signal transduction cascades. EGFR is a transmembrane molecule that works by activating intracellular tyrosine kinase (TK). Overexpression of EGFR is associated with unregulated cell growth and a poor prognosis. Drugs that inhibit EGFR suppress cell proliferation and promote *apoptosis* (programmed cell death).

EGFRs belong to the same receptor family as human epidermal growth factor receptor-2 (HER-2). It is the target for trastuzumab

(Herceptin), a drug mainly used to treat breast cancer. HER-2 is overexpressed in certain cancers (especially breast cancers). It is associated with more aggressive disease and decreased survival. Trastuzumab is a monoclonal antibody (MoAb) that binds to HER-2. It is given IV to inhibit the growth of breast cancer cells that overexpress the HER-2 protein. Lapatinib (Tykerb) is an oral agent used for breast cancer that overexpresses HER-2.

Chronic myeloid leukemia (CML) cells make an abnormal active enzyme called BCR-ABL tyrosine kinase. Drugs, such as imatinib (Gleevec), that inhibit this enzyme suppress proliferation of CML cells and promote cell death.

Angiogenesis inhibitors work by preventing the mechanisms and pathways necessary for vascularization of tumors. Bevacizumab (Avastin), a recombinant human MoAb, binds with vascular endothelial growth factor (VEGF), a compound that stimulates blood vessel growth. When bevacizumab binds with VEGF, it prevents VEGF from binding with its receptors on vascular endothelial cells and promoting new vessel formation. As a result, further tumor growth is inhibited.

Proteasomes are intracellular multienzyme complexes that degrade proteins. In cancer cells, proteasome inhibitors (e.g., bortezomib [Velcade]) promote accumulation of proteins that leads to cell death.

Cancer cells can become resistant to targeted therapies. This can occur because the (1) target changes through mutation and the therapy no longer interacts with it and (2) the tumor finds a new growth pathway and no longer depends on the target. Because of the possibility of resistance, targeted therapies work best in combination or in combination with a chemotherapy drug.

Side Effects of Immunotherapy and Targeted Therapy

The administration of one type of immunotherapy usually induces the endogenous release of other agents. The release and action of these agents result in systemic immune and inflammatory responses. The

toxicities and side effects are related to dose and schedule.

Common side effects include flu-like symptoms, including headache, fever, chills, myalgias, fatigue, malaise, weakness, photosensitivity, anorexia, and nausea. Those receiving interferon therapy almost always have flu-like symptoms. Their severity generally decreases over time. Acetaminophen given every 4 hours, as prescribed, and large amounts of fluids often reduce the severity of the flu-like syndrome. The patient is often premedicated with acetaminophen to try to prevent or decrease the intensity of these symptoms.

Tachycardia and orthostatic hypotension are common. IL-2 and MoAbs can cause *capillary leak syndrome,* which can result in pulmonary edema. Other toxic and side effects may involve the CNS, renal and hepatic systems, and cardiovascular system. These effects are found with interferons and IL-2.

A wide range of neurologic problems can occur with interferon and IL-2 therapy. The nature and extent of these problems are not yet completely understood. They are frightening to the patient and caregivers. Teach them to observe for neurologic problems (e.g., confusion, memory loss, difficulty making decisions, insomnia), report their occurrence, and institute safety and support measures.

MoAbs are given by infusion. Patients may have infusion-related symptoms, including fever, chills, urticaria, mucosal congestion, nausea, diarrhea, and myalgias.

Skin rashes are common in patients receiving EGFR inhibitors. They manifest generally as erythema and acneiform-like rash that can cover a large part of the upper body. Angiogenesis inhibitors can cause arterial thrombi, hemorrhage, hypertension, impaired wound healing, and proteinuria. Other toxicities of MoAbs include hepatotoxicity, bone marrow depression, and CNS effects.

TABLE 15.13 Drug TherapySelect Immunotherapies and Targeted Therapies

Mechanism of Action	Examples
Angiogenesis Inhibitors	
Bind vascular endothelial growth factor (VEGF), thereby inhibiting angiogenesis.	bevacizumab (Avastin) pazopanib (Votrient) ramucirumab (Cyramza)
CD20 Monoclonal Antibodies	
Bind CD20 antigen, causing cytotoxicity and radiation injury.	ibritumomab tiuxetan/yttrium-90 (Zevalin)
Bind CD20 antigen, causing cytotoxicity.	ofatumumab (Arzerra) rituximab (Rituxan)
CD52 Monoclonal Antibody	
Bind CD52 antigen (found on T and B cells, monocytes, natural killer [NK] cells, neutrophils).	alemtuzumab (Campath)
Cytokines (see Table 13.4)	
Inhibit DNA and protein synthesis. Suppress cell proliferation. Increase cytotoxic effects of NK cells.	α-interferon (Intron A)
Stimulate proliferation of T and B cells. **Activate NK cells.**	interleukin-2 (aldesleukin [Proleukin])
Human Epidermal Growth Factor Receptor-2 (HER-2)	
Monoclonal antibody to HER-2 that attaches to the antigen. It is taken into the cells and eventually kills them.	pertuzumab (Perjeta) trastuzumab (Herceptin)
Trastuzumab connected to a chemotherapy drug called DM1.	ado-trastuzumab emtansine (Kadcyla)
Immunomodulatory Drugs (IMiDs)	
Inhibit production of TNF, IL-6, and VEGF (which leads to its antiangiogenic effects). Stimulate T and NK cells and increase γ-interferon and IL-2 production.	apremilast (Otezla) lenalidomide (Revlimid) pomalidomide (Pomalyst) thalidomide (Thalomid)
Kinase Inhibitors	
Anaplastic Lymphoma Kinase (ALK) Inhibitors	
Inhibit anaplastic lymphoma kinase (ALK).	ceritinib (Zykadia) crizotinib (Xalkori)
BCR-ABL Tyrosine Kinase Inhibitors	
Inhibit BCR-ABL TK. Primarily used in chronic myeloid leukemia.	bosutinib (Bosulif) dasatinib (Sprycel) imatinib (Gleevec) nilotinib (Tasigna)
BRAF and MEK Kinase Inhibitors	
Inhibit BRAF and MEK enzymes.	dabrafenib (Tafinlar) trametinib (Mekinist) vemurafenib (Zelboraf) cobimetinib (Cotellic)
EGFR Tyrosine Kinase (TK) Inhibitors	
Inhibit epidermal growth factor receptor (EGFR) TK.	cetuximab (Erbitux) erlotinib (Tarceva) gefitinib (Iressa) panitumumab (Vectibix)
Inhibit EGFR-TK and binds HER-2.	lapatinib (Tykerb)
Multi-Tyrosine Kinase Inhibitors	
Inhibit multiple TKs.	axitinib (Inlyta) cabozantinib (Cometriq) pazopanib (Votrient) regorafenib (Stivarga) sorafenib (Nexavar) sunitinib (Sutent) vandetanib (Caprelsa)
mTOR Kinase Inhibitors	
Inhibit a specific protein known as the mechanistic target of rapamycin (mTOR).	everolimus (Afinitor) temsirolimus (Torisel)
	Table Continued

Mechanism of Action	Examples
Programmed Death Receptor (PD)-1 Blockers	
Block PD-1, a protein on T cells that normally helps keep these cells from attacking other cells. This boosts immune response against cancer cells.	nivolumab (Opdivo) pembrolizumab (Keytruda)
Proteasome Inhibitors	
Inhibit proteasome activity, which functions to regulate cell growth.	bortezomib (Velcade) carfilzomib (Kyprolis)
Vaccines	
Live attenuated strain of *Mycobacterium bovis* induces immune response. Used intravesically to treat bladder cancer (see Chapter 45).	BCG vaccine
Vaccine against prostate cancer that stimulates the immune system against the cancer (see Chapter 54).	sipuleucel-T (Provenge)

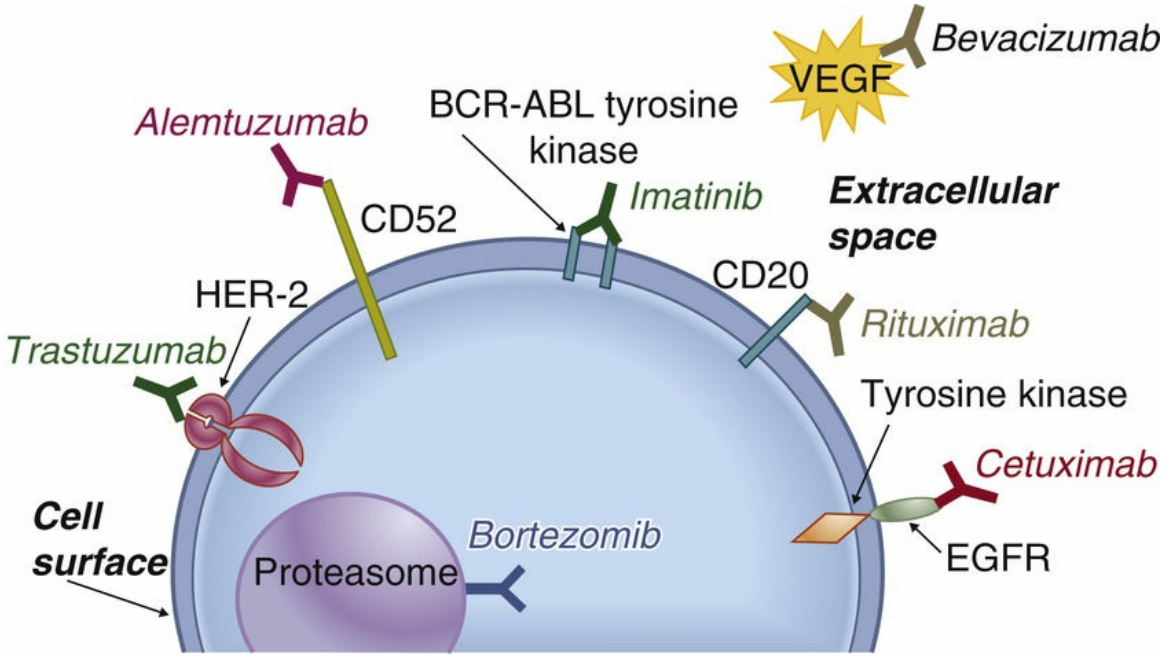

FIG. 15.16 Sites of action of targeted therapy. Examples of targeted therapy drugs that work at the specific site of action are shown in colored, italicized font. *EGFR,* Epidermal growth factor receptor; *HER-2,* human epidermal growth factor receptor-2; *VEGF,* vascular endothelial growth factor.

Nursing Management: Immunotherapy and Targeted Therapy

Some problems experienced by the patient receiving immunotherapy and targeted therapy are different from those seen with more

traditional forms of cancer treatment. These effects occur more acutely and are dose limited (e.g., effects resolve when therapy is over). Patients may be hesitant to inform the HCP of intolerable side effects. Some may be afraid to discuss side effects because they may think that the drug will be stopped. Or, they decide to stop the drug because of side effects. Assess and evaluate the patient's side effects and tolerance. Appropriate proactive nursing care can prevent these problems because you are able to intervene.

Capillary leak syndrome and pulmonary edema are problems that require critical care nursing. Bone marrow depression is generally more transient and less severe than that seen with chemotherapy. Fatigue associated with immunotherapy and targeted therapy can be so severe that it is a dose-limiting toxicity. When these agents are combined with chemotherapy, the spectrum of therapy-related effects expands.

Nursing interventions for flu-like syndrome include giving acetaminophen before treatment and every 4 hours after treatment. IV meperidine (Demerol) has been used to control the severe chills or rigors associated with some agents. Other nursing measures include monitoring vital signs and temperature, planning for periods of rest for the patient, assisting with activities of daily living (ADLs), and monitoring for adequate oral intake.

Hormone Therapy

Hormones are substances that are made in endocrine glands and function as chemical messengers in the body. The hormones estrogen and progesterone can enhance the growth of some breast cancers. Androgen (testosterone) can enhance the growth of some prostate cancers. When given as a cancer treatment, drugs (hormone therapy) can block the effects of the hormone and stop the growth of cancer cells (Table 15.14).

Corticosteroids are used in combination with many drug regimens for cancer. They are antiinflammatory agents that reduce swelling and inflammation, which may be contributing to cancer pain. They may be

used with other drugs, such as ondansetron and aprepitant, to control and prevent nausea and vomiting caused by chemotherapy.

In addition to drug manipulation of hormones, surgical interventions (oophorectomy, castration) can be used to remove the effects of the hormone on cancer growth.

Hematopoietic Growth Factors

Hematopoietic growth factors are used to support patients through their cancer treatment (Table 15.15). Colony-stimulating factors (CSFs) are a family of glycoproteins made by various cells. CSFs stimulate production, maturation, regulation, and activation of cells of the hematologic system. The name of the CSF is based on the specific cell line it affects.

Erythropoiesis-stimulating agents (ESAs) should be used only when treating anemia specifically caused by chemotherapy. ESA use is avoided in patients receiving chemotherapy with the intent to cure the disease. Their use has raised safety concerns. They can cause potential harm (thromboembolic events, shorter survival) and increase the risk for death and serious cardiovascular events when given to achieve a target hemoglobin of greater than 12 g/dL. Thus the lowest dose should be used that will gradually increase hemoglobin to the lowest level sufficient to avoid the need for blood transfusion. Monitor the hemoglobin level regularly.

TABLE 15.14 Drug TherapyHormone Therapy

Androgen Receptor Blockers	
Selectively attach to androgen receptors, blocking androgen from binding. Inhibits tumor growth.	flutamide, bicalutamide (Casodex), enzalutamide (Xtandi)
Aromatase Inhibitors	
Inhibit aromatase, thus preventing the production of estrogen.	anastrozole (Arimidex), exemestane (Aromasin), letrozole (Femara)
Corticosteroids	
Disrupt the cell membrane and inhibit synthesis of protein. Decrease circulating lymphocytes, inhibit mitosis, depress immune system, increase sense of well-being.	cortisone, dexamethasone, hydrocortisone, methylprednisolone, prednisone
Estrogens	
Interfere with the effect of testosterone.	estradiol, estramustine (Emcyt), estrogen (Menest)
Estrogen Receptor Blockers	
Selectively attach to estrogen receptors, blocking estrogen from binding. Inhibits tumor growth.	fulvestrant (Faslodex), tamoxifen, toremifene (Fareston)
Estrogen Receptor Modulator	
Has both estrogen-agonistic effects on bone and estrogen-antagonistic effects on breast tissue.	raloxifene (Evista)

TABLE 15.15 Drug TherapyHematopoietic Growth Factors Used in Cancer Treatment

Growth Factor	Drug Name	Indications	Side Effects
Erythropoietin	epoetin alfa (Epogen, Procrit)	Anemia of chronic cancer	Hypertension, thrombosis, headache
	darbepoetin alfa (Aranesp)	Anemia related to chemotherapy	Hypertension, thrombosis, headache
Granulocyte colony-stimulating factor (G-CSF)	filgrastim (Neupogen) filgrastim-sndz (Zarxio) pegfilgrastim (Neulasta) tbo-filgrastim (Granix)	Chemotherapy-induced neutropenia	Bone pain, nausea, vomiting
Granulocyte-macrophage colony-stimulating factor (GM-CSF)	sargramostim (Leukine)	Myeloid cell recovery after bone marrow transplantation	Nausea, vomiting, diarrhea, fever, chills, myalgia, headache, fatigue
Interleukin-11 (platelet growth factor)	oprelvekin (Neumega)	Thrombocytopenia related to chemotherapy	Fluid retention, peripheral edema, dyspnea, tachycardia, nausea, mouth sores

Hematopoietic Stem Cell Transplantation

Hematopoietic stem cell transplantation (HSCT) and **peripheral stem cell transplantation (PSCT)** are effective, lifesaving procedures

for the treatment of several malignant and nonmalignant diseases (Table 15.16). Both allow for the safe use of very high doses of chemotherapy agents and/or radiation therapy in patients whose tumors have developed resistance (refractory) or did not respond to standard doses of chemotherapy and radiation. Although these procedures are lifesaving, patients may have long-term or delayed complications that can affect their quality of life.

This therapeutic approach was referred to as bone marrow transplant because the bone marrow was the original source of stem cells when the procedure was first developed. However, advances in harvesting and cryopreservation technologies have opened new pathways to the collection of stem cells from the peripheral blood.[20] Consequently, the terminology has changed. Overall cure rates are steadily increasing. Even when cure is not achieved, transplantation can result in a period of remission.

TABLE 15.16 Indications for Hematopoietic Stem Cell Transplantation

Malignant Diseases
- Acute and chronic lymphocytic leukemia
- Acute and chronic myelogenous leukemia
- Hodgkin's lymphoma
- Multiple myeloma
- Myelodysplastic syndrome
- Non-Hodgkin's lymphoma

Nonmalignant Diseases
- Aplastic anemia
- Chronic granulomatous disease
- Fanconi's anemia
- Hematologic diseases
- Immunodeficiency diseases
- Severe combined immunodeficiency disease (SCID)
- Sickle cell disease (severe)
- Thalassemia
- Wiskott-Aldrich syndrome

The approach in HSCT is to eradicate diseased tumor cells and/or clear the bone marrow of its components to make way for engraftment of the transplanted, healthy stem cells. This is done by giving higher than usual dosages of chemotherapy with or without radiation therapy. Life-threatening consequences associated with pancytopenia and other adverse effects can result from this procedure. After chemotherapy and radiation therapy are over, healthy stem cells are infused. These healthy stem cells "rescue" the damaged bone marrow through subsequent proliferation and differentiation of the donated stem cells in the recipient.

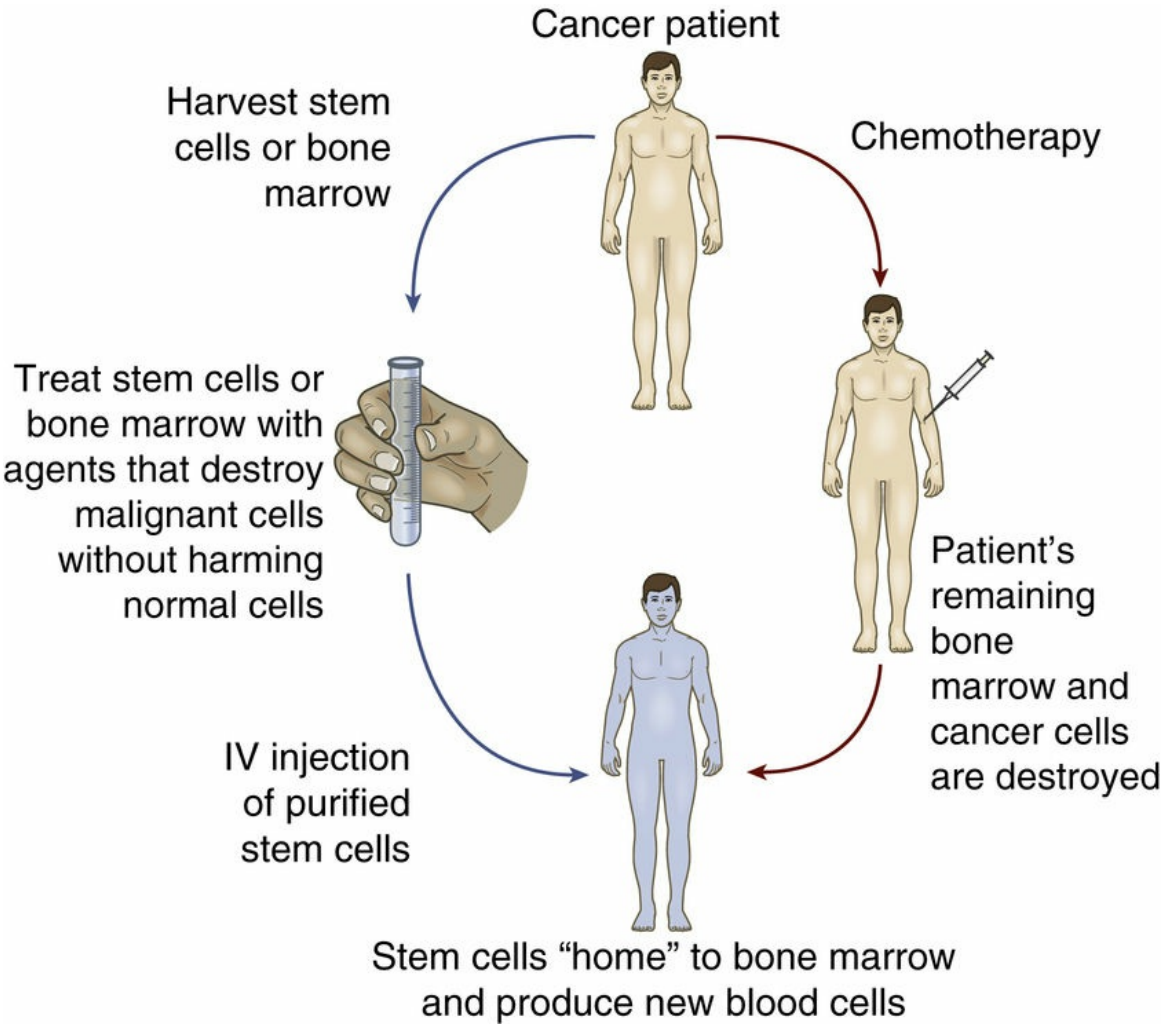

FIG. 15.17 Autologous stem cell transplant.

HSCT is an intensive procedure with many risks. Some patients die from treatment-related complications or from recurrence of the original disease. Because it is a highly toxic therapy, the patient must weigh the significant risks for treatment-related death or treatment failure (relapse) against the hope of cure.

Types of Hematopoietic Stem Cell Transplants

HSCTs are categorized as allogeneic, syngeneic, or autologous. The sources of stem cells include the bone marrow, peripheral circulating blood, and umbilical cord blood. In *allogeneic transplantation,* stem cells are acquired from a donor (graft) who, through human leukocyte antigen (HLA) tissue typing, has been determined to be HLA matched to the recipient (host). HLA typing involves testing WBCs to identify genetically inherited antigens common to both donor and recipient that are important in compatibility of transplanted tissue. (HLA tissue typing is discussed in Chapter 13.) The donor is often a family member. It may be an unrelated donor found through a national or international bone marrow registry (e.g., National Marrow Donor Program). These are known as matched unrelated donor (MUD) transplants. Increased risks and toxicities may be associated with a MUD. Common indications for allogeneic transplant are certain leukemias, multiple myeloma, and lymphoma.

Syngeneic transplantation is a type of allogeneic transplant that involves obtaining stem cells from one identical twin and infusing them into the other. Identical twins have identical HLA types and are a perfect match

In *autologous transplantation,* patients receive their own stem cells back after *myeloablative* (destroying bone marrow) chemotherapy (Fig. 15.17). The aim of this approach is purely "rescue." It allows patients to receive intensive chemotherapy and/or radiation by supporting them with their previously harvested stem cells until their marrow generates blood cells again on its own. Restoration usually takes about 4 to 6 weeks.

The newer, nonmyeloablative or reduced intensity transplant uses lower doses of radiation or chemotherapy that result in less toxicity

and myelosuppression. HSCT continues to be investigated in managing some solid tumors resistant to treatment.

Procedures

Harvest Procedures

Hematopoietic stem cells are *harvested* from a donor (for allogeneic transplantation) or from the recipient (for autologous transplantation) via 2 methods. The procedure used for harvesting stem cells from bone marrow is done in the operating room using general or spinal anesthesia. Multiple bone marrow aspirations (usually from the iliac crest, but sometimes from the sternum) are carried out to obtain stem cells. The harvested marrow is processed to strain out bone fragments. The entire bone marrow harvest procedure takes about 1 to 2 hours. The patient can be discharged after recovery. Postharvest, the donor may have pain at the collection site that lasts up to 7 days. It can be treated with mild analgesics. The donor's body will replenish the removed bone marrow in a few weeks.

In the other procedure, peripheral stem cell transplants are obtained from the peripheral blood in an outpatient procedure. It is done using cell separator equipment that automatically separates the stem cells from the blood circulating through the machine and returns the remaining blood components to the donor. The process averages about 2 to 4 hours. Sometimes it takes longer depending on donor factors and the quality of the venous access. Often it takes more than one procedure to obtain enough stem cells. Because the blood has fewer stem cells than the bone marrow, "mobilization" of stem cells from the bone marrow into the peripheral blood can be achieved with chemotherapy and/or hematopoietic growth factors.

To increase stem cell production for collection, common growth factors that are used are granulocyte-macrophage colony-stimulating factor (GM-CSF) and granulocyte colony-stimulating factor (G-CSF) (see Table 15.15). When patients are given growth factors for mobilization, stem cells are harvested 4 or 5 days after growth factor injections.

After collection, the marrow or peripheral stem cells are used immediately or bagged with preservative for cryopreservation and storage until they are needed. Since they come from the patient, autologous stem cells are sometimes treated (purged) to remove undetected cancer cells. Many different pharmacologic, immunologic, physical, and chemical agents are used for this purpose.

Umbilical cord blood is rich in hematopoietic stem cells. Successful allogeneic transplants have been done using this source. Cord blood can be HLA-typed and cryopreserved. A disadvantage of cord blood is the possibility of insufficient numbers of stem cells to allow transplant to adults. Considerable research is currently ongoing to define the optimal use of this technology.

Preparative Regimens and Stem Cell Infusions

Patients receive myeloablative dosages of chemotherapy with or without adjunctive radiation to treat the underlying disease. Total-body irradiation (TBI) can be used for immunosuppression or to treat the disease. These preparative therapies are known as the *conditioning regimen.*

Stem cell infusions are given IV. They can be injected via the slow bolus method or infused much like a blood transfusion (using tubing without a filter). The infused stem cells reconstitute the bone marrow elements, "rescuing" the recipient's hematopoietic system. It usually takes 2 to 4 weeks for the transplanted marrow to start making hematopoietic blood cells. During this period the patient has pancytopenia. The patient must be protected from exposure to infectious agents and supported with electrolyte supplements, nutrition, and blood component transfusions (as needed) to maintain adequate levels of circulating RBCs and platelets.

Complications

Bacterial, viral, and fungal infections are common after HSCT. Prophylactic therapies are used to reduce their incidence. A potentially serious complication of allogeneic transplant is graft-versus-host disease. This occurs when the T cells from the donated

marrow (graft) recognize the recipient (host) as foreign and begin to attack certain organs, such as the skin, liver, and GI tract. (Graft-versus-host disease is discussed in Chapter 13.)

The occurrence and severity of posttransplant complications depend on the drugs used (some are more toxic than others) and the stem cell source. Because stem cells in the peripheral blood are more mature than those harvested from the marrow, the hematologic recovery period in PSCT is shorter, and fewer, less severe complications are seen.

Gene Therapy

Gene therapy is an experimental therapy that involves introducing genetic material into a person's cells to fight disease. At this time, the use of gene therapy is investigational. (Gene therapy is discussed in Chapter 12.)

Complications of Cancer

The patient may develop complications related to the continual growth of the cancer into normal tissue or to the side effects of treatment.

Nutritional Problems

Malnutrition

The patient with cancer may have protein and calorie malnutrition characterized by fat and muscle depletion. The assessment of malnutrition is discussed in Chapter 39.

Soft, nonirritating high-protein and high-calorie foods should be eaten throughout the day. Foods suggested for increasing the protein intake are shown in Table 15.17. High-calorie foods that provide energy and minimize weight loss are shown in Table 15.18. Foods in a high-calorie, high-protein diet are outlined in Table 39.10.

Teach the patient to avoid extremes of temperature, tobacco, alcohol, spicy or rough foods, and other irritants. Encourage nutritional supplements (e.g., Ensure) as an adjunct to meals and fluid intake. Weigh the patient at least twice each week to monitor for weight loss.

Suggest a referral for nutritional counseling to the patient or HCP as soon as a 5% weight loss is noted or if the patient has the potential for protein and calorie malnutrition. Monitor albumin and prealbumin levels. Once a 10-lb (4.5-kg) weight loss occurs, it may be hard to maintain the patient's nutritional status.

Teach the patient to use nutritional supplements in place of milk when cooking or baking. Foods to which nutritional supplements can be easily added include scrambled eggs, pudding, custard, mashed potatoes, cereal, and cream sauces. Packages of instant breakfast can be used as indicated or sprinkled on cereals, desserts, and casseroles.

Caregivers are an integral part of the health care team. As symptom severity increases, the caregiver's role in helping the patient eat becomes increasingly critical.

If the malnutrition cannot be treated with dietary intake, it may be necessary to use enteral or parenteral nutrition. (Enteral and parenteral nutrition are discussed in Chapter 39.)

TABLE 15.17 Nutritional TherapyProtein Foods With High Biologic Value

Cheese

- Cottage: ½ cup = 15 g protein.
- American: 1 slice = 3 g protein.
- Cheddar: 1 slice = 6 g protein.
- Cream: 1 Tbsp = 1 g protein.
- Use cheese in a sandwich or as a snack.
- Add cheese to salads, casseroles, sauces, and baked potatoes.

Eggs

- Egg: 6 g protein.

- Eggnog: 1 cup = 15.5 g protein.
- Add eggs to salads, casseroles, and sauces. Deviled eggs are especially well tolerated.
- Desserts that contain eggs include angel food cake, sponge cake, custard, and cheesecake.

Meat, Poultry, Fish

- Pork: 3 oz = approx. 19 g protein.
- Chicken: ½ breast = approx. 26 g protein.
- Fish: 3 oz = approx. 30 g protein.
- Tuna fish: 6½ oz = approx. 44.5 g protein.
- Add meat, poultry, and fish to salads, casseroles, and sandwiches.
- Add strained and junior baby meats to soups and casseroles.

Milk

- Whole milk: 1 cup = 9 g protein.
- Double-strength milk (1 quart of whole milk plus 1 cup of dried skim milk blended and chilled): 1 cup = 14 g protein.
- Milk shake (1 cup of ice cream plus 1 cup of milk): 15 g protein, 415 cal.
- Use evaporated milk, double-strength milk, or half-and-half to make casseroles, hot cereals, sauces, gravies, puddings, milk shakes, and soups.
- Yogurt (regular and frozen): Select brands with high protein content: 1 cup = 10 g protein

TABLE 15.18 Nutritional TherapyHigh-Calorie Foods

Mayonnaise	1 Tbsp	=	101 cal
Butter or margarine	1 tsp	=	35 cal
Sour cream	1 Tbsp	=	72 cal
Peanut butter	1 Tbsp	=	94 cal
Whipped cream	1 Tbsp	=	53 cal
Corn oil	1 Tbsp	=	119 cal
Jelly	1 Tbsp	=	49 cal
Ice cream	1 cup	=	256 cal
Honey	1 Tbsp	=	64 cal

Altered Taste Sensation (Dysgeusia)

Cancer cells may release substances that stimulate the bitter taste buds. The patient may have changes in the sweet, sour, and salty taste sensations. Meat may taste bitter or bland. We do not know the cause of these taste changes.

Teach patients with altered taste problems to avoid foods that they dislike. Often, the patient may feel compelled to eat certain foods that

are believed to be beneficial. Tell the patient to try different ways to mask the taste changes. Some find stronger seasonings and spices effective. Others find it better to avoid strong flavors and eat more bland foods. Avoiding strong smells, drinking more water with food, oral care before eating, eating smaller amounts more often, and using plastic utensils may help.[21]

Cancer Cachexia

Cancer cachexia (wasting syndrome) is a complex, multifactorial syndrome characterized by anorexia and/or unintended loss of weight and appetite. It is accompanied by generalized tissue wasting, skeletal muscle atrophy, immune dysfunction, and metabolic problems. The weight loss cannot be reversed nutritionally. Patients with upper GI and pancreatic cancers are prone to cachexia. As cancer progresses, cachexia can affect many cancer patients. It is associated with increased morbidity.[22]

The best management of cancer cachexia is to effectively treat the cancer. Unfortunately, this is not a realistic goal for patients with advanced cancer. A second option is to increase nutritional intake, but this does not completely reverse the wasting associated with cachexia. A third option is to use megestrol acetate (Megace). It is a synthetic form of the hormone progesterone, which stimulates appetite in patients with cachexia.

Infection

Infection is a leading cause of death in the patient with cancer. The usual sites of infection include the lungs, GU system, mouth, rectum, peritoneal cavity, and blood (septicemia). Infection occurs because of the ulceration and necrosis caused by the tumor, the tumor compressing vital organs, and neutropenia from the cancer or cancer treatment.

Teach patients at risk for neutropenia to call their HCP if they have a temperature of 100.4° F (38° C) or greater. Assessment often includes

signs and symptoms of fever, determination of possible cause (e.g., sinuses, mucous membranes, respiratory, GI, urinary, sites of any tubes or lines), and CBC.

Many patients are neutropenic when an infection develops. In these persons, infection may cause significant morbidity. It may be rapidly fatal if not treated promptly. The classic manifestations of infection are often subtle or absent in a patient with neutropenia and a depressed immune system. (Neutropenia was discussed earlier in this chapter on p. 248. It is also discussed in Chapter 30.)

Oncologic Emergencies

Oncologic emergencies are life-threatening emergencies that can occur because of cancer or cancer treatment. These emergencies can be obstructive, metabolic, or infiltrative (Table 15.19).

Obstructive Emergencies

Obstructive emergencies are mainly caused by tumor obstruction of an organ or blood vessel. They include superior vena cava syndrome (Fig. 15.18), spinal cord compression syndrome, third space syndrome, and intestinal obstruction.

Metabolic Emergencies

Metabolic emergencies are caused by the production of ectopic hormones directly from the tumor or from metabolic problems caused by the cancer or cancer treatment. Ectopic hormones arise from tissues that do not normally make these hormones. Cancer cells return to a more embryonic form, thus allowing the cells' stored potential to become evident.

Metabolic emergencies include syndrome of inappropriate antidiuretic hormone secretion (Chapter 49), hypercalcemia (Chapter 16), tumor lysis syndrome, septic shock (Chapter 66), and disseminated intravascular coagulation (Chapter 30).

Infiltrative Emergencies

Infiltrative emergencies occur when cancer infiltrates major organs or from cancer treatment. The most common infiltrative emergencies are cardiac tamponade and carotid artery rupture.

Cancer Pain

Moderate to severe pain occurs in around 50% of patients who are receiving active treatment for their cancer and in 80% to 90% of patients with advanced cancer.[23] What is concerning is that these statistics have not changed in the past 30 years. Undertreatment of cancer pain is common. It causes needless suffering, decreases quality of life, and increases the burden on caregivers.

Pain Assessment

Inadequate pain assessment is the single greatest barrier to effective pain management. Data, such as vital signs and patient behaviors, are not reliable indicators of pain, especially long-standing, chronic pain. It is important to know if pain is persistent or episodic, positional, or breakthrough pain. It is essential that a comprehensive pain assessment include a detailed history to elicit the characteristics of pain. This includes the quality, location, intensity, duration, and precipitating and alleviating factors. Distinguishing between types of pain (e.g., visceral, bone, neuropathic) is important in developing an effective pain management plan.

Assess pain on an ongoing basis to determine the effectiveness of the treatment plan. Obtain data and document at regular intervals the location and intensity of the pain, what it feels like, and how it is relieved. Assess change in pain (e.g., a change in the intensity, character, worsening, or location of pain) to determine the cause (e.g., progression of disease).

Always believe the patient's report and accept it as the primary source of assessment data. Table 15.20 presents assessment questions

that may facilitate data collection. Have patients keep a pain management diary.[23]

Pain Management

Pain management for the cancer patient must address both persistent and breakthrough components of pain if they are present. Adjuvant therapies need to be delivered specific to the type or nature of the pain.

Drug therapy, including NSAIDs (e.g., ibuprofen), opioids (e.g., morphine), and adjuvant pain medications, should be used and selected based on the character and/or cause of the pain. Opioids normally are prescribed for the treatment of moderate to severe cancer pain. Drug dosages are adjusted to control pain with the fewest side effects. Analgesic medications (e.g., morphine, fentanyl) should be given on a regular schedule (around the clock) with more doses available as needed for breakthrough pain. In general, oral administration is preferred. Other routes (e.g., transdermal, transmucosal) are options.

Treatment plans should be developed that balance analgesia and side effects to maintain optimal functional status. It is important for you to pay attention to common side effects of pain medications (e.g., constipation) to ensure the patient's well-being and adherence with the pain management program. NSAIDs often serve as helpful adjuncts to opioid therapy, especially for bone pain. Antidepressant and antiseizure drugs may be helpful in managing neuropathic pain, which is often resistant to opioids.

TABLE 15.19 Oncologic Emergencies

Description	Manifestations	Management
Obstructive Emergencies		
Spinal Cord Compression		
• **Neurologic emergency caused by cancer in epidural space of spinal cord.** • **Common causes are breast, lung, prostate, GI, renal cancers, melanoma.** • **Lymphomas can invade epidural space.**	• Intense, localized, and persistent back pain with vertebral tenderness. • Motor weakness, sensory paresthesia and loss. • Autonomic dysfunction (e.g., change in bowel or bladder function).	• Radiation therapy, corticosteroids. • Surgical decompressive laminectomy. • Activity limitations and pain management.
Superior Vena Cava Syndrome (SVCS)		
• **Results from obstruction of superior vena cava by tumor or thrombosis.** • **Common causes are lung cancer, non-Hodgkin's lymphoma, metastatic breast cancer.** • **Presence of central venous catheter and previous mediastinal radiation increase risk.**	• Facial edema, periorbital edema. • Distention of veins of head, neck, and chest (Fig. 15.18). • Headache, seizures. • Mediastinal mass on chest x-ray.	• Considered a serious medical problem. • Radiation therapy to site of obstruction. • Chemotherapy for tumors more sensitive to this therapy.
Third Space Syndrome		
• **Shifting of fluid from vascular space to interstitial space.** • **Occurs due to extensive surgical procedures, immunotherapy, septic shock.**	• Signs of hypovolemia: hypotension, tachycardia, low central venous pressure, decreased urine output.	• Fluid, electrolyte, plasma protein replacement. • During recovery hypervolemia can occur, causing hypertension, increased central venous pressure, weight gain, shortness of breath.
Metabolic Emergencies		
Hypercalcemia		
• **Occurs in metastatic disease of bone or multiple myeloma, or when a parathyroid hormone–like substance is secreted by cancer cells.** • **Immobility and dehydration can contribute to or worsen hypercalcemia.**	• Serum calcium higher than 12 mg/dl. (3 mmol/L) often produces symptoms. • Apathy, depression, fatigue, muscle weakness, ECG changes, polyuria and nocturia, anorexia, nausea, vomiting. • High calcium elevations can be life threatening. • Chronic hypercalcemia can result in nephrocalcinosis and irreversible renal failure.	• Treat primary disease. • Hydration (3 L/day) and bisphosphonate therapy. • Diuretics (especially loop diuretics) used to prevent heart failure or edema. • Infusion of bisphosphonate zoledronate (Zometa) or pamidronate (Aredia).
Syndrome of Inappropriate Antidiuretic Hormone (SIADH)		
• **Tumor cells can produce abnormal or sustained production of antidiuretic hormone (ADH).** • **Many chemotherapy agents may contribute to ectopic ADH production or potentiate ADH effects.**	• Water retention and hyponatremia (hypotonic hyponatremia) (see Chapter 49). • Weight gain without edema, weakness, anorexia, nausea, vomiting, personality changes, seizures, oliguria, decrease in reflexes, coma.	• Treat underlying cancer. • Take measures to correct sodium-water imbalance, including fluid restriction, oral salt tablets or isotonic (0.9%) saline administration, and IV 3% sodium chloride solution (severe cases). • Furosemide (Lasix) used in early phases. • Monitor sodium level. Correcting SIADH quickly may cause seizures or death.
Tumor Lysis Syndrome (TLS)		
• **Metabolic complication characterized by rapid release of intracellular components in response to chemotherapy and radiation therapy (less often).** • **Massive cell destruction releases intracellular components (potassium, phosphate, DNA, RNA) that are metabolized to uric acid by liver.**	• *Hallmark signs*: hyperuricemia, hyperphosphatemia, hyperkalemia, hypocalcemia. • Weakness, muscle cramps, diarrhea, nausea, vomiting. • Occurs within 24–48 hr after starting chemotherapy. • May last 5–7 days. • Metabolic abnormalities and concentrated uric acid (which crystallizes in distal tubules of kidneys) can lead to acute kidney injury.	• Identify patients at risk. • Increase urine production using hydration therapy. • Decrease uric acid concentrations using allopurinol. • Use IV sodium bicarbonate to counter effects of acidic properties that are released.
Infiltrative Emergencies		
Cardiac Tamponade		
• **Fluid accumulation in pericardium.** • **Caused by constriction of pericardium by tumor or pericarditis from radiation therapy to the chest.**	• Heavy feeling over chest, shortness of breath, tachycardia, cough, dysphagia, hiccups, hoarseness. • Nausea, vomiting, excessive perspiration. • Decreased level of consciousness, distant or muted heart sounds. • Extreme anxiety.	• Decrease fluid around heart using (1) surgery to create a pericardial window or an (2) indwelling pericardial catheter. • Administer O_2 therapy, IV hydration, and vasopressor therapy.

Description	Manifestations	Management
Carotid Artery Rupture		
• **Invasion of arterial wall by tumor or erosion following surgery or radiation therapy.** • **Occurs most often in patients with head and neck cancer.**	• Bleeding: ranges from minor oozing to spurting of blood in the case of a "blowout" of artery.	• Give IV fluids and blood products. • Surgery: ligation of carotid artery above and below rupture site and reduction of local tumor.

FIG. 15.18 Superior vena caval obstruction in bronchial cancer. Note the swelling of the face and neck and the development of collateral circulation in the veins.
From Forbes CD, Jackson WF: *Colour atlas and text of clinical medicine,* ed 3, London, 2003, Mosby.

TABLE 15.20 Pain Assessment in Cancer Patients

Characteristic	Questions to Ask
Location	• Where is the pain? • Is the pain in more than one place? Is the pain in a new location? • Does location of pain correlate with known diagnosis?
Intensity	• How bad is the pain? • Rate the pain on a scale of 0 to 10. (See Chapter 8 for rating scales.)
Quality	• What does the pain feel like—sharp, dull, burning, shooting, aching, or other? (See Chapter 8 for descriptors.)
Pattern	• Has the pain changed? • Is the pain getting better, worse, or unchanged? • What makes the pain better or worse?
Relief measures	• What do you do to control your pain? • Do you use medications? • Do the relief measures help much? How much?

Radioactive drugs (e.g., samarium-153) may help patients with diffuse bone pain, especially if no further chemotherapy is planned. Patients may have an initial pain *flare* after administration. Nerve blocks or epidural or intrathecal analgesia may be used to treat patients with unrelieved pain or to minimize the use of opioids.

Discuss the goals of analgesic therapy with patients, especially those needing large or chronic doses of opioids. You need to assess the patient for risk factors for opioid misuse. Patient teaching should clarify myths and misconceptions and reassure patients and caregivers that cancer pain can be effectively relieved. Fear of addiction is not warranted. However, it must be addressed as part of patient teaching. It is a significant barrier for patients and nurses in appropriate pain management. Stress that addiction and tolerance are not problems associated with effective cancer pain management. Nondrug interventions, including relaxation therapy and imagery, can be effectively used to manage pain (see Chapter 6). Other strategies to relieve pain are discussed in Chapter 8.

Coping with Cancer and Treatment

You have a key role in assisting patients in coping with the psychosocial issues associated with cancer and cancer treatment. The patient may have a variety of concerns, including fears of dependency, loss of control, family and relationship stress, financial burden, and fear of death. Anxiety and fear may occur throughout the

cancer continuum, including at diagnosis, during or after treatment, and in association with long-term follow-up.

TABLE 15.21 Factors Affecting How Patients Cope With Cancer

Factor	Description
Ability to cope with stressful events in the past	How patients coped with previous stressful events (e.g., loss of job, major disappointment, significant traumatic event) affects how they cope with diagnosis of cancer.
Ability to express feelings and concerns	Patients who express feelings and needs and ask for help cope better than those who internalize feelings and needs.
Age at the time of diagnosis	Age determines coping strategies to a great degree. For example, a young mother with cancer may have different concerns than a 70-yr-old woman with cancer.
Attitude associated with the cancer	Patients who feel in control and have a positive attitude about cancer and cancer treatment cope better with the diagnosis and treatment of cancer than those who feel hopeless, helpless, and out of control.
Availability of significant others	Patients who have effective support systems cope better than those who do not.
Disruption of body image	Disruption of the body image (e.g., radical neck dissection, alopecia, mastectomy) may intensify the psychologic impact of cancer.
Extent of disease	Cure or control of the disease process is usually easier to cope with than the reality of terminal illness.
Past experience with cancer	Negative experiences with cancer (personal or in others) influence perceptions about the current situation.
Symptoms	Symptoms such as fatigue, nausea, diarrhea, and pain may intensify the psychologic impact of cancer.

Repetitive office visits or hospitalizations, continuing medications, and frequent laboratory testing force the patient to confront the cancer on a daily basis. Treatment-related uncertainties and fears are often most evident at the beginning of therapy. However, anxiety and fear

may be present throughout treatment and when therapy is completed (e.g., fear of recurrence, less available support).

Adaptation and coping with a cancer diagnosis may be influenced by a variety of patient factors. These include demographics, prior coping skills and strategies, social support, and religious and spiritual beliefs (Table 15.21). You are in a key position to assess the patient's and caregiver's responses and support positive coping strategies. To promote effective coping and to support them during the various stages of cancer, you should:

- Be available and continue to be available, especially during difficult times.
- Exhibit a caring attitude.
- Listen actively to fears and concerns.
- Help provide relief from distressing symptoms.
- Provide accurate, essential information about cancer and cancer care.
- Help establish realistic expectations about what the patient will experience.
- Maintain a relationship based on trust and confidence. Be open, honest, and caring in the approach.
- Use touch to show caring. A squeeze of the hand or a hug may at times be more effective than words.
- Help the patient in setting realistic, reachable short-term and long-term goals.
- Help the patient maintain usual lifestyle patterns.
- Maintain hope, which is the key to effective cancer care.

Hope varies, depending on the patient's status—hope that the symptoms are not serious, hope that the treatment is curative, hope for independence, hope for relief of pain, hope for a longer life, hope to achieve meaningful goals, or hope for a peaceful death. Hope provides control over what is occurring and is the basis of a positive attitude toward cancer and cancer care.

Tell patients that they will be followed, and reassure them that

support is ongoing. Give information and support to help minimize the negative impact of cancer treatment on quality of life. Patient teaching and symptom management help patients to self-manage their illness (e.g., adjusting treatment schedules to allow patients to work when possible, making referrals to support groups). Work with the oncology nurse navigators, who serve as the liaison between the patient and members of the interprofessional care team.

Arrange for patients to meet with people who have successfully completed therapy. This can increase their hopefulness and confidence. Make regular supportive telephone contacts between office visits. Assist with planning for transportation, nutrition, and emotional support.

Do not forget the caregivers. They need education and support throughout the trajectory of diagnosis, treatment, and follow-up. Patients and caregivers may benefit from a variety of psychosocial interventions. These include supportive listening, stress management techniques, individual or group counseling, and cognitive-behavioral therapy. Assess the psychosocial concerns and emotional responses of patients, caregivers, and families so you can connect them with appropriate supportive care resources. Use the available resources in the community, such as the ACS, Cancer Lifeline, churches, and other community resources.

Gerontologic Considerations: Cancer

Cancer is usually a disease of aging, with 78% of cancers occurring in people 55 years or older.[1] Cancer mortality rates are exceedingly high in older adults. Of all deaths due to cancer, 70% occur in those over age 65. This is especially important since the normal life span is increasing and the proportion of the population who are older than 65 years is increasing.

Manifestations of cancer in older adults may be mistakenly attributed to age-related changes and ignored by the person.[24] Older adults are especially at risk for complications of both cancer and cancer treatment. This is due to their decline in physiologic

functioning, social and emotional resources, and cognitive function.

The older adult's functional status should be taken into consideration when developing a treatment plan. Age alone is not a good predictor of tolerance or response to treatment. Advances in cancer treatment are making cancer therapies beneficial to more older adults, including those with suboptimal health.

Ethical/Legal Dilemmas

Medical Futility

Situation

D.M., a 65-yr-old Asian woman, has breast cancer with metastasis to the liver and bone. The family asks you why their mother is not receiving chemotherapy. They want to make sure that she will be resuscitated should her heart stop. They are aware of her diagnosis and that she only has a few months to live. In morning rounds, you were told that D.M. does not want any more treatment that would prolong her life.

Ethical/Legal Points for Consideration

- Although court decisions have varied, legally there is substantial consensus about the right to privacy (a constitutional right), right to informed consent and refusal of treatment, and rights about end-of-life decision making. The *Code of Ethics for Nurses* addresses the key components in the informed consent process that nurses must address.[1]
- A patient who is an adult and is competent (defined as capable of understanding and interpreting information, making choices, and communicating those choices) solely retains the right to make personal health care decisions.
- The Patient Self-Determination Act requires that the patient be asked on admission whether they have an advance directive. If

available, it is placed in the medical record. If the patient does not have an advance directive, it must be documented.

- The National POLST Paradigm is an approach to end-of-life planning that emphasizes patients' wishes about the care they receive. The POLST Paradigm is an approach to end-of-life planning emphasizing the medical orders and includes coverage regardless of location (e.g., hospital, home, assisted living).[2]
- Often families have difficulty accepting the finality of a terminal diagnosis.
- Sometimes family members have conflicting interests (e.g., finances, property, inheritance rights) that influence their decision-making abilities.

Discussion Questions

1. How can you help D.M. communicate her wishes to her family?
2. How can you and the interprofessional team help the family in planning end-of-life care that incorporates their mother's wishes?
3. What are the cultural issues in D.M.'s case?

Assess the patient at the time of diagnosis to identify important issues that may affect decisions about treatment options. Issues to assess include projected life expectancy, estimate of morbidity from

cancer, co-morbidities that would affect treatment, and patient decision-making capacity and wishes.

Some important questions to consider when an older adult is diagnosed with cancer include: Will the treatment provide more benefits than harm? Will they be able to tolerate the treatment safely? Is there a need to treat co-morbidities or nutritional or functional status before starting treatment? What are the patient's preferences and wishes?

Cancer Survivorship

As the overall death rate from cancer decreases, the number of cancer survivors continues to increase. It is estimated that there are currently more than 14.5 million cancer survivors in the United States. Some of these persons are cancer free. Others still have evidence of cancer and may be receiving treatment. The increase in survivorship is attributed to the aging and growth of the population and improvements in early detection and treatment. Survival statistics vary by the type and stage of cancer.[1,25]

TABLE 15.22 Patient TeachingCancer Survivors

You can help cancer survivors by doing the following:

1. Provide all cancer patients with a treatment summary and care plan outlining treatment exposures, risk for late effects, preventive care recommendations, and follow-up surveillance plan after completion of treatment.
    - Care plans should clearly identify all members of the interprofessional team and their responsibilities for follow-up care.
    - Include referrals to appropriate supportive care and community resources that would help the patient in recovery or ongoing care.
2. Coordinate care among the oncology team, primary HCP, and other specialists.

3. Teach HCPs about the needs of cancer survivors, including long-term effects of cancer and cancer treatments.

4. Teach cancer survivors to look for and report any ongoing symptoms resulting from treatment, including late effects of radiation therapy and chemotherapy.

5. Teach cancer survivors healthy behaviors:

- *Prevention:* good nutrition, exercise, smoking avoidance, maintaining proper weight, cardiac risk reduction, bone health.
- *Early detection:* routine health screenings (e.g., breast, colon), cholesterol, diabetes, osteoporosis screening as recommended.

6. Encourage cancer survivors to have regular follow-up examinations with their HCP.

7. Assess for psychologic, financial, health insurance, or vocational problems related to cancer. Assist patients in getting appropriate help if necessary.

The rapid increase in cancer survivors has been accompanied by a greater awareness of the long-term health and quality-of-life issues that a cancer diagnosis imposes. Cancer survivors have a variety of long-term and late effects after treatment. You need to be aware of the effects of the various treatments so that you can teach patients and their caregivers.

The impact of cancer and its treatment confers greater risk for non–cancer-related death and co-morbidities (e.g., heart disease, diabetes, metabolic syndrome, endocrine dysfunction, osteoporosis) among cancer survivors. Cancer survivors may continue to have symptoms or functional impairment related to treatment for years after treatment.

The impact of a cancer diagnosis can affect many aspects of a patient's life. Cancer survivors often report financial, vocational, marital, and spiritual concerns long after treatment is over. Psychosocial and emotional issues can play a profound role in a patient's life after cancer. Many find living in uncertainty challenging.

Some patients may wish to return to their normal lives as soon as possible. They may not go to scheduled follow-up appointments. Others become cancer advocates or active members of a cancer support group. Still others allow their lives to revolve around the cancer and may even resist giving up the illness role.

Tips to help cancer survivors are described in Table 15.22. Connecting cancer survivors to online support and resources is a strategy to enhance positive health outcomes (Table 15.23).

TABLE 15.23 Resources for Cancer Survivors

Organization	Purpose
ACS Cancer Survivors Network	Provides survivorship information and resources and online forum for connecting with others affected by cancer. (https://csn.cancer.org/)
CancerCare	Provides a variety of free support services delivered by professional oncology social workers for patients and anyone else affected by cancer. (www.cancercare.org)
Cancer.Net	American Society of Clinical Oncology (ASCO) patient support site that includes extensive information and resources for cancer survivors. (www.cancer.net)
National Cancer Institute Office of Cancer Survivorship	Supports research into the short- and long-term physical, social, emotional, and economic effects of cancer survivorship. Offers educational and support resources for cancer survivors, caregivers, and advocates. (www.cancercontrol.cancer.gov/ocs/)
National Coalition for Cancer Survivorship	Advocates for quality cancer care. Seeks to teach patients and advocates about issues that affect the quality of life of cancer survivors. (www.canceradvocacy.org)

Culturally Competent Care: Cancer

Cancer incidence and death rates are disproportionately higher in blacks than in whites and other minority groups. Although overall racial disparities in cancer death rates have been declining, death rates continue to be higher among blacks than whites. Blacks are more likely to have later stage disease at the time of diagnosis than whites.[1]

Promoting Health Equity

Cancer

- Cancer incidence and death rates for men are highest among blacks, followed by whites, Hispanics, and Asians/Pacific Islanders.
- Cancer incidence rates for women are highest among whites, followed by blacks, Hispanics, and Asians/Pacific Islanders.
- Cancer death rates for women are highest among blacks, followed by whites, Hispanics, and Asians/Pacific Islanders.

Differences in survival rates from cancer are attributed to a combination of factors. These include poverty, difficult access to and poorer quality of health care, more co-morbid conditions, and differences in tumor biology. Disparities in cancer care exist throughout the continuum from cancer prevention and screening to end-of-life care and survivorship. The disparity in prevention and screening results in cancer being in advanced stages at the time of diagnosis.[1,2]

Culturally competent care in oncology is needed to meet the needs of diverse groups. It involves awareness of personal background, how culture affects care delivery, and how to adapt to meet cultural needs. Nurses need to actively seek to understand cultural differences to meet the patient's needs. Culture is discussed in Chapter 2. Culturally competent care related to specific cancers is in the chapters in which the cancer is discussed.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Trends in the incidence and death rates of cancer include the fact that

   a. a higher percent of women than men have lung cancer.

b. lung cancer is the most common type of cancer in men.
c. blacks have a higher death rate from cancer than whites.
d. breast cancer is the leading cause of cancer deaths in women.

2. What features of cancer cells distinguish them from normal cells *(select all that apply)*?
a. Cells lack contact inhibition.
b. Cells undergo rapid proliferation.
c. Cells return to a previous undifferentiated state.
d. Proliferation occurs when there is a need for more cells.
e. New proteins characteristic of embryonic stage emerge on cell membrane.

3. A characteristic of the stage of progression in cancer development is
a. oncogenic viral transformation of target cells.
b. a reversible steady growth facilitated by carcinogens.
c. a period of latency before clinical detection of cancer.
d. proliferation of cancer cells despite host control mechanisms.

4. The primary protective role of the immune system related to malignant cells is
a. surveillance for cells with tumor-associated antigens.
b. binding with free antigens released by all cancer cells.
c. producing blocking factors that immobilize cancer cells.
d. reacting to a new set of antigenic determinants on cancer cells.

5. The nurse is caring for a 59-year-old woman who had

surgery 1 day ago to remove an ovarian cancer mass. The patient is awaiting the pathology report. She is tearful and says that she is scared to die. The *most* effective nursing intervention at this point is to use this opportunity to

a. motivate change in an unhealthy lifestyle.

b. teach her about the 7 warning signs of cancer.

c. discuss healthy stress relief and coping practices.

d. let her communicate about the meaning of this experience.

6. The goals of cancer treatment are based on the principle that

a. surgery is the single most effective treatment for cancer.

b. initial treatment is always directed toward cure of the cancer.

c. a combination of treatment modalities is effective for controlling many cancers.

d. although cancer cure is rare, quality of life can be increased with treatment modalities.

7. The *most* effective method of administering a chemotherapy agent that is a vesicant is to

a. give it orally.

b. give it intraarterially.

c. use an Ommaya reservoir.

d. use a central venous access device.

8. The nurse explains to a patient undergoing brachytherapy of the cervix that she

a. must undergo simulation to locate the treatment area.

b. requires the use of radioactive precautions during nursing care.

c. may have desquamation of the skin on the abdomen and upper legs.

d. requires shielding of the ovaries during treatment to prevent ovarian damage.

9. A patient on chemotherapy and radiation for head and neck cancer has a WBC count of $1.9 \times 10^3/\mu L$, hemoglobin of 10.8 g/dL, and a platelet count of $99 \times 10^3/\mu L$. Based on the CBC results, what is the *most* serious clinical finding?

a. Cough, rhinitis, and sore throat

b. Fatigue, nausea, and skin redness at site of radiation

c. Temperature of 101.9° F, fatigue, and shortness of breath

d. Skin redness at site of radiation, headache, and constipation

10. To prevent fever and shivering during an infusion of rituximab (Rituxan), the nurse should premedicate the patient with

a. aspirin.

b. acetaminophen.

c. sodium bicarbonate.

d. meperidine (Demerol).

11. The nurse counsels the patient receiving radiation therapy or chemotherapy that

a. effective birth control methods should be used for the rest of the patient's life.

b. after successful treatment, patients can expect a return to

their previous level of function.

c. the cycle of fatigue-depression-fatigue that may occur during treatment may be reduced by restricting activity.

d. nausea and vomiting can usually be managed with antiemetic drugs, diet modification, and other interventions.

12. A patient on chemotherapy for 10 weeks started at a weight of 121 lb. She now weighs 118 lb and has no sense of taste. Which nursing intervention would be a *priority*?

a. Discuss with the provider the need for parenteral nutrition.

b. Teach the patient to eat foods that are fatty, fried, or high in calories.

c. Tell the patient to drink a nutritional supplement beverage three times a day.

d. Have the patient try various spices and seasonings to enhance the flavor of food.

13. A 70-year-old male patient has multiple myeloma. His wife calls to report that he sleeps most of the day, is confused when awake, and reports nausea and constipation. Which complication of cancer is this *most* likely caused by?

a. Hypercalcemia

b. Tumor lysis syndrome

c. Spinal cord compression

d. Superior vena cava syndrome

14. A patient has recently been diagnosed with early stages of breast cancer. What is *most* appropriate for the nurse to

focus on?

a. Maintaining the patient's hope

b. Preparing a will and advance directives

c. Discussing replacement child care for the patient's children

d. Discussing the patient's past experiences with her grandmother's cancer

1. c, 2. a, c, e, 3. d, 4. a, 5. d, 6. c, 7. d, 8. b, 9. c, 10. b, 11. d, 12. d, 13. a, 14. a

Fluid, Electrolyte, and Acid-Base Imbalances

Margaret R. Rateau

LEARNING OUTCOMES

1. Describe the composition of the major body fluid compartments.
2. Define processes involved in regulating the movement of water and electrolytes between the body fluid compartments.
3. Describe the etiology, laboratory diagnostic findings, clinical manifestations, and nursing and interprofessional management of the following disorders:
   a. Extracellular fluid volume imbalances: fluid volume deficit and fluid volume excess
   b. Sodium imbalances: hypernatremia and hyponatremia
   c. Potassium imbalances: hyperkalemia and hypokalemia
   d. Magnesium imbalances: hypermagnesemia and hypomagnesemia
   e. Calcium imbalances: hypercalcemia and hypocalcemia
   f. Phosphate imbalances: hyperphosphatemia and hypophosphatemia
4. Identify the processes involved in maintaining acid-base balance.
5. Discuss the etiology, diagnostic findings, clinical manifestations, and nursing and interprofessional management of the following acid-base imbalances: metabolic acidosis, metabolic alkalosis, respiratory acidosis, and respiratory alkalosis.
6. Describe the composition of and indications for common IV fluid solutions.
7. Discuss the types and nursing management of commonly used

central venous access devices.

Conceptual Focus

Acid-Base Balance
Fluids and Electrolytes
Nutrition

Homeostasis

Body fluids and electrolytes play an important role in maintaining *homeostasis,* the body's stable internal environment. Body fluids are in constant motion transporting nutrients, electrolytes, and oxygen to cells and carrying waste products away from cells. The body uses many adaptive responses to keep the composition and volume of fluids and electrolytes within narrow limits to maintain homeostasis and promote health.

Many diseases and their treatments affect fluid and electrolyte balance. Conceptually, these imbalances are often reflected by changes in perfusion, gas exchange, mobility, and cognition. For example, a patient with metastatic colon cancer may develop hypercalcemia because of bone destruction from tumor invasion and have severe muscle weakness and confusion. Chemotherapy used to treat the cancer may result in nausea and vomiting, which causes dehydration and acid-base imbalances. When correcting dehydration with IV fluids, the patient needs close monitoring to prevent fluid overload.

It is important to anticipate the potential for fluid and electrolyte imbalances associated with certain disorders and medical therapies, recognize the signs and symptoms of imbalances, and intervene with the appropriate action. This chapter describes the (1) normal control of fluids, electrolytes, and acid-base balance; (2) conditions that disrupt homeostasis and resulting manifestations; and (3) actions that the health care provider and you can take to manage fluid, electrolyte, and acid-base imbalances and restore homeostasis.

Water Content of the Body

The body is composed primarily of water. It accounts for about 50% to 60% of body weight in the adult. Water content varies with body mass, gender, and age (Fig. 16.1). Lean body mass has a higher percentage of water, while adipose tissue has a lesser percentage of water. So, the more fat present in the body, the less the total water content. Women generally have a lower percentage of body water because they tend to have less lean body mass than men. Older adults also tend to have less lean body mass, resulting in a lower percentage of body water when compared to younger adults. In older adults, body water content averages 45% to 50% of body weight. This places them at a higher risk for fluid-related problems than young adults.

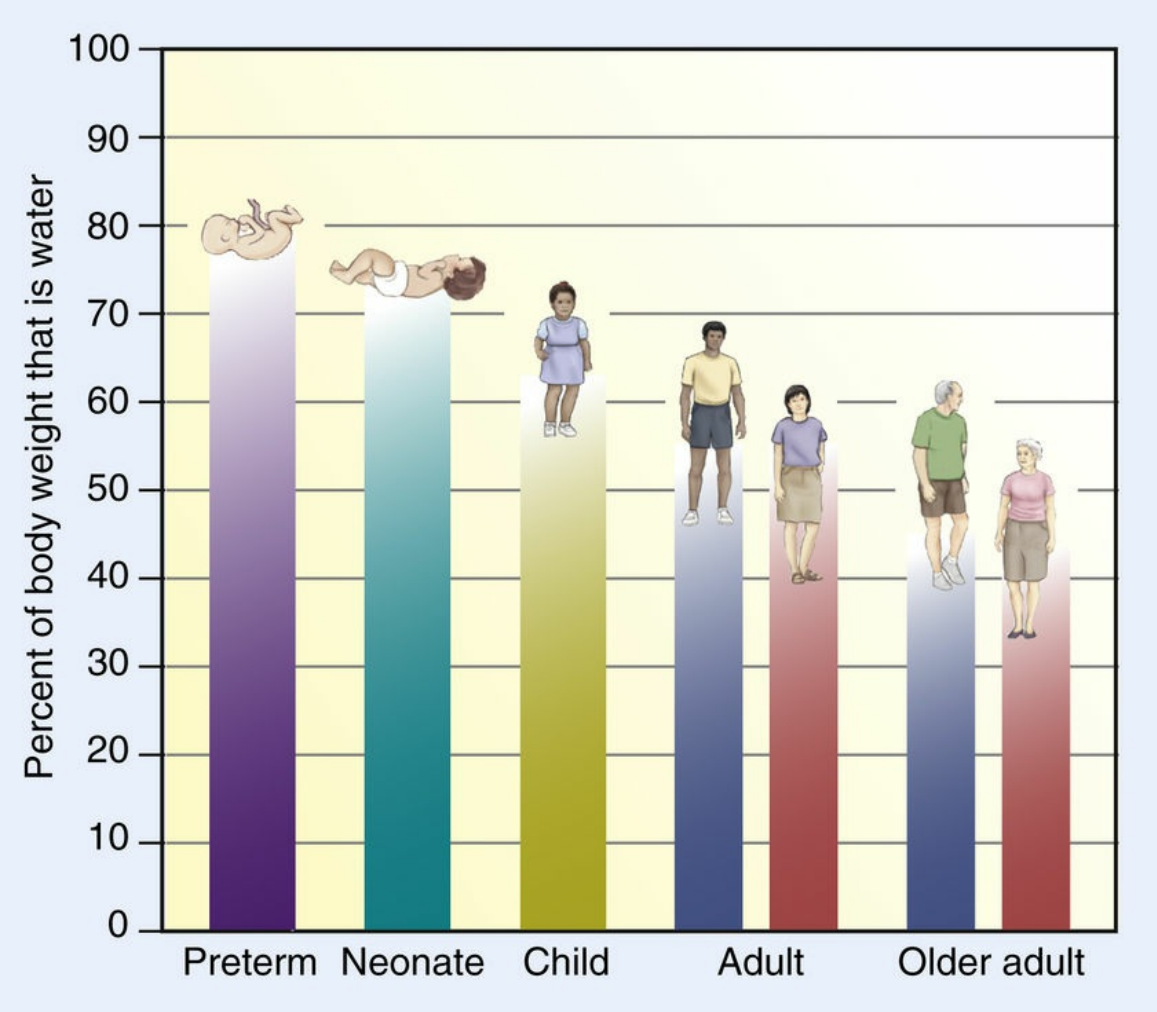

FIG. 16.1 Body water over the life span.

Body Fluid Compartments

The 2 fluid compartments in the body are the *intracellular space* (inside the cells) and the *extracellular space* (outside the cells) (Fig. 16.2). About two thirds of body water is found within cells and is termed *intracellular fluid* (ICF). ICF makes up about 40% of body weight of an adult. This means a 70-kg young man would have about 42 L of water, with about 28 L of that water within his cells.

The fluid in the extracellular space is *extracellular fluid* (ECF). The 2 main compartments containing ECF are the *interstitial fluid,* or the fluid in the spaces between cells, and the intravascular fluid or *plasma,* the liquid part of blood. Other ECF compartments include lymph and

transcellular fluids. Transcellular fluids include cerebrospinal fluid; fluid in the gastrointestinal (GI) tract and joint spaces; and pleural, peritoneal, intraocular, and pericardial fluid. ECF makes up about one third of the body water; this amounts to about 14 L in a 70-kg man. About one third of ECF is in the intravascular space as plasma (3 L in a 70-kg man), and two thirds is in the interstitial space (10 L in a 70-kg man). The fluid in the transcellular spaces totals about 1 L at any given time.

Calculation of Fluid Gain or Loss

One liter of water weighs 2.2 lb. (1 kg). Body weight change, especially sudden change, is an excellent indicator of overall fluid volume loss or gain. For example, if a patient drinks 240 mL (8 oz) of fluid, weight gain will be 0.5 lb (0.23 kg). A patient receiving diuretic therapy who loses 4.4 lb (2 kg) in 24 hours has a fluid loss of about 2 L. An adult patient who is fasting may lose 1 to 2 lb/day. A weight loss exceeding this is likely due to loss of body fluid.

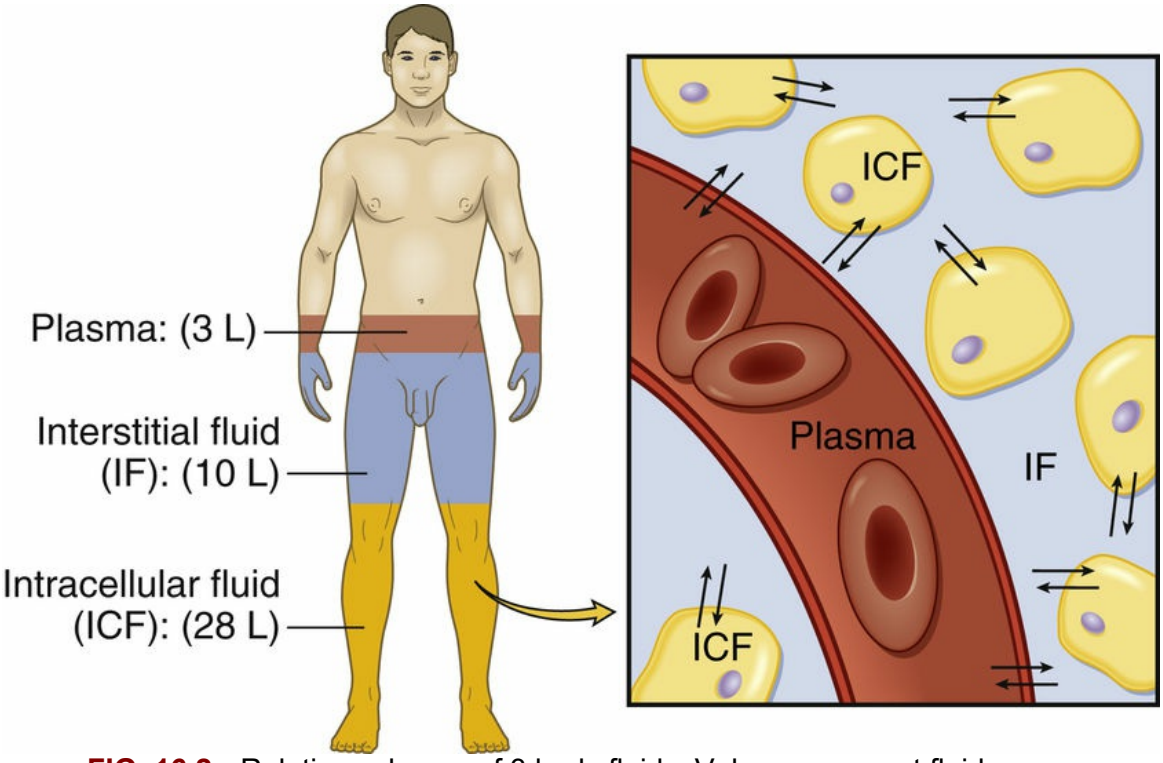

FIG. 16.2 Relative volumes of 3 body fluids. Values represent fluid distribution in a young male adult.

Electrolytes

Electrolytes are substances whose molecules dissociate, or split, into ions when placed in water. *Ions* are electrically charged particles. **Cations** are positively charged ions. Examples include sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}) ions. **Anions** are negatively charged ions. Examples include bicarbonate (HCO_3^-), chloride (Cl^-), and phosphate (PO_4^{3-}) ions. Most proteins bear a negative charge and thus are anions.

Measurement of Electrolytes

The concentration of electrolytes in body fluids is expressed in milliequivalents (mEq) per liter. Since electrolytes are active chemicals, it is useful to express their concentration according to their

chemical activity, or the number of electrolytes able to combine chemically. Ions combine milliequivalent for milliequivalent. For example, 1 mEq (1 mmol) of sodium combines with 1 mEq (1 mmol) of chloride.

Electrolyte Composition of Fluid Compartments

Electrolyte composition varies between ECF and ICF. The overall concentration of electrolytes is nearly the same in the ECF and ICF. However, concentrations of specific ions differ greatly (Fig. 16.3). In ECF the main cation is sodium, with small amounts of potassium, calcium, and magnesium. The primary ECF anion is chloride, with small amounts of bicarbonate, sulfate, and phosphate anions.

In ICF the prevalent cation is potassium, with small amounts of magnesium and sodium. The prevalent ICF anion is phosphate, with some protein and a small amount of bicarbonate. Table 16.1 lists normal serum electrolyte values.

Mechanisms Controlling Fluid and Electrolyte Movement

The movement of electrolytes and water between ICF and ECF to maintain homeostasis involves many different processes, including simple diffusion, facilitated diffusion, and active transport. Water moves as driven by 2 forces: hydrostatic pressure and osmotic pressure.

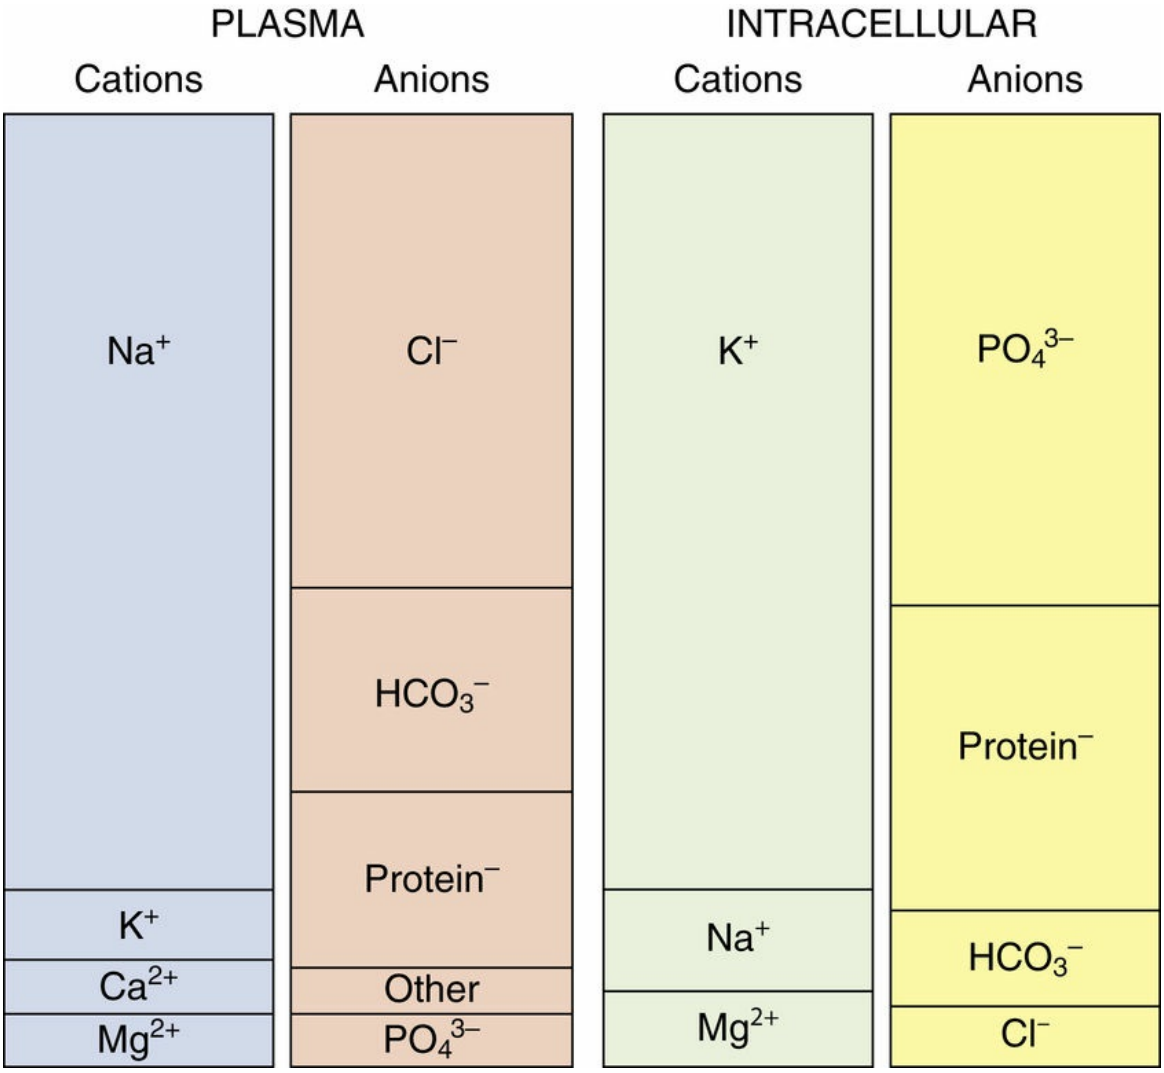

FIG. 16.3 The relative concentrations of the major cations and anions in the intracellular space and the plasma.

TABLE 16.1 Normal Serum Electrolyte Values

Electrolyte	Reference Interval
Anions	
Bicarbonate (HCO_3^-)	22–26 mEq/L (22–26 mmol/L)
Chloride (Cl^-)	98–106 mEq/L (98–106 mmol/L)
Phosphate (PO_4^{3-})	3.0–4.5 mg/dL (0.97–1.45 mmol/L)
Cations	
Calcium (Ca^{2+}) (total)	9.0–10.5 mg/dL (2.25–2.62 mmol/L)
Calcium (ionized)	4.5–5.6 mg/dL (1.05–1.3 mmol/L)
Magnesium (Mg^{2+})	1.3–2.1 mEq/L (0.65–1.05 mmol/L)
Potassium (K^+)	3.5–5.0 mEq/L (3.5–5.0 mmol/L)
Sodium (Na^+)	136–145 mEq/L (136–145 mmol/L)

Diffusion

Diffusion is the movement of molecules from an area of high concentration to low concentration (Fig. 16.4). Net movement of molecules stops when the concentrations are equal in both areas. It occurs in liquids, gases, and solids. Simple diffusion requires no external energy.

Facilitated Diffusion

Facilitated diffusion involves the use of a protein carrier in the cell membrane. The protein carrier combines with a molecule, especially one too large to pass easily through the cell membrane, and helps move the molecule across the membrane from an area of high to low concentration. Like simple diffusion, facilitated diffusion is passive and requires no energy. An example of facilitated diffusion is glucose transport into the cell. The large glucose molecule must combine with a carrier molecule to be able to cross the cell membrane and enter most cells.

Active Transport

Active transport is a process in which molecules move against the concentration gradient. External energy is needed for this process. An example is the sodium-potassium pump. The concentrations of sodium and potassium differ greatly intracellularly and extracellularly (Fig. 16.3). To maintain this concentration difference,

the cell uses active transport to move sodium out of the cell and potassium into the cell (Fig. 16.5). The energy source for this movement is adenosine triphosphate (ATP), which is made in the cell mitochondria.

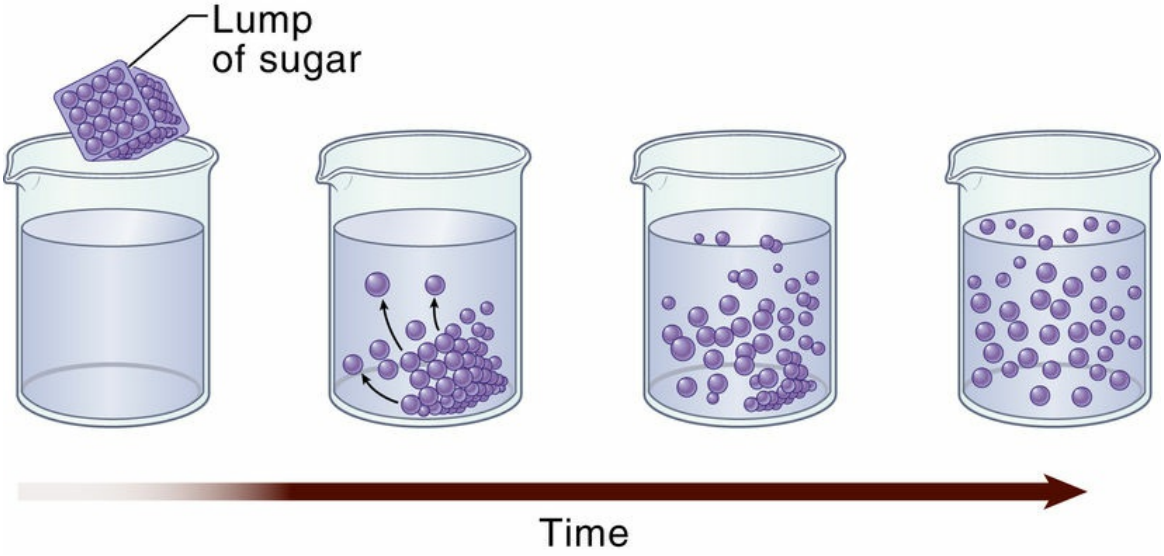

FIG. 16.4 Diffusion is the movement of molecules from an area of high concentration to an area of low concentration. Eventually, the sugar molecules are evenly distributed.

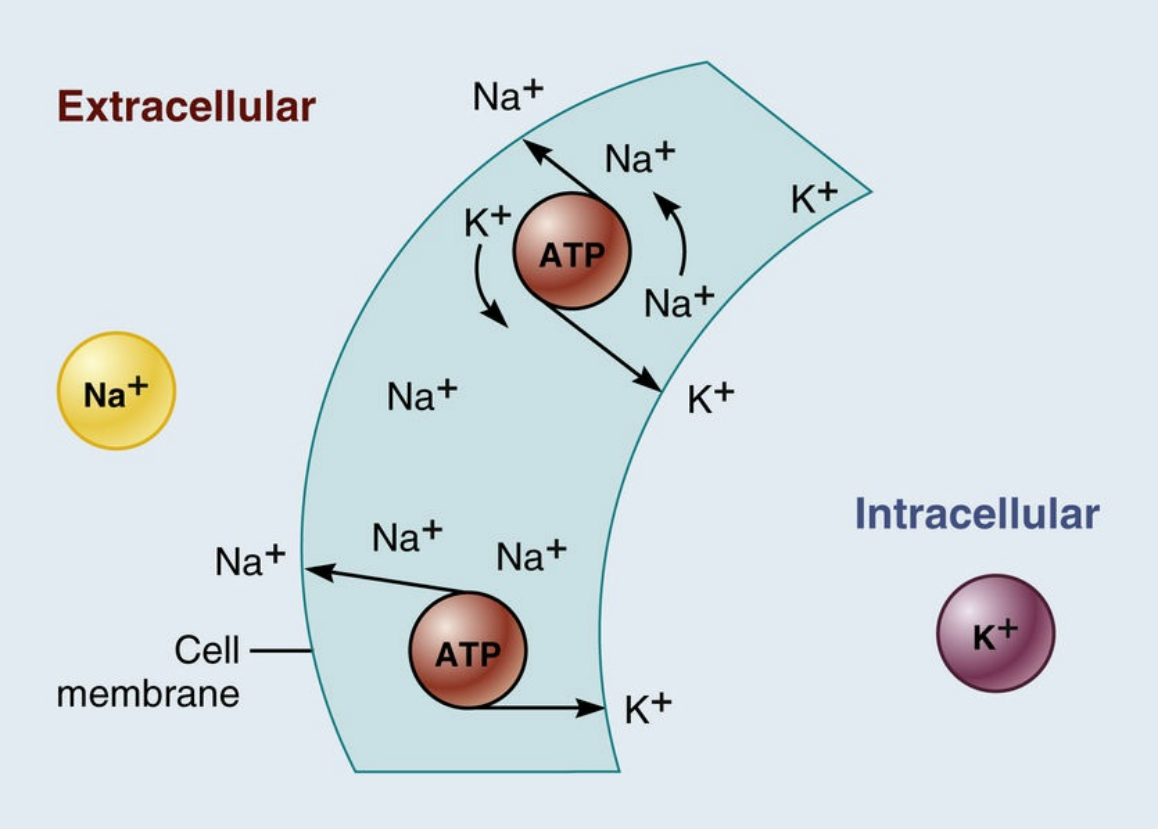

FIG. 16.5 Sodium-potassium pump. As sodium *(Na^+)* diffuses into the cell and potassium *(K^+)* diffuses out of the cell, an active transport system supplied with energy delivers Na^+ back to the extracellular compartment and K^+ to the intracellular compartment. *ATP,* Adenosine triphosphate.

Osmosis

Osmosis is the movement of water "down" a concentration gradient, that is, from a region of low solute concentration to one of high solute concentration, across a semipermeable membrane. Osmosis requires no outside energy sources. It stops when the concentration differences disappear or when hydrostatic pressure builds and opposes any further movement of water. Imagine a chamber with 2 compartments separated by a semipermeable membrane, one that allows only the movement of water (Fig. 16.6). If you add albumin to one side, water will move from the less concentrated side (has more water) to the more concentrated side of the chamber (has less water) until the

concentrations are equal.

Whenever dissolved substances are contained in a space with a semipermeable membrane, they can pull water into the space by osmosis. The concentration of the solution determines the strength of the osmotic pull. The higher the concentration, the greater a solution's pull, or **osmotic pressure**. Osmotic pressure is measured in milliosmoles (mOsm). It may be expressed as either fluid osmolarity or fluid osmolality. Although you will often see the terms *osmolarity* and *osmolality* used interchangeably, they are different measurements. *Osmolarity* measures the total milliosmoles per liter of solution, or the concentration of molecules per volume of solution (mOsm/L). **Osmolality** measures the number of milliosmoles per kilogram of water, or the concentration of molecules per weight of water. Osmolality is the preferred measure to evaluate the concentration of plasma, urine, and other body fluids, as changes in the ECF osmolality can significantly influence changes in the ICF osmolality. These changes can affect normal cell function.[1]

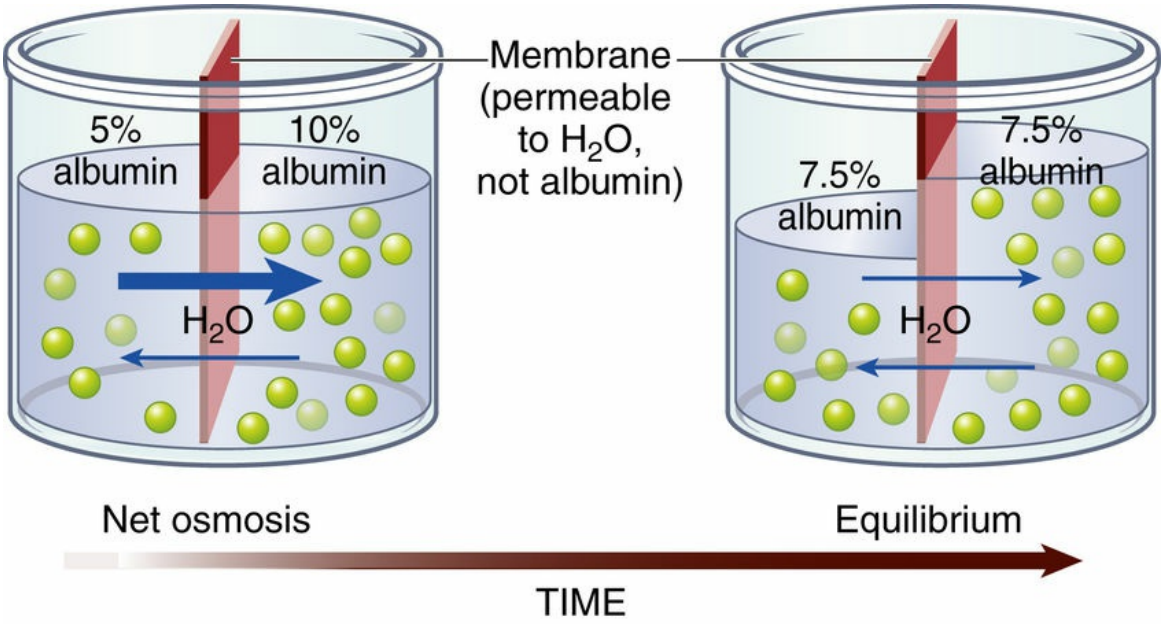

FIG. 16.6 Osmosis is the process of water movement through a semipermeable membrane from an area of low solute concentration to an area of high solute concentration.

Measurement of Osmolality

Osmolality is nearly the same in the various body fluid spaces. Therefore measuring or estimating plasma osmolality is a useful way to assess the state of the body's water balance. Calculate the plasma osmolality using the following formula.[2]

$$\text{Plasma osmolality} = (2 \times \text{Na}) + (\text{BUN}/2.8) + (\text{Glucose}/18)$$

Normal plasma osmolality is between 280 and 295 mOsm/kg. A value greater than 295 mOsm/kg indicates that the concentration of solute is too great, or the water content is too little. This condition is termed *water deficit.* A value less than 275 mOsm/kg indicates too little solute for the amount of water or too much water for the amount of solute. This condition is termed *water excess*. Both conditions are clinically significant.

Urine osmolality can range from 100 to 1300 mOsm/kg. It depends on fluid intake, the amount of antidiuretic hormone (ADH) in circulation, and the renal response to ADH.

Osmotic Movement of Fluids

The osmolality of the fluid surrounding cells affects them. Fluids with the same osmolality as the cell interior are **isotonic**. Normally, ECF and ICF are isotonic to one another, so no net movement of water occurs.

Changes in the osmolality of ECF change the volume of cells. Solutions in which the solutes are less concentrated than in the cells are **hypotonic** (hypoosmolar). If a cell is surrounded by hypotonic fluid, water moves into the cell, causing it to swell and possibly burst. Fluids with solutes more concentrated than in cells, or an increased osmolality, are **hypertonic** (hyperosmolar). If hypertonic fluid surrounds a cell, water leaves the cell to dilute ECF. The cell shrinks

and may eventually die (Fig. 16.7).

Hydrostatic Pressure

Hydrostatic pressure is the force of fluid in a compartment pushing against a cell membrane or vessel wall. In the blood vessels, hydrostatic pressure is the BP generated by the heart's contraction. Hydrostatic pressure in the vascular system gradually decreases as the blood moves through the arteries until it is about 30 mm Hg in the capillary bed. At the capillary level, hydrostatic pressure is the major force that pushes water out of the vascular system and into the interstitial space.

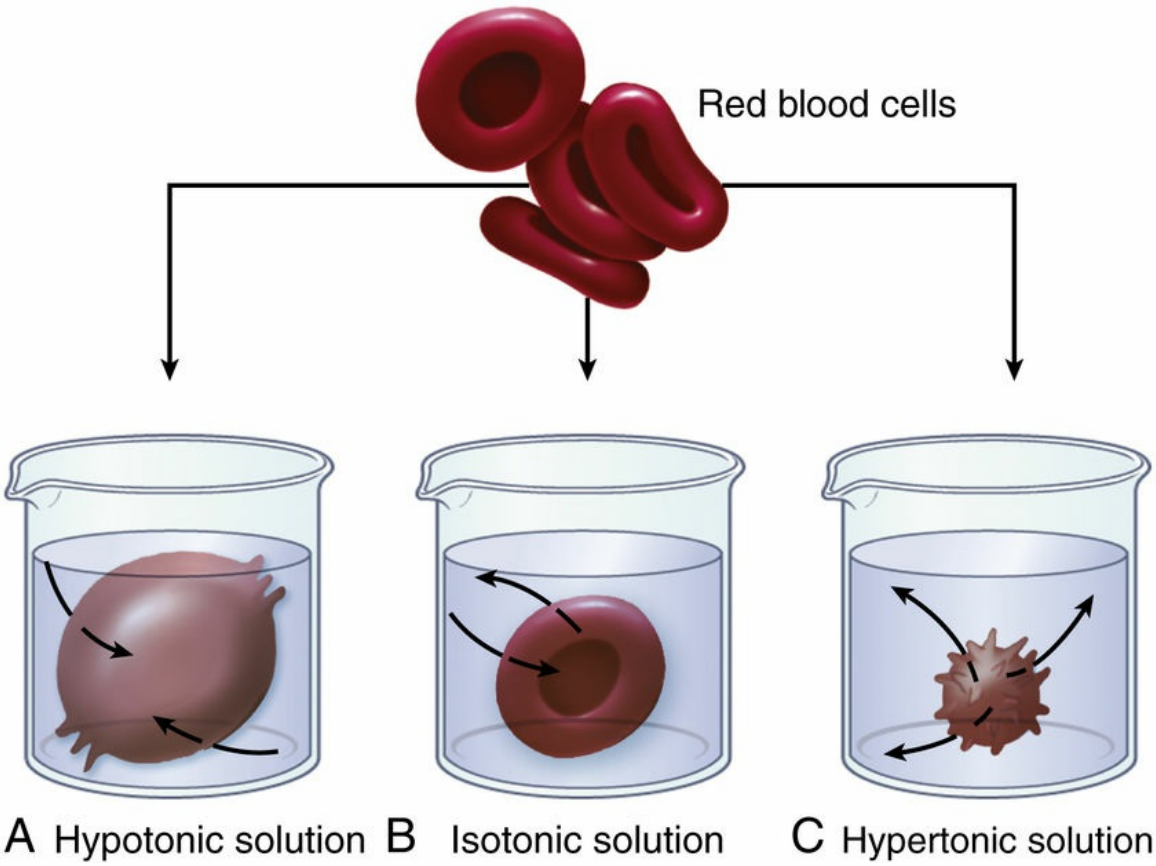

FIG. 16.7 Effects of water status on red blood cells. **A,** Hypotonic solution (H_2O excess) results in cellular swelling. **B,** Isotonic solution (normal H_2O balance) results in no change. **C,** Hypertonic solution (H_2O deficit) results in cellular shrinking.

Oncotic Pressure

Oncotic pressure (colloidal osmotic pressure) is the osmotic pressure caused by plasma colloids (large molecules) in solution. The major colloids in the vascular system contributing to osmotic pressure are proteins, such as albumin. Plasma has large amounts of protein, while the interstitial space has very little. Plasma protein molecules attract water, pulling fluid from the tissue space to the vascular space. Under normal conditions, plasma oncotic pressure is about 25 mm Hg. The small amount of protein found in the interstitial space exerts an oncotic pressure of about 1 mm Hg.

Fluid Movement in Capillaries

As plasma flows through the capillary bed, 4 factors determine if fluid moves out of the capillary and into the interstitial space or if fluid moves back into the capillary from the interstitial space. The amount and direction of movement are determined by the interaction of (1) capillary hydrostatic pressure, (2) plasma oncotic pressure, (3) interstitial hydrostatic pressure, and (4) interstitial oncotic pressure.

Capillary hydrostatic pressure and interstitial oncotic pressure move water out of the capillaries. Plasma oncotic pressure and interstitial hydrostatic pressure move fluid into the capillaries. At the arterial end of the capillary, capillary hydrostatic pressure exceeds plasma oncotic pressure, and fluid moves into the interstitial space. At the venous end of the capillary, the capillary hydrostatic pressure is lower than plasma oncotic pressure, drawing fluid back into the capillary by the oncotic pressure created by plasma proteins (Fig. 16.8).

Fluid Shifts

If capillary or interstitial pressures change, fluid may abnormally shift from one compartment to another, resulting in edema or dehydration.

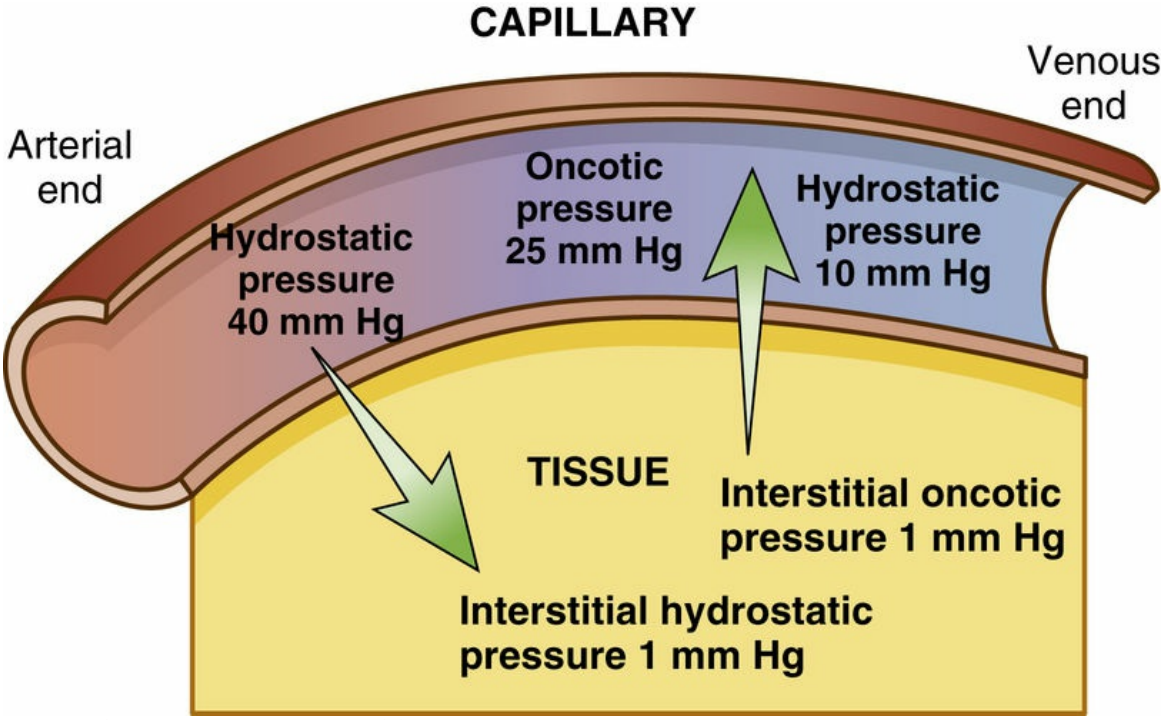

FIG. 16.8 Dynamics of fluid exchange between a capillary and tissue. An equilibrium exists between forces filtering fluid out of the capillary and forces absorbing fluid back into the capillary. Note that the hydrostatic pressure is greater at the arterial end of the capillary than at the venous end. The net effect of pressures at the arterial end of the capillary causes a movement of fluid into the tissue. At the venous end of the capillary, there is net movement of fluid back into the capillary.

Shifts of Plasma to Interstitial Fluid

Edema, an accumulation of fluid in the interstitial space, occurs if venous hydrostatic pressure rises, plasma oncotic pressure decreases, or interstitial oncotic pressure rises. Edema may also develop if an obstruction of lymphatic outflow causes a decrease in the removal of interstitial fluid.

Elevation of Venous Hydrostatic Pressure

Increasing the pressure at the venous end of the capillary inhibits fluid movement back into the capillary, which results in edema. Causes of increased venous pressure include fluid overload, heart failure, liver failure, obstruction of venous return to the heart (e.g., tourniquets, restrictive clothing, venous thrombosis), and venous insufficiency

(e.g., varicose veins).

Decrease in Plasma Oncotic Pressure

Fluid stays in the interstitial space if the plasma oncotic pressure is too low to draw fluid back into the capillary. Low plasma protein content decreases oncotic pressure. This can result from excess protein loss (renal disorders), deficient protein synthesis (liver disease), and deficient protein intake (malnutrition).

Elevation of Interstitial Oncotic Pressure

Trauma, burns, and inflammation can damage capillary walls and allow plasma proteins to accumulate in the interstitial space. This increases interstitial oncotic pressure, draws fluid into the interstitial space, and holds it there.

Shifts of Interstitial Fluid to Plasma

An increase in the plasma osmotic or oncotic pressure draws fluid into the plasma from the interstitial space. This could happen when we give colloids, dextran, mannitol, or hypertonic solutions. Increasing the tissue hydrostatic pressure is another way of causing a shift of fluid into plasma. Wearing elastic compression gradient stockings or hose to decrease peripheral edema is a therapeutic application of this effect.

Fluid Spacing

Fluid spacing is a term used to describe the distribution of body water. *First spacing* describes the normal distribution of fluid in ICF and ECF compartments. *Second spacing* refers to an abnormal accumulation of interstitial fluid (i.e., edema). *Third spacing* occurs when excess fluid collects in the nonfunctional area between cells. This fluid is trapped where it is difficult or impossible for it to move back into the cells or blood vessels. Third spacing occurs with ascites; fluid leaking into the abdominal cavity with peritonitis or pancreatitis;

and edema associated with burns, trauma, or sepsis.

TABLE 16.2 Normal Fluid Balance in the Adult

Intake	
Fluids	1200 mL
Solid food	1000 mL
Water from oxidation	300 mL
Total	2500 mL
Output	
Insensible loss (skin and lungs)	900 mL
In feces	100 mL
Urine	1500 mL
Total	2500 mL

Regulation of Water Balance

Many factors are involved in maintaining the finely tuned balance among water intake, use, and excretion. For proper fluid balance, an average healthy adult needs a daily water intake between 2000 and 3000 mL (Table 16.2). This amount replaces what the body loses in urinary output and insensible losses. Oral fluid intake accounts for most of the water intake. Water intake also includes water from food metabolism and water present in solid foods.

Insensible water loss, which is invisible vaporization from the lungs and skin, helps regulate body temperature. Accelerated body metabolism, which occurs with increased body temperature and exercise, increases the amount of water lost and may result in the need for additional water replacement.

Do not confuse water loss through the skin with the vaporization of water excreted by sweat glands. Insensible perspiration causes only water loss. Excess sweating *(sensible perspiration)* caused by exercise, fever, or high environmental temperatures may lead to large losses of water and electrolytes.

Hypothalamic-Pituitary Regulation

Water ingestion equals water loss in the person who has free access to water, intact thirst and ADH mechanism, and normally functioning kidneys. A body fluid deficit or increase in plasma osmolality activates osmoreceptors in the hypothalamus. This stimulates thirst and the release of ADH from the posterior pituitary gland. ADH acts on the distal tubules and collecting ducts in the kidney by making them more permeable to water. The result is increased water reabsorption from the tubular filtrate into the blood and decreased excretion in the urine. Because ADH is only able to regulate how much water the body holds onto, an intact thirst mechanism is our main protection against developing dehydration or hyperosmolality. Thirst causes us to increase the amount of water we drink. Together these result in increased free water in the body, decreasing plasma osmolality and restoring fluid volume.

Many factors influence ADH secretion and thirst. Decreased BP, nausea, pain, hypoglycemia, and hypoxemia stimulate ADH release. In the postoperative patient, the stress response to surgery and receiving analgesics and anesthesia cause ADH release and decreased osmolality. The unconscious or cognitively impaired patient is at increased risk for fluid deficit and hyperosmolality because of an inability to express thirst and act on it. A dry mouth will cause a person to drink, even when there is no body water deficit.

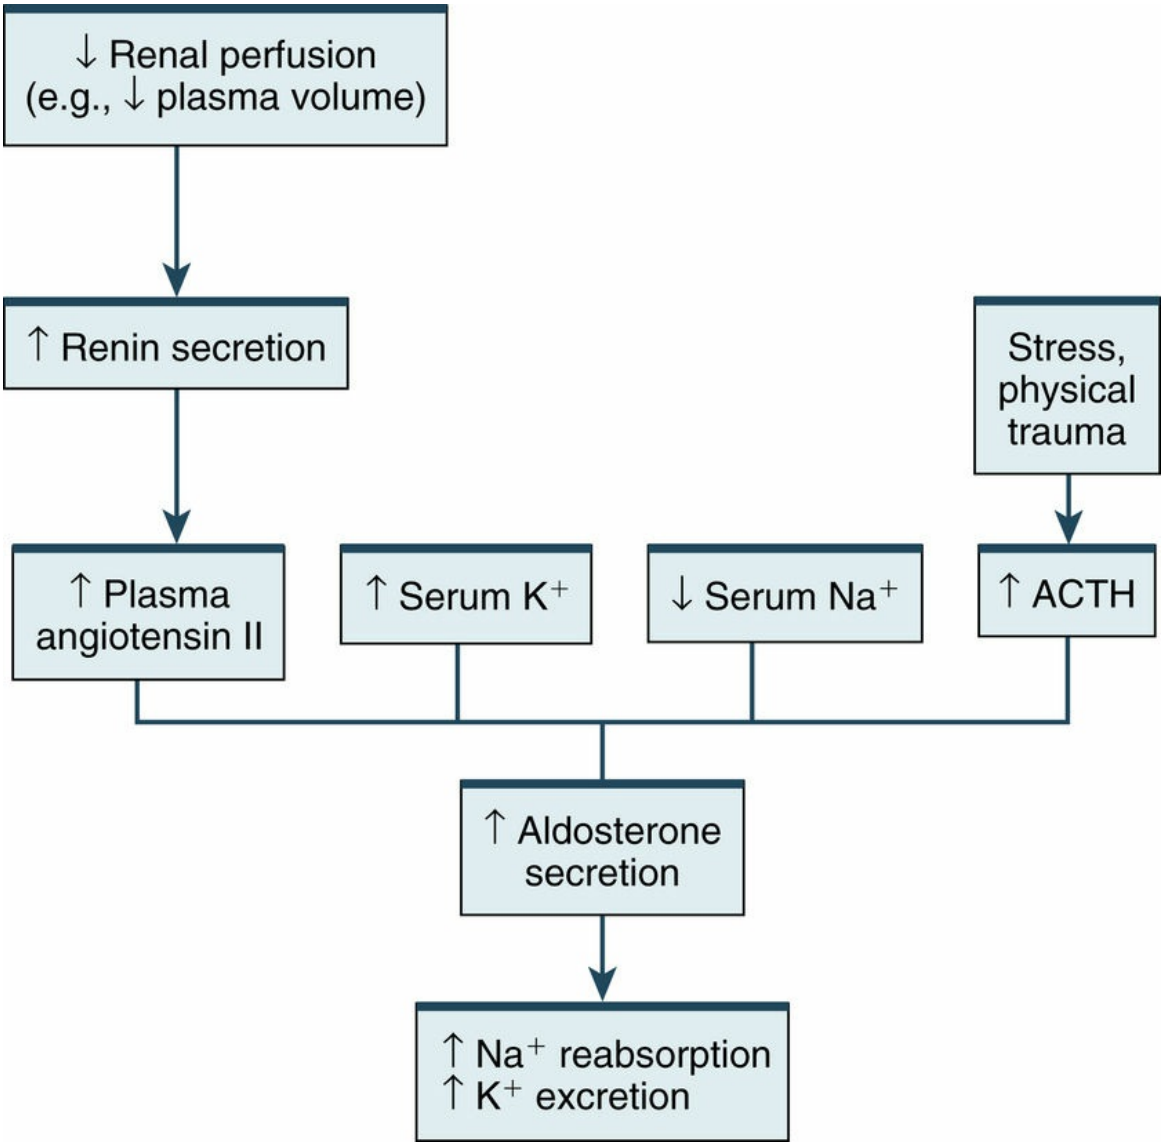

FIG. 16.9 Factors affecting aldosterone secretion. *ACTH,* Adrenocorticotropic hormone.

Renal Regulation

The primary function of the kidneys is to regulate fluid and electrolyte balance by adjusting urine volume and the excretion of most electrolytes (see Chapter 44). The kidneys filter the total plasma volume many times each day. In the average adult, the kidneys reabsorb 99% of this filtrate, producing around 1.5 L of urine per day. Under the influence of ADH, aldosterone, and other hormones,

selective reabsorption and secretion of water and electrolytes in the renal tubules result in urine that is different in composition and concentration from plasma. This process helps maintain normal plasma osmolality, electrolyte balance, blood volume, and acid-base balance.

With severely impaired renal function, the kidneys cannot maintain fluid and electrolyte balance. This condition results in edema, potassium and phosphate retention, acidosis, and other electrolyte imbalances (see Chapter 46).

Adrenal Cortical Regulation

Glucocorticoids and mineralocorticoids secreted by the adrenal cortex help regulate water and electrolyte balance. The glucocorticoids (e.g., cortisol) primarily have an antiinflammatory effect and increase serum glucose levels. The mineralocorticoids (e.g., aldosterone) enhance sodium retention and potassium excretion (Fig. 16.9). When sodium is reabsorbed, water follows because of osmotic changes.

Aldosterone is a mineralocorticoid with strong sodium-retaining and potassium-excreting capabilities. Decreased renal perfusion or decreased sodium in the distal part of the renal tubule activates the renin-angiotensin-aldosterone system (RAAS), resulting in aldosterone secretion. In addition to the RAAS, increased serum potassium, decreased serum sodium, and adrenocorticotropic hormone (ACTH) stimulate aldosterone secretion. Aldosterone increases sodium and water reabsorption in the renal distal tubules, decreasing plasma osmolality and restoring fluid volume.

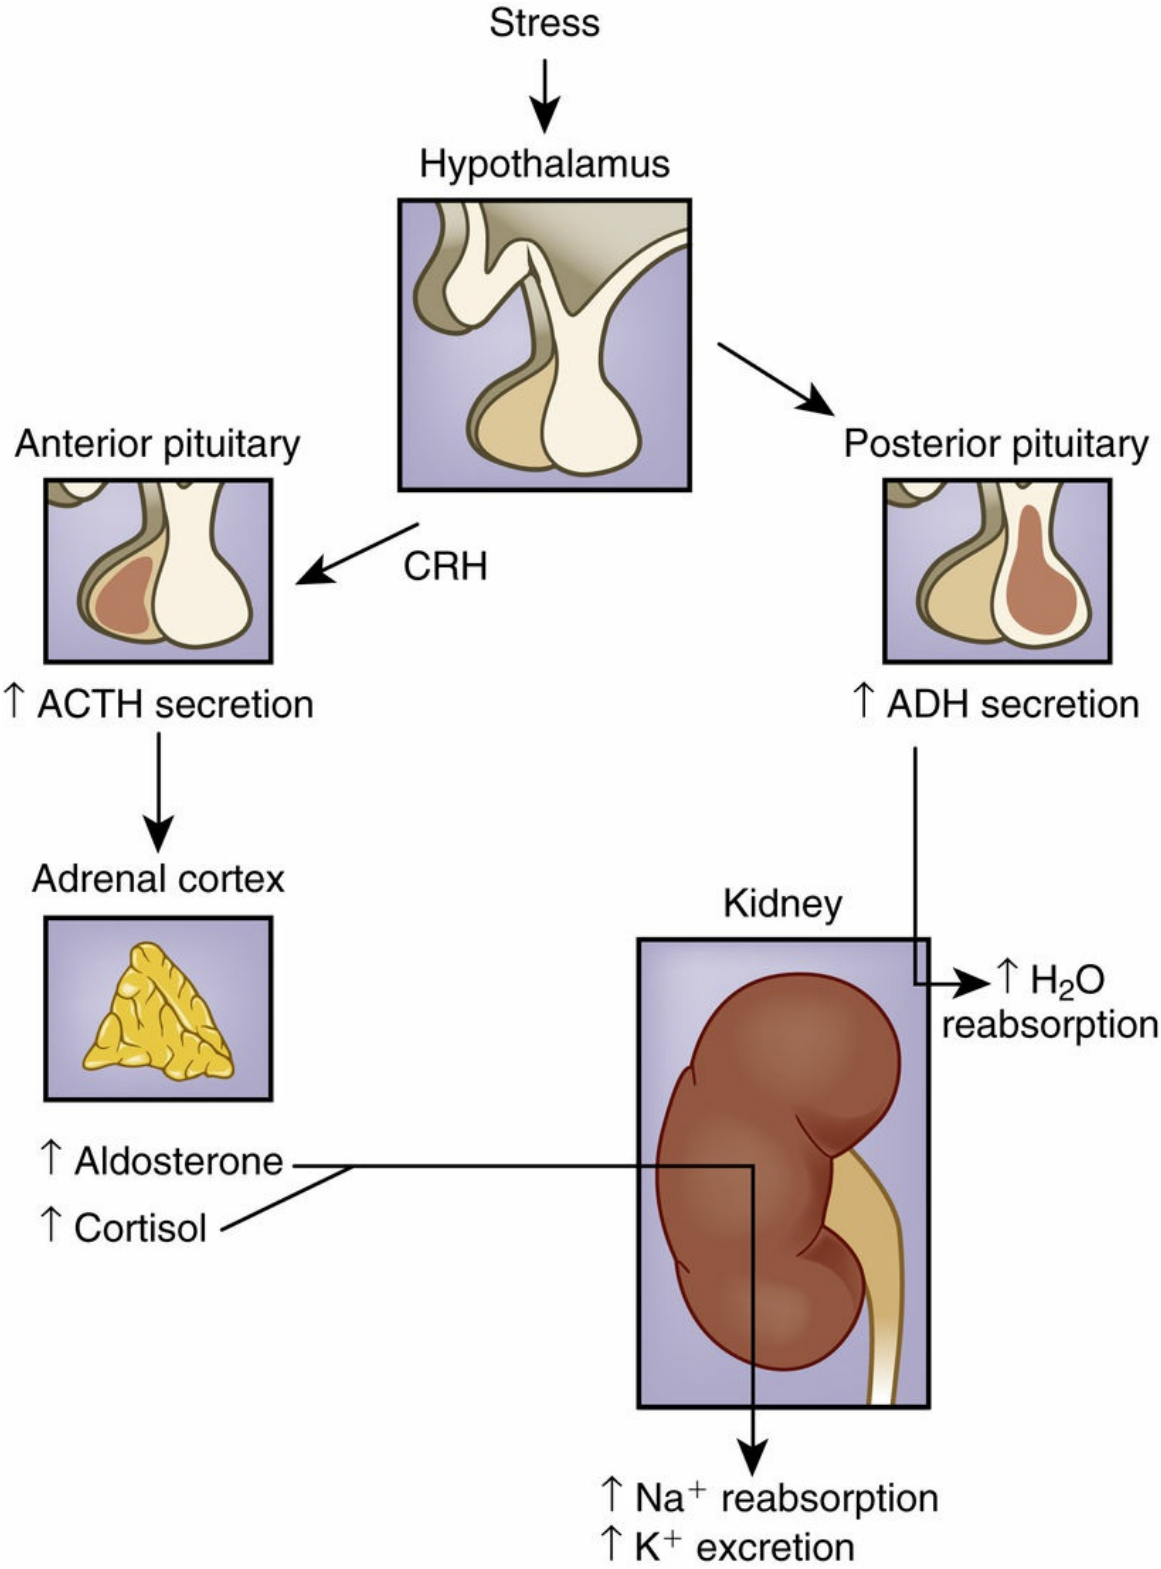

FIG. 16.10 Effects of stress on fluid and electrolyte balance. *ACTH,* Adrenocorticotropic hormone; *ADH,* antidiuretic hormone; *CRH,* corticotropin-releasing hormone.

Cortisol is the most abundant glucocorticoid. In large doses, cortisol has both glucocorticoid (glucose-elevating and antiinflammatory) and mineralocorticoid (sodium-retention) effects. Normally cortisol secretion is in a diurnal or circadian pattern. Increased cortisol secretion occurs in response to physical and psychologic stress. This affects many body functions, including fluid and electrolyte balance (Fig. 16.10).

Cardiac Regulation

Natriuretic peptides, including atrial natriuretic peptide (ANP) and b-type natriuretic peptide (BNP), are hormones made by cardiomyocytes. They are made in response to increased atrial pressure (increased volume, such as occurs in heart failure) and high serum sodium levels. They are natural antagonists to the RAAS and suppress secretion of aldosterone, renin, and ADH, and the action of angiotensin II. In the renal tubules, peptides promote excretion of sodium and water, decreasing blood volume and BP.

Gastrointestinal Regulation

In addition to oral intake, the GI tract normally secretes around 8000 mL of digestive fluids each day. The GI tract normally reabsorbs most of this fluid, with only a small amount eliminated in feces. This is why diarrhea and vomiting, which prevent GI reabsorption of secreted fluid, can lead to significant fluid and electrolyte loss.

Gerontologic Considerations: Fluid and Electrolytes

The older adult has normal physiologic changes that increase susceptibility to fluid and electrolyte imbalances. Structural changes to the kidneys and a decrease in the renal blood flow lead to decreased glomerular filtration rate and loss of the ability to concentrate urine and conserve water. Hormonal changes include a

decrease in renin and aldosterone and an increase in ADH and ANP. Subcutaneous tissue loss and thinning of the dermis lead to increased moisture lost through the skin and an inability to respond quickly to heat or cold.

Do not automatically attribute older patients' fluid and electrolyte problems to the natural processes of aging. Throughout this chapter are suggestions for adapting your assessment and nursing interventions when caring for the older adult.

Fluid Volume Imbalances

Fluid and electrolyte imbalances occur in most patients with a major illness or injury because illness disrupts normal homeostatic mechanisms. Illness or disease directly causes some fluid and electrolyte imbalances (e.g., burns, heart failure). Other times, therapeutic measures (e.g., colonoscopy preparation, diuretics) cause or contribute to imbalances. Perioperative patients are at risk for developing fluid and electrolyte imbalances because of fluid restrictions, blood or fluid loss, and the stress of surgery.

Fluid and electrolyte imbalances are commonly classified as *deficits* or *excesses.* ECF volume deficit *(hypovolemia)* and ECF volume excess *(hypervolemia)* are common clinical conditions. ECF volume imbalances are usually accompanied by one or more electrolyte imbalances, particularly changes in the serum sodium level.

Although each imbalance is discussed separately in this chapter, it is common for more than one imbalance to occur in the same patient. For example, a patient with prolonged nasogastric (NG) suction will lose sodium, potassium, hydrogen, and chloride ions. This may result in sodium and potassium deficiencies, a fluid volume deficit, and metabolic alkalosis caused by the loss of HCl acid.

Fluid Volume Deficit

Fluid volume deficit can occur with abnormal loss of body fluids (e.g., diarrhea, vomiting, hemorrhage, polyuria), inadequate fluid intake, or

a shift from plasma to interstitial fluid. Though often used interchangeably, *fluid volume deficit* and *dehydration* are not the same. *Dehydration* refers to loss of pure water alone without a corresponding loss of sodium. Table 16.3 lists causes and manifestations of fluid volume deficit.

Interprofessional Care

Managing fluid volume deficit involves correcting the underlying cause and replacing both water and any needed electrolytes. Replacement therapy depends on the severity and type of volume loss. In mild losses, we can use oral rehydration. If the deficit is more severe, we replace volume with blood products or balanced IV solutions, such as isotonic (0.9%) sodium chloride or lactated Ringer's solution. The choice of fluid depends on the cause and patient's electrolyte status. For rapid volume replacement, 0.9% sodium chloride is preferred. Blood is given when volume loss is due to blood loss.

TABLE 16.3 Extracellular Fluid ImbalancesCauses and Manifestations

ECF Volume Deficit	ECF Volume Excess
Causes	
• ↑ Insensible water loss or perspiration (high fever, heatstroke) • Diabetes insipidus • Osmotic diuresis • Hemorrhage • GI losses: vomiting, NG suction, diarrhea, fistula drainage • Overuse of diuretics • Inadequate fluid intake • Third-space fluid shifts: burns, pancreatitis	• Excess isotonic or hypotonic IV fluids • Heart failure • Renal failure • Primary polydipsia • SIADH • Cushing syndrome • Long-term use of corticosteroids
Manifestations	
• Restlessness, drowsiness, lethargy, confusion • Thirst, dry mucous membranes • Cold clammy skin • Decreased skin turgor, ↓ capillary refill • Postural hypotension, ↑ pulse, ↓ CVP • ↓ Urine output, concentrated urine • ↑ Respiratory rate • Weakness, dizziness • Weight loss • Seizures, coma	• Headache, confusion, lethargy • Peripheral edema • Jugular venous distention • S_3 heart sound • Bounding pulse, ↑ BP, ↑ CVP • Polyuria (with normal renal function) • Dyspnea, crackles, pulmonary edema • Muscle spasms • Weight gain • Seizures, coma

Fluid Volume Excess

Fluid volume excess may result from excess intake of fluids, abnormal retention of fluids (e.g., heart failure, renal failure), or a shift of fluid from interstitial fluid into plasma fluid. Weight gain is the most consistent manifestation of fluid volume excess. Table 16.3 lists causes and manifestations of fluid volume excess.

Interprofessional Care

Managing fluid volume excess involves treating the underlying cause and removing fluid without producing abnormal changes in the electrolyte composition or osmolality of ECF. Diuretics and fluid restriction are the primary forms of therapy. Some patients also need sodium restrictions. If the fluid excess leads to ascites or pleural effusion, an abdominal paracentesis or thoracentesis may be needed.

Nursing Management: Fluid Volume Imbalances

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with a fluid imbalance include:

ECF volume deficit:

- Fluid imbalance
- Impaired cardiac output
- Acute confusion
- Potential complication: hypovolemic shock

ECF volume excess:

- Fluid imbalance
- Impaired gas exchange
- Impaired tissue integrity
- Activity intolerance
- Disturbed body image
- Potential complications: pulmonary edema, ascites

Nursing Implementation

Daily Weights

Daily weights are the most accurate measure of volume status. An increase of 1 kg (2.2 lb) is equal to 1000 mL (1 L) of fluid retention, provided the person has maintained usual dietary intake or has not been on NPO status. Obtain the weight under standardized conditions. Weigh the patient at the same time every day, wearing the same clothes and on the same carefully calibrated scale. Remove excess bedding and empty all drainage bags before the weighing. If items are present that are not there every day, such as bulky dressings or tubes, note this along with the weight.

Intake and Output

Intake and output records give valuable information about fluid and electrolyte problems. An accurately recorded intake and output will

identify sources of excess intake or fluid losses. Intake should include oral and IV fluids, tube feedings, and retained irrigation solutions. Output includes urine, excess perspiration, wound or tube drainage, vomitus, and diarrhea. Estimate fluid loss from wounds and perspiration. Note the amount and color of the urine and measure the urine specific gravity. Readings greater than 1.025 mean urine is concentrated, while readings less than 1.010 mean urine is dilute.

Laboratory Findings

Monitor laboratory results when available and calculate the serum osmolality. The patient with a fluid volume deficit often has increased blood urea nitrogen (BUN), sodium, and hematocrit levels with increased plasma and urine osmolality. With fluid volume excess, the patient will have decreased BUN, sodium, and hematocrit levels, with decreased plasma and urine osmolality.

Nursing Management

Fluid Volume Changes

- Assess patient for manifestations of fluid imbalances.
- Give IV fluids and medications as ordered.
- Give O_2 therapy as ordered.
- Implement fall precautions.
- Monitor patient for effectiveness of therapy.
- Oversee UAP:
    - Obtain daily weights and vital signs.
    - Offer frequent oral care.
    - Record accurate intake and output.
    - Perform skin care and frequent position changes.
    - Elevate edematous extremities.
    - Encourage oral fluids as appropriate.

Cardiovascular Care

Monitor vital signs and perform a thorough cardiovascular assessment as needed. Changes in BP, central venous pressure, pulse force, and jugular venous distention reflect ECF volume imbalances. In fluid volume excess, the pulse is full, bounding, and not easily obliterated. Increased volume causes distended neck veins (jugular venous distention), increased central venous pressure, and high BP. Auscultate heart sounds, being alert for the presence of an S_3.

In mild to moderate fluid volume deficit, sympathetic nervous system compensation increases the heart rate and results in peripheral vasoconstriction to try to keep BP within normal limits. Pulses may be weak and thready. Assess for orthostatic changes. A change in position from lying to sitting or standing may decrease BP or further increase the heart rate (orthostatic hypotension). In more severe deficits, hypotension may be present.

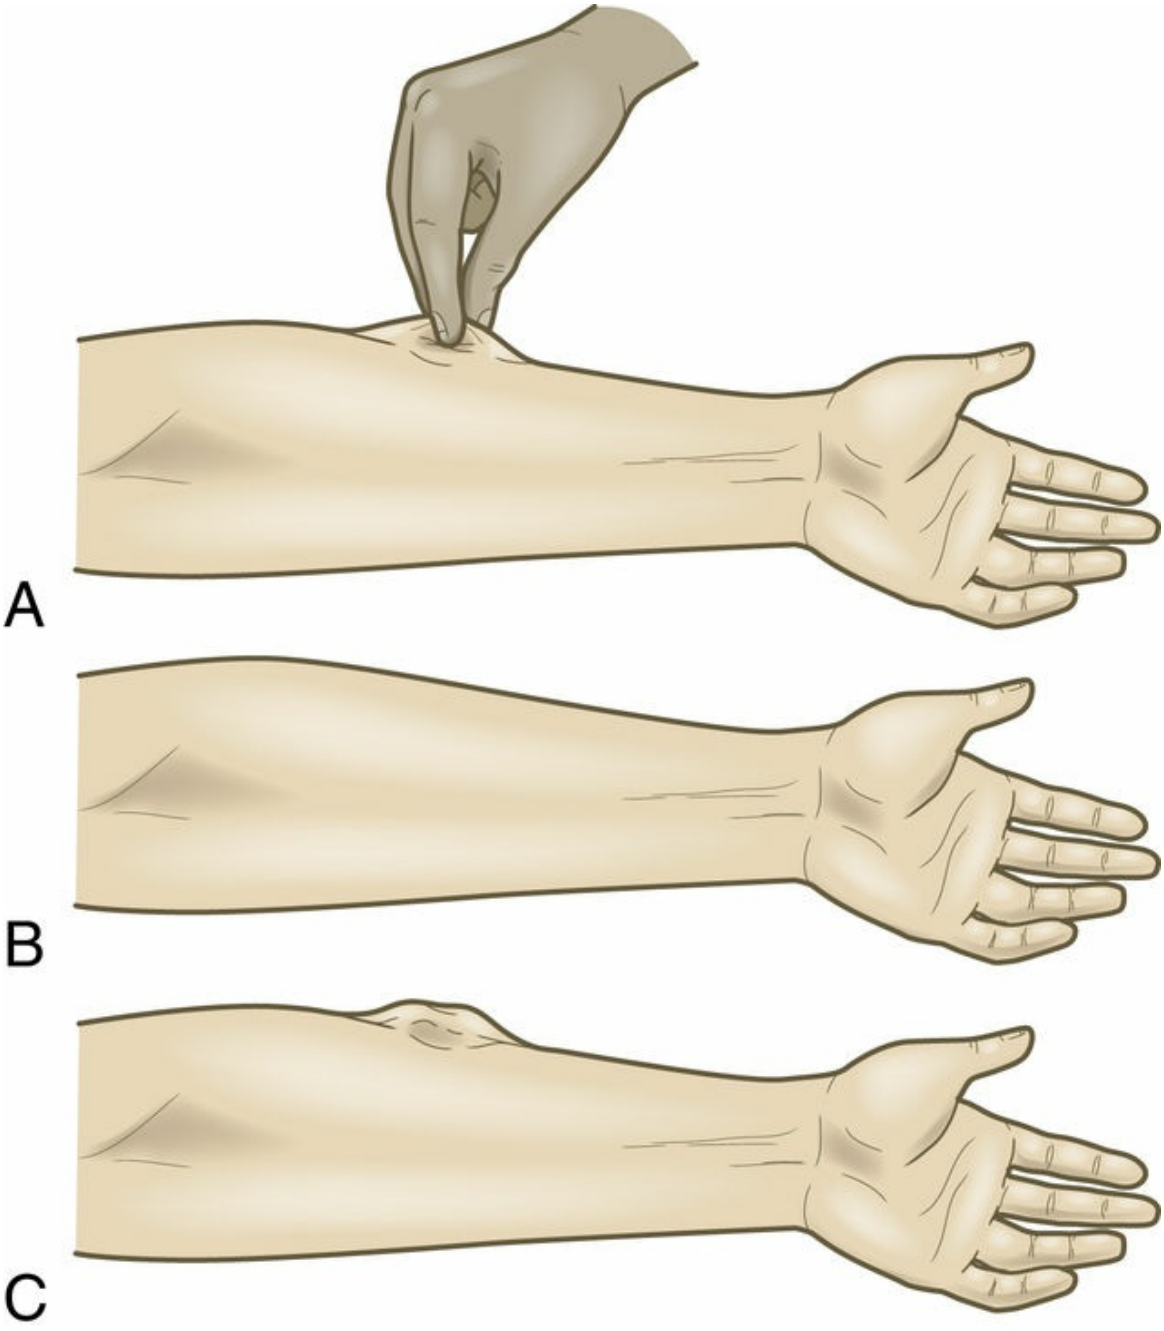

FIG. 16.11 Assessment of skin turgor. **A** and **B,** When normal skin is pinched, it resumes shape in seconds. **C,** If the skin stays wrinkled for 20 to 30 seconds, the patient has poor skin turgor.

Respiratory Care

Monitor pulse oximetry and auscultate lung sounds as needed. ECF excess can cause pulmonary congestion and pulmonary edema, as

increased hydrostatic pressure in the pulmonary vessels forces fluid into the alveoli. The patient will have shortness of breath and moist crackles on auscultation. The patient with ECF deficit will have an increased respiratory rate because of decreased tissue perfusion and resultant hypoxia. Give O_2 as ordered.

Patient Safety

The patient with fluid volume deficit is at risk for falls because of orthostatic hypotension, muscle weakness, and changes in level of consciousness. Assess level of consciousness, gait, and muscle strength. Implement fall precautions. If orthostatic hypotension is present, teach the patient to change positions slowly when rising from a bed or chair. Place alarm monitors on patients who are confused and try to get out of bed without help.

Skin Care

Assess the skin for turgor and mobility. Normally, a fold of skin, when pinched, will readily move and, on release, rapidly return to its former position. In ECF volume deficit, there is diminished skin turgor with tenting, or a lag in the pinched skinfold's return to its original state. Skin areas over the sternum, abdomen, and anterior forearm are the usual sites we use to assess turgor (Fig. 16.11). In older people, decreased skin turgor is less predictive of fluid deficit because of the loss of tissue elasticity.

In mild fluid deficits, the skin may appear warm, dry, and wrinkled. These signs may be hard to assess in the older adult because the person's skin may be normally dry, wrinkled, and non-elastic. In more severe deficits, the skin may be cool and moist if there is vasoconstriction to compensate for the decreased fluid volume. Oral mucous membranes will be dry, the tongue may be furrowed, and the person often is thirsty. Routine oral care is critical for the comfort of a patient who is dehydrated or on a fluid restriction.

Edematous skin may feel cool because of fluid accumulation and a decrease in blood flow secondary to the pressure of the fluid. The fluid can stretch the skin, causing it to feel taut and hard. Assess

edema by pressing with a thumb or forefinger over the edematous area. Use a grading scale to standardize the description if an indentation (ranging from 1+ [slight edema; 2-mm indentation] to 4+ [pitting edema; 8-mm indentation]) remains when pressure is released. Assess for edema in areas where soft tissues overlie a bone, particularly the tibia, fibula, and sacrum.

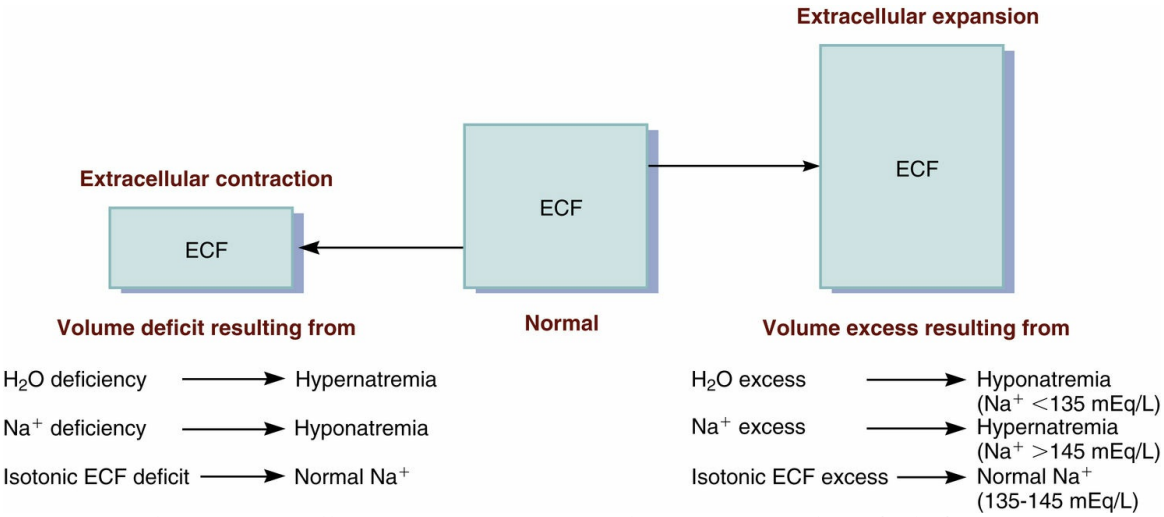

FIG. 16.12 Differential assessment of extracellular fluid (ECF) volume.

Good skin care is important. Protect tissues from extremes of heat and cold, prolonged pressure, and trauma. Frequent skin care and changes in position will prevent skin breakdown. Elevate edematous extremities to promote venous return and fluid reabsorption. Dehydrated skin needs frequent care without the use of soap. Applying moisturizing creams or oils increases moisture retention and stimulates circulation.

Fluid Therapy

Give IV fluids as ordered. Carefully monitor the rates of infusion of IV fluid solutions, especially when you are giving large volumes of fluid. This is especially true in patients with heart, renal, or neurologic problems.

In the presence of fluid volume deficit, you can use several

interventions to maintain adequate oral intake. Assess the patient's ability to obtain adequate fluids independently, express thirst, and swallow effectively. Fluids should be easily accessible. Provide a variety of fluids that the patient likes.[3] Serve fluids at a temperature preferred by the patient. Offer fluids every 1 to 2 hours and at select times, such as when giving medications. Remind the patient to finish all drinks.

If the patient is choosing to limit intake to decrease nocturia or incontinence, make it easier for the patient to reach the toilet when needed.[3] Help those with physical limitations, such as arthritis, to open and hold containers. Involve the dietitian, speech therapist, or occupational therapist for help with patients with dysphagia or physical limitations.

Sodium Imbalances

Sodium, the main cation of ECF, plays a major role in maintaining the concentration and volume of ECF and influencing water distribution between ECF and ICF. Sodium is important in generating and transmitting nerve impulses, muscle contractility, and regulating acid-base balance.

The serum sodium level reflects the ratio of sodium to water, not necessarily the amount of sodium in the body. Changes in the serum sodium level can reflect a primary water imbalance, primary sodium imbalance, or combination of the two. Sodium imbalances are typically associated with imbalances in ECF volume (Figs. 16.12 and 16.13). Because sodium is the primary determinant of ECF osmolality, sodium imbalances are typically associated with parallel changes in osmolality.

The GI tract absorbs sodium from foods. Typically, daily intake of sodium far exceeds the body's daily requirements. Sodium leaves the body through urine, sweat, and feces. The kidneys primarily regulate sodium balance. The kidneys control ECF sodium concentration by excreting or retaining water under the influence of ADH. Aldosterone plays a smaller role in sodium regulation by promoting sodium

reabsorption from the renal tubules.

Hypernatremia

Hypernatremia (high serum sodium) may occur with inadequate water intake, excess water loss, or, rarely, sodium gain. Because sodium is the major determinant of ECF osmolality, hypernatremia causes hyperosmolality. ECF hyperosmolality causes water to move out of the cells to restore equilibrium, leading to cellular dehydration. As discussed earlier, the primary protection against the development of hyperosmolality is thirst. Hypernatremia is not a problem in an alert person who has access to water, can sense thirst, and is able to swallow. Hypernatremia from water deficiency is often the result of an impaired level of consciousness or inability to obtain fluids.

Several clinical states can produce hypernatremia from water loss (Table 16.4). A deficiency in the synthesis or release of ADH from the posterior pituitary gland (central diabetes insipidus) or a decrease in kidney responsiveness to ADH (nephrogenic diabetes insipidus) can result in profound diuresis, producing a water deficit and hypernatremia. Hyperosmolality with osmotic diuresis can result from hyperglycemia associated with uncontrolled diabetes or giving concentrated hyperosmolar tube feedings.

Excess sodium intake with inadequate water intake can also lead to hypernatremia. Examples of sodium gain include IV administration of hypertonic saline or sodium bicarbonate, use of sodium-containing drugs, excess oral intake of sodium (e.g., ingesting seawater), and *primary aldosteronism* (excess aldosterone secretion) caused by a tumor of the adrenal glands.

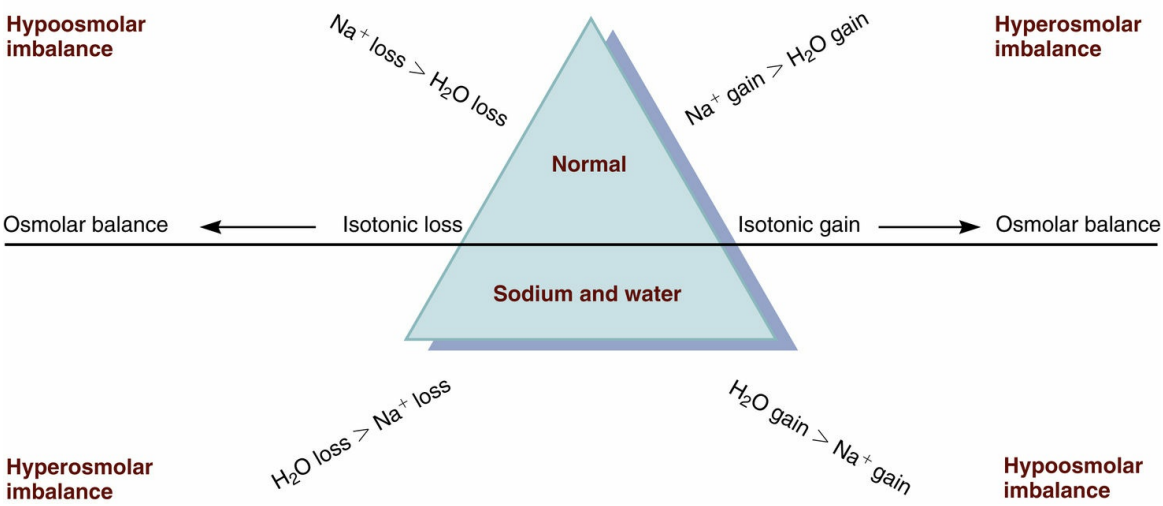

FIG. 16.13 Isotonic gains and losses affect mainly the extracellular fluid (ECF) compartment, with little or no water movement into the cells. Hypertonic imbalances cause water to move from inside the cell into the ECF to dilute the concentrated sodium, causing cell shrinkage. Hypotonic imbalances cause water to move into the cell, causing cell swelling.

TABLE 16.4 Sodium ImbalancesCauses and Manifestations

Hypernatremia (Na^+ >145 mEq/L [mmol/L])	Hyponatremia (Na^+ <136 mEq/L [mmol/L])
Causes	
Excess Sodium Intake	***Excess Sodium Loss***
• IV fluids: hypertonic NaCl, excess isotonic NaCl, IV sodium bicarbonate • Hypertonic tube feedings without water supplements • Near-drowning in salt water	• *GI losses:* diarrhea, vomiting, fistulas, NG suction • *Renal losses:* diuretics, adrenal insufficiency, Na^+ wasting renal disease • *Skin losses:* burns, wound drainage
Inadequate Water Intake	***Inadequate Sodium Intake***
• Unconscious or cognitively impaired persons	• Fasting diets
Excess Water Loss (↑ sodium concentration)	***Excess Water Gain (↓ sodium dilution)***
• ↑ Insensible water loss (high fever, heatstroke, prolonged hyperventilation) • Osmotic diuretic therapy • Diarrhea	• Excess hypotonic IV fluids • Primary polydipsia
Diseases	***Diseases***
• Diabetes insipidus • Primary hyperaldosteronism • Cushing syndrome • Uncontrolled diabetes	• SIADH • Heart failure • Primary hypoaldosteronism • Cirrhosis
Manifestations	
With Decreased ECF Volume	***With Decreased ECF Volume***
• Restlessness, agitation, lethargy, seizures, coma • Intense thirst, dry swollen tongue, sticky mucous membranes • Postural hypotension, ↓ CVP, weight loss, ↑ pulse • Weakness, muscle cramps	• Irritability, apprehension, confusion, dizziness, personality changes, tremors, seizures, coma • Dry mucous membranes • Postural hypotension, ↓ CVP, ↓ jugular venous filling, ↑ pulse, thready pulse • Cold and clammy skin
With Normal or Increased ECF Volume	***With Normal or Increased ECF Volume***
• Restlessness, agitation, twitching, seizures, coma • Intense thirst, flushed skin • Weight gain, peripheral and pulmonary edema, ↑ BP, ↑ CVP	• Headache, apathy, confusion, muscle spasms, seizures, coma • Nausea, vomiting, diarrhea, abdominal cramps • Weight gain, ↑ BP, ↑ CVP

Clinical Manifestations

The manifestations of hypernatremia are primarily the result of water shifting out of cells into ECF with resultant dehydration and shrinkage of cells (Table 16.4). Dehydration of brain cells results in changes in mental status, ranging from drowsiness, restlessness, confusion, and lethargy to seizures and coma.[4] If there is an accompanying ECF volume deficit, manifestations such as postural hypotension, tachycardia, and weakness occur.

Nursing and Interprofessional Management: Hypernatremia

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with

hypernatremia include:

- Electrolyte imbalance
- Fluid imbalance
- Risk for injury
- Potential complications: Seizures and coma

Nursing Implementation

Managing hypernatremia depends on the underlying cause and the patient's volume status. In primary water deficit, fluid replacement is given either orally or IV with isotonic solutions such as 0.9% sodium chloride.[2] If the problem is sodium excess, expect diluting the high sodium concentration with sodium-free IV fluids, such as 5% dextrose in water, and promoting sodium excretion with diuretics. Dietary sodium intake is often restricted. If the patient has an altered sensorium or is having seizures, initiate seizure precautions.

Monitor serum sodium levels, serum osmolality, and the patient's response to therapy. The serum sodium level should not decrease by more than 8 to 15 mEq/L in an 8-hour period.[2] Quickly reducing levels can cause a rapid shift of water back into the cells, causing cerebral edema and neurologic complications. This risk is greatest in the patient who developed hypernatremia over several days or longer.

Hyponatremia

Hyponatremia (low serum sodium) may result from a loss of sodium-containing fluids, water excess in relation to the amount of sodium (dilutional hyponatremia), or a combination of both (Table 16.4). Hyponatremia is usually associated with ECF hypoosmolality from the excess water. To restore balance, fluid shifts out of the ECF and into the cells, leading to cellular edema.

Common causes of hyponatremia from loss of sodium-rich body fluids include draining wounds, diarrhea, vomiting, and primary adrenal insufficiency. Inappropriate use of sodium-free or hypotonic

IV fluids causes hyponatremia from water excess. This may occur in patients after surgery or major trauma, or if we give fluids to patients with renal failure. Patients with psychiatric disorders may have an excess water intake. Syndrome of inappropriate antidiuretic hormone secretion (SIADH) results in dilutional hyponatremia caused by abnormal retention of water (see Chapter 49).

Clinical Manifestations

The manifestations are due to cellular swelling and first appear in the central nervous system (CNS). Mild hyponatremia has minor, nonspecific neurologic symptoms, including headache, irritability, and difficulty concentrating. More severe hyponatremia can cause confusion, vomiting, seizures, and even coma. If hyponatremia is severe and develops rapidly, irreversible neurologic damage or death from brain herniation can occur.

Nursing and Interprofessional Management: Hyponatremia

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with hyponatremia include:

- Electrolyte imbalance
- Risk for injury
- Acute confusion
- Potential complication: seizures and coma

Nursing Implementation

Managing hyponatremia from fluid loss includes replacing fluid using isotonic sodium-containing solutions, encouraging oral intake, and withholding all diuretics.[2] In mild hyponatremia caused by water

excess, fluid restriction may be the only treatment. Loop diuretics and demeclocycline may be given. If hyponatremia is acute or more serious, small amounts of IV hypertonic saline solution (3% sodium chloride) can restore the serum sodium level while the body is returning to a normal water balance.[5]

Vasopressor receptor antagonists (drugs that block the activity of ADH) are used to treat patients who cannot tolerate fluid restrictions or have more severe symptoms.[6] These drugs include conivaptan (Vaprisol) and tolvaptan (Samsca). Conivaptan is given IV to hospitalized patients with severe hyponatremia from water excess. Tolvaptan is given orally to treat hyponatremia from heart failure or SIADH.

Monitor serum sodium levels and the patient's response to therapy. Avoid rapid correction or overcorrection. The level should not increase by more than 6 to 12 mEq/L per hour in the first 24 hours and 18 mEq/L or less per hour within 48 hours.[6] Quickly increasing sodium levels can cause osmotic demyelination syndrome with permanent damage to nerve cells in the brain. An accurate urine output record is essential. The patient may need a urinary catheter placed if unable to help with monitoring output. If the patient has an altered sensorium or is having seizures, initiate seizure precautions.

Potassium Imbalances

Potassium is the major ICF cation, with 98% of the body potassium being in cells. For example, potassium concentration within muscle cells is around 140 mEq/L; potassium concentration in ECF is 3.5 to 5.0 mEq/L. The sodium-potassium pump in cell membranes maintains this concentration difference by pumping potassium into the cell and sodium out. Insulin helps by stimulating the sodium-potassium pump.

Because the ratio of ECF potassium to ICF potassium is the major factor in the resting membrane potential of nerve and muscle cells, potassium imbalances often affect neuromuscular and cardiac function. Potassium is involved with regulating intracellular

osmolality and promoting cellular growth. It is required for glycogen to be deposited in muscle and liver cells. It also plays a role in acid-base balance (discussed in the section on Acid-Base Regulation later in this chapter).

Diet is the main source for potassium. The typical Western diet contains roughly 50 to 100 mEq of potassium daily, mainly from protein-rich foods and various fruits and vegetables. Many salt substitutes used in low-sodium diets have substantial potassium. Patients may receive potassium from parenteral sources, including IV fluids; transfusions of stored, hemolyzed blood; and certain medications (e.g., potassium penicillin).

The kidneys are the primary route for potassium loss, eliminating about 90% of the daily potassium intake. Potassium excretion depends on the serum potassium level, urine output, and renal function. When serum potassium is high, urine potassium excretion increases, and when serum levels are low, excretion decreases. Large urine output can cause excess potassium loss. Impaired kidney function can cause potassium retention. There is an inverse relationship between sodium and potassium reabsorption in the kidneys. Factors that cause sodium retention (e.g., low blood volume, hyponatremia, aldosterone secretion) cause potassium excretion.

Hyperkalemia

Hyperkalemia (high serum potassium) may result from impaired renal excretion, a shift of potassium from ICF to ECF, a massive intake of potassium, or a combination of these factors (Table 16.5). The most common cause of hyperkalemia is renal failure. Adrenal insufficiency with subsequent aldosterone deficiency leads to potassium retention. Factors that cause potassium to move from ICF to ECF include acidosis, massive cell destruction (as in burn or crush injury, tumor lysis, severe infections), and intense exercise. In metabolic acidosis, potassium ions shift from ICF to ECF in exchange for hydrogen ions moving into the cell.

Digoxin-like drugs and β-adrenergic blockers (e.g., propranolol) can

impair entry of potassium into cells, resulting in higher ECF potassium concentrations. Several drugs, such as NSAIDs, potassium-sparing diuretics, angiotensin II receptor blockers (e.g., losartan), and angiotensin-converting enzyme (ACE) inhibitors (e.g., lisinopril), can contribute to hyperkalemia by reducing the kidney's ability to excrete potassium.[7]

Clinical Manifestations

The increased potassium concentration outside the cell changes the normal ECF and ICF ratio. This results in increased cell excitability and changes in impulse transmission to the nerves and muscles. The most clinically significant problems are the changes in cardiac conduction. The initial finding is tall, peaked T waves. As potassium increases, cardiac depolarization decreases, leading to loss of P waves, a prolonged PR interval, ST segment depression, and widening QRS complex (Fig. 16.14). Heart block, ventricular fibrillation, or cardiac standstill may occur.[7]

The patient may have fatigue, confusion, tetany, muscle cramps, paresthesias, and weakness. As potassium increases, loss of muscle tone and weakness or paralysis of other skeletal muscles, including the respiratory muscles, can occur, leading to respiratory arrest. Abdominal cramping, vomiting, and diarrhea occur from hyperactivity of GI smooth muscles.

Nursing and Interprofessional Management: Hyperkalemia

Nursing Diagnoses

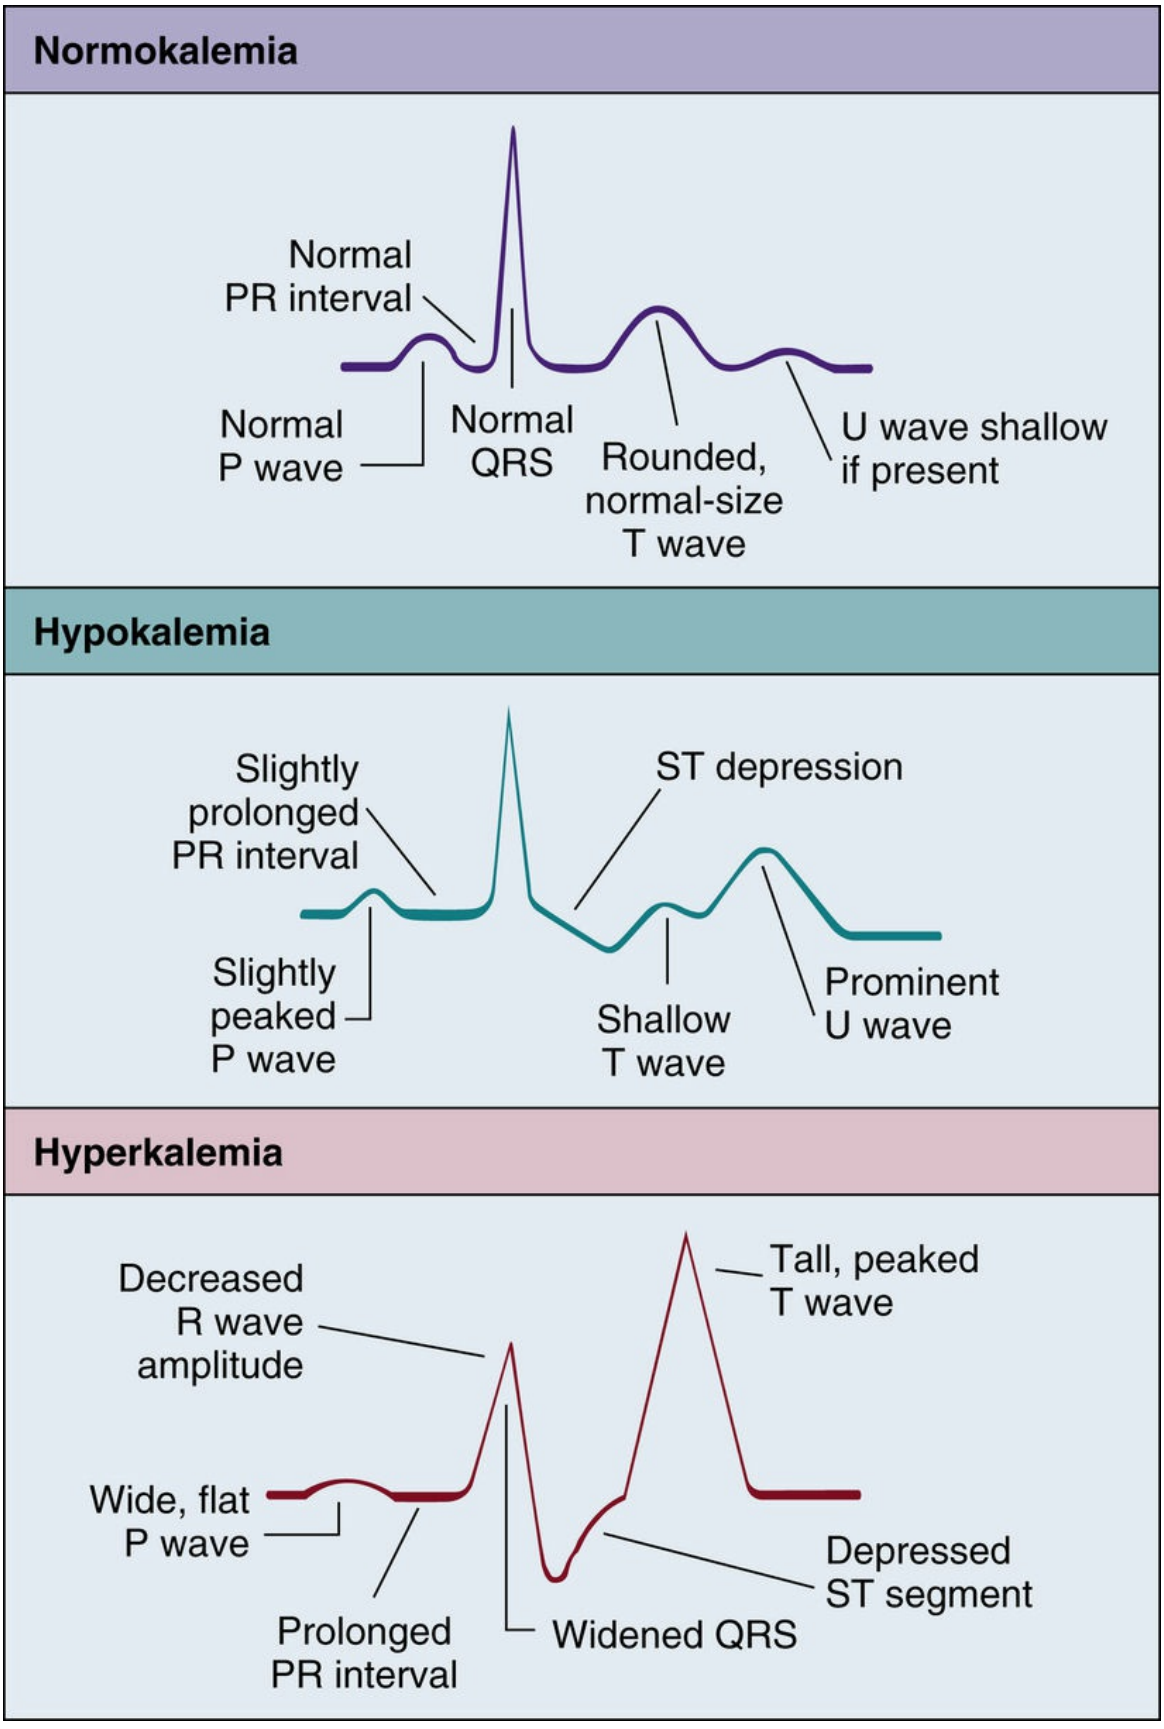
Nursing diagnoses and collaborative problems for the patient with hyperkalemia include:

- Electrolyte imbalance

- Activity intolerance
- Impaired cardiac output
- Potential complication: dysrhythmias

TABLE 16.5 Potassium ImbalancesCauses and Manifestations

Hyperkalemia (K^+ >5.0 mEq/L [mmol/L])	Hypokalemia (K^+ <3.5 mEq/L [mmol/L])
Causes	
Excess Potassium Intake	***Potassium Loss***
• Excess or rapid parenteral administration • Potassium-containing drugs (e.g., potassium penicillin) • Potassium-containing salt substitute	• *GI losses:* diarrhea, vomiting, fistulas, NG suction, ileostomy drainage • *Renal losses:* diuretics, hyperaldosteronism, magnesium depletion • *Skin losses:* diaphoresis • Dialysis
Shift of Potassium Out of Cells	***Shift of Potassium Into Cells***
• Acidosis • Tissue catabolism (e.g., fever, crush injury, sepsis, burns) • Intense exercise • Tumor lysis syndrome	• Increased insulin release (e.g., IV dextrose load) • Insulin therapy (e.g., with diabetic ketoacidosis) • Alkalosis • ↑ Epinephrine (e.g., stress)
Failure to Eliminate Potassium	***Lack of Potassium Intake***
• Renal disease • Adrenal insufficiency • *Medications:* Angiotensin II receptor blockers, ACE inhibitors, heparin, potassium-sparing diuretics, NSAIDs	• Starvation • Diet low in potassium • Failure to include potassium in parenteral fluids if NPO
Clinical Manifestations	
• Fatigue, irritability • Muscle weakness, cramps • Loss of muscle tone • Paresthesias, decreased reflexes • Abdominal cramping, diarrhea, vomiting • Confusion • Irregular pulse • Tetany	• Fatigue • Muscle weakness, leg cramps • Soft, flabby muscles • Paresthesias, decreased reflexes • Constipation, nausea, paralytic ileus • Shallow respirations • Weak, irregular pulse • Hyperglycemia
ECG Changes	***ECG Changes***
• Tall, peaked T wave • Prolonged PR interval • ST segment depression • Widening QRS • Loss of P wave • Ventricular fibrillation • Ventricular standstill	• Flattened T wave • Presence of U wave • ST segment depression • Prolonged QRS • Peaked P wave • Ventricular dysrhythmias • First- and second-degree heart block



Normokalemia
Normal PR interval
Normal P wave
Normal QRS
Rounded, normal-size T wave
U wave shallow if present
Hypokalemia
Slightly prolonged PR interval
ST depression
Slightly peaked P wave
Shallow T wave
Prominent U wave
Hyperkalemia
Decreased R wave amplitude
Tall, peaked T wave
Wide, flat P wave
Depressed ST segment
Prolonged PR interval
Widened QRS

FIG. 16.14 ECG changes associated with changes in potassium levels.

Nursing Implementation

Management of hyperkalemia consists of the following:

1. Stop oral and parenteral potassium intake (Table 16.6).
2. Increase potassium excretion. This may be done with loop or thiazide diuretics, dialysis, patiromer (Veltassa), and/or sodium polystyrene sulfonate (Kayexalate). Kayexalate, given orally or rectally, is used acutely to bind potassium in the bowel. Each gram of the drug removes roughly 1 mEq of potassium. Patients with renal failure need hemodialysis.[7] Patiromer, given orally, also binds potassium in the GI tract. It takes several hours to days to work and is best for patients with chronic hyperkalemia. Patiromer binds with many other oral drugs and reduces their effectiveness. You should not give it within 6 hours of other drugs.
3. Force potassium from ECF to ICF. A combination of IV regular insulin with dextrose and a β-adrenergic agonist stimulates the sodium-potassium pump, shifting potassium into cells. Using these drugs together is more effective than using either alone. Both metered-dose inhalers and nebulized β-adrenergic agonists (e.g., nebulized albuterol) are equally effective. IV sodium bicarbonate is an option if the patient is acidotic.[7]
4. Stabilize cardiac membranes. IV calcium chloride or calcium gluconate does not lower the potassium but serves as an antagonist to reverse the toxic effects on the cardiac cell membrane. This protects the patient from life-threatening dysrhythmias.[7]

TABLE 16.6 Nutritional TherapyHigh-Potassium

Foods

Fruits	Vegetables	Other Foods
• **Apricot, raw (medium)**	• Baked beans	• Bran or bran products
• **Avocado (¼ whole)**	• Butternut squash	• Chocolate (1.5–2 oz)
• **Banana (¼ whole)**	• Refried beans	• Granola
• **Cantaloupe**	• Black beans	• Milk, all types (1 cup)
• **Dried fruits**	• Broccoli, cooked	• Nutritional supplements (use only under the direction of physician or dietitian)
• **Grapefruit juice**	• Carrots, raw	• Nuts and seeds (1 oz)
• **Honeydew**	• Greens, except kale	• Peanut butter (2 Tbsp)
• **Orange (medium)**	• Mushrooms, canned	• Salt substitutes, Lite Salt
• **Orange juice**	• Potatoes, white and sweet	• Salt-free broth
• **Prunes**	• Spinach, cooked	• Yogurt
• **Raisins**	• Tomatoes or tomato products	
	• Vegetable juices	

When the potassium elevation is mild and the kidneys are functioning, it may be enough to (1) withhold potassium from the diet and IV sources and (2) increase renal potassium excretion by giving fluids and loop or thiazide diuretics. Patients with severe hyperkalemia or symptomatic patients should receive treatment to force potassium into cells.

Use continuous ECG monitoring for all patients with clinically significant hyperkalemia to detect dysrhythmias and monitor the effects of therapy. The patient with dangerous dysrhythmias should receive IV calcium immediately. Monitor BP because giving calcium rapidly can cause hypotension. When giving insulin, monitor for hypoglycemia and give glucose as needed. Monitor serum potassium levels as appropriate.

Hypokalemia

Hypokalemia (low serum potassium) can result from an increased loss of potassium, an increased shift of potassium from ECF to ICF, or, rarely, from deficient dietary potassium intake. The most common causes are abnormal losses from either the kidneys or GI tract. GI tract losses are associated with diarrhea, laxative misuse, vomiting, and ileostomy drainage. Renal losses occur when a patient is diuresing or has a low magnesium level. Low magnesium levels stimulate renin

and aldosterone release, resulting in potassium excretion.

Among the factors causing potassium to move from ECF to ICF are insulin therapy, especially in conjunction with diabetic ketoacidosis, and β-adrenergic stimulation (catecholamine release in stress, coronary ischemia). Alkalosis can cause a shift of potassium into cells in exchange for hydrogen, lowering potassium in ECF and causing symptomatic hypokalemia.

Clinical Manifestations

Hypokalemia alters the resting membrane potential, resulting in hyperpolarization (an increased negative charge within the cell) and impaired muscle contraction. Therefore the manifestations of hypokalemia involve changes in cardiac and muscle function (Table 16.5).

The most serious clinical problems are cardiac changes, including impaired repolarization, resulting in a flattened T wave, depressed ST segment, and the presence of a U wave. The P waves peak and the QRS complex is prolonged (Fig. 16.14). There is an increased incidence of heart block and potentially lethal ventricular dysrhythmias.

As with hyperkalemia, skeletal muscle weakness and paresthesias may occur. Severe hypokalemia can cause paralysis. This usually involves the extremities but can involve the respiratory muscles, leading to shallow respirations and respiratory arrest. Changes in smooth muscle function may lead to decreased GI motility (e.g., constipation, paralytic ileus). Finally, hypokalemia impairs insulin secretion, leading to glucose intolerance and hyperglycemia.

Nursing and Interprofessional Management: Hypokalemia

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with hypokalemia include:

- Electrolyte imbalance
- Activity intolerance
- Impaired cardiac output
- Potential complication: dysrhythmias

Nursing Implementation

Managing hypokalemia consists of oral or IV potassium chloride (KCl) supplements and increased dietary intake of potassium. Consuming potassium-rich foods can usually correct mild hypokalemia. See Table 16.6 for foods that are high in potassium. Clinically significant hypokalemia requires giving oral or IV KCl.

Safety Alert

IV KCl

- Always dilute IV KCl and do not give in concentrated amounts.
- Never give KCl via IV push or as a bolus.
- Invert IV bags containing KCl several times to ensure even distribution in the bag.
- Do not add KCl to a hanging IV bag to prevent giving a bolus dose.

IV KCl infusion rates should not exceed 10 mEq/hr unless the patient is in a critical care setting with continuous ECG monitoring and central line access for administration.[5] IV KCl must be given by infusion pump to ensure correct administration rate. Because KCl is irritating to the vein, assess IV sites at least hourly for phlebitis and infiltration. Infiltration can cause necrosis and sloughing of the surrounding tissue.

Patients who are critically ill and those at risk for hypokalemia should have continuous ECG monitoring to detect cardiac changes.

Monitor serum potassium levels and urine output as appropriate.

Check Your Practice

You are taking care of a 78-yr-old female patient with heart failure. She is taking furosemide (Lasix) and digitalis.

- What should you be alert for in a patient who takes both drugs?

KCl is usually given only if the urine output is at least 0.5 mL/kg of body weight per hour. Because patients on digoxin therapy have an increased risk for toxicity if their serum potassium level is low, monitor the patient for digitalis toxicity. Patients who have confusion, lethargy, or GI problems, including nausea/vomiting or poor appetite, may have digitalis toxicity. Visual problems, including blurred vision and changes in color vision, may be seen in digitalis toxicity.[8]

TABLE 16.7 Patient & Caregiver TeachingPrevention of Hypokalemia

Include the following instructions when teaching at-risk patients how to prevent hypokalemia:

1. For all patients at risk:
    - Report the signs and symptoms of hypokalemia (Table 16.5) to the HCP.
    - Have serum potassium levels checked regularly.
    - Regularly include foods high in potassium in your diet (Table 16.6).
    - Consume alcohol in moderation only.
    - Avoid consuming large amounts of licorice.
2. For patients taking oral potassium supplements:
    - Take the medication as prescribed to prevent

overdosing.
- Take the supplement with a full glass of water. Do not crush or chew tablets.

Teach patients ways to prevent hypokalemia (Table 16.7). Patients at risk should have regular monitoring of serum potassium levels. Teach the patient taking digitalis to report signs and symptoms of digoxin toxicity at once to the HCP.

Calcium Imbalances

Calcium has a role in many metabolic processes. It is the major cation in bones and teeth. Calcium plays a role in blood clotting, transmission of nerve impulses, myocardial contractions, and muscle contractions. The major source for calcium is dietary intake. Calcium absorption requires the active form of vitamin D. Vitamin D is obtained from foods or made in the skin by the action of sunlight on cholesterol.

The total body content of calcium is about 1200 g. The bones contain 99% of the body' calcium; the rest is in plasma and body cells. Of the calcium in plasma, 50% is bound to plasma proteins, primarily albumin; 40% is in a free or ionized form, and the rest is found bound with phosphate, citrate, or carbonate. The ionized or free calcium is biologically active. The serum pH influences how much calcium is ionized or bound to albumin. A decreased plasma pH (acidosis) decreases calcium binding to albumin, leading to more ionized calcium. An increased plasma pH (alkalosis) increases calcium binding, leading to decreased ionized calcium.

Serum calcium levels reflect the total level of all forms of plasma calcium. Serum albumin levels affect the interpretation of total calcium levels. Total calcium values increase or decrease directly with serum albumin levels. Ionized calcium levels are measured using special laboratory techniques or calculated using a formula. Albumin levels do not affect ionized calcium levels.

Parathyroid hormone (PTH) and calcitonin regulate calcium levels.

Since the bones serve as a readily available store of calcium, the body can usually keep calcium levels normal by regulating the movement of calcium into or out of the bone. Low serum calcium levels stimulate the parathyroid glands to make and release PTH. PTH increases bone resorption (movement of calcium out of bones), increases GI absorption of calcium, and increases renal tubule reabsorption of calcium. High serum calcium levels stimulate the release of calcitonin from the thyroid gland. Calcitonin has the opposite effect of PTH. It lowers the serum calcium level by increasing calcium deposition into bone, increasing renal calcium excretion, and decreasing GI absorption.

TABLE 16.8 Calcium ImbalancesCauses and Manifestations

Hypercalcemia (Ca^{2+} >10.5 mg/dL [2.62 mmol/L])	Hypocalcemia (Ca^{2+} <9.0 mg/dL [2.25 mmol/L])
Causes	
Increased Total Calcium	***Decreased Total Calcium***
• **Hyperparathyroidism** • **Hematologic cancer** • **Cancers with bone metastasis** • **Prolonged immobilization** • **Vitamin A or D overdose** • **Paget's disease** • **Adrenal insufficiency** • **Thyrotoxicosis** • **Thiazide diuretics** • **Excess dairy intake** • **Calcium-containing antacids** • ***Mycobacterium* infection**	• Primary hypoparathyroidism • Renal insufficiency • Acute pancreatitis • High phosphate level • Vitamin D deficiency, malnutrition • Low magnesium level • Bisphosphonates • Tumor lysis syndrome • Loop diuretics • Chronic alcohol use • Diarrhea • ↓ Serum albumin
Increased Ionized Calcium	***Decreased Ionized Calcium***
• **Acidosis**	• Alkalosis • Receiving excess citrated blood
Manifestations	
• **Lethargy, weakness, fatigue** • **Decreased memory** • **Depressed reflexes** • **↑ BP** • **Confusion, psychosis** • **Anorexia, nausea, vomiting** • **Bone pain, fractures** • **Polyuria, dehydration** • **Nephrolithiasis** • **Seizures, coma**	• Weakness, fatigue • Depression, irritability, confusion • Hyperreflexia, muscle cramps • ↓ BP • Numbness and tingling in extremities and region around mouth • Chvostek's sign • Trousseau's sign • Laryngeal and bronchial spasms • Tetany, seizures
ECG Changes	***ECG Changes***
• **Shortened ST segment** • **Shortened QT interval** • **Ventricular dysrhythmias** • **Increased digitalis effect**	• Elongation of ST segment • Prolonged QT interval • Ventricular tachycardia

Hypercalcemia

Hypercalcemia (high serum calcium) is caused by hyperparathyroidism in about two thirds of persons. Cancers, especially hematologic, breast, and lung cancers, cause the remaining third. Cancers lead to hypercalcemia through tumor-producing factors that prompt osteoclastic activity and bone resorption.[9] More rare causes include thiazide diuretic use, prolonged immobilization, and increased calcium intake (e.g., use of calcium-containing antacids).

Excess calcium acts like a sedative, leading to reduced excitability of muscles and nerves. Neurologic manifestations begin with fatigue, lethargy, weakness, and confusion and progress to hallucinations, seizures, and coma. Changes in cardiac conduction can lead to dysrhythmias, including heart block and ventricular tachycardia.

Table 16.8 lists the causes and manifestations of hypercalcemia.

Nursing and Interprofessional Management: Hypercalcemia

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with hypercalcemia include:

- Electrolyte imbalance
- Acute confusion
- Impaired physical mobility
- Potential complication: dysrhythmias

Nursing Implementation

Management depends on the degree of hypercalcemia, patient's condition, and underlying cause. Patients with mild hypercalcemia should stop any medications related to hypercalcemia, start a diet low in calcium, increase weight-bearing activity, and maintain adequate hydration. The patient must drink 3000 to 4000 mL of fluid daily to promote the renal excretion of calcium and decrease the chance of kidney stone formation. Fluids that promote urine acidity (cranberry or prune juice) will help to prevent formation of stones.

Managing severe hypercalcemia includes giving IV isotonic saline, a bisphosphonate, and calcitonin. IV saline therapy requires careful monitoring. Fluid overload can occur in patients who cannot excrete the excess sodium because of impaired renal function. Bisphosphonates (e.g., pamidronate, zoledronic acid) are the gold standard in treating hypercalcemia, particularly when caused by cancer. They interfere with the activity of osteoclasts, cells that break down bone. Because it takes 2 to 4 days for them to achieve maximum effect, patients receive calcitonin injections for an immediate effect. Calcitonin rapidly increases renal calcium excretion. However,

therapy is effective for only a few days and may cause tachycardia. For patients who do not respond to bisphosphonates or have renal impairment, denosumab (Prolia) may be used as an alternative treatment.[9] Dialysis is an option in life-threatening situations.

Hypocalcemia

Hypocalcemia (low serum calcium) can result from any condition associated with PTH deficiency. This may occur with surgical removal of part of, or injury to, the parathyroid glands during thyroid or neck surgery or with neck radiation. The patient who receives multiple blood transfusions can develop hypocalcemia because citrate, used as an anticoagulant in blood bags, binds with calcium, decreasing ionized calcium levels. Sudden alkalosis may result in symptomatic hypocalcemia despite a normal total serum calcium level. The high pH increases calcium binding to protein, decreasing the amount of ionized calcium. Table 16.8 lists causes and manifestations of hypocalcemia.

Low ionized calcium levels decrease the threshold for activating the sodium channels that cause cell membrane depolarization. This results in increased nerve excitability and sustained muscle contraction, or *tetany.* Clinical signs of tetany include Chvostek's sign and Trousseau's sign. *Chvostek's sign* is contraction of facial muscles in response to a tap over the facial nerve in front of the ear (Fig. 16.15, *A*). *Trousseau's sign* refers to carpal spasms induced by inflating a BP cuff on the arm (Fig. 16.15, *B* and *C*). When you inflate the cuff above the systolic pressure, carpal spasms occur within 3 minutes if hypocalcemia is present. Other manifestations of tetany are laryngeal stridor, dysphagia, paresthesia, and numbness and tingling around the mouth or in the extremities. Cardiac effects include decreased cardiac contractility and ECG changes. A prolonged QT interval may develop into ventricular tachycardia.

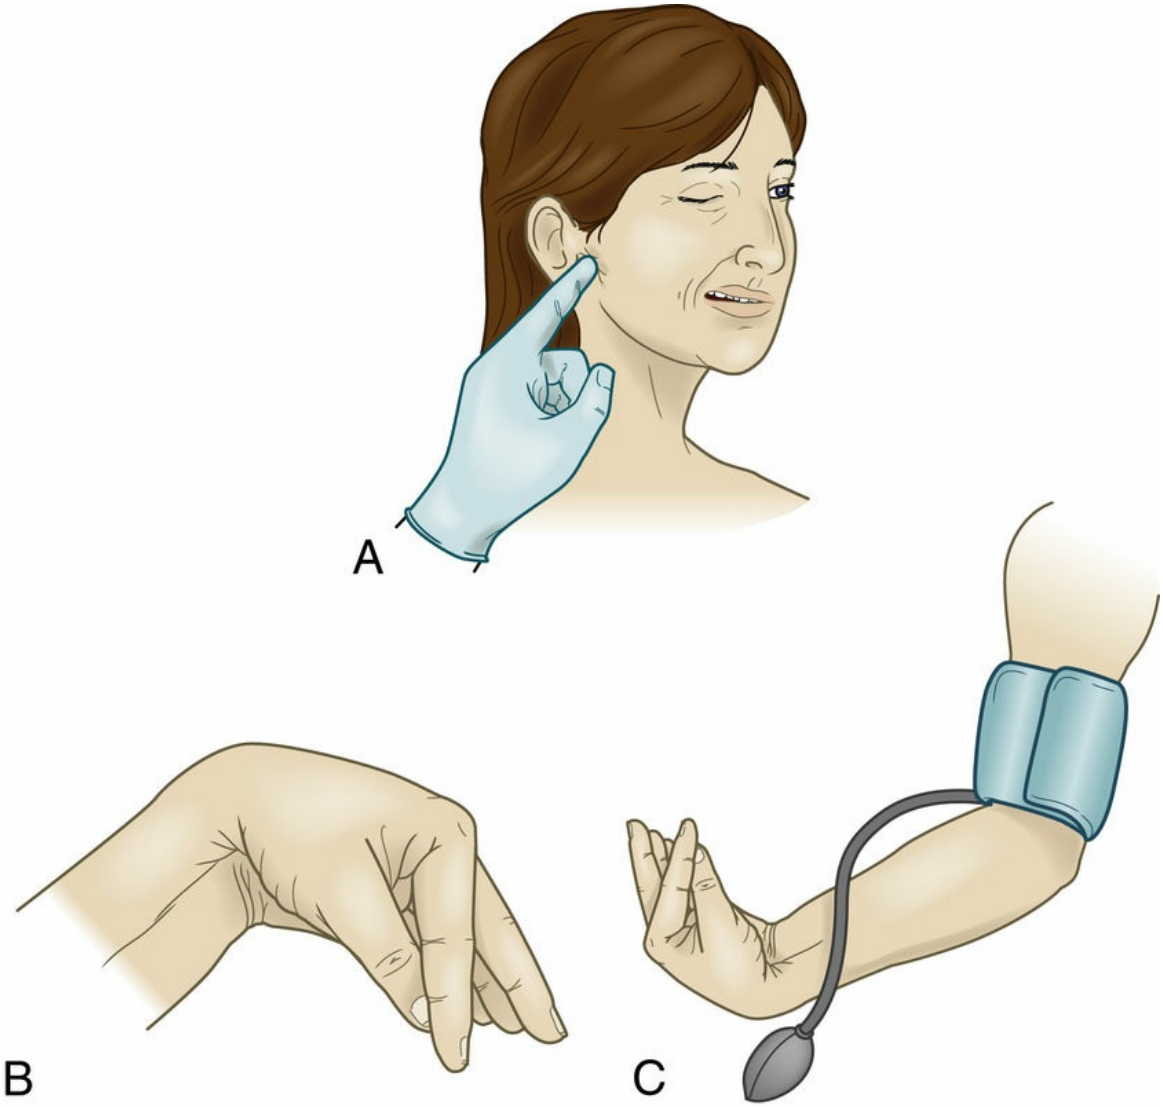


FIG. 16.15 Tests for hypocalcemia. **A,** Chvostek's sign is contraction of facial muscles in response to a light tap over the facial nerve in front of the ear. **B,** Trousseau's sign is a carpal spasm induced by **(C)** inflating a BP cuff above the systolic pressure for a few minutes.

Nursing and Interprofessional Management: Hypocalcemia

Nursing Diagnoses

Nursing diagnoses and collaborative problems for the patient with hypocalcemia include:

- Electrolyte imbalance
- Impaired breathing
- Activity intolerance
- Potential complications: fracture, respiratory arrest

Nursing Implementation

Managing hypocalcemia depends on the underlying cause and the presence of symptoms. Treating mild or asymptomatic hypocalcemia involves a diet high in calcium-rich foods and calcium and vitamin D supplementation. Symptomatic hypocalcemia is treated with IV calcium gluconate.[10] Measures to promote CO_2 retention, such as breathing into a paper bag or sedating the patient, can control muscle spasm and other symptoms of tetany until the calcium level is corrected. Patients taking loop diuretics may need to change to thiazide diuretics to decrease urinary calcium excretion. Closely assess any patient who had thyroid or neck surgery in the immediate postoperative period for manifestations of hypocalcemia because of the proximity of the surgery to the parathyroid glands. Adequately treat pain and anxiety because hyperventilation-induced respiratory alkalosis can precipitate hypocalcemic symptoms.

Phosphate Imbalances

Phosphorus is the primary anion in ICF and the second most abundant element in the body after calcium. Most phosphorus is in bones and teeth as calcium phosphate. The remaining phosphorus is metabolically active in the form of phosphate salts. Thus, we use the terms *phosphorus* and *phosphate* interchangeably in this text. Phosphate is essential to the function of muscle, red blood cells, and the nervous system. It is involved in the acid-base buffering system; the mitochondrial formation of ATP; cellular uptake and use of glucose; and carbohydrate, protein, and fat metabolism.

PTH maintains serum phosphate levels and balance. Proper phosphate balance requires adequate renal functioning because the

kidneys are the major route of phosphate excretion. When the phosphate level in the glomerular filtrate falls below normal or PTH levels are low, the kidneys reabsorb more phosphate. A reciprocal relationship exists between phosphate and calcium. This means a low serum calcium level will result in a high phosphate level and vice-versa.[10]

Hyperphosphatemia

Hyperphosphatemia (high serum phosphate) is common in patients with acute kidney injury or chronic kidney disease, which alter the kidney's ability to excrete phosphate. Other causes include excess phosphate intake from the use of phosphate-containing laxatives or enemas or a shift of phosphate from ICF to ECF. This may occur in patients with tumor lysis syndrome or rhabdomyolysis. Hypoparathyroidism and vitamin D intoxication cause increased kidney phosphate reabsorption. Table 16.9 describes causes and manifestations of hyperphosphatemia.

Hyperphosphatemia can be asymptomatic unless calcium binds with phosphate, leading to manifestations of hypocalcemia. These include tetany, muscle cramps, paresthesias, hypotension, dysrhythmias, and seizures.[10] Long-term, increased phosphate levels result in the development of calcified deposits outside of the bones. These calcium deposits can be found in soft tissues, such as joints, arteries, skin, corneas, and kidneys, and cause organ dysfunction, notably renal failure.

Managing hyperphosphatemia involves identifying and treating the underlying cause. Restrict the intake of foods and fluids high in phosphorus (e.g., dairy products). Oral phosphate-binding agents (e.g., calcium carbonate) limit intestinal phosphate absorption and increase phosphate secretion in the intestine. With severe hyperphosphatemia, hemodialysis may be used to rapidly decrease levels. Volume expansion and forced diuresis with a loop diuretic may increase phosphate excretion. If hypocalcemia is present, institute measures to correct calcium levels. See Chapter 46 for more

information about treating hyperphosphatemia associated with kidney disease.

Hypophosphatemia

Hypophosphatemia (low serum phosphate) can result from decreased intestinal absorption, increased urinary excretion, or ECF to ICF shifts. Malabsorption, diarrhea, and phosphate-binding antacids lead to decreased absorption. Phosphate shifts occur in respiratory alkalosis, treatment of diabetic ketoacidosis, and refeeding syndrome (reinstitution of nutrition to patients who are severely malnourished). Hypophosphatemia may occur in those who are malnourished or receive parenteral nutrition with inadequate phosphorus replacement. Table 16.9 lists causes and manifestations of hypophosphatemia.

TABLE 16.9 Phosphate ImbalancesCauses and Manifestations

Hyperphosphatemia (PO_4^{3-} >4.5 mg/dL [1.45 mmol/L])	Hypophosphatemia (PO_4^{3-} <3.0 mg/dL [0.97 mmol/L])
Causes	
• Renal failure • Phosphate enemas (e.g., Fleet Enema) • Excess ingestion (e.g., phosphate-containing laxatives) • Rhabdomyolysis • Tumor lysis syndrome • Thyrotoxicosis • Hypoparathyroidism • Sickle cell anemia, hemolytic anemia • Hyperthermia	• Malabsorption syndromes • Chronic diarrhea • Malnutrition, vitamin D deficiency • Parenteral nutrition • Chronic alcohol use • Phosphate-binding antacids • Diabetic ketoacidosis • Hyperparathyroidism • Refeeding syndrome • Respiratory alkalosis
Manifestations	
• Hypocalcemia • Numbness and tingling in extremities and region around mouth • Hyperreflexia, muscle cramps • Tetany, seizures • Calcium-phosphate precipitates in skin, soft tissue, cornea, viscera, blood vessels	• CNS depression (confusion, coma) • Muscle weakness, including respiratory muscle weakness • Polyneuropathy, seizures • Heart problems (dysrhythmias, heart failure) • Osteomalacia, rickets • Rhabdomyolysis

Most of the manifestations of hypophosphatemia result from impaired cellular energy and O_2 delivery due to low levels of cellular

ATP and 2,3-diphosphoglycerate (2,3-DPG), an enzyme in RBCs that facilitates O_2 delivery to the tissues. Mild to moderate hypophosphatemia is often asymptomatic. Severe hypophosphatemia may be fatal because of decreased cellular function. Acute manifestations include CNS depression, muscle weakness and pain, respiratory failure, and heart failure. Chronic hypophosphatemia alters bone metabolism, resulting in rickets and osteomalacia.

Managing mild phosphate deficiency involves increasing oral intake with dairy products or phosphate supplements. Dairy products are better tolerated because phosphate supplements are often associated with adverse GI effects, including diarrhea and bloating.[11] Symptomatic hypophosphatemia can be fatal and usually requires IV administration of sodium phosphate or potassium phosphate. During IV replacement, monitor serum calcium and phosphate levels every 6 to 12 hours.[11] Perform frequent assessment during IV therapy, as complications include hypocalcemia, hyperkalemia, hypotension, and dysrhythmias.

Magnesium Imbalances

Magnesium, the second most abundant intracellular cation, plays a key role in essential cellular processes. It is a cofactor in many enzyme systems, including those responsible for carbohydrate metabolism, DNA and protein synthesis, blood glucose control, and BP regulation. Magnesium is needed for the production and use of ATP, the energy source for the sodium-potassium pump. Muscle contraction and relaxation, normal neurologic function, and neurotransmitter release depend on magnesium.

Table 16.10 Magnesium ImbalancesCauses and Manifestations

Hypermagnesemia (Mg^+ >2.1 mEq/L [1.05 mmol/L])	Hypomagnesemia (Mg^+ <1.3 mEq/L [0.65 mmol/L])
Causes	
• Renal failure • IV administration of magnesium, especially for treatment of eclampsia • Tumor lysis syndrome • Hypothyroidism • Metastatic bone disease • Adrenal insufficiency • Antacids, laxatives	• GI tract fluid losses (e.g., diarrhea, NG suction) • Chronic alcohol use • Malabsorption syndromes • Prolonged malnutrition • Acute pancreatitis • ↑ Urine output • Hyperglycemia • Proton pump inhibitor therapy
Manifestations	
• Lethargy, drowsiness • Muscle weakness • Urinary retention • Nausea, vomiting • Diminished deep tendon reflexes • Flushed, warm skin, especially facial • ↓ Pulse, ↓ BP	• Confusion • Muscle cramps • Tremors, seizures • Vertigo • Hyperactive deep tendon reflexes • Chvostek's and Trousseau's signs • ↑ Pulse, ↑ BP, dysrhythmias

About 50% to 60% of the body's magnesium is stored in muscle and bone; 30% is in cells, with only 1% in ECF. The kidneys and GI system regulate serum magnesium by controlling the amount of magnesium reabsorbed in the ascending loop of Henle and distal tubules and absorption in the small intestine. GI absorption and renal reabsorption increase when magnesium levels are low.

Hypermagnesemia

Hypermagnesemia (high serum magnesium level) usually occurs only with increased magnesium intake accompanied by renal insufficiency or failure. A patient with chronic kidney disease who ingests products containing magnesium (e.g., Maalox, Milk of Magnesia) will have a problem with excess magnesium. Magnesium excess could develop in a pregnant woman receiving magnesium sulfate for the treatment of eclampsia or in patients taking laxatives and antacids that contain magnesium. Table 16.10 lists the causes and manifestations of hypermagnesemia.

Excess magnesium inhibits acetylcholine release at the myoneural junction and calcium movement into cells, impairing nerve and muscle function. Initial manifestations include hypotension, facial flushing, lethargy, urinary retention, nausea, and vomiting. As the serum magnesium level increases, deep tendon reflexes are lost,

followed by muscle paralysis and coma. Respiratory and cardiac arrest can occur.

Management begins with avoiding magnesium-containing drugs and limiting dietary intake of magnesium-containing foods (e.g., green vegetables, nuts, bananas, oranges, peanut butter, chocolate). If renal function is adequate, increased fluids and diuretics promote urinary excretion of magnesium. The patient with impaired renal function may need dialysis. If hypermagnesemia is symptomatic, giving IV calcium gluconate will oppose the effects of the excess magnesium on cardiac muscle.[12]

Hypomagnesemia

Hypomagnesemia (low serum magnesium level) occurs in patients with limited magnesium intake or increased GI or renal losses. Causes of hypomagnesemia from insufficient food intake include prolonged fasting or starvation and chronic alcohol use. Another potential cause is prolonged parenteral nutrition without magnesium supplementation. Fluid loss from the GI tract, acute pancreatitis, and poorly controlled diabetes may contribute to hypomagnesemia. Diuretics, proton-pump inhibitors, and certain antibiotics may lead to magnesium loss.[12] Table 16.10 lists the causes and manifestations of hypomagnesemia.

Clinically, hypomagnesemia resembles hypocalcemia. Neuromuscular manifestations are common, such as muscle cramps, tremors, hyperactive deep tendon reflexes, Chvostek's sign, and Trousseau's sign. Neurologic manifestations include confusion, vertigo, and seizures. Dysrhythmias, such as torsades de pointes and ventricular fibrillation, can occur.

Management depends on the underlying cause and the patient's symptoms. Mild magnesium deficiency involves oral supplements and increased dietary intake of foods high in magnesium. If the deficiency is severe or if hypocalcemia is present, IV magnesium (e.g., magnesium sulfate) is given. Monitor vital signs and use an infusion pump, since rapid administration can lead to hypotension and cardiac

or respiratory arrest.

Acid-Base Imbalances

The body normally maintains a steady balance between the acids continually produced during normal metabolism and the bases that neutralize and promote the excretion of the acids. Because these acids alter the body's internal environment, their regulation is necessary to maintain homeostasis and acid-base balance. Many health problems may lead to acid-base imbalances. Patients with diabetes, chronic obstructive pulmonary disease (COPD), and kidney disease often develop acid-base imbalances.

Remember that an acid-base imbalance is not a disease but a symptom of an underlying health problem. Always consider the possibility of acid-base imbalance in patients with serious illnesses.

pH And Hydrogen lON Concentration

The acidity or alkalinity of a solution depends on its hydrogen ion (H^+) concentration. An increase in H^+ concentration leads to acidity; a decrease leads to alkalinity. H^+ concentration is usually expressed as a negative logarithm (symbolized as *pH*). The use of the negative logarithm means that the lower the pH, the higher is the H^+ concentration.

The pH of a chemical solution may range from 1 to 14. A solution with a pH of 7 is considered neutral. An acid solution has a pH less than 7, and an alkaline solution has a pH greater than 7. Blood is slightly alkaline and has a normal arterial pH of 7.35 to 7.45. Medically, if the pH drops below 7.35, a person has **acidosis**. If the blood pH is greater than 7.45, the person has **alkalosis** (Fig. 16.16).

Acid-Base Regulation

The body uses 3 mechanisms to regulate acid-base balance and keep

the pH between 7.35 and 7.45. These are the buffer systems, respiratory system, and renal system. Each mechanism reacts at different speeds. Buffers are the fastest, reacting immediately. The respiratory system responds in minutes and reaches maximum effectiveness in hours. The renal response occurs hours to days after a change in pH. The kidneys can maintain balance indefinitely in patients with chronic imbalances. But, if the person has impaired kidney function, the kidneys will not be effective in maintaining acid-base balance.

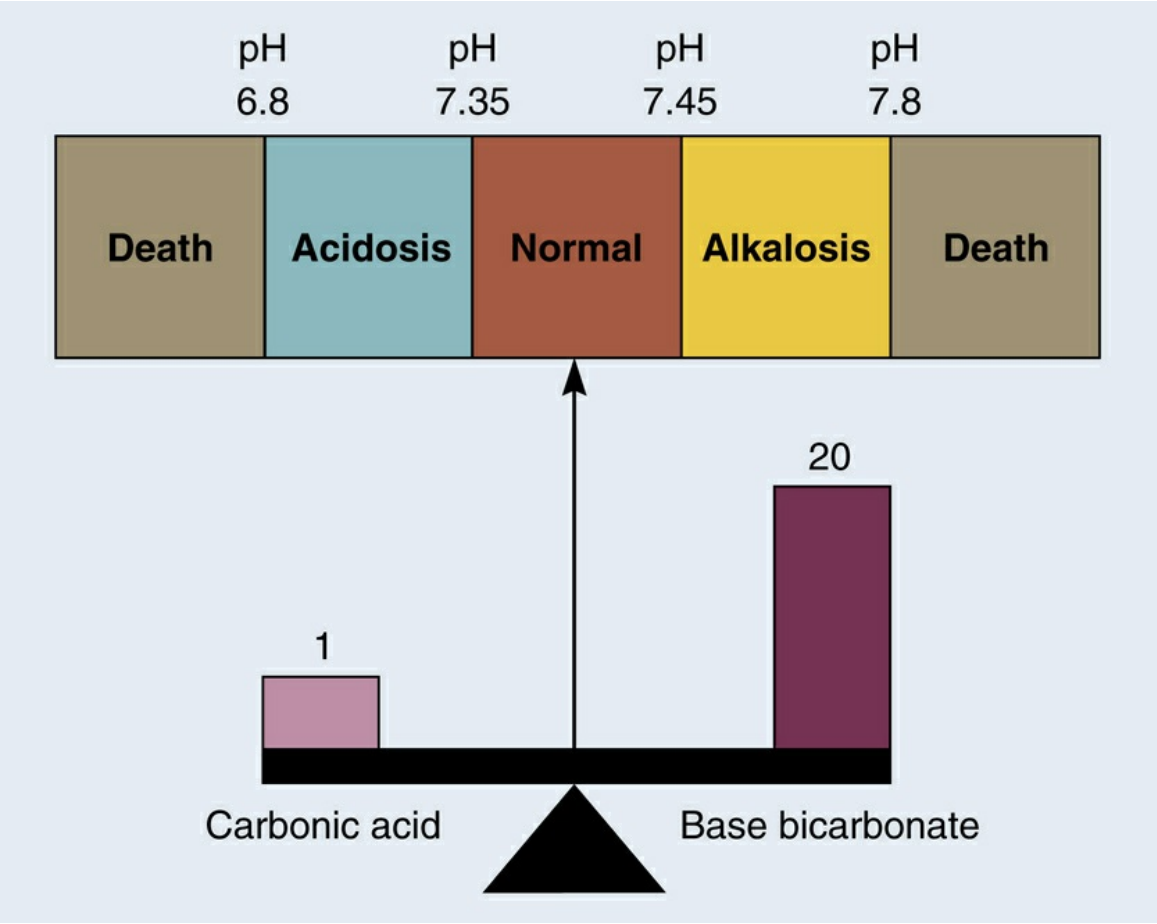

FIG. 16.16 The normal range of plasma pH is 7.35 to 7.45. A normal pH is maintained by a ratio of 1 part carbonic acid to 20 parts bicarbonate.

Buffer System

Buffering is the primary regulator of acid-base balance. **Buffers** act chemically to change strong acids into weaker ones or bind acids to neutralize them. This minimizes the effect of acids on blood pH until they can be excreted from the body. Buffers can maintain pH only if the respiratory and renal systems function adequately.

All body fluids contain buffers. The major buffer in ECF is the carbonic acid–bicarbonate system (H_2CO_3/HCO_3^-). Other buffer systems include phosphate, protein, and hemoglobin. The cell can act as a buffer by shifting H^+ in and out of the cell. When ECF levels of H^+ are increased, H^+ enters the cell in exchange for potassium. This may result in hyperkalemia as potassium moves into the ECF. Conversely, with decreased H^+ levels, H^+ enters plasma in exchange for potassium. This is why a patient with alkalosis can develop hypokalemia.

A buffer consists of a weak acid, which releases H^+ when fluid is too alkaline, or a base and its salt, which takes up H^+ when fluid is too acidic. The carbonic acid–bicarbonate buffer system neutralizes hydrochloric acid (HCl), a strong acid, by combining it with a strong base. This prevents the acid from making a large decrease in pH.

$$\underset{\text{Strong Acid}}{HCL} + \underset{\text{Strong Base}}{Na_2CO_3} \rightarrow \underset{\text{Salt}}{NaCl} + \underset{\text{Weak Acid}}{H_2CO_3}$$

The carbonic acid is broken down into H_2O and CO_2. The lungs excrete CO_2, either combined with insensible H_2O as carbonic acid or alone as CO_2.

The phosphate, protein, and hemoglobin buffer systems act in the same way as the bicarbonate system. The main components of the phosphate system are monohydrogen phosphate (HPO_4^{2-}) and dihydrogen phosphate ($H_2PO_4^-$). A phosphate, combined with

sodium, can neutralize a strong acid, such as HCl, by forming sodium chloride (NaCl) and sodium biphosphate (NaH_2PO_4), a weak acid. If a strong base, such as sodium hydroxide (NaOH), is present, sodium biphosphate (NaH_2PO_4) neutralizes it to a weaker base (Na_2HPO_4) and H_2O.

Intracellular and extracellular proteins can act as an acid or base. Because the chemical structure of amino acids has an acid and a base, they can accept H^+ if pH decreases or release H^+ if fluid is too alkaline. Some amino acids have basic radicals (NH_3OH [ammonium hydroxide]) that can dissociate into NH_3^+ (ammonia) and OH^- (hydroxide). The OH^- can combine with H^+ to form H_2O.

Hemoglobin can bind with both H^+, forming a weak acid, and CO_2, forming carbaminohemoglobin ($HbCO_2$). $HbCO_2$ dissociates in the lungs, releasing CO_2 for exhalation. Because H^+ can combine only with hemoglobin that has released its O_2, venous blood is a better buffer than arterial blood, which contains saturated hemoglobin. Hemoglobin also aids in controlling pH by shifting chloride in and out of RBCs in exchange for bicarbonate.

The buffer system maintains a 20:1 ratio between HCO_3^- and carbonic acid in ECF. The body's ability to keep this ratio is important in controlling pH. For example, excess carbonic acid increases the ratio and decreases pH, resulting in acidosis. In response, the body can increase HCO_3^- levels to keep the ratio 20:1 and keep the pH near normal, a state called *compensation*. For example, a ratio of 40:2 is present in compensated acid-base balance.

Respiratory System

The lungs help maintain a normal pH by excreting CO_2 and water, which are by-products of cellular metabolism. When released into the circulation, CO_2 enters RBCs and combines with H_2O to form H_2CO_3. Carbonic acid dissociates into H^+ and HCO_3^-. Hemoglobin buffers the

free H^+, and the HCO_3^- diffuses into the plasma. This process is reversed in the pulmonary capillaries, forming CO_2 that is excreted by the lungs.

The amount of CO_2 in the blood directly relates to carbonic acid and H^+ concentration. With increased respirations, more CO_2 is expelled and less stays in the blood. This leads to less carbonic acid and less H^+. With decreased respirations, more CO_2 stays in the blood. This leads to increased carbonic acid and more H^+.

The respiratory center in the medulla controls the rate of excretion of CO_2. If increased amounts of CO_2 or H^+ are present, the respiratory center stimulates an increased rate and depth of breathing to "blow off" CO_2 through hyperventilation. If the center senses low H^+ or CO_2 levels, respirations are reduced and CO_2 retained. The older adult has an impaired compensatory ability due to decreased respiratory function.

Renal System

Under normal conditions, the body depends on the kidneys to reabsorb and conserve all the HCO_3^- they filter and excrete some of the acid produced by cellular metabolism. The 3 mechanisms of acid excretion include (1) secreting small amounts of free hydrogen into the renal tubule, (2) combining H^+ with ammonia (NH_3) to form ammonium (NH_4^+), and (3) excreting weak acids.

The kidneys normally excrete acidic urine (average pH is 6). As a compensatory mechanism, the pH of the urine can decrease to 4 or increase to 8. To compensate for acidosis, the kidneys can reabsorb more HCO_3^- and excrete excess H^+. This increases the blood pH and decreases the urine pH. In the older adult, the kidneys are less able to compensate for acid load.

Alterations in Acid-Base Balance

An acid-base imbalance results when there is a change in the ratio of 20:1 between base and acid content. This occurs when a disease or process alters one side of the ratio (e.g., CO_2 retention in pulmonary disease) and the compensatory processes that maintain the other side of the ratio (e.g., increased renal HCO_3^- reabsorption) either fail or are inadequate. The compensatory process may be inadequate because either the pathophysiologic activity is overwhelming or there is not enough time for the compensatory process to work.

Acid-base imbalances are classified as respiratory or metabolic. *Respiratory imbalances* result from changes in carbonic acid concentration. *Metabolic imbalances* affect the base HCO_3^-. Acidosis occurs with an increase in carbonic acid (respiratory acidosis) or decrease in HCO_3^- (metabolic acidosis). Alkalosis occurs with a decrease in carbonic acid (respiratory alkalosis) or increase in HCO_3^- (metabolic alkalosis). Imbalances are further classified as acute or chronic. Chronic imbalances allow greater time for compensatory changes.

Respiratory Acidosis

Respiratory acidosis (carbonic acid excess) occurs when a person has hypoventilation (Table 16.11). Hypoventilation leads to a buildup of CO_2, resulting in an accumulation of carbonic acid in the blood. Carbonic acid dissociates, releasing H^+ and decreasing pH. If CO_2 is not eliminated from the blood, acidosis results from the accumulation of carbonic acid (Fig. 16.17, *A*).

During acute respiratory acidosis, the renal compensatory mechanisms begin to work within 24 hours. The kidneys conserve HCO_3^- and secrete increased H^+ into the urine. Until the renal mechanisms have an effect, the serum HCO_3^- level will usually be normal and then increase.

Respiratory Alkalosis

Respiratory alkalosis (carbonic acid deficit) occurs with hyperventilation, or an increase in respiratory rate or volume (Table 16.11). The primary cause of respiratory alkalosis is hypoxemia from acute pulmonary disorders (e.g., pneumonia, pulmonary embolus). Hyperventilation can occur as a physiologic response to metabolic acidosis and increased metabolic demands (e.g., fever). Pain, anxiety, and some CNS disorders can increase respirations without a physiologic need. The decrease in the arterial CO_2 level leads to decreased carbonic acid concentration in the blood and an increased pH (Fig. 16.17, *A*).

Compensated respiratory alkalosis is rare. In acute respiratory alkalosis, aggressive treatment of the cause of hypoxemia is essential and usually does not allow time for compensation to occur. If the respiratory alkalosis is caused by significant pain, anxiety, or panic, breathing into a closed system to rebreathe eliminated CO_2 can aid in the compensatory process. Some buffering may occur with shifting of HCO_3^- into cells in exchange for chloride ions (Cl^-). In chronic respiratory alkalosis that occurs with pulmonary fibrosis or CNS disorders, compensation may include renal excretion of HCO_3^-.

Metabolic Acidosis

Metabolic acidosis (base bicarbonate deficit) occurs when an acid other than carbonic acid accumulates in the body or when bicarbonate is lost in body fluids (Table 16.11 and Fig. 16.17, *B*). Ketoacid accumulation in diabetic ketoacidosis and lactic acid accumulation with shock are examples of acid accumulation. Severe diarrhea resulting in loss of HCO_3^- is an example of a base deficit. In renal disease, the kidneys lose their ability to reabsorb HCO_3^- and secrete H^+. To compensate for metabolic acidosis, the kidneys try to excrete extra acid and the lungs increase CO_2 excretion. The patient often develops *Kussmaul respirations* (deep, rapid breathing) when trying to compensate for metabolic acidosis.

TABLE 16.11 Acid-Base Imbalances

Causes	Pathophysiology	Laboratory Findings
Respiratory Acidosis		
• Chronic respiratory disease (e.g., COPD) • Barbiturate or sedative overdose • Chest wall abnormality • Severe pneumonia • Atelectasis • Respiratory muscle weakness • Mechanical hypoventilation • Pulmonary edema	• ↑ CO_2 retention from hypoventilation • Compensatory response is ↑ HCO_3^- retention by kidney	↓ Plasma pH ↑ $PaCO_2$ HCO_3^- normal (uncompensated) ↑ HCO_3^- (compensated) *Sample ABG* Uncompensated: pH 7.31 $PaCO_2$ 54 mm Hg HCO_3^- 25 mEq/L
Respiratory Alkalosis		
• Hyperventilation (e.g., hypoxia, anxiety, fear, pain, exercise, fever) • Stimulated respiratory center (e.g., septicemia, stroke, meningitis, encephalitis, brain injury, salicylate poisoning) • Liver failure • Mechanical hyperventilation	↑ CO_2 excretion from hyperventilation Compensatory response is ↑ HCO_3^- excretion by kidney	↑ Plasma pH ↓ $PaCO_2$ HCO_3^- normal (uncompensated) ↓ HCO_3^- (compensated) *Sample ABG* Uncompensated: pH 7.52 $PaCO_2$ 27 mm Hg HCO_3^- 24 mEq/L
Metabolic Acidosis		
• Diabetic ketoacidosis • Lactic acidosis • Starvation • Diarrhea • Renal tubular acidosis • Renal failure • GI fistulas • Shock	• Gain of fixed acid, inability to excrete acid or loss of base • Compensatory response is ↑ CO_2 excretion by lungs	↓ Plasma pH $PaCO_2$ normal (uncompensated) ↓ $PaCO_2$ (compensated) ↓ HCO_3^- *Sample ABG* Uncompensated: pH 7.29 $PaCO_2$ 38 mm Hg HCO_3^- 18 mEq/L
Metabolic Alkalosis		
• Vomiting • NG suctioning • Diuretic therapy • Hypokalemia • Excess $NaHCO_3$ intake • Mineralocorticoid use	• Loss of strong acid or gain of base • Compensatory response is ↑ CO_2 retention by lungs	↑ Plasma pH $PaCO_2$ normal (uncompensated) ↑ $PaCO_2$ (compensated) ↑ HCO_3^- *Sample ABG* Uncompensated: pH 7.50 $PaCO_2$ 40 mm Hg HCO_3^- 34 mEq/L

If metabolic acidosis is present, calculating the anion gap helps determine the source of the acidosis. The *anion gap* is the difference between the measured serum cations and anions in ECF.

$$\text{Anion gap} = Na^+ - (HCO_3^- + Cl^-)$$

A normal anion gap is 8 to 12 mmol/L. The anion gap increases in metabolic acidosis associated with acid gain (e.g., lactic acidosis, diabetic ketoacidosis) but is normal in metabolic acidosis caused by bicarbonate loss (e.g., diarrhea).

Metabolic Alkalosis

Metabolic alkalosis (base bicarbonate excess) occurs when a loss of acid (e.g., from prolonged vomiting or gastric suction) or a gain in HCO_3^- (e.g., from ingestion of baking soda) occurs (Table 16.11 and Fig. 16.17, *B*). Renal excretion of HCO_3^- occurs in response to metabolic alkalosis. The lung's compensatory response is limited. The respiratory rate decreases to retain plasma CO_2. However, once hypoxemia occurs or plasma CO_2 reaches a certain level, stimulation of chemoreceptors will increase respirations.

Mixed Acid-Base Disorders

A mixed acid-base disorder occurs when 2 or more disorders are present at the same time. The pH depends on the type, severity, and acuity of each disorder involved and any compensatory mechanisms at work. Respiratory acidosis combined with metabolic alkalosis (e.g., a patient with atelectasis and NG suction) may result in a near-normal pH. Respiratory acidosis combined with metabolic acidosis causes a greater decrease in pH than either disorder alone. An example of a mixed acidosis is a patient in severe shock with poor perfusion and hypoventilation. Mixed alkalosis can occur in a patient hyperventilating because of postoperative pain who is losing acid from NG suctioning.

Clinical Manifestations of Acid-Base Imbalances

The manifestations of acidosis and alkalosis are outlined in Tables 16.12 and 16.13. In both respiratory and metabolic acidosis, the CNS is depressed. Headache, lethargy, weakness, and confusion develop, leading eventually to coma and death. Compensatory mechanisms also produce specific manifestations. For example, the deep, rapid (Kussmaul) respirations of a patient with metabolic acidosis occur with respiratory compensation.

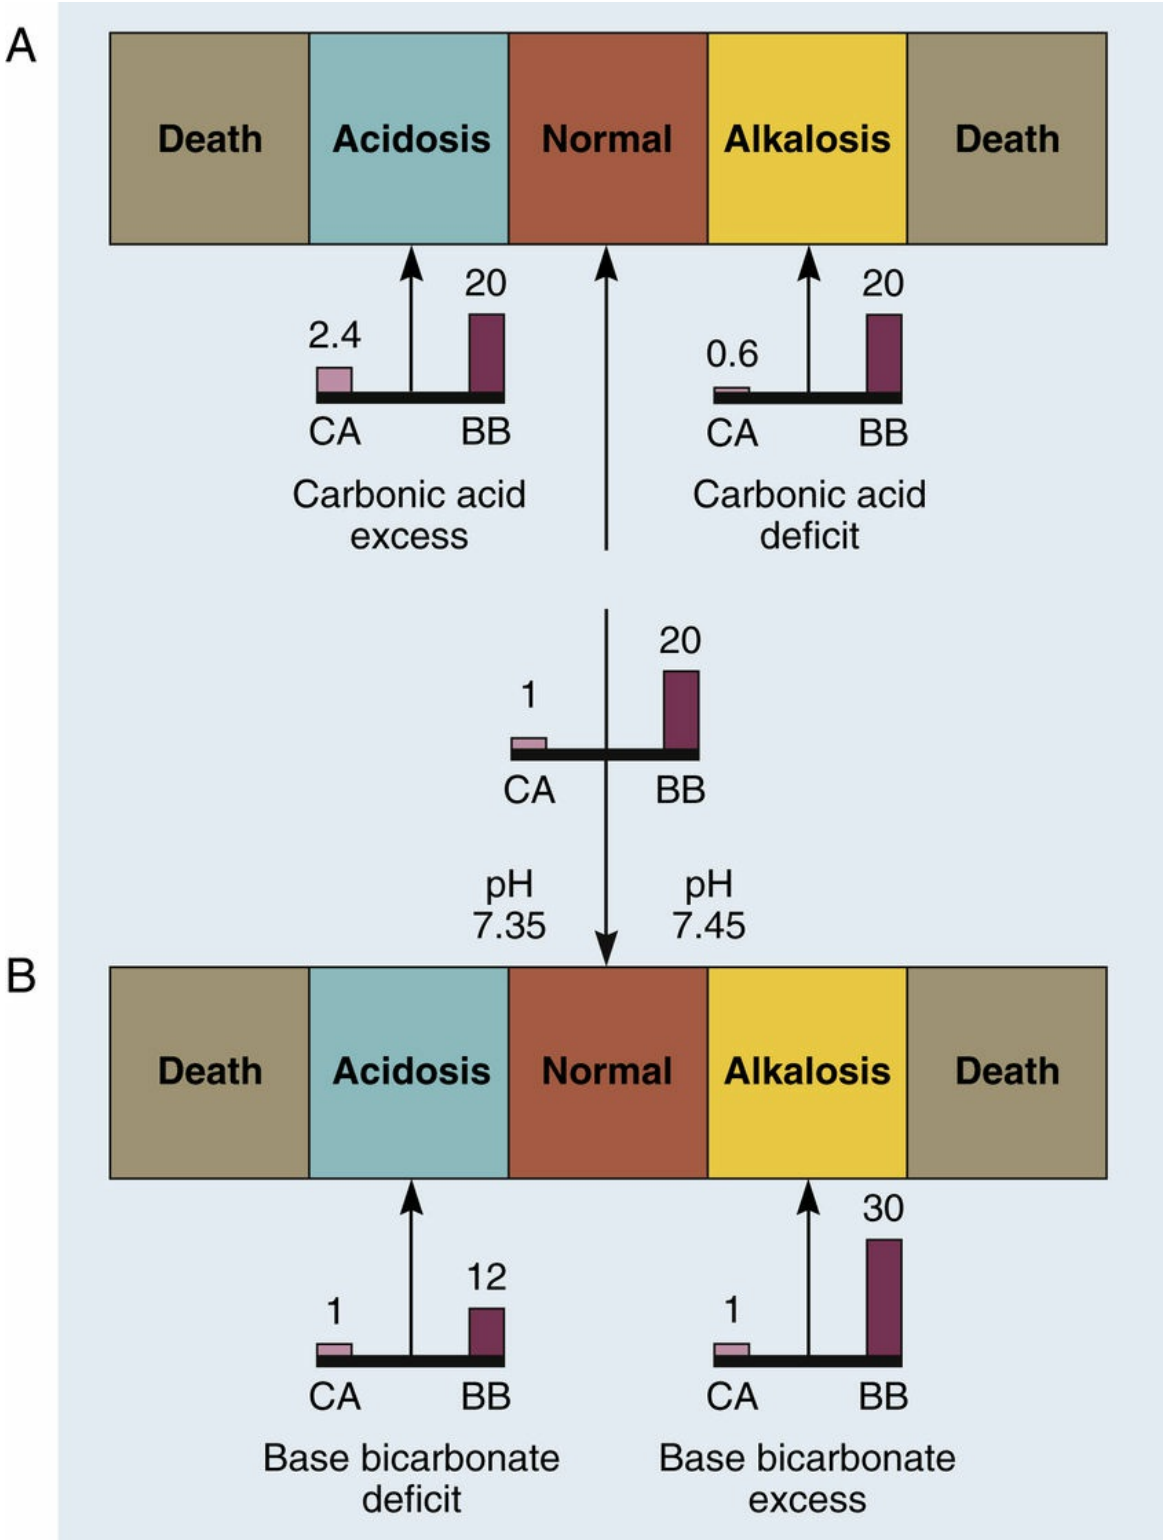

FIG. 16.17 Kinds of acid-base imbalances. **A,** Respiratory imbalances caused by carbonic acid *(CA)* excess and carbonic acid deficit. **B,** Metabolic imbalances caused by base bicarbonate *(BB)* deficit and base bicarbonate excess.

TABLE 16.12 Manifestations of Acidosis

Respiratory (↑ $PaCO_2$)	Metabolic (↓ HCO_3^-)
Neurologic	
Lethargy	Lethargy
Confusion	Confusion
Dizziness	Dizziness
Headache	Headache
Coma	Coma
Cardiovascular	
↓ BP	↓ BP
Ventricular fibrillation (related to hyperkalemia from compensation)	Dysrhythmias (related to hyperkalemia from compensation)
Warm, flushed skin	Cold, clammy skin
Gastrointestinal	
No significant findings	Nausea, vomiting, diarrhea, abdominal pain
Neuromuscular	
Seizures	Muscle weakness
Respiratory	
Hypoventilation with hypoxia	Deep, rapid respirations

TABLE 16.13 Manifestations of Alkalosis

Respiratory (↓ $PaCO_2$)	Metabolic (↑ HCO_3^-)
Neurologic	
Dizziness	Irritability
Light-headedness	Lethargy
Confusion	Confusion
Headache	Headache
Cardiovascular	
Tachycardia	Tachycardia
Dysrhythmias (related to hypokalemia from compensation)	Dysrhythmias (related to hypokalemia from compensation)
Gastrointestinal	
Nausea, vomiting, diarrhea	Nausea, vomiting
Epigastric pain	Anorexia
Neuromuscular	
Tetany	Tetany
Numbness	Tremors
Tingling of extremities	Tingling of fingers and toes
Hyperreflexia	Muscle cramps, hypertonic muscles
Seizures	Seizures
Respiratory	
Hyperventilation (lungs are unable to compensate if there is a respiratory problem)	Hypoventilation (compensatory action by lungs)

TABLE 16.14 Normal Arterial Blood Gas Values

Parameter	Reference Interval
pH	7.35–7.45
$PaCO_2$	35–45 mm Hg
Bicarbonate (HCO_3^-)	22–26 mEq/L (mmol/L)
PaO_2*	80–100 mm Hg
SaO_2	>95%
Base excess	±2.0 mEq/L

* Decreases above sea level and with increasing age.

In both types of alkalosis, symptoms usually result from an accompanying electrolyte abnormality rather than the alkalosis. Hypocalcemia occurs due to increased calcium binding with albumin, lowering the amount of ionized, active calcium. Therefore muscle cramping and symptoms of CNS excitability, including tingling and numbness of the fingers and tetany, occur. If left untreated, respiratory alkalosis can be life-thereatening.[13]

Blood Gas Values

Arterial blood gas (ABG) values give objective information about a patient's acid-base status, the underlying cause of an imbalance, and the body's ability to regulate pH. Knowing the patient's clinical situation and the extent of renal and respiratory compensation allows you to identify acid-base disorders and the patient's ability to compensate. Blood gas analysis also shows the partial pressure of arterial O_2 (PaO_2) and O_2 saturation. Table 16.14 lists normal blood

gas values. These values help you evaluate the patient's overall oxygenation status and identify hypoxemia. Table 16.15 shows *ROME*, a quick memory device for understanding acid-base imbalances.

TABLE 16.15 ROMEMemory Device for Acid-Base Imbalances

For acid-base imbalances, use this quick memory device (mnemonic).

In ***Respiratory*** conditions, the pH and the $PaCO_2$ go in ***Opposite*** directions.

- In respiratory alkalosis, the pH is ↑ and the $PaCO_2$ is ↓.
- In respiratory acidosis, the pH is ↓ and the $PaCO_2$ is ↑.

In ***Metabolic*** conditions, the pH and the HCO_3^- go in the same direction ***(Equal).*** The $PaCO_2$ may also go in the same direction.

- In metabolic alkalosis, pH and HCO_3^- are ↑ and the $PaCO_2$ is ↑ or normal.
- In metabolic acidosis, pH and HCO_3^- are ↓ and the $PaCO_2$ is ↓ or normal.

To interpret the results of an ABG, perform the following 5 steps:

1. Look at each of the values. If the pH is between 7.35 and 7.45, and the CO_2, HCO_3^-, and PaO_2 are within normal limits, the ABGs are normal. If any value is out of normal, then continue.
2. Look at the pH first. Values less than 7.35 indicate acidosis and values greater than 7.45 indicate alkalosis. A normal pH means there is normal acid-base status, compensation is occurring, or a mixed disorder is present.
3. Use ROME (Table 16.15) to figure out if the origin is respiratory or metabolic. Remember respiratory opposite and metabolic equal.

4. Once the metabolic or respiratory origin is determined, look at the remaining value, either the CO_2 or HCO_3^-, to figure the level of compensation. If the value is moving in the opposite direction, the body is trying to compensate. If the remaining value moving to compensate is abnormal and the pH is higher or lower than normal, *partial compensation* has occurred. If the pH is within normal limits, *full compensation* has occurred.
5. Assess the PaO_2 and O_2 saturation. If these values are abnormal, hypoxemia is present.

Table 16.16 explains how to analyze ABG results. The laboratory findings section of Table 16.11 shows ABG findings of the 4 major acid-base imbalances. See Chapter 25 for further discussion of ABGs.

Assessment of Fluid, Electrolyte, and Acid-Base Imbalances

Assessing patients for fluid, electrolyte, and acid-base imbalances is an important part of your nursing practice. In addition to assessing for the manifestations discussed earlier in this chapter, obtain subjective and objective data from any patient with suspected fluid, electrolyte, or acid-base imbalances.

Subjective Data

Important Health Information

Past Health History

Question the patient about any history of problems involving the kidneys, heart, GI system, or lungs that could affect the present fluid, electrolyte, and acid-base balance. Ask about specific diseases such as diabetes, diabetes insipidus, COPD, renal failure, ulcerative colitis, and Crohn's disease. Assess for any prior fluid, electrolyte, or acid-base disorders.

Medications

Assess the patient's current and past use of medications. The ingredients in many drugs, especially over-the-counter drugs, are often hidden sources of sodium, potassium, calcium, magnesium, and other electrolytes. Many prescription drugs, including diuretics, corticosteroids, and electrolyte supplements, can cause fluid and electrolyte imbalances.

TABLE 16.16 Applying Arterial Blood Gas (ABG) Analysis

Sample ABG Values	Analysis
pH 7.32 **$PaCO_2$ 30** **HCO_3^- 16** **PaO_2 95**	1. Look at each of the values. If the pH is between 7.35 and 7.45, and the CO_2, HCO_3^-, and PaO_2 are within normal limits, the ABGs are normal. If any value is out of normal, then continue. *The pH, CO_2, HCO_3^- are all abnormally low. Continue with analysis.* 2. Look at the pH first. Values less than 7.35 indicate acidosis and values greater than 7.45. *The pH is below 7.35, indicating acidosis.* 3. Use ROME to figure out if the origin is respiratory or metabolic. Remember respiratory opposite and metabolic equal. *Using ROME, the pH and CO2 are not going in the opposite direction (the disorder is not respiratory in origin). The pH and HCO3 − are moving in the same or equal direction, so the disorder is metabolic in origin.* 4. Once the metabolic or respiratory origin is determined, look at the remaining laboratory value (either CO_2 or HCO_3^-) to figure the level of compensation. *Since the disorder is metabolic in origin, review the remaining laboratory value (in this case the CO_2) The CO_2 is low, meaning the lungs are trying to compensate by lowering acid levels.* 5. Assess the PaO_2 and O_2 saturation. If these values are abnormal, hypoxemia is present. *The PaO_2 is normal and does not indicate hypoxemia.*
Interpretation	
This ABG is interpreted as metabolic acidosis with partial compensation. Partial compensation is occurring because the pH remains abnormal. Full compensation would occur after the pH returns within normal limits.	

Surgery or Other Treatments

Ask the patient about past or present renal dialysis, kidney surgery, or bowel surgery resulting in a temporary or permanent external collecting system, such as an ileostomy.

Functional Health Patterns

Health Perception–Health Management Pattern

If the patient currently has a problem related to fluid, electrolyte, and acid-base balance, obtain a careful description of the illness, including onset, course, and treatment. Ask the patient about any recent changes in body weight.

Nutritional-Metabolic Pattern

Ask the patient about diet and any special dietary practices. Weight reduction diets, fad diets, or any eating disorders, such as anorexia or bulimia, can lead to fluid and electrolyte problems. If the patient is on a special diet, such as low sodium or high potassium, assess the ability to adhere to the dietary prescription.

Elimination Pattern

Make note of the patient's usual bowel and bladder habits. Carefully document any deviations from the expected elimination pattern, such as diarrhea, oliguria, polyuria, or incontinence.

Activity-Exercise Pattern

Ask about the patient's exercise pattern and any excess perspiration. Determine if the patient is exposed to extremely high temperatures during leisure or work activity. Ask the patient what he or she does to replace fluid and electrolytes lost through excess perspiration. Assess the patient's activity level to determine any functional problems that could lead to lack of ability to obtain food or fluids.

Cognitive-Perceptual Pattern

Ask about any changes in sensations, such as numbness, tingling, or muscle weakness, which could indicate a fluid and electrolyte problem. Ask the patient and caregiver if there have been any changes in mentation or alertness, such as confusion, memory impairment, or lethargy.

Objective Data

Physical Examination

Perform a complete physical examination because fluid, electrolyte, and acid-base balance affects all body systems. As you assess each system, check for manifestations that you would expect with an imbalance. Common abnormal assessment findings of major body systems offer clues to possible imbalances (Table 16.17).

TABLE 16.17 Assessment AbnormalitiesFluid and Electrolyte Imbalances

Finding	Possible Cause
Blood Pressure	
Hypotension	Fluid volume deficit, low Ca^{2+}, high Mg^{2+}
Hypertension	Fluid volume excess, high Ca^{2+}, low Mg^{2+}
Muscular	
Chvostek's sign	Low Ca^{2+}, high PO_4^{3-}, low Mg^{2+}
Muscle cramping	High K^+, low Ca^{2+}, high PO_4^{3-}, low Mg^{2+}
Muscle weakness	High or low K^+, high Ca^{2+}, low PO_4^{3-}, high Mg^{2+}
Trousseau's sign	Low Ca^{2+}, high PO_4^{3-}, low Mg^{2+}
Neurologic	
Confusion	Fluid volume excess, high or low Na^+, high or low K^+, low Ca^{2+}, high or low Mg^{2+}, low PO_4^{3-}
Decreased level of consciousness	Fluid volume deficit or excess, high or low Na^+, low PO_4^{3-}
Fatigue	Fluid volume deficit, low K^+, high Ca^{2+}
Irritability	Low Na^+, high K^+, low Ca^{2+}, high PO_4^{3-}
Tremors, seizures	High Na^+, low K^+, low Ca^{2+}, high PO_4^{3-}, low Mg^{2+}
Respirations	
Crackles	Fluid volume excess
Dyspnea	Fluid volume excess
Rapid respirations	Fluid volume deficit
Restricted airway	Low Ca^{2+}, high PO_4^{3-}
Pulse	
Bounding pulse	Fluid volume excess
Rapid, weak, thready pulse	Fluid volume deficit
Weak, irregular, rapid pulse	Severe low K^+, low Mg^{2+}
Weak, irregular, slow pulse	Severe high K^+, high Mg^{2+}
Skin	
Cold, clammy skin	Fluid volume deficit, low Na^+
Flushed, dry skin	High Na^+, High Mg^{2+}
Pitting edema	Fluid volume excess
Poor skin turgor	Fluid volume deficit

Laboratory Values

Assessing serum electrolyte values is a good starting point for evaluating fluid and electrolyte balance (Table 16.1). Serum electrolytes can also provide important information about a patient's acid-base balance. Changes in the serum HCO_3^- (often reported as total CO_2 or CO_2 content on an electrolyte panel) indicate metabolic acidosis (low HCO_3^- level) or alkalosis (high HCO_3^- level).

Safety Alert

Managing Critical Test Results

- Promptly report critical laboratory values to the HCP.
- Assess the patient and take appropriate actions (e.g., ECG monitoring).

Remember that serum electrolyte values often provide limited information. They reflect the concentration of that electrolyte in ECF but not necessarily in ICF. For example, most potassium is found in the cells. Changes in serum potassium values may be the result of a true deficit or excess of potassium or reflect the movement of potassium into or out of the cell during acid-base imbalances. An abnormal serum sodium level may reflect a sodium problem or, more likely, a water problem.

Other useful laboratory tests include serum and urine osmolality, serum glucose, blood urea nitrogen, serum creatinine, venous blood gas sampling, urine specific gravity, and urine electrolytes.

Oral Fluid and Electrolyte Replacement

In all cases of fluid, electrolyte, and acid-base imbalances, the primary treatment involves correcting the underlying cause. Oral rehydration

solutions containing water, potassium, sodium, and glucose may be used to correct mild fluid and electrolyte deficits. Glucose not only provides calories but also promotes sodium and water absorption in the small intestine. Commercial oral rehydration solutions are now available for home use. Avoid cola drinks because they do not contain adequate electrolyte replacement, and the sugar content may lead to osmotic diuresis.

IV. Fluid and Electrolyte Replacement

IV fluid and electrolyte therapy are necessary to treat many different fluid and electrolyte imbalances. Many patients need maintenance IV fluid therapy when they cannot take oral fluids (e.g., during and after surgery). Other patients need corrective or replacement therapy for losses that are ongoing or have already occurred. The amount and type of solution is determined by the normal daily maintenance requirements and by imbalances identified by laboratory results. We classify IV replacement solutions by their concentration or tonicity (Table 16.18). Tonicity is a key factor in determining the appropriate solution to correct imbalances.

Solutions

Hypotonic

A hypotonic solution has a lower osmolality when compared to plasma.[14] Infusing a hypotonic solution dilutes ECF, lowering serum osmolality. Osmosis then produces a movement of water from ECF to interstitial spaces and cells, causing cells to swell. After achieving equilibrium, ICF and ECF have the same osmolality. Hypotonic solutions (e.g., 0.45% NaCl) are useful in treating patients with hypernatremia. They are a good maintenance fluid because normal daily losses are hypotonic. They are not good for replacement because they can deplete ECF and lower BP. Because hypotonic solutions have the potential to cause cellular swelling, monitor patients for changes in mentation that may indicate cerebral edema.

Although 5% dextrose in water is technically an isotonic solution, the dextrose quickly metabolizes. The net result is the administration of hypotonic free water with equal expansion of ECF and ICF. One liter of a 5% dextrose solution provides 50 g of dextrose, or 170 calories. While this amount of dextrose is not enough to meet caloric requirements, it helps prevent ketosis associated with starvation.

Isotonic

An isotonic solution has an osmolality similar to plasma.[14] Because of this similarity, giving an isotonic solution expands only ECF and the fluid does not move into cells. This makes isotonic solutions the ideal fluid replacement for patients with ECF volume deficits. Examples of isotonic solutions include 0.9% NaCl and lactated Ringer's solution.

Isotonic saline (0.9% NaCl), or *normal saline,* has a sodium concentration (154 mEq/L) slightly higher than that of plasma (135 to 145 mEq/L) and a chloride concentration (154 mEq/L) significantly higher than the plasma chloride level (96 to 106 mEq/L). Therefore giving too much isotonic saline has the potential to increase sodium and chloride levels. Isotonic saline is used when a patient has had both fluid and sodium losses (e.g., diarrhea, vomiting).

Lactated Ringer's solution contains sodium, potassium, chloride, calcium, and lactate (the precursor of bicarbonate) in about the same concentrations as ECF. This makes it the ideal fluid in certain situations, such as surgery, burns, or GI fluid losses. Patients with liver dysfunction, hyperkalemia, and severe hypovolemia should not receive lactated Ringer's because they have a decreased ability to convert the lactate to bicarbonate.

Hypertonic

A hypertonic solution has a higher osmolality than plasma.[14] The higher osmotic pressure draws water out of the cells into ECF. It is useful in the treatment of hyponatremia and trauma patients with head injury. Those receiving hypertonic solutions need frequent monitoring of BP, lung sounds, and serum sodium levels because of the risk for intravascular fluid volume excess.

TABLE 16.18 Common Crystalloid Solutions

Solution	Tonicity	mOsm/kg	Contents	Indications and Considerations
Dextrose in Water				
5%	Isotonic, but physiologically hypotonic	278	50 g/L dextrose	• Contains free water only, no electrolytes • Provides 170 cal/L • Used to replace water losses and treat hypernatremia
10%	Hypertonic	556	100 g/L dextrose	• Contains free water only, no electrolytes • Provides 340 cal/L • Used with parenteral nutrition
Saline				
0.45%	Hypotonic	154	77 mEq/L Na^+ 77mEq/L Cl^-	• Contains free water, Na^+, and Cl^-, no calories • Used to treat hypernatremia and uncontrolled hyperglycemia • Used as a maintenance solution
0.9%	Isotonic	308	154 mEq/L Na^+ 154mEq/L Cl^-	• Contains Na^+ and Cl^- in excess of plasma levels • Does not contain free water or calories • Used to expand intravascular volume and replace extracellular fluid losses • Only solution given with blood products • May cause volume overload in patients with heart or kidney disease
3.0%	Hypertonic	1026	513 mEq/L Na^+ 513 mEq/L Cl^-	• Contains Na^+ and Cl^- in excess of plasma levels • Used to treat symptomatic hyponatremia and trauma patients with head injury • Give slowly because it may cause volume overload and pulmonary edema
Dextrose in Saline				
5% in 0.25%	Isotonic	355	50 g/L dextrose 34 mEq/L Na^+ 34 mEq/L Cl^-	• Provides Na^+, Cl^-, and free water • Used to replace hypotonic losses and treat hypernatremia • Provides 170 cal/L
5% in 0.45%	Hypertonic	432	50 g/L dextrose 77 mEq/L Na^+ 77 mEq/L Cl^-	• Provides Na^+, Cl^-, and free water • Used as a maintenance solution
5% in 0.9%	Hypertonic	586	50 g/L dextrose 154 mEq/L Na^+ 154 mEq/L Cl^-	• Contains Na^+ and Cl^- in excess of plasma levels • Used to treat metabolic alkalosis and volume deficits in patients with hyponatremia
Multiple Electrolyte Solutions				
Ringer's solution	Isotonic	309	147 mEq/L Na^+ 156 mEq/L Cl^- 4 mEq/L K^+ 4 mEq/L Ca^{2+}	• Similar in composition to plasma except that it has excess Cl^-, no Mg^{2+}, no HCO_3^- • Does not provide free water or calories • Used to expand the intravascular volume and replace extracellular fluid losses
Lactated Ringer's (Hartmann's) solution	Isotonic	273	130 mEq/L Na^+ 109 mEq/L Cl^- 4 mEq/L K^+ 3 mEq/L Ca^{2+} 28 mmol/L lactate	• Similar in composition to normal plasma except does not contain Mg^{2+} • Does not provide free water or calories • Used to treat hypovolemia, burns, and GI fluid losses • Cannot be used in patients with alkalosis or lactic acidosis

Although concentrated dextrose and water solutions (10% dextrose or greater) are hypertonic solutions, once the dextrose is metabolized, the net result is the administration of water. This free water ultimately expands ECF and ICF. The primary use of these solutions is providing calories as part of parenteral nutrition (see Chapter 39). You may give solutions containing 10% dextrose or less through a peripheral line. You must use a central line to give solutions with dextrose concentrations greater than 10%.

IV. Additives

Additives in basic IV solutions replace specific losses. KCl, $CaCl_2$, $MgSO_4$, and HCO_3^- are common additives. The use of each was described earlier in the discussion of the specific electrolyte deficiencies. Many premixed IV solutions containing specific additives are available. Using these solutions reduces error as the solution contains the correct amount of the electrolyte in the proper volume and type of IV solution.

Colloids

Colloid solutions contain large molecules that increase oncotic pressure and pull fluid into the blood vessels. Because this action restores blood volume, colloids are also called *volume expanders* or *plasma expanders.* Colloids include human plasma products (albumin, fresh frozen plasma, blood) and semisynthetic solutions (dextran, starches).

Albumin is available in 5% and 25% solutions. The 5% solution has an albumin concentration similar to that of plasma and results in plasma volume expansion equal to the volume infused. This makes it ideal for treating hypovolemic patients. In contrast, 25% albumin solution is hypertonic and draws fluid from the interstitial space. This makes it useful in treating patients with burns, hepatic failure, and ascites.

Dextran solutions are synthetic complex sugar solutions. There are 2 types: low-molecular-weight dextran (dextran 40) and high-

molecular-weight dextran (dextran 70). Because dextran metabolizes slowly, it stays in the vascular system for a prolonged period. It pulls fluid into the intravascular space, expanding it by more volume than what is infused. Hydroxyethyl starches (e.g., Hespan) are synthetic colloids that work similarly to dextran to expand plasma volume.

Colloids can lead to circulatory overload because they pull fluid into ECF. Monitor vital signs and urine output frequently and assess for signs and symptoms of fluid volume excess. All colloids affect blood coagulation, with dextran and starches having the strongest anticoagulation effect.[14] Monitor coagulation times and implement any necessary precautions. Fatal anaphylactic reactions have occurred with Hespan and dextran. Monitor the patient closely for a hypersensitivity reaction and stop an infusion at once if a reaction occurs.

If the patient has lost blood, whole blood or packed RBCs are given. Packed RBCs have the advantage of giving the patient primarily RBCs rather than RBCs and fluid volume. Although packed RBCs have a decreased plasma volume, they increase the oncotic pressure and pull fluid into the intravascular space. The use of whole blood, with its added fluid volume, may cause circulatory overload, particularly in patients who are susceptible to complications from excess circulating volume (e.g., heart failure). To prevent fluid volume excess, loop diuretics may be given with blood and colloids. See Chapter 30 for more information on giving blood and blood products.

Nursing Management

IV Therapy

- Assess patient for manifestations of fluid and electrolyte imbalances.
- Determine if ordered IV therapies are appropriate.
- Choose and insert appropriate IV catheters and infusion devices.

- Give IV fluids and medications.
- Monitor for adverse reactions to IV fluids or medications.
- Assess for manifestations of fluid overload or hypovolemia and initiate appropriate changes in IV fluids.
- Evaluate if IV therapies are addressing patient's fluid and electrolyte needs.
- Collaborate with the pharmacist to:
    - Determine appropriateness of IV therapies and need for dose adjustments.
    - Prepare IV infusions and medications.
    - Screen for potential problems, such as compatibility issues.
    - Monitor response to therapy.

Central Venous Access Devices

Central venous access devices (CVADs) are catheters placed in large blood vessels (e.g., subclavian vein, jugular vein) of people who need frequent or special access to the vascular system. There are 3 main types of CVADs: centrally inserted catheters, peripherally inserted central catheters (PICCs), and implanted ports.

Advantages of CVADs include immediate access to the central venous system, a reduced need for multiple venipunctures, and decreased risk for extravasation injury. CVADs permit frequent, continuous, rapid, or intermittent administration of fluids and medications. They allow for the administration of drugs that are potential *vesicants* (agents that can cause tissue damage), blood and blood products, and parenteral nutrition. CVADs can provide a means to perform hemodynamic monitoring and obtain venous blood samples. They are useful with patients who have limited peripheral vascular access or who have a projected need for long-term vascular access. CVADs also can be used to inject radiopaque contrast media. Table 16.19 gives examples of when CVADs are used.

The major disadvantages of CVADs are an increased risk for

systemic infection and the invasiveness of the procedure. Extravasation (leakage of fluid) can still occur if there is displacement of or damage to the device.

Centrally Inserted Catheters

The tip of centrally inserted catheters (also called central venous catheters [CVCs]) rests in the distal end of the superior vena cava near its junction with the right atrium (Fig. 16.18). The other end of the catheter exits through a separate incision on the chest or abdominal wall. *Nontunneled catheters* are usually placed in the subclavian or internal jugular vein, more rarely in the femoral vein. They are best for patients with short-term needs in an acute care setting. *Surgically placed tunneled catheters* (e.g., Hickman, Broviac, Groshong) are suitable for long-term needs. Tunneling of the catheter through subcutaneous tissue and the synthetic cuff used to anchor the catheter provide stability and decrease infection risk. After the site heals, the catheter does not need a dressing, making it easier for the patient to maintain the site at home.

CVCs are available with single-, double-, or triple-lumens. Multilumen catheters are useful in the critically ill patient because each lumen can be used simultaneously to provide a different therapy. For example, incompatible drugs infuse in separate lumens without mixing while a third lumen gives access for blood sampling.

TABLE 16.19 Common Indications for Central Venous Access Devices (CVADs)

Condition	Indications for Use
Autoimmune disorders	Perform plasmapheresis
Blood sampling	Multiple blood draws for diagnostic tests over time
Blood transfusions	Infusion of blood or blood products
Heart failure	Perform ultrafiltration
Hemodynamic monitoring	Used to measure central venous pressure to assess fluid balance
Medication administration	
• **Cancer**	Chemotherapy, infusion of irritating or vesicant medications
• **Contrast media**	Inject radiopaque contrast media for diagnostic testing
• **Infection**	Long-term administration of antibiotics
• **Pain**	Long-term administration of pain medication
• **Drugs at risk for causing phlebitis**	Epoprostenol (Flolan) Calcium chloride Potassium chloride Amiodarone
Nutritional replacement	Infusion of parenteral nutrition Infusion of high percentage dextrose solutions
Renal failure	Perform hemodialysis (especially on an acute basis) or continuous renal replacement therapy
Shock, burns	Infusion of high volumes of fluid and electrolyte replacement

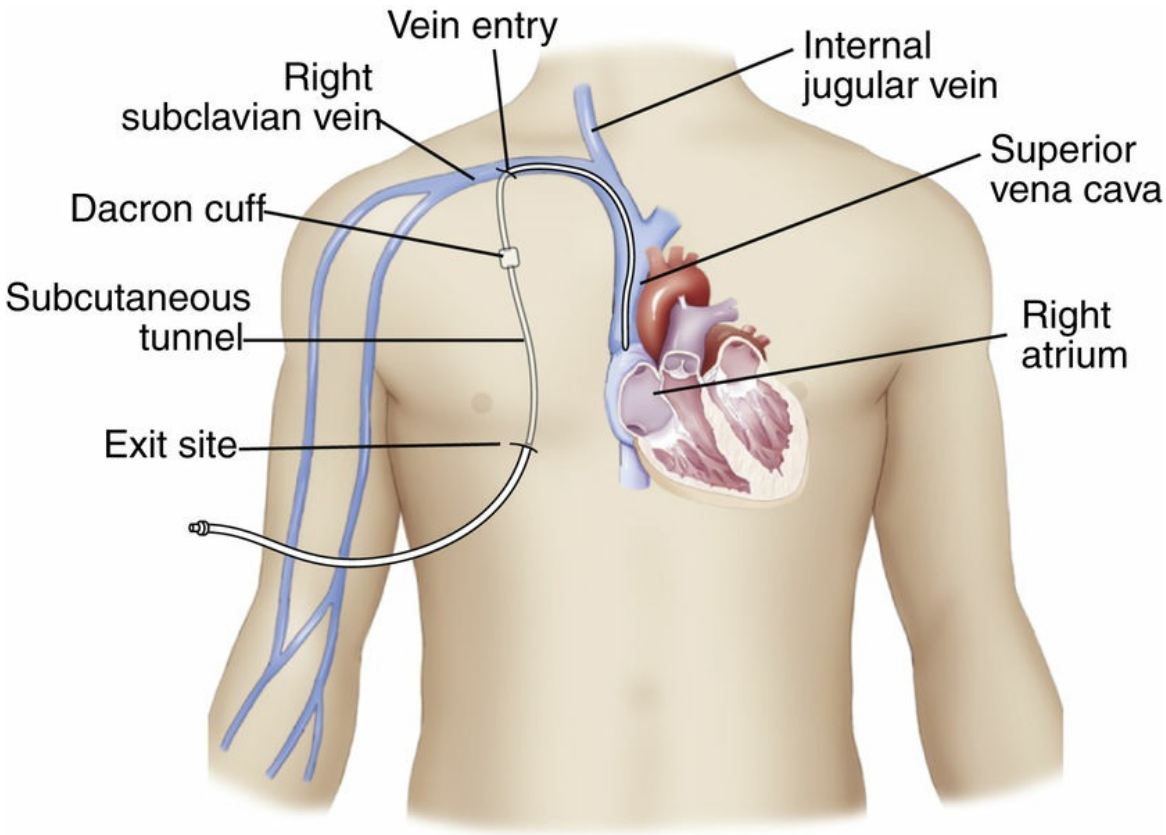

FIG. 16.18 Tunneled central venous catheter. Note tip of the catheter in the superior vena cava.

Peripherally Inserted Central Catheters

Peripherally inserted central catheters (PICCs) are CVCs inserted into a vein in the arm. The basilic vein is best because of its large diameter (Fig. 16.19). The cephalic, median cubital, or brachial veins are other options. Single-, double-, or triple-lumens are available. Double lumens are preferred because they allow for simultaneous uses. PICCs are used with patients who need vascular access for 1 week to 6 months, but they can be in place for longer periods.

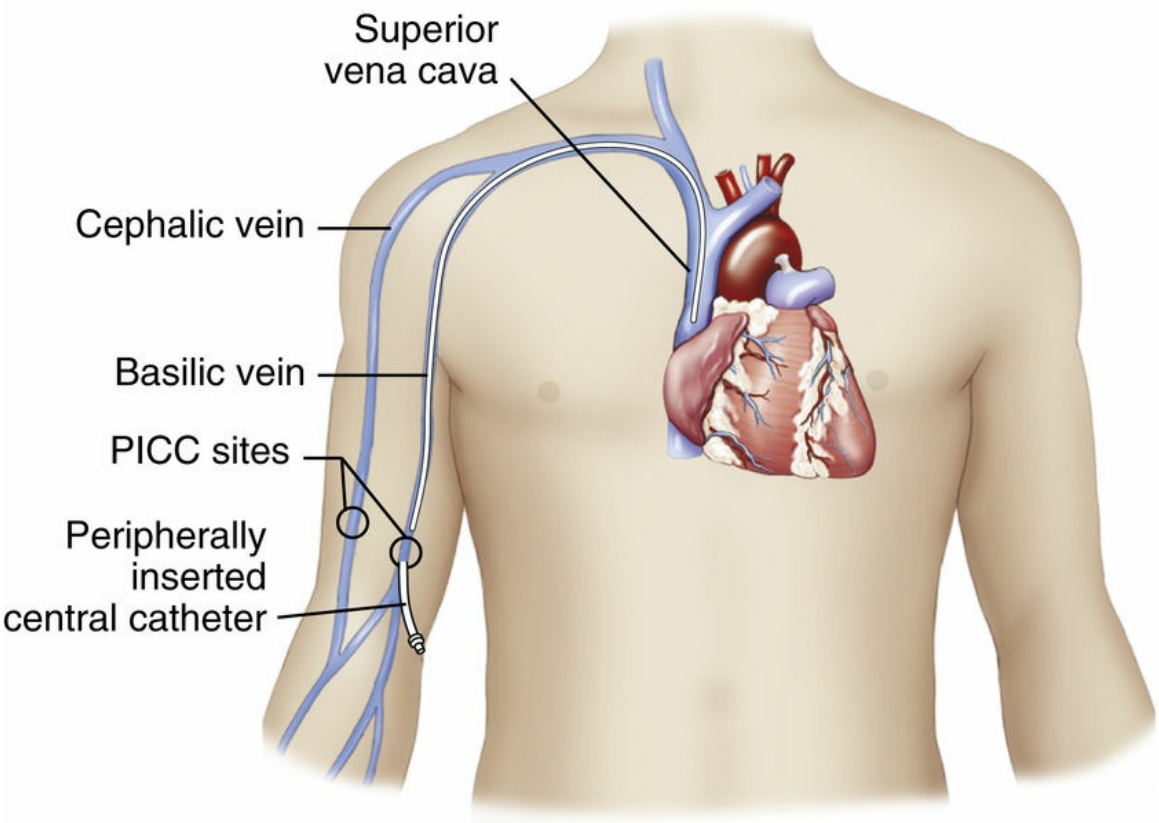

FIG. 16.19 Peripherally inserted central catheter (PICC) can be inserted using the basilic or cephalic vein.

Advantages of a PICC over a CVC are lower infection rate, fewer insertion-related complications, decreased cost, and ability to insert at the bedside or in an outpatient area. PICCs, however, are associated with an increased risk for deep vein thrombosis and phlebitis (Table 16.20). If phlebitis occurs, it usually happens within 7 to 10 days after

insertion. Do not use the arm with the PICC to take a BP reading or draw blood. When the BP cuff is inflated, the PICC can touch the vein wall, increasing the risk for vein damage and thrombosis.

Implanted Infusion Ports

An implanted infusion port consists of a surgically implanted CVC connected to a reservoir or port (Fig. 16.20, *A*). The catheter tip lies in the desired vein. The port lies in a surgically created subcutaneous pocket on the upper chest or arm. It consists of a titanium or plastic reservoir covered with a self-sealing silicone septum. You access the port by using a special noncoring needle with a deflected tip. This prevents damage to the septum that could make the port useless (Fig. 16.20, *B*).

Drugs are placed in the reservoir either by a direct injection or through injection into an established IV line. The reservoir then slowly releases the medicine into the bloodstream. Implanted ports are good for long-term therapy and have a low risk for infection. The hidden port offers the patient cosmetic advantages and overall has less maintenance than other types of CVADs. Monitor accessed ports for infiltration that can occur if the needle is not in place or dislodges.

Midline Catheters

Midline catheters technically are peripheral catheters because they do not enter a central vein. However, their use and care are similar to a PICC. A specially trained nurse can insert a midline catheter. A catheter can be from 3 to 8 inches long and have single or double lumens. They are inserted in the antecubital area through either the basilic or cephalic vein, often under ultrasound guidance. The basilic vein is best since it has a larger diameter. The tip rests right below the axilla, staying below the shoulder joint to reduce the risk for vein irritation from moving the shoulder. These lines can stay in place for up to 4 weeks.

TABLE 16.20 Complications of Central Venous Access Devices (CVADs)

Possible Cause	Manifestations	Management
Catheter Migration		
• **Improper suturing** • **Insertion site trauma** • **Changes in intrathoracic pressure** • **Forceful catheter flushing** • **Spontaneous**	• Sluggish infusion or aspiration • Edema of chest or neck during infusion • Patient reports gurgling sound in ear • Dysrhythmias • Increased external catheter length	• Prepare for fluoroscopy to verify position • Assist with removal and new CVAD placement
Catheter-Related Infection (Local or Systemic)		
• **Contamination during insertion or use** • **Migration of organisms along catheter** • **Immunosuppressed patient**	• *Local:* redness, tenderness, purulent drainage, warmth, edema • *Systemic:* fever, chills, malaise	Local • Culture drainage from site • Apply warm, moist compresses • Remove catheter if needed Systemic • Take blood cultures • Give antibiotic therapy • Give antipyretic therapy • Remove catheter if needed
Catheter Occlusion		
• **Clamped or kinked catheter** • **Tip against wall of vessel** • **Thrombosis** • **Precipitate buildup in lumen**	• Sluggish infusion or aspiration • Inability to infuse and/or aspirate	• Have patient change position, raise arm, and cough • Assess and alleviate any clamping or kinking • Flush with normal saline using a 10-mL syringe. Do not force flush • Instill anticoagulant or thrombolytic agent
Embolism		
• **Catheter breaking** • **Dislodgment of thrombus** • **Entry of air into circulation**	• Chest pain • Respiratory distress (dyspnea, tachypnea, hypoxia, cyanosis) • Hypotension • Tachycardia	• Apply O_2 • Clamp catheter • Place patient on left side with head down (air emboli) • Notify provider
Pneumothorax		
• **Perforation of visceral pleura during insertion**	• Decreased or absent breath sounds • Respiratory distress (cyanosis, dyspnea, tachypnea) • Chest pain • Distended unilateral chest	• Apply O_2 • Place in semi-Fowler's position • Prepare for chest tube insertion

Complications

CVADs always have a potential for complications. Careful monitoring and assessment will help you to identify potential complications early. Table 16.19 lists common complications, potential causes, manifestations, and interventions.

Nursing Management: Central Venous

Access Devices

Nursing management of CVADs includes assessment, dressing changes and cleansing, injection cap changes, and maintenance of catheter patency. The exact frequency and procedures for these requirements vary by type of CVAD and facility, so it is important to follow your facility's policies and procedures. The following section discusses some general guidelines.

Catheter and insertion site assessment includes inspecting the site for redness, edema, warmth, drainage, tenderness, or pain. Observing the catheter for misplacement or slippage is important. Perform a comprehensive pain assessment, particularly noting any reports of chest or neck discomfort, arm pain, or pain at the insertion site. Do not use a newly placed CVAD until the tip position is verified with a chest x-ray.

Check Your Practice

You are taking care of a 74-yr-old patient with a left triple-lumen subclavian catheter. When you are changing the transparent dressing, you note some redness at the site with a small amount of yellow, foul-smelling drainage.

- What should you do?

Before manipulating a catheter for any reason, perform hand hygiene. Perform dressing changes and cleanse the catheter insertion site using strict sterile technique. Typical dressings include transparent semipermeable dressings or gauze and tape. If the site is bleeding, a gauze dressing may be preferable. Otherwise, transparent dressings are best. They allow observation of the site without having to remove the dressing. Transparent dressings may be left in place for up to 1 week. Change any dressing at once if it becomes damp, loose, or soiled.

Cleanse the skin around the catheter insertion site according to facility policy. A chlorhexidine-based preparation is the cleansing agent of choice. Its effects last longer than either povidone-iodine or alcohol, offering improved killing of bacteria.[15] When using chlorhexidine, cleansing the skin with friction is critical to preventing infection. When applying a new dressing, allow the area to air dry completely. Secure the lumen ports to the skin above the dressing site. Document the date and time of the dressing change and initial the dressing.

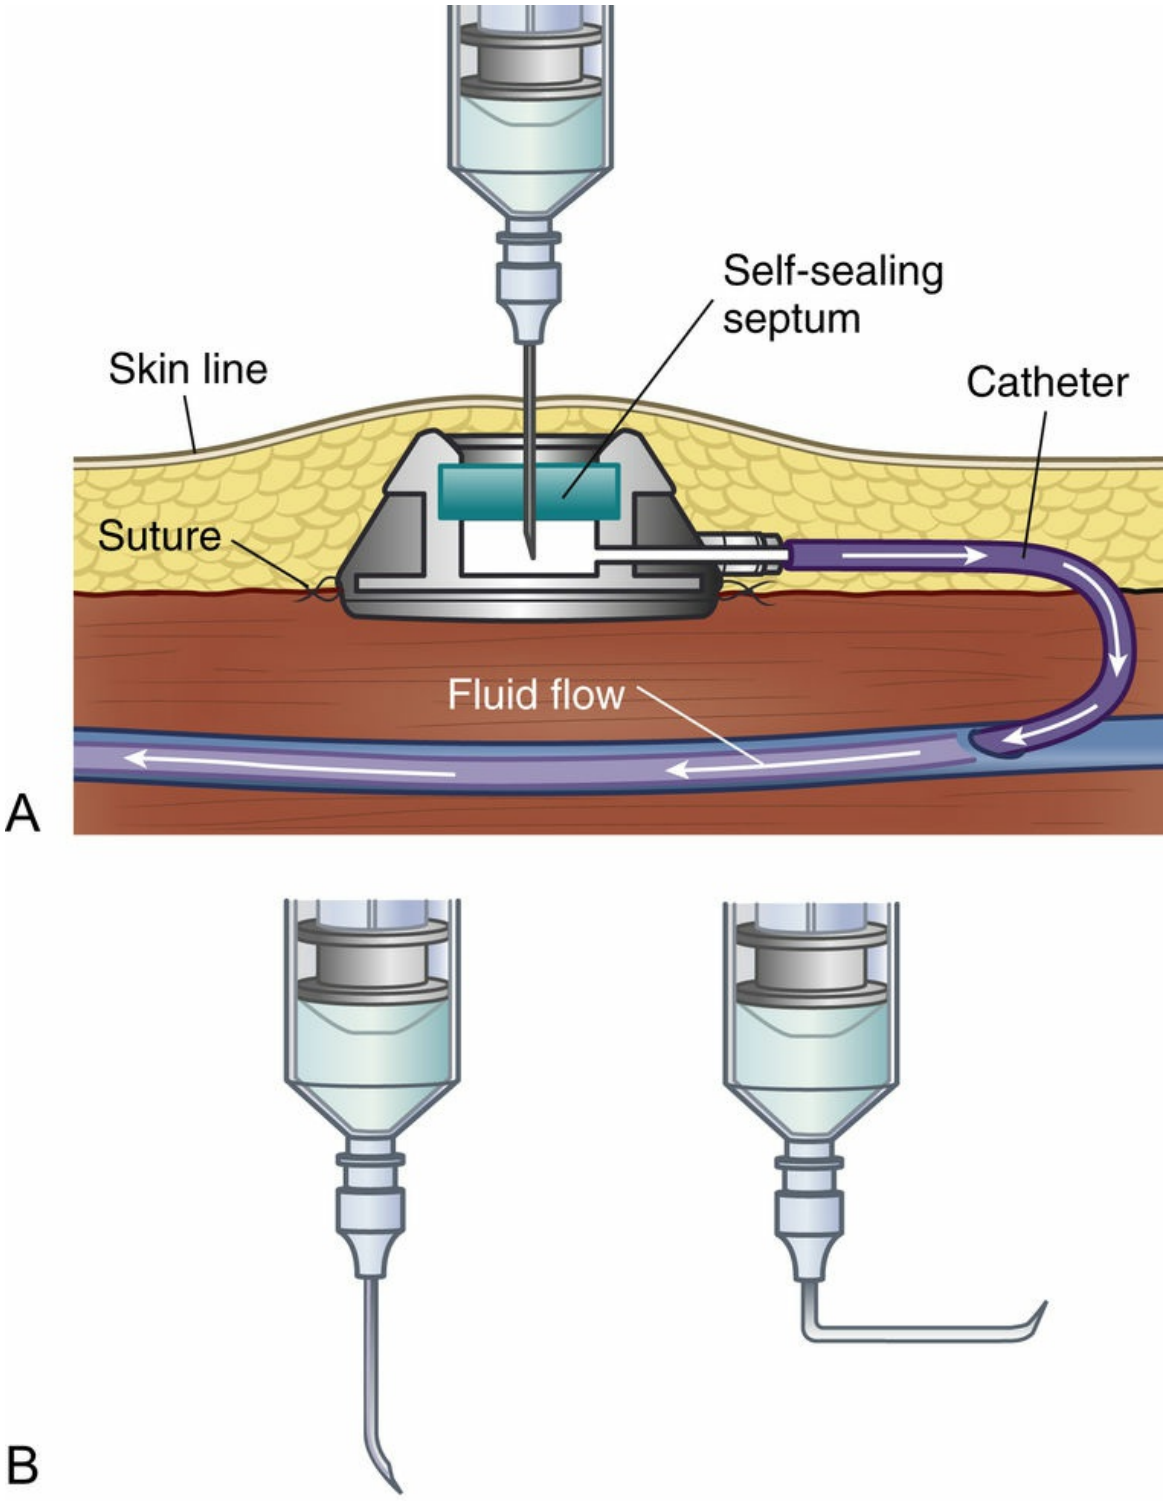

FIG. 16.20 **A,** Cross section of implantable port displaying access of the port with the Huber-point needle. Note the deflected point of the Huber-point needle, which prevents coring of the port's septum. **B,** 2 Huber-point needles used to enter the implanted port. The 90-degree needle is used for top-entry ports for continuous infusion.

Disinfect catheter hubs, needleless connectors, and injection ports before accessing the catheter. Use an alcoholic chlorhexidine preparation, 70% alcohol, or povidone-iodine. Change injection caps at regular intervals according to facility policy, or if they have damage from excess punctures. Use strict sterile technique. Teach the patient to turn the head to the opposite side of the insertion site during cap change. If you cannot clamp the catheter, have the patient lie flat in bed and perform the Valsalva maneuver whenever the catheter is open to air to prevent an air embolism.

Flushing is one of the most effective ways to maintain catheter patency. It also keeps incompatible drugs or fluids from mixing. Use a normal saline solution in a syringe that has a barrel capacity of 10 mL or more to avoid excess pressure on the catheter. If you feel resistance, do not apply force. This could result in a ruptured catheter or create an embolism if a thrombus is present. Because of the risk for contamination and infection, use solution from prefilled syringes or single-dose vials rather than multiple-dose vials when flushing catheters. If you are not using a positive-pressure valve cap, clamp any unused lines after flushing.

Use the push-pause technique when flushing all catheters. Push-pause creates turbulence within the catheter lumen, promoting the removal of debris that adheres to the catheter lumen and decreasing the chance of occlusion. This technique involves injecting saline with a rapid alternating push-pause motion, instilling 1 to 2 mL with each push on the syringe plunger. If you are using a negative-pressure cap or neutral pressure cap, clamp the catheter while maintaining positive pressure while instilling the last 1 mL of saline. This prevents reflux of blood back into the catheter. If a positive-pressure valve cap is present, it works to prevent the reflux of blood and resultant catheter lumen occlusion. Remove the syringe before clamping the catheter to allow the positive pressure valve to work correctly.

CVAD Removal

Removing a CVAD is done according to agency policy and the nurse's scope of practice. In many agencies, nurses with demonstrated

competency can remove PICCs and nontunneled central venous catheters. The procedure involves removing any sutures and then gently withdrawing the catheter. Have the patient perform the Valsalva maneuver as the last 5 to 10 cm of the catheter is withdrawn. Immediately apply pressure to the site with sterile gauze to prevent air from entering and to control bleeding. Inspect the catheter tip to determine that it is intact. After bleeding has stopped, apply an antiseptic ointment and sterile dressing to the site.

Case Study

Fluid and Electrolyte Imbalance

© Kevin Peterson/Photodisc/Thinkstock.

Patient Profile

S.S., a 63-yr-old white woman with acute lymphocytic leukemia, has been receiving chemotherapy on an outpatient basis. She completed her third treatment 5 days ago and has had nausea and vomiting for 2 days despite using ondansetron (Zofran). S.S.'s daughter brings her to the hospital, where she is admitted to the medical unit. As the admitting nurse, you perform a thorough assessment.

Subjective Data

- Reports lethargy, weakness, dizziness, and dry mouth
- States she has been too nauseated to eat or drink anything for 2 days

Objective Data

- Heart rate 110 beats/min, pulse thready
- BP 100/65
- Weight loss of 5 lb since she received her chemotherapy treatment 5 days ago
- Dry oral mucous membranes

Discussion Questions

1. Based on her manifestations, what fluid imbalance does S.S. have?
2. What additional assessment data should you obtain?
3. What are her risk factors for fluid and electrolyte imbalances?
4. You draw blood for a serum chemistry evaluation. What electrolyte imbalances are likely and why?
5. S.S. is at risk for which acid-base imbalance? Describe the changes that would occur in S.S.'s ABGs with this acid-base imbalance. How would the body compensate?
6. ***Priority Decision:*** What are the priority nursing interventions for S.S.?
7. ***Collaboration:*** Who should be the primary members of the interprofessional team in caring for S.S.? What is the interprofessional team's priority at this time for S.S.?
8. The provider orders dextrose 5% in 0.45% saline to infuse at 100 mL/hr. What type of solution is this, and how will it help S.S.'s fluid imbalance?

9. ***Evidence-Based Practice:*** S.S. has a double-lumen PICC in her left arm. One lumen is connected to the IV infusion; the other is unused. What is the recommended practice for maintaining the patency of the unused lumen?
10. ***Quality Improvement:*** What outcomes will indicate that interprofessional care was effective?

Case Study

Managing Care of Multiple Patients

You and another RN are assigned to care for the following 3 patients in the intensive care unit. There is also an unlicensed assistive personnel (UAP) on duty.

Patients

 **(© Stockphoto/Thinkstock.)**	G.N., a 65-yr-old black man, was admitted to the ICU after falling into a lit gas grill. He has partial-thickness burns on his face, neck, and upper trunk. He has undergone surgical repair of right tibia and left hip fractures and debridement of a severely lacerated right leg. His voice is slightly hoarse, and he is coughing up sooty sputum. He is receiving O_2 at 4 L/min via nasal cannula, and his O_2 saturation is 93%. His WBC count is 26,400/μL (26.4×10^9/L) with 80% neutrophils (10% bands).
	J.N., a 65-yr-old black man, was transferred to the ICU from the clinical unit last evening with acute respiratory failure. He was diagnosed 2 days ago with AIDS and *Pneumocystis jiroveci* pneumonia (PCP). Prior to this hospital admission he was started on oral trimethoprim/sulfamethoxazole (Bactrim) and combination antiretroviral therapy. However, his respiratory distress worsened, and he was transferred to the ICU for intubation and mechanical ventilation. He is now receiving IV Bactrim.

 **(© iStock.com/Cecilie_Arcurs.)**	
 **(© Kevin Peterson/Photodisc/Thinkstock.)**	S.S., a 63-yr-old white woman with acute lymphocytic leukemia, has been receiving chemotherapy on an outpatient basis. She completed her third treatment 5 days ago and has been experiencing nausea and vomiting for 2 days despite using ondansetron (Zofran). She was initially admitted to the clinical unit but was transferred to the ICU for close monitoring after becoming severely hypotensive overnight. Her most recent blood pressure was 98/50, HR 82 and regular, O_2 saturation 95% on 2 L via nasal cannula, RR 22 and regular.

Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide your rationale.
2. ***Collaboration:*** Which morning tasks should you delegate to the UAP *(select all that apply)*?
    a. Take BP readings on S.S.
    b. Perform respiratory assessment on G.N.
    c. Document strict intake and output on S.S.
    d. Provide oral care around the endotracheal tube for J.N.
    e. Titrate S.S.'s IV infusion rate based on her BP reading.
3. ***Priority Decision and Collaboration:*** When you enter J.N.'s room, the ventilator alarms are going off. The UAP had just finished providing oral care, and she tells you that J.N. has become increasingly agitated within the last 5 minutes. Which

initial action would be *most* appropriate?

a. Suction J.N.'s endotracheal tube.
b. Have the UAP stay with J.N. while you obtain IV sedation for him.
c. Ask the UAP to describe exactly what she did when she was providing oral care.
d. Assess the ventilator to identify what alarm is going off and to make sure all connections are secure.

Case Study Progression

J.N.'s ventilator tubing became disconnected. You quickly reconnect his tubing, and as he settles down his oxygenation improves. You ask the UAP to obtain vital signs on your other patients while you begin a more thorough assessment of J.N.

4. During your assessment of J.N., you note gray-white patches on the inside of his mouth. You recognize these as *most* likely caused by
    a. *Candida albicans.*
    b. poor oral hygiene.
    c. *Coccidioides immitis.*
    d. irritation from recent mouth care.
5. G.N.'s family asks you why surgery was performed on his leg wound. Your response is based on the knowledge that debridement *(select all that apply)*
    a. is used to remove infected tissue.
    b. is used to remove nonviable tissue.
    c. prepares the wound bed for healing.
    d. can be accomplished only in surgery.
    e. is necessary in any burn wound involving the skin.
6. S.S.'s morning laboratory results reveal a serum potassium level of 2.8 mEq/L. You notify the health care provider and obtain an order for IV potassium. During infusion of the potassium replacement, you prioritize assessment of S.S.'s
    a. bowel function.

b. cardiac rhythm.
c. muscle strength.
d. level of consciousness.

7. ***Priority Decision:*** As the day continues, you find that you are getting busy. Which nursing task should be your priority?
    a. Changing the sterile dressings on G.N.'s leg wounds
    b. Performing routine suctioning of J.N.'s endotracheal tube
    c. Starting a 500-mL fluid bolus to S.S., whose most recent BP is 76/42
    d. Calling the hospital chaplain to speak with S.S., who is upset over her condition
8. ***Priority Decision:*** Which medication should you administer first?
    a. Daily subcutaneous enoxaparin to G.N.
    b. IV Bactrim, ordered twice daily, to J.N.
    c. IV proton pump inhibitor, ordered twice daily, to S.S.
    d. As needed IV morphine to G.N., who reports pain at a level 9 (1 to 10 scale)
9. ***Management Decision:*** While sitting at the computer charting your patients' morning assessments, you overhear the UAP telling a nursing student that J.N. deserves what he got because HIV is God's way of punishing those who sin. Your *most* appropriate response would be to
    a. report the UAP's actions to the supervisor.
    b. ask the UAP to keep her opinions to herself.
    c. ignore the conversation because it does not affect patient care.
    d. talk to the UAP and student about keeping personal feelings separate from patient care.

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. During the postoperative care of a 76-year-old patient, the nurse monitors the patient's intake and output carefully, knowing that the patient is at risk for fluid and electrolyte imbalances primarily because
   a. older adults have an impaired thirst mechanism and need reminding to drink fluids.
   b. water accounts for a greater percentage of body weight in the older adult than in younger adults.
   c. older adults are more likely than younger adults to lose extracellular fluid during surgical procedures.
   d. small losses of fluid are significant because body fluids account for 45% to 50% of body weight in older adults.

2. During administration of a hypertonic IV solution, the mechanism involved in equalizing the fluid concentration between ECF and the cells is
   a. osmosis.
   b. diffusion.
   c. active transport.
   d. facilitated diffusion.

3a. An older woman is admitted to the medical unit with GI bleeding. Assessment findings that indicate fluid volume deficit include (*select all that apply*)
   a. weight loss.
   b. dry oral mucosa.
   c. full bounding pulse.
   d. engorged neck veins.

e. decreased central venous pressure.

3b. The nursing care for a patient with hyponatremia and fluid volume excess includes

a. fluid restriction.

b. administration of hypotonic IV fluids.

c. administration of a cation-exchange resin.

d. placement of an indwelling urinary catheter.

3c. The nurse should be alert for which manifestations in a patient receiving a loop diuretic?

a. Restlessness and agitation

b. Paresthesias and irritability

c. Weak, irregular pulse and poor muscle tone

d. Increased blood pressure and muscle spasms

3d. Which patient is at *greatest* risk for developing hypermagnesemia?

a. 83-year-old man with lung cancer and hypertension

b. 65-year-old woman with hypertension taking β-adrenergic blockers

c. 42-year-old woman with systemic lupus erythematosus and renal failure

d. 50-year-old man with benign prostatic hyperplasia and a urinary tract infection

3e. It is important for the nurse to assess for which manifestation(s) in a patient who has just undergone a total thyroidectomy (*select all that apply*)?

a. Confusion

b. Weight gain

c. Depressed reflexes

d. Circumoral numbness

e. Positive Chvostek's sign

3f. The nurse expects the long-term treatment of a patient with hyperphosphatemia from renal failure will include

a. fluid restriction.

b. calcium supplements.

c. magnesium supplements.

d. increased intake of dairy products.

4. The lungs act as an acid-base buffer by

a. increasing respiratory rate and depth when CO_2 levels in the blood are high, reducing acid load.

b. increasing respiratory rate and depth when CO_2 levels in the blood are low, reducing base load.

c. decreasing respiratory rate and depth when CO_2 levels in the blood are high, reducing acid load.

d. decreasing respiratory rate and depth when CO_2 levels in the blood are low, increasing acid load.

5. A patient has the following arterial blood gas results: pH 7.52, $PaCO_2$ 30 mm Hg, HCO_3^- 24 mEq/L. The nurse determines that these results indicate

a. metabolic acidosis.

b. metabolic alkalosis.

c. respiratory acidosis.

d. respiratory alkalosis.

6. The typical fluid replacement for the patient with a fluid

volume deficit is

a. dextran.

b. 0.45% saline.

c. lactated Ringer's solution.

d. 5% dextrose in 0.45% saline.

7. The nurse is unable to flush a central venous access device and suspects occlusion. The *best* nursing intervention would be to

a. apply warm moist compresses to the insertion site.

b. try to force 10 mL of normal saline into the device.

c. place the patient on the left side with the head down.

d. have the patient change positions, raise arm, and cough.

1. d, 2. a, 3a. a, b, e, 3b. a, 3c. c, 3d. c, 3e. a, d, e, 3f. b, 4. a, 5. d, 6. c, 7. d

Perioperative Care

OUTLINE

17. Preoperative Care

18. Intraoperative Care

19. Postoperative Care

17

Preoperative Care

Janice A. Neil

LEARNING OUTCOMES

1. Distinguish the common purposes and settings of surgery.
2. Apply knowledge of the purpose and components of a preoperative nursing assessment.
3. Interpret the significance of data related to the preoperative patient's health status and operative risk.
4. Analyze the components and purpose of the patient's informed consent for surgery.
5. Examine the nursing role in the physical, psychological, and educational preparation of the surgical patient.
6. Prioritize the nursing responsibilities related to day-of-surgery preparation for the surgical patient.
7. Discern the purposes and types of common preoperative medications.
8. Apply knowledge of the special considerations of preoperative preparation for the older adult surgical patient.

Conceptual Focus

Anxiety
Patient Education
Safety

Surgery is the art and science of treating diseases, injuries, and deformities by operation and instrumentation. The total surgical episode is called the *perioperative period.* This period includes the time before surgery (preoperative period), the time spent during the actual surgical procedure (intraoperative period), and the period after the surgery is over (postoperative period).

The surgical experience involves an interprofessional team, including the patient, surgeon, anesthesia care provider (ACP), nurse, and other health care team members. Preparing patients for surgery is an important nursing role. This chapter discusses preoperative care that applies to all surgical patients. Preparation measures for specific surgical procedures (e.g., abdominal, thoracic, or orthopedic surgery) are discussed in the appropriate chapters of this book.

Surgery is performed for many reasons. These include:

- *Diagnosis:* Determine the presence and extent of a pathologic condition (e.g., lymph node biopsy, bronchoscopy).
- *Cure:* Eliminate or repair a pathologic condition (e.g., removal of ruptured appendix or benign ovarian cyst).
- *Palliation:* Alleviate symptoms without cure (e.g., cutting a nerve root [rhizotomy] to reduce pain, creating a colostomy to bypass an inoperable bowel obstruction).
- *Prevention:* Reduce risk of developing a condition (e.g., removal of a mole before it becomes malignant, removal of the colon in a patient with familial polyposis to prevent cancer).
- *Cosmetic improvement*: Alter physical appearance (e.g., repairing a burn scar, breast reconstruction after a mastectomy).
- *Exploration:* Determine the nature or extent of a disease (e.g., laparotomy). With the use of advanced diagnostic tests, exploration is less common because we can identify many problems noninvasively.

Surgical procedures are usually described by combining specific suffixes with a body part or organ (Table 17.1).

TABLE 17.1 Suffixes Describing Surgical Procedures

Suffix	Meaning	Example
-ectomy	Excision or removal of	Appendectomy
-lysis	Destruction of	Electrolysis
-orrhaphy	Repair or suture of	Herniorrhaphy
-oscopy	Looking into	Endoscopy
-ostomy	Creation of opening into	Colostomy
-otomy	Cutting into or incision of	Tracheotomy
-plasty	Repair or reconstruction of	Mammoplasty

Surgical Settings

Surgery may be a carefully planned event (**elective surgery**) or may arise with unexpected urgency (**emergency surgery**). Both elective and emergency surgeries are done in a variety of settings. The type of surgery, potential complications, and the patient's health status influence the setting where a patient can safely undergo a surgical procedure

For inpatient surgery, patients who are going to be admitted to the hospital are usually admitted on the day of surgery (**same-day admission**). Patients who are in the hospital before surgery are usually there because of acute or chronic medical conditions.

Most surgical procedures are performed as **ambulatory surgery** (also called *same-day* or *outpatient surgery*). Many of these surgeries use minimally invasive techniques (e.g., laparoscopic techniques). Ambulatory surgery often occurs in endoscopy clinics, physicians' offices, freestanding surgical clinics, and outpatient surgery units in hospitals. These procedures can involve the use of general, regional, or local anesthetic. Patients require less than a 24-hour stay after surgery. Many go home with a caregiver within hours of surgery.

Patients and HCPs often prefer ambulatory surgery. Generally, it requires fewer laboratory tests and medications and reduces the patient's risk for health care–associated infections. Patients like the convenience of recovering at home. HCPs prefer the flexibility in scheduling. The costs are usually less for the patient and the insurer.

You play an essential role in preparing the patient for surgery, caring for the patient during surgery, and aiding the patient's recovery after surgery. To perform these functions effectively, first know the reason the patient is undergoing surgery and any co-morbidities. Second, identify the individual patient's response to the stress of surgery. Third, know the results of preoperative diagnostic tests. Last, identify potential risks and complications associated with the surgical procedure and any special considerations that should be addressed in the plan of care. The nurse caring for the patient before surgery is likely to be different from the nurse in the operating room

(OR), postanesthesia care unit (PACU), surgical intensive care unit (SICU), or surgical unit. Communication and documentation of important preoperative assessment findings are essential for quality care.

Patient Interview

One of the most important nursing actions is the preoperative interview. The nurse who works in the physician's office, ambulatory surgery center, or hospital may do the interview.

The preoperative interview can occur in advance or on the day of surgery. The primary purposes of the patient interview are to (1) obtain the patient's health information, including drug and food allergies; (2) provide and clarify information about the planned surgery, including anesthesia; and (3) assess the patient's emotional state and readiness for surgery, including his or her expectations about the surgical outcomes. The interview gives the patient and caregiver an opportunity to ask questions about the surgery, anesthesia, and postoperative care. Often patients ask about taking their routine drugs, such as insulin, anticoagulants, or heart medications, and if they will have pain. By being aware of the patient's and caregiver's needs, you can provide the information and support needed during the perioperative period.

Nursing Assessment of Preoperative Patient

The overall goal of the preoperative assessment is to identify risk factors and plan care to ensure patient safety throughout the surgical experience. To achieve this, you will need to do the following:

- Establish baseline data for comparison in the intraoperative and postoperative period.
- Determine the patient's psychologic status to reinforce the use

of coping strategies during the surgical experience.
- Determine physiologic factors directly or indirectly related to the surgical procedure that may contribute to operative risk factors.
- Participate in the identification and documentation of the surgical site according to agency protocol.
- Identify prescription drugs, over-the-counter (OTC) drugs, and herbs taken by the patient that may result in drug interactions affecting the surgical outcome.
- Review the results of all preoperative diagnostic studies in the patient's record and share this information with the appropriate HCPs.
- Identify cultural and ethnic factors that may affect the surgical experience.
- Determine if the patient received adequate information from the surgeon to make an informed decision to have surgery and that the consent form is signed and witnessed.

Subjective Data

Psychosocial Assessment

Surgery is a stressful event, even when the procedure is minor. The psychologic and physiologic reactions to surgery may elicit the stress response (e.g., elevated BP and heart rate). The stress response enables the body to meet the demands in the perioperative period. If stressors or the responses to the stressors are excessive, the stress response can be magnified and may affect recovery. Many factors influence the patient's reaction to stress, including age, past experiences with illness and pain, current health, and socioeconomic status.

The use of common language and avoidance of medical jargon are essential. Use words and language that are familiar to the patient to help the patient understand the surgery. Familiar language also helps reduce anxiety.

Your role in psychologically preparing the patient for surgery is to assess the patient for potential or actual stressors that could negatively

affect surgery (Table 17.2). Communicate all concerns to the appropriate surgical team member, especially if the concern requires intervention later in the surgical experience. Because many patients are admitted directly into the preoperative area from their homes, you must be skilled in assessing important psychologic factors in a short time. The most common psychologic factors are anxiety, fear, and hope.

TABLE 17.2 Psychosocial Assessment of Preoperative Patient

Situational Changes

- Define current degree of personal control, decision making, and independence
- Determine the presence of hope and anticipation of positive results
- Consider the impact of surgery and hospitalization and possible effects on lifestyle
- Identify support systems, including family, other caregivers, and religious and spiritual groups

Concerns With the Unknown

- Identify degree of anxiety and fears related to the surgery (e.g., pain)
- Identify expectations of surgery, changes in current health status, effects on daily living, and sexual activity (if appropriate)

Concerns With Body Image

- Identify current roles or relationships and view of self

- Determine perceived or potential changes in roles or relationships and their impact on body image

Past Experiences

- Review previous surgical experiences, hospitalizations, and treatments
- Determine responses to those experiences (positive and/or negative)
- Identify current perceptions of surgical procedure in relation to the above and information from others (e.g., a friend's view of a personal surgical experience)

Lack of Knowledge

- Determine the amount and type of information the patient wants
- Assess understanding of surgical procedure, including preparation, care, interventions, preoperative activities, restrictions, and expected outcomes
- Review the accuracy of information the patient has received from others, including health care team, family, friends, and media

Anxiety

Most people are anxious when facing surgery because of the unknown. This is normal and is an inborn survival mechanism. However, a high anxiety level can impair cognition, decision making, and coping abilities.

Anxiety can arise from lack of knowledge. This can range from not knowing what to expect to uncertainty about the outcome and may result from past experiences or stories heard through friends or the media. You can decrease some anxiety for the patient by giving information about what to expect. This is often done through classes or Web-based or audiovisual teaching materials before surgery.

Inform the surgeon if the patient needs more information or has excessive anxiety.

Patients may have anxiety when surgery conflicts with their religious or cultural beliefs. Identify, record, and communicate patient decisions about the possibility of blood transfusions. For example, Jehovah's Witnesses may choose to refuse blood or blood products.[1]

Common Fears

Patients fear surgery for many reasons. The most common fear is the risk for death or permanent disability resulting from surgery. Sometimes the fear comes after hearing or reading about the risks during the informed consent process. Other fears are related to pain, change in body image, or results of diagnostic procedures.

Evidence-Based Practice

Music and Preoperative Anxiety

You are taking care of D.G., a 67-yr-old woman scheduled for a renal mass biopsy to rule out metastatic disease. She was admitted early this morning to the preoperative unit. Unfortunately, an emergency surgery has resulted in at least a 4-hour delay of her procedure. You note that she has a high level of anxiety.

Making Clinical Decisions

Best Available Evidence. Complementary and alternative therapies include a variety of interventions, such as mental imagery, aromatherapy, acupuncture, and music. Music intervention in the preoperative period, including listening to pre-recorded music or individually tailored music given by a trained therapist, can help reduce anxiety. While sedatives and antianxiety drugs are often given before surgery, these drugs can have negative side effects, especially in the older adult.

Clinician Expertise. Anxiety can increase BP and pulse rate and

may lengthen postoperative recovery. Excessive anxiety can even result in surgery being canceled.

Patient Preference and Values. D.G. tells you that she cannot relax and would like "a strong pill" to help her calm down. D.G.'s family mentioned to you earlier that she enjoys listening to classical music at home.

Implications for Practice

1. What information would you share with D.G. related to the use of drugs to reduce her anxiety?
2. How would you respond to D.G. when she asks how music could possibly help in reducing her anxiety?

Reference for Evidence

Bradt J, Dileo C, Shim M. Music interventions for preoperative anxiety. *Cochrane Database Syst Rev*. 2013;6:CD006908 (Classic).

Fear of death can be extremely harmful. Notify the HCP if the patient has a strong fear of death. A patient's strong fear of impending death may prompt the HCP to delay the surgery because the emotional state influences the stress response and thus the surgical outcome.

Fear of pain and discomfort during and after surgery is common. If the fear is extreme, notify the ACP or the surgeon. Reassure the patient that drugs are available for anesthesia and analgesia during surgery. For pain after surgery, tell patients to ask for pain medication before pain becomes severe. Teach the patient how to use a pain intensity scale (e.g., 0 to 10, FACES). See Chapter 8 for more on pain scales.

The patient may receive drugs that provide an amnesic effect so that the patient will not remember what occurs during surgery. Tell the patient that helps decrease anxiety after surgery.

Fear of mutilation or an *altered body image* can occur whether the surgery is radical, such as amputation, or minor, such as a breast

biopsy. Even a small scar on the body can upset some, and others fear keloid development (overgrowth of a scar). Listen to and assess the patient's concern about this fear with an accepting attitude.

Fear of anesthesia may arise from the unknown, personal experience, or tales of others' bad experiences. These concerns can also result from information about the risks of anesthesia (e.g., brain damage, paralysis). Many patients fear losing control while under anesthesia. If you identify any of these fears, inform the ACP at once so that he or she can talk further with the patient.

Fear of disruption of life functioning may be present in varying degrees. It can range from fear of permanent disability to concern about not being able to engage in activities of daily living for a few weeks. You may find concerns about loss of role function, separation from family, and how the family will manage. Financial concerns include dealing with an expected loss of income and the costs of surgery.

If you find any of these fears, a consult with the patient's caregiver, a social worker, a spiritual advisor, or a psychologist may be appropriate. Financial advisors at the hospital may be able to give information about financial support.

Check Your Practice

Your 19-yr-old male patient is in the holding area. He is scheduled for an orchiectomy for testicular cancer. He is visibly sweating and agitated. When you ask him how he is doing, he responds, "I am scared. Wouldn't you be?"

- What can you do to reduce his fear?

Hope

Although many psychologic factors related to surgery seem to be negative, hope is a positive attribute. Hope may be the patient's strongest method of coping. To deny or minimize hope may negate

the positive mental attitude necessary for a quick and full recovery. Some patients hopefully anticipate surgery. These can be the surgeries that repair (e.g., plastic surgery for burn scars), rebuild (e.g., total joint replacement to reduce pain and improve function), or save and extend life (e.g., repair of aneurysm, organ transplant). Assess and support the presence of hope and the patient's anticipation of positive results.

Past Health History

Ask the patient about any previous health problems and surgeries. Determine if the patient understands the need for surgery. For example, the patient scheduled for a total knee replacement may say that increasing pain and immobility are the reasons for the surgery.

Record the reason for any past hospitalizations, including previous surgeries and the dates. Identify any problems with previous surgeries. For example, the patient may have had a wound infection or a reaction to a drug.

Ask women about their menstrual and obstetric history. This includes the date of their last menstrual period, the number of pregnancies, and any history of cesarean section.

When obtaining a family health history, ask the patient and caregiver about any inherited traits, since they may contribute to the surgical outcome. Record any family history of heart and endocrine diseases. For example, if a patient reports a parent with hypertension, sudden cardiac death, or myocardial infarction, this should alert you to the possibility that the patient may have a similar predisposition or condition. Obtain information about the patient's family history of adverse reactions to or problems with anesthesia. For example, malignant hyperthermia has a genetic predisposition. If present, measures will be taken to decrease complications associated with this condition (see Chapter 18).

Medications

Document all current medication use, including OTC drugs and herbs. Many surgery centers ask patients to bring their medications with them when reporting for surgery. This helps to accurately assess

and document the name and dosage of medications.

The interaction of the patient's current drugs and anesthetics can increase or decrease the desired physiologic effect of anesthetics. Consider the effects of opioids and prescribed drugs for chronic health conditions (e.g., heart disease, hypertension, depression, seizure disorder, diabetes). For example, certain antidepressants can potentiate the effect of opioid agents used for anesthesia or pain control. Antihypertensive drugs may predispose the patient to shock from the combined effect of the drug and the vasodilator effect of some anesthetic agents. Insulin or oral hypoglycemic drugs may need adjustments during the perioperative period because of increased body metabolism, decreased oral intake, stress, and anesthesia. Antiplatelet drugs (e.g., aspirin, clopidogrel [Plavix]) and nonsteroidal antiinflammatory drugs (NSAIDs) inhibit platelet aggregation and may contribute to postoperative bleeding.

HCPs may have patients withhold medications before surgery. Specific timeframes for withholding medications depend on the medication and the patient. Patients on long-term anticoagulation therapy (e.g., warfarin [Coumadin], rivaroxaban [Xarelto], dabigatran [Pradaxa], apixaban [Eliquis]) present a unique challenge. The options for these patients include (1) continuing therapy, (2) withholding therapy for a time before and after surgery, or (3) withholding the therapy and starting subcutaneous or IV heparin therapy during the perioperative period. The management strategy selected is based on the patient history and the nature of the surgery.[2]

Ask about the use of herbs and dietary supplements because their use is so common. Many patients do not think to include supplements in their list of medications. They believe that herbal and dietary supplements are "natural" and do not pose a surgical risk.[3] Excess use of vitamins and herbs can cause harmful effects in patients undergoing surgery. In those taking anticoagulants or antiplatelets, herbal supplements can produce excess postoperative bleeding that may require a return to the OR.[3] The Complementary & Alternative Therapies box lists the effects of specific herbs that are of concern during the perioperative period.

Complementary & Alternative Therapies

Herbal Products and Surgery

Use the following as a guide for patient teaching:

- Notify your HCP of all vitamins, herbs, and dietary supplements that you are taking.
- Avoid astragalus and ginseng, since they can increase BP before and during surgery.
- Avoid garlic, vitamin E, ginkgo, and fish oils because they can increase bleeding.
- Avoid kava and valerian because they can cause excessive sedation.
- In general, stop taking all herbs 2 to 3 weeks before any surgical procedure. Consult your HCP for specific instructions.
- Take multivitamins until the day before surgery. Taking them on the day of surgery on an empty stomach may contribute to nausea and vomiting after surgery.

Ask the patient about any substance use. The most likely used substances include tobacco, alcohol, opioids, marijuana, cocaine, and amphetamines. Ask questions about use in a frank manner. Stress that substance use may affect the type and amount of anesthesia the patient will need. When patients become aware of the potential interactions of these substances with anesthetics, most patients respond honestly about using them.

Chronic alcohol use can place the patient at risk because of lung, GI, or liver damage. Decreased liver function prolongs the metabolism of anesthetic agents, alters nutritional status, and increases the potential for postoperative complications. Alcohol withdrawal can occur during lengthy surgery or in the postoperative period. Proper planning and management are needed to avoid this life-threatening event (see Chapter 10).

Record and share all findings of the drug history with the perioperative health care team. The ACP will decide the best schedule and dose of the patient's routine drugs before and after surgery. Ensure that you identify all the patient's drugs, implement any changes in the medication plan, and monitor the patient for potential interactions and complications.

Allergies

Ask the patient about drug intolerances and drug allergies. Drug intolerance usually results in side effects that are unpleasant for the patient but are not life threatening. These effects can include nausea, constipation, diarrhea, or *idiosyncratic* (opposite than expected) reactions. A true drug allergy produces hives and/or an anaphylactic reaction, causing cardiopulmonary compromise (e.g., hypotension, tachycardia, bronchospasm). Being aware of drug intolerances and drug allergies helps the health care team maintain patient comfort and safety.

Record all drug intolerances and allergies and, if needed, place an allergy identification band on the patient on the day of surgery.

Safety Alert

Allergies

- Some local anesthetic agents contain bisulfite preservatives.
- Notify the ACP if the patient reports an allergy to sulfur-containing drugs.

Ask about nondrug allergies, specifically food and environmental (e.g., latex, pollen, animals) allergies. The patient with a history of any allergic reactions has a greater potential for hypersensitivity reactions to drugs given during anesthesia. Screen all patients for latex allergies by gathering data about:

- Risk factors
- Contact dermatitis
- Contact urticaria (e.g., hives)
- Aerosol reactions
- History of reactions that suggest an allergy to latex

Risk factors for latex allergy include long-term, multiple exposures to latex products, such as those experienced by health care and rubber industry workers. Other risk factors include a history of hay fever, asthma, and allergies to certain foods (e.g., eggs, avocados, bananas, chestnuts, potatoes, peaches).[4] Latex allergies are discussed in Chapter 13.

Review of Systems

The last part of the patient history is the body systems review. Ask specific questions to confirm the presence or absence of any diseases. Current health problems can alert you to areas that you will need to examine in the preoperative physical examination. The combined review of systems and patient history provide essential data to determine the specific preoperative tests that the patient needs.

Cardiovascular System

Evaluate cardiovascular (CV) function to determine preexisting disease or problems (e.g., coronary artery disease, prosthetic heart valve). In reviewing the CV system, you may find a history of hypertension, angina, dysrhythmias, heart failure, or myocardial infarction (MI). Ask about the patient's current treatment for any CV condition (e.g., drugs) and the level of functioning. A cardiology consult is often needed before surgery if the patient has a significant CV history (e.g., recent MI, valvular heart disease, implantable cardioverter-defibrillator).

If indicated, the patient should have a 12-lead electrocardiogram (ECG) and coagulation studies and the results should be on the chart before surgery. The CV assessment provides data on what other

measures the patient needs. For example, the patient who is on diuretic therapy needs to have a serum potassium level drawn before surgery. If the patient has hypertension, the ACP may give vasoactive drugs to maintain adequate BP during surgery. The patient with a prosthetic heart valve may receive antibiotic prophylaxis before surgery to decrease the risk for infective endocarditis (see Chapter 36).

Venous thromboembolism (VTE), a condition that includes deep vein thrombosis and pulmonary embolism, is a concern for any surgical patient. Patients at high risk for VTE include those with a history of previous thrombosis, blood-clotting disorders, cancer, varicosities, obesity, tobacco use, heart failure, or chronic obstructive pulmonary disease (COPD).[5] People are also at risk for developing a VTE because of immobility and positioning during the operative procedure. Intermittent pneumatic compression devices (IPCs) may be applied in the preoperative holding area.

Respiratory System

Ask the patient about any recent or chronic respiratory disease or infections. Elective surgery may be postponed if the person has an upper respiratory tract infection. Upper airway infections may increase the risk for bronchospasm, laryngospasm, decreased O_2 saturation, and problems with respiratory secretions. Report a patient's history of dyspnea at rest or with exertion, coughing (dry or productive), or hemoptysis (coughing blood) to the ACP and surgeon.

If a patient has a history of asthma, ask about the use of inhaled or oral corticosteroids and bronchodilators, as well as the frequency and triggers of asthma attacks. The patient with a history of COPD is at high risk for pulmonary complications, including hypoxemia and atelectasis.

Gather information about the patient's tobacco use. The HCP and you should encourage the patient to stop smoking at least 6 weeks before surgery. Smoking increases the risk for pulmonary complications during and after surgery. Report conditions likely to affect respiratory function such as sleep apnea, obesity, and spinal, chest, and airway deformities. For example, patients are often asked to

bring their sleep apnea devices with them to the hospital or surgical center. Depending on the patient's history and physical examination, baseline pulmonary function tests and arterial blood gases may be done before surgery.

Neurologic System

Evaluation of neurologic functioning includes assessing the patient's ability to respond to questions, follow commands, and maintain orderly thought patterns. Changes in the patient's hearing and vision may affect responses and the ability to follow directions throughout the perioperative assessment and evaluation. Record the patient's ability to pay attention, concentrate, and respond appropriately to establish a baseline for postoperative comparison.

If you note deficits in cognitive function, determine the extent of the problems and whether they can be corrected before surgery. If the problems cannot be corrected, it is important to involve a legal guardian or person with durable power of attorney for health care to aid the patient and provide informed consent for surgery.

Preoperative assessment of the older person's baseline cognitive function is especially crucial for comparison during and after surgery. The older adult may have intact mental abilities before surgery but is more prone to adverse outcomes during and after surgery than the younger adult. This is due to the added stressors of the surgical procedure, dehydration, hypothermia, and anesthesia and adjunctive drugs. These factors may contribute to the development of *emergence delirium,* a condition that may be falsely labeled as senility or dementia.

In the review of the neurologic system, obtain about any history of strokes, transient ischemic attacks, or spinal cord injury. Ask about neurologic diseases, such as myasthenia gravis, Parkinson's disease, and multiple sclerosis, and any treatments used.

Genitourinary System

Assess for a history of renal or urinary tract diseases, such as chronic kidney disease or repeated urinary tract infections. Record the present

disease state and current treatment. Renal dysfunction is associated with several problems, including fluid and electrolyte imbalances, coagulopathies, increased risk for infection, and impaired wound healing. Because the kidneys metabolize and excrete many drugs, a decrease in renal function can lead to an altered response to drugs and unpredictable drug elimination. Renal function tests (e.g., serum creatinine, blood urea nitrogen [BUN]) are often done before surgery.

Record and share with the perioperative team if the patient has problems voiding (e.g., incontinence, hesitancy). Older male patients may have an enlarged prostate that can interfere with the insertion of a bladder catheter or impair voiding after surgery.

For a woman of childbearing age, determine if she is pregnant or thinks she could be pregnant. Most agencies perform a pregnancy test for all women of childbearing age before surgery.[6] Immediately tell the surgeon if the patient states that she may be pregnant. Maternal and fetal exposure to anesthetics should be avoided during the first trimester.

Hepatic System

The liver is involved in glucose homeostasis, fat metabolism, protein synthesis, drug and hormone metabolism, and bilirubin formation and excretion. The liver detoxifies many anesthetics and adjunctive drugs. The patient with hepatic dysfunction may have an increased perioperative risk for clotting abnormalities and adverse responses to drugs. Consider the presence of liver disease if there is a history of jaundice, hepatitis, alcohol abuse, or obesity.

Integumentary System

Ask about a history of skin problems. Assess the current condition of the skin, especially at the incision site, for rashes, breakdown, or other skin conditions. A patient with a history of pressure injuries may need extra padding during surgery. Skin problems can affect wound healing.

Body art such as tattoos and piercings are increasingly common. When possible, select pigment-free areas for injections, IV sites, and

laboratory draws.

Musculoskeletal System

Note any musculoskeletal and mobility problems, especially in the older adult. If the patient has arthritis, identify all affected joints. Mobility restrictions may influence intraoperative and postoperative positioning and ambulation. Spinal anesthesia may be difficult if the patient cannot flex the lumbar spine enough to allow easy needle insertion. If the neck is affected, intubation and airway management may be difficult. Any mobility aids (e.g., cane, walker) should be with the patient on the day of surgery.

Endocrine System

The patient with diabetes is especially at risk for adverse effects of anesthesia and surgery. Hypoglycemia, hyperglycemia, delayed wound healing, and infection are common complications of diabetes during the perioperative period. Clarify with the surgeon or ACP whether the patient should take the usual dose of insulin or oral hypoglycemic agents on the day of surgery. ACPs may vary the usual insulin dose based on the patient's status and history of glucose control. Measure serum or capillary glucose levels the morning of surgery to establish baseline levels. Assess the patient's glucose levels regularly and, if necessary, manage according to agency protocol.

Determine if the patient has a history of thyroid dysfunction. Hyperthyroidism or hypothyroidism can place the patient at surgical risk because of changes in metabolic rate. If the patient takes a thyroid replacement drug, check with the ACP about administering the drug on the day of surgery. If the patient has a history of thyroid dysfunction, laboratory tests may be done to determine current levels of thyroid function.

The patient with Addison's disease needs special consideration during surgery. Addisonian crisis or shock can occur if a patient abruptly stops taking replacement corticosteroids. The patient may need additional IV corticosteroid therapy from the stress of surgery[7] (see Chapter 49).

Immune System

Note if the patient has a history of a compromised immune system or takes immunosuppressive drugs. Corticosteroids used in immunosuppressive doses may be tapered before surgery. Impairment of the immune system can lead to delayed wound healing and increased risk for infections.[8] Elective surgery may be cancelled if the patient has an acute infection (e.g., sinusitis, influenza). Patients with active chronic infections such as hepatitis B or C, acquired immunodeficiency syndrome, or tuberculosis may have surgery if needed. However, when preparing the patient for surgery, remember to take infection control precautions for the protection of the patient and staff. Infection control guidelines are discussed in Chapter 14.

Fluid and Electrolyte Status

Ask the patient about any recent conditions that increase the risk for fluid and electrolyte imbalances, such as vomiting, diarrhea, or completing a bowel prep. Identify drugs that change fluid and electrolyte status, such as diuretics. Serum electrolyte levels are often assessed before surgery. Many patients may have restricted fluids for a specific period of time before surgery. They could develop dehydration if surgery is delayed. A patient with or at risk for dehydration may need more fluids and electrolytes before or during surgery.

Complete a preoperative fluid balance history for all patients. This is especially critical for older adults. Their reduced adaptive capacity leaves a narrow margin of safety between overhydration and underhydration.

Nutritional Status

Nutritional problems include overnutrition and undernutrition, both of which need considerable time to correct. However, knowing that a patient has a nutritional problem can help the health care team provide more customized care. For example, if the patient is thin, place more padding than usual on the OR table. Notify the team if a

patient is severely obese (body mass index [BMI] greater than 40 kg/m^2) to allow time to obtain special equipment needed for the patient's care (e.g., longer instruments for abdominal surgery).

Obesity stresses the heart and lung systems and makes access to the surgical site and anesthesia administration more difficult.[9] It predisposes the patient to wound dehiscence, wound infection, and incisional herniation after surgery. Adipose tissue is less vascular than other types of tissue. The patient may be slower to recover from anesthesia because adipose tissue absorbs and stores inhalation agents, so they leave the body more slowly. See Chapter 40 for the special needs of obese patients undergoing surgery.

Nutritional problems impair the ability to recover from surgery. Remember that the obese patient or the very thin patient can be protein and vitamin deficient. If the problem is severe, surgery may be postponed. Protein and vitamins A, C, and B complex deficiencies are particularly important because these substances are essential for wound healing.[10] Patients who are malnourished may receive supplemental nutrition during the perioperative period. The older adult is often at risk for malnutrition and fluid volume deficits.

TABLE 17.3 American Society of Anesthesiologists' (ASA) Physical Classification System

Rating	Definition
P1 (ASA I)	Normal healthy person
P2 (ASA II)	Patient with mild systemic disease
P3 (ASA III)	Patient with severe systemic disease
P4 (ASA IV)	Patient with severe systemic disease that is a constant threat to life
P5 (ASA V)	Moribund patient who is not expected to survive without surgery
P6 (ASA VI)	Declared brain-dead patient whose organs are being removed for donor purposes

Source: American Society of Anesthesiologists: ASA physical status classification system, 2014. Retrieved from *www.asahq.org/resources/clinical-information/asa-physical-status-classification-system*.

Identify patients who consume large quantities of coffee or caffeinated soft drinks. In many cases, withholding caffeinated beverages before surgery or for some time after surgery can lead to severe withdrawal headaches.[11] These headaches can be confused with spinal headaches if the preoperative data are not recorded. Giving caffeinated beverages after surgery, when possible, may prevent these headaches.

Objective Data

Physical Examination

The Joint Commission requires that all patients admitted to the OR have a documented history and physical examination (H&P) in their chart.[12] This may be done in advance of surgery or on the day of surgery. Any qualified HCP, including advanced practice nurses, physicians, physician assistants, or ACPs, may perform the H&P. Findings from the H&P enable the ACP to assign the patient a physical status rating for anesthesia administration (Table 17.3). This rating is an indicator of the patient's perioperative risk and may influence perioperative decisions. It uses a scale of P1 to P6. A rating of P6 is reserved for a brain-dead patient undergoing organ procurement. Patients undergoing surgery in ambulatory or outpatient settings generally have ratings of P1, P2, or P3. Other designations can be added to the ASA status (e.g., "E" to designate an "emergent" procedure).

Complete a physical examination of the patient before surgery (Table 17.4). Review the documentation already present in the patient's chart, including the H&P, to better proceed with your examination. Record all findings and share any relevant findings at once with the surgeon or ACP.

TABLE 17.4 Health Assessment and Physical Examination of Preoperative Patient*

Cardiovascular System

- Identify acute or chronic problems. Note presence of angina, hypertension, heart failure, recent myocardial infarction.
- Identify any drugs (e.g., aspirin) or herbs (e.g., ginkgo) that may affect coagulation.
- Identify patients with prosthetic heart valves, pacemakers, or implantable cardioverter-defibrillators.
- Assess for edema (including dependent areas), noting location and severity.
- Inspect neck veins for distention.
- Obtain bilateral baseline BPs.
- Assess capillary refill and pulses for rate, rhythm, and quality: apical, radial, and pedal.

Gastrointestinal System

- Determine patterns of food and fluid intake and any recent changes in weight.
- Review usual pattern of bowel movements, including date of last bowel movement.
- Assess for presence of dentures and bridges (loose dentures or teeth may be dislodged during intubation).
- Weigh patient.
- Auscultate abdomen for presence of bowel sounds.

Genitourinary System

- Identify any infection or preexisting disease.
- Determine ability to void.
- Note color, amount, and characteristics of urine.
- Determine pregnancy status (if appropriate).

Hepatic System

- Review any substance use, especially alcohol and IV drug use.
- Inspect skin color and sclera of eyes for any signs of jaundice.

Immune System

- Note any immunodeficiency or autoimmune disorders.
- Assess for use of corticosteroids or other immunosuppressant drugs.

Integumentary System

- Determine skin status. Note any current or previous skin problems (e.g., pressure injuries, eczema, bruising).
- Inspect skin for rashes, boils, or infection, especially around the planned surgical site.
- Inspect mucous membranes and skin turgor for signs of dehydration.
- Assess skin moisture and temperature.

Musculoskeletal System

- Examine skin around bone pressure points.
- Assess for limitations in joint range of motion and muscle strength.

- Assess for joint or muscle pain.
- Assess mobility, gait, and balance.

Neurologic System

- Determine orientation to person, place, and time.
- Assess baseline mental status. Note any confusion, disorderly thinking, or inability to follow commands.
- Identify any history of strokes, transient ischemic attacks, or neurologic diseases (e.g., Parkinson's disease, multiple sclerosis).

Respiratory System

- Identify acute or chronic problems. Note presence of infection, chronic obstructive pulmonary disease, or asthma.
- Note use of continuous positive airway pressure (CPAP) machine.
- Assess tobacco history, including date/time of last cigarette and number of pack-years.
- Determine baseline O_2 saturation and respiratory rate and rhythm.
- Observe for cough, dyspnea, and use of accessory muscles of respiration.
- Auscultate lungs for normal and adventitious breath sounds.

---

* See specific body system chapters for more detailed assessments and related laboratory studies.

TABLE 17.5 Common Preoperative Diagnostic

Studies

Test	Assessment
ABGs, pulse oximetry	Respiratory and metabolic function, oxygenation status
Blood glucose	Metabolic status, diabetes
Blood urea nitrogen, creatinine	Renal function
Chest x-ray	Lung disorders, cardiac enlargement, heart failure
CBC: RBCs, Hgb, Hct, WBCs	Anemia, immune status, infection
Electrocardiogram	Heart disease, dysrhythmias
Electrolytes	Metabolic status, renal function, diuretic side effects
hCG	Pregnancy status
Liver function tests	Liver status
PT, PTT, INR, platelet count	Coagulation status
Pulmonary function studies	Pulmonary status
Serum albumin	Nutritional status
Type and crossmatch	Blood available for replacement (elective surgery patients may have own blood available)
Urinalysis	Renal status, hydration, urinary tract infection

CBC, Complete blood count; *hCG,* human chorionic gonadotropin; *Hct,* hematocrit; *Hgb,* hemoglobin; *INR,* international normalized ratio; *PT,* prothrombin time; *PTT,* partial thromboplastin time.

Diagnostic Studies

Obtain and assess the results of diagnostic studies ordered before surgery (Table 17.5). For example, a patient taking an antiplatelet drug (e.g., aspirin) may have a coagulation profile done or a patient on diuretic therapy may have a potassium level checked. A woman of childbearing age may receive a pregnancy test. An ECG is done for many who take drugs for dysrhythmias or have high blood pressure. Patients with diabetes undergo blood glucose monitoring. In many settings, patients are tested for methicillin-resistant *Staphylococcus*

aureus. Those with positive results are prescribed antibiotics for several days before surgery.[13]

Ideally, preoperative tests are ordered based on the patient's H&P. However, many agencies and insurers have protocols for preoperative tests, which may not include all those in Table 17.5. In addition, some tests may be done days before surgery. Ensure that all laboratory and diagnostic reports are in the patient's chart. Missing reports may result in a delay or cancellation of the surgery.

Nursing Management: Preoperative Patient

Base the preoperative nursing interventions on the nursing assessment, depending on the patient's specific needs. The pending surgery and routines of the surgery setting guide the patient's physical preparation. Preoperative teaching may be minimal or extensive. The Association of periOperative Registered Nurses (AORN) provides standards and recommended practices to guide nursing interventions in all perioperative settings.[5]

Preoperative Teaching

The patient has a right to know what to expect and how to take part effectively during the surgical experience. Preoperative teaching increases patient satisfaction and can reduce postoperative fear, anxiety, and stress.[14] Teaching may decrease the development of complications, length of hospitalization, and recovery time after discharge.

In most surgical settings, patients often arrive only a short time before their surgery. Preoperative teaching for these patients generally occurs in the surgeon's office or a preadmission surgical clinic and is reinforced on the day of surgery. After ambulatory surgery, the patient usually goes home several hours after recovery, depending on the patient's progress and procedure-specific needs. Teaching must

include information that focuses on the patient's safety. Give written materials for patients and caregivers to use for review and reinforcement at home. Discharge teaching is required for all patients (see Chapter 19).

When delivering teaching, find a balance between explaining so much that the patient is overwhelmed and telling so little that the patient is unprepared. If you observe and listen carefully to the patient, you can usually figure out how much information is enough. Remember that anxiety and fear may limit learning ability. Assess what the patient wants to know and give priority to those concerns.

Generally, preoperative teaching includes 3 types of information: sensory, process, and procedural. Different patients, with varying cultures, backgrounds, and experience, may want different types of information. See Table 4.6 for factors affecting patient teaching.

With *sensory information,* patients find out what they will see, hear, smell, and feel during the surgery. For example, you may tell them that the OR will be cold, but they can ask for a warm blanket; the lights in the OR are bright; or many unfamiliar sounds and specific smells will be present.

Patients wanting *process information* may not want specific details but just the general flow of what is going to happen. This information would include the patient's transfer to the holding area, visits by the nurse and the ACP before transfer to the OR, and waking up in the PACU.

With *procedural information,* patients desire details that are more specific. For example, this information would include saying an IV line will be started while the patient is in the holding area and the surgeon will mark the operative area with an indelible marker to verify the surgical site.[5]

Share the preoperative teaching given to the patient with the nurses providing postoperative care to evaluate learning and avoid duplication of teaching. Because there is limited time for teaching, a team approach is often used. For example, teaching may start in the outpatient setting. Your responsibility is to assess the patient's understanding of this teaching and fill in the gaps at this point in the

surgical process.

Record all teaching in the patient's chart. A guide for preoperative patient and caregiver teaching is outlined in Table 17.6. See Chapter 4 for more on patient and caregiver teaching.

General Surgery Information

Unless it is contraindicated (e.g., after craniotomy, tonsillectomy), all patients should receive instruction about deep breathing, coughing, and early ambulation postoperatively. This is essential because patients may not want to do these activities after surgery unless they know the reason for them and practice them before surgery. Tell patients and caregivers if tubes, drains, monitoring devices, or special equipment will be used after surgery. Explain that these devices help you to safely care for the patient. Examples of specific teaching may include how to use incentive spirometers or patient-controlled analgesia pumps. Patients should have a clear understanding of how to rate their pain and how their pain will be managed[10] (see Chapter 8).

TABLE 17.6 Patient & Caregiver TeachingPreoperative Preparation

Include the following information in the preoperative teaching plan for the patient and caregiver.

Sensory Information

- Preoperative holding area may be noisy
- Drugs and cleaning solutions may be odorous
- Operating room (OR) can be cold. Forced air warming devices may be used. Warm blankets are available
- Talking may be heard but may be distorted because of masks. Ask questions if something is not understood
- OR bed will be narrow. A safety strap will be applied over the

thighs
- Lights in the OR may be bright
- Monitoring machines may be heard (e.g., beeping noises) when awake

Procedural Information

- What to bring and what type of clothing to wear to the surgery center
- Any changes in time of surgery
- Fluid and food restrictions
- Physical preparation needed (e.g., shower, bowel, or skin preparation)
- Purpose of frequent vital signs assessment
- Pain control and other comfort measures
- Why turning, deep breathing, and coughing after surgery are important. Do practice sessions
- Insertion of IV lines
- Procedure for anesthesia administration
- Surgical site may be marked with indelible ink or marker

Process Information
Information About General Flow of Surgery

- Admission area
- Preoperative holding area, OR, and postanesthesia care unit (PACU)
- Caregivers can usually stay in preoperative holding area until surgery
- Caregivers will be able to see patient after discharge from the PACU or possibly in PACU once the patient is awake

- Identification of any technology that may be present on awakening, such as monitors, central lines, intermittent pneumatic compression devices

Where Caregivers Can Wait During Surgery

- Encourage caregivers to ask questions and express any concerns
- OR staff will update caregivers during surgery and when surgery is over
- Surgeon will usually talk with caregivers after surgery

The patient should also receive surgery-specific information. For example, a patient having a total joint replacement may have an immobilizer after surgery. Tell a patient having open heart surgery about waking up in the intensive care unit.

Ambulatory Surgery Information

The ambulatory surgery patient or the patient admitted to the hospital the day of surgery needs to receive information before admission. Some ambulatory surgical centers telephone patients several days before the procedure to obtain health information, give instructions, and answer questions. Each center has policies and procedures for communicating this information.

In addition to specifics on the procedure, patients need information on day-of-surgery events such as arrival time, registration, parking, what to wear, what to bring, and the need to have a responsible adult present for transportation home after surgery.

Traditionally, we tell patients having elective surgery to have nothing by mouth (NPO) starting at midnight on the night before surgery. Evidence-based guidelines for healthy patients of all ages undergoing elective surgery (except women in labor) from the American Society of Anesthesiologists are less strict[15] (Table 17.7). Restricting fluids and food is designed to reduce the risk for pulmonary aspiration and nausea and vomiting. Protocols may vary

for patients having local anesthesia or surgery scheduled late in the day. Follow the NPO protocol of each surgical setting. The patient who has not followed the NPO instructions may have surgery delayed or cancelled. It is critical that the patient understands the reason for and follows all restrictions.

TABLE 17.7 Preoperative Fasting Recommendations

Liquid and Food Intake	Minimum Fasting Period (hr)
Clear liquids (e.g., water, clear tea, black coffee, carbonated beverages, fruit juice without pulp)	2
Breast milk	4
Nonhuman milk, including infant formula	6
Light meal (e.g., toast and clear liquids)	6
Regular meal (may include fried or fatty food, meat)	8 or more

Source: Practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration: Application to healthy patients undergoing elective procedures, *Anesthesiology* 126:376, 2017.

Legal Preparation for Surgery

Legal preparation for surgery consists of checking that all required forms have been correctly signed and are present in the patient's chart and that the patient and caregiver clearly understand what is going to happen. Standard consent forms include those for the surgical procedure and blood transfusions. Other forms may include advance directives and durable power of attorney for health care (see Chapter 9).

Consent for Surgery

Before nonemergency surgery can be legally performed, the patient must voluntarily sign an informed consent form in the presence of a witness. **Informed consent** is an active, shared decision-making process between the HCP and recipient of care. Three conditions must be met for consent to be valid. First, there must be *adequate disclosure* of the (1) diagnosis; (2) nature and purpose of the proposed treatment; (3) risks and consequences of the proposed treatment; (4) probability of a successful outcome; (5) availability, benefits, and risks of alternative treatments; and (6) prognosis if treatment is not instituted. Second, the patient must show a clear *understanding* of the information before receiving sedating preoperative drugs. If a patient is sedated prior to signing the consent, surgery may be cancelled or delayed. Third, the recipient of care must *give consent voluntarily.* The patient must not be persuaded or coerced in any way by anyone to undergo the procedure.

The surgeon is ultimately responsible for obtaining the patient's consent for surgical treatment. You may be asked to witness the patient's signature on the consent form. At this time, you must be a patient advocate, verifying that the patient understands the information in the consent and the implications of consent, and that consent for surgery is truly voluntary. If the patient is unclear about the surgical plans, contact the surgeon about the patient's need for more information. The patient should be aware that consent, even when signed, can be withdrawn at any time.

If the patient is a minor, unconscious, or mentally incompetent to sign the permit, a legally appointed representative or responsible family member may give written permission. An *emancipated minor* is one who is younger than the legal age of consent but is recognized as having the legal capacity to provide consent.[10] Procedures for obtaining consent vary among states and agencies. Follow your state's nurse practice act and agency policies that apply to a specific situation.

Ethical/Legal Dilemmas

Informed Consent

Situation

J.S., a 72-yr-old woman, is waiting in the preoperative holding area. You are discussing her impending surgery when you realize that this competent adult does not fully understand her surgery and was not informed of the alternatives to this surgery. Although she has previously signed a consent form, your assessment is that she was not fully informed about her treatment options or does not recall them.

Ethical/Legal Points for Consideration

- Informed consent requires that patients have complete information about the proposed treatment, as well as alternative treatments, risks and benefits of each treatment option, and possible consequences of the surgical procedure. The person (usually the surgeon) performing the procedure usually has this responsibility.
- An opportunity to have questions answered about the various treatment options and their possible outcomes is a crucial element of informed consent.
- A patient can revoke the consent at any time, even at the very last minute. It is essential that you report any circumstance that suggests that the patient does not understand the information or is revoking the informed consent to the person who obtained the consent.
- In most states, the registered nurse's legal role is to witness the signing of the document. This means that as a nurse, you attest to the fact that the patient's signature was valid.

Discussion Questions

1. What do you think you should do next?

2. What is your role as a patient advocate in the informed consent process?
3. What should you do if the patient states that she does not want to know about the surgical procedure or alternatives to surgery?

A true medical emergency may override the need to obtain consent.[10] The next of kin may give consent when immediate medical treatment is necessary to preserve life or prevent serious impairment to life or limb and the patient is incapable of giving consent. If reaching the next of kin is not possible, the HCP may begin treatment without written consent. A note in the chart must document the medical necessity of the procedure. In the case of an emergency in which consent cannot be obtained, you will usually need to complete an event report because it is an occurrence that is inconsistent with routine agency practices.

Day-of-Surgery Preparation

Nursing Role

Day-of-surgery preparation varies a great deal depending on whether the patient is an inpatient or an ambulatory surgical patient. Your responsibilities immediately before surgery include final preoperative teaching, assessment, and communication of pertinent findings. In addition, ensure that all preoperative orders are done and that the chart is complete and goes with the patient to the OR. It is especially important to verify the presence of a signed informed consent form, results of laboratory and diagnostic studies, an H&P, a record of any consultations, baseline vital signs, proper skin preparation, and completed nursing notes. The surgical site is identified and marked with an indelible marker by the surgeon and documented to show that the patient agrees.[5]

FIG. 17.1 The nurse performs a safety check by verifying that the patient has an identification band (wristband) as part of the preoperative preparations before she goes to surgery.
Courtesy Susan R. Volk, RN, MSN, CCRN, CPAN, Staff Development Specialist, Christiana Care Health System, Newark, DE.

Hospitals often require that a patient wear a hospital gown with no underclothes. Surgical centers may allow the patient to wear underwear, depending on the procedure. The patient should remove any cosmetics, since observation of skin color is important. Remove nail polish and artificial nails so you can assess capillary refill and pulse oximetry. Place an identification band on the patient and, if applicable, an allergy band (Fig. 17.1). Return all patient valuables to a

caregiver or secure according to agency policy. All prostheses, including dentures, contact lenses, and glasses, are generally removed to prevent loss or damage. If electrocautery devices will be used during surgery, jewelry in piercings must be removed as a safety measure. Leave hearing aids in place to allow the patient to better follow instructions. Return glasses to the patient as soon as possible after surgery.

Encourage the patient to void before you give preoperative drugs and before transfer to the OR. An empty bladder prevents involuntary elimination under anesthesia and reduces the risk for urinary retention during the early postoperative recovery.

Many preoperative drugs interfere with balance and increase the risk for a fall during ambulation. Carefully assess each patient for responses to drugs given and adjust the plan of care as needed.

Check Your Practice

You are caring for an older female patient who received a dose of alprazolam (Xanax) for preoperative anxiety. One hour later, she requests to use the bathroom. You ask her if she can walk and she replies "yes." When helping her to stand, she becomes dizzy and almost falls. You return her to bed.

- Instead of trying to help this patient ambulate to the bathroom, what should have you done?

TABLE 17.8 Drug TherapyCommonly Used Preoperative Medications

Class	Drug	Purpose
Antibiotics	cefazolin	Prevent postoperative infection
Anticholinergics	atropine glycopyrrolate	↓ Oral and respiratory secretions
	scopolamine (Transderm Scop)	Prevent nausea and vomiting Provide sedation
Antidiabetics	insulin (Humulin R)	Stabilize blood glucose
Antiemetics	metoclopramide (Reglan)	↑ Gastric emptying
	ondansetron (Zofran)	Prevent nausea and vomiting
Benzodiazepines	diazepam (Valium) lorazepam (Ativan) midazolam	↓ Anxiety, induce sedation, amnesic effects
β-Blockers	labetalol	Manage hypertension
Histamine (H_2)-receptor antagonists	famotidine ranitidine	↓ HCl acid secretion, ↑ pH, ↓ gastric volume
Opioids	fentanyl morphine	Relieve pain during preoperative procedures

Preoperative Medications

Preoperative medications are used for a variety of reasons (Table 17.8). A patient may receive a single drug or a combination of drugs. Benzodiazepines are used for their sedative and amnesic properties. Anticholinergics are sometimes given to reduce secretions. Opioids may be given to decrease pain and anesthetic requirements during surgery. Antiemetics can decrease nausea and vomiting.

Other drugs that may be given before surgery include antibiotics, eyedrops, and routine prescription drugs. Antibiotics may be given throughout the perioperative period for patients with a history of prosthetic heart valve to prevent infective endocarditis and for patients with previous joint replacement. They also may be given when wound contamination is a potential risk (e.g., GI surgery). Antibiotics are most often given IV. We often give a single or first dose within 30 to 60 minutes of the surgical incision.

Informatics in Practice

Computer-Based Timing for Antibiotic Administration

- A patient who receives the appropriate preoperative antibiotic

has a decreased risk for a health care–associated infection.

- Using a computer to time antibiotic administration can decrease the incidence of wound infections.
- Computer-based timing systems aid with quality of care by tracking patient outcomes.
- You can look at the time patients received antibiotics and compare the rate of wound infections for those who did and did not receive timely treatment.

People with known hypertension or coronary artery disease may receive β-adrenergic blockers (β-blockers) to control BP or reduce the chances of MI and cardiac arrest.[16] Those with diabetes are carefully monitored and may receive insulin in the preoperative period.[10] Eyedrops are often given prior for the patient undergoing cataract and other eye surgery. Many times, the patient will need multiple sets of eyedrops given at 5-minute intervals. It is important to give these drugs as ordered and on time to adequately prepare the eye for surgery.

Patients may or may not receive drugs they routinely take on the day of surgery. To aid patient teaching and remove confusion about which drugs patients are taking, carefully check written preoperative orders and clarify the orders with the surgeon and/or ACP if there is any question.

Preoperative drugs may be given by mouth (PO), IV, or subcutaneously. Provide PO drugs with a small sip of water 60 to 90 minutes before the patient goes to the OR unless otherwise ordered. Subcutaneous injections (e.g., insulin) and IV drugs are usually given to the patient after arrival in the preoperative holding area. Teach the patient about the expected effects of the drugs (e.g., drowsiness).

Safety Alert

Preoperative Checklist

- Use a preoperative checklist (Table 17.9) to make sure you have completed all required preparations.
- This is especially important to do before the patient receives any sedating drugs.

Transportation to the Operating Room

For inpatients, transport staff move the patient by stretcher to the OR. Help the patient in moving from the bed to the stretcher and raise the side rails. Ensure that the completed chart and any needed equipment goes with the patient. In many agencies, the caregiver may go with the patient to the holding area.

In an ambulatory surgical center, the patient may go to the OR by stretcher or wheelchair. If no sedatives have been given, the patient may even walk with someone to the OR. In all cases, it is important to ensure patient safety during transport. Record the method of transportation and the person who transports the patient to the OR. Provide the hand-off communication to the nurse receiving the patient. This allows each of you to ensure you have shared all pertinent information about the patient. To avoid adverse events related to miscommunication, AORN recommends the use of the Situation-Background-Assessment-Recommendation (SBAR) model for the hand-off process in this setting[5] (see Table 1.4).

Show the caregiver where to wait for the patient during surgery. Many hospitals have a surgical waiting room where OR staff communicate the patient's status to the caregiver(s) and let them know when the surgery is complete. The surgeon can find the caregiver in this room after surgery to discuss the outcome. Some hospitals give pagers to caregivers so that they may eat or do errands during the surgery.

Culturally Competent Care: Preoperative Patient

Include cultural considerations when assessing and implementing care for the patient's preoperative needs. For example, culture often determines one's expression of pain, family expectations, and ability to verbally express needs. One's culture may require that the family be included in any decision making. For example, many older Hispanic women may defer to their family for the decision whether to have surgery. Respect these decisions. If the patient or caregiver does not speak English, you must use a qualified interpreter (translates orally) or translator (interprets written text) communication system.[17] See more on culturally competent care in Chapter 2.

Gerontologic Considerations: Preoperative Patient

Many patients older than 65 years of age undergo surgery. Surgery on older adults requires careful evaluation. Frequently performed procedures in older adults include cataract extraction, coronary and vascular procedures, prostate surgery, cholecystectomy, and joint repair or replacement. Communication is important. The patient's primary HCP is usually not the surgeon. Often several HCPs are involved in the patient's care.

Be particularly alert when assessing and caring for the older adult surgical patient. An event that has little effect on a younger adult may be overwhelming to the older patient. Hospitalization may represent a physical decline and loss of health, mobility, and independence. The older adult may view the hospital as a place to die or as a stepping-stone to a nursing home. Help to decrease anxieties and fears while maintaining the self-esteem of the older adult during the surgical experience.

The risks associated with anesthesia and surgery increase in the older patient. In general, the older the patient, the greater are the risks for complications after surgery. In planning care, consider the patient's physiologic status, not only the chronologic age. The surgical risk in the older adult relates to normal physiologic aging and changes that compromise organ function, reduce reserve capacity, and limit the body's ability to adapt to stress. This decreased ability to cope with stress, often compounded by the burden of one or more chronic illnesses, and the surgery itself increase the risk for complications.

Confirm and document the patient's goals and treatment preferences. In those with advance directives, discuss any new risks associated with the surgical procedure. Make sure the approach for treating any potential problems is consistent with the patient's preferences.[18]

Older adults may have some sensory deficits. Bright lights may bother those with eye problems. They can have reduced vision and hearing. Thought processes and cognitive abilities may be slowed or

impaired. Assess and record baseline sensory and cognitive function. Physical reactions are often slowed because of mobility and balance problems. Because of these changes, the older adult may need more time to complete preoperative testing and understand preoperative instructions. These changes also require you to pay more attention to promote patient safety and prevent injury.

When older adults live in a long-term care or assisted living facility, you may need to coordinate transportation from these facilities so that timely arrival allows for surgery preparation. A legal representative of the patient must be present to provide consent for surgery if the patient cannot sign for himself or herself.

Finally, determine the presence of or need for caregiver support for the older adult undergoing surgery. With the increase in outpatient surgical procedures and shorter length of stays after surgery, caregiver support is critical in the continuity of care for this population.

Case Study

Preoperative Patient

© Ryan McVay/Photodisc/Thinkstock.

Patient Profile

F.D., a 72-yr-old Hispanic retired librarian, is admitted to the hospital with compromised circulation of the right lower leg and a necrotic right foot. She has diabetes and takes insulin to maintain appropriate blood glucose levels. She has been NPO since midnight. It is now 10

AM on the morning of the surgery.

Subjective Data

- History of type 2 diabetes for 30 years; states, “My blood sugar is hard to control” and “I just started taking insulin”
- History of hypertension and peripheral vascular disease
- History of stage 2 chronic kidney disease
- History of macular degeneration in right eye; reports poor vision
- Surgical history: cesarean section at age 30, cholecystectomy at age 65; reports poor wound healing after last surgery
- States her Social Security checks barely cover her living expenses
- States she often runs out of her drugs and cannot always afford to refill them right away
- Reports chronic burning pain in both legs and has trouble sleeping at night
- Lives alone but has family who want her to move in with them after surgery
- Uses herbs to control blood glucose levels and often skips her insulin

Objective Data

Physical Examination

- Alert, cognitively intact, anxious, older woman with numbness and lack of feeling in right leg
- Weight 190 lb, height 5 ft 3 in
- BP 180/94, pulse 84 and slightly irregular
- Wears glasses for close work and reading

Diagnostic Studies

- Admission serum blood glucose level 272 mg/dL (15.2 mmol/L), glycosylated hemoglobin (Hb A1C) 14%
- Morning capillary blood glucose level 198 mg/dL (11 mmol/L)
- Doppler pulses for right lower leg weak, absent in right foot
- Doppler pulses in left lower leg present, weak in left foot
- Serum creatinine 2.0 mg/dL (176 mmol/L)

Interprofessional Care

- Scheduled for a below-the-knee amputation of the right leg at 1 PM today

Discussion Questions

1. What factors may influence F.D.'s response to hospitalization and surgery?
2. ***Priority Decision:*** Given F.D.'s history, what priority preoperative nursing assessments would you want to complete and why?
3. What potential perioperative complications may you expect for F.D.?
4. ***Priority Decision:*** What priority topics would you include in F.D.'s preoperative teaching plan?
5. ***Priority Decision:*** Based on the assessment data presented, identify the priority nursing diagnoses and related interventions. Are there any collaborative problems?
6. ***Collaboration:*** Identify appropriate interventions that could be delegated to unlicensed assistive personnel (UAP).
7. ***Safety:*** To ensure F.D.'s safety, what preoperative nursing interventions are essential?
8. ***Evidence-Based Practice:*** F.D. asks you why she received insulin this morning when she has not eaten anything since midnight. How would you respond to her?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to NCLEX Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An overweight patient (BMI 28.1 kg/m^2) is scheduled for a laparoscopic cholecystectomy at an outpatient surgery setting. The nurse knows that
   a. surgery will involve multiple small incisions.
   b. this setting is not appropriate for this procedure.
   c. surgery will involve removing a part of the liver.
   d. the patient will need special preparation because of obesity.
2. The patient tells the nurse in the preoperative setting that she has noticed she has a reaction when wearing rubber gloves. What is the *most* appropriate action?
   a. Notify the surgeon so that the surgery can be cancelled.
   b. Ask additional questions to assess for a possible latex allergy.
   c. Notify the OR staff at once so they can use latex-free supplies.
   d. No action is needed because the patient's rubber sensitivity has no bearing on surgery.
3. A 59-yr-old man scheduled for a herniorrhaphy in 2 days reports that he takes ginkgo daily. What is the *priority* intervention?
   a. Inform the surgeon, since the procedure may have to be

rescheduled.

b. Notify the anesthesia care provider, since this herb interferes with anesthetics.

c. Ask the patient if he has noticed any side effects from taking this herbal supplement.

d. Tell the patient to continue to take the herbal supplement up to the day before surgery.

4. A 17-yr-old patient with a leg fracture who is scheduled for surgery is an emancipated minor. She has a statement from the court for verification. Which intervention is *most* appropriate?

a. Witness the permit after the surgeon obtains consent.

b. Call a parent or legal guardian to sign the permit since the patient is under 18.

c. Notify the hospital attorney that an emancipated minor is consenting for surgery.

d. Obtain verbal consent since written consent is not necessary for emancipated minors.

5. A *priority* nursing intervention to aid a preoperative patient in coping with fear of postoperative pain would be to

a. inform the patient that pain medication will be available.

b. teach the patient to use guided imagery to help manage pain.

c. describe the type of pain expected with the patient's particular surgery.

d. explain the pain management plan, including the use of a pain rating scale.

6. A patient is scheduled for surgery requiring general anesthesia at an ambulatory surgical center. The nurse asks him when he ate last. He replies that he had a light breakfast a couple of hours before coming to the surgery center. What should the nurse do *first*?
   a. Tell the patient to come back tomorrow, since he ate a meal.
   b. Have the patient void before giving any preoperative medications.
   c. Proceed with the preoperative checklist, including site identification.
   d. Notify the anesthesia care provider of when and what the patient last ate.
7. A patient who normally takes 40 units of glargine insulin (long acting) at bedtime asks the nurse what to do about her dose the night before surgery. The *best* response would be to have her
   a. skip her insulin altogether the night before surgery.
   b. get instructions from her surgeon or HCP on any insulin adjustments.
   c. take her usual dose at bedtime and eat a light breakfast in the morning.
   d. eat a moderate meal before bedtime and then take half her usual insulin dose.
8. Preoperative considerations for older adults include *(select all that apply)*
   a. using only large-print educational materials.
   b. speaking louder for patients with hearing aids.

c. recognizing that sensory deficits may be present.

d. providing warm blankets to prevent hypothermia.

e. teaching important information early in the morning.

1. a, 2. b, 3. a, 4. a, 5. d, 6. d, 7. b, 8. c, d

LEARNING OUTCOMES

1. Distinguish various areas of perioperative department and appropriate attire.
2. Outline the roles and responsibilities of interprofessional surgical team members.
3. Prioritize needs of patients undergoing surgery.
4. Analyze role of a perioperative nurse in the management of patients undergoing surgery.
5. Apply basic principles of infection prevention and aseptic technique in the operating room.
6. Recognize operating room safety measures related to patients, equipment, and anesthesia.
7. Distinguish various anesthesia techniques and common anesthesia drugs.

Conceptual Focus

Gas Exchange
Pain
Perfusion
Safety
Tissue Integrity

Historically, surgery took place in the traditional environment of the hospital operating room (OR). Now, many surgical procedures are done as ambulatory surgery (outpatient surgery). In addition, the use of *minimally invasive surgery* (MIS) is rapidly increasing. More procedures use endoscopes, robotics, and other advanced technologies that lead to decreased blood loss, incision size, pain, recovery time, and hospital length of stay. Hybrid ORs, which allow for MIS, such as endovascular procedures, and the traditional open incision approach within the same room, are becoming more common. This chapter discusses the basics of intraoperative care that apply to

all surgical patients regardless of where or how the surgery is done.

Physical Environment of the Operating Room

Department Layout

The surgery department is a controlled environment designed to minimize the spread of pathogens and allow a smooth flow of patients, staff, and equipment needed to give safe surgical patient care. The department is divided into 3 distinct zones: (1) unrestricted, (2) semirestricted, and (3) restricted (Fig. 18.1). The *unrestricted zone* is where people in street clothes interact with those in scrub attire. These areas typically include the points of entry for patients (e.g., holding area), staff (e.g., locker rooms), and information (e.g., nursing station or control desk). The *semirestricted zone* includes the surrounding support areas and corridors. Only authorized staff are allowed access to semirestricted areas. All staff in the semirestricted area should wear clean surgical attire. This includes scrub attire that was laundered in an accredited laundry facility, long-sleeved jacket, shoes dedicated for surgery use or shoe covers, surgical head cover and mask that covers all head and facial hair, and any appropriate personal protective equipment (e.g., face shield). The *restricted zone* is found within the semirestricted area. It includes the surgical suite (OR) where the invasive procedure takes place and the sterile core (Fig. 18.2). Masks should be worn and traffic minimized whenever sterile supplies are open in the restricted area.[1]

The physical layout is designed to reduce cross-contamination. The flow of clean and sterile supplies and equipment is separate from contaminated supplies, equipment, and waste by space, time, and traffic patterns. Staff members move supplies from clean areas, such as the sterile core, through the OR for surgery, and on to the instrument decontamination and sterilization area (e.g., central processing department [CPD]).

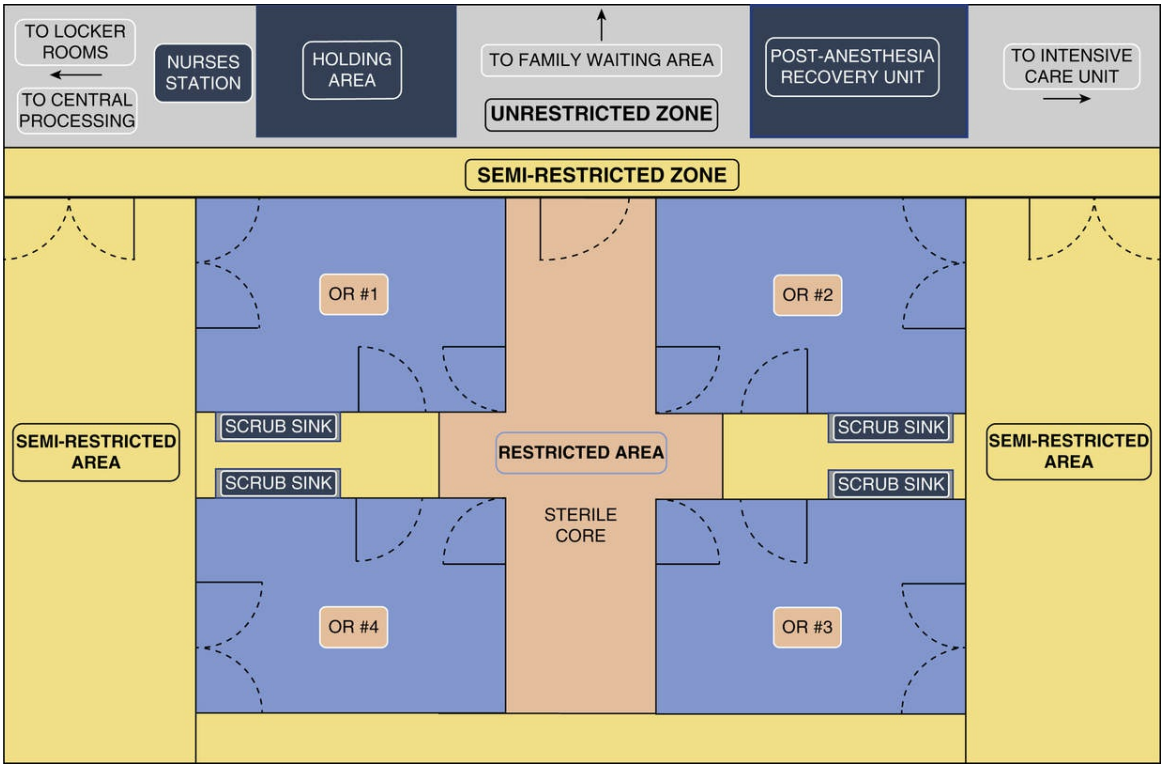

FIG. 18.1 Perioperative department layout.

FIG. 18.2 Typical OR.
© iStock.com/windslegend.

Holding Area

The *holding area,* often called the *preoperative holding area,* is an unrestricted zone where patient identification and assessment take place. The size can range from a large centralize area that handles many patients to a small designated area right outside of the OR.

In some settings, the holding area is called the *admission, observation, and discharge* (AOD) unit. An AOD unit is designed to allow early morning admission for outpatient surgery, same-day admission, and inpatient holding before surgery. The patient is identified and assessed before and after surgery, before being discharged home or transferred to an inpatient room. The AOD unit is important in outpatient surgery and prevents unnecessary overnight stays in the inpatient setting.

Operating Room

The traditional OR is a unique setting separate from other clinical units. This restricted zone is controlled geographically, environmentally, and aseptically (Fig. 18.1). It is best to have the OR next to the postanesthesia care unit (PACU) and the surgical intensive care unit. This allows for quick transport of the patient after surgery and close proximity to anesthesia staff if complications occur.

We use several methods to prevent the transmission of infection in the OR. Filters and controlled airflow in the ventilating systems provide dust control. Positive air pressure in the rooms prevents air from entering the OR from the halls and corridors. ORs are kept within a narrow range of temperature and humidity to prevent bacteria growth. ORs follow strict protocols for cleaning between cases and terminal cleaning at the end of the day. The use of ultraviolet lighting reduces the number of microorganisms in the air.[2]

Using OR furniture that is adjustable, easy to clean, and easy to move promotes safety and comfort. All equipment is checked frequently to ensure proper functioning and electrical safety. The lighting is designed to give a low- to high-intensity range for a precise view of the surgical site. A communication system offers a way to deliver routine and emergency messages.[3]

Surgical Team

Registered Nurse

The *perioperative nurse* is a registered nurse (RN) who collaborates with the rest of the surgical team and implements the patient's plan of care during perioperative period. Depending on the size of the OR department, this role may include three domains: (1) preoperative RN, (2) OR RN, and (3) PACU RN. As an OR RN, you are the patient's advocate during surgery. This includes (1) maintaining the patient's safety, dignity, and confidentiality; (2) communicating with the patient, the surgical team, and other departments (e.g., CPD, PACU, laboratory); and (3) providing nursing care discussed in the Nursing

Management section of this chapter.

TABLE 18.1 Intraoperative Nursing Activities

Circulating, Nonsterile Activities

- Helps prepare room, ensuring that supplies and equipment are available, in working order, and sterile
- Maintains aseptic technique in all required activities
- Monitors practices of aseptic technique in self and others
- Checks mechanical and electrical equipment and environmental factors
- Conducts a preprocedure verification process
- Assesses patient's physical and emotional status
- Confirms and implements facility protocols and safety measures
- Plans and coordinates intraoperative nursing care
- Checks chart and relates pertinent data to team members
- Helps with applying monitoring devices and insertion of invasive lines and other devices
- Assists with and ensures patient safety in transferring and positioning patient
- Aids with anesthesia induction
- Monitors draping
- Takes part in surgical time-out
- Records intraoperative care
- Prepares, records, labels, and sends blood, pathology, and any anatomic specimens to proper locations
- Measures blood, urine output, and other fluid loss
- Confirms, dispenses, and records drugs used, including local anesthetics
- Coordinates all intraoperative activities with team members and other staff and departments
- Works with scrubbed personnel to keep correct count of sponges, needles, instruments, and medical devices
- Facilitates patient transfer to PACU
- Gives hand-off report to PACU nurse with information relevant to care of patient

Scrubbed, Sterile Activities

- Helps prepare the OR
- Completes surgical hand antisepsis and gowns and gloves self and other members of surgical team
- Prepares instrument table and arranges sterile equipment for functional use
- Assists with draping
- Takes part in surgical time-out procedure
- Passes instruments to surgeon and assistants by anticipating their needs
- Keeps correct count of sponges, needles, instruments, and medical devices that could be retained in the patient
- Monitors practices of aseptic technique in self and others
- Keeps track of irrigation solutions used for calculation of blood loss
- Accepts, verifies, and reports drugs used by surgeon and/or ACP, including local anesthetics

During surgery, the OR RN assumes functions that involve either sterile or unsterile activities (Table 18.1). The *scrub nurse* (sterile) follows the designated surgical hand antisepsis and glove and gown sterile attire and prepares and manages the sterile field and instrumentation. The *circulating nurse* stays in the unsterile field, facilitates the progress of the procedure, and keeps documentation.[4] Examples of nursing activities that occur during each phase of the surgical experience are outlined in Table 18.2.

After meeting specific criteria (e.g., 2 years of experience), perioperative RNs can obtain OR certification (CNOR). CNOR certification is an objective measure (written test) that validates a nurse has essential knowledge and skills in perioperative nursing.[5]

Licensed Practical/Vocational Nurse and Surgical Technologist

Depending on the state's nurse practice act, an LPN/VN or a surgical technologist may fill the role of the circulating or scrub nurse. Surgical technologists attend an associate degree program or a vocational, hospital, or military training program. The Association of Surgical Technologists sets the standards for education, provides continuing education opportunities, and offers certification for surgical technologists.[6]

If the circulating nurse is not an RN, the LPN/VN or surgical technologist must always have access to an RN. As an OR RN, you take on responsibility for supervising an LPN/VN or surgical technologist performing delegated nursing tasks.[7]

Surgeon and Assistant

The *surgeon* is the physician who does the surgical procedure. The surgeon is primarily responsible for:

- Preoperative medical history and physical assessment, directing preoperative testing, and postoperative management

Obtaining informed consent
- Leading the surgical team and directing the course of a procedure

The *surgeon's assistant* can be another physician, registered nurse first assistant (RNFA), physician's assistant, surgical resident or fellow, medical student, or a certified surgical first assistant. The assistant usually holds retractors to expose surgical areas and helps with hemostasis and suturing. In some agencies, especially in educational settings, the assistant may perform some portions of the surgery under the surgeon's direct supervision.

Registered Nurse First Assistant

The *registered nurse first assistant* (RNFA) works with the surgeon to achieve an optimal surgical outcome for the patient. The Association of periOperative Registered Nurses (AORN) states that you must have formal education for this role and work collaboratively with the surgeon, patient, and surgical team.[8] CNOR nurses or nurse practitioners can complete RNFA program to assume this expanded role. RNFAs can obtain certification (C-RNFA).

Anesthesia Care Provider

Anesthesiology is a medical specialty that focuses on clinical management of the patient in the perioperative period, pain management, critical care, trauma, airway management, and cardiopulmonary resuscitation. The **anesthesia care provider (ACP)** is the person responsible for administering anesthetic agents and managing vital life functions (e.g., breathing, BP) during the perioperative period.[9] This can be an anesthesiologist, nurse anesthetist, or anesthesiologist assistant (AA).

A **nurse anesthetist** is a master's or a doctorate prepared RN who has graduated from an accredited nurse anesthesia program and completed a national certification examination to become a certified

registered nurse anesthetist (CRNA).

The CRNA's scope of practice includes:[10]

- Performing and documenting a preanesthetic assessment and evaluation
- Developing and implementing a plan for delivering anesthesia
- Choosing, obtaining, and administering anesthesia, adjuvant drugs, and fluids
- Choosing, applying, and inserting appropriate monitoring devices
- Managing a patient's airway and pulmonary status
- Managing emergence and recovery from anesthesia
- Releasing or discharging patients from a PACU
- Ordering, starting, or modifying pain relief therapy
- Responding to emergency situations by providing airway management

TABLE 18.2 Common Perioperative Nursing Activities

Before Surgery	During Surgery	After Surgery
Home, Clinic, Holding Area • **Starts preoperative assessment** • **Plans teaching appropriate to patient's needs** • **Involves caregiver** **Surgical Unit** • **Completes preoperative assessment** • **Coordinates patient teaching with staff** • **Develops a plan of care that reflects patient's level of function and ability** • **Safely gives ordered drugs** **Surgical Suite** • **Conducts preprocedure verification** • **Assesses patient's level of consciousness, skin integrity, mobility, emotional status, and functional limitations** • **Reviews chart** • **Ensures all supplies and equipment needed are available, functioning, and sterile, if appropriate**	**Safety Maintenance** • Ensures integrity of sterile field • Ensures that sponge, needle, instrument, and medical device counts are correct • Positions patient to ensure correct alignment, exposure of surgical site, and prevention of injury • Prevents chemical injury from prepping solutions, drugs, etc. • Ensures safe use of electrical equipment • Safely gives ordered drugs **Monitoring Physical Status** • Monitors and reports changes in patient's vital signs • Monitors blood loss and urine output **Monitoring Psychologic Status** • Gives emotional support to patient • Ensures patient's right to privacy • Communicates patient' emotional status to health care team	**Postanesthesia, Discharge Area** • Determines patient's response to surgical intervention • Monitors ABCs, vital signs, level of consciousness • Safely gives ordered drugs **Clinical Unit** • Evaluates effectiveness of nursing care in OR using patient outcome criteria • Determines patient's level of satisfaction with care given • Assesses patient's psychologic status • Helps with discharge planning **Home, Clinic** • Seeks patient's perception of surgery in terms of effects of anesthetic agents, impact on body image, immobilization • Determines caregiver's perceptions of surgery

An AA is a master's-prepared health professional who serves under the direction of an anesthesiologist. AAs have completed an accredited program and passed a national certification examination. They take part in all types of anesthesia. This includes giving drugs, obtaining vascular access, applying and interpreting monitors, maintaining airways, and helping with preoperative assessment.

Nursing Management: Patient Before Surgery

The preoperative assessment of the surgical patient provides baseline data for intraoperative and postoperative care and is used to plan intraoperative care. Preoperative care of the patient is discussed in Chapter 17.

Provide physical and emotional comfort for the patient and caregivers along with teaching about the upcoming surgery. This is particularly important in the same-day surgery settings, where caregivers must assume greater responsibility for postoperative care.

Psychosocial Assessment

Knowing about the activities that occur when a patient moves into the OR allows you to provide teaching and comfort, especially to the anxious patient. You can usually answer general questions about surgery and anesthesia, such as, "When will I go to sleep?" "Who will be in the room?" "When will my surgeon arrive?" "How much of my body will be exposed?" "Will I be cold?" "When will I wake up?" Refer specific questions about the details of the surgery and anesthesia to the surgeon or ACP. For patients who do not speak English, use a qualified interpreter (see Table 2.10).

Separation from caregivers just before surgery can produce anxiety for the patient. Allowing the caregiver to wait with the patient in the holding area until we transfer the patient to the OR can reduce anxiety.

Physical Assessment

Perform a thorough physical assessment during the preoperative preparation of the patient (see Chapter 17).

Chart Review

Required chart data vary with agencies, patient conditions, and surgical procedures. Tables 17.2 and 17.4 provide examples of data we obtain during the preoperative assessment. This information gives an understanding of past and present medical history and an opportunity to anticipate and prepare for potential needs during surgery, such as obtaining equipment or drugs. You can discuss any abnormal findings or concerns for infection and other complications with the surgeon or ACP.

Check Your Practice

Your patient has arrived in the holding area. As you review the chart, you realize the patient has not signed the consent for blood. You see the patient has Alzheimer's disease and is not mentally competent to give consent.

- How would you proceed?

Admitting the Patient

Agency policy guides the protocol you follow when admitting the patient to the holding area and OR. A general routine includes initial greeting, proper identification, and offer of human contact and warmth.

The admitting process continues with reassessment of the patient and time for last-minute questions. Determine if any other tasks need to be done. Complete the chart review for the previously mentioned data and note any problems or changes. Ask the patient about

valuables, prostheses, and last intake of food and fluid. Confirm that any ordered preoperative drugs were given. Provide a pillow or adjust the patient's position if requested. Most agencies require the patient's hair to be covered just before transfer to the OR suite to reduce potential shedding.

You may offer complementary and alternative therapies, such as aromatherapy, music therapy, guided imagery, and distraction (see the Complementary & Alternative Therapies box). These therapies may decrease anxiety, promote relaxation, and reduce pain.[11] Some agencies start these therapies before the patient is admitted to the OR. In others, such as ambulatory settings, they may start after the patient arrives in the holding area.

Complementary & Alternative Therapies

Music Therapy

Music is an ancient healing tool recognized in the writings of Plato.

Scientific Evidence

Strong evidence supports using music therapy to reduce stress and anxiety and enhance mood.

Nursing Implications

- To be effective, the music used must be appropriate for the situation. Music can have many different physiologic effects.
- Listening to calming music can result in slower, deeper breathing and a decrease in heart rate and BP. Both indicate relaxation.
- Music with a faster pace can energize a person and promote mental alertness.
- Music therapy is safe in combination with other treatment approaches.

Source: Daniel E: Music used as anti-anxiety intervention for patients

during outpatient procedures: a review of the literature, *Complement Ther Clin Pract* 22:21, 2016.

Nursing Management: Patient During Surgery

Patient care in the surgical setting is dynamic and depends on the knowledge, skills, and judgment of the RN.[4] The circulating nurse is responsible for implementing the intraoperative plan of care and serving as the patient's advocate. The circulating nurse focuses on the whole patient. This involves ongoing assessment, reassessment, and adjusting the care plan to promote the best surgical outcomes.

Room Preparation

Before transferring the patient into the OR, prepare the room to ensure privacy, prevention of infection, and safety. Individualized preparation is essential to achieve the expected patient outcomes.

When a patient is severely obese, extra staff and special equipment may be needed to safely position and transfer the patient to and from the OR bed. During surgery, special equipment (e.g., extra-long instrumentation, bariatric OR bed) may be used.

Check Your Practice

You are assigned to observe in the OR. A severely obese patient is admitted to the holding area. The circulating nurse tells you that the team will address the unique needs of the patient for a safe surgical experience.

- What special considerations are needed for this patient?

All people entering the OR wear surgical attire (Fig. 18.3). All

electrical and mechanical equipment is checked for proper functioning. Each surgical item is opened and placed on the instrument table using aseptic technique. Sponges, needles, instruments, and small medical devices (e.g., surgical clip cartridges, universal adapters) are counted according to strict processes to ensure accurate retrieval at the end of the procedure. Any retained surgical supplies, devices, or instruments are sentinel events (never events) or serious reportable events (SREs) that can result in negative outcomes for the patient.[1,4] (Sentinel events and SREs are discussed in Chapter 1.)

FIG. 18.3 All surgical personnel wear surgical attire.
© iStock.com/Ridofranz.

During room preparation and the surgical procedure, the scrub person does surgical hand antisepsis, dons sterile gown and gloves, and touches only items in the sterile field. The circulating nurse stays in the unsterile field and does those activities that involve contact with

all unsterile items and the patient. This coordinated effort allows for smooth functioning throughout the procedure.

Transferring Patient

The patient is moved into the OR after the preoperative assessment is complete and the surgical suite is ready. Always maintain privacy during transfers through public areas by covering the patient with a gown and/or blanket. Each time a patient is transferred between beds, the wheels of each must be locked. Enough staff members using ergonomic tools for safe patient handling and movement should be available to lift, guide, and prevent accidental falling or injury to staff and the patient. Once the patient is on the OR bed, ensure that there is always someone on both sides of the patient until a safety strap is secured to prevent falls. The monitor leads (e.g., ECG leads), BP cuff, and pulse oximeter are usually applied after the patient is safe on the OR bed.

Scrubbing, Gowning, and Gloving

Surgical hand antisepsis is required of all sterile members of the surgical team (scrub nurse, surgeon, assistant). When wet scrubbing is the chosen method for surgical hand antisepsis, your finger nails are cleaned first, followed by scrubbing each plane of individual fingers, palms, and forearms in the distal to proximal fashion. The hands should always be held away from surgical attire and higher than the elbows. This prevents contamination from clothing or detergent suds and water from draining from the unclean area above the elbows to the clean and previously scrubbed areas of the hands and fingers.

Waterless, alcohol-based agents are replacing soap and water in many agencies. When using an alcohol-based surgical hand-scrub product, prewash hands and forearms with soap and dry completely before applying the alcohol-based product. After applying the alcohol-based product, rub hands and forearms thoroughly until dry before donning sterile attire.[1,4]

Once surgical hand antisepsis is completed, the team members

enter the OR to put on sterile gowns and 2 pairs of gloves. This protects patients and themselves from the transmission of microorganisms.[1,4] Because the gowns and gloves are sterile, those who have scrubbed can manipulate and organize all sterile items for use during the procedure.

Basic Aseptic Technique

Aseptic technique is practiced in the OR to prevent infection. This is done through the creation and maintenance of a sterile field. The center of the sterile field is the site of the surgical incision. Items used in the sterile field, including surgical instruments and equipment, have been sterilized by appropriate sterilization methods.

Team members must understand specific principles to practice aseptic technique (Table 18.3). If these principles are not followed, the patient's safety is compromised and the risk for infection is increased.[1,4]

The surgical team is also responsible for following the guidelines established by the U.S. Occupational Safety and Health Administration (OSHA) and the AORN to protect the patient and the team from exposure to blood-borne pathogens.[12] These guidelines emphasize (1) standard and transmission-based precautions, (2) engineering and work practice controls, and (3) the use of personal protective equipment, such as gloves, gowns, caps, face shields, masks, and protective eyewear. This is especially important in the OR because of the high potential for exposure to blood-borne pathogens.

Assisting Anesthesia Care Provider

While you check the OR to complete the final preparations, the ACP prepares the patient for receiving anesthesia. You need to understand the effects of the anesthetic agents and know the location of all emergency drugs and equipment.

TABLE 18.3 Principles of Aseptic Technique in Operating Room

- All materials that enter the sterile field must be sterile.
- If a sterile item comes in contact with an unsterile item, it is contaminated.
- Contaminated items are removed at once from the sterile field. If the unsterile item is small (e.g., unopened suture), once it is removed, the area is marked off (i.e., covered with a sterile drape). If the entire field is contaminated, it should be set up again with all new materials.
- The surgical team working in the operative field must wear sterile gowns and gloves. Once dressed for procedure, they must recognize that the only parts of the gown considered sterile are the front from chest to table level and sleeves to 2 inches above elbow.
- A wide margin of safety is maintained between sterile and unsterile fields.
- Tables are sterile only at tabletop level. Items extending beneath this level are contaminated.
- The edges of a sterile package are contaminated once the package has been opened. If a sterile package (e.g., package of sutures) is placed on the sterile field, that entire package stays sterile even when opened.
- Microorganisms travel on airborne particles and will enter the sterile field with excessive air movements and currents.
- Microorganisms travel by capillary action through moist fabrics, resulting in contamination.
- Microorganisms on the patient's and team members' hair, skin, and respiratory tracts must be confined by proper attire.

If you are the circulating nurse, you may be involved in placing monitoring devices used during the procedure (e.g., ECG leads). If the patient is having general anesthesia, stay at the patient's side to ensure safety and aid the ACP. These responsibilities may include measuring BP and helping maintain the patient's airway. During the procedure, you are a vital communication link for the ACP to other departments, such as the laboratory or blood bank.

Positioning Patient

The surgical team carefully plans the patient's positioning and monitors the patient throughout the procedure. Positioning is a critical part of every procedure and usually follows induction of anesthesia. The ACP says when to begin positioning. The patient's position should allow for accessibility to the operative site,

administering and monitoring of anesthetic agents, and maintaining the patient's airway. We use a variety of surgical positions, including supine, prone, lateral, lithotomy, or sitting. The supine is the most common position. It allows operating on most body systems, including the abdomen, heart, chest, or head. The prone position is often used in spine surgery (e.g., laminectomy). The lithotomy position is used for various gynecological, genitourinary, and colon procedures.

With any position, take great care to prevent injury to the patient. Take care to (1) provide correct musculoskeletal alignment; (2) prevent undue pressure on nerves, skin over bony prominences, earlobes, and eyes; (3) provide for adequate thoracic excursion; (4) prevent occlusion of arteries and veins; (5) provide modesty in exposure; and (6) recognize and respect individual needs, such as previously assessed pains or deformities. It is your responsibility to secure the extremities, provide adequate padding and support, and have physical or mechanical help to avoid unnecessary straining of the staff and patient.

Because anesthesia blocks the sensory nerve impulses, the patient will not feel pain, discomfort, or stress placed on nerves, muscles, bones, and skin. General anesthesia causes peripheral vessels to dilate. Position changes affect where the pooling of blood occurs. If the head of the OR bed is raised, the lower torso will have increased blood volume and the upper torso may become compromised. Hypovolemia and cardiovascular disease can further compromise the patient's status. Improper positioning can potentially result in muscle strain, joint damage, pressure injuries, nerve damage, and other untoward effects.

Electrosurgery and Smoke

Care must be taken to correctly place the grounding pad and all electrosurgical equipment to prevent injury from burns or fire. When an electrosurgical unit is in use, the patient must be properly grounded to prevent unintended injury (Fig. 18.4). Excess hair, adipose tissue, bony prominences, fluid (edema), adhesive failure, and

scar tissue can compromise safety. Fire in the OR can have devastating consequences for the patient. Fortunately, we can prevent surgical fires with awareness of the hazards and emphasis on safe practices.[13]

Preparing Surgical Site

The purpose of skin preparation, or "prepping," is to reduce the number of microorganisms available to migrate to the surgical wound. The circulating nurse, surgeon, or surgical assistant completes the task of prepping before surgery.

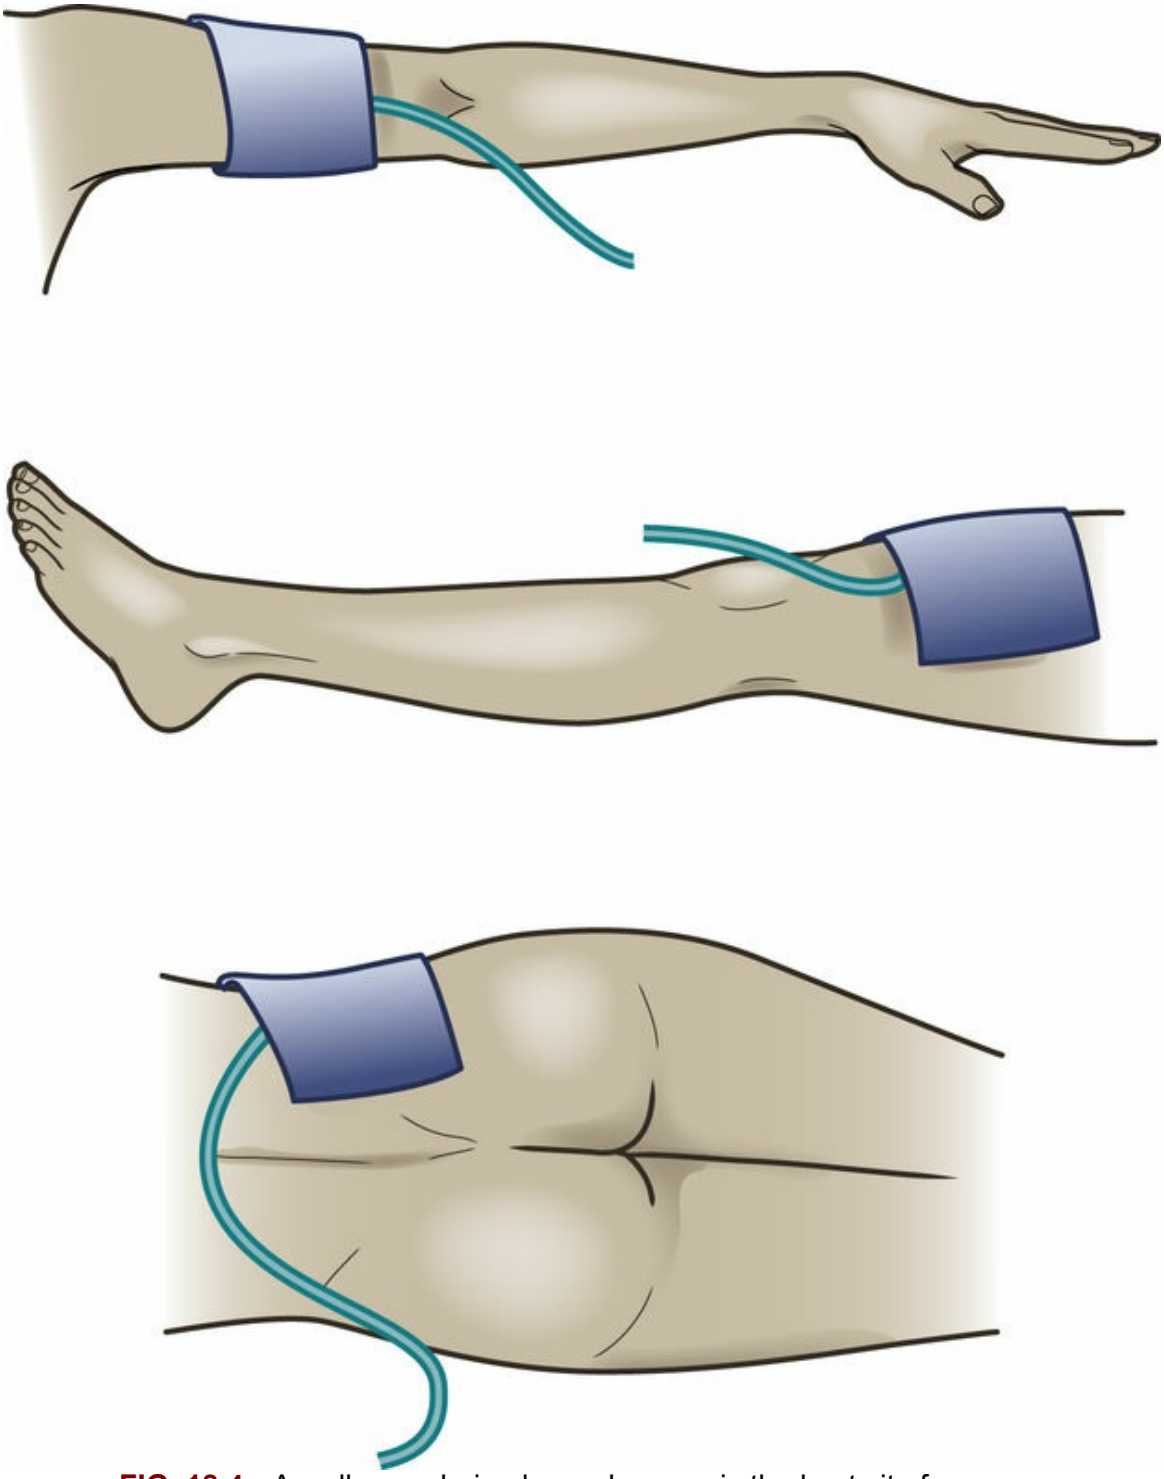

FIG. 18.4 A well-vascularized muscle mass is the best site for grounding.
Courtesy Covidien, Mansfield, MA.

The skin is prepared by mechanically scrubbing or cleansing the surgical site with an antimicrobial agent specific to the procedure.

Follow manufacturer's instructions for proper application of the prepping agent. The principle of scrubbing from the clean area (site of the incision) to the dirty area (distal to the incision) is always followed.

Antiseptic agents used for skin preparation may contain alcohol and therefore are flammable. Skin injury can occur if these agents pool under the patient. Care must be taken to ensure that these agents are properly confined and allowed to fully dry. After the skin is prepped and the fumes are allowed to dispel to reduce the risk for fire, the sterile members of the surgical team drape the area. Only the site to be incised is left exposed.

Safety Considerations

All surgical procedures put the patient at risk for injury. These injuries include infections, physical trauma from positioning or equipment used, or physiologic effects of surgery itself. Although technical skills, such as operating equipment or proper instrument handling, are a critical part of OR RN competency, there is strong research supporting that nontechnical skills (NTS) also have a high impact on outcomes. These include proper and clear communication, teamwork, situational awareness (e.g., anticipatory cognitive skills), and stress and fatigue management.[14] Considering the importance of NTS skills, especially in crisis events, some agencies use special training programs to develop these skills. There are standard approaches, such as a variety of communication tools, that promote safe patient care and minimize the potential negative effects of human factors.

Communication

Many team members care for patients as they move through the perioperative continuum. Chances for error arise whenever team members share information. The Joint Commission requires that all health care providers use a standardized approach to hand-off communication. As a RN, use SBAR (see Table 1.4) to ensure that a complete and accurate hand-off is done every time patient care is

transferred to another provider (e.g. change of shift, surgeon to nurse, OR RN to PACU RN).

Surgical Care Improvement Project

The *Surgical Care Improvement Project* (SCIP) is a national quality partnership of organizations focused on improving surgical care by significantly reducing the number of complications from surgery.[2] Specific SCIP measures include (1) a prophylactic antibiotic started within 30 to 60 minutes before the surgical incision to decrease risk for infection, (2) applying a warming blanket to prevent unintended hypothermia, and (3) applying intermittent pneumatic compression devices (IPCs) to minimize the risk for VTE.

Time Out and Surgical Checklist

The National Patient Safety Goals (NPSGs) require a preprocedure verification process. This includes verification of relevant documentation (e.g., history and physical examination, signed consent forms, nursing and preanesthetic assessment) and the results of any diagnostic studies (e.g., x-rays, biopsy reports). Any needed blood products, implants, devices, and special equipment must be available.

The *Universal Protocol,* one of the NPSGs, is followed to prevent wrong site, wrong procedure, and wrong surgery. Wrong surgical procedure and surgery on the wrong body part or wrong patient are *sentinel events (never events)* or *SREs* (described in Chapter 1). The AORN has a position statement about correct site surgery and guidelines for implementing the Universal Protocol.[15] The surgeon marks the procedure site. If possible, the marking is done with the patient's involvement.[3]

A patient safety checklist for ORs is the cornerstone of a major focus to make surgery safer. Using the World Health Organization (WHO) Surgical Safety Checklist has improved compliance with standards and decreased complications from surgery (Fig. 18.5). In addition, OR staff complete a fire risk assessment to identify and reduce the potential for a fire.

Safety Alert

Surgical Time-Out

- Before anesthesia induction, ask the patient to confirm name, birthdate, procedure and site, and consent.
- All members of the surgical team stop what they are doing just before the procedure starts to verify patient identification, procedure, and surgical site.

Nursing Management: Patient After Surgery

Through constant observation of the surgical process, the ACP anticipates the end of the procedure. The ACP gives proper types and doses of anesthetic agents so that their effects will be minimal at the end of the surgery. This allows greater physiologic control of the patient during the transfer to the PACU.

The ACP and you or another member of the surgical team go with the patient to the PACU. The hand-off, including the patient's status and the procedure done, is communicated to the nurse receiving the patient in the PACU to promote safe, ongoing care.

Anesthesia

The American Society of Anesthesiologists (ASA) defines anesthesia according to the effect that it has on the patient's sensorium and pain perception. These definitions include minimal sedation (e.g., anxiolysis), moderate sedation/analgesia, deep sedation/analgesia, and general anesthesia. The science of providing anesthesia continues to evolve. For example, noninvasive electroencephalogram-based technology allows ACPs to track the level of patient awareness (i.e.,

awareness monitoring) during surgery and adjust anesthesia as needed.

FIG. 18.5 WHO Surgical Safety Checklist.

The anesthetic technique and agents are chosen by the ACP in collaboration with the surgeon and patient. The ACP has ultimate responsibility for the choice of anesthesia. Contributing factors include the patient's current physical and mental status, age, allergies, pain history, expertise of the ACP, and factors related to the procedure (e.g., length, site, discharge plans). An absolute contraindication to any anesthetic technique or agent is patient refusal.

The ACP obtains anesthesia consent, writes orders for preoperative and postoperative drugs, and assigns the patient an anesthesia classification. The ASA physical status classification system is based on the patient's physiologic status. It uses a scale of P1 to P6 (see Table 17.3). An intraoperative complication is more likely to develop with a higher classification number.

Anesthesia Techniques

Types of anesthesia techniques include moderate to deep sedation, monitored anesthesia care (MAC), general anesthesia, and local and regional anesthesia (Table 18.4).

Moderate to Deep Sedation

Moderate to deep sedation is used for procedures done outside of the OR (e.g., reduction of dislocated joints in the emergency department). The presence of an ACP is not needed. Trained RNs who are allowed by agency protocols and state nurse practice acts can provide this type of anesthesia.[16] It is given by the nurse under the direct supervision of a physician.

Monitored Anesthesia Care

Monitored anesthesia care (MAC) is used for diagnostic or therapeutic procedures done in or outside of the OR (e.g., endoscopy clinic). It includes varying levels of sedation, analgesia, and anxiolysis. A critical part of MAC is the assessment and management of any physiologic problems that may develop. The provider of MAC must be an ACP since it may be necessary to change to general anesthesia during the procedure.

General Anesthesia

The goals of anesthesiology include the (1) control of excessive biologic responses induced by a variety of stressors and (2) protection of patients from stress-induced complications. To this end, *total intravenous anesthesia (TIVA)* and newer inhalation agents have a fast onset, fast elimination, and fewer undesirable side effects than earlier agents. These factors promote early discharge from the PACU and ambulatory surgery centers.

General anesthesia is the technique of choice for patients who are having surgical procedures that are of significant duration, need

skeletal muscle relaxation, require uncomfortable operative positions because of the location of the incision site, or require control of ventilation. Other reasons include patient refusal of local or regional techniques, contraindications to other techniques, and uncooperative patients. Patients may be uncooperative due to intoxication, emotional lability, head injury, impaired cognition, or inability to remain immobile for any length of time. Phases of general anesthesia are outlined in Table 18.5.

TABLE 18.4 Anesthesia Techniques and Effects

Technique	Patient Effects
General anesthesia	• Loss of sensation with loss of consciousness • Combination of hypnosis, analgesia, and amnesia • Usually involves use of inhalation agents • Skeletal muscle relaxation • Elimination of coughing, gagging, vomiting, and sympathetic nervous system responsiveness • Requires advanced airway management
Local anesthesia	• Loss of sensation without loss of consciousness • Induced topically or via infiltration, intracutaneously, or subcutaneously • Topical applications may be aerosolized or nebulized
Moderate sedation/analgesia (formerly called *conscious sedation*)	• Sedative, anxiolytic, and/or analgesic drugs used • Does not include use of inhalation agents • Patient responsive and breathes without assistance • Not expected to induce level of sedation that would impair patients' ability to protect their airway • Most often used for minor therapeutic procedures (e.g., fracture realignment in the emergency department)
Monitored anesthesia care (MAC)	• Sedative, anxiolytic, and/or analgesic drugs used • Does not usually involve inhalation agents • Patient less responsive and may need airway management • Gives greatest flexibility to match sedation level to patient needs and procedural requirements • Often used in conjunction with regional or local anesthesia • Often used for minor therapeutic and diagnostic procedures (e.g., eye surgery, colonoscopy)
Regional anesthesia	• Loss of sensation to a region of body without loss of consciousness • Involves blocking a specific nerve or group of nerves by administering a local anesthetic • Includes spinal, caudal, and epidural anesthesia and IV and peripheral nerve blocks (e.g., interscalene, axillary, infra-/supra-clavicular, popliteal, femoral, sciatic)

TABLE 18.5 Phases of General Anesthesia

Preinduction	Induction	Maintenance	Emergence
Description			
• **Period starting with initiation of IV or arterial access, application of monitors (e.g., ECG), administration of preoperative drugs**	• Initiation of drugs that make patient unconscious • Airway secured with airway assist devices	• Period during which procedure is done • Patient stays in an unconscious state with measures to ensure airway safety	• Period when procedure is completed • Patient is prepared for return to consciousness and removal of airway assist devices
Role of Anesthesia Care Provider			
• **Determine anesthetic care plan** • **Insert and monitor IV or arterial access** • **Confirm antibiotic prophylaxis** • **Give drugs for anxiety, aspiration prophylaxis**	• Give appropriate drugs • Secure airway • Position patient appropriately for procedure	• Monitor patient's physiologic status • Give drugs and titrate fluids as appropriate	• Reverse residual neuromuscular blocking agents • Assess for return of all protective reflexes • Remove airway assist devices • Assess pain
Role of Perioperative Nurse			
• **Complete preoperative assessment** • **Check and confirm signed informed consent** • **Complete surgical time-out**	• Help with application of monitors (noninvasive and invasive) • Assist with airway management	• Adjust patient position as needed • Monitor patient safety	• Help place dressing • Protect patient during return of reflexes • Prepare patient to move to PACU
Classes of Drugs Used (Tables 17.8, 18.6, and 18.7)			

• **Benzodiazepines**
• **Opioids**
• **Antibiotics**
• **Aspiration prophylaxis:**
  • **H_2 receptor blockers (e.g., ranitidine)**
  • **Gastric motility agents (e.g., metoclopramide)**
  • **Anticholinergics (e.g., scopolamine)**
	• Benzodiazepines
	• Opioids
	• Barbiturates
	• Hypnotics
	• Volatile gases
		• Benzodiazepines
		• Opioids
		• Barbiturates
		• Hypnotics
		• Volatile gases
		• Neuromuscular blocking agents
			• Reversal agents (PRN):
			  • Anticholinesterases (e.g., neostigmine)
			  • Opioid antagonists (e.g., naloxone)
			  • Benzodiazepine antagonists (e.g., flumazenil)
			  • Neuromuscular block reversal of rocuronium [Zemuron] and vecuronium [Norcuron] (e.g., sugammadex [Bridion])
			• Supplemental opioids (PRN)
			• Antiemetics (PRN)

General anesthesia may be induced by IV or inhalation and maintained by either or a combination of the two (Table 18.6). A *balanced technique,* using adjunctive drugs to complement the induction, is the most common approach used for general anesthesia.

IV. Agents

All routine general anesthetics begin with an IV induction agent, whether it is a hypnotic, an anxiolytic, or a dissociative agent. When used during the initial period of anesthesia, these agents induce sleep with a rapid onset of action. A single dose lasts only a few minutes. This is long enough for placement of a laryngeal mask airway (LMA) or an endotracheal (ET) tube. Once this is done, the ACP gives the inhalation and IV agent(s).

Recent advances in IV hypnotics (e.g., dexmedetomidine

[Precedex]) and opioids (e.g., remifentanil [Ultiva]) have led to the more frequent use of TIVA. However, the patient may still need advanced airway management (e.g., LMA, ET tube) to receive oxygen/air mixtures.

Inhalation Agents

Inhalation agents are the cornerstone of general anesthesia. They may be volatile liquids or gases. Volatile liquids are given through a specially designed vaporizer after being mixed with oxygen as a carrier gas. This gas mixture is then delivered to the patient through the anesthesia circuit. Waste gases are removed using negative evacuation pressure venting to the outside of the agency.

TABLE 18.6 Drug TherapyGeneral Anesthesia

Drugs	Advantages	Adverse Effects	Nursing Interventions
IV Agents			
Barbiturates			
methohexital (Brevital)	Rapid induction, duration of action <5 min.	Cardiac effects (e.g., myocardial depression), hypotension, respiratory depression, excitation, involuntary movement.	Usually have minimal effects after surgery because of short duration of action. Increased incidence of nausea in patients with barbiturate sensitivity, histamine-triggered nausea, vomiting.
Nonbarbiturate Hypnotics			
etomidate (Amidate)	Has little effect on cardiovascular function. Useful for hemodynamically unstable patients. Only minor respiratory depression. No histamine release.	Myoclonia, nausea and vomiting, hiccups, adrenocortical inhibition.	Observe for myoclonia, nausea and vomiting, hiccups, hypotension, hypoglycemia.
propofol (Diprivan)	Ideal for short outpatient procedures because of rapid onset of action, metabolic clearance. May be used for induction and maintenance of anesthesia.	Bradycardia and other dysrhythmias, hypotension, apnea, transient phlebitis, nausea and vomiting, hiccups. May cause hypertriglyceridemia.	Monitor for hypotension, bradycardia. Monitor serum triglycerides q24hr when sedated >24 hr.
Inhalation Agents			
Gaseous Agents			
nitrous oxide	Potentiates volatile agents, thus speeding induction and reducing total dosage and side effects. Weak anesthetic, rarely used alone. Good analgesic potency.	Little or no toxicity at therapeutic concentrations.	Avoid in patients with bone marrow depression. Must be given with O_2 to prevent hypoxemia. Avoid in patients with strong history of nausea and vomiting.
Volatile Liquids			
desflurane (Suprane) **isoflurane (Forane)** **sevoflurane (Ultane)**	All cause skeletal muscle relaxation. *desflurane:* Fastest onset and emergence, widely used in ambulatory settings. Least postoperative cognitive dysfunction. Potential airway irritant. *isoflurane:* No increase in ventricular irritability. Does not cause liver or renal toxicity. Resistant to metabolic breakdown. *sevoflurane:* Predictable effects on cardiovascular and respiratory systems, rapid acting. Preferred for inhalation induction as nonirritating to respiratory tract.	All cause respiratory depression, hypotension, myocardial depression. *desflurane and isoflurane:* May be unsuitable for patients with coronary artery disease. *sevoflurane:* May be associated with emergence delirium (see Chapter 19) and atypical seizure-like activity.	Assess and treat pain during early anesthesia recovery. Assess for adverse reactions such as cardiopulmonary depression with hypotension and prolonged respiratory depression. Monitor for nausea and vomiting.
Dissociative Anesthetic			
ketamine (Ketalar)	Given IV or IM. Potent analgesic and amnesic.	May cause hallucinations and nightmares, ↑ intracranial and intraocular pressure, ↑ heart rate, ↑ BP.	Anticipate use of a benzodiazepine if agitation and hallucinations occur. Calm, quiet environment is essential in postoperative care.

Inhalation agents enter the body through the alveoli in the lungs. Ease of administration and rapid excretion by ventilation make them desirable agents. One undesirable trait is the irritating effect some inhalation agents (e.g., desflurane [Suprane]) have on the respiratory tract. Complications include coughing, laryngospasm, and increased secretions.

Once the patient has been induced with an IV agent, the choice for delivering inhalation agents is usually through an ET tube or LMA. The ET tube allows control of ventilation and protects the airway from

aspiration. LMAs are currently an important option for patients with difficult airways, but they do not provide access to the trachea or airway protection with the same certainty as ETs. Complications of ET tube or LMA use are primarily related to insertion and removal. These include failure to intubate, damage to teeth and lips, laryngospasm, laryngeal edema, sore throat, and hoarseness caused by injury or irritation of the vocal cords or surrounding tissues.

Adjuncts to General Anesthesia

General anesthesia is rarely limited to a single agent. Drugs added to an inhalation anesthetic (other than an IV induction drug) are termed *adjuncts*. Adjuncts are added to the anesthetic regimen to achieve unconsciousness, analgesia, amnesia, muscle relaxation, or autonomic nervous system control. They include opioids, benzodiazepines, neuromuscular blocking agents (muscle relaxants), and antiemetics (Table 18.7). It is important to know that we often give these drugs in combination and they may have synergistic or antagonistic effects. You may see deeper levels of sedation or more drug-related side effects beyond those seen with inhalation anesthetics alone. If needed, drugs are available to reverse the effects of some of these adjuncts.

TABLE 18.7 Drug TherapyAdjuncts to General Anesthesia

Agents	Intended Effect	Adverse Effects	Nursing Interventions
Antiemetics (See Table 41.1)			
aprepitant (Emend) **granisetron** **metoclopramide (Reglan)** **ondansetron (Zofran)** **palonosetron** **prochlorperazine** **promethazine** **rolapitant (Varubi)**	Counteract emetic effects of inhalation agents and opioids. Prophylactic prevention of nausea and vomiting related to histamine release, vagal stimulation, vestibular disturbance, procedure (e.g., abdominal laparoscopy).	Headache, dizziness, IV irritation, dysrhythmias, dysphoria, dystonia, dry mouth, central nervous system sedation.	• Monitor heart rhythm, cardiopulmonary status, level of central nervous system excitation or sedation, ability to move limbs, presence of nausea or vomiting.
Benzodiazepines			
diazepam (Valium) **lorazepam (Ativan)** **midazolam (Versed)**	Reduce anxiety, induce and maintain anesthesia, induce amnesia, treat emergence delirium. Supplement sedation in local and regional anesthesia and MAC.	Synergistic effect with opioids, increasing potential for respiratory depression. Hypotension and tachycardia. Prolonged sedation or confusion.	• Monitor level of consciousness. Assess for respiratory depression, hypotension, and tachycardia. • Reverse severe benzodiazepine-induced respiratory depression with flumazenil (Romazicon).
Neuromuscular Blocking Agents			
Depolarizing agent: **succinylcholine (Anectine)**	Promote endotracheal intubation, promote skeletal muscle relaxation (paralysis) to enhance access to surgical sites.	Apnea related to paralysis of respiratory muscles. Duration of action of nondepolarizing agents may be longer than surgery. Reversal agents may not completely eliminate effects. Confusion and nausea. Recurrence of muscle weakness with correction of hypothermia.	• If intubated, monitor return of muscle strength, level of consciousness, and ventilation. • Maintain patent airway. Monitor respiratory rate and rhythm until patient able to cough and return to previous levels of muscle strength. Ensure availability of nondepolarizing reversal agents (e.g., neostigmine) and emergency respiratory support equipment. • Monitor temperature and levels of muscle strength with temperature changes.
Nondepolarizing agents: • **atracurium** • **cisatracurium (Nimbex)** • **pancuronium** • **rocuronium**	Effects of nondepolarizing agents are usually reversed toward end of surgery by giving anticholinesterase agents (e.g., neostigmine).		
Opioids			
alfentanil (Alfenta) **fentanyl (Sublimaze)** **hydromorphone (Dilaudid)** **morphine sulfate** **remifentanil (Ultiva)** **sufentanil (Sufenta)**	Induce and maintain anesthesia, reduce stimuli from sensory nerve endings, provide analgesia during surgery and recovery in PACU.	Respiratory depression, vomiting, bradycardia, peripheral vasodilation (when combined with anesthetics). High risk for pruritus with both regional and IV administration.	• Assess respiratory rate and rhythm, monitor pulse oximetry, protect airway in anticipation of vomiting. • Use standing orders for antipruritics and antiemetics. • Reverse opioid-induced respiratory depression with naloxone. If used, reversal of analgesic effects also occurs.
Other Agents			
dexmedetomidine (Precedex)	Induces and maintains sedation in nonintubated patients prior to and/or during surgery.	Hypotension, bradycardia, sinus arrest, transient hypertension during administration of loading dose.	• Monitor heart rate and rhythm, and BP for side effects.

Dissociative Anesthesia

Dissociative anesthesia interrupts associative brain pathways while blocking sensory pathways. The patient may appear catatonic, is amnesic, and has profound analgesia that lasts into the postoperative period. Ketamine (Ketalar) (given IV or IM) is a common dissociative anesthetic. It is a potent analgesic and amnesic. Ketamine is given to asthmatic patients because it promotes bronchodilation. In trauma

patients, it increases heart rate and helps maintain cardiac output. Because ketamine is a phenyl cyclohexyl piperidine (PCP) derivative, the drug may cause hallucinations and nightmares, limiting its usefulness. Concurrent use of midazolam (Versed) can reduce or eliminate the hallucinations. Providing a quiet, unhurried environment in the PACU is especially important for all patients receiving dissociative anesthesia.

Local and Regional Anesthesia

Local anesthesia interrupts the generation of nerve impulses by changing the flow of sodium into nerve cells. The result is autonomic nervous system blockade, anesthesia, and skeletal muscle flaccidity or paralysis. Local anesthetics are topical, ophthalmic, nebulized, or injected. A local anesthetic is applied to a specific area of the body by the surgeon or ACP. It does not involve sedation or loss of consciousness.

Regional anesthesia (or block) using a local anesthetic is always injected. It involves a central nerve (e.g., spinal) or group of nerves (e.g., plexus) that innervate a site remote to the point of injection. Administration of a local or regional anesthetic may involve concurrent use of MAC or moderate to deep sedation (Table 18.4), either preinjection or intraoperatively. Regional blocks are used as preoperative analgesia, during surgery to manage surgical pain, and after surgery to control pain. Indwelling catheters that deliver local anesthetic to the surgical site through a pump implanted during surgery can give continuous pain relief up to 72 hours after surgery.

Advantages of local and regional anesthesia include rapid recovery and discharge with continued postoperative analgesia without any accompanying cognitive dysfunction. They can be safely used in patients who have co-morbidities that prevent the use of general anesthesia.

Disadvantages include the potential for technical problems, discomfort at the injection site, and the inability to precisely match the agent's duration of action to the duration of the procedure. Another disadvantage is the risk for inadvertent vascular injection leading to

local anesthetic systemic toxicity (LAST). LAST first presents as confusion, metallic taste, oral numbness, and dizziness.[17] Without treatment, seizures, coma, and dysrhythmias may occur.

The topical applications of creams, ointments, aerosols, and liquids are standard methods to administer local anesthesia. The drug is applied directly to the skin, mucous membranes, or open surface. Eutectic mixture of local anesthetics (EMLA cream, a combination of prilocaine and lidocaine) is an example. It is applied to the site 30 to 60 minutes before a procedure. The success of injected local anesthetics may be limited by prolonged duration of procedure or infection at the injection site that interferes with drug absorption.

In ambulatory or outpatient procedures, you may aid the ACP in administering a peripheral or regional block. You must be familiar with the drugs, including the methods of administration and adverse and toxic effects. Initial assessment of the patient should include the patient's history with the use of local anesthetics and any adverse events associated with their use by the patient or blood relatives.

Many patients report "allergies" to local anesthetics. Although true allergies to local anesthetics occur, they are rare. Allergies are likely to be a result of additives or preservatives in the preparation. Some local anesthetics are combined with epinephrine to provide localized vasoconstriction. This decreases absorption and extends the action of the agent. However, if the local anesthetic is absorbed in the tissues or inadvertently injected IV and enters the general circulation, the patient may have tachycardia, hypertension, and a general feeling of panic.

Examples of common regional nerve blocks include brachial plexus block; IV regional anesthesia (IVRA) or Bier block anesthesia; and femoral, axillary, cervical, sciatic, ankle, and retrobulbar blocks. For IVRA or Bier block, the patient has a double-cuff tourniquet applied as a safety measure.

You can promote the success of regional anesthesia by properly positioning the patient, monitoring vital signs during block delivery, applying oxygen therapy, and using supporting devices (at the direction of the ACP) that contribute to the anesthesia (e.g.,

ultrasound imaging, nerve stimulator, tourniquets). When a patient is receiving regional anesthesia, airway equipment, emergency drugs, and a cardiac monitor/defibrillator should be available to provide advanced airway and cardiopulmonary support if needed.

Spinal and Epidural Anesthesia

Spinal anesthesia and epidural anesthesia are also types of regional anesthesia. **Spinal anesthesia** involves the injection of a local anesthetic into the cerebrospinal fluid in the subarachnoid space, usually below the level of L2 (Fig. 18.6, *A*). The local anesthetic mixes with cerebrospinal fluid. Depending on the extent of its spread, various levels of anesthesia are achieved. Because the local anesthetic is given directly into the cerebrospinal fluid, a spinal anesthetic produces an autonomic, sensory, and motor blockade. Patients develop vasodilation and may become hypotensive from the autonomic block. They feel no pain because of the sensory block. They cannot move because of the motor block. The duration of action of the spinal anesthetic depends on the drug used and the dose given. A spinal anesthetic may be used for procedures involving the extremities (e.g., joint replacements) and lower gastrointestinal, prostate, and gynecologic surgeries.

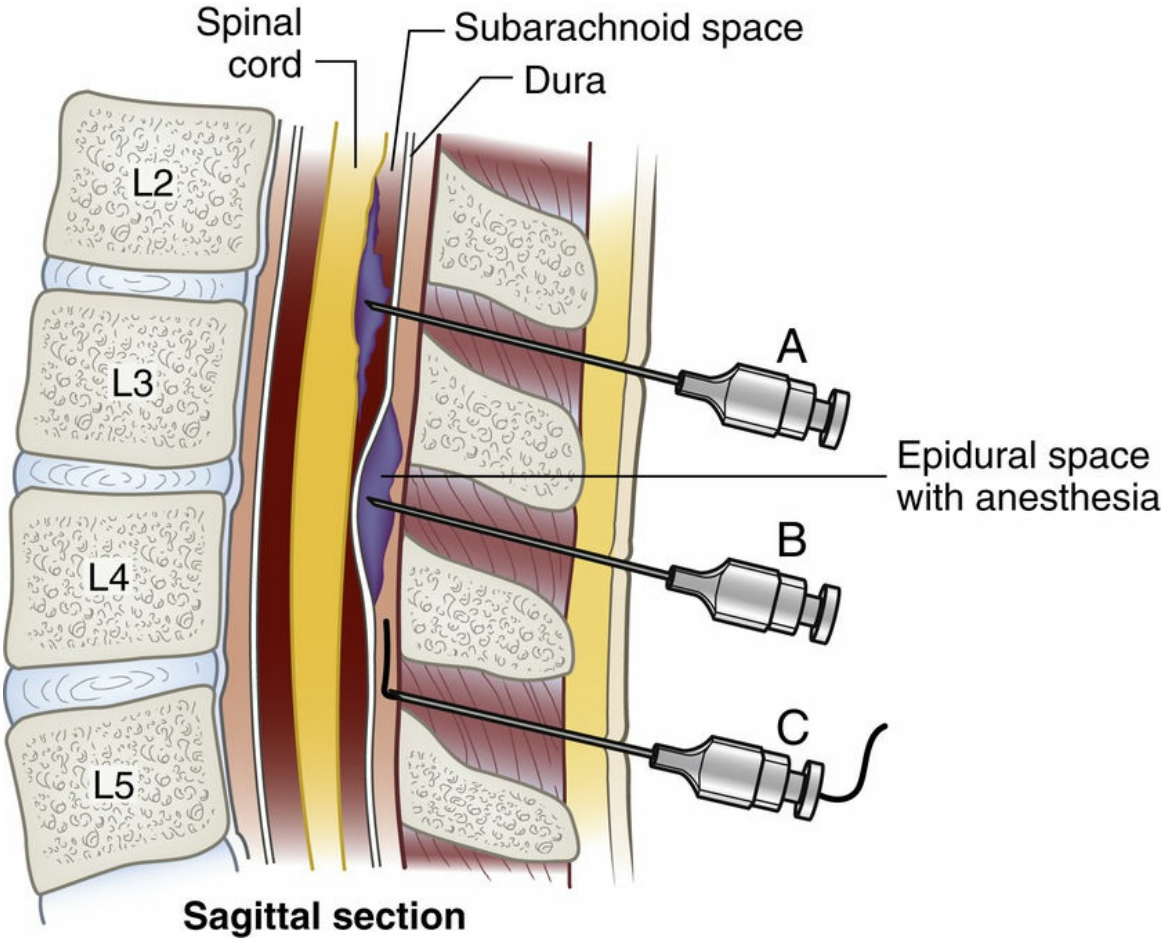

FIG. 18.6 Location of needle point and injected anesthetic relative to dura and spinal cord. A, Spinal anesthesia. B, Single-injection epidural. C, Epidural catheter. (Interspaces most often used are L2-3, L4-5, L3-4.)

An **epidural block** involves injection of a local anesthetic into the epidural space via a thoracic or lumbar approach (Fig. 18.6, *B*). The anesthetic agent does not enter the cerebrospinal fluid but binds to nerve roots as they enter and exit the spinal cord. With the use of a low concentration of local anesthetic, sensory pathways are blocked but motor fibers are still intact. In higher doses, sensory and motor fibers are blocked. Epidural anesthesia may be the sole anesthetic for a surgical procedure. In addition, a catheter may be placed to allow for intraoperative use and continued analgesia in the postoperative period (Fig. 18.6, *C*). For postoperative analgesia, lower doses of epidural local anesthetic, usually in combination with an opioid, are used. Epidural anesthesia is often used for analgesia or in combination

with MAC or general anesthesia, in obstetrics, vascular procedures involving the lower extremities, lung resections, and renal and midabdominal surgeries. The desirable effects of vasodilation and analgesia contribute to better surgical outcomes.

With spinal or epidural anesthesia, the patient can stay fully conscious, receive MAC, or choose general anesthesia. The onset of spinal anesthesia is more rapid than that of epidural anesthesia. Both may be extended in duration using indwelling catheters, thus allowing for more doses of anesthetic.

With either anesthesia, closely observe the patient for manifestations of autonomic nervous system blockade. These include hypotension, bradycardia, nausea, and vomiting. There is less autonomic nervous system blockade with epidural anesthesia than with spinal anesthesia. Should "too high" a block be present, the patient may have tingling in the arms and hands or inadequate breathing and apnea. Other complications include postdural puncture headache, back pain, isolated nerve injury, and meningitis.

Gerontologic Considerations: Patient During Surgery

Although anesthetic agents have become safer and more predictable, the aging process affects the absorption, distribution, and metabolism of drugs. This results in changes in their onset, peak, and duration independent of the route of administration. Because of this, anesthetic drugs need to be carefully titrated when given to older adults. Physiologic changes in aging may also change the patient's response to blood and fluid loss and replacement, hypothermia, pain, and tolerance of the procedure and positioning. Carefully monitor the older adult's response to all anesthetic agents. Postoperative delirium is a common complication in this population and associated with adverse surgical outcomes.[18] Assess the postoperative recovery from anesthesia before the patient is transferred out of the PACU.

Some older adults may have a hard time communicating and following directions because of problems with hearing or vision.

These factors increase the need for clear and concise communication in the OR, especially when preoperative sedation is combined with already existing sensory deficits. Because of decreased ability to perceive discomfort or pressure on vulnerable areas and a loss of skin elasticity, the older adult's skin is at risk for injury from tape, electrodes, warming and cooling blankets, and certain types of dressings. Pooling of solutions used to prepare the skin in dependent areas can quickly create skin burns or abrasions.

Care and vigilance are needed in preparing and positioning the older patient. The older adult often has osteoporosis and/or osteoarthritis. Misalignment, pressure, or other insults to arthritic joints desensitized from an anesthetic may create long-term injury and disability. Older adults are at a greater risk for perioperative hypothermia. Consider using warming devices and carefully monitor them when used.

Perioperative Crisis Events

Although the incidence of crisis events has significantly decreased with scientific advancements, there is an inherent risk with surgery for an adverse outcome, which may be of critical nature. Some events may be expected (e.g., cardiac arrest in an unstable patient, massive blood loss during trauma surgery). Others may occur without warning (e.g., air embolism, hypoxia), demanding immediate intervention by all members of the OR team. More rare events include anaphylactic reactions and malignant hyperthermia.

Anaphylactic Reactions

Anaphylaxis is the most severe form of an allergic reaction, manifesting with life-threatening pulmonary and circulatory complications. ACPs give patients a variety of drugs, including anesthetics, antibiotics, and blood products. Anesthetic agents, antibiotics, and latex cause many allergic reactions. Vigilance and rapid intervention are essential. Anesthesia may mask the initial manifestations of anaphylaxis. An

anaphylactic reaction causes hypotension, tachycardia, bronchospasm, and pulmonary edema. Anaphylaxis is discussed in Chapter 13.

Latex allergy has become a concern in the surgical setting. Gloves, catheters, and many devices contain natural rubber latex. Latex allergy protocols should be set up in each agency to provide a latex-safe environment for susceptible patients.[19] Latex allergies are discussed in Chapter 13.

Malignant Hyperthermia

Malignant hyperthermia (MH) is a rare disorder characterized by hyperthermia with skeletal muscle rigidity. It can result in death. MH occurs in susceptible people when they are exposed to certain anesthetic agents. Succinylcholine (Anectine), especially when given with volatile inhalation agents, is the primary trigger of MH. Other factors include stress, trauma, and heat. When MH does occur, it is usually during general anesthesia. It may occur in the recovery period, too.[20]

MH is an autosomal dominant trait. It is variable in its genetic manifestation, so predictions based on family history are important but not reliable. The fundamental defect is hypermetabolism of skeletal muscle resulting from altered control of intracellular calcium. This leads to muscle contracture, hyperthermia, hypoxemia, lactic acidosis, and hemodynamic and cardiac problems. Tachycardia, tachypnea, hypercarbia, and ventricular dysrhythmias may occur but are nonspecific to MH.

MH is diagnosed after ruling out other causes of the hypermetabolism. The rise in body temperature is not an early sign of MH. Unless promptly detected and treated, MH can result in cardiac arrest and death. The definitive treatment of MH is prompt administration of dantrolene (Dantrium, Ryanodex).[20] Dantrolene slows metabolism, reduces muscle contraction, and mediates the catabolic processes associated with MH.

To prevent MH, take a careful family history and be alert to the development of MH perioperatively. The patient known or suspected

to be at risk for this disorder can receive anesthesia with minimal risks if proper precautions are taken. Patients with MH need to be aware of the condition so that family members may be genetically tested.

Case Study

Intraoperative Patient

© shironosov/iStock/Thinkstock.

Patient Profile

G.S., a 63-yr-old retired accountant, was admitted to the hospital for severe pain from acute cholecystitis. G.S.'s medical history includes hypertension and type 2 diabetes. His pain has been managed with hydromorphone (Dilaudid) using patient-controlled analgesia. Intractable nausea and vomiting required the placement of a NG

tube. He is scheduled for a laparoscopic cholecystectomy. The surgery will be done under general anesthesia.

Subjective Data

- G.S. is awake and able to identify himself, his birth date, procedure, and surgical site
- Rates pain as a 4 on a 0- to 10 scale on arrival to the holding area

Objective Data

- Admitted to the holding area with an NG tube in place and one peripheral IV catheter
- Capillary blood glucose 1 hour ago was 125 mg/dL
- Oxygen saturation 96% on room air

Interprofessional Care

- Vital signs per holding area routine
- 0.9 normal saline solution at 100 mL/hr
- Titrate O_2 therapy to keep O_2 saturation >90%
- NG tube connected to low, intermittent suction

Discussion Questions

1. What are the potential intraoperative problems that you may expect with G.S.?
2. ***Priority Decision:*** What priority nursing interventions would be appropriate to prevent these complications from occurring?
3. ***Collaboration:*** What are the interprofessional team's priorities for G.S.?
4. ***Evidence-Based Practice:*** G.S. tells you that he is cold despite a

blanket in place. Why is it important that G.S. stays warm?

5. ***Safety:*** Identify 2 areas of risk for injury to G.S. What actions can be taken to ensure patient safety?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Proper attire for the semirestricted area of the surgery department is
   a. street clothing.
   b. surgical attire and head cover.
   c. scrub attire, head cover, shoe covers.
   d. street clothing with the addition of shoe covers.
2. Activities that the nurse might perform in the role of a scrub nurse during surgery include (*select all that apply*)
   a. checking electrical equipment.
   b. preparing the instrument table.
   c. assisting with draping the patient.
   d. passing instruments to the surgeon and assistants.
   e. documenting activities occurring in the operating room.
3. The nurse is caring for a patient undergoing surgery for a knee replacement. What is critical to the patient's safety during the procedure (*select all that apply*)?
   a. Universal protocol is followed.
   b. The ACP is an anesthesiologist.

c. The patient has adequate health insurance.

d. The patient's family is in the surgery waiting area.

e. The patient's allergies are conveyed to the surgical team.

4. The nurse's *primary* responsibility for the care of the patient undergoing surgery is

a. developing an individualized plan of nursing care for the patient.

b. carrying out specific tasks related to surgical policies and procedures.

c. ensuring that the patient has been assessed for safe administration of anesthesia.

d. performing a preoperative history and physical assessment to identify patient needs.

5. When scrubbing at the scrub sink, the nurse should

a. scrub from elbows to hands.

b. scrub without mechanical friction.

c. scrub for a minimum of 10 minutes.

d. hold the hands higher than the elbows.

6. When positioning a patient in preparation for surgery, the nurse understands that injury to the patient can occur because of *(select all that apply)*

a. loss of pain perception.

b. incorrect musculoskeletal alignment.

c. vasoconstriction of the peripheral vessels.

d. hypovolemia contributing to decreased perfusion.

e. inability to sense pressure over bony prominences.

7. IV induction for general anesthesia is the method of choice

for *most* patients because

a. the patient is not intubated.

b. the agents are nonexplosive.

c. induction is rapid and controlled.

d. emergence is longer but with fewer complications.

1. c, 2. b, c, d, 3. a, e, 4. a, 5. d, 6. a, b, d, e, 7. c

LEARNING OUTCOMES

1. Prioritize nursing responsibilities related to managing patients in the postanesthesia care unit (PACU).
2. Prioritize nursing responsibilities to maintain patient safety and prevent postoperative complications in the PACU and clinical unit.
3. Apply data from the initial nursing assessment to the management of the patient after transfer from the PACU to the clinical unit.
4. Select nursing interventions to manage potential problems during the postoperative period.
5. Distinguish discharge criteria from Phase I and Phase II postanesthesia care.

Conceptual Focus

Gas Exchange
Fluids and Electrolytes
Infection
Pain
Perfusion
Safety
Tissue Integrity

The postoperative period begins immediately after surgery and continues until the patient is discharged from medical care. This chapter focuses on the multiple concepts central to postoperative nursing. Nursing plays a vital role in supporting ventilation and perfusion, maintaining fluid and electrolyte balance, promoting comfort, reducing infection, and promoting safety. Specific surgical procedures and related postoperative care are discussed in the appropriate chapters of this text.

Postoperative Care of Surgical Patient

The patient's immediate recovery period is managed in a *postanesthesia care unit* (*PACU*). It is usually next to the operating room (OR). This location limits transportation of the patient right after

surgery and gives ready access to anesthesia and OR staff. The goals of PACU care are to maintain patient safety during recovery from anesthesia and identify actual and potential patient problems that may occur because of anesthesia and surgery and intervene appropriately.

Postanesthesia Care Unit Admission

The patient's admission to the PACU is a joint effort among the anesthesia care provider (ACP), OR nurse, and PACU nurse. This collaboration fosters a smooth transfer of care to the PACU and helps determine which phase we assign the patient.

PACU Progression

There are 3 phases of postanesthesia care. During each phase, we provide different levels of care depending on the patient's needs[1] (Table 19.1). How patients move through the phases of care is determined by their condition and the type of anesthesia they received. If a patient assigned to Phase I care on admission to the PACU is stable and recovering well, the patient may rapidly progress through Phase I to either Phase II care or an inpatient unit. This accelerated progress is called rapid postanesthesia care unit progression (RPP). Another accelerated system of care is fast-tracking, which involves admitting ambulatory surgery patients directly to Phase II care. Although RPP and fast-tracking can result in time and cost savings, the patient's safety is the primary factor determining where and at what level we provide postoperative care.

TABLE 19.1 Phases of Postanesthesia Care

Phase I
• Care during the immediate postanesthesia period

- ECG and more intense monitoring (e.g., arterial BP monitoring, mechanical ventilation)

Goal: Prepare patient for transfer to Phase II level of care, an inpatient unit, or intensive care setting

Phase II

- Ambulatory surgery patients
- Fast-tracking (i.e., patients who have bypassed Phase I level of care)

Goal: Prepare patient for transfer to extended observation, home, or extended care facility

Extended Observation

- Extended care or observation after transfer/discharge from Phase I or Phase II levels of care

Goal: Prepare patient for self-care

Blended Levels of Care

- Various levels of care offered in the same environment

Source: American Society of PeriAnesthesia Nurses: *2015-2017 Perianesthesia nursing standards, practice recommendations and interpretive statements*, Cherry Hill, NJ, 2015, The Society.

Phase I Initial Assessment

On admission of the patient to the PACU, the ACP gives you a postanesthesia hand-off report (Table 19.2). Hand-off reports should be standardized and interactive, allowing you to ask questions and clarify information.[2] The ACP should stay in the PACU until you

accept responsibility for the care of the patient. Potential problems in the postoperative period are shown in Fig. 19.1. Table 19.3 describes key parts of a PACU assessment.

Begin your initial assessment by evaluating the patient's airway, breathing, and circulation (ABC) status. Residual neuromuscular blockade, opioid use, and patient characteristics such as sleep-disordered breathing (e.g., obstructive sleep apnea [OSA], abnormal airway anatomy) affect oxygenation and ventilation. Be alert for signs of inadequate oxygenation and ventilation (Table 19.4). Any sign of respiratory distress needs prompt intervention.

Pulse oximetry monitoring is a noninvasive means of assessing oxygenation and can provide an early warning of hypoxemia. *Transcutaneous carbon dioxide ($PtcCO_2$)* and *end-tidal CO_2 ($PetCO_2$) (capnography) monitoring* are used to detect respiratory depression in high-risk patients.[3] Volumetric capnography and acoustic respiratory rate monitoring can help you detect respiratory distress early.[4] Pulse oximetry, capnography, $PtcCO_2$, and $PetCO_2$ are discussed in Chapter 25.

Note and assess changes in ECG findings from the preoperative baseline. Measure the BP and compare it with baseline readings. Invasive monitoring (e.g., arterial BP) may be needed. Assess body temperature, peripheral pulses, capillary refill, and skin condition (e.g., color, moisture). Any signs of inadequate tissue perfusion need prompt intervention.

Focus the initial neurologic assessment on level of consciousness; orientation; sensory and motor status; and size, equality, and reactivity of the pupils. The patient may be awake, drowsy but arousable, or asleep. Because hearing is the first sense to return in the unconscious patient, explain all activities to the patient from the time of admission to the PACU. If the patient received a regional anesthetic (e.g., spinal, epidural), sensory and motor blockade may still be present and you should assess dermatome levels (Fig. 19.2). During recovery from regional anesthesia, sensory and motor function first returns distal to the site where the anesthetic was given. This means the areas near the site of injections are the last to recover.

TABLE 19.2 PACU Hand-Off Report

General Information

- Patient name and age
- Surgeon and anesthesia care provider
- Surgical procedure
- Presence of tubes, drains, catheters, and IV lines
- Type of anesthesia (e.g., general, regional, monitored anesthesia care)
- Use of any reversal agents
- Airway status (artificial airway and/or interventions to maintain adequate oxygenation)
- Pain management interventions
- NPO status and postoperative orders that need started

Patient History

- Indication for surgery
- Medical history, medications, allergies
- Preoperative or baseline vital signs, laboratory and diagnostic findings
- Level of consciousness, orientation
- Specific patient characteristics (e.g., hearing loss, vision impairment, mobility limitations)
- Patient preferences (e.g., cultural, personal beliefs/restrictions)
- Patient emotional status on arrival to OR

Intraoperative Management

- Anesthetic agents
- Other drugs received preoperatively or intraoperatively
- Last dose of opioid administration/pain management plan
- Total fluid replacements, including blood transfusions
- Total fluid losses (e.g., blood, nasogastric drainage)
- Urine output

Intraoperative Course

- Unexpected anesthetic events or reactions
- Unexpected surgical events
- Most recent vital signs and monitoring trends
- Results of laboratory tests and x-rays

Safety Alert

Regional Anesthesia

- Monitor for complications of regional anesthesia.
- Be alert for respiratory distress, hypotension, dysrhythmias, changes in heart rate, bleeding or hematoma at site, headache, neurologic deficit or prolonged block, urinary retention, nausea, and pruritis.
- Implement treatment protocols and notify the health care provider (HCP) as needed.

Assess the urinary system by measuring intake and output and determining fluid balance. Intraoperative fluid totals are part of the ACP report. Note the presence of all IV lines; all irrigation solutions and infusions; and all output devices, including catheters and wound drains. Assess the surgical site. Note the condition of any dressings

and the type and amount of any drainage. Implement orders related to incision care.

The rest of this chapter discusses the nursing management of select problems. You can apply this information to patients in both the PACU and clinical unit.

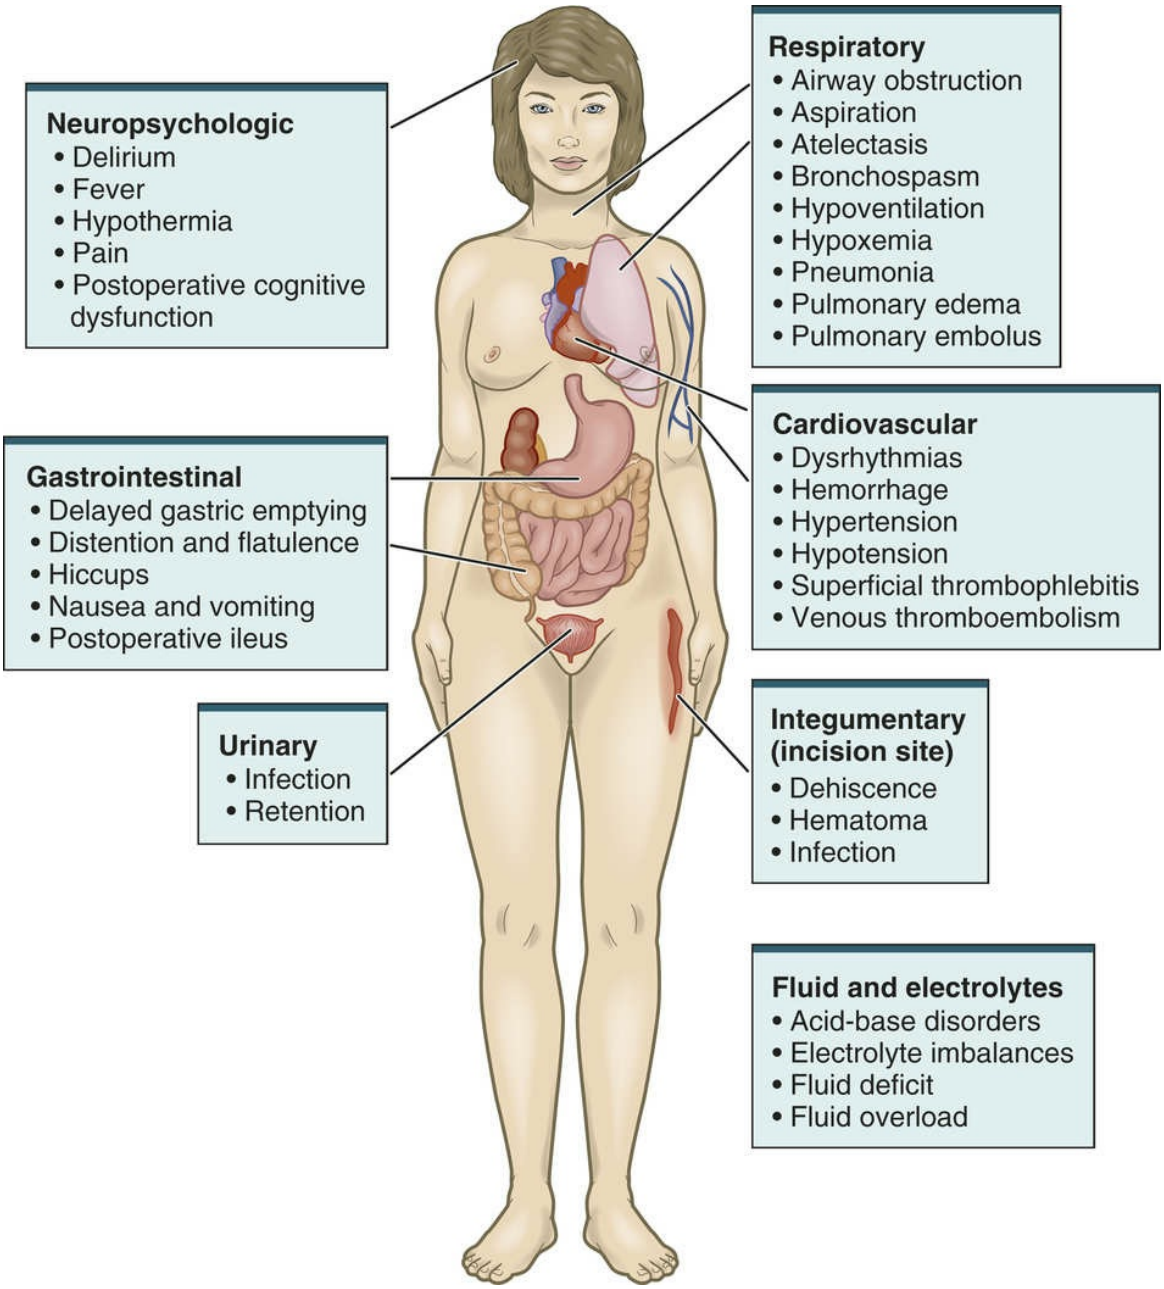

FIG. 19.1 Potential problems in the postoperative period.

TABLE 19.3 Initial PACU Assessment

Airway

- Patency

- Oral or nasal airway
- Laryngeal mask airway
- Endotracheal tube with ventilator settings

Breathing

- Respiratory rate and quality
- Auscultated breath sounds
- Pulse oximetry
- Capnography or other technology-supported monitoring if indicated
- Supplemental O_2

Circulation

- ECG monitoring: rate and rhythm
- BP: noninvasive or arterial line
- Hemodynamic pressure readings (if applicable)
- Temperature
- Capillary refill
- Color, temperature, moisture of skin
- Apical and peripheral pulses

Neurologic

- Level of consciousness
- Orientation
- Sensory and motor status
- Pupil size and reaction

Surgical Site

- Dressings and visible incisions
- Drains: type, patency, and drainage
- IV assessment: location and condition of sites, solutions infusing

Genitourinary

- Urine output

Gastrointestinal

- Nausea, vomiting
- Intake (fluids, irrigations)
- Output (vomitus)
- Bowel sounds

Pain

- Incision
- Other

Patient Safety Needs

- Patient position
- Fall risk assessment

TABLE 19.4 Signs of Inadequate Oxygenation

Cardiovascular System

- Hypertension
- Hypotension
- Tachycardia
- Bradycardia
- Dysrhythmias
- Delayed capillary refill
- Weak peripheral pulses
- Decreased O_2 saturation

Central Nervous System

- Restlessness
- Agitation
- Confusion
- Muscle twitching
- Seizures
- Coma

Integumentary System

- Flushed, cool, or moist skin
- Cyanosis

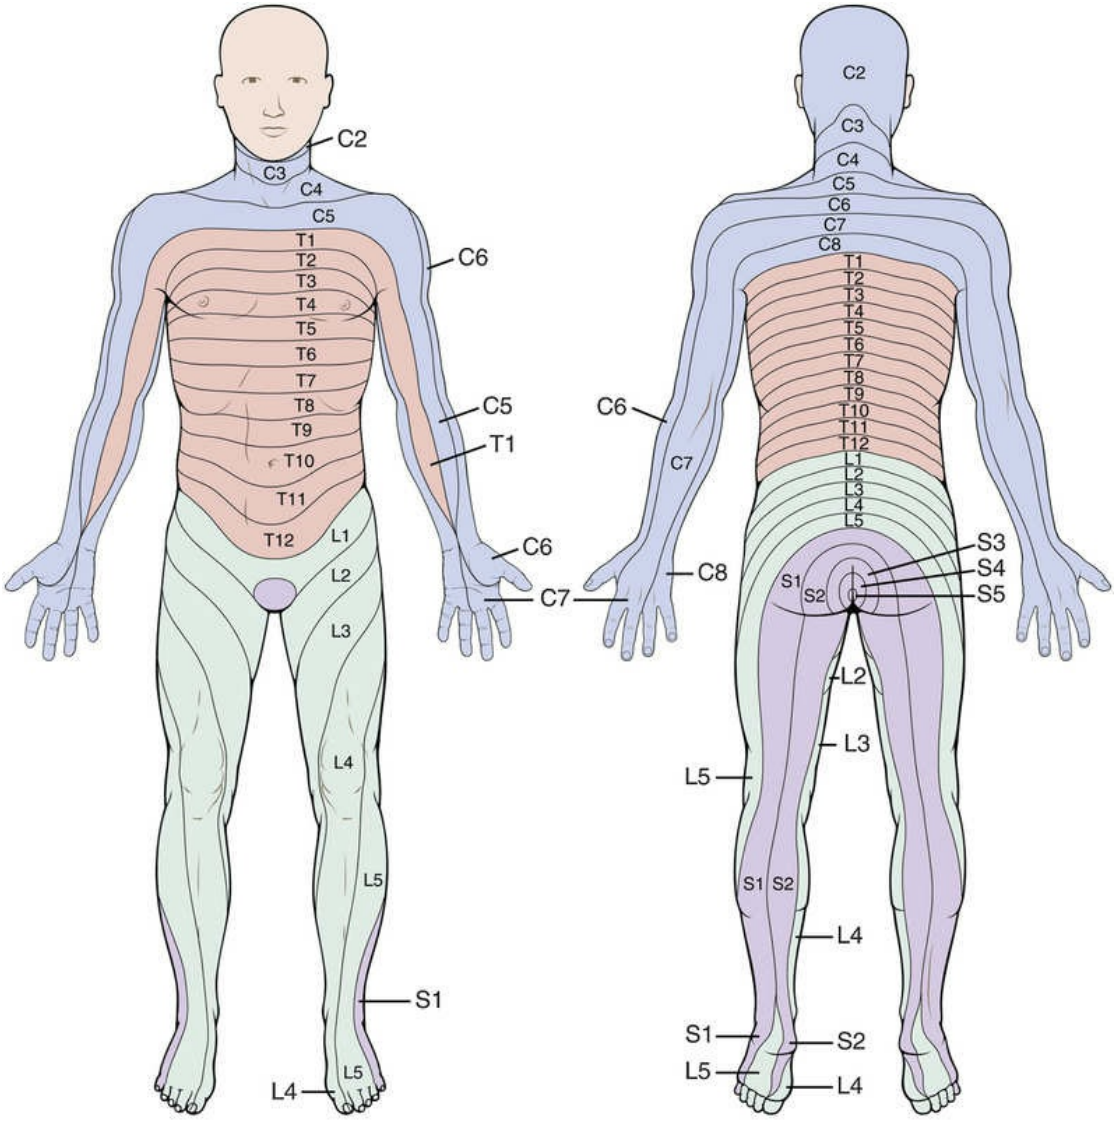
Renal System

- Urine output <0.5 mL/kg/hr

Respiratory System

- Increased to absent respiratory effort
- Use of accessory muscles
- Abnormal breath sounds
- Abnormal arterial blood gas values

Nursing Management



Caring for the Postoperative Patient

In the PACU, patients need frequent assessment and intervention by RNs. On the clinical units, the RN is responsible for assessment, developing an individualized plan of care, implementing and evaluating the plan of care, and discharge teaching. The RN can delegate much of the care to LPNs/VNs and UAP. Respiratory and physical therapy may have a role in the patient's care, depending on the type of surgery and the patient's past medical history.

PACU	Clinical Unit

• **Assess patient's initial airway, breathing, and circulation status.**
• **Evaluate for the return to consciousness, ability to maintain airway and breathing.**
• **Perform ongoing assessments for postoperative problems (e.g., airway obstruction, hypoventilation, hypotension or hypertension, dysrhythmias, emergence delirium).**
• **Administer and titrate O_2 based on agency protocols.**
• **Give analgesics and IV fluids.**
• **Evaluate patient's readiness for transfer to clinical unit or discharge from ambulatory surgery.**
• **Give hand-off report to RN about patient status when transferring patient to clinical unit.**
• **Provide discharge teaching for patient and caregiver after ambulatory surgery.**
• **Oversee UAP:**
  • **Assist with positioning of patients in the lateral recovery position.**
  • **Obtain vital signs, pulse oximetry and capillary blood glucose levels (per agency policy). Report abnormal levels to RN.**
  • **Aid patient with elimination needs.**
	• Assess patient on initial admission to the unit.
	• Assess for complications (e.g., atelectasis, hemodynamic instability, cognitive dysfunction, pain, fluid and electrolyte imbalance, fever or hypothermia, nausea and vomiting, urinary retention, wound infection).
	• Develop and implement an individualized plan of care based on identification of patient risk factors and potential complications.
	• Titrate O_2 administration according to prescribed parameters.
	• Monitor pain level and give prescribed analgesics.
	• Give medications.
	• Provide wound care, including dressing changes.
	• Insert urinary catheter as prescribed for urinary retention.
	• Develop and implement individualized patient and caregiver education, including discharge teaching.
	• Oversee UAP:
	  • Record oral intake and output.
	  • Obtain vital signs, pulse oximetry and capillary blood glucose levels (per agency policy). Report abnormal levels to RN.
	  • Aid patient with nutrition, elimination, and hygienic needs.
	  • Reposition and ambulate patient as instructed.
	  • Help patient with deep breathing and coughing exercises.

Collaborate With Interprofessional Team	
Respiratory Therapist	
• **Provide respiratory care modalities that support patient recovery from anesthesia (e.g., O_2 therapy, nebulizer treatments, pulmonary drainage procedures, mechanical ventilation, and airway support).** • **Institute extubation protocols.** • **Monitor pulse oximetry, capnography, or other technology-assisted means of assessing hypoxemia or hypoventilation.** • **Assist with O_2 and/or ventilation management during patient transport.** • **Perform arterial blood gas sampling in the absence of an arterial line.**	• Institute rapid intubation protocols if needed in the absence of ACP. • Provide respiratory care modalities (e.g., O_2 therapy, nebulizer treatments, pulmonary drainage procedures). • Assist with O_2 and/or ventilation support during patient transport. • Monitor pulse oximetry and capnography and titrate O_2 as needed. • Perform arterial blood gas sampling as needed.
Physical Therapist	
• **Perform initial assessment to determine normal functioning level if surgery was emergent.** • **Support patient motion and joint mobility.**	• Support patient motion and joint mobility. • Support patient return to baseline functional mobility following surgery. • Support nursing staff on best measures for joint positioning, transferring from bed to chair, and/or ambulation.

Sensory level anesthesia necessary for surgical procedures

Sensory level	Type of surgery
S2-S5	Hemorrhoidectomy
L2-L3 (knee)	Foot surgery
L1-L3 (inguinal ligament)	Lower extremity surgery
T10 (umbilicus)	Hip surgery Transurethral resection of the prostate Vaginal delivery
T6-T7 (xiphoid process)	Lower abdominal surgery Appendectomy
T4 (nipple)	Upper abdominal surgery Cesarean section

FIG. 19.2 Sensory innervation by spinal nerves and sensory level required for various surgical procedures.

Respiratory Problems

Etiology

PACU

In the immediate postanesthesia period the most common causes of airway compromise include obstruction, hypoxemia, and hypoventilation (Table 19.5). Patients at high risk include those who (1) have had general anesthesia; (2) are older than 55 years of age; (3) have a history of tobacco use; (4) have preexisting lung disease and/or sleep-disordered breathing; (5) are obese; (6) have co-morbidities (e.g., renal disease, diabetes, hypertension); or (7) have undergone airway, thoracic, or abdominal surgery. Pulmonary complications pose the greatest risk to patients in the postanesthesia period and in the immediate postoperative period. High-risk patients should be monitored in a critical care or postanesthesia care unit.[5]

Airway obstruction is often caused by the patient's tongue blocking the airway (Fig. 19.3). The base of the tongue falls backward against the soft palate and occludes the pharynx. It is most pronounced in the supine position and in the patient who is extremely sleepy after surgery.

Hypoxemia, a partial pressure of arterial oxygen (PaO_2) less than 60 mm Hg, is characterized by a variety of nonspecific clinical signs and symptoms, ranging from agitation to somnolence, hypertension to hypotension, and tachycardia to bradycardia. Pulse oximetry will show low O_2 saturation (less than 92%).

The most common cause of hypoxemia after surgery is atelectasis. **Atelectasis** (alveolar collapse) may be the result of bronchial obstruction caused by retained secretions, decreased respiratory excursion, or general anesthesia. Atelectasis occurs when mucus

blocks bronchioles or there is not enough alveolar surfactant (substance that holds the alveoli open) (Fig. 19.4). As air becomes trapped beyond the plug and is absorbed, the alveoli collapse. Atelectasis may affect a part of or an entire lobe of the lung.

Other causes of hypoxemia include pulmonary edema, pulmonary embolism (PE), aspiration, and bronchospasm. An accumulation of fluid in the alveoli can cause *pulmonary edema*. It may be the result of fluid overload, heart failure, prolonged airway obstruction, sepsis, or aspiration.

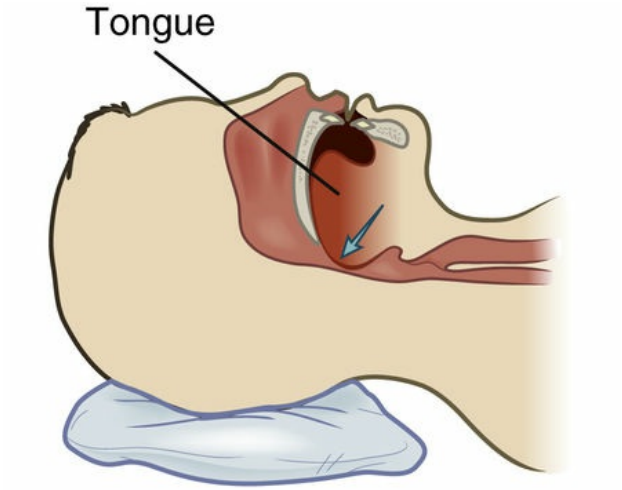
After surgery patients are at risk for *aspiration* of gastric contents into the lungs. This can occur because anesthesia depresses the respiratory protective airway reflexes. Gastric aspiration is a potentially serious emergency. It may result in laryngospasm, pneumonia, and pulmonary edema. Because of the grave consequences of aspiration of gastric fluids, prevention is the goal.

Bronchospasm is the result of an increase in bronchial smooth muscle tone with resulting closure of small airways. Airway edema develops, causing secretions to build up in the airway. The patient will have wheezing, dyspnea, use of accessory muscles, hypoxemia, and tachypnea. Bronchospasm may be due to aspiration, endotracheal intubation, pharyngeal suctioning, or an allergic response. (Allergic responses are discussed in Chapter 13.) Bronchospasm may occur in any patient. It occurs more often in patients with a history of smoking, asthma, and chronic obstructive pulmonary disease (COPD).

Hypoventilation, a common complication in the PACU, is characterized by a decreased respiratory rate or effort, hypoxemia, and increasing hypercapnia (increasing $PaCO_2$). It may result from depression of the central respiratory drive (from anesthesia or use of opioids), poor respiratory muscle tone (from neuromuscular blockade or disease), or a combination of both.

Safety Alert

Hypoventilation

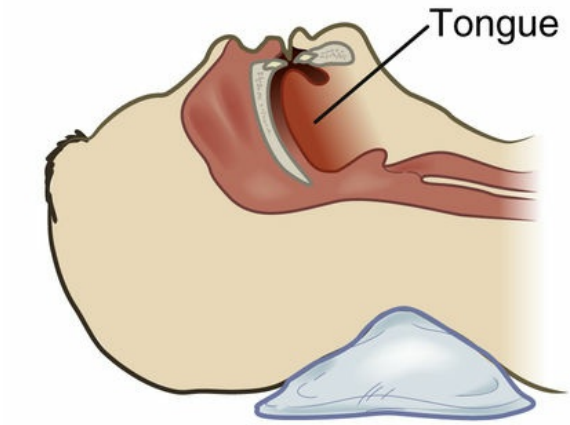


- Always assess for respiratory depression when giving opioids.
- Use a sedation assessment scale (e.g., Richmond Agitation and Sedation Scale, available at *www.icudelirium.org/docs/RASS.pdf*) to assess for levels of sedation and promote patient safety when giving opioids in the PACU.
- Begin emergency management protocols if hypoventilation is present.

Clinical Unit

Common causes of respiratory problems are atelectasis and pneumonia, especially in patients with co-morbidities (e.g., OSA, COPD, heart failure) and after abdominal and thoracic surgery.[6,7] The development of mucous plugs and decreased surfactant production is directly related to hypoventilation, immobility and bed rest, ineffective coughing, and history of tobacco use. Increased bronchial secretions occur when the respiratory passages have been irritated by heavy smoking, COPD, pulmonary infection, or dry mucous membranes that occurs with intubation, inhalation anesthesia, and dehydration. Without intervention, atelectasis can progress to pneumonia.

TABLE 19.5 Postoperative Respiratory Complications



Complications	Mechanisms	Manifestations	Interventions
Airway Obstruction			
Laryngeal edema	Allergic drug reaction Mechanical irritation from intubation Fluid overload	Similar to laryngospasm	O_2 therapy Antihistamines Corticosteroids Sedatives Possible intubation
Laryngospasm	Irritation from endotracheal tube, anesthetic gases, or gastric aspiration Most likely to occur after removal of endotracheal tube	Inspiratory stridor (crowing respirations) Sternal retraction Acute respiratory distress	O_2 therapy Positive pressure ventilation IV muscle relaxant Lidocaine Corticosteroids
Retained thick secretions	Secretion stimulation by anesthetic agents Dehydration of secretions	Noisy respirations Coarse crackles	Suctioning Deep breathing and coughing IV hydration Chest PT
Tongue falling back	Muscular flaccidity associated with ↓ consciousness and muscle relaxants	Use of accessory muscles Snoring respirations ↓ Air movement	Patient stimulation Head tilt, jaw thrust (Fig. 19.3) Artificial airway
Hypoxemia			
Aspiration	Inhalation of gastric contents into lungs	Unexplained tachypnea Bronchospasm ↓ O_2 saturation Atelectasis Interstitial edema Alveolar hemorrhage Respiratory failure	O_2 therapy Cardiopulmonary support Antibiotics
Atelectasis	Bronchial obstruction caused by retained secretions or ↓ lung volumes	↓ Breath sounds ↓ O_2 saturation	Humidified O_2 therapy Deep breathing Incentive spirometry Early mobilization
Bronchospasm	↑ Smooth muscle tone with closure of small airways	Wheezing Dyspnea Tachypnea ↓ O_2 saturation	O_2 therapy Bronchodilators
Pulmonary edema	Fluid overload ↑ Hydrostatic pressure ↓ Interstitial pressure ↑ Capillary permeability	↓ O_2 saturation Crackles Infiltrates on chest x-ray	O_2 therapy Diuretics Fluid restriction
Pulmonary embolism	Thrombus dislodged from peripheral venous system and lodged in pulmonary arterial system	Acute tachypnea Dyspnea Tachycardia Hypotension ↓ O_2 saturation Bronchospasm	O_2 therapy Cardiopulmonary support Anticoagulant therapy
Hypoventilation			
Depressed central respiratory drive	Medullary depression from anesthetics, opioids, sedatives	Shallow respirations ↓ Respiratory rate, apnea ↓ PaO_2 ↑ $PaCO_2$	Start capnography or other technology-supported respiratory monitoring Stimulation Reversal of opioids or benzodiazepines Mechanical ventilation
Mechanical restriction	Tight casts, dressings, abdominal binders Positioning and obesity preventing lung expansion	As above	Elevate head of bed Repositioning Loosen dressings
Pain	Shallow breathing to prevent incisional pain	↑ Respiratory rate Hypotension Hypertension ↓ $PaCO_2$ ↓ PaO_2 Reports of pain Guarding behavior	Opioid analgesic drug therapy Nonsteroidal antiinflammatory drug therapy Complementary and alternative therapies (e.g., music, imagery)
Poor respiratory muscle tone	Neuromuscular blockade Neuromuscular disease	As above	Reversal of paralysis Mechanical ventilation

Tongue occluding airway

Manually elevate the jaw
while tilting the head back

Airway cleared

FIG. 19.3 Etiology and relief of airway obstruction.

Nursing Management: Respiratory Problems

Nursing Assessment

Respiratory assessment requires evaluation of airway patency; chest symmetry; and depth, rate, and character of respirations. Impaired ventilation may first be seen as slowed breathing or reduced chest and abdominal movement during breathing. Abdominal or accessory muscle use may occur with respiratory distress. Auscultating breath sounds will alert you to decreased or absent breath sounds. These findings may mean airflow is diminished or obstructed. Arouse patients with poor respiratory effort, noisy respirations, or other signs of respiratory distress at once and have them take deep breaths.

Regular monitoring of vital signs, including pulse oximetry, capnography, or other technology-supported monitoring (e.g., acoustic monitoring), and a thorough respiratory assessment allow you to recognize early signs of respiratory problems. Manifestations of hypoxemia include tachypnea, gasping, anxiety, restlessness, confusion, and a rapid or thready pulse.

Note and record the characteristics of sputum or mucus. Mucus from the trachea and throat is normally colorless and thin in consistency. Sputum from the lungs and bronchi is normally thick with a pale, yellow tinge. Changes in sputum (e.g., color) may indicate a respiratory infection.

Nursing Diagnoses

Nursing diagnoses and collaborative problems related to respiratory problems include:

- Impaired airway clearance

- Impaired breathing
- Impaired gas exchange
- Risk for aspiration
- Potential complications: pneumonia, atelectasis

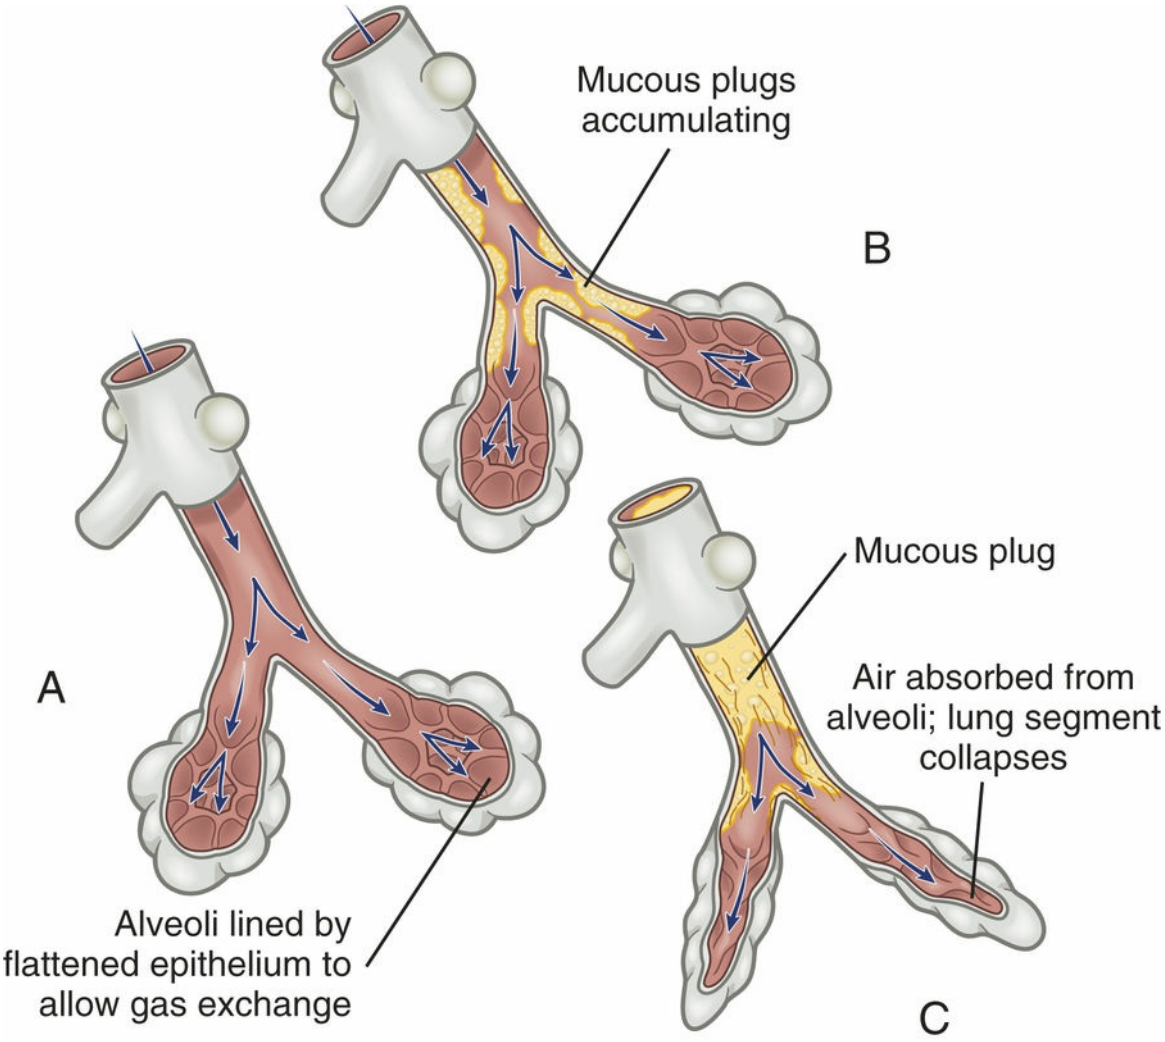


FIG. 19.4 Postoperative atelectasis. **A,** Normal bronchiole and alveoli. **B,** Mucous plug in bronchiole. **C,** Collapse of alveoli resulting from atelectasis after absorption of air.

Nursing Implementation

In the PACU, nursing interventions are aimed at preventing and

treating respiratory problems. Proper positioning of the patient aids breathing and protects the airway.

Safety Alert

Postoperative Patient Positioning

- Position the unconscious patient in a lateral "recovery" position (Fig. 19.5).
- This position keeps the airway open and reduces the risk for aspiration if vomiting occurs.

Once conscious, place the patient in a supine position with the head of the bed elevated. This position maximizes expansion of the thorax by decreasing the pressure of the abdominal contents on the diaphragm.

Start O_2 therapy via nasal cannula or face mask if ordered. O_2 helps to eliminate anesthetic gases and meet the increased demand for O_2 resulting from decreased blood volume or increased metabolism.

All postoperative patients are at risk for atelectasis. Encourage deep breathing to aid gas exchange and promote the return to consciousness. Once the patient is more awake, deep breathing, coughing, and use of an incentive spirometer help prevent alveolar collapse and move respiratory secretions to larger airway passages for expectoration. One technique, known as *sustained maximal inspiration,* requires the patient to inhale as deeply as possible and, at the peak of inspiration, hold the breath for a few seconds, and then exhale. This is followed by another deep breath and cough.

The use of an incentive spirometer helps by giving visual feedback of respiratory effort (Fig. 19.6). Diaphragmatic or abdominal breathing involves inhaling slowly and deeply through the nose, holding the breath for a few seconds, and then exhaling slowly and completely through the mouth. Place the patient's hands lightly over the lower

ribs and upper abdomen so that the patient can feel the abdomen rise during inspiration and fall during expiration. Unless contraindicated, have the patient perform these maneuvers 10 times every hour while awake.

FIG. 19.5 Position of patient during recovery from general anesthesia.

FIG. 19.6 Proper use of an incentive spirometer.

Courtesy Christine R. Hoch, MSN, RN, ACNS-BC, Nursing Instructor, University of Delaware, Newark, DE.

Effective coughing is essential in mobilizing secretions. If secretions are in the respiratory tract, deep breathing often moves them up and stimulates the cough reflex. Splinting an abdominal incision with a pillow or a rolled blanket supports the incision and aids in coughing and expectorating secretions (Fig. 19.7).

Change the patient's position every 1 to 2 hours to allow full chest expansion and increase perfusion of both lungs. Help the patient sit in a chair and ambulate as soon as ordered. Provide adequate and regular pain medication. Incisional pain often is the greatest barrier to patient participation in effective breathing exercises and ambulation. Reassure the patient that these activities will not cause the incision to open. Adequate hydration, either parenteral or oral, is essential to maintain the integrity of mucous membranes and to keep secretions thin and loose for easy expectoration.

Other nursing interventions for specific respiratory problems are detailed in Table 19.5. A nursing care plan for the postoperative patient (eNursing Care Plan 19.1) is available on the website for this chapter.

Informatics in Practice

Respiratory Monitoring

- Continuous monitoring of respiratory rate is important for those receiving patient-controlled analgesia (PCA) for pain management, as opioids can cause respiratory depression and place patients at risk for serious injury or death.
- Acoustic respiration rate (RRa) is a new measurement that allows for the noninvasive and continuous assessment of patients' breathing. RRa uses a sensor with an acoustic transducer that is placed on the patient's neck.

- The respiratory signal is displayed as a continuous respiration rate.

Cardiovascular Problems

Etiology

PACU

In the immediate postanesthesia period the most common cardiovascular problems include hypotension, hypertension, and dysrhythmias. Patients at greatest risk for altered cardiovascular function include those with altered respiratory function, those with a history of cardiovascular disease, older adults, the debilitated, and the critically ill.

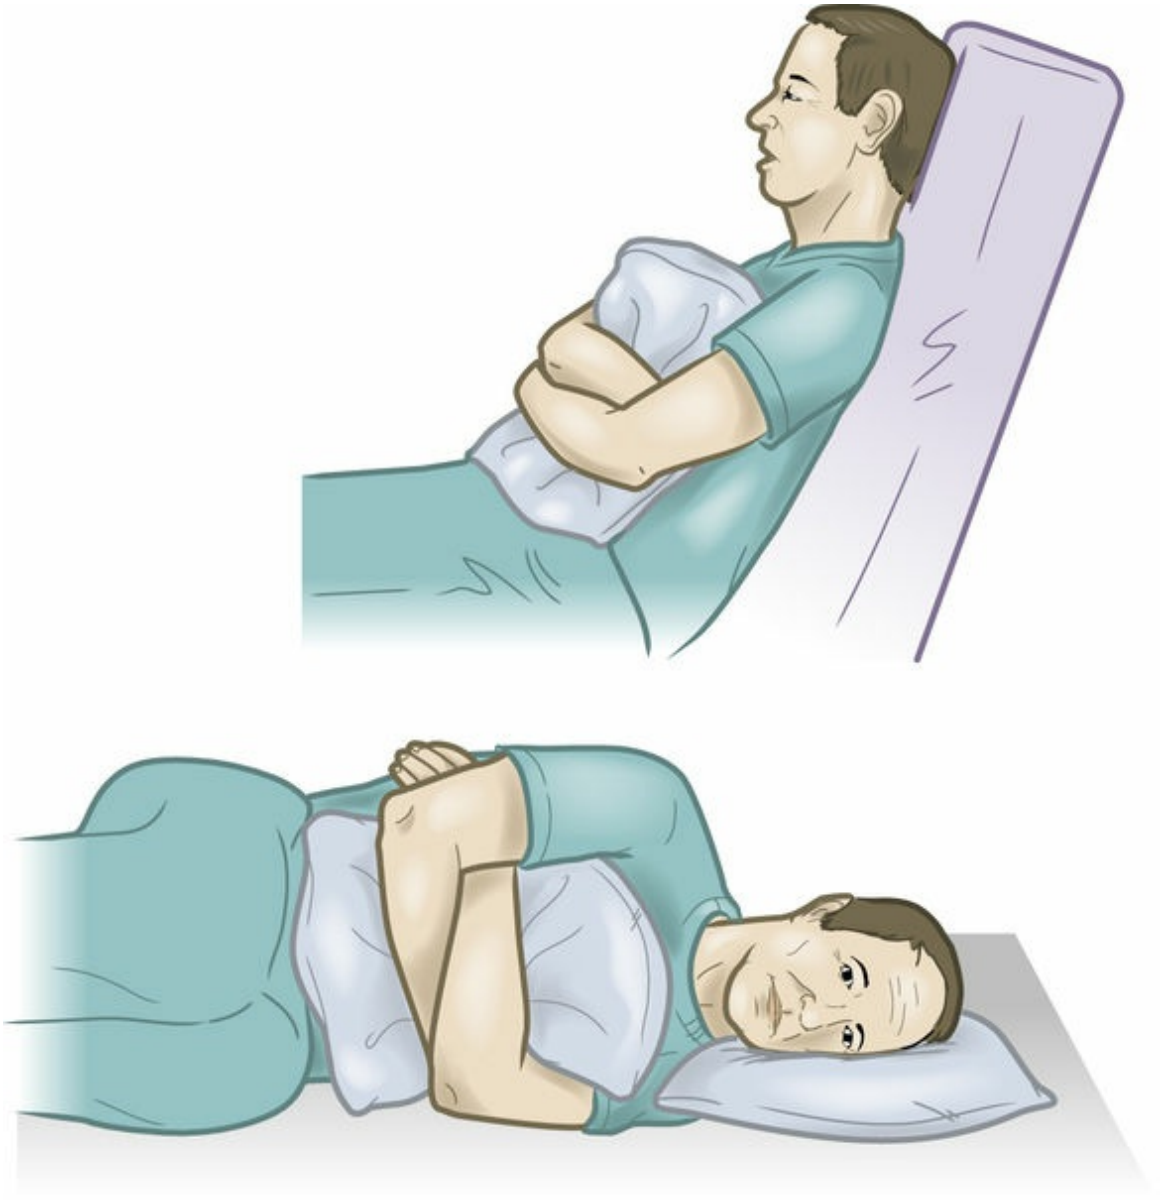

FIG. 19.7 Techniques for splinting incision when coughing.

Hypotension can cause hypoperfusion to the vital organs, especially the brain, heart, and kidneys. Clinical signs of disorientation, loss of consciousness, chest pain, and oliguria reflect hypoperfusion, hypoxemia, and the loss of physiologic compensation. Intervention must be prompt to prevent the devastating complications of cardiac ischemia or infarction, cerebral ischemia, renal ischemia, and bowel infarction.

The most common cause of hypotension in the PACU is fluid and

blood loss, which may lead to hypovolemic shock. Hemorrhage is always a risk of surgery. Marked blood loss is possible when cauterization or sutures fail. Hemorrhage most often occurs internally. Assess for changes in level of consciousness and vital signs. If detected, treatment is aimed toward restoring circulating volume. If there is no response to fluid administration, heart dysfunction may be the cause of hypotension.

Primary heart dysfunction, which may occur in myocardial infarction, cardiac tamponade, or PE, results in an acute drop in cardiac output. Secondary heart dysfunction occurs because of the negative *chronotropic* (rate of heart contraction) and negative *inotropic* (force of heart contraction) effects of drugs, such as β-adrenergic blockers, digoxin, or opioids. Other causes of hypotension include decreased systemic vascular resistance and dysrhythmias.

Hypertension most often occurs from sympathetic nervous system stimulation. This may be the result of pain, anxiety, bladder distention, or respiratory distress. Hypertension may be related to hypothermia and preexisting hypertension.

Many problems can cause dysrhythmias. These include hypoxemia, hypercapnia, electrolyte and acid-base imbalances, circulatory instability, preexisting heart disease, hypothermia, pain, surgical stress, and many anesthetic agents.

Clinical Unit

On the clinical unit, postoperative fluid and electrolyte imbalances are contributing factors to heart problems. Such imbalances may result from a combination of the body's normal response to the stress of surgery, excessive fluid losses, and IV fluid replacement. The body's fluid status directly affects cardiac output.

Fluid retention during postoperative days 1 to 3 can result from the stress response, which maintains both blood volume and BP. Fluid retention results from the release of antidiuretic hormone (ADH) and adrenocorticotropic hormone (ACTH) and activation of the renin-angiotensin-aldosterone system (RAAS). ADH release leads to increased water reabsorption and decreased urine output, increasing

blood volume. ACTH stimulates the adrenal cortex to secrete cortisol and, to a lesser degree, aldosterone (see Figs. 16.9 and 16.10). Fluid losses resulting from surgery decrease kidney perfusion, stimulating the RAAS and causing marked release of aldosterone. Both mechanisms that increase aldosterone lead to significant sodium and fluid retention, thus increasing blood volume.

Fluid overload may occur during this period of fluid retention if we infuse IV fluids too rapidly, when chronic disease (e.g., heart, kidney) exists, or when the patient is an older adult. Fluid deficits from untreated preoperative dehydration, blood loss during surgery, or slow or inadequate fluid replacement can decrease cardiac output and tissue perfusion. Losses from vomiting, bleeding, wound drainage, or suctioning can contribute to fluid deficits.

Hypokalemia can result from urinary and gastrointestinal (GI) tract losses. Low serum potassium levels directly affect the heart's contractility and may contribute to decreases in cardiac output and tissue perfusion. The patient can receive potassium replacement, usually 40 mEq/day, if renal function is adequate. A urine output of at least 0.5 mL/kg/hr and a normal serum creatinine are considered indicative of adequate renal function.

The state of tissue perfusion or blood flow affects cardiovascular status. The stress response contributes to an increase in clotting tendencies by increasing platelet production. A *venous thromboembolism (VTE)* may form in leg veins because of venous stasis, vein injury, or a hypercoagulable state. VTE is especially common in older adults, obese persons, immobilized patients, and patients with a history of PE or predisposition to clotting. It is a potentially life-threatening complication because it may lead to PE and infarction. Suspect PE in any patient with tachypnea, chest pain, hypotension, agitation, tachycardia, and dyspnea, especially when the patient is already receiving O_2 therapy. Superficial thrombophlebitis is an uncomfortable but less serious complication. It may develop in a leg vein because of venous stasis or in the arm veins because of irritation from IV catheters or solutions. (PE and VTE are discussed in Chapters 27 and 37, respectively.)

Syncope (fainting) may result from decreased cardiac output, fluid deficits, or defects in cerebral perfusion. Syncope often occurs because of postural hypotension when the patient ambulates. It is more common in the older adult or in the patient who has been immobile for long periods. Normally when the patient stands up quickly, the arterial baroreceptors respond to the accompanying fall in BP with sympathetic nervous system stimulation. This produces vasoconstriction and maintains BP. These sympathetic and vasomotor functions may be diminished in the older adult, immobile, or postanesthesia patient.

Nursing Management: Cardiovascular Problems

Nursing Assessment

The most important aspect of the cardiovascular assessment is frequent vital sign monitoring. Plan to obtain vital signs every 15 minutes in Phase I, or more often until stabilized and then less often in Phase II. Compare postoperative vital signs with preoperative and intraoperative findings to determine when the signs are returning to baseline. Notify the ACP or HCP if any of the following occurs:

- Systolic BP <90 mm Hg or >160 mm Hg
- Pulse rate <60 beats/min or >120 beats/min
- Pulse pressure (difference between systolic and diastolic BP) narrows
- BP trends gradually decrease or increase over several consecutive readings
- Change in heart rhythm

Hypotension accompanied by a normal pulse and warm, dry, pink skin is usually from the residual vasodilating effects of anesthesia and suggests only a need for continued observation. Hypotension

accompanied by a rapid or weak pulse and cold, clammy, pale skin may indicate impending hypovolemic shock and needs immediate treatment.

ECG monitoring is recommended for patients who have a history of heart disease and for all older patients who have undergone major surgery, regardless of whether they have heart problems. Assess the apical-radial pulse carefully and report any deficits or irregularities. Assess peripheral pulses and skin color, temperature, and moisture for valuable information about tissue perfusion.

Nursing Diagnoses

Nursing diagnoses and collaborative problems related to cardiovascular problems include:

- Altered blood pressure
- Impaired cardiac output
- Risk for bleeding
- Potential complications: hypovolemic shock, VTE

Nursing Implementation

PACU

Begin treatment of hypotension with O_2 therapy to promote oxygenation of hypoperfused organs. Because the most common cause of hypotension is fluid loss, give IV fluid boluses to normalize BP. Inspect the surgical incision to determine if excess bleeding is the cause of volume loss. Primary heart dysfunction may require drug intervention. Peripheral vasodilation and hypotension may require vasoconstrictive drugs to increase systemic vascular resistance.

Treatment of hypertension centers on removing the cause of sympathetic nervous system stimulation. This may include giving analgesics, assisting with voiding, and correcting respiratory problems. Rewarming corrects hypothermia-induced hypertension. The patient with preexisting hypertension or who has undergone

heart or vascular surgery usually needs drug therapy to reduce BP.

Since most dysrhythmias seen in the PACU have identifiable causes, treatment is directed toward removing the cause. Correcting the cause usually corrects the dysrhythmias. With life-threatening dysrhythmias (e.g., ventricular tachycardia), follow your agency's protocol for advanced cardiac life support.

Clinical Unit

Continue to monitor vital signs. Keep an accurate intake and output record, monitor laboratory findings (e.g., electrolytes, hematocrit), and manage IV therapy after surgery.

Early ambulation is the most significant general nursing measure to prevent complications. The exercise associated with walking (1) increases muscle tone; (2) stimulates circulation, which prevents venous stasis and VTE, and speeds wound healing; and (3) increases vital capacity and supports normal respiratory function. Begin progression to ambulation by first raising the head of the patient's bed for 1 to 2 minutes. Then help the patient to sit, with legs dangling, while monitoring the pulse rate. If you do not note changes or problems, start ambulation with ongoing monitoring of the pulse. If you note changes in the pulse or dizziness occurs, sit the patient in a nearby chair. The patient should stay in this location until the BP and pulse are stable. Then help the patient back to the bed. If dizziness occurs, it is often frightening for the patient. Injury can result from a fall, so take measures to ensure patient and staff safety.

Check Your Practice

You are caring for an older, obese male patient who is 1 day post colon resection with activity orders for moving out of the bed to a chair. While he is in bed, you help him to a sitting position with his legs dangling. He tells you that he feels dizzy. You take his BP and it is 108/64 and his pulse is 124.

- What should you do?

Neurologic and Psychologic Problems

Etiology

PACU

Postoperatively, **emergence delirium** is a short-term neurologic change manifested by behaviors such as restlessness, agitation, disorientation, thrashing, and shouting. If delirium occurs, first suspect hypoxia. Other causes include anesthetic agents, bladder distention, pain, long duration of preoperative fasting, residual neuromuscular blockade, or the presence of an endotracheal tube.

Delayed emergence can be a problem after surgery. Patients with delayed emergence spend longer periods in the PACU and have prolonged hospital courses. Identifying the causative factors is critical for determining appropriate interventions.[8] The most common cause of delayed emergence after anesthesia is drug-related. This includes anesthetic agents as well as drugs used during the perioperative period. Contributory nonpharmacologic causes include metabolic disorders, electrolyte imbalances, hypertension, liver disease, uremia, central anticholinergic syndrome, and hypothyroidism. Other causes can include hypoxia, hypercapnia, hemorrhage, and embolism.

Clinical Unit

Two types of cognitive impairments seen in surgical patients are *postoperative cognitive dysfunction (POCD)* and *delirium.* POCD is a decline in the patient's cognitive function (e.g., memory, ability to concentrate) for weeks or months after surgery. POCD occurs primarily in the older surgical patient. Preexisting cognitive impairment, duration of anesthesia, complications during surgery, and infection contribute to the development of POCD. Quickly and thoroughly investigate any changes in mental status as the causes may be life threatening.

Postoperative delirium is more common in the older patient, but it

can occur in patients of any age. Delirium may be the result of severe pain, fluid and electrolyte imbalances, hypoxemia, drug effects, sleep deprivation, and sensory deprivation or overload. Signs include cognitive dysfunction, varying levels of consciousness, altered psychomotor activity, and a disturbed sleep/wake cycle. See Chapter 59 for more about delirium.

Anxiety and depression may occur and correlate with an increased likelihood for complications.[9] These responses may be part of grieving for lost body parts or altered body function or for loss of independence during recovery and rehabilitation.

Alcohol withdrawal delirium results from the patient undergoing alcohol withdrawal. It is characterized by restlessness, insomnia, nightmares, irritability, and auditory or visual hallucinations. Chapter 10 discusses the identification and management of alcohol withdrawal delirium.

Nursing Management: Neurologic and Psychologic Problems

Nursing Assessment

Assess the patient's level of consciousness, orientation, memory, and ability to follow commands. Determine the size, reactivity, and equality of the pupils. Assess the patient's sleep/wake cycle and sensory and motor status. Determine the possible cause if the patient has an altered neurologic status. If the patient was mentally alert before surgery and becomes cognitively impaired after surgery, you need to do further assessment to rule out hypoxia, delirium, or POCD.

Nursing Diagnoses

Nursing diagnoses related to neurologic and psychologic problems include:

- Confusion

- Disturbed body image
- Sleep deprivation

Nursing Implementation

PACU

The most common cause of agitation in the PACU is hypoxemia. So, you need to focus attention on evaluating respiratory function. Once you have ruled out hypoxemia or other known causes of postoperative delirium, sedation may be beneficial in controlling agitation. Because the most common cause of delayed emergence is prolonged drug action, delays in awakening usually spontaneously resolve with time. If necessary, antagonists can reverse the effects of benzodiazepines and opioids.

Interventions to prevent perioperative delirium, other than reducing the depth of anesthesia, have not significantly reduced the incidence of emergence delirium [10] Until the patient is awake and able to communicate effectively, you are responsible for patient safety. This includes monitoring physiologic status, having the side rails up and the call bell available, securing equipment (e.g., IV lines, artificial airways), using 2 patient identifiers before giving drugs or completing treatments, and verifying allergies.

Clinical Unit

To prevent or manage postoperative delirium or POCD, address any potential contributing factors. Maintain normal physiologic function by achieving fluid and electrolyte balance, adequate nutrition and sleep, pain management, proper bowel and bladder function, and early mobilization. To help orient the patient, use specific aids, such as clocks, calendars, and photos.

To prevent or limit psychologic problems, provide adequate support for the patient. This includes listening to and talking with the patient, offering explanations and reassurance, and encouraging the presence and aid of the patient's caregiver(s). Evaluate the patient's behavior to distinguish a normal reaction to a stressful situation from

one that is becoming abnormal or excessive. Recognizing alcohol withdrawal delirium can be a challenge. Record and report any unusual or disturbed behavior so that a diagnosis can be made and treatment started.

Pain and Discomfort

Etiology

Despite the availability of pain-relieving drugs and techniques, pain is a common problem and a significant fear for patients. Pain is caused by the interaction of several physiologic and psychologic factors. The incision and retraction during surgery traumatize the skin and underlying tissues. In addition, there may be reflex muscle spasms around the incision. Anxiety and fear, sometimes related to the anticipation of pain, create tension and further increase muscle tone and spasm. Positioning during surgery and the use of internal devices such as an endotracheal tube or catheters may also cause discomfort. The effort and movement associated with deep breathing, coughing, and ambulating may worsen pain by creating tension on the incision area. Other sources of discomfort include nausea and vomiting, environmental noises, noxious odors, and shivering.

The patient does not feel pain when the internal viscera are cut. Pain, does, however, come from pressure in the internal viscera. This means deep visceral pain may signal a complication such as intestinal distention, bleeding, or abscess formation. Pain increases the risk for atelectasis and impaired respiratory function.

Nursing Management: Pain

Nursing Assessment

Assess the patient on arrival to the PACU and at frequent intervals. The patient's self-report is the single most reliable indicator of pain. Use a pain scale, such as a numeric or FACES pain scale, to assess the

severity or intensity of pain. (Pain scales are discussed in Chapter 8.) Assess pain levels at rest and during activities. Since verbalization of pain is not always possible in the PACU, assess the patient for other indications of pain (e.g., restlessness, grimacing, changes in vital signs). You need to identify the location of the pain. Expect that patients will have incisional pain, especially with movement, and with certain procedures (e.g., removal of drains). Other causes of pain, such as a full bladder, may be present.

Always involve patients in the assessment and management of their pain. Assessing patients from different cultures or who do not speak English may be challenging. Take extra time to explore the pain experience with these patients. Adapt care as needed to meet the patient's unique needs and expectations for pain control.

Nursing Implementation

Begin before surgery to develop a plan for pain control that includes behavioral modalities and control of anxiety. Evaluate any adjustments to or continuation of drugs used to treat any chronic pain during the preoperative phase. During this time, teach patients to report pain and how it will be managed after surgery. Share pain management plans during the hand-off report.

The acute pain of surgery almost always requires the use of analgesics. Organizational approaches can reduce pain intensity with fewer side effects associated with the analgesic use. These approaches include using procedure-specific pain management guidelines with titration of analgesia based on specific patient needs.[11]

Pain control techniques include the use of single modalities (e.g., opioid drugs, PCA, regional analgesic [local anesthetic infiltration]), or multimodal analgesia. *Multimodal analgesia,* or the use of 2 or more analgesics with different mechanisms of action (e.g., an opioid and a nonsteroidal antiinflammatory drug [NSAID]), is recommended. Multimodal analgesia reduces pain, opioid use, and opioid-related adverse effects. It also enhances recovery and increases patient satisfaction.[12] These drugs may be given via the same or different

routes. The choice of modalities should be procedure and patient specific.

The HCP often writes orders for pain medication and other comfort measures on an as-needed (PRN) basis. Time giving analgesics to ensure that they are in effect during activities that may be painful, such as walking. Although opioid analgesics are often essential for the patient's comfort, there are undesirable side effects. The most common include constipation, nausea and vomiting, respiratory and cough depression, and hypotension.

Before giving any analgesic, first assess the patient's pain, including location, quality, and intensity; vital signs; and level of consciousness. Treat incisional pain as ordered. If the patient reports chest or leg pain, analgesics may mask a complication (e.g., VTE). If it is gas pain, opioids can worsen it. If the analgesic either does not relieve the pain or makes the patient lethargic or somnolent, notify the HCP and request a change in the order.

Patient-controlled analgesia (PCA) allows the self-administration of predetermined doses of analgesia by the patient. The goals of PCA are to provide immediate analgesia and maintain an acceptable level of pain control. Continuous infusions allow for a steady blood level of analgesia with additional patient doses used prior to painful events (e.g., walking, deep breathing, and coughing) or for breakthrough pain. Opioid-tolerant patients may need patient-administered boluses. The route of delivery may be IV, oral, epidural, or transdermal. The transdermal route is for short-term pain management and may offer advantages over the IV route (e.g., needleless, low infection risk, decreased drug errors associated with pump malfunction or inaccurate programming). Some advantages of PCA are early ambulation, better pain management than with as-needed analgesia, and greater patient satisfaction. (PCA is discussed in Chapter 8.)

Safety Alert

Patient-Controlled Analgesia (PCA)

- Carefully check the HCP's order and properly program the pump for IV or epidural PCA to deliver the ordered dose of analgesic (e.g., continuous rate, bolus dose, maximum dose).
- A patient's death or serious injury associated with a drug error (e.g., wrong drug, wrong dose, wrong patient, wrong rate) is a serious reportable event (never event).

Epidural analgesia is the infusion of opioid analgesics through a catheter placed into the epidural space surrounding the spinal cord. The goal of epidural analgesia is delivery of the drug directly to opiate receptors in the spinal cord. Administration methods include intermittent bolus dosing, continuous infusion, and epidural PCA. This technique results in a constant circulating level and a reduced total dose of medication. The use of epidural analgesia for managing pain after surgery is increasing.

Perineural local anesthesia, the infiltration of a nonopioid drug into the surgical site, is another way to manage postoperative pain. A disposable or mechanical infusion pump delivers the local anesthetic via a catheter directly to the surgical incision site. A single dose of bupivacaine liposome injectable suspension (Exparel) provides pain relief with reduced opioid needs for up to 72 hours.

Complementary and alternative therapies such as music therapy, guided imagery, relaxation exercises, and aromatherapy are effective adjuncts in pain management. Nondrug approaches such as repositioning, massage, and distraction can enhance pain management.

Check Your Practice

Although PCA is infusing as ordered, your postoperative patient reports ongoing pain that is rated 8 on a 0 to 10 scale.

- What steps would you take next to manage this patient's pain more effectively?

Temperature Changes

Etiology

Knowing the patient's temperature in the postoperative period is valuable (Table 19.6). We are giving increased attention to the importance of maintaining a normal body temperature. Perioperative temperature management is a quality measure by the Surgical Care Improvement Project (SCIP), a national partnership of organizations whose goal is to reduce surgical site infections (SSIs).[13]

Hypothermia

Perioperative *hypothermia* is a core body temperature less than 96.8°F (36°C). Hypothermia occurs when heat loss exceeds heat production. Heat loss may occur due to skin exposure, use of cold irrigants, skin preparations, and unwarmed inhaled gases. Although all patients are at risk for postoperative hypothermia, patients with low preoperative core body temperatures, those with systolic BP less than 140 mm Hg, older patients, female patients, and patients who receive epidural or spinal anesthesia are at a higher risk.[1] Long surgical procedures, open cavity procedures (e.g., abdominal or thoracic) and prolonged anesthetic administration lead to redistribution of body heat from the core to the periphery. This places the patient at an increased risk for hypothermia and complications.[14]

Complications associated with hypothermia can include vasoconstriction with resulting hypertension, compromised immune function, bleeding, untoward cardiac events, SSIs, altered drug metabolism, increased pain, and shivering. Shivering can increase resting energy expenditure and O_2 consumption up to 500%, which can lead to hypoxemia and myocardial ischemia (angina). Shivering can also increase carbon dioxide production; increase heart rate, BP, and intracranial pressure; and significantly affect the patient's comfort level.[1]

Fever

Fever may occur at any time after surgery (Table 19.6). SSI, particularly from aerobic organisms, is often accompanied by a fever that spikes in the afternoon or evening and returns to near-normal levels in the morning. The respiratory tract may be infected from stasis of secretions in areas of atelectasis. Urinary tract infections (UTIs) may occur from catheterization. Superficial thrombophlebitis may occur at the IV site. VTE in the leg veins may raise temperature.

Surgical patients who receive antibiotic therapy are at risk for *Clostridium difficile* infections. Manifestations of *C. difficile* may include fever, diarrhea, and abdominal pain.

Intermittent high fever accompanied by shaking chills and diaphoresis suggests septicemia. This may occur at any time after surgery. It can result from microorganisms being introduced into the bloodstream during surgery, especially in GI or genitourinary (GU) procedures. Septicemia may occur later from a wound or UTI.

Malignant hyperthermia (MH) is a muscle metabolism disorder that is triggered by general anesthetic agents. Although often a late sign, it is characterized by a rapid rise in core body temperature and severe muscle rigidity. Other signs of MH include tachycardia, hypercarbia, metabolic and respiratory acidosis, myoglobinuria, and elevated creatine kinase levels. MH is a life-threatening complication. While most cases of MH occur during general anesthesia, the 1-hour period right after surgery (e.g., in the PACU) is a critical time.[1]

TABLE 19.6 Postoperative Temperature Changes

Time After Surgery	Temperature	Possible Causes
Up to 12 hr	Hypothermia: ≤96.8°F (36°C)	Effects of anesthesia, body heat loss during surgical procedure
First 48 hr (postoperative days 1 and 2)	Mild elevation: ≤100.4°F (38°C)	Inflammatory response to surgical stress
	Moderate elevation: >100.4°F (38°C)	Lung congestion, dehydration
After first 48 hr (postoperative day 3 and later)	Elevation >100°F (37.8°C)	Infection (e.g., wound, urinary, respiratory)

Nursing Management: Temperature Changes

Nursing Assessment

Take the patient's temperature on arrival to the PACU and every hour if the patient stays normothermic. If the patient is hypothermic, take the temperature every 15 minutes until normothermia is reached. Use the same route of measuring temperature during the patient's stay in the PACU.

Assess the color and temperature of the skin. Communicate risk factors for hypothermia or MH to all members of the perioperative team. Observe the patient for early signs of inflammation and infection that may precede a fever so that any complications can be treated promptly.

Nursing Diagnoses

Nursing diagnoses related to altered temperature include:

- Hypothermia
- Hyperthermia

Nursing Implementation

Passive warming measures include the use of warmed cotton blankets, socks, and reflective blankets and limiting skin exposure. *Active warming measures* involve the application of external warming devices, including forced air warmers; heated water mattresses; radiant warmers; heated, humidified O_2; and warmed IV fluids. When using any external warming device, record body temperature and the patient's comfort level at 15-minute intervals. In addition, take care to prevent skin injuries.

Apply O_2 therapy via nasal cannula or mask to treat the increased demand for O_2 caused by shivering. Shivering can be treated with

opioids (e.g., meperidine). Keep the supplies readily available to manage MH. Treatment for MH includes the administration of dantrolene (Dantrium), measures to cool the patient (e.g., ice packs), and correcting acid-base imbalances.

Use meticulous asepsis with wound and IV site care. Encourage airway clearance with deep breathing, coughing, and use of the incentive spirometer. If fever develops, chest x-rays may be taken, and antipyretic drugs given. Depending on the suspected cause of the fever, obtain cultures of the wound, sputum, urine, or blood. If a bacterial infection is the source of the fever, start antibiotics as soon as you obtain cultures. If the fever rises above 103°F (39.4°C), you may use body-cooling measures.

Gastrointestinal Problems

Etiology

Postoperative nausea and vomiting (PONV) are the most common complications affecting as many as 80% of high-risk patients. Risk factors include younger age (under 50 years of age), gender (female), history of motion sickness or previous PONV, nonsmoking status, action of anesthetics or opioids, and duration and type of surgery.[2] Delayed gastric emptying and slowed peristalsis that result from handling of the bowel during abdominal surgery contribute to PONV, as does starting oral intake too soon after surgery.

Constipation may occur after surgery. It can be due to anesthetics used during surgery that may paralyze the intestine; immobility; changes in diet and fluid intake; and the use of opioids for pain relief. Opioids contribute to constipation by decreasing peristalsis and slowing fecal transport through the intestinal tract. They may also decrease a patient's urge to defecate.

Postoperative ileus (POI) is the temporary impairment of gastric and bowel motility after surgery. It results from the handling or reconstruction of the intestine during surgery and limited dietary intake before and after surgery. POI is normal after abdominal

surgery and may occur after nonabdominal surgery. After abdominal surgery, motility in the large intestine may be reduced for 2 to 7 days. Motility in the small intestine resumes within several hours after surgery.

Risk factors for POI include the use of opioids, immobility, older age, prior abdominal surgery, and early postoperative feeding. Use of opioid analgesia may prolong the duration of POI. Abdominal cramps, increasing abdominal distention, constipation, nausea, vomiting, and dehydration often accompany POI.[15]

Hiccups (singultus) are intermittent spasms of the diaphragm caused by irritation of the phrenic nerve, which innervates the diaphragm. The phrenic nerve may be irritated after surgery by gastric distention, intestinal obstruction, intraabdominal bleeding, or a subphrenic abscess. Indirect irritation of the phrenic nerve may occur with acid-base and electrolyte imbalances. Reflex irritation may come from drinking hot or cold liquids or from the presence of a nasogastric (NG) tube. Hiccups usually last a short time and stop spontaneously.

Nursing Management: Gastrointestinal Problems

Nursing Assessment

Ask the patient about feelings of nausea. If nausea is present, assess the severity using a verbal descriptor or numeric scale. If vomiting occurs, determine the quantity, characteristics, and color of the vomitus. Assess the abdomen for distention and presence of bowel sounds. Because bowel sounds are often absent or diminished right after surgery, auscultate all 4 quadrants to determine the presence, frequency, and characteristics of the sounds. The return of normal bowel motility is usually accompanied by passing gas or stool and the ability to tolerate oral intake without nausea or vomiting.

Nursing Diagnoses

Nursing diagnoses and collaborative problems related to GI problems include:

- Nausea and vomiting
- Electrolyte imbalance
- Fluid imbalance
- Potential complications: POI, hiccups

Nursing Implementation

When the patient is NPO, give IV fluids to maintain fluid and electrolyte balance. Begin oral fluids as ordered and tolerated. Depending on the type of the surgery, the patient may begin oral intake as soon as the gag reflex returns. When starting oral intake, offer clear liquids first and continue the IV fluids, usually at a reduced rate. If the patient tolerates oral intake, the IV fluids are stopped.

Be alert to prevent aspiration if the patient vomits while still sleepy from anesthesia. Position the patient in the lateral recovery position and have suction equipment available. Interventions for PONV include monitoring fluid status and giving antiemetic drugs (see Table 41.1). Consider prophylactic antiemetic drugs for patients at high risk for PONV.[16] Complementary and alternative therapy interventions for PONV (e.g., imagery, music, aromatherapy, acupressure) may help.

Constipation may be prevented using bowel protocols that include the use of a stool softener and laxative. Assess the patient regularly to detect the return of peristalsis. Encourage the patient to expel gas. Gas pains tend to become pronounced on the second or third postoperative day. Ambulation and frequent repositioning may provide relief. Positioning the patient on the right side permits gas to rise along the transverse colon and aids its release. Bisacodyl (Dulcolax) suppositories may be given to stimulate colonic peristalsis and expulsion of gas and stool. Resuming a normal diet after bowel sounds have returned also aids the return of normal peristalsis.

The goal of treatment for POI is the relief of associated symptoms and return of normal GI function. Management includes bowel rest or

the withholding of solid foods with a gradual reintroduction of food starting with clear liquids. Advance the diet to solid food with an ongoing assessment of tolerance to oral intake.

An NG tube may be needed to decompress the stomach to prevent nausea, vomiting, and abdominal distention. Oral care is critical for comfort and stimulation of salivary glands when the patient is NPO or has an NG tube.

Urinary Problems

Etiology

Low urine output (800 to 1500 mL) in the first 24 hours after surgery may be expected regardless of fluid intake. Causes include increased aldosterone and ADH secretion resulting from the stress of surgery; fluid restriction before surgery; and fluid loss through surgery, drainage, and diaphoresis. By the second or third day, after fluid has been mobilized and the immediate stress reaction subsides, the patient will begin to have increasing urine output.

Acute urinary retention can occur for a variety of reasons. Anesthesia depresses the nervous system, including the micturition reflex arc and the higher centers that influence it. This allows the bladder to fill more completely than normal before the patient feels the urge to void. Anesthesia also impedes voluntary micturition. Anticholinergic and opioid drugs interfere with the ability to start voiding or to empty the bladder completely.

Urinary retention is more likely to occur after lower abdominal or pelvic surgery because spasms or guarding of the abdominal and pelvic muscles interferes with their normal function in micturition. Pain may alter perception and interfere with the patient's awareness of bladder filling. Immobility and bed rest impair voiding ability. The supine position reduces the ability to relax the perineal muscles and external sphincter.

Oliguria (diminished output of urine) can be a sign of renal failure and is a less common, although more serious, problem after surgery. It

may result from renal ischemia caused by inadequate renal perfusion.

Nursing Management: Urinary Problems

Nursing Assessment

Examine the urine for both quantity and quality. Note the color, amount, and odor of the urine. Assess indwelling catheters for patency. Urine output should be at least 0.5 mL/kg/hr. To decrease the risk for catheter-associated urinary tract infection (CAUTI), remove the catheter as soon as possible or within 24 hours, unless there is a reason to continue its use. Most patients void within 6 to 8 hours after surgery. If no voiding occurs, scan or percuss the suprapubic area for signs of bladder fullness or distention.

Nursing Diagnoses

Nursing diagnoses and collaborative problems related to urinary problems include:

- Urinary retention
- Potential complication: CAUTI, acute kidney injury

Nursing Implementation

Reassure the patient about the ability to void. You can promote voiding by helping the patient into a normal position. Other helpful techniques include providing privacy, running water, offering water for the patient to drink, or pouring warm water over the perineum. Walking, preferably to the bathroom, and the use of a bedside commode are other measures to help with voiding.

The HCP often leaves an order to catheterize the patient in 6 to 8 hours if voiding has not occurred. Because of the risk for CAUTI, first confirm that the bladder is full. Consider fluid intake during and after

surgery and determine bladder fullness (e.g., discomfort with bladder palpation). Scan the bladder with a portable ultrasound to assess volume of urine in the bladder and avoid unnecessary catheterization. If catheterization is needed, a straight catheterization, as compared to an indwelling catheter, is preferred to limit the risk for CAUTI.

Integumentary Problems

Etiology

Surgery generally involves an incision through the skin and underlying tissues, disrupting the protective skin barrier. Wound healing is a major concern after surgery. One of the greatest risks during the perioperative period is SSI. SSIs account for 14% to 16% of hospital-acquired infections and are associated with prolonged hospitalizations, increased costs, and poor patient outcomes.[17] Many are preventable with using evidence-based strategies (e.g., hand hygiene; selection, timing, and duration of prophylactic antibiotics; surgical site skin preparation; maintaining perioperative normothermia).[18] Adhering to these strategies can reduce the incidence of SSIs, a major goal of the SCIP initiative.[14]

SSIs may result from wound contamination from 3 major sources: (1) exogenous flora present in the environment and on the skin, (2) oral flora, and (3) intestinal flora. The incidence of SSI is higher in patients who are malnourished, immunosuppressed, or older, or who have had a long hospital stay or a lengthy surgical procedure (more than 3 hours). Patients post bowel surgery, particularly after a traumatic injury, are at high risk. SSI may involve the entire incision and may extend downward through deeper tissues. An abscess may form locally, or it may spread throughout entire body cavities, as in peritonitis.

Evidence of SSI usually does not become clear before the third to fifth postoperative day. Local manifestations include redness, swelling, and increasing pain and tenderness at the site. Systemic manifestations are fever and leukocytosis.

An accumulation of fluid in a wound may create pressure, impair circulation and wound healing, and predispose the patient to infection. To allow for drainage, the HCP may place a drain in the incision or make a stab wound next to the incision. Drains may be of soft rubber and drain into a dressing, or firm catheters attached to a Hemovac or other source of gentle suction.

Adequate nutrition is essential for wound healing. The patient who is well nourished before surgery can tolerate the lack of nutritional intake for several days. However, the patient with preexisting nutritional deficits that occur with chronic diseases (e.g., diabetes, ulcerative colitis, alcoholism) is more prone to problems of wound healing. The patient who cannot meet nutritional needs may need enteral or parenteral nutrition to promote healing.

Nursing Management: Surgical Wounds

Nursing Assessment

Assessment of the wound and dressing requires knowledge of the type of wound, the drains inserted, and expected drainage related to the specific type of surgery. Immediately after surgery, check the wound every 15 to 30 minutes or as ordered. When drainage appears on the dressing, record the type, amount, color, and odor of drainage. Assess the effect of position changes on drainage. A small amount of serous drainage is common from any type of wound. If a drain is in place, assess the amount of drainage and compare to what is expected. Expected drainage from tubes is outlined in Table 19.7. An abdominal incision with an accompanying drain will likely have a moderate amount of serosanguineous drainage in the first 24 hours. In contrast, an inguinal herniorrhaphy should have only minimal serous drainage.

In general, expect the drainage to change from sanguineous (red) to serosanguineous (pink) to serous (clear yellow). Purulent drainage may occur with an SSI. The drainage should decrease over hours or days, depending on the type of surgery. *Wound dehiscence* (separation

and disruption of previously joined wound edges) may be preceded by a sudden discharge of brown, pink, or clear drainage. (Wound dehiscence is discussed in Chapter 11.) Notify the HCP of any excess or abnormal drainage or significant changes in vital signs.

Nursing Diagnoses

Nursing diagnoses related to surgical wounds include:

- Surgical wound
- Risk for infection

Nursing Implementation

The incision may be covered with a dressing right after surgery. Many HCPs prefer to change the first postoperative dressing. If the initial operative dressing is saturated, follow agency policy as to whether you should change or simply reinforce the dressing. Skin graft dressings may stay in place for 3 to 5 days to avoid disturbing the graft site and promote graft acceptance. Specially trained nurses may change these dressings. (Skin grafts are discussed in Chapter 23.)

TABLE 19.7 Output From Tubes, Drains, and Catheters

Substance	Daily Amount	Color	Odor	Consistency
Indwelling Catheter				
Urine	800–1500 mL for first 24 hr Minimum expected output: 0.5 mL/kg/hr	Clear, yellow	Ammonia	Watery
Nasogastric Tube or Gastrostomy Tube				
Gastric contents	<1500 mL/day	Pale, yellow-green Bloody after GI surgery	Sour	Watery
Open Drains (e.g., Penrose)				
Wound drainage	Varies with procedure May decrease over hours or days	Varies with procedure Initially may be sanguineous or serosanguineous, changing to serous	Same as wound dressing Foul odor may indicate infection	Thin, watery
Closed Suction Drains (e.g., Hemovac, Jackson-Pratt)				
Wound drainage	Varies with procedure May decrease over hours or days	Varies with procedure Initially may be sanguineous or serosanguineous, changing to serous	Little to no odor Foul odor may indicate infection	Thin, watery
T-Tube				
Bile	500 mL	Bright yellow to dark green	Acid	Thick
Mediastinal Chest Tube				
Wound drainage post cardiothoracic surgery	Varies with procedure Should decrease over several hours after surgery	Sanguineous or serosanguineous	N/A	Thin
Pleural Chest Tube				
Fluid that has collected in the pleural space	Varies with procedure Decreases over hours or days >100 mL/hr is considered excessive	Varies with indication for insertion and fluid collected in the pleural spaces	N/A	Varies with indication for insertion

When you change a dressing, note the number and type of drains present and avoid dislodging the drains. Inspect the incision site carefully. The area around the sutures may be slightly reddened and swollen, which is an expected inflammatory response. However, the skin around the incision should be of normal color and temperature. If the wound is healing by primary intention, has little or no drainage, or has no drains in place, a single-layer dressing or no dressing is sufficient. Use a multilayer dressing when drains are in place, moderate to heavy drainage is occurring, or healing occurs other than by primary intention. (Wound healing and care are discussed in Chapter 11.)

Discharge from The Pacu

The choice of discharge site is based on patient acuity, access to follow-up care, and the potential for complications. The decision to

discharge the patient from the PACU is based on written discharge criteria approved by the agency's anesthesiology and medical staff[1] (Table 19.8). Standardized scoring systems (e.g., *Modified Aldrete Scoring System*) are often used to determine the patient's general condition and readiness for discharge from the PACU.

Discharge to Clinical Unit

Before discharging the patient from the PACU to the clinical unit, give a hand-off report about the patient to the receiving nurse. The report summarizes the operative and postanesthesia period. It should include information as to where the patient's caregivers are waiting. Nurse-to-nurse communication must be accurate and allow for questions. The use of a standardized communication tool, such as SBAR *(Situation-Background-Assessment-Recommendation),* provides a complete report and enhances a safe transfer of the patient from PACU to the clinical unit (Table 19.9).

When you receive the patient on the clinical unit, assist the PACU transport staff to safely move the patient from the stretcher to the bed. Take care to protect IV lines, drains, and traction devices. Obtain vital signs and compare the patient status with the report provided by the PACU nurse. After this, perform a more focused assessment and initiate postoperative orders and nursing care (Table 19.10).

TABLE 19.8 Surgery Discharge Criteria

PACU Discharge Criteria (Phase I)

- Patient awake, easily arousable (or baseline)
- Vital signs at baseline or stable
- No excess bleeding or drainage
- No respiratory depression
- O_2 saturation >90%

- Pain controlled or acceptable
- Nausea and vomiting controlled
- Report given

Ambulatory Surgery Discharge Criteria (Phase II or Extended Observation)

- All PACU discharge criteria (Phase I) met
- No IV opioid drugs for last 30 minutes
- Voided if appropriate to surgical procedure or orders
- Able to ambulate if not contraindicated
- Responsible adult present to accompany and drive patient home
- Written discharge instructions given and patient and caregiver understanding confirmed

TABLE 19.10 Nursing Assessment

Care of Patient on Admission to Clinical Unit

1. Record time of patient's return to unit and assess airway, breathing, and circulation.
2. Obtain baseline vital signs, including O_2 saturation.
3. Assess neurologic status, including level of consciousness and movement of extremities.
4. Assess level of pain:
    - Last dose and type of pain control
    - Current pain rating
5. Assess wound, dressing, and drainage tubes:
    - Type and amount of drainage
    - Tubing connected to gravity or suction drainage (per orders)
6. Assess color, temperature, and appearance of skin.
7. Position for airway maintenance, comfort, and safety (bed in low position, side rails up).
8. Check IV infusion:
    - Type of solution

- Amount of fluid remaining
- Patency and flow rate
- Condition of insertion site and size of catheter

9. Assess urinary status:
    - Time of voiding
    - Presence of catheter, patency, and total output
    - Bladder distention or urge to void
10. Assess for any nausea or vomiting.
    - Availability of emesis basin and tissues
11. Position call bell within reach, and orient patient to use of call bell.
12. Determine emotional state and provide support as needed.
13. Check for presence of caregiver.
    - Patient and caregiver oriented to immediate environment
14. Check and carry out postoperative orders.

Ambulatory Surgery

Phase II and Extended Observation

Advances in minimally invasive and noninvasive procedures, anesthesia, and analgesia have resulted in an increase in ambulatory surgical procedures. Ambulatory surgery patients include those patients receiving Phase II and extended observation postoperative care (Table 19.1). PONV and pain are common problems after ambulatory surgery. These can lead to delirium, prolonged PACU stay, delayed discharge, readmission, delayed resumption of usual activities, and decreased patient satisfaction.

Ambulatory Surgery Discharge

The patient leaving an ambulatory surgery setting must be hemodynamically stable, mobile, alert, and able to provide a degree of self-care when discharged to home (Table 19.8). PONV and pain must

be under control. Overall, the patient must be stable and near the level of preoperative functioning for discharge from the unit. The patient may not drive and must be accompanied by an adult at the time of discharge. Carefully assess the patient's readiness for discharge and home care needs. Determine availability of caregivers (e.g., family, friends) and access to (1) a pharmacy for prescriptions, (2) a phone in the case of an emergency, and (3) follow-up care.

Informatics in Practice

Discharge Teaching

- When discharging a patient who needs a complex dressing change and the written instructions are not adequate, consider using a video. This may be available on the hospital's television system or the Internet (e.g., YouTube).
- If using a video from the Internet, check to ensure that the procedure is properly performed.
- The patient and caregiver can view the video or pictures at home as a reference when performing the procedure.
- Have the patient and/or caregiver provide teach back information and/or demonstration.

Planning for Discharge and Follow-up Care

Preparation for the patient's discharge is an ongoing process that begins before surgery. Include the patient and caregiver in discharge planning and provide them with the information and support to make informed decisions about ongoing care. The informed patient is prepared as events unfold and gradually assumes more responsibility for self-care during the postoperative period.

As discharge approaches, be sure that the patient and caregiver(s) have the following information:

- Symptoms to report (e.g., fever, increased incisional drainage, unrelieved incisional pain, discomfort in other parts of the body)
- When and how to take prescribed drugs and possible side effects
- Care of incision and any dressings, including bathing recommendations
- Activities allowed and prohibited, when various activities can be resumed safely (e.g., driving, return to work, sexual intercourse, leisure activities)
- Dietary restrictions or modifications
- Where and when to return for follow-up appointment
- Answers to any questions or concerns

Common reasons patients seek help after discharge include unrelieved pain, need for advice about drugs, and wound issues (e.g., drainage). Attention to complete discharge instructions may prevent needless distress for the patient and caregiver. Standardized, preprinted discharge instructions that are surgery specific and easy to read ensure that information is complete.

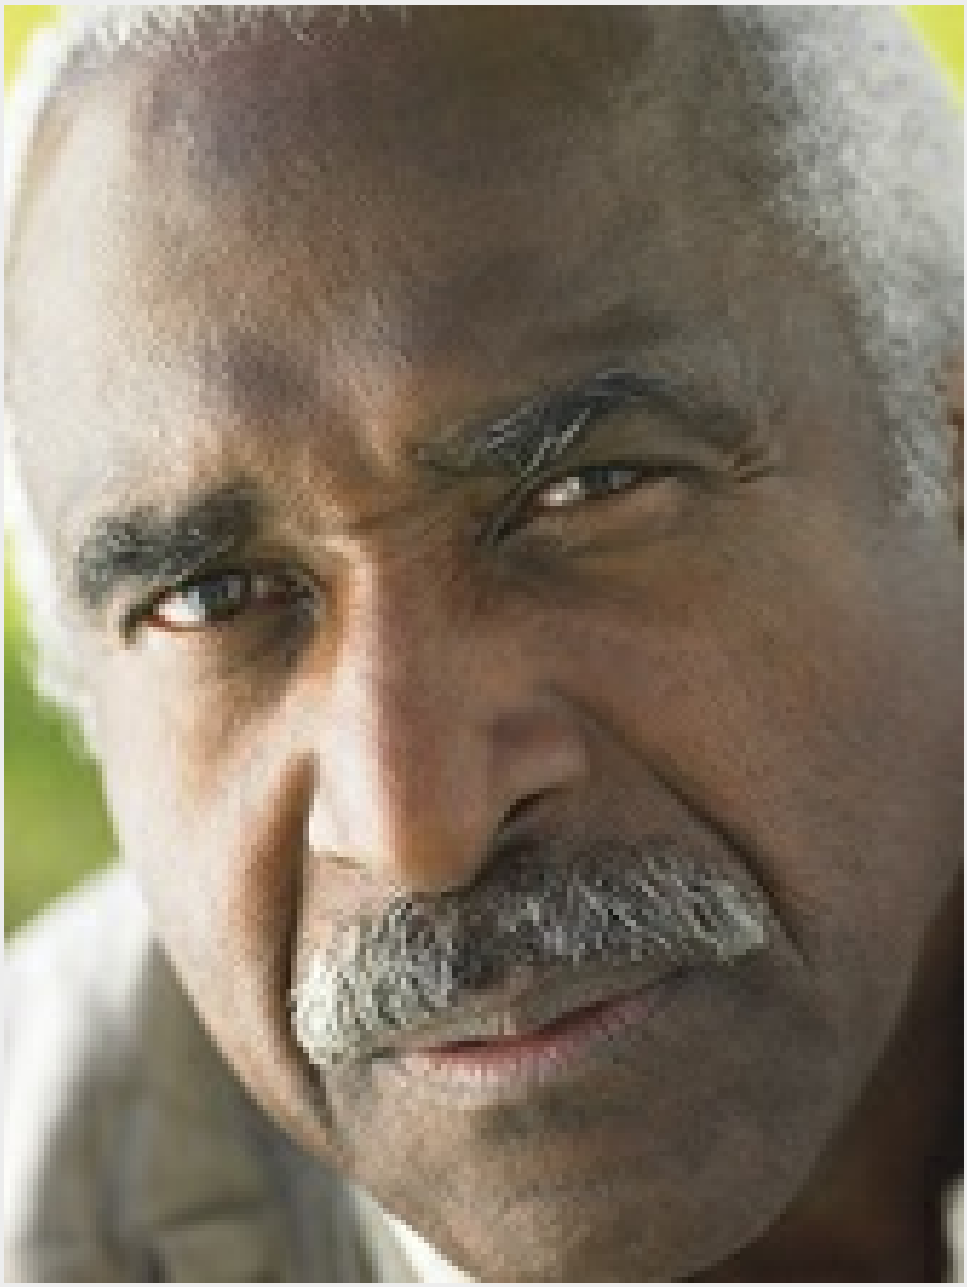
Record the discharge teaching in the chart. For the patient, the postoperative phase of care continues and extends into the recuperative period. Assessment and evaluation of the patient after discharge may be done with a follow-up call or by a visit from a home health nurse, who can address any specific questions and concerns.

Increasingly, patients are discharged from the hospital with many care needs. They may be transferred to transitional care facilities, to long-term care facilities, or directly to their homes. When discharged directly to home, the patient is expected to continue self-care, with help from caregivers or home health care personnel (e.g., nurses, physical therapists). The care may include dressing changes, wound care, catheter or drain care, home antibiotics, or continued physical therapy. Working together with the discharge planner or case manager, ensure the patient's safe transition from hospital-based care to community- or home-based care.

Gerontologic Considerations: Postoperative Patient

The older surgical patient deserves special consideration. The older adult has decreased respiratory function, including decreased ability to cough and decreased thoracic compliance. These changes lead to an increase in the work of breathing and a decreased ability to eliminate drugs. Carefully monitor reactions to anesthetic drugs. Pneumonia is a common complication in older adults.

Altered vascular function in the older adult is due to atherosclerosis and decreased elasticity in the blood vessels. Cardiac function is often compromised with limited compensatory responses to changes in BP and volume. Circulating blood volume decreases. Hypertension is common. Cardiovascular status needs to be monitored closely throughout surgery and the postoperative period.



Drug toxicity is a potential problem in the older adult. Renal perfusion normally decreases, along with a reduced ability to remove drugs that the kidneys excrete. Decreased liver function leads to reduced drug metabolism and increased drug activity. Carefully assess renal and liver function to prevent drug overdose and toxicity.

Observing for changes in mental status is an important part of postoperative care in older adults. Factors such as age, history of alcohol abuse, poor baseline cognition, hypoxia, metabolic imbalances, hypotension, and polypharmacy can contribute to postoperative delirium. Anesthetics, especially anticholinergic and benzodiazepine drugs, increase the risk for delirium.

Pain control in the older patient is challenging because of possible preexisting cognitive deficits, impaired communication, and physiologic changes that affect drug metabolism. Patients may hesitate to ask for pain medication because they believe pain is inevitable with surgery. Some older patients may fear addiction or be nervous about using PCA machines. Thoroughly assess pain in a surgical patient who does not report any pain. Encourage the use of analgesics. Explain to the patient and caregiver that untreated pain has a negative effect on recovery.

Case Study

Postoperative Patient

© BananaStock/BananaStock/Thinkstock.

Patient Profile

E.G., a 74-yr-old retired college professor, has just undergone surgery for a fractured hip. He fell off a ladder while painting his house. E.G.'s medical history includes type 2 diabetes and COPD. The surgery, done while he was under general anesthesia, lasted 3 hours.

Subjective Data

- Active walker in his home community
- Smokes 1 pack of cigarettes per day × 58 years
- Always had problems sleeping
- Difficulty hearing, wears hearing aid
- Upset with injury and its impact on life
- Is a widower and has no relatives nearby or friends to assist with care
- Reports pain is 8 on a 0 to 10 scale on arrival to PACU

Objective Data

- Admitted to PACU with abduction pillow between his legs, one peripheral IV catheter, a self-suction drain from the hip dressing, an indwelling urinary catheter
- O_2 saturation 91% on 40% O_2 face mask

Interprofessional Care

Postoperative Orders

- Vital signs per PACU routine
- Capillary blood glucose level on arrival and every 4 hours. Call for blood glucose level <70 mg/dL or >250 mg/dL. Follow agency guidelines for management of hypoglycemia.
- 0.45 normal saline at 100 mL/hr

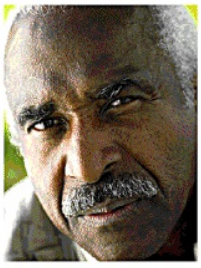
- Morphine via patient-controlled analgesia 1 mg q10min (20 mg max in 4 hr) for pain
- Advance diet as tolerated
- Incentive spirometry q1hr × 10 while awake
- O_2 therapy to keep O_2 saturation >90%
- Respiratory: albuterol 2.5 mg via nebulizer every 4 hours PRN for wheezing
- Neurovascular checks q1hr × 4 hr
- Empty and measure self-suction drain every shift
- Strict intake and output

Discussion Questions

1. What are the potential postanesthesia problems you may expect with E.G.?
2. ***Priority Decision:*** What priority nursing interventions would be appropriate to prevent these problems from occurring?
3. ***Collaboration:*** Which interventions could you delegate to unlicensed assistive personnel (UAP)?
4. What factors predispose E.G. to the following problems: atelectasis, SSI, and VTE?
5. How would you determine E.G. is sufficiently recovered from general anesthesia to be discharged to the clinical unit?
6. What potential postoperative problems on the clinical unit might you expect?
7. What are risk factors for his developing postoperative delirium? What are the signs and symptoms of delirium?
8. Why is drug toxicity a potential problem for E.G.?
9. ***Priority Decision:*** Based on the assessment data, identify 3 priority nursing diagnoses. Are there any collaborative problems?
10. ***Evidence-Based Practice:*** E.G. tells you he does not want the "catheter" out because he does not want anyone to help him to

the bathroom. How would you respond to this request?

11. ***Patient-Centered Care:*** What teaching will you provide so that E.G. can successfully self-manage his care?
12. ***Collaboration:*** What referrals may be indicated based on E.G.'s medical history?
13. ***Safety:*** Identify 2 areas of risk for injury to E.G. What actions can you take to ensure patient safety?
14. ***Quality Improvement:*** What outcomes would indicate that interprofessional care with respiratory therapy was effective?



Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Case Study

Managing Care of Multiple Patients

You have been called into work at 10:00 AM to cover patients for a nurse who had a family emergency. You take over care for the following 3 patients on a surgical unit. You have 1 UAP available who is assigned to help you. Two other RNs are on the unit.

Patients

 © Ryan McVay/Photodisc/Thinkstock.	F.D., a 72-yr-old woman, was admitted to the hospital with compromised circulation of the right lower leg and a necrotic right foot as a complication of her diabetes. She is scheduled for a below-the-knee amputation of the right leg at 1:00 PM today. She has been NPO since midnight. Her morning capillary blood glucose level was 198 mg/dL. She received 4 units of regular insulin at 8 AM. She has an IV of normal saline infusing at 125 mL/hr.
 © shironosov/iStock/Thinkstock.	G.S., a 63-yr-old man, was admitted to the hospital for severe pain and intractable vomiting from acute cholecystitis. G.S.'s medical history includes hypertension and type 2 diabetes. He had a laparoscopic cholecystectomy yesterday afternoon. His capillary blood glucose 1 hour ago was 135 mg/dL.
 © BananaStock/BananaStock/Thinkstock.	E.G., a 74-yr-old man, had surgery for a fractured hip yesterday. He is currently receiving dextrose 5% in 0.45 normal saline at 100 mL/hr, morphine via patient-controlled analgesia at 1 mg q10min (20 mg max in 4 hr) for pain, heparin 5000 units subcutaneously every 12 hours, and O_2 to keep O_2 saturation >93%. He has a self-suction drain in place at the surgical site. He has good respiratory effort when using his incentive spirometer.

Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide a rationale for your decision.
2. ***Collaboration:*** Which tasks should you delegate to the UAP? *(select all that apply)*
    a. Explain discharge instructions to G.S.
    b. Obtain noon vital signs on E.G. and F.D.
    c. Measure capillary blood glucose levels on F.D. and G.S.
    d. Confirm E.G.'s understanding of how to use the PCA pump.

e. Remind E.G. and G.S. to use their incentive spirometers every hour.

3. ***Priority Decision and Collaboration:*** When you enter F.D.'s room, you find her somewhat withdrawn and lethargic. Her face is cool and slightly clammy. What initial action would be most appropriate?
    a. Give 1 ampule of D_{50} IV stat.
    b. Increase F.D.'s IV rate to 150 mL/hr.
    c. Obtain a stat capillary blood glucose level.
    d. Ask the UAP to give F.D. a glass of orange juice.

Case Study Progression

F.D.'s capillary blood glucose reading was 52 mg/dL. You notify her HCP and give 1 ampule of D_{50} IV dextrose as ordered. You then change her IV infusion to D_5 ½NS. You check her capillary blood glucose within 15 minutes and then monitor her blood glucose levels each hour.

4. A preoperative checklist for F.D. is used to ensure completion of *(select all that apply)*
    a. removal of nail polish and jewelry.
    b. signed and witnessed informed consent.
    c. patient understanding of sensory information.
    d. identification of surgical site with surgical skin marker.
    e. notification of family of where to wait during the surgery.
5. F.D. tells you that she is afraid they may amputate the wrong leg. She tells you she has read stories of that happening at other hospitals. Your *best* response to F.D. would be to
    a. ask her if she would like a sedative to calm her fears.
    b. reassure her that it has never happened in this hospital.
    c. explain the "time-out" procedure for preventing such

errors.

d. offer to go to the operating room with her to ensure the correct leg is amputated.

6. ***Priority Decision:*** The laboratory calls to report that E.G.'s aPTT (activated partial thromboplastin time) is 84 seconds. You assess him and find that the hip dressing is saturated with serosanguinous drainage. The next dose of heparin is due at 2100 this evening; the last dose was at 0900 this morning. His blood pressure is 92/54 with a heart rate of 110 bpm. Respiratory rate is 30 breaths/min, and O_2 saturation is 98% on 2 L of O_2. The nursing *priority* for this patient would be to

   a. notify physical therapy that his session today will have to be postponed until evening.

   b. notify the previous RN that a medication error occurred with the patient's heparin dose at 0900.

   c. send an order to the laboratory for stat CBC and type and screen for 4 units of packed red blood cells.

   d. notify the provider of the aPTT result and anticipate orders for reversal agent, such as protamine.

7. ***Collaboration:*** Which instructions should you give to the UAP who will be helping E.G. with ADLs? *(Select all that apply.)*

   a. Use a soft toothbrush for oral care.

   b. Provide an emery board for nail care.

   c. Avoid overinflating blood pressure cuffs.

   d. Use an electric razor to shave the patient.

   e. Offer mouthwash with alcohol for rinsing.

8. ***Management Decision:*** When providing discharge instructions to G.S., he tells you that the UAP told him that he could do whatever activity he was comfortable doing—to let pain guide his progress. Your *initial* reaction to this statement should be to

   a. ask the UAP to clarify what was said to G.S.

   b. report the UAP's actions to the nurse manager.

   c. teach G.S. about the reason for activity restrictions.

   d. clarify the discharge instructions with the health care provider.

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Bridge to Nclex Examination

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. What are the *priority* interventions the nurse performs when admitting a patient to the PACU?
   a. Assess the surgical site, noting presence and character of drainage.
   b. Assess the amount of urine output and the presence of bladder distention.
   c. Assess for airway patency and quality of respirations and obtain vital signs.
   d. Review results of intraoperative laboratory values and medications received.
2. A patient is admitted to the PACU after major abdominal surgery. During the initial assessment the patient tells the nurse he thinks he is going to "throw up." A *priority* nursing intervention is to
   a. increase the rate of the IV fluids.
   b. give antiemetic medication as ordered.
   c. obtain vital signs, including O_2 saturation.
   d. position patient in lateral recovery position.
3. After admitting a postoperative patient to the clinical unit, which assessment data require the *most* immediate attention?
   a. O_2 saturation of 85%

b. Respiratory rate of 13/min

c. Temperature of 100.4°F (38°C)

d. Blood pressure of 90/60 mm Hg

4. A 70-kg postoperative patient has an average urine output of 25 mL/hr during the first 8 hours. The *priority* nursing intervention(s) given this assessment would be to

a. notify the surgeon and expect obtaining blood work to evaluate renal function.

b. perform a straight catheterization to measure the amount of urine in the bladder.

c. continue to monitor the patient because this is a normal finding during this time period.

d. evaluate the patient's fluid volume status since surgery and obtain a bladder ultrasound.

5. Discharge criteria for the Phase II patient include (*select all that apply*)

a. no nausea or vomiting.

b. ability to drive self home.

c. no respiratory depression.

d. written discharge instructions understood.

e. opioid pain medication given 45 minutes ago.

1. c, 2. d, 3. a, 4. d, 5. c, d, e

Assessment and Management

Visual Problems

Jonel L. Gomez

LEARNING OUTCOMES

1. Describe the structures and functions of the visual system.
2. Explain the physiologic processes involved in normal vision.
3. Obtain significant subjective and objective assessment data related to the visual system.
4. Perform a physical assessment of the visual system using the appropriate techniques.
5. Distinguish normal from common abnormal findings of a physical assessment of the visual system.
6. Link the age-related changes in the visual system to differences in assessment findings.
7. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the visual system.
8. Compare and contrast the types of refractive errors and appropriate corrections.
9. Describe the common causes and assistive measures for severe visual impairment.
10. Discuss nursing measures that promote eye health.

11. Explain the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with ocular disorders.
12. Discuss the general preoperative and postoperative care of patients undergoing surgery of the eye.

Sensory Perception

Visual System

For people to be as independent as possible and take part in fulfilling activities, it is important that the visual system is as functional as possible. The impact of poor vision or blindness can be devastating to activities of daily living (ADLs) and independence. The psychosocial consequences can include decreased quality of life, social isolation, depression, and loss of self-esteem. Vision loss also takes a huge toll on caregivers. This makes our being involved in vision-loss prevention, detection, and treatment strategies important.

Structures and Functions of Visual System

The visual system is part of the central nervous system (CNS). It consists of 2 main parts, the eyes, which contain the image receptors, and the brain. The brain functions to process and interpret the information transmitted from the receptors into images. Anatomically, the visual system is made up of the orbit, the ocular adnexa (external tissues and structures surrounding the eye), the eye, and the visual pathway (optic nerve, optic chiasm, lateral geniculate nucleus, and visual cortex). The entire visual system is important for visual function.

Periocular Structures

Orbit

The orbits, or eye sockets, are the bony structures that house the eyeballs. Seven bones form the orbit: frontal, zygoma, maxilla, ethmoid, sphenoid, lacrimal, and palatine (Fig. 20.1). The average orbit is 35 mm high and 40 mm wide. In addition to the eye, the orbits contain the associated muscles, nerves, blood vessels, and fat.[1]

Within the orbit are 3 main orbital openings, or *fissures,* the optic canal, the superior orbital fissure, and the inferior orbital fissure. They are all important conduits for arteries, veins, and nerves. The optic canal is located at the top of the socket. It provides an entry point for the optic nerve (CN II). The superior orbital fissure is a small slit in the posterior orbit. It is the main entry point for several other cranial nerves to enter the orbit from the brain. These include the oculomotor nerve (CN III), trochlear nerve (CN IV), trigeminal nerve (CN V), and abducens nerve (CN VI). The inferior orbital fissure is in the floor of the orbit. It holds the zygomatic branch of the maxillary nerve.

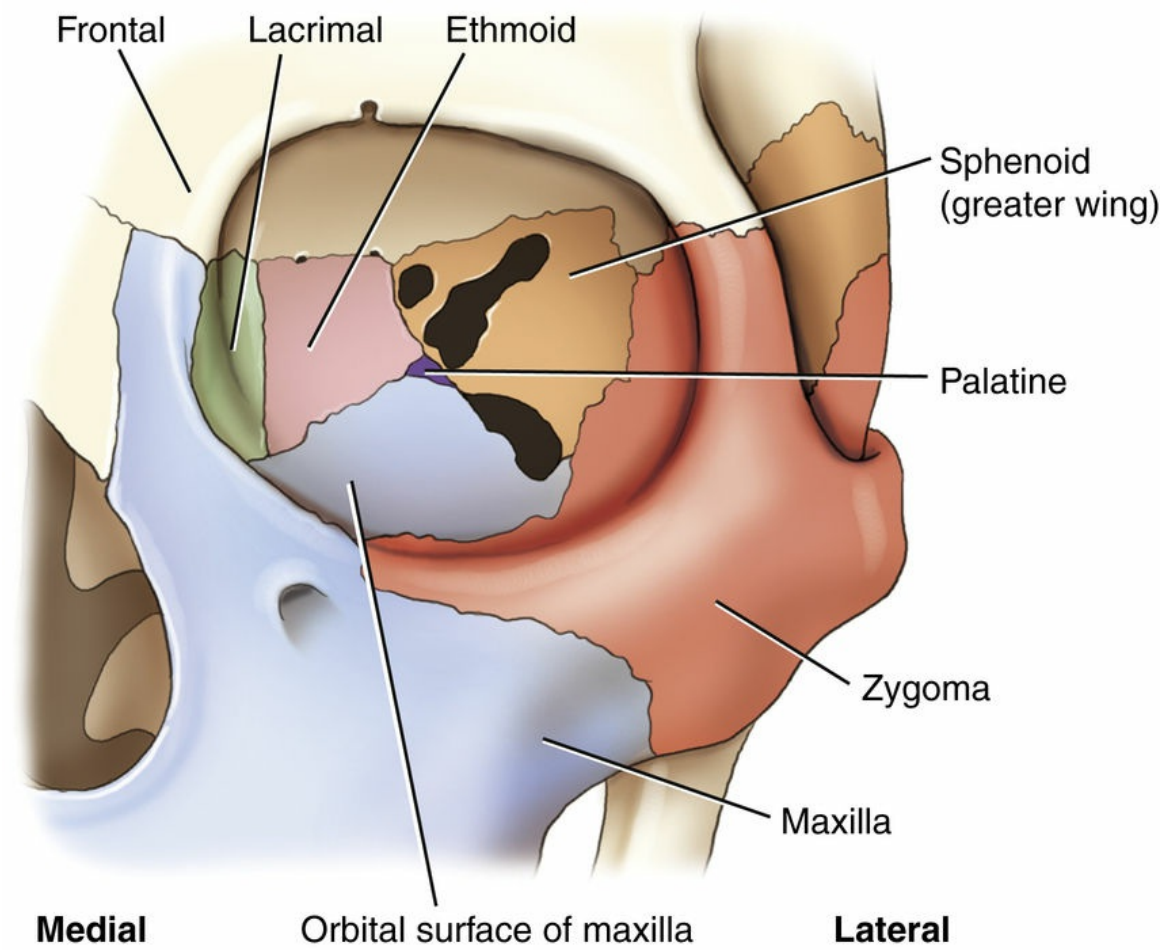

FIG. 20.1 Bones that form the orbit, or eye socket.
From Lampignano J, Kendrick L: *Bontrager's textbook of radiographic positioning and related anatomy*, ed 9, St Louis, 2018, Mosby.

There are 6 extraocular muscles: (1) superior and inferior rectus muscles, (2) medial and lateral rectus muscles, and (3) superior and inferior oblique muscles. They emerge from the apex of the orbit and attach to the eye to stabilize and move it (Fig. 20.2). Neuromuscular coordination produces simultaneous movement of the eyes in the same direction.

Ocular Adnexa

The ocular adnexa include the eyebrows, eyelids, eyelashes, and lacrimal system. Eyebrows, eyelids, and eyelashes are vital in protecting the eye. They are a physical barrier to dust and foreign particles. Blinking protects the eye from injury, distributes tears over

the anterior surface of the eyeball, and supplies necessary nourishment to surface cells.

The upper and lower eyelids join at the medial and lateral canthi. Eyelid skin is the thinnest skin in the human body, measuring less than 1 mm thick. The upper eyelids contain the levator palpebrae superioris muscle, innervated by the superior division of CN III. This muscle elevates and retracts the upper eyelid. The eyelids close through the action of the orbicularis muscle, which is innervated by CN VII.

Lacrimal System

The lacrimal system includes the structures needed for tear production and drainage. The main lacrimal gland and accessory lacrimal glands make tears. The lacrimal glands, in the superotemporal orbit, are exocrine glands. They make and secrete the aqueous layer of tear film and are responsible for reflex tear production. The tear film moistens the eye and supplies oxygen to the cornea. The accessory lacrimal glands, the *glands of Wolfring* and *glands of Krause,* are found within the conjunctiva of the upper eyelid. They are responsible for baseline tear production. Tears pass over the surface of the eye and then enter the nasolacrimal system. The nasolacrimal drainage system includes the puncta, canaliculi, lacrimal sac, and nasolacrimal duct (Fig. 20.3).

Eyeball

The eyeball, or globe, is composed of 3 layers (Fig 20.4). The tough outer layer is composed of the cornea, conjunctiva, and sclera. The middle layer consists of the uveal tract (iris, choroid and ciliary body), and the innermost layer, the retina. The *anterior cavity* is divided into the anterior and posterior chambers. The anterior chamber lies between the iris and posterior surface of the cornea. The posterior chamber lies between the anterior surface of the lens and posterior surface of the iris. The *posterior cavity* lies in the large space behind the lens and in front of the retina.

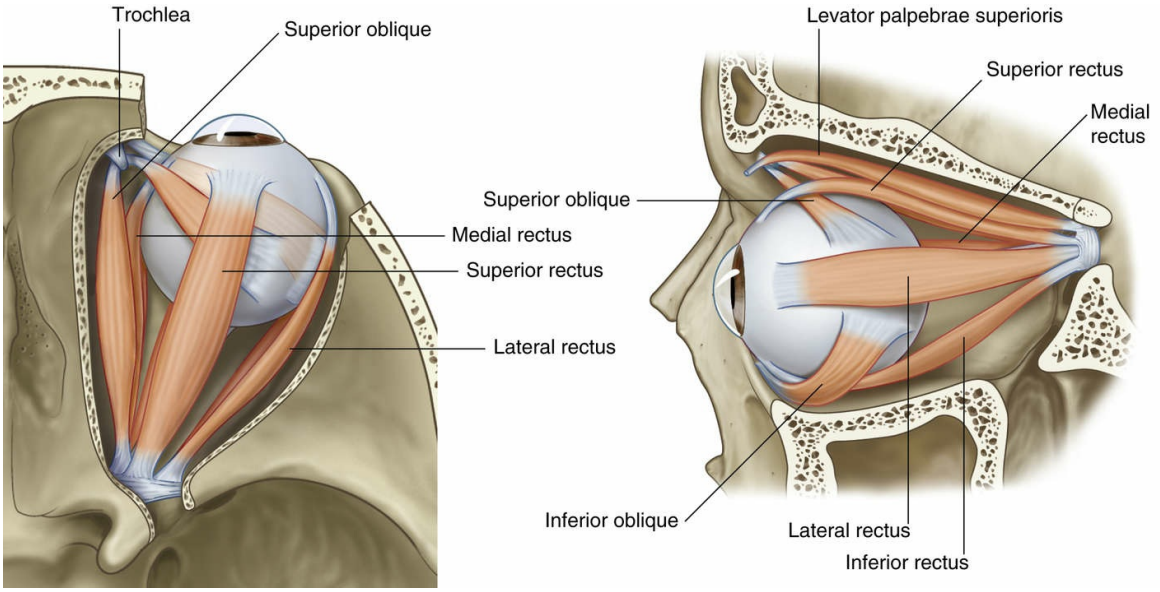

FIG. 20.2 The 6 extraocular muscles.
From Drake R, Vogl AW, Mitchell AWM: *Gray's anatomy for students,* ed 3, Philadelphia, 2015, Churchill Livingstone.

External Ocular Structures

The conjunctiva is a transparent mucous membrane that covers the inner surfaces of the eyelids and extends over the sclera. Glands in the conjunctiva secrete mucus and tears. Tenon's capsule, also called the fascia bulbi, is a thin layer of fascia that encases the eyeball behind the conjunctiva. The capsule extends posteriorly, ultimately fusing with the optic nerve.

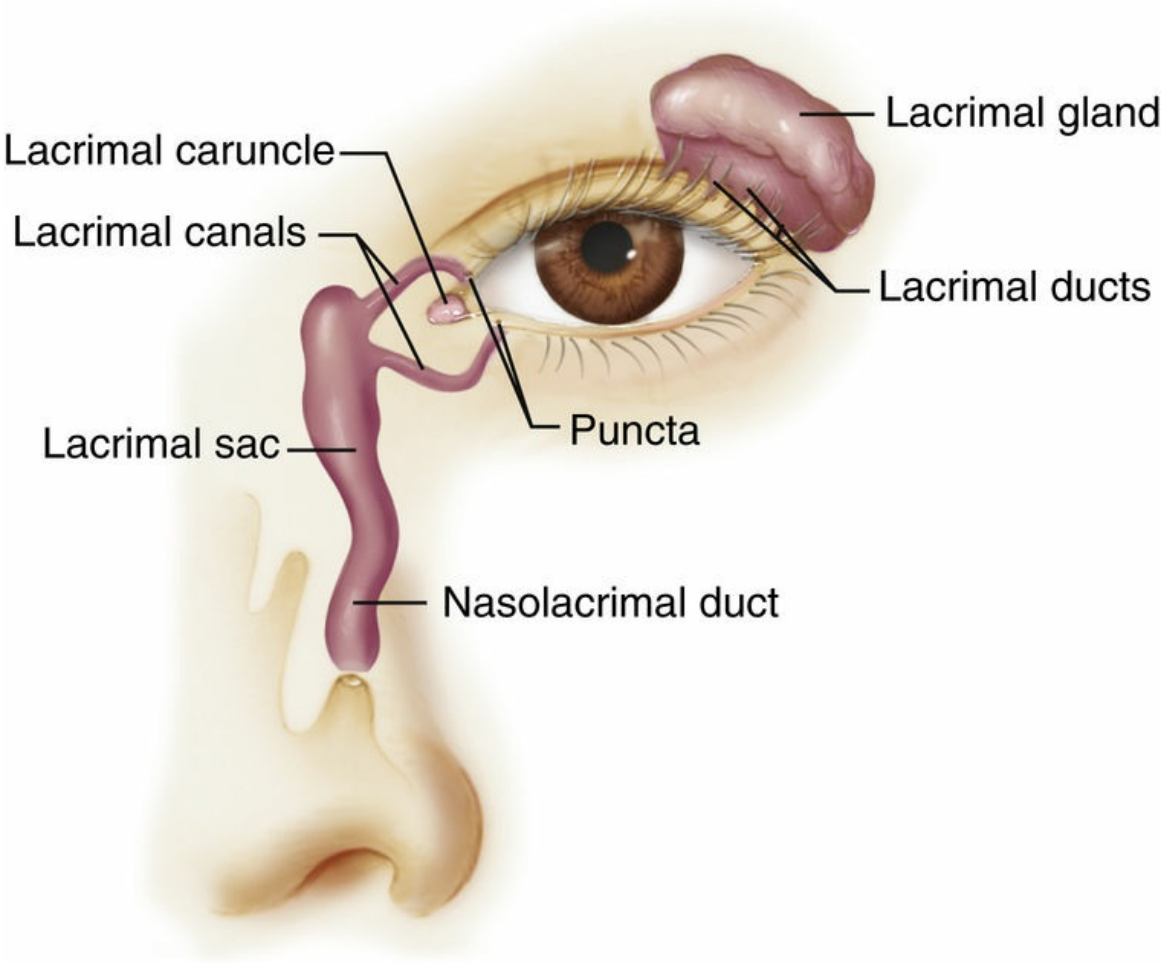

FIG. 20.3 External eye and lacrimal apparatus. Tears made in the lacrimal gland pass over the surface of the eye and enter the lacrimal canal. From there the tears are carried through the nasolacrimal duct to the nasal cavity.
Modified from Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 8, St Louis, 2013, Mosby.

The cornea allows light to enter the eye. It is transparent and avascular. Its curved shape refracts or bends incoming light rays to help focus them on the retina. The cornea has 6 layers: epithelium, Bowman's layer, stroma, Descemet's membrane, Dua's layer, and endothelium.

The sclera, the white part of the eye, is a fibrous connective tissue layer that protects the eye and helps the eye maintain its shape and structure. The sclera extends from the cornea to the optic nerve. We call the junction of the sclera and cornea the limbus.

Middle Ocular Structures

The iris gives the eye its color. It has a small round opening in the center, the *pupil,* which allows light to enter the eye. The pupil constricts by action of the iris sphincter muscle (under parasympathetic control) and dilates by action of the iris dilator muscle (under sympathetic control). This controls the amount of light that enters the eye.

The ciliary body contains the ciliary muscle and ciliary processes. It is behind the iris. The ciliary muscle helps us focus by changing the shape of the lens to refract light onto the retina. The ciliary processes make aqueous humor for both the anterior and posterior chamber. The choroid is a highly vascular structure that nourishes the ciliary body, iris, and outer part of the retina. It lies inside and parallel to the sclera.

Internal Structures

Aqueous Humor

Aqueous humor fills the anterior chamber of the eye. It is a clear watery fluid composed of electrolytes, growth factors, and proteins. It nourishes the nonvascular structures of the anterior chamber, such as the lens. Aqueous humor is made from capillary blood in the ciliary body. It is secreted into the posterior chamber and flows through the pupil to enter the anterior chamber. Aqueous humor exits the eye through the *trabecular meshwork* and into the *canal of Schlemm* and venous circulation or through the ciliary muscle. Balanced secretion and excretion of aqueous humor is important. Excess production or decreased outflow can increase intraocular pressure (IOP) above the normal 10 to 21 mm Hg, a condition termed *glaucoma.*

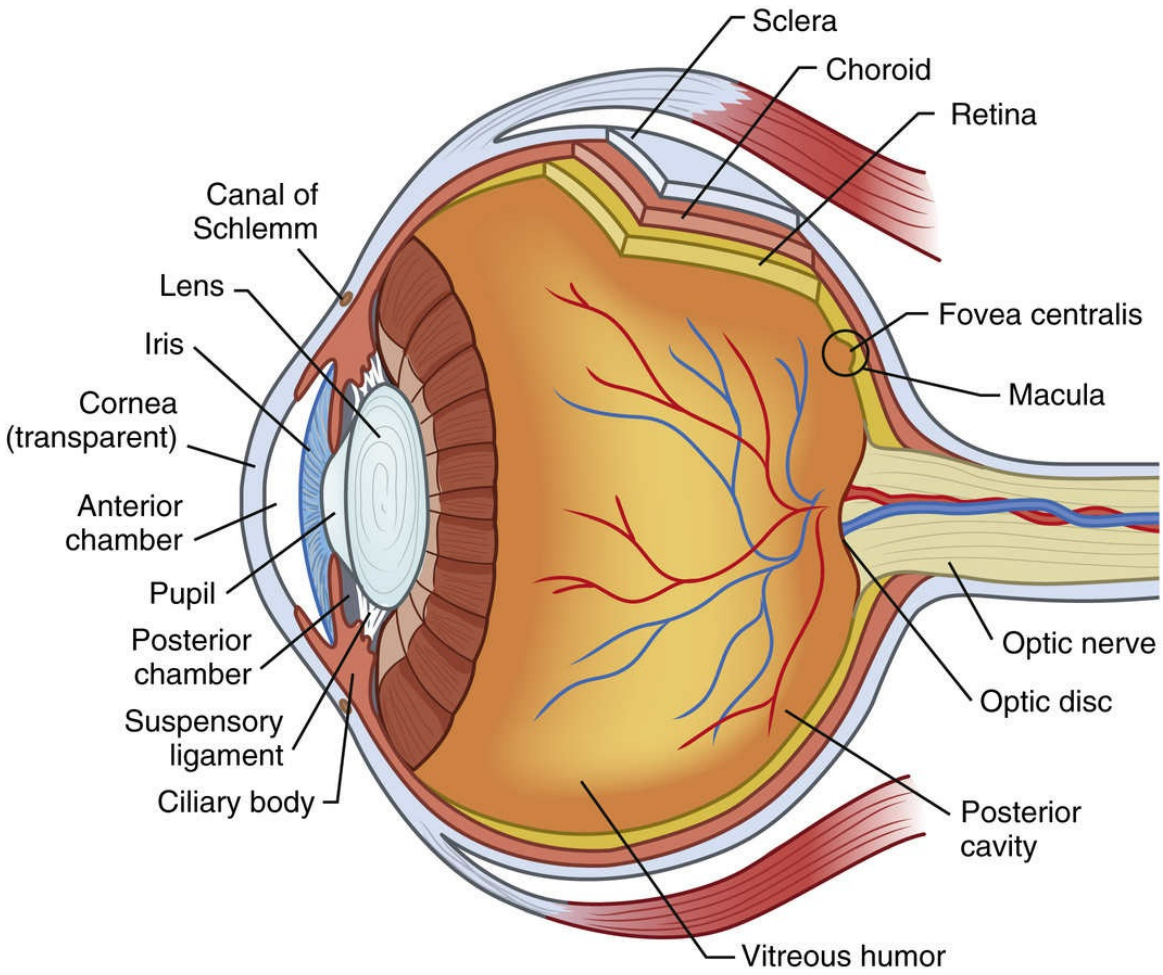

FIG. 20.4 The human eye.
Modified from Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 8, St Louis, 2013, Mosby.

Lens

The lens is a biconvex structure behind the iris. It is kept in place by small fibers collectively called the suspensory ligament, or the zonule. The ligament is a series of microscopic wire-like threads that connect the lens to the ciliary body. The primary function of the lens is to change shape to alter the focal distance of the eye. It works with the cornea to refract, or bend light. The lens shape is changed by action of the ciliary body as part of accommodation, a process that allows a person to focus. An example of accommodation is the ability to focus on near objects, such as when reading.

Vitreous Humor

The retina lines the back of the eye, extending from the area of the optic nerve to the ciliary body (Fig. 20.4). Neurons make up most of the retina. Therefore retinal cells are unable to regenerate if destroyed. The retina converts images into a form that the brain can understand and process as vision.

The retina has 2 main parts, the peripheral retina and central retina. The central retina contains the macula and fovea. The macula is about 6 mm in diameter. It is responsible for the central visual field. The fovea is at the center of the macula. This area provides the sharpest visual acuity, which we need for activities in which detail is important, like reading and driving.

The retina contains light-sensitive structures called photoreceptor cells. There are 2 types of photoreceptors, rods and cones. Rods and cones convert light to neural signals, which the nervous system translates into vision. Rods are mostly found in the peripheral retina. They are responsible for most of our peripheral vision and night vision. Rods only perceive light and dark and do not contribute to color vision. Cones are in the central retina, condensed mostly in the fovea. They are responsible for central vision and color vision. There are 3 types of cone cells, red, green, and blue. They all work together to create the full color spectrum.

The retina receives oxygen and nutrients from the choroid and the retinal vasculature. The central retinal artery carries blood and nutrients into the retina. The central retinal vein carries blood away from the retina.

Optic Nerve

The optic nerve, or CN II, transmits visual information from the retina to the brain. The optic nerve begins at the optic disc, which is the region of the retina where the optic nerve and vessels leave the retina. Because there are no photoreceptor cells over the optic disc, there is an anatomic blind spot in this area. In the center of the optic disc is a white, cup-shaped area called the optic cup.

Visual Pathway

For light to reach the retina, it must pass through many structures: the cornea, aqueous humor, lens, and vitreous humor. These structures must be clear for light to reach the retina and stimulate the photoreceptor cells. Once the image travels through the refractive media, it is focused on the retina (Fig. 20.5). From the retina, the impulses travel through the optic nerve to the optic chiasm, where the nasal fibers of each eye cross over to the other side. Fibers from the left field of both eyes form the left optic tract and travel to the left occipital cortex. The fibers from the right field of both eyes form the right optic tract and travel to the right occipital cortex.

Gerontologic Considerations: Effects of Aging on the Visual System

Every structure of the visual system is subject to changes as a person ages. While many of these changes are relatively benign, others may result in severely compromised visual acuity in the older adult. Age-related changes in the visual system and differences in assessment findings are shown in Table 20.1.

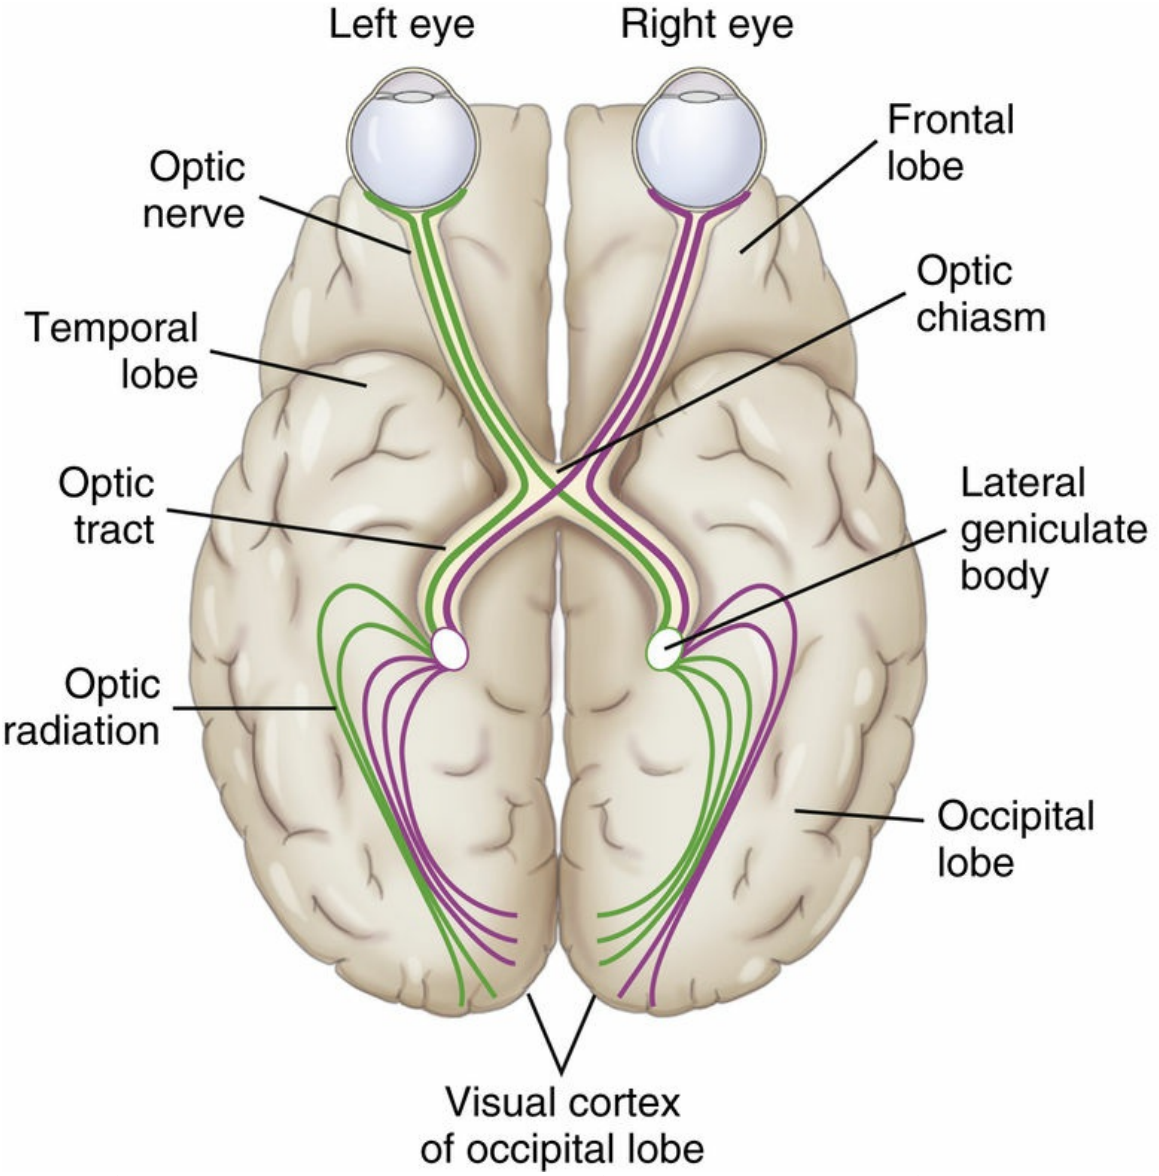

FIG. 20.5 The visual pathway. Fibers from the nasal portion of each retina cross over to the opposite side of the optic chiasma, ending in the lateral geniculate body of the opposite side. Location of a lesion in the visual pathway determines the resulting visual defect.

Assessment of Visual System

Assessment of the visual system may be as simple as determining a patient's visual acuity or as complex as collecting complete subjective and objective data pertinent to the visual system. The patient in a clinic or office setting is often seeking routine eye care or a change in

the prescription of eyewear. However, the patient may have some underlying concerns that he or she does not mention or even recognize. To perform an appropriate visual evaluation, assess what is necessary for the specific patient. While many of these assessments are within your scope of practice, some require special training.

Case Study

Patient Introduction

© Jack Hollingsworth/Photodisc/Thinkstock.

F.M. is an 81-yr-old Hispanic woman who comes to the emergency department with visual changes. F.M. states that her vision “looks like everything is covered with a spider web.” She reports seeing periodic light flashes and small white spots “floating” in the air.

Discussion Questions

1. What are the possible causes of F.M.'s vision problems?
2. What type of assessment would be most appropriate for F.M.: comprehensive, focused, or emergency?
3. What assessment questions will you ask her?

You will learn more about F.M. and her condition as you read through this assessment chapter.

(See p. 354 for more information on F.M.)

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

TABLE 20.1 Gerontologic Assessment DifferencesVisual System

Changes	Differences in Assessment Findings
Eyebrows and Eyelashes	
Loss of pigment in hair	Graying of eyebrows, eyelashes
Eyelids	
Loss of orbital fat, decreased muscle tone	Entropion, ectropion
Tissue atrophy and stretching, prolapse of fat into eyelid tissue, loosening of the levator palpebrae superioris muscle	Dermatochalasis (excess upper lid skin), ptosis
Conjunctiva	
Tissue damage related to chronic exposure to ultraviolet light or to other chronic environmental exposure	Pinguecula (small yellowish spot usually on medial aspect of conjunctiva)
Sclera	
Lipid deposition	Scleral color yellowish as opposed to bluish
Cornea	
Cholesterol deposits in peripheral cornea	Arcus senilis (milky white-gray ring encircling periphery of cornea) (Fig. 20.6)
Tissue damage related to chronic exposure	Pterygium (thickened, triangular bit of pale tissue that extends from inner canthus of eye to nasal border of cornea)
Decrease in water content, atrophy of nerve fibers	Decreased corneal sensitivity and corneal reflex
Epithelial changes	Loss of corneal luster
Accumulation of lipid deposits	Blurring of vision
Lacrimal Apparatus	
Decreased tear secretion	Dryness
Malposition of eyelid and punctal eversion resulting in tears overflowing lid margins instead of draining through puncta	Tearing, irritated eyes
Iris	
Increased rigidity of iris	Decreased pupil size
Dilator muscle atrophy or weakness	Slower recovery of pupil size after light stimulation
Loss of pigment	Change of iris color
Ciliary muscle becoming smaller, stiffer	Decrease in near vision and accommodation
Lens	
Biochemical changes in lens proteins, oxidative damage, chronic exposure to ultraviolet light	Cataracts
Increased rigidity of lens	Presbyopia
Opacities in lens (also may be related to opacities in cornea and vitreous)	Reports of glare, night vision impaired
Accumulation of yellow substances	Yellow color of lens
Retina	
Retinal vascular changes related to atherosclerosis and hypertension	Narrowed, pale, straighter arterioles. Acute branching
Decrease in number of cones	Changes in color perception, especially blue and violet
Loss of photoreceptor cells, retinal pigment, epithelial cells, and melanin	Decreased visual acuity
Age-related macular degeneration because of vascular changes	Loss of central vision, presence of yellow deposits, atrophy of macular retinal pigment
Vitreous	
Liquefaction and detachment of vitreous	Increased "floaters"

Subjective Data

Important Health Information

Past Health History

Take information about the patient's past health history, including the

ocular and nonocular history. The patient's nonocular history can be significant in assessing and treating an eye condition. Ask the patient about systemic diseases that may have ocular manifestations. These include diabetes, hypertension, cancer, rheumatoid arthritis, syphilis and other sexually transmitted infections (STIs), acquired immunodeficiency syndrome (AIDS), muscular dystrophy, myasthenia gravis, multiple sclerosis, inflammatory bowel disease, and hypothyroidism or hyperthyroidism. Include any history of stroke or neurologic problems as these have the potential to result in visual field defects.

Obtain a history of tests for visual acuity, including the date of the last examination and change in glasses or contact lenses. Ask the patient about a history of strabismus, amblyopia, cataracts, retinal detachment, refractive surgery, or glaucoma. Note any trauma to the eye, its treatment, and sequelae.

Obtain information about allergies. Allergies often cause eye symptoms, such as itching, burning, watering, drainage, and blurred vision.

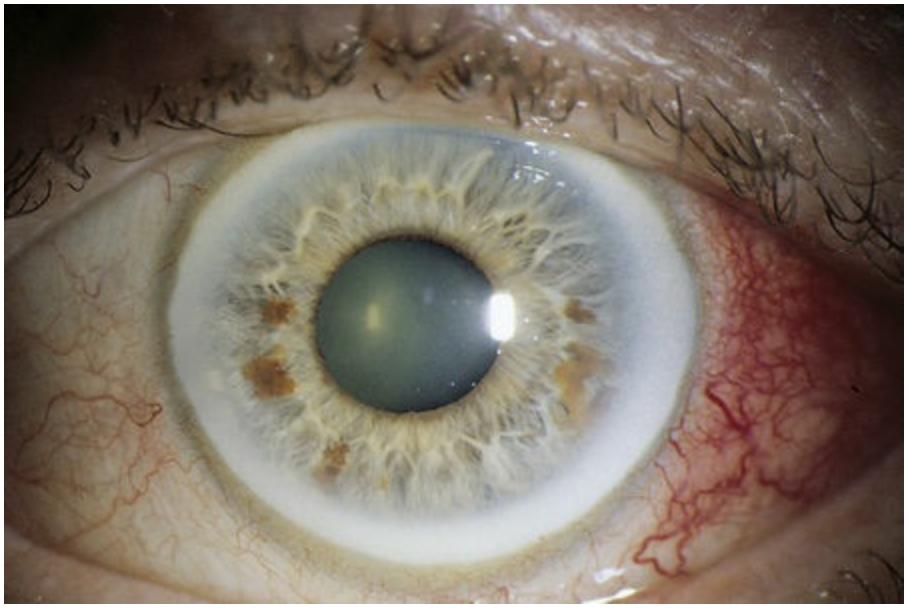

FIG. 20.6 Arcus senilis, or age-related degeneration of the cornea. From Kanski JJ: *Clinical ophthalmology: A synopsis,* ed 2, New York, 2009, Butterworth-Heinemann.

Medications

Obtain a complete medication history, including dosage and frequency of over-the-counter (OTC) medicines, eyedrops, herbal therapies, and dietary supplements. Many of these drugs have ocular effects. For example, many cold preparations contain a form of epinephrine (e.g., pseudoephedrine) that can dilate the pupil. Note the use of any antihistamine or decongestant, since these drugs can cause ocular dryness. Ask whether the patient uses any prescription drugs, such as corticosteroids, thyroid medications, or oral hypoglycemics and insulin. Long-term use of corticosteroid preparations can contribute to the development of glaucoma or cataracts.[2] Note whether the patient is taking any β-blockers, since β-blockers used to treat glaucoma can potentiate their effects. Hydroxychloroquine, which is used to treat rheumatoid arthritis and other autoimmune diseases, has the potential to result in retinal toxicity. It is important that these patients have annual comprehensive eye examinations.

Surgery or Other Treatments

Obtain a comprehensive history of both ocular and nonocular surgeries. Include laser-based surgery and invasive treatments, such as retinal injections.

Functional Health Patterns

The focus of the functional health pattern assessment depends on the presence or absence of vision loss and whether the loss is permanent or temporary. Table 20.2 lists suggested health history questions related to the functional health patterns.

Health Perception–Health Management Pattern

Patient characteristics, such as gender, ethnicity, and age, are important in assessing eye problems. Men are more likely than women to have color blindness. The leading cause of blindness among blacks is glaucoma.[3]

The patient's visual health can affect activities at home or at work. It is important to know how the patient perceives the current health problem. As outlined in Table 20.2, guide the patient in describing the current problem. Assess the patient's ability to perform self-care, especially any eye care related to the patient's eye problem.

The patient may not recognize the importance of eye-safety practices, like wearing protective eyewear during potentially hazardous activities or avoiding noxious fumes and other eye irritants. Ask about the use of sunglasses in bright light. Prolonged exposure to ultraviolet (UV) light can affect the retina. Ask about night driving habits and any problems encountered. Today, millions of people wear contact lenses, but many do not care for them properly. The type of contact lenses used and the patient's wearing and care habits may provide an opportunity for teaching.

TABLE 20.2 Health HistoryVisual System

Health Perception–Health Management

- Describe the change in your vision. Describe how this affects your daily life.
- Do you wear protective eyewear (sunglasses, safety goggles, hats)?*
- Do you wear contact lenses? If so, how do you take care of them?
- If you use eyedrops, how do you instill them?
- Do you have any allergies that cause eye symptoms?*
- Do you have a family history of cataracts, glaucoma, or macular degeneration?*

Nutritional-Metabolic

- Do you take any nutritional supplements?*

- Does your visual problem affect your ability to obtain and prepare food?*

Elimination

- Do you have to strain to void or defecate?*

Activity-Exercise

- Are your activities limited in any way by your eye problem?*
- Do you take part in any leisure activities that have the potential for eye injury?*

Sleep-Rest

- Is your vision affected by the amount of sleep you get?*
- Does your eye problem affect your sleeping patterns?*

Cognitive-Perceptual

- Does your eye problem affect your ability to read?*
- Do you have any eye pain?*
- Do you have any eye itching, burning, or foreign body sensation? *

Self-Perception–Self-Concept

- How does your eye problem make you feel about yourself?

Role-Relationship

- Do you have any problems at work or home because of your eyes?*
- Have you made any changes in your social activities because of your eyes?*

Sexuality-Reproductive

- Has your eye problem caused a change in your sex life?*
- For women: Are you pregnant? Do you use birth control pills?*
- For men: Do you use any erectile dysfunction drugs? Any vision problems with their use?*

Coping–Stress Tolerance

- Do you feel able to cope with your eye problem?*
- How do you feel that your eye problem has affected your life, and how do you cope with these changes?*

Value-Belief

- Do you have any conflicts about the treatment of your eye problem?*

---

* If yes, describe.

Hereditary systemic diseases (e.g., sickle cell anemia) can significantly affect eye health. In addition, many refractive errors and

other eye problems are hereditary. Ask whether the patient has a family history of arteriosclerosis, diabetes, thyroid disease, hypertension, arthritis, or cancer. Determine whether the patient has a family history of eye problems, including cataracts, tumors, glaucoma, refractive errors (especially myopia, hyperopia), and retinal degenerative conditions (e.g., macular degeneration, retinal detachment).

Genetic Risk Alert

Glaucoma

- Certain types of glaucoma have a strong genetic link. We have discovered many different glaucoma genes.
- The risk for developing glaucoma is higher in people with a positive family history.

Age-Related Macular Degeneration (AMD)

- Some cases of AMD have a genetic link. Multiple genes may be associated with AMD.

Nutritional-Metabolic Pattern

High doses of vitamins containing antioxidant, carotenoids, and omega-3 fatty acids (vitamins C and E, beta-carotene, zinc) may be important to ocular health. Some patients with age-related macular degeneration (AMD) may benefit from supplements of these vitamins.

Elimination Pattern

Straining to defecate (Valsalva maneuver) can raise IOP. After patients have eye surgery, many HCPs do not want them to strain. Assess the patient's usual pattern of elimination and determine whether there is

the potential for constipation in the patient who has had eye surgery.

Activity-Exercise Pattern

The patient's usual level of activity or exercise may be affected by reduced vision, symptoms accompanying an eye problem, or activity restrictions after surgery. Ask about leisure activities during which the patient may incur an eye injury. For example, gardening, woodworking, and other craft activities can result in corneal or conjunctival foreign bodies or even penetrating injuries of the globe. Sports activities, such as racquetball, baseball, and tennis, carry risks for blunt trauma to the eyes. People should wear protection goggles for these sports.

Sleep-Rest Pattern

In the otherwise healthy person, lack of sleep may cause ocular irritation, especially if the patient wears contact lenses. Painful eye problems, such as corneal abrasions, may disrupt normal sleep patterns.

Cognitive-Perceptual Pattern

Assess for other cognitive or perceptual problems. For example, the functional ability of a patient with a visual deficit will be further compromised if the patient also has hearing problems. The patient who cannot see to read may find it harder to follow discharge instructions if he or she also has trouble hearing or remembering verbal instructions. Eye pain is always an important symptom to assess. If eye pain is present, ask the patient about treatment and response.

Self-Perception–Self-Concept Pattern

The loss of independence that can follow a partial or complete loss of vision, even if the condition is temporary, can have devastating effects on the patient's self-concept. Evaluate the potential effect of vision loss on the patient's self-image. For instance, disabling glare from a

cataract may prevent nighttime driving. In today's highly mobile society, losing the ability to drive can represent a significant loss of independence and self-esteem.

Role-Relationship Pattern

Eye problems can negatively affect the patient's ability to take part in roles and responsibilities in the home, work, and social environments. For example, with decreased visual acuity, the patient may no longer adequately function at work. Many occupations place workers in conditions in which eye injury may occur. For example, factory workers may be at risk from flying metal debris. Eye-safety practices, such as the use of goggles or safety glasses, are now a legal requirement in some workplaces. The patient with diabetes may not be able to see well enough to self-administer insulin. This patient may resent dependence on a caregiver who takes over this function. Sensitively ask if the problem has affected the patient's preferred roles and responsibilities.

Sexuality-Reproductive Pattern

The patient with severe vision loss may develop such a poor self-image that the ability to be sexually intimate is lost. Assure the patient that low vision or blindness does not affect a person's ability to be sexually expressive. Often touch is more important than vision.

Coping–Stress Tolerance Pattern

The patient with temporary or permanent visual problems may have emotional stress. Assess the patient's coping strategies and availability of support systems.

Value-Belief Pattern

Be sensitive to each patient's individual values and spiritual beliefs as these may guide decisions about eye care. It can be hard to understand why a patient refuses treatment that has potential benefit or wants treatment that may have limited potential benefit.

Case Study

Subjective Data

© Jack Hollingsworth/Photodisc/Thinkstock.

A focused subjective assessment of F.M. revealed the following information:

- ***PMH:*** Extraocular extraction of cataract on right eye (OD) with implantation of intraocular lens 2 mo ago. Type 2 diabetes, hypothyroidism, and hypertension.
- ***Medications:*** Glucophage 500 mg twice daily, levothyroxine 100 mcg daily, metoprolol 50 mg daily.
- ***Health Perception–Health Management:*** States she used antibiotic and corticosteroid eyedrops after surgery as directed and followed-up with surgeon. Recovery was uneventful. Eyedrops were stopped 2 wk ago. Does not have allergies. Had excellent eyesight until today.
- ***Elimination:*** Has had problems moving bowels with increased straining. Trying prune juice to help.
- ***Activity-Exercise:*** Walks in the mall at least ½ mile 3 times a week. No resistance or isotonic exercises.
- ***Cognitive-Perceptual:*** Denies eye pain, itching, or tearing. Having difficulty reading.
- ***Coping–Stress Tolerance:*** Afraid she is having a stroke.

Discussion Questions

1. Which subjective assessment findings are of most concern to you?
2. What should be included in the physical assessment? For what would you be looking?
3. How will you individualize the assessment based on her age, ethnic/cultural background, and condition?

You will learn more about the physical assessment of the visual system in the next section.

(See p. 358 for more information on F.M.)

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Objective Data

Physical Examination

Physical examination of the visual system includes inspecting the ocular structures and determining the status of their respective functions. Physiologic functional assessment includes (1) assessing the patient's visual acuity, ability to judge closeness and distance, and extraocular muscle function; (2) evaluating visual fields; (3) checking pupil function; and (4) measuring IOP. Assessment of ocular structures should include examining the ocular adnexa, external eye, and internal structures. Some structures, such as the retina, blood vessels, and optic disc, must be assessed with an ophthalmoscope.

TABLE 20.3 Normal Physical Assessment of Visual System

- Visual acuity 20/20 OU. No diplopia
- External eye structures symmetric and without lesions or deformities
- Lacrimal apparatus nontender and without drainage
- Conjunctiva clear. Sclera white
- PERRLA (pupils equal, round, reactive to light and accommodation)
- Lens clear
- EOMs intact (extraocular movements intact)
- Optic disc margins sharp
- Retinal vessels without hemorrhages or spots

Normal physical assessment of the visual system is outlined in Table 20.3. Assessment techniques related to vision are described in Table 20.4. Table 20.5 shows select assessment abnormalities.

A *focused assessment* is used to evaluate the status of previously identified visual problems and to monitor for signs of new problems. A focused assessment of the visual system is shown in the box above.

Focused Assessment

Visual System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Changes in vision (e.g., acuity, blurred)	Y	N
Eye redness, itching, discomfort	Y	N
Drainage from eyes	Y	N

Objective: Physical Examination

Inspect

Eyes for any discoloration or drainage	✓
Conjunctiva and sclera for color and vascularity	✓
Lens for clarity	✓
Eyelid for ptosis	✓

Assess

Vision based on patient looking at nurse or Snellen chart	✓
Extraocular movements (EOMs)	✓

Peripheral vision	✓
PERRLA	✓

PERRLA, Pupils equal, round, reactive to light and accommodation.

Initial Observation

Your initial observation of the patient can provide information that will help focus the assessment. A patient dressed in clothing with unusual color combinations may have a color-vision deficit. Note an unusual head position. The patient with diplopia may hold the head in a skewed position to try to see a single image. The patient with a corneal abrasion or photophobia will cover the eyes with the hands to try to block out room light. Make a crude estimate of depth perception by extending a hand for the patient to shake.

During the initial observation, observe the patient's overall facial and eye appearance. The eyes should be symmetric and normally placed on the face. The globes should not have a bulging or sunken appearance.

TABLE 20.4 Nursing AssessmentAssessment Techniques: Visual System

Description	Purpose
Color Vision Testing	
In the Ishihara test, a patient identifies numbers or paths formed by pattern of dots in series of color plates.	Determines ability to distinguish colors
Confrontation Visual Field Test	
Patient faces examiner, covers one eye, fixates on examiner's face, and counts number of fingers that examiner brings into patient's field of vision.	Determines if patient has a full field of vision, without obvious blind spots or vision loss
Intraocular Pressure Testing: Tonometry	
Covered end of probe is gently touched several times to anesthetized corneal surface. Examiner records several readings to obtain a mean IOP.	Measures IOP. Normal pressure is 10–21 mm Hg
Keratometry	
Examiner aligns projection and notes readings of corneal curvature. Often done before fitting contact lenses, before refractive surgery, or after corneal transplantation.	Measures corneal curvature
Ophthalmoscopy	
Examiner holds ophthalmoscope close to patient's eye, shining light into back of eye and looking through aperture on ophthalmoscope. Examiner adjusts dial to choose the ophthalmoscope lens that produces desired amount of magnification to inspect retina.	Provides magnified view of retina and optic nerve (Fig. 20.7)
Pupil Function Testing	
Examiner shines light into patient's pupil and checks pupillary response. Each pupil is examined independently. Examiner also checks for consensual and accommodative response.	Determines if patient has normal pupillary response
Visual Acuity Testing	
Patient reads from Snellen chart at 20 ft (distance vision test) or Jaeger chart at 14 in (near vision test). Examiner notes smallest print patient can read on each chart.	Determines distance and near visual acuity

Assessing Functional Status

Visual acuity

Always record the patient's visual acuity for medical and legal reasons. When doing a physical examination of the eyes, assess the right eye first and then the left eye. Use the abbreviations right eye "OD," left eye "OS," and both eyes "OU." Record the patient's visual acuity before the patient receives any eye care.

To assess visual acuity, position the person on a mark exactly 20 ft (6 m) from the Snellen eye chart. If the person wears glasses or contacts, leave them on. Using an occlude, cover one eye at a time during the test. Ask the person to read down the lines of the chart to the smallest line of letters and numbers possible. Record the result using the numeric fraction at the end of the last successful line read. Indicate whether any letters were missed and if corrective lenses were worn (e.g., "Right eye, 20/30-2, with contacts"). Next ask the patient to cover the other eye and repeat the process. Normal visual acuity is 20/20. The first number indicates the distance the person is standing or sitting from the chart. The second number gives the distance at which

a normal eye can read the particular line. *Legal blindness* is defined as the best-corrected vision in the better eye of 20/200 or less.

TABLE 20.5 Assessment AbnormalitiesVisual System

Finding	Description	Possible Etiology and Significance
Subjective Data		
Blurred vision	Gradual or sudden inability to see clearly	Refractive errors, corneal opacities, cataracts, migraine aura, retinal changes (detachment, macular degeneration)
Diplopia	Double vision	Abnormal extraocular muscle action related to muscle or cranial nerve pathologic condition
Dryness	Discomfort, sandy, gritty, irritation, or burning	Decreased tear formation or changes in tear composition because of aging or various systemic diseases
Pain	Foreign body sensation	Superficial corneal erosion or abrasion. Can result from contact lens wear or trauma. Conjunctival or corneal foreign body
	Severe, deep, throbbing	Anterior uveitis, acute glaucoma, infection. Acute glaucoma also associated with nausea, vomiting
Photophobia	Persistent abnormal intolerance to light	Inflammation or infection of cornea or anterior uveal tract (iris and ciliary body)
Spots, floaters	Patient describes seeing spots, "spider webs," "curtain," or floaters within the field of vision	Most common cause is vitreous liquefaction (benign phenomenon). Other causes include hemorrhage into the vitreous humor, retinal holes or tears
Objective Data		
Eyelids		
Allergic reactions	Redness, excessive tearing, and itching of lid margins	Many possible allergens. Associated eye trauma can occur from rubbing itchy eyelids
Blepharitis	Redness, swelling, and crusting along lid margins	Bacterial invasion of lid margins. Often chronic
Dermatochalasis	Excess eyelid skin	May eventually obstruct superior and peripheral vision
Ectropion	Outward turning of lower lid margin	Age-related tissue changes, posttraumatic changes, facial paralysis
Entropion	Inward turning of upper or lower lid margin, unilateral or bilateral	Age-related tissue changes, posttraumatic changes, facial paralysis
Hordeolum (sty) (Fig. 20.8)	Small, superficial white nodule along lid margin	Infection of meibomian gland of eyelid. Causative organism is usually bacterial (most often *Staphylococcus aureus*)
Ptosis	Drooping of upper eyelid, unilateral or bilateral	Myasthenia gravis, congenital, or mechanical causes from eyelid tumors or excess skin
Conjunctiva		
Conjunctivitis	Redness, swelling of conjunctiva. May be itchy	Bacterial or viral infection. May be allergic response or inflammatory response to chemical exposure
Subconjunctival hemorrhage	Appearance of blood spot on sclera. May be small or can affect entire sclera	Conjunctival blood vessels rupture, leaking blood into the subconjunctival space.
Cornea		
Corneal abrasion	Localized painful disruption of the epithelial layer of cornea. Can be seen with fluorescein dye	Trauma. Overwear or improper fit of contact lenses
Globe		
Exophthalmos (Fig. 20.9)	Protrusion of globe beyond its normal position within bony orbit. Sclera often visible above iris when eyelids are open	Intraocular or periorbital tumors Hyperthyroidism
Pupil		
Abnormal response to light or accommodation	Pupils respond asymmetrically or abnormally to light stimulus or accommodation	CNS disorders, general anesthesia
Anisocoria	Pupils unequal (constricted)	CNS disorders. Slight difference in pupil size is normal in some people
Extraocular Muscles		
Strabismus	Deviation of eye position in one or more directions	Overaction or underaction of one or more extraocular muscles
Lens		
Cataract	Opacification of lens. Pupil can appear cloudy or white when opacity is visible behind pupil opening.	Aging, trauma, diabetes, long-term systemic corticosteroid therapy
Visual Field Defect		
Central	Loss of central vision	Macular disease
Peripheral	Partial or complete loss of peripheral vision	Glaucoma. Interruption of visual pathway (e.g., tumor). Migraine headache

If the patient reports near vision difficulty or is 40 years of age or older, use a hand-held vision screener with varying print sizes (e.g., a

Jaeger chart). Hold the card at 14 in (35 cm) from the eye in good light to assess near vision. Examine each eye separately, with glasses on if worn. A normal result is "14/14" in each eye, read without hesitancy and without the patient moving the card. If you must assess near visual acuity without access to a Jaeger eye chart, you can still make an accurate assessment using newsprint or the label on a container. Record the acuity as "reads newspaper headline at X inches." If the patient is unable to read any of the lines on both the near and distant visual acuity charts, the next step is to assess whether they can see hand motion and light perception.

Extraocular muscle functions

Assess the corneal light reflex to evaluate for weakness or imbalance of the extraocular muscles. In a darkened room, ask the patient to look straight ahead while shining a penlight directly on the cornea. The light reflection should be in the center of both corneas as the patient faces the light source.

To assess eye movement, hold a finger or an object within 10 to 12 inches of the patient's nose. Ask the patient to follow with eyes only the movement of the object or finger in the 6 cardinal positions of gaze. This test can indicate weakness or paralysis in the extraocular muscles and cranial nerves (CN III, CN IV, and CN VI).

Pupil function and intraocular pressure

Pupil function is determined by inspecting the pupils and their reactions to light. The normal finding is often abbreviated as PERRL (pupils are equal [in size], round, and reactive to light). The pupils should react to light directly (pupil constricts when a light shines into the eye) and consensually (pupil constricts when a light shines into the opposite eye). In a small number of people, the pupils are normally unequal in size (*anisocoria*).

To test for accommodation, ask the person to focus on a distant object. This process dilates the eyes. Then have the person shift the focus to a near object (e.g., your finger held about 3 inches from the person's nose). A normal response is constriction of the eyes and

convergence (inward movement of both eyes toward each other). When accommodation is assessed with the pupillary light reflex, a normal response is *PERRLA* (pupils are equal, round, and reactive to light and accommodation).

IOP (Table 20.4) is measured by a variety of methods, including tonometry. Normal IOP ranges from 10 to 21 mm Hg.

Assessing Structures

We assess the visual system structures primarily by inspection. The visual system is unique because we can inspect not only the external structures but also many of the internal structures. The iris, lens, vitreous, retina, and optic nerve can be seen directly through the clear cornea and pupil opening.

This direct inspection requires special observation equipment, such as the slit lamp microscope or ophthalmoscope. These permit examination of the conjunctiva, sclera, cornea, anterior chamber, iris, lens, vitreous, and retina under magnification. The *ophthalmoscope* is a hand-held instrument with a light source and magnifying lenses that is held close to the patient's eye to visualize the posterior part of the eye. Little pain or discomfort is associated with these examinations.

Eyebrows, eyelashes, and eyelids

All structures should be present and symmetric, without deformities, redness, or swelling. Eyelashes extend outward from the lid margins. In normal closing, the upper and lower eyelid margins just touch. The lacrimal puncta should be open and positioned properly against the globe.

Conjunctiva and sclera

The conjunctiva and sclera are easily examined at the same time. Assess the color, smoothness, and presence of lesions or foreign bodies. The conjunctiva covering the sclera is normally clear, with fine blood vessels visible. These blood vessels are more common in the periphery.

The sclera is normally white. A slight yellow cast may be found in

some dark-skinned people, such as blacks and Native Americans, or in the older adult from lipid deposition. A pale blue cast caused by scleral thinning can be normal in older adults.

Cornea

The cornea should be clear, transparent, and shiny. The iris should appear flat and not bulge toward the cornea. The area between the cornea and iris should be clear, with no blood or purulent material visible in the anterior chamber.

Iris

Both irises should be of similar color and shape. However, a color difference between the irises occurs normally in a small number of people.

Retina and optic nerve

We can get vital information about the vascular system and CNS through direct visualization with an ophthalmoscope. It is used to magnify the retina and optic nerves and bring them into crisp focus (Fig. 20.7). Skilled use of this instrument takes practice.

Examine the optic nerve or disc for size, color, and abnormalities. The optic disc is creamy yellow with distinct margins. A central depression in the disc, called the *physiologic cup,* may be seen. This area is the exit site for the optic nerve. The cup should be less than half the diameter of the disc. Normally, no hemorrhages or exudates are present in the fundus (retinal background). Careful inspection of the fundus can reveal retinal holes, tears, detachments, or lesions. Small hemorrhages can be associated with diabetes or hypertension and can appear in various shapes, such as dots or flames. Finally, examine the macula for shape and appearance. This area is normally devoid of any blood vessels.

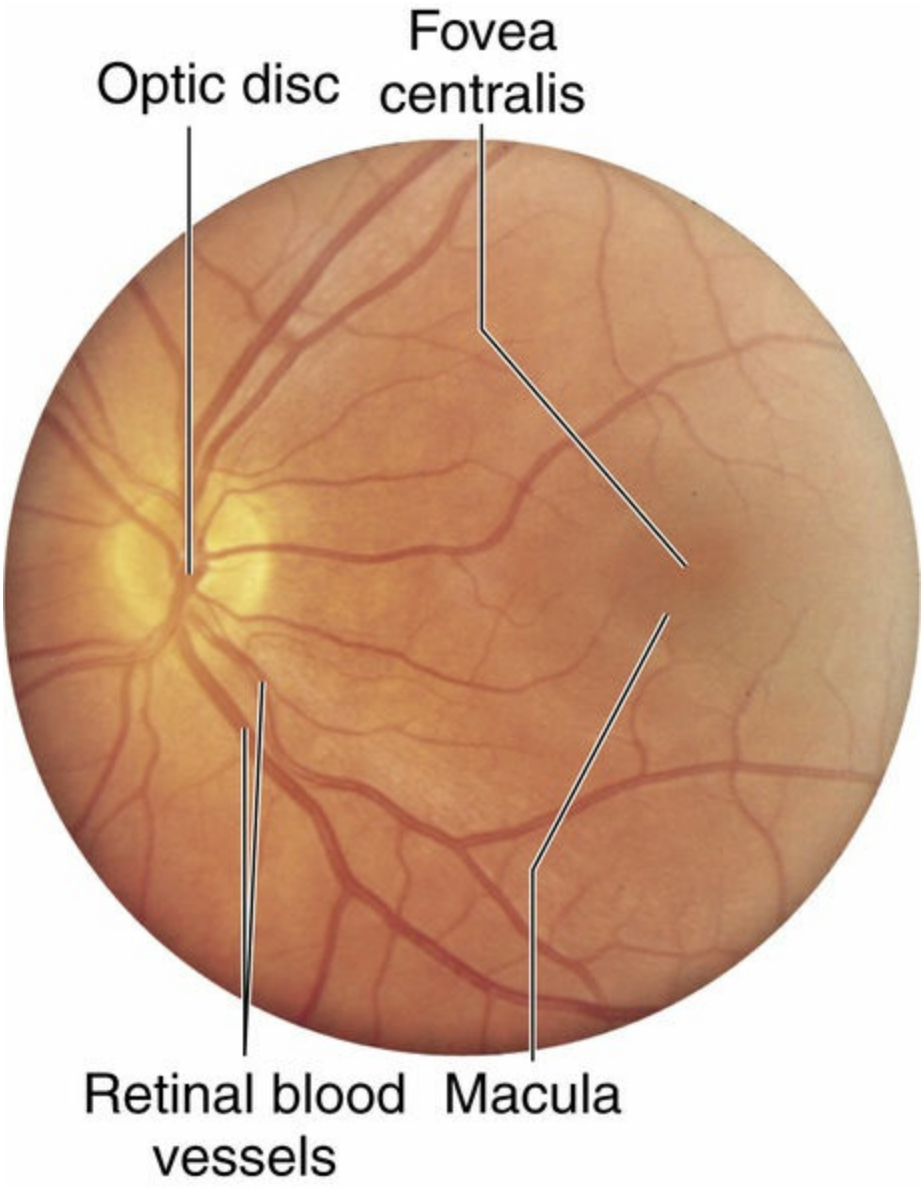

FIG. 20.7 Magnified view of retina through the ophthalmoscope. From Newell FW: *Ophthalmology: Principles and concepts,* ed 7, St Louis, 1992, Mosby.

Special Assessment Techniques

Color Vision

Testing the patient's ability to distinguish colors is an important part of the overall assessment. Some occupations require accurate color discrimination. The Ishihara color test determines the patient's ability

to distinguish a pattern of color in a series of color plates.

Stereopsis

Stereoscopic vision allows a patient to see objects in 3 dimensions. An event that causes a patient to have monocular vision (e.g., enucleation, patching) results in the loss of stereoscopic vision. Without stereopsis, the person's ability to judge distances or the height of a step is impaired. This can have profound consequences if the person trips over a step when walking or follows too closely behind another vehicle when driving.

Case Study

Objective Data: Physical Examination and Diagnostic Studies

© Jack Hollingsworth/Photodisc/Thinkstock.

Physical examination findings of F.M. were as follows:

- PERRL. No abnormalities noted on visual examination of external eye structures. EOMs intact and symmetric.

The HCP performs an ophthalmoscopic examination and finds a partial retinal detachment. Ultrasonography confirms the diagnosis.

Discussion Questions

1. Are these the diagnostic studies that you expected to be ordered?
2. Which diagnostic study results are of most concern to you?

Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

Diagnostic Studies of Visual System

Diagnostic studies of the visual system provide vital information in monitoring the patient's condition and planning appropriate interventions. These studies are considered objective data. Table 20.6 presents common diagnostic studies of the visual system.

Visual Problems

Refractive Errors

Refraction is the eye's ability to bend light rays so that they fall on the retina. In the normal eye, parallel light rays are focused through the lens into a sharp image on the retina. When the light does not focus properly, it is called a refractive error. This defect prevents light rays from converging into a single focus on the retina. Defects are a result of irregularities of the corneal curvature, focusing power of the lens, or length of the eye.

Refractive errors are the most common visual problem. Blurred vision is the major symptom. In some cases, the patient may have eye discomfort, eyestrain, or headaches. Most refractive errors can be corrected using eyeglasses or contact lenses, refractive eye laser surgery, or surgical implantation of an artificial lens.

Myopia (nearsightedness) is an inability to accommodate for objects

at a distance. It causes light rays to be focused in front of the retina. This means the person can see near objects but objects in the distance are blurry. Myopia may occur because of excessive light refraction by the cornea or lens or because of an abnormally long eye. Myopia is the most common refractive error. About 30% of Americans have this disorder.[4] There is strong evidence that many people inherit myopia, or at least the tendency to develop myopia.[4]

TABLE 20.6 Diagnostic StudiesVisual System

Study	Description, Purpose, and Nursing Responsibility
Amsler Grid test	Self-administered test using a hand-held card printed with a grid of lines (like graph paper) (Fig. 20.15). Using one eye at a time, patient fixates on center dot and records any abnormalities of grid lines, such as wavy, missing, or distorted areas. Used to monitor macular problems.
Fluorescein angiography	Fluorescein injected IV into peripheral vein followed by serial photographs (over 10-min period) of retina through dilated pupils Provides diagnostic information about flow of blood through retinal vessels. If extravasation occurs, fluorescein is toxic to tissue. Tell patient that dye can sometimes cause transient nausea or vomiting. Yellow-orange discoloration of urine and skin may occur.
Perimetry (visual field) testing	Can detect changes in central and peripheral vision, which may be caused by various conditions, including glaucoma, stroke, brain tumors, or other neurologic deficits. Person sits and looks inside a bowl-shaped instrument called a *perimeter*. While staring at the center of bowl, a light flashes, and the person presses a button each time flash is seen. A computer records the results, and a printout shows if there are areas where flashes of light are not seen.
Refractometry	Measure of refractive error. Patient sits looking through apertures at Snellen acuity chart and lenses are changed. Patient chooses lenses that make acuity sharpest. Dilation of eyes may help visualize retina and optic nerves. Procedure is painless. Pupil dilation, which may last 3–4 hr, makes it difficult to focus on near objects.
Ultrasonography	*A-scan* determines the right power of a lens implant before cataract surgery. *B-scan* used to diagnose ocular pathologic conditions, including intraocular foreign bodies or tumors, vitreous opacities, retinal detachments.

Hyperopia (farsightedness) is an inability to accommodate for near objects. It causes the light rays to focus behind the retina and requires the person to use accommodation to focus the light rays on the retina for near objects. The person with hyperopia can see distant objects clearly. This type of error occurs when the cornea or lens does not have adequate focusing power or when the eyeball is too short.

Presbyopia is the loss of accommodation associated with age. One usually begins to notice this condition in the early to mid-40s. As the eye ages, the lens becomes larger, firmer, and less elastic. These changes, which progress with aging, result in an inability to focus on

near objects.

Astigmatism is an uneven or irregular curvature of the cornea. The irregularity causes the incoming light rays to be bent unequally. Thus, the light rays do not come to a single point of focus on the retina, which results in visual distortion. Astigmatism can occur in conjunction with any of the other refractive errors.

Aphakia is the absence of the lens. Rarely, the lens may be absent congenitally, or it may be removed during cataract surgery. A lens that is traumatically injured is removed and replaced with an intraocular lens (IOL) implant. The absence of the lens results in a significant refractive error. Without the focusing ability of the lens, images are projected behind the retina.

Nonsurgical Corrections

Corrective Glasses

The right corrective lenses can enhance vision in those with myopia, hyperopia, presbyopia, and astigmatism. Glasses for presbyopia are often called "reading glasses" because they are usually worn only for close work. Presbyopic correction may be combined with a correction for another refractive error, such as myopia or astigmatism. In these combined glasses, the presbyopic correction is in the lower part of the spectacle lens. A traditional bifocal or trifocal has visible lines. However, most lenses today that correct vision at various distances do not have visible lines. The prescription varies throughout the lens, allowing distance focusing in the top two thirds and near focus in the bottom one third of the lens.

Contact Lenses

Contact lenses are another way to correct refractive errors. Contact lenses are made from various plastic and silicone substances. They are highly permeable to oxygen and have a high water content. These features allow for increased wearing time with greater comfort. If the oxygen supply to the cornea is decreased, it becomes swollen, visual acuity decreases, and the patient has severe discomfort.

In general, you need to know whether the patient wears contact lenses, the pattern of wear (daily versus extended), and care practices. Shining a light obliquely on the eyeball can help visualize a contact lens. Contact lenses are associated with microbial keratitis, a severe sight-threatening complication. Risk factors for keratitis include poor hand cleaning, poor lens case hygiene, and inadequate lens cleaning. Teach the patient the importance of following recommended cleaning practices and reporting redness, sensitivity, vision problems, and pain to the eye care provider. Teach the patient to remove contact lenses at once if any of these problems occur.

Surgical Therapy

Surgery can eliminate or reduce the need for eyeglasses or contact lenses and correct refractive errors by changing the focus of the eye. Surgical management for refractive errors includes laser surgery and IOL implantation.

Laser

Laser-assisted in situ keratomileusis (LASIK) may be considered for patients with low to moderately high amounts of myopia or hyperopia, with or without astigmatism. The procedure first involves using a laser or surgical blade to create a flap in the cornea. The flap is folded back, exposing the middle section (stroma) of the cornea. Pulses from a computer-controlled laser vaporize a part of the stroma. The flap is then repositioned, adhering on its own without sutures in a few minutes.[5]

Photorefractive keratectomy (PRK) is indicated for low to moderate amounts of myopia or hyperopia, with or without astigmatism. It is a good option for a patient with insufficient corneal thickness for a LASIK flap. In PRK, the epithelium is removed and the laser sculpts the cornea to correct the refractive error. *Laser-assisted subepithelial keratomileusis* (LASEK) is similar to PRK, except that the epithelium is replaced after surgery.

Implant

Refractive intraocular lens (refractive IOL) implantation is an option for patients with a high degree of myopia or hyperopia. Like cataract surgery, it involves removing the patient's natural lens and implanting an IOL. The IOL implant used is a special lens designed to correct the patient's refractive error. Refractive IOLs can correct both myopia and presbyopia.

Phakic intraocular lenses (phakic IOLs) are sometimes called *implantable contact lenses.* They are implanted into the eye without removing the eye's natural lens. They are used for patients with high degrees of myopia or hyperopia. Unlike refractive IOLs, the phakic IOL is placed in front of the eye's natural lens. Leaving the natural lens preserves the eye's ability to focus for reading vision.

Promoting Health Equity

Visual Problems

- Glaucoma has an increased incidence and severity among blacks compared with whites.
- Hispanic Americans have an increased incidence of diabetic retinopathy.
- Whites have a higher incidence of macular degeneration than Hispanics, blacks, and Asian Americans.

Visual Impairment

Visual impairment describes vision that cannot be fully corrected by corrective lenses, medical treatment, or surgery. The term *visual impairment* includes conditions ranging from low vision to the absence of all vision (total blindness). Many terms are used when people refer to visual impairment, including:

- *Low vision* refers to impaired vision that cannot be improved

by conventional eyeglasses, contact lenses, medications, or surgery in which some good usable vision remains.

- *Severe visual impairment* describes visual impairment in people who are unable to read ordinary newsprint even with correction. People with a severe visual impairment may or may not be legally blind.
- *Legal blindness* refers to central visual acuity of 20/200 or less in the better eye with correction or a peripheral visual field of 20 degrees or less.[6]

Most blindness in the United States is the result of common eye diseases, including cataracts, glaucoma, age-related macular degeneration, and diabetic retinopathy.

Nursing Management: Visual Impairment

Nursing Assessment

It is important to assess how long the patient has had a visual impairment. Recent loss of vision has different implications for nursing care. Determine how the patient's visual impairment affects normal functioning. Ask the patient about the level of difficulty involved in doing certain tasks. For example, how hard is it for the patient to read, write a check, move from one room to the next, or view the television? Other questions can help determine the personal meaning that the patient attaches to the visual impairment. Ask how the vision loss has affected specific aspects of the patient's life, whether the patient has lost a job, or what activities the patient does not engage in because of the visual impairment.

Determine the patient's emotional reactions, coping strategies, and support systems. The patient may attach many negative meanings to the impairment because of societal views of blindness. For example, the patient may view the impairment as punishment or view

themselves as useless and burdensome.

Planning

The overall goals are that the patient with impaired vision will (1) make a successful adjustment to the impairment, (2) discuss feelings related to the loss, (3) identify personal strengths and support systems, and (4) use appropriate coping strategies. If the patient has been functioning at an appropriate or acceptable level, the goal is to maintain the current level of function.

Nursing Implementation

Health Promotion

Encourage the patient with preventable causes of further visual impairment to seek appropriate health care. For example, the patient with vision loss from glaucoma may be able to prevent further visual loss by with prescribed therapies and eye examinations.

Acute Care

Provide emotional support and direct care to the patient with recent visual impairment. Allow the patient to express fear, anger, and grief. Help the patient identify positive coping strategies. Caregivers are intimately involved in the experiences that occur with vision loss. With the patient's knowledge and permission, include caregivers in discussions and encourage them to express their concerns.

Many people are uncomfortable around a person with visual impairment because they are not sure what behaviors are appropriate. Being sensitive to the patient's feelings without being overly worried or smothering the patient's independence is vital in creating a therapeutic nursing presence. Always communicate in a normal conversational tone and manner with the patient and address the patient, not the caregiver. Common courtesy dictates introducing yourself and any other people who approach the patient. It is important to say good-bye when leaving the patient's presence.

Making eye contact with the patient achieves several goals. It ensures that you are speaking while facing the patient so that the patient has no difficulty hearing. Your head position confirms that you are attentive to the patient. In addition, establishing eye contact ensures that you can observe the patient's facial expressions and reactions.

Help the patient using a *sighted-guide technique*. Stand slightly in front and to one side of the patient and offer an elbow for the patient to hold. Serve as the sighted guide, walking slightly ahead of the patient with the patient holding the back of your arm. As you walk, describe the environment to help orient the patient. For example, "We're going through an open doorway and approaching 2 steps down." Help the patient sit by placing one of his or her hands on the seat of the chair.

Ambulatory Care

In working with the patient who is visually impaired, remember that a person classified as legally blind may have some useful vision. Rehabilitation after partial or total loss of vision can foster independence, self-esteem, and productivity. Know what services and devices are available and make appropriate referrals. For the legally blind patient the primary resource for services is the state agency for rehabilitation of the blind. Legally blind persons are often eligible for federal and state assistance and income tax benefits. A list of agencies that serve the partially sighted or blind patient is available from the American Foundation for the Blind *(www.afb.org)*.

Braille or audio books for reading and a cane or guide dog for ambulation are examples of vision substitution techniques. These are usually best for the patient with no functional vision. For most patients who have some remaining vision, vision enhancement techniques can help in learning to ambulate, read printed material, and perform ADLs.

Optical Devices for Vision Enhancement

A wide range of newer technologies are available to help people with low vision. These devices include desktop video magnification/closed

circuit units, electronic hand-held magnifiers, text-to-speech scanners (material read aloud to you), E-readers, and computer tablets (material read aloud, magnification, image zooming, brighter screen, voice recognition). Many of these devices require some training by an assistive technology professional. Encourage patients to practice with the technologic device to ensure they can use it successfully.

Nonoptical Methods for Vision Enhancement

Approach magnification is a simple way to enhance the patient's residual vision. Recommend that the patient sit closer to the television or hold books closer to the eyes. Contrast enhancement techniques include watching television in black and white, using a black felt-tip marker, and using contrasting colors (e.g., a red stripe at the edge of steps or curbs). Increased lighting can be provided by halogen lamps, direct sunlight, or gooseneck lamps that are aimed directly at the reading material or other near objects. Large type is often helpful, especially when used with other vision enhancements.

Non–24-Hour Sleep/Wake Disorder

A common problem that can occur in blind people, especially those who are totally blind, is *non–24-hour sleep/wake disorder (Non-24).* It is a circadian rhythm sleep disorder in which a person's biologic clock does not synchronize to a 24-hour day.[7] It is caused by lack of light input to the circadian clock.

People with Non-24 have problems falling asleep or staying asleep at night. During the day, they may have an uncontrollable urge to sleep. This can result in severe sleep issues, including insomnia, excessive sleepiness, changing patterns of when a person sleeps, and social and work consequences.

Taking melatonin can shift the circadian clock earlier (an advance) or later (a delay). Tasimelteon (Hetlioz), a melatonin receptor agonist, also can be used for treatment. It works by targeting receptors in the brain that control the timing of the sleep/wake cycle.

Evaluation

The overall expected outcomes are that the patient with visual impairment will:

- Follow treatment plan to prevent further loss of vision
- Be able to use adaptive coping strategies
- Maintain self-esteem and take part in social interactions
- Function safely within her or his own environment

Promoting Population Health

Responsible Eye Care

- Regular hand washing prevents the spread of disease from one eye to the other.
- Seeking appropriate health care can lead to early detection of disease and prevent further loss of vision in patients with certain types of partial vision loss.
- Wearing sunglasses and practicing proper nutrition may help prevent cataract development and age-related macular degeneration.
- Wearing eye protection during potentially hazardous work, hobby, and sport activities reduces the risk for eye injuries.

Gerontologic Considerations: Visual Impairment

The older adult is at an increased risk for vision loss caused by eye disease. They may have other deficits, such as cognitive impairment or limited mobility, that further affect the ability to function in usual ways. Societal devaluation of older adults may compound the self-esteem or isolation issues associated with visual impairment.

Financial resources may be inadequate to secure vision services or assistive devices.

The older patient may become increasingly confused or disoriented when visually compromised. The combination of decreased vision and confusion increases the risk for falls, which can have serious consequences. Decreased vision may compromise the older patient's ability to function, resulting in concerns about independence and a diminished self-image. Decreased manual dexterity may make instilling prescribed eyedrops hard. Those with low vision are more likely to make medication errors that are potentially dangerous, such as taking too much insulin or mistaking one drug for another.

Eye Trauma

Although the eyes are well protected by the bony orbit and fat pads, everyday activities can result in eye trauma. The most common eye injuries in the United States are due to falls and fights. Injuries at home may be caused by cleaning, gardening, power tool use, and home repair work. Sport- and work-related injuries are other causes of eye trauma.[8]

Check Your Practice

You are working in your garden when your neighbor comes running into your yard. She is screaming and waving her arms. Her husband was using a chain saw to cut down a tree when a piece of wood chip flew into his eye. When you go to your neighbor's yard, the husband is on the ground crying in pain and you assess that the wood chip is embedded in his eye.

- What should you do next?

Table 20.7 outlines the emergency management of the patient with an eye injury. Chemical burns can be devastating to the eye and need

immediate attention. Alkaline chemicals with a pH greater than 7 are the most harmful. They can penetrate the eye and damage the inner components. Acidic chemicals with a pH of less than 7 are unable to penetrate the eye but can damage the cornea. Both types of injury have the potential to result in blindness.

A *Morgan lens* may be used to provide continuous irrigation of an injured eye. It consists of a sterile plastic device resembling a contact lens that floats over the eye (never physically touches it) and allows copious irrigation of the eye. The device is connected to tubing that delivers irrigating solution. The Morgan lens provides relief for chemical or thermal burns and removes nonembedded foreign materials in the eye.

Trauma is often a preventable cause of visual impairment. Many eye injuries could be prevented by wearing protective eyewear. Your role in individual and community education is extremely important in reducing the incidence of eye trauma.

Extraocular Disorders

Inflammation and Infection

One of the most common eye conditions is inflammation or infection of the external eye. Many external irritants or microorganisms can affect the eye, conjunctiva, and avascular cornea.

An external **hordeolum** (or a *sty*) is an infection of the meibomian glands in the lid margin (Fig. 20.8). The most common bacterial infective agent is *Staphylococcus aureus.* A red, swollen, circumscribed, and acutely tender area develops rapidly. Have the patient apply warm, moist compresses at least 4 times a day until it improves. This may be the only treatment needed. If it tends to recur, teach the patient to do lid scrubs daily. On occasion, antibiotic ointments or drops may be needed.

A *chalazion* is a chronic inflammatory granuloma of the meibomian glands in the lid. It may evolve from a hordeolum or occur in response to the material released into the lid when a blocked gland ruptures.

The chalazion usually appears on the upper lid as a swollen, tender, reddened area that may be painful. Initial treatment is like that for a hordeolum. If warm, moist compresses are ineffective in promoting spontaneous drainage, the HCP may drain the lesion or inject it with corticosteroids.

TABLE 20.7 Emergency ManagementEye Injury

Etiology	Assessment Findings	Interventions
Chemical Burn • **Acid** • **Alkaline** **Foreign Bodies** • **Ceramics** • **Glass** • **Metal** • **Plastic** • **Wood** **Thermal Burn** • **Direct burn from hot surface** • **Indirect burn from UV light (e.g., welding torch, looking directly at sun)** **Trauma** • **Blunt (e.g., fist)** • **Penetrating (e.g., glass, metal, or wood fragments; knife, stick, other object)**	• Pain • Photophobia • Redness—diffuse or localized • Swelling • Bruising • Tearing • Blood in the anterior chamber • Absent eye movements • Fluid drainage from eye (e.g., blood, aqueous humor) • Abnormal or decreased vision • Visible foreign body • Prolapsed globe • Abnormal IOP • Visual field defect	Initial • Determine mechanism of injury. • Ensure airway, breathing, and circulation. • Assess for other injuries. • Assess for chemical exposure. • Begin ocular irrigation *immediately* in case of chemical exposure. Do not stop until emergency personnel arrive to continue irrigation. Use sterile saline or water if saline is unavailable. • Assess visual acuity. • Do not put pressure on the eye. • Tell patient not to blow nose. • Do not try to treat the injury (except as noted above for chemical exposure). • Stabilize foreign objects. • Cover the eye(s) with dry, sterile patches and a protective shield. • Do not give the patient food or fluids. • Elevate head of bed 45 degrees. • Give proper analgesia. Ongoing Monitoring • Reassure the patient. • Monitor pain. • Anticipate surgical repair for penetrating injury, globe rupture, or globe avulsion.

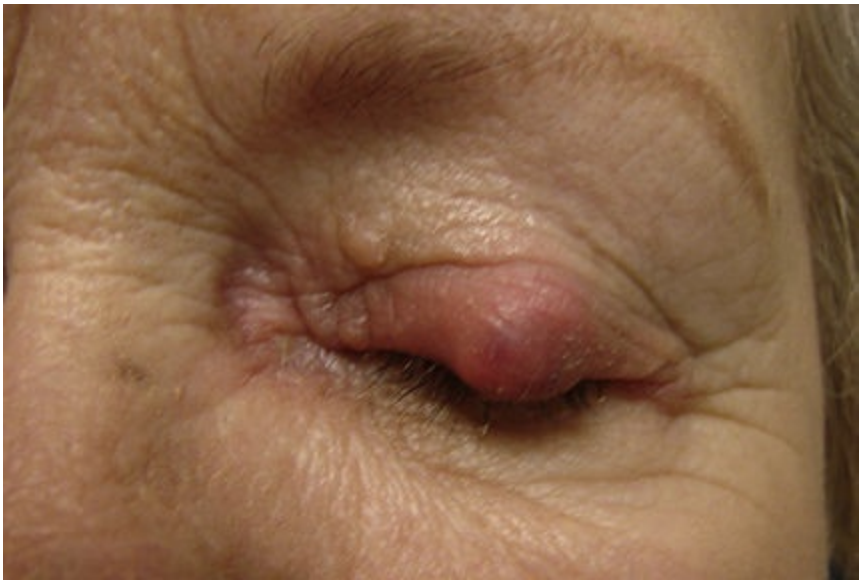

FIG. 20.8 Hordeolum (sty) on the upper eyelid caused by staphylococcal infection.
Courtesy Stephen J. Laquis, MD, FACS Ophthalmic Facial Plastic Surgery Specialists, Fort Myers, FL.

Blepharitis is a common chronic bilateral inflammation of the lid margins. The lids are red rimmed with many scales or crusts on the lid margins and lashes. The patient mainly has itching but may also have burning, irritation, and photophobia.

If a staphylococcal infection caused blepharitis, an eye antibiotic ointment must be used. Often blepharitis is caused by both staphylococcal and seborrheal microorganisms. The treatment must be more vigorous to avoid hordeolum, *keratitis* (inflammation of the cornea), and other eye infections. Emphasize thorough cleaning practices of the skin and scalp. Gentle cleansing of the lid margins with baby shampoo or lid scrubs can effectively soften and remove crusting.

Conjunctivitis

Conjunctivitis is an infection or inflammation of the conjunctiva. Infections may be bacterial or viral. Conjunctival inflammation may result from exposure to allergens or chemical irritants. Careful hand washing and use of individual or disposable towels help prevent spreading the condition.

Bacterial Infections

Acute bacterial conjunctivitis *(pinkeye)* is a common infection. Although it occurs in every age group, epidemics are common among children. *S. aureus* is the most common cause. The patient with bacterial conjunctivitis may have discomfort, pruritus, redness, and a mucopurulent drainage. Although it typically occurs initially in one eye, it generally spreads to the unaffected eye. It is usually self-limiting, but treatment with antibiotic drops shortens the course of the disorder. Teach patients the importance of hand washing and avoiding contact with an infected person.

Viral Infections

Many different viruses cause conjunctival infections. The patient with viral conjunctivitis may have tearing, foreign body sensation, redness, and mild photophobia. This condition is usually mild and self-limiting. However, it can be severe, with increased discomfort and subconjunctival hemorrhaging. Adenovirus conjunctivitis may be contracted in contaminated swimming pools and through direct contact with an infected patient.

Epidemic keratoconjunctivitis (EKC) is the most serious ocular adenoviral disease. EKC is spread by direct contact. In the medical setting, contaminated hands and instruments can be the source of spread. The patient may have tearing, redness, photophobia, and foreign body sensation. In most patients, the disease involves only one eye. Treatment is primarily palliative and includes ice packs and dark glasses. Therapy for severe cases can include mild topical corticosteroids to temporarily relieve symptoms and topical antibiotic ointment. Teach the patient the importance of good hygiene practices to avoid spreading the disease.

Chlamydial Infections

Trachoma is a chronic conjunctivitis caused by *Chlamydia trachomatis* (serotypes A through C). It is a major cause of blindness worldwide. Trachoma is most often seen in underdeveloped countries. It is transmitted mainly by the hands and by flies. Adult inclusion

conjunctivitis (AIC) is caused by *C. trachomatis* (serotypes D through K). AIC is becoming more prevalent in the United States because of the increase in sexually transmitted chlamydial infection.[9]

Manifestations of both trachoma and AIC are mucopurulent eye discharge, irritation, redness, and lid swelling. For unknown reasons, AIC does not carry the long-term consequences of trachoma. Antibiotic therapy is usually effective for trachoma and AIC. Patients with AIC have a high risk for concurrent chlamydial genital infection and STIs that may need treatment.

Allergic Conjunctivitis

Conjunctivitis caused by exposure to an allergen can be mild and transitory, or it can be severe enough to cause significant swelling. The defining symptom of allergic conjunctivitis is itching. The patient may have burning, redness, and tearing. The patient may develop allergic conjunctivitis in response to pollens, animal dander, ocular solutions, and medications. Teach the patient to avoid known allergens if possible. Artificial tears can be effective in diluting the allergen and washing it from the eye. Topical medications include antihistamines and corticosteroids.

Keratitis

Keratitis is an inflammation or infection of the cornea. It is caused by a variety of microorganisms or by other factors. The condition may involve the conjunctiva and/or the cornea. When it involves both, the disorder is termed *keratoconjunctivitis.*

Bacterial Infections

The cornea can become infected by a variety of bacteria. Risk factors include mechanical or chemical corneal epithelial damage, contact lens wear, nutritional deficiencies, immunosuppressed states, and contaminated products (e.g., lens care solutions and cases, topical medications, cosmetics). Treatment includes topical antibiotics. In some cases, the patient may need subconjunctival antibiotic injection

or, in severe cases, IV antibiotics.

Viral Infections

Herpes simplex virus (HSV) keratitis is the most common infectious cause of corneal blindness in the Western hemisphere. It is a growing problem, especially with immunosuppressed patients. The corneal ulcer has a characteristic dendritic (tree-branching) appearance. Pain and photophobia are common.

Current treatment for HSK includes acyclovir, ganciclovir, trifluorothymidine, penciclovir, and valacyclovir.[10] Therapy may also involve corneal debridement. Topical corticosteroids are usually contraindicated because they contribute to a longer course and possible deeper ulceration of the cornea.

The varicella-zoster virus (VZV) causes both chickenpox and herpes zoster ophthalmicus (HZO). HZO may occur by reactivation of an endogenous infection that has persisted in a latent form after an earlier attack of varicella or by contact with a patient with chickenpox or herpes zoster. It occurs most often in the older adult and immunosuppressed patient. Care of the patient with acute HZO may include analgesics for pain, topical corticosteroids to reduce inflammation, antiviral agents to reduce viral replication, mydriatic agents to dilate the pupil and relieve pain, and topical antibiotics to combat secondary infection. The patient may apply warm compresses and povidone-iodine gel to the affected skin.

Other Causes of Keratitis

Keratitis may be caused by fungi, such as *Aspergillus*, *Candida*, and *Fusarium* species. This is especially true in the case of eye trauma in an outdoor setting where fungi are prevalent in the soil and moist organic matter.

Acanthamoeba keratitis is caused by a parasite that is associated with contact lens wear, usually from contaminated lens care solutions or cases. Homemade saline solution is particularly susceptible to *Acanthamoeba* contamination. Teach the patient who wears contact lenses about good lens care practices. The treatment of *Acanthamoeba*

keratitis is difficult since the organism is resistant to most drugs. Antifungal agents (e.g., ketoconazole) may be given. If antimicrobial therapy fails, the patient may need a corneal transplant.

Exposure keratitis occurs when the eyelids cannot adequately close. The patient with *exophthalmos* (protruding eyeball) from thyroid eye disease or masses posterior to the globe is susceptible to exposure keratitis (Fig. 20.9).

Corneal Ulcer

Tissue loss caused by a corneal infection produces a *corneal ulcer* (infectious keratitis) (Fig. 20.10). The infection can be due to bacteria, viruses, or fungi. Corneal ulcers are often painful. The patient may feel as if there is a foreign body in the eye. Other symptoms can include tearing, purulent or watery discharge, redness, and photophobia. Treatment is aggressive to avoid permanent vision loss. Antibiotic, antiviral, or antifungal eyedrops may be given as often as every hour for the first 24 hours. An untreated corneal ulcer can result in corneal scarring and perforation, or hole in the cornea. A corneal transplant may be needed.

Nursing Management: Inflammation and Infection

Assess ocular changes, such as edema, redness, decreased visual acuity, feelings that a foreign body is present, or discomfort. Record the findings in the patient's record. Consider the psychosocial aspects of the patient's condition, especially when vision is impaired.

The patient's primary need is for information about prescribed care and how to perform that care. Careful asepsis and frequent, thorough hand washing are essential to prevent spreading organisms from one eye to the other, to other patients, to caregivers, and to health care team members. Teach the patient and caregivers how to avoid sources

of ocular irritation or infection and to respond appropriately if an eye problem occurs. The patient with infective disorders that may have a sexual mode of transmission needs specific information about those disorders.

Apply warm or cool compresses as needed. Darkening the room and giving an analgesic are other comfort measures. If the patient's visual acuity is decreased, modify the environment and activities for safety. Suggest alternative ways to perform daily activities and self-care.

The patient may need eyedrops as often as every hour. If the patient receives 2 or more different drops, stagger the eye drops to promote maximum absorption. For example, if 2 different eyedrops are ordered hourly, give 1 drop on the hour and 1 drop on the half hour (unless otherwise prescribed). The patient who needs to instill eyedrops frequently may have sleep deprivation. Review the proper technique for eye drop instillation.

Review the use and care of lenses and lens care products. Teach the patient who wears contact lenses and develops infections to discard all opened or used lens care products and cosmetics. This will decrease the risk for reinfection from contaminated products.

Dry Eye Disorders

Keratoconjunctivitis sicca (dry eyes) is a common problem, especially in older adults and people with certain systemic autoimmune diseases, such as scleroderma, systemic lupus erythematosus, and Sjögren's. It is caused by a decrease in the quality or quantity of the tear film. Patients with dry eyes report irritation or "sand in my eye." The sensation typically worsens through the day.

Treatment is aimed at the underlying cause. With decreased tear secretion, the patient may use artificial tears or ointments. Cyclosporine ophthalmic emulsion (Restasis) helps to increase the eyes' natural ability to make tears. In severe cases, closure of the lacrimal puncta may be done.

Strabismus

Strabismus is a condition in which a person cannot consistently focus both eyes simultaneously on the same object. One eye may deviate in *(esotropia),* out *(exotropia),* up *(hypertropia),* or down *(hypotropia).* Strabismus in an adult may be caused by thyroid disease, neuromuscular problems of the eye muscles, retinal detachment repair, or cerebral lesions. The primary problem is double vision.

Corneal Disorders

Corneal Scars

Any wound (e.g., trauma, infection) to the cornea can cause it to become scarred and opacified, thus decreasing the normal transparency. The treatment is a corneal transplant.

Keratoconus

Keratoconus is a noninflammatory, usually bilateral disease with a familial tendency. Keratoconus usually appears during adolescence and slowly progresses between ages 20 and 60 years. The anterior cornea thins and protrudes forward, taking on a cone shape. The only symptom is blurred vision. The astigmatism may be corrected with glasses or rigid contact lenses.

Intacs inserts are generally used to delay the need for a corneal transplant when contact lenses or glasses no longer help a patient achieve adequate vision. They are clear plastic lenses surgically inserted on the cornea perimeter to reduce astigmatism and myopia.

Sometimes, the cornea can perforate as central corneal thinning progresses. In these cases, a corneal transplant is done before the cornea can perforate.

Corneal Transplant

Around 46,000 corneal transplants are done in the United States each

year. The surgery is one of the fastest and safest of all tissue or organ transplant surgeries.[11] Indications for corneal transplants (keratoplasty) are corneal scarring and keratoconus. Types include penetrating (full thickness) corneal transplant and lamellar corneal transplant.

Penetrating (full thickness) cornea transplant involves transplanting all the layers of the cornea using a donor cornea. In this procedure, the HCP removes the full thickness of the patient's cornea and replaces it with a donor cornea that is sutured into place (Fig. 20.11). Vision may not be restored for up to 12 months.

During a *lamellar cornea transplant,* only some layers of the cornea are replaced with the transplant. This can include the deepest layer, called the *endothelium* (posterior lamellar cornea transplant). Versions of this procedure include Descemet's stripping endothelial keratoplasty (DSEK) or Descemet's membrane endothelial keratoplasty (DMEK). Lamellar transplants may be better than full penetrating transplants when the disease process is limited to only part of the cornea.

The time between the donor's death and the removal of the tissue should be as short as possible. Eye banks test donors for human immunodeficiency virus (HIV) and hepatitis B and C. The tissue is preserved in a special nutritive solution. Improved methods of tissue procurement and preservation, postoperative topical corticosteroids, and careful follow-up have decreased graft rejection. Matching the blood type of the donor and recipient improves the success rate.

Intraocular Disorders

Cataract

A **cataract** is an opacity within the lens. The patient may have a cataract in one or both eyes. If cataracts are present in both eyes, one may affect the patient's vision more than the other. Cataract removal is the most common surgery in the United States.[12]

Etiology and Pathophysiology

Although most cataracts are age related *(senile cataracts),* they can be associated with other factors. These include blunt or penetrating trauma, smoking, alcohol use, radiation or UV light exposure, certain drugs (e.g., steroids), and ocular inflammation. The rate of cataract development varies from patient to patient. The patient with diabetes tends to develop cataracts at a younger age.[13]

In senile cataract formation, altered metabolic processes within the lens cause an accumulation of water and changes in the lens fiber structure. These changes affect lens transparency, causing vision changes.

Clinical Manifestations and Diagnostic Studies

The patient with cataracts may have a decrease in vision, abnormal color perception, and glare. Glare is due to light scatter caused by the lens opacities. It may be significantly worse at night when the pupil dilates. The visual decline is gradual.

Diagnosis is based on decreased visual acuity or other visual problem. The opacity is directly observable by ophthalmoscopic or slit lamp microscopic examination. A totally opaque lens creates the appearance of a white pupil. Table 20.6 lists other diagnostic studies that may be helpful in evaluating a cataract.

Interprofessional Care

The presence of a cataract does not necessarily indicate a need for surgery. For many patients the diagnosis is made long before they decide to have surgery. Interprofessional care for cataracts is outlined in Table 20.8.

Nonsurgical Therapy

Currently, no treatment is available to "cure" cataracts other than surgical removal. Often changing the patient's eyewear prescription can improve visual acuity, at least temporarily. Other visual aids, such as strong reading glasses or magnifiers, may help the patient with

near vision. Increasing the amount of light to read or do other near-vision tasks is useful. The patient may be willing to adjust his or her lifestyle to adjust to visual decline. For example, if glare makes it hard to drive at night, a patient may choose to drive only during daylight hours or to have a someone else drive at night. Sometimes, informing and reassuring the patient about the disease process makes the patient comfortable about choosing nonsurgical measures, at least temporarily.

Surgical Therapy

When palliative measures no longer provide an acceptable level of visual function, the patient is a candidate for surgery. The patient's occupational needs and lifestyle changes are also factors affecting the decision to have surgery. In some instances, factors other than the patient's visual needs may influence the need for surgery. Lens-induced problems, such as increased IOP, may require lens removal. Opacities may prevent the HCP from getting a clear view of the retina in the patient with diabetic retinopathy or other sight-threatening pathologic conditions. In those cases, the cataract is removed to allow visualization of the retina and adequate management of the problem.

TABLE 20.8 Interprofessional CareCataract

Diagnostic Assessment

- History and physical examination
- Visual acuity measurement
- Ophthalmoscopy (direct and indirect)
- Slit lamp microscopy
- Glare testing, potential acuity testing in selected patients
- Keratometry and A-scan ultrasound (if surgery is planned)
- Other tests (e.g., visual field perimetry) to determine cause of visual loss

Management

Nonsurgical

- Change in glasses prescription
- Strong reading glasses or magnifiers
- Increased lighting
- Lifestyle adjustment

Acute Care: Surgical Therapy

Preoperative

- Mydriatic, cycloplegic agents
- Nonsteroidal antiinflammatory drugs
- Topical antibiotics
- Antianxiety medications

Surgery

- Removal of lens
- Phacoemulsification
- Extracapsular extraction
- Correction of surgical aphakia
- Intraocular lens implantation (most frequent type of correction)
- Contact lenses

Postoperative

- Topical antibiotic
- Topical corticosteroid or other antiinflammatory agent
- Mild analgesia, if necessary

- Eye patch or shield and activity as prescribed

Preoperative Phase

Before surgery, obtain an appropriate history and physical examination. Because most patients have local anesthesia, they do not need extensive preoperative physical assessment. However, most patients with cataracts are older adults who may have several medical problems that should be evaluated and controlled before surgery. Most patients are admitted on an outpatient basis. The patient normally presents several hours before surgery to allow time for preoperative procedures.

The patient receives a nonsteroidal antiinflammatory eyedrop to reduce inflammation and dilating drops. One type of drug used for dilation is a *mydriatic,* an α-adrenergic agonist that produces pupillary dilation by contracting the iris dilator muscle. Another type of drug is a *cycloplegic*, such as tropicamide (Mydriacyl), which are anticholinergic agents. They block the effects of acetylcholine on the ciliary body muscles. This produces paralysis of accommodation (cycloplegia), and on the iris sphincter muscle, pupillary dilation (mydriasis). The patient may receive antianxiety medication before surgery.

Drug Alert

Cycloplegics and Mydriatics

- Teach the patient to wear dark glasses to minimize photophobia.
- Monitor for signs of systemic toxicity (e.g., tachycardia, CNS effects).

Intraoperative Phase

The most common form of cataract surgery is *phacoemulsification.* In this procedure, a very small incision is made in the surface of the eye in or near the cornea. A thin ultrasound probe is inserted into the eye and ultrasonic vibrations are used to dissolve the clouded lens into fragments. These pieces are then suctioned out through the same

ultrasound probe. The small incisions are self-sealing and usually do not need sutures.

An *extracapsular cataract extraction procedure* is used for very advanced cataracts where the lens is too dense to dissolve into fragments. This technique requires a larger incision so that the cataract can be removed in one piece without being fragmented inside the eye. Sutures are needed to close the larger wound, and visual recovery is often slower.

Most patients have an IOL implanted at the time of cataract extraction surgery (Fig. 20.12). The lens of choice is a posterior chamber lens that is placed in the capsular bag behind the iris. At the end of the procedure, other drugs, such as antibiotics and corticosteroids, may be given.

Postoperative Phase

Unless complications occur, the patient is usually ready to go home as soon as the effects of sedative agents have worn off. Postoperative medications usually include antibiotic drops to prevent infection and corticosteroid drops to decrease the inflammatory response. The eyedrops are gradually reduced in frequency and then stopped when the eye has healed.

Recommendations for activity restrictions and nighttime eye shielding vary based on the HCP's preference. Many prefer that the patient avoid activities that increase the IOP, such as bending or stooping, coughing, or lifting.

During each postoperative examination, the HCP measures the patient's visual acuity, checks anterior chamber depth, assesses corneal clarity, and measures IOP. Even on the operative day, the patient's uncorrected visual acuity in the operative eye may be good. However, it is not unusual if the patient's visual acuity is reduced right after surgery. Multifocal IOL can correct for both near and far vision. Some patients may still need glasses or contact lenses to achieve their best visual acuity.

Nursing Management: Cataracts

Nursing Assessment

Assess the patient's distance and near visual acuity. If the patient is going to have surgery, especially note the visual acuity in the patient's unoperated eye. Use this information to determine how visually compromised the patient may be while the operative eye is healing. Assess the psychosocial impact of the visual disability and the level of knowledge about the disease process and therapeutic options. After surgery, assess the patient's level of comfort and ability to follow the discharge plan.

Planning

Preoperatively, the overall goals are that the patient with a cataract will (1) make informed decisions about therapeutic options and (2) have minimal anxiety. Postoperatively, the overall goals are that the patient with a cataract will (1) understand and follow discharge instructions, (2) maintain an acceptable level of physical and emotional comfort, and (3) remain free of infection and other complications.

Nursing Implementation

Health Promotion

There are no proven measures to prevent cataract development. However, it is wise to suggest that the patient wear sunglasses, avoid unnecessary radiation, and maintain appropriate intake of antioxidant vitamins (e.g., vitamins C, E) and good nutrition. Provide information about vision enhancement techniques for the patient who chooses not to have surgery.

Acute Care

Before surgery, the patient with cataracts needs accurate information

about the disease process and treatment options, since cataract surgery is considered an elective procedure. Be available to the patient and caregiver to help them make an informed decision about treatment. For the patient having surgery, provide information, support, and reassurance about the surgical and postoperative experience to reduce anxiety.

Photophobia is common when receiving pupil dilation medications. Therefore decreasing the room lighting is helpful. These medications produce transient stinging and burning.
