Human Milk, Breastfeeding, and Transmission of Human Immunodeficiency Virus Type 1 in the United States

ABSTRACT. Transmission of human immunodeficiency virus type 1 (HIV-1) through breastfeeding has been conclusively demonstrated. The risk of such transmission has been quantified, the timing has been clarified, and certain risk factors for breastfeeding transmission have been identified. In areas where infant formula is accessible, affordable, safe, and sustainable, avoidance of breastfeeding has represented one of the main components of mother-to-child HIV-1 transmission prevention efforts for many years. In areas where affordable and safe alternatives to breastfeeding may not be available, interventions to prevent breastfeeding transmission are being investigated. Complete avoidance of breastfeeding by HIV-1-infected women has been recommended by the American Academy of Pediatrics and the Centers for Disease Control and Prevention and remains the only means by which prevention of breastfeeding transmission of HIV-1 can be absolutely ensured. This technical report summarizes the information available regarding breastfeeding transmission of HIV-1.

ABBREVIATIONS. INTRODUCTION

The benefits of breastfeeding are well recognized and include significantly decreased infant morbidity and mortality rates by providing optimal nutrition, by protecting against common childhood infections such as gastrointestinal and respiratory tract infections, and by promoting child spacing.[1–6] Breastfeeding is particularly important in resource-poor regions of the world, where limited access to clean water increases the risk of diarrheal disease if replacement feeding is used. However, human immunodeficiency virus type 1 (HIV-1) is transmitted through human milk, leading to the dilemma that use of replacement feeding in resource-poor settings, although protecting the infant against HIV-1 infection, also could place the infant at risk of mortality from other infections. Shortly after the first report of transmission of HIV-1 through breastfeeding,[7] the Centers for Disease Control and Prevention (CDC) recommended that HIV-1-infected women in the United States avoid breastfeeding,[8] because replacement feeding is safe, affordable, and culturally acceptable. The CDC and the American Academy of Pediatrics (AAP)[9] have continued to recommend counseling HIV-1-infected women in the United States not to breastfeed or provide their milk for the nutrition of their own or other infants. Avoidance of breastfeeding remains an important component of mother-to-child HIV-1 transmission prevention efforts in the United States,[10] where perinatal transmission of HIV-1 has been substantially decreased.[11] However, in areas of the world where breastfeeding is the norm and safe replacement feeding generally is not possible, the enormous and unremitting epidemic of mother-to-child transmission of HIV-1 continues.[12] Research efforts focused on the continuing problem of breastfeeding transmission in much of the world have yielded additional information regarding mechanisms of HIV-1 transmission through breastfeeding as well as the timing of and risk factors for such transmission. This technical report summarizes the available information regarding transmission of HIV-1 through human milk. Complete avoidance of breastfeeding by HIV-1-infected women remains the only means by which prevention of breastfeeding transmission of HIV-1 can be absolutely ensured.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

EVIDENCE OF BREASTFEEDING TRANSMISSION OF HIV-1

Over nearly 2 decades, the understanding of mother-to-child HIV-1 transmission through breastfeeding has increased tremendously. Beginning with the earliest clinical evidence of breastfeeding transmission of HIV-1 (case reports), additional information regarding breastfeeding transmission has come from both other epidemiologic studies (descriptive and analytic) and laboratory studies.

Evidence From Epidemiologic Studies

Descriptive Studies

In 1985, Ziegler and colleagues[7] in Australia described the case of an HIV-1-infected infant who apparently acquired the infection after being breastfed by his previously healthy mother, who received a postpartum transfusion of HIV-1-contaminated blood. Over the next several years, this report was confirmed by other case reports from around the world.[13–26] In general, these case reports described acquisition of HIV-1 infection by children of breastfeeding mothers, with the mothers being at low risk of HIV-1 infection and presumed HIV-1-seronegative until acquisition of infection after delivery, usually through HIV-1-contaminated blood transfusions. On the basis of a case series of 10 breastfeeding women, the estimated risk of breastfeeding transmission among women with acquisition of HIV-1 infection after delivery was 27% (95% confidence interval [CI]: 6%–61%).[27] Because of viremia associated with primary infection with HIV-1 and the presumably high viral load concomitantly in human milk, women who breastfeed during primary infection with HIV-1 could represent a particularly high-risk group. Therefore, the generalizability of the implications of these case reports to breastfeeding women with HIV-1 infection acquired before delivery, who represent most HIV-1-infected breastfeeding women, was not clear. However, on the basis of these case reports and because of concern that women with chronic HIV-1 infection also could be at risk of transmitting HIV-1 to their infants through breastfeeding, in 1985 the CDC issued the recommendation that HIV-1-infected women avoid breastfeeding.[8]

Studies of mother-to-child transmission of HIV-1 in different countries around the world yielded transmission rates, in the absence of interventions to decrease transmission, ranging from 13% to 42%.[28] The finding that transmission rates were generally higher in countries where virtually all mothers breastfeed compared with countries such as the United States, where breastfeeding by HIV-1-infected women is unusual,[29,30] suggested the possibility that breastfeeding transmission accounted for some of the discrepancy in rates between different settings.

Observational, Analytic Studies

Higher rates of HIV-1 infection among breastfed children compared with formula-fed children were reported in several studies.[31–35] On the basis of a systematic review of published studies meeting criteria allowing the determination of the quantitative risk of breastfeeding transmission of HIV-1,[36] the estimated risk of transmission of HIV-1 through breastfeeding by mothers who acquired HIV-1 infection postnatally was 29% (95% CI: 16%–42%). Similar analysis of published studies with mothers who had chronic HIV-1 infection resulted in an estimated further risk of transmission through breastfeeding (in addition to in utero and/or intrapartum transmission) of 14% (95% CI: 7%–22%).

On the basis of the information available at the time, consensus statements from the World Health Organization (WHO) in 1987[37] and 1992[38] included recommendations that were intended to result in the greatest likelihood of prevention of infant mortality and of mother-to-child transmission of HIV-1 through breastfeeding in different regions of the world. These recommendations were that breastfeeding should be advised for women, including HIV-1-infected women, in areas of the world where most infant deaths were attributable to infections and malnutrition. In addition, it was recommended that in other areas of the world where infectious diseases were not the main causes of infant death, HIV-1-infected women be advised not to breastfeed but instead to use safe feeding alternative(s) for their infants.

Prospective cohort studies published in the mid-1990s[39–42] provided estimates of the excess risk of HIV-1 transmission attributable to breastfeeding ranging from 4% to 22%. In 1997[43] and 1998,[44–46] the WHO along with the United Nations Children's Fund (UNICEF) and the Joint United Nations Program on HIV/AIDS (UNAIDS) issued revised recommendations regarding breastfeeding and HIV-1 transmission. These recommendations called for giving women access to HIV-1 counseling and testing as well as information that would allow them to make fully informed decisions regarding infant feeding.

Interventional, Analytic Study

A randomized clinical trial of breastfeeding versus formula feeding among HIV-1-infected women in Kenya demonstrated HIV-1 transmission through breastfeeding.[47] This trial enrolled 425 HIV-1-infected pregnant women. Compliance was higher in the breastfeeding arm (any use of human milk, 96%) compared with the formula-feeding arm (complete avoidance of human milk, 70%). The median duration of breastfeeding was 17 months. The cumulative probability of HIV-1 infection in the children at 24 months of age was significantly higher in the breastfed children (36.7% [95% CI: 29.4%–44.0%] in the breastfeeding arm vs 20.5% [95% CI: 14.0%–27.0%] in the formula-feeding arm [$P = .001$]). Most breastfeeding transmission occurred early (75% by 6 months of age), but transmission continued throughout the duration of human milk exposure.

Individual Patient Data Meta-analysis

The objectives of the Breastfeeding and HIV-1 International Transmission Study, a meta-analysis of individual patient data from randomized, placebo-controlled clinical trials conducted in Africa, are to estimate the contribution of breastfeeding to the overall risk of mother-to-child transmission of HIV-1, to clarify the timing of breastfeeding transmission, and to identify determinants of late postnatal transmission through breastfeeding.[48] The large sample size and the application of uniform definitions across trials in this meta-analysis should provide more reliable and precise estimates than have previous studies of the risk and timing of late postnatal transmission of HIV-1 through breastfeeding.

Laboratory Studies

Early reports indicated HIV-1 could be detected in human milk from HIV-1-infected women.[49–52] Subsequent studies confirmed the detection of HIV-1 in human milk as both cell-free virus and cell-associated virus.[53–56] HIV-1 proviral DNA has been detected in human milk cells in 44% to 58% of samples in different studies,[53,55–58] with detection of HIV-1 DNA associated with lower maternal $CD4^+$ cell counts and severe deficiency of vitamin A (a micronutrient deficiency associated with diminished epithelial integrity and systemic immunity).[59] In a study in Kenya, cell-free virus (HIV-1 RNA) was detectable in 39% of human milk samples,[60] with the prevalence being higher in mature milk (47%) than in colostrum (27%). A higher human milk viral load is associated with a higher risk of mother-to-child transmission.[61,62] In South Africa, HIV-1 RNA was detectable in 63% of samples, with higher human milk viral load being associated with a greater risk of transmission of HIV-1 to the infant (odds ratio [OR] = 2.82 [95% CI = 1.22%–6.51%] for each log increase in viral load).[63] Similarly, a higher plasma viral load is associated with higher probability of breastfeeding transmission per liter of milk ingested by the infant.[62] The viral load in different body fluids (plasma, human milk, and genital secretions) is correlated.[64]

RISK FACTORS FOR BREASTFEEDING TRANSMISSION OF HIV-1

Because breastfeeding transmission of HIV-1 does occur, and because avoidance of breastfeeding is impossible in many settings, identification of risk factors for transmission of HIV-1 through breastfeeding is important to design interventions to prevent such transmission. Potential risk factors for breastfeeding transmission of HIV-1 include duration of breastfeeding as well as characteristics of the mother, the infant, and the human milk or type of breastfeeding (Table 1).

Duration of Breastfeeding

The cumulative risk of breastfeeding transmission of HIV-1 has been estimated. In a study conducted in Malawi, the cumulative risk of infection for infants of HIV-1-infected mothers continuing to breastfeed after 1 month of age was 3.5% at the end of 5 months, 7.0% at the end of 11 months, 8.9% at the end of 17 months, and 10.3% at the end of 23 months.[65] A pooled analysis of individual data from prospective cohort studies of HIV-1-infected women and their children[66] incorporated data from studies in Rwanda, the Ivory Coast, and Kenya, where breastfeeding is the norm. Late postnatal transmission (defined as acquisition of HIV-1 infection after 2.5 months of age) occurred among 49 of 902 children (5%). The overall estimated risk of breastfeeding transmission was 3.2% per 100 child-years of breastfeeding (95% CI: 3.1%–3.8%). With information regarding the timing of breastfeeding transmission available for 20 of the 49 children, the cumulative probability of acquisition of late postnatal transmission was 0.6% (95% CI: 0.2%–2.2%) at 6 months of age, 0.95% (95% CI: 0.4%–2.5%) at 9 months of age, 2.5% (95% CI: 1.3%–4.7%) at 12 months of age, 6.3% (95% CI: 3.9%–9.95%) at 18 months of age, 7.4% (95% CI: 4.5%–12.1%) at 24 months of age, and 9.2% (95% CI: 5.3%–15.5%) at 36 months of age. Differences in the cumulative risk of transmission between these 2 studies could be related to different definitions of late postnatal transmission (acquisition after 1 month of age in the Malawi study and after 2.5 months of age in the pooled analysis).

Longer durations of breastfeeding by mothers infected with HIV-1 are associated with an increased risk of HIV-1 transmission to their infants. In Italy,[35] univariate analyses suggested a higher likelihood of HIV-1 infection among breastfed children (compared with bottle-fed children), with an increasing likelihood of HIV-1 infection with increasing duration of breastfeeding (OR = 2.16 [95% CI: 1.17%–4.00%] for children breastfed for 20 days or less, increasing to OR = 6.41 [95% CI: 2.98%–13.79%] for children breastfed more than 92 days). In a small study in South Africa, a 15% increased risk of HIV-1 transmission was observed with breastfeeding compared with formula feeding, and the data suggested higher transmission rates with longer durations of breast-

TABLE 1. Potential Risk Factors for Human Milk Transmission of HIV-1

Category	Risk Factor
Duration of breastfeeding	Longer duration
Maternal characteristics	Younger age
	Higher parity
	Lower $CD4^+$ count
	Higher peripheral blood viral load
	Breast abnormalities
	Breast abscess
	Mastitis
	Nipple lesions
Infant characteristics	Oral candidiasis
Human milk characteristics	Higher viral load
	Lower concentrations of antiviral substances (eg, lactoferrin, lysozyme, SLPI, epidermal growth factor)
	Lower concentration of virus-specific cytotoxic T-lymphocytes
	Lower secretory IgA
	Lower IgM
Exclusivity of breastfeeding	Mixed breastfeeding

IgA indicates immunoglobulin A, IgM, immunoglobulin M.

feeding.[67] In a meta-analysis of published data from prospective cohort studies of HIV-1-infected women and their children,[68] 499 HIV-1-infected women who breastfed their children were identified. The estimated risk of breastfeeding transmission of HIV-1 was 16% (95% CI: 9%–22%). Among breastfed infants, 47% of HIV-1 infections were attributable to breastfeeding. Breastfeeding transmission occurred in 21% (10%–22%) of those who breastfed for a median length of 3 or more months and 13% (95% CI: 4%–21%) among infants who breastfed for a median of less than 2 months.

Characteristics of the Mother and Infant

Characteristics of the mother and infant have been associated with increased risk of breastfeeding transmission of HIV-1. Maternal factors associated with breastfeeding transmission of HIV-1 include younger maternal age and higher parity,[65] maternal HIV-1 disease stage, and breast abnormalities. More advanced maternal disease stage, as manifested by low $CD4^+$ cell counts, is a risk factor for postnatal transmission of HIV-1,[61,63,69] along with higher maternal peripheral blood or human milk viral load.[61–63] An early case report of the temporal association of acquisition of HIV-1 infection by the child of an HIV-1-infected woman with a breast abscess suggested the ingestion of inflammatory cells related to the bacterial infection of the breast contributes to breastfeeding transmission of HIV-1.[70] Later studies confirmed the association of transmission of HIV-1 through breastfeeding with maternal breast abnormalities, such as breast abscesses, mastitis, and nipple lesions. In Kenya, mastitis and breast abscesses were associated with late postnatal transmission of HIV-1 (relative risk [RR] = 21.8 [95% CI: 2.3%–211.0%] and RR = 51.6 [95% CI: 4.7%–571.0%], respectively).[68] In Malawi, women with increased human milk sodium concentrations consistent with subclinical mastitis had higher human milk viral loads than did women without increased human milk sodium concentrations.[61] In another study in Kenya, maternal nipple lesions (OR = 2.3 [95% CI: 1.1%–5.0%]) and mastitis (OR = 2.7 [95% CI: 1.1%–6.7%]) were each associated with an increased risk of postnatal transmission.[69] Oral candidiasis before 6 months of age is associated with late postnatal transmission (OR = 2.8 [95% CI: 1.3%–6.2%]).[69] Results of a study in the Ivory Coast suggested maternal breast abscesses and cracked nipples, as well as oral candidiasis in infants, were risk factors for late postnatal transmission of HIV-1 through breastfeeding.[42]

Characteristics of Human Milk or Type of Breastfeeding

In addition to higher human milk viral load, characteristics of human milk possibly associated with a higher risk of breastfeeding transmission of HIV-1 include lower concentrations of antiviral substances, such as lactoferrin,[71,72] lysozyme, secretory leukocyte protease inhibitor (SLPI),[73] and epidermal growth factor,[74] as well as lesser specific, local immune responses to HIV-1. Interestingly, HIV-1-infected women with subclinical mastitis, higher human milk viral loads, and higher rates of mother-to-child transmission had higher human milk concentrations of lysozyme and SLPI than did HIV-1-infected women without subclinical mastitis.[75] However, SLPI concentrations in human milk have not been found by other investigators to be associated with HIV-1 transmission through breastfeeding.[76] It has been suggested that epidermal growth factor in colostrum helps to make the gastrointestinal tract less permeable to viral infection.[74] Higher mother-to-child transmission of HIV-1 has been associated with lower human milk concentrations of secretory immunoglobulin A and immunoglobulin M during the first several weeks of life in some[55] but not all studies.[77]

When feeding patterns among infants born to HIV-1-infected women in Brazil were analyzed, neither a history of colostrum intake nor a history of mixed feeding (human milk with other milk, tea, or juice) was associated with transmission.[78] However, in South Africa, data from a randomized clinical trial of vitamin A supplementation to prevent mother-to-child transmission were reanalyzed to evaluate a possible association between feeding patterns among infants of breastfeeding HIV-1-infected mothers and mother-to-child transmission.[79,80] In this study, breastfeeding was categorized as exclusive or mixed (ie, without or with water, other fluids, and food). Women who chose to breastfeed were counseled to consider exclusive breastfeeding. Follow-up visits after birth, during which an infant feeding history was obtained, occurred at 1 week, 6 weeks, and 3 months of age and every 3 months thereafter. By 15 months of age, children who ever breastfed were more likely to have become HIV-1-infected (31.6%) than were children who never breastfed (19.4% [$P = .007$]). Of children who ever breastfed, those who exclusively breastfed until at least 3 months of age but no longer than 6 months of age had a lower estimated transmission point estimate than did those with mixed feeding, but the confidence limits for these point estimates overlap (exclusive: 24.7% [95% CI: 16.0%–34.4%]; mixed: 35.9% [95% CI: 26.7%–45.1%]). The authors proposed that the mechanism of their findings was that contaminated fluids and foods given to infants with mixed breastfeeding damaged the bowel and facilitated the entry of HIV-1 into tissues. The results of this hypothesis-generating study have prompted several investigators to pursue new studies of exclusive breastfeeding to assess more carefully the risk of HIV-1 transmission according to feeding modality.

POTENTIAL INTERVENTIONS TO PREVENT BREASTFEEDING TRANSMISSION OF HIV-1

There are several potential interventions to prevent breastfeeding transmission of HIV-1 (Table 2). The first is conceptually the simplest: complete avoidance of human milk. If breastfeeding does occur, several interventions could potentially prevent transmission of HIV-1 through human milk. First, early weaning (eg, at 6 months of age) will limit the duration of exposure to human milk. Other interventions to potentially prevent breastfeeding transmis-

TABLE 2. Proven or Potential Interventions to Prevent Human Milk Transmission of HIV-1

Risk Factor for Transmission	Associated Intervention
Longer exposure to human milk from an HIV-1-infected woman	Complete avoidance of breastfeeding Early weaning
Greater maternal infectivity (eg, higher maternal viral load in peripheral blood and in human milk)	Maternal antiretroviral therapy while breastfeeding
Factors facilitating viral transfer from mother to child (eg, mixed breastfeeding)	Avoidance of mixed breastfeeding (encouragement of exclusive breastfeeding)
Infant susceptibility to infection	Improvement of infant defenses against infection (eg, with passive immunization or with antiretroviral prophylaxis to breastfeeding infants)

sion of HIV-1 can be categorized as follows: decreasing human milk viral load (eg, with maternal antiretroviral therapy or by treating human milk by pasteurization or other means), preventing or treating factors facilitating transfer of HIV-1 from mother to child (eg, preventing or treating maternal breast abnormalities and infant candidiasis, avoiding mixed breastfeeding), and improving infant defenses against HIV-1 infection (eg, by passive or active immunization or antiretroviral prophylaxis to breastfeeding infants). Recent WHO recommendations[81] reaffirm previous recommendations for all HIV-1-infected mothers to receive counseling, including provision of general information about risks and benefits of various infant feeding options and specific guidance in selecting the option most likely to be suitable for their situation, and call for mothers to be supported in the their choices regarding their infants' feeding.

Complete Avoidance of Breastfeeding

Complete avoidance of breastfeeding (eg, by using infant formula) is an intervention of obvious utility in settings where it is feasible (ie, where clean water is available), affordable, and culturally acceptable. The randomized clinical trial of breastfeeding versus formula feeding demonstrated breastfeeding by HIV-1-infected women causes more mother-to-child transmission than does formula feeding.[47] However, although transmission of HIV-1 was much higher in the children of women randomized to breastfeeding versus formula feeding (36.7% vs 20.5% at 2 years of age [$P = .001$]), the 2 groups experienced similar rates of mortality during the first 2 years of life.[82] Mortality rates at 24 months of age were 24.4% (95% CI: 18.2%–30.7%) among children whose mothers were randomized to breastfeeding and 20.0% (95% CI: 14.4%–25.6%) among those children whose mothers were randomized to formula feeding. Additionally, infants in the breastfeeding arm had better nutritional status than did those in the formula feeding arm, particularly during the first 6 months of life, although the overall prevalence of malnutrition was not different in the 2 study groups. The better growth of breastfed infants during the first 6 months of life highlights the importance of nutritional counseling for mothers who decide to give formula to their children, and the WHO recommends that HIV-1-infected women who decide not to breastfeed their children should receive specific guidance and support during at least the first 2 years of their children's lives to ensure adequate replacement feeding.[81]

Interventions Among Breastfeeding Women

Before considering specific interventions to prevent breastfeeding transmission of HIV-1, it is important to consider the potential effects of breastfeeding on the HIV-1-infected woman herself. One such potential effect is an increased mortality rate among breastfeeding HIV-1-infected women.

Potential Consequences of Breastfeeding for the Mother

The results of 2 studies evaluating the risk of mortality among HIV-1-infected women according to infant feeding modality (breastfeeding compared with formula feeding) have been conflicting. Data from the randomized clinical trial of breastfeeding versus formula feeding in Kenya were analyzed to assess maternal mortality according to infant feeding modality.[83] Analysis of maternal mortality was by intention to treat (ie, by randomized assignment of mothers to breastfeeding or formula feeding). Maternal mortality over the 2-year period after delivery was higher among those in the breastfeeding group (18 deaths among 197 [9%]) compared with those in the formula feeding group (6 deaths among 200 [3%]; $P = .009$). The cumulative probability of maternal death at 24 months after delivery was 10.5% in the breastfeeding group and 3.8% in the formula group ($P = .02$). The relative risk of death for mothers assigned to breastfeeding compared with those assigned to formula feeding was 3.2 (95% CI: 1.3%–8.1% [$P = .01$]), and the attributable risk of maternal death attributable to breastfeeding was 69%. There were significant associations between $CD4^+$ lymphocyte counts and maternal death as well as between viral load and maternal death. The authors hypothesized that a combination of the metabolic demands of breastfeeding on HIV-1-infected women (who already might have borderline nutritional status) and of HIV-1 infection itself could be associated with substantial nutritional impairment, which could result in an increased risk of death. Indeed, women in the breastfeeding group had greater weight loss after delivery than did women in the formula-feeding group.

Data from a second study, a randomized clinical trial of vitamin A supplementation in South Africa, were analyzed to assess maternal mortality among HIV-1-infected women according to infant feeding modality (breastfeeding or not breastfeeding).[84] In this trial, mothers chose whether to breastfeed or not (ie, there was no randomization regarding infant

feeding modality). Of 566 mothers whose data were analyzed, 410 breastfed their infants and 156 never breastfed. No differences in maternal mortality rates according to infant feeding modality were observed. Over a mean follow-up period after delivery of 10 months, 0.49% (2 of 410) of women who ever breastfed were known to have died, compared with 1.92% (3 of 156) of those who never breastfed. Morbidity among those who breastfed for more than 3 months was similar to that of women who breastfed for less than 3 months.

The reasons for the differences in the results of these 2 studies are not clear, and additional research is needed in this area. With a pooled sample size of several thousand HIV-1-infected women, the Breastfeeding and HIV-1 International Transmission Study[48] represents a unique resource for further exploration of the issue of maternal mortality and infant feeding modality.

Early Weaning

If complete avoidance of human milk is not possible, early weaning from human milk (eg, at 6 months of age), if feasible, would limit exposure to HIV-1-infected human milk while allowing the child to experience benefits of breastfeeding. Human milk provides sufficient nutritional requirements for optimal growth and development for approximately the first 6 months of life[85–87] (although vitamin D and iron supplementation may be required before 6 months of age in some infants[88]). Although human milk remains a valuable source of nutrition for many months thereafter, it is possible for children to be weaned successfully from human milk and provided other sources of nutrition after 6 months of age. The increased risk of morbidity and mortality associated with replacement feeding (because of malnutrition and infectious diseases other than HIV-1) is especially high during the first 6 months of life and decreases in magnitude thereafter.[89] Assessment of the feasibility of early weaning involves consideration of an individual woman's situation and local circumstances. For many women, early weaning of their children from human milk is not possible because of financial or other constraints. Early weaning from human milk is being evaluated in trials in Zambia[90] and Botswana.[91] The WHO recommends that HIV-1-infected women who decide to wean their children from human milk early receive specific guidance and support during at least the first 2 years of their children's lives to ensure adequate replacement feeding.[81]

Decreasing Viral Load in Human Milk

Maternal Antiretroviral Therapy

Several studies in Africa are planned to evaluate antiretroviral therapy for HIV-1-infected women during breastfeeding for the prevention of breastfeeding transmission of HIV-1. In observational and interventional studies, the effectiveness and efficacy of maternal combination antiretroviral therapy for prevention of mother-to-child transmission, especially breastfeeding transmission, will be assessed.

Treating Human Milk

Treatment of human milk with chemical agents or heat to inactivate HIV-1 has been investigated. Sodium dodecyl sulfate, a microbicidal agent active against HIV-1 and other viruses, does not alter protein content of human milk and can be efficiently removed from human milk samples.[92] In one study, allowing expressed human milk to stand at room temperature for 6 hours did not destroy proviral DNA, but boiling expressed human milk appeared to decrease HIV-1 infectivity of the milk.[93] Pasteurization of human milk,[94,95] including using devices that can be used in a home setting,[96–98] can decrease the infectious titer of cell-free HIV-1 and HIV-1-infected cells by more than 5 logs and 6 logs, respectively.[95] Use of any or all of these methodologies would not be feasible in many settings and may not be culturally acceptable. Additionally, although they decrease human milk viral load, these methodologies are unlikely to eliminate HIV-1 from milk completely. Finally, with any treatment to inactivate HIV-1, the extent to which the treatment diminishes the protective or nutritional components of human milk must be carefully assessed.

Preventing or Treating Factors Related to Facilitation of Transfer of HIV-1 From Mother to Child

Preventing or Treating Maternal Breast Abnormalities and Infant Candidiasis

In light of the evidence of the association of maternal breast abnormalities and breastfeeding transmission, the WHO recommends that HIV-1-infected women who breastfeed receive education and counseling to ensure good breastfeeding technique to decrease the risk of development of such conditions, and if such conditions arise, be treated as quickly and completely as possible.[81] Similarly, infant candidiasis should be treated promptly. One program underway in Zimbabwe involves education of women who choose to breastfeed. Individual counseling, if provided, concerns the following subjects: exclusive breastfeeding until the infant is 4 to 6 months of age followed by rapid weaning, proper positioning during breastfeeding, prompt seeking of medical care if breast abnormalities develop or if the infant develops oral candidiasis or other lesions, avoiding breastfeeding from a breast affected by abnormalities, and safe sex practices while breastfeeding.

Avoiding Mixed Breastfeeding

Exclusive breastfeeding during the first 4 to 6 months of life is associated with greater benefits than is mixed feeding in terms of morbidity and mortality from infectious diseases other than HIV-1.[99,100] The suggestive, but not definitive, results of analyses of feeding modality among breastfeeding children of HIV-1-infected women indicating a lower risk of transmission with exclusive breastfeeding compared with mixed breastfeeding[79,80] have prompted the development of additional studies[90,91] to evaluate further the role of exclusive versus mixed breastfeeding in vertical transmission of HIV-1. However, exclusive breastfeeding is not the norm in Africa and other

parts of the world. For example, only approximately half of Indian children younger than 4 months of age are exclusively breastfed.[101] In Zimbabwe, only 39% of infants were exclusively breastfed during the first 3 months of life, and only 7% were exclusively breastfed between 4 and 6 months of age.[102] Despite this, programs to promote exclusive breastfeeding have had some success. For example, the prevalence of exclusive breastfeeding at 5 months of age increased from 6% to 70% with home-based counseling by peer counselors (mothers from the local community with training for 10 days) in Bangladesh.[103] The Section on Breastfeeding of the American Academy of Pediatrics supports exclusive breastfeeding for approximately the first 6 months after birth.[87]

Improving Infant Defenses Against HIV-1 Infection

Passive Immunization

In some animal studies, the presence of circulating antibodies to HIV-1 in infants has been associated with a decreased risk of mother-to-child transmission of HIV-1.[104–108] Therefore, it has been hypothesized that passive immunization with anti-HIV-1 antibodies may decrease the likelihood of mother-to-child transmission of HIV-1 in humans. A clinical trial of HIV-1 immune globulin was conducted in the United States, but because of the unexpectedly low mother-to-child transmission rate among the study population with universal receipt of zidovudine prophylaxis, this trial was discontinued early.[109] Another randomized clinical trial of HIV-1 immune globulin with nevirapine versus 2 different regimens of nevirapine is planned in Uganda.

Active Immunization

Research regarding active immunization of infants to prevent postnatal acquisition of HIV-1 infection through breastfeeding is ongoing. Infant studies to evaluate the safety and immunogenicity of HIV-1 vaccines are underway in the United States and are planned in Africa.[110] Because no vaccine will produce immediate immunity, the goal is to provide protection against early postnatal transmission through administration of antiretroviral drugs or through passive immunization of the infant until an adequate immune response is induced in the infant by the HIV-1 vaccine.

Antiretroviral Prophylaxis to Breastfeeding Infants

The efficacy of continued administration of antiretroviral prophylaxis to breastfeeding infants is being investigated in several studies in India and different parts of Africa. These studies are evaluating administration of different antiretroviral drugs to the infant for varying lengths of time. Antiretroviral drugs being evaluated include zidovudine, lamivudine, and nevirapine. The planned duration of infant prophylaxis in these studies ranges from 1 week to 6 months of age. Preliminary results of some of these studies have been released.[91,111–113]

CONCLUSIONS

HIV-1 transmission through breastfeeding has been demonstrated conclusively. Additionally, the risk of such transmission has been quantified, the timing has been clarified, certain risk factors for breastfeeding transmission have been identified, and interventions to prevent breastfeeding transmission are being developed. Additional research is needed to characterize more completely the mechanism(s) of human milk transmission of HIV-1. Complete avoidance of breastfeeding by HIV-1-infected women remains the only means by which prevention of breastfeeding transmission of HIV-1 can be absolutely ensured. In settings such as the United States, with virtually universal access to clean water and with widespread cultural acceptance of formula feeding as an alternative to breastfeeding, avoidance of breastfeeding by HIV-1-infected women is possible. In other parts of the world where breastfeeding is the norm, affordable, feasible, and culturally acceptable interventions to decrease the risk of breastfeeding transmission of HIV-1 are urgently needed.

Identification and Care of HIV-Exposed and HIV-Infected Infants, Children, and Adolescents in Foster Care

ABSTRACT. As a consequence of the expanding human immunodeficiency virus (HIV) epidemic and major advances in medical management of HIV-exposed and HIV-infected persons, revised recommendations are provided for HIV testing of infants, children, and adolescents in foster care. Updated recommendations also are provided for the care of HIV-exposed and HIV-infected persons who are in foster care.

ABBREVIATIONS. HIV, human immunodeficiency virus; AAP, American Academy of Pediatrics; PCR, polymerase chain reaction.

An estimated 500 000 children and adolescents in the United States are in foster care.[1] Entrance to the foster care system may occur as a consequence of parental substance abuse, neglect, physical abuse, sexual abuse, or loss of biologic parent(s) resulting from abandonment, incarceration, disability, or death. As many as 78% of children in foster care have a parent with a history of substance abuse, and as many as 94% of infants in foster care are born to women who abuse substances.[2] The number of women with human immunodeficiency virus (HIV) infection has increased substantially, and most of these women are of childbearing age. Approximately 7000 births occur annually in the United States to HIV-infected women, and most of these women have been infected through heterosexual contact or as a consequence of drug use.[3] Seroprevalence of HIV infection in pregnancy nationwide is 1.7 per 1000 pregnant women, and in New York, where all newborns are tested for the HIV antibody, seroprevalence is 4 per 1000 pregnant women.[4] An inner-city study found that newborns placed in foster care at the time of hospital discharge were 8 times more likely to have been born to HIV-infected women than were newborns discharged to the care of their mothers.[5]

In addition to the increased risk of perinatally acquired HIV infection for those in foster care, children and adolescents in foster care may have been sexually abused, placing them at risk for acquisition of HIV infection. Adolescents who use drugs or are sexually active are also at risk for acquisition of HIV infection, and adolescent risky behavior may precede placement in foster care or may occur while in foster care. Although advances in antiretroviral therapy for adults have helped decrease the projections of 80 000 to 150 000 children and adolescents orphaned in the United States by the death of their mother to acquired immunodeficiency syndrome by the year 2000,[6,7] many HIV-infected women will still not survive to raise their offspring to adulthood, and their children may enter the foster care system as a consequence of maternal disability or death. Data from the Pediatric Spectrum of Disease project revealed that 45% of children born to HIV-infected women resided with a primary caregiver who was not the biological parent.[8]

Advances in the management of HIV infection include prenatal and postnatal administration of zidovudine to reduce the risk of infection of the infant, recommendations for initiation of *Pneumocystis carinii* pneumonia prophylaxis by 6 weeks of age for all infants born to HIV-infected women, variations in immunization recommendations for infected persons and infants at risk of infection, and recommendations for consideration of early and aggressive combination antiretroviral therapy for those who are infected.[9–11] The American Academy of Pediatrics (AAP) therefore issues recommendations in accordance with these recent advances to address the identification and care of HIV-exposed and HIV-infected infants, children, and adolescents in foster care.

HIV TESTING OF A CHILD IN FOSTER CARE WHO IS 1 YEAR OF AGE OR YOUNGER

The AAP, the American College of Obstetricians and Gynecologists, and the US Public Health Service have recommended that all pregnant women in the United States receive counseling about HIV infection and the benefits to the mother and her infant of knowing her serologic status and that all pregnant women should undergo routine testing for HIV.[12–14] The Institute of Medicine recently recommended a nationwide policy of HIV testing during pregnancy (with right of refusal).[4] In addition, if the mother's HIV status was not determined during pregnancy, the AAP recommends that, after birth of the infant, the pediatrician discuss with the mother the benefits to the infant of knowing the mother's serologic status and recommend testing at that time.[12]

The management of the HIV-exposed infant is complex and includes continuation of zidovudine prophylaxis during the first 6 weeks after birth, initiation of prophylaxis for *Pneumocystis carinii* pneumonia by 6 weeks of age in all infants born to HIV-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

infected women, monitoring of hematologic and immunologic parameters, specific laboratory testing to determine HIV infection status (DNA polymerase chain reaction [PCR] or viral culture), and variations in immunization recommendations.[9] Advances in laboratory diagnosis (DNA PCR and viral culture for HIV) enable physicians to determine infant infection status by 28 days of age in as many as 96% of infants born to HIV-infected women.[15,16] Published data suggest that RNA PCR may prove useful for early identification of infant infection status.[17,18] Prompt identification of infected infants permits early initiation of aggressive antiretroviral therapy with the potential to prevent the rapid progression of illness seen in some HIV-infected infants.

Thus, to provide appropriate medical care for the infant, it is necessary that foster care agencies obtain information about HIV exposure status, if known, for infants placed in foster care. If the maternal serologic status is unknown, the HIV exposure status of infants in foster care, including infants placed in foster care at nursery discharge and infants placed in foster care who are 1 year of age or younger, should be determined by testing the infants for HIV antibody. When the authority to consent to medical care has been transferred from the biological parents to a foster care agency, and the HIV-exposure status of the infant is unknown, the agency should provide consent for HIV testing of the infant and have an established mechanism to facilitate testing and to allow exchange of confidential information with appropriate persons (eg, physician, nurse, caseworker coordinating care for the foster child, biological parents, and the foster parents). Occasionally, legal restrictions may prevent testing of the infant in foster care without maternal consent. In such cases, the physician may need to consult with the foster care agency and legal authorities. Efforts should be made to educate the biological mother, if available, of the potential benefits to herself and to her infant of knowing maternal serologic status. Communication of information about any positive test results to the biological parent(s) or the foster parent(s) should occur in a health care setting with appropriate social service support available at the time of the meeting. Infants who are identified as HIV-exposed (born to an HIV-infected woman) should be managed in accordance with established guidelines.[9]

HIV TESTING OF CHILDREN IN FOSTER CARE WHO ARE OLDER THAN 1 YEAR

HIV-infected children may remain asymptomatic for years or have mild nonspecific symptoms (anemia, poor growth, developmental delay) that are not recognized as secondary to HIV infection. In a cohort of HIV-infected children, 32 (17.7%) of 181 HIV-infected children were first diagnosed at 4 years of age or older.[19] In another cohort of 42 perinatally infected long-term survivors between the ages of 9 and 15 years, 36 had no symptoms until after the age of 4 years.[20] Two children with perinatally acquired HIV infection have remained asymptomatic for almost 13 years.[21,22] In addition, transfusion-acquired HIV infection may be associated with an asymptomatic or a minimally symptomatic phase of illness, thus delaying diagnosis of HIV infection.[23] Because of the increasing recognition of HIV infection among older children, foster care agencies should create policies to facilitate testing of older children. Testing for HIV should be performed for all children in foster care with symptoms or physical findings compatible with HIV infection and for all children with a sibling or parent who is HIV-infected. Because factors that lead to placement of children in foster care frequently are associated with an increased risk of HIV infection in the child and parents, determining the status of all older children who are in the foster care system whose maternal serologic status is unknown may be prudent.

Diagnosis of HIV infection is made in a child 18 months of age or older when antibody testing by enzyme-linked immunosorbent assay and the Western blot technique is positive or when the child meets diagnostic criteria for the younger infant (positive HIV-specific diagnostic assays, ie, DNA PCR or viral culture on 2 separate blood specimens from the infant). Results of tests should be provided by the child's physician to foster parents, biological parents (if possible), foster care agency, and the child (if old enough to comprehend and if disclosure is appropriate to the developmental level of the child).[24]

HIV TESTING OF SEXUALLY ABUSED CHILDREN

Annually, more than 125 000 children and adolescents are sexually abused in the United States, and sexual abuse has been the mode of acquisition of HIV infection in at least 26 children younger than 13 years.[25] As part of sexual abuse evaluation, laboratory testing when performed should include HIV testing. Testing for HIV should be performed at the time of the initial assessment with repeated serologic testing at 6 weeks, 3 months, and 6 months after the incident of sexual abuse for children whose initial test results are negative.[26] Testing also should be repeated if symptoms suggestive of HIV infection occur. Foster care agencies should develop mechanisms to ensure that initial and follow-up serologic tests are obtained when indicated.

HIV TESTING OF ADOLESCENTS IN FOSTER CARE

HIV-infected adolescents may be unaware of their infection status. Adolescents in foster care, just as those who are not in the foster care system, may acquire HIV infection as a consequence of their own sexual activity or illicit drug use or may have been infected by previous sexual abuse or, rarely, by perinatal transmission. Adolescents who have been victims of sexual abuse are more likely to engage subsequently in sexual behavior that may place them at increased risk for acquiring HIV infection and other sexually transmitted diseases.[27] Homeless adolescents frequently engage in prostitution in exchange for money, food, or shelter, and a period of homelessness may occur before an adolescent is placed in foster care. In a New York City shelter for homeless adolescents, 6% of the residents were seropositive.[28] Intravenous drug use has long been recognized as a risk factor for HIV infection. Cocaine use also has

been reported as a risk factor for HIV infection because it may involve the exchange of sex for drugs or engaging in risky sexual behavior while under the influence of the drug.[29,30] It is important, though, to recognize that the epidemiology of HIV infection is changing and that there is an increased incidence of HIV transmission in the adolescent population through homosexual and heterosexual contact.

For adolescents in foster care (as for adolescents who are not in foster care), HIV testing should be recommended for those who have symptoms or physical findings suggestive of HIV infection and for those who have any of the following known risk factors for HIV infection: a sibling, or parent who is HIV infected, a current or past sexual partner who is HIV-infected or at increased risk of HIV infection; receipt of a blood transfusion before 1985; a history of sexual abuse; a diagnosis of a sexually transmitted disease; or a history of illicit substance use or abuse. In addition, HIV testing should be considered for all adolescents in foster care who are sexually active or have a history of sexual activity and for those whose medical history and family history are unavailable or inadequate for assessment of the aforementioned risk factors. Evaluation should be performed in the context of provision of comprehensive adolescent health care, and all adolescents should receive education and counseling from a health care professional about prevention of transmission of HIV infection.

All states allow adolescents to consent to confidential evaluation and treatment for sexually transmitted diseases.[31] In some states, adolescents may legally consent to confidential HIV testing and treatment. Testing of the adolescent should be performed with assent of the adolescent.[32] If testing of the adolescent is performed in association with evaluation for sexual abuse or because of high-risk behavior, foster care agencies and physicians providing such care should ensure that appropriate follow-up testing is obtained. Communication of positive test results to the adolescent should occur in the health care setting. State regulations may require consent of the adolescent for disclosure of test results to other individuals or agencies participating in the adolescent's care.

ISSUES RELATED TO THE CARE OF HIV-EXPOSED AND HIV-INFECTED INFANTS, CHILDREN, AND ADOLESCENTS IN FOSTER CARE

Provision of Medical Care

Foster care agencies should periodically review, with physician guidance, the agency policies pertaining to the care of HIV-exposed infants and HIV-infected infants, children, and adolescents. In addition, periodic review should occur of policies related to acquisition and communication of medical information and other confidential information for those in foster care, including infants placed in foster care at the time of hospital discharge. It is the responsibility of the discharging physician to provide records, including confidential HIV-related information, to the physician designated to assume care or to the agency for provision to the physician who will assume care. Similarly, when a child or adolescent initially is placed in foster care, the agency should contact the physician providing care to obtain complete medical records and determine if there are acute or chronic medical problems that require medical follow-up, the immunization status, and whether the person is taking medication.

Maintenance of a "medical home" is important in the care of all foster children and is particularly beneficial for those with chronic health problems, such as HIV infection.[33] Foster care agencies should ensure, in the event of a change in physicians, that complete medical and immunization records are transferred to the new physician. Agencies providing foster care should minimize or eliminate barriers to sharing confidential information among counselors, mental health professionals, caseworkers, and the physician providing care to the child or adolescent. Comprehensive care for HIV-exposed infants and HIV-infected infants, children, and adolescents requires coordination of care among multiple health care professionals and social service agencies. Use of the "health passport" (a booklet summarizing medical information, including illnesses, medications, immunizations, family history, and names of current and previous physicians) for children in foster care can assist in communication of information if the child changes physicians or is placed in a new foster home.[34]

With the increasing identification of HIV infection among pregnant women, there also has been increasing use of prophylactic zidovudine to reduce the risk of perinatal HIV infection.[35] This regimen is considered safe for mother and child.[36] However, the long-term consequences of in utero exposure to zidovudine and other antiretroviral agents are unknown. It is critical that information about in utero exposure to antiretroviral drugs be included in the medical records of infants born to HIV-infected women. All such infants, whether infected or uninfected, should receive long-term follow-up.

Owing to rapid advances in management of HIV infection, involvement in clinical trials may provide benefit to HIV-exposed infants and HIV-infected infants, children, and adolescents in foster care. In addition, clinical trials that do not involve a therapeutic agent but provide long-term follow-up of HIV-exposed and HIV-infected children and adolescents provide important benefits. Agencies providing foster care should have established procedures for access to studies and to clinical trials.

Foster Parent Education

Foster care agencies should provide education about HIV to all foster parents as part of their initial training. Such education should be updated periodically and should include infection control guidelines for use in the home setting.[37] Foster parents should be aware that there may be HIV-infected infants, children, and adolescents in foster care whose HIV status is unknown. Foster parents providing care to HIV-exposed infants should be educated about all issues in the management of the HIV-exposed infant that usually are discussed with the biological parent.[9]

Because provision of medical care for HIV-ex-

posed infants and HIV-infected infants, children, and adolescents is complex and requires frequent office visits, foster care agencies should develop procedures to ensure that those in foster care are seen at intervals deemed appropriate by the physician. If an HIV-exposed or HIV-infected child in foster care is transferred to a different foster home, the physician should be notified promptly (preferably before the transfer) to enable the physician to adequately inform the new foster parents about the child's health care needs, provide ongoing medication, and assist with additional education of new foster parents about HIV infection.

Permanency Planning

Although many children born to HIV-infected women are already in foster care or in the care of relatives outside the foster care system before the onset of debilitating complications in the mother or maternal death, infected women may not have made plans for provision of care for their children. In addition to determining who will provide care, it is necessary that provisions be made for long-term access to health care (physical and psychological) for HIV-infected offspring and for uninfected offspring. Permanency planning is a coordinated effort involving health care professionals, mental health professionals, social workers, foster care agencies, legal personnel, the biological family, and the designated "second family."[38]

CONCLUSION

These recommendations about HIV testing of infants, children, and adolescents in foster care and for enhanced coordination of care by physicians and foster care agencies are made to provide maximal opportunity for those in foster care to benefit from the dramatic medical advances in the care of HIV-exposed and HIV-infected infants, children, and adolescents.

RECOMMENDATIONS

1. Physicians and foster care agencies should be jointly responsible for the determination of HIV exposure status and HIV infection status for all infants in foster care. If maternal serologic status during the most recent pregnancy is unknown, and the state has guardianship and the authority to consent to medical care, the infant should be tested for HIV antibody. Infants exposed to HIV should be managed in accordance with established guidelines.[9]
2. Testing for HIV should be performed for all children in foster care who have:
   - symptoms or physical findings suggestive of HIV infection;
   - been sexually abused;
   - a sibling who is HIV-infected; or
   - a parent who is HIV-infected or is at increased risk of HIV infection.

   Testing for HIV also should be considered for all foster children whose maternal serologic status is unknown.
3. Testing for HIV (with assent of the adolescent) is recommended for all adolescents in foster care who have:
   - symptoms or physical findings suggestive of HIV infection;
   - a sibling who is HIV-infected;
   - a parent who is HIV-infected or at increased risk of HIV infection:
   - a current or past sexual partner who is HIV-infected or at increased risk of HIV infection;
   - received a transfusion before 1985;
   - a history of sexual abuse or a diagnosis of sexually transmitted disease; or
   - a history of illicit substance use or abuse.

   Testing for HIV also should be considered for all adolescents in foster care who are sexually active or have a history of sexual activity and for those whose medical history and family history are unavailable or inadequate for assessment of the aforementioned risk factors.
4. Physicians and foster care agencies should take joint responsibility to ensure appropriate exchange of complete medical records and confidential information necessary for the management of infants, children, and adolescents in foster care.
5. All foster parents should receive education about HIV infection, and the content of such education should be updated regularly.
6. All foster parents should be informed of the HIV exposure or infection status of infants and children in their care. Disclosure of adolescent HIV status should legally require the consent of the adolescent.
7. Foster care agencies should have established procedures to provide access for HIV-infected and HIV-exposed foster children to treatment-related and non–treatment-related clinical trials.

CLINICAL REPORT

Identification and Evaluation of Children With Autism Spectrum Disorders

Guidance for the Clinician in Rendering Pediatric Care

Chris Plauché Johnson, MD, MEd, Scott M. Myers, MD, and the Council on Children With Disabilities

ABSTRACT

Autism spectrum disorders are not rare; many primary care pediatricians care for several children with autism spectrum disorders. Pediatricians play an important role in early recognition of autism spectrum disorders, because they usually are the first point of contact for parents. Parents are now much more aware of the early signs of autism spectrum disorders because of frequent coverage in the media; if their child demonstrates any of the published signs, they will most likely raise their concerns to their child's pediatrician. It is important that pediatricians be able to recognize the signs and symptoms of autism spectrum disorders and have a strategy for assessing them systematically. Pediatricians also must be aware of local resources that can assist in making a definitive diagnosis of, and in managing, autism spectrum disorders. The pediatrician must be familiar with developmental, educational, and community resources as well as medical subspecialty clinics. This clinical report is 1 of 2 documents that replace the original American Academy of Pediatrics policy statement and technical report published in 2001. This report addresses background information, including definition, history, epidemiology, diagnostic criteria, early signs, neuropathologic aspects, and etiologic possibilities in autism spectrum disorders. In addition, this report provides an algorithm to help the pediatrician develop a strategy for early identification of children with autism spectrum disorders. The accompanying clinical report addresses the management of children with autism spectrum disorders and follows this report on page 1162 [available at www.pediatrics.org/cgi/content/full/120/5/1162]. Both clinical reports are complemented by the toolkit titled "*Autism: Caring for Children With Autism Spectrum Disorders*: *A Resource Toolkit for Clinicians*," which contains screening and surveillance tools, practical forms, tables, and parent handouts to assist the pediatrician in the identification, evaluation, and management of autism spectrum disorders in children.

INTRODUCTION

Public and physician awareness of autism has increased markedly in the new millennium because of increased media coverage and a rapidly expanding body of knowledge published in professional journals. Professionals who specialize in autism have proliferated over the past 2 decades and have introduced the terminology "autism spectrum disorders" (ASDs) to reflect the broader spectrum of clinical characteristics that now define autism.[1,2] ASDs represent 3 of the pervasive developmental disorders defined in the *Diagnostic and Statistical Manual of Mental*

Disorders, Fourth Edition (DSM-IV),[3] and the newer *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* (DSM-IV-TR)[4]: autistic disorder (AD), Asperger syndrome (AS [this terminology will be used in this report, although "Asperger's disorder" is used in the aforementioned publications]), and pervasive developmental disorder–not otherwise specified (PDD-NOS). In addition to being a spectrum disorder, autism has wide variability with respect to the presence and intensity of symptoms, even within the DSM-IV-TR categories, which indicates that there may be additional subtypes.

ASDs are not rare; many primary care pediatricians (PCPs) care for several children with ASDs. In fact, a survey completed in 2004 revealed that 44% of PCPs reported that they care for at least 10 children with ASDs; however, only 8% stated that they routinely screened for ASDs.[5] Another survey indicated that although PCPs were aware of the current DSM-IV-TR diagnostic criteria, they sometimes held beliefs about ASDs that were outdated.[6] It is critical that PCPs recognize the early signs of ASDs and be aware of new data that support better outcomes in children whose conditions are diagnosed early and who participate in appropriate intervention programs.[7–11] Because it is a chronic condition, the PCP also needs to feel comfortable with the ongoing care of children with ASDs within the context of the medical home. To support PCPs in the identification and care of children with ASD, the American Academy of Pediatrics (AAP) has developed and distributed several documents:

- The "*Autism A.L.A.R.M.*"[12]: a flyer that highlights the prevalence of autism, the importance of screening and listening to parents' concerns, and the urgency of making simultaneous referrals to specialists in ASDs and early intervention programs to promote improved outcomes.
- "*Is Your One-Year-Old Communicating With You?*"[13]: a brochure that focuses on early identification of social communication deficits and behavior problems that may be associated with developmental disorders, primarily ASDs. This brochure is intended for distribution to all parents of infants at the 9- or 12-month well-child visit. It encourages parents to share any concerns they have about their infant's language development and social skills with the pediatrician as early as possible.
- "*Understanding Autism Spectrum Disorders*"[14]: a 48-page introductory booklet for parents of children in whom an ASD has been diagnosed recently or is suspected strongly.

In addition, the AAP has developed an ASD toolkit and resource guide to assist the PCP with implementation of the principles discussed herein.

Although ASDs are neurodevelopmental conditions with strong genetic underpinnings, their exact etiology is unknown. In 1943, Leo Kanner, a psychiatrist at Johns Hopkins University, first described autism in a small group of children who demonstrated extreme aloofness and total indifference to other people.[15] In 1944, Hans Asperger, an Austrian pediatrician who was unaware of Kanner's work, published an article[16] that described children who demonstrated symptoms similar to those of Kanner's patients, with the exception that verbal and cognitive skills were higher. The term "infantile autism" first appeared as a diagnostic label in the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition* (DSM-III).[17] Since then, terminology has changed and diagnostic criteria have broadened.[18] Diagnostic criteria for AS were not included in the DSM until the fourth edition (DSM-IV). The most recent criteria for AD and AS (Asperger's disorder) are found in the DSM-IV-TR[4] (Tables 1 and 2, respectively). PDD-NOS, the remaining ASD, is described in the DSM-IV-TR as a subthreshold diagnostic term used when a child demonstrates severe and pervasive impairments in reciprocal social skills associated with deficits in language skills or with the presence of stereotypic behaviors or restricted interests or activities but does not meet full criteria for AD or AS. Although Rett syndrome and childhood disintegrative disorder are included in the DSM-IV-TR listings, they are not considered ASDs but should be considered in the differential diagnosis of each child, depending on the presenting signs and symptoms.

EPIDEMIOLOGY

Authors of studies published early in the new millennium concluded that the best estimate of current prevalence of ASDs in Europe and North America is approximately 6 per 1000.[19–27] In 2000, the Centers for Disease Control and Prevention organized the Autism and Developmental Disabilities Monitoring Network, a multisite, records-based surveillance program, to study the prevalence of ASDs. The network uses systematic screening of developmental evaluation records for autistic behaviors rather than depending on a medical or educational diagnostic label of an ASD. In 2007, the network reported ASD rates for 8-year-old children ranging from 1 in 303 to 1 in 94 for 2 time periods (2000 and 2002) in a total of 14 sites in the United States; the average rate was 1 in 150 or 6.6 per 1000 8-year-olds.[28–31] Although these studies reflect a 10-fold increase from studies published a half-century ago that chiefly targeted AD alone, most of the newer studies also included individuals with AS and PDD-NOS. One of the few studies that analyzed the prevalence in regard to type of ASD revealed that in Canada, where the overall rate was 6.5 per 1000, the individual rates were 2.2 per 1000 for AD, 1.0 per 1000 for AS, and 3.3 per 1000 for PDD-NOS.[27] Studies have varied in design, and

TABLE 1 Diagnostic Criteria for 299.00: AD

A. A total of six (or more) items from (1), (2), and (3), with at least two from (1), and one each from (2) and (3):
   (1) qualitative impairment in social interaction, as manifested by at least two of the following:
      (a) marked impairment in the use of multiple nonverbal behaviors such as eye-to-eye gaze, facial expression, body postures, and gestures to regulate social interaction
      (b) failure to develop peer relationships appropriate to developmental level
      (c) a lack of spontaneous seeking to share enjoyment, interests, or achievements with other people (eg, by a lack of showing, bringing, or pointing out objects of interest)
      (d) lack of social or emotional reciprocity
   (2) qualitative impairments in communication as manifested by at least one of the following:
      (a) delay in, or total lack of, the development of spoken language (not accompanied by an attempt to compensate through alternative modes of communication such as gesture or mime)
      (b) in individuals with adequate speech, marked impairment in the ability to initiate or sustain a conversation with others
      (c) stereotyped and repetitive use of language or idiosyncratic language
      (d) lack of varied, spontaneous make-believe play or social imitative play appropriate to developmental level
   (3) restricted repetitive and stereotyped patterns of behavior, interests, and activities, as manifested by at least one of the following:
      (a) encompassing preoccupation with one or more stereotyped and restricted patterns of interest that is abnormal either in intensity or focus
      (b) apparently inflexible adherence to specific, nonfunctional routines or rituals
      (c) stereotyped and repetitive motor mannerisms (eg, hand or finger flapping or twisting, or complex whole-body movements)
      (d) persistent preoccupation with parts of objects
B. Delays or abnormal functioning in at least one of the following areas, with onset before 3 years old: (1) social interaction, (2) language as used in social communication, or (3) symbolic or imaginative play.
C. The disturbance is not better accounted for by Rett's Disorder or childhood disintegrative disorder.

TABLE 2 Diagnostic Criteria for 299.80: Asperger's Disorder (Referred to as AS in This Report)

A. Qualitative impairment in social interaction, as manifested by at least two of the following:
   (1) marked impairment in the use of multiple nonverbal behaviors such as eye-to-eye gaze, facial expression, body postures, and gestures to regulate social interaction
   (2) failure to develop peer relationships appropriate to developmental level
   (3) a lack of spontaneous seeking to share enjoyment, interests, or achievements with other people (eg, by a lack of showing, bringing, or pointing out objects of interest to other people)
   (4) lack of social or emotional reciprocity
B. Restricted repetitive and stereotyped patterns of behavior, interests, and activities, as manifested by at least 1 of the following:
   (1) encompassing preoccupation with one or more stereotyped and restricted patterns of interest that is abnormal either in intensity or focus
   (2) apparently inflexible adherence to specific, nonfunctional routines or rituals
   (3) stereotyped and repetitive motor mannerisms (eg, hand or finger flapping or twisting, or complex whole-body movements)
   (4) persistent preoccupation with parts of objects
C. The disturbance causes clinically significant impairment in social, occupational, or other important areas of functioning.
D. There is no clinically significant general delay in language (eg, single words used by 2 years old, communicative phrases used by 3 years old).
E. There is no clinically significant delay in cognitive development or in the development of age-appropriate self-help skills, adaptive behavior (other than in social interaction), and curiosity about the environment in childhood.
F. Criteria are not met for another specific Pervasive Developmental Disorder or Schizophrenia.

case-ascertainment strategies make comparisons difficult.[20–22,24,31–34]

With recent heightened public awareness, parents are more likely to raise a concern specifically about autism.[35–37] In addition, as screening tools and more reliable evaluation instruments have been developed, professionals have become increasingly proficient in recognizing and diagnosing ASD. Apart from greater awareness and better ascertainment, additional reasons for the apparent increase have been debated hotly in the lay media; in fact, the publicized "autism epidemic" may be one of the most challenging public health issues today.

The prevalence of autism and, more recently, ASDs is closely linked to a history of changing criteria and diagnostic categories. Autism first appeared as a separate entity with specific criteria in the DSM-III in 1980.[17] In 1987, the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition, Revised* (*DSM-III-R*)[38] listed broadened AD criteria and the new subthreshold category of PDD-NOS, both of which promoted inclusion of milder cases. Later, these changes received criticism for being too inclusive and for promoting overdiagnosis.[39] The DSM-IV[3] criteria published in 1994 reflected the result of years of analyses to reduce the overinclusiveness of the DSM-III-R criteria; however, it included AS for the first time, which, in effect, broadened the range of disorders. Studies have revealed that the DSM-IV criteria have better specificity (0.87) than DSM-III-R criteria.[40] The DSM-IV-

TR[4] criteria for AD and AS are unchanged; however, the text description of PDD-NOS was edited slightly to increase specificity. Collaboration with European groups that worked on the revised *International Statistical Classification of Diseases and Related Health Problems* (10th edition)[41] promoted better conformity between the 2 classification systems.

AD did not become a diagnosis for which children became eligible to receive special education services until passage of the Individuals With Disabilities Education Act (IDEA) in 1990.[42] Before the IDEA was enacted, children were labeled as having conditions such as mental retardation (MR), learning disability, speech impairment, or emotional disturbance to obtain eligibility for services.[43] Hence, after passage of the IDEA, the resulting increase in the number of children served under the AD category reflected both newly diagnosed young children entering the school system and older children who were previously eligible for special services under a different educational label. This reflects the phenomenon of "diagnostic substitution," whereby the number of children receiving special education under other categories (primarily MR, speech impairment, and learning disabilities) has decreased over the same time period. In addition, some increase in prevalence may be attributable to inaccuracies in diagnosis for a number of reasons, including labeling biases when schools used less rigorous criteria than those needed for a DSM diagnosis,[44–48] when educational funding trends influenced diagnosis,[49] and/or when parents of children with marginal criteria advocated for the AD label to qualify for supplementary services (eg, year-round schooling) described in the IDEA amendments.[50,51] The impact of these factors on current prevalence estimates has been controversial and illustrates the reason why educational administrative data reported in some studies that receive media attention should not be considered for epidemiologic studies.[47,48,52–56]

Just at the time when school eligibility laws were changing, the Americans With Disabilities Act of 1990[57] was passed, obliging states to administer their programs in the most integrated settings appropriate to the needs of the person with disabilities. This was the culmination of a long series of state and federal legislation that promoted closure of institutions and encouraged governments to support families in their efforts to raise their children with disabilities at home. Thus, children with autism, especially those with comorbid MR and behavior problems who might have been institutionalized in the past, began to attend community schools and to be "counted" in educational prevalence data.

Other factors that may also be contributing to the perceived increase in prevalence include the recent identification of children with genetic disorders unrelated to ASDs who also sometimes can meet criteria for an ASD, such as Down syndrome[58,59] and CHARGE (coloboma, heart disease, choanal atresia, retarded growth and development and/or central nervous system anomalies, genital anomalies and/or hypogonadism, and ear anomalies and/or deafness) syndrome.[60] Finally, diagnosis of an ASD may be made in an older family member with milder symptoms that were previously unrecognized until after the diagnosis of a younger child.[61]

Regardless of the study, the year conducted, or the reported rate of prevalence, more boys than girls are consistently found to be affected with ASDs, with male-to-female ratios ranging from 2:1 to 6.5:1.[24,28,29,34,62] The male-to-female ratio is even higher for high-functioning autism and AS, ranging from 6:1 to as high as 15:1.[63] (In recognition of these statistics and for the sake of brevity, this report uses masculine pronouns.)

ETIOLOGY

ASDs are biologically based neurodevelopmental disorders that are highly heritable.[64] Despite this fact, the exact cause still is unknown. Finding the cause has been daunting because of genetic complexity and phenotypic variation. ASDs are complex heritable disorders that involve multiple genes and demonstrate great phenotypic variation. Estimates of recurrence risks, based on family studies of idiopathic ASDs, are approximately 5% to 6% (range: 2%–8%) when there is an older sibling with an ASD and even higher when there are already 2 children with ASDs in the family.[65–68]

In a minority of cases (<10%), ASDs may be associated with a medical condition or a known syndrome.[20,21] Although ASDs are believed to be mainly genetic in origin, environmental factors may modulate phenotypic expression.[64,69] Advanced paternal age[70,71] and maternal age[71,72] have been shown to be associated with an increased risk of having offspring with ASDs, possibly because of de novo spontaneous mutations and/or alterations in genetic imprinting. Environmental exposures may act as central nervous system teratogens in early gestational life.[73] Some researchers have suggested that an epigenetic mechanism (heritable changes in gene expression that occur without changes in DNA sequence) may be responsible.[74] Thus, it has become more and more apparent that the etiology is multifactorial with a variety of genetic and, to a lesser extent, environmental factors playing a role.[75]

Two major strategies have been used in the search for the ASD genes: targeted cytogenetic/molecular studies and whole-genome screens of families of children with ASD.[76–79] The first strategy depends on developing a hypothesis regarding the pathogenesis of ASDs, focusing on a potential candidate gene and testing it genetically for an association with ASDs. Candidate genes in ASDs include, among others, those that seem to play a role in brain development (eg, cerebellar Purkinje cell proliferation) or neurotransmitter function (eg, serotonin).[80] The second strategy uses an indirect method and does

not require investigators to make assumptions regarding the mechanism of inheritance. Instead, families with multiple members who demonstrate an ASD (multiplex families) are studied to identify recurring DNA markers (break points, translocations, duplications, and deletions) present in affected members but not in unaffected members. Unfortunately, progress in determining a genetic etiology using this method has been impaired, because the phenotypic end points of ASDs are not well defined. Changing DSM criteria and inconsistent ascertainment strategies, which results in a hazy delineation between affected versus unaffected family members, obscure outcomes and challenge interpretation of results.[67] This phenotypic heterogeneity has challenged molecular searches for the ASD gene(s) despite several genome-wide screens of the International Molecular Genetic Study of Autism Consortium and multicenter collaborative efforts over the past couple of decades.[78,81–84] Although at least 1 autism-linked abnormality has been found on almost every chromosome, sites on a few chromosomes (X, 2, 3, 7, 15, 17, and 22) seem to be more promising than others.[67,68,75,79,85–90] Maternally derived 15q duplications are common; depending on the investigator, yields vary from 1% to 10%,[91] with most in the range of 1% to 3%.[92,93] Patients with these duplications may not display dysmorphic features, but they often have hypotonia and/or global developmental delay (GDD) and may develop seizures later. The abnormality can often be identified on high-resolution karyotype analysis. Other less common abnormalities have also been reported.[94]

Finally, the male predominance noted above also suggests a genetic role in the inheritance of autism. Several genetic processes can lead to male predominance, including causative genes located on the X chromosome (X-linked disorders) and imprinted genes, but the reason for male predominance in autism is not completely understood.[95]

In a discussion of etiology, subtyping ASDs as either idiopathic or secondary is helpful.[67,79,95] For the purposes of this discussion, the term "idiopathic" ASDs refers to cases in which children meet criteria for ASDs but do not have a comorbid associated medical condition known to cause ASDs. Most individuals with an ASD have the idiopathic type. Children with idiopathic ASDs demonstrate variable behavioral phenotypes, are somewhat less likely to have comorbid GDD/MR, and generally do not have dysmorphic features that herald a recognizable syndrome. Nevertheless, twin and family studies have revealed that idiopathic ASDs are heritable and have a recurrence rate of 5% to 6%.[67,94,95] The term "secondary" ASDs refers to cases with an identifiable syndrome or medical disorder known to be associated with ASDs. Whereas earlier reviews reported that the proportion of individuals with ASDs who have a comorbid syndrome or medical condition was 10% to 20%,[2,96–98] the proportion has decreased to less than 10% when using more recent data sets.[79,89,95,99–101] In a meta-analysis of 23 epidemiologic studies, Chakrabarti and Fombonne[20,21] revealed that a recognizable condition was identified in only 6% of those with a confirmed ASD. The rate of coexisting MR (cognitive impairment associated with an IQ of <70) in children with ASDs seemed to decrease from 90% before the 1990s to less than 50% after 2000,[28,29,34,35,102,103] possibly because of improved methods in testing intelligence in this population and to the increased awareness of children with ASD with milder features and higher functioning. This trend is important, because coexisting severe MR, especially in the presence of dysmorphic features, increases the likelihood of identifying a known disorder.[89,104–108] Neurogenetic syndromes that seem to play a causative role or otherwise are associated with ASDs include, but are not limited to:

- Fragile X syndrome[109,110]: Fragile X syndrome is the most common known genetic cause of AD and of MR in males. The phenotype includes MR, macrocephaly, large pinnae, large testicles (particularly after puberty), hypotonia, and joint hyperextensibility. Identifying a patient with fragile X syndrome is important for genetic counseling purposes, because the diagnosis has implications for other family members. Depending on the prevalence of comorbid MR in study subjects with ASD, the etiologic yield of fragile X syndrome–DNA testing has ranged from 0% to 8%, with a median of approximately 3% to 4%.[99,109,111] On the other hand, as many as 30% to 50% of individuals with genetically confirmed fragile X syndrome will demonstrate some characteristics of ASDs.[102,110]
- Neurocutaneous disorders: Tuberous sclerosis[112–116] is characterized by hypopigmented macules (sometimes requiring a Wood's lamp examination for visualization in young children), fibroangiomata, kidney lesions, central nervous system hamartomas, seizures, MR, and autistic and/or attention-deficit/hyperactivity disorder (ADHD)–like behaviors. Although tuberous sclerosis is a dominant disorder (with genes located at 9q and 16p), most cases represent new mutations. Although it is the most common neurocutaneous disorder, neurofibromatosis is less likely to be associated with ASDs. It also is autosomal-dominant, with half of cases representing new mutations of the neurofibromatosis 1 gene on 17q.[117] It is characterized by café au lait macules and freckling in the axillary and inguinal regions, neurofibromas, and ocular Lisch nodules. Although most patients have a benign course and normal intelligence, a small subset of individuals have MR and behavioral features that are consistent with ASDs.
- Phenylketonuria[118]: phenylketonuria now is a rare cause of ASDs and MR in the United States, because it

is preventable as a result of newborn screening and dietary intervention.

- Fetal alcohol syndrome[119]: Children who are exposed to alcohol during gestation have an increased risk of ASDs in addition to other neurodevelopmental disorders.
- Angelman syndrome[93,94,120–123]: Angelman syndrome is associated with loss of the maternally expressed ubiquitin-protein ligase gene (*UBE3A*) on 15q through deletion, paternal uniparental disomy, or imprinting errors. Children with Angelman syndrome present with GDD (and often are nonverbal), hypotonia in early childhood, wide-based ataxic gait, seizures, and progressive spasticity. Angelman syndrome associated with a deletion of 15q can be detected with fluorescence in situ hybridization (FISH) testing; however, when it results from uniparental disomy, methylation studies are necessary.
- Rett syndrome[124–127]: Rett syndrome usually presents with a classic phenotype and should be considered in all females who demonstrate autistic-like regression, especially if they have microcephaly, seizures, and hand-wringing stereotypies. Retrospective videos have revealed early subtle motor symptoms during the first year of life.[128] Now that it is possible to confirm this diagnosis with DNA testing (methyl CpG-binding protein 2 [*MECP2*]) in approximately 80% of cases, it has become apparent that there is a spectrum of severity, and some patients may present with atypical features including those consistent with ASDs. Rett syndrome is much less common in males, and the presentation is more varied. Some males die in infancy as a result of neonatal encephalopathy; others with comorbid Klinefelter syndrome (as well as a few males [in isolated case reports] with a normal number of sex chromosomes) demonstrate more classic symptoms.[129,130]
- Smith-Lemli-Opitz syndrome[131]: Smith-Lemli-Opitz syndrome is a rare (1 in 20 000) autosomal-recessive disorder caused by a metabolic error in cholesterol biosynthesis. Although most patients present with multiple congenital anomalies, failure to thrive, and MR, some may present with subtle physical features such as webbing (syndactyly) of the second and third toes, mild hypotonia, and autistic features. Recurrence risk is 25%; thus, appropriate genetic counseling is important.

Whether the aforementioned conditions play a direct or indirect etiologic role or simply are associated with ASDs, they still represent a small minority of patients with ASDs. Conversely, a few children with genetic syndromes that are characterized by features quite different from ASDs also may meet DSM-IV-TR criteria. For example, recent studies have reported that 6% to 7% of children with Down syndrome (typically characterized by relatively good social skills compared with those in other domains)[59] and almost 50% of children with CHARGE syndrome (associated with mutations of the *CHD7* gene[132]) meet criteria for one of the ASDs.[60] There have also been a few isolated reports of a mitochondrial and/or metabolic abnormality (eg, carnitine deficiency) being associated with an ASD, but the significance of these reports is not clear.[133]

Increased and decreased levels of T lymphocytes, immunoglobulins, and antibrain autoantibodies in the systemic circulation have been reported.[134] These have been observed chiefly in retrospective case studies of patients with idiopathic ASDs, but systematic prospective studies have confirmed neither their existence nor their relevance.[87] Prospective studies have revealed that, except for a few individuals with recurrent infections, healthy children with ASDs generally have normal immune function.[135] Some studies have reported increased rates of autoimmune disorders in families of children with ASDs,[136] particularly in the mothers (eg, thyroid disorders[137] and psoriasis[138]); however, the relevance of these common disorders to ASDs in children is unknown. Furthermore, studies have shown no increase in autoimmune disorders of the central nervous system, and patients with ASDs did not themselves exhibit autoimmune disorders.[139] The contribution of possible immunologic dysfunction remains to be further defined.

Environmental Issues

Regardless of the mechanism, a review of studies published in the past 50 years revealed convincing evidence that most cases of ASDs result from interacting genetic factors.[67,95] However, the expression of the autism gene(s) may be influenced by environmental factors.[66,67,69,140] Although currently under investigation, these factors may represent a "second-hit" phenomenon that primarily occurs during fetal brain development. That is, environmental factors may modulate already existing genetic factors responsible for the manifestation of ASDs in individual children.

Prenatal Period

Because many of the developmental brain abnormalities known to be associated with ASDs occur during the first and second trimesters of pregnancy,[141,142] environmental factors (eg, teratogens, such as thalidomide and valproic acid)[73] are more likely to play a role in the fetus via maternal factors. It is possible that maternal illness (eg, rubella) during pregnancy plays a role.[143,144] Recently, the possible association between fetal testosterone concentration and certain autistic behaviors such as abnormal social relationships and restricted interests at 4 years of age was investigated.[145]

Perinatal Period

The effects of birth weight, duration of gestation, and events around the time of birth have been investigated also, but findings have not been consistent.[72,146–152] A significant association between term newborn encephalopathy and children later diagnosed with ASD was reported recently.[72,150] Badawi et al[150] reported that 5% of survivors of newborn encephalopathy were diagnosed with an ASD, which represented an almost sixfold increase compared with matched controls. This increase may represent a genetically derived predisposition (which makes the infants vulnerable to both encephalopathy and ASD) or an independent mechanism.

Postnatal Period

Etiologic possibilities occurring after birth have been proposed—in particular, measles-mumps-rubella (MMR) vaccine[153] and mercury-containing vaccines.[154–156] In 2001, the Institute of Medicine[157] reviewed epidemiologic population-based studies and concluded that there was no evidence of a causal association between the MMR vaccine and autism. Studies that examined the association between MMR vaccine and autism since the publication of that review have supported this conclusion.[27,95,103,158–161] Questions also have been raised about the effects of environmental mercury exposure (including mercury-containing vaccines) on brain development in ASDs and other developmental disabilities.[154–156] Mercury, in its organic form, is a known neurotoxin with neurologic sequelae, including motor impairment and visual and intellectual deficits, depending on the age at exposure and the type of mercury. There is no evidence to date that children with neurodevelopmental disabilities, including autism, in the United States have increased mercury concentrations or environmental exposures.[162] Using large data sets from the United States, Sweden, and Denmark, to date, no consistent association has been found between thimerosal-containing vaccines and neurodevelopmental outcomes or prevalence of ASDs.[27,95,162–164] Despite evidence to the contrary, a recent survey of parents of children with ASDs revealed that 54% believed that their child's ASD was caused by immunizations; 53% thought it was caused by genetics.[165]

Although the previous discussion reveals the wide variety of conditions known to be associated with ASDs, currently, an etiologic investigation of the individual child with an ASD infrequently identifies a known cause in the absence of GDD/MR, dysmorphic features, a positive family history, and/or a focal neurologic examination.[2,20,21,89,101,106–108]

NEUROPATHOLOGY AND NEUROIMAGING

In recent years, intense research efforts have focused on elucidating the neurobiological basis of ASDs. A growing body of evidence from neuropathology and neuroimaging studies indicates that there are fundamental differences in brain growth and organization in people with ASDs that have their origin in the prenatal period but extend through early childhood and into adulthood.

Neuropathologic studies of brain tissue from people with autism have revealed several abnormalities[166–171] including:

- reduced numbers of Purkinje cells in the cerebellum;
- abnormal maturation of the forebrain limbic system, including reduced neuronal size, increased cell-packing density, and decreased complexity of the neuropil (ie, the complex net of axonal, dendritic, and glial branching in which the nerve cell is embedded);
- abnormalities in frontal and temporal lobe cortical minicolumns, which are more numerous, smaller, and less compact in their cellular configuration and demonstrate reduced neuropil space in the periphery[167];
- developmental changes in cell size and number in the nucleus of the diagonal band of Broca, deep cerebellar nuclei, and inferior olive; and
- brainstem abnormalities and neocortical malformations (eg, heterotopias).[171]

The most consistent neuropathologic findings suggest pathology that arises in utero. The association of increased risk of ASDs associated with prenatal exposure to teratogens, such as thalidomide and valproic acid, suggests that early insults during critical periods of brain development (as early as 20–24 days after conception in the case of thalidomide) may be sufficient to cause ASDs.[171] However, all of these neuropathologic findings are based on detailed study of a relatively small number of brains, and further investigation is required. Limited availability of brain tissue from people with well-characterized ASDs and age-matched controls has impeded neuropathologic investigations. Efforts to remedy this are underway with the establishment of the Autism Tissue Project (1-800-272-4622 [for physicians] or 1-877-333-0999 [for families]; www.memoriesofhope.org).[168]

Kanner, in his initial clinical description of autism, noted large head size in several of his patients.[15] Increased head circumference has since been shown to be a common physical finding in children with ASDs, and 20% to 30% have macrocephaly, defined as a head circumference that measures more than 2 SDs above the mean.[172,173] MRI studies have supported the finding of increased brain volume in children with ASDs, with 90% of toddlers with ASDs having larger-than-normal brain volumes in 1 study.[174,175] Postmortem brain weights also are increased.[166] Children later diagnosed with an ASD have been shown, as a group, to have average or below-average head circumference at birth, with acceleration in brain growth during the first year of

life, leading to above-average head circumference or overt macrocephaly.[176,177] Fewer adults with ASDs have been found to exhibit increased brain size compared with controls, indicating that there may be deceleration of brain growth at some point beyond early childhood.[176,178,179] It is interesting to note that increased blood concentrations of brain-derived neurotrophic factor and several other neurotrophins have been detected in newborn infants who are later diagnosed with ASDs.[180] This finding, if replicated, may have implications regarding the mechanism of early brain overgrowth. Age-related differences in serotonin synthesis capacity also have been demonstrated between children with ASDs and children in control groups,[181] which leads to speculation regarding the neurotrophic role of serotonin in abnormal brain growth and organization in children with ASDs.

In addition to whole-brain volume differences, specific regional gray- and white-matter volumetric differences have been described. The frontal, limbic, basal ganglia, and cerebellar regions have been implicated most consistently.[172,182–184] Abnormalities in sulcal and gyral anatomy have been found by using surface-mapping techniques.[185,186] The regional gray- and white-matter volume differences also seem to be age related, although larger cross-sectional studies and longitudinal studies are needed to clarify the meaning of these findings.

A variety of functional MRI studies during cognitive tasks or in response to visual or auditory stimuli suggest that individuals with ASDs use different cognitive strategies and, in some cases, different brain areas to process certain types of information.[182,187] For example, functional neuroimaging techniques have indicated the presence of abnormalities in face recognition and executive functioning in adults with high-functioning ASDs.[188] Hypoactivation of the fusiform gyrus in face-recognition tasks has been one of the most consistent findings[187] and, in concert with abnormalities in amygdala activation, may relate to the abnormalities in gaze fixation that are seen in people with ASDs.[189] Functional MRI evidence has also been used to postulate impaired "connectivity" between various cortical regions in the brains of people with ASDs.[190–192] Most recently, some investigators have attempted to explain deficits in empathy, imitation, and language as abnormalities in the functioning of mirror neuron systems.[193] These systems are a newly discovered subset of cells found in several areas of the brain that seem to fire when an individual simply observes another's actions—that is, it seems they directly reflect actions performed by another in the observer's brain. They also may play a role in the ability to recognize and empathize with or "mirror" the feelings of others. These functional brain differences provide intriguing links between the neuroanatomical substrate and the characteristic clinical features of people with ASDs.

Although neuroimaging research has identified volumetric and other abnormalities in groups of patients with ASDs compared with controls, a reliable marker has not been identified, and routine clinical neuroimaging for individuals with ASDs is not recommended.[106,107,183,194]

CLINICAL SIGNS

Whereas severe social skills deficits and restricted, repetitive, and stereotyped patterns of behavior, interests, and activities are core features of all ASDs, significant language delays are characteristic of only AD and PDD-NOS.[3,4] One of the most challenging aspects in recognizing ASDs is the wide heterogeneity of features in individual children. There is no pathognomonic feature; however, a few of the early social deficits (eg, delayed or absent joint attention [JA]) seem to be fairly reliable red flags for ASDs. The autism spectrum encompasses an extremely heterogeneous phenotype with indistinct end points, especially at the mild end of the spectrum. The severity of each of the core deficits varies significantly among children with ASDs.

Although the social deficits occur earlier and may be more specific, they can be subtle and less often recognized or articulated by parents. Speech delays usually prompt parents to raise concerns to their child's PCP. Most parents become concerned between 15 and 18 months of age but may delay discussing their concerns with their child's physician for several months.[35,195–198] Recently, the media and public agencies have raised public awareness about the importance of recognizing the early signs, including those present during the first years of life. This being the case, it is anticipated that parents may begin to voice concerns to their infant's pediatrician earlier and that these concerns may now target the often earlier-appearing social deficits. Presentations can differ widely from one child to the next; some are perceived by parents as "different" during the first few months of life, others present with delayed speech development during the second year of life, and still others may appear to be normal only to regress and lose skills after the first year of life.[199,200] AS in children may go unnoticed until they are of school age, when teachers notice difficulties with peer interactions. Expanded reviews regarding early signs are available.[201–203]

Social Skills Deficits

Although more specific than language deficits, social deficits appearing in the first 2 years of life often have escaped parent recognition.[204–206] Children with ASDs universally demonstrate deficits in social relatedness defined as the inherent drive to connect with others and share complementary feeling states.[207] Children with ASDs often do not appear to seek connectedness; they are content being alone, ignore their parents' bids for attention, and seldom make eye contact or bid for others' attention with gestures or vocalizations. In later

years, they have difficulty sharing the emotional state of others in cooperative games and group settings and may have few, if any, friends.

Deficits in JA seem to be one of the most distinguishing characteristics of very young children with ASDs.[198,208–216] JA is a normal, spontaneously occurring behavior whereby the infant shows enjoyment in sharing an object (or event) with another person by looking back and forth between the two. Later, gestures and/or speech also can be used to engage another's attention with regard to the objects and events simply for the enjoyment of sharing the experiences. Just like other developmental skills, development of JA skills is stepwise; it occurs in stages beginning in the first few months of life. Similar to language skills, receptive JA skills usually are mastered before expressive ones. JA begins with joyous smiling in recognition of and response to a parent or familiar caregiver's smiles and vocalizations. At approximately 8 months of age, an infant will follow the parent's gaze and look in the same direction when a parent looks away (ie, to check the time). Children begin to "follow a point" at approximately 10 to 12 months of age. If a parent points in the direction of an interesting object or event and says, "Look!" the typically developing child will look in the intended direction and then, after seeing the object/event, look back at the parent in acknowledgment and shared expression. Infants with ASD may not follow a point, even when one tries repeatedly in a loud voice calling their name or uses physical prompts, such as touching the child's shoulder before pointing.[204] They may look in the indicated direction eventually, but this is not followed by shared looking and expression.

At approximately 12 to 14 months of age, the typically developing child will begin himself to initiate a point, at first to request a desired object that is out of reach and, a couple of months later, to draw the parent's attention to share an interesting object, person, or event. Depending on his speech skills, he may utter simple sounds ("uh") or actual words while pointing. Pointing to request an object is called "protoimperative pointing." Deficits vary, as some children with ASDs may make rudimentary pointing efforts by opening and closing their hand while it is raised in the direction of the desired item but without any back-and-forth looking between it and the caregiver. Another frequent strategy is to take the parent's hand to lead him or her to the object. At 14 to 16 months of age, the typically developing child will begin to point simply to "comment" about or "share" an interesting object/event (which is called "protodeclarative pointing"). As he points, he will look alternatively between the object/event of interest and the parent. It is the shared social experience, not the tangible object/event, that the child seeks. Children with ASDs consistently fail to point to "comment" at age-appropriate times, and when they do, they are less likely to show positive affect and connectedness during the act. Some high-functioning children with ASDs may point to label objects, shapes, and colors that they have learned in a rote fashion, but this often is done without any intent of communicating in a social context and is not considered JA. Mastery of JA seems to be necessary for functional language development; in fact, mastery of protodeclarative pointing seems to be a reliable predictor of functional language development within 1 year.[7,217–219] JA skills progress to involve ongoing back-and-forth bids for attention and social interactions with multiple emotional expressions, sounds, words, and other gestures.

Orienting to social stimuli—in particular, turning consistently to respond to one's own name—is an early skill (8–10 months of age) that often is deficient in children with ASDs.[215,220] However, it is not specific to children with ASDs, because children with hearing impairments also may fail to orient to their name. In fact, parents of children later diagnosed with ASDs often raise a concern about hearing. Hearing seems "selective" in that children with ASDs may hear and attend well to environmental sounds but not to human voices.[221] Social referencing[222] is the ability to recognize the emotional states of others as they respond to various stimuli. When faced with a novel situation, a typically developing infant might look to his mother for an indication of delight, anger, or fear in her facial expression. His facial expression then usually will mimic hers, although he may not fully understand the situation. A child with an ASD engages in less imitation.[223]

Because children with ASDs lack fundamental social skill building blocks, they may be less likely to develop appropriate peer relationships according to age and language ability. They may have few or no friends, and when they do, the relationships may evolve around the child's own special interests. Another factor that impedes lasting friendships is impaired central coherence or the inability to interpret stimuli in a global way.[224,225] Instead, they focus on the parts, make less use of context, and miss the "big picture," which makes social interactions challenging. They also have difficulties understanding the perspective of others or lack "theory-of-mind" (ToM) skills. ToM is the awareness that others have thoughts and emotions that are independent from one's own; it is the ability that allows one to infer states of mind on the basis of external behavior.[226,227] Typically developing children begin to have some sense of mental states of others by 4 years of age.[197,228,229] Because of ToM impairments, children with ASDs have difficulties with empathy, sharing, and comforting. Baron-Cohen[230] coined the term "mindblindedness" when referring to persons with ASDs who demonstrate severe ToM deficits.

Communication Deficits

Most children who are later diagnosed with AD and PPD-NOS present to their PCP with "speech delay," al-

though this may change as parents are becoming more aware of social milestones. As noted previously, most parents sense something is wrong by the time the child is 18 months old.[195–198] Lack of speech has been considered a hallmark of AD, especially when it is associated with the lack of desire to communicate and lack of nonverbal compensatory efforts such as gestures. However, children with milder symptoms, especially those with normal cognitive skills, may have some speech. Their speech may not be functional or fluent and may lack communicative intent. It can be scripted (from favorite videos or television programs) and stereotypic. Echolalia, sometimes called "parroting," is the repetition of another person's speech. Echolalia is classified as "immediate" when the child repeats vocalizations promptly after hearing them or "delayed" when there is a time lapse (hours, days, weeks). Typically developing children pass through a "vocabulary-burst stage," when brief periods of immediate echolalia are not unusual.[197] On the other hand, echolalia in children with ASDs may persist throughout the life span and consist of a mixture of immediate and delayed varieties. Utterances of children with ASDs may be more clearly articulated, have a more monotone quality, and/or consist of larger verbal "chunks" (ie, entire television advertisement jingles, video reenactments, or recitations of nursery rhymes) than those of typically developing children. Sometimes, echolalia may even give the impression of "advanced" speech because of sophisticated vocabulary, grammar, and syntax. The clinician should be careful to differentiate between typical and autistic echolalia; usually, a formal evaluation by a speech-language pathologist (SLP) is needed. Such an assessment also may reveal a dissociation between these "advanced" expressive skills and delayed receptive ones in that the child may be unable to follow simple 1-step commands, which is a 12- to 14-month-old skill. Some parents will note that their child seems overly "independent" because, rather than ask for desired objects, he uses advanced motor skills to obtain them himself (ie, moving a stool to a counter top to obtain an object at an age younger than typically expected). Some children with ASDs become quite skilled at rotely labeling colors, shapes, numbers, and letters of the alphabet, yet they are unable to point to them when asked to do so by another or incorporate the labels into functional language. A few may later develop hyperlexia or advanced verbal reading without corresponding comprehension skills.

Some children with ASDs say "pop-up words" without any apparent stimulus or communicative intent. They are spontaneous and inconsistent, although sometimes they may occur during acutely stressful situations. These words are said out of context for a short period of time (days or weeks) and then, as suddenly as they might pop up for no apparent reason, they disappear.[197,119] Children with ASDs also may develop "language" in overlearned or gestalt phrases that are acquired and spoken almost as a single "giant-word" (ie, Whatisit? Idontknow). At the same time, they are unable to combine words in novel or original phrases or sentences that convey true meaning.

Although lack of speech, scripted speech, parroting without communicative intent, and pop-up and giant words are common classic presentations, earlier prespeech deficits often exist that, if detected, could facilitate earlier diagnosis.* These deficits include:

- lack of appropriate gaze;
- lack of warm, joyful expressions with gaze;
- lack of the alternating to-and-fro pattern of vocalizations between infant and parent that usually occurs at approximately 6 months of age (ie, infants with ASDs usually continue vocalizing without regard for the parent's speech);
- lack of recognition of mother's (or father's or consistent caregiver's) voice;
- disregard for vocalizations (ie, lack of response to name), yet keen awareness for environmental sounds;
- delayed onset of babbling past 9 months of age;
- decreased or absent use of prespeech gestures (waving, pointing, showing);
- lack of expressions such as "oh oh" or "huh";
- lack of interest or response of any kind to neutral statements (eg, "Oh no, it's raining again!")

The AAP brochure "*Is Your One-Year-Old Communicating With You?*"[13] was developed to help raise parent and physician awareness of these earlier social communication milestones and to promote recognition of symptoms of ASDs before 18 months of age.

Regression

Approximately 25% to 30% of children with ASDs begin to say words but then stop speaking, often between the ages of 15 and 24 months.[199,200,208] Regression of skills in children with ASDs may also include loss of gestural communication (wave, point, etc) and social skills (eg, eye contact and response to praise) or a combination of both. Regression can be gradual or sudden, and it may be superimposed on subtle preexisting developmental delays or atypical development, such as an unusually intense interest in objects or other nonsocial stimuli during the first year of life.[205] Although it may be tempting to attribute regression to environmental stressors (eg, birth of a new sibling or a move to a new house), this results in a delay in diagnosis. Regression is a well-documented hallmark of ASDs and should always alert the PCP to consider ASDs.

*Refs 197, 204, 213, 214, 219, and 222.

Asperger Syndrome

Children with AS may have mild or limited speech delays (see the DSM-IV-TR[4] criteria in Table 2) and escape recognition until preschool or early school age, when their inability to make friends becomes a concern. Although often unnoticed, language development usually is atypical. Children with AS often are quite verbal about a certain topic of interest, but they are unable to express simple feelings or recognize the feelings and viewpoints of others. Speech may be fluent but limited to only a few topics, typically those that hold a strong, all-consuming interest for the child. Speech also can be overly formal (pedantic), which is a reason why children with AS sometimes are described as "little professors."[227] Children with AS also have deficits in the social use of language (pragmatics): how to choose a topic of conversation; understanding and producing appropriate tempo, facial expression, and body language during conversation; turn taking; recognizing when the partner has lost interest in a topic; knowing when to start, sustain, and end a conversation on the basis of listener cues; knowing when and how to repair a communication breakdown; and using the appropriate degree of formality and politeness.[197,227] Children with AS especially have difficulty sustaining a conversation on a topic that is initiated by another. Language may seem odd, self-centered, and not listener responsive and results in a monotone monologue. They may demonstrate unique delivery of speech (prosody) in regard to intonation, volume, rhythm, pitch, and personal space that also tends to disregard listener needs. Children with AS may have difficulty with abstract reasoning and discussion of thoughts and opinions of others. Inability to discern and judge the conversational intents of others, especially when their conversation includes words or phrases with ambiguous meanings, impairs their ability to understand metaphors, humor, teasing idioms, irony, lies, jokes, and faux pas.[226,227,229] Older children with high-functioning AD or PDD-NOS and fluent speech also may demonstrate some of the above-mentioned language characteristics.

Play Skills

Lack of, or significantly delayed, pretend play skills coupled with persistent sensory-motor and/or ritualistic play are characteristic of ASDs. Some children with severe ASDs may never progress past the sensory-motor play stage. They mouth, twirl, bang, and manipulate objects in a stereotypic or ritualistic manner. The play of children with ASDs often is repetitive and lacks creativity and imitation.[3,4] Typical examples include spinning the wheels or lining up cars instead of "driving" them, arranging crayons instead of coloring with them, or stacking blocks in the same sequence time after time. Often they prefer to play with common objects (string, sticks, rocks, or ballpoint pens) rather than store-bought toys with the exception of trains or characters from favorite videos and television shows. Puzzles, especially shape-matching ones and computerized "puzzle games," also are quite popular.[222] Children with ASDs often are content to play alone for hours, requiring little attention or supervision. Often this "play" is either constructive (puzzles, computer games, and blocks), ritualistic (lining objects up or sorting/matching shapes or colors) or sensory-motor (mouthing, banging, twirling) in nature. Children with ASDs may seem to enjoy chase games and roughhousing, but it is often the sensory-motor aspects of these activities, rather than their social aspects, that are enjoyable. They have trouble interacting in groups and cooperating in the social rules of more sophisticated games. Often they are left out, ignored, and at high risk of being victimized and bullied by peers.[231]

Restricted, Repetitive, and Stereotyped Patterns of Behavior, Interests, and Activities

Children with ASDs can demonstrate atypical behaviors in a variety of areas including peculiar mannerisms, unusual attachments to objects, obsessions, compulsions, self-injurious behaviors, and stereotypies. Stereotypies are repetitive, nonfunctional, atypical behaviors such as hand flapping, finger movements, rocking, or twirling.[3,4,203] Although most stereotypies are harmless, they are problematic in that they may prevent the child from accomplishing a task or learning new skills. Although stereotypies are distinctive and obvious, they are not specific to children with ASDs, because many children with profound MR and/or severe sensory deficits also demonstrate stereotypies. Even typically developing toddlers, especially before the onset of fluent language, may flap their arms briefly when they are excited or frustrated. Stereotypies associated with ASDs often do not appear until after 3 years of age[232] and commonly manifest as finger flicking, unusual eye gazing, habitual toe walking, and/or persistent sniffing and licking of nonfood items.

Although most children, at some time during their early development, form attachments with a stuffed animal, special pillow, or blanket, children with ASDs may prefer hard items (ballpoint pens, flashlight, keys, action figures, etc). Moreover, the attachment is more persistent, in that they may insist on holding the object at all times, although these are rarely, if at all, used in real "play." Whereas younger children with ASDs may have restricted interests in regards to objects, the restricted interests in those with AS more often relate to topics and facts.[227] For example, rather than carrying a toy train at all times, there is an obsession with train schedules. Sometimes the item/topic of interest may be typical for any child, but it is the degree of interest that is abnormal. For example, similar to typically developing children, a child with an ASD may be fascinated with dinosaurs, but he knows far more details about them and persists in playing or discussing them to the exclusion of all else.

Perseveration, or continuation of speech or play to an exceptional degree or beyond a desired point, is common in children with ASDs. Children with ASDs may protest vigorously when forced to transition from an activity or topic of interest or when a usual routine is changed. Without warning, these protests may quickly escalate to severe and prolonged temper tantrums characterized by aggression or self-injurious behaviors.

Self-injurious behaviors (head banging, skin picking, eye poking, hand biting) are stereotypies that may cause bodily harm and are more common in children with severe GDD/MR (intellectual disabilities) or ASDs with comorbid GDD/MR.[233] Self-injurious behaviors may be precipitated by frustration during unsuccessful communication attempts, transitions, anxiety in new environments, boredom, depression, fatigue, sleep deprivation, or pain. The presence of self-injurious behaviors, aggression, and other extreme behaviors may prevent the child from participating in integrated activities in the community with typically developing peers and cause significant family stress.

Additional Coexisting Conditions That Are Not Core Features in the DSM-IV-TR

Cognitive Abnormalities (GDD/MR or Intellectual Disability, Learning Differences, and Splinter/Savant Skills)

The prevalence of comorbid GDD/MR or intellectual disability (the appropriate term depends on age and availability of both a standardized IQ score and a formal assessment of adaptive skills) with ASDs was estimated to be approximately 90% before 1990.[62] On the basis of later studies published in the 1990s, consensus guidelines reported the prevalence as approximately 70% to 75%.[1,2,106,107,234] Prevalence studies published in the new millennium have reported rates of ASDs with comorbid GDD/MR of just under 50%,[28,29,34,103] whereas 2 English studies reported rates as low as 26% to 29%.[20,21] Better ascertainment of children without cognitive deficits (in particular AS, which by definition is characterized by normal intelligence), improved professional training, and more effective strategies/tools for evaluating cognitive abilities in children with ASDs all may contribute to the decreasing prevalence of comorbid GDD/MR.

One unique characteristic of ASDs is the "unevenness" of skills. Abilities may be significantly delayed in some areas of development yet "advanced" in others, often because of exceptional focusing, memory, calculation, music, or art abilities.[235] They may be labeled as "splinter skills" when they serve no purpose in day-to-day life and do not improve functional outcomes. Rarely, highly developed talents or savant skills may promote a vocation that provides financial independence and, occasionally, national recognition.[236–238]

Sensory-Motor Symptoms

Although sensory symptoms (eg, hyperacusis) are more frequent and prominent in children with ASDs, there is no evidence that sensory symptoms differentiate children with ASDs from children with other developmental disabilities.[239] Children with ASDs may demonstrate simultaneous hyposensitivities and hypersensitivities for stimuli within the same sensory modality.[240] For example, they may seem overly sensitive to certain environmental noises but lack response to human voice, or they may visually inspect the details of an object but not notice the comings and goings of other people in the room. Others may have oral aversions and/or total-body "tactile defensiveness" to soft touch (fabric bumps on socks and sweatshirts) or hugs yet be insensitive to pain.[241] Sensory factors related to food, such as texture, color, and taste, may lead to highly restricted diets. More research is needed to operationalize the concept of sensory integration and possible interventions and define its role in ASDs.

In addition to unusual motor stereotypies that serve as defining characteristics of ASDs discussed previously, some children with ASDs also may demonstrate atypical motor development, poor coordination, or deficits in praxis (motor planning, execution, and sequencing).[240] Some investigators believe that, although not a defining characteristic by DSM standards, motor clumsiness is a distinguishing characteristic of AS.[86,242] Finally, some children may appear to be "hyperactive" and motor driven with an exterior focus of attention and actually meet criteria for comorbid ADHD (although current DSM-IV-TR criteria exclude making the diagnosis of ADHD in the presence of an ASD).[8,240,243] Other children may be hypoactive and withdrawn and have an interior focus of attention.[240]

In summary, ASDs are characterized by a broad array of clinical features; some are more specific to ASDs than others (JA deficits versus stereotypies). Familiarity with the early social and preverbal communication deficits will help the PCP recognize ASDs earlier, which should, in turn, facilitate the prompt initiation of appropriate interventions.

SURVEILLANCE AND SCREENING

Because the prevalence of ASDs is approximately 6 to 7 per 1000 in the United States,[28,29] PCPs are likely to provide care for children with ASDs. Early identification of ASDs is important, because it allows early intervention, etiologic investigation, and counseling regarding recurrence risk. The medical home is an important setting for surveillance and screening to detect ASDs and other developmental disorders. In the past, it was not unusual for parents' initial concerns to be dismissed and for diagnosis and intervention to be delayed.[195,196,244,245] In a recent study in metropolitan Atlanta, Georgia, the mean age of the first evaluation for 115 8-year-old chil-

dren with ASDs was 48 months, and the mean age of the first ASD diagnosis was 61 months.[35]

The goal of this clinical report is to help pediatricians identify children at an earlier age who are at risk of an ASD. An ASD-specific surveillance and screening algorithm (Fig 1) has been developed to facilitate the identification process. It builds on the developmental surveillance and screening algorithm for pediatric preventive care visits that was published in the 2006 policy statement "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening."[246]

General Developmental Surveillance and Screening

According to the AAP policy statement "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening,"[246] "surveillance" is the ongoing process of identifying children who may be at risk of developmental delays, and "screening" is the use of standardized tools at specific intervals to support and refine the risk. As an analogy, whereas surveillance represents a "moving picture" of the child's unfolding development, screening represents "snapshots" of the child's development at specific times. Developmental surveillance should occur at every preventive visit throughout childhood and includes the following components: eliciting and attending to the parents' concerns; maintaining a developmental history; making accurate and informed observations of the child; identifying the presence of risk and protective factors; and documenting the process and findings.[246] Research has revealed that parents have valid concerns about their children's development, although careful interpretation of the concerns is needed.[247,248] However, parental concerns may not be shared if the PCP does not ask about the child's development, and lack of parental concern about development does not imply typical development.[247–250] Therefore, a systematic surveillance strategy must be used for all children.[246] Screening with a standardized developmental tool should be performed whenever concerns are raised through the ongoing surveillance process. The AAP also recommends that all children be screened with a standardized developmental tool at specific intervals (ie, at the 9-, 18-, and 24- or 30-month visits) regardless of whether a concern has been raised or a risk has been identified during the surveillance process (see the AAP developmental screening and surveillance algorithm[246]).

Surveillance for ASD

Surveillance at the first preventive care visit (Fig 1, *Steps 1a* and *2*) should begin with a family history to determine if there are any family members, especially a sibling, who have been diagnosed with ASDs. Because the risk of having symptoms of ASDs in younger siblings of children with ASDs is approximately 10 times higher, the pediatrician needs to be extra vigilant in monitoring for early abnormal signs. Studies of infant siblings with ASDs have revealed that very subtle early signs do exist and can be perceived during the first year of life.[204,205] Until recently, most knowledge regarding very early signs was obtained from retrospective systematic reviews of home videos, particularly first birthday party videos.[251] Studies of home videos at earlier ages have provided additional retrospective information that reveals subtle abnormalities in infants who were thought to be typically developing and later diagnosed as having regressive autism.[205] Several groups of investigators are following younger siblings of children diagnosed with ASDs and providing prospective information as symptoms emerge in these infants at high risk.[204] Preliminary results support the feasibility of recognizing subtle signs of ASDs in infants at high risk.[204,206,213,214,252,253] Some of the very early signs reported by several investigators include extremes of temperament and behavior (ranging from marked irritability to alarming passivity); poor eye contact; poor response to other's voices, especially to one's name being called[252]; poor attempts at interactive play; more interest in looking at objects than people; delayed pointing to request or share; decreased to-and-fro babbling and jargoning; and lack of warm, joyful, reciprocating expressions.

Surveillance should include asking parents open-ended questions about their concerns regarding the child's development and behavior (*Step 2*). Parental concerns about inconsistent hearing or unusual responsiveness also are important; for example, parents may notice that the child responds consistently to a quiet sound, such as the crinkle of a plastic snack bag, but not to a human voice calling his name. In addition, parent concerns may be stimulated by comments made by other care providers such as child care staff or preschool teachers. Recently, however, the public media have significantly increased awareness of ASDs and sometimes has stimulated unnecessary concerns. The AAP patient education brochure "*Is Your One-Year-Old Communicating With You?*"[13] can be distributed to all parents at their child's 9- or 12-month preventive visit to educate them about early social communication milestones to help them identify valid areas of concern.

Surveillance also includes asking age-specific questions about whether certain developmental milestones have been attained. When this approach is used, it is important to include social and emotional milestones in addition to the traditional motor, language, and problem-solving milestones[254,255] (see www.firstsigns.org). To recognize ASDs as early as possible, it is important to ask about the development of verbal and nonverbal communication, reciprocal social interaction (including eye contact, JA and social referencing, and sharing of interests or achievements), and representational or pretend play skills. The American Academy of Neurology and

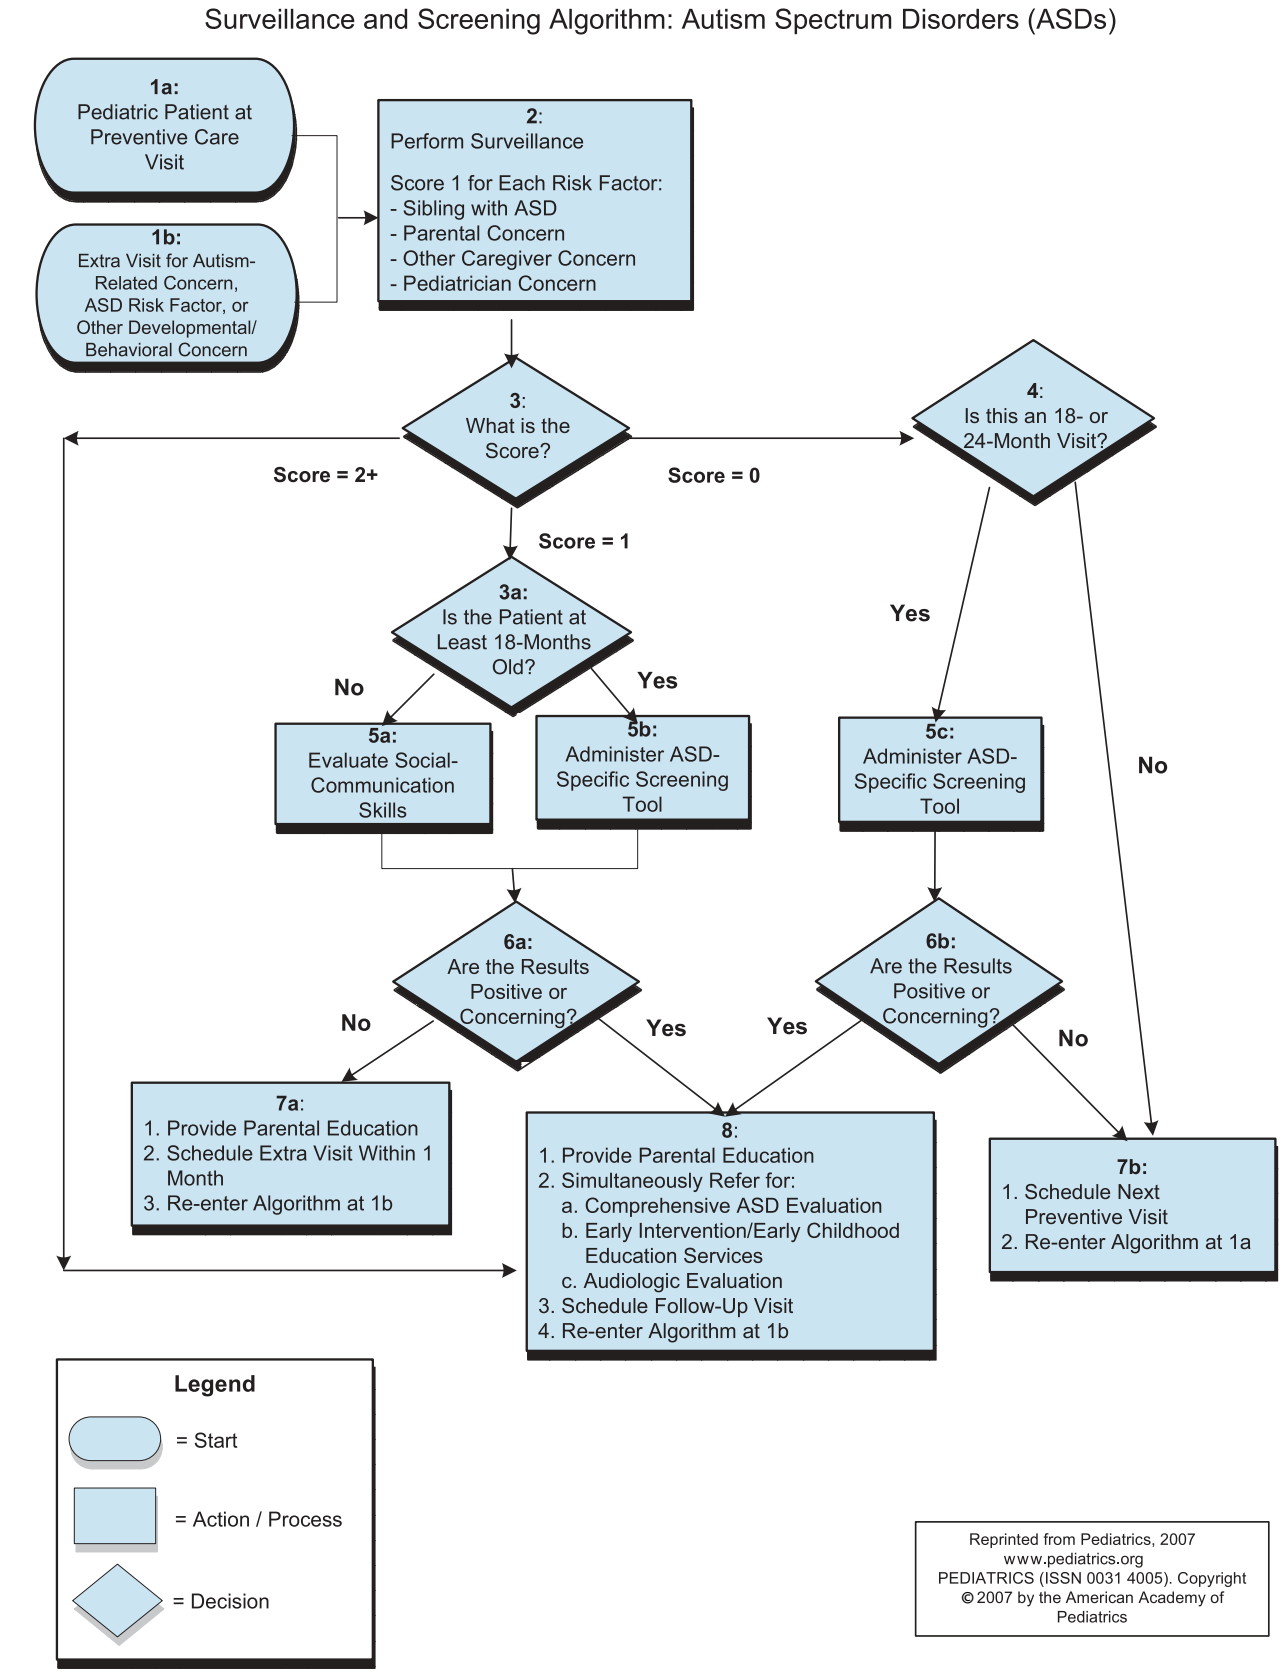

FIGURE 1
Surveillance and screening algorithm: ASDs.

Surveillance and Screening Algorithm: Autism Spectrum Disorders (ASDs)

1a: Pediatric Patient at Preventive Care Visit

1a - Developmental concerns, including those about social skill deficits, should be included as one of several health topics addressed at each pediatric preventive care visit through the first 5 years of life. *(Go to step 2)*

1b: Extra Visit for Autism-Related Concern, ASD Risk Factor, or Other Developmental/ Behavioral Concern

1b ï At the parentsô request, or when a concern is identified in a previous visit, a child may be scheduled for a ñproblem-targetedò clinic visit because of concerns about ASD. Parent concerns may be based on observed behaviors, social or language deficits, issues raised by other caregivers, or heightened anxiety produced by ASD coverage in the media. *(Go to step 2)*

2:
Perform Surveillance

Score 1 for Each Risk Factor:
- Sibling with ASD
- Parental Concern
- Other Caregiver Concern
- Pediatrician Concern

2 - Developmental surveillance is a flexible, longitudinal, continuous, and cumulative process whereby health care professionals identify children who may have developmental problems. There are 5 components of developmental surveillance: eliciting and attending to the parentsô concerns about their childôs development, documenting and maintaining a developmental history, making accurate observations of the child, identifying the risk and protective factors, and maintaining an accurate record and documenting the process and findings. The concerns of parents, other caregivers, and pediatricians all should be included in determining whether surveillance suggests that the child may be at risk of an ASD. In addition, younger siblings of children with an ASD should also be considered at risk, because they are 10 times more likely to develop symptoms of an ASD than children without a sibling with an ASD. Scoring risk factors will help determine the next steps. *(Go to step 3)*

For more information on developmental surveillance, see ñIdentifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screeningò (*Pediatrics* 2006;118:405-420).

3: What is the Score?

3 - Scoring risk factors:

- If the child does not have a sibling with an ASD and there are no concerns from the parents, other caregivers, or pediatrician: Score=0 *(Go to step 4)*
- If the child has only 1 risk factor, either a sibling with ASD or the concern of a parent, caregiver, or pediatrician: Score=1 *(Go to step 3a)*
- If the child has 2 or more risk factors: Score=2+ *(Go to step 8)*

3a: Is the Patient at Least 18-Months Old?

3a ï

- If the childôs age is <18 months, *Go to step 5a*
- If the childôs age is ³18 months, *Go to step 5b*

4: Is this an 18- or 24-Month Visit?

4 ï In the absence of established risk factors and parental/provider concerns (score=0), a level-1 ASD-specific tool should be administered at the 18- and 24-month visits. *(Go to step 5c)* If this is not an 18- or 24-month visit, *(Go to step 7b).*

Note: In the AAP policy, ñIdentifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screeningò, a general developmental screen is recommended at the 9-, 18-, and 24-or 30-month visits and an ASD screening is recommended at the 18-month visit. This clinical report also recommends an ASD screening at the 24-month visit to identify children who may regress after 18 months of age.

5a: Evaluate Social-Communication Skills

5a - If the childôs age is <18 months, the pediatrician should use a tool that specifically addresses the clinical characteristics of ASDs, such as those that target social-communication skills. *(Go to step 6a)*

5b: Administer ASD-Specific Screening Tool

5b - If the childôs age is ³18 months, the pediatrician should use an ASD-specific screening tool. *(Go to step 6a)*

5c: Administer ASD-Specific Screening Tool

5c ï For all children ages 18 or 24 months (regardless of risk factors), the pediatrician should use an ASD-specific screening tool. *(Go to step 6b)*

AAP-recommended strategies for using ASD screening tools: ñ*Autism: Caring for Children with Autism Spectrum Disorders: A Resource Toolkit for Cliniciansò(in press)**

6a: Are the Results Positive or Concerning?

6a ï When the result of the screening is *negative*, *Go to step 7a*

When the result of the screening is *positive*, *Go to step 8*

6b: Are the Results Positive or Concerning?

6b ï When the result of the ASD screening (at 18- and 24-month visits) is *negative, Go to step 7b*

When the result of the ASD screening (at 18- and 24-month visits) is *positive*, *Go to step 8*

7a:
1. Provide Parental Education
2. Schedule Extra Visit Within 1 Month
3. Re-enter Algorithm at 1b

7a ï If the child demonstrates risk but has a negative screening result, information about ASDs should be provided to parents. The pediatrician should schedule an extra visit within 1 month to address any residual ASD concerns or additional developmental/ behavioral concerns after a negative screening result. The child will then re-enter the algorithm at 1b. A ñwait-and-seeò approach is discouraged. If the only risk factor is a sibling with an ASD, the pediatrician should maintain a higher index of suspicion and address ASD symptoms at each preventive care visit, but an early follow-up within 1 month is not necessary unless a parental concern subsequently arises.

7b:
1. Schedule Next Preventive Visit
2. Re-enter Algorithm at 1a

7b ï If this is not an 18- or 24-month visit, or when the result of the ASD screening is *negative*, the pediatrician can inform the parents and schedule the next routine preventive visit. The child will then re-enter the algorithm at 1a.

8:
1. Provide Parental Education
2. Simultaneously Refer for:
   a. Comprehensive ASD Evaluation
   b. Early Intervention/Early Childhood Education Services
   c. Audiologic Evaluation
3. Schedule Follow-up Visit
4. Re-enter Algorithm at 1b

8 ï If the screening result is *positive* for possible ASD in step 6a or 6b, the pediatrician should provide peer reviewed and/or consensus-developed ASD materials. Because a positive screening result does not determine a diagnosis of ASD, the child should be referred for a comprehensive ASD evaluation, to early intervention/early childhood education services (depending on childôs age), and an audiologic evaluation. A categorical diagnosis is not needed to access intervention services. These programs often provide evaluations and other services even before a medical evaluation is complete. A referral to intervention services or school also is indicated when other developmental/behavioral concerns exist, even though the ASD screening result is negative. The child should be scheduled for a follow-up visit and will then re-enter the algorithm at 1b. All communication between the referral sources and the pediatrician should be coordinated.

FIGURE 1
Continued

Child Neurology Society practice parameter on screening and diagnosis of autism[107] suggests that the following "red flags" are absolute indications for immediate evaluation:

- no babbling or pointing or other gesture by 12 months;
- no single words by 16 months;
- no 2-word spontaneous (not echolalic) phrases by 24 months; and
- loss of language or social skills at any age.

Pediatricians should become concerned (*Step 2*) if the answers to these questions reveal deficits or delays in milestones or if behaviors typical of ASD are observed during an office visit.

In older, more developmentally advanced children, including many with AS, surveillance questions (*Step 2*) may elicit concerns about social interaction difficulties related to more subtle communication problems, such as pragmatic language impairment and lack of understanding of nonliteral forms of communication (figures of speech, humor, sarcasm, metaphor, etc), difficulty taking the perspective of another (resulting in inappropriate or offensive behavior, gullibility, and lack of common sense), and obsession with facts, details, or collections. Pragmatic language refers to the use of language in social interaction and includes instinctive rules governing factors, such as topic maintenance and turn taking in conversation, how sentences are made to fit in with the flow of a conversation, how unspoken premises are inferred, how degrees of formality and politeness are signaled, and prosody (modulation of the intonation, rhythm, volume, timing, and stress of the voice). The parents may note that the child lacks true friendships and is viewed as odd, eccentric, or "weird" by his 'peers.

In addition, during the well-child visit, the PCP may try to interact with the patient by using a few simple strategies depending on the child's age. For example, the PCP can note the response when calling the child's name at the 12-month well-child visit, and/or the JA milestone of "following a point" can be elicited at the 12-, 18-, and 24-month well-child visits as part of routine developmental surveillance. In the latter, the pediatrician points to an object at a distance, such as a picture on the wall or a mobile, while making a verbal request for the child to look. Whereas a typically developing child would look in the direction of the point and then afterward engage in eye contact with the physician or the parent, a child with an ASD may appear to be oblivious to the PCP's gesture and verbal request. This is true even if the PCP increases the intensity of the stimulus by calling louder, adding the child's name, or touching the child's shoulder first and then pointing and exclaiming, "Look!" The child may still fail to respond even if the parent repeats the maneuvers. With an older, higher-functioning child, the PCP may enter into conversation with the child to determine if he has difficulty interpreting a figure of speech, telling a joke, or explaining why a joke is funny. In addition, the PCP may ask a question or two about one of the child's areas of interest to observe a response that is characteristic of AS, such as a long-winded, overly precise, or pedantic reply. Any of these responses should raise the concern of a PCP.

Each concern raised by a parent, other caregiver, or the pediatrician constitutes a separate risk factor, as does a positive family history of a sibling with an ASD (*Step 2*). To determine how to proceed, the pediatrician should assess the number of risk factors (*Step 3*). Possible scores include 0, 1, 2, 3, or 4.

1. If no concerns have been raised during the course of the preventive visit and the child is not the sibling of a child who has already been diagnosed with an ASD, then the PCP should proceed to *Step 4*. ASD-specific screening is indicated only if the visit is the 18- or 24-month preventive visit. See *Step 5c* below.
2. If the child's only risk factor is having a sibling with an ASD, then the PCP should make sure the parents are aware of early signs of ASDs and continue to monitor carefully.[253] If the parents call with a concern between scheduled routine preventive visits, the child should be seen within 1 or 2 weeks and reenter the algorithm at *Step 1b* for a "targeted visit" to address concerns about ASDs. If the score = 1 as a result of a single concern (parent, other caregiver, or PCP), the PCP should screen the child formally with a standardized tool; the choice of tool will depend on the child's age (*Step 3a*) (see "Screening Tools for Implementation of *Step 5*").
3. If 2 or more risk factors are identified, then the PCP should proceed directly to *Step 8*, which includes several activities that should be accomplished simultaneously and without delay.

Screening for ASDs (*Steps 5a–5c*)

Physician estimates of the developmental status of children are much less accurate when only clinical impressions, rather than formal screening tools, are used,[256,257] yet a minority of PCPs use formal developmental screening instruments,[258,259] and few pediatricians specifically screen for ASDs.[5] A standardized screening tool should be administered at any point when concerns about ASDs are raised spontaneously by a parent or as a result of clinician observations or surveillance questions about social, communicative, and play behaviors (*Steps 5a* and *5b*).[246,260] In the general developmental screening and surveillance policy statement discussed previously, the AAP also recommended administering a standardized autism-specific screening tool on all children at the 18-month preventive care visit (*Step 5c*).[246] The AAP Autism Expert Panel responded to the statement with a com-

mentary[260] that suggested a repeat screening be performed at 24 months of age (*Step 5c*) to identify those who may regress after 18 months of age.

Screening Tools for Implementation of *Step 5*

A variety of general developmental screening tools are available to practitioners.[246] General developmental screening tools are appropriate for use with unselected primary care populations and are likely to detect ASDs in many young children because of associated language and cognitive delays, but they do not differentiate children with ASDs from those with other developmental disorders, and data are not available on sensitivity for detection of ASDs. Tools to screen specifically for ASDs also have been designed (Table 3), but they have not yet been validated on children younger than 18 months. The PCP should remember that screening tools are likely to be overinclusive, so children with developmental and behavioral disorders other than ASDs also might have positive screening results. Similar to other developmental screening measures, ASD-specific screening tools may rely entirely on parent report, or they may require direct observation and engagement by the clinician. Parent-report tools often have the advantage of being brief, inexpensive, and practical in the office setting. The people who know the child best are surveyed and can describe the child's behavior over time in a variety of settings rather than being constrained to sampling behavior in one setting at one point in time.

Step 5a*: Tools for Use in "at-Risk" Children Younger Than 18 Months*

Although several tools are in development for screening children younger than 18 months, none are available yet for routine clinical use. The Infant/Toddler Checklist from the Communication and Symbolic Behavior Scales Developmental Profile[261] (which can be downloaded at www.brookespublishing.com/store/books/wetherby-csbsdp/CSBSDP_Checklist.pdf) may be particularly well suited for identifying 6- to 24-month-old children who are at risk of ASDs, because it focuses on social and communication skills. It is anticipated that this and other screening tools under investigation as possible ASD-specific tools for use in infants younger than 18 months may prove valuable in identifying children at high risk and will become available to clinicians in the near future.[213,262,263]

Step 5b*: Tools for at-Risk Children 18 Months and Older*

ASD-specific screening tools are available for children 18 months and older, and many of them are age specific. Recently, such tools have been classified as "level 1" or "level 2" screening tools.[264] Level 1 screening tools are administered to all children within the context of a primary care medical home and are designed to differentiate children who are at risk of ASDs from the general population, especially those with typical development. Level 2 screening tools are used more often in early intervention programs or developmental clinics that serve children with a variety of developmental problems; they help to differentiate children who are at risk of ASDs from those at risk of other developmental disorders such as GDD or specific language impairment. Level 2 screening tools generally require more time and training to administer, score, and interpret than level 1 measures. There is considerable overlap between the concept of a level 2 screening tool and that of a diagnostic instrument.[264,265] Level 2 screening measures may be used as part of a diagnostic evaluation, but they should not be used in isolation to make a diagnosis.

Properties of some level 1 and 2 ASD screening tools are reviewed in Table 3. Reported sensitivity and specificity values are included, but in most cases, sensitivity and specificity of the instruments have been determined only in clinical samples or in populations that included a mixture of clinical and population-based samples, and they must be interpreted with caution. Estimates of sensitivity and specificity of developmental screening tests may be unstable, and they are not the only criteria that should be used to assess validity.[266] In low-prevalence conditions, such as ASDs, the positive predictive value of screening tools will be low even with good sensitivity and specificity, whereas the negative predictive value will be quite high. Many of the existing ASD-specific screening measures are being revised or further evaluated, and new tools are being developed to address some of their weaknesses.

Some measures, such as the Checklist for Autism in Toddlers (CHAT),[267] Modified Checklist for Autism in Toddlers (M-CHAT),[268] and Pervasive Developmental Disorders Screening Test-II Primary Care Screener,[269] were designed specifically for early detection of ASDs in young children. The CHAT and M-CHAT are level 1 screening tools that are available at no cost to practitioners for use in primary care (Table 3).

For older children who are diagnosed later with AS, school personnel often raise concerns to the parents. Staff may then administer a published AS-specific tool. Although many level 2 screening tools have been marketed for use in older children who have been identified as being at risk of AS, further study is needed before any one of them can be recommended as superior to others.[270] See Table 3 for characteristics of selected AS screening tools.

Step 5c*: Tools for Screening Children Without Risk Factors at the 18- and 24-Month Preventive Visit*

Level 1 ASD tools described in *Step 5b* also are appropriate for routine screening of young children without any identified risk.

Among the tools designed for screening the elementary school–aged population, only the Childhood Asperger Syndrome Test (CAST) has been assessed in a

TABLE 3 **Selected Level 1 and 2 ASD Screening Measures**

Screening Tool	Age	Format (No. of Items)	Time to Complete, min	Reported Sensitivity	Reported Specificity	Selected Key References	Availability
Level 1[a]							
CHAT	18–24+ mo	Parent interview or questionnaire and interactive (parent: 9; clinician: 5)	5	0.18–0.38[b]; 0.65[c]	0.98–1.0[b]; 1.0[c]	Baron-Cohen et al,[267] Baron-Cohen et al,[272] Baird et al,[19] Scambler et al[273]	Download: www.autismresearchcentre.com/tests/chat_test.asp
CHAT, Denver Modifications	18–24+ mo	Parent interview or questionnaire and interactive (parent: 9; clinician: 5)	5	0.85[c]	1.0[c]	Scambler et al[273]	CHAT scoring modifications; available in Scambler et al[273]
Checklist for Autism in Toddlers-23 (CHAT-23)	16–86 mo (all had mental ages of 18–24 mo)	Parent interview or questionnaire and interactive (parent: 23, clinician: 5)	10	0.84–0.93[c] (part A); 0.74[c] (part B)	0.77–0.85[c] (part A); 0.91[c] (part B)	Wong et al[274]	Combination of M-CHAT and CHAT items; protocol available in Wong et al[274]
CAST	4–11 y	Questionnaire completed by parent (37)	10	0.88–1.0[d]	0.97–0.98[d]	Scott et al,[275] Williams et al,[235] Williams et al[276]	Download: www.autismresearchcentre.com/tests/cast_test.asp
M-CHAT	16–48 mo	Questionnaire completed by parent (23)	5–10	0.85[d]	0.93[d]	Dumont-Matthieu and Fein,[277] Robins et al[268]	Download: www.dbpeds.org/media/mchat.pdf or www.firstsigns.org/downloads/m-chat.pdf; for scoring: www.firstsigns.org/downloads/m-chat_scoring.PDF
Pervasive Developmental Disorders Screening Test-II, Primary Care Screener (PDDST-II PCS)	18–48 mo	Questionnaire completed by parent (22)	10–15	0.92[c]	0.91[c]	Siegel[269]	Purchase: PsychCorp/Harcourt Assessment (www.harcourtassessment.com)
Level 2							
Asperger Syndrome Diagnostic Scale (ASDS)	5–18 y	Questionnaire completed by parent, teacher, or clinician (50)	10–15	0.85[c]		Myles et al,[278] Campbell[270]	Purchase: Pro-Ed (www.proedinc.com)
Autism Behavior Checklist (ABC)	≥18 mo	Behavioral checklist completed by interviewer (57)	10–20	0.38–0.58[c]	0.76–0.97[c]	Krug et al[279]	Purchase: Pro-Ed (www.proedinc.com) as part of the Autism Screening Instrument for Educational Planning (ASIEP-2)
Autism Quotient (AQ)–Adolescent Version	11–16 y	Questionnaire completed by parent (50)	15	0.89[c]	1.0[c]	Baron-Cohen et al[280]	Download: www.autismresearchcentre.com/tests/aq_adolescent_test.asp
Autism Spectrum Screening Questionnaire (ASSQ)	6–17 y	Questionnaire completed by parent (27)	10	0.62–0.82[c] (parent); 0.65–0.70[c] (teacher)		Ehlers et al[281]	Questions are included as an appendix in Ehlers et al[281]
Childhood Autism Rating Scale (CARS)	>2 y	Behavioral checklist completed by trained interviewer/observer (15)	Variable	0.92–0.98[c]; 0.94[c]	0.85[c]	Eaves and Milner,[282] Perry et al,[283] Schopler et al[284], Sevin et al[285]	Purchase: Western Psychological Services (www.wpspublish.com)
Gilliam Asperger's Disorder Scale (GADS)	3–22 y	Questionnaire completed by parent, teacher, or clinician (32)	10			Gilliam,[286] Campbell[270]	Purchase: Pro-Ed (www.proedinc.com)
Gilliam Autism Rating Scale–2nd Edition (GARS-2)	3–22 y	Questionnaire completed by parent or teacher (42)	5–10			Gilliam[287]	Purchase: Pro-Ed (www.proedinc.com)

TABLE 3 **Continued**

Screening Tool	Age	Format (No. of Items)	Time to Complete, min	Reported Sensitivity	Reported Specificity	Selected Key References	Availability
Krug Asperger's Disorder Index (KADI)	6–21 y	Questionnaire completed by parent or clinician (32)	15–20	0.78[c]	0.94[c]	Krug and Arick,[288] Campbell[270]	Purchase: Pro-Ed (www.proedinc.com)
Pervasive Developmental Disorders Screening Test-II, Developmental Clinic Screener (PDDST-II, DCS)	18–48 mo	Questionnaire completed by parent (14)	10–15	0.73[c]	0.49[c]	Siegel[269]	Purchase: PsychCorp/Harcourt Assessment (www.harcourtassessment.com)
Pervasive Developmental Disorders Screening Test-II, Autism Clinic Severity Screener (PDDST-II, ACSC)	18–48 mo	Questionnaire completed by parent (12)	10–15	0.58[c]	0.60[c]	Siegel[269]	Purchase: PsychCorp/Harcourt Assessment (www.harcourtassessment.com)
Screening Tool for Autism in Two-Year-Olds (STAT)	24–36 mo	Interactive, requires specific training (12)	20	0.92[d]	0.85[d]	Stone et al,[289] Stone et al[290]	Author: Wendy Stone, PhD (triad@vanderbilt.edu)
Social Communication Questionnaire (SCQ) (formerly the Autism Screening Questionnaire [ASQ])	≥4 y	Questionnaire completed by parent (40)	5–10	0.85–0.96[c]	0.67–0.80[c]	Berument et al,[291] Rutter et al[292]	Purchase: Western Psychological Services (www.wpspublish.com)

The measures were selected on the basis of availability of some published psychometric properties (in English) with scoring instructions and pass/fail cutoffs or the equivalent.

[a] Level 1 tools are most likely to be used in primary care settings.

large, unselected population as a level 1 screening tool.[271] The authors concluded that the CAST is useful as a screening test for ASDs in epidemiologic research but that there is not enough evidence to recommend it for routine screening in the general population as part of a public health program.[271] In addition, the AAP does not currently recommend universal screening of school-aged children with a level 1 AS-specific tool.

See Appendix 1 for reimbursement codes.

Results of Screening (*Steps 6a* and *6b*)

If the screening result for an at-risk child is negative in *Step 6a*, the PCP should proceed to *Step 7a*, provide parent educational materials (such as the AAP brochure, "*Is Your One-Year-Old Communicating With You?*"[13] or the AAP parent booklet, "*Understanding Autism Spectrum Disorders*"[14]) and schedule an extra visit (*Step 1b*) within 1 month to address residual concerns. If the only risk factor is having a sibling with an ASD, an extra visit is not necessary unless the parents become concerned after the visit. When the screening result is negative for children without risk at the 18- or 24-month preventive visit (*Step 6b*), the PCP should proceed to *Step 7b* and schedule the next routine preventive care visit (*Step 1a*). If the screening result is positive (*Steps 6a* or *6b*) or 2 or more risk factors are present at *Step 3*, the PCP should proceed to *Step 8*, at which simultaneous activities should take place in an expedient manner. The PCP should consider the possibility that the child with a negative ASD screening result may have another developmental disorder that would warrant further investigation and referral to resources similar to those listed in *Step 8*.

When surveillance does not identify any risk factors and the visit is not an 18- or 24-month visit (*Step 4*), no screening is recommended, and the PCP may proceed directly to *Step 7b*.

Step 8: Activities Needed When Multiple Risk Factors Are Present or When the ASD Screening Result Is Positive

Activities described herein will depend on certain community characteristics, especially in regard to obtaining a comprehensive evaluation. Depending on the number of ASD experts in a given community, the interval wait for an appointment may be long. Thus, it is important that the PCP simultaneously accomplish all of *Steps 8.1* through *8.4* while the family is waiting for a specialty appointment to confirm or rule out an ASD diagnosis.

Step 8.1*: Provide Parental Education*

If the PCP feels fairly certain that the child has a developmental disorder that falls somewhere in the autism spectrum, it will be helpful to give the parents reading materials. As discussed in the introduction to this report, the AAP has published "*Understanding Autism Spectrum Disorders*," an educational booklet for parents with this intent.[14] The comprehensive evaluation will progress more efficiently if the parents are more knowledgeable about the characteristic clinical symptoms of ASDs and can report them more accurately. Some PCPs are reticent to share their concerns with parents, fearful that premature "labeling," although it is tentative, might cause undo stress and anxiety on the part of the family. However, sincerity, honesty, and admitting uncertainty is appreciated by most parents. On the other hand, concealing a concern and taking a "wait-and-see" approach rarely is appreciated; in fact, this strategy often breeds parental discontent and, worse, resentment and anger. With the recent high visibility in the media, most parents (unlike before the 1990s) now are aware of ASDs and may suspect it and search the Internet for information. It is important that they receive peer-reviewed and consensus-driven information that is evidence based and that they understand how to interpret Web-site information that is not peer reviewed.

Step 8.2.a: *ASD Comprehensive Evaluation*

For some children, the diagnosis might be quite obvious to the PCP who is using the DSM-IV-TR criteria as a guide. In others, the diagnosis may be challenging, especially when externalizing behavioral symptoms are mild or variable and/or there are associated comorbid disorders. Ideally, the definitive diagnosis of an ASD should be made by a team of child specialists with expertise in ASDs. Unfortunately, teams are not available in every locale, and when they are, long waiting lists may exist. Most communities will have at least 1 pediatric subspecialist (eg, child neurologist, developmental pediatrician, psychiatrist) with at least some expertise in making an ASD diagnosis. Other professionals, such as child psychologists, SLPs, pediatric occupational therapists, and social workers with expertise in ASDs, can be helpful by performing independent evaluations, often using standardized tools that can assist in the diagnostic process, especially when no team or pediatric "expert" is available. Child psychologists with appropriate training and experience can make the diagnosis independently and often do so, especially in school systems. Recently, the American Speech-Language-Hearing Association published guidelines that stated that an SLP with expertise in ASDs can make the diagnosis independently when other resources are not available.[294,295] Older children who first present with symptoms of AS after school entry often are first recognized and evaluated by the school district's educational diagnostic team and subsequently, but unfortunately not always, referred to a health care professional.

If it seems fairly certain, on the basis of general developmental screening and/or available psychometric testing with standardized tools, that the child also has GDD or intellectual disability, then the PCP might order high-resolution karyotype and DNA testing for fragile X

syndrome. If the child has clinical features (history, family history, physical examination) that are characteristic of a specific genetic or neurologic disorder that can be easily confirmed by a specific laboratory test, then the PCP may want to proceed with that test. On the other hand, the PCP may opt to refer the child to pediatric subspecialists for assistance with an etiologic workup and/or a search for coexisting conditions. Depending on availability and the nature of the concern(s), the PCP should consider a referral to a developmental pediatrician, a geneticist, and/or a child neurologist.[104,296] See the next section for a more extensive discussion of the components of a comprehensive evaluation.

Step 8.2.b: *Early Intervention/Early Childhood Education Services*

As soon as an infant or toddler is suspected of having a delay or being at risk of a delay or developmental disorder such as an ASD, he should be referred immediately to an early intervention program (a government-subsidized public program designed to serve children with special needs and/or developmental delays from the time the problem is identified until the third birthday). If the child has had his third birthday, the referral should be made to the special education department in the local school. Among other professionals, assessment teams will almost always include SLPs and occupational therapists who can develop appropriate intervention plans without a categorical diagnosis. Intervention is important and often can be effective, even if it begins as generic speech therapy (ie, therapy that addresses most forms of language delay) and general developmental strategies. This intervention plan can be revised later to a more specific ASD intervention protocol (such as teaching JA) once the diagnosis is made. Experienced therapists often recognize ASD symptomatology and use strategies tailored to the child's individual deficits, even without a definitive ASD diagnosis.

Step 8.2.c: *Audiology Evaluation*

All children with language delays, including those suspected of having ASDs, should undergo an audiologic evaluation, even if the neonatal screening result was normal. This testing may be challenging to accomplish, because children with ASDs often are uncooperative for behavioral audiometry, the test most frequently used with toddlers. If the attempt is unsuccessful, an auditory brainstem response or brainstem auditory evoked-response test can be ordered; it is likely that sedation will be required. Sedation may be challenging, because some children with ASDs may respond paradoxically to sedatives.

Steps 8.3 *and* **8.4:** *Schedule Follow-up Visit and Reenter Algorithm*

The child should be scheduled for a targeted follow-up visit within 1 month and reenter the algorithm at *Step 1b* to determine the status of the aforementioned referrals and to discuss any additional parental concerns once they have had the opportunity to read and learn more about ASDs.

COMPREHENSIVE EVALUATION (SEE *STEP 8.2.a*)

There are 3 major diagnostic challenges in the comprehensive assessment of a child with a suspected ASD: determining the child's overall level of functioning; making the categorical diagnosis of an ASD; and determining the extent of the search for an associated etiology. To accomplish these 3 goals, a comprehensive evaluation should include the following components[212,297,298]:

1. Health, developmental, and behavioral histories that include at least a 3-generation family pedigree and a review of systems.
2. Physical examination including a thorough search for dysmorphic features and neurologic abnormalities and a Wood's lamp examination of the skin.
3. Developmental and/or psychometric evaluation (depending on age/skill level) to determine the child's overall level of functioning and whether a discrepancy between motor-adaptive problem-solving and social communication skills is evident.[299,300]
4. Determination of the presence of a categorical DSM-IV-TR diagnosis, preferably with standardized tools that operationalize the DSM criteria.
5. Assessment of the parents' knowledge of ASDs, coping skills, and available resources and supports.
6. A laboratory investigation to search for a known etiology or coexisting condition guided by information obtained in *Steps 1* through *5*.

When appropriate, the evaluation should include information from multiple sources, because the child's performance may vary among settings and caregivers. Depending on level of comfort, the PCP may opt to refer to an experienced pediatric subspecialist, such as a neurologist, geneticist, or developmental pediatrician, to further evaluate the child, especially when there is an abnormal neurologic finding, seizures, regression, dysmorphic features, and/or a complex family history.

Laboratory testing for children with ASDs (component 6 above) is controversial. Newer technology has been developed since publication of the 2001 AAP statement and technical report[1,2]; however, some tests are not yet clinically available. Various specialists hold differing opinions about the definition of a "positive yield," defined herein as a positive test result that indicates a known autism-related etiology (eg, a positive result on

DNA testing for fragile X syndrome or a karyotype revealing a mutation at 9q or 16p indicating tuberous sclerosis). They also promote varying clinical indications for extensive molecular testing and neuroimaging when the clinical validity of a positive finding is yet unknown in many cases.[301] Some investigators have reported a positive yield when, in fact, the identified abnormality was nonspecific, did not relate to a known autism-related etiology, and did not affect counseling and/or management (eg, delayed myelinization on MRI).[302] Medical symptoms should be evaluated on a case-by-case basis; rather than reflect an etiology, an abnormal test result may indicate that a child with an ASD has a coexisting condition (eg, a gastrointestinal disorder). Thus, an abnormal laboratory test result does not necessarily indicate a positive yield but may, indeed, indicate a condition that needs medical attention (see the AAP clinical report "Management of Children With Autism Spectrum Disorders"[303]). Reporting it as a positive yield makes it difficult to translate research methodology into recommendations that will help the clinician in the care of any given patient.

The yield of an etiologic investigation may be more highly correlated with the presence or absence of coexisting GDD/MR (intellectual disability) rather than with an isolated ASD. In fact, the presence of autism in a cohort of children with GDD/MR (intellectual disability) decreased the chance of a positive yield.[304] Depending on the population characteristics, specific test(s) studied, and the decision-making process by which they were ordered (ie, as a screening technique for all study patients with ASDs versus a targeted test indicated by a specific clinical finding), positive yields range from as low as 0%[101,305,306] to as high as 25% to 40%,[307–309] but most yield rates fall between 2% and 10%.† It is difficult to compare studies because of variability in the workups, analysis in terms of GDD/MR or other phenotypic variables, and interpretation of positive test results (eg, delayed myelinization on MRI) or symptoms (eg, gastrointestinal) that are not definitively associated with ASDs.[310]

Although the original ASD-specific consensus guidelines published between 1999 and 2001[1,2,106,107] have been helpful in guiding the etiology-search strategy in children with ASDs, the presence of coexisting GDD/MR (intellectual disability) in a cohort of children with ASD (especially severe GDD/MR or intellectual disability associated with dysmorphic features) is more highly correlated with a positive yield and a recognizable syndrome.[108] Thus, guidelines that address the etiologic workup of children with GDD/MR[104,296,311,312] also should be considered when evaluating a child with both an ASD and GDD/MR but not necessarily a child with an isolated ASD.

Among laboratory tests, high-resolution chromosome analysis by G-banding and molecular testing for fragile X syndrome have the highest yield in determining etiology in patients with ASDs.‡ Some investigators have suggested a battery of additional screening cytogenetic and molecular studies for all patients with ASDs regardless of gender, presence or absence of coexisting GDD/MR, dysmorphic features, or family history.[309] However, current data do not support extensive testing of all children with ASDs in clinical settings. Published studies have begun to address some of the newer molecular genetic techniques that have revolutionized genetic testing by detecting microdeletions, duplications, and rearrangements not visible with high-resolution chromosomal testing. Targeted FISH studies can be used to screen for deletions or duplications, such as those associated with chromosomes 15q and 22q.[305,310] A relatively recent use of FISH technology is genome-wide subtelomere screening, which detects clinically significant abnormalities in 2.5% of individuals with unexplained GDD/MR.[313] This technology can detect a wide variety of abnormalities, including some such as 22q13.3 deletion, that have been reported in a subset of children with ASDs.[314,315] Several studies that examined the yield of subtelomere FISH screening in ASD failed to detect a single abnormality, which suggests that it may not be helpful in the routine evaluation of these patients.[89,305] However, additional studies are needed. Comparative genomic hybridization-microarray analysis is a promising tool that may become standard of care in the future, but this technique has not been evaluated systematically in children with ASDs.

Screening neurologic tests also have been suggested—for example, electroencephalography (EEG [routine and/or prolonged sleep studies]) for all children with ASDs.[316] Although nonspecific abnormalities have been found in most children, the significance of these abnormalities is not clear, and additional research is needed to determine if intervention is of any value. Thus, there is no evidence to support universal screening EEG without a clinical indication.[317,318] An EEG should be considered for children who demonstrate clinical signs that might represent seizures and for children with clear language regression. However, EEGs in children that demonstrate "classic autistic regression" between 12 and 24 months are often nonspecific and not helpful in the diagnostic process. Previously published guidelines contain clear recommendations that screening MRIs on all children who present with ASDs, including those with isolated macrocephaly, are not necessary.[106,107,194] Given the heterogeneity of ASDs, the likelihood of multiple etiologies, and the questionable clinical validity of an extensive battery of screening tests on all children with ASDs, more evidence is needed before a battery of genetic and neurologic testing becomes standard of care.

†Refs 20, 23, 33, 89, 97, 101, 105, 302, and 310.

‡Refs 20, 23, 33, 89, 101, 105, 302, and 310.

Although for the individual patient, it is important to differentiate an idiopathic ASD (with a recurrence rate of 5%–6% [range: 2%–8%]) from an ASD-associated syndrome that may have a higher or lower recurrence rate, there is no simple 1-size-fits-all search strategy.[1,2,106,107,300] Instead, the search should be guided by clinical judgment based on history (eg, health, birth, developmental, behavioral, family) and clinical presentation (eg, comorbid MR, regression, seizures, neurodevelopmental findings, dysmorphic features, comorbid medical conditions). The importance of dysmorphic features and/or neurologic abnormalities in predicting a positive yield particularly has been emphasized.[108] Family characteristics (eg, insurance status, concern about the child's discomfort, or interest in pursuing a "no-stone-left-unturned" etiologic workup) also may affect parental decisions regarding the extent of the workup. Finally, the availability of technology, the need for and feasibility of sedation, managed care cost/benefit guidelines, and physician motivation each may play a role. There are certainly many advantages to having a diagnosis, including genetic counseling and provision of recurrence risks of known syndromes, the possibility of a specific treatment strategy, counseling regarding the natural history of a known disorder, anticipation of a later associated comorbid disorder, prevention of secondary disorders, availability of prenatal diagnosis, access to public support systems, access to syndrome-specific parent support groups, and, in some cases, the psychological benefits of knowing that empower parents to move on and focus on habilitative interventions.

A "search strategy" might be conceptualized as consisting of 3 levels.

1. Studies that should be considered for all young children with ASDs (ie, an audiology evaluation; however, school-based hearing screening may be adequate in the older child with AS and no significant language or learning deficits).

2. Studies that should be considered in all children with both an ASD and coexisting GDD/MR or intellectual disability (ie, high-resolution karyotype [650 bands] and DNA testing for fragile X syndrome). Although a high-resolution karyotype might reveal larger duplications, some clinicians believe that FISH testing for 15q duplications also might be indicated.[92,93] In the future, a microarray analysis may replace high-resolution karyotyping. A methyl CpG-binding protein 2 (*MECP2*) analysis should be considered in females who present with regression and autistic features that are also consistent with Rett syndrome.[310]

3. Targeted studies (eg, EEG, metabolic studies, MRI) should be considered when specific clinical findings are identified by history or physical examination (eg, seizures, cyclic vomiting and lethargy associated with mild illnesses and/or unusual odors, hypopigmented macules). Identification of more subtle indicators and their corresponding appropriate laboratory tests might be facilitated by referral to a geneticist, pediatric neurologist, and/or developmental pediatrician.

Ongoing multisite studies are investigating specific test protocols. Such evaluations are not recommended as clinical standard of care at this time until analysis of the data indicates which of the extended tests, if any, are indicated and for which ASD populations. These research protocols include many tests that are investigational, have unknown medical validity, and currently are not available for clinical use. Some of these tests include functional neuroimaging, immunologic studies, metabolic testing, fibroblast karyotypes, neuroligin gene testing, mitochondrial gene sequencing, genomic microarrays, and identification of endophenotypes.[90,319] Although these tests may not be relevant in clinical practice, they do have the potential to expand the fund of knowledge about ASDs, reveal more specific ASD subtypes, and provide a better understanding of coexisting disorders and future prognosis. As the fund of knowledge regarding genetic markers for ASDs expands and technology continues to become more sophisticated, the yield of these laboratory investigations may eventually prove to be useful in the routine clinical evaluation of children with idiopathic ASDs. For now, the existing dichotomy regarding the extent of testing in research versus clinical settings is challenging.[301] Existing data do not support routine application of any particular test battery, nor do they suggest that tests currently under investigation be routinely performed on all children with ASDs at this time.

Prognosis

Although prognosis is one of the parents' most pressing concerns at the time of diagnosis, it depends on many factors and usually cannot be predicted during early childhood, especially in children younger than 3 years.[320] Important early predictors include JA skills, functional play skills,[321] cognitive abilities, and severity of ASD symptoms.[322–334] Recent studies have revealed that although most children diagnosed with AD retain their diagnosis at 9 years of age,[208] many, especially those with PDD-NOS, improve, and a minority have optimal outcomes; that is, they have normal intelligence and function reasonably well in mainstream classrooms without an aid but still exhibit residual clinical signs of social awkwardness, restrictive interests, or mild, infrequent stereotypies. Some may show signs of ADHD, language-based learning disabilities, or other learning challenges.[8–11,217] Poorer outcomes are associated with lack of JA by 4 years of age and lack of functional speech by 5 years of age,[7,217] MR, seizures (especially with onset during adolescence), comorbid medical (eg, tuberous sclerosis) or psychiatric (eg, schizophrenia) disorders, and severe autistic symptoms, especially when associated with extreme "aloofness." Factors associated with better out-

comes include early identification resulting in early enrollment in appropriate intervention programs[7,332] and successful inclusion in regular educational and community settings with typically developing peers.

Adult outcomes seem to correlate better with level of cognitive-adaptive functioning than with the severity of autistic symptoms. People with normal intelligence/adaptive functioning and milder autistic symptoms generally have the best outcomes, those with MR or intellectual disability and severe autistic symptoms have the worst outcomes within the continuum, and those with normal cognitive-adaptive skills and severe autistic symptoms generally do better than those with MR or intellectual disability and mild autistic symptoms,[328,333] which reaffirms the contribution of intelligence rather than degree of atypicality (autistic symptoms). However, within the subgroup of children with normal intelligence, the degree of atypicality then becomes more important in determining prognosis. Many believe that people with AS have better outcomes than those with other ASDs. This may be true, because by definition, all those with AS have normal intelligence. One adult outcome study found that although those with AS tend to have a greater likelihood of earning a college degree than those with high-functioning autism/PDD-NOS, the college education did not significantly affect employment or marriage status.[331,334]

Genetic Counseling

Genetic counseling regarding recurrence risk in siblings is important even when the etiologic evaluation is negative, because the recurrence risk is approximately 5% to 6% (range: 2%–8%) in a family with 1 child with an idiopathic ASD.[67,68] The prevalence of abnormality in siblings is even higher, perhaps 20%, when the broader phenotype or milder constellation of similar social, communication, and behavioral abnormalities is considered.[68] If there are already 2 siblings with ASDs in a family, it is likely that the recurrence risk for a strictly defined ASD in subsequent offspring is well above 8% and may approach 25%, but there is insufficient evidence to be more precise.[68] It is important to discuss the recurrence risk promptly after diagnosis to provide parents with this information before they conceive another child.[67] When an etiology is determined, the recurrence risk may be lower or higher than the risk in idiopathic ASD, depending on the syndrome or condition identified, and prenatal diagnosis may be possible.

GUIDANCE FOR PEDIATRICIANS REGARDING THE IDENTIFICATION AND EVALUATION OF CHILDREN WITH ASDs

In summary, most PCPs can expect to care for several children with ASDs in the context of the medical home.[5] No two children with ASDs will be exactly alike; each will have his or her own constellation of diagnostic and management challenges. The PCP has an important role in the early identification of children with ASDs. PCPs should do the following:

1. Conduct surveillance at every well-child visit. Be a good listener and recognize the early subtle red flags that indicate the possibility of an ASD. Be especially vigilant for younger siblings of a child who has already been diagnosed with an ASD.[253]
2. Screen at 18[246,260] and 24[260] months and any other time when parents raise a concern about a possible ASD. Although no screening tool is perfect, choose and become comfortable with at least 1 tool for each age group and use it consistently. Before 18 months of age, screening tools that target social and communication skills may be helpful in systematically looking for early signs of ASDs.[261]
3. If an ASD-specific screening result is negative but either the parents or the PCP remain somewhat concerned, then the PCP should schedule the child for an early, targeted clinic visit to address these persistent concerns.
4. Act on a positive screening result or when a child demonstrates 2 or more risk factors. Do not take a "wait-and-see" approach. Depending on the age of the child, simultaneously refer for all 3: comprehensive ASD evaluation; early intervention/early childhood education services; and an audiologic evaluation. Do not wait for a definitive diagnosis of an ASD to refer for developmental services; early intervention can be beneficial even if it targets the child's unique deficits. The intervention strategy can be modified if needed when the child is determined to have an ASD.

The science of ASDs is expanding rapidly. Newer tools are under development and should become available to clinicians so that children can be screened and evaluated more efficiently and with greater accuracy in the future.

The reader is referred to the accompanying AAP clinical report, "Management of Children With Autism Spectrum Disorders,"[303] to learn more about specific techniques and challenges in caring for children with ASDs within the context of a pediatric medical home.

APPENDIX 1: REIMBURSEMENT FOR SCREENING ACTIVITIES

Reimbursement for the administration of developmental and ASD-specific screening tools is an important aspect of screening. Developmental screening tests, including ASD-specific tests that are completed by a parent or nonphysician staff member and are reviewed and interpreted by the physician, can be billed appropriately by using *Current Procedural Terminology* (CPT) code 96110.[246]

Tools that include a direct clinical observation component have the benefit of providing some potentially more objective information, and aspects of behavior that parents may not have noticed can be sampled. Extended

screening tests that include a direct testing component can be billed appropriately by using CPT code 96111.[246]

Clinical Report—Identification and Management of Eating Disorders in Children and Adolescents

abstract

FREE

The incidence and prevalence of eating disorders in children and adolescents has increased significantly in recent decades, making it essential for pediatricians to consider these disorders in appropriate clinical settings, to evaluate patients suspected of having these disorders, and to manage (or refer) patients in whom eating disorders are diagnosed. This clinical report includes a discussion of diagnostic criteria and outlines the initial evaluation of the patient with disordered eating. Medical complications of eating disorders may affect any organ system, and careful monitoring for these complications is required. The range of treatment options, including pharmacotherapy, is described in this report. Pediatricians are encouraged to advocate for legislation and policies that ensure appropriate services for patients with eating disorders, including medical care, nutritional intervention, mental health treatment, and care coordination. *Pediatrics* 2010;126: 1240–1253

INTRODUCTION

Increases in the incidence and prevalence of anorexia nervosa (AN), bulimia nervosa (BN), and other eating disorders in children and adolescents make it critically important that pediatricians be familiar with early detection and appropriate management of these disorders. Results of epidemiologic studies have indicated that the numbers of children and adolescents with eating disorders increased steadily from the 1950s onward.[1–4] During the past decade, the prevalence of obesity in children and adolescents has also increased dramatically,[5–9] accompanied by further emphasis on dieting and weight loss among children and adolescents.[10–15]

The epidemiology of eating disorders has gradually changed; there is an increasing prevalence of eating disorders in males[16–19] and minority populations in the United States[20–23] as well as in countries in which eating disorders had not been commonly seen.[3,4,24,25] Of particular concern is the increasing prevalence of eating disorders at progressively younger ages.[19,26,27] A recent analysis by the Agency for Healthcare Research and Quality revealed that from 1999 to 2006, hospitalizations for eating disorders increased most sharply—119%—for children younger than 12 years.[19]

It is estimated that approximately 0.5% of adolescent girls in the United States have AN, that approximately 1% to 2% meet diagnostic criteria for BN, and that up to 5% to 10% of all cases of eating disorders occur in males. A large number of people with eating disorders do not meet the strict criteria set forth in the American Psychiatric Association's

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR) for AN or BN and are labeled as having "partial syndromes" or "eating disorder not otherwise specified" (ED NOS).[28] There are many more patients with ED NOS than there are patients with AN or BN; the prevalence is estimated to be between 0.8% and 14%, depending on the definition used.[29] These patients often experience the same physical and psychological consequences as do those who reach the threshold for diagnosis of AN or BN.[28–34] Athletes and performers, particularly those who participate in sports and activities that reward a lean body habitus (eg, gymnastics, running, wrestling, dance, modeling) may be at particular risk of developing partial-syndrome eating disorders.[35,36]

The etiology of eating disorders is multifactorial, and there is increasing evidence from both family and twin studies for a strong genetic component that is shared between AN and BN.[37,38] The mechanism(s) by which genetic factors influence risk have not been elucidated, but various hypotheses have been proposed. Genetic predisposition to various trait disturbances such as behavioral rigidity, perfectionism, or harm avoidance may be more salient than genetic influences on eating, hunger, or satiety.[39–41] Genetic effects seem to be "activated" by puberty,[42–44] and there is strong evidence for genetic-environment interactions.[39,40]

Dieting has also been implicated as a potent proximal risk factor in the development of disordered eating and eating disorders.[45–47] In 1 community-based study, dieters at 5-year follow-up were at significantly higher risk of disordered eating behaviors (eg, vomiting or using diet pills or laxatives) than nondieters and were also at increased risk of obesity.[47] In another large community cohort, dieters were 5 times more likely to develop an eating disorder and severe dieters were 18 times more likely to develop an eating disorder than nondieters.[48]

Neuroendocrine abnormalities have been implicated in the etiology of eating disorders. Leptin is a circulating hormone produced in adipose tissue and seems to have a significant role in mediating the neuroendocrine effects of AN. Leptin concentrations are sensitive to the acute metabolic effects of decreased intake and energy deficits, and decreased circulating leptin concentrations reflect depleted stores of body fat.[49–51] Physical hyperactivity is a common feature of AN and sometimes manifests as restlessness, athleticism, or compulsive exercise. This hyperactivity also seems to be mediated by leptin.[51]

Physical hyperactivity associated with weight loss seems to occur in animals as well, apparently mediated by hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis. Syndromes that resemble AN, characterized by food refusal, physical overactivity, and extreme weight loss, occur in pigs, sheep, and goats bred for leanness.[52] Caloric restriction coupled with environmental stress produces animal models for binge-eating.[53] These animals overeat dramatically despite nutritional satiety and normal energy status, which strongly suggests that reward circuits are being activated rather than metabolic needs being satisfied.[43,53]

In community-based studies of adolescents, disturbances of body image and overconcern about body shape are common, although the prevalence of eating disorders remains low.[54] These results reinforce the likelihood of epigenetic effects in which the development of eating disorders reflects the intersection between genetic predisposition, environmental triggers, and personal experience.

SCREENING FOR EATING DISORDERS IN PRACTICE

Primary care providers are in a unique position to detect the onset of eating disorders at the earliest stages and to stop their progression.[32,33] Pediatricians should screen for eating disorders as part of annual health supervision or during preparticipation sports examinations by monitoring weight and height longitudinally and paying careful attention to potential signs and symptoms of disordered eating.

Screening questions about eating patterns and body image should be asked of all preteens and adolescents. The *Bright Futures* guidelines provide examples for addressing this issue with adolescents of different ages.[55] The SCOFF questionnaire, although validated only in adults, can provide a framework for screening (Table 1).[56] Weight, height, and BMI should be determined regularly and plotted on appropriate growth charts. Deviations from normal are easier to identify visually, because nutritional insufficiency may be manifest by falloff in either height or weight percentiles rather than actual weight loss. Growth charts are available for plotting changes in weight, height, and BMI over time and for comparing individual measurements with age-appropriate population norms.

Any evidence of excessive weight concern, inappropriate dieting, or a pattern of weight loss requires further attention, as does primary or secondary

TABLE 1 The SCOFF Questionnaire[56]

1. Do you make yourself **sick** because you feel uncomfortably full?
2. Do you worry you have lost **control** over how much you eat?
3. Have you recently lost **>1 stone** (6.3 kg or 14 lb) in a 3-mo period?
4. Do you believe yourself to be **fat** when others say you are too thin?
5. Would you say that **food** dominates your life?

One point should be given for every "yes" answer; a score of ≥2 indicates a likelihood of AN or BN.

amenorrhea or a failure to achieve appropriate increases in weight or height in growing children. In each of these situations, careful assessment for the possibility of an eating disorder and close monitoring at intervals as frequent as every 1 to 2 weeks may be needed until the situation is clarified. Adolescent girls who seek physician care for weight, shape, or eating concerns have been shown to be at significantly higher risk of a subsequent diagnosis of AN.[57]

A number of studies have shown that most adolescent girls express concerns about being overweight, and many may diet inappropriately.[10–12,14] Most of these children and adolescents do not have an eating disorder. On the other hand, it is known that patients with eating disorders often try to hide their illness, so simple denials by the adolescent do not exclude the possibility of an eating disorder. Obtaining collateral history from a parent may help identify abnormal eating attitudes or behaviors, although parents may, at times, be unaware or in denial as well. When an adolescent is referred to a pediatrician because parents, friends, or school personnel suspect the possibility of an eating disorder, it is likely that disordered eating is present. Pediatricians must, therefore, not be lulled into a false sense of security if the adolescent denies all symptoms. Table 2 outlines questions that are useful in eliciting a history of eating disorders, and Table 3 delineates possible physical findings in children and adolescents with eating disorders.

DSM-IV-TR criteria[28] for the diagnosis of AN and BN are outlined in Table 4. These criteria focus on the weight loss, attitudes and behaviors, and amenorrhea displayed by patients with eating disorders. Limitations of these criteria, especially as they relate to children and adolescents, have been discussed extensively in the literature,[54,58–61] and revisions to these criteria have been proposed for the fifth edition of the manual.[60,61] Alternative schema for the classification of eating disorders in children have been described to better reflect the range of eating issues seen.[58,62]

Younger patients (<13 years of age) with eating disorders are more likely to have premorbid psychopathology (depression, obsessive-compulsive disorder, or other anxiety disorders) and are less likely to have binge/purge behaviors associated with their illness. The predominance of females is far less; among the youngest patients with eating disorders, males and females may be equally affected. Weight loss often occurs at a faster rate than in older patients. Still, studies have shown that more than half

TABLE 2 History

Specific history
What is the most you ever weighed? How tall were you then? When was that?
What is the least you ever weighed in the past year? How tall were you then? When was that?
What do you think is your healthy weight?
What would you like to weigh?
Exercise: how much, how often, level of intensity? How stressed are you if you miss exercising?
Current eating habits: adequacy of intake, portion sizes, food restrictions, picky eating, fluid intake, ritualized eating habits? Recent vegetarianism? Excessive noncaloric fluid intake?
24-h diet history?
Calorie-counting? Fat gram–counting? Carbohydrate-counting?
Any binge-eating? Frequency? Triggers?
Purging history?
Use of diuretics, laxatives, diet pills, or ipecac? Ask about elimination pattern, constipation, diarrhea. Any vomiting? Frequency? Timing in relation to meals?
Any previous therapy? What kind and how long? What was and was not helpful?
Symptoms of hyperthyroidism, diabetes, malignancy, infection, inflammatory bowel disease?
Family history: obesity, eating disorders, depression, other mental illness (especially anxiety disorders and obsessive-compulsive disorder), substance abuse by parents or other family members?
Menstrual history: age at menarche? Regularity of cycles? Last menstrual period?
Use of cigarettes, drugs, alcohol?
Use of anabolic steroids (especially in boys)?
Use of stimulants?
Involvement with proanorexia ("pro-ana") or probulimia ("pro-mia") Web sites
History of physical or sexual abuse?
Review of symptoms
Dizziness, presyncope, syncope, fatigue?
Pallor, easy bruising or bleeding?
Cold intolerance? Cold extremities?
Palpitations, chest pain, shortness of breath? Exercise intolerance?
Hair loss, lanugo, dry skin?
Fullness, bloating, abdominal pain, epigastric burning?
Vomiting, symptoms of gastroesophageal reflux?
Change in bowel habits? Diarrhea, constipation, rectal bleeding?
Weakness, muscle cramps?
Menstrual irregularities?

TABLE 3 Physical Examination Findings Sometimes Seen in Children and Adolescents With Eating Disorders

Sinus bradycardia; other cardiac arrhythmias
Orthostatic changes in pulse (>20 beats per min) or blood pressure (>10 mm Hg)
Hypothermia
Cachexia; facial wasting
Cardiac murmur (one-third with mitral valve prolapse)
Dull, thinning scalp hair
Sialoadenitis (parotitis most frequently reported)
Angular stomatitis; palatal scratches; oral ulcerations; dental enamel erosions
Dry, sallow skin; lanugo
Bruising/abrasions over the spine related to excessive exercise
Delayed or interrupted pubertal development
Atrophic breasts; atrophic vaginitis (postpubertal)
Russell sign (callous on knuckles from self-induced emesis)
Cold extremities; acrocyanosis; poor perfusion
Carotenemia (orange discoloration of the skin, particularly palms and soles)
Edema of the extremities
Flat or anxious affect

TABLE 4 Diagnosis of AN, BN, and Eating Disorders Not Otherwise Specified, From DSM-IV-TR[28]

AN

1. Refusal to maintain body weight at or above a minimally normal weight for age and height (ie, weight loss that leads to maintenance of body weight 85% of that expected or failure to make expected weight gain during period of growth and leads to a body weight of 85% of that expected).
2. Intense fear of gaining weight or becoming fat, even though underweight
3. Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of current body weight
4. In postmenarcheal females, amenorrhea (ie, the absence of at least 3 consecutive menstrual cycles)

Types

- Restricting type: no regular bingeing or purging (self-induced vomiting or use of laxatives and diuretics)
- Binge-eating/purging type: regular bingeing or purging behavior

BN

1. Recurrent episodes of binge-eating characterized by (*a*) eating, in a discrete period of time, an amount of food that is definitely larger than most people would eat in a similar period of time and under similar circumstances and (*b*) a sense of lack of control over eating during the episode
2. Recurrent inappropriate compensatory behavior to prevent weight gain, such as self-induced vomiting, misuse of laxatives, diuretics, enemas, or other medications; fasting; or excessive exercise
3. The binge-eating and inappropriate compensatory behaviors both occur, on average, at least twice per week for 3 mo
4. Self-evaluation unduly influenced by body shape or weight
5. The disturbance does not occur exclusively during episodes of AN

Types

- Purging type: the person has regularly engaged in self-induced vomiting or misuse of laxatives, diuretics, or enemas
- Nonpurging type: the person has used other inappropriate compensatory behaviors, such as fasting or excessive exercise, but has not regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas

Eating disorder not otherwise specified

Disorders of eating that do not meet the criteria for either AN or BN; examples include

- All criteria for AN are met except the patient has regular menses
- All criteria for AN are met except that despite significant weight loss, weight remains in the normal range
- All criteria for BN are met except that binge-eating and inappropriate compensatory behaviors occur less frequently than twice per week or for a duration of <3 mo
- A patient with normal body weight who regularly engages in inappropriate compensatory behavior after eating small amounts of food (eg, self-induced vomiting after eating 2 cookies)

TABLE 5 Differential Diagnosis of Eating Disorders

Gastrointestinal disorders
Inflammatory bowel disease
Celiac disease
Infectious diseases
Chronic infections (human immunodeficiency virus infection, tuberculosis, others)
Endocrine disorders
Hyperthyroidism (hypothyroidism)
Diabetes mellitus
Other endocrine disorders (eg, hypopituitarism, Addison disease)
Other psychiatric disorders
Obsessive-compulsive disorder and anxiety disorders
Substance abuse
Other disorders
Central nervous system lesions (including malignancies)
Other cancers
Superior mesenteric artery syndrome (more commonly a consequence of severe weight loss)

of all children and adolescents with eating disorders may not fully meet all DSM-IV-TR criteria for AN or BN because they do not articulate body-image dissatisfaction or because their inadequate nutrition is manifest by growth failure rather than weight loss to less than 85% of expected weight.[63,64] These patients experience the same medical and psychological consequences of their disorders as do patients who meet criteria for AN or BN. Indeed, because the sequelae of weight loss (or failure to gain weight appropriately) may have even more worrisome implications for younger patients, relaxation of the diagnostic criteria for children and adolescents has been proposed in the development of the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* to facilitate earlier diagnosis and treatment.[61]

INITIAL EVALUATION OF THE PATIENT WITH DISORDERED EATING

When screening raises suspicion of an eating disorder, initial evaluation includes establishing the diagnosis, evaluating medical and nutritional status, determining severity, and performing an initial psychosocial evaluation. This comprehensive evaluation is often performed in the pediatric primary care setting, and primary care clinicians who feel competent and comfortable in performing this assessment are encouraged to do so. Others should refer to appropriate medical subspecialists and mental health personnel to ensure that a complete evaluation is performed. A differential diagnosis for the adolescent with symptoms of an eating disorder can be found in Table 5.

Because eating disorders can affect every organ system and the medical complications can be serious or even life-threatening, a comprehensive history should be taken and a comprehensive physical examination should be performed. The most frequently seen medical complications are listed in Table 6 and are detailed in the following section.

Most laboratory results will be normal in patients with eating disorders; however, normal laboratory results do not exclude serious illness or medical instability in these patients. Still, an initial laboratory assessment should include a complete blood cell count; measurement of serum electrolytes, calcium, magnesium, and glucose; liver function tests; urinalysis; and measurement of thyrotropin level. Additional studies (eg, urine pregnancy test, serum luteinizing and follicle-stimulating hormones, serum prolactin, and se-

TABLE 6 Medical Complications That Result From Eating Disorders

General
Dehydration
Hypokalemia
Hypomagnesemia
Hyponatremia
Irreversible cardiomyopathy and myositis (ipecac toxicity)
Amenorrhea and menstrual irregularities
Low bone mineral density; osteoporosis
Cognitive deficits
Mood symptoms
Obsessive/compulsive symptoms
Suicide
Caloric restriction and weight loss
Inability to maintain body temperature
Prolonged corrected QT interval or increased QT dispersion (uncommon but may predispose patient to sudden death)
Dysrhythmias (including supraventricular beats and ventricular tachycardia, with or without exercise)
Other electrocardiographic abnormalities
Mitral valve prolapse
Pericardial effusions
Delayed gastric emptying and impaired gastrointestinal tract motility
Constipation
Bloating; postprandial fullness
Hypoglycemia
Hypercholesterolemia
Abnormal liver function test results
Sterile pyuria
Anemia, leukopenia; thrombocytopenia
Sick-euthyroid syndrome
Growth retardation
Cortical atrophy
Vomiting-related
Hypochloremic metabolic alkalosis (vomiting)
Esophagitis
Gastroesophageal reflux
Dental erosions
Mallory-Weiss tears
Esophageal or gastric rupture (rare)
Aspiration pneumonia (rare)
Laxative-related
Hyperchloremic metabolic acidosis (laxative abuse)
Hyperuricemia
Hypocalcemia
Fluid retention (may gain up to 10 lb in 24 h) with laxative withdrawal
Refeeding
Diaphoresis and night sweats
Polyuria and nocturia
Peripheral edema
Refeeding syndrome

rum estradiol) may be indicated for patients with amenorrhea. Bone densitometry, using age-appropriate software, should also be considered for those with amenorrhea for more than 6 to 12 months. Other studies including erythrocyte-sedimentation rate, screening for celiac disease, or radiographic imaging, such as computed tomography or MRI of the brain or studies of the upper or lower gastrointestinal system, should be considered if there are uncertainties about the diagnosis. An electrocardiogram should be performed for any patient with cardiovascular signs or symptoms, for any patient with electrolyte abnormalities, or for any patient with significant purging or weight loss.

The initial mental health assessment should include an evaluation of the patient's obsession with food and weight, his or her understanding of the diagnosis, and his or her willingness to receive help. The patient's social functioning at home, in school, and with friends should be assessed. Psychiatric comorbidity is common with eating disorders and is often previously undiagnosed.[34,65] The pediatrician should identify other potential psychiatric diagnoses (such as depression, anxiety, or obsessive-compulsive disorder), which may be a cause or consequence of disordered eating. Use of tobacco, alcohol, or illicit drugs or misuse of prescription or over-the-counter medications may also complicate the management of eating disorders. Suicidal ideation and history of physical or sexual abuse or violence should also be assessed. Suicide attempts and completed suicide are relatively common, particularly for patients who have binge/purge or purging behavior and are a major contributor to eating disorder–associated mortality. Death from suicide is 50 times more likely in patients with AN,[66] and 25% to 35% of patients with BN report a history of attempted suicide.[34]

The parents' reaction to the illness should also be assessed. Parental indifference or denial of the problem or inconsistent views about treatment may affect the course of the illness and recovery.

Determining where and by whom the patient will be treated is an important and practical component of the initial evaluation. Patients with limited nutritional, medical, and psychological dysfunction can be managed in the pediatrician's office in conjunction with outpatient nutrition and mental health support. Patients who are more ill often require more intensive services, ideally delivered by a specialized multidisciplinary team, and sometimes in day-treatment, hospital, or residential settings.

MEDICAL COMPLICATIONS IN PATIENTS WITH EATING DISORDERS

Medical complications associated with eating disorders are listed in Table 5, and details of these complications have been described in many reviews.[32,33,67–74] Significant complications are seen in both outpatients and inpatients.[75] Most of the medical complications of eating disorders resolve with refeeding and/or resolution of purging.[70] However, there is increasing concern that some complications—particularly growth retardation, structural brain changes, and low bone mineral density—may, with time, become irreversible.[72] Malnutrition underlies many of the somatic symptoms seen initially, and these changes are often adaptive to the associated energy deficits. Over time, adaptation fails and signs and symptoms reflect the inability to compensate for inadequate nutrition. Metabolic rate decreases, body temperature can no longer be maintained, and nearly every organ system is compromised.[70,75,76]

Common cardiovascular signs and symptoms include orthostasis with blood pressure and/or pulse changes, bradycardia, and poor peripheral perfusion characterized by cold extremities, delayed capillary refill, and sometimes

acrocyanosis. Conduction abnormalities may occur as a result of myocardial atrophy and are thought to be the most common proximal cause of death with AN. Repolarization abnormalities, characterized by QTc prolongation and/or increased QT dispersion, are reported with widely variable prevalence and seem to be more frequent in older patients and with increasing duration of illness.[77] Repolarization abnormalities are potentially life-threatening and should be managed aggressively. Pericardial effusion, a functional mitral valve prolapse, myocardial dysfunction, and emetine (ipecac-related) cardiomyopathy are all seen less frequently. Congestive heart failure can occur during refeeding, particularly in the setting of electrolyte abnormalities.[72,73,78]

Gastrointestinal complaints are common and sometimes precede diagnosis of the eating disorder. Delayed gastric emptying and increased intestinal transit time often contribute to subjective descriptions of bloating and postprandial fullness, which can further compromise nutritional restoration. In patients who vomit, symptoms of gastroesophageal reflux are common, and upper gastrointestinal bleeding sometimes occurs. Severe bleeding secondary to Mallory-Weiss tears of the esophagus is rare. Constipation is common and often difficult to manage. Nutritional strategies, stool softeners, or polyethylene glycol 3350 (Miralax) are the treatments of choice; stimulant laxatives should be avoided. Rectal prolapse sometimes occurs in the setting of constipation and/or laxative abuse. Hepatic transaminase levels are often elevated as a consequence of malnutrition and are not usually indicative of viral hepatitis. Hypertrophy of the salivary glands often occurs and may be a clue to binge-eating and/or vomiting. Esophageal or gastric rupture are catastrophic but rare complications that usually occur during refeeding.[73]

Fluid and electrolyte abnormalities may occur as a result of purging or with increasing cachexia. Dehydration can be seen in any patient with an eating disorder and can sometimes lead to orthostatic symptoms, presyncope, or syncope. Chronic dehydration and the body's effort to conserve water may induce a pseudohyperaldosteronism, which also leads to hypokalemia. However, significant deficits in total body potassium and the associated risk of arrhythmia may exist even with a normal serum potassium level. Patients with vomiting may have a hypochloremic metabolic alkalosis because of chronic loss of hydrochloric acid. Patients who abuse laxatives may have a hyperchloremic metabolic acidosis related to bicarbonate wasting. Dilutional hyponatremia can be seen in patients who "water load" instead of eating or to misrepresent their weight at outpatient visits. Hypomagnesemia that results from inadequate intake is associated with sudden cardiac death, may interfere with potassium repletion in patients who are hypokalemic, and sometimes contributes to refeeding syndrome.[70] Edema, sometimes significant, may be seen as a result of hypoproteinemia, during refeeding, or in association with laxative abuse.[70]

Endocrine dysfunction is common and includes hypothyroidism, hypercortisolism, and disturbances of the HPA axis, which result in hypogonadotropic hypogonadism, luteal phase abnormalities, and anovulation. Euthyroid-sick syndrome (low free thyroxine, normal thyrotropin) is the most common thyroid abnormality and is reversible with refeeding. Supplemental thyroid hormone is not indicated. Activation of the HPA axis has been clearly demonstrated. In addition to its deleterious effects on growth, thyroid function, and the reproductive system, HPA hyperactivity also contributes to the appetite suppression and physical overactivity that characterize eating disorders.[79] Hypothalamic suppression causing amenorrhea is attributable not only to weight loss but also to physical overactivity, emotional stress, and the metabolic changes associated with acute energy deficits[70,75]; it sometimes precedes weight loss.[70] Hypothalamic secretion of gonadotropins reverts to a prepubertal pattern that reverses with refeeding.[70] Amenorrhea is an important marker for increased risk of low bone mineral density and osteoporosis (discussed in a later paragraph),[80–83] and an intriguing recent report suggested that amenorrhea is also associated with the cognitive impairments seen with AN.[84]

Common skin changes include lanugo, dry scaly skin, and yellow discoloration related to carotenemia. Acrocyanosis can be seen when perfusion is poor. Hair and nail changes are often seen as well, and angular stomatitis may be related to either vomiting or vitamin deficiencies.[70]

Growth retardation, short stature, and pubertal delay may all be seen in prepubertal and peripubertal children and adolescents with eating disorders.[75,85] Many endocrine abnormalities contribute to this growth failure; abnormal thyroid function, abnormal adrenal function, low levels of sex steroids, and uncoupling of growth hormone from insulin-like growth factor 1 (IGF-1) have all been implicated.[72] Catch-up growth has been inconsistently reported in the literature; younger patients may have greater and more permanent effects on growth.[72,86]

Low bone mineral density is a frequent complication of eating disorders in both male and female patients. It is worrisome not only because of the increased risk of pathologic fractures

but also because of its potential to be irreversible and compromise skeletal health across the entire life span. The pathophysiology of abnormal bone mineralization in the eating disorders is likely to be multifactorial; proposed mechanisms include deficiencies of gonadal steroids (estrogen and/or testosterone), deficiencies of calcium and vitamin D, reduction in lean muscle mass and its mechanical effects on bone, and excesses of endogenous glucocorticoids related to hyperactivity of the HPA axis. The reversibility of skeletal changes is unclear and probably varies on the basis of disease severity, the timing of illness and recovery, and perhaps genetic factors. Because adolescence is a critical period for bone mineralization, younger patients with AN are at higher risk of skeletal changes than are older patients. Treatment strategies, such as supplemental estrogen, bisphosphonates, calcium, and vitamin D replacement, have not been shown to be consistently effective, are not a substitute for nutritional recovery, and are not recommended for routine use.[72,87,88]

Volume deficits in both gray and white matter of the brain and associated increases in the cerebrospinal fluid space occur with weight loss in AN and are proportional to weight loss. Brain changes may be associated with elevated cortisol concentrations related to HPA-axis dysfunction, analogous to changes now being reported in other psychiatric disorders such as posttraumatic stress disorder.[89] Cognitive impairment has been demonstrated across the wide range of neuropsychological domains but does not seem to be directly proportional to structural brain changes.[84] Functional imaging studies of the brain show decreases in both global and localized brain activity, but it is unknown whether these decreases precede or are a consequence of weight loss or whether they are reversible.[90] Normalization of white matter occurs with refeeding; however, gray matter changes seem to persist despite weight recovery.[84,89]

TREATMENT CONTINUUM FOR CHILDREN AND ADOLESCENTS WITH EATING DISORDERS

Most adolescent patients with eating disorders will be treated in outpatient settings. Pediatricians play an important role in the management of these patients, assessing treatment progress, screening for and managing medical complications, and coordinating care with nutrition and mental health colleagues. Some pediatricians in primary care practice will feel comfortable in coordinating care; others will choose to refer some or all patients with eating disorders to those with special expertise. Depending on the availability of local resources, these providers may be a specialty eating disorders program, an adolescent medicine specialist, a psychiatrist, or another mental health provider.[32,91]

Collaborative Outpatient Care

Most children and adolescents with eating disorders will be managed in an outpatient setting by a multidisciplinary team coordinated by a pediatrician or medical subspecialist with expertise in the care of children and adolescents with eating disorders. Pediatricians generally work with nursing, nutrition, and mental health colleagues in provision of the medical, nutrition, and mental health care required by these patients.

It is generally accepted that medical stabilization and nutritional rehabilitation are the most important determinants of short-term outcomes and are essential for correcting cognitive deficits to allow for effective mental health interventions. Components of nutritional rehabilitation required in the management of patients with eating disorders have been presented in several reviews.[32,33,92–95] In the United States, oral refeeding is clearly the preferred modality for nutritional rehabilitation. However, for patients who are unwilling or unable to eat, supplements or nasogastric feeding may be life-saving.

Meals and snacks generally are reintroduced or improved in a stepwise manner for those with AN, which leads, in most cases, to an eventual intake of 2000 to 3000 kcal (or more) per day and a weight gain of 0.25 to 1 kg per week. Smaller, more frequent meals; increasing the caloric density of foods; and substituting nutrient fluids (eg, fruit juice) for water can sometimes help patients overcome the postprandial fullness and psychological barriers associated with the substantial increase in caloric intake that is required. Patients with abdominal complaints from acquired nutritionally mediated lactase deficiency may benefit from supplemental lactase. Meals are changed to ensure ingestion of 2 to 3 servings of protein per day. Daily fat intake should be slowly shifted toward a goal of 30 to 50 g per day. The stereotypical and obsessional eating habits favored by many patients with eating disorders and the observation that similar levels of weight loss and malnutrition can lead to dramatically different medical consequences suggest that deficiencies of specific micronutrients may share responsibility with protein-calorie malnutrition for the medical consequences in eating disorders.[70] Food variety should be encouraged, and a multivitamin should be recommended. Behavioral interventions are often required to encourage reluctant (and often resistant) patients to meet necessary caloric intake and weight-gain goals.[96–99]

Ranges for treatment goal weight should be individualized and based on age, height, pubertal stage, premorbid

weight, and previous growth trajectory. Furthermore, for growing children or adolescents, the goal weight range should be reevaluated at regular intervals (eg, every 3 to 6 months) on the basis of changing age and height. In postmenarcheal girls, resumption of menses provides an objective measure of biological health[100]; in 1 recent study, resumption of menses occurred at a mean BMI percentile of 27; 75% of the girls resumed menstruating once they had achieved and sustained approximately the 40th percentile for BMI.[101] Resumption of menses can also be used to refine the treatment goal weight.

Family-Based ("Maudsley") Therapy

Over the past decade, specialized eating disorder–focused family-based interventions, based on work originally performed at the Maudsley Hospital in London, have gained attention in the treatment of adolescent AN because of promising short-term and long-term outcomes. Although the etiologic underpinnings of this treatment approach have lost much of their support over time (ie, it is no longer believed that eating disorders are caused mainly by family dysfunction), family-based interventions, nevertheless, remain an effective and evidence-based treatment strategy for adolescent AN in both open trials and randomized controlled studies.[102–105] Family-based interventions are typically described as having 3 phases. In the first phase, parents, supported by the therapist, take responsibility to make certain that their adolescent is eating adequately and limiting other pathologic weight-control behaviors. In the second phase, substantial weight recovery has already occurred, and the adolescent is helped to gradually resume responsibility for his or her own eating. In the final phase of treatment, weight has been restored, and the therapy shifts to address the more general issues of adolescent development and how they may have been derailed by the eating disorder.[102] A manual for providers[106] and a family-support manual[107] are now available. Unfortunately, family-based treatment by experienced providers is not available in all communities. Nevertheless, the essential principles of family-based treatment can still be encouraged by community providers in their work with patients and families.[105] Family-based treatment may not be suitable for all patients; caution has been advised for families in which there is parental psychopathology or hostility toward the affected child, for older patients, or for patients who are the most medically compromised.[102,104] Additional randomized controlled studies of family-based treatment, including studies of long-term outcomes, are still needed. Family-based approaches are now being evaluated for the treatment of BN as well.[108]

Treatment of BN in adolescents has been poorly studied, and there is little evidence to guide treatment recommendations. For adults, BN-focused cognitive behavioral therapy is the treatment of choice. Pharmacotherapy (see "Pharmacotherapy") has been helpful as well.

Day-Treatment Programs

Day-treatment programs (day hospitalization, partial hospitalization) have been developed to provide an intermediate level of care for patients with eating disorders who require more than outpatient care but less than 24-hour hospitalization.[109–112] These programs have been used in an attempt to prevent the need for hospitalization; in some cases, they are used as a "step-down" from inpatient to outpatient care. Day-treatment programs are less costly and more accessible than traditional hospitalization. In addition, they allow for more family and social support and for recovery to occur in a more naturalistic environment that may be more generalizable.[109] Day treatment typically involves 8 to 10 hours of care (including meals, therapy, groups, and other activities) by a multidisciplinary staff 5 days/week. Evaluation of day-treatment programs has been characterized by small samples and the difficulty in undertaking randomized controlled trials.[113] Still, short-term outcomes have generally been reported to be good.[110,113,114] A recent study that used a range of outcome measures, including BMI and measurement of binge-purge behavior, demonstrated day treatment to be highly effective in the treatment of both restrictive and binge-purge AN and BN. Furthermore, these results were sustained or improved over 18 months of follow-up.[113]

Hospital-Based Treatment

Hospital-based treatment for eating disorders is less common when intensive outpatient or day-treatment programs are available. Hospitalization is much more frequently required for adolescent patients with AN than for patients with BN. Criteria for hospitalization of children and adolescents with eating disorders have been enumerated by the Society for Adolescent Medicine and are listed in Table 7.[32] Similar criteria are endorsed in the American Psychiatric Association's practice guideline for the treatment of patients with eating disorders[33] and by other organizations.[115] These criteria acknowledge that hospitalization may be required because of medical or psychiatric needs or when there is failure of outpatient treatment to achieve medical, nutritional, or psychiatric goals. Unfortunately, many third-party payers in the United States do not adhere to these criteria and make it difficult for some children and adolescents with eating disorders to receive the

TABLE 7 Criteria for Hospital Admission for Children, Adolescents, and Young Adults With Eating Disorders[32]

AN
<75% ideal body weight or ongoing weight loss despite intensive management
Refusal to eat
Body fat < 10%
Heart rate < 50 beats per min daytime; <45 beats per min nighttime
Systolic pressure < 90 mm Hg
Orthostatic changes in pulse (>20 beats per min) or blood pressure (>10 mm Hg)
Temperature < 96°F
Arrhythmia
BN
Syncope
Serum potassium concentration < 3.2 mmol/L
Serum chloride concentration < 88 mmol/L
Esophageal tears
Cardiac arrhythmias including prolonged QTc
Hypothermia
Suicide risk
Intractable vomiting
Hematemesis
Failure to respond to outpatient treatment

recommended level of care.[116,117] Children and adolescents have the best prognosis if their disease is treated rapidly and aggressively (an approach that may not be as effective for adults with a more long-term, protracted course).[91] Hospitalization, when indicated, allows for medical stabilization, adequate weight gain, and establishment of safe and healthy eating habits and improves the prognosis for children and adolescents. Discharge of hospitalized patients too soon often results in medical complications, a worse clinical course, and readmission. In 1 study, patients with AN who were discharged while still underweight had a 50% readmission rate compared with a rate of less than 10% for patients who had reached at least 90% of their recommended average body weight before discharge.[118]

The pediatrician involved in the treatment of hospitalized patients must be prepared to provide nutrition via a nasogastric tube or even intravenously when necessary. In hospitalized male adolescents, supplemental nighttime nasogastric feedings have been shown to significantly increase both weight gain and improvement in BMI compared with oral refeeding alone.[119]

Refeeding syndrome may occur in severely malnourished patients, particularly in the setting of aggressive nutritional rehabilitation. Refeeding syndrome refers to a constellation of metabolic, cardiovascular, neurologic, and hematologic complications primarily related to shifts of phosphate from extracellular to intracellular spaces in the setting of total body phosphorus depletion. The syndrome is most common in hospitalized patients during the first week of hospitalization and patients who are receiving supplemental enteral or parenteral nutrition. Cautious refeeding, careful monitoring of serum electrolyte, magnesium, phosphorus, and glucose levels, and a low threshold for phosphorus supplementation prevent the development of refeeding syndrome.[71,72,120–123] Refeeding syndrome is unusual after the first 2 weeks of nutritional rehabilitation or in patients being treated in the outpatient setting.

Pharmacotherapy

No medications have been approved by the US Food and Drug Administration for the treatment of AN.[124] Pharmacotherapy is sometimes prescribed but is typically targeted at comorbid symptoms of depression and anxiety. Selective serotonin-reuptake inhibitors (SSRIs) are most often used but may not be effective in severely malnourished patients. There is also limited evidence for the use of SSRIs for relapse prevention in AN.[125] In recent case reports and open-label trials, atypical neuroleptic agents, predominantly olanzapine (Zyprexa), have been noted to improve both weight gain and dysfunctional thinking in patients with AN.[126] A recently completed randomized, double-blind, placebo-controlled trial in adults showed a significant increase in weight gain in those who were taking olanzapine and a concomitant decrease in obsessive symptoms, although the effect size was modest.[127] Further evaluation of the effectiveness of these agents is underway, and caution is warranted because of the risk of developing insulin resistance and metabolic syndrome.

In contrast to AN, several pharmacologic agents have been demonstrated to be effective for the treatment of BN. Although only fluoxetine has been approved by the Food and Drug Administration, other SSRIs, serotonin/norepinephrine-reuptake inhibitors (eg, venlafaxine), and tricyclic antidepressants have also been shown to decrease binge-eating and purging in BN.[124,128] Topiramate has been shown to significantly decrease binge-eating and may be an option for patients who do not respond to or are not able to tolerate SSRIs.[129] Other drugs, including naltrexone and ondansetron (Zofran), are being used with some success in BN, although data are lacking to recommend their use more broadly.[130]

Hormonal supplementation, although capable of restoring menstruation, has not been shown to reliably improve bone mineral density and is not a substitute for nutritional rehabilitation and restoration of positive energy balance.

PROGNOSIS

The prognosis of eating disorders in adolescents has varied widely in the literature, and outcomes have depended on methodology, definitions of recovery, and duration of follow-up in the studies reported.[131] Adolescent outcomes are significantly better than the outcomes reported in adults. Longitudinal reports reflect a more optimistic and less hopeless outcome; followed over time, the majority of patients fully recover, and an even

larger proportion have a behavioral cure (normal eating, normal weight, and resumption of menses). However, these results accrue only after more than 10 years of follow-up; therefore, patients, their families, and clinicians must be prepared to remain engaged in what may sometimes be a protracted treatment process.[132–134]

Strober et al[132] conducted an important study in which 95 people who had been hospitalized for AN as adolescents were followed for 10 to 15 years. By the end of follow-up, 86.3% had achieved partial or complete recovery, and there were no deaths. However, the median time to partial recovery was 57.4 months, and the median time to full recovery (met by >75% of the study population) was 79.1 months. A study from Germany produced similar findings; at 10-year follow-up, 69% of the patients (including 7 boys) had achieved full recovery, and there were no deaths. Again, however, the course was protracted and the authors pointed out a high rate of residual psychiatric disorders even after full recovery from AN.[135]

Patients with an earlier age of onset seem to have a better prognosis.[85,134] Other characteristics associated with a better prognosis include shorter duration of symptoms and a better parent-child relationship. Purging behavior, physical hyperactivity, more significant weight loss, and disease chronicity are all associated with a less favorable prognosis.[134] Even after recovery, there are high rates of residual psychiatric illness—predominantly depression and anxiety—that persist.[133,136,137] A meta-analysis of 119 AN outcome studies showed little improvement in the success of treatment over the 5 decades reviewed.[133]

Mortality rates for adolescents with both AN and BN are lower than those that have historically been reported.[133,134] In a recent meta-analysis, the mortality rate among adolescents with AN was reported to be 1.8% compared with a mortality rate of 5.9% when adults and adolescents were considered together.[134] Mortality, when it does occur, is most often attributable to the complications of starvation or to suicide.[66]

PEDIATRICIANS' ROLE IN PREVENTION AND ADVOCACY

Efforts to prevent eating disorders can take place both in practice and community settings, such as schools. Primary care pediatricians can help families and children learn to apply the principles of proper nutrition and physical activity and to avoid an unhealthy emphasis on weight and dieting.[138] In addition, pediatricians can screen to detect the early onset of disordered eating and be careful to avoid seemingly innocuous statements (such as "you could stand to lose a little weight") that are sometimes reported by patients to have triggered the onset of their eating disorder. At the community level, there is general agreement that changes in the cultural approaches to weight, dieting, and body image will be required to decrease the growing numbers of children and adolescents at risk of developing eating disorders. This cultural shift is made more challenging by the increasing prevalence of obesity and the competing responsibility to address its health risks as well.[15]

A variety of successful programs for preventing eating pathology have been developed for various settings.[139] The largest effect sizes were seen in programs targeted at high-risk populations, in programs that were interactive rather than didactic, and in programs aimed at older adolescents. Content varied even in the most successful programs, which suggests that a variety of approaches may be effective. Multisession programs were more effective than single-session programs,[140] and there has even been some concern that single-session programs may be counterproductive.[141–146] An important question currently being asked is whether we can work simultaneously toward the prevention of eating disorders and obesity.[15]

Reimbursement issues continue to limit the access of many patients with eating disorders to appropriate services. Availability of mental health services, lack of mental health parity, and service "carve-outs" all have been barriers to patients and families who seek clinically necessary treatment and seem to be disproportionately problematic for patients with eating disorders. Despite evidence of its effectiveness, family-based treatment is not available in many communities. Through advocacy, pediatricians can help support health care reform efforts that will ensure that children and adolescents with eating disorders are able to receive necessary care.

GUIDANCE FOR PEDIATRICIANS

1. Pediatricians need to be knowledgeable about the risk factors and early signs and symptoms of disordered eating and eating disorders.
2. When counseling families on preventing obesity, pediatricians should focus on healthy eating and building self-esteem while still addressing weight concerns. Care needs to be taken not to inadvertently enable excessive dieting, compulsive exercise, or other potentially unhealthy weight-management strategies.
3. Pediatricians should be encouraged to calculate and plot weight, height, and BMI by using age- and gender-appropriate charts and assess menstrual status in girls at annual health supervision visits.
4. Pediatricians should screen patients for disordered eating

and related behaviors and be prepared to intervene when necessary.

5. Pediatricians should monitor or refer patients with eating disorders for medical and nutritional complications.
6. Pediatricians need to be familiar with treatment resources in their communities so that they can coordinate or facilitate multidisciplinary care.
7. Pediatricians can play a role in primary prevention during office visits and through school-based and community interventions with a focus on education, early screening, and advocacy.
8. Pediatricians are encouraged to advocate for legislation and policy changes that ensure appropriate services for patients with eating disorders, including medical care, nutritional intervention, mental health treatment, and care coordination, in settings that are appropriate for the severity of the illness.

LEAD AUTHOR

David S. Rosen, MD, MPH

COMMITTEE ON ADOLESCENCE, 2009–2010

Margaret J. Blythe, MD, Chairperson
Paula K. Braverman, MD
Cora C. Breuner, MD, MPH

POLICY STATEMENT

Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Children With Disabilities
Section on Developmental Behavioral Pediatrics
Bright Futures Steering Committee
Medical Home Initiatives for Children With Special Needs Project Advisory Committee

ABSTRACT

Early identification of developmental disorders is critical to the well-being of children and their families. It is an integral function of the primary care medical home and an appropriate responsibility of all pediatric health care professionals. This statement provides an algorithm as a strategy to support health care professionals in developing a pattern and practice for addressing developmental concerns in children from birth through 3 years of age. The authors recommend that developmental surveillance be incorporated at every well-child preventive care visit. Any concerns raised during surveillance should be promptly addressed with standardized developmental screening tests. In addition, screening tests should be administered regularly at the 9-, 18-, and 30-month visits. (Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age. In addition, because the frequency of regular pediatric visits decreases after 24 months of age, a pediatrician who expects that his or her patients will have difficulty attending a 30-month visit should conduct screening during the 24-month visit.) The early identification of developmental problems should lead to further developmental and medical evaluation, diagnosis, and treatment, including early developmental intervention. Children diagnosed with developmental disorders should be identified as children with special health care needs, and chronic-condition management should be initiated. Identification of a developmental disorder and its underlying etiology may also drive a range of treatment planning, from medical treatment of the child to family planning for his or her parents.

INTRODUCTION

Early identification of developmental disorders is critical to the well-being of children and their families. It is an integral function of the primary care medical home[1] and an appropriate responsibility of all pediatric health care professionals. Delayed or disordered development can be caused by specific medical conditions

and may indicate an increased risk of other medical complications. Delayed or disordered development may also indicate an increased risk of behavior disorders or associated developmental disorders. Early identification should lead to further evaluation, diagnosis, and treatment. Early intervention is available for a wide range of developmental disorders; their prompt identification can spur specific and appropriate therapeutic interventions. Identification of a developmental disorder and its underlying etiology may also affect a range of treatment planning, from medical treatment of the child to family planning for his or her parents.

Current detection rates of developmental disorders are lower than their actual prevalence, which suggests that the challenges to early identification of children with developmental disorders have not been overcome.[2–4] A recent survey of American Academy of Pediatrics (AAP) members revealed that despite publication of the 2001 policy statement "Developmental Surveillance and Screening of Infants and Young Children"[5] and national efforts to improve developmental screening in the primary care setting, few pediatricians use effective means to screen their patients for developmental problems.[2] This 2006 statement replaces the 2001 policy statement and provides an algorithm as a strategy to support health care professionals in developing a pattern and practice of attention to development that can and should continue well beyond 3 years of age.

We recommend that developmental surveillance, as described later, be incorporated at every well-child visit. Any concerns raised during surveillance should be promptly addressed. In addition, standardized developmental screening tests should be administered regularly at the 9-, 18-, and 30-month* visits. Pediatric health care professionals may also find it useful to conduct school-readiness screening before the child's attendance at preschool or kindergarten. These recommendations represent our consensus; further research to evaluate the effectiveness of the proposed approach and available screening tools is encouraged. Separate recommendations aimed at the screening of children for behavioral and emotional disorders are also under consideration by the AAP and are not included in this document.

The detection of developmental disorders is an integral component of well-child care. Title V of the Social Security Act (42 USC Chapter 7, Subchapter V §§701-710 [1989]) and the Individuals With Disabilities Education Improvement Act (IDEA) of 2004 (Pub L No. 108-446) reaffirm the mandate for child health professionals to provide early identification of, and intervention for, children with developmental disabilities through community-based collaborative systems. The medical home is the ideal setting for developmental surveillance and screening of children and adolescents. Parents expect their medical home, as the site of their child's continuous and comprehensive care, to be interested in children's development throughout childhood and adolescence, to competently identify developmental strengths and weaknesses, and to be knowledgeable of available community resources to facilitate referrals when needed.

Developmental screening is included in the AAP "Recommendations for Preventive Pediatric Health Care"[6] or "periodicity schedule" and is further recommended by the 2 current AAP compilations of well-child care guidelines: *Bright Futures*[7] and *Guidelines for Health Supervision III*.[8] In collaboration with other experts in child health care, the AAP is currently revising *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*. It is hoped that the third edition of *Bright Futures* being developed by the AAP and the revised periodicity schedule will be consistent with the recommendations of this document.

Note Regarding Language

Within the context of this document, clear distinctions have been drawn among (1) surveillance, the process of recognizing children who may be at risk of developmental delays, (2) screening, the use of standardized tools to identify and refine that recognized risk, and (3) evaluation, a complex process aimed at identifying specific developmental disorders that are affecting a child. These definitions build on existing definitions.[9] In a further effort to ensure clarity throughout the document, we have purposefully avoided the term "assessment." Although the Individuals With Disabilities Education Improvement Act of 2004—and others—use "assessment" as a synonym for "evaluation," this usage is not universally shared.

"Developmental delay" is used in this statement for the condition in which a child is not developing and/or achieving skills according to the expected time frame. The terms "delayed development," "disordered development," and "developmental abnormality" are used synonymously. "Developmental disorder" and "developmental disability" refer to a childhood mental or physical impairment or combination of mental and physical impairments that result in substantial functional limitations in major life activities.[10]

THE ALGORITHM†

1. Pediatric Patient at Preventive Care Visit

Developmental concerns should be included as one of several health topics addressed at each pediatric pre-

*Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age. In addition, because the frequency of regular pediatric visits decreases after 24 months of age, a pediatrician who expects that his or her patients will have difficulty attending a 30-month visit should conduct screening during the 24-month visit.

†Numbers and headings refer to steps in the algorithm (Fig 1).

ventive care visit throughout the first 5 years of life (see Fig 1).[6] Many children are born with risk factors that predispose them to delayed development and developmental disorders; other children will show delayed or disordered development in early childhood, which if undetected and untreated, can contribute to early school failure and attendant social and emotional problems. Some children will have delayed development attributable to a specific medical condition for which medical treatments may be indicated. Early therapeutic intervention may be available for a wide range of developmental disorders.

2. Perform Surveillance

Developmental surveillance is a flexible, longitudinal, continuous, and cumulative process whereby knowledgeable health care professionals identify children who may have developmental problems. Surveillance can be useful for determining appropriate referrals, providing patient education and family-centered care in support of healthy development, and monitoring the effects of developmental health promotion through early intervention and therapy.

A great breadth and depth of information is considered in comprehensive developmental surveillance; it is important to note, however, that much of this information (eg, static risk factors such as low birth weight, results of previous screenings) will accumulate within the child's health record, where it can be reviewed and flagged as necessary before the visit.

There are 5 components of developmental surveil-

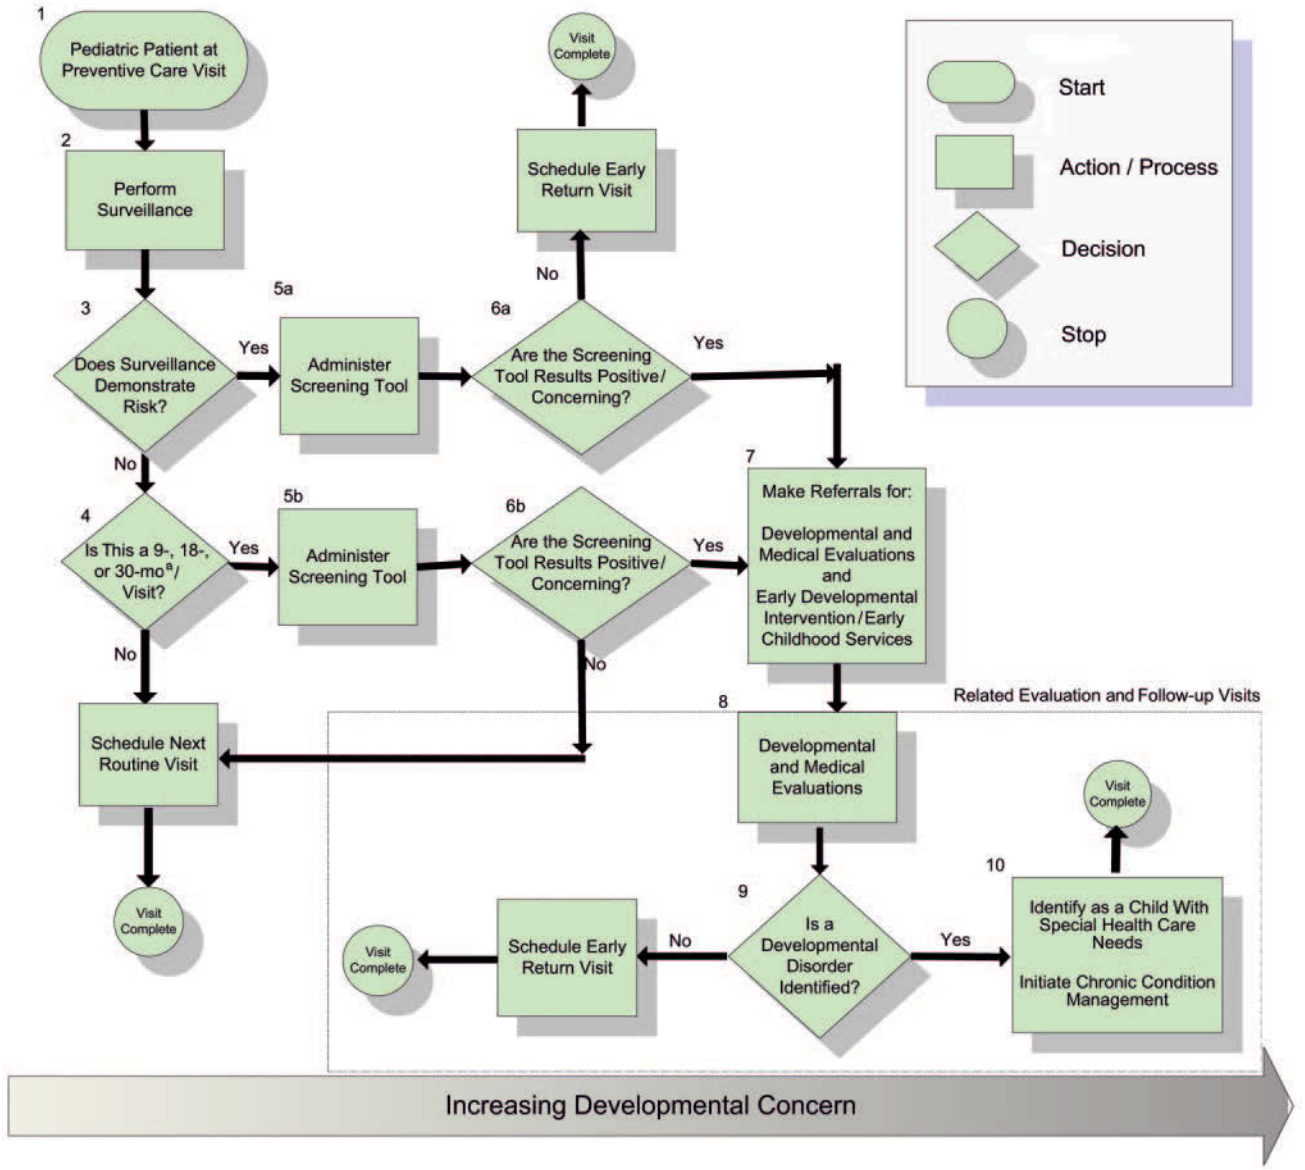

FIGURE 1

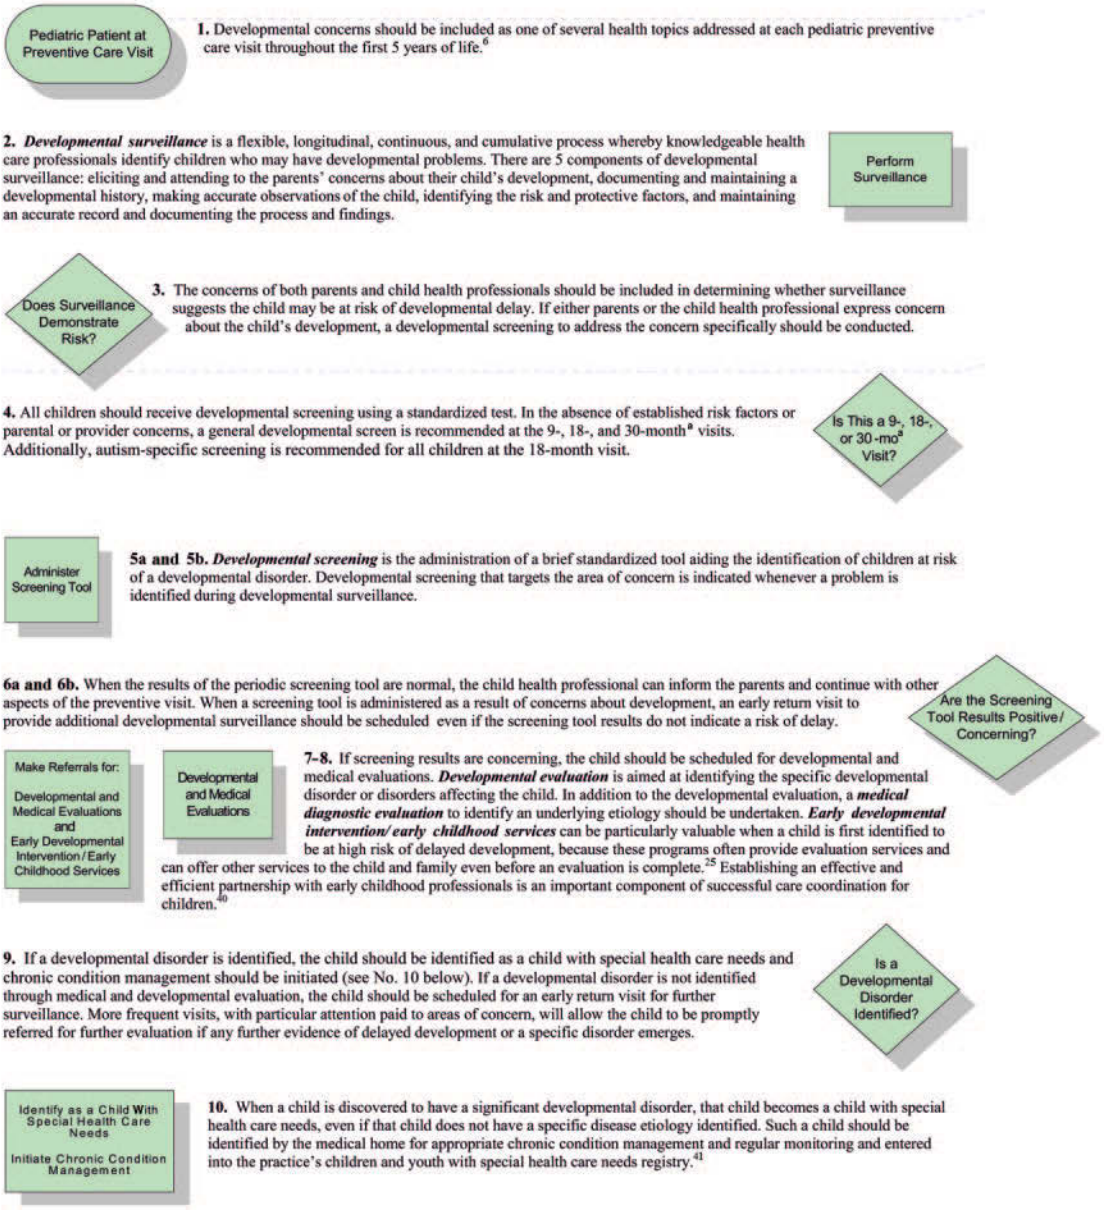
Developmental surveillance and screening algorithm within a pediatric preventive care visit. [a] Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age.



lance: eliciting and attending to the parents' concerns about their child's development; documenting and maintaining a developmental history; making accurate observations of the child; identifying risk and protective factors; and maintaining an accurate record of documenting the process and findings.

Eliciting and Attending to the Parents' Concerns

Parents and child health professionals have valuable observation skills, and they share the goal of ensuring optimal health and developmental outcome for the child. In the optimal situation, the child health professional elicits parental observations, experiences, and concerns and recognizes that parental concerns mandate serious attention. The literature suggests that posing simple questions to parents related to concerns about the child's development, learning, or behavior can elicit quality information.[11–13] Health care professionals might ask, for example, "Do you have any concerns about your child's development? Behavior? Learning?" Asking parents specifically about their child's behavior can yield valuable information regarding development, because parents do not necessarily differentiate between behavior and development, and developmental delays often manifest through behavior. The absence of parental concern does not preclude the possibility of serious developmental delays.[14] The health care professional must attend to all aspects of developmental surveillance.

Maintaining a Developmental History

"What changes have you seen in your child's development since our last visit?" A developmental history, updated through this or similar questions, should be a component of any history taken during a well-child visit and can assist a child health professional in identifying developmental abnormalities that warrant further investigation. Age-specific queries, such as asking whether the child is walking or pointing, are also valuable.

In addition to attending to delayed development—whereby children acquire skills more slowly than their peers—child health professionals should give equal consideration to other developmental abnormalities.[15] Deviations in development, whereby children develop skills out of the usual sequence, are recognized in disorders such as cerebral palsy and autism. Dissociation—differing rates of development in different developmental spheres—commonly occurs with developmental disorders. Children with mental retardation or autistic spectrum disorders, for example, commonly display normal motor skills and delayed language development. Conversely, children with cerebral palsy of the spastic diplegic type often display delayed motor skills with normal language function. Regression, the loss of developmental skills, is a very serious developmental problem suggestive of an active, ongoing neurologic problem.

Making Accurate and Informed Observations of the Child

As trained and experienced professionals, pediatricians and other child health professionals have the expertise and comparative knowledge to identify developmental concerns. A careful physical and developmental examination within the context of the preventive care visit is integral to developmental surveillance.[16] Limited evidence suggests that observation of the parent-child interaction may aid in identifying children with delayed development.[17]

Identifying the Presence of Risk and Protective Factors

A risk assessment is an important part of developmental surveillance. Environmental, genetic, biological,[16,18] social, and demographic factors[19] can increase a child's risk for delays in development. Multiple risk factors can amplify each other.[20,21] Children with established risk factors may be referred directly for developmental evaluation or may require developmental surveillance at more frequent intervals than children without risk factors.

Child health professionals should identify protective factors as well as risk factors in children's lives. Strong connections within a loving, supportive family, along with opportunities to interact with other children and grow in independence in an environment with appropriate structure, are important assets in a child's life. These factors, associated with resiliency in older children, are important components in each family's story.[22]

Documenting the Process and Findings

Medical charts, in paper or electronic form, should document all surveillance and screening activities during preventive care visits. In addition, specific actions taken or planned, such as scheduling an earlier follow-up visit, scheduling a visit to discuss developmental concerns more fully, or referrals to medical specialists or early childhood programs and specialists, should also be noted. A paper medical chart might contain a "developmental growth chart" on which the results of developmental surveillance and formal screens are recorded in relationship to the child's age and the dates at the time the findings were obtained. An electronic chart, on the other hand, may allow for the development of a form on which developmental findings and plans are recorded and from which prompts for further action may occur automatically. Recent technologies that automate developmental risk assessments within the waiting room through computer-interpreted paper forms or information kiosks are also increasingly commonplace. We encourage continued development and scientific evaluation of these technologies given their potential to facilitate the process of developmental surveillance and screening.

3. Does Surveillance Demonstrate Risk?

The concerns of both parents and child health professionals should be included in determining whether surveillance suggests that the child may be at risk of developmental problems. If parents or the child health professional express concern about the child's development, a developmental screening to address the concern specifically should be conducted. This screening may require a separate visit; if so, the visit should be held as soon as possible.

Reassurance has a role in the clinical encounter but varies depending on the progress and outcome of developmental surveillance. Reassurance should be rooted in and reference the findings of developmental surveillance. If, for example, developmental surveillance indicates that the child is at low risk of a developmental disorder, reassurance can be offered with caution and a planned outcome. Specific, simple, age-specific developmental goals can be identified, and parents can be encouraged to schedule recheck appointments if the child is not attaining those goals. In reassuring the parents, the pediatrician should emphasize the importance of continual surveillance and screening.

4. Is This a 9-, 18-, or 30-Month* Visit?

All children, most of whom will not have identifiable risks or whose development appears to be proceeding typically, should receive periodic developmental screening using a standardized test. In the absence of established risk factors or parental or provider concerns, a general developmental screen is recommended at the 9-,

TABLE 1 Developmental Screening Tools

	Description	Age Range	No. of Items	Administration Time	Psychometric Properties[a]	Scoring Method	Cultural Considerations	Purchase/Obtainment Information	Key References
General developmental screening tool									
Ages & Stages Questionnaires (ASQ)	Parent-completed questionnaire; series of 19 age-specific questionnaires screening communication, gross motor, fine motor, problem-solving, and personal adaptive skills; results in pass/fail score for domains	4–60 mo	30	10–15 min	Normed on 2008 children from diverse ethnic and socioeconomic backgrounds, including Spanish speaking; sensitivity: 0.70–0.90 (moderate to high); specificity: 0.76–0.91 (moderate to high)	Risk categorization; provides a cutoff score in 5 domains of development that indicates possible need for further evaluation	English, Spanish, French, and Korean versions available	Paul H. Brookes Publishing Co: 800/638-3775; www.brookespublishing.com	Squires J, Potter L, Bricker D. *The ASQ User's Guide*. 2nd ed. Baltimore, MD: Paul H. Brookes Publishing Co; 1999
Battelle Developmental Inventory Screening Tool, 2nd ed (BDI-ST)	Directly administered tool; designed to screen personal-social, adaptive, motor, communication, and cognitive development; results in pass/fail score and age equivalent; can be modified for children with special needs	Birth to 95 mo	100	10–15 min (<3 y old) or 20–30 min (≥3 y old)	Normed on 2500 children, demographic information matched 2000 US Census data; additional bias reviews performed to adjust for gender and ethnicity concerns; sensitivity: 0.72–0.93 (moderate to high); specificity: 0.79–0.88 (moderate)	Quantitative; scaled scores in all 5 domains are compared with cutoffs to determine need for referral	English and Spanish versions available	Riverside Publishing Co: 800/323-9540; www.riverpub.com	Newborg J. *Battelle Developmental Inventory*. 2nd ed. Itasca, IL: Riverside Publishing; 2004
Bayley Infant Neurodevelopmental Screen (BINS)	Directly administered tool; series of 6 item sets screening basic neurologic functions; receptive functions (visual, auditory, and tactile input); expressive functions (oral, fine, and gross motor skills); and cognitive processes; results in risk category (low, moderate, high risk)	3–24 mo	11–13	10 min	Normed on ~1700 children, stratified on age, to match the 2000 US Census; sensitivity: 0.75–0.86 (moderate); specificity: 0.75–0.86 (moderate)	Risk categorization; children are graded as low, moderate, or high risk in each of 4 conceptual domains by use of 2 cutoff scores	English and Spanish versions available	Psychological Corp: 800/211-8378; www.harcourtassessment.com	Aylward GP. *Bayley Infant Neurodevelopmental Screener*. San Antonio, TX: Psychological Corp; 1995; Aylward GP, Verhulst SJ, Bell S. Predictive utility of the BSID-II Infant Neurodevelopmental Screener (BINS) risk status classifications: clinical interpretation and application. *Dev Med Child Neurol*. 2000; 42:25–31
Brigance Screens-II	Directly administered tool; series of 9 forms screening articulation, expressive and receptive language, gross motor, fine motor, general knowledge and personal social skills and preacademic skills (when appropriate); for 0–23 mo, can also use parent report	0–90 mo	8–10	10–15 min	Normed on 1156 children from 29 clinical sites in 21 states; sensitivity: 0.70–0.80 (moderate); specificity: 0.70–0.80 (moderate)	All results are criterion based; no normative data are presented	English and Spanish versions available	Curriculum Associates Inc: 800/225-0248; www.curriculumassociates.com	Glascoe FP. *Technical Report for the Brigance Screens*. North Billerica, MA: Curriculum Associates Inc; 2005; Glascoe FP. The Brigance Infant-Toddler Screen (BITS): standardization and validation. *J Dev Behav Pediatr*. 2002;23: 145–150
Child Development Inventory (CDI)	Parent-completed questionnaire; measures social, self-help, motor, language, and general development skills; results in developmental quotients and age equivalents for different developmental domains; suitable for more in-depth evaluation	18 mo–6 y	300	30–50 min	Normative sample included 568 children from south St Paul, MN, a primarily white, working class community; Doig et al included 43 children from a high-risk follow-up program, which included 69% with high school education or less and 81% Medicaid; sensitivity: 0.80–1.0. (moderate to high); specificity: 0.94–0.96 (high)	Quantitative; provides age equivalents in each domain as well as SDs	English and Spanish versions available	Behavior Science Systems Inc: 612/850-8700; www.childdevrev.com	Ireton H. *Child Development Inventory Manual*. Minneapolis, MN: Behavior Science Systems Inc; 1992; Doig KB, Macias MM, Saylor CF, Craver JR, Ingram PE. Social Communication Questionnaire (SCQ) (formerly Autism Screening Questionnaire-ASQ)	Parent-completed questionnaire; designed to identify children at risk of autistic spectrum disorders from the general population; based on items in the ADI-R	≥4 y	40 (No. of questions/items [averaged])	5–10 min	Validated using the ADI-R and DSM-IV on 200 subjects (160 with pervasive developmental disorder, 40 without pervasive developmental disorder); for use in children with mental age of at least 2 y and chronologic age ≥4 y; available in 2 forms: lifetime and current; sensitivity: 0.85 (moderate); specificity: 0.75 (moderate)	Risk categorization (pass/fail)	English and Spanish versions available	Western Psychological Corp: www.wpspublish.com	Rutter M, Bailey A, Lord C. *The Social Communication Questionnaire (SCQ) Manual.* Los Angeles, CA: Western Psychological Services; 2003

The AAP does not approve/endorse any specific tool for screening purposes. This list is not exhaustive, and other tests may be available. ADI-R indicates Autism Diagnostic Interview-R; ICD-10, *International Classification of Diseases, 10th revision*; ADOS-G, Autism Diagnostic Observation Schedule-Generic; CARS, Childhood Autism Rating Scale; DSM-IV, *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*.

[a] Sensitivity and specificity were categorized as follows: low = 69 or below; moderate = 70 to 89; high = 90 or above.

18-, and 30-month* visits. Consideration of a number of factors, including the time available to focus on developmental concerns during a routine pediatric visit, led to these recommended ages.

- Nine months of age: At 9 months of age, many issues involving motor skills development can be reliably identified. A 9-month screening provides an additional opportunity to attend to the child's visual and hearing abilities. Early communication skills may be emerging—evidence suggests symptoms of autism, such as lack of eye contact, orienting to name being called, or pointing, may be recognizable in the first year of life.[23,24] Early intervention to address specific developmental disorders is available to infants from birth and should be accessed to address any delays detected at 9 months.[25] At-risk 9-month-old infants should also be referred to early intervention programs if not previously referred. The 9-month preventive care visit also provides a good opportunity for the child health professional to educate parents about developmental screening and to encourage parents to pay special attention to communication and language skills. Social and nonverbal communication, including vocalizations and gestures, are important aspects of emerging communication that can be assessed at 9 months. Because of the rapid development of motor, language, and cognitive skills, parents should be encouraged to express any concerns they have about their child's progress rather than waiting until the 18-month visit. The AAP brochure *Is Your One-Year Old Communicating With You?*[26] might be distributed at the 9-month visit to educate parents about communication and target any concerns they have. (If practices have eliminated the 9-month visit, this screening should be performed at the 12-month visit.)
- Eighteen months of age: Delays in communication and language development are often evident by 18 months of age. Mild motor delays that were undetected at the 9-month screening may be more apparent at 18 months of age. Medical interventions for motor disorders have been shown to be effective in children at 18 months of age, and effective early intervention for delayed language development is also available.[27] In addition to a general developmental screening tool, an autism-specific tool should be administered to all children at the 18-month visit.[28] Symptoms of autism are often present at this age, and effective early intervention strategies are available.[29]
- Thirty months* of age: By 30 months of age, most motor, language, and cognitive delays may be identified with screening instruments, leading to evaluation of and intervention for those children with delayed development. A 30-month visit focusing on child development and developmental screening would allow the health care provider to devote special attention to this area. Therefore, addition of this preventive care visit to the periodicity schedule is being considered by Bright Futures.

When child health professionals use only clinical impressions rather than formal screening, estimates of children's developmental status are much less accurate.[30] Including developmental screening tools at targeted developmental ages is intended to enhance the precision of the developmental surveillance process. These recommended ages for developmental screening are suggested only as a starting point for children who appear to be developing normally; surveillance should continue throughout childhood, and screenings should be conducted anytime that concerns are raised by parents, child health professionals, or others involved in the care of the child. At the 4-year visit, a screening for school readiness is appropriate.

5a and 5b: Administer Screening Tool

Developmental screening is the administration of a brief standardized tool that aids the identification of children at risk of a developmental disorder. Many screening tools can be completed by parents and scored by nonphysician personnel; the physician interprets the screening results.

Developmental screening does not result in either a diagnosis or treatment plan but rather identifies areas in which a child's development differs from same-age norms. Developmental screening that targets the area of concern is indicated whenever a problem is identified during developmental surveillance. Because development is dynamic in nature and surveillance and screening have limits, periodic screening with a validated instrument should occur so that a problem not detected by surveillance or a single screening can be detected by subsequent screening. Repeated and regular screening is more likely than a single screening to identify problems, especially in later-developing skills such as language. Waiting until a young child misses a major milestone such as walking or talking may result in late rather than early recognition, increasing parental dissatisfaction and anxiety and depriving the child and family of the benefits of early identification and intervention.

Table 1 provides a list of developmental screening tools; a discussion of how to choose an appropriate screening tool is included in "Implementing the Algorithm."

6a and 6b: Are the Screening-Tool Results Positive/Concerning?

When the results of the periodic screening tool are normal, the child health professional can inform the parents and continue with other aspects of the preventive visit. Normal screening results provide an opportunity to focus on developmental promotion. However, when a screening tool is administered because of con-

cerns about development, an early return visit to provide additional developmental surveillance should be scheduled even if the screening-tool results do not indicate a risk of delay.

7. Make Referrals for Developmental and Medical Evaluations and Early Developmental Intervention/Early Childhood Services

If screening results are concerning, the child should be scheduled for developmental and medical evaluations. These evaluations may occur at a different visit or series of visits or often in a different setting by other professionals. The separate box in which these steps are placed in the algorithm (Fig 1) is intended to represent the possibility that these actions will occur at a different time and location. However, they should be scheduled as quickly as possible, and professionals should coordinate activities and share findings.

8. Developmental and Medical Evaluations

Developmental Evaluation

When developmental surveillance or screening identifies a child as being at high risk of a developmental disorder, diagnostic developmental evaluation should be pursued. This evaluation is aimed at identifying the specific developmental disorder or disorders affecting the child, thus providing further prognostic information and allowing prompt initiation of specific and appropriate early childhood therapeutic interventions.

Children with neurodevelopmental disorders also often have other associated developmental or behavior disorders.[31–33] Identification of these disorders can lead to further evaluation and treatment. Pediatric subspecialists such as neurodevelopmental pediatricians, developmental and behavioral pediatricians, child neurologists, pediatric physiatrists, or child psychiatrists can perform the developmental diagnostic evaluation, as can other early childhood professionals in conjunction with the child's primary care provider. Such early childhood professionals include early childhood educators, child psychologists, speech-language pathologists, audiologists, social workers, physical therapists, and occupational therapists, ideally working with families as part of an interdisciplinary team and with the medical home.

Medical Evaluation

In addition to the developmental evaluation, a medical diagnostic evaluation to identify an underlying etiology should be undertaken. This evaluation should consider biological, environmental, and established risk factors for delayed development.[34–37] Vision screening and objective hearing evaluation; review of newborn metabolic screening and growth charts; and an update of environmental, medical, family, and social history for additional risk factors are integral to this evaluation.

A comprehensive medical evaluation is essential whenever a delay is confirmed. This evaluation varies somewhat with the risk factors and findings and may include brain imaging, electroencephalogram (EEG), genetic testing, and/or metabolic testing.[37]

Identification of an etiology may provide parents with a greater depth of understanding of their child's disability. Identifying an etiology also can affect various aspects of treatment planning, including specific prognostic information, genetic counseling around recurrence risk and family planning, specific medical treatments for improved health and function of the child, and therapeutic intervention programming.[38] An underlying etiology will be identified in approximately one quarter of cases of delayed development, with higher rates (>50%) in children with global developmental delays and motor delays and lower rates (<5%) in children with isolated language disorders.[39]

This evaluation can be performed by a trained and skilled pediatrician; a pediatric subspecialist such as a neurodevelopmental pediatrician, child neurologist, or developmental/behavioral pediatrician; or through affiliated medical professionals such as pediatric geneticists or physiatrists. The primary care provider within the medical home should develop an explicit comanagement plan with the specialist(s).

Early Developmental Intervention/Early Childhood Services

Early intervention programs can be particularly valuable when a child is first identified to be at high risk of delayed development, because these programs often provide evaluation services and can offer other services to the child and family even before an evaluation is complete.[25] These services can include developmental therapies, service coordination, social work services, assistance with transportation and related costs, family training, counseling, and home visits. The diagnosis of a specific developmental disorder is not necessary for an early intervention referral to be made. Child health professionals should realize that a community-based early intervention evaluation may not address children with specific medical risks, and further developmental and medical evaluation will often be necessary for children with established delays.

Establishing an effective and efficient partnership with early childhood professionals is an important ingredient of successful care coordination for children within the medical home. The partnership is built on shared interest in the developmental outcomes of children and recognition of the different skill sets of child health professionals and educators. For additional information regarding care coordination, see the AAP policy statement "Care Coordination in the Medical Home: Integrating Health and Related Systems of Care for Children With Special Health Care Needs."[40]

Given the variety of community settings in which health care is provided, the pediatrician may consult

early childhood professionals who work in specialized health care centers, university centers, early intervention programs, early childhood educational programs, or private practices. Whenever possible, communities should coordinate resources; this is especially true in preventing delays in care or unnecessary duplication of service.

The child's medical charts, whether electronic or paper, should be organized to create a system that guarantees continuity of care, especially when the child is referred to specialists and/or community agencies. In addition, a means of incorporating information about a child's developmental status from sources outside the medical home should be available. The child health care chart should be designed to alert the clinician if further attention is needed between regular periodic visits.

9. Is a Developmental Disorder Identified?

If a developmental disorder is identified, the child should be identified as a child with special health care needs, and chronic-condition management should be initiated (see No. 10 below). If a developmental disorder is not identified through medical and developmental evaluation, the child should be scheduled for an early return visit for further surveillance, as mentioned previously. More frequent visits, with particular attention paid to areas of concern, will allow the child to be promptly referred for further evaluation if any additional evidence of delayed development or a specific disorder emerges.

10. Identify as a Child With Special Health Care Needs and Initiate Chronic-Condition Management

When a child is discovered to have a significant developmental disorder, that child becomes a child with special health care needs even if that child does not have a specific disease etiology identified. Such a child should be identified by the medical home for appropriate chronic-condition management and regular monitoring and entered into the practice's children and youth with special health care needs registry.[41] Every primary care practice should create a registry for the children in the practice who have special health care needs.

The medical home provides a triad of key primary care services including preventive care, acute illness management, and chronic-condition management. A program of chronic-condition management provides proactive care for children and youth with special health care needs, including condition-related office visits, written care plans, explicit comanagement with specialists, appropriate patient education, and effective information systems for monitoring and tracking.

Management plans should be based on a comprehensive needs assessment conducted with the family. Management plans should include relevant, measurable, and valid outcomes. These plans must be reviewed on a regular basis and updated as necessary. The child health professional should actively participate in all care-coordination activities for children who have complex health conditions in addition to developmental problems. Decisions regarding appropriate therapies and their scope and intensity should be determined in consultation with the child's family, therapists, and educators (including early intervention or school-based programs) and should be based on knowledge of the scientific evidence for their use.

Children with established developmental disorders often benefit from referral to community-based family support services such as respite care, parent-to-parent programs, and advocacy organizations. Some children may qualify for additional benefits such as supplemental security income, public insurance, waiver programs, and state programs for children and youth with special health care needs (Title V). Parent organizations, such as Family Voices, and condition-specific associations can provide parents with information and support and can also provide an opportunity for advocacy.

IMPLEMENTING THE ALGORITHM

Choosing Developmental Screening Tools

Although all developmental screening tools are designed to identify children with potentially delayed development, each one approaches the task in a different way. There is no universally accepted screening tool appropriate for all populations and all ages. Currently available screening tools vary from broad general developmental screening tools to others that focus on specific areas of development, such as motor or communication skills. Their psychometric properties vary widely in characteristics such as their standardization, the comparison group used for determining sensitivity and specificity, and population risk status.

Broad screening tools should address developmental domains including fine and gross motor skills, language and communication, problem solving/adaptive behavior, and personal-social skills. Screening tools also must be culturally and linguistically sensitive. Many screening tools are available, and the choice of which tool to use depends on the population being screened, the types of problems being screened for in that population, administration and scoring time, any administration training time, the cost of the tool, and the possibilities for adequate payment.

Screening tests should be both reliable and valid, with good sensitivity and specificity.

- Reliability is the ability of a measure to produce consistent results.
- The validity of a developmental screening test relates to its ability to discriminate between a child at a determined level of risk for delay (ie, high, moderate) and the rest of the population (low risk).

- Sensitivity is the accuracy of the test in identifying delayed development.
- Specificity is the accuracy of the test in identifying individuals who are not delayed.

If a test incorrectly identifies a child as delayed, it will result in overreferrals. If a test incorrectly identifies a child as normal, it results in underreferrals. For developmental screening tests, scoring systems must be developed that minimize underreferrals and overreferrals. Trade-offs between sensitivity and specificity occur when devising these scoring systems. Sensitivity and specificity levels of 70% to 80% have been deemed acceptable for developmental screening tests.[42] These values are lower than generally accepted for medical screening tests because of the challenges inherent in measuring child development and the absence of specific curative and clearly effective treatments. However, combining developmental surveillance and periodic screening increases the opportunity for identification of undetected delays in early development. Overidentification of children using standardized screening tools may indicate that this group of children includes some with below-average development and/or significant psychosocial risk factors.[43] These children may benefit from other community programs as well as closer monitoring of their development by their families, pediatric health professionals, and teachers or caregivers.

Table 1 provides a list of developmental screening tools and their psychometric testing properties. These screening tools vary widely in their psychometric properties. This list is not exhaustive; other standardized, published tools are available. We look forward to further evaluation/validation of available screening instruments as well as the continued development of new tools with stronger properties. Child health professionals are encouraged to familiarize themselves with a variety of screening tools and choose those that best fit their populations, practice needs, and skill level.

Incorporating Surveillance and Screening in the Medical Home

A quality-improvement approach may be the most effective means of building surveillance and screening elements into the process of care in a pediatric office.[44] Improving developmental screening and surveillance should be regarded as a "whole-office" endeavor and not simply a matter of clinician continuing education or the addition of tasks to well-child visits. Front-desk procedures, such as appropriate scheduling for screening visits and procedures for flagging children with established risk factors, need to be explicitly designed by the office staff. Nonphysician staff may need training in the administration of developmental screening tools. The input of consumers is crucial to developing an effective system and can be accomplished by adding a parent to an office planning team, by using parent focus groups, or by administering parent questionnaires. Specific to developmental screening could be consumer opinion about preferences for completing questionnaires in the office or before the visit, how they would like to be informed about the results of screening, how parents of children with identified conditions associated with developmental delay would like to have their children's development monitored, or feedback on parental satisfaction with their child's developmental screening or feedback on the referral process.

Screening Payment

Separate *Current Procedural Terminology* (CPT)[45] codes (see Table 2) exist for developmental screening (96110: developmental testing; limited) and testing (96111: developmental testing; extended). The relative values for these codes are published in the Medicare Resource-Based Relative Value Scale and reflect physician work, practice expenses, and professional liability expenses. Table 2 outlines the appropriate codes to use when billing for the processes described in the algorithm. Health plans are encouraged to adhere to CPT guidelines and provide coverage and payment for developmental screening and testing.

Billing processes related to developmental screening and surveillance should be carefully reviewed to ensure that appropriate CPT codes are used to document screening procedures and ensure proper payment. CPT code 96110 for limited developmental testing does not include any payment for medical provider services. The expectation is that a nonphysician will administer the screening tool to the parent and then score their responses. The physician reviews and interprets the screening results; the physician's work is included in the evaluation and management code used for the child's visit. Medicaid may not pay separately for developmental screening when provided as part of early and periodic screening, diagnostic, and treatment services. If non-Medicaid carriers are involved, the preventive care code is used with the modifier 25 appended and 96110 listed for each screening tool administered. The CPT code 96111, extended developmental testing, includes medical provider work. This code would more appropriately be used when the medical provider observes the child performing a task and demonstrating a specific developmental skill.

The codes in Table 2 may be applicable to the phases of developmental surveillance, screening, and evaluation described in the proposed algorithm (Fig 1).

SUMMARY

Developmental surveillance should be a component of every preventive care visit. Standardized developmental screening tools should be used when such surveillance

TABLE 2 **CPT Codes for Developmental Screening**

Services/Step in Algorithm	Notes	CPT Code	Comments
Pediatric preventive care visit	All preventive care visits should include developmental surveillance; screening is performed as needed or at periodic intervals	99381–99394 (EPSDT[a])	
Developmental screening	The expectation is that the screening tool will be completed by a parent or nonphysician staff member and reviewed by the physician	96110	Limited developmental testing, with interpretation and report
Developmental/medical evaluation	If performed by the physician as an outpatient office visit	99210–99215[b] or 96110; or 96111 if objective developmental testing is performed	99214 is used for evaluations performed by the physician that are detailed and moderately complex or take at least 25 min (with over half spent counseling); 99215 is used for evaluations that are comprehensive and highly complex or take >40 min (with over half spent counseling) 99244 is used for "moderate activities" of up to 60 min; 99245 is used for "high" activity of up to 80 min
	Outpatient consultation; typically performed by a tertiary, local out-of-office referral source or another physician with the requisite skills in the same practice as the referring physician; the request for consultation must be recorded in the patient's chart; services/procedures and consulting physician's impressions must be recorded; time spent counseling and coordinating care should be specifically documented; these codes include "reporting" of the consulting physician, if completed by letter or office notes	99241–99245	
	If a more extensive report is developed, this code is used; these costs may not be reimbursable	99080	
Developmental disorder identified	For follow-up visits with the patient and parents to complete the consultation or to discuss the results of the initial consultation; for rendering opinions and addressing questions, not assuming care; once care is assumed, established office-visit coding is used	99241–99245	
Identify as a child with special health care needs, and initiate chronic-condition management	Children with special health care needs are likely to require expanded time and a higher level of medical decision-making found in these "higher-level" outpatient codes; these codes are appropriate for services in the office and for outpatient facility services for established patients; these codes may be reported using time alone as the factor if more than half of the reported time is spent in counseling	99211–99215	99213; 99214; 99215 (see above)
Prolonged services	At any point during the algorithm when outpatient office or consultation codes are used, prolonged physician service codes may be reported in addition when visits require considerably more time than typical for the base code alone; both face-to-face and non–face-to-face codes are available in CPT	99354	99354 for first 30–74 min of outpatient face-to-face prolonged services
		99355	99355 for each additional 30 min
		99358	99358 for first 30–74 min of non–face-to-face prolonged services
		99359	99359 for each additional 30 min
Extended developmental testing/evaluation	Used for extended developmental testing typically provided by the medical provider (often up to 1 h) including the evaluation interpretation and report	96111	Reported in addition to evaluation and management (E/M) services provided on the same date

[a] EPSDT (Early and Periodic Screening, Diagnosis, and Treatment) is the federal Medicaid program for preventive services. States may require physicians to use different codes to report these services. In general, for non-Medicaid commercial insurers, the evaluation and management CPT codes for preventive medicine services (99381-99394) are used for the basic service (history, physical examination, and counseling/anticipatory guidance), with separate CPT codes reported additionally for the additional screening of hearing, vision, development, laboratory services, and immunization administration.
[b] CPT evaluation and management code levels are selected on the basis of the amount of physician work (history, physical examination, and medical decision-making) and/or time used in the encounter.

identifies concerns about a child's development and for children who appear to be at low risk of a developmental disorder at the 9-, 18-, and 30-month* visits.

When a child has a positive screening result for a developmental problem, developmental and medical evaluations to identify the specific developmental disorders and related medical problems are warranted. In addition, children who have positive screening results for developmental problems should be referred to early developmental intervention and early childhood services and scheduled for earlier return visits to increase developmental surveillance.

Children diagnosed with developmental disorders should be identified as children with special health care needs; chronic-condition management for these children should be initiated.

RECOMMENDATIONS

For the Medical Home

1. Perform developmental surveillance at every preventive visit throughout childhood, and ensure that such surveillance includes eliciting and attending to parents' concerns, obtaining a developmental history, making accurate and informed observations of the child, identifying the presence of risk and protective factors, and documenting the process and findings.
2. Administer a standardized developmental screening tool for children who appear to be at low risk of a developmental disorder at the 9-, 18-, and or 30-month* visits and for those whose surveillance yields concerns about delayed or disordered development.
3. Schedule early return visits for children whose surveillance raises concerns that are not confirmed by a developmental screening tool.
4. Refer children about whom developmental concerns are raised to early intervention and early-childhood programs.
5. Coordinate developmental and medical evaluations for children who have positive screening results for developmental disorders.
6. Initiate a program of chronic-condition management for any child identified with a developmental disorder.
7. Document all surveillance, screening, evaluation, and referral activities in the child's health chart.
8. Establish working relationships with state and local programs, services, and resources.
9. Use a quality-improvement model to integrate surveillance and screening into office procedures and to monitor their effectiveness and outcomes.

For Policy and Advocacy

10. Provide appropriate payment for developmental surveillance, screening, and evaluation.
11. Teach child health professionals, through training and continuing education programs, to conduct developmental surveillance and screening as an integral responsibility of the medical home.

For Research and Development

12. Develop information systems and data-gathering tools to automate the algorithm recommended by this policy statement for ease and consistency of use.
13. Expand the evidence base for the effectiveness of developmental surveillance activities.
14. Improve the effectiveness of developmental screening tools in the identification of children with developmental disorders in the medical home.
15. Expand the evidence base for the use and effectiveness of the proposed algorithm, including the optimal timing of the recommended developmental screening.

Council on Children With Disabilities, Section on Developmental Behavioral Pediatrics, Bright Futures Steering Committee, Medical Home Initiatives for Children With Special Needs Project Advisory Committee. Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening. PEDIATRICS 2006;118: 405–420.

There were errors in the American Academy of Pediatrics policy statement "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening" published in the July 2006 issue of *Pediatrics* (doi:10.1542/peds.2006-1231). In Table 2, third row, CPT code 99210 should have been 99211. Also, in the fourth row, the notes should have corresponded with CPT codes as follows:

For follow-up visits with the patient and parents to complete the consultation or to discuss the results of the initial consultation	99211–99215[c]
For rendering opinions and addressing questions, not assuming care; once care is assumed, established office visit coding is utilized (see above[c])	99241–99245

Finally, a new footnote (c) accompanies the changes above as follows:

[c] The office or other outpatient consultation codes (99241–99245) are reported only when requested by another physician or other appropriate source. If more than one visit is necessary to complete a consultation, each subsequent visit beyond the first is reported with an established patient office or other outpatient service code (99211–99215). Only if an additional request for an opinion or advice regarding the same or a new problem is received and documented in the medical record may the consultation codes be reported again.

The revised table follows.

TABLE 2 **CPT Codes for Developmental Screening**

Services/Step in Algorithm	Notes	CPT Code	Comments
Pediatric preventive care visit	All preventive care visits should include developmental surveillance; screening is performed as needed or at periodic intervals	99381–99394 (EPSDT[a])	
Developmental screening	The expectation is that the screening tool will be completed by a parent or nonphysician staff member and reviewed by the physician	96110	Limited developmental testing, with interpretation and report
Developmental/ medical evaluation	If performed by the physician as an outpatient office visit	99211–99215[b] or 96110; or 96111 if objective developmental testing is performed	99214 is used for evaluations performed by the physician that are detailed and moderately complex or take at least 25 min (with over half spent counseling); 99215 is used for evaluations that are comprehensive and highly complex or take >40 min (with over half spent counseling); 99244 is used for "moderate activities" of up to 60 min; 99245 is utilized for "high" activity of up to 80 min
	Outpatient consultation; typically performed by a tertiary, local out-of-office referral source or another physician with the requisite skills in the same practice as the referring physician; the request for consultation must be recorded in the patient's chart; services/procedures and consulting physician's impressions must be recorded; time spent counseling and coordinating care should be specifically documented; these codes include "reporting" of the consulting physician, if completed by letter or office notes	99241–99245	

(continued)

TABLE 2 **CPT Codes for Developmental Screening *(Continued)***

Services/Step in Algorithm	Notes	CPT Code	Comments
	If a more extensive report is developed, this code is used; these costs may not be reimbursable	99080	
Developmental disorder identified	For follow-up visits with the patient and parents to complete the consultation or to discuss the results of the initial consultation	99211–99215[c]	
	For rendering opinions and addressing questions, not assuming care; once care is assumed, established office visit coding is utilized (see above[c])	99241–99245	
Identify as a child with special health care needs, initiate chronic condition management	Children with special health care needs are likely to require expanded time and a higher level of medical decision making found in these "higher-level" outpatient codes; these codes are appropriate for services in the office and for outpatient facility services for established patients; these codes may be reported using time alone as the factor if more than half of the reported time is spent in counseling	99211–99215	99213; 99214; 99215 (see above)
Prolonged services	At any point during the algorithm when outpatient office or consultation codes are used, prolonged physician service codes may be reported in addition when visits require considerably more time than typical for the base code alone; both face-to-face and non–face-to-face codes are available in CPT	99354 99355 99358 99359	99354 for first 30–74 min of outpatient face-to-face prolonged services 99355 for each additional 30 min 99358 for first 30–74 min of non–face-to-face prolonged services 99359 for each additional 30 min
Extended developmental testing/evaluation	Used for extended developmental testing typically provided by the medical provider (often up to 1 h) including the evaluation interpretation and report	96111	Reported in addition to evaluation and management (E/M) services provided on the same date

[a] EPSDT (Early and Periodic Screening, Diagnosis, and Treatment) is the federal Medicaid program for preventive services. States may require physicians to use different codes to report these services. In general, for non-Medicaid commercial insurers, the evaluation and management CPT codes for preventive medicine services (99381–99394) are used for the basic service (history, physical examination, and counseling/anticipatory guidance), with separate CPT codes reported additionally for the additional screening of hearing, vision, development, laboratory services, and immunization administration.

[b] CPT evaluation and management code levels are selected on the basis of the amount of physician work (history, physical examination, and medical decision-making) and/or time used in the encounter.

[c] The office or other outpatient consultation codes (99241–99245) are reported *only* when requested by another physician or other appropriate source. If more than 1 visit is necessary to complete a consultation, each subsequent visit beyond the first is reported with an established patient office or other outpatient service code (99211–99215). Only if an *additional request* for an opinion or advice regarding the same or a new problem is received and documented in the medical record may the consultation codes be reported again.

Family Violence Prevention Fund

For more than two decades, the **Family Violence Prevention Fund (FVPF)** has worked to end violence against women and children around the world. Instrumental in developing the landmark Violence Against Women Act passed by Congress in 1994, the FVPF has continued to break new ground by reaching new audiences including men and youth, promoting leadership within communities to ensure that violence prevention efforts become self-sustaining, and transforming the way health care providers, police, judges, employers and others address violence.

The FVPF is a national non-profit organization committed to mobilizing concerned individuals, allied professionals, women's rights, civil rights, other social justice organizations and children's groups through public education/prevention campaigns, public policy reform, model training, advocacy programs and organizing.

American Academy of Family Physicians

Founded 1947, the **American Academy of Family Physicians** represents more than 93,500 physicians and medical students nationwide. It is the only medical specialty organization devoted solely to primary care. Family physicians, like other medical specialists, complete an extensive three-year residency program in the specialty after graduating from medical school. As part of their residency, family physicians receive training in six major medical areas: pediatrics, obstetrics and gynecology, internal medicine, psychiatry and neurology, surgery and community medicine. They also receive instruction in many areas including geriatrics, emergency medicine, ophthalmology, radiology, orthopedics, otolaryngology and urology. As a result, family physicians are the only specialists qualified to treat most ailments, and to provide comprehensive health care for people of all ages.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

The American Academy of Pediatrics (AAP) is an organization of 57,000 primary care pediatricians, pediatric medical sub-specialists and pediatric surgical specialists dedicated to the health, safety and well-being of infants, children, adolescents and young adults. The AAP's major activities include furthering the professional education of its members through continuing education courses, annual scientific meetings, seminars and publications. Our organization is committed to ensuring that children's health needs are taken into consideration as legislation and public policy are developed and implemented.

With over 43,000 members, the **American College of Obstetricians and Gynecologists (ACOG)** is the nation's leading group of professionals providing health care for women. ACOG is dedicated to the advancement of women's health through education, advocacy, practice, and research. It is a private, nonprofit organization. ACOG works in four primary areas: 1) serving as a strong advocate for quality health care for women; 2) maintaining high standards of clinical practice and continuing education for its members 3) Promoting patient education and stimulating patient understanding of, and involvement in, medical care; and 4) Increasing awareness among its members and the public of the changing issues facing women's health care. In fulfilling its purpose, ACOG develops and sponsors continuing medical education programs, creates guidelines to evaluate and improve medical practice, promotes access to the latest research through its publications and clinical gatherings, and supports programs for improved graduate medical education in obstetrics and gynecology.

CENTER BOSTON MEDICAL

The Child Witness to Violence Project, a program of the Department of Pediatrics at Boston Medical Center was established in 1992 to provide mental health and advocacy services to young children and their families who are affected by violence in the home or community. The project provides clinical services to children and conducts training and technical assistance to a wide range of professionals working with young children and families. The Project has been nationally recognized as an innovative and effective initiative for families affected by domestic violence.

National Association of Pediatric Nurse Practitioners (NAPNAP) was founded in 1973 as a non-profit specialty nursing organization devoted to improving the quality of infant and child health care. The pediatric nurse practitioner provides an advanced level of care to children and their families, including: counseling on normal development and behavioral problems, the prevention of illness and preventable injuries, and care of children with acute or chronic conditions. NAPNAP promotes high standards of child health care through education, research, and legislative action involving over 6,650 members in 50 chapters across the country.

Office for Victims of Crime
OVC

The Office for Victims of Crime (OVC) is a federal agency located within the Office of Justice Programs of the U.S. Department of Justice (DOJ) that Congress formally established in 1988 through an amendment to the 1984 Victims of Crime Act (VOCA). OVC provides leadership and federal funds to support victim compensation and assistance programs around the country and promotes victim services worldwide. OVC administers formula and discretionary grants designed to benefit victims, provides training for diverse professionals who work with victims, develops projects to enhance victims' rights and services, and undertakes public education and awareness activities on behalf of crime victims. The Office for Victims of Crime is a component of the Office of Justice Programs, which also includes the Bureau of Justice Assistance, the Bureau of Justice Statistics, the National Institute of Justice, and the Office of Juvenile Justice and Delinquency Prevention.

Preparation of this publication was supported by grant number 2000-VF-GX-K006, awarded by the Office for Victims of Crime, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions expressed in this publication are those of the authors and do not necessarily represent the official position or policies of the U.S. Department of Justice.

ACKNOWLEDGEMENTS

These guidelines were guided by members of the Advisory Committee that met in Boston, MA on December 7, 2001. Their input resulted in further revisions and a final review by the Advisory Committee. The Office of Victims of Crime also reviewed it before finalization.

The Family Violence Prevention Fund (FVPF) wishes to thank the following individuals for their time and rigorous attention to the development of these guidelines. Their expertise, experience and guidance were invaluable

PART I

OVERVIEW

OVERVIEW

OVERVIEW

PART 1 | OVERVIEW

Over the past 15 years, there has been a growing recognition among health care professionals that domestic violence is a major health problem with devastating effects on individuals, families and communities. Health care professional associations have issued position statements or guidelines for their members that describe the impact of domestic violence on patients and suggest strategies for inquiring about domestic violence *(See the **Appendix I** for position statements from several professional associations).* Studies show that regular screening for domestic violence in medical settings has been effective in identifying women who are victims[1,2,3] and that victims are not offended when asked about domestic violence.[4,5,6,7,8]

In 1998, the American Academy of Pediatrics (AAP) issued a position statement declaring, "The abuse of women is a pediatric issue."[9] The statement made a strong case for recognizing domestic violence in child health care settings, but did not offer specific guidelines for inquiry and response or discuss the policy and practice dilemmas that arise when child health providers implement inquiry and response protocols.

The guidelines offered here provide specific recommendations for assessing and responding to domestic violence in child health settings, which provide a unique and important opportunity to inquire about for domestic violence and to educate parents about the impact of such violence on children. Virtually every child is seen at some point by a health provider. Thus, it is possible to assess every family that uses the health care system.

These guidelines also speak to the need for child health providers to engage in, model, and take leadership in delivering effective primary prevention of domestic violence, as well as other types of family and community violence, by highlighting violence prevention during well child and other routine visits, as a component of routine anticipatory guidance.

Part One of the guidelines presents an overview of the impact of domestic violence on children and adolescents, and the rationale for regular and universal assessment for domestic violence in child health settings. Part Two addresses dilemmas that providers may encounter in discussing domestic violence with parents of their patients and adolescents. Part Three contains the specific guidelines for inquiry and response. Part Four recommends elements to create a clinical environment that effectively responds to domestic violence. Several useful resources have been included in the Appendices.

DEFINITIONS

The term **"family violence"** and sometimes **"domestic violence"** has been used to describe acts of violence between family members, including adult partners, a parent against a child, caretakers or partners against elders and between siblings. While all forms of family violence can be devastating, this monograph focuses only on domestic violence or "intimate partner violence." In this monograph, "intimate partner violence" will be used to more specifically define a range of behaviors between intimate or dating partners:

> *Intimate partner violence is a pattern of purposeful coercive behaviors that may include inflicted physical injury, psychological abuse, sexual assault, progressive social isolation, stalking, deprivation, intimidation and threats. These behaviors are perpetrated by someone who is, was or wishes to be involved in an intimate or dating relationship with an adult or adolescent victim and are aimed at establishing control of one partner over the other.*[10]

Legal definitions of domestic violence or intimate partner violence are generally more restrictive and refer specifically to threats or acts of physical or sexual violence including forced rape, stalking, harassment, certain types of psychological abuse and other crimes where civil or criminal justice remedies apply. Laws vary from state to state. Since evidence exists that non-physical intimate partner violence has many devastating physical, psychological, behavioral and developmental effects, the definition used in these Guidelines is better suited for the identification and treatment of intimate partner violence in the health care setting.

> *"Child exposure to domestic violence or intimate partner violence" is a term encompassing a wide range of experiences for children whose caregivers are being abused physically, sexually, or emotionally by an intimate partner. This term includes the child who actually observes his/her parents being harmed, threatened or murdered, who overhears this behavior from another part of the home or who is exposed to the short- or long-term physical or emotional aftermath of caregiver's abuse without hearing or seeing a specific aggressive act. Children exposed to intimate partner violence may see their parents' bruises or other visible injuries, or bear witness to the emotional consequences of violence such as fear or intimidation without having directly witnessed violent acts.*[11]

Studies consistently show that the vast majority of victims of intimate partner violence are women. In fact, the latest United States Bureau of Justice Statistics report on intimate violence report found that 85 percent of victims are women.[12] The language in this monograph reflects this trend. However, it is important to note that some victims of intimate partner violence are men, and that violence exists in same sex relationships as well. All victims should be responded to appropriately.

DEFINITIONS

Prevalence of Intimate Partner Violence

Intimate partner violence is a health problem of enormous proportions. It is estimated that 20 percent to 30 percent of all women and 7.5 percent of men in the United States have been physically and/or sexually abused by an intimate partner at some point in their adult lives.[13,14,15] *Heterosexual women are five to eight times more likely than heterosexual men to be victimized by an intimate partner.*[16] *From 1993 to 1998, victimization by an intimate accounted for 22 percent of the violence experienced by females and three percent of the violent crime sustained by males.*[17] *Females are also approximately ten times more likely to be killed by an intimate partner than males.*

For adolescents, rates of experiencing some form of dating violence vary from 20 to 60 percent.[19,20,21] Women age 16 to 24 experience the highest per capita rate of intimate partner violence with 15.6 victimizations per 1,000 females age 16 to 24, as opposed to 5.8 per 1,000 females in general.[22] Teens are also at higher risk for abuse during pregnancy: 21.7 percent of pregnant teens experience abuse as opposed to 15.9 percent of pregnant adults.[23] While studies indicate that boys and girls may accept physical and sexual aggression as normal in dating and intimate partner relationships, female teens are more likely to receive more significant physical injuries and to be sexually victimized by their partners.[24] Finally, adolescent girls who have been sexually and physically hurt by dating partners are six to nine times more likely to attempt suicide or have suicidal ideation than those who reported no abuse.[25]

Far less data exist on lesbian, gay, transgender, and bisexual (or LGTB) victimization, however available literature suggests similarly high rates for LGTB adolescents and adults.[26,27] Intimate partner violence occurs in every community—urban, suburban or rural; in all social classes; and in all ethnic groups. Consequently, all health care settings and professionals are affected by intimate partner violence.

The estimates of numbers of children who are exposed to intimate partner violence vary from 3.3 million to ten million children per year, depending on the specific definitions of witnessing violence, the source of interview and the age of child included in the survey.[28]

Children who are five and under are disproportionately represented in households in which there is intimate partner violence and a sizable number of these children are involved because they calling for help, are identified as the cause of the dispute that led to violence, are caught in the cross fire, or are directly physically abused by the perpetrator.[29] In a study conducted in an urban outpatient pediatric clinic, 40 percent of a sample of 160 mothers had filed a restraining order against a boyfriend or husband.[30] In another study conducted in an office-based pediatric practice, 2.5 percent of mothers reported current intimate partner abuse and 14.7 percent reported abuse in past relationships.[31] In the Adverse Childhood Experiences (ACE) Study, conducted on a large sample of members

(30,000 adults) of the Kaiser Health Plan in California, 12.5 percent of respondents indicated childhood exposure to intimate partner violence and 10.8 percent indicated a history of child abuse, including physical, sexual and emotional abuse.[32] Together these studies indicate that children who witness intimate partner violence are seen with both frequency and regularity in virtually all health settings and that young children are disproportionately represented in the population of children who live with intimate partner violence.

Health Effects of Intimate Partner Violence on Adult and Teen Victims

In addition to injuries sustained by women during violent episodes, physical and psychological abuse are linked to a number of adverse physical health effects including arthritis, chronic neck or back pain, migraine and other frequent headaches, stammering, sexually transmitted infections, chronic pelvic pain, peptic ulcers, spastic colon, and frequent indigestion, diarrhea or constipation.[33] Additionally, optimal management of other chronic illnesses such as asthma, HIV/AIDS, seizure, diabetes and hypertension may be problematic in women who are being abused. Emerging research shows that women who are abused are less likely to engage in important preventive health care behaviors such as regular mammography.[34] Intimate partner violence is also linked with significant short- and long-term mental health consequences for victims.[35,36,37,38,39]

Female adolescents who reported being sexually or physically abused are more than twice as likely to report smoking, drinking and using illegal drugs as non-abused teens.[40] In addition, 32 percent of teen victims report bingeing and purging, compared to 12 percent of non-abused teens. Adolescent women who are battered are also less likely to attend school and less likely to receive good grades if they are in school.[41]

Adolescents' experiences with sex are also associated with their history of dating violence. A study of adolescents found that those who experienced dating violence were more likely than their non-abused peers to have sexual intercourse before age 15 and to have had three or more sex partners in the past three months.[42] Among young mothers on public assistance, half (51 percent) report birth control sabotage by a dating partner.[43] Additionally, high school girls reporting violence from dating partners are approximately four to six times more likely than their non-abused peers to have ever been pregnant.[44] The experience of interpersonal violence is correlated with rapid repeat pregnancy and higher incidences of miscarriage among low-income adolescents.[45] Finally, abused teens are more likely to enter prenatal care later in their pregnancy: 24 percent of teens identified as abused enter prenatal care in the third trimester compared to only nine percent of non-abused teens.[46]

Health Effects of Intimate Partner Violence on Children

More than 100 studies have explored the effects of intimate partner violence on children. These studies enumerate both short and long term effects of intimate partner violence on children.[47] The most obvious and potentially dangerous risk for children who live in homes in which there is intimate partner violence is that they become direct victims of abuse. In 30 to 60 percent of families affected by intimate partner violence, children are also directly abused.[48] Young children and adolescents are more vulnerable to the abuse. Very young children cannot get out of harm's way, and adolescents more frequently intervene to stop the violence, thereby putting themselves at greater risk for injury.[49]

Children who are exposed to intimate partner violence, particularly chronic episodes of violence, often show symptoms associated with posttraumatic stress disorder. One study found that exposure to intimate partner violence (without being directly victimized) was sufficiently traumatic to precipitate moderate to severe symptoms of posttraumatic stress in 85 percent of the children.[50]

Children who are exposed to intimate partner violence are more likely to exhibit behavioral and physical health problems including chronic somatic complaints, depression, anxiety and violence towards peers.[51] They are also more likely to attempt suicide, abuse drugs and alcohol, run away from home, engage in teenage prostitution and commit sexual assault crimes.[52] Children who are exposed to intimate partner violence have increased difficulties with learning and school functioning.[53] Symptoms of trauma including sleep difficulties, hyper-vigilance, poor concentration and distractibility which interfere with a child's ability to focus and to complete academic tasks in a school setting.

Intimate partner violence also affects parenting. The emotional consequences of being injured, harassed or terrified may be significant for the parent who is victimized. That parent may be less attuned to children's needs or less emotionally available to the children. However this does not mean that victims of intimate partner violence are inherently abusive or neglectful of their children. Parents who batter are generally less involved with child rearing, more likely to use physical punishment and less able to distinguish or recognize the child's needs as separate from the parent's needs.

Children who grow up with violence in the home learn early and powerful lessons about the use of violence in interpersonal relationships. They learn that violence is an acceptable way to assert one's views, get one's way or to discharge stress. These children also learn that violence may be an inherent part of loving relationships. Exposure to violence thus provides justification for children to use violence in their own relationships. This may be particularly true for adolescents.[54]

Studies demonstrate that children are not equally affected by exposure to intimate partner violence.[55,56,57] Children react in different ways to trauma, and they have a range of strengths and vulnerabilities to cope with this stress. Some children appear to be more resilient; others may be deeply affected. Variables such as age, gender, proximity to the violence and the frequency and severity of the violence affect children's responses. In addition, the response of the caregiver and other characteristics of the family and community affect children's responses.

Working Cross Culturally

Intimate partner violence affects people regardless of race, ethnicity, class, sexual and gender identity, religious affiliation, age, immigration status and ability. The term culture is used in this context to refer to those axes of identification and other shared experiences. Because of the sensitive nature of abuse, providing culturally relevant care is critical when working with victims of abuse. In order to provide care that is accessible and tailored to each patient and their family, providers must consider the multiple issues that victims may deal with simultaneously (including language barriers, limited resources, homophobia, acculturation, accessibility issues and racism) and recognize that each victim of intimate partner violence will experience both the abuse and the health system in culturally specific ways.

Disparities in access to and quality of health care also have an impact on ability of providers to help victims of intimate partner violence. For example, women who are members of racial and ethnic minority groups are more likely than white women to experience difficulty communicating with their doctors, and often feel they are treated disrespectfully in the health care setting.[58] English-speaking Latinos, Asians and Blacks report not fully understanding their doctors and feeling like their doctors were not listening to them.[59] People with disabilities that affect cognitive or communication may be dependent on an abusive intimate partner and thus at especially high risk. In addition, some patients may experience abuse from the health care system itself and this may affect their approach to and utilization of the health care system.[60]

Providers also enter health care encounters with their own cultural experiences and perspectives that may differ from those of the victim. In a successful health care interaction within a diverse client population, the provider communicates effectively with the patient, is aware of personal assumptions, asks questions in a culturally sensitive way and provides relevant interventions. Eliciting specific information about the patient's beliefs and experience with abuse, sharing general information about intimate partner violence relevant to that experience and providing culturally accessible resources in the community, improves the quality of care for victims of violence. In addition, having skilled interpreters who are trained to understand intimate partner violence (and not family members, caregivers or children) is crucial when helping non-English speaking patients [61] and their families. Culturally sensitive inquiry questions for all caretakers and adolescent patients can facilitate discussion and help providers offer appropriate and effective interventions.

Recent Trends

These guidelines reflect an important shift in terminology. "Assessment" or "inquiry" has replaced the work "screening" throughout this document. The concept of screening in the medical model usually involved the use of a standardized clinical test to detect disease in asymptomatic patients. Psychosocial health issues like IPV do not fit well into a disease-based approach, particularly when identification of the health concern relies primarily on the patient's response to a question. The U.S. Preventive Services Task Force (USPSTF) uses the term "assessment" in their recommendations for many psychosocial issues such as tobacco use and alcohol consumption. The USPSTF and other prominent medical organizations have identified the problems with fitting IPV into a traditional screening paradigm. The FVPF believes that using the term "assessment" will lead to a more appropriate evaluation of the importance of routine inquiry for IPV in the health care setting.

With growing recognition of the connection between IPV and other risk factors, there is a trend to integrate routine inquiry for IPV into assessment tools addressing a wide range of psychosocial issues associated with current or past victimization such as tobacco use, weight control, and access to preventive health care. This has led to innovative strategies for more comprehensive assessment and integrated service delivery. The Maternal and Child Health Bureau has funded several perinatal demonstration projects to develop as assessment tool for IPV, depression, and substance abuse. Another exciting initiative through the Substance Abuse and Mental Health Services Administration (SAMHSA) promotes coordinated services for women who experience violence, mental health problems, and have substance abuse issues.

Identifying and Responding to Abuse Can Make a Difference

The health care system plays an important role in identifying and preventing public health problems. Models developed to identify other chronic health problems may effectively be applied to intimate partner violence. **A primary starting point to improve the medical practice approach to intimate partner violence is routine assessment, with a focus on early identification of all families and victims of intimate partner violence whether or not symptoms are immediately apparent.**

Since nearly all young children and teens are seen at some point in a health care setting, these settings present a compelling opportunity to identify teens, mothers and children who may be living with intimate partner violence. A 2001 study in North Carolina found that only 23 percent of women injured by a partner shortly after pregnancy received treatment for their injuries. However, almost all of these women used health care services for their infants, indicating that child health settings are potentially important for identifying intimate partner violence.[62]

Universal and regular face-to-face screening of women in adult health settings by skilled health care providers markedly increases the identification of victims of intimate partner violence, as well as those who are at risk for verbal, physical and sexual partner abuse.[63,64] Expert opinion suggests that such interventions in adult health settings may lead to reduced morbidity and mortality.[65] Inquiry for IPV can assist clinicians in their diagnosis and assure more appropriate care for a victim's health symptoms by treating the underlying problems. Inquiry also gives victims a valuable opportunity to tell their providers about their experiences with abuse.[66] Battered women report that one of the most important parts of their interactions with their physicians is being listened to about the abuse. *(See* ***Appendix III****: Abstracts of selected studies on Provider and Patient Attitudes: Forward Screening for IPV in the Child Health Setting.)*

Although there is no research as yet that proves the efficacy of assessment in child health settings, it is reasonable to assume that such inquiry would increase opportunities for identification and intervention within families, thereby enabling pediatric, family practice and primary care providers to assist both victims and their children. When child witnesses of intimate partner violence, victims or those at risk for intimate partner violence are identified early, providers may be able to intervene to help patients understand their options, live more safely within the relationship or safely leave the relationship. The child health care provider's direct discussion about safety at home tells the family that this is an important topic and one that belongs in the realm of pediatric and family practice care. Even if a woman denies that she is being abused, the provider can often lay the groundwork for the possibility of future disclosure or discussion of the issue.

PART II

DILEMMAS FACED BY PROVIDERS

DILEMMAS

DILEMMAS

Family Violence Prevention Fund

PART II | DILEMMAS FACED BY PROVIDERS

A policy of universal and regular inquiry for intimate partner violence in child health settings presents dilemmas to the providers who assess that may not exist when assessing patients in an adult health setting. Perhaps the fundamental difference lies in the fact that adults are not the primary patients during pediatric visits. This section reviews several major dilemmas and provides specific recommendations for responding. Because these dilemmas present challenging practice and ethical questions for the provider, this panel strongly recommends that child health practices have access to legal consultation, as well as consultation from battered women's service providers, child protection and child mental health. These resources can be helpful in making decisions about how to intervene in ways that do not increase risk for the family or unnecessarily alienate the non-offending parent.

When Does Child Exposure to Intimate Partner Violence Become Child Maltreatment?

Because of the high rate of co-occurrence of intimate partner violence and child abuse, child health providers need to be concerned about the possibility of child abuse whenever intimate partner violence is disclosed. Whenever a child is abused, either intentionally or unintentionally, as a result of intimate partner violence, state law requires health care providers to report this abuse to child protection services. Mandated reporters would also report any high-risk situation of intimate partner violence in which children are at risk.

However, state laws are less clear about whether exposure to domestic violence in the absence of injury or serious risk of injury to the child would require a report to children's protective services.

- In some states, stringent rules/laws require mandated reporters to notify child protection services whenever a child is in the home and has been exposed to a parent's abuse, whether or not the child has been directly abused. Proponents of this definition point to the ample documentation of the overlap between adult intimate partner violence and child abuse and the adverse psychological effects on children who witness intimate partner violence. Opponents of this policy believe it penalizes women for abuse that they have no control over and may discourage women from seeking help.

- In other states, a child's exposure to intimate partner violence does not automatically require a mandatory child protection report. The provider has wider discretion to assess whether a child has been directly involved and what other factors may exist to put the child at risk. In these states, a provider would take into account the existence of direct injury to a child, the potential danger of the situation, and the capacity of the mother to keep her children safe in deciding whether to notify Child Protective Services (CPS).

Many victim advocates recommend having the victim place a phone call themselves to CPS from the practitioner's office, thus protecting her from charges of "failure to protect" while simultaneously protecting the child and meeting statutory child abuse reporting laws.

Unless a child health care provider is legally required to report all incidences of intimate partner violence to CPS, it is preferable to make this decision based on the specifics of the case and the provider's clinical judgment. In some instances, the children are not in danger; the victim has planned for their safety and is responding adequately to the child's needs or emotional reactions. In these cases, a provider should offer voluntary services and support instead of simply submitting a report to CPS, especially if not mandated.

A policy that automatically defines child exposure to intimate partner violence as neglect or maltreatment assumes that victims are neglectful parents solely because their children witnessed the abuse, implying that somehow the victim could have stopped the abuse. This approach implies that not only are these parents victims of abuse, but that they also bear the responsibility for child neglect. This may be inaccurate and unfair. This policy also makes the assumption that all children are adversely affected by exposure to violence, no matter the circumstances. It ignores the fact that some children are more adversely affected than others and that some families and communities are more able to support children than others. Finally, opponents of this policy allege that mandatory reports also would increase the demands on protective services—a system that is already overburdened and under funded in most states.[67] In addition, the practice of routinely reporting intimate partner violence incidents that involve children to protective services discourages victims from seeking help with intimate partner violence. If a victim believes that children may be removed from her care, she will be less likely to seek help from medical professionals. A mandatory reporting policy also may discourage child health care providers from assessing for intimate partner violence because they do not want to involve protective services in their patient's life.

RECOMMENDATIONS:

Know your state's child abuse reporting laws *(see **Appendix XI**)* and its specific policies on defining child exposure to intimate partner violence as child maltreatment *(see **Appendix X**)*. In a state that requires mandated reporting in all cases of intimate partner violence, the provider should inform the non-offending parent of the obligation to file a report to CPS, assess the safety needs of the victim, and inform CPS about the specifics of the perpetrator, his anticipated response and the potential for danger. In states where more discretion is left to the provider, the provider should assess the specifics of each situation as a means of making a decision about whether it is necessary to make a report. The assessment should include inquiries about injury or abuse to children, the current safety of the home, and whether the perpetrator has made threats to the children. Depending on the answers to these questions, the provider can make a decision about the imminent risk of harm to

the child and victim. If the situation is not currently dangerous, the provider can refer the victim to voluntary services: battered women's services, counseling (preferably with a provider who has worked with victims of intimate partner violence), or child-focused services. If the situation is currently dangerous to the child, a report needs to be filed. Consider involving the mother in filing the report and follow the recommendations above to maximize the protection afforded to the mother during the CPS investigation.

BOX 1

In States with Mandatory Reporting Requirements for Child Exposure to Intimate Partner Violence

PROVIDERS SHOULD:

- Inform the non-offending parent of obligation to report to CPS
- Assess the safety needs of the victim
- Give CPS specific information about the perpetrator, the intimate partner violence, and the potential for danger
- Have resources available for the non-offending parent

In States with Less Specific Reporting Requirements for Child Exposure to Intimate Partner Violence

PROVIDERS SHOULD DECIDE WHETHER TO FILE A REPORT WITH CPS BASED ON:

- An inquiry about direct injury to child
- An assessment of potential for danger (threats, weapons, substance abuse)
- An assessment of mother's ability to plan for children's safety
- An assessment of support and connections to community

If provider decides not to report to CPS, he/she should offer referrals to voluntary services and provide follow-up care.

IF PROVIDER DOES DECIDE TO REPORT:

- Consider asking the mother to file a report herself to avoid charges of "failure to protect"
- Follow all the steps outlined above for reports in mandated states

Intimate Partner Violence Victimization Reporting Requirements for Health Care Providers

While all states mandate reporting of child abuse or neglect, most states have also enacted general mandatory reporting laws which require the reporting of specified injuries and wounds, suspected abuse or intimate partner violence for individuals being treated by a health care professional. These mandatory reporting laws are distinct from child abuse, elder abuse or vulnerable adult abuse reporting laws, in that the individuals to be protected are not limited to a specific class. These laws pertain to all individuals to whom the health care professional provides treatment or medical care, or who come before the health care facility.

The laws vary from state to state, but generally fall into four categories: 1) states that require reporting of injuries caused by weapons; 2) states that mandate reporting for injuries caused in violation of criminal laws, as a result of violence, or through non-accidental means; 3) states that specifically address reporting in intimate partner violence cases; and 4) states that have no general mandatory reporting laws. *(See **Appendix IX** for state codes on Intimate Partner Violence Victimization Reporting Requirements for Health Care Providers).*

In the majority of states, neither statutory nor case law specifies if a health care provider must report a parent's injuries if they are observed or discovered during a health care visit with that parent's child. Therefore, under a strict reading of most laws, if a child's health care provider is not providing treatment or medical care to the abused parent during the child's visit, the health care provider would not be required to make a report. In family practice situations where the child and parent are the provider's patients, and the current visit appointment is for the child, the same reasoning could be applied, although it is less clear-cut. That is, the health care provider would not be required to report since he or she is not treating the parent for the specified injuries during the appointment. This issue merits further discussion among health care providers, advocates, licensing authorities, and other professionals, as it is uncharted territory. There has been much debate about the benefit of mandatory reporting of intimate partner violence by health care providers. A more extensive discussion of these laws, their risks and benefits, and their application to pediatric and family practice providers can be found in ***Appendix VIII***.

RECOMMENDATIONS:

Providers should know their state's intimate partner violence reporting law, including who is required to report and under what conditions. *(**Appendix IX** contains a chart listing state codes)*. In order to maximize patient input regarding law enforcement action, providers should also familiarize themselves with how their local law enforcement agency responds to such reports. Becoming familiar with such procedures will allow the

provider to better assist the patient in safety planning, and in knowing what to expect. Intimate partner violence reporting responsibilities should be carefully discussed with teens prior to assessing for dating violence or intimate partner violence in their homes. Additionally, recent federal privacy regulations require providers to inform patients of health information use and disclosure practices in general, and whenever a specific report has been made. Health care facilities should ensure that their intimate partner violence protocols and training materials address their state reporting laws and federal regulations.

Asking about Intimate Partner Violence with a Child in the Room

Providers differ in their practice of asking sensitive questions to the mother when the child is present. Generally, if the child is under age three, most providers assume that asking a mother about safety or other sensitive issues is appropriate. However, there is not consensus about whether to require that an older child not be present in the room when screening the mother for intimate partner violence. Some providers are concerned about asking questions when older children are present. They assert that having the child in the room will be a barrier to disclosure because parents will avoid discussing it in front of their children. Some say that it would be upsetting for children to hear such conversation or that children may reveal the conversation to the batterer which may endanger the mother and child. Other providers believe that the assessment questions about intimate partner violence should be asked regardless of the age of the child. They assert that children generally are aware of the intimate partner violence and that mothers will indicate if they are uncomfortable with the subject, thus giving the provider the opportunity to schedule a more private conversation with the parent.

RECOMMENDATIONS:

It is best to conduct assessment without children in the room and should occur regardless of the age of the child. In some practices it is possible to have the child wait in a supervised waiting area or under the supervision of another staff member. In other practice settings, it is not possible to have children leave the exam room. In these situations, providers can ask general questions and should always be sensitive to the comfort level of the parent. If the parent seems uncomfortable, the provider can offer other options for talking more privately, either by telephone or in a follow-up visit. Providers should be aware of the impact of a disclosure on a child, and should ask follow-up questions about the child and family's safety.

BOX 2

Asking about Intimate Partner Violence with a Child in the Room

Child in the Room

PRACTICAL POINTS:

1. Ask general questions first.
2. Be sensitive to comfort level of parent.
3. If parent is uncomfortable, schedule a time to talk without the child present.

Child not in the Room

PRACTICAL POINTS:

1. Ask during routine parts of visit when child is not in the room: vision screening, immunizations, laboratory work.
2. Have the child wait briefly in a supervised waiting area if possible.

Documentation

There is no consensus over the procedure for documenting the presence of intimate partner violence in a family in a child's chart. If the batterer is the biological or custodial parent, he may have access to the chart and the information about the victim would thus not be confidential. Therefore, putting information about intimate partner violence disclosures in the child's chart may not be advisable. On the other hand, the information is important and other providers who work with the family should know about this risk factor if they read the child's chart. Charting can also be helpful to the victim should custody disputes arise.

RECOMMENDATIONS:

A review of the literature and current practice reveals that recommendations for documentation are contradictory and inconsistent. One recommendation is for the provider to document all screenings for intimate partner violence in the child's chart. The suggested notation, perhaps in the section on anticipatory guidance, is: "The parent was routinely asked about verbal abuse, threats, physical violence in the home and community. If so, the parent was offered information about community resources for safety planning and counseling." This type of routine documentation is recommended for tracking and quality assurance. If possible, the documentation for the outcome of the inquiry (if positive for abuse) should be placed in the woman's health chart or in social work notes where there is more protection of confidentiality. Some practices use non-specific terms or a code word to indicate the presence of intimate partner violence in a child's chart: for example, "family problems," "difficult home situation" or "+ wtv." Some practices maintain a section of the child's chart that is confidential and is not released when there is a request for medical records. A brief notation of intimate partner violence in this section is appropriate. Intimate partner violence should not be listed as a discharge diagnosis or billing information that is sent home or can be viewed by the perpetrator.

If the provider is unsure about documentation and its confidentiality from the battering parent, he/she should consult with medical records experts, billing personnel, risk management professionals or attorneys.

BOX 3

Options for Documentation

- Document that inquiry has occurred.
- Document results of inquiry by using non-specific terms or code works: "family problems," "difficult home situation," or "wtv."
- Maintain a section of the child's chart that is confidential (not released with a request for medical records). Document finding of intimate partner violence in this section.
- If possible, document the existence of intimate partner violence in the woman's health chart or in social work notes where there is more confidentiality.

Responding to a Child's Disclosure of Intimate Partner Violence in the Home

Direct disclosures of intimate partner violence occur more frequently with older children or teenagers who see child health providers without their parents. If the parents are unaware of the disclosure, the provider must decide how to inform the parents in a way that protects the child and does not create an unsafe situation in the home. The provider may feel uncomfortable about how to handle this disclosure. Should the provider notify child protective services? What are the consequences for the child of telling someone outside the family about the violence? What are the issues and laws related to confidentiality?

RECOMMENDATIONS:

Find out as much specific information as possible about the abuse and the extent of risk for the child and the adult victim. If the situation is dangerous, notify protective services. Inform the child of your concern about his/her safety and tell the child that you would like to speak to the non-offending parent about the situation. Inform the non-offending parent of the child's concerns, taking care to stress that you are concerned and that you want to be helpful and supportive. Ask if the parent is safe and what types of supports would be helpful. If possible, make a referral to an intimate partner violence support agency or to counseling/social services/mental health. Schedule a follow-up appointment for the next week.

BOX 4

Responding to Child Disclosure of Intimate Partner Violence

PRACTICAL POINTS:

- Inform the child of your concern about her/his safety and that you intend to speak to the non-offending parent about the situation.
- Inform the non-offending parent of the child's concerns.
- Ask if the parent is safe and what types of supports would be helpful.
- If possible make a referral to an intimate partner violence support agency or to counseling/social services/mental health for the adult or adolescent victim and their children.
- Schedule a follow-up appointment for the next week.
- Notify protective services if there are safety concerns about the child.

PART III

CONSENSUS RECOMMENDATIONS

CONSENSUS RECOMMENDATIONS

PART III | CONSENSUS RECOMMENDATIONS

ASSESSING FOR INTIMATE PARTNER VIOLENCE WHEN YOUR PATIENT IS A CHILD OR ADOLESCENT

All health care providers seeing children and adolescents should provide intimate partner violence assessment as part of routine patient care in public health, private practice and managed care settings.

Who and How Often to Assess:

- Assess female caregivers/parents who accompany their children during new patient visits; at least once per year at well child visits; and, thereafter, whenever they disclose a new intimate relationship.
- Assess female and male caregivers/parents known to be in same-sex relationships who accompany their children during new patient visits; at least once per year at well-child visits; and, thereafter; whenever they disclose a new intimate relationship.
- Assess adolescents during new patient visits; at health maintenance visits once per year; or whenever they disclose a new intimate relationship.
- Ask pregnant teens at first pre-natal visit; at least once per trimester; and at the postpartum visit.[i]
- Also ask whenever signs and symptoms raise concerns:[ii]
  - Specifically, assess when the child or adolescent has:
    - Obvious physical signs of physical or sexual abuse;
    - Behavioral or emotional problems, such as increased aggression, increased fear or anxiety, difficulty sleeping or eating, or other signs of emotional distress; or
    - Chronic somatic complaints.
  - When adults present with obvious physical injuries or a history of intimate partner violence.

*(See **Appendix IV**: Dilemmas When Assessing All Patients for Victimization.)*

[i] Recommended by the American College of Obstetricians and Gynecologists

[ii] See Appendix V: Indicators of Abuse.

BOX 5

Who and How Often to Assess:

TYPE OF VISIT	WHO TO ASSESS	WHEN TO ASSESS
New Born	Caregiver	At postpartum visit
New Patient	Caregiver & Adolescent	At first visit
Well Child:		
Child	Caregiver	At 2, 6 and 12 months, then yearly
Adolescent	Adolescent	Yearly
Prenatal	Adolescent Mother	Once per trimester
Mental Health	Caregiver & Adolescent	At initial visit
Emergency	Caregiver & Adolescent	At every visit
Other Visits	Caregiver or Adolescent	Whenever there are physical or behavioral indicators or chronic somatic complaints

How to Assess:

- Direct questions should be asked, whether or not signs or symptoms are present and whether or not the provider suspects abuse has occurred.
- Inform patient about the limits of practitioner/patient confidentiality related to intimate partner violence prior to assessing.
- Use language that is direct, specific and easy to understand.
- Conduct assessment in a private room.
- For a parent, it should take place without the intimate partner or other adult family members present.
- For adolescents, it should take place without the parent (or partner) in the room.
- Can be included as part of a written health questionnaire or health history, but this should not replace face-to-face assessment.
- Should be conducted in a patient's primary language.
- If an interpreter is used, it should not be an acquaintance or relative of the family. Children should never be used as interpreters.

What to Ask:[iii]

Intimate partner violence questions can be framed within discussion of other safety issues such as car and bicycle helmet safety, and assessing for guns at home or community violence.

[iii] There are no controlled studies of the efficacy of screening questions in pediatric or family practice settings. The questions we propose are drawn from three sources: Family Violence Prevention Fund, Preventing Domestic Violence: Clinical Guidelines on Routine Screening. San Francisco, October, 1999. Groves, B. (1994). Children who Witness Violence, in Developmental and Behavioral Pediatrics: A Handbook for Primary Care. Parker, S. and Zuckerman, B., eds. Boston, Little Brown & Co. 334-336. McNamara M. (2001). "Clinical guidelines for screening and responding to child and youth exposure to domestic violence for healthcare providers". LINC (Living in a Nonviolent Community), UCSF Department of Pediatrics, November 2001.

For adults who accompany their children:

INTRODUCTORY STATEMENTS OR QUESTIONS:

- "I have begun to ask all of the women/parents/caregivers in my practice about their family life as it affects their health and safety, and that of their children. May I ask you a few questions?"
- "Violence is an issue that unfortunately effects everyone today and thus I have begun to ask all families in my practice about exposure to violence. May I ask you a few questions?"

INDIRECT QUESTIONS:

- "What happens when there is a disagreement with your partner/husband/boyfriend or other adults in your home?"
- "Do you feel safe in your home and in your relationship?"

DIRECT QUESTIONS:

- "Have you ever been hurt or threatened by your partner/husband or boyfriend?"
- "Do you ever feel afraid of (or controlled or isolated by) your partner/husband/boyfriend?"[iv]
- "Has your child witnessed a violent or frightening event in your neighborhood or home?"

For adolescents:

INTRODUCTORY STATEMENTS OR QUESTIONS:

- "Many teens your age experience threats, name calling, uninvited touching, sex or violence, so I ask all my teen patients about it. May I ask you a few questions?"
- " I don't know if this is a concern for you, but many teens I see are dealing with violence or bullying issues, so I've started asking questions about violence routinely."
- "Sometimes when I see an injury like yours, it's because somebody got hit. How did you get this injury/bruise?"
- " Now I am going to ask you confidential questions. The answers are confidential, unless your health is in immediate danger."
- "How are disagreements handled in your family?"

INDIRECT QUESTIONS:

- "Are you in a relationship or seeing anyone?" or "Do you have a boyfriend or girlfriend? What happens when you disagree with them?"
- "How are your parents getting along?"

[iv] In case of same sex relationships we recommend using "partner" or mirroring the language of the adult being screened. For example, if a parent refers to her same sex partner as "roommate," use "roommate." If the sexual orientation is unknown, we recommend "partner."

- "How often do you have yelling or screaming fights? Do any of them involve pushing or slapping?"

DIRECT QUESTIONS:

- "Sometimes if someone is being hurt in her/his own relationship, they may have seen it happen in their own family. Have you seen anyone get hurt in your home?"
- "Teens see a lot of violence these days. Seeing parents or other adults fight can feel as bad as being hit yourself. Has this happened to you?"
- "We all have disagreements sometimes with family members or friends. Have you ever been hurt or threatened by anyone?"
- "Have you ever been hurt – hit, kicked, slapped, shoved, pushed by a friend or person you know?"
- "Have you ever been forced to do something sexual that you didn't want to do?" —as part of sexual history.
- "Do you ever feel afraid of or controlled by someone you're dating or a friend?"
- "Has anyone hit you at home in the last year?"

QUESTIONS BASED ON INDICATORS:

- "I noticed that you have an injury. Sometimes injuries like that come from someone hurting you. What happened to you?"

Asking about Intimate Partner Violence with a Child in the Room

There are different opinions about whether inquiry about sensitive issues such as intimate partner violence should take place with the child in the room or whether the questions should be asked without the child's presence. For further discussion of this issue, see page 10.

- If it is possible to see the parent without the child, (e.g. the child is old enough to wait alone; the child is in a supervised waiting area; the child is having laboratory work or vision /hearing screening done), questions can be asked in the manner mentioned in the section "What to Ask" above.

- For children under age three, asking the mother questions about safety and relationships in the presence of the child is generally not an issue.

IF THE CHILD IS IN THE ROOM:

- Begin inquiry with an indirect question (see section "What to Ask" above).
- If parent appears uncomfortable or upset and it is not possible to see the parent alone in this visit, ask if there is another time to speak by telephone or to follow-up.
- If parent appears comfortable with the questions, proceed to ask more specific questions about intimate partner violence.

Who Should Assess:

QUESTIONS CAN BE ASKED BY ANY HEALTH CARE PROVIDER WHO IS:

- Educated about the dynamics of intimate partner violence, how children are affected and how to assess safety of children and/or know what resources are available for further assessment and counseling services;
- Trained on how to ask about abuse, how to assess the safety needs of an abuse victim, and how to assist the victim, and who recognizes her autonomy and right to make her own decision or is trained to refer the patient to someone who can assess safety needs and further assist her;
- Sensitive to issues of culture and class in interactions with patients; and
- Knowledgeable about community resources.

RESPONDING TO INTIMATE PARTNER VIOLENCE WHEN YOUR PATIENT IS A CHILD OR ADOLESCENT

If the patient or his/her mother tells you that s/he has been abused, you become an important part of her/his support system. Living with intimate partner violence or making the decision to leave a relationship are ongoing issues for both patient and family that affect their health care. Providers need to respect the integrity and authority of victims of intimate partner violence to make decisions about their own relationships, even if the provider does not agree with those decisions. The health care provider can play an important role in the victim's decision making process by asking the right questions, providing information about the nature of intimate partner violence, giving messages of support, and letting her know about resources available to her. At times it will be appropriate for the health care provider to make recommendations about what to do, but only after understanding the reality of the victim's situation and only with the understanding that, ultimately, the victim must and will make her own choices, not withstanding child abuse laws.

Support the Victim:

- Express concern for the patient's or parent's safety.
- If the victim is comfortable, encourage her/him to talk about what has happened.
- Listen without making judgments.
- Tell victims that they are not alone and that you and other people can help them.
- Tell her/him that the violence is not their fault, s/he does not deserve to be abused and that only her/his abuser can stop the abuse, and that there is no excuse for intimate partner violence.
- Make sure s/he knows that there is help available and that there are people s/he can turn to for support.
- Remind the victim that you are a resource, should s/he need further assistance.

- Inform the attending parent or adolescent of any reporting laws and requirements.

Provide Information on Intimate Partner Violence:

- Intimate partner violence is common (among all social strata, educational levels and ethnic groups).
- Most violence continues for a long time and often gets more frequent and more severe.
- Violence happens in all kinds of relationships – including teen relationships and lesbian and gay relationships.
- Violence in the home can harm all family members including children, both physically and emotionally
- There are resources for families, and this clinic/practice/provider can help find them.
- Intimate partner violence affects victim health and the health of the family.

What to Say to the Child Who has Witnessed Intimate Partner Violence:

If a parent discloses intimate partner violence, the provider with the parent's permission can specifically acknowledge the disclosure with the child by saying:

- "What are your worries about the fighting at home?"
- "I am concerned about the safety of people in your home and I am glad your mother told me about this."
- "What is going on in your house is not your fault."
- "You are not responsible for solving these problems. I am going to work with your mother (father, caretaker, etc.) to try to make things better."

The way in which the provider discusses these issues with children will vary by their age and level of cognitive development. For a four-year-old, it is probably sufficient to provide simple acknowledgment and reassurance about safety. For an eight-year-old, it may be appropriate to add more specific reassurances about what steps the parent is taking to handle the situation. For an older child or an adolescent, it may be important to offer the opportunity to talk about their perspectives of the situation at home.

For Adolescents Who are Victims of Violence:

- Address the health issues by obtaining a complete history.
- If possible, conduct a complete, unclothed, physical exam. Look for – and document – evidence of current or previous injuries and of sexual abuse.
- Ask about medical and psychological effects resulting from abuse, such as chronic pain, worsening of existing medical conditions, psychological distress, anxiety, sleeping and eating disorders, miscarriages or substance abuse.
- Schedule a follow-up appointment, encourage your patient to return and make other

appropriate referrals.
- Encourage the patient to talk to his/her parents or trusted adult about dating violence.
- For severe violence, inform adolescents that you must inform their parents or guardian to keep them safe. In this case, you may need to inform state protective service if the caretaker will not protect the child.

Assess and Address Safety Issues:

Before your adolescent patient or a parent leaves, talk with her/him about immediate and future safety. These questions can also be asked over time and during subsequent visits.

- Ask her/him about her/his immediate plans. Is s/he going home to the person who hurt her/him? Does s/he have a friend or relative s/he can talk to? If s/he is going to leave, where is s/he going to go?
- Depending on the amount of time the clinician has, the following issues can be pursued to assess current danger:
    - What happened during the latest incident? Is the abuse increasing in frequency or severity?
    - Were weapons involved?
    - Have there been prior incidents?
    - Have you sought any kind of assistance for previous battering? Have you ever left before?
    - Has the abuser ever threatened or physically injured the children?
- Assess for suicidal ideation and risk of homicide:
    - Have you ever considered, threatened or attempted suicide?
    - What injuries did you sustain during the worst incident of violence?
    - Has the violence increased in frequency and/or severity?
    - Has the abuser ever threatened to kill you? Do you believe s/he is capable of killing you? Has the abuser used a weapon or threatened you with a weapon before?
    - Are you planning to leave/divorce him in the near future?
    - Are there firearms or other weapons in the house?
- Help parents think about safety issues for their children. For example:
    - Do the kids usually get involved when a violent incident occurs?
    - What do they do when violence erupts?
    - Do you talk with them about it? What do you say?
    - Children should be taught that their job in a violent situation is to stay safe, not to protect their parents or stop the fighting. They should be taught now to call 911(where age appropriate).
    - Help the victim think about options and their implications.
- Inquire about the possibility of referring a victim to appropriate services from a battered women's shelter or support network and/or other culturally relevant agency such as a

community center, church or other organization serving the victim's community. *(See **Appendix VII** for a Safety Plan and Instructions).*

Referrals for Adult Parents and Adolescents:

Help your patient find culturally appropriate support from a hospital or community-based social worker or advocate who can help the victim with:

- Emergency shelter or permanent housing
- Emergency financial assistance or transportation
- Counseling and/or support groups for victims and their children
- Child care, visitation centers
- Legal assistance
- Mental health and substance abuse treatment
- Social services
- Batterer intervention programs
- Independent living centers

Note: Couples treatment and mediation are not usually recommended[v]

When possible, refer patients to organizations that reflect their cultural background or address their special needs such as organizations with multiple language capacity and those who specialize in working with teen, disabled or LGBT (lesbian, gay, bisexual, or transgender) clients.

Allow her/him to use your phone to make calls. If you don't have information about intimate partner violence programs in your area, call the National Domestic Violence Hotline at 800-799-SAFE (800-799-7233 or TDD: 800-787-3224).

[v] Mediation and couples counseling imply that both parties are responsible for the perpetrator's violent behavior, a message that blames victims and fails to hold offenders accountable for their crimes. Mediation also presumes that both parties have equal power and can negotiate a mutually agreeable settlement. Where there is domestic violence, sexual assault, or stalking behavior, however, one party has controlled the other through sexual, physical, emotional and/or economic abuse. Even the most skilled mediator or therapist cannot shift the balance of power when one party has abused or assaulted the other, making mediation and joint counseling dangerous and ineffective in such cases.

Referrals For Children:

Children react to witnessing intimate partner violence in many different ways. The family's capacity to support these children also varies, as do their beliefs or ways of seeking help. If the parent is concerned about her child, options for help should be discussed, including a counseling referral, mental health assessment or other support services (such as Big Brother/Big Sister). A referral would be strongly recommended in the following circumstances:

- If the child has witnessed severe violence resulting in injury or hospitalization of either the child, sibling or the parent.
- If the child's symptoms have persisted for more than three months.
- If there has been a change in behavior or an increase in aggression or depression.
- If the caretaker is unable to be emotionally attuned to the child's needs.
- If the violence has resulted in the death of a parent.

Reporting Requirements for Child Abuse and Intimate Partner Violence:

Know your state's child abuse and intimate partner violence reporting laws. *(Discussion of the complexity of these issues can be found in **Appendices VIII, IX & X**).* Contact your local prosecutor or state attorney general, and local law enforcement to interpret the law.

- Before asking about intimate partner violence, you may want to disclose any limits of confidentiality. Since many adolescents who are victimized by an intimate partner do not want their family to know about an intimate relationship, it is important that you understand and explain the limits of confidentiality of both their medical record and reporting before screening.[vi]
- If the child has been injured, or if your state requires mandated reporting in all cases of a child's exposure to intimate partner violence, you must:
- Follow the state guidelines for completing a report.
- Encourage the victim to place a call to CPS themselves from the practitioners office, thus protecting her from charges of "failure to protect" while simultaneously protecting the child and meeting statutory child abuse reporting laws.
- If possible, when making the report yourself, tell the attending parent what you will say in the report and/or allow her to read/hear what you will say.
- When making the report to CPS, inform the screener or intake worker about the specifics of the domestic abuse and give as much information as possible about the risks for safety of the mother and child, the perpetrator, his current location, the anticipated response and the potential for subsequent violence.

[vi] Federal health privacy regulations allow parents of teens to access health information unless the teen is emancipated or legally seeking care without parental consent such as services offered in Title XX, family planning clinics or STD clinics.

How to Document Intimate Partner Violence:

Documentation provides information on the effects of intimate partner violence over time and improves continuity of care. Make sure you are following your institution, state and federal privacy policies.

- Documentation is recommended. However, use caution in documenting intimate partner violence in a child's chart if the abuser is the biological or custodial parent. It may be advantageous to document on a separate form.
- For adolescents, documentation should be handled consistently with documentation of other sensitive issues, such as sexual activity, alcohol or drug use.[vi]
- When documenting, use direct quotes like " Mother/Patient states...". Avoid judgmental terms such as "patient alleges" or "patient claims."
- With permission, photograph or draw picture of any injuries.

What to Do if a Patient Says "No" or Will Not Discuss Abuse:

Many victims of intimate partner violence will talk about their experiences if asked to do so in a sensitive and empathetic way. However, some victims may be reluctant to talk about their experiences regardless, because they are embarrassed or ashamed, or afraid that if they tell anyone they may face more severe abuse. There may be financial issues and or immigration concerns. Patients need to decide for themselves about whether they wish to disclose. If you suspect intimate partner violence and the victim remains reluctant to discuss or disclose, let her/him know that should s/he need your assistance in the future, you are available. The goal is not to get the victim to admit to the problem, but to let her/him know that you are a resource should intimate partner violence ever be an issue for them.

PART IV

PREPARING YOUR CHILD HEALTH PRACTICE

PREPARING YOUR PRACTICE

PREPARING YOUR PRACTICE

Family Violence Prevention Fund

PART IV | PREPARING YOUR CHILD HEALTH PRACTICE

It is important that the practice or clinic setting be set up to support the staff in responding effectively and efficiently to disclosures of intimate partner violence. In preparing your practice to begin routine inquiry for and response to intimate partner violence, it is advisable to obtain support from the leadership and administration, as well as to solicit staff input.

Physical environment should:

- Allow for confidential interviewing
- Have posters on intimate partner violence that are multicultural and multilingual; that present available resources; and that include information about victims, perpetrators, and/or other family and community members affected by family violence
- Have brochures/pocket cards for victims and perpetrators and resources that describe the impact of intimate partners violence on children.
- Have brochures placed in exam rooms and private places such as bathrooms
- Patient materials should include: brochures, discharge instructions, safety planning handouts and referral information on services for on-site or off-site advocacy, counseling, and legal and other community-based services for child witnesses, victims, perpetrators and others affected by intimate partner violence

*(See **Appendix XII** for resources or www@endabuse.org/health for materials.)*

Training for staff should include:

- Short- and long-term developmental and behavioral effects of childhood exposure to domestic violence and child abuse
- Survivors' perspectives
- Cultural competency
- Dynamics of victimization and perpetration
- Skills building—how to assess, intervene supportively and document appropriately
- Interactive role playing and modeling of inquiry and response techniques
- Information on where employees in abusive relationships can access help

Training should be part of staff orientation; ongoing, repeated and institutionalized; and mandatory for all employees. Providers who will be assessing and documenting in the medical record should receive training on dynamics and clinical response. Other staff —including allied health professionals, receptionists and security, who can play an essential role in identifying and protecting victims and their children — should receive general awareness training on intimate partner violence. Interpreters in particular should be trained in advance about the dynamics of intimate partner violence, childhood exposure to violence, the importance of confidentiality and non-judgmental interpretation, and appropriate word choices for translation of routine assessment.

Protocols should include:

- Definitions, guiding principles, routine assessment, intervention and documentation strategies, reporting policies and confidentiality rules
- Roles and responsibilities of staff

All staff should receive an orientation on the protocol. It should also be updated regularly and informed by new knowledge, laws and policies regarding intimate partner violence. It should be accessible to all staff.

Continuous Quality Improvement (CQI) Program:

- Scheduled audits of medical records to review compliance with the protocol
- Patient satisfaction surveys
- Regular discussions during staff meetings regarding functioning of intimate partner violence program
- Links to other quality improvement efforts
- Links to medical information system developments
- CQI goals publicized

Provider resources should include:

- Chart prompts in the medical record
- Documentation and assessment forms
- Posters and practitioner pocket cards
- Materials that are easily accessible to providers and regularly updated
- Consultation with on-site or off-site domestic violence advocates, legal and forensic experts, counselors with expertise in trauma treatment, and community experts from diverse communities (LGBT, disability, elder, teen, and ethnic-specific, immigrant, and others)
- Feedback mechanisms for providers

Employee assistance or human resources programs (for large facilities) should:

- Address intimate partner violence victimization and perpetration
- Be confidential (within legal limits), easily accessible and well publicized
- Be incorporated into managerial training
- Include intimate partners violence information in employee publications and alerts

POSITION STATEMENTS FROM HEALTH PROFESSIONAL ASSOCIATIONS —EXCERPTS—

AMERICAN ACADEMY OF PEDIATRICS
COMMITTEE ON CHILD ABUSE AND NEGLECT

The Role of the Pediatrician in Recognizing and Intervening on Behalf of Abused Women (RE9748)

ABSTRACT. Pediatricians are in a position to recognize abused women in pediatric settings. Intervening on behalf of battered women is an active form of child abuse prevention. Knowledge of local resources and state laws for reporting abuse are emphasized.

The abuse of women is a pediatric issue. The American Academy of Pediatrics (AAP) and its membership recognize the importance of improving the physician's ability to recognize partner violence as well as child abuse and other forms of family violence.[1] Intervention is crucial because children whose mothers are being assaulted are also likely to be victims. Identifying and intervening on behalf of battered women may be one of the most effective means of preventing child abuse. [7]

Abuse of spouses and intimate partners is a pediatric issue even when children are not being physically assaulted. Pediatricians should be aware of the profound effects family violence has on children who witness it or even overhear it. Witnessing violence in the home can be as traumatic for children as being the victim of physical or sexual abuse. Children whose mothers are abused may experience serious emotional distress and manifest severe behavioral problems as a result.[6,8] Adolescents who observe abusive relationships at home may repeat that dynamic in dating or other relationships. (Men and older persons of both genders also can be victims of partner and intimate violence, but they are less likely to be seen in pediatric settings.)

Abused women are unlikely to seek care for their injuries from pediatricians. However, mothers of children seen by pediatricians may show signs of injury such as facial bruising. They may have other less obvious signs of abuse such as depression, anxiety, failure to keep medical appointments, reluctance to answer questions about discipline in the home, or frequent office visits for complaints not borne out by the medical evaluation of their child. Women may reveal the abuse to the pediatrician if they are questioned in a sympathetic and sensitive manner, in a confidential setting, away from the abuser, and provided some assurance of safety.

Questions about family violence should become part of anticipatory guidance. Pediatricians must understand the dynamics of abusive relationships. Excellent guidelines for managing situations of abuse have been published,[9-13] and pediatricians need to become familiar with them. There also are increasing numbers of continuing education opportunities available to learn intervention techniques.

Pediatricians should have a protocol or action plan that has been reviewed with local authorities on domestic violence. Because of time constraints in a busy office practice or emergency room setting, an interdisciplinary approach to family violence may be most appropriate. Pediatricians can call on nurses, social workers or advocacy groups with expertise in assisting and counseling victims. The AMA's 1996 Diagnostic and Treatment Guidelines on Domestic Violence state that optimal care for the woman in an abusive relationship depends on the physician's working knowledge of community resources that can provide safety, advocacy, and support. The AMA and many state medical associations provide directories of agencies that provide services or information about all forms of family violence.

Pediatricians can provide education to agencies that deal with battered women about the risk of primary and secondary abuse to children whose mothers are abused. Every effort should be made to secure counseling for children who have been exposed to family violence. Such treatment may be provided in groups or individually, but the focus should be on understanding violence and how to avoid it. There is increasing evidence that children who grow up with violence are prone to violent behavior themselves, and pediatricians are in a position to break the cycle.

THE AAP RECOGNIZES THAT FAMILY AND INTIMATE PARTNER VIOLENCE IS HARMFUL TO CHILDREN. THE AAP RECOMMENDS THAT:

1. Residency training programs and continuing medical education (CME) program leaders incorporate education on family and intimate partner violence and its implications for child health into the curricula of pediatricians and pediatric emergency department physicians;
2. Pediatricians should attempt to recognize evidence of family or intimate partner violence in the office setting;
3. Pediatricians should intervene in a sensitive and skillful manner that maximizes the safety of women and children victims; and
4. Pediatricians should support local and national multidisciplinary efforts to recognize, treat and prevent family and intimate partner violence.

American Academy of Child and Adolescent Psychiatry
This statement has been approved by the Council on Child and Adolescent Health.
The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

AMERICAN ACADEMY OF FAMILY PHYSICIANS-Violence (Position Paper)

Family violence permeates our society. It affects us as individuals, family physicians, parents, spouses, educators and citizens. The breadth of the problem is staggering. Public health officials identify family violence as a public health issue of epidemic proportions.

THE FAMILY PHYSICIAN'S ROLE

Family violence will affect at least one third of the patients cared for by family physicians, and the impact of family violence may become evident in the one-on-one relationship of the family physician and the patient. It is imperative that physicians be aware of the prevalence of violence in all sectors of society and be alert for its effects in their encounters with virtually every patient.

Violence against women will be the form of family violence most frequently seen in family practice. Physicians need to recognize that women who are victims of domestic violence will be patients in every family practice in this country because one in every four women has been a victim of domestic violence at some point in her life, and one in seven women has been victimized in the past year. Pregnancy confers no protection. In fact, abuse often begins or escalates during pregnancy. One in six pregnant women is abused during pregnancy and 17 percent of physical or sexual abuse of women occurs during pregnancy. One study reported abuse in 37 percent of obstetric patients and showed that class, race and educational level made no difference.

THE ROLE OF THE FAMILY PHYSICIAN IN THE IDENTIFICATION AND TREATMENT OF FAMILY VIOLENCE

Despite barriers to the diagnosis and treatment of victims of family violence, family physicians are in an ideal position to take on this challenge and are compelled to do so by the sheer magnitude of the problem. Family physicians are better able to identify those at risk because they are trained to care for the whole family and for the individual as a part of the larger community. Because of the continuity of care family physicians provide, they can gain patient confidence over time and can serve as sympathetic listeners and patient advocates. Family physicians can provide early intervention to break the cycle of violence through routine screening and the identification of abuse. They can help by teaching parenting skills and counseling patients on the stress of caring for children or elderly parents. Physicians can talk with women and men about their experiences of previous abuse and can be a central referral source for other resources in the community.

AAFP INITIATIVES TO DECREASE FAMILY VIOLENCE

Among activities for the American Academy of Family Physicians (AAFP) to consider are the following:

1. Developing or adapting teaching modules for members to present to medical students, residents, hospital staff and community groups;
2. Creating an ongoing education program for members on screening, recognition and treatment of violence, including distribution of the American Medical Association's guidelines for history-taking around issues of violence and abuse;
3. Supporting or developing university-, hospital- or office-based protocols and policies about family violence;
4. Publicizing to members the hot-line numbers for organizations that help physicians and

patients deal with abuse;
5. Offering continuing medical education for members to increase their skills in screening for, identifying and treating cases of domestic violence;
6. Participating in public policy initiatives and legislative reform to protect victims and rehabilitate batterers and partnering with other organizations committed to decreasing family violence;
7. Promoting reasonable and responsible control of firearms and other weapons.

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS

Division of Women's Health Issues, ACOG Educational Bulletin, No. 257, December 1999
Domestic Violence –

SCREENING AND IDENTIFICATION

Specific measures can be taken to improve identification and facilitate disclosure of domestic violence. A prefacing statement followed by a few simple, direct questions will identify most women with a history of abuse or assault. The introduction or preface should establish that screening is universal. The screening assessment should follow with direct questioning.

Children in violent homes should be evaluated by a professional who can assess the child's behavioral patterns and help the child address the emotional impact of the violence. Referrals to such resources are essential, because the victim may not be willing or able to do so on her own, especially if she fears removal of the child more than the violence.

Physicians or other health care workers who provide acute or chronic medical care to the older adult may see the older adult on a regular basis and have unique opportunities for screening and assessment. Additionally, an opportunity for screening and recognition exists during all health-related encounters of older individuals, such as routine gynecologic examinations.

SUMMARY

Many physicians, especially in the current managed care environment, are concerned that abuse screening and disclosure will require inordinate amounts of time, but with an established protocol and referral system this important problem can be managed. Screening all patients is the key to identifying abuse. With disclosure of ongoing domestic violence, the physician's responsibility should incude acknowledgement of abuse, making a safety assessment, assisting with a safety plan, providing appropriate referrals, documentation, and continued support. For disclosure of past violence, the responsibilities are similar but generally do not require immediate intervention. Women with a history of past victimization need to have that history identified and acknowledged and may need referral to other professionals to assist with the resolution of their trauma-related issues. Regardless of the types of victimization a woman has experienced, providing a safe setting in which she can discuss the problem and receive support is an important part of her recovery. Through these measures, the health care team can help abused women take the first steps toward ending the violence and achieving a healthy recovery.

APPENDIX III | ABSTRACTS OF SELECTED STUDIES ON PROVIDER AND PATIENT ATTITUDES

Knocking Down Walls: Barrier Myths to Screening for Violence in Primary Care

Marilyn Augustyn, Tracy Magee, Mary Duffy Pediatrics, Boston University School of Medicine, Boston, MA; Nursing, Boston College, Boston, MA

BACKGROUND: In 1998 the AAP in a policy statement recommended that "questions about domestic violence(DV) should become part of anticipatory guidance". Since that time, studies have shown that providers are hesitant to follow the recommendation. Barriers have been sited from child presence in the room to fear of offending parents.

OBJECTIVE: This study explored how frequently providers in an urban practice screened for DV, whether children's age and/presence in the room, length of time providers knew the family and how providers perceived parents response influenced screening.

DESIGN/METHODS: At baseline, 24 providers in an urban pediatric practice completed an interview about their current practices of screening for a child's exposure to violence. Over the following 4 weeks, they completed a form at the conclusion of well child care visits(children birth to 12 years) which covered several areas including whether they screened for DV and a Likert scale rating provider perceptions of parents' response to being asked these questions.

RESULTS: The providers were 16 residents, 6 attending pediatricians, 1 Nurse practicioner and 1 fellow. 84% reported they asked screening questions with the child in the room. During the 4 week period of the study, 60% of the providers reported that they screened for DV with 60% also reporting screening for community violence (CV). 93% of the time, providers asked these questions with the child in the room. Of these encounters, 78% were first visits with the family. Of the 22% that were repeat visits, 80% had known the family more than 6 months. 70% of the providers rated parent response as an 8 or higher on a 10 point scale (10 being most receptive). Controlling for child age and how long the provider knew the family, providers were more likely to screen when the child was older whether or not they had known the family previously.

CONCLUSIONS: Over 3 years after the statement was issued recommending universal screening for DV, providers continue to struggle with several barriers. In this pilot data of an urban practice, only 60% of visits were screened and these primarily were visits among older children. Interestingly, child presence in the room did not appear to be a barrier nor did parent response to the questions. Since the greatest risk for DV is often when children are less than 5 years of age, providers perhaps need to consider alternative methods to screen more effectively.

Maternal Screening for Domestic Violence during Pediatric Visits: Physicians' Practices and Perspectives

Linda Chamberlain, Ph.D. MPH

OBJECTIVES: Very little is known about how physicians respond to domestic violence in the pediatric setting. Our objectives were to examine physicians' maternal screening and intervention practices for domestic violence and to investigate perceived barriers to screening during child health care visits.

METHODS/DESIGN: A 17-question survey about current screening and intervention practices, training and perspectives on perceived screening barriers was conducted by mail.

SAMPLE STUDIED: All physicians practicing in Alaska who provided health care to children, age 18 or younger.

PRELIMINARY RESULTS: Surveys were completed by 393 (73%) of the 540 eligible physicians, including 208 family practitioners and general practitioners; 70 pediatricians and 48 emergency medicine physicians. Forty-nine percent of physicians had specific training on the effects of domestic violence on children. More than one-quarter (29%) estimated that 1 in 10 children in their practices had lived in a household with domestic violence. The majority of physicians screened often or always for domestic violence when the mother had signs of injury (88%) or when they suspected child abuse (95%). Routine screening was less common at initial pediatric visits (16%), well-child visits (11%), urgent care visits (31%), and when providing counseling/anticipatory guidance to mothers of newborn infants (16%). Commonly reported intervention strategies included providing information on victim services (87%), talking to the mother about safety concerns (81%), and talking to the child alone when appropriate (51%). The majority of physicians did not consider commonly perceived barriers such as inadequate training and concerns about child witness reporting requirements as major barriers to screening. Nearly all (98%) respondents agreed that witnessing domestic violence in an important health issue for children. Eighty-five percent of physicians agreed that they have a responsibility as part of their practice to screen mothers for domestic violence when providing health care to children. There was nearly total agreement (99.5%) among respondents that helping a mother who is being battered can make a difference in the lives of her children.

CONCLUSION: While physicians frequently screen mothers for domestic violence when there is evidence of maternal injury or suspected child abuse, opportunities to screen at other child health care visits are being missed. Most physicians agreed that domestic violence is an important children's health care issue that should be addressed in the pediatric setting. Many commonly perceived barriers to screening may not be predictive of physicians'maternal screening practices

Mothers' and health care providers' perspectives on screening for intimate partner violence in a pediatric emergency department

M. Denise Dowd, MD, MPH; Christopher Kennedy, MD; Jane F. Knapp, MD
From the Division of Emergency Medicine, Children's Mercy Hospital, Kansas City, MO
NOTE: This abstract with full article will be published in Archives of Pediatric and Adolescent Medicine, August, 2002. For full citation with pages send email to apam@u.washington.edu

OBJECTIVE: To determine the attitudes, feelings and beliefs of mothers and pediatric emergency department health care providers toward routine intimate partner violence screening.

METHODS: This qualitative project employed focus groups of mothers who brought their children to a children's hospital emergency department for care and physicians and nurses who staffed the same department. We held six ethnically homogeneous mother groups: two Caucasian, two African-American, two Latina and four provider groups: two predominately female nurse groups and two physician groups: one male and one female. Professional moderators conducted the sessions using a semi-structured discussion guide. All groups were audio- and videotaped and tapes were reviewed for reoccurring themes.

RESULTS: A total of 59 mothers, 21 nurses and 17 physicians participated. Mothers identified intimate partner violence as a common problem in their communities and most remarked that routine screening for adult intimate partner violence is an appropriate activity for a pediatric emergency department. However, many expressed concern that willingness to disclose might be affected by a fear of being reported to child protective services. They stressed the importance of addressing the child's health problem first, that screening be done in an empathetic way and that immediate assistance be available if needed. Themes identified in the provider groups included concerns about time constraints, fear of offending and concerns that unless immediate intervention was available the victim could be placed in jeopardy. Many said they would feel obligated to notify child protective services upon disclosure of intimate partner violence.

CONCLUSIONS: Intimate partner violence screening protocols in the pediatric emergency department should take into consideration the beliefs and attitudes of both those doing the screening and those being screened. Those developing screening protocols for a pediatric emergency department should consider:1) Those assigned to screen must demonstrate empathy, warmth and a helping attitude. 2) The importance of addressing the child's medical needs first and a screening process that is minimally disruptive to the emergency department. 3) A defined, organized approach to assessing danger to the child and how and when it is appropriate to notify CPS when a caregiver screens positive. 4) Resources must be available immediately to a victim who requests them.

Pediatrician's views on the treatment and preventions of violent injuries to children

LM Olson, KG O'Connor, H Spivak & MZ Esquivel, American Academy of Pediatrics, Elk Grove Village, IL.
(PERIODIC SURVEY OF FELLOWS, American Academy of Pediatrics, Division of Health Policy Research from PEDIATRIC ACADEMIC SOCIETIES , May 2001)

OBJECTIVE: To assess the portion of pediatricians treating violent injuries and their perceived capacity to address violence in the office setting.

DESIGN: National random sample, mailed survey.

PARTICIPANTS: 574 U.S. members of the American Academy of Pediatrics who provide direct patient care.

RESULTS: Many pediatricians report they treated (in the past 12 months) injuries due to child abuse (61%), domestic violence (43%) or community violence (45%). Substantial numbers of respondents believe that pediatricians should address, in the community and in practice, violence against children. However, while pediatricians generally feel confident about their skills in treating child abuse, they are less likely to feel adequately prepared to treat children at risk for domestic violence.

	Proportion of Pediatricians Indicating Agreement (%)		
	CHILD ABUSE	DOMESTIC VIOL.	COMMUNITY VIOL.
Are confident in ability to identify children at risk for.....	63.7	35.1	32.6
Are confident in ability to manage cases of.....	62.6	43.1	46.4
Have received adequate training in the area of.....	48.5	19.7	15.8

CONCLUSION: Injury from violence is a problem confronting large numbers of pediatric practices. The identified gaps can help shape new training programs and interventions to help practitioners address this critical risk to children.

Should Children Be in the Room When the Mother Is Screened for Partner Violence?

Zink, Therese MD, MPH
The Journal of Family Practice, © 2000 by Appleton & Lange. All rights reserved.
Volume 49(2) February 2000 pp 130-136

BACKGROUND: The goal of our study was to understand the important issues to consider when screening women for intimate partner violence in front of their children.

METHODS: Interviews and focus groups were conducted with experienced family physicians and pediatricians and family violence experts (child psychologists, social workers, and domestic violence agency directors). Session transcripts were coded and categorized.

RESULTS: Experts disagreed on the appropriateness of general screening for intimate partner violence in front of children older than 2 to 3 years. The majority thought that general questions were appropriate, if the in-depth questioning of the abused parent was done in private. Screening for child abuse when domestic violence is identified (and for domestic violence when child abuse is discovered) was recommended. Documentation about intimate partner violence in the child's medical chart raises questions about confidentiality, since the person committing the abuse may have access, if he or she is a legal guardian. Physicians need more education on the symptoms of children who are exposed to violence between adults.

CONCLUSIONS: More research is needed to understand appropriate questions and methods of screening for intimate partner violence in front of children. The tension is between practical recommendations for routine screening and preserving the safety of the parent and the children. Intimate partner violence screening by physicians is important. Interrupting the cycle of violence may give a child a better chance at maturing into a healthy adult.

APPENDIX IV | DILEMMAS WHEN ASSESSING ALL PATIENTS FOR VICTIMIZATION

Routinely assessing all parents and caretakers (both female and male) for IPV victimization raises additional policy and practice issues for providers and there is debate in the field about appropriate responses. Those opposed to these policies assert that the risks of alerting perpetrators to protocols identifying and assessing IPV outweigh the benefits. The concerns are that perpetrators may limit their partners' access to health care, may threaten victims who disclose, or may learn about safety planning materials which could ultimately undermine victim safety. Proponents of policies to assess men and women assert that, because men in same sex relationships experience DV at equal rates as women in heterosexual relationships, and some men in heterosexual couples experience abuse, it is critical to identify and assist as many victims as possible. Proponents also argue that determined perpetrators can already access safety planning materials and that assessing all patients offers unparalleled opportunities for abuse prevention. Still others maintain that because the majority of IPV victims are women, providers should begin by assessing all female patients and integrate inquiries for men as a second step, after gaining more experience in screening for victimization and developing policies to address some of the difficult practical concerns that are raised when assessing all parents and caretakers. Providers and health facilities should consider the dilemmas and recommendations listed below as they develop their unique protocols.

DILEMMAS:

It may be difficult to assess who the victim is. The accounts of one or both parties may lead to significant confusion about the incident.

- Male perpetrators often claim victimization to avoid consequences or as a tactic to further control victims.[69] Because of the majority of IPV perpetrators are male, assessing men increases the likelihood of assessing perpetrators who may claim they are victims. There is not sufficient experience with female perpetrators of violence to know if this is also true in with female batterers.
- Victims may take the blame for the abuse because they have been told repeatedly by their partners that the problems in the relationship are their fault or because they used violence or other tactics in self-defense.
- Both parties may use physical force in an incident.

Whether the patient is viewed as a victim or perpetrator will influence the health care providers' response and may lead to inappropriate treatment.

- A victim who takes the blame for the abuse might prevent providers from offering them support and information about IPV
- Perpetrators who falsely claim they are victims might lead providers to sharing safety-planning strategies with perpetrators, inadvertently colluding with them and

undermining victims' safety planning efforts.
- What is recorded in the medical record by the health care provider can have legal ramifications for the victim particularly in divorce, custody or other legal cases.

While it is not the role of the health care provider to determine if the patient is telling the truth, the provider should take care in evaluating the patient's information and in identifying whether or not she/he is a victim of IPV, just as they take care in evaluating other patient's reports of health concerns. Understanding the definition of IPV and being skilled in behavioral inquiry assists providers in making accurate identification of victimization.

RECOMMENDATIONS FOR POLICY IMPLEMENTATION:

The Family Violence Prevention Fund recommends that providers implement policies to assess all male and female parents for victimization only after taking precautions to protect victims whose perpetrators claim to be abused. Training providers on perpetrator dynamics and responses to gay, lesbian and straight victims is critical for all IPV programs, including those that target women only. When implementing a policy to assess all patients, first:

- Contact local DV programs (and batterer's intervention programs that they recommend) and explain that you are considering a plan to assess all patients for victimization. This will prepare them for referrals and will give them an opportunity to inform the development of your protocol.
- Inform all patients that you assess men and women for victimization and make safety planning materials available to both, so that victims who are concerned about perpetrators sabotaging their safety plan efforts can plan accordingly. Make information available about advocates on-site or in the community that can help the victim with these plans, regardless of whether the victim discloses abuse.
- Understand and conduct training on the IPV prevalence studies. Emerging research demonstrates that IPV occurs at similar rates in LGTB adolescent and adult populations[70] with higher rates in male same sex relationships than female.[71] Most studies indicate that about 5-10%[72] of all victims are men (an unknown percentage of whom are gay). Because of this, you should expect to see a fairly small percentage of heterosexual male victims in your practice – but should be prepared to respond to all victims.
- Understand and conduct training on the dynamics of IPV: IPV serves the purpose of establishing power and control through various tactics. This establishment of an abusive imbalance of power and control is fundamentally what distinguishes IPV perpetrators from victims. There are multiple indicators of abusive behavior (denying access to friends/family, intimidation, etc) not just physical abuse, and victims' lives generally become more limited and controlled.

Recommendations for Clinical Practice:

- Do not blame patients or force them to prove their "victimhood."
- Assessments should be handled sensitively and without bias.
- Even if you are unsure if your patient is a victim, document that you inquired, the patients' response, and note the details of the abuse and health consequences. Offer the patient educational materials about IPV and referrals.

HEALTH CARE PROVIDER RESPONSE TO GAY, LESBIAN AND HETEROSEXUAL MALE VICTIMS

Lesbian, Gay Bisexual and Transgendered victims of abuse:

Emerging research demonstrates that IPV occurs at similar rates in LGTB adolescent and adult populations as in heterosexual populations[vii] with higher rates in male same sex relationships than female[viii]. However, it is important to realize that the statistics may be low because those in a same sex relationships may not be comfortable stating their sexual preference. A policy to assess all patients should include specific recommendations for responding to lesbian, gay bisexual, and transgendered (LGBT) victims. Specialized services may be limited in your area so, when unavailable, refer patients to national organizations or the National Domestic Violence Hotline.

PRIOR TO IMPLEMENTING A PROGRAM TO ASSESS ALL PATIENTS, IT IS IMPORTANT TO:

- Beware of your own bias and/or homophobia
- Call your local IPV program and determine what resources are available for lesbian, gay, bisexual and transgendered clients
- Call any local programs for LGBT communities and determine what resources they offer for victims of IPV
- In addition (or if no programs exist in your area), provide LGBT victims with the national DV hotline number for more information or materials.
- Have educational and safety materials available that are appropriate for LGBT victims (for materials, go to the FVPF website www.endabuse.org/health)
- Refer gay male victims of IPV to Community United Against Violence (San Francisco), Gay Men's Domestic Violence Project (Boston) or other organizations for information and support *(See **Appendix XII**).*

[vii] Bureau of Justice Statistics Special Report, Intimate Partner Violence and Age of Victim, 1993-99, United States Department of Justice, October 2001.

[viii] Morrow, Jeanie (April 1994). Identifying and treating battered lesbians. San Francisco MedicineLetellier, Patrick (April 1994). Identifying and treating battered gay men in a medical setting. San Francisco Medicine. Goodenow, Carol. (1998). 1997 Massachusetts Youth Risk Behavior Survey. Malden, MA: Massachusetts Department of Education. Renzetti, C. Violent Betrayal: Partner Abuse in Lesbian Relationships. Sage Publications. 1992, 18.

- Refer lesbian victims to the Network for Battered Lesbians and Bisexual Women (Boston), Anti-Violence Project and/or other local organizations for information and support *(See **Appendix XII**).*

Heterosexual Male Victims

There is limited research on male victims of IPV in heterosexual relationships. Most major studies on male victimization do not clarify if male victims are in gay or heterosexual relationships. However, a policy to assess all patients should include specific recommendations for responding to heterosexual male victims. Services for male victims may be very limited in your area, so be prepared to refer patients to national or international programs and the National Domestic Violence Hotline. Prior to implementing a program it is important to:

- Be aware of your own bias regarding heterosexual male victims of abuse.
- Call your local DV program and learn about their policy on heterosexual male victims
- Refer patients to any local programs available, the National Domestic Violence Hotline or other resources including:www.vix.com/menmag/batamen.htm.
- Have gender neutral educational materials available about abuse or refer patients to the websites listed in Appendix VIII for more educational materials for battered men.

APPENDIX V | INDICATORS OF ABUSE

Many victims of IPV will talk about their experiences if asked to do so in a sensitive and empathetic way. However, other victims may be reluctant to disclose. They may be embarrassed, ashamed, or afraid that if they tell anyone they may be at risk for more severe abuse. There may be financial issues and/or concerns about immigration status, or they may lack trust in people because trust was violated in their intimate relationship. Below are some of the reasons one might suspect IPV and might ask follow-up questions.

For Adults

- Failure to keep medical appointments, or comply with medical protocols
- Secrecy or obvious discomfort when interviewed about relationship
- The presence of a partner who comes into the examining room with the patient and controls or dominates the interview, is overly solicitous and will not leave the patient alone with her/his provider
- The patient returns repeatedly with vague complaints
- A patient who presents with health problems associated with abuse
- Unexplained injuries or injuries inconsistent with the history given
- Somatic complaints
- Delay between an injury and seeking medical treatment
- Injury to the head, neck, chest, breasts, abdomen, or genitals
- Bilateral or multiple injuries, especially if in different stages of healing
- Physical injury during pregnancy, especially on the breasts and abdomen
- Chronic pain without apparent etiology
- An unusually high number of visits to health care providers
- High number of STI's, pregnancies, miscarriages, and abortions repeat vaginal and urinary tract infections.

*(See **Appendix VI** for others)*

For Children and Adolescents

All of the applicable health problems listed above as well as:

- Age inappropriate injuries, burns, injuries to the genital areas
- Developmental & behavioral problems
- Psychological distress such as depression, suicidal ideation or attempts, attachment problems, anxiety, sleeping and/or eating disorders, panic attacks, symptoms of PTSD, and substance use/abuse problems

If you see any of these indicators, or if you suspect abuse, yet the patient remains reluctant to discuss or disclose, provide the patient with a hotline number and other resources in case they need them in the future. Let the patient know that should s/he ever need it, you are available as a resource. Bring the issue up during the next visit. The goal is not to force the victim to admit to a problem, but to try and anticipate his/her concerns about disclosure and to let her/him know that you can be a resource should this ever be a problem. Encourage her/him to return and schedule a follow-up visit within a short time.

APPENDIX VI | EXPANDED ASSESSMENT FOR VICTIMS OF DOMESTIC VIOLENCE

Assessment time will vary with the severity of the abuse, the readiness of the domestic violence victims to discuss it and time available with the provider. Unless the patient is in crisis, the assessment can be conducted over time. Expanded health assessments can include assessment of associated health problems and/or expanded assessment of the abuse. Provide the victim an opportunity to talk with someone else from the community who is trained on IPV if they are uncomfortable speaking with the provider. These assessments can occur in primary care, ob/gyn, mental health settings or in any setting where a trained health care provider, social worker, or advocate can conduct the assessment in private.

Expanded Assessment of Related Health Problems

A positive identification for lifetime or current exposure to IPV should trigger expanded health assessment (either by the provider who identified the patient or a specialist to whom the patient is referred). Consider and address the following areas:

- Health issues related to IPV: injuries, chronic pain (neck, back, pelvic migraines) peptic ulcers, irritable bowel syndrome, STI's (including HIV/AIDS), insomnia, vaginal and urinary tract infections, multiple pregnancies, miscarriages and abortions
- Substance abuse by the patient: (such as tobacco, alcohol, or others)
- Ability to manage other illnesses (such as hypertension, diabetes, asthma, HIV/AIDS)
- Mental health problems: depression, PTSD, anxiety, stress, suicide risk
- If pregnant: pregnancy complications such as miscarriages, low weight gain, anemia, infections, first and second trimester bleeding, and low birth weight babies
- If forced sex occured: assess for gynecological problems including STI's, anal/vaginal tearing, sexual dysfunction, and ask about safe sex practices and family planning
- If choking/head injury and the patient was unconscious: conduct a neurological exam
- Particularly for teens: Assessment of exposure to dating violence or forced use of drugs such as Rohypnol (RH) "rophies", GHB (Gama Hydroxybutyric acid) etc.
- Preventive health behaviors: encourage and help facilitate preventive health behaviors: such as regular mammography, pap smears, early pre-natal care, etc.

Expanded assessment of the history and extent of the abuse

- Discussion of childhood history of abuse in family of origin
- Discussion about whether abuser is limiting access to friends, family or co-workers
- Assessment of supports in place including friends, family, community, church, etc.
- Discussion of separation, divorce, or seeking shelter
- Assessment of the victim's community's response to abuse, marriage, divorce, health and healing, and find out how the victim responds to cultural expectations
- Assessment of how the abuse has affected the children (physically, emotionally, etc.)
- Assessment of how abuse affected her/his life, work, school, and relationships
- Assessment of whether threats have been made, or violence has been carried out against the family pet(s).

EXPANDED ASSESSMENT FOR VICTIMS OF DOMESTIC VIOLENCE

Questions about the batterer

- Does the batterer use illicit drugs and/or alcohol? How much? How often?
- Does batterer increase his/her violent behavior when under the influence?
- Does the batterer have any mental health problems?
- Is the batterer taking medications, if so what?
- Does the batterer have a criminal record?

Suicide and Homicide Assessment Questions

To assess the risk for victim's homicidal and suicidal ideation follow:

RISK OF SUICIDE BY THE VICTIM

- Have you ever felt so bad that you didn't want to go on living?
- Have you ever attempted or thought about suicide in the past?
- Are you thinking about killing yourself? Do you have a plan?
- Do you feel this way now?

RISK OF HOMICIDAL THOUGHT BY THE VICTIM

- How do you perceive your options for safety?
- Have you ever attempted or thought about homicide in the past?
- Have you thought about how you would do it? Do you have a homicide plan?
- Assess if the patient is expressing anger or a genuine intent to kill.

If there is significant risk of suicide or homicidal ideation the patient should be kept safe until emergency psychiatric evaluation can be obtained.

APPENDIX VII | SAFETY PLAN AND INSTRUCTIONS

SAFETY PLAN FOR ADULT VICTIMS LIVING WITH THEIR ABUSERS

STEP 1: Safety during a violent incident. I can use some or all of the following strategies:

A. If I have/decide to leave my home, I will go _____

B. I can tell _____ (neighbors) about the violence and request they call the police if they hear suspicious noises coming from my house.

C. I can teach my children how to use the telephone to contact the police.

D. I will use _____ as my code word so someone can call for help.

E. I can keep my purse/car keys ready at (place) _____ , in order to leave quickly.

F. I will use my judgment and intuition. If the situation is very serious, I can give my partner what he/she wants to calm him/her down. I have to protect myself until I/we are out of danger.

STEP 2: Safety when preparing to leave. I can use some or all of the following safety strategies:

A. I will keep copies important documents, keys, clothes and money at _____.

B. I will open a savings account by _____ , to increase my independence.

C. Other things I can do to increase my independence include: _____ .

D. I can keep change for my phone calls on me at all times. I understand that if I use my telephone credit card, the telephone bill will show my partner those numbers that I called after I left.

E. I will check with _____ to see who would be able to let me stay with them or lend me some money.

F. If I plan to leave, I won't tell my abuser in advance face-to-face, but I will call or leave a note from a safe place.

STEP 3: Safety in my own residence. Safety measures I can use include:

A. I can change the locks on my doors and windows as soon as possible.

B. I can replace wooden doors with steel/metal doors.

C. I can install additional locks, window bars, poles to wedge against doors, and electronic systems etc.

D. I can install motion lights outside.

E. I will teach my children how to make a collect call to _____ if my partner takes the children.

F. I will tell people who take care of my children that my partner is not permitted to pick up my children.

G. I can inform _____ (neighbor) that my partner no longer resides with me and they should call the police if he is observed near my residence.

STEP 4. Safety with a protection order. The following are steps that help the enforcement of my protection order.

A. Always carry a certified copy with me and keep a photocopy.

B. I will give my protection order to police departments in the community where I work and live.

C. I can get my protection order to specify and describe all guns may partner may own and authorize a search for removal.

SAFETY INSTRUCTIONS

If you are currently being abused...

Are you here as a result of someone hitting or threatening you—a spouse, boyfriend, lover, relative or someone you know? Have you been sexually abused by someone you know? As you read this, you may be feeling confused, frightened, sad, angry or ashamed. **You are not alone!** Unfortunately, what happened to you is very common. Domestic violence does not go away on its own. It tends to get worse and more frequent with time. There are people who can help you. If you want to begin talking about the problem, need a safe place to stay or want legal advice—call one of the agencies listed on the back of this instruction sheet today.

While still at the clinic...

- Think about whether it is safe to return home. If not, call one of the resources listed on the back of this instruction sheet or stay with a friend or relative.
- You have received instructions on caring for your injuries and taking medications prescribed. Remember, if you have received tranquilizers they may help you rest but they won't solve the problem of battering.
- Battering is a crime and you have the right to legal intervention. You should consider calling the police for assistance (see information on back of this sheet). You may also obtain a court order prohibiting your partner from contacting you in any way (including in person or by phone). Contact a local DV program or an attorney for more information.
- Ask the doctor or nurse to take photos of your injuries to become part of your medical record.

When you get home...

- Develop an "exit plan" in advance for you and your children. Know exactly where you could go even in the middle of the night—and how to get there.
- Pack an "overnight bag" in case you have to leave home in a hurry. Either hide it yourself or give it to a friend to keep for you.
- Pack toilet articles, medications, an extra set of keys to the house and car, an extra set of clothing for you and your children, and a toy for each child.
- Have extra cash, loose change for phone calls, checkbook, or savings account book hidden or with a friend.
- Pack important papers and financial records (the originals or copies), such as social security cards, birth certificates, green cards, passports, work authorization and any other immigration documents, voter registration cards, medical cards and records, drivers license, rent receipts, title to the car and proof of insurance, etc.
- Notify your neighbors if you think it is safe

APPENDIX VIII

INTIMATE PARTNER VIOLENCE VICTIMIZATION REPORTING REQUIREMENTS: HOW IT AFFECTS CHILD HEALTH SETTINGS

Most states have enacted mandatory reporting laws, which require the reporting of specified injuries and wounds, suspected abuse or domestic violence for individuals being treated by a health care professional, or who come before the health care facility.[ix] Mandatory reporting laws are distinct from elder abuse or vulnerable adult abuse reporting laws,[x] in that the individuals to be protected are not limited to a specific class, but pertain to all individuals[xi] whom the health care professional provides treatment or medical care to, or who come before the health care facility.

The elements that trigger these reports vary, from specific injuries such as gunshot and stab wounds to more broadly described "wounds indicating violence." With few exceptions, these reporting laws were not passed with domestic violence in mind. However, as the health care community became more aware of domestic violence, many asked how mandatory reporting laws should be applied in cases of domestic violence.

THE LAWS VARY FROM STATE TO STATE, BUT GENERALLY FALL INTO FOUR CATEGORIES:

1. States that require reporting of injuries caused by weapons;
2. States that mandate reporting for injuries caused in violation of criminal laws, as a result of violence, or through non-accidental means;
3. States that specifically address reporting in domestic violence cases;
4. States that have no general mandatory reporting laws.

In a majority of states, existing laws would most likely not apply in those cases when a child health provider is treating a child and screening the child's parent for domestic violence. In the pediatric visit where the parent is not the patient and not seeking treatment, the clinician is generally under no legal obligation to report because the parent does not fall within the purview of the reporting law. However, for family physician visits, the case may be more complicated. The parent may be a patient of the provider, even though she is not seeking treatment during the particular visit. Additionally, if the child is also presenting with injuries, child abuse reporting laws may require the physician to report.

(See page 13: When does child exposure to intimate partner violence become child abuse?)

[ix] Different states have different reporting requirements of various health care professionals, and various health care facilities. Because the differences vary widely, we do not include them in this paper. Please be sure to consult your state law and/or local expert for further information on reporting requirements in your state. A list of the specific codes can be found in Appendix VII.

[x] Elder abuse or vulnerable adult abuse reporting laws seek to protect a specific class of individuals being treated, i.e. the elderly, or mentally or physically incapacitated individuals.

[xi] Please note that all states with general mandatory reporting laws except for California, Georgia, Kentucky, and Wisconsin use the term "person(s)" in the text of the law. Georgia, California, and Wisconsin use the term "patient." Kentucky's general mandatory reporting law is an exception, as it uses the term "adult," rather than "person(s)" or "patient."

Appendix VIII

INTIMATE PARTNER VIOLENCE VICTIMIZATION REPORTING REQUIREMENTS

There has been much debate about the benefit of mandatory reporting of domestic violence by health care providers. Most advocates and providers support state laws that require reports to law enforcement only in the case of gunshot or other potentially life-threatening assault. However, several laws require reports of any domestic violence assault, regardless of severity or victim preference. The intended goals of these laws include assisting officers in solving crimes, enhancing patient safety, holding batterers accountable, and improving domestic violence data collection and documentation. Opponents argue that there are serious risks created by these laws, including unintentionally endangering victims, deterring victims who do not want or need police involvement from seeking medical care, and reducing victim autonomy, control, and ability to plan for safety for herself and her children.

Providers should know their state's domestic violence reporting law, including who is required to report, and under what conditions. (***Appendix IX*** contains a chart listing state codes). In order to maximize patient input regarding law enforcement action, providers should also familiarize themselves with how their local law enforcement agency responds to such reports. Becoming familiar with such procedures will also allow the provider to better assist the patient in safety planning, and in knowing what to expect. Additionally, recent federal privacy regulations require providers to inform patients of health information use and disclosure practices in general, and whenever a specific report has been made. Health care facilities should also ensure that their domestic violence protocols and training materials address their state reporting laws and federal regulations.

How do mandatory reporting laws apply to the pediatric and family practice setting?

In the vast majority of states, neither statutory nor case law specifies when or if a health care provider must report a parent's injuries if they are observed or discovered during a health care visit with that parent's child. Therefore, under a strict reading of most laws, if a child's health care provider is not providing treatment or medical care to the abused parent during the child's visit, the health care provider would not be required to make a report. In family practice situations where the child and parent are the provider's patients, and the current visit appointment is for the child, the same reasoning could be applied, although it is less clear-cut. That is, the health care provider would not be required to report since he or she is not treating the parent for the specified injuries during the appointment. This issue merits further discussion among health care providers, advocates, licensing authorities, and other professionals, as it is uncharted territory.

INTIMATE PARTNER VIOLENCE VICTIMIZATION REPORTING REQUIREMENTS

Georgia, Kentucky, and Ohio[xii] require reports when a provider believes that an individual has suffered certain injuries, or observes such injuries, but is not necessarily providing treatment or medical care. Since these laws do not specifically require that the individual must be seeking treatment or medical care in order to trigger the reporting requirement, a parent with visible injuries accompanying a child to a child health appointment may fall within the class of individuals the statutes apply to, and reporting would be required.

There are also two states that do not fit either category of laws: Michigan and Pennsylvania. In both of these states, the laws do not mention whether the physician must be providing treatment or medical care in order to trigger the reporting requirement. Additionally, the laws do not contain any language regarding a physician's belief or observance of the specified injuries. Thus, practitioners in these states should consult a local expert regarding further interpretation of these laws.

[xii] The Family Violence Prevention Fund opposes laws that specifically mandate health care providers to report all injuries, including those that may not be serious, to law enforcement or to any other authorities. See the paper entitled Mandatory Reporting of Domestic Violence by Health Care Providers: A Policy Papef (November, 1997), prepared by Ariella Hyman for the Family Violence Prevention Fund (FVPF), published by the FVPF: (415) 252-8900.

APPENDIX IX

STATE CODES ON INTIMATE PARTNER VIOLENCE VICTIMIZATION REPORTING REQUIREMENTS FOR HEALTH CARE PROVIDERS[xiii]

Current through March 8, 2002

			IF ANY OF THE FOLLOWING TYPES OF INJURIES ARE PRESENT, PRACTITIONERS IN THE STATE MUST MAKE A REPORT:								
	Code Number	States with General Mandatory Reporting Laws	Injuries Resulting from Domestic Violence or Abuse	Injuries Resulting from Criminal Activity	Injuries Resulting from General Violence	Intentionally Inflicted Injuries	Injuries Inflicted by Gun or Firearm	Injuries Inflicted by Knife or Other Sharp Object	Burn Injuries	Injuries Likely to Cause Death	Treatment of Specified Injuries Requires Practitioners to Report[xiv]

[xiii] This document is intended to provide a cursory overview of mandatory reporting laws. Please be sure to consult the complete set of mandatory reporting laws in your state for further information. If you note any changes or errors on this document, please contact the FVPF at 415-252-8900.

[xiv] Under a strict reading of these laws, practitioners must be providing treatment or medical care to the person with specified injuries in order to trigger the reporting requirement. Therefore, in a pediatric or family practice setting, if an attending parent with injuries is bringing her child in for a health care appointment, the attending parent is not actually receiving treatment or medical care from the practitioner, and thus the practitioner in the state would not be required to report. Further discussion is merited, given the lack of statutory or case law that have been developed around this area.

[xv] The law provides an exception to reporting if the patient is over the age of 18, did not suffer a gunshot wound, and does not consent to reporting.

[xvi] Report is made for medical data collection purposes only, and does not contain identification information.

APPENDIX X

LEGISLATION REGARDING CHILD WITNESSES TO DOMESTIC VIOLENCE

The following introduction was taken in part from Child Abuse and Neglect State Statutes Series Compendium of Laws:

CHILD WITNESS TO DOMESTIC VIOLENCE, 2002

Approximately 20 States and Puerto Rico have enacted legislation that specifically includes children who witness acts of domestic violence as a class of persons in need of legal protection. The majority of these States provide enhanced criminal penalties for the commission of domestic violence offenses in the presence of a child. Other States mandate counseling for child witnesses, allow courts to find a child witness in need of aide, require supervised visitation for such behavior, presume that a child witness many have sustained physical injury for purposes of restitution and consider such conduct an aggravating factor for courts to consider in sentencing. Although there is great variation across States as to the particular requirements imposed by this legislation, these statutes share common elements. The Statutes generally define which particular children are protected under the legislation, the meaning of "in the presence of a child," those actions that constitute domestic violence and whether one witnessing incident is sufficient or exposure to repeated incidents is required.

NATIONAL COUNCIL OF JUVENILE AND FAMILY COURT JUDGES, FAMILY VIOLENCE DEPARTMENT provides technical assistance to those working in the field of domestic violence and child protection and custody. The Resource Center identifies and develops model policies, protocols, and programs that are sensitive to the legal, cultural and

psychological dynamics of child protection and custody cases involving family violence. P.O. Box 8970, Reno, Nevada 89507 phone: (800)527-3223 email: www.ncjfcj.org/dept/fvd

NATIONAL NETWORK TO END DOMESTIC VIOLENCE THE NATIONAL NETWORK TO END DOMESTIC VIOLENCE is a membership and advocacy organization of state domestic violence coalitions, allied organizations and supportive individuals and is a leading voice among domestic violence advocates in public policy. website: *www.nnedv.org*

SACRED CIRCLE: THE NATIONAL RESOURCE CENTER TO END VIOLENCE AGAINST NATIVE WOMEN. Dedicated to the Actions that promote the Sovereignty and Safety of Women. 722 St. Joseph St. Rapid City, SD 57701 (605) 341-2050. 1 (877) RED-ROAD (733-7623)

ASIAN & PACIFIC ISLAND INSTITUTE ON DOMESTIC VIOLENCE: Strives to eliminate domestic violence in Asian and Pacific Islander communities by increasing awareness about the extent and depth of the problem making culturally specific issues visible; strengthening community models of prevention and intervention; identifying and expanding resources; informing and promoting research and policy and deepening understanding and analysis of the issues surrounding violence against women. 942 Market Street, Suite 200, San Francisco, CA 94102 (415) 954-9964 (p) (415) 954-9999 (f) website: *www.apiahf.org*

INSTITUTE ON DOMESTIC VIOLENCE IN THE AFRICAN AMERICAN COMMUNITY: Provides an interdisciplinary vehicle and forum by which scholars, practitioners, and observers of family violence within the African American community will have the continual opportunity to articulate their perspectives on family violence through research findings, the examination of service delivery and intervention mechanisms, and the identification of appropriate and effective responses to prevent/reduce family violence in the African American community. 290 Peters Hall 1404 Gortner Avenue St. Paul, MN 55108-6142 (p) (877) NID-VAAC (643-8222) Fax (612) 624-9201 website: *www.dvinstitute.org*

NATIONAL LATINO ALLIANCE FOR THE ELIMINATION OF DOMESTIC VIOLENCE A network of nationally recognized Latina and Latino advocates, community activists, practitioners, researchers, and survivors of domestic violence working together to promote understand, sustain dialogue, and generate solutions to move toward the elimination of domestic violence in Latino communities, with an understanding of the sacredness of all relations and communities. P.O. Box 322086 Fort Washington New York, NY 10032 Tel (800) 342-9903 Fax (800) 216-2404. website: *www.dvalianza.org*

CLINICAL MATERIALS FOR THE HEALTH CARE SETTING

THE NATIONAL HEALTH RESOURCE CENTER ON DOMESTIC VIOLENCE a project of the FVPF, provides support to thousands of health care professionals, policy makers and domestic violence advocates through its four main program areas: model training strategies,

practical tools, technical assistance, and public policy. phone: (888) Rx-ABUSE fax: (415) 252-8991 e-mail: *health@endabuse.org* website: *www.endabuse.org/health*

THE CHILD WITNESS TO VIOLENCE PROJECT AT BOSTON MEDICAL CENTER provides mental health services to young children exposed to violence. Staff also provide training and technical assistance to a wide range of professionals working with young children and families affected by violence and have published a training curriculum for mental health professionals and victim advocates: "Shelter from the Storm: Clinical Intervention with Young Children Affected by Domestic Violence". For more information, call (617) 414-4244. The project website is *www.bostonchildhealth.org/special/CWTV/overview.html*

ALASKA FAMILY VIOLENCE PREVENTION PROJECT specializes in training for health care and service providers, have articles, curricula in PowerPoint that can be downloaded, run a clearinghouse of education materials. website: http://*www.hss.state.ak.us/dph/chems*

HOWARD S. KING, MD, MPH AND MELINDA STRAUSS, ACSW, LISCW authors of Routine Screen for Domestic Violence in Pediatric Practice written to help pediatricians and family practitioners become aware of the problem of domestic violence and to consider screening for it during the routine office visit. View or download this publication at *www.drkingsoffice.com*

THE INSTITUTE FOR SAFE FAMILIES' (ISF) mission is to prevent family violence and to offer an alternative vision for wholeness, healing, family health, and personalempowerment. ISF is conducting a Philadelphia area initiative to address domestic violence within the pediatric setting and has developed a pocket card on what to do, with a variety of materials in development. ISF, 3502 Scotts Lane, Philadelphia, PA 19129, (215) 843-2046, website: *ISF2002@aol.com*

Websites of Interest for Adolescents

THE EMPOWER PROGRAM works with youth to end the culture of violence. 1312 8th Street, Washington, DC 20001 phone: (202) 882-2800 fax: (202) 234-1901 e-mail: *empower@empowered.org* website: *www.empowered.org*

GIRLS INCORPORATED NATIONAL RESOURCE CENTER is a national youth organization dedicated to inspiring all girls to be strong, smart and bold. 441 West Michigan Street, Indianapolis, IN 46202 phone: (317) 634-7546 fax: (317) 634-3024 e-mail: *girlsinc@girls-inc.org* website: *www.girlsinc.org*

LIZ CLAIBORNE INC. produces "A Teen's Handbook" and web pages to help teens learn about dating violence by providing facts, guidance and resources. To order a free handbook, phone: (800) 449-STOP (7867) website: *www.lizclaiborne.com/lizinc/lizworks/women/handbook.asp#teen*

LESBIAN, GAY, BISEXUAL, TRANSGENDERED, QUEER (LGBTQ)

COMMUNITY UNITED AGAINST VIOLENCE (CUAV) is a 20-year old multicultural organization working to end violence against and within lesbian, gay, bisexual, transgender and queer/questioning (LGBTQ) communities. 973 Market St., #500, San Francisco, CA 94103 phone: (415)777-5500 Fax: (415)777-5565 24 Hr. Support Line: (415) 333-HELP (4357) e-mail: *cuav@aol.com* website: *www.cuav.org*

PARENTS, FAMILIES, AND FRIENDS OF LESBIANS AND GAYS (PFLAG) is a national organization that promotes the health and well-being of gay, lesbian, bisexual and transgendered persons, their families and friends. Their Web site provides users with information on local chapters, advocacy and support information and other resources that support the family and friends of gays and lesbians. 1726 M Street, NW, Suite 400, Washington, DC 20036 phone: (202) 467-8180 fax: (202) 467-8194 e-mail: *info@pflag.org* website: *www.pflag.org*

GAY MEN'S DOMESTIC VIOLENCE PROJECT is a grassroots, non-profit organization in Boston providing community education and direct services for clients. GMDVP offers shelter, guidance, and resources to allow gay, bisexual, and transgender men in crisis to remove themselves from violent situations and relationships GMDVP, PMB 131, 955 Mass Ave. Cambridge, MA 02139 Fax: 617 354 6072, Bus: (617) 354-6056 Crisis: (800) 832-1901 website: *www.gmdvp.org* 1-800-832-1901.

NETWORK FOR BATTERED LESBIANS AND BISEXUAL WOMEN. The Network/La Red was formed to address battering in lesbian, bisexual women's, and transgender communities. Through a) the formation of a community-based multi-cultural organization in which battered/formerly battered lesbians, bisexual women, and transgender folks hold leadership roles; b) community organizing, education, and the provision of support services, we seek to create a culture in which domination, coercion, and control are no longer accepted and operative social norms. The Network POB 6011 Boston, MA 02114. Office (v/tty) (617) 695-0877. Hotline (v/tty)(617) 423-7233. website: *www.thenetworklared.org*

TEEN PREGNANCY

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS (ACOG) has a membership of 40,000 physicians and is the nation's leading group of professionals providing health care for women. ACOG's website provides adolescent sexual assault screening tools as well as other teen pregnancy materials. To request free copies of their educational bulletins, call: (202) 638-5577 or e-mail: *violence@acog.org*. ACOG, 409 12th Street, SW, PO Box 96920 Washington, DC 20024. phone: (202) 863-2487 fax: (202) 484-3917 e-mail: *adolhlth@acog.org* website: *www.acog.org*

SEXUAL ASSAULT

CENTER FOR THE PREVENTION OF SEXUAL AND DOMESTIC VIOLENCE is an interreligious educational resource addressing issues of sexual and domestic violence whose goal is to engage religious leaders in the task of ending abuse, and to serve as a bridge between religious and secular communities. 936 North 34th St., Suite 200, Seattle, WA 98103 phone: (206) 634-1903 fax: (206) 634-0115
e-mail: *cpsdv@cpsdv.org* website: *www.cpsdv.org*

RAPE ABUSE & INCEST NATIONAL NETWORK (RAINN) *(see **"Hotlines"** for further info)*

SEXUAL ASSAULT RESOURCE SERVICE (SARS) is designed for nursing professionals involved in providing evaluations of sexually abused victims. SARS' website provides information and technical assistance to individuals and institutions interested in developing new SANE-SART programs or improving existing ones. website: *www.sane-sart.com*

ANIMAL CRUELTY AND FAMILY VIOLENCE

THE HUMANE SOCIETY OF THE UNITED STATES, through its First Strike campaign, is dedicated to raising public and professional awareness about the connection between animal cruelty and family violence. 2100 L Street, NW, Washington, DC 20037 phone: (301) 258-3076; toll-free (888) 213-0956 fax: (301) 258-3074 e-mail: *firststrike@hsus.org* website: *www.hsus.org/firststrike*

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Immunization Information Systems

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Practice and Ambulatory Medicine

ABSTRACT

The American Academy of Pediatrics continues to support the development and implementation of immunization information systems, previously referred to as immunization registries, and other systems for the benefit of children, pediatricians, and their communities. Pediatricians and others must be aware of the value that immunization information systems have for society, the potential fiscal influences on their practice, the costs and benefits, and areas for future improvement.

BACKGROUND

IMMUNIZATION INFORMATION SYSTEMS (IISs), previously known as immunization registries, have rapidly developed over recent years.[1] Appropriate functioning standards for IISs[2] that also address privacy and confidentiality have been adopted by the National Immunization Program,[3] and the American Immunization Registry Association has developed registry standards of excellence that provide a standardized self-assessment tool.[4,5] The American Academy of Pediatrics (AAP) continues to welcome and support the development of this technology and other systems for the benefit of children, pediatricians, and their communities. It is important for pediatricians to be aware of the value that IISs have for society, the potential fiscal influences on their practices, and areas for future efforts.

IISs AND SOCIETY

Since 1993, the United States Public Health Service (through the Immunization Grant Program, also called the "317 program"), the Robert Wood Johnson Foundation, and the National Immunization Program of the Centers for Disease Control and Prevention have provided funding for the development of IIS projects in virtually every state.[2] The projected annual cost of a nationwide network of IISs is $78 million for children 0 to 5 years of age ($100 million for children 0–6 years of age).[6] Annual cost offsets are estimated at $280 million.[6,7] These savings would result from improved efficiencies in the following areas:

- $168 million in immunization-assessment activities for entry in school, child care, and Head Start programs;
- $58 million in manual pulling of records for all children entering kindergarten;
- $16.2 million in manual pulling of records for changing health care professionals;
- $26.5 million in duplicated immunizations;
- $2 million in Health Plan Employer Data and Information Set (HEDIS) reports; and

IISs would be helpful in identifying and improving immunization rates in vulnerable populations. They would also be a valuable tool for public health efforts in infection control and prevention during outbreaks. Also, recent catastrophic events suggest a need for seriously examining the role of IISs in disaster preparations.

IISs AND PATIENTS

Pediatric patients and their families would benefit from having a regional or national immunization record instead of a paper one. There would be a decrease in duplication of immunizations. Interstate agreements are being developed that would enable physicians to access IISs from an adjacent state.

Reports vary about whether IISs improve immunization rates. In Oregon, immunization rates improved from 32% to 36% as a result of having accurate immunization data from the registry.[8] Another study reported improved accuracy of immunization data, but the "up-to-date" rate did not change after 3 years of IIS use.[9] A report from Minneapolis stated improved rates in one practice environment but not in another.[2]

IISs provide an automated reminder recall system. One study with an inner-city population reported a 2% improvement (38%–40%) in immunization rates by 2 years of age using an automated telephone recall system[10]; another study showed no improvement in immunization rates and identified the rate-limiting step as reaching the families, not generating a reminder.[11]

IISs AND PEDIATRIC PRACTICE

Although recently there has been more published research about IISs in the private sector, there continues to be a paucity of information on the fiscal effect on private practices. The savings from not having to manually pull a chart for immunization records are estimated at $14.70 per chart.[12] The fiscal effect on a practice depends on whether immunization data can be directly downloaded into the IIS from billing information, which in most cases requires the practice to purchase appropriate software. This downloaded information would provide the date and type of vaccine to the IIS but not the other required fields, such as lot numbers, site, administering personnel, etc. One study reported that manually entered data would cost $3.24 per shot, compared with $0.24 if the entry were automated.[13]

A study in 2004 reported an increase in cost of $0.56 per shot after implementation of an IIS in the private sector, with nurses spending 3.4 minutes per shot on registry activities.[14] There are no reports on the cost to practices to enter historical immunization data on patients to populate the database of the IIS.

It is important that both the public and private sectors continue to study the financial implications of these systems, not only on the practice, but on the system of care itself. A recent task force of America's Health Insurance Plans (AHIP), an organization representing the nation's major health plans, has been charged with exploring collaborative opportunities or promoting provider participation with IISs and to share health insurance plans' experiences and initiatives.[15]

RECOMMENDATIONS

1. The AAP supports continued improvement in IISs.
2. The AAP supports the continued evaluation of IISs to determine their cost-effectiveness in increasing immunization rates.
3. The AAP supports further needed research into the cost and benefits of IISs for the practicing pediatrician.
4. Physicians should be reimbursed for entering historical immunization data into the database of the IIS.
5. Data in IISs should be used as tools to improve quality of immunization services and not to penalize physicians whose immunization coverage is below average.
6. IISs must be integrated with electronic medical chart systems.

abstract

FREE

Additional strategies are needed to protect children from vaccine-preventable diseases. In particular, very young infants, as well as children who are immunocompromised, are at especially high risk for developing the serious consequences of vaccine-preventable diseases and cannot be immunized completely. There is some evidence that children who become infected with these diseases are exposed to pathogens through household contacts, particularly from parents or other close family contacts. Such infections likely are attributable to adults who are not fully protected from these diseases, either because their immunity to vaccine-preventable diseases has waned over time or because they have not received a vaccine. There are many challenges that have added to low adult immunization rates in the United States. One option to increase immunization coverage for parents and close family contacts of infants and vulnerable children is to provide alternative locations for these adults to be immunized, such as the pediatric office setting. Ideally, adults should receive immunizations in their medical homes; however, to provide greater protection to these adults and reduce the exposure of children to pathogens, immunizing parents or other adult family contacts in the pediatric office setting could increase immunization coverage for this population to protect themselves as well as children to whom they provide care. *Pediatrics* 2012;129:e247–e253

INTRODUCTION

Prevention of infectious diseases through administration of vaccines according to recommended childhood and adolescent immunization schedules is an effective strategy to improve child health. Childhood immunizations are one of the greatest advances in modern medicine, markedly reducing morbidity and mortality. Data from the Centers for Disease Control and Prevention (CDC)'s 2009 National Immunization Survey of more than 17 000 households revealed that immunization rates against most vaccine-preventable diseases in children 19 to 35 months of age were >90%; <1% of children received no vaccines.[1]

Despite widespread adherence to childhood immunization schedules, some children remain unprotected.[2] This includes infants who are too young to be vaccinated, children who do not receive all scheduled immunizations at appropriate times, young infants who have not received a full primary series and are not yet fully immune, and vaccine recipients who experience vaccine failure or waning immunity in

adolescence or adulthood.[3] Children who receive immunosuppressive agents as a result of cancer, organ transplantation, autoimmune diseases, and other primary and secondary immune deficiencies may be incapable of mounting an adequate immune response to any vaccine, and certain live-attenuated vaccines (eg, measles-mumps-rubella and varicella vaccines) may be contraindicated for medical reasons.

Thus, additional strategies are needed to protect children from vaccine-preventable diseases, such as immunizing household contacts of children to reduce their exposure to vaccine-preventable pathogens. This can be facilitated by immunizing parents and other close family contacts in the pediatric office setting. With this in mind, the goals of this technical report are as follows:

1. review the literature to determine how immunization of close family contacts could be used to protect vulnerable children;
2. explore potential issues surrounding implementation of this practice in the pediatric office setting; and
3. develop objectives and a research plan to advance this concept.

BACKGROUND

The objective of providing immunizations for parents and other close family contacts of children in pediatric practice is to decrease infections in the family member, with subsequent reduction in exposure to the children. This strategy is referred to as "cocooning."[4–6] Exposure to infected parents or family members is a risk factor for many infections. For example, infants with pertussis are often infected in their home by family members or other close contacts.[7–10] Bisgard et al[9] examined 774 cases of infant pertussis from 4 states and determined the source of contagion in these infants through family interviews. An infectious source was identified in 43% of the case infants; of these, mothers were the source in 32% of cases, and another family member was the source in 43% of cases. The specific ages of the infectious source persons were described in 36% of reports; of these, 38 (17%) were 0 to 4 years of age, 16 (7%) were 5 to 9 years of age, 43 (20%) were 10 to 19 years of age, 45 (21%) were 20 to 29 years of age, and 77 (35%) were 30 years of age or older. Thus, more than half of the infectious sources were adults. Similarly, a prospective study conducted between 2006 and 2008 concluded that if parental immunity to pertussis was maintained, 35% to 55% of infant pertussis cases could have been prevented.[10]

Several studies have documented that vaccination of pregnant women against influenza reduces the incidence of influenza in their offspring.[11,12] Although research has documented a benefit of influenza vaccination of pregnant women for their babies, no studies have been conducted to determine whether postpartum vaccination or vaccination of other close family contacts with influenza vaccine reduces the incidence of influenza in their children. A 2010 report by Rekhtman et al[13] found that 69% of infants younger than 2 months of age hospitalized with influenza A had a history of exposure to a family member with upper respiratory tract infection symptoms. The ages and immunization status of the contacts, however, were not reported.

Several parental immunization programs have been conducted to reduce the burden of disease in their children. Healy et al[14] provided tetanus toxoid, reduced diphtheria toxoid, and reduced-content acellular pertussis vaccine (Tdap) to medically underserved, uninsured women postpartum in Houston through a standing order protocol. Nearly all (96%) of the women without self-reported contraindications to vaccination received Tdap before hospital discharge. Shah and colleagues[15,16] conducted several immunization campaigns of parents whose infants were hospitalized in NICUs. During one influenza season, all parents of infants admitted to the NICU were offered trivalent inactivated influenza vaccine at their infant's bedside. Of the 158 infants admitted to the NICU, 95% of the parents were immunized. Remarkably, 23% of the parent population had never received trivalent inactivated influenza vaccine previously, despite having indications for personal influenza immunization.[15] The same group offered Tdap to all parents of infants admitted to the NICU. During the 4-month study period, 352 children were admitted to the NICU, and 87% of their parents received Tdap. However, 11% of parents refused vaccination, citing that pertussis was not a significant health threat or that they did not believe that vaccinations were protective.[16] Overall, these programs highlight the observation that most parents are likely to agree to immunizations for the purpose of protecting their infants.

In addition to the hospital setting, the practice of offering Tdap to all parents of infants during the first month of life was evaluated in a pediatric office setting. Two hundred parents were approached for immunization. Of eligible parents, more than 50% (82/160) received the vaccine. Interestingly, 60% of these parents opting for immunization received the vaccine the first time they were approached, and 40% received the vaccine at a subsequent office visit during the baby's first month of life.[4]

In summary, there is considerable evidence that children are exposed to infections in their home environment from parents and other family members

and that parents are willing to be immunized to protect their infants from vaccine-preventable diseases.

BARRIERS TO IMMUNIZATION OF ADULTS

Data from the CDC in 2010 reported that Tdap coverage among adults who have contact with an infant was only 5%.[17] Another study conducted in 2004–2005 reported that 74% of insured adults did not receive influenza vaccine.[18] With evidence to support the benefits of immunization of parents and other close family contacts for the protection of children, several barriers to adult immunization remain. First, there are patient factors, such as a reluctance of healthy adults to seek preventive health care. Many adults see little need for a visit to a health care provider in the absence of an acute or chronic illness. Even among insured adults, influenza vaccination represented the least frequently received preventative health service among routine recommended services (26%) during a 2-year study period.[18] Second, lack of insurance coverage for vaccine-eligible adults and potential loss of income (because of the need to take time from work for preventive care) add to the challenges. Third, many healthy adults are unaware of the continuing need for immunization and the risks to themselves or others when their immunizations are not current.[19,20] Therefore, many adults do not receive recommended adult immunizations.

Physician and health care system factors contribute to low immunization rates in adults. Physicians may not have enough time during health maintenance visits to address immunizations, given the multiple chronic conditions or acute illnesses they are frequently managing[21,22]; thus, patients may not become aware of the importance of immunization for their own health or the health of their children. Physicians also face financial barriers in providing immunizations to adults. Pediatricians, for whom immunization is part of their core mission and business, report that economic concerns are a problem. Freed et al[23] reported in 2009 that 49% of pediatricians had delayed purchasing immunizations because of financial concerns. This study also reported that 5% of pediatricians and 21% of family practitioners were considering discontinuing immunization services. Presumably, practices in these disciplines have far more experience and expertise in the vaccine-purchasing realm than do practices that focus solely on adult patient populations. A survey of internists and family physicians published in 2011[24] found that although 96% of such practices stocked at least 1 adult immunization, only 27% stocked all recommended adult immunizations. Nearly three-quarters of respondents listed payment and coverage issues as a barrier. In addition, many adults seek specialty care and do not have a medical home where a primary care provider who routinely reviews the immunization status of patients. The adult health care system is often more focused on either treating disease or the secondary and tertiary levels of health prevention than on primary prevention associated with immunizations.[19,20]

IMMUNIZATION VENUES FOR ADULTS

In addition to the traditional medical home, there are a number of venues for immunizing adults.[25] At the start of the influenza season each year, "flu clinics" in pharmacies, supermarkets, department stores, workplace settings, and even airports are common. Many local and state health departments provide annual seasonal influenza vaccine clinics. Hospitals have been implementing standing orders for pneumococcal and influenza immunization before patient discharge for many years. Additionally, greater numbers of women have been immunized in obstetric offices, given the increased appreciation of the burden of influenza in this population. Recent immunization coverage rates among pregnant women during the 2009–2010 influenza season, according to the CDC, were 51% for seasonal influenza and 47% for 2009 H1N1. In addition, women for whom vaccination was recommended by their health care provider were three- to 10-fold more likely to receive vaccine than were women whose health care provider did not encourage vaccination. A 50% coverage rate is encouraging, but because it is recommended that all pregnant women receive influenza vaccine, much work remains to ensure that the Healthy People 2020 goal of 80% influenza vaccine coverage is achieved.[26,27]

The American College of Obstetricians and Gynecologists, American Academy of Pediatrics, American Academy of Family Physicians, and CDC recommend that when possible, postpartum women should receive Tdap before being discharged from the hospital to protect them and their infants from pertussis and that immunization should be confirmed during the 6-week follow-up visit.[28,29] Additionally, in June 2011, the Advisory Council on Immunization Practices voted to recommend Tdap immunization to pregnant women in the late second or third trimester.[30] A recent provider survey of members of the American College of Obstetricians and Gynecologists, however, found that only 78.7% routinely stock and administer vaccines.[31] Among that group, 91% stocked human papillomavirus vaccine, 66.8% stocked influenza vaccine, and 30% stocked Tdap. The overwhelming majority reported financial issues as the major barrier to providing immunization services. Of

respondents who provide primary care, 61% reported that they administer influenza vaccine, and only 30% reported that they administer Tdap. Respondent obstetrician-gynecologists also reported that immunization training during medical school and residency was not adequate (40% and 35%, respectively). Because obstetrician-gynecologists are the primary care providers for many women of childbearing age, the lack of immunization opportunities in that setting is concerning.[31]

POTENTIAL BENEFITS AND CONCERNS OF IMMUNIZING PARENTS IN THE PEDIATRIC OFFICE SETTING

There are many potential benefits of adding the pediatric office as another venue for adult immunization. Probably the most compelling is convenience for parents who must balance parenting responsibilities with work demands. Limited access to immunizations has been identified as one of the primary barriers to adult immunization.[32] One study reported that alternative locations for immunization, such as the workplace, can successfully address the issue of inconvenience in the vaccination decision.[33] Parents visit the pediatric office frequently with their infants and young children, where most vaccines needed for immunization of both children and adults are available. These visits represent an opportunity to immunize parents or other adult caregivers with minimal disruption for both the adults and the practice. Immunizations represent a major focus for pediatric care, and many educational opportunities exist for the pediatrician to explain the benefits of immunization for the child and for close family contacts. Thus, convenience, physician vaccine knowledge and encouragement, and vaccine availability are strong factors for immunizing parents and close family contacts in the pediatric office.

However, there are a numbers of concerns. First, most parents and close family contacts would be older than the usual patients seen by pediatricians. Pediatricians may be comfortable immunizing this population but are not likely to deliver other types of preventive health care. It is possible that adults who receive immunizations in the pediatric office may defer other preventive services usually delivered by family physicians, internists, and obstetrician-gynecologists.[34] Effort should be made to avoid compromising the adult medical home, and attempts should be made to ensure this does not happen. Parents and close family contacts should be encouraged to receive other primary care services in their medical homes.

Pediatricians may have concerns about safety, including whether they can obtain complete medical information to evaluate for contraindications and whether they have adequate facilities for dealing with adverse events in adults in a pediatric practice setting. Pediatricians may be concerned about liability if an adverse event occurs during adult immunization.[34] However, physicians are protected by the National Childhood Vaccine Injury Act of 1986 (Public Law No. 99-660), which limits the liability for vaccine manufacturers and established the Vaccine Injury Compensation Program. The act both protects and requires physicians to report suspected adverse events, and the Vaccine Injury Compensation Program covers all vaccines recommended for routine use in children, regardless of the age of the person being vaccinated. Claims arising from covered vaccines must be adjudicated through the program before civil litigation can be pursued.[35] Therefore, because both Tdap and influenza vaccines are recommended for children, this act would protect pediatricians when administering these vaccines to adults.[35] In addition, pediatricians would need to provide the adult being immunized the required Vaccine Information Statement[32,36] prior to vaccination.

There also are a number of medical record issues. Vaccination of parents and close family contacts of pediatric patients, including any required consent for treatment, would need to be documented by the pediatric office. Thus, close family contacts would likely need their own brief medical record documenting the vaccines administered and any required consent. The vaccinated close family contacts could be provided with a vaccine card listing the names and dates of vaccines received. The type of communication between pediatric offices and adult primary care offices or state immunization registries regarding the immunization status of the adults would need to be determined.

Logistical and financial issues will need to be addressed. Obtaining adequate supplies of vaccine for both children and close family contacts will be critical. Although supplies of influenza vaccine have been plentiful in the past few years, there have been years of shortages and occasional rationing of various vaccines. Because nearly all privately supplied influenza vaccine is preordered months in advance, there is a risk of using the ordered supply too quickly when immunizing both close family contacts and children. This is less likely, given that increasing numbers of manufacturers are producing influenza vaccine annually. Alternatively, too much vaccine might be ordered if the pediatrician were planning on immunizing both adults and children. Influenza vaccine may not be returnable to the manufacturer, leaving practices at economic risk of unused doses. This is a significant concern, given the narrow financial margins for immunizations.[34,37]

Immunizing parents and close family contacts must be financially viable for

pediatric practices, and the practices must determine whether they are able or willing to submit vaccine charges to adult insurers or simply require payment at the time of service. Many practices that currently provide this service as a convenience for the close family contacts require payment at the time of service or before administration of vaccines. Issues of source of supply must also be considered. In universal purchase states, practices may be legally enjoined from charging parents for doses supplied by the state, although administration fees might be charged. Pediatricians in such states may not be able to provide immunizations for adults and should check with their state vaccine purchase programs regarding use of these vaccines for this purpose. In most states, vaccines supplied to pediatricians by the Vaccines for Children Program may not be used for adults and certainly cannot be billed. If a practice chooses to involve itself in the insurance coverage of parents and close family contacts, it will produce a significantly increased burden that may make the provision of such services nonviable. If parents wish to submit to insurance, they should be informed that receiving vaccines at a location outside of their primary provider's practice may not be reimbursed and, therefore, it may be financially beneficial for them to obtain the vaccine through their primary health care provider. Ultimately, financial arrangements will be up to the individual practice and the individual adult involved. Payment details must be carefully evaluated before the provision of this service and communicated clearly to the family contacts seeking immunization.

Additional logistic concerns exist. For example, pediatric offices may need additional staff to immunize parents and close family contacts. However, it would seem logical that the same nurse providing care for the child could also administer vaccine to the adult. In addition, pediatricians must decide whether to vaccinate only parents or also immunize grandparents, child care providers, and other household contacts, because the reasons for immunizing parents also apply to other care providers.[6] Finally, the spectrum of vaccinations available for close family contacts in the practice must be determined.

Despite the challenges, pediatricians already are immunizing parents and other adults. One recent study quantified influenza vaccination of parents and guardians in pediatric offices and found that over the course of 2 influenza seasons, 43 (51%) of the 84 offices surveyed administered 2033 seasonal influenza vaccinations to parents or guardians.[38] The authors concluded that many pediatricians offered influenza vaccine to parents and other care providers, but that the actual number of doses administered was small. In addition, a 2006 survey of nonretired fellows of the American Academy of Pediatrics reported that 30% of respondent pediatricians usually offer influenza vaccination to parents of at-risk children.[39] No similar studies have evaluated the administration of Tdap by pediatric practices.

RESEARCH NEEDS

Further studies are needed to investigate the extent of this practice; the level of family contact satisfaction with the practice; how practices handle the logistic, liability, legal, and financial barriers that limit or complicate this service; and most importantly, how this practice will affect disease rates in children and adults.

SUMMARY

Although additional data are needed to assess the effects of pediatricians providing immunizations for parents and close family contacts on the burden of infectious diseases in children, the following reasonable statements can be made at this time for pediatricians considering vaccinating parents and other adult care providers.

1. Pediatric offices may choose to serve as an alternate venue for adult care provider vaccination if the practice is acceptable to both pediatricians and the adults who are to be vaccinated. However, the practice's decision of whether to offer vaccinations to adult care providers is not a deviation from the pediatric standard of care.
2. Pediatric practices choosing to offer immunizations to parents and close family contacts may avoid compromising the adult medical home by inquiring about the availability and likelihood of the family contact obtaining vaccines in that setting and notifying their medical homes if vaccines are administered. Offering immunizations in the pediatric practice setting would not be intended to undermine the adult medical home model but could serve as an additional venue for adult care providers to receive vaccinations. Pediatricians may actively encourage all parents and close family contacts to have their own medical home for their health care needs.
3. As part of their anticipatory guidance, pediatricians can actively support educating adults about the value of immunizations and emphasize that such medical care is not just for children.
4. If choosing to vaccinate parents and close family contacts, appropriate indications, contraindications, and precautions to vaccination of adults would need to be assessed and documented in a medical record. A Vaccine Information Statement would need to be provided,

and necessary consent to treatment would need to be documented.

5. Parents and close family contacts immunized in the pediatric office would need to receive a record of administered immunizations. In addition, if adults are included in vaccine registries, the immunizations provided in the pediatric practice would need to be recorded in the registry.
6. At the present time, if a practice chooses to provide such services, the focus of parent and close family contact immunization in the pediatric practice would be centered on influenza (either inactivated or live-attenuated vaccine) and Tdap. Decisions about other vaccines can be made on an individual basis.
7. Liability issues surrounding parent and close family contact immunizations in the pediatric office may be discussed with the malpractice insurance carriers for the pediatric practice, with the knowledge that policies may vary on a state-by-state basis. Pediatricians providing the aforementioned vaccinations would be protected by the Vaccine Injury Compensation Program.
8. Pediatricians may investigate insurance regulations within their states. Expectations for method of payment for parents and close family contact immunizations would need to be clearly outlined with the adult seeking vaccination. Pediatricians also may need to be aware of any state funds available to provide vaccines to adults at no cost.
9. Further research is needed to address the clinical implications of immunizing parents and close family contacts in the pediatric office, patient satisfaction, public health benefit, effects on adult medical homes, and cost-effectiveness.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Impact of Music, Music Lyrics, and Music Videos on Children and Youth

abstract

Music plays an important role in the socialization of children and adolescents. Popular music is present almost everywhere, and it is easily available through the radio, various recordings, the Internet, and new technologies, allowing adolescents to hear it in diverse settings and situations, alone or shared with friends. Parents often are unaware of the lyrics to which their children are listening because of the increasing use of downloaded music and headphones. Research on popular music has explored its effects on schoolwork, social interactions, mood and affect, and particularly behavior. The effect that popular music has on children's and adolescents' behavior and emotions is of paramount concern. Lyrics have become more explicit in their references to drugs, sex, and violence over the years, particularly in certain genres. A teenager's preference for certain types of music could be correlated or associated with certain behaviors. As with popular music, the perception and the effect of music-video messages are important, because research has reported that exposure to violence, sexual messages, sexual stereotypes, and use of substances of abuse in music videos might produce significant changes in behaviors and attitudes of young viewers. Pediatricians and parents should be aware of this information. Furthermore, with the evidence portrayed in these studies, it is essential for pediatricians and parents to take a stand regarding music lyrics. *Pediatrics* 2009;124:1488–1494

INTRODUCTION

Music plays an important role in the socialization of children and adolescents.[1–3] Listening to popular music is considered by society to be a part of growing up.[2] Music provides entertainment and distraction from problems and serves as a way to relieve tension and boredom. Some studies have reported that adolescents use popular music to deal with loneliness and to take control of their emotional status or mood.[2,4] Music also can provide a background for romance and serve as the basis for establishing relationships in diverse settings.[2] Adolescents use music in their process of identity formation,[4–11] and their music preference provides them a means to achieve group identity and integration into the youth culture.[5,7–9,12,13] Some authors have suggested that popular music provides adolescents with the means to resolve unconscious conflicts related to their particular developmental stage[2,7,12,14] and that their music preference might reflect the level of turmoil of this stage.[14–17]

Adolescents' choice of music and their reactions to and interpretations of it vary with age, culture, and ethnicity.[2,13,14,18–25] Research has shown that

there also is a difference in these variables between the genders.[25] Female adolescents are more likely than male adolescents to use music to reflect their emotional state, in particular when feeling lonely or "down."[2,26,27] Male adolescents, on the other hand, are more likely to use music as a stimulant, as a way to "boost" their energy level, or to create a more positive image of themselves.[2,4,26]

To understand the importance of music in the life of adolescents, a survey performed in the early 1990s of 2760 American adolescents aged 14 through 16 years revealed that they listened to music an average of 40 hours per week.[28] In another study in 2000, North et al[4] found that a sample of 2465 adolescents in England reported listening to music for an average of 2.45 hours per day. On a study performed in 2005 to assess media use of 8- to 18-year-olds in the United States, Roberts et al[25] reported that on a given day, 85% of 8- to 18-year-olds listen to music. Although time devoted to listening to music varies with age group, American youth listen to music from 1.5 to 2.5 hours per day. Still, a study performed with a small sample of at-risk youth revealed an average of up to 6.8 hours of music-listening per day.[29] Furthermore, Roberts et al found that 33% of those listening to music did so while performing other tasks or activities. These data support the idea that the prevalence of music-listening in adolescents may be even higher than that of television viewing. The reason for this is that popular music is present almost everywhere, from the supermarket to the mall, often as background music. It also is easily available through the radio, various recordings, the Internet, and new technologies,[11,25] allowing adolescents to hear it in diverse settings and situations, alone or shared with friends.

Adolescents are not the only young consumers of popular music. A study with 100 fourth- through sixth-graders revealed that 98% of these children listened to popular music, 72% of them on "most days" or every day.[30] Furthermore, it has been reported that children 8 to 10 years of age listen to music an average of 1 hour per day.[25] With many children and adolescents listening on iPods or other devices using headphones, parents may have little knowledge of what their children are listening to.

Research on popular music has explored several areas such as its effects on schoolwork,[31] social interactions, mood and affect,[20,26,27,32,33] and particularly behavior.[10,11,34–36] Several theories have been developed to explain the relationship between music and behavior,[15,37,38] and a number of studies have demonstrated that there is a relationship between music and emotions, regardless of age.[20,23,27,39–41] Although the emotional response to music depends on the way it is presented, it is also true that it is closely related to the age of the listener and the experiences or preconceived ideas they bring to the music.[2,14,39] The effect that popular music has on children's and adolescents' behavior and emotions is of paramount concern.[40] There is particular concern related to the lyrics of some genres of music and their effect on children and adolescents.[3,10,11,42–45]

Lyrics have become more explicit in their references to drugs, sex, and violence over the years.[11] A content analysis of the top 10 CDs performed by the National Institute on Media in 1999 revealed that each of these CDs included at least 1 song with sexual content. Forty-two percent of the songs on these CDs contained very explicit sexual content.[46] Lyrics of some music genres, such as rock, heavy metal, rap, and new emerging genres such as reggaeton, have been found to revolve around topics such as sexual promiscuity, death, homicide, suicide, and substance abuse.[9,13,17,43,45,46–53] Most recently, some rap music has been characterized by the presence of explicit sexual language in its lyrics as well as messages of violence, racism, homophobia, and hatred toward women.[9,10,42,54] Drug, tobacco, and alcohol use also tend to be glorified in these songs.

In refuting concerns about the effect of lyrics, some have argued that children and adolescents use music only for entertainment, that little or no attention is paid to the words, and if any attention is given, understanding tends to be limited and related to the experiences lived by the listener.[32,55] However, other studies have demonstrated the contrary.[56] Approximately 17% of male adolescents and 25% of female adolescents expressed that they liked their favorite songs specifically because the lyrics were a reflection of their feelings.[2] Also, it has been found that the more importance adolescents give to a certain type of music, the more attention they will pay to the lyrics.[2,55,57,58] Furthermore, Knobloch-Westerwick et al have stated that although young listeners might not understand all the details in lyrics, they recognize enough to obtain a general idea of the message they bring.[11]

Regarding the effects of popular music on behavior, several studies have demonstrated that preference for certain types of music could be correlated or associated with certain behaviors,* such as the association of drug and alcohol use with "rave" music or electronic music dance events.[13,50,51,62] Roberts et al[39] performed a study in 1997 at an adolescent clinic, and their results suggested that probably the best predictor of risk in adolescents related to music is their self-report of negative feelings or emotions when listening to any type of music. The au-

*Refs 2, 10, 17, 29, 37, 39, 42, and 59–65.

thors of that study described an association between negative emotional response to music and risk-taking behaviors and even suggested that what triggers risky behavior in some adolescents is the negative emotional response rather than the type of music. Scheel and Westefeld[61] supported this suggestion in 1999. Heavy metal and some rock music have been associated in some studies with an increased risk of suicide.[17,61,63,66,67] Fans of heavy metal music have been reported in the literature to have more problems with school authorities and teachers than students who are not fans of that type of music.[2] Heavy metal music-listening has also been associated with increased depression, delinquency risk behavior,[63–65] smoking, and conduct problems.[60] Fans of heavy metal and rap music showed a greater tendency to engage in reckless behavior than their peers who were not fans of those types of music.[2,14,37,68] A study performed to explore the possible effect of heavy metal music containing either sexually violent or nonviolent lyrics on males' attitudes toward women revealed that those exposed to heavy metal music, with either sexually violent or nonviolent lyrics, showed significantly more negative stereotyped attitudes toward women than those in a group instead exposed to classical music.[2,69] Likewise, in a study performed by Fischer and Greitemeyer,[42] men who listened to misogynistic lyrics showed increased aggressive responses toward women as well as a more negative perception of them.

In a study in which adolescents who preferred heavy metal and rap music were compared with those who preferred other types of music, results indicated that the former consistently showed below-average current and elementary school grades, with a history of counseling in elementary school for academic problems.[14] A study performed in 1999 with a sample of 345 mothers from public schools revealed that 47% of the mothers believed that violent messages in rap music contribute to school violence[70]; yet, according to a 2007 report from the Kaiser Family Foundation on parents, children, and the media,[44] only 9% of parents revealed being concerned about inappropriate content in music.

The preference for heavy metal music, rap, and associated genres among adolescents must alert us to an increased vulnerability and tendency toward risky behaviors. Adolescents at risk and with a feeling of alienation because of previous failures or problems tend to prefer these types of music, which might reflect their pessimistic view of life and the world.[2,9,14,17,19,37,71] Correlational studies, however, have inherent limitations and cannot identify cause-and-effect relationships, but the associations reflect the status of the current research.

Research related to music and its effects on children and adolescents has been expanded into another expression of popular music: the music video. Music videos are appealing to children and adolescents. Considering that music videos mix 2 media that are attractive to youth (television and popular music), it is important to study their effects on a young audience and to be concerned about the messages these music videos promote.[30,72] Music videos have been widely studied.[29,30,55,72–93] They are mainly classified as either performance or concept videos. For a performance video, an artist or a group is filmed during a performance, usually a concert. Concept videos, on the other hand, tell the viewer a story that may or may not evolve from the song. This story may sometimes add content to the lyrics and provide a particular interpretation that is reinforced every time the viewer hears the song.[72,73,75] As with popular music, the perception and the effect of music-video messages on children and adolescents is related to the age and developmental and emotional stage of the viewer, as well as the level of exposure.

The prevalence of music-video–watching has been studied in both the United States and Europe.[30,79,90,92,94] A study of 100 fourth- to sixth-graders revealed that 75% of them watched music videos, with 60% of them self-describing their frequency of viewing videos as either "pretty much" or "a lot." Of these children, 62% watched music videos either "most days" or "every day," and 7% watched them even before going to school.[30] In 2003, a report of the Kaiser Family Foundation[90] revealed that 3 of 4 of those in the 16- to 24-year-old group watch MTV, 58% watch it at least once a week, and 20% watch it for an hour or more every day. More recently, a study revealed that a sample of 12- to 15-year-olds watched music videos on an average of 4.3 days per week.[92]

Research on music videos has been focused mainly on content analyses. A study published in 1997 by DuRant et al[76,82] described an analysis of 518 music videos on 4 television networks (MTV, VH1, CMT, and BET). This study revealed that the percentage of violence in music videos ranged from 11.5% to 22.4%, with the most violent videos having been presented on MTV. When analyzed according to type of music, rap videos had the highest portrayal of violence (20.4%), closely followed by rock videos (19.8%). Using the same sample, another study revealed that although the percentage of videos that portrayed alcohol use showed no significant differences among networks, the percentage portrayed was still significant, ranging from 18.7% to 26.9%. Of the networks, MTV had the highest percentage of alcohol representation and also the

highest percentage of videos that portrayed smoking behaviors (25.7%). Of these videos, rap music videos showed a higher content of alcohol or tobacco use than did other types of videos.[75] In 1998, Rich et al[82] reported on the findings of content analyses that looked for gender or race differences in aggressors or victims of acts of violence portrayed in the same sample of 518 music videos. The analyses showed that black individuals were overrepresented as aggressors (25%) and as victims (41%), compared with the percentage of black individuals in the general population (12%). Studies performed by Smith and Boyson in 2002[93] and Gruber et al in 2005[91] validated these findings.

Analysis of the content in music videos is important, because research has reported that exposure to violence, sexual messages, sexual stereotypes, and use of substances of abuse in music videos might produce significant changes in behaviors and attitudes of young viewers.† Frequent watching of music videos has been related to an increased risk of developing beliefs in false stereotypes and an increased perceived importance of appearance and weight in adolescent girls.[83] In studies performed to assess the reactions of young males exposed to violent rap music videos or sexist videos, participants reported an increased probability that they would engage in violence, a greater acceptance of the use of violence, and a greater acceptance of the use of violence against women than did participants who were not exposed to these videos.[29,35,77,78,92]

In 1999 Kalof[84] reported that college students who were exposed to videos with stereotyped sexual images showed more acceptance of adversarial relationships than those who were not exposed. Kaestle et al[92] reported in 2007 that in a group of seventh- and eighth-grade boys, watching music videos and professional wrestling was associated with an increased acceptance of date rape. A survey performed among 214 adolescents revealed that there was an association between music-video–watching and permissive sexual behaviors.[76] It has also been reported that after watching MTV, adolescents' attitudes were more accepting of premarital sex.[52,53,80] A survey performed among 2760 American adolescents demonstrated that listening to music and watching television and music videos more frequently was associated with increased risky behaviors[68] and alcohol use[85,86]; these results were validated by van den Bulck and Beullens,[94] who demonstrated a longitudinal relationship between adolescents' exposure to music videos and alcohol use while going out to a bar, party, disco, etc. In 2003, Wingwood et al[89] reported on a study in which 522 black female adolescents with a median exposure to rap music videos of 14 hours per week were followed for 12 months. After controlling for all the covariates, greater exposure to rap music videos was independently associated with a wide variety of risky behaviors such as increased promiscuity and use of drugs and alcohol, among others. Of importance, a study performed by Austin et al[98] in 2000 revealed that the potential risks of exposure to music videos can be moderated by parental reinforcement and counterreinforcement of conducts observed.

RECOMMENDATIONS

The American Academy of Pediatrics understands that, given the findings presented and our knowledge of child and adolescent development, pediatricians and parents should be aware of this information. Furthermore, with the evidence portrayed in these studies, it is essential for pediatricians and parents to take a stand regarding this issue. Therefore, the following recommendations are made.

1. Pediatricians should become familiar with the role of music in the lives of children and adolescents and identify music preferences of their patients as clues to emotional conflict or problems.[99]
2. Pediatricians should become familiar with the literature available on the effects of music and music videos on children and adolescents.[36,38,100–103]
3. Pediatricians should explore with patients and their parents what types of music they listen to and music videos they watch and under which circumstances they consume these media.
4. Pediatricians should encourage parents to take an active role in monitoring the type of music to which their children and adolescents are exposed and to be aware of the music they purchase.[104–106] Parents can find lyrics by typing "music lyrics" into an Internet search engine and accessing 1 or more of the Web sites that appear. Pediatricians also should counsel parents and caregivers to monitor and regulate television-viewing according to the age and maturity of their children and adolescents.
5. Pediatricians should encourage parents and caregivers to become media literate.
6. Pediatricians should sponsor and participate in local and national coalitions to discuss the effects of music on children and adolescents to make the public and parents aware of sexually explicit, drug-oriented, or violent lyrics on CDs and cassettes, in music videos, on the Internet, and in emerging technologies.
7. The public, and parents in particular, should be aware of and use

†Refs 29, 35, 52, 53, 68, 72, 76–78, 80, 85, 89, 92 and 94–97.

the music industry's parental advisory warning of explicit content. The advisory label is a black-and-white logo and should be located on the front of the CD, cassette, album, videocassette, or DVD. It may help protect children from certain offensive materials.

8. Performers should serve as positive role models for children and teenagers.
9. The music-video industry should produce videos with more positive themes about relationships, racial harmony, drug avoidance, nonviolent conflict resolution, sexual abstinence, pregnancy prevention, and avoidance of promiscuity.
10. Further research on the effects of popular music, lyrics, and music videos on children and adolescents is important and should be conducted.[107]

Guidance for the Clinician in Rendering Pediatric Care

Clinical Report—The Impact of Social Media on Children, Adolescents, and Families

abstract

FREE

Using social media Web sites is among the most common activity of today's children and adolescents. Any Web site that allows social interaction is considered a social media site, including social networking sites such as Facebook, MySpace, and Twitter; gaming sites and virtual worlds such as Club Penguin, Second Life, and the Sims; video sites such as YouTube; and blogs. Such sites offer today's youth a portal for entertainment and communication and have grown exponentially in recent years. For this reason, it is important that parents become aware of the nature of social media sites, given that not all of them are healthy environments for children and adolescents. Pediatricians are in a unique position to help families understand these sites and to encourage healthy use and urge parents to monitor for potential problems with cyberbullying, "Facebook depression," sexting, and exposure to inappropriate content. *Pediatrics* 2011;127:800–804

SOCIAL MEDIA USE BY TWEENS AND TEENS

Engaging in various forms of social media is a routine activity that research has shown to benefit children and adolescents by enhancing communication, social connection, and even technical skills.[1] Social media sites such as Facebook and MySpace offer multiple daily opportunities for connecting with friends, classmates, and people with shared interests. During the last 5 years, the number of preadolescents and adolescents using such sites has increased dramatically. According to a recent poll, 22% of teenagers log on to their favorite social media site more than 10 times a day, and more than half of adolescents log on to a social media site more than once a day.[2] Seventy-five percent of teenagers now own cell phones, and 25% use them for social media, 54% use them for texting, and 24% use them for instant messaging.[3] Thus, a large part of this generation's social and emotional development is occurring while on the Internet and on cell phones.

Because of their limited capacity for self-regulation and susceptibility to peer pressure, children and adolescents are at some risk as they navigate and experiment with social media. Recent research indicates that there are frequent online expressions of offline behaviors, such as bullying, clique-forming, and sexual experimentation,[4] that have introduced problems such as cyberbullying,[5] privacy issues, and "sexting."[6] Other problems that merit awareness include Internet addiction and concurrent sleep deprivation.[7]

Many parents today use technology incredibly well and feel comfortable and capable with the programs and online venues that their chil-

dren and adolescents are using. Nevertheless, some parents may find it difficult to relate to their digitally savvy youngsters online for several reasons. Such parents may lack a basic understanding of these new forms of socialization, which are integral to their children's lives.[8] They frequently do not have the technical abilities or time needed to keep pace with their children in the ever-changing Internet landscape.[8] In addition, these parents often lack a basic understanding that kids' online lives are an extension of their offline lives. The end result is often a knowledge and technical skill gap between parents and youth, which creates a disconnect in how these parents and youth participate in the online world together.[9]

BENEFITS OF CHILDREN AND ADOLESCENTS USING SOCIAL MEDIA

Socialization and Communication

Social media sites allow teens to accomplish online many of the tasks that are important to them offline: staying connected with friends and family, making new friends, sharing pictures, and exchanging ideas. Social media participation also can offer adolescents deeper benefits that extend into their view of self, community, and the world, including[1,10]:

1. opportunities for community engagement through raising money for charity and volunteering for local events, including political and philanthropic events;
2. enhancement of individual and collective creativity through development and sharing of artistic and musical endeavors;
3. growth of ideas from the creation of blogs, podcasts, videos, and gaming sites;
4. expansion of one's online connections through shared interests to include others from more diverse backgrounds (such communication is an important step for all adolescents and affords the opportunity for respect, tolerance, and increased discourse about personal and global issues); and
5. fostering of one's individual identity and unique social skills.[11]

Enhanced Learning Opportunities

Middle and high school students are using social media to connect with one another on homework and group projects.[11] For example, Facebook and similar social media programs allow students to gather outside of class to collaborate and exchange ideas about assignments. Some schools successfully use blogs as teaching tools,[12] which has the benefit of reinforcing skills in English, written expression, and creativity.

Accessing Health Information

Adolescents are finding that they can access online information about their health concerns easily and anonymously. Excellent health resources are increasingly available to youth on a variety of topics of interest to this population, such as sexually transmitted infections, stress reduction, and signs of depression. Adolescents with chronic illnesses can access Web sites through which they can develop supportive networks of people with similar conditions.[13] The mobile technologies that teens use daily, namely cell phones, instant messaging, and text messaging, have already produced multiple improvements in their health care, such as increased medication adherence, better disease understanding, and fewer missed appointments.[14] Given that the new social media venues all have mobile applications, teenagers will have enhanced opportunities to learn about their health issues and communicate with their doctors. However, because of their young age, adolescents can encounter inaccuracies during these searches and require parental involvement to be sure they are using reliable online resources, interpreting the information correctly, and not becoming overwhelmed by the information they are reading. Encouraging parents to ask about their children's and adolescents' online searches can help facilitate not only discovery of this information but discussion on these topics.

RISKS OF YOUTH USING SOCIAL MEDIA

Using social media becomes a risk to adolescents more often than most adults realize. Most risks fall into the following categories: peer-to-peer; inappropriate content; lack of understanding of online privacy issues; and outside influences of third-party advertising groups.

Cyberbullying and Online Harassment

Cyberbullying is deliberately using digital media to communicate false, embarrassing, or hostile information about another person. It is the most common online risk for all teens and is a peer-to-peer risk.

Although "online harassment" is often used interchangeably with the term "cyberbullying," it is actually a different entity. Current data suggest that online harassment is not as common as offline harassment,[15] and participation in social networking sites does not put most children at risk of online harassment.[16] On the other hand, cyberbullying is quite common, can occur to any young person online, and can cause profound psychosocial outcomes including depression, anxiety, severe isolation, and, tragically, suicide.[17]

Sexting

Sexting can be defined as "sending, receiving, or forwarding sexually explicit messages, photographs, or images via cell phone, computer, or other digital devices."[18] Many of these images become distributed rapidly via cell phones or the Internet. This phenomenon does occur among the teen population; a recent survey revealed that 20% of teens have sent or posted nude or seminude photographs or videos of themselves.[19] Some teens who have engaged in sexting have been threatened or charged with felony child pornography charges, although some states have started characterizing such behaviors as juvenile-law misdemeanors.[20,21] Additional consequences include school suspension for perpetrators and emotional distress with accompanying mental health conditions for victims. In many circumstances, however, the sexting incident is not shared beyond a small peer group or a couple and is not found to be distressing at all.[4]

Facebook Depression

Researchers have proposed a new phenomenon called "Facebook depression," defined as depression that develops when preteens and teens spend a great deal of time on social media sites, such as Facebook, and then begin to exhibit classic symptoms of depression.[22–27] Acceptance by and contact with peers is an important element of adolescent life. The intensity of the online world is thought to be a factor that may trigger depression in some adolescents. As with offline depression, preadolescents and adolescents who suffer from Facebook depression are at risk for social isolation and sometimes turn to risky Internet sites and blogs for "help" that may promote substance abuse, unsafe sexual practices, or aggressive or self-destructive behaviors.

PRIVACY CONCERNS AND THE DIGITAL FOOTPRINT

The main risk to preadolescents and adolescents online today are risks from each other, risks of improper use of technology, lack of privacy, sharing too much information, or posting false information about themselves or others.[28] These types of behavior put their privacy at risk.

When Internet users visit various Web sites, they can leave behind evidence of which sites they have visited. This collective, ongoing record of one's Web activity is called the "digital footprint." One of the biggest threats to young people on social media sites is to their digital footprint and future reputations. Preadolescents and adolescents who lack an awareness of privacy issues often post inappropriate messages, pictures, and videos without understanding that "what goes online stays online."[8] As a result, future jobs and college acceptance may be put into jeopardy by inexperienced and rash clicks of the mouse. Indiscriminate Internet activity also can make children and teenagers easier for marketers and fraudsters to target.

INFLUENCE OF ADVERTISEMENTS ON BUYING

Many social media sites display multiple advertisements such as banner ads, behavior ads (ads that target people on the basis of their Web-browsing behavior), and demographic-based ads (ads that target people on the basis of a specific factor such as age, gender, education, marital status, etc) that influence not only the buying tendencies of preadolescents and adolescents but also their views of what is normal. It is particularly important for parents to be aware of the behavioral ads, because they are common on social media sites and operate by gathering information on the person using a site and then targeting that person's profile to influence purchasing decisions. Such powerful influences start as soon as children begin to go online and post.[29] Many online venues are now prohibiting ads on sites where children and adolescents are participating. It is important to educate parents, children, and adolescents about this practice so that children can develop into media-literate consumers and understand how advertisements can easily manipulate them.

ON TOO YOUNG: MIXED MESSAGES FROM PARENTS AND THE LAW

Many parents are aware that 13 years is the minimum age for most social media sites but do not understand why. There are 2 major reasons. First, 13 years is the age set by Congress in the Children's Online Privacy Protection Act (COPPA), which prohibits Web sites from collecting information on children younger than 13 years without parental permission. Second, the official terms of service for many popular sites now mirror the COPPA regulations and state that 13 years is the minimum age to sign up and have a profile. This is the minimum age to sign on to sites such as Facebook and MySpace. There are many sites for preadolescents and younger children that do not have such an age restriction, such as Disney sites, Club Penguin, and others.

It is important that parents evaluate the sites on which their child wishes to participate to be sure that the site is appropriate for that child's age. For sites without age stipulations, however, there is room for negotiation, and parents should evaluate the situation via active conversation with their preadolescents and adolescents.

In general, if a Web site specifies a minimum age for use in its terms of service, the American Academy of Pediatrics (AAP) encourages that age to be respected. Falsifying age has become

common practice by some preadolescents and some parents. Parents must be thoughtful about this practice to be sure that they are not sending mixed messages about lying and that online safety is always the main message being emphasized.

THE ROLE OF PEDIATRICIANS

Pediatricians are in a unique position to educate families about both the complexities of the digital world and the challenging social and health issues that online youth experience by encouraging families to face the core issues of bullying, popularity and status, depression and social anxiety, risk-taking, and sexual development. Pediatricians can help parents understand that what is happening online is an extension of these underlying issues and that parents can be most helpful if they understand the core issues and have strategies for dealing with them whether they take place online, offline, or, increasingly, both.

Some specific ways in which pediatricians can assist parents include:

1. Advise parents to talk to their children and adolescents about their online use and the specific issues that today's online kids face.
2. Advise parents to work on their own participation gap in their homes by becoming better educated about the many technologies their youngsters are using.
3. Discuss with families the need for a family online-use plan that involves regular family meetings to discuss online topics and checks of privacy settings and online profiles for inappropriate posts. The emphasis should be on citizenship and healthy behavior and not punitive action, unless truly warranted.
4. Discuss with parents the importance of supervising online activities via active participation and communication, as opposed to remote monitoring with a "net-nanny" program (software used to monitor the Internet in the absence of parents).

In addition, the AAP encourages all pediatricians to increase their knowledge of digital technology so that they can have a more educated frame of reference for the tools their patients and families are using, which will aid in providing timely anticipatory media guidance as well as diagnosing media-related issues should they arise.

To assist families in discussing the more challenging issues that kids face online, pediatricians can provide families with reputable online resources, including "Social Media and Sexting Tips" from the AAP (www.aap.org/advocacy/releases/june09socialmedia.htm),[30] the AAP Internet safety site (http://safetynet.aap.org),[31] and the AAP public education site, Healthy Children.org (www.healthychildren.org/english/search/pages/results.aspx?Type=Keyword&Keyword=Internet+safety),[32] and encourage parents to discuss these resources with their children. Pediatricians with Web sites or blogs may wish to create a section with resources for parents and children about these issues and may suggest a list of or links to social media sites that are appropriate for the different age groups. In this way, pediatricians can support the efforts of parents to engage and educate youth to be responsible, sensible, and respectful digital citizens.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Child Health Financing

Implementation Principles and Strategies for the State Children's Health Insurance Program

ABSTRACT. This policy statement presents principles and implementation and evaluation strategies recommended for the State Children's Health Insurance Program (SCHIP). The statement summarizes the current status of SCHIP, the needs of uninsured children, and the potential benefits of SCHIP programs. Principles and recommended strategies include expanding eligibility, maximizing funding, providing comprehensive benefits, including pediatricians in program design and evaluation, providing adequate reimbursement and access to pediatricians, ensuring choices for families and pediatricians, and establishing simple administrative procedures.

ABBREVIATIONS. SCHIP, State Children's Health Insurance Program; FPL, federal poverty level; AAP, American Academy of Pediatrics; HCFA, Health Care Financing Administration; EPSDT, Early and Periodic Screening, Diagnosis, and Treatment Program.

THE CURRENT STATUS OF THE STATE CHILDREN'S HEALTH INSURANCE PROGRAM (SCHIP)

The Balanced Budget Act of 1997[1] established SCHIP as Title XXI of the Social Security Act.[2] This program is a historic milestone in the financing of health care for children. Not since the enactment of Medicaid has there been a greater investment in children's health care. Although SCHIP did not create universal coverage for all children, it did offer an unprecedented opportunity to expand insurance coverage to a large portion of uninsured children. Title XXI of the Social Security Act provides more than $40 billion in federal grants to states over a 10-year period to provide health insurance coverage to children through 18 years of age who are uninsured and ineligible for Medicaid. States must, however, contribute a defined share of funds to obtain federal matching funds. The legislation gives flexibility to states in designing and implementing their programs.

Under SCHIP, states selected from among 3 approaches to providing health insurance coverage to children. These approaches include: 1) expanding Medicaid; 2) creating or expanding a non-Medicaid children's health insurance program; or 3) combining both options. Most states have created a non-Medicaid SCHIP program for at least some of their SCHIP-eligible children. Sixteen states created a non-Medicaid SCHIP program only, and 17 created a state program in combination with a Medicaid expansion. The remaining 17 states, the District of Columbia, Puerto Rico, Guam, and the Virgin Islands used SCHIP funds to expand Medicaid only.[3] Whichever approach a state chose, they receive an enhanced federal matching rate above their Medicaid rate. In addition, states can request to provide coverage through direct service support. In certain circumstances, states can also subsidize the purchase of family coverage.

States have used SCHIP funds to significantly expand eligibility. By January 2001, 38 states and the District of Columbia had established eligibility levels at or above the congressional target family income of 200% of the federal poverty level (FPL).[4] By October 2000, 3.3 million children were enrolled in SCHIP programs.[5] Many states are moving forward to expand coverage for children and their parents. For example, New Jersey covers children in families with incomes up to 350% of the FPL and approved expansion of coverage for parents with a household income up to 200% of the FPL. Vermont provides insurance for children in families with incomes up to 300% of the FPL. Many more states are using their tobacco funds and taking advantage of prosperous economies to expand health care coverage for children.

This statement presents a set of principles and implementation and evaluation strategies that the American Academy of Pediatrics (AAP) recommends the federal government and states adopt as they amend their SCHIP programs. These principles address issues related to financing, eligibility, outreach, enrollment, benefits, cost sharing, reimbursement, managed care, and accountability. SCHIP offers an opportunity for every state to develop an effective program to reduce the number of uninsured children, but this will require a strong partnership of SCHIP lead agencies, public health programs, health plans and managed care organizations, pediatricians and other physicians, business and advocacy groups, consumers, and other coalitions interested in the welfare of children.

THE NEEDS OF UNINSURED CHILDREN AND THE POTENTIAL BENEFITS OF SCHIP

Despite the eligibility expansions of SCHIP, the number and proportion of American children lacking health insurance remains high. In 1999, 10.8 million children younger than 19 years were uninsured.[6]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Between 1998 and 1999, the percentage of children who were uninsured dropped from 15.5% to 14.1%, the first significant decrease since 1993. Among children younger than 19 years with family incomes near the poverty level (between 100% and 125% of the FPL), the decline was even more dramatic, falling from 27.2% to 19.7%, according to analysis of US Census Bureau survey results (American Academy of Pediatrics, Division of Health Policy Research, unpublished data, 2000). Adolescents and young adults continue to be most likely to be uninsured, although they also experienced a drop in the rate of uninsured; 29.0% of those 18 through 24 years of age did not have insurance in 1999, down from 29.7% in 1998.[7] Factors contributing to the decrease in the number of uninsured children include the establishment of SCHIP, a philosophic shift toward increasing enrollment, the simplification of the Medicaid application process in many states, the unprecedented outreach and enrollment efforts, and the improving economy, in which increasing numbers of employers are offering health insurance.[8]

Children who are eligible for SCHIP (Medicaid expansions and non-Medicaid state programs) are more likely to have parents who are self-employed or employed in industries and occupations in which health insurance coverage is less available or less affordable. Compared with children who are privately insured, SCHIP-eligible children are twice as likely to be in poor health and 3 times as likely to be Hispanic.[9]

Health insurance is a critically important determinant of access to and use of health care services among children. The uninsured are 3 times as likely as the privately insured to go without needed medical care.[10] Uninsured low income children are 4 times as likely to rely on an emergency department or have no regular source of care.[11]

Although complete evaluations of the first year of SCHIP implementation are not yet available, preliminary results from New York State's Child Health Plus[12,13] and Pennsylvania's BlueCHIP and Caring programs,[14] prototype models for the SCHIP program, demonstrate the positive impact of health insurance programs and the potential impact of SCHIP. After enrollment in New York's Child Health Plus between 1991 and 1993, participants' access to and use of primary care increased, continuity of care improved, and many quality-of-care measures improved. Use of specialty, emergency, and inpatient care did not change. Many parents reported improved health status for their children as a result of enrollment in the insurance program. Similarly, after extending health insurance to uninsured children in western Pennsylvania in 1995, health insurance resulted in better access to health care, more appropriate use, and reduced family stress.[14] It is not clear how generalizable results from these 2 states are to all programs.

FACTORS AFFECTING ENROLLMENT OF ELIGIBLE CHILDREN AND USE OF SERVICES

Children are often uninsured because parents do not know they qualify for public coverage, according to a study funded by The Robert Wood Johnson Foundation. Six of 10 parents of uninsured children think that because they work and are not on welfare, their children do not qualify for federal health programs. Four of 5 parents said they would enroll their children in federal health programs if they knew they were eligible.[15]

Expanding coverage to parents may increase the number of children enrolled. Although most children without health insurance have an employed parent, their parents are likely not offered health benefits for children by their employers or they cannot afford to pay the premium contributions. A study of 3 states that implemented Medicaid expansions that included parents had greater Medicaid participation rates among low-income children than states that did not expand coverage to parents.[16]

Cost sharing may decrease participation in SCHIP and use of health services needed by children. Higher premium charges were associated with lower participation rates, according to a study of 4 states with sliding-scale premium health insurance programs.[17] Direct and indirect effects of cost sharing negatively affect the receipt of preventive counseling in health maintenance organizations and preferred provider organizations.[18]

Adequate physician participation is critical to ensuring that enrolled children have access to services. Pediatrician participation in Medicaid and non-Medicaid SCHIP programs varies substantially among states. The reasons cited by pediatricians to be most important for limiting participation in Medicaid and SCHIP are low payment, paperwork concerns, and unpredictable payment. States with the lowest pediatrician participation in Medicaid and SCHIP have the lowest rates of reimbursement and the highest rates of complaints about paperwork.[19]

Involuntary disenrollment of children from health plans plagues Medicaid and SCHIP. The dropping of individuals from plans may occur because of plan requirements for frequent reenrollment, excess paper work, or other vestiges of the philosophy to limit Medicaid enrollment. Changes in enrollment affect the integrity of the state's insurance programs, continuity of care, and the financial stability of safety net hospitals and community health centers.[20] It has been demonstrated that intermittent coverage compromises continuity of care.[21] This process also adds costs for outreach and reenrollment efforts.

PRINCIPLES AND RECOMMENDED IMPLEMENTATION AND EVALUATION STRATEGIES

As states continue to refine their SCHIP programs, the Academy suggests that the following principles and implementation and evaluation strategies be incorporated in their efforts:

1. **Expand Comprehensive Coverage**. SCHIP programs should provide comprehensive, quality health care coverage to the largest number of uninsured children possible.
   A. Congress should expand SCHIP to allow states to include children through 21 years of age.

States should adopt the highest income eligibility allowable and should discontinue asset testing to determine eligibility. To reach even more children, more flexible income limits should be considered.

B. States should allow adolescent emancipated minors to be evaluated for SCHIP eligibility based on their own income.[22]
C. States should consider offering a SCHIP buy-in option for children whose family incomes are above their state's SCHIP eligibility level but who do not have access to or cannot afford comprehensive private insurance.
D. States should consider applying for Section 1115 Research and Demonstration waivers from the Health Care Financing Administration (HCFA) to expand coverage for pregnant women or other parents if they have already maximized comprehensive coverage and full enrollment of children.
E. Although they will not be able to receive federal matching funds, states should consider using the SCHIP delivery system to provide health care to immigrant children who are not eligible for SCHIP.
F. States should offer 12-month continuous eligibility for Medicaid- and SCHIP-enrolled children. Continuous eligibility saves on outreach and enrollment so administrative costs for certifying income eligibility on a monthly basis are not incurred.
G. States should also implement presumptive eligibility for all children, allowing health care providers and other designated agencies, including schools and child care centers, to grant eligibility for up to 60 days while a child goes through the enrollment process.[23] Although the Academy understands that there must be some safeguards to ensure appropriate use of this option, this process should be administratively simple. Pediatricians' offices should be included as enrollment sites, when feasible. By doing so, children will receive health services and insurance coverage as rapidly as possible. If the child is determined ineligible, pediatricians and other caregivers should still be reimbursed for services rendered. Failure to pay for these services is a disincentive for physician participation. Presumptive eligibility offers qualified entities an added incentive to engage in outreach to their patients and clients.
H. States should adopt program eligibility rules that promote coordination between SCHIP and Medicaid and ease enrollment. Ending age-based income eligibility would enable all children from the same family to become enrolled in the same program. Currently, in many states the income eligibility for Medicaid varies by age.
I. Public and private, statewide, and community-based outreach programs to families and their employers should be designed to enroll all families with eligible children in SCHIP programs. Although the start-up of such efforts has been successful, sustaining the efforts may be another challenge. Creative approaches should be encouraged and supported. For example, using electronic application processes targeted to minority children served in child care centers, linking children receiving school lunch subsidies with health care coverage, and conducting door-to-door outreach to families in farming communities have been tried. State Medicaid and SCHIP agencies should coordinate outreach efforts and use consistent income assessment and documentation methods and enrollment procedures for the best long-term results. Outreach efforts should develop a seamless system to process applications for Medicaid and non-Medicaid programs. States should use community-based agencies for outreach, including offices where parents apply for government-subsidized programs, such as the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC); child care centers; schools; and other resource and referral agencies that provide services to families with young children. Community health programs and personnel and outreach workers for the Early and Periodic Screening, Diagnosis, and Treatment Program (EPSDT) can be used to enroll potential applicants. For example, the Agricultural Risk Protection Act of 2000[24] allows states to share information between SCHIP and school lunch programs. AAP chapter leaders and community pediatricians should be actively involved in developing outreach plans including education of peers and other physicians about program activities.
J. Simplified, joint application forms and expedited eligibility determination processes for SCHIP should be offered and coordinated with the state's Medicaid program and other public assistance programs offered for children in the state. From the family's perspective, a simplified process eases enrollment paperwork. States with a short application form, no asset testing, and similar documentation requirements for Medicaid and SCHIP have been most efficient.
K. States should implement proactive enrollment processes. Children who are found to be ineligible for Medicaid should be enrolled in SCHIP, if eligible, (or vice versa) through the use of automatic enrollment in the appropriate program without requiring families to submit additional application forms.[25] Reasonable fees or incentive payments with safeguards to prevent abuse may be provided to nonprofit agencies, community-based organizations, and safety net hospitals to enroll children in SCHIP or Medicaid. Use of 1 program name, 1 agency to determine eligibility, a SCHIP/Medicaid simplified joint application, and the same point of entry promotes coordination. Opera-

tional enhancements occur when simplified verification requirements are the same for both programs, easy transitions between programs occur when eligibility is redetermined, and a common service delivery system is used.[26] Pediatricians should be involved in the design and implementation of these administrative strategies. Frequent communication among agency staff is critical; single-agency governance may be more efficient.

L. Meaningful implementation of SCHIP must include an effort to maintain continuous health care coverage. Expanding health insurance programs and increasing enrollment in existing programs is not sufficient to reap maximum benefits for children. States should strive for full enforcement of existing state guaranteed eligibility laws, integration of plans into the recertification process, a streamlined recertification process, and where possible, multiple-year eligibility reviews. States should also link government-subsidized health care programs so that low-income children can move automatically from 1 program to another while maintaining continuity of care relationships with the same physicians and health plan, whenever possible.[20] States concerned about families or employers dropping private insurance coverage in favor of SCHIP, referred to as "crowding out," should monitor their policies so they do not penalize families who do not have access to coverage or only have access to individually purchased health insurance plans. If a state requires applicants to be uninsured for a period of time before becoming eligible, that time period should be short and allow for exceptions, for example, for children with special health care needs or acute catastrophic health events.

2. **Maximize Funding and Flexibility.** States should optimize their ability to draw down their full federal match for SCHIP. HCFA and Congress should allow greater flexibility for funding outreach and maximize appropriations for expanded coverage of uninsured children. SCHIP funds must be preserved for the primary purpose of increasing coverage of uninsured children.
3. **Provide Comprehensive Benefits.** All SCHIP plans should include a comprehensive scope of benefits. Because non-Medicaid programs often offer limited coverage for many special or chronic care services for children, states with such programs should consider expanding their benefit packages. This could be accomplished by emphasizing the use of the EPSDT provision in Medicaid to pay for services considered medically necessary or by creating wraparound programs for children meeting specific chronic or serious condition criteria.

A. Each benefit package should cover the services defined in the AAP policy statement "Scope of Health Care Benefits for Newborns, Infants, Children, Adolescents, and Young Adults Through Age 21 Years," including dental services and the full range of mental health services including substance abuse treatment.[27] Preventive care, immunization standards, and periodicity schedules should be consistent with current AAP requirements. Limited benefits packages limit the long-term cost-effectiveness for children.

B. Congress should ensure that all children enrolled in non-Medicaid SCHIP programs are eligible for the Vaccines for Children program.

C. To determine medical necessity and approval of services, states should use guidelines of recognized national professional organizations such as the Academy or recommendations of professional peer-review panels if evidence-based guidelines do not exist. Services should be reimbursed if they meet 1 or more of the following criteria: 1) the service is appropriate for the age and health status of the individual; 2) the service will prevent or ameliorate the effects of a condition, illness, injury, or disorder; 3) the service will aid the overall physical and mental growth and development of the individual; or 4) the service will assist in achieving or maintaining functional capacity.[28]

D. States should carefully assess the impact of premium cost sharing on participation and service use. States that impose cost sharing should eliminate differences in copayments and coinsurance for physical and mental health services. Tracking mechanisms for determining when families reach the 5% cost-sharing maximum should be handled at the plan level. Requiring families to track out-of-pocket expenditures should be discouraged.

Cost-sharing policies should be carefully designed so they do not simply shift cost to pediatricians, hospitals, and other providers. They should not deter the use of medically necessary services and should ensure that children with needs above and beyond the usual have access to necessary health care. Point-of-service cost sharing holds the greatest risks for children failing to seek or receive needed care and preventive services.

The Academy is not opposed to premium sharing with families, as long as the cost to families is moderate and based on a sliding income scale. For families with 1 child, individual premiums should be charged. For families with 2 or more children, a single premium rate should be charged to cover all children. Copayments for all SCHIP beneficiaries should be limited to the nominal level legislated for children in families with incomes up to 150% of the FPL. The Academy opposes the use of deductibles and coinsurance for any SCHIP-eligible children.

Consistent with SCHIP legislation and AAP policy, all preventive services should be exempt from copayments. The Academy believes that eliminating patient cost sharing for selected preventive services is a relatively easy

and effective means of improving the rates of delivery for recommended clinical preventive care.[29]

4. **Include Pediatricians in Program Design and Outcome-based Evaluation**. States should ensure that pediatricians, pediatric medical subspecialists including pediatric mental health professionals, and pediatric surgical specialists are involved in developing and reviewing the SCHIP program, annual reports, and evaluations that are required through the SCHIP legislation. States should have an ongoing SCHIP monitoring and advisory panel that includes pediatricians. State SCHIP evaluations, ideas, and forms can be found on the HCFA and AAP Web sites (http://www.hcfa.gov/init/chpa-map.htm and http://www.aap.org/advocacy/evaluation.htm, respectively).
   A. Primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists are critical stakeholders in developing SCHIP performance measurements. States are encouraged to use the AAP SCHIP Evaluation Tool, which includes Health Employer Data Information System measures. Process indicators should include age-appropriate immunization and comprehensive well child visit rates. Outcome indicators should include rates of hospitalization for ambulatory sensitive conditions and injuries, percent of SCHIP-enrolled children reporting missed school because of health problems as well as unmet medical, dental and vision needs, percent of SCHIP-enrolled adolescents reporting risky health behaviors and attempted suicide, and percent of family income used for health care.[30] States should develop uniform quality performance measurements for children insured by Medicaid and SCHIP and encourage use of these standards for employer-based plans.
   B. Performance goals should include short-term and long-term health care outcomes. Important features of SCHIP evaluation include monitoring eligibility thresholds and projected enrollment volume, program retention, transitions in coverage, access to medical care, assessments of process and outcomes of pediatric care, and family and provider satisfaction.[31]
   C. Congress should adopt proposals to authorize more funding for SCHIP evaluations and allow greater access to state data for research.
   D. States, local communities, and managed care organizations should publish pediatric-specific quality data that allow consumers and purchasers to evaluate and compare quality performance, including pediatric provider network composition among competing SCHIP plans.
5. **Provide Adequate Payment and Access to Pediatricians.** SCHIP plans should provide reimbursement for pediatric services comparable to rates offered in private insurance plans.
   A. In states with low provider payment rates for Medicaid services, SCHIP plans should engage in concurrent efforts to raise Medicaid rates to levels that are at least 90% of the usual, customary, or reasonable rates or equivalent to Medicare rates, whichever is higher. States with better levels of physician participation should serve as benchmarks for other states. Historically, states with low Medicaid reimbursement rates have lower participation rates. Efforts should be made by states to base payment rates for Medicaid and SCHIP on current market rates, although in some cases they may be inadequate.
   B. States should ensure that physicians receive adequate payment when new vaccines are recommended, particularly when physicians receive payment under a capitated arrangement. State should ensure that provisions are made to reimburse physicians for the cost of the new vaccines until new contracts are negotiated. In addition, physicians should receive payment for the expenses associated with the administration of each vaccine.
   C. In states using managed care models as a health delivery system for SCHIP, different strategies should be evaluated, such as pediatric risk-adjusted capitation rates and risk pools. The goal of such strategies is to reduce the negative financial consequences for health plans that enroll and pediatricians who serve high-risk children and the positive financial consequences for plans that enroll and pediatricians who serve low-risk children. Risk adjustment is a corrective tool designed to reorient the current incentive structure of the insurance market. Health plans should develop risk adjusted capitation at the primary care level. Enhanced payments for providing case management and care coordination for children with special health care needs should also be considered. Reimbursement levels must ensure reasonable clinician compensation in relation to the increased time required to coordinate and provide care for children, particularly those with special health care needs.[32]
   D. All health plans should provide access to pediatric primary care and pediatric medical subspecialty and pediatric surgical specialty services, as described in the AAP policy statement "Guiding Principles for Managed Care Arrangements for the Health Care of Newborns, Infants, Children, Adolescents, and Young Adults."[28]
   E. HCFA and states must monitor network capacity and pediatrician participation when developing plans. Failure to do so results in less adequate access to care providers for children.
6. **Ensure Choices for Families and Pediatricians**. SCHIP plans should allow choices to be made by patients and pediatricians.
   A. Parents should have the ability, with proactive outreach and information from the state, to

choose their child's pediatrician and managed care plan. Securing a medical home and continuity of care should be encouraged when families choose or are assigned to managed care plans. Families should be allowed to disenroll with cause at any time. However, to support the medical home optimally, families should be required to adhere to their choices or assignments for 1 year unless there is due cause to change.

B. Pediatricians, pediatric medical subspecialists, and pediatric surgical specialists are discouraged from accepting exclusive contracts with a single managed care plan. They should consider contracting with several plans to ensure that parents and children have a choice and to ensure that access to primary and specialty pediatric services is not lost if a single plan fails.

7. **Establish Simple Administrative Procedures**. SCHIP plans should establish simplified and efficient administrative systems.
   A. States should streamline and simplify their eligibility determination and enrollment process, cost-sharing policies, and copayment collection procedures.
   B. Health plans should simplify or eliminate procedures for preauthorization, obtaining second opinions, utilization review and quality assurance administration, claims processing, specialty referrals, and physician payment.[33]
   C. States should provide training for pediatricians, other physicians, and their office staff about how to participate in SCHIP. State Medicaid agencies can provide grants to optimize physician use of Medicaid and SCHIP. States should provide education and training to physicians about how to refer patients for SCHIP enrollment.

CONCLUSION

SCHIP has the potential to dramatically increase and maintain the number of children in the United States with health insurance coverage. To maximize the benefits of this legislation, states have an obligation to implement programs created in such a way that the most children receive the most comprehensive health care services available. To do this, states must ensure that all children who are eligible for coverage are enrolled and have access to high-quality care. The success of these programs will depend on the number of previously uninsured children who are now insured, the resulting increase in their access to health care services, and the ultimate improvement in their health and well-being. Although SCHIP does not create universal coverage for all children, it is an important step toward the goal of ensuring that all children in the United States have health insurance and, ultimately, access to high-quality health care.

CLINICAL REPORT

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bonds

Guidance for the Clinician in Rendering Pediatric Care

Kenneth R. Ginsburg, MD, MSEd, and the Committee on Communications and the Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT

Play is essential to development because it contributes to the cognitive, physical, social, and emotional well-being of children and youth. Play also offers an ideal opportunity for parents to engage fully with their children. Despite the benefits derived from play for both children and parents, time for free play has been markedly reduced for some children. This report addresses a variety of factors that have reduced play, including a hurried lifestyle, changes in family structure, and increased attention to academics and enrichment activities at the expense of recess or free child-centered play. This report offers guidelines on how pediatricians can advocate for children by helping families, school systems, and communities consider how best to ensure that play is protected as they seek the balance in children's lives to create the optimal developmental milieu.

INTRODUCTION

Play is so important to optimal child development that it has been recognized by the United Nations High Commission for Human Rights as a right of every child.[1] This birthright is challenged by forces including child labor and exploitation practices, war and neighborhood violence, and the limited resources available to children living in poverty. However, even those children who are fortunate enough to have abundant available resources and who live in relative peace may not be receiving the full benefits of play. Many of these children are being raised in an increasingly hurried and pressured style that may limit the protective benefits they would gain from child-driven play. Because every child deserves the opportunity to develop to their unique potential, child advocates must consider all factors that interfere with optimal development and press for circumstances that allow each child to fully reap the advantages associated with play.

No single set of guidelines could do justice to the many factors that impact on children's play, even if it was to focus only on children living in the United States. These guidelines will focus on how American children with adequate resources may be limited from enjoying the full developmental assets associated with play because of a family's hurried lifestyle as well as an increased focus on the fundamentals of academic preparation in lieu of a broader view of education. Those forces that prevent children in poverty and the working class from benefiting fully from play deserve full, even urgent, attention, and will be addressed in a future

document. Those issues that impact on play for children with limited resources will be mentioned briefly here to reinforce that play contributes to optimal child development for all children and that we must advocate for the changes specific to the need of each child's social and environmental context that would enhance the opportunities for play.

These guidelines were written in response to the multiple forces that challenge play. The overriding premise is that play (or some available free time in the case of older children and adolescents) is essential to the cognitive, physical, social, and emotional well-being of children and youth. Although the guidelines were written in defense of play, they should not be interpreted as being against other forces that compete for children's time. Academic enrichment opportunities are vital for some children's ability to progress academically, and participation in organized activities is known to promote healthy youth development.[2,3] It is essential that a wide variety of programming remain available to meet the needs of both children and families. Rather, these guidelines call for an inclusion of play as we seek the balance in children's lives that will create the optimal developmental milieu to prepare our children to be academically, socially, and emotionally equipped to lead us into the future.

THE BENEFITS OF PLAY

Play allows children to use their creativity while developing their imagination, dexterity, and physical, cognitive, and emotional strength. Play is important to healthy brain development.[4–6] It is through play that children at a very early age engage and interact in the world around them. Play allows children to create and explore a world they can master, conquering their fears while practicing adult roles, sometimes in conjunction with other children or adult caregivers.[7–14] As they master their world, play helps children develop new competencies that lead to enhanced confidence and the resiliency they will need to face future challenges.[7,10,15] Undirected play allows children to learn how to work in groups, to share, to negotiate, to resolve conflicts, and to learn self-advocacy skills.[7,10,11,16] When play is allowed to be child driven, children practice decision-making skills, move at their own pace, discover their own areas of interest, and ultimately engage fully in the passions they wish to pursue.[7,10,11] Ideally, much of play involves adults, but when play is controlled by adults, children acquiesce to adult rules and concerns and lose some of the benefits play offers them, particularly in developing creativity, leadership, and group skills.[17] In contrast to passive entertainment, play builds active, healthy bodies. In fact, it has been suggested that encouraging unstructured play may be an exceptional way to increase physical activity levels in children, which is one important strategy in the resolution of the obesity epidemic.[18,19] Perhaps above all, play is a simple joy that is a cherished part of childhood.

Children's developmental trajectory is critically mediated by appropriate, affective relationships with loving and consistent caregivers as they relate to children through play.[4] When parents observe their children in play or join with them in child-driven play, they are given a unique opportunity to see the world from their child's vantage point as the child navigates a world perfectly created just to fit his or her needs. (The word "parent" is used in this report to represent the wide range of adult caregivers who raise children.) The interactions that occur through play tell children that parents are fully paying attention to them and help to build enduring relationships.[6,13,14,20,21] Parents who have the opportunity to glimpse into their children's world learn to communicate more effectively with their children and are given another setting to offer gentle, nurturing guidance. Less verbal children may be able to express their views, experiences, and even frustrations through play, allowing their parents an opportunity to gain a fuller understanding of their perspective. Quite simply, play offers parents a wonderful opportunity to engage fully with their children.

Play is integral to the academic environment. It ensures that the school setting attends to the social and emotional development of children as well as their cognitive development. It has been shown to help children adjust to the school setting and even to enhance children's learning readiness, learning behaviors, and problem-solving skills.[22–32] Social-emotional learning is best integrated with academic learning; it is concerning if some of the forces that enhance children's ability to learn are elevated at the expense of others. Play and unscheduled time that allow for peer interactions are important components of social-emotional learning.[33,34]

REDUCED CHILD-DRIVEN PLAY AND THE POTENTIAL REPERCUSSIONS

Despite the numerous benefits derived from play for both children and parents, time for free play has been markedly reduced for some children. This trend has even affected kindergarten children, who have had free play reduced in their schedules to make room for more academics. A 1989 survey taken by the National Association of Elementary School Principals found that 96% of surveyed school systems had at least 1 recess period. Another survey a decade later found that only 70% of even kindergarten classrooms had a recess period.[35,36]

Currently, many schoolchildren are given less free time and fewer physical outlets at school; many school districts responded to the No Child Left Behind Act of 2001[37] by reducing time committed to recess, the creative arts, and even physical education in an effort to focus on reading and mathematics.[38,39] This change may have implications on children's ability to store new in-

formation, because children's cognitive capacity is enhanced by a clear-cut and significant change in activity.[35,40] A change in academic instruction or class topic does not offer this clear-cut change in cognitive effort and certainly does not offer a physical release. Even a formal structured physical education class may not offer the same benefit as free-play recess.[35,41] Reduced time for physical activity may be contributing to the discordant academic abilities between boys and girls, because schools that promote sedentary styles of learning become a more difficult environment for boys to navigate successfully.[42,43]

Some children are given less time for free exploratory play as they are hurried to adapt into adult roles and prepare for their future at earlier ages.[44–46] Parents are receiving carefully marketed messages that good parents expose their children to every opportunity to excel, buy a plethora of enrichment tools, and ensure their children participate in a wide variety of activities.[45,47] Children are exposed to enrichment videos and computer programs from early infancy as well as specialized books and toys designed to ensure that they are well-rounded and adequately stimulated for excelled development. Specialized gyms and enrichment programs designed for children exist in many communities, and there is an abundance of after-school enrichment activities. These tools and programs are heavily marketed, and many parents have grown to believe that they are a requirement of good parenting and a necessity for appropriate development. As a result, much of parent-child time is spent arranging special activities or transporting children between those activities. In addition to time, considerable family financial resources are being invested to ensure that the children have what are marketed as the "very best" opportunities.[33,34,47–49]

It is clear that organized activities have a developmental benefit for children, especially in contrast to completely unsupervised time.[2] Some research substantiates that for most children, benefits increase with higher levels of participation.[2] In addition, it has been suggested that because this lifestyle is associated with middle-class families, it may have a benefit in maintaining social class or in creating upward mobility.[50] It is less clear, however, at what point a young person may be "overscheduled" to their developmental detriment or emotional distress. Free child-driven play known to benefit children is decreased, and the downtime that allows parents and children some of the most productive time for interaction is at a premium when schedules become highly packed with adult-supervised or adult-driven activities.[45–47,51,52]

It is left to parents to judge appropriate levels of involvement, but many parents seem to feel as though they are running on a treadmill to keep up yet dare not slow their pace for fear their children will fall behind. In addition, some worry they will not be acting as proper parents if they do not participate in this hurried lifestyle.[45–47,51,52]

Although most highly scheduled children are thriving,[2] some are reacting to the associated pressures with anxiety and other signs of increased stress.[45,46,53] In this regard, highly scheduled children have less time for free, child-driven, creative play,[45,46,47,54] which offers benefits that may be protective against the effects of pressure and stress.[45,54] There is evidence that childhood and adolescent depression is on the rise through the college years.[55–60] Although there are certainly many factors involved, and a direct link between the early pressure-filled intense preparation for a high-achieving adulthood and these mental health concerns cannot be made on the basis of current research, it is important that we consider the possibility of this linkage. We can be certain that in some families, the protective influences of both play and high-quality family time are negatively affected by the current trends toward highly scheduling children.

As trusted child advocates, pediatric health professionals are ideally suited to help parents consider the appropriate balance between preparing for the future and living fully in the present through play, child-centered organized activities, and rich parent-child interaction. It is likely that the balance that needs to be achieved will be different for every child on the basis of the child's academic needs, temperament, environment, and the family's needs. Because there are so many forces that influence the trend toward focusing on future preparation, it is important that parents have a medical home that can reinforce the importance of some of the basic, tried-and-true aspects of child rearing.

FACTORS THAT HAVE CHANGED THE ROUTINE OF CHILDHOOD

There may be as many explanations for the current trends as there are families, but several key factors that have led to decreased free play should be considered.

1. There are more families with a single head of household or 2 working parents and fewer multigenerational households in which grandparents and extended family members can watch the children. Therefore, fewer families have available adult supervision in the home during the workday, which makes it necessary for children to be in child care or other settings in which they can be monitored by adults throughout the day.[61] Organized after-school activities and academic enrichment opportunities offer valuable alternatives to children who might otherwise be left with minimal or no adult supervision.
2. Many parents have learned how to become increasingly efficient in balancing work and home schedules. They wish to make the most effective use of limited time with their children and believe that facilitating their children to have every opportunity

is the best use of that time. Some may use some of the standards of efficiency and productivity they have mastered at work to judge their own effectiveness as parents; this is sometimes referred to as the professionalization of parenthood.[51] This phenomenon may create guilt in parents who find it difficult to balance competing demands after a taxing workday. Parents who understand that high-interaction, at-home activities (eg, reading or playing with children) present opportunities for highly effective parenting may feel less stress than those who feel compelled to arrange out-of-home opportunities.

3. Parents receive messages from a variety of sources stating that good parents actively build every skill and aptitude their child might need from the earliest ages. They are deluged in parenting magazines and in the media with a wide range of enrichment tools and activities that tout their ability to produce superachieving children. They read about parents who go to extreme efforts, at great personal sacrifice, to make sure their children participate in a variety of athletic and artistic opportunities. They hear other parents in the neighborhood talk about their overburdened schedules and recognize it is the culture and even expectation of parents.[51,52]
4. The college-admissions process has become much more rigorous in recent years, largely because of a baby boom hitting the college years. Parents receive the message that if their children are not well prepared, well balanced, and high-achieving, they will not get a desired spot in higher education. Even parents who wish to take a lower-key approach to child rearing fear slowing down when they perceive everyone else is on the fast track.[62,63] Children are encouraged to build a college resume through both academic excellence and a wide variety of activities and volunteer efforts starting at younger ages. In some cases, parents feel pressured to help their child build a strong resume.
5. In response to the increasingly rigorous college-admissions process, many secondary schools are judged by the rates in which their students are accepted by the most prestigious centers of higher learning. Partly in response to this, many students have been encouraged to carry increasingly rigorous academic schedules, including multiple advanced-placement courses. In addition, many students are taking preparation courses for standardized entrance examinations. These students are left with less free time because of the home preparatory time needed for their classes.
6. The pressure for admission to select schools begins for some families long before college. Selection for private preschool programs can even be competitive, and parents may need to consider how best to "package" their preschoolers.
7. There is a national trend to focus on the academic fundamentals of reading and arithmetic. This trend, spearheaded by the No Child Left Behind Act of 2001, is a reaction to the unacceptable educational performance of America's children in some educational settings. One of the practical effects of the trend is decreased time left during the school day for other academic subjects, as well as recess, creative arts, and physical education.[38,39] This trend may have implications for the social and emotional development of children and adolescents.[33] In addition, many after-school child care programs prioritize an extension of academics and homework completion over organized play, free play, and physical activity.[64]
8. The decrease in free play can also be explained by children being passively entertained through television or computer/video games. In sharp contrast to the health benefits of active, creative play and the known developmental benefits of an appropriate level of organized activities, there is ample evidence that this passive entertainment is not protective and, in fact, has some harmful effects.[65–68]
9. In many communities, children cannot play safely outside of the home unless they are under close adult supervision and protection. This is particularly true in areas that are unsafe because of increased violence or other environmental dangers.

WHY IS IT A PROBLEM?

It would be wrong to assume that the current trends are a problem for all children; some excel with a highly driven schedule. Because we need skilled young people to be well prepared to be tomorrow's leaders, we must recognize the advantages to the increased exposures and enriched academics some of our children are receiving. In fact, many of our children, particularly those in poverty, should receive more enrichment activities. But even children who are benefiting from this enrichment still need some free unscheduled time for creative growth, self-reflection, and decompression and would profit from the unique developmental benefits of child-driven play.

However, for some children, this hurried lifestyle is a source of stress and anxiety and may even contribute to depression.[45,46] Increased pressure to achieve is likely to manifest in school avoidance and somatic symptoms.[69–72] The challenge for society, schools, and parents is to strike the balance that allows all children to reach their potential without pushing them beyond their personal comfort limits and while allowing them personal free playtime.

It appears that the increased pressures of adolescence

have left some young people less equipped to manage the transition toward the college years. Many student health services and counseling centers on college campuses have not been able to keep pace with the increased need for mental health services, and surveys have substantiated this need by reporting an increase in depression and anxiety among college students.[57–59] A survey by the American College Health Association reported that 61% of college students had feelings of hopelessness during the previous academic year, 45% felt so depressed they had trouble functioning, and 9% suffered suicidal ideation.[57] Several studies have linked feelings of anxiety and depression with that of perfectionism and an overly critical self-evaluation.[72–77] Other studies have linked this perfectionism with highly critical parents who instill pressures to excel.[78–82] Perfectionism is challenging to the individual and has a broader effect on society because it may stifle creativity and unencumbered thinking.[83] There are no longitudinal studies that directly link intense preparation for adulthood during childhood to this rise in mental health needs, and there certainly are other causes, but some experts believe today's pressured lifestyle is an important contributor.[46,84]

Children may also have received an unintended message from this hurried, intense preparation for adulthood. They may have learned that the end-point goal—the best school or the best job—must be reached at all costs. High schools, colleges, and universities throughout the country are reporting that more students may be cheating to achieve the desired end result of a superior grade.[85,86] Despite grade inflation over the last decades, many teachers report increased stress in students when they achieve less-than-perfect scores.[87–89] This competitive era may be producing a minority of young people so intensely worried about the appearance of high achievement that they will forsake core values such as fairness and honesty for the sake of acquiring good grades.

FAMILY CONSIDERATIONS

Some families whose children are highly scheduled may also suffer. Adults who may already be burdened by work responsibilities and maintaining a household find themselves sacrificing their downtime because they need to arrange activities and transport children between appointments.[45–47] In addition, because of the pressures they feel to meet every one of the needs they perceive (or are told) their child requires to excel, they may feel inadequate and ultimately have less personal satisfaction in parenting.[51,52] Most importantly, parents lose the opportunity for perhaps the highest-quality time with their children. Some of the best interactions occur during downtime—just talking, preparing meals together, and working on a hobby or art project, playing sports together, or being fully immersed in child-centered play.

As parents prepare their children for the future, they cannot know precisely which skills each will need for the workforce. With added anxiety over their inability to adequately predict the future, they become susceptible to the promises of success and full preparation offered by all of the special enrichment programs and vulnerable to the belief that if their children are at least exposed to everything, they will have the best chance to be prepared. Although no one can be sure what skills will be needed, certain character traits will produce children capable of navigating an increasingly complex world as they grow older. These traits include confidence, competence or the ability to master the environment, and a deep-seated connectedness to and caring about others that create the love, safety, and security that children need to thrive. In addition, to be resilient—to remain optimistic and be able to rebound from adversity—young people need the essential character traits of honesty, generosity, decency, tenacity, and compassion. Children are most likely to gain all of these essential traits of resiliency within a home in which parents and children have time to be together and to look to each other for positive support and unconditional love.[90–95] Many families are successfully navigating a wide variety of commitments without sacrificing high-quality parent-child time,[2] but some families' ability to maintain essential parent-child time may be compromised by this hurried lifestyle. In these families, overscheduling may lead to less emotionally competent, well-buffered children.

WHAT ARE THE SOLUTIONS?

Because there are at least several causes for the decreased amount of child-directed play, there is no single position that child advocates should take. For example, in the case of a child who is economically disadvantaged and does not reside in a safe neighborhood, it may be unwise to simply propose more child-centered play. Although parents can be encouraged to optimize conditions for this kind of play in the home, there must be broad societal responses that address poverty, social inequities, and violence before we can advise parents to allow unsupervised play. In addition, for children in poverty, enhanced child care services, early community-based education (eg, Head Start), increased academic programming, more enrichment activities, and greater opportunities for community-based adult-supervised activities are warranted. Some of the needed solutions for this group of disadvantaged children remain beyond the scope of this article and are raised here to emphasize that the suggestions offered here need to be individualized; one size does not fit all.

For all children, however, advocates need to promote the implementation of those strategies known to promote healthy youth development and resiliency. Some of those strategies are community based, and others are school based, but many reside within the family. They are rooted in the deep connection that develops when

parents engage with their children.[92,93,95] Play remains an ideal venue for parents to engage fully, and child professionals must reinforce the value of this play. Some play must remain entirely child driven, with parents either not present or as passive observers, because play builds some of the individual assets children need to develop and remain resilient.

Parents need to feel supported to not passively accept the media and advertising messages that suggest there are more valuable means of promoting success and happiness in children than the tried, trusted, and traditional methods of play and family togetherness. Purveyors of these special programs should be encouraged to produce long-term evidence that define how their products/strategies produce more successful children. In parallel, we would encourage independent researchers to evaluate both the benefits and problems associated with these enrichment tools. Researchers should also continue to explore the type and quantity of activities that are likely to be enriching for children with different needs.

Colleges are seeing a generation of students who appear to be manifesting increased signs of depression, anxiety, perfectionism, and stress. They should clarify their messages about the type of students they seek in the face of widespread folklore that they seek only super-achieving students. Colleges certainly seek a physically and emotionally healthy student body with the character traits that support learning. Colleges could reduce the stress levels of young people and their parents if they offered clear, more realistic expectations about the type of students they seek and helped families to understand that there is a match for each reasonably prepared student. In addition, colleges should address the myth that desirable students are those who excel in every area. In the adult world, people rarely excel in more than 1 or 2 areas, while well-balanced individuals enjoy several others. Colleges should recognize the possibility that when children believe that they must excel in all areas to gain admission, they might respond to those perceived and unrealistic expectations with stress and anxiety.[62,63]

ADVICE FOR PEDIATRICIANS*

In the midst of so many conflicting messages about what parents should do to prepare their child for what is perceived to be an increasingly complicated, competitive world, pediatricians have a natural role to serve as caring, objective child professionals with whom parents can discuss their approach to child rearing and reflect on their own desires for their children. Because pediatricians have a unique and important role in promoting the physical, emotional, and social well-being of children and adolescents, it is important that they promote strategies that will support children to be resilient and to reduce excessive stressors in their lives.

- Pediatricians can promote free play as a healthy, essential part of childhood. They should recommend that all children are afforded ample, unscheduled, independent, nonscreen time to be creative, to reflect, and to decompress. They should emphasize that although parents can certainly monitor play for safety, a large proportion of play should be child driven rather than adult directed.
- Pediatricians should emphasize the advantages of active play and discourage parents from the overuse of passive entertainment (eg, television and computer games).
- Pediatricians should emphasize that active child-centered play is a time-tested way of producing healthy, fit young bodies.
- Pediatricians should emphasize the benefits of "true toys" such as blocks and dolls, with which children use their imagination fully, over passive toys that require limited imagination.
- Pediatricians can educate families regarding the protective assets and increased resiliency developed through free play and some unscheduled time.
- Pediatricians can reinforce that parents who share unscheduled spontaneous time with their children and who play with their children are being wonderfully supportive, nurturing, and productive.
- Pediatricians can discuss that, although very well intentioned, arranging the finest opportunities for their children may not be parents' best opportunity for influence and that shuttling their children between numerous activities may not be the best quality time. Children will be poised for success, basking in the knowledge that their parents absolutely and unconditionally love them. This love and attention is best demonstrated when parents serve as role models and family members make time to cherish one another: time to be together, to listen, and to talk, nothing more and nothing less. Pediatricians can remind parents that the most valuable and useful character traits that will prepare their children for success arise not from extracurricular or academic commitments but from a firm grounding in parental love, role modeling, and guidance.
- Pediatricians should be a stable force, reminding parents that the cornerstones of parenting—listening, caring, and guiding through effective and developmentally appropriate discipline—and sharing pleasurable time together are the true predictors of childhood, and they serve as a springboard toward a happy, successful adulthood.

* This guidance is offered by the American Academy of Pediatrics and, therefore, is targeted to pediatricians. Other health professionals who serve children and adolescents, including other physicians, pediatric and family nurse practitioners, and physician assistants, are welcome to consider incorporating these guidelines into practice.

- Pediatricians should help parents evaluate the claims made by marketers and advertisers about the products or interventions designed to produce super-children.
- Pediatricians should emphasize the proven benefits of reading to their children, even at very early ages.
- Pediatricians can be available to parents as sounding boards to help parents evaluate the specific needs of their child in terms of promoting resiliency, developing confidence and competence, and ultimately enhancing that child's trajectory toward a successful future.
- Pediatricians can support parents to organize playgroups beginning at an early preschool age of approximately 2.5 to 3 years, when many children move from parallel play to cooperative play in the process of socialization.
- Pediatricians can advocate for developing "safe spaces" in underresourced neighborhoods, perhaps by opening school, library, or community facilities to be used by children and their parents after school hours and on weekends.
- Pediatricians can educate themselves about appropriate resources in their own community that foster play and healthy child development and have this information available to share with parents.
- Pediatricians should support children having an academic schedule that is appropriately challenging and extracurricular exposures that offer appropriate balance. What is appropriate has to be determined individually for each child on the basis of their unique needs, skills, and temperament, not on the basis of what may be overly pressurized or competitive community standards or a perceived need to gain college admissions.
- Pediatricians should encourage parents to allow children to explore a variety of interests in a balanced way without feeling pressured to excel in each area. Pediatricians should encourage parents to avoid conveying the unrealistic expectation that each young person needs to excel in multiple areas to be considered successful or prepared to compete in the world. In parallel, they should promote balance in those youth who are strongly encouraged to become expert in only 1 area (eg, a particular sport or musical instrument) to the detriment of having the opportunity to explore other areas of interest.
- As parents choose child care and early education programs for their children, pediatricians can reinforce the importance of choosing settings that offer more than "academic preparedness." They should be guided to also pay attention to whether the settings attend to the social and emotional developmental needs of the children.
- Pediatricians can join with other child professionals and parents to advocate for educational settings that promote optimal academic, cognitive, physical, social, and emotional development for children and youth.
- Pediatricians should assess their patients for the manifestations of stress, anxiety, and depression in family-centered interviews for children and privately conducted interviews with adolescents.
- Because stress often manifests with physical sensations, pediatricians should be highly sensitized to stress as an underlying cause of somatic illness.
- Pediatricians should refer to appropriate mental health professionals when children or their parents show signs of excessive stress, anxiety, or depression.

CONCLUSIONS

Play is a cherished part of childhood that offers children important developmental benefits and parents the opportunity to fully engage with their children. However, multiple forces are interacting to effectively reduce many children's ability to reap the benefits of play. As we strive to create the optimal developmental milieu for children, it remains imperative that play be included along with academic and social-enrichment opportunities and that safe environments be made available to all children. Additional research is needed to explore the appropriate balance of play, academic enrichment, and organized activities for children with different temperaments and social, emotional, intellectual, and environmental needs.

NEW YORK PLANS TO MAKE GENDER PERSONAL CHOICE

"Separating anatomy from what it means to be a man or a woman, New York City is moving forward with a plan to let people alter the sex on their birth certificate even if they have not had sex-change surgery. Under the rule being considered by the city's Board of Health, which is likely to be adopted soon, people born in the city would be able to change the documented sex on their birth certificates by providing affidavits from a doctor and a mental health professional laying out why their patients should be considered members of the opposite sex, and asserting that their proposed change would be permanent. Applicants would have to have changed their name and shown that they had lived in their adopted gender for at least two years, but there would be no explicit medical requirements."

CLINICAL REPORT

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bond: Focus on Children in Poverty

Regina M. Milteer, MD, Kenneth R. Ginsburg, MD, MSEd, and the COUNCIL ON COMMUNICATIONS AND MEDIA and COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH

abstract

FREE

Play is essential to the social, emotional, cognitive, and physical well-being of children beginning in early childhood. It is a natural tool for children to develop resiliency as they learn to cooperate, overcome challenges, and negotiate with others. Play also allows children to be creative. It provides time for parents to be fully engaged with their children, to bond with their children, and to see the world from the perspective of their child. However, children who live in poverty often face socioeconomic obstacles that impede their rights to have playtime, thus affecting their healthy social-emotional development. For children who are underresourced to reach their highest potential, it is essential that parents, educators, and pediatricians recognize the importance of lifelong benefits that children gain from play. *Pediatrics* 2012;129:e204–e213

KEY WORDS

children, development, parents, pediatrician, play, poverty

ABBREVIATIONS

AAP—American Academy of Pediatrics

More than 15 million children in the United States younger than 18 years live in poverty.[1] These children experience disparities in education, health care, and socioeconomic resources.[2–6] Children living in poverty may also be deprived of the benefits of safe and creative playtime and access to age-appropriate extracurricular activities. The implications of play deprivation may be substantial, because play is essential to the social, emotional, cognitive, and physical well-being of children beginning in early childhood.[7] In addition, play offers an opportunity for parents to view the world from their child's perspective as they engage fully with their children during playtime; all families deserve ready access to this bonding opportunity. Even before the United Nations High Commission for Human Rights cited play as a right of every child, philosophers and psychologists, such as Plato, Piaget, and Friedrich Froebel, recognized the importance of play in healthy child development.[8–10]

This report addresses issues that may deprive children who live in poverty from gaining the maximum benefit from play. Because it follows an earlier report that focused on factors reducing free playtime for children whose families have resources, this report addresses issues specific to children from lower-income families.[7] Although some of the factors covered in the previous report may also apply to children from lower-income and poor families, 3 issues disproportionately affect these children and merit special attention. First, access to recess and other in-school creative and physical

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

outlets (eg, physical education, art, music), as well as after-school youth development programs are reduced. Second, out-of-school opportunities for play may be compromised by a lack of safe play areas, because parks and playgrounds are less abundant in lower-income areas and, in some cases, may be unsafe because of drug dealing, violence, and vandalism.[11,12] Finally, because lower-income parents have to deal with additional social, emotional, and economic stressors of daily living, they may have less time, energy, and resources available to provide active and creative playtime at the park, playground, or even in the home.

All children deserve the opportunity to reach their highest potential. The optimal developmental milieu for children includes academic enrichment, as well as opportunities for physical, cognitive, social, and emotional growth offered in school, home, and community settings. There are different forms of play—free unstructured play, which uses unlimited creativity, and semistructured play, which is guided play with joint attention by parent and child. It is beyond the scope of this report to define and divide, but poverty may prevent challenges to both unstructured and guided play.

Free unstructured play, as well as creative and physical outlets, contribute to social and emotional growth. This report offers guidance on how pediatricians can advocate for children by helping families, school systems, and communities consider how best to ensure play is protected and promoted as the optimal developmental milieu for positive child and youth development is explored.

THE BENEFITS OF PLAY

It could be argued that active play is so central to child development that it should be included in the very definition of childhood. Play offers more than cherished memories of growing up, it allows children to develop creativity and imagination while developing physical, cognitive, and emotional strengths. A previous manuscript described the benefits of play in fuller detail.[7]

Play enhances physical health by building active, healthy bodies. Physical activity beginning in early childhood prevents obesity.[13] In fact, play may be an exceptional way to increase physical activity levels in children and, therefore, may be included as an important strategy in addressing the obesity epidemic.[14,15]

Play contributes to healthy brain development.[16–18] Children engage and interact with the world around them through play from a very early age. Even in the academic environment, play helps children adjust to the school setting, thereby fostering school engagement, and enhances children's learning readiness, learning behaviors, and problem-solving skills.[19–31] In addition, play and recess may increase children's capacity to store new information, as their cognitive capacity is enhanced when they are offered a drastic change in activity.[19,20]

Play is essential to developing social and emotional ties. First, play helps to build bonds within the family. Children's healthy development is mediated by appropriate nurturing relationships with consistent caregivers.[16] Play allows for a different quality of interaction between parent* and child, one that allows parents to "listen" in a very different, but productive, way. When parents observe their children playing or join them in child-driven play, they can view the world through their child's eyes and, therefore, may learn to communicate or offer guidance more effectively. Less-verbal children may be able to express themselves, including their frustrations, through play, allowing their parents an opportunity to better understand their needs. Above all, the intensive engagement and relaxed interactions that occur while playing tell children that their parents are fully paying attention to them and, thereby, contribute to a strong connection.[17,32,33] Play also helps forge connections between children. It allows them to learn how to share, to negotiate and resolve conflicts, and to learn self-advocacy skills when necessary.[34,35] It teaches them leadership as well as group skills that may be useful in adult life.

Play should be an integral component of school engagement. School engagement is best realized when the educational setting attends to the social and emotional development of children as well as their cognitive development. The challenge is to make each child feel competent in a school setting, because the experience of success forms positive associations with school attendance.[9] Although we hope for each child to demonstrate academic strengths, opportunities to exhibit social, physical, and creative strengths optimizes the chances that children will realize their areas of strength. Play, recess time, and classes that foster creative aptitude and physical fitness allow for peer interactions that contribute both to school engagement and social-emotional learning. Social-emotional learning should not be thought of as distinct from academic learning, because it can creatively be integrated with academic learning and has been shown to enhance children's ability to learn.[36–38]

Play is a natural tool that children can and should use to build their resilience. At its core, the development of resilience is about learning to overcome challenges and adversity. As mentioned, children learn to deal with

*The word "parent" is used in this report to represent the wide range of adult caregivers who raise children.

social challenges and navigate peer relationships on the playground. In addition, even small children use imaginative play and fantasy to take on their fears and create or explore a world they can master. Play allows them to create fantasy heroes that conquer their deepest fears. It allows them to practice adult roles, sometimes while playing with other children and sometimes while play-acting with adults.[34,39–41] Sensitive adults can observe this play and recognize the fears and fantasies that need to be addressed; however, in many cases, play itself helps children meet their own needs. As they experience mastery of the world they create, children develop new competencies that lead to enhanced confidence and the resilience they need to address future challenges.[34,42]

FACTORS THAT REDUCE PLAY FOR CHILDREN IN POVERTY AND THE POTENTIAL IMPLICATIONS

Reduced Access to Play in Schools

There has been a national trend over the past decade of reducing playtime as an integral part of the school day. This trend is most easily observed in the reduction and, in some cases, elimination of recess; however, there are more subtle changes throughout the school day that reduce children's opportunity to play. First, the approach to early education that naturally incorporated play into the school day is shifting toward a more academically oriented instructional approach as new standards for reading readiness have changed for even kindergarten students.[9] Second, in many districts, there is less school time allocated to the creative arts and physical education.[9,43,44] These subjects contribute to a well-rounded education for a variety of reasons but share some of the benefits of play. They allow for a break from the standard academic subjects, foster creative and physical expression, and teach relaxation and stress-reduction skills that will last a lifetime.[9,13] Finally, even after-school activities have shifted away from play and physical activity and toward being an extension of academics and a space for homework completion.[43] This report focuses on reduced recess for illustrative purposes.

Many of these trends are disproportionately affecting underresourced school districts because of targeted efforts to reduce significant academic disparities. It is a national imperative that all children are given the opportunity to reach their academic potential, and efforts to reduce disparities between children with varying levels of resources are urgently needed. It remains important, however, that what is known about child development, including social and emotional learning, remains at the forefront of consideration as policies to raise academic standards and performance for children are created and implemented. Play, in all its forms, needs to be considered as the ideal educational and developmental milieu for children is created. Because poorer children are most dramatically affected by these policies, stakeholders must remain vigilant in ensuring that children do not inadvertently suffer from the diminution of play in their lives while exploring potential solutions to benefit them academically.

A report by the National Center for Education Statistics revealed that children who attend schools with high minority and high poverty rates in urban settings are more likely to have reduced recess time as compared with their peers in more affluent suburban areas.[44–46] Twenty-eight percent of schools with students who have the highest poverty rates had no recess at all.

The No Child Left Behind Act of 2001, designed to decrease the achievement gap of disadvantaged students, allocated additional educational resources and enrichment programs while decreasing recess time to allow more formal educational encounters.[47] At its inception, child development experts, including educators and pediatricians, voiced caution about the demise of playtime for young children with the proposed increased curriculum time of the program.[9] The experts supported the Alliance for Childhood recommendations that children from low-income families be afforded time to learn how to play and time to play.[9] Perhaps in recognition of the importance of the social and emotional development, as well as academic success of children who live at or below the poverty line, the US Department of Education in 2009 announced the Race to the Top Program, an education initiative that financially rewards school districts that support improving social, cognitive, physical, and emotional school readiness of disadvantaged students. In bids to receive the rewards, school districts must demonstrate focused programs that prepare students in the core academic subjects and other subjects that contribute to the development of well-rounded students, such as physical education and the arts.[48] Thus, children who might otherwise not be afforded opportunities for physical activity and enrichment programs outside of the school day have designated time to enhance their total development.

The disparity between access to recess between middle-income and lower-income districts may be explained by factors other than recess time being transferred to reading and math instruction. It has been suggested that reduced recess in poorer areas is reflective of adult concerns that it is not safe for poorer children to have

unstructured time; yet, it has not been proven that recess is unsafe. A time to play is different from the environment in which play occurs. When children have toys and equipment with which to play and attention is paid to helping the children transition back to class, the benefits of recess in terms of expressivity, exercise, and socialization suggest its vital role in the child's school day and overall well-being. Some experts believe the real danger is that the misunderstanding has led to the removal of playtime.[49] The reduction of recess and other in-school opportunities to play affect all children but may have a particularly detrimental effect on poorer children, because they are likely to have fewer opportunities to play outside of school.[11,12] In addition, because school is often the first true socialization environment for vulnerable children, the opportunity for social and emotional learning must not be compromised.

Poor children enter the educational system at a lower level of readiness, averaging 2 years behind their middle- and upper-class peers.[50] This may be explained in part by their increased exposure to social stressors (higher rates of single mothers who lack social supports and financial resources, absent fathers, limited access to early childhood education, unsafe neighborhoods, lack of preventive health care). They mainly enter schools in poor communities that lack financial resources to enhance the educational process.[51] Schools, under pressure to increase academic performance and to decrease the achievement gap of students, have increased direct educational time, including after-school enrichment and tutorial programs. Although it is important to decrease academic disparities, enhanced nonacademic interactions are also essential to prepare children for future success. If the overall goal is to decrease school failure, which could ultimately lead to depression, entry into the juvenile justice system, and continued economic deprivation, a response to the problem has to include efforts to promote school engagement.[49] As previously discussed, opportunities for play and social and emotional learning enhance school engagement. Quite simply, school engagement occurs when children succeed academically, have other nonacademic opportunities for success (creative arts, physical education), and consider school a place in which they feel safe and enjoy spending time.

Play in the school day offers benefits to academic as well as social and emotional learning. A recent report by Barros and others stated that a break during the school day of $\geq$15 minutes was associated with better teachers' ratings of classroom behavior scores.[19] Good behavior in the classroom is associated with a more productive learning environment secondary to increased attentiveness.[19,20] In addition, children's ability to store new information is increased, because their cognitive capacity is enhanced by a drastic change in activity.[51–53] A change in academic subject and even physical education class may not offer the same benefit as free-play recess.[49] A reduction of time for physical activity may have even greater implications for boys. Schools that use only sedentary styles of learning may be a more difficult environment for boys to navigate successfully and contribute to the discordant academic abilities between boys and girls.[54,55] These findings suggest that decreasing and eliminating recess for students at risk for school failure may be counterproductive.

Finally, it is recognized among educators that recess represents the most powerful strategy to get the most children to participate in physical activity.[56] In its "Physical Activity Guidelines for Americans," the US Department of Health and Human Services recommends 1 hour or more of physical activity per day, with a major part of the hour dedicated to moderate to vigorous physical activity at least 3 times per week for children and adolescents.[57] Physical education curricula should enhance attitudes, habits, and behavioral skills that result in continued physical activity throughout life.[14] Overall, recess offers the most available opportunity for children to play and to engage in physical activity, followed by physical education classes and after-school activities.[58]

Reduced Out-of-School Opportunities for Play

Children cannot play safely outside of the home in many poor communities —urban, suburban, and rural—unless they are under close adult supervision and protection. This is particularly true in areas that are unsafe because of increased violence or where other environmental dangers exist.[11,12] In the past, when neighbors knew each other and often supervised each other's children, there was an extra layer of protection for neighborhood children when they played outside. In today's society, it is not unusual for neighbors not to know one another. Therefore, parents are alone in protecting and supervising their children, which can severely limit outside playtime.

Children who are not engaged in play and physical activity outside of school hours spend time engaged in sedentary activities, such as viewing hours of television, playing video games, or listening to music. This time is often spent in isolation without social interaction and without adult supervision. In sharp contrast to the benefits of

active, creative play, there is substantial evidence that excessive screen time has adverse effects.[59–64] The AAP policy statement on media education presented research that associates media exposure with negative physical and behavioral health problems in children, including obesity, violent and aggressive behavior, depression, anxiety, earlier sexual behaviors, poor academic performance and self-image, nightmares, and tobacco and substance abuse.[63,64]

The sedentary lifestyle is associated with obesity, for which children from low income and minority families are already disproportionally at risk.[65] The AAP and others have reported that children who are obese in early childhood are more likely to be obese adults and to be at risk for the comorbidities associated with obesity, including type 2 diabetes mellitus, hypertension, coronary artery disease, hypercholesterolemia, hyperlipidemia, asthma, and sleep apnea.[14,66,67] In addition to the long-term health effects, obesity may be associated with immediate social and emotional consequences, including low self-esteem, negative body image, depression, teasing and bullying, social marginalization, and discrimination.[63,64,66,67] Obesity can have socioemotional effects on academic achievement and opportunities and can, therefore, thwart educational trajectories associated with long-term success.[66,67]

Family Considerations

Although lower-income parents have the same desires for their children to succeed and reach their full potential as do parents with greater economic and social assets, they must focus primarily on the family's day-to-day survival. When food and shelter are at risk, ensuring time for the children to have free and creative playtime may not be a priority. Economic hardship is a major obstacle for these families, in which the parents are more likely to have a lower educational level or be single heads of households. Minority households (black and Hispanic) and immigrant parents are at increased risk of having children who live in poverty.[1,68] There is more likely to be a history of substance abuse in poorer families. The neighborhoods in which they live lack community resources, such as community centers, parks, and fully equipped supervised playgrounds that offer safe places for children to play and to gather. Children have fewer opportunities to participate in organized sports. Because of fear of violence, families do not venture outside with their children for fun physical activities, such as walking, bike riding, swinging, swimming, playing tennis, or jogging.[11,12,69] In a safe environment with community resources, these activities would not be an additional financial burden to already challenged families.

Poor families may also be at a disadvantage in a material-driven culture in which marketing messages, often claims without proof, abound about what children need to prosper. They may absorb the messages that the best toys are those that are the most expensive or that children are only academically prepared for preschool if exposed to a variety of enrichment tools and activities that claim to produce high-achieving children. Parents who cannot afford these market-driven materials may feel disempowered to actively play with and enrich their children using the most effective known tools—themselves. Children's creativity is enhanced with the most basic (and least expensive) toys, blocks, dolls, and art supplies. Children's academic preparedness may be most developed with low-cost time spent reading with parents. They will learn to love books when they associate quality time with their parents with reading.[70]

Lower-income parents may have fewer resources, including time, to invest in playing with their children. Because play holds so many benefits, including fostering connection between parents and children, less play may be an added, although rarely mentioned, risk of poverty. No one is certain what skills will be needed for our children to be best prepared to lead us into the future, but we do have insight into which character traits will produce children capable of navigating an increasingly complex world. These include confidence, the ability to master the environment, and a connection to others. In addition, to be resilient—to retain hope and to be able to overcome adversity—young people need the added character traits of honesty, generosity, decency, tenacity, and compassion.[71] Children gain these essential traits within a home, when parents and children interact in a supportive manner and share unconditional love.[71–76] Play is a time-tested way for families to have these types of interactions.

WHAT ARE THE SOLUTIONS?

Because there are many causes for the decreased amount of play in the lives of lower-income and poor children, there is no single solution. In addition, simplistic proposed solutions might not take into consideration the complex interplay of factors that have led to decreased play, including the need for safety. For example, if a child does not reside in a safe neighborhood, it may be unwise to simply propose more outdoor child-centered play. Similarly, it may be naïve to insist on more recess without simultaneously coming up with solutions that address the very substantive issue of educational disparities. It is critical, however, that as strategies are developed that

address educational needs and safety, the recognition of children's need to play be strongly advocated, because play is known to promote healthy development and resilience.[46,52,55,58] To effectively preserve play in the lives of economically disadvantaged children, its presence in schools, communities, and homes must be supported.

In schools, the need to support social and emotional learning and healthy child development must be held alongside the need to increase academic scores. Otherwise, school engagement might suffer and efforts at creating a better-prepared generation might fail. The bottom line to school engagement is that schools should be the kind of places that children and adolescents want to be. This means that educators and policy makers must make opportunities for lower-income children to gain the benefits offered from physical education, recess, and the arts so they can reach their highest potential for cognitive, social, and physical development and so children and adolescents will like school. Advocates can also promote programs such as Head Start, the purpose of which is the promotion of school readiness for low-income children. Head Start provides an environment that enhances students' emotional, social, and cognitive development and has demonstrated effectiveness.[77] One of the keys to the success of Head Start has been the involvement of parents in social interaction with their children in playing, reading, and reading-related activities.[78]

Policy makers and community leaders must work together to prioritize the need for safe spaces for families to gather and for children to play. Supervised after-school programs can be critical to children who live in communities where outside playing might be dangerous or unsupervised. Community-based programs that offer a wide variety of services, ranging from homework assistance to athletic programs and from character development to the creative arts can contribute heavily to the positive development of youth. Keeping school facilities open for use by community families in the evenings and on weekends when they are usually closed may increase engagement in these activities. Communities can also offer strategies to link families at or below the poverty level to early education, health care, family support, and parenting education.

Parents of all income levels should use time together at home to engage in both free and structured play with their children. Playtime is bonding time for families. A first step may be education about the value of play that simultaneously refutes false notions that for play to be effective, it must involve expensive toys. Parents from across the economic spectrum need to understand that it is their presence and their attention that enrich their children and that one-on-one play is a time-tested, effective way of being fully present. In parallel, we must be sensitive to the fact that time itself is a commodity when struggling for economic survival. The most comprehensive solutions, therefore, must address broader economic disparities and other factors that create stresses for economically disadvantaged parents.

Certainly, these solutions are broad and societal, going beyond the purview of the pediatrician's office. But as child health professionals committed to the attainment of optimal physical, mental, and social health and well-being for all infants and children, pediatricians have a role in advocating for broad-based solutions that will preserve child play.

ADVICE FOR PEDIATRICIANS

As caring, objective child health professionals, pediatricians have a natural role to advocate for the conditions that allow for the optimal physical, emotional, and social development of children and adolescents. Because play contributes substantially to the healthy development and well-being of children, it is important that pediatricians promote the inclusion of play in homes, schools, and communities.†

- Pediatricians can educate parents about the importance of free, unstructured play in the normal development of children.
- Parents may be influenced by marketing messages that suggest the best toys are those that are financially out of reach. They should be educated that simple, inexpensive toys, such as dolls, jump ropes, blocks, balls, and buckets, are more effective in allowing children to be creative and imaginative than more expensive toys, which can make play a more passive and less physically involved experience.
- Pediatricians can educate parents about the benefits of using play as an opportunity to engage fully with their children. Playtime offers opportunities for parent-child bonding. Playtime offers parents the opportunity to promote healthy social-emotional development in their children through active engagement and shared imagination.
- Pediatricians can encourage parents to use love and understanding to encourage children to try again even when at first they fail. Parents can be informed that

†The guidance in this report is offered by the AAP and, therefore, is targeted to pediatricians. Other health professionals who serve children and adolescents, including other physicians, pediatric and family nurse practitioners, and physician assistants are welcome to consider incorporating this guidance into practice.

positive reinforcement goes further than negative responses as children engage in play alone and with others.

- Pediatricians can use well-child encounters to educate parents about the benefits of play to enhance physical activity that can help prevent childhood obesity. Parents should be educated about the potential for lifelong obesity in obese children, the lifelong health morbidities associated with obesity, and the long-term psychosocial impact of obesity.
- Parents should be encouraged to participate in physical activities with their children that will not have a financial impact on the family.
- Pediatricians can provide parents with information about resources that can provide financial, educational, and mental health assistance to families that have been marginalized by poverty. This may address the underlying stressors that interfere with parents' ability to engage fully in play activities.
- Pediatricians can educate parents about the negative impact of media exposure on children and encourage them to limit screen time and substitute other activities, including playtime and outdoor activities, for screen time. This is an opportunity to educate parents about the AAP recommendations regarding no media time for children younger than 2 years and fewer than 2 hours per day for older children.
- Pediatricians can provide parents and families with information about community resources that provide physical activities for children, such as team sports and camps. They should provide information about organizations that provide "scholarships" or grants that pay for activities that have associated costs.
- Pediatricians can educate parents about the importance of children's play outdoors in nature. Spending unstructured time in nature, surrounded by dirt, trees, grass, rocks, flowers, and insects inspires children's play and offers physical and emotional benefits.
- Pediatricians can advocate for safe play spaces for children who live in communities and attend schools with a high proportion of low-income and poor children by emphasizing that the lifelong success of children is based on their ability to be creative and to apply the lessons learned from playing.
- Pediatricians may consider offering presentations to help educators, community leaders, faith-based groups, and politicians understand the developmental benefits of play to children.
- Pediatricians may advocate for policies that reduce educational disparities while supporting the inclusion of recess, physical outlets, and the creative arts as means to enhance social and emotional learning and school engagement.

CONCLUSIONS

Children who live at or below poverty level in the United States experience educational and health disparities from early childhood. These children deserve additional resources to achieve academically, foster school engagement, and develop their social and emotional competencies. Many children reside in families that face stresses related to daily survival, including whether they will have food or safe shelter, leaving less energy to focus on enrichment opportunities, including play. Some live in neighborhoods where violence may be the norm and children playing on neighborhood playgrounds the exception. School systems are focused on overcoming their academic deficiencies in a safe environment often at the expense of time for arts, recess, physical education classes, and after-school activities that include playing, despite evidence that supports that what happens in play contributes substantially to social and emotional learning, even in the classroom.

Regardless of their socioeconomic status, all children have the right to safe places to play regularly, during which they develop cognitive, communication, problem-solving, negotiation, and leadership skills. They have the right to engage in safe and regular physical activity that will decrease the incidence of lifelong health disparities. The physically and emotionally healthy children of today will become the productive citizens who will contribute positively to society in the future.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Child Health Financing and Committee on Substance Abuse

Improving Substance Abuse Prevention, Assessment, and Treatment Financing for Children and Adolescents

ABSTRACT. The numbers of children, adolescents, and families affected by substance abuse have sharply increased since the early 1990s. The American Academy of Pediatrics recognizes the scope and urgency of this problem and has developed this policy statement for consideration by Congress, federal and state agencies, employers, national organizations, health care professionals, health insurers, managed care organizations, advocacy groups, and families.

ABBREVIATIONS. SCHIP, State Children's Health Insurance Program; LSD, lysergic acid diethylamide; PCP, phencyclidine hydrochloride; ADHD, attention-deficit/hyperactivity disorder.

INTRODUCTION

Leading the list of Americans' concerns for children is drug abuse, according to a 1997 Harvard study.[1] The numbers of children, adolescents, and families affected by substance abuse have sharply increased since the early 1990s.[2] Unfortunately, the availability of and financing for substance abuse prevention, assessment, and treatment have not kept pace with the needs of young people. Access to substance abuse services has decreased during the past decade because of inadequate insurance coverage, managed care controls, and low reimbursement rates. Although there are no national estimates of unmet need for substance abuse services for children, the surgeon general estimated that as many as 75% to 80% of children who are in need of mental health treatment fail to receive it.[3] The consequences of failing to intervene early and not providing age-appropriate substance abuse and mental health treatment are substantial and long-term.

This policy statement includes a summary of the prevalence of substance abuse among children and adolescents along with a review of financing problems experienced by those who are insured through private health insurance, Medicaid, and the State Children's Health Insurance Program (SCHIP), and those who are uninsured. The statement concludes with specific recommendations for financing substance abuse prevention, assessment, and treatment for children and adolescents. By necessity, these recommendations incorporate mental health problems and interventions because of the high prevalence of comorbid psychiatric disorders among children with substance abuse problems.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PREVALENCE AND IMPACT OF SUBSTANCE ABUSE AMONG CHILDREN AND ADOLESCENTS

Substance abuse by young people has increased in the past decade, and it is occurring at younger ages. According to results from the *Monitoring the Future Study* conducted in 1999 at the University of Michigan Institute for Social Research, 33% of 12th graders and 9% of eighth graders reported being drunk 1 or more times during the last 30 days.[2] As many as 23% of high school seniors and 10% of eighth graders reported using marijuana in the last 30 days, up from 14% and 3%, respectively, in 1991. The percentage of adolescents who reported using hallucinogens, lysergic acid diethylamide (LSD), phencyclidine hydrochloride (PCP), cocaine and crack cocaine, heroin, amphetamines, methamphetamines, barbiturates, and tranquilizers also increased between 1991 and 1999. In addition, cigarette use among adolescents, which is a risk factor for use of marijuana and other illicit drugs, also markedly increased during this decade. In 1999, 35% of 12th graders reported smoking cigarettes during the last 30 days, up from 28% in 1991. Among eighth graders, the reported 30-day cigarette use rate increased from 14% to 18%.

Epidemiologic data revealed that 9% of adolescent females and 20% of adolescent males meet adult diagnostic criteria for an alcohol use disorder.[4] Among adolescents and young adults with a substance abuse disorder, 41% to 65% also have a mental health disorder.[3] The most common of these are depression, conduct disorder, and attention-deficit/hyperactivity disorder (ADHD) in combination with conduct disorder. ADHD and learning disorders in combination with depression and anxiety disorders also carry a high risk of substance abuse. If the significant number of drug-exposed infants and the 1 in 6 children exposed to substance abuse within their families are added to these estimates, the size of the population affected by substance abuse and, therefore, potentially needing assistance dramatically increases.[5]

Obtaining accurate estimates of the prevalence of substance abuse among children and adolescents is very difficult. Most national studies survey only students, but many high-risk youth do not regularly attend school and, thus, are not included in these estimates. Other difficulties in obtaining reliable estimates are the results of coverage and reimbursement problems. Rather than using a substance abuse

diagnosis, health care professionals may be using procedure codes for treating associated symptoms of substance abuse, such as fatigue, irritability, weight loss, headache, abdominal pain, or depression. The lack of use of substance abuse codes may also reflect health care professionals' attempt to avoid stigmatizing a child. Consequently, existing prevalence data likely underestimate the scope of the problem.

Data specific to adolescents are limited, but there is growing evidence that successful early intervention and treatment carries significant benefit for the individual and society.[6] The most appropriate assessment of costs and benefits of treatment are based on broader outcome measures rather than abstinence alone. Despite the fact that there is no single treatment approach that works for all patients, standard treatments have been shown to produce significant decreases in drug use and in drug-related problems of crime, family violence, unemployment, welfare dependence, underachievement, and other antisocial behaviors.[7]

EXTENT OF FINANCING PROBLEMS FOR SUBSTANCE ABUSE SERVICES

Although most families whose children require substance abuse services experience financial difficulties related to high out-of-pocket expenses, those who are uninsured are at the greatest disadvantage. An estimated 14 million or 15.9% of children younger than 22 years had no health insurance coverage in 1999.[8] These families must rely exclusively on publicly funded services through their state's substance abuse and mental health agencies or must pay for care themselves. Often, uninsured youth receive uncompensated hospital and emergency care for acute symptoms only, which is seldom coordinated with primary care and behavioral health services. Unfortunately, publicly supported substance abuse and mental health services are underfunded and are typically available only for youth with serious emotional disturbances whose families meet a certain income threshold. Many young people, particularly those who are just beginning to abuse alcohol and other drugs, do not have serious emotional disturbances and, therefore, do not qualify for state-funded services. Moreover, children who are privately insured but without adequate substance abuse and mental health benefits are seldom eligible for state-funded services.

Most children under age 22 (65.4% or 57.7 million) are privately insured by plans purchased by their families individually or through their employers.[8] Often, these families rapidly exhaust their annual and even lifetime allotment of substance abuse benefits and must pay for needed services themselves or rely exclusively on self-help organizations, such as Alcoholics Anonymous and Narcotics Anonymous. Most private health insurance plans impose benefit limitations and cost-sharing requirements on substance abuse and mental health services that are greater than those imposed on general medical services.[9,10] For example, coverage of outpatient substance abuse services, when available, is typically short in duration and is often capped at an inadequate number of visits. Family therapy is often excluded. Inpatient substance abuse services are sometimes excluded altogether or covered only for acute detoxification purposes. Coverage of prevention, assessment, early intervention, relapse prevention, crisis intervention, partial hospitalization or day treatment, and residential care is seldom covered by private plans. Mental health benefits, however, are often provided somewhat more generously than are substance abuse benefits.[2,11]

In addition to benefit limitations, many private insurance plans require higher copayments or coinsurance in addition to separate deductibles for substance abuse benefits.[11] The Mental Health Parity Act of 1996 prohibits plans from imposing higher annual and lifetime out-of-pocket maximums for mental health services than for general medical services.[12] Although many states have passed mental health parity legislation, substance abuse parity is often not included. Thus, many of the gains that have been made in achieving parity only apply to mental health. This may perpetuate the pattern of physicians using procedure codes for treating associated symptoms of substance abuse rather than codes for a substance abuse diagnosis, which further distorts prevalence statistics. Also, the lack of specific data furthers the misconception that substance abuse is a consequence of mental illness rather than a primary disease, a comorbidity, or a significant precipitant of mental health problems.

Medicaid, the source of insurance for 16.4 million or 18.7% of all children younger than 22 years, has historically covered fewer adolescents than younger children.[8] Not until the enactment of SCHIP have many states taken the option to expand Medicaid to cover all adolescents from families with incomes at 100% of the federal poverty level. Unlike private coverage, Medicaid's benefits for children and adolescents are comprehensive and cover a continuum of inpatient and outpatient substance abuse and mental health services. Although Medicaid benefits are expansive, reimbursement rates have been very low and, as a result, serve as a disincentive to provide qualified pediatric and substance abuse services.

Regardless of the source of health insurance coverage, most substance abuse and mental health services are delivered by managed behavioral plans, distinct from general managed care plans and primary pediatric medical care. Although the literature shows that managed behavioral health plans have provided greater overall access to mental health services and a greater continuum of care, it also shows that as a result of tight utilization management, rates of ambulatory visits and hospitalizations have decreased.[3] Pediatricians and other referring health care providers report persistent problems in obtaining authorization for substance abuse treatment for children and adolescents. Often, utilization review criteria address the needs of adults, and children's conditions must be severe or associated with comorbidities to warrant extended counseling or hospital stays. For example, criteria such as chronicity, loss of work, and adult comorbidities—which are inappro-

priate for young people—are often used to determine whether substance abuse treatment is medically necessary. Moreover, many behavioral health plans have closed panels of mental health professionals with limited pediatric substance abuse training or experience. Seldom does coordination between primary care and behavioral health care take place effectively. Problems have also been reported in sharing medical information between behavioral health plans and primary care providers.

Compounding these difficulties is the overall shortage of ambulatory and inpatient substance abuse and mental health services for children and adolescents. Many inpatient facilities have closed during recent years. These shortages have resulted from many factors, including historically low rates of reimbursement provided to substance abuse and mental health professionals. To serve this population effectively is very labor intensive, and insurance dollars and public funds consistently fail to provide adequate reimbursement. Also contributing to payment and service gaps is the fact few insurers recognize the new *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition: Primary Care Version*, which was developed jointly by the pediatric and mental health communities to encourage earlier identification and primary behavioral interventions.[13] In addition, pediatricians are seldom able to receive reimbursement for providing counseling and education services to children at high risk of developing substance abuse problems.

Serious problems exist in the availability and organization of behavioral health services for the treatment of substance abuse problems among youth. Although there are substantial problems with low payment and persistent obstacles in gaining access to needed interventions, pediatricians are in a unique role to identify and intervene with children and adolescents who have or are at risk of substance abuse problems.[14] In addition, a cadre of physicians needs to be trained in the field of pediatric addiction medicine. However, the recruitment and retention of pediatricians and other health care providers in the field of addiction medicine has been very difficult, which seriously compromises the provision of high-quality substance abuse care.[14]

FINANCING RECOMMENDATIONS

Many changes need to be made to the financing and delivery of substance abuse care to improve the availability of services for all children and adolescents. Change in this area, however, is not likely to occur without the participation of a coalition of national and state legislators, public purchasers, employers, health professionals, families, and health services researchers. The American Academy of Pediatrics, together with other participating behavioral health organizations and consumer groups, released a consensus statement on insurance coverage for mental health and substance abuse services for children and adolescents, which highlights the deterioration of mental health and substance abuse services and recommends access, coordination, and monitoring strategies for achieving service improvements.[15] That article and this policy statement on financing should serve as blueprints for Congress, federal and state policy-makers, and employers.

The American Academy of Pediatrics recommends that Congress authorize the Substance Abuse and Mental Health Services Administration to conduct a comprehensive national study of the supply, distribution, financing, and quality of substance abuse prevention, assessment, and treatment services for children and adolescents.

Additional recommendations address the needs of all children, regardless of insurance status. In addition, there are specific recommendations that apply to those with private insurance, those with Medicaid or SCHIP coverage, and those who are uninsured.

For All Children and Adolescents, Regardless of Insurance Status

1. Ensure that substance abuse and mental health benefits are sufficient in amount, duration, and scope to reasonably achieve their purpose.
2. Allow pediatricians and safety net providers trained or experienced in substance abuse prevention, assessment, evaluation, and management services to be included in panels of professionals that provide these services.
3. Create an integrated system of referral and treatment for substance abuse that is consistent with the referral and treatment process of other chronic diseases.
4. Simplify and coordinate processes for families attempting to access substance abuse and mental health services for their children across public and private insurers plans, and public programs.
5. Improve preauthorization and utilization review criteria to be consistent with national standards on the treatment of substance abuse among youth developed by the American Academy of Pediatrics,[16] the Substance Abuse and Mental Health Services Administration,[17] the National Institute on Alcohol Abuse and Alcoholism,[18] and the American Society of Addiction Medicine.[19]
6. Provide reasonable compensation and allow reimbursement of counseling, coordination, and consultation procedure codes to enable pediatricians and other primary care providers to provide primary substance abuse and mental health services.
7. Adjust capitation rates to take into account substance abuse service needs and recommended clinical guidelines for length of care for children and adolescents rather than relying on historic utilization rates to establish capitation amounts.[19]
8. Encourage payers to reimburse for individual and group counseling and risk factor reduction interventions for children at risk of substance abuse problems.
9. Establish financing mechanism for smoking cessation programs for children.
10. Create financial incentives for comanagement of substance abuse treatment between primary care and behavioral health care (eg, transferring some behavioral health dollars into primary care).

11. Create mechanisms for sharing risk among public and private payors to allow for coverage of a comprehensive set of interventions to better manage children with complex cases.
12. Establish clear delineation of responsibilities with regard to children involved with multiple state agencies and required court-ordered treatment.
13. Ensure that health plans and health care providers adopt medical record and billing procedures to protect the confidentiality of children and adolescents.

For Privately Insured Children and Adolescents

1. Extend benefits to include a broader array of substance abuse prevention, assessment, and treatment services.
2. Establish parity between medical services and substance abuse and mental health services so that coverage of the management of substance abuse and mental health disorders is the same as coverage of other chronic conditions.
3. Reduce limitations on substance abuse and mental health services and allow for substitution of mental health and substance abuse benefits and use of alternative sites of care, including schools and homes.
4. Eliminate exclusions for specific diagnostic categories, chronic disorders, and preexisting conditions.
5. Reduce cost-sharing requirements for substance abuse services to encourage their use.

For Medicaid and SCHIP Insured Children and Adolescents

1. Target outreach efforts to ensure that Medicaid- and SCHIP-eligible adolescents are covered.
2. Ensure that a continuum of substance abuse and mental health services for children and adolescents are specified in state Medicaid plans and contracts, using a variety of benefit categories, including Early and Periodic Screening, Diagnosis, and Treatment expanded services.
3. In non-Medicaid SCHIP programs, offer supplemental or wraparound benefits to allow expanded behavioral health coverage for those who meet certain risk criteria.

For Uninsured Children and Adolescents

1. Expand SCHIP income eligibility levels to the maximum possible.
2. Expand the eligibility criteria of states' substance abuse and mental health service programs to include children with all levels of substance abuse and mental health risk.
3. Increase funding of state substance abuse and mental health programs for children and adolescents on the basis of comprehensive needs assessments and behavioral risk profiles of local communities.
4. Earmark a reasonable share of state block grants for prevention, assessment, and treatment services for children and adolescents.
5. Identify new revenue sources to increase availability of substance abuse services, including tobacco settlement funds and new taxes on alcohol.

The Inappropriate Use of School "Readiness" Tests (RE9512)

AMERICAN ACADEMY OF PEDIATRICS

Committee on School Health and Committee on Early Childhood, Adoption and Dependent Care

All children who reach the legal age of required school attendance are entitled to an appropriate education in the least restrictive environment.[1,2] Most communities offer some form of "school readiness testing" to screen for children with special educational needs, and most schools do this appropriately. However, readiness testing can vary greatly in its sophistication, and can easily be incorrectly applied and interpreted. When instruments and procedures designed for screening are used for diagnostic purposes,[3] or when tests are administered by individuals who have a limited perspective on the variations of normal development, or when staff with little formal training in test administration perform the screening, children can be wrongly identified and their education jeopardized. For these reasons, the use of readiness testing that is designed for screening should not be used to make placement decisions. No child should be excluded from school, placed in a special education setting, or provided with special educational services on the basis of such testing.

The decision that a child will require special educational services for developmental problems should be based upon the analysis of data obtained from individually administered, standardized developmental tests completed by qualified professionals with experience working with children of this age.[4] Such professionals include child psychologists, speech and language pathologists, special education diagnosticians, and pediatricians who have expertise in early childhood development. Special educational placement or services for developmental problems in the preschool and kindergarten years should be recommended only when appropriately administered developmental assessments clearly document significant developmental delays or serious emotional or behavioral problems.[5]

Because normal development is highly variable during the kindergarten and 1st grade years, school programs should be flexible and adaptable to each child's individual characteristics.[6-9]

The following principles are important:

1. All children are entitled to education in an environment where the great variability in early childhood development is understood and supported.
2. "Readiness" testing that relies on screening instruments and procedures should not be the sole basis for special education placement or services, nor should it be used to keep a child from access to formal education if the child is of legal age to attend school in that state or community.
3. If readiness screening suggests that the child has significant developmental delays or signs of emotional or behavioral problems, well-standardized tests that evaluate all relevant aspects of development need to be administered to the child in an individual setting by qualified professionals, experienced with children of this age, to determine if special class placement or special services are needed.

Clinical Report—Incorporating Recognition and Management of Perinatal and Postpartum Depression Into Pediatric Practice

abstract

FREE

Every year, more than 400 000 infants are born to mothers who are depressed, which makes perinatal depression the most underdiagnosed obstetric complication in America. Postpartum depression leads to increased costs of medical care, inappropriate medical care, child abuse and neglect, discontinuation of breastfeeding, and family dysfunction and adversely affects early brain development. Pediatric practices, as medical homes, can establish a system to implement postpartum depression screening and to identify and use community resources for the treatment and referral of the depressed mother and support for the mother-child (dyad) relationship. This system would have a positive effect on the health and well-being of the infant and family. State chapters of the American Academy of Pediatrics, working with state Early Periodic Screening, Diagnosis, and Treatment (EPSDT) and maternal and child health programs, can increase awareness of the need for perinatal depression screening in the obstetric and pediatric periodicity of care schedules and ensure payment. Pediatricians must advocate for workforce development for professionals who care for very young children and for promotion of evidence-based interventions focused on healthy attachment and parent-child relationships. *Pediatrics* 2010;126:1032–1039

BACKGROUND

Maternal and paternal depression affect the whole family.[1] This report will specifically focus on the impact of maternal depression on the young infant and the role of the primary care clinician in recognizing perinatal depression. Perinatal depression is a major/minor depressive disorder with an episode occurring during pregnancy or within the first year after birth of a child. A family history of depression, alcohol abuse, and a personal history of depression increase the risk of perinatal depression.[2]

The incidence of perinatal depression varies with the population surveyed, but estimated rates for depression among pregnant and postpartum women have ranged from 5% to 25%. Studies of low-income mothers and pregnant and parenting teenagers have reported rates of depressive symptoms at 40% to 60%. In general, as many as 12% of all pregnant or postpartum women experience depression in a given year, and for low-income women, the prevalence is doubled.[1] The rate of major and minor depression varies during pregnancy from 8.5% to 11.0%, and in the first year after birth of a child, the rate ranges from

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

6.5% to 12.9%; the rate of major depression during pregnancy ranges from 3.1% to 4.9%, and in the first year after birth of a child, the rate ranges from 1.0% to 6.8%. The timing shows a peak of 6 weeks after birth of a child for major depression and 2 to 3 months for minor depression.[2] There is another peak of depression 6 months after birth of a child.

The spectrum of depressive symptoms in the postpartum period ranges from "maternity blues" to postpartum depression and postpartum psychosis. Maternity blues affects 50% to 80% of new mothers and occurs during the first few days after delivery. Symptoms include crying, worrying, sadness, anxiety, and mood swings. Symptoms are usually gone after a few days or within 1 to 2 weeks. It does not impair function and can be treated with reassurance and emotional support. Postpartum depression occurs in 13% to 20% of women after birth. It meets the criteria of the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (DSM-IV) for depression and is distinct from maternity blues.[3]

Postpartum psychosis affects approximately 1 to 3 mothers of 1000 deliveries and most often occurs in the first 4 weeks after delivery. Mothers with postpartum psychosis are severely impaired and may have paranoia, mood shifts, hallucinations, delusions, and suicidal and homicidal thoughts. This is a serious condition that requires immediate medical attention and usually hospitalization. Preexisting bipolar disorder is a risk factor for developing postpartum psychosis.

Depression: A Family Issue

Fathers

Paternal depression is estimated at 6%.[4] Eighteen percent of fathers of children in Early Head Start had symptoms of depression. In an 18-city study, depressed fathers had higher rates of substance abuse.[5] The rate of paternal depression is higher when the mother has postpartum depression, which compounds the effect on children.[5,6] A nondepressed father has a protective effect on children of depressed mothers and is a factor in resilience.[7–9]

Family

Perinatal depression may be comorbid with marital discord, divorce, family violence (verbal and/or physical), substance use and abuse, child abuse and neglect, failure to implement the injury-prevention components from anticipatory guidance (eg, car safety seats and electrical plug covers),[10] failure to implement preventive health practices for the child (eg, Back to Sleep),[10–13] and difficulty managing chronic health conditions such as asthma or disabilities in the young child.[11,14] Families with a depressed parent (ie, any parental depression) overutilize health care and emergency facilities.[14] Studies of families of a person with major depression that began before 30 years of age demonstrate that the parent, siblings, and children are 3 to 5 times more likely to have major depression themselves. It is likely that some types of depression have genetic determinants.

THE IMPACT OF MATERNAL DEPRESSION ON THE INFANT

Maternal postpartum depression threatens the mother-child (dyad) relationship (attachment and bonding) and, as such, creates an environment for the infant that adversely affects the infant's development. The processes for early brain development—neuronal migration, synapse formation, and pruning—are responsive to and directed by environment as well as genetics. For example, it is known that an infant living in a neglectful environment, which is common with depressed mothers, can have adverse changes visible on MRI of the brain.[15,16] Infants who live in a setting of depression are likely to show impaired social interaction and delays in development. If the maternal depression persists untreated and there is not intervention for the mother and the dyadic relationship, the developmental issues (particularly attachment) for the infant also persist and are likely to be less responsive to intervention over time.[17] Addressing maternal depression in a timely and proactive fashion is essential to ensure healthy early brain and child development and readiness to succeed.[18]

In their evidence report, "Breastfeeding and Maternal and Infant Health Outcomes in Developed Countries,"[19] the Agency for Healthcare Research and Quality reviewed 6 prospective cohort studies regarding postpartum depression and breastfeeding. It revealed an association between not breastfeeding, or early cessation of breastfeeding, and postpartum depression. The report noted that "it is plausible that postpartum depression led to early cessation of breastfeeding as opposed to breastfeeding altering the risk of depression." It also noted that both effects might occur and that further investigation is needed to assess the nature of this association.

The consequences of maternal depression include negative effects on cognitive development, social-emotional development, and behavior of the child. Language acquisition depends on the number of words used by the family, playing, and having fun and cuddling with the infant and child,[20] which are likely to occur less frequently in the family of a depressed mother. As early as 2 months of age, the infant looks at the depressed mother less often, shows less engagement with objects, has a lower activity level, and has poor state regulation. Infants are at risk for failure to thrive, attachment disorder (deprivation/maltreatment disorder

of infancy as defined the *Diagnostic Classification of Mental Health and Developmental Disorders of Infancy and Early Childhood: DC0-3R*[21]), and developmental delay on the Bayley Scales of Infant Development at 1 year of age. Such infants are at risk for insecure attachment, which is associated with later conduct disorders and behavior problems. Maternal depression impairs parenting skills and can affect attention to and judgment regarding child supervision for safety and health management. The presence of other risks to healthy parenting, such as poverty, substance abuse, domestic violence, and previous trauma, in addition to depression, creates an increased cumulative risk. The infant's temperament is another factor, which may increase parental stress (difficult temperament) or impart resilience for the infant (easy temperament). Maternal depression in infancy predicts a child's likelihood of increased cortisol levels at preschool age, which in turn has been linked with internalizing problems such as anxiety, social wariness, and withdrawal.[22] Behavior problems, attachment disorders, depression, and other mood disorders in childhood and adolescence can occur more frequently in children of mothers with major depression.

Treating a mother's depression is associated with improvement of depression and other disorders in her child.[24] The STAR*D–Child (Sequenced Treatment Alternatives to Relieve Depression–Child) project is a study that began in December 2001 and followed 151 mother-child pairs in 8 primary care and 11 psychiatric outpatient clinics across 7 regional centers in the United States. The children were assessed every 3 months. The researchers concluded that "continued efforts to treat maternal depression until remission is achieved are associated with decreased psychiatric symptoms and improved functioning in the offspring."[24,25]

THE ROLE OF THE PRIMARY CARE PROVIDER

Many experts see a role for primary care practices in screening for depression, in general, and specifically for postpartum depression. The 1999 report of the Surgeon General on mental health,[26] the 2000 report of the Surgeon General's Conference on Children's Mental Health,[27] and *Bright Futures* guidelines[28] call for early identification and treatment of mental health problems and disorders. In a recent policy statement, "The Future of Pediatrics: Mental Health Competencies for Pediatric Primary Care," the American Academy of Pediatrics (AAP) also recognized the unique advantage of the primary care clinician for surveillance, screening, and working with families to improve mental health outcomes.[29] The AAP Medical Home Initiative[30] and the AAP policy statement on the family[31] addressed family-centered pediatric care. The President's New Freedom Act of 2004 states that early screening, assessment, and treatment of mental health problems must become a national goal.[32] Using data from the National Evaluation of Healthy Steps for Young Children (in the Healthy Steps practices, mothers were assessed for depression), the effect of maternal depressive symptoms on the children's receipt of well-child care was assessed. Minkovitz et al concluded that "Increased provider training for recognizing maternal depressive symptoms in office settings, more effective systems of referral, and development of partnerships between adult and pediatric providers could contribute to enhanced receipt of care among young children."[33]

A recent study from the University of Pittsburgh followed 731 families to examine the effect of intervention for maternal depression on behavior outcomes for children at the ages of 3 and 4 years. The researchers concluded that "reductions in maternal depression mediated improvements in both child externalizing and internalizing problem behavior."[23]

The majority of pediatricians agree that screening for perinatal depression is in the scope of pediatric practice.[34] In a survey by Olson et al,[35] few of the pediatricians felt that they were responsible for diagnosis and management, but the majority reported that they had provided brief interventions. Most of the pediatricians indicated that they had insufficient training to diagnose and treat maternal depression. The Parental Well-being Project of Dartmouth Medical School, which included 6 community pediatric practices in New Hampshire and Vermont, showed that pediatricians, using a simple 2-question screen, could effectively screen for perinatal depression. In the 6 months of the pilot, screening was performed at 67% of well-child visits.

As with other screening (developmental and behavioral, psychosocial) initiatives in practice, there have been perceived barriers to implementation, including lack of time, incomplete training to diagnose/counsel, lack of adequate mental health referral sources, fear that screening means ownership of the problem, and lack of reimbursement.[36] However, since 2000, there have been many successful models of screening in primary care practices, including developmental and behavioral screening, maternal depression screening, and psychosocial screening. In these projects, strategies have been implemented to integrate screening into office flow, to improve reimbursement, and to assist practices with identifying and collaborating with community resources, including mental health resources.[37] The

ABCD (Assuring Better Child Health and Development) Project, funded by the Commonwealth Fund and administered by the National Academy for State Health Policy, now involves 28 states and their AAP chapters. The Medicaid agency in Illinois, one of the ABCD states, pays pediatricians who use the Edinburgh Postpartum Depression Scale. Details of the various state initiatives and practice and parent materials are available at www.abcdresources.org and www.nashp.org. Heneghan et al,[38] in their discussion of factors associated with management of maternal depression by pediatricians, reported that in their sample, 511 of 662 pediatricians reported identifying maternal depression and addressing it in practice. They discussed the practice characteristics and attitudes related to this and the need for changes in attitude and practice to improve identification and management. In their article about the legal and ethical considerations of postpartum depression screening at well-child visits, Chaudron et al concluded: "We believe that from the perspective of feasibility, and now from the legal and ethical standpoints, the benefits of screening outweigh the risks."[39]

The primary care provider (PCP) has a particularly important role in the early identification of maternal depression and facilitation of intervention to prevent adverse outcomes for the infant, the mother, and the family. The PCP may be the first clinician to see the infant and mother after the infant is born; therefore, the PCP has very early access. In addition, it is the PCP who has continuity with the infant and family, and by the nature of this relationship, the PCP practices with a family perspective.

Screening for postpartum depression does not require that the PCP treat the mother. The infant is the PCP's patient. However, the PCP has a role in supporting the mother and facilitating her access to resources to optimize the child's healthy development and the healthy functioning of the family. For the mother, the infant's PCP provides information for family support, therapy resources, and/or emergency services as indicated. The PCP does provide guidance, support, referrals, and follow-up for the infant and the dyad relationship.

IMPLEMENTATION

Over the course of routine well-child care, the PCP and the family are developing a longitudinal relationship. Communication at each visit is tailored to the developmental process for the child and for the family. Anticipatory guidance addresses this dynamic developmental process. A crucial part of this communication is eliciting parent/family/child strengths and risks. Both parental and provider concerns determine the anticipatory guidance discussion.

Screening and surveillance for risk and protective factors are an integral part of routine care and the relationship with the child and family. This communication includes discussion of family support systems and other psychosocial factors such as poverty, parental mental health, and substance use. It begins as early as the prenatal visit. According to a recent AAP statement, a prenatal visit allows for getting to know the parent(s) and is an opportunity to identify any high-risk conditions to anticipate special care needs.[40] In this statement, the AAP also recommended that pediatricians communicate with obstetricians in their community to inform them of their prenatal visit policies so that obstetricians might refer patients for the prenatal visit. This would also provide an opportunity for the pediatrician to become aware of depression during the pregnancy and to plan for support and follow-up of the mother-infant relationship. Perinatal/postpartum depression is an early risk to the infant, to the mother-infant bond, and to the family unit. Surveillance and screening for perinatal/postpartum depression is part of family-centered well-child care. Including postpartum depression screening in the practice's preventive services prompting system can help ensure a reliable process for addressing risk.

The new *Bright Futures* guidelines include surveillance regarding parental social-emotional well-being. The US Preventive Services Task Force has endorsed the Edinburgh Postnatal Depression Scale as well as the general 2-question screen for depression.[2,41] Given the peak times for postpartum depression specifically, the Edinburgh scale would be appropriately integrated at the 1-, 2-, 4-, and 6-month visits. The *Current Procedural Terminology* (CPT) code 99420 is recommended for this screening, recognizing the Edinburgh scale as a measure for risk in the infant's environment, to be appropriately billed at the infant's visit.

The Edinburgh Postpartum Depression Scale is a simple, 10-question screen that is completed by the mother. A score of $\geq$10 indicates risk that depression is present. An affirmative response on question 10 (suicidality indicator) also constitutes a positive screen result. The screen is in the public domain and is freely downloadable. It is available in English and Spanish.

The 2-question screen for depression[41] is:

Over the past 2 weeks:

1. Have you ever felt down, depressed, or hopeless?
2. Have you felt little interest or pleasure in doing things?

One yes answer is a positive screening result. This screen is suitable to indicate risk of depression for adults in

general and is not specific to postpartum depression. Beyond the postpartum period, incorporating surveillance for parental mental health is warranted as well and might be accomplished by use of this 2-question screen.

Responses to a positive postpartum depression screening result range from reassurance (maternity blues) to supportive strategies (maternity blues, minor depression) and referral for specific interventions (minor and major depression). In the situation of milder symptoms, demystification and parent education may be effective in addressing concerns. Demystification lets the mother know that (1) she is not alone (postpartum depression happens to many women to varying degrees), (2) she is not to blame (hormonal changes play a big role), and (3) she will get better. Provision of extra return visits for support may be all the family needs and can build a strong foundation for the ongoing relationship between physician and family. Given the association with cessation of breastfeeding, particular promotion and encouragement of breastfeeding is indicated. When concerns are significant enough to warrant referral, there are several options and considerations. For the mother, particularly if the depression is more than mild, referral for therapy and/or medication may be needed. In some models, mothers have been referred to their obstetricians for follow-up; in others, mothers have been referred to mental health providers or their PCPs. It is important for pediatricians to communicate with the mothers' obstetricians and/or PCPs when these situations arise, because the obstetricians/PCPs will want to know about the mother's depression and may have a better understanding of the mental health system for adults.

When the mother needs specific follow-up for herself, there are often access issues because of uninsured or underinsured status. Community mental health programs may also provide limited services for these mothers. Care for the mother is an advocacy issue for all who serve children and their families, and it is an issue for state AAP chapters to address in states where access for mothers is limited because of state policy and service and payment structure.

If suicidality or psychosis is a concern, or the score on the Edinburgh scale is greater than 20, accessing crisis intervention services for the mother is necessary. In this instance and for other mental health emergencies, the practice should know and use the referral process for local public mental health crisis/emergency services.

Treatment must address the mother-child dyad relationship. For the child and mother together, there are generally more referral options. If the child is in an environment of maternal depression, he or she is at risk for attachment issues, failure to thrive, abuse/neglect, and, ultimately, developmental delay. At the very least, close follow-up of the child in the medical home is warranted. Specific screening for social-emotional development, as well as for general development and behavior, should be included. Pilowsky et al, in the STAR*D–Child (Sequenced Treatment Alternatives to Relieve Depression–Child) study described above, recommended that children of depressed mothers be followed and assessed.[42,43] The infant (with the mother) can be referred to a mental health clinician (with expertise for treatment of very young children) to address the dyad relationship. (Note that, depending on the family situation, this referral might be for the father or both parents.) For women with mild symptoms who need support, it may be enough to refer them to a parent support organization.

There are research-based programs for treatment of the dyad to promote healthy attachment and relationship. These programs include the Circle of Security, parent-child interactive therapy, and child-parent psychotherapy.[44,45] The Circle of Security is a parent education and psychotherapy program. It is an individualized video-based intervention based on attachment theory to strengthen the parents' ability to observe and improve their caregiving capacity. Child-parent psychotherapy is a therapeutic treatment for mothers and young children to increase attachment security.[45]

Referral to early intervention (Part C of the Individuals With Disabilities Education Act) services can provide general developmental intervention (education), which, if performed in the home, also provides mentoring for healthy interaction. If the infant exhibits specific delays, specific therapies can also be provided. (To identify lead agencies and contacts according to state, see www.nectac.org and www.nichcy.org.)

For many families, referral to Early Head Start, Mother's Morning Out programs, or child care is an effective option as well. Mothers may receive services through Healthy Families America, a Nurse-Family Partnership (if the referral occurs prenatally), other evidence-based home-visiting programs, or local volunteer organizations. (To locate Head Start programs, see http://eclkc.ohs.acf.hhs.gov/hslc/HeadStartOffices.)

Whatever the treatment and referral options implemented, follow-up of the infant and mother by the PCP (to monitor progress and to support the family) is necessary.

The AAP Task Force on Mental Health and the Committee on the Psychosocial Aspects of Child and Family Health have promoted collaborative, colocated, and integrated models for mental health services within primary care medical homes. In such settings, social work staff or mental health providers, who are colocated in the practice as part of the care team, can provide immediate triage for positive screening results, support and follow-up for mothers, and linkage and referral for more specialized services. Colocated and integrated mental health providers can perform secondary screenings and collaborate with the PCP for ongoing care.

Concurrent with the implementation of screening, the practice needs to identify support and intervention resources, both within the practice and in the community. Although it is often the case that PCPs do not perceive that there are resources in the community, many public and private resources may be discovered in the process of engaging community partners. Networking with community providers may be a new activity for a primary care practice. It can be accomplished by invitation to a lunch meeting at the practice to discuss the planned screening and referral activities, or a larger meeting called by a group of practices may be possible. Sending out a brief inquiry or survey to local mental health providers or family support groups may yield additional contacts. Partnering with parents in finding community resources is the essence of the medical home.

MODELS AND RESOURCES

- Virginia Bright Futures has a training Web site and has developed a new parent kit that includes information on perinatal depression and is given to 70% of new parents. Virginia Bright Futures partnered with the Virginia chapter of the AAP, the state Early Periodic Screening, Diagnosis, and Treatment (EPSDT), Resource Mothers, and Healthy Families Virginia[47] and recommends adopting perinatal depression screening guidelines in the state budget.
- *Parental Depression Screening for Pediatric Clinicians: An Implementation Manual*, by Ardis Olson, MD (available on the Commonwealth Fund Web site at (www.cmwf.org): In her studies, Olson has found that a 2-question paper-based screen, followed by a brief discussion with the mother and the pediatrician, was both feasible and effective in identifying women who needed follow-ups or referrals. One of the studies examined the difference between a verbal interview and a paper form; the paper screen was found to be far more effective.[35,47,48]
- *Depression During and After Pregnancy: A Resource for Women, Their Families, and Friends* (www.mchb.hrsa.gov/pregnancyandbeyond/depression): This Web site has information for the woman and/or her family about the definition and symptoms of postpartum depression and when to seek treatment.
- National Center for Children in Poverty, Project Thrive (www.nccp.org): The Public Policy Analysis and Education Center for Infants and Young Children at the National Center for Children in Poverty has as its core mission increasing knowledge and providing policy analysis that will help states build and strengthen comprehensive early childhood systems and link policies to ensure access to high-quality health care, early care and learning, and family support. The National Center for Children in Poverty has a document entitled "Reducing Maternal Depression and Its Impact on Young Children" (January 2008) that is an excellent source for pediatricians and AAP state chapters.
- Bright Futures (http://brightfutures.aap.org).
- The American College of Obstetricians and Gynecologists recommends psychosocial screening of pregnant women at least once per trimester (or 3 times during prenatal care) by using a simple 2-question screen and further screening if the preliminary screen result indicates possible depression.[49]
- The National Women's Health Information Center (www.4women.gov) is a federal government source for women's health information.

SUMMARY AND CONCLUSIONS

The primary care pediatrician, by virtue of having a longitudinal relationship with families, has a unique opportunity to identify maternal depression and help prevent untoward developmental and mental health outcomes for the infant and family. Screening can be integrated, as recommended by *Bright Futures* and the AAP Mental Health Task Force, into the well-child care schedule and included in the prenatal visit. This screening has proven successful in practice in several initiatives and locations and is a best practice for PCPs caring for infants and their families. Intervention and referral are optimized by collaborative relationships with community resources and/or by colocated/integrated primary care and mental health practices.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Increasing Antiretroviral Drug Access for Children With HIV Infection

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric AIDS, Section on International Child Health

ABSTRACT

Although there have been great gains in the prevention of pediatric HIV infection and provision of antiretroviral therapy for children with HIV infection in resource-rich countries, many barriers remain to scaling up HIV prevention and treatment for children in resource-limited areas of the world. Appropriate testing technologies need to be made more widely available to identify HIV infection in infants. Training of practitioners in the skills required to care for children with HIV infection is required to increase the number of children receiving antiretroviral therapy. Lack of availability of appropriate antiretroviral drug formulations that are easily usable and inexpensive is a major impediment to optimal care for children with HIV. The time and energy spent trying to develop liquid antiretroviral formulations might be better used in the manufacture of smaller pill sizes or crushable tablets, which are easier to dispense, transport, store, and administer to children.

INTRODUCTION

Background

It is estimated that 540 000 (420 000–670 000) children younger than 15 years were infected with HIV in 2006, mostly through mother-to-child transmission during pregnancy, delivery, or breastfeeding. Effective prevention services, including prenatal HIV testing, perinatal antiretroviral (ARV) prophylaxis, and safe alternatives to breastfeeding, are offered to fewer than 10% of pregnant women worldwide. Because of this global failure in prevention of HIV in children, by the end of 2005 an estimated 2.3 million (1.7–3.5 million) children were living with HIV infection globally; of these children, 2.0 million reside in sub-Saharan Africa.[1]

In the absence of treatment, most infants and children younger than 5 years with perinatally acquired HIV infection experience rapid progression to severe symptomatic disease and death, particularly in resource-limited countries. In a study of almost 3500 children enrolled in 7 perinatal trials in Africa, 35% of infected children had died by 1 year of age, and 53% had died by 2 years of age.[2] In older African children with perinatally acquired HIV infection, most already suffer severe symptoms at the time of diagnosis, including profound growth retardation, and few live to reach adulthood.[3]

In sharp contrast, most children with perinatally acquired HIV infection in resource-rich countries are treated early with highly active ARV therapy (ART).[4,5] Such ART, consisting of a combination of 3 or more potent ARV drugs, has been shown to dramatically modify the course of HIV infection in children, reducing

FDC—fixed-dose combination

mortality by fivefold or more and resulting in high survival rates (>90%) into adulthood.[6–8]

There are now intensive efforts by governments as well as multilateral and nongovernmental organizations to increase the number of people being treated with ART in resource-limited parts of the world (eg, the Global Fund, the US government–sponsored President's Emergency Plan for AIDS Relief [PEPFAR], the World Health Organization [WHO]– and United Nations–led "3 by 5 Initiative" and Universal Access, the Clinton Foundation). It is estimated that children accounted for approximately 15% of the 5 million new HIV infections that occurred globally in 2005. The rapid progression to death disproportionately decreases the number of children living with HIV to approximately 6% of the total infected population. In 2005, it was estimated that at least 660 000 children were in need of ART.[1] Of those, 90% live in sub-Saharan Africa. However, fewer than 5% of those who receive ART through the WHO 3 by 5 Initiative are children,[1] and through March 2005 only an estimated 9500 children living in PEPFAR "focus countries" were treated under PEPFAR funding.

Initial WHO guidelines on ART in 2002 (updated in 2003) included only one chapter on ARV management for HIV-infected children.[9] These guidelines have been updated as a pediatric-dedicated guideline document,[10] driven by the recognition that children have lagged severely behind adults in receiving ART and that there are numerous barriers to delivery of ART to children in resource-limited settings.[1,11]

Providing all pregnant women with the most effective prevention services possible within local settings, including prenatal care, HIV diagnosis, ARV prophylaxis, and appropriate feeding options, is important for minimizing the risk of HIV infection for their child. For children infected with HIV, overcoming barriers that limit access to ART is critical, and the enormous scale of the problem makes this an issue of worldwide concern. These issues have been addressed by organizations that are actively involved in prevention of mother-to-child transmission of HIV, deliver ART to children worldwide, and train practitioners in the appropriate use of ART. These organizations include the WHO, the Baylor International Pediatric AIDS Initiative,[12] the Elizabeth Glaser Pediatric AIDS Foundation (see "What About Us" at www.pedaids.org/News/Publications/Other/Children_s%20Battle%20to%20Access%20AI.aspx), Medecins Sans Frontieres, the Children's HIV Association of UK and Ireland, the Forum for Collaborative HIV Research (www.hivforum.org/projects/Pediatric%20Formulations.htm), and the Clinton Foundation.

This statement lists these barriers and potential ways to overcome them and provides strong support for the critical and urgent need for provision of ART to HIV-infected children globally. Multiple pediatric organizations throughout the world have endorsed this statement (see "Organizations That Endorsed This Statement").

Barrier 1: HIV Diagnostic Testing

Barriers to testing infants and children for HIV infection lead to a delay in diagnosis, and many infants and young children die before HIV is diagnosed or therapy can be given. Most pediatric HIV infections worldwide are attributable to mother-to-child transmission, with transmission occurring during pregnancy, around the time of birth, or through breastfeeding. Special tests are needed to diagnose HIV infection in infants and young children.

For adults and children older than 18 months, diagnosis of HIV infection is made by identification of antibodies to HIV in serum. However, because of the passive transplacental transfer of maternal HIV antibodies to the infant, newborn infants and children younger than 18 months will often test positive for the presence of anti-HIV antibodies even in the absence of true infection. Therefore, definitive diagnosis of HIV infection among infants and children younger than 18 months often requires the use of HIV-specific RNA or DNA nucleic acid tests to detect the virus itself,[13] instead of the inexpensive and readily available serologic assays that can be used in adults and children older than 18 months. These HIV-specific RNA or DNA assays are more expensive and more complex to perform and are not available in many areas of the world in which the risk of HIV infection in infancy is highest. In such settings, HIV antibody testing may be used to exclude HIV infection in nonbreastfed infants older than 9 to 12 months, because loss of passively transmitted maternal HIV antibody (seroreversion) occurs by 12 months of age in 95% of HIV-exposed but uninfected infants.[14]

Appropriate use of these nucleic acid tests requires that exposure of the infant or young child to HIV be identified by determination of maternal HIV-infection status. Ideally, this would occur before or during pregnancy. However, communication of maternal HIV-infection status from the mother's health care professional to the child's health care professional often does not occur. The linking of infant exposure to maternal infection will require system changes to optimize infant testing. The lack of appropriate testing in the youngest age group with the highest risk of HIV-related death prevents ART from being used in the very infants and young children who could potentially benefit the most from treatment with ARV drugs. To allow for early identification of HIV-infected infants and young children younger than 18 months, appropriate virologic testing technologies must be made available in resource-limited settings.

Psychological barriers to testing infants also may lead to a delay in diagnosis. The social stigma of the diagnosis for mother and child[15] and lack of treatment availability[16] may keep women from testing themselves to learn their

own HIV status and testing their children for HIV. Community-wide fear of discussing HIV infection in children may compound the effect of this barrier.

Barrier 2: Clinicians to Provide Care for Children With HIV

Even where appropriate HIV diagnostic testing is available and drugs for treatment of HIV infection and prophylaxis for HIV-associated infections are accessible, lack of personnel trained in treatment of children with HIV severely limits access to treatment for large numbers of children. In many areas of the world, medical care is provided by physicians, nurses, and other clinicians with training and experience in the management of adult, but not pediatric, patients. Even the best programs for training health care professionals in the principles of HIV care for children offer little practical exposure to treating pediatric patients, which is time- and resource-intensive. Some programs send health care professionals from resource-rich areas of the world to resource-limited areas to train local practitioners (eg, Medecins Sans Frontieres, the Baylor Pediatric AIDS Corps, the Clinton Foundation, the Children's HIV Association of UK and Ireland, UK/Kwazulu-Natal, the South Africa Collaboration). Additional efforts are needed to expand the availability of clinicians who are skilled in pediatric HIV care in resource-limited areas of the world,[17] including integrating pediatric HIV care into existing comprehensive child health programs, expanding local networks of experienced health care professionals, and linking local clinicians with local, regional, and international experts.

Barrier 3: ARV-Drug Formulations

Assuming that appropriate HIV diagnostic testing is available and the necessary clinical personnel are available to provide care and treatment to HIV-infected children, appropriate formulations of ARV agents for children are also necessary. Lack of availability of appropriate ARV formulations that are inexpensive and easily usable is a major impediment to access to economical health care for children with HIV. As of September 2005, 21 ARV agents were approved by the US Food and Drug Administration (FDA) for use in HIV-infected adults and adolescents older than 16 to 18 years in the United States, but only 13 were approved for children and adolescents younger than 16 to 18 years, and only 11 have pediatric formulations available[4] (see www.aidsinfo.nih.gov/other/cbrochure/english/13_en.pdf for a complete listing of HIV medications available in oral [liquid, capsule, and tablet] and intravenous formulations).

Because of the lack of appropriate pediatric formulations for certain drugs, caregivers of pediatric HIV patients may break or crush tablets meant for an adult patient in an attempt to produce child-size doses. With tablets that are asymmetric or not scored, this may lead to administration of erratic and inappropriate doses. Even with symmetrical tablets scored in the middle, the large quantity of medication in pills meant for adult use could mean that accurately breaking a scored tablet in half might not allow administration of a dosage small enough for an infant or young child, nor will it allow the incremental increases in doses required as the child grows. This problem can be addressed by developing products that contain smaller drug amounts per tablet or tablets that are scored to allow division accurately into halves or quarters. For regulatory purposes, bioequivalence studies may need to be performed by using the divided pills. Drug companies that are currently developing such drug formulations are to be commended.

Even when liquid formulations are available, special requirements and characteristics of such formulations may preclude their widespread use. For example, liquid drug formulations often require special storage such as refrigeration. The large volume of liquid formulations dispensed to allow ART to continue uninterrupted between clinic visits may make use of such drugs difficult in settings where transportation and storage are a challenge. For example, a 10-kg child who is being treated with standard doses of stavudine, lamivudine, and nevirapine, for whom a 3-month supply of drugs is dispensed at a clinic visit, would require 18 bottles of liquid that weigh almost half as much as the child (4.3 kg). For a rural family who may have walked a long distance to reach the clinical center, this is a significant issue. One commonly used ARV agent (zidovudine) requires high volumes of liquid and storage in brown glass bottles, which adds difficulty to treatment efforts.

Another problem with liquid formulations is the taste. When liquid formulations are developed, the taste is often so unpleasant that they may be practically unusable. Bad-tasting drugs are a well-recognized factor in treatment failures in children and lead practitioners to try many approaches to improve palatability of ARV drugs for children. When these attempts fail, some practitioners in resource-rich countries sometimes resort to insertion of gastrostomy tubes for medication administration.[18–20]

Finally, liquid formulations may contain excipients (additives to maintain the drug in solution) that could be harmful to children. For example, the oral solution of amprenavir has a high content of propylene glycol and vitamin E and should not be used in children younger than 4 years; other liquid formulations may contain high amounts of alcohol. Liquid formulations may contain high concentrations of sugar, which can be detrimental to dental health—a particular problem for children with HIV, many of whom have severely decayed teeth.

Although pharmaceutical companies may spend time and resources attempting to formulate different ARV medications into liquid formulations, this approach may not enable widespread, global access to ART for children. Such time and resources might be better used in the development of formulations that are more acceptable to

children and families than some of the liquid formulations that are currently available. Specifically, in addition to production of appropriate liquid formulations, development of the following should be strongly considered: (1) smaller tablets; (2) tablets in which active drug is uniformly distributed and in shapes that can be easily and accurately divided into halves or quarters to administer smaller doses; (3) capsule sprinkle formulations that can be opened and mixed with food; or (4) tablets that can be crushed, dissolved in water, or chewed.

Barrier 4: Appropriate Dosing of ARV Drugs in Children

Even when appropriate formulations of ARV agents are available for children, pharmacokinetic data may be insufficient to appropriately guide drug dosing, especially in the youngest children, who metabolize these drugs differently,[21] but also in adolescents, who may need higher than the "maximum adult dose" for adequate drug exposure.[22] For many available drugs, dosage recommendations made by European or US guideline-writing groups on the basis of pharmacokinetic and clinical studies in children may differ from doses approved by the FDA and European Medicines Agency.[4,5] The variability of drug exposure achieved by administration of "standard doses" of ARV drugs to children results in wide differences in plasma concentrations for many drugs, and some suggest the need for monitoring drug plasma concentrations in children to improve therapeutic outcomes[23]; this is clearly not practical in resource-limited settings.

Completion of the appropriate studies of new ARV agents for use in children younger than 13 years lags behind those in adults. Although it may be appropriate to perform initial phase 1 or 2 studies in adults for initial determination of drug safety, pharmacokinetic studies in children need to follow along quickly to ensure that when the drugs are approved and available for use in adults, information is already available to define appropriate use in children. When new formulations are developed to allow once-daily dosing in adults, these formulations need to be appropriately tested in children, and regulatory approval needs to be gained through the FDA or European Medicines Agency to ensure that the advantages of once-daily dosing become more widely available to children and younger adolescents 13 to 18 years of age. This is particularly critical for life-threatening diseases such as HIV. Government regulations need to be tightened to enforce this approach to pediatric drug development and approval. International cooperation is crucial for successful completion of pharmacokinetic studies of ARV medications in children.

Earlier evaluation of ARV-drug safety and pharmacokinetics in children is needed so that when new ARV formulations are approved for use in adults, there are also preparations available for children; enough information about drug pharmacokinetics in children is available to allow rational dosing recommendations.

Appropriate dosing of drugs in pediatric patients requires measurement of weight and height and the complex calculation of body surface area. The requirement for different doses according to age, weight, and body surface area may put accurate prescribing and safe dispensing of ART and other drugs to pediatric patients beyond the reach of many of the front-line health care professionals who manage children with HIV. Dosing by weight band (recommending a specific dose for an all-inclusive range of weights, so that complex dosing calculations are not needed) has been recommended (see http://bayloraids.org/resources/DosingGuide.pdf), and studies of this approach have shown safety and efficacy for patients as well as acceptability to practitioners.[24,25] Additional work on this approach is needed, including educating practitioners in its safety and effectiveness. Simplified dosing guides have been developed by the WHO and are readily available to clinicians who care for children and adolescents with HIV infection in resource-limited settings (see www.who.int/hiv/paediatric/en/index.html). These guides will increase the accuracy of dosing and dispensing ARV medications to these patients.

Barrier 5: Other Issues Related to ARV Drugs for Infants, Children, and Adolescents With HIV Infection

Many drugs are now being coformulated into tablets that contain 2 or 3 different ARV agents. These fixed-dose combinations (FDCs)[26–28] are easier to prescribe and dispense, which minimizes errors. A lower pill burden may enhance patient adherence to therapy. Many FDCs have been developed as generic drugs and are offered in resource-constrained settings at reduced prices, thus improving availability of ARV medications for adults in many areas of the world.

FDCs for adults cannot just be cut or directly scaled down for children without appropriate pharmacokinetic studies,[29] because the component medications may be required in different proportions for children than adults. Moreover, if the tablets are not formulated in equal layers, breaking the tablet may result in unequal doses being administered. FDCs are not currently available for children. Developing FDCs that are appropriately formulated for children should be a high priority for pharmaceutical companies.[11] In addition, development of pediatric FDCs as generic drugs, which are more affordable, will enhance availability of FDCs for use in children as it has in adults. However, with generic formulations being manufactured in many countries, formulations need to be standardized to minimize prescribing errors that might occur if pills are supplied in nonstandard sizes.

Drug administration to children is more complex than it is to adults. Finding the best way to get liquids out of a bottle and measured appropriately while avoiding spillage and fully using all of the medication in a bottle is not necessarily straightforward. Syringes enhance dos-

ing accuracy, but without the use of special bottle tops, there may be wastage of liquid left in the bottom of a bottle or spillage when trying to get to the liquid at the bottom. Dividing or crushing tablets takes time and may diminish adherence if it is too difficult. These issues of ease and accuracy of drug administration need to be considered in the effort to increase access to ART for children.

SUMMARY AND RECOMMENDATIONS

To increase the availability and appropriateness of the use of ARV medications for children, the following are suggested ways of overcoming the aforementioned barriers.

Barrier 1: HIV Diagnostic Testing

- Enhance early identification of infants with HIV infection by making appropriate virologic testing technologies available throughout the world.
- Support political, religious, and other community leaders in their endorsement of the value of HIV testing linked to treatment and prevention. Cultural leaders need to demonstrate acceptance and community support of HIV-infected individuals.

Barrier 2: Clinicians to Provide Care for Children With HIV Infection

- Work to expand education of practitioners in the care of children with HIV and expand the number of such practitioners in resource-limited areas of the world.
- Integrate pediatric HIV care into comprehensive child health programs.
- Facilitate collaboration among experts to build capacity and expand expertise in areas of need.

Barrier 3: ARV-Drug Formulations

- Produce pill formulations in smaller milligram amounts and smaller pill sizes.
- Configure tablets so they can be divided easily. This requires that thought be given to production of scored tablets of symmetrical shape with uniform dispersal of active drugs within the tablet, which can be divided accurately and then easily crushed or dissolved.
- In addition to production of liquid formulations, consider production of other formulations for pediatric use, including tablets for dispersal, chewable tablets, or sprinkle formulations.
- Consider best-possible attributes of liquid formulations, including taste, color, consistency, and the highest concentration possible, but recognize that the extra time and expense needed to develop a liquid formulation may be at too high of a cost if it delays availability of medications that are appropriately formulated for infants and children.
- Expedite the availability of new drugs for use in children by requiring that pediatric formulations (liquids and/or appropriate tablet dosage forms and sizes) be available at the time of country approval of the use of the drug in adults unless there is a biological imperative not to develop the drug for use in children.
- Develop formulations and perform necessary studies to allow once-daily dosing in children at the same time as planned for adults.

Barrier 4: Appropriate Dosing of ARV Drugs in Children

- Require studies of drug pharmacokinetics in infants, children, and adolescents at the time that phase 2 and 3 studies are being conducted in adults so that when drugs are approved for use in adults, there is adequate information to allow their appropriate dosing in each of those specific age groups.
- Provide dosing tables for pediatric formulations, preferably weight-band–based tables, to increase the accuracy of dosing and dispensing ART to children.

Barrier 5: Other Issues Related to ARV Agents for HIV-Infected Infants, Children, and Adolescents

- Increase the availability of FDCs for pediatric use.
- Make pediatric formulations affordable in the manner that adult formulations have been made more affordable in many countries.
- Provide drug-administration devices and tools with medications (eg, syringes, bottle tops for use with syringes, medicine spoons, tablet cutters, tablet crushers) and devices to aid adherence, including pill boxes that can accommodate a month's worth of pills or calendars with medications attached.

abstract

FREE

In 1977, the American Academy of Pediatrics issued a statement calling for universal immunization of all children for whom vaccines are not contraindicated. In 1995, the policy statement "Implementation of the Immunization Policy" was published by the American Academy of Pediatrics, followed in 2003 with publication of the first version of this statement, "Increasing Immunization Coverage." Since 2003, there have continued to be improvements in immunization coverage, with progress toward meeting the goals set forth in *Healthy People 2010*. Data from the 2007 National Immunization Survey showed that 90% of children 19 to 35 months of age have received recommended doses of each of the following vaccines: inactivated poliovirus (IPV), measles-mumps-rubella (MMR), varicella-zoster virus (VZB), hepatitis B virus (HBV), and *Haemophilus influenzae* type b (Hib). For diphtheria and tetanus and acellular pertussis (DTaP) vaccine, 84.5% have received the recommended 4 doses by 35 months of age. Nevertheless, the *Healthy People 2010* goal of at least 80% coverage for the full series (at least 4 doses of DTaP, 3 doses of IPV, 1 dose of MMR, 3 doses of Hib, 3 doses of HBV, and 1 dose of varicella-zoster virus vaccine) has not yet been met, and immunization coverage of adolescents continues to lag behind the goals set forth in *Healthy People 2010*. Despite these encouraging data, a vast number of new challenges that threaten continued success toward the goal of universal immunization coverage have emerged. These challenges include an increase in new vaccines and new vaccine combinations as well as a significant number of vaccines currently under development; a dramatic increase in the acquisition cost of vaccines, coupled with a lack of adequate payment to practitioners to buy and administer vaccines; unanticipated manufacturing and delivery problems that have caused significant shortages of various vaccine products; and the rise of a public antivaccination movement that uses the Internet as well as standard media outlets to advance a position, wholly unsupported by any scientific evidence, linking vaccines with various childhood conditions, particularly autism. Much remains to be accomplished by physician organizations; vaccine manufacturers; third-party payers; the media; and local, state, and federal governments to ensure dependable vaccine supply and payments that are sufficient to continue to provide immunizations in public and private settings and to promote effective strategies to combat unjustified misstatements by the antivaccination movement.

Pediatricians should work individually and collectively at the local, state, and national levels to ensure that all children without a valid contraindication receive all childhood immunizations on time. Pediatricians and pediatric organizations, in conjunction with government agencies such as the Centers for Disease Control and Prevention, must communicate effectively with parents to maximize their understanding of the overall safety and efficacy of vaccines. Most parents and children have not experienced many of the vaccine-preventable diseases, and the general public is not well informed about the risks and sequelae of these conditions. A number of recommendations are included for pediatricians, individually and collectively, to support further progress toward the goal of universal immunization coverage of all children for whom vaccines are not contraindicated. *Pediatrics* 2010;125:1295–1304

BACKGROUND INFORMATION

In 1977, the American Academy of Pediatrics (AAP) issued a statement calling for universal immunization of all children for whom vaccines are not contraindicated.[1] Most immunizations in the United States are provided by private health care providers. Data from the 2004 National Immunization Survey show that 60.4% of children were vaccinated solely by a private health care provider, and an additional 24.2% received at least some of their vaccinations from a private provider.[2] Immunizations protect the individual child being vaccinated, but for most vaccine-preventable diseases, achieving high levels of immunization in the community offers indirect protection to others, because they are not exposed to infectious organisms. Children with contraindications to some vaccines, such as children with immunodeficiencies, who cannot receive measles vaccine, are indirectly protected when there is high coverage with measles-containing vaccines around that child. The 1995 AAP policy statement "Implementation of the Immunization Policy"[3] supported specific guidelines for improving the vaccine-delivery system and increase immunization rates. Many of the 1995 recommendations have been achieved, including the expansion of immunization financing through the Vaccines for Children (VFC) program,[4] production of parent-friendly vaccine information statements (VISs), promotion of the standards for child and adolescent immunization practices,[5] and development of safer and combination vaccines. Additional recommendations in the initial policy statement included (1) sending parent reminders for upcoming visits and implementation of client reminder/recall systems, (2) using prompts during all office visits to remind parents and staff about immunizations needed at that visit, (3) repeatedly measuring practice-wide immunization rates over time as part of a quality-improvement effort, and (4) having in place standing orders for nurses, physician assistants, and medical assistants to identify opportunities to administer immunizations, unless such standing orders are prohibited by statute or other regulation.[6]

Childhood immunization rates are one of the leading health indicators used to assess the health of the nation as part of the US Department of Health and Human Services' *Healthy People 2010* initiative.[7] *Healthy People 2010* set targets for immunization coverage rates for children and adolescents, for individual vaccines, and for the aggregate series of vaccines. For children 19 through 35 months of age, *Healthy People 2010* set a target of 90% coverage for each of the following: 4 doses of diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine, 3 doses of *Haemophilus influenzae* type b (Hib) vaccine, 3 doses of hepatitis B virus (HBV) vaccine, 1 dose of measles-mumps-rubella (MMR) vaccine, 3 doses of inactivated poliovirus (IPV) vaccine, and 1 dose of varicella-zoster virus (VZV) vaccine.[8] For children who attend licensed child care and children in kindergarten through first grade, an additional target of 95% coverage was set for the DTaP, MMR, and IPV vaccines.[9] An aggregate target for children in the 19- to 35-month age group was set for a minimum of 80% coverage for the full set of vaccines, referred to as 4:3:1:3:3:1 (at least 4 doses of DTaP vaccine, 3 doses of IPV vaccine, 1 dose of MMR vaccine, 3 doses of Hib vaccine, 3 doses of HBV vaccine, and 1 dose of VZV vaccine).[10] For teenagers 13 to 15 years of age, *Healthy People 2010* sets a target of 90% coverage for each of the following: at least 3 doses of HBV vaccine, 2 doses of MMR vaccine, 1 or more doses of a tetanus-diphtheria booster (tetanus toxoids and diphtheria booster [Td] or tetanus-diphtheria-acellular pertussis booster [TdaP] vaccine), and 1 or more doses of VZV vaccine (excluding those who have had varicella disease).[11]

CHALLENGES

With the implementation of many of the recommendations from the 1995 AAP policy statement[3] as well as the revised version published in 2003,[6] much progress has been made toward achieving universal immunization, which was announced as a goal of the AAP in 1977. According to data from the 2007 National Immunization Survey, although only 77.4% of US toddlers 19 to 35 months of age had completed the combined immunization series (4:3:1:3:3:1) described previously,[7] individual coverage for each of these vaccines, with the exception of the 4-dose series of DTaP vaccine, exceeded 90% for the first time. In 2007, 95.5% of children 19 to 35 months of age had received at least 3 doses of DTaP vaccine, and 84.5% had received 4 doses of DTaP vaccine.[12] Although the Institute of Medicine, in its 2000 report on vaccine financing, cited differences in vaccination rates on the basis of race/ethnicity, poverty, and location in inner-city or rural areas versus suburban areas,[13] data from the 2007 National Immunization Survey showed similar vaccination rates for the 4:3:1:3:3:1 series for all ethnic/racial groups after controlling for poverty status and a difference in immunization rate of only 3.2% when comparing children at or above the poverty level with children living below the poverty level.[12] Also encouraging are recent data that showed rates of immunization coverage for American Indian/Alaska Native children to be comparable to those of white children.[12] There have been, and will continue to be, challenges to the vaccine-delivery system in terms of the science, economics, and social impact

of immunization, and these challenges have only increased as new vaccines and new vaccine combinations have been developed. Although new vaccines have the potential to improve the health of America's children, they have increased the burden on an already strained vaccine-delivery system.[14] Today's vaccine-delivery system is actually a poorly integrated set of separate systems that include vaccine production, distribution, and financing. Immunization coverage of adolescents is a special challenge, and rates for adolescent immunization remain below targets set by *Healthy People 2010*. For example, data from the National Immunization Survey showed that for teenagers 13 to 17 years of age, only 30.4% had received TdaP vaccine, and only 72% had received at least 1 dose of either Td or TdaP vaccine after 10 years of age.[15] Only 32.4% of adolescents had received meningococcal conjugate vaccine, and only 25.1% of female adolescents had initiated the 3-dose human papillomavirus (HPV) series. Coverage rates for some vaccines were higher but still below the *Healthy People 2010* targets for adolescents 13 through 15 years of age; only 89% of these adolescents had received at least 3 doses of HBV vaccine, 69% had received at least 2 doses of MMR vaccine, and 80% of those without a history of varicella disease had received at least 1 dose of VZV vaccine.[15]

Disruptions of Vaccine Supply

Shortages of specific vaccines during 2001–2002 brought to light the fragile nature of the US childhood vaccine supply and resulted in significant disruptions to childhood immunizations. Subsequent to the last publication of this statement in 2003, there have been increasingly disruptive shortages in vital vaccines. Over the past 10 years, shortages of heptavalent pneumococcal conjugate, Hib, HBV, influenza, hepatitis A virus, VZV, and meningococcal conjugate vaccines have led to missed opportunities to immunize and have placed a large administrative burden on the delivery system. Some of these disruptions have lasted for an extended period of time; for example, the recent shortage of Hib vaccine has left a cohort of children not fully immunized with their final dose of Hib vaccine. Shortages of vaccines may lead to parental anxiety and increased demands on the practice setting. Children who fall behind in their coverage because of these systemic delivery disruptions should be tracked and then encouraged to return for these missed vaccine doses by using a reminder/recall system, which will be more easily accomplished with the adoption of electronic health records.

High Vaccine-Acquisition Costs and Inadequate Payment

With the introduction of VZV and heptavalent pneumococcal conjugate vaccines, a new era of higher-cost vaccines began. The introduction of other new vaccines, such as rotavirus and HPV, and combination vaccines such as Pediarix (GlaxoSmithKline Biologicals, Rixensart, Belgium) (HBV, IPV, DTaP) and Pentacel (Aventis Pasteur, Toronto, Ontario, Canada) (Hib, IPV, DTaP), as well as new indications for additional doses of existing vaccines, further increased the acquisition cost and complexity of delivering childhood immunizations. The introduction of HPV vaccine, with its single-dose acquisition cost of more than $120, brought this issue into acute focus. Estimates from the Centers for Disease Control and Prevention (CDC) for the cost of fully immunizing an otherwise healthy child through the age of 18 years, based on the VFC federal acquisition-cost data chart, indicate that the total acquisition cost has increased to more than $900 for boys and more than $1200 for girls, which represents more than a sixfold increase since 1995.[16] These increased acquisition costs are primarily the result of the addition of new vaccines or substitution of newer vaccines for older products by vaccine manufacturers (eg, IPV replacing oral poliovirus vaccine), as well as regular increases in the acquisition cost of older products, which often go unrecognized and unpaid by third-party payers.

Although payment for nearly all vaccines is available through either public or private sources, the high cost of buying, storing, and administering these products has increased to the point that the financial viability of many clinics and private practices is threatened unless realistic payments are provided. For some physicians, the strong desire to provide complete and timely immunizations to their patients is no longer sufficient to overcome these financial barriers. Even with universal purchase of vaccines, the administrative payment level varies tremendously and is often inadequate to justify the actual cost of administering the recommended immunizations, particularly by the Medicaid program, but also by other third-party payers. Third-party payers do not consistently pay at a level adequate to cover the cost of acquisition, storage, and administration of recommended vaccines to their intended recipients. Private payers often delay their coverage of new vaccines and fail to maintain adequate payment as acquisition costs increase, thereby resulting in payments that are insufficient to cover the costs of procuring and delivering vaccines. In a recent survey, half of the pediatricians and family physicians responded that they had delayed purchase of specific new vaccines because of financial reasons, and 5% of pediatricians and 20% of family physicians reported that they were seriously considering discontinuing the vaccination of privately insured patients because of vaccine-

acquisition cost, administration, and payment issues.[17] This will be a larger problem for rural children and children who live in sparsely populated areas with shortages of pediatricians, where family practitioners are called on to provide the bulk of pediatric care. Should the financial situation worsen, the potential remains for more physicians, including pediatricians, to discontinue providing immunization services.

The public sector now purchases more than half of all vaccines administered in the United States through 3 sources of public funding: the federal VFC program, Section 317 federal discretionary grants, and state funds. Children who are eligible for the VFC program include uninsured children and recipients of government-funded health coverage such as Medicaid and the Children's Health Insurance Program in some states, children identified as Alaska Native/American Indian, and underinsured children if they receive vaccine at federally qualified health centers or rural health clinics. States also use Section 317 discretionary funds and their own funds to provide vaccines to children who are not covered by the VFC program or private third-party insurance.

The availability of vaccines through the VFC program and other government sources can be confusing. The VFC program is governed by a set of federal rules that define eligibility. Although VFC eligibility rules do not vary according to state, rules that govern Medicaid eligibility do vary according to state, thereby leading to variation in eligibility for VFC vaccines. These different Medicaid eligibility rules lead to disparities in access, with some states allowing VFC use for children from families with income up to 400% of the federal poverty level, whereas other states may limit VFC use to families with income only 100% of the poverty level. The burden of record-keeping in the practice setting and inconsistencies in vaccine supply for vaccines funded through Section 317 and other funds places a large administrative burden on practices that elect to participate in these programs. Although the VFC program includes coverage for all CDC-recommended vaccines, variations in supply of vaccines covered by other vaccine sources as well as privately sourced vaccines introduce further complexity for practices that participate in these programs. In some states, such as Georgia, state funds are used to expand the supply of publicly available vaccines by adding these additional vaccine types to their VFC inventory of vaccines, which leads to yet more confusion for providers. Many states prohibit the interchange of VFC-sourced vaccines with private-sourced vaccines, which leads to the uncomfortable situation of having different vaccines available in the office for different groups of patients. In practices that care for both publicly and privately insured patients, these differences in vaccine availability, acquisition cost, and delivery lead to administrative confusion, vaccine-administration errors, and financial uncertainty. In many states, payments for the administration of VFC vaccines are less than the actual costs of administration, further eroding physician participation in the VFC program. Also, although Medicaid may attempt to cover administration costs for its beneficiaries, providers who care for other children enrolled in the VFC program, such as those who are uninsured, are not entitled to payment for their administrative costs of vaccination. Clearly the current "public-private partnership" for purchase, distribution, and administration of immunizations must be redesigned to maintain a consistent supply of vaccines at an acquisition cost that is predictable. This partnership also needs to provide funding to compensate providers for storage, administration, and overhead that is sufficient to motivate practitioners to continue to participate in immunization services. Given the fact that the vast majority of immunizations are now administered by private-sector providers, it is unlikely that the public sector has the infrastructure to immunize the numbers of children who would be referred to it if private providers stopped administering vaccines. Current levels of payment to pediatricians for administration of vaccines by Medicaid and many private payers are far less than Medicare payments for administration of vaccines to adults, although administering vaccines to consenting adult patients takes significantly less work than administering vaccines to children, who are frequently nonverbal and less cooperative. Furthermore, payment for the administration of combination vaccines should be increased above that of single-component vaccines, or calculated on a per-component basis, in recognition of the fact that the additional components require additional effort on the part of the provider to explain the risks and benefits of each, and the payment should not be lower than that for the individual-component vaccines. The National Vaccine Advisory Committee recently issued a report listing 24 recommendations to ensure adequate supply, distribution, and administration of vaccines in the United States, including the elimination of the financial barriers described previously.[18]

Safety Concerns and Media Distortion

Another significant challenge to immunization delivery is the increasing concern within a segment of the general public about the safety and potential adverse effects of childhood immunizations. New and existing organizations and Web sites that portray

themselves as official resources for credible information on vaccines continue to appear on the Internet. These sites provide flawed or biased information that serves to fuel public concern regarding the safety of childhood immunizations, which leads to increased rates of immunization refusal or delays in on-time immunization.[19] Celebrity opponents to vaccination, who are given national coverage by broadcast and cable networks because of their celebrity status, argue their case without scientific support or expert rebuttal. Adding further confusion to the public debate, well-known physicians have also published books that make recommendations, without any scientific or evidentiary basis, for altered vaccine schedules that contradict AAP and CDC recommendations. As a result, pediatricians are seeing an increasing number of parents who are demanding alternate schedules or completely refusing immunizations.[20] Pediatricians find themselves spending large amounts of time convincing frightened parents to follow published evidence-based recommendations for vaccine administration, thereby reducing time available for other important components of anticipatory guidance. To counter these antivaccination advocates, the CDC, AAP, and other professional agencies and organizations are also making use of the Internet and other media to promote greater acceptance of universal vaccination by providing evidence-based information and culturally sensitive and language-appropriate educational materials concerning the benefits of immunizations and their risks (eg, www.vaccinateyourbaby.org). Social marketing techniques should also be explored as a promising strategy for promoting acceptance of immunizations among members of the general public who remain hesitant or resistant to vaccinate their children.[21]

In response to the need for greater transparency and accountability regarding vaccine safety and the need to maintain constant surveillance of adverse events after vaccination, the CDC has established the Immunization Safety Office (ISO). Along with the Vaccine Adverse Event Reporting System, a cooperative program between the Food and Drug Administration and CDC, the ISO provides an infrastructure for high-quality vaccine-safety research, surveillance, and effective clinical translation of important vaccine-research findings, with an emphasis on enhanced follow-up of potential adverse events by using innovative research methods. A new and growing area of interest in the field of vaccine safety is the use of genomic research techniques to identify potential gene-based individual differences in vaccine recipients who experience adverse but not causally related events, such as Guillain-Barré syndrome or wheezing episodes after influenza vaccination and rheumatoid arthritis after HBV vaccination. In 2009, the ISO issued a statement on the CDC Web site categorically denying any scientific evidence for the highly publicized alleged linkage between vaccines and autism.[22]

OPPORTUNITIES FOR IMPROVEMENT IN IMMUNIZATION COVERAGE

Despite the many challenges described, opportunities exist to improve immunization coverage in the future. With widespread implementation of the VFC program and continued availability of federal Section 317 discretionary funds and state funds, fewer children remain unimmunized in the United States because of purely financial obstacles. It is unfortunate that the level of funding for Section 317 funds is at the discretion of the federal budget and has not always kept pace with the growing cost of vaccine delivery. Continued efforts at the local, state, and federal levels are needed to further reduce the financial barriers to physicians and families associated with the complex system of vaccine financing described previously.

As reported in the previous version of this policy statement,[6] the Task Force on Community Preventive Services, convened by the US Department of Health and Human Services with support from the CDC, reviewed evidence from published reports of interventions designed to improve the timely immunization of children and adults.[23] On the basis of the strength of this evidence as applied to the pediatric age group, the task force recommended a number of strategies for increasing immunization coverage for children.[24] They grouped these recommendations into 3 overall strategies: increase in community demand for vaccinations; enhancement of access to vaccination services; and provider-based interventions (see Table 1). The task force did not evaluate the extent to which financial constraints on those that provide immunizations (clinics, private offices) also affect the availability of immunizations to their clients.

In 2003, the National Vaccine Advisory Committee (NVAC) published a report titled "Standards for Child and Adolescent Immunization Practices."[5] This report highlighted 17 immunization practices that were recommended to enhance immunization practices in the United States, including standards for vaccine availability; assessment of vaccination status at every health care encounter; improved communication with parents and patients about vaccine benefits and risks; proper storage, handling, administration, and documentation of immunizations; and a number of specific strategies for increasing coverage, such as reminder systems, office- and clinic-based patient record reviews, and community-

TABLE 1 Quality of Evidence Available to Support Potential Strategies for Increasing Immunization Coverage[24]

Evidence Sufficient to Strongly Recommend or to Recommend	Insufficient Evidence to Evaluate or to Recommend
Client reminder/recall systems	Community education
Requirements for child care, school, and college enrollment	Patient incentives
Multicomponent patient education	Patient-held medical records
Reducing out-of-pocket costs	Using schools and child care centers as vaccination sites
Increasing vaccination settings closer to patients' homes	Provider education
Expanding clinic hours	Using standing orders
Using emergency departments and subspecialty clinics	
Using WIC sites	
Offering drop-in vaccination services	
Home-visiting services	
Use of electronic records	
Office-based quality-improvement activities	

based approaches. This extensive list of recommended immunization practices overlaps with those recommended by the CDC task force, as described previously, but does not specifically include the task force's recommended strategies involving Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) offices, home-visitation programs, or requirements for entry into child care, school, and college.

In September 2008, the NVAC endorsed a set of principles and recommendations for increasing provider and patient participation in immunization information systems (IISs), formerly known as immunization registries, as another strategy for increasing immunization coverage. The AAP, in its own policy statement in 2006, also endorsed the continued development and implementation of IISs.[25] To be most effective, IISs must provide bidirectional flow of vaccination information, allowing providers to enter vaccination data and retrieve patient-specific vaccination histories. It is unfortunate that many current IISs are incompatible with existing electronic medical records and, thus, present an added cost to those practices that are required or wish to participate in these systems. The time and cost of entering vaccination information into an IIS can be considerable; therefore, payments by government and private insurers to support the entry of patient immunization data into IISs will be necessary for clinical practices that currently use paper-based records to participate in these new systems. Although the deployment of IISs will make it easier to identify patients who are behind on their immunizations, the provision of vaccinations during sick visits or emergency department visits may not be desirable in all situations because of the possible impact on patient compliance with recommendations for well-child care.[26]

RECOMMENDATIONS

Recommendations below are based on evidence reviewed by the CDC Task Force on Community Preventive Services[24] and in the NVAC "Standards for Child and Adolescent Immunization Practices" report[5] and are updated to include newer recommendations for the use of IISs and to emphasize the importance of the pediatric medical home as the optimal location for the delivery of pediatric immunization services. Additional recommendations beyond those addressed directly in either of these previous publications acknowledge the extensive financial and administrative barriers that private pediatricians and pediatric clinics face in purchasing and delivering an adequate supply of vaccines to their patients and the current use of various media to influence parental decision-making by those who oppose a policy of universal childhood immunizations. In its most recent report, the NVAC included a set of 24 recommendations that address financial barriers that continue to undermine efforts to reach the goal of universal immunization coverage for children in whom vaccinations are not contraindicated.[18] Where appropriate, those recommendations have been incorporated into this policy statement.

1. Collectively, pediatricians and child health care professionals should join with the AAP and its chapters in the following activities.
   - Advocate for all children to receive comprehensive health care, including childhood immunizations, in a medical home[27] and improve access for children who are most likely to experience barriers to comprehensive care in a medical home, including members of racial and ethnic minorities, poor or uninsured children, children who live in inner-city or rural areas, and children with chronic medical conditions. Pediatricians can further assist by collaborating with local public and private child health services to identify children without access to a medical home and providing assistance in referring them to an appropriate medical home. The medical home should maintain the children's health records, including immunization records; furthermore, the pediatric medical home requires a level of payment at least as great as that for the adult medical home.
   - Assist in the identification of other venues in which vaccina-

tions can be delivered if a significant number of children in a community do not have convenient access to a medical home or if existing medical homes are not able to meet the demand. If sufficient pediatric medical homes are not available, additional venues could include public health department clinics, WIC program offices, child care centers, school-based health clinics, and, in those states that allow it, pharmacies. Elimination of the financial barriers to immunization delivery, as described in this statement, would reduce the need to consider such alternative venues.

- Advocate for reform in the distribution and payment systems that apply to the procurement, storage, and administration of immunizations and that often act as a barrier to physicians who wish to provide immunizations in their private offices and in their clinics. It is important that private- and public-sector payers provide payments to practitioners and clinics for immunization services sufficient not only to cover the direct and indirect costs of these services but also to provide a financial incentive for ongoing participation in this vital service to the community. Using "The Business Case for Vaccine Pricing" (available from Practice Management Online [PMO] at http://practice.aap.org/content.aspx?aid=1808), physicians and other child health providers can better understand and advocate for adequate payment for immunization services, including the direct costs of vaccine procurement, storage, and administration as well as the cost of related materials and the professional time involved in providing counseling to concerned parents. These payments must also be sufficient to cover the added indirect opportunity costs of stocking and purchasing expensive vaccines, as well as the predictable costs of wastage, refrigeration, and space. A vaccine-cost calculator is now available on the PMO Web site (http://practice.aap.org/vaccinecalculator.aspx). Private physicians should also be encouraged to participate in vaccine-purchasing pools.
- Advocate for a public-private partnership in the manufacture and distribution of vaccines so that purchasers of vaccines (eg, physicians, the VFC program) know what their acquisition costs will be and what to expect in payment for these services before exposing themselves to potential financial losses because of changes in pricing and third-party payment. These efforts would also include advocating for immediate recognition of and payment for newly recommended vaccines, adjustments in payments when prices increase on existing vaccines, and payment of administrative fees per component, not per injection, so as not to discourage the use of combination vaccines. When new vaccines are introduced or when price increases are announced, manufacturers should offer reasonable terms for payment to facilitate their introduction, thereby allowing physicians to purchase and receive payment for vaccines without experiencing excessive financial burden.
- Advocate for the removal of economic and administrative barriers for physicians who wish to participate in the VFC program and other state vaccination programs. Public health department clinics and private physician offices should be included as venues for underinsured VFC-eligible children to receive immunizations, rather than limiting access for these children to federally qualified health centers and rural health clinics.
- Advocate for the removal of economic barriers to immunizations for parents by minimizing their out-of-pocket expenses for immunizations. Public and private payers should provide first-dollar coverage for all recommended vaccines (ie, without copays or deductibles). Use of a uniform acquisition-price standard as the basis for acquisition cost for all vaccine products should be advocated. Such a basis could be the CDC Private Sector Price List, as posted on its Web site (www.cdc.gov/vaccines/programs/vfc/cdc-vac-price-list.htm). Funding is also encouraged to support studies that periodically estimate the actual financial burdens, both direct and indirect, of administering vaccines, and that third-party payers should be expected to honor and pay for these costs.
- Advocate with vaccine manufacturers and state and federal governments to maintain an adequate supply of all childhood vaccines at all times and to provide adequate notice, quick planning, and equitable distribution to all entities that administer immunizations to deal with shortages as they arise.
- Advocate for studies that ensure that the safest and most effective vaccines and combination products are available to children.
- Work with other physician organizations and their representa-

tives to advocate with state and federal governments, private payers, and employers who purchase health care to ensure that timely access to all immunizations recommended by the CDC, the AAP, and the American Academy of Family Physicians for all children remains a high public policy priority.

- Advocate for interoperability of IISs and electronic health records that accommodate bidirectional flow of information to facilitate pediatrician participation in these systems. IISs should also provide support for automated identification of vaccine products (eg, bar codes or radiofrequency tags) and include integrated, up-to-date VISs.
- Advocate for payment by commercial and government payers for the entry of patient immunization information into county and state IISs or for the interfaces necessary to allow transfer of these data from electronic health records to these IISs to support pediatric care provider participation in these systems. Likewise, schools must have adequate funding to cover the costs that arise from their mandate to verify immunization coverage for their students.
- Support ongoing education and quality-improvement programs for pediatricians and other child health care professionals about important vaccine-related issues, including the dissemination of peer-reviewed evidence for more effective immunization delivery. Educational programs should be offered to help physicians incorporate optimal business practices in their office or clinic setting to maximize their opportunities to offer immunizations to all children for whom vaccines are not contraindicated.
- Vigorously mount a public relations campaign to better inform the public and counter the influence of misinformation spread by celebrities and others who participate in the antivaccination movement to minimize the negative impact of this false information on the health of children. The public must be educated with regard to the risks associated with vaccine-preventable diseases and the impact of immunizations on their prevalence by using culturally effective materials in English and other languages.

2. Individually, pediatricians and other child health professionals are encouraged to do the following to increase the immunization coverage of those under their care.
   - Expand opportunities to immunize in the setting of a medical home by extending office hours when possible, making vaccinations available during visits for minor illnesses (if appropriate), and maintaining accurate and up-to-date records of immunizations received by each patient. Participation in IISs, including those that cross political boundaries, is also recommended.
   - Implement reminder/recall systems based on office charts or electronic information systems and minimize out-of-pocket costs to patients being immunized.
   - Undertake office- and clinic-based assessment and improvement activities necessary to maximize their practices' effectiveness in immunizing children. Offices and clinics should maintain up-to-date protocols that are accessible wherever immunizations are delivered and ensure that medically accepted contraindications to immunizations are accurately identified. This goal can be supported by using an IIS that is easily updated with new vaccine information and changes in protocols for existing vaccines.
   - Ensure that all those who administer immunizations are fully immunized (unless contraindicated), are knowledgeable about immunizations, and participate in continuing education activities regarding immunizations, including their proper administration, storage, and handling.
   - Always provide and document the most current VIS to educate parents about vaccine risks and benefits of immunizations, in accordance with the Vaccine Injury Compensation Program and CDC recommendations (available on the AAP Web site at www.aap.org). Physicians are encouraged to discuss the benefits and risks of immunizations with parents who refuse or delay age-appropriate vaccinations and to document ongoing discussion and refusal by using a form such as the AAP "Refusal to Vaccinate" template (http://practice.aap.org/popup.aspx?aID=2685&language). Although the AAP strongly discourages pediatricians from discharging patients from their practices solely as a result of vaccine refusal, pediatricians may encourage a family to find another physician or practice if there is a substantial level of distrust, differences in philosophy of care, or persistent poor quality of communication.[28]
   - Provide their patients with the addresses (URLs) of reliable and

accurate immunization and vaccine-information Web sites that discuss immunization issues (eg, www.aap.org/healthtopics/immunizations.cfm, www.immunize.org, www.cdc.gov/vaccines, www.vaccinateyourbaby.org).

- Report all adverse events related to vaccines by using the Vaccine Adverse Event Reporting System (see http://vaers.hhs.gov/index for forms and instructions), as directed by the National Childhood Vaccine Injury Act.[29]
- Support and implement the standards for child and adolescent immunization practices as endorsed by the AAP and the NVAC.[5]

Indications for Management and Referral of Patients Involved in Substance Abuse (RE9947)

AMERICAN ACADEMY OF PEDIATRICS

Committee on Substance Abuse

ABSTRACT. This statement addresses the challenge of evaluating and managing the various stages of substance use by children and adolescents in the context of pediatric practice. Approaches are suggested that would assist the pediatrician in differentiating highly prevalent experimental and occasional use from more severe use with adverse consequences that affect emotional, behavioral, educational, or physical health. Comorbid psychiatric conditions are common and should be evaluated and treated simultaneously by child and adolescent mental health specialists. Guidelines for referral based on severity of involvement using established patient treatment-matching criteria are outlined. Pediatricians need to become familiar with treatment professionals and facilities in their communities and to ensure that treatment for adolescent patients is appropriate based on their developmental, psychosocial, medical, and mental health needs. The family should be encouraged to participate actively in the treatment process.

ABBREVIATIONS. *DSM-IV, Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition; DSM-PC, Diagnostic and Statistical Manual for Primary Care Child and Adolescent Version.*

The stages of substance use leading to abuse and dependency were defined more than a decade ago (Table 1).[1] Since then, the American Academy of Pediatrics has published a number of related policy statements and has defined the role of the pediatrician in the management of substance abuse by children and adolescents.[2] One challenge that remains for the practitioner, however, is to determine the severity of the young person's drug involvement and then make a decision about continued office follow-up or referral for evaluation and possible treatment. If specialized treatment is needed, the practitioner should determine the most appropriate referral for that patient.

The early stages of substance abuse are often the most difficult to evaluate. Although experimentation with mood-altering chemicals, including nicotine, is common, it is important that the experimentation not be condoned or trivialized by adults. The first and only use of even the so-called gateway drugs (alcohol, marijuana, and inhalants) may result in tragic consequences as a result of unintentional injuries or even death. Often the early user is naive about the effects of a substance, is uninitiated in its use, and has no tolerance for the effects of the drug.

For the young person who is experimenting with drugs (stage 2), the pediatrician can have an important role in the educational process for the patient and the family. If there have been no adverse consequences, brief counseling and in-office follow-up may be all that are needed. For the young person who has begun to experience adverse consequences of substance abuse, such as injuries associated with acute intoxication, trouble with the law, truancy, decline in school performance, or deterioration in physical or mental health, intervention is indicated.

Although confidentiality is the cornerstone of establishing a relationship with older children and adolescents, sometimes the behaviors of a young person are dangerous enough to justify and require a discussion with the parents. Depending on the circumstances, maintenance of confidentiality with the adolescent and the family may not be possible. A level of substance abuse associated with injuries, legal entanglements, failure in school, or deterioration of physical or mental health requires that family members be made aware of the dangers so that they can become involved in the therapeutic process.

At follow-up office visits, the pediatrician has the opportunity to assess continued use or abuse. Families should be advised to set firm rules about their children's involvement with tobacco, alcohol, and other drugs, and the consequences for use should be defined so that all persons understand the expectations. Behavior by parents, teachers, other adults, and health care professionals that enables tobacco, alcohol, and other drug use (such as tolerating an adolescent's erratic behavior, decline in school performance, or association with known substance users) must be recognized and avoided. The pediatrician can become part of the chain of adults emphasizing the non-use message by providing clear and consistent information to parents and their children while maintaining a trusting and caring relationship. A nonjudgmental approach that emphasizes health risk is paramount.

Some adolescents are able to discontinue the use of alcohol and other drugs by making a personal commitment with little formal treatment and with the aid of self-help groups or family support only. Developmentally, most teenagers will stop abusing alcohol or other drugs by early adulthood. The goal should be not only to recommend treatment, but also to identify the consequences of a lifestyle of alcohol and other drug abuse and motivate the patient to seek the help needed to initiate and maintain recovery. This can be most difficult with the adolescent patient, and literature is emerging on the role of motivational interviewing to encourage change in the patient who is dependent on nicotine or other psychoactive drugs.[3,4] Physicians can enhance the motivational process in their patients by expressing their concerns and encouraging an evaluation or formal assessment. Successful recovery usually begins when the patient stops denying that substance abuse is the cause of the life consequences experienced. Active participation by the pediatrician can assist in breaking down the denial and facilitate entry into the recovery process.

The decision to refer more heavily involved children and adolescents (stages 3-5) is straightforward if their symptoms and signs are recognized as being caused by substance abuse or dependence. Deciding where to refer the identified adolescent in need of treatment often is more complicated. For admission, most treatment programs require a diagnosis of abuse or dependence based on the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*[5]

(*DSM-IV*), (Tables 2 and 3). Some treatment programs or communities have education and prevention services available for those identified early. Although most primary care practitioners do not have a working knowledge of *DSM-IV* diagnoses, an understanding of "substance abuse" and "substance dependence" criteria can help decide who needs referral and where the person should be referred.[5] The *Diagnostic and Statistical Manual for Primary Care* (*DSM-PC*) *Child and Adolescent Version*, published by the American Academy of Pediatrics in 1996, also classifies substance use/abuse by adolescents.[6] Any adolescent meeting the *DSM-IV* criteria for abuse or dependence should be assessed by a professional experienced in adolescent chemical dependency. If the patient or family is unwilling to pursue evaluation in this phase of the drug use continuum, it may be a challenge to avoid an adversarial relationship as the pediatrician makes referral recommendations that clearly are indicated but not accepted by the patient or family. Although resistance and denial are intrinsic to the disease and are expected at this stage, it is important to make the best recommendation for the teenager and family while remaining available and supportive.

DUAL DIAGNOSIS

Adolescents who manifest psychiatric diagnoses in addition to substance abuse raise additional diagnostic concerns. [7-10] Other psychiatric disorders, especially major depressive disorders and conduct disorder, have been demonstrated in adolescents who use tobacco, alcohol, and other drugs.[11] Although a high prevalence of comorbidity has been reported in adolescent substance abusers receiving inpatient treatment,[12-16] the number of adolescents who exhibit psychiatric symptoms because of the substance abuse disorder and the number who have a primary or coexisting psychiatric diagnosis is unclear. Miller and Fine[17] believe that methodological considerations, including the length of abstinence required before the diagnosis is made, the population sampled, and the perspective of the examiner, affect prevalence rates for psychiatric disorders in substance abusers and account for the variability. They see the prevalence rates for psychiatric disorders as being artificially elevated by the tendency to establish a diagnosis before some of the psychiatric symptomatology secondary to the substance use abates. Ideally, the patient in a stable condition should be observed for a minimum of 1 month after discontinuing drug use and before diagnosing a comorbid disorder or initiating treatment with a psychopharmacologic agent. In this era of very brief (or no) hospitalization, it may make sense to diagnose and prescribe medication sooner, especially if the disorder predates the substance use or if there is a family history of psychiatric disorder.

Awareness of the prevalence and manifestations of psychiatric diagnoses is essential for the quality treatment of adolescent substance abusers, and the clinician needs to know what kind of comorbid conditions are commonly seen. Large-scale population studies have not been conducted on children and adolescents, but the National Institute of Mental Health's Epidemiologic Catchment Area Study[18] attempted to estimate the true prevalence rates of alcohol abuse, other drug abuse disorders, and mental disorders in a community and institutional sample of more than 20 000 adults standardized to the US census. Of persons with alcohol disorders, 37% had another mental disorder, with the highest prevalence for affective, anxiety, and antisocial personality disorders. More than 50% of those with drug disorders other than alcohol use disorders had a comorbid mental disorder: 28% had anxiety disorders, 26% had affective disorders, 18% had antisocial personality disorder, and 7% had schizophrenia. The study[18] verified the widely held impression that comorbidity rates are much higher for patients in treatment and institutional settings than in the general population.

The diagnostic categories most likely to be encountered in the pediatrician's office are affective, anxiety, and disruptive behavior disorders. Pediatricians will best serve these patients if they:

1. Conduct a complete evaluation of each patient that includes a comprehensive psychosocial history and physical examination, as well as a mental status examination and an inquiry into other psychiatric symptomatology by using information obtained from collateral sources, such as parents or teachers;
2. Have a high index of suspicion for psychiatric comorbidity in adolescents whose conditions do not respond to treatment or who are presenting problems in treatment;
3. Individualize treatment to accommodate other psychiatric diagnoses; and
4. Have a working relationship with and know when to consult a mental health specialist. The close integration of mental health care and primary care are important; managed care arrangements that separate mental health and addiction services from primary care make this coordination more difficult.

WHERE TO REFER PATIENTS

In addiction medicine, the concept of "patient-treatment matching" has become increasingly important in determining the appropriate level of care for the patient with a diagnosis of substance abuse or dependence.[19] Matching is based on a comprehensive biopsychosocial assessment of the patient and considers the history of current and past drug use, previous treatment, health consequences, comorbid psychiatric conditions, family and social issues, vocational-educational effects, experience with the justice system, motivation for treatment, and support systems available.

Managed care dictates treatment options in chemical dependency and mental health as rigorously as for medical and surgical treatments, and the primary care physician is routinely required to approve referrals for substance abuse and mental health treatment. Firm guidelines are being established that determine the level of care and length of treatment, and inpatient treatment is no longer the norm for the initial referral. More commonly, the patient must be unsuccessful at outpatient treatment before being recommended for inpatient treatment. The presence of a comorbid psychiatric condition may necessitate an earlier inpatient admission.

The American Society of Addiction Medicine has published *Patient Placement Criteria* that define levels of adult and adolescent treatment.[20] Adolescent levels include early intervention, outpatient treatment, and medically monitored or managed inpatient care. Placement is based on 6 dimensions that include acute intoxication/withdrawal potential, previous medical conditions and complications, emotional/behavioral conditions and complications, treatment acceptance/resistance, relapse/continued use potential, and recovery environment (Table 4). The publication also includes parameters for continued stay and discharge from the various levels of treatment.

A more comprehensive and detailed description of the continuum of adolescent treatment options based on multiple client assessment criteria has been published by the Center for Substance Abuse Treatment.[21] The treatment levels include more intensive outpatient options, as well as long-term residential psychosocial care (therapeutic communities), half-way houses, and group home living arrangements for seriously involved adolescents.

Successful addiction treatment usually involves more than one level of care during a long recovery process. The treatment may involve outpatient or inpatient care in the beginning with continued care at a level appropriate for the patientôs recovery process. Most chemically dependent patients in treatment consider themselves "recovering" rather than "recovered" and are involved in sequential treatment levels that usually include a formal structured program, attendance at 12-step self-help groups (eg, Alcoholics Anonymous, Narcotics Anonymous), and continued self-recovery work. Relapse is an

expected part of recovery and can be viewed as a learning opportunity that is important to the process rather than a failure. If relapse occurs, pediatricians once again can have an important supportive role or initiate further referral if additional formal treatment is required. By collaborating with a counselor or addiction specialist, as well as the insurance company, the school, and the family, the pediatrician can make a meaningful contribution to the recovery process.

CRITERIA FOR THE SELECTION OF A SUBSTANCE ABUSE TREATMENT PROGRAM

Appropriate substance abuse treatment facilities for children and adolescents must have staff with adequate experience in dealing with these age groups. The following criteria may be useful in evaluating an inpatient or outpatient adolescent substance abuse treatment program.

1. The program views drug and alcohol abuse as a primary disease rather than a symptom.
2. The program includes a comprehensive evaluation of the patient and appropriately manages or refers for treatment any associated medical, emotional, or behavioral problems identified in the initial assessment.
3. The program adheres to an abstinence philosophy. Any use is abuse. Drug use is a chronic disease, and a drug-free environment is essential. Tobacco use ideally should be prohibited, or nicotine cessation treatment should at least be part of the overall treatment plan.
4. There is a low ratio of patients to staff. Treatment professionals should be knowledgeable in the treatment of chemical dependency and adolescent behavior and development.
5. Professionally led support groups and self-help groups are integral parts of the program.
6. Adolescent groups are separate from the adult groups if both are treated at the same facility.
7. The entire family is involved in treatment. The program relates to parents and patients with compassion and concern with the goal of reunification of the family whenever possible.
8. Follow-up and continuing care are integral parts of the program.
9. As progress is made in the program, patients have an opportunity to continue academic and vocational education and are assisted in restructuring family, school, and social life.
10. The program administration discusses costs and financial arrangements for inpatient and outpatient care and facilitates communication with managed care organizations.
11. The program is as close to home as possible to facilitate family involvement, even though separation of the adolescent from the family may be indicated initially.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Pediatricians need to become familiar with the patterns of adolescent nicotine, alcohol, and drug use and the stages of substance abuse. Knowledge of the *DSM-IV* and *DSM-PC* criteria for diagnosis is useful for differentiating experimental use from problem use.
2. A thorough psychosocial and medical assessment of the patient is essential before making a referral for evaluation or treatment. Familiarity with the levels of treatment available and the multidimensional assessment criteria used to determine the intensity of services required can assist the pediatrician to make an appropriate referral.
3. Substance abuse is a potentially fatal disease. Use to the point at which school, activities, home, or work is affected represents symptomatic substance abuse and usually warrants parental involvement and a comprehensive interview and assessment.
4. Awareness of the high prevalence of psychiatric disorders among adolescents who abuse or are dependent on psychoactive substances will affect the decision as to where to refer the adolescent. If the pediatrician suspects a comorbid psychiatric diagnosis and needs assistance in determining appropriate treatment, psychiatric consultation should be obtained.
5. As advocates for adolescents and families requiring substance abuse treatment, pediatricians have the opportunity and obligation to become familiar with professionals and programs in their communities that provide education, prevention, and treatment services, including smoking cessation. A close working relationship facilitates referrals and communication.
6. Pediatricians also can advocate with local managed care organizations to provide quality mental health and substance abuse services that are appropriate for specific ages and developmental stages and that are integrated with primary care. Knowledge of the criteria for selecting an adolescent treatment program and the American Society of Addiction Medicine *Patient Placement Criteria* form the basis for these advocacy efforts.
7. Pediatricians must be familiar with state and federal regulations governing confidential exchange of information about substance abuse treatment. These are available from the state alcohol and substance abuse treatment regulatory agencies.

TABLE 1
Stages of Adolescent Substance Abuse*

Stage	Description
1	Potential for abuse
	Decreased impulse control
	Need for immediate gratification
	Availability of tobacco, drugs, alcohol, inhalants
	Need for peer acceptance
2	Experimentation: learning the euphoria
	Use of inhalants, tobacco, marijuana, and alcohol with friends
	Few, if any, consequences
	May increase to regular weekend use

	Little change in behavior
3	Regular use: seeking the euphoria
	Use of other drugs, eg, stimulants, lysergic acid diethylamide (LSD), sedatives
	Behavioral changes and some consequences
	Increased frequency of use; use alone
	Buying or stealing drugs
4	Regular use: preoccupation with the "high"
	Daily use of drugs
	Loss of control
	Multiple consequences and risk-taking
	Estrangement from family and "straight" friends
5	Burnout: use of drugs to feel normal
	Use of multiple substances; cross-addiction
	Guilt, withdrawal, shame, remorse, depression
	Physical and mental deterioration
	Increased risk-taking, self-destructive behavior, or suicidal behavior

* Adapted from Comerci.[1(pp58-59)]

TABLE 2
*DSM-IV** Criteria for Substance Abuse[5]

1. A maladaptive pattern of substance use leading to clinically significant impairment or distress, as manifested by 1 (or more) of the following, occurring within a 12-month period:
a. recurrent substance use resulting in a failure to fulfill major role obligations at work, school, or home (eg, repeated absences or poor work performance related to substance use; substance-related absences, suspensions, or expulsions from school; neglect of children or household)
b. recurrent substance use in situations in which it is physically hazardous (eg, driving an automobile or operating a machine when impaired by substance use)
c. recurrent substance-related legal problems (eg, arrests for substance-related disorderly conduct)
d. continued substance use despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of the substance (eg, arguments with spouse about consequences of intoxication, physical fights)
2. The symptoms have never met the criteria for substance dependence for this class of substance.

* *DSM-IV* indicates *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition.*[5(pp182-183)]

TABLE 3
*DSM-IV** Criteria for Substance Dependence[5(p181)]

A maladaptive pattern of substance use, leading to clinically significant impairment or distress, as manifested by 3 (or more) of the following, occurring at any time in the same 12-month period:
1. tolerance, as defined by either of the following:
a. a need for markedly increased amounts of the substance to achieve intoxication or desired effect
b. markedly diminished effect with continued use of the same amount of the substance
2. withdrawal, as manifested by either of the following:
a. the characteristic withdrawal syndrome for the substance
b. the same (or a closely related) substance is taken to relieve or avoid withdrawal symptoms
3. the substance is often taken in larger amounts or over a longer period than was intended
4. there is a persistent desire or unsuccessful efforts to cut down or control substance use
5. a great deal of time is spent in activities necessary to obtain the substance (eg, visiting multiple doctors or driving long distances), use the substance (eg, chain-smoking), or recover from its effects
6. important social, occupational, or recreational activities are given up or reduced because of substance use
7. the substance use is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance (eg, current cocaine use despite recognition of cocaine-induced depression or continued drinking despite recognition that an ulcer was made worse by alcohol consumption)

* *DSM-IV* indicates *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition.*[5(p181)]

TABLE 4
Adolescent Criteria: Crosswalk of Levels 0.5 Through IV*

Criteria Dimensions			Levels of Service		
	Level 0.5 Early Intervention	Level I Outpatient Treatment	Level II Intensive Outpatient Treatment	Level III Medically Monitored Intensive Inpatient Treatment	Level IV Medically Managed Intensive Inpatient Treatment
Dimension I: acute intoxication and/or withdrawal potential	No withdrawal risk	No withdrawal risk	Manifests no overt symptoms of withdrawal risk	Risk of withdrawal syndrome is present but manageable in Level III	Severe withdrawal risk
Dimension 2: biomedical conditions and complications	None or very stable	None or very stable	None or, if present, does not distract from addiction treatment; manageable at Level II	Require Medical monitoring but not intensive treatment	Requires 24-hour medical and nursing care
Dimension 3: emotional/behavioral	None or very stable	None or manageable in an outpatient structured environment	Mild severity, with the potential to distract from recovery efforts	Moderate severity; requires a 24-hour structured setting	Severe problems require 24-hour psychiatric care, with concomitant addiction treatment
Dimension 4: treatment acceptance/resistance	Willing to understand how current use may affect personal goals	Willing to cooperate but needs motivating and monitoring strategies	Resistance high enough to require structured program but not so high as to render outpatient treatment ineffective	Resistance high despite negative consequences; needs intensive motivating strategies in a 24-hour structured setting	Problems in this dimension do not qualify patient for level IV treatment
Dimension 5: relapse/continued use potential	Needs understanding of, or skills to change, current use patterns	Able to maintain abstinence and recovery goals with minimal support	Intensification of addiction symptoms; high likelihood of relapse without close monitoring and support	Unable to control use despite active participation in less intensive care; needs 24-hour structure	Problems in this dimension do not qualify patient for level IV treatment
Dimension 6: recovery environment	Social support system or significant others increase risk of personal conflict about alcohol/other drug use	Supportive recovery environment and/or patient has skills to cope	Environment unsupportive but, with structure or support, patient can cope	Environment dangerous for recovery, necessitating removal from the environment; logistical impediments to outpatient treatment	Problems in this dimension do not qualify patient for level IV treatment

* This overview of the adolescent admission criteria is an approximate summary to illustrate the principal concepts and structure of the criteria.

Infant Methemoglobinemia: The Role of Dietary Nitrate in Food and Water

ABSTRACT. Infants for whom formula may be prepared with well water remain a high-risk group for nitrate poisoning. This clinical report reinforces the need for testing of well water for nitrate content. There seems to be little or no risk of nitrate poisoning from commercially prepared infant foods in the United States. However, reports of nitrate poisoning from home-prepared vegetable foods for infants continue to occur. Breastfeeding infants are not at risk of methemoglobinemia even when mothers ingest water with very high concentrations of nitrate nitrogen (100 ppm). *Pediatrics* 2005;116: 784–786; *methemoglobinemia.*

INTRODUCTION

Nitrate poisoning resulting in methemoglobinemia continues to be a problem in infants in the United States. Most reported cases have been ascribed to the use of contaminated well water for preparation of infant formula.[1–3] Fifteen million families in the United States obtain their drinking water from unregulated wells.[4] In a survey of 5500 private water supplies from 9 Midwestern states, 13% of the wells were found to have nitrate concentrations >10 mg/L or 10 ppm nitrate nitrogen,[5] the federal maximum contaminant level.[6] It is estimated that 2 million families drink water from private wells that fail to meet the federal drinking-water standard for nitrate, and 40 000 infants younger than 6 months live in homes that have nitrate-contaminated water supplies.[4] In urban areas, municipal wastewater-treatment discharges (a source of nutrients) on surrounding farmland aggravate the problem.[7]

There have been occasional cases of nitrate poisoning in infants from ingestion of plant nitrates,[8–13] only one of which was reported from the United States.[9] Nitrates are natural constituents of plant material, and the effect of commercial nitrate-containing fertilizers on the nitrate content of vegetables is inconsistent.[14] Because the intake of naturally occurring nitrates from foods such as green beans, carrots, squash, spinach, and beets can be as high as or higher than that from well water, these foods should be avoided before 3 months of age, although there is no nutritional indication to add complementary foods to the diet of the healthy term infant before 4 to 6 months of age.[14,15] Some commercially prepared infant food vegetables are voluntarily monitored for nitrate content by private industry, including spinach, squash, and carrots. A target concentration of nitrate nitrogen for food of <100 ppm is desirable for infants. Because this concentration is frequently exceeded in spinach, this product is often labeled not to be used in infants younger than 3 months.

For breastfed infants, there is no evidence of an increased risk of methemoglobinemia from maternal ingestion of water with nitrate nitrogen concentrations as high as 100 ppm, because these mothers do not produce milk with high nitrate concentrations.[16] Furthermore, the predominant organism in the gastrointestinal tract (*Lactobacillus* species) of the breastfed infant does not reduce nitrate to nitrite (see following section).[14]

PATHOPHYSIOLOGY

The potential hazard of nitrate in either food or water is from its conversion to methemoglobin-producing nitrites before and/or after ingestion. The nitrite ion oxidizes ferrous iron in hemoglobin to the ferric state. The resulting compound, methemoglobin, is incapable of binding molecular oxygen and produces a leftward shift in the oxygen-dissociation curve, which results in hypoxemia. Absorbed nitrate that has not been converted to nitrite can be readily excreted in the urine without adverse effects.[14]

There are many factors that influence the incidence of methemoglobinemia in infancy.[14,17] The gastric pH of infants is higher than that in older children and adults, with resultant proliferation of intestinal flora that can reduce the ingested nitrate to nitrite. Fetal hemoglobin, the predominant form in infants up to 3 months of age, is oxidized more readily to methemoglobin by nitrite than is adult hemoglobin. Red blood cells contain methemoglobin reductases that convert methemoglobin back to hemoglobin. Ninety-nine percent of this reduction activity is accounted for by cytochrome-b_5 methemoglobin reductase; the activity of this enzyme is reduced by half in

PEDIATRICS (ISSN 0031 4005).

infants compared with adults.[18] Although these factors explain the higher incidence of methemoglobinemia in infants, there are not enough data to identify a specific level of nitrate intake that is safe for all infants.

CLINICAL MANIFESTATION

Methemoglobinemia generally manifests with few clinical signs other than cyanosis. Methemoglobin represents only 1% of the total hemoglobin of the healthy adult, although it can be slightly higher in preterm and term newborn infants.[19] Obvious cyanosis can occur with methemoglobin concentrations as low as 3% in infants with low hemoglobin concentrations. Symptoms are usually minimal until methemoglobin concentrations exceed 20%.[20] The mucous membranes of infants with methemoglobinemia tend to have brown (rather than blue) discoloration. This discoloration increases with the concentration of methemoglobin, as do the manifestations of irritability, tachypnea, and altered mental status.[20] In the absence of respiratory symptoms, history of cardiovascular disease, abnormal pulse, or abnormal pulse oximetry, a diagnosis of methemoglobinemia should be considered in a child who becomes acutely cyanotic and fails to respond to oxygen administration. When significant concentrations of methemoglobin (>30%) are present, a pulse oximeter is very misleading and will detect only mild to moderate oxygen desaturations in the 82% to 86% range.[20]

TREATMENT AND PREVENTION

Health care professionals who suspect that an infant has methemoglobinemia are advised to consult with the local poison control center or a toxicologist to help guide management. An asymptomatic infant with cyanosis who has a methemoglobin concentration of <20% usually requires no treatment other than identifying and eliminating the source of exposure (assuming a normal hematocrit). Anemic children will display toxicity at lower methemoglobin concentrations. More detailed information on diagnosis and treatment has been reviewed elsewhere.[20]

Clinical diagnosis and treatment for methemoglobinemia is not sufficient. Preventive strategies are needed to identify and eliminate the sources of exposure.[21] Assessment of potential nitrate exposure includes questions about the family residence, parental occupations, drinking water, foods ingested, topical medications, and folk remedies. Prenatal and newborn care for patients with private wells should include recommendation for testing well water for nitrate contamination. Water with high nitrate concentrations should not be ingested by the infant or used for preparation of infant formulas or infant foods. Use of alternative sources of water should be advised, including deeper wells, public water supplies, or bottled water free of nitrate. Boiling water with nitrate nitrogen concentrations of <10 ppm for 1 minute generally is sufficient to kill microorganisms without over concentrating nitrate.[21]

Effective in-home systems for nitrate removal include ion-exchange resins and reverse osmosis; however, these systems can be expensive. Ordinary water softeners used in the home do not remove nitrates.[22] Water testing for nitrate can be obtained from any reference or public health laboratory using laboratory methods approved by the US Environmental Protection Agency. Most state health departments have listings of these certified laboratories.

There is limited information on the nitrate content of commercial infant foods, although the highest concentrations (>100 ppm of nitrate nitrogen) are found in beets, carrots, spinach, squash, and green beans.[14,15] Preventive strategy would be not to introduce home preparations of these vegetables to infants before 3 months of age, although there is no nutritional indication to add complementary foods to the diet of the healthy term infant before 4 to 6 months of age.[23] Infants fed commercially prepared infant foods after 3 months of age generally are not at risk of nitrate poisoning, although the containers should be refrigerated after first use and discarded within 24 hours of opening.

SUMMARY

1. The greatest risk of nitrate poisoning (methemoglobinemia) occurs in infants fed well water contaminated with nitrates. All prenatal and well-infant visits should include questions about the home water supply. If the source is a private well, the water should be tested for nitrate. The nitrate nitrogen concentration of the water should be <10 ppm.
2. Infants fed commercially prepared infant foods generally are not at risk of nitrate poisoning. However, home-prepared infant foods from vegetables (eg, spinach, beets, green beans, squash, carrots) should be avoided until infants are 3 months or older, although there is no nutritional indication to add complementary foods to the diet of the healthy term infant before 4 to 6 months of age.
3. Breastfed infants are not at risk of nitrate poisoning from mothers who ingest water with high nitrate content (up to 100 ppm nitrate nitrogen), because nitrate concentration does not increase significantly in the milk.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Infection Prevention and Control in Pediatric Ambulatory Settings

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Infectious Diseases

ABSTRACT

Since the American Academy of Pediatrics published a statement titled "Infection Control in Physicians' Offices" (*Pediatrics*. 2000;105[6]:1361–1369), there have been significant changes that prompted this updated statement. Infection prevention and control is an integral part of pediatric practice in ambulatory medical settings as well as in hospitals. Infection prevention and control practices should begin at the time the ambulatory visit is scheduled. All health care personnel should be educated regarding the routes of transmission and techniques used to prevent transmission of infectious agents. Policies for infection prevention and control should be written, readily available, updated annually, and enforced. The standard precautions for hospitalized patients from the Centers for Disease Control and Prevention, with a modification from the American Academy of Pediatrics exempting the use of gloves for routine diaper changes and wiping a well child's nose or tears, are appropriate for most patient encounters. As employers, pediatricians are required by the Occupational Safety and Health Administration to take precautions to identify and protect employees who are likely to be exposed to blood or other potentially infectious materials while on the job. Key principles of standard precautions include hand hygiene (ie, use of alcohol-based hand rub or hand-washing with soap [plain or antimicrobial] and water) before and after every patient contact; implementation of respiratory hygiene and cough-etiquette strategies for patients with suspected influenza or infection with another respiratory tract pathogen to the extent feasible; separation of infected, contagious children from uninfected children when feasible; safe handling and disposal of needles and other sharp medical devices and evaluation and implementation of needle-safety devices; appropriate use of personal protective equipment such as gloves, gowns, masks, and eye protection; and appropriate sterilization, disinfection, and antisepsis.

INTRODUCTION

Infection-prevention and -control practices have long been recognized as an important means of preventing transmission of infectious agents. In the ambulatory setting, the goal is to prevent transmission of infectious agents to patients and visitors, health care personnel, and other employees. Infection prevention and control should start at the time an ambulatory visit is scheduled and is important in every patient encounter. In general, the standards for infection prevention and control are the same in all health care delivery settings, whether inpatient or outpatient, hospital or freestanding ambulatory facility. Recommendations for infection-prevention and -control practices in hospitals are well documented and

updated on a regular basis.[1–5] Because most patient encounters are with outpatients, the prevention of transmission of infection in ambulatory settings is critical.[2,6,7] In addition to the risk of health care–associated infection during medical evaluation and treatment, the reception and waiting areas of ambulatory facilities present opportunities for transmission of infectious agents among patients and accompanying persons.[8] Outbreaks of measles,[9,10] tuberculosis,[11] hepatitis B and C,[12] airborne infections,[9–11] and other infectious diseases have been traced to ambulatory visits.[6,13] Most disease outbreaks reported in ambulatory facilities were associated with nonadherence to recommended infection-prevention and -control procedures.[13]

This statement provides practical information that updates the 2000 American Academy of Pediatrics (AAP) policy statement[14] regarding infection-prevention and -control procedures as applied to ambulatory medical settings. Major changes include the endorsement of routine use of alcohol-based hand rub for hand hygiene and, where feasible, the addition of respiratory hygiene/cough etiquette to standard precautions to decrease transmission of influenza and other respiratory tract pathogens; evaluation and implementation of safer medical devices designed to reduce the risk of needle sticks; use of 2% chlorhexidine gluconate/70% isopropyl alcohol-based solutions for skin antisepsis under certain circumstances; and immunization of health care personnel with appropriate vaccines, including influenza vaccine and a vaccine to protect adults against pertussis. Additional prevention and control recommendations not covered in this statement may be necessary for other ambulatory settings such as dialysis centers, chemotherapy centers, procedure suites (eg, for endoscopy), emergency centers, and outpatient surgery suites.[6]

MODES OF TRANSMISSION OF INFECTIOUS AGENTS

To understand infection-prevention and -control issues, modes of transmission of infectious agents should be considered.[2,6,7,15] Transmission can result via direct contact (direct "contact transmission," contact with body substances including blood, urine, stool, and respiratory tract secretions), when the infectious agent is transferred directly from an infected person to a susceptible person, or, more commonly, via indirect contact transmission, when the infectious agent is transferred through a contaminated intermediate object such as a stethoscope, a countertop, a door handle, or a person's contaminated hands. Examples of pathogens transmitted via the contact route include gastrointestinal tract pathogens such as rotavirus and respiratory tract pathogens such as respiratory syncytial virus. Fomites such as toys and ambulatory facility equipment have been implicated in the transmission of some pathogens. Bloodborne pathogens can be spread via contaminated needles and other sharp instruments if recommended procedures to prevent exposure to blood or blood-containing body fluids are not implemented and followed. Pathogens in respiratory tract secretions can be transmitted a few feet through the air via droplets ("droplet transmission"; eg, influenza virus, *Bordetella pertussis*, adenovirus, and severe acute respiratory syndrome [SARS]–related coronavirus) or become airborne in small-particle aerosols ("airborne transmission"; eg, rubeola [measles virus], varicella virus, and *Mycobacterium tuberculosis*) and be transmitted over longer distances and remain suspended in the air for a long period of time. Overall, contaminated hands are the predominant mode of transmission of infectious agents, which underscores the importance of appropriate hand hygiene (ie, use of alcohol-based hand rub or hand-washing with soap and water) before and after contact with each patient or his or her immediate environment.

GUIDELINES FOR PREVENTION OF TRANSMISSION OF INFECTIOUS AGENTS

As with hospitalized patients, health care personnel should observe standard precautions[1] with every patient encounter in the ambulatory setting. "Standard precautions" refers to a single set of precautions that should be followed for all patients regardless of their diagnosis or presumed infection status and is predicated on the principle that every patient may harbor an unrecognized infectious agent that can be transmitted by blood or body fluids or via their skin or mucous membranes (Table 1). Standard precautions are supplemented with transmission-based precautions[2] when additional measures are needed to reduce the risk of contact, droplet, or airborne transmission and may include the use of a mask (a procedure mask or surgical mask), a respirator (a special mask that requires individual-fit testing and education for safe and effective usage), gowns, gloves, and/or protective eyewear such as a face shield or goggles.

Hand Hygiene

Hand hygiene (ie, using an alcohol-based hand rub or washing with soap and water) is the single most important method of preventing transmission of infectious agents (Table 1).[1,2,4,16–18] Use of an alcohol-based hand rub product in gel, rinse, or foam form is the preferred method of hand hygiene in most situations, because this method is convenient, acts rapidly, and is highly effective in inactivating microbes. Hands are decontaminated by using an alcohol-based hand rub and applying the product (using an amount recommended by the manufacturer) to the palm of one hand and rubbing the hands together, covering all surfaces of the hands and fingers, until the hands are dry.[4] Alcohol-based hand rub should be used (or hands should be washed with soap and water) before and after each contact with patients; between dirty and clean procedures on the same patient; after removing gloves; and before and after performing

TABLE 1 Standard Precautions, as Recommended by the CDC for Hospitalized Patients and Modified by the AAP for Children, Should Be Used With All Patients

Hand hygiene
- Hands should be disinfected with an alcohol-based hand rub (or washed with plain or antimicrobial soap and water) before and after each patient encounter or an encounter with the patient's immediate environment.
- Hands and other body surfaces should be washed with soap (antimicrobial preferred, but plain is acceptable) and water if visibly soiled or contaminated with blood or other body fluids or if exposure to spores (eg, *C difficile*) is likely to have occurred.
- Hands should be disinfected with an alcohol-based hand rub or washed with soap and water after removal of gloves.
- Barrier precautions to prevent skin and mucous membrane exposure
- Gloves should be worn for contact with blood, all body fluids, secretions and excretions, mucous membranes, nonintact skin, and items or surfaces contaminated with body fluids. Gloves need not be used for routine care of well children, including changing diapers and wiping the nose or eyes of children, except when required as part of contact precautions.[14,19]
- Gloves should be worn when performing venipuncture and other vascular-access procedures.
- Gloves are not routinely required when administering injections, including immunizations, unless the person administering the injection is likely to come into contact with body substances or has open lesions on his or her hands.
- Appropriate masks and protective eyewear or face shields should be used during procedures that are likely to generate droplets of blood or body fluids.
- Fluid-impermeable gowns or aprons should be worn during procedures that are likely to generate splashes of blood or other body fluids.

Respiratory hygiene/cough etiquette: see Table 2 and text[2,22]

Handling of sharp instruments to minimize risk of injury: see "Prevention of Exposure to Bloodborne Pathogens by Needles and Other Sharp Instruments"

Resuscitation equipment
- Equipment should be available for use in areas in which the need for resuscitation is predictable.
- Mouth-to-mouth resuscitation should be avoided.

Source: Garner JS; Hospital Infection Control Practices Advisory Committee. *Infect Control Hosp Epidemiol.* 1996;17:53–80.

invasive procedures. Repetitive use of alcohol-based hand rubs can be less drying to skin than repetitive use of soap and water. Hands should be washed with soap and water instead of alcohol-based hand rub whenever they are visibly soiled or contaminated with blood or other body fluids, if exposure to spores (eg, *Clostridium difficile*) is likely to have occurred, before eating, and after using the toilet. For hand-washing, antimicrobial soap may be preferable to plain soap, because plain soap may fail to remove pathogens from the hands, and use of an antimicrobial soap results in a significantly lower bacterial count on the skin.[4] Routine hand-washing should consist of the following steps: (1) wet hands with warm (not hot) water; (2) apply soap (plain or antimicrobial) to hands; (3) vigorously rub the hands together for at least 15 seconds, covering all surfaces of the hands and fingers; (4) rinse hands with warm water; (5) dry hands with a disposable towel; and (6) use the towel to turn off the faucet.[4] Disposable towels are preferred for hand-drying and always should be available and within easy reach by health care personnel. If used, hand lotions should be available in containers that are replaced frequently to avoid extrinsic contamination.[16] Hand lotions should not be petroleum based, because petroleum can cause deterioration of latex material and thereby reduce the effectiveness of latex gloves.

Hand hygiene before performing invasive procedures should consist of prewashing with soap and water and thorough drying followed by use of an alcohol-based surgical scrub with persistent activity or washing with an antimicrobial soap, such as chlorhexidine or povidone iodine, for the length of time specified by the manufacturer (usually 2 to 6 minutes).[4] In addition, fingernails need to be cleaned with disposable manicure sticks. Employees who perform direct patient care activities in practices that include immunocompromised patients at high risk of infection should keep their fingernails short and avoid wearing artificial fingernails and extenders, because these have been shown to harbor microorganisms that are not easily removed by hand hygiene.

Standard Precautions

Standard precautions include performing hand hygiene before and after every patient contact (Table 1).[1] Standard precautions require that gloves be available for use by all health care personnel and should be worn when contact with blood, body fluids, secretions, excretions, and items contaminated with these fluids is reasonably anticipated. However, the AAP modified standard precautions for well-child care by indicating that although hand hygiene should be performed, gloves do not need to be worn for routine procedures such as changing a diaper or wiping the nose or eyes of a well child except when required as part of contact precautions.[14,19,20] Gloves are not required when administering vaccines unless the health care professional has open hand lesions or will come into contact with potentially infectious body fluids.[21,22] When gloves are used, hand hygiene should be performed after gloves are removed, because contamination can occur during removal or from microscopic breaks in the glove.[23] A surgical-grade mask and face shield or protective eyewear, such as goggles, should be worn if splashing of body fluids is anticipated. Skin surfaces contaminated with blood or other body fluids should be washed immediately and thoroughly with soap and water.

The Centers for Disease Control and Prevention (CDC) added "respiratory hygiene/cough etiquette" to standard precautions to prevent transmission of influenza and potentially other pathogens that cause respiratory infection in reception areas, common waiting areas, and examination rooms in ambulatory facilities (Table 2).[2,24] Full implementation of this strategy requires education of patients and accompanying persons, including visual alerts on covering the nose and mouth when coughing or sneezing and coughing and sneezing into

TABLE 2 **Respiratory Hygiene/Cough Etiquette to Minimize Transmission of Influenza and Other Respiratory Tract Pathogens[2,24]**

1. Visual alerts for patients at the entrance to ambulatory facilities instructing patients and accompanying persons to inform staff of symptoms of a respiratory tract infection when they first register for care and to practice respiratory hygiene/cough etiquette
2. Components of respiratory hygiene/cough etiquette for patients and accompanying individuals with suspected respiratory virus infection
   - Cover the nose/mouth when coughing or sneezing; cough or sneeze into elbow rather than hand
   - Use tissues to contain respiratory tract secretions and dispose of them in the nearest waste receptacle after use
   - Perform hand hygiene (ie, use of alcohol-based hand rub, hand-washing with soap and water, or use of an antiseptic handwash) after having contact with respiratory tract secretions and contaminated objects/materials
   - If tolerated and feasible, consider providing a size-appropriate mask for the patient to wear to prevent respiratory droplet dispersal while in common reception and waiting areas[a]
3. Components of respiratory hygiene/cough etiquette for staff
   - Educate patients and accompanying persons on the need for and components of respiratory hygiene/cough etiquette
   - In reception area, have tissues and no-touch receptacles for used tissue disposal available
   - If feasible, provide conveniently located, but out of reach of young children, dispensers of alcohol-based hand rub with instructions for use (or have a sink available with consistently available soap and disposable towels)
   - When space and chair availability permit, cluster chairs for a coughing patient and accompanying persons at least 3 feet away from other patients
   - Consider having masks available for distribution to symptomatic patients by staff
   - In addition to hand hygiene before and after patient contact, health care personnel should consider wearing a mask when examining an ambulatory patient with suspected influenza[a]

In reception and common waiting areas of ambulatory facilities, implementation of some or all components of respiratory hygiene/cough etiquette should be considered for patients with suspected influenza or other respiratory tract pathogens. Influenza or another respiratory tract pathogen is suspected in patients with a new onset of cough or increased respiratory tract secretions, especially in the presence of fever.
[a] The use of masks and eyewear protection is strongly recommended if human cases of avian influenza or SARS have been diagnosed in the community.

the elbow rather than hand, maintaining a separation of at least 3 feet between symptomatic patients and others in common waiting areas, availability of materials and facilities for performing hand hygiene, and the use of masks by patients with symptoms of influenza or other respiratory tract infection before being placed in an examination room. Health care personnel who examine such patients should observe droplet precautions that include the use of masks. The effectiveness of these strategies for reducing transmission of influenza or other respiratory pathogens in the ambulatory setting has not been evaluated, but both covering a cough or sneeze and wearing a mask have been shown to prevent dispersion of respiratory droplets into the air[25] and decrease transmission of *Streptococcus pyogenes*.[26] The use of these measures evolved from the experience during SARS outbreaks in which individuals in emergency departments who were not suspected of having SARS were the source of continued transmission. Although respiratory hygiene/cough etiquette was designed primarily to reduce transmission of influenza including pandemic influenza strains, it may also reduce transmission of other agents that cause respiratory infection. Some features of respiratory hygiene/cough etiquette may be difficult to implement. For example, in many ambulatory settings, supplying masks for patients with suspected respiratory tract infection may not be feasible, and ensuring effective use of these masks in young children may not be possible. However, implementation of some of the features of respiratory hygiene/cough etiquette is likely to be more effective than no implementation. The individual ambulatory practice can determine whether to implement respiratory hygiene/cough-etiquette practices only during periods of increased prevalence of respiratory infections in the community or year-round.

Prevention of Exposure to Bloodborne Pathogens by Needles and Other Sharp Instruments

The following measures should be implemented to minimize risk of injuries by needles and other sharp instruments and of transmission of bloodborne pathogens to health care personnel or other patients:

1. Prepare a written policy for prevention of needlestick injuries.
2. Educate personnel.
3. Implement a practice not to recap, bend, or break needles or remove needles from a syringe by hand.
4. Evaluate safer medical devices designed to reduce the risk of needle sticks with the input of staff members who use needles, and implement use of devices that are likely to improve safety. Evaluation (with input from staff members) and implementation of needle safety devices is a requirement of the Occupational Safety and Health Administration (OSHA) of the US Department of Labor[27] and a number of states.[28]

5. Dispose needles into impermeable and puncture-proof needle-disposal containers that are available in areas where needles or other disposable sharps are used. Such containers should not be overfilled and should be out of reach of young children.
6. Prepare and follow policies consistent with state and local regulations for removal and incineration or sterilization.
7. Place reusable sharp instruments in puncture-resistant containers for transport to reprocessing areas.
8. Use a sterile, single-use, disposable needle and syringe for each injection given.
9. Preferentially use single-dose medication vials when medications are administered to more than 1 patient.
10. Develop a bloodborne pathogens exposure-control plan for management of contaminated–sharp-object injuries that includes written policies, is readily available to all staff, and is reviewed regularly. A workbook is available through the CDC[29] for designing, implementing, and evaluating a sharps injury-prevention program.

Transmission-Based Precautions

A mask is indicated and is adequate for protection of personnel from respiratory tract pathogens that are transmitted by respiratory droplets, such as influenza virus or *Bordetella pertussis*. However, OSHA guidelines require use of special particulate respirators (eg, National Institute for Occupational Safety and Health–approved N-95 or higher respirators) when caring for patients with infections such as pulmonary tuberculosis, which is transmitted via the airborne route in small-particle aerosols[30]; use of these respirators requires medical screening, individual-fit testing, and education to ensure proper use. It is important not to confuse the use of a surgical or procedure mask with the use of a particulate respirator that may have a similar appearance to some masks. A need for use of such respirators in pediatric ambulatory facilities is uncommon, because almost all children with tuberculosis who are younger than 12 years are not contagious, although an adult with contagious tuberculosis may be in their household and may be accompanying them for their health care visit.[31] Ideally, anyone suspected of having contagious tuberculosis should not be permitted in the ambulatory facility, because they pose a hazard to patients and staff. However, if an adult or adolescent suspected of having pulmonary tuberculosis is present in an ambulatory facility, a mask should be provided to and worn by that individual, and a referral should be made to a facility that is capable of appropriately isolating, evaluating, and treating tuberculosis.

General Health Considerations of Staff

As employers, pediatricians are required by the OSHA to institute procedures to protect staff from blood and other potentially infectious materials, including procedures to minimize the risk of sharp-instrument–related injuries and infections and to minimize exposure to tuberculosis while on the job. The OSHA has published bloodborne pathogen standards for protection of health care personnel from bloodborne agents.[32,33] Guidance on compliance with OSHA regulations, including education of personnel, writing a bloodborne pathogen exposure-control plan, sharp injuries and prevention, tuberculosis exposure, emergency procedures, emergency preparedness, hazardous chemical safety, and general facility safety, can be found in the *OSHA Safety Program Manual* from the Medical Group Management Association[34] and a technical manual from the OSHA.[35]

Management of Injuries by Needles and Other Sharp Instruments and Blood and Body-Fluid Contact

A written bloodborne pathogens exposure-control plan that includes written policies for management of contaminated–sharp-object injuries should be developed, readily available to all staff, and reviewed regularly. Policies for management of needle-stick injuries as described in Table 3 should address potential exposures to hepatitis B, hepatitis C, and HIV[36,37] and should be understood by employees. OSHA requirements for management of sharps injuries and education of employees on the management of sharp-instrument–related injuries should be followed. Skin surfaces that are contaminated with blood or other body fluids should be washed immediately and thoroughly with soap and water. Health care personnel with direct contact with patients should receive hepatitis B immunization if they have not been immunized previously.

Personnel Illness

Health care personnel may pose a risk to patients and other personnel if they develop a communicable disease. Written policies, therefore, should exist regarding exclusion of staff members with contagious illnesses.[38] Recommended work restrictions for health care personnel with selected infections are listed in Table 4. Respiratory tract infections may not be a reason to exclude personnel, but precautions should be taken with an emphasis on hand hygiene before every patient contact, and use of a mask should be considered when having direct patient contact. The inability to contain secretions and control coughing and sneezing is an indication to exclude personnel from patient contact. In addition, symptomatic health care personnel should avoid contact with immunosuppressed patients.

TABLE 3 Management of Potential Occupational Exposure to Bloodborne Pathogens

A written policy should be developed, available, and followed.

Definition of exposure that might place health care personnel at risk of hepatitis B, hepatitis C, or HIV infection: A percutaneous injury (eg, needle stick or cut with a sharp object) or contact of mucous membrane or nonintact skin (eg, exposed skin that is chapped, abraded, or afflicted with dermatitis) with blood, tissue, or other body fluids that are potentially infectious. Body fluids that are potentially infectious include those contaminated with visible blood, semen, vaginal secretions, cerebrospinal fluid, synovial fluid, pleural fluid, peritoneal fluid, pericardial fluid, and amniotic fluid. Feces, nasal secretions, saliva, sputum, sweat, tears, urine, and vomitus are not considered potentially infectious for these pathogens unless they contain blood; the risk of transmission of these pathogens from these fluids and materials is extremely low.[34,35]

The exposed employee should immediately follow these steps:

- Wash needle-stick site or cut with soap and water.
- If splashes to the nose, mouth, or skin occur, flush involved area with water.
- If splashes to the eye occur, irrigate eyes with clean water, saline, or sterile irrigants.
- Report the incident to your supervisor and immediately seek medical treatment.
- Document the type of injury including the involvement of blood, the source of the blood, and the extent of the injury (eg, deep injection, blood spill onto intact skin).

In all cases, the physician should:

1. Document the type of injury, including the involvement of blood.
2. Identify the source patient, if possible, and make a judgment of the likelihood that the source patient may have HIV, hepatitis B, or hepatitis C infection.
3. Have an established policy for management of an exposure such as that described below or an arrangement for immediate referral to a person or location with expertise in management of such exposures such as the emergency department of a specific hospital or the occupational health department of a large health care organization.
4. Ensure follow-up for the potentially exposed employee.
5. Ensure that all employees know how to access this policy.

Management includes the following steps:

Step 1: Determine the status of the source patient. If this is not possible, base actions on the likelihood of exposure considering source of needle and type of exposure. If the source is known, obtain permission consistent with local statutes and determine the serologic status of the source for hepatitis B virus, hepatitis C virus, and HIV. FDA-approved methods for rapid testing for HIV antibody are available.

Step 2: Determine the immunity of the employee. Was hepatitis B vaccine received? Was the employee tested for HBsAg? If response to immunization is unknown, obtain blood to test for anti-HBsAg. Test for antibody to hepatitis C. Obtain consent and test for antibody to HIV.

Step 3: Hepatitis B—follow the steps outlined below for hepatitis B prophylaxis after percutaneous or permucosal exposure:

A. If exposed person is unimmunized against hepatitis
   - Source HBsAg-positive: administer HBIG (0.06 mL/kg; maximum dose: 5 mL) intramuscularly and begin hepatitis B vaccine series.
   - Source HBsAg-negative: begin hepatitis B vaccine series.
   - Source not tested or unknown: begin hepatitis B vaccine series.

B. If exposed person was immunized and responded:
   - No treatment is necessary.

C. If exposed person was immunized and did not respond:
   - Source HBsAg-positive: HBIG immediately and in 1 mo or HBIG and initiate reimmunization.
   - Source HBsAg-negative: no treatment.
   - Source not tested or unknown: if high-risk source, consider HBIG or HBIG and HBV reimmunization as for HBsAg-positive source.

D. If exposed person was immunized and not tested for a response or response is unknown:
   - Source HBsAg-positive: test exposed for anti-HBs; if positive, no treatment; if negative, 1 dose of HBIG and 1 dose of vaccine, retest exposed for anti-HBs 4 to 6 mo later.

Step 4: Consider prophylaxis against HIV.[34,35] Antimicrobial prophylaxis should be initiated as soon as possible but within 24 h of exposure. Thus, clinicians in ambulatory settings should be prepared to prescribe and manage anti-HIV medications or arrange for urgent consultation with a specialist in the management of HIV infection who will also provide follow-up care of the employee. There are 2 postexposure HIV-prophylaxis regimens: the "basic regimen," a 4-wk course of 1 of several regimens containing 2 anti-HIV drugs, and an "expanded regimen" containing 3 anti-HIV drugs for exposures with an increased risk of transmission.[34,35] Updated information can be found at AIDSinfo (http://aidsinfo.nih.gov) or the National HIV/AIDS Clinician's Post Exposure Hotline (PEPline) at 1-888-448-4911. The PEPline provides consultation 24 h per day, 7 days per week for questions about managing occupational exposures to HIV, hepatitis B and C, and other bloodborne pathogens.

Step 5: Use this opportunity to educate the exposed person regarding risks of exposure, safe handling of sharps, immunization, standard precautions, and safe work habits.

Step 6: Repeat serologic testing for hepatitis C and HIV at 6 mo after potential exposure. Repeat serologic testing for hepatitis B (HBsAg and anti-HBs) at 6 mo if the exposed person was not previously documented to be anti-HBs-positive.

HBsAg indicates anti– hepatitis B surface antigen; HBIG, hepatitis B immunoglobulin.

Tuberculosis

In adults, screening for tuberculosis using a tuberculin skin test (TST) or a blood assay for *M tuberculosis* (eg, QuantiFERON-TB Gold test [Cellestis Limited, Carnegie, Victoria, Australia], which measures γ-interferon release by T cells after incubation of whole blood with 2 *M tuberculosis*–specific antigens[39,40]) should be performed before employment to ensure that persons with tuberculous infection are detected early and are treated. Employees with active pulmonary or laryngeal tuberculosis should be excluded from work until they are no longer contagious.[13,41] A TST result is considered positive in a

TABLE 4 **Work-Restriction Policies for Employees**

Infection	Restriction	Length of Restriction
Conjunctivitis	Restrict from direct patient care	Until discharge resolves
Gastroenteritis	Restrict from direct patient care and food preparation	Until symptoms resolve or person is deemed noncontagious
Hepatitis A	Restrict from direct patient care	Until 1 wk after onset of jaundice
Hepatitis B	None[a]	
Hepatitis C	None[a]	
Herpes simplex		
Orofacial	None (cover lesion if feasible)	
Whitlow	Restrict from direct care of newborn infants	Until lesions are crusted
HIV	None[a]	
Measles	Exclude from ambulatory facility	Until 7 d after onset of rash
Mumps	Exclude from ambulatory facility	Until 5 d after onset of parotitis
Pertussis	Exclude from ambulatory facility	Until treated for 5 d with appropriate antimicrobial therapy
Rubella	Exclude from ambulatory facility	Until 5 d after onset of rash
Staphylococcal skin infection	Restrict from direct patient care	Until treated for 24 h with an agent active against the isolate
Streptococcal group A pharyngitis	Restrict from direct patient care	Until treated for 24 h
Tuberculosis, active	Exclude from ambulatory facility	Until proven noninfectious
Varicella	Exclude from ambulatory facility	Until lesions crusted (usually 6 d after the onset of rash)
Zoster	If lesions are covered, may have contact with patients (other than immunocompromised patients and newborns); if lesions cannot be covered, restrict from patient care	Until lesions crusted

[a] Health care personnel with these infections should avoid performing procedures that are considered to be at risk for transmission of blood from health care personnel to a patient.

health care staff member who is otherwise healthy if the transverse diameter of the area of induration is at least 10 mm. For new employees with a negative TST and who have not had a TST within the past year, a 2-step TST (ie, use of a second TST 1–3 weeks after the initial skin test) is recommended, because it will boost the size of the induration in an individual with remote latent tuberculosis infection whose initial reading was less than 10 mm.[42] For employees with an immunocompromising condition, such as HIV infection, or close contact with a person with active tuberculosis, induration of 5 mm is considered a positive result.[42] If the TST result is positive, the employee is referred for evaluation and appropriate management. A blood assay for *M tuberculosis* is an acceptable alternative to a TST in adults, including health care personnel.[39,40] In contrast to a TST, there is no need for a second test if the initial result is negative. For ambulatory settings classified as having low risk of tuberculosis transmission, additional screening of employees is not necessary unless an exposure to *M tuberculosis* occurs.[40]

Staff Immunization

Policies should be established regarding immunization of employees, volunteers, students, and resident physicians against vaccine-preventable infections (Table 5).[22,43] Immunization records should be maintained for all employees. Immunization with hepatitis B vaccine at no cost to the employee is mandated by the OSHA and must be offered to all persons whose job category, specified in the bloodborne pathogen exposure-control plan for the facility, indicates likely exposure to bloodborne pathogens.[32,33] In 2005, a trivalent vaccine for protection against tetanus, diphtheria, and pertussis designed for adolescents and adults (Tdap; Adacel, Sanofi Pasteur, Swiftwater, PA) was licensed for persons 11 to 65 years of age.[44] (A second Tdap vaccine, Boostrix [GlaxoSmithKline Biologicals, Rixensart, Belgium] has been licensed for use in persons 10–18 years of age.[44]) Tdap is given instead of the tetanus-diphtheria booster to protect health care personnel and their patients from pertussis and provide protection against tetanus and diphtheria (Table 5). In 2006, the CDC recommended administering a single dose of Tdap to health care personnel with direct patient contact. This vaccine should be provided by the health care facility at no cost to the employee. Employees should be immunized against measles, mumps, rubella, and varicella unless immunity is documented by serologic testing or previous immunization or infection (Table 5). For the protection of health care personnel and their patients, the CDC also recommended that health care facilities provide influenza vaccine annually to all health care personnel at no cost to the employees.[45]

Staff Education

At the time of orientation, all employees should receive and review information regarding infection-prevention and -control policies and procedures, including precautions for minimizing the risk of transmission of bloodborne pathogens. Annual education regarding the OSHA bloodborne pathogens standard is required.[33] Furthermore, regularly scheduled educational sessions for all staff members are important to ensure that the levels of hand hygiene and infection-prevention and -control

TABLE 5 **Suggested Immunizations for Staff**

All staff members should receive the following immunizations:

- MMR vaccine
  - → All health care personnel born after 1956 should have received 2 doses of MMR vaccine. Ambulatory facility health care personnel often have contact with pregnant women; thus, it is optimal to ensure that all personnel are immune to rubella. Because birth before 1957 is only presumptive evidence of immunity to measles, mumps, and rubella, ambulatory facilities should consider recommending 1 dose of MMR vaccine for unimmunized workers born before 1957 who do not have a history of physician-diagnosed measles, mumps, and rubella or laboratory evidence of immunity to these viruses. Some experts recommend serologic screening for all employees to ensure immunity to measles, mumps, and rubella.
- Hepatitis B vaccine
  - → Hepatitis B vaccine should be strongly recommended for any employee who may come in contact with blood. The OSHA requires that hepatitis B vaccine must be offered to all employees who may be at risk of bloodborne exposures on the basis of job categories determined by the organization's bloodborne pathogen exposure-control plan. If the employee refuses immunization, this should be documented in the employee's file; the OSHA declination form is useful for this purpose.
- Varicella vaccine
  - → All employees should be questioned about a history of varicella. Employees with a negative or unknown history of disease who have not previously received 2 doses of varicella vaccine should be offered vaccine. Alternatively, employees with no history of disease or immunization can have a varicella antibody test performed, and vaccine can be offered to those who lack detectable varicella antibody. Adults require 2 doses of varicella vaccine separated by a minimum of 4 wk. If the employee has a medical contraindication to varicella vaccine or refuses immunization, this information should be placed in the employee's file.
- Influenza vaccine
  - → Vaccine use should be strongly promoted and offered free of charge yearly to all employees. Employee education and the use of a declination form should be considered to enhance immunization rates.
- Adolescent-adult Tdap vaccine
  - → This vaccine is recommended by the CDC for all health care personnel with direct patient contact. There should be a minimum of a 2-y interval between administration of Tdap and the most recent dose of Td vaccine.[43]

MMR indicates measles-mumps-rubella; Td, tetanus-diphtheria.

Source: Centers for Disease Control and Prevention. *MMWR Recomm Rep.* 2004;43(RR-13):1–132.

awareness remain high.[46,47] Policies for infection prevention and control should be written, available, read by staff, and enforced. All staff members should be aware of and motivated to follow these policies.[48]

Communication With Local and State Health Authorities

State and local health authorities determine which diseases should be reported. Physicians and staff in ambulatory facilities must be aware of the rules and regulations in their municipalities. Policies and procedures for communication with local and state health authorities regarding reportable diseases and suspected outbreaks should be established while adhering to current regulations of the Health Insurance Portability and Accountability Act (HIPAA).[49]

Minimize the Likelihood of Liability to Third Parties

A number of third-party liability cases involve infectious diseases (ie, cases alleging that a physician is liable for injury to others as a result of exposure to a contagious patient seen by the physician). A third party might include a family member or another close contact of a patient. Although some courts have concluded that there can be no liability without a physician-patient relationship, other courts have held that the physician has a duty to third parties if contact with the infected patient is "reasonably foreseeable." Third-party liability can occur not only from failing to warn the third party but also from failing to diagnose the disease in the patient or negligently advising the third party that there was no danger of infection. Therefore, physicians should be aware of their potential responsibility to third parties and should enact and document appropriate measures to minimize such risks. These measures include (1) informing the patient about the contagious nature of the disease, including treatments, potential risk to third parties, and advice about preventing the spread of the infection, (2) learning the relevant communicable diseases–reporting statutes and complying with them (although reporting may not be sufficient to satisfy the physician's duty to protect the third party), and (3) informing the patient of any action the physician intends to take to protect third parties at risk of contact with the patient.[50]

Ambulatory Facility Design, Procedures, and Patient Flow: Waiting and Reception Areas

Measures to prevent transmission of contagious infectious agents in ambulatory facilities that begin at the time the visit is scheduled should be developed and implemented. For example, during a telephone call request for an urgent visit for an ill child, the staff person should inquire whether the child has a skin rash. Parents of a child suspected of being contagious should register with the receptionist immediately on arrival; in some

cases, the child may be asked to use a separate entrance to avoid the waiting area and may be escorted directly into an examination room. Year-round (or during the winter season) and on the basis of recommendations from local public health departments and the CDC, travel- or symptom-based questions should be asked of patients/parents on arrival.[51] Staff should question patients and parents to determine if the patient has a rash or symptoms of a respiratory infection or has been exposed to individuals with specific infections (eg, tuberculosis, pertussis, measles). On the basis of current recommendations from local public health departments and the CDC, patients should be questioned about recent travel (eg, to countries with avian influenza infection or SARS-related coronavirus infection)[51] that might signify that the patient or an accompanying person has a contagious infection (Table 2). Signs should be displayed prominently at the entrance and reception areas with (1) instructions to patients and parents to notify staff immediately if the patient has a rash or symptoms of a respiratory infection or has been exposed to individuals with specific infections (eg, tuberculosis, pertussis, measles, varicella) and (2) instructions on implementing respiratory hygiene/cough etiquette (such as those prepared by the CDC[52,53]).

Waiting rooms and reception areas offer the opportunity for child-to-child interaction with concomitant child-to-child transmission of infectious agents. Waiting rooms are comparable with child care settings, where contamination of the environment and transmission of infectious agents occur at an increased rate compared with the home setting. Efforts should be made to limit transmission of infectious agents by designing waiting areas as multiple smaller rooms if possible, avoiding crowding, shortening waiting times, and minimizing the sharing of toys. To the extent feasible, respiratory hygiene/cough-etiquette guidelines (Table 2), including the use of tissues and hand-hygiene products (which should be supplied by the ambulatory facility), should be followed by children and adults with respiratory tract symptoms. Infected children who are symptomatic should be segregated from well children as quickly as possible. However, no studies document the need for, or benefit of, separate waiting areas for well and ill children.[8] Sick adults should be discouraged from spending time in waiting areas. Pathogenic bacteria have been recovered from toys in ambulatory waiting areas,[54] and contaminated bath toys have been implicated in an outbreak of *Pseudomonas aeruginosa* infection in a hospital.[55] A suggestion can be made to parents to bring along their child's personal book and toys for the office visit to minimize sharing of toys. Toys in ambulatory facility reception and waiting areas should be disposable or washable and of appropriate sizes and shapes to avoid aspiration or other injuries. Furry toys are less desirable because of the inability to clean them.[54] The value of antibacterial agents incorporated within toys is unproven. Ideally, toys should be cleaned between uses to avoid transfer of infectious agents.[56] Toys contaminated with body fluids should be removed until cleaned. Toys should be cleaned by washing with soap and water and then disinfecting (using a freshly prepared 1:100 dilution of household bleach or a product that meets the standards of the Environmental Protection Agency [EPA] for "hospital-grade" germicide that is nontoxic for children), rinsing, and air drying or by cleaning in a dishwasher that is designed for sanitizing dishes. Although smooth surfaces that are able to be scrubbed have not been demonstrated to have an infection-control advantage over carpeting and cloth upholstery, it may be prudent to use such materials in waiting areas because of their ease of cleaning and maintenance.

Sterilization, Disinfection, and Antisepsis

Sterilization completely eliminates or destroys all forms of microbial life, including spores. Disinfection reduces, but does not eliminate, the microbial burden. The extent of disinfection depends on the type of disinfectant and its concentration, the resistance of the microbes, contact time, and amount of organic material. Cleaning with detergent to remove organic material from medical instruments and other devices is a prerequisite to sterilization and disinfection. Antisepsis refers to the process used to decontaminate the skin of a patient or health care professional.

All patient care equipment should be cleaned at least daily while in use or when visibly contaminated and should be stored where it will not become contaminated. Reusable equipment having contact with mucous membranes requires high-level disinfection, whereas instruments that penetrate skin or sterile body cavities must be sterile (Table 6).[57–59]

Sterilization

Sterilization is accomplished by exposure to high-temperature steam, dry heat, or chemical sterilizing agents.[57,59] Items must be cleaned manually with soap and water to remove organic debris before autoclaving. Steam autoclaving uses distilled water that must reach a temperature of 121 to 132°C. The time for exposure of items and temperature depend on the type of sterilizer and what is being sterilized. Dry-heat sterilization in an oven is used only for items that cannot be sterilized by autoclaving. The oven temperature should be 170°C for an exposure time of 1 hour. For sterilizing specific instruments, the manufacturer's instructions must be followed. Unwrapped instruments should be used immediately or aseptically transferred to a sterile container.

A chemical indicator should be included with the equipment to be sterilized to ensure that sterilization has occurred. Instrument indicators ensure that a machine reaches the correct temperature and pressure. Chemical

TABLE 6 **Sterilization, Disinfection, and Antisepsis**

Instrument	Level of Disinfection	Methods (Examples)
Critical instrument or device: any instrument that enters tissue (eg, needles, surgical instruments, urinary catheters, some semicritical items)	Sterilization	Steam, low-temperature gas plasma, immersion in liquid chemical sterilants, ethylene oxide gas
Semicritical instrument or device: any instrument that contacts mucous membranes but does not enter tissue (eg, laryngoscope)	High-level disinfection	Wet pasteurization at 70°C for 30 min, chemical sterilants, liquid-chemical high-level disinfectants (eg, >2% glutaraldehyde, 0.55% ortho-phthalaldehyde [OPA], 7.5% hydrogen peroxide alone or in combination with peracetic acid)
Noncritical instruments or devices: instruments that touch only intact skin (eg, stethoscopes, blood pressure cuffs), including those with visible blood	Intermediate-level disinfection	1:50 dilution of sodium hypochlorite (1000 ppm of chlorine), 70%–90% isopropyl and ethyl alcohol, phenolic germicidal detergent solution, iodophor germicidal detergent solution
Environmental surfaces: knobs, handles, carts, or tabletops (with no visible blood)	Soap and water or low-level disinfection	EPA-approved disinfectants labeled for use against hepatitis B virus and/or tuberculocidal activity (eg, quaternary ammonium compounds), 1:500 dilution of sodium hypochlorite (100 ppm of chlorine)

Sources: Merriman E, Corwin R, Ikram R. *Br J Gen Pract*. 2002;52:138–140; Buttery JP, Alabaster SJ, Heine RG, et al. *Pediatr Infect Dis J*. 1998;17:509–513; and Geyer SA. *J Healthc Mater Manage*. 1986;4:52–53.

indicators are useful in showing that the wrapped package has been through the sterilization process. Biological indicators are necessary to ensure sterility. The procedure recommended by the manufacturer to document that sterility has been achieved should be performed at least weekly, and results should be recorded.

Packs that have been sterilized should be appropriately identified and stored in clean, dry areas to minimize recontamination. As long as the integrity of the sterile packaging is clean and intact, studies have shown that sterility of the product has no expiration date. Written policies and procedures for sterilization should be prepared, distributed to staff, and reviewed at regular intervals to be sure that policies are followed.

Disinfection

For this statement, the terms for disinfection are taken from the standards for sterilization, disinfection, and antisepsis used in hospitals.[57,59] High-level disinfection is used for instruments that have had contact with mucous membranes or nonintact skin. High-level disinfection is most often achieved by using liquid chemicals. Chemical disinfection is accomplished with several chemicals or combination of chemicals, including glutaraldehyde, 0.55% ortho-phthalaldehyde, or stabilized hydrogen peroxide (a combination of hydrogen peroxide and peracetic acid). The solution should be prepared according to manufacturer instructions and applied for the specified contact time, which varies with the chemical and the concentration. Activated glutaraldehyde solutions are used most commonly; however, these products have potential toxicity if proper ventilation is not ensured. After disinfection, instruments are rinsed with sterile water, dried, and stored in a clean, dry place to avoid extrinsic contamination.

Intermediate-level disinfection is accomplished with 70% ethyl or isopropyl alcohol, iodine and iodophors, or a 1:50 dilution of sodium hypochlorite.

Low-level disinfection is appropriate for equipment that does not touch mucous membranes; examples include bedpans, blood pressure cuffs, crutches, stethoscopes, and tabletops. Low-level disinfectants include phenolic compounds, quaternary ammonium compounds, and a 1:500 dilution of sodium hypochlorite.

Written policies and procedures for disinfection should be prepared, distributed to staff, and reviewed at regular intervals to be sure that policies are being followed.

Antisepsis

Antiseptics are chemical agents intended for use on skin or tissue. Skin-preparation agents include isopropyl alcohol, chlorhexidine gluconate, iodine, and iodophors. The preferred skin-preparation agent for immunization and venipuncture for routine blood collection (except obtaining blood for culture) is 70% isopropyl alcohol. Most skin-preparation agents must be allowed to dry before surface bacteria are killed. For children 2 months and older, a preparation that contains 2% chlorhexidine gluconate/70% isopropyl alcohol is the preferred skin-preparation agent for invasive procedures, including placement of central venous catheters. Tincture of iodine and povidone iodine are acceptable alternatives, may be used for infants younger than 2 months, and are routinely used for obtaining blood for culture. Contamination of antiseptics has been associated with outbreaks of infections and pseudoepidemics attributable to false-positive blood cultures.[60] To prevent contamination, bottles of antiseptics should be dated, should not be refilled, and should be inspected and discarded if not used within 28 days after opening. Alcohol pads, chlorhexidine gluconate, and iodine products prepared in single-use pack-

aging are available and eliminate the need for multiple-use bottles of these antiseptics.

General Housekeeping

All areas in ambulatory facilities should be cleaned on a regular basis and kept visibly clean. Examination rooms and frequently used equipment should be cleaned daily. Surfaces in examination rooms and patient waiting areas should be cleaned with a detergent and low-level disinfectant such as a disinfectant-grade quaternary ammonium compound "registered" by the EPA (ie, EPA approved). Linoleum and sealed wood floors are optimal floor surfaces, because they can be cleaned without difficulty. Furniture made of nonporous materials offers a similar advantage compared with furniture with cloth upholstery.

Spills and Environmental Contamination

Contaminated environmental surfaces should be cleaned with a detergent and then treated with a freshly prepared (ie, within the past 24 hours) 1:100 dilution of household bleach with contact time of at least 1 minute or a proprietary germicidal product on the EPA's list E (registered antimicrobial products effective against *M tuberculosis*, human HIV-1, and hepatitis B virus; see www.epa.gov/oppad001/chemregindex.htm). For spills with blood or body fluids contaminated by blood, visible organic matter should be removed with absorbable material (eg, paper towels) and discarded into a leak-proof, properly labeled container before cleaning and decontaminating. Chlorine, the active agent in household bleach, can be inactivated by blood and other organic material, and full-strength solution or a 1:10 dilution is required if the surface is not cleaned before disinfection. Gloves should be worn during cleaning.[3]

Examination Rooms

Each examination room in a pediatric ambulatory care setting should have a sink and alcohol-based hand rub. Properly functioning sinks, ideally with faucets that operate in a "hands-free" manner, with adjacent soap dispensers (with plain or antimicrobial soap) and disposable towels or dispensers with alcohol-based hand rub, should be located conveniently in all patient care areas. Installation of solid-surface sinks with continuous countertops and backsplashes may offer fewer opportunities for water trapping in seams. Soap should generally be in liquid form in pump dispensers that are designed to minimize the risk of extrinsic contamination. Bar soaps are less desirable, because bars frequently are wet and easily contaminated with potential pathogens; if used, small bars of soap and soap racks that facilitate drainage and drying of the soap should be used. Faucet aerators should be avoided, because they often become contaminated by *Pseudomonas* species and other waterborne organisms.

Equipment that makes physical contact with the patient should be cleaned after each use. Although furniture in the room generally is not a major concern for transfer of infectious agents, contamination of the examining table can be a problem. Covering the table with disposable paper or linen, which is changed between patients, decreases the risk of transmission of microbes. More-thorough cleaning should be performed if contamination, such as soiling from a diaper change, is visible. In such cases, a detergent should be used to remove visible soil followed by application of a freshly diluted solution of household bleach (1:100) applied for 1 minute to disinfect the surface, rinsing with water, and allowing to dry or using an EPA-approved low-level disinfectant disposable wipe indicated to inactivate *M tuberculosis* and/or hepatitis B virus. If reusable patient linens/gowns are used, they should be handled in a manner that minimizes contamination of the environment. Soiled linens should be contained or placed in a soiled linen bag at the point of use.[3] Provision should be made for the laundering of soiled linen.

Rest Rooms

Rest rooms for use by staff and patients should be cleaned daily and whenever visibly soiled. A diaper-changing area with disposable paper and a closed receptacle for soiled diapers and paper should be provided in at least 1 rest room.

Air Flow

Certain infections, including varicella, measles, and tuberculosis, are transmitted by the airborne route. Unfortunately, the number of air exchanges in buildings that house ambulatory facilities often is low, and the air is recirculated frequently.

Physicians should be aware of air-flow patterns to limit transmission of airborne pathogens. Special arrangements are recommended for patients who are considered to be contagious with an airborne pathogen, including (1) making efforts to see these patients at the end of the day, (2) placing a mask on the patient and quickly triaging these patients out of common waiting areas, and (3) closing the door of the examination room and limiting access to the patient by visitors and staff members who are not immune to the suspected disease. In some practices, it may be feasible for the clinician to perform a "car visit" by evaluating the patient in the family car in the parking area of the ambulatory facility. The duration of time that airborne pathogens remain in a room depends on air-exchange rates. For example, in hospitals where air-exchange rates are 6 to 8 per hour, several air exchanges occur within 30 minutes. Recommended air-exchange rates depend on the stated use of a room. Recommendations and guidelines for design and construction of hospitals and health care facilities are made by the American Institute of Architects and the

Facility Guidelines Institutes with guidance from the US Department of Health and Human Services.[61] These guidelines have been adopted in whole or in part as regulations in nearly all states and enforced by the Joint Commission (formerly called the Joint Commission on Accreditation of Healthcare Organizations). Another nonregulatory resource is the American Society of Heating, Refrigerating and Air-Conditioning Engineers. The current recommended air-exchange rate for a medical examination room is 6 air changes per hour, with 2 outside air exchanges per hour.

Diagnostic and Personal Equipment

The role of stethoscopes and other examining devices in transmitting infectious agents is unclear; however, studies have shown that stethoscopes can be contaminated with viral and bacterial agents, including bacteria that are resistant to multiple antimicrobial agents. A reasonable means of decreasing contamination is to wipe the bell and diaphragm of the stethoscope as well as the handle and body of otoscopes or ophthalmoscopes regularly, and whenever they become soiled, by using an EPA-approved disinfectant wipe labeled to be effective against hepatitis B or a 70% isopropyl alcohol wipe. Ear curettes, if not disposable, should be cleaned with 70% isopropyl alcohol after each use and, if grossly contaminated by blood/body substances, should be cleaned and then disinfected by using a sodium hypochlorite solution.

In most cases, blood pressure cuffs are placed on intact skin; therefore, the risk of transmission of infectious agents with their use is minimal. These reusable cloth cuffs should not be placed in direct contact with damaged or nonintact skin.

Whenever economically and medically feasible, disposable supplies should be used. Electronic thermometers have single-use shields, but care must be taken to avoid contaminating the housing of the thermometer. The "box" and the probe handle should be wiped with a low-level EPA-approved disinfectant whenever soiled. Care should be taken to avoid contamination of pulse-oximetry and tympanometry equipment with any body secretions, and equipment should be cleaned according to manufacturer recommendations after each use. Other equipment, such as electrocardiography machines and Denver Developmental Testing kits (Denver Developmental Materials Incorporated, Denver, CO), should be cleaned and disinfected with an intermediate-level disinfectant whenever they become soiled or contaminated by patient secretions.

Ballpoint pens, patient charts, computer mice and keyboards, and personal digital assistant devices can be contaminated with infectious agents that can be transmitted by hands to other environmental sources. Because these items are not cleaned after each use, hand hygiene before and after contact with the patient or immediate environment is necessary to minimize the potential transfer of bacteria and viruses from equipment to patients. A daily cleaning schedule that includes use of an EPA-approved low-level disinfectant is recommended for such items as computer mice and keyboards, blood pressure cuffs, and other commonly touched items in the patient's environment.

Disposal of Medical Wastes

The federal OSHA standards, as well as local and state regulations, dictate the proper disposal of medical wastes including dressings, needles, sharps, and body-fluid samples.[3,62] All physicians should be aware of the policies in their state and municipality and ensure that regulated wastes are disposed of appropriately. Basic principles include defining which items constitute infectious waste and which do not; appropriately separating, labeling, storing, and transporting items in these 2 categories; instructing staff on how to handle infectious waste; and developing plans for managing spills and inadvertent exposures.

Judicious Use of Antimicrobial Agents and Antimicrobial-Resistant Bacteria

Another aspect of infection prevention and control is diagnosis of infection and institution of antimicrobial therapy when indicated. Inappropriate use of antimicrobial agents in hospitals and ambulatory settings has contributed to the emergence of antimicrobial-resistant microorganisms. The CDC and the AAP have provided guidelines for the judicious use of antimicrobial agents.[63–69]

Guidelines have been published for isolation and precautions for hospitalized children and adults who acquire resistant flora.[70–72] Patients may continue to harbor antimicrobial-resistant bacteria as part of their skin, respiratory tract, or gastrointestinal tract flora. These organisms include methicillin-resistant *Staphylococcus aureus*, vancomycin–intermediately susceptible *S aureus* (glycopeptide–intermediately susceptible *S aureus*), vancomycin-resistant *Enterococcus* species, and extended-spectrum β-lactamase–producing and other multiply resistant Gram-negative bacteria. Many patients harboring these bacteria will not be identified, because the bacteria may not cause symptoms. Hand hygiene before and after contact with colonized children with or without the use of gloves is appropriate; no guidelines for management of these patients in ambulatory settings have been published. However, these resistant bacteria could contaminate the environment; thus, if a patient is known to have been infected or colonized with multidrug-resistant bacteria and has a draining wound or is in diapers, contact precautions may be beneficial, hand hygiene should be performed with an alcohol-based hand rub or washing with antimicrobial soap and water, and surfaces

in the examination room with which the patient had contact should be disinfected.

SUMMARY OF INFECTION-PREVENTION AND -CONTROL POLICIES (SEE APPENDIX FOR DESCRIPTION OF EVIDENCE CATEGORIES)

1. Written policies and procedures concerning infection prevention and control should be developed, incorporated into the ambulatory practice safety program, available at all times to office staff, and reviewed at least every 2 years (categories IB and IC).
2. Educational programs for staff concerning infection prevention and control should be implemented, reinforced, and evaluated on a regular basis (category IB).
3. Staff should receive influenza immunization annually and be immunized against or show documentation of immunity to other vaccine-preventable infections, including pertussis, measles, mumps, rubella, varicella, and hepatitis B, that can be transmitted in an ambulatory setting (categories IB and IC).
4. All health care personnel should perform hand hygiene by using an alcohol-based hand rub or handwashing with soap (plain or antimicrobial) and water before and after patient contact or contact with the patient's immediate environment (category IA).
5. Standard precautions (Table 1) should be used in every interaction with a patient (categories IB and IC).
6. In waiting rooms of ambulatory facilities, use of some or all components of respiratory hygiene/cough etiquette should be considered for patients and accompanying persons with suspected respiratory infection (category II).
7. Patients with potentially contagious diseases and immunocompromised children should be promptly triaged. Contact between contagious children and uninfected children should be minimized. Policies to deal with children who present with highly contagious infections, such as varicella, measles, pertussis, influenza, and mumps, should be devised and implemented (category IB).
8. Alcohol is preferred for skin antisepsis before immunization and routine venipuncture. Skin preparation for incision, suture, and collection of blood for culture requires either 2% chlorhexidine gluconate/70% isopropyl alcohol-based solutions (for children older than 2 months) or iodine (1% or 2% tincture of iodine, 2% povidone iodine) (category IB).
9. Physicians should be aware of requirements of government agencies, such as the OSHA, as they relate to the operation of ambulatory facilities (category IC).
10. Needles and sharps should be handled with great care. Needle-disposal units that are impermeable and puncture-proof should be available next to the areas used for injection or venipuncture. The containers should not be overfilled and should be kept out of reach of young children. Procedures should be established for removal and incineration or sterilization of contents. Needle devices with safety features should be evaluated periodically with input from staff members who use needles, and use of devices that are likely to improve safety should be implemented (categories IA and IC).
11. A written bloodborne pathogens exposure-control plan that includes written policies for management of contaminated–sharp-object injuries should be developed, readily available to all staff, and reviewed annually (category IC).
12. Standard guidelines for sterilization, disinfection, and antisepsis should be followed (category IC).
13. Policies and procedures should be developed for communication with local and state health authorities regarding reportable diseases and suspected outbreaks (category IC).
14. Antimicrobial agents should be used appropriately, and standard precautions (Table 1) should be observed to limit the emergence and spread of antimicrobial-resistant bacteria (category IB).

APPENDIX: EVIDENCE-BASED GUIDELINES CATEGORIES

CDC Healthcare Infection Control Practices Advisory Committee (HICPAC) guidelines[2,4] were used for categorizing the evidence base for each recommendation. Each recommendation is categorized on the basis of existing scientific data, theoretical rationale, applicability, and economic impact. The CDC/HICPAC system for categorizing recommendations is as follows:

Category IA. Strongly recommended for implementation and strongly supported by well-designed experimental, clinical, or epidemiologic studies.

Category IB. Strongly recommended for implementation and supported by certain experimental, clinical, or epidemiologic studies and a strong theoretical rationale.

Category IC. Required for implementation, as mandated by federal or state regulation or standard.

Category II. Suggested for implementation and supported by suggestive clinical or epidemiologic studies or a theoretical rationale.

No recommendation. Unresolved issue; practices for

which insufficient evidence or no consensus regarding efficacy exist.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Bioethics

The statement on informed consent, parental permission, and patient assent has a long and extraordinary history. The first draft of this document, prepared by William G. Bartholome, MD, was presented to the original American Academy of Pediatrics (AAP) Committee on Bioethics in 1985. Bill put his soul into the manuscript and has watched over it carefully ever since. Now, a decade later, those who have worked on its continued development and urged its adoption as Academy policy applaud its publication. No one is more gratified than its primary author and champion. Those who have had the privilege to know Dr Bartholome share his sense of accomplishment, but cannot help but experience a cruel sense of irony. Just as the work Bill considers his most important contribution has become available for public appreciation, Dr Bartholome suffers from a serious illness that threatens his life
Bill always wanted "the experience, perspective, and power of children" to be taken most seriously. Through the years of the statement's revisions and re-presentation within the Academy, Bill "had faith in the power of the text and the ideas it contained, ... that its time would come." The statement embodies Bill Bartholome's dedication to children. Throughout his career, he worked to make medicine and medical research safer and more friendly for children. The AAP and its Committee on Bioethics, on behalf of all our colleagues, extend heartful thanks to Dr William G. Bartholome for helping us more fully appreciate that children are in the process of becoming, in his words, "intelligent, observant, capable, and responsible persons" who deserve our utmost respect.

AN OVERVIEW

Since the 1976 publication of an AAP policy statement on the legal concept of informed consent in pediatric practice, the concept has evolved and become more formal.[1] A better understanding now exists as to how physicians should collaborate with patients and parents in making these decisions. Patients should participate in decision-making commensurate with their development; they should provide assent to care whenever reasonable. Parents and physicians should not exclude children and adolescents from decision-making without persuasive reasons. Indeed, some patients have specific legal entitlements to either consent or to refuse medical intervention. Although physicians should seek parental permission in most situations, they must focus on the goal of providing appropriate care and be prepared to seek legal intervention when parental refusal places the patient at clear and substantial risk.[2] In cases of serious conflict, physicians and families should seek consultative assistance and only in rare circumstances look to judicial determinations.

We now realize that the doctrine of "informed consent" has only limited *direct* application in pediatrics. Only **patients** who have appropriate decisional capacity and legal empowerment can give their **informed consent** to medical care. In all other situations, parents or other surrogates provide **informed permission** for diagnosis and treatment of children with the **assent** of the child whenever appropriate.

In this statement, the AAP provides an updated analysis of 1) the concept of informed consent; 2) the ethics of informed consent and the concept of the right to refuse treatment; 3) the concept of "proxy consent"; 4) the concepts of parental permission and child assent; and 5) informed consent of adolescents.

CHANGES IN MEDICAL DECISION-MAKING

The authority to make medical decisions used to lie squarely in the hands of physicians. However, complex social changes have resulted in acceptance of the idea that patients have a right to know about their health, to know about available diagnostic and treatment options and their risks and probable benefits, and to choose among the alternatives.[3] Many now regard traditional practices based on the theory that "doctor knows best" as unacceptably paternalistic.[4] Society recognizes that patients or their surrogates have a right to decide, in consultation with their

physicians, which proposed medical interventions they will or will not accept. Decision-making power or authority is increasingly seen as something to be shared by equal partners in the physician-patient or physician-surrogate relationship. For many patients and family members, personal values affect health care decisions, and physicians have a duty to respect the autonomy, rights, and preferences of their patients and their surrogates.[5]

ETHICS AND INFORMED CONSENT

The doctrine of informed consent reminds us to respect persons by fully and accurately providing information relevant to exercising their decision-making rights. Experts on informed consent include at least the following elements in their discussions of the concept:[6]

1. Provision of information: patients should have explanations, in understandable language, of the nature of the ailment or condition; the nature of proposed diagnostic steps and/or treatment(s) and the probability of their success; the existence and nature of the risks involved; and the existence, potential benefits, and risks of recommended alternative treatments (including the choice of no treatment).
2. Assessment of the patient's understanding of the above information.
3. Assessment, if only tacit, of the capacity of the patient or surrogate to make the necessary decision(s).
4. Assurance, insofar as is possible, that the patient has the freedom to choose among the medical alternatives without coercion or manipulation.

The goals of this consent process include the development of the patient's comprehensive understanding of the clinical situation, and the timely exercise, by the patient, of active choices regarding the circumstances.[7,8]

INFORMED CONSENT AND THE RIGHT TO REFUSE TREATMENT

Health care providers should engage in the process of informed consent with patients before undertaking any medical intervention. Patients generally have a moral and legal right to refuse proposed medical intervention, except when the patient has diminished decision-making capacity or must undergo legally authorized "involuntary" treatment. Respect for competent patients' autonomy ordinarily extends even to the refusal or discontinuation of their own life-sustaining treatment.[9]

PROBLEMS WITH THE CONCEPT OF "CONSENT" BY PROXY

In attempting to adapt the concept of informed consent to pediatrics, many believe that the child's parents or guardians have the authority or "right" to give consent by proxy. Most parents seek to safeguard the welfare and best interests of their children with regard to health care, and as a result proxy consent has seemed to work reasonably well.

However, the concept encompasses many ambiguities. Consent embodies judgments about proposed interventions and, more importantly, consent (literally "to feel or sense with") expresses something for one's self: a person who consents responds based on unique personal beliefs, values, and goals.

Thus "proxy consent" poses serious problems for pediatric health care providers. Such providers have legal and ethical duties to their child patients to render competent medical care based on what the patient needs, not what someone else expresses. Although impasses regarding the interests of minors and the expressed wishes of their parents or guardians are rare, the pediatrician's responsibilities to his or her patient exist independent of parental desires or proxy consent.[10]

PARENTAL PERMISSION AND SHARED RESPONSIBILITY

Decision-making involving the health care of young patients should flow from responsibility shared by physicians and parents. Practitioners should seek the informed permission of parents before medical interventions (except in emergencies when parents cannot be contacted). The informed permission of parents includes all of the elements of standard informed consent, as outlined previously.

Usually, parental permission articulates what most agree represents the "best interests of the child." However, the Academy acknowledges that this standard of decision-making does not always prove easy to define. In a pluralistic society, one can find many religious, social, cultural, and philosophic positions on what constitutes acceptable child rearing and child welfare. The law generally provides parents with wide discretionary authority in raising their children.[11] Nonetheless, the need for child abuse and neglect laws and procedures makes it clear that parents sometimes breach their obligations toward their children. Providers of care and services to children have to carefully justify the invasion of privacy and psychologic disruption that come with taking legal steps to override parental prerogatives.

THE DEVELOPMENT OF THE CHILD AS PERSON AND THE CONCEPT OF ASSENT

Decision-making involving the health care of older children and adolescents should include, to the greatest extent feasible, the **assent of the patient** as well as the participation of the parents and the physician. Pediatricians should not necessarily treat children as rational, autonomous decision makers, but they should give serious consideration to each patient's developing capacities for participating in decision-making, including rationality and autonomy. If physicians recognize the importance of **assent,** they empower children to the extent of their capacity.[12] Even in situations in which one should not and does not solicit the agreement or opinion of patients, involving them in

discussions about their health care may foster trust and a better physician-patient relationship, and perhaps improve long-term health outcomes.

Assent should include at least the following elements:

1. Helping the patient achieve a developmentally appropriate awareness of the nature of his or her condition.
2. Telling the patient what he or she can expect with tests and treatment(s).
3. Making a clinical assessment of the patient's understanding of the situation and the factors influencing how he or she is responding (including whether there is inappropriate pressure to accept testing or therapy).
4. Soliciting an expression of the patient's willingness to accept the proposed care. Regarding this final point, we note that no one should solicit a patient's views without intending to weigh them seriously. In situations in which the patient will have to receive medical care despite his or her objection, the patient should be told that fact and should not be deceived.

As children develop, they should gradually become the primary guardians of personal health and the primary partners in medical decision-making, assuming responsibility from their parents.

Just as is the case with informed consent, the emphasis on obtaining assent should be on the interactive process in which information and values are shared and joint decisions are made. The Academy does not in any way recommend the development of new bureaucratic mechanisms, such as "assent forms," which could never substitute for the relational aspects of consent or assent.

THE PATIENT'S REFUSAL TO ASSENT (DISSENT)

There are clinical situations in which a persistent refusal to assent (ie, dissent) may be ethically binding.[13] This seems most obvious in the context of research (particularly that which has no potential to directly benefit the patient).[14] A patient's reluctance or refusal to assent should also carry considerable weight when the proposed intervention is not essential to his or her welfare and/or can be deferred without substantial risk.

Medical personnel should respect the wishes of patients who withhold or temporarily refuse assent in order to gain a better understanding of their situation or to come to terms with fears or other concerns regarding proposed care. Coercion in diagnosis or treatment is a last resort.[15]

ETHICAL CONFLICT AND ITS RESOLUTION

Social forces tend to concentrate authority for health care decisions in the hands of physicians and parents and this tendency diminishes the moral status of children.[12] Thus, those who care for children need to provide for measures to solicit assent and to attend to possible abuses of "raw" power over children when ethical conflicts occur. This is particularly important regarding the initiation, withholding, or withdrawing of life-sustaining treatment.[16,17] Examples of mechanisms to resolve ethical conflicts include additional medical consultation(s); short-term counseling or psychiatric consultation for patient and/or family; "case management" or similar multidisciplinary conference(s); and/or consultation with individuals trained in clinical ethics or a hospital-based ethics committee. In rare cases of refractory disagreement, formal legal adjudication may be necessary.

LEGAL EMANCIPATION AND INFORMED CONSENT

The traditional notion of informed consent clearly applies to patients who have reached the legal age of majority, except when the patient has been determined to be incompetent. In addition, laws designate two settings in which minors have sole authority to make health care decisions.[11] First, certain minors are deemed "emancipated" and treated as adults for all purposes. Definitions of the emancipated minor include those who are: 1) self-supporting and/or not living at home; 2) married; 3) pregnant or a parent; 4) in the military; or 5) declared to be emancipated by a court. Second, many states give decision-making authority (without the need for parental involvement) to some minors who are otherwise unemancipated but who have decision-making capacity ("mature minors") or who are seeking treatment for certain medical conditions, such as sexually transmitted diseases, pregnancy, and drug or alcohol abuse.[18] The situations in which minors are deemed to be totally or partially emancipated are defined by statute and case law and may vary from state to state.[19] Legal emancipation recognizes a special status (eg, independent living) or serious public and/or individual health problems that might not otherwise receive appropriate attention (eg, sexually transmitted disease).

PRACTICAL APPLICATIONS

The following illustrations may help practitioners when applying the concepts developed above. These examples are intended to provide a focus for discussion and clarification and do not suggest new legal standards for pediatric practice.

In cases involving the following kinds of medical care for infants and young children, the Academy encourages physicians to seek the **informed permission of the parents** before: 1) providing immunizations; 2) performing invasive diagnostic testing for a congenital cardiac defect; 3) beginning long-term anticonvulsant therapy to control a seizure disorder; 4) initiating serial casting to correct congenital "clubfoot"; or 5) undertaking surgical removal of a "suspicious" neck mass.

Even in pressing situations, informed permission should be sought for actions such as performing a lumbar puncture to evaluate the possibility of meningitis. (In this situation, if parents deny permission for the procedure, one should obtain permission from the parents to initiate treatment based on reasonable clinical judgment, rather than delaying care or risking liability for performing the lumbar puncture

without appropriate authorization).

In cases involving the following kinds of medical care for older school-age children, the Academy encourages physicians to seek the **assent of the patient** as well as the **informed permission of the parents:** 1) venipuncture for a diagnostic study in a nine-year-old; 2) diagnostic testing for recurrent abdominal pain in a 10-year-old; 3) psychotropic medication to control an attention-deficit disorder in a third grader; 4) an orthopedic device to manage scoliosis in an 11-year-old; 5) an "alarm" system to treat nocturnal enuresis in an eight-year-old; or 6) surgical repair of a malformed ear in a 12-year-old. In some cases, treatment may proceed over the objection of the patient. However, physicians and parents should realize that overruling the child may undermine their relationship(s) with the child.

In situations such as the following that involve adolescents and young adults, the Academy encourages physicians to obtain the **informed consent** of the patient, in most instances: 1) performance of a pelvic examination in a 16-year-old; 2) diagnostic evaluation of recurrent headache in an 18-year-old; 3) a request for oral contraceptives for fertility control in a 17-year-old; 4) proposed long-term oral antibiotics administration for severe acne in a 15-year-old; or 5) surgical intervention for a bone tumor in a 19-year-old. Such patients frequently have decision-making capacity and the legal authority to accept or reject interventions, and, in that event, no additional requirement to obtain **parental permission** exists. However, the Academy encourages parental involvement in such cases, as appropriate.

Review of the limited relevant empirical data suggests that adolescents, especially those age 14 and older, may have as well developed decisional skills as adults for making informed health care decisions.[20-22] Ethical and legal factors, (ie, confidentiality and/or privacy), suggest that the physician involve parents after appropriate discussion with the adolescent elicits his or her permission to do so. In some cases in which the patient has no legal entitlement to authorize treatment, the physician may have a legal obligation in some jurisdictions to obtain **parental permission** or to notify parents in addition to obtaining the patient's consent. An adolescent's refusal of consent in cases such as these may well be legally (and ethically) binding. If "conflict resolution" fails, formal legal adjudication may be needed.

CONCLUSION

A re-analysis of informed consent leads to the identification of important limitations and problems in its application to pediatric practice. Two additional concepts are needed: **parental permission** and **patient assent.** The American Academy of Pediatrics believes that in most cases, physicians have an ethical (and legal) obligation to obtain **parental permission** to undertaken recommended medical interventions. In many circumstances, physicians should also solicit a **patient assent** when developmentally appropriate. In cases involving emancipated or mature minors with adequate decision-making capacity, or when otherwise permitted by law, physicians should seek **informed consent** directly from patients.

CLINICAL REPORT

Inhalant Abuse

Guidance for the Clinician in Rendering Pediatric Care

Janet F. Williams, MD, Michael Storck, MD, and the Committee on Substance Abuse and Committee on Native American Child Health

ABSTRACT

Inhalant abuse is the intentional inhalation of a volatile substance for the purpose of achieving an altered mental state. As an important, yet-underrecognized form of substance abuse, inhalant abuse crosses all demographic, ethnic, and socioeconomic boundaries, causing significant morbidity and mortality in school-aged and older children. This clinical report reviews key aspects of inhalant abuse, emphasizes the need for greater awareness, and offers advice regarding the pediatrician's role in the prevention and management of this substance abuse problem.

TYPES OF CHEMICALS AND PRODUCTS ABUSED

The term "inhalant" encompasses a wide range of pharmacologically diverse substances that readily vaporize. Most other substances of abuse are classified by grouping together substances that share a specific central nervous system action or perceived psychoactive effect, but inhalant substances that are abused are grouped by having a common route of drug use. Inhalant abuse, sometimes referred to as solvent or volatile substance abuse, can be better understood when the expansive list of inhalants is classified into 3 groups on the basis of what is currently known pharmacologically: group I includes volatile solvents, fuels, and anesthetics; group II includes nitrous oxide; and group III includes volatile alkyl nitrites (Table 1). This classification is also consistent with reported differences in user populations, patterns of abuse, and associated problems seen clinically.[1–3] Drugs that do not readily vaporize at room temperature, such as cocaine, heroin, nicotine, or alcohol, can also be abused through inhalation, but characteristic pharmacologic properties distinguish these substances from inhalants.

Inhalant abusers use volatile products that are capable of producing a quick and generally pleasurable sensory experience, or "high," with rapid dissipation and minimal "hangover" symptoms. Inhaled substances are widely available, convenient, inexpensive, easily concealed, and legal for specific intended uses but are intentionally misused by abusers. Many of these qualities are important factors that promote use in a young age group, because children have less sophisticated resources for acquiring alternative substances of abuse. The most commonly abused inhalants are the group I aliphatic, aromatic, or halogenated hydrocarbons found in thousands of commonly used and readily available consumer products. Virtually any hydrocarbon can have mind-altering effects when inhaled in large doses. Nitrous oxide or "laughing gas" is diverted from medical or dental anesthesia use and sold in balloons for inhalation or is simply inhaled from whipped cream aerosol cans. Alkyl nitrites or "poppers" are also abused; prototypically, amyl nitrite ampules intended to treat angina are "popped" open and inhaled.

TABLE 1 **Pharmacologic Classification of Inhalants: Selected Common Street Names and Chemical Content of Product Examples**

I. Volatile solvents, fuels, and anesthetics (air blast, discorama, hippie crack, medusa, moon gas, oz, poor man's pot)
Solvents: toluene, acetone, methylene chloride, ethyl acetate, TCE in paint thinner, paint and polish removers, correction fluid, and felt-tip marker fluid; TCE and tetrachloroethylene in degreasers, spot removers, and dry-cleaning fluids; toluene, hexane, TCE, ethyl acetate, and methyl chloride in glues and rubber cement; propellants and solvents such as butane, propane, chlorofluorocarbons, hydrocarbons in aerosol spray paint, computer/electronics-cleaning spray, spray deodorant, hair spray, vegetable-oil cooking spray, air-freshener spray, fabric-guard spray, and analgesic sprays
Fuels: butane or propane lighters or pressurized fuel tanks, gasoline, racing car octane boosters, refrigerants
Anesthetics: ether, halothane, enflurane, ethyl chloride
II. Nitrous oxide (laughing gas, buzz bomb, shoot the breeze): diverted medical anesthetic, whipped-cream dispenser charger (whippets), whipping-cream aerosol
III. Volatile alkyl nitrites (poppers, snappers, boppers, pearls, amys [isoamyl nitrite diverted from medical use], quicksilver, and brand/slang terms Rush, Bolt, Thrust, Climax, Locker Room): videocassette-recorder head cleaner, liquid aroma/liquid incense air fresheners or room odorizers (mostly cyclohexyl nitrite), isobutyl nitrite or butyl nitrite, isopropyl nitrite

TCE indicates 1,1,1-trichloroethane.

EPIDEMIOLOGY

Inhalant abuse occurs throughout the world, in industrialized nations as well as developing countries. Several studies have helped define the epidemiology of volatile substance abuse in the United States.[3–11] The peak age of inhalant abuse is 14 to 15 years, with onset in children as young as 5 or 6 years of age. Use typically declines by 17 to 19 years of age but can continue into adulthood. Use by adults may predominate under particular circumstances, such as when certain occupations make abusable solvents, propellants, or anesthetics readily available. Inhaled nitrites have a long history of being abused in certain social settings, particularly when men have sex with men.[3] The type, frequency, and method of volatile substance abuse vary widely in relation to age of the abuser, geographic region, and ease of availability.

The National Survey on Drug Use and Health (NSDUH), an annual survey of drug use in the general US noninstitutionalized civilian population 12 years and older, has documented inhalant abuse initiation by both adolescents and adults.[10] In 2005 and similar to previous years, 72.3% of the 877 000 new volatile substance abusers aged 12 to 49 years were younger than 18 years, with a mean age of 16.1 years. Since 2002, no significant change has occurred in the number of inhalant initiates, the average age of first use, or the rates of inhalant abuse by either youth or adults. This survey again showed no significant male-female difference in lifetime prevalence of inhalant abuse in the 12- to 17-year age group but confirmed a greater prevalence of inhalant abuse by men in the 18- to 25-year age group, suggesting that sustained use of inhalants is more common in males. Comparison of 2004 NSDUH findings with the Canadian Addiction Survey, a telephone survey in early 2004 of Canadian household residents 15 years and older, showed that US residents were 7 times more likely (9.5%) than Canadians (1.3%) to have ever used inhalants.[12]

According to the National Institute on Drug Abuse and the University of Michigan's annual Monitoring the Future (MTF) survey results[11]:

- Prevalence of lifetime inhalant use ("ever used") among 12th-graders has ranged between 10.3% in 1976 (when first included in the survey) and 18.0%, the 1990 peak. The 2006 rate of 11.1% has been stable since 2002.
- Since 1979, prevalence has additionally been reported after adjustment for the underreporting of amyl and butyl nitrite use. Adjusted lifetime prevalence figures remained at or above 17.0% until 1997 before steadily declining and stabilizing near the 2004 low of 11.4%. Adjusted lifetime and annual-use ("at least once in the past year") rates for 12th-graders (11.5% and 4.7%, respectively, in 2006) are among the lowest levels in survey history.
- Roughly similar declines in prevalence of inhalant use have been documented in the 8th- and 10th-grade age groups, which the MTF survey has included since 1991 but does not adjust for possible nitrite use.
- Recent data on perceived harmfulness may be portentous. Since 2001, the percentages of 8th- and 10th-graders who indicated that they "think people risk harming themselves (physically or in other ways) if they try inhalants once or twice" or "try inhalants regularly" have decreased. Past research has shown that decreasing perceived risk of using a drug often precedes an upswing in use of that drug.

MTF survey results have consistently shown that the reported prevalence of inhalant use by 8th-graders has been, on average, approximately 2% to 3% greater than that of 10th-graders, which runs approximately 2% greater than that of 12th-graders. This pattern, which is opposite that of nearly all other abused substances, may simply reflect that early experimentation with this easily acquired drug class is greater in younger age groups, that older students may fail to report inhalant use that occurred in earlier grades, or that many 8th-grade inhalant abusers subsequently drop out of school and are, therefore, no longer included in the survey population.[6,13,14] Research has shown that inhalant use often occurs in conjunction with other risk behaviors and that higher rates of inhalant abuse occur among children who have poor grades or have dropped out of school compared with classmates who remain in good standing at school.[6,13–15]

Although inhalant abuse is more prevalent among

geographically isolated and socioeconomically disadvantaged populations, it crosses all demographic boundaries and occurs in rural as well as urban settings and among all ethnic groups in the United States.[4,6–11] Important universal factors that promote initial experimentation with inhalants and their continued use include peer use and low perceived harm from use.[8,11,16] Inhalant use is often associated with impoverished living conditions, delinquency, criminal behavior, incarceration, depression, suicidal behavior, greater antisocial attitudes, family disorganization and conflict, or a history of abuse, violence, or other substance abuse, including injection drug use.[4,13,15–21]

MTF surveys have documented lower rates of past-year inhalant use among Hispanic compared with white individuals, with the lowest rates consistently among black individuals.[11] Similarly, most other studies have found rates of inhalant use by Hispanic youth to be the same as or lower than use by non-Hispanic white youth.[4–8,10,11] NSDUH data consistently show that rates of inhalant abuse by Asian American youth are among the lowest.[4,10] Inhalant use has been seen as a particularly serious problem among American Indian/Alaska Native youth for many years.[6,10,22] Research to discern factors contributing to inhalant abuse suggests that adverse socioeconomic conditions, including isolation and lower educational levels rather than racial or cultural factors per se, account for the reported higher rates among these minority populations. Eskimo children 10 to 19 years of age living in 14 isolated Bering Strait villages reported a lifetime prevalence of inhalant use of 48%.[23] American Indian youth living on reservations have been shown to have higher rates of inhalant abuse than do either American Indian youth living off reservations or non-Hispanic white youth.[22] Paralleling the decreasing inhalant abuse shown by the MTF studies until 2004, a promising downward trend has also been demonstrated since 1995 by the annual survey of American Indian students living on reservations.[8] Because use of other drugs during much of this time period also decreased, substitution of other drug use for solvent use was not felt to explain the trend. Despite these epidemiologic data, inhalants remain among the least studied groups of abused substances. Much research is needed to understand all aspects of inhalant use, including the neuropharmacologic effects and psychosocial correlates.

MECHANISM OF ABUSE AND IMMEDIATE EFFECTS OF INHALANTS

Inhalants are abused through a variety of methods, and many "street" terms for this activity have been generated, such as (glue) sniffing, snorting, huffing, glading, and dusting. Product fumes are usually inhaled through the mouth (huffing) or nose (sniffing or snorting) from the original container. Abusers may also inhale vapors from a chemical-saturated rag held to the face or stuffed in the mouth, which is also called huffing. Some aerosols are sprayed directly into the mouth or nose, and volatile solvents can be applied onto the nasal mucosa or a nearby surface such as fingernails or a shirt collar or cuff and then inhaled. "Glading" refers to the inhalation of air-freshener aerosols, whereas a recently coined term, "dusting," refers to the abuse of aerosol computer and personal electronics cleaning products by placing the canister straw into the mouth or nose. Familiar and innocuous containers are often used to help conceal inhalant abuse (eg, inhaling spray paint fumes out of a soft drink can or nitrous oxide–filled balloons). A paper or plastic bag containing the inhalant can be held to the mouth and nose or over the head ("bagging").

Unusual fads in inhalant abuse products or methods have been reported, such as heating volatile substances and inhaling the released vapors, as has been done with certain fertilizers or "snotballs" of rubber cement.[24] Mothballs have been abused by bagging or chewing.[25] Products combining inhalants with nonrespirable toxic ingredients, such as antiperspirants containing the toxic compound aluminum chlorohydrate, can be bubbled through water.[26] Combined alcohol and inhalant abuse by drinking "ocean" has been a periodic problem on and near some southwest American Indian reservations. Mixing water or mouthwash with the contents of a hairspray can, usually AquaNet, containing ethanol, methanol, and a propellant, produces foamy "ocean water" and combined toxicities.[27]

Inhalants are readily absorbed through the lungs, with immediate and brief effects, and then relatively rapidly metabolized predominately through the cytochrome P450 system of the liver. Inhalants, except nitrites, are depressants that act directly on the central nervous system through a wide range of mechanisms yet to be completely elucidated.[1,28] As a group, inhalants most resemble alcohol, whereby different cellular mechanisms are responsible for myriad pharmacologic and toxicologic effects. Opiate receptor involvement likely plays a role in the analgesic effects of nitrous oxide, but there is evidence for γ-aminobutyric acid (GABA)–mediated behavioral effects.[1] Volatile hydrocarbons also have GABAergic effects and a possible role in the inhibition of glutamatergic neurotransmission involving *N*-methyl-D-aspartate (NMDA) receptors.

The immediate effects of inhaling volatile solvents, fuels, anesthetics, or nitrous oxide are similar to the early stages of anesthesia. The user feels an initial stimulating "rush," then is light-headed, disinhibited, excitable, and prone to impulsive behavior. Intoxication lasts only a few minutes but can be extended for several hours by breathing inhalants repeatedly. Slurred speech, dizziness, diplopia, ataxic gait, and disorientation occur as the inhalant dose increases. Euphoria is followed by drowsiness, a lingering headache, and sleep, particularly after repeated cycles of inhalation. Visual hallucinations

are possible with prolonged use. Coma is unusual, because as the user becomes drowsy, exposure to the inhalant is usually terminated before a large enough dose is absorbed to cause severe neurologic and respiratory depression. Mucous membrane irritation may manifest as rhinorrhea, epistaxis, sneezing, coughing, excess salivation, and conjunctival injection. Some patients experience nausea, vomiting, diarrhea, abdominal cramps, dyspnea, or wheezing.[28,29]

Nitrites significantly differ pharmacologically from other inhalants, because instead of direct central nervous system effects, they primarily cause vasodilation and smooth muscle relaxation. The sensations of floating and increased skin tactility as well as warmth and throbbing occur within 10 seconds of inhalation but diminish within 5 minutes. Nitrite abuse may result in tachycardia, flushing, blurred vision, headache, lightheadedness, significant hypotension, syncope, and sufficient methemoglobinemia to cause cyanosis and lethargy.[1,3,29] Other inhalants are used to alter mood, but nitrites are inhaled to enhance sexual feelings, penile engorgement, and anal sphincter relaxation to intensify sexual experience.[3,29]

MORBIDITY AND MORTALITY

Patterns of inhalant abuse are similar to those of other substance abuse, and users can generally be described as experimenters, intermittent users, or chronic inhalant abusers. Similarly, morbidity and mortality increase as frequency of use increases, with the important exception that "sudden sniffing death syndrome" is a risk during any use, even during initial experimentation. In 1 study, 22% of inhalant abusers whose deaths were attributed to sudden sniffing death syndrome had no history of previous inhalant abuse.[30] Sudden sniffing death syndrome is the leading cause of fatality related to inhalant abuse.

Bass[31] originally described sudden sniffing death and elucidated its pathophysiology. Hydrocarbons and other inhalants "sensitize" the myocardium to epinephrine, and when this hormone is produced in response to any of a number of stimuli, most commonly sudden stress or fright, a fatal cardiac arrhythmia can result. Instead of truly sensitizing the cells, volatile substances stabilize myocardial cell membranes to depolarization. Because of variable individual myocardial cell response and the complex way that myocardial electrical impulses are propagated, greater cell stability actually blocks electrical impulse conduction and increases arrhythmia risk. During inhalant use, arrhythmias can occur even with normal epinephrine concentrations, but an adrenaline surge, such as when hallucinating or when discovered by or running from an authority figure, increases the risk.[32] Sudden sniffing death can occur during inhalation or in the subsequent few hours, because a volatile substance dissolved in lipid-rich cell membranes dissipates relatively slowly.[32] This unpredictable and unpreventable type of death leaves no specific macroscopic or microscopic postmortem features, so no cause can be identified at autopsy.

Death caused by inhalant abuse can also occur through a variety of other mechanisms but is usually attributable to an acute and related event, most likely suffocation, aspiration, or accidental injury (Table 2). From 1981 to 1985 in Britain, suffocation, aspiration, and accidental injury each accounted for approximately 15% of deaths attributable to inhalant abuse, and the remaining 56% of deaths were attributed to sudden sniffing death syndrome.[30] Suffocation occurs when the mode of use involves inhalation through the nose and mouth from a plastic bag, which may occlude the airway if the user loses consciousness. The risk of death caused by aspiration, usually of vomitus, is similar to that for alcohol or other depressants and is related to the combination of a decreased level of consciousness and the loss of protective airway reflexes. While under the influence of inhalants, users become less inhibited as well as less alert and oriented, which can promote their engaging in risk behaviors and lead to accidental injury and death, such as from a motor vehicle crash, drowning, fire, a jump or fall from heights, or hypothermia from exposure to the elements.

The United Kingdom, with a population approximately one fifth that of the United States, has been the only major part of the Western world to track in a systematic way deaths associated with volatile substance abuse. Since 1999 legislation banned the sale of butane cigarette lighter refills to youth younger than 18 years, there has been a significant drop in inhalant use deaths in both this age group and older individuals. The 2003 volatile substance abuse–related death total of 51 was the lowest number recorded for the United Kingdom since 1983. Of the 9 individuals younger than 18 years who died, 6 did so in relation to inhalation of butane lighter refills, compared with 15 of the 24 deaths in this age group in 2002.[33]

Three reports shed light on the US inhalant abuse mortality rate. The Toxic Exposure Surveillance System (TESS) database of the American Association of Poison Control Systems showed 63 deaths in 11 670 cases of

TABLE 2 Causes of Death From Inhalant Abuse

Acute
Direct causes: immediate or "postponed" sudden sniffing death syndrome; methemoglobinemia
Indirect causes: suffocation, aspiration, trauma, drowning, fire, other
Delayed
Cardiomyopathy
Central nervous system toxicity: toluene dementia and brainstem dysfunction
Hematologic: aplastic anemia, leukemia
Hepatocellular carcinoma
Renal toxicity: nephritis, nephrosis, tubular necrosis

intentional inhalant abuse reported from 1996 to 2001 to poison-control centers nationwide.[9] Actual mortality rates are likely greater, as evidenced by extrapolation from 2 studies that examined state death records that mentioned inhalants as a contributing cause of death at any age.[34,35] These studies found 39 deaths in Virginia from 1987 to 1996 and 144 deaths in Texas from 1988 to 1998. In Virginia, 70% of those who died were 22 years and younger, and in Texas, 28.7% of victims were 8 to 17 years of age. Of the inhalant abuse cases reported to the TESS, 54% were in youth 13 to 19 years of age, 15% were in children 6 to 12 years of age, and 0.4% were in children 5 years and younger. The 63 fatalities occurred almost exclusively in adolescents and young adults. Three types of inhalants were associated with the majority of deaths reported to the TESS: gasoline (45%), air fresheners (26%), and propane/butane (11%). These same group I inhalants (Table 1) were associated with the majority of deaths in both Virginia and Texas, particularly fuels including refrigerants and various solvents.

There is as diverse a list of possible sequelae of chronic inhalant abuse as there is diversity in the types of volatile solvents, fuels, and anesthetics used and the dose and frequency of exposure. If chronic solvent abuse is terminated, there is remarkable reversibility of many of the pathologic effects, but compared with other organ systems, the nervous system has less regenerative capacity. Of all biological membranes, myelin has the highest fat content at 75%, and neuronal membranes may contain up to 45% lipid. The primary consequence of frequent and longer-term inhalant use over months to years is chronic nervous system absorption of these highly lipophilic substances and significant nervous system damage, resulting in muscle weakness, tremor, peripheral neuropathy, cerebellar dysfunction, chronic encephalopathy, and dementia, including mood changes[28,29,36–39] (Table 3). Loss of coordination, gait disturbance, and spasticity, particularly in the legs, have also been noted.[37–39] Computed tomography has demonstrated a loss of brain mass, and magnetic resonance imaging has shown white-matter degeneration and subcortical abnormalities, particularly in the thalamus, basal ganglia, pons, and cerebellum.[40] Cognitive impairment has been reported with deficits found in memory, attention, auditory discrimination, problem-solving abilities, visual learning, and visual-motor function.[29,38] A limitation of the few studies that have investigated cognitive and neuropsychiatric functioning of inhalant abusers is that most of them have not adequately demonstrated that the impairments were not premorbid deficits. Most of the acute neurologic, neuropsychiatric, and cognitive sequelae of volatile solvent abuse seem to be reversible, but the resolution of chronic symptoms is much slower and less complete.[29,38]

TABLE 3 **Major Neurotoxic Consequences of Inhalant Abuse**

Cerebellar ataxia
Cranial neuropathy: usually cranial nerves V and VII
Encephalopathy: acute or chronic
Multifocal: both cortical and subcortical central nervous system damage, both central nervous system and peripheral nerve effects
Optic neuropathy: visual loss
Parkinsonism
Peripheral neuropathy

Other causes of morbidity and mortality are related to the specific volatile chemical(s) used, associated health risk behaviors, drug-drug interactions, or additional material(s) found in the various inhaled products. Toxic effects attributed to specific chemicals include an ichthyosis-like dermatitis on the extremities,[25] decreased visual acuity,[41,42] sensorineural hearing loss,[42] cardiomyopathy,[43] toxic hepatitis,[44] distal renal tubular acidosis,[45] metabolic acidosis,[46] leukemia,[47] and aplastic anemia.[48] There is evidence that tolerance, dependence, and withdrawal symptoms can occur, and reported morbidities also include toluene embryopathy and neonatal withdrawal.[49–52] Lung damage from paint pigments, lead poisoning from leaded gasoline, and other such toxicities have been reported when an inhalant contains another potential toxin.[53] Inhalant abuse is associated with the abuse of other substances, including pharmaceuticals, alcohol, tobacco, and illicit drugs, which can obscure the diagnosis of inhalant abuse and increase potential morbidity.[21,54,55] Combining other drugs with inhalants expands the potential for risk behaviors, altered drug metabolism, and drug-drug interactions, including potentiation of drug effects, particularly depressant effects. High flammability and accidental combustion of volatile agents have led to burns and other fire-related injuries.[3,24]

Chronic nitrous oxide abuse causes short-term memory loss and peripheral neuropathy, which subside with discontinuation of the abuse.[29] Peripheral neuropathy results from nitrous oxide inactivating vitamin B_{12} and mediating a pernicious anemia-type syndrome, which includes anemia, leukopenia, sensorimotor neuropathy, and posterior/lateral column spinal cord disease.[29] Nitrite inhalation has been associated with hemolytic anemia in patients with glucose-6-phosphate dehydrogenase deficiency.[56] Because nitrites are abused mainly for their sensory and sexual effects, use may promote higher-risk sexual practices, facilitate transmission of sexually transmitted infections, and result in drug interactions, such as with sildenafil.[3] Chronic abuse of volatile alkyl nitrites has documented hematologic and immune system effects without associated cognitive deficits.[1,29,56]

DETECTION OF INHALANT ABUSE

Inhalant abuse may not readily come to the attention of others, including pediatricians, because signs and symptoms of use are often subtle. Abuse of inhalants should

be suspected when a cache of a potential inhalant is discovered or when products with abuse potential are found stored in unusual locations, such as cans of gasoline or spray paint under a youth's bed. Changes in an adolescent's behavior, including apathy, malaise, poor appetite, a significant shift in choice of friends or activities, or an unexplained drop in school grades, can also be signs of inhalant abuse. Those who are chronic and heavy inhalant abusers may be identifiable because of their combination of poor hygiene and grooming, weight loss from decreased caloric intake, and chronic complaints of, for example, fatigue, rhinitis, conjunctivitis, recurrent epistaxis, and oral or nasal ulcerations. Chronic neuropsychiatric changes, such as confusion, poor concentration, depression, irritability, hostility, or paranoia,[28,29,57] may predominate. Symptoms of other organ system toxicities from long-standing inhalant use may also bring the abuser to medical attention.

Inhalant abusers may present with obvious intoxication and evidence of use, such as a conspicuous odor of the inhalant. This chemical odor is most often present because the abuser excretes a significant proportion of the absorbed dose when exhaling, and the odor can persist on the breath for many hours.[57] If the abused product spilled onto clothing during use or was intentionally put on clothing, the odor may also persist, and clothing stains or paint may be found. Paint or glitter may also be seen on the abuser's face or hands, or there may be a "huffer's rash," classically a perioral or perinasal dermatitis with pyoderma.[24,58] Contact with inhalants dries the skin and leads to small cracks, which allow bacteria to enter. The dermatitis may look like a nonspecific contact hypersensitivity reaction or perioral eczema or, with nitrite use, may have a yellow crust attributed to nitric acid, which can promote a xanthoprotein reaction.[58] Refrigerants and chlorofluorohydrocarbon propellants, such as those found in computer-cleaning aerosols, have been reported to cause frostbite on the face or in the nose or oral cavity that can lead to airway compromise.[59]

Similar to the approach to other substance abuse, providing appropriate medical care for any child or adolescent using inhalants results from a keen diagnostic awareness leading to detection, intervention, and treatment. Regular office screening for inhalant abuse as well as other substance abuse and health risk behaviors must be part of standard pediatric care. Inhalants are not detected by using routine urine drug screening, so detection relies on knowledgeable medical personnel who consistently include screening questions as part of conducting a thorough history and physical examination.[26] When considered in certain clinical contexts, abnormal nontoxicologic laboratory results, such as elevated liver enzymes, may arouse or confirm a suspicion of inhalant abuse. Blood and other tissues, usually brain or liver, can be tested by specific gas chromatography technique when inhalant detection is necessary, such as in a fatality.[26] Specific urine drug testing is sometimes useful as part of the treatment-compliance plan when benzene, toluene, or a similar agent has been chronically abused, because major urinary metabolites (phenol and hippuric acid, respectively) are detectable when there has been a high level of use.[26]

INHALANT ABUSE PREVENTION AND MANAGEMENT CONSIDERATIONS

As with other types of substance abuse, the most effective way to curtail use is through broad prevention efforts, particularly primary prevention through education paired with skills-building. Developmentally and culturally sensitive educational strategies should be implemented, such as those implemented in many American Indian communities through a prevention initiative in conjunction with the American Indian Institute at the University of Oklahoma.[8]

Limiting the availability of volatile substances is impractical, because they constitute products that are universally available and legal and have legitimate uses. Restricting the availability of some of these products, such as the United Kingdom ban on the sale of butane lighter refills to youth, can be successful but may also promote the use of other more-available products or create a black market for the restricted products. Adding a noxious chemical to the product to prevent misuse was tried with plastic glue and found to be ineffective, because multiple products would require such adulterants, abusers switch products, and legitimate consumers and product efficacy might be adversely affected.[60] Reformulating the product by replacing the hydrocarbon with other chemicals has occurred when economically feasible and when product efficacy could be maintained. Product warning labels can alert the public to inhalant dangers but may also promote easy identification of abusable substances.[61] Most states have laws making the use of inhalants or sale to minors illegal, and although difficult to enforce and of yet-unproven efficacy, such laws serve as a reminder that society condemns inhalant abuse.

Most acutely intoxicated inhalant abusers do not seek medical attention, and only when intoxication is life-threatening or has led to serious injury will an abuser present to the emergency department. Acute medical management of inhalant abuse starts with applying the "ABCs" of life support to assess and stabilize the patient and address any specific acute injury or toxicity, such as combating methemoglobinemia by administering intravenous methylene blue. Hydration and cardiorespiratory status should be monitored closely. Myocardial sensitization by inhalants necessitates a calm and supportive environment in which the use of pressor medications and bronchodilators are relatively contraindicated. No medications reverse acute inhalant intoxication or have

been found to be helpful with dependence or withdrawal symptoms. Decontamination of the patient's clothing and skin may be indicated. Laboratory testing can help monitor oxygenation and hematologic status and detect other substances being abused. Testing for organ-system damage should be considered only when there is a history of regular and long-term inhalant use. After acute stabilization, comprehensive medical care includes documenting a detailed history and physical examination and specifically evaluating the patient's mental health, substance abuse history, and psychosocial needs so that appropriate inpatient or outpatient interventions can be initiated.[28,29,57]

Little research exists concerning treatment needs and successful treatment modalities specific to inhalant users, so clinicians rely on applying methods that are used to treat other addictive disorders, such as cognitive-behavioral therapy, multisystem and family therapy, 12-step facilitation, and motivational enhancement techniques,.[62] Inhalant abusers seem to respond best to a treatment program that includes an extended detoxification or "treatment readiness" period of 4 or more weeks, during which basic supportive care and general orientation are emphasized. If sufficient time is not allowed, individuals seem incapable of engaging in the treatment program.[63] Some treatment facilities have used a peer-advocate system for patients, which seems to offer a nonthreatening and supportive treatment approach.[64] Neuroleptics and other forms of pharmacotherapy are usually not useful in the treatment of inhalant abusers except to address comorbid conditions. Increasing personal and ethnic self-identity through role-modeling has been suggested as helpful in treating some groups of inhalant abusers, and positive cultural identification has been shown to be important in American Indian/Alaska Native populations.[65] Treatment challenges are posed by the diversity of abused inhalants and user populations, comorbid psychopathology, psychosocial problems, polydrug use, and the physiologic and neurologic effects of inhalant abuse.[62,63] Treatment of longer-term inhalant users is hindered by the fact that there are few programs designed specifically for inhalant abuse treatment, access to care may be limited, providers generally have a pessimistic view about users' neurologic damage and chance for recovery, and providers often lack sufficient knowledge and training about inhalant abuse, inhalant users, and their treatment needs.[64] Although the principles of effective substance abuse treatment in general apply to inhalant abuse treatment, any treatment regimen must address the many clinical, emotional, social, academic, pharmacologic, neurocognitive, cultural, and demographic factors that make this type of substance abuse unique. Treatment strategies are still under development, and additional research is needed to identify effective strategies for the treatment of children and adolescents who use inhalants.

CONCLUSIONS AND ADVICE

The American Academy of Pediatrics has established recommendations[66] regarding the pediatrician's role in the prevention, identification, and management of substance abuse and advises the following to promote that role with regard to inhalant use by youth.

1. Pediatricians are encouraged to:
   - be aware that inhalant abuse occurs in all patient populations, including their own;
   - be knowledgeable about the epidemiology of inhalant abuse, particularly about local and regional trends, as well as resources, such as the telephone number 1-800-222-1222 to contact the nearest poison-control center;
   - be knowledgeable about health consequences of inhalant abuse and, in particular, about unique clinical features such as central nervous system damage and sudden sniffing death syndrome;
   - assist in educating children, adolescents, parents, teachers, media representatives, and vendors of volatile substances regarding inhalant abuse prevention and the health risks of inhalant use; and
   - serve as a community resource regarding inhalant use awareness, prevention, detection, and management using national and local community resources such as the National Inhalant Prevention Coalition (1-800-269-4237 or www.inhalants.com), an information and referral clearinghouse.
2. Inhalant abuse education can be included in all substance abuse prevention curricula in the primary and secondary grades, using approaches that effectively warn against the dangers of inhalant use yet do not inadvertently introduce youth to available substances with abuse potential.
3. Widespread accessibility and use of research-based resources such as National Institute on Drug Abuse publications (available at www.drugabuse.gov/DrugPages/Inhalants.html) are encouraged.
4. Increased research efforts to evaluate prevention and treatment approaches specific to inhalant abuse and to identify those with efficacy are needed.

Committee on Injury and Poison Prevention

Injuries Associated With Infant Walkers

ABSTRACT. In 1999, an estimated 8800 children younger than 15 months were treated in hospital emergency departments in the United States for injuries associated with infant walkers. Thirty-four infant walker-related deaths were reported from 1973 through 1998. The vast majority of injuries occur from falls down stairs, and head injuries are common. Walkers do not help a child learn to walk; indeed, they can delay normal motor and mental development. The use of warning labels, public education, adult supervision during walker use, and stair gates have all been demonstrated to be insufficient strategies to prevent injuries associated with infant walkers. To comply with the revised voluntary standard (ASTM F977-96), walkers manufactured after June 30, 1997, must be wider than a 36-in doorway or must have a braking mechanism designed to stop the walker if 1 or more wheels drop off the riding surface, such as at the top of a stairway. Because data indicate a considerable risk of major and minor injury and even death from the use of infant walkers, and because there is no clear benefit from their use, the American Academy of Pediatrics recommends a ban on the manufacture and sale of mobile infant walkers. If a parent insists on using a mobile infant walker, it is vital that they choose a walker that meets the performance standards of ASTM F977-96 to prevent falls down stairs. Stationary activity centers should be promoted as a safer alternative to mobile infant walkers.

ABBREVIATIONS. NEISS, National Electronic Injury Surveillance System; CPSC, Consumer Product Safety Commission; JPMA, Juvenile Products Manufacturers Association.

OVERVIEW

An infant walker, or baby walker, consists of a wheeled base supporting a rigid frame that holds a fabric seat with leg openings and usually a plastic tray. The device is designed to support a preambulatory infant, with feet on the floor, and to allow mobility while the infant is learning to walk. Some walkers are equipped with bouncing mechanisms, activity toys, or locking devices that keep them from moving, and some fold flat for storage.

Estimated annual sales of walkers are more than 3 million.[1] Older studies have found that 55% to 92% of infants between 5 and 15 months of age use walkers.[2–6] Parents give various reasons for using walkers—to keep the infant quiet and happy, to encourage mobility and promote walking, to provide exercise, and to hold the infant during feeding.[4,5,7] One third of parents in one study used walkers because they believed that walkers would keep their infants safe.[5]

DATA

According to the National Electronic Injury Surveillance System (NEISS) of the US Consumer Product Safety Commission (CPSC), an estimated 8800 children younger than 15 months were treated in hospital emergency departments in the United States in 1999 for injuries associated with the use of infant walkers.[8] This represents a 56% decrease in these injuries since 1995, when 20 100 injuries were reported.[8] Thirty-four deaths associated with the use of infant walkers were reported to the CPSC during the years 1973 through 1998 (D. Tinsworth, personal communication, November 2000). Population surveys suggest that there may be as many as 10 times more injuries that are sufficiently minor that they are treated in physicians' offices or do not require medical attention.[5] Parents report that walker-related injuries occur at some time in 12% to 40% of infants who use walkers.[6,9] A study of 65 Virginia children injured in walkers estimated the annual incidence of walker injuries resulting in emergency department visits to be 8.9 per 1000 children younger than 1 year. Severe injuries occurred at a rate of 1.7 per 1000.[10] Approximately one fourth of infant walker-associated injuries reported to the NEISS are described as "more severe," and these are nearly all fractures and closed head injuries. Skull fractures accounted for almost 10% of all walker-related injuries in one large series of patients.[11]

Reported injuries are overwhelmingly caused by falls, either from the walker or with the infant remaining in the walker. Stairs are implicated in 75% to 96% of cases and in almost all of the severe injuries.[11] A small number of pinch injuries to fingers and toes occur.[1,12] Burns account for 2% to 5% of walker-related injuries.[7,8,10] Walkers also have been commonly associated with poisonings of infants under 1 year of age.[13] These burns and poisonings are attributable to the increased access to these hazards afforded by an infant's increased mobility in a walker. Although submersion is not a commonly reported mechanism of nonfatal injury, 4 of the 11 deaths reported between 1989 and 1993 were from drowning (in a pool or toilet), 4 were from suffocation (compression of the neck against the feeding tray), and 3 were from falls.[12]

Little effort has been made to compare the rates and severity of various injuries in children of the

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

same age who do or do not use walkers. A report from Toronto's Hospital for Sick Children, however, states that during 1984, 123 infants who had fallen down stairs in walkers were evaluated; only 1 infant in the same age group who had fallen down stairs was not in a walker.[7] Although walkers do not consistently account for the majority of infant injuries associated with falls down stairs, in another study,[14] walkers accounted for 45% of falls down stairways causing head injury in children younger than 24 months, and these walker-related stairway falls caused more severe injury. The study authors[14] believe that the walker predisposes infants to more serious injury by increased kinetic energy resulting from the larger mass and higher initial speed (speeds of more than 3 ft/sec have been recorded[15]) and because the infant tends to remain in the walker while falling, resulting in unprotected head exposure.[14]

Parents who use infant walkers often express their perception that the walker keeps their child safe (a form of baby-sitting), or that it helps the infant learn to walk. Data supporting such benefits do not exist. One study that evaluated children between 6 and 15 months of age demonstrated that walker-experienced infants sat, crawled, and walked later than no-walker controls, and they scored lower on Bayley scales of mental and motor development.[16] At first, the unassisted gait of infants who use walkers may be slightly abnormal.[2] There is no evidence, however, that such effects are lasting in typical children or that they have any impact on the child's ultimate motor development or intelligence.[2,17] Anecdotal reports suggest that children with cerebral palsy who use walkers experience exaggerated abnormal motor reactions and delay in development of normal balance and protective responses; however, the duration of these signs and the consequences of these observations have not been addressed systematically.[18–20] Beyond parental impressions that infants seem happier in walkers, it does not appear that any real benefits of using a walker can be found to balance the considerable risk of injury.

PREVENTION

Strategies to prevent infant walker-related injuries include 1) warning labels and public education, 2) adult supervision during walker use, 3) barriers such as stair gates, 4) infant walker design changes to prevent falls down stairs, and 5) a proposed ban on mobile infant walkers.

Until the 1996 revision of the voluntary standard for infant walkers (ASTM F977-96),[21] injuries attributable to falls were addressed only through warning labels, which was an ineffective strategy in reducing these injuries.[1] Several studies have shown that even the occurrence of a walker-related injury does not deter parents from the continued use of walkers for the injured child or subsequent siblings. In one study, 32% of parents reported that they used the walker again after the injury, and 59% acknowledged that they were aware of the potential dangers of walkers before the injury episode.[11] Thus, more labeling and educational efforts are not likely to lead to an additional decrease in walker-related injuries.[4,5,7,11]

Adult supervision also cannot be relied on to prevent infant walker-related injuries. Moving at more than 3 ft/sec, an infant can be across the room before an adult has time to react. In one study, 78% of children were being supervised at the time of the injury, including supervision by an adult in 69% of cases.[11] Other studies have also shown that many of these events occur with 1 or both parents in the room.[7,12,22] Stair gates are not uniformly effective even when present; more than one third of falls down stairs in one study occurred with stair gates in place, but the gates were either left open or improperly attached.[7]

Both mandatory and voluntary standards exist for infant walkers. The mandatory standard that has been in effect since 1971 (16 CFR 1500.86 [a]4) primarily addresses injuries to digits caused by pinching or shearing in the frame of the walker and by collapse of the walker. Judging from CPSC statistics, these types of injuries are infrequent, suggesting that these standards are effective.[1] The voluntary standard (ASTM F977) addresses the more difficult problems of falls and tip-overs. The standard's performance requirements to prevent walker tip-overs and structural failures appear to have been effective, because these types of incidents are now uncommon.

In 1996, the voluntary standard was revised to include performance standards for infant walkers to prevent falls down stairs. To comply, walkers manufactured after June 30, 1997, must be wider than a 36-in doorway or must have a braking mechanism designed to stop the walker if 1 or more wheels drop off the riding surface, such as at the top of a stairway. A similar voluntary standard was adopted in Canada in June 1989 requiring the width of walkers to be at least 900 mm (35.4 in).[23] In the United States, CPSC data confirm that basement stairs are involved in approximately half of walker injuries and that about 80% of the doorways to these stairs are 36 in wide or less.[12] Although walkers meeting the new standard began appearing in retail stores at the end of 1997, overall industry compliance remains to be evaluated. Because compliance is voluntary, the incentive for manufacturers to meet the new safety standards is a product certification by the Juvenile Products Manufacturers Association (JPMA). The manufacturers most likely to comply with the revised voluntary standard are members of the JPMA; however, nearly 40% of the new baby walkers sold in the United States are manufactured by firms that do not belong to the JPMA. Because the rule-making proceeding that the CPSC began in 1994 is still open, the CPSC could pursue the development of a mandatory standard to prevent infant walker stairway falls if the industry's compliance with the voluntary standard were judged to be inadequate.

Baby walker-like devices that do not roll across the floor on wheels are also available to consumers. These stationary activity centers allow children to bounce, swivel, and tip, and they provide parents an alternative to the use of mobile infant walkers. Injury data for these devices are not yet available. Their

stationary design eliminates the risk of stair-related falls, however, and therefore they should be safer than mobile walkers. The recent decrease in the number of baby walker-associated injuries is likely to be attributable in part to the availability of walker alternatives, such as stationary activity centers, and a decrease in the use of baby walkers manufactured before July 1997.

RECOMMENDATIONS

1. Because data indicate a considerable risk of major and minor injury and even death from the use of walkers, and because there is no clear benefit from their use, the American Academy of Pediatrics recommends a ban on the manufacture and sale of mobile infant walkers.
2. If a parent insists on using a mobile walker, it is vital that they choose a walker that meets the performance standards of ASTM F977-96 to prevent falls down stairs.
3. Efforts should be made, through media campaigns and during anticipatory guidance, to educate parents about the hazards and lack of benefits of walkers. The particular risk of walkers in households with stairs should be emphasized.
4. Even if walkers are banned, the life span of existing devices is considerable, and community programs should be developed to encourage proper disposal of walkers so that they can be destroyed and the materials recycled.
5. Agencies responsible for licensing child care facilities should not permit the use of walkers in approved child care centers and homes. Hospitals should not permit the use of walkers in their facilities.
6. Because the safest baby walker is one without wheels, stationary activity centers should be promoted as a safer alternative to mobile walkers.
7. The CPSC should closely monitor the compliance of infant walker manufacturers with the voluntary standard ASTM F977-96 to ensure that noncomplying walkers do not continue to be manufactured and sold.
8. The CPSC should collect surveillance data on children injured while using walkers that are in compliance with ASTM F977-96.

Clinical Report—Injuries in Youth Soccer

abstract

Injury rates in youth soccer, known as football outside the United States, are higher than in many other contact/collision sports and have greater relative numbers in younger, preadolescent players. With regard to musculoskeletal injuries, young females tend to suffer more knee injuries, and young males suffer more ankle injuries. Concussions are fairly prevalent in soccer as a result of contact/collision rather than purposeful attempts at heading the ball. Appropriate rule enforcement and emphasis on safe play can reduce the risk of soccer-related injuries. This report serves as a basis for encouraging safe participation in soccer for children and adolescents. *Pediatrics* 2010; 125:410–414

INTRODUCTION

Soccer (known as football outside the United States) is one of the most popular team sports in the world and continues to provide healthy exercise for many young people. Participation in soccer is an effective way for children to increase their level of physical activity and fitness, because it requires intensive physical effort over an extended period of time through practice and games.[1] In the United States, an estimated 15.5 million[2] people participate in soccer. Two national youth organizations have registered 650 000[3] and 3.2 million[4] participants younger than 19 years, with a 7% increase in female adolescent players from 2001 to 2007.[2] More than 700 000 girls and boys played soccer in US high schools in 2008–2009,[5] placing soccer among the top sports for increased participation.[5] With this growing participation comes a greater number of injuries, leading to an increasing prevalence of soccer-related cases presenting to the pediatrician.

INJURY RISK

Soccer has a higher injury rate than many contact/collision sports such as field hockey, rugby, basketball, and football, although in 1 community study of 7- to 13 year-old players, football did have a higher percentage of serious injuries and higher frequency of injury per team per season.[6,7] The US Consumer Product Safety Commission (CPSC), through its National Electronic Injury Surveillance System, estimated that there were 186 544 soccer-related injuries in 2006.[8] Approximately 80% of these injuries affected participants younger than 24 years, and approximately 44% occurred in participants younger than 15 years. It is unfortunate that there is a wide variation in the reported incidence of soccer injuries as a result of study differences in factors such as level of competition, intensity of exposure, definition, classifications, and reporting of injuries. Because of difficulties with interstudy com-

parisons, standard definitions and methodology have been proposed to ensure consistent and comparable results in the future.[9]

With respect to age, participants younger than 15 years tend to have a higher relative injury risk and greater prevalence of injuries compared with older players.[6,10–14] According to the National Electronic Injury Surveillance System, soccer injuries among young athletes in the United States occur at a peak of 2 injuries per 1000 participants.[10] For soccer players older than 12 years, rates of 4 to 7.6 injuries per 1000 player-hours have been reported.[11,13,14] Over an entire soccer season, girls' and boys' teams may expect 4.0 and 3.5 injuries per season, respectively.[15] It is notable that the risk of injury is greater during competition than during practice sessions.[6,11,13–17]

Although suffering a previous injury within the past year confers a 1.74 relative risk of a new injury,[11] there have been no consistent findings to support a higher risk to any position on the field. Some have reported overall injury rates to be similar between boys and girls,[18] but others have found higher prevalence of injuries in female players, with girls having an increased risk of anterior cruciate ligament (ACL) tears and concussions and being more likely than boys to be injured in training situations. In contrast, boys have a greater relative risk of injury during competition.[12,17]

Indoor and outdoor soccer environments have a similar relative risk of injury, including contact injury across age groups; however, knee injuries are more prevalent in outdoor soccer.[11] Field surface and shoe characteristics can affect injury risk, especially in outdoor soccer. Appropriate monitoring of field conditions, specifically holes or other irregularities, can reduce lower-extremity injuries. More specifically, uneven playing surfaces can result in excessive loading of ligaments and muscles and may contribute to improper landing after jumping. Inappropriate footwear can lead to either too little or too much frictional force, which can increase the risk of lower-extremity injury.[6] A common overuse injury in skeletally immature players, especially during peak growth velocity, is calcaneal apophysitis (Sever disease), attributable in part to play on hard fields with cleats that have insufficient heel/arch support.[19]

TYPES OF INJURIES

Soccer is classified as a high- to moderate-intensity contact/collision sport,[19] with most injuries overall occurring from either player-to-player or player-to-ground/ball/goalpost contact rather than overuse.[14–16] Contact injuries occur primarily when the player is tackling the ball, being tackled, or heading the ball as 1 or more defenders are impeding the play.[6] The mechanisms of noncontact injury include running, twisting/turning, shooting, and landing. Most injuries are classified as minor and require nothing more than basic first aid or a maximum of 1 week's absence from soccer participation.[6,14,18]

Injuries to the lower extremities are most common, with the majority of injuries resulting from nonbody contact.[6,10,11,12,16,18] Ankle injuries account for 16% to 29%[15,16] of these injuries and are more frequent in male players.[6,14] Knee injuries occur in 7% to 36% of injured players[16,17] and are seen more frequently in females.[6,14] The lower leg (5%–6%),[14,16] upper leg (9%–22%),[15,16] and groin/torso (5%)[16] are less commonly affected. Contusions and sprains/strains of the lower extremities are the most common injury types[6]; more sprains and strains are seen in the emergency department setting than either contusions/abrasions or fractures.[10] Fractures account for less than 10% of injuries.

One serious lower-extremity injury that presents frequently to physician offices or the emergency department is a rupture of the ACL. This injury is more common in female players than in male players. Arendt et al[20] reported that female collegiate soccer players have a 2.8 times greater risk of ACL rupture than do male players, and other studies have indicated a 4 to 6 times greater risk in female players than in age-matched male counterparts in the same activity.[18,21] Most injuries in female participants are the result of valgus hyperextension of the knee during landing, cutting, or turning.[21] Many contributing factors for this gender-based imbalance have been postulated, including hormonal influences, anatomic differences in lower-extremity alignment, ligament size and laxity, and dissimilar neuromuscular activation patterns.[21] Functional knee braces have proven unsuccessful at preventing ACL injuries.[20,22]

Prophylactic neuromuscular and proprioceptive exercise programs have been designed to train girls how to adopt particular muscle-recruitment strategies that decrease joint movement and protect the ACL from high-impact loading during high-risk athletic maneuvers.[21,23] Statistically significant reductions in ACL ruptures have been demonstrated in adolescent and college-aged females participating in such programs.[23,24] Results of a meta-analysis demonstrated that neuromuscular training decreases the potential biomechanical risk factors for ACL injuries and ACL tears in older adolescent and adult players as a result.[25] Studies indicating knee-injury risk along with potential risks and benefits of prophylactic exercise programs in preadolescent players are lacking. At the time of this writing, 2

Qualified instructors can reduce injury risk by helping to ensure proper technique (especially with plyometric loading and progression).

knee-injury risk-reduction programs have been studied (Table 1).

Upper-extremity injuries represent 3% to 12%[16,17] of total injuries, with the shoulder (1.1%–1.8% of total injuries) and the wrist/hand/elbow (3%–5% of total injuries) being uncommonly affected.[14]

Direct impact to the abdomen can result in intraabdominal organ damage, and although most cases are relatively minor in severity, life-threatening and even fatal cases of abdominal trauma have been reported.[10,26]

Fatalities Resulting From Goalpost Contact

Fatalities from soccer-related injuries are associated almost exclusively with traumatic contact with goalposts.[10] Since 1979, 28 fatalities have been reported from incidents associated with falling soccer goalposts.[8] These findings have prompted specific recommendations from equipment manufacturers and the CPSC[27] to ensure that soccer goalposts are adequately secured during play and when not in use. Padding of goalposts has also been recommended, but evidence of efficacy of pads in preventing injury is lacking.

Concussion

The concussion rate among soccer players is similar for both elite and recreational athletes to that of American football and ice hockey players.[28] Although some studies have indicated that head/facial injuries, including concussions, account for only 3% of total injuries, there may be significant underreporting.[14] Female high school soccer players have a slightly higher risk of concussion than do their male counterparts.[29] The most frequent cause of concussion in elite college soccer players was found to be contact with another player's head, elbow, or foot (47%), and contact with the ball (24%), ground/goalpost (17%), and combinations of objects (10%) were less frequent causes of concussions.[30] General sport-related concussion management and return-to-play guidelines have been published[31,32]; however, there are currently no postconcussion return-to-play guidelines specific to soccer.

Collision, rather than purposeful heading, was found to be the most likely cause for acute head injuries in soccer players treated in emergency departments.[33] The contribution of purposeful "heading" of the soccer ball to both acute and potential long-term concussive effects, such as cognitive dysfunction, seems less controversial today than previously.[28,33] A critical review of the literature does not support the contention that purposeful heading contacts are likely to lead to either acute[34,35] or cumulative brain damage,[36–39] and additional study is necessary to provide confirmatory evidence of neuropsychological consequences of subconcussive soccer-related head contacts.[40]

Efforts to reduce potential injury from heading the soccer ball are warranted. Proper heading techniques, the appropriate age at which to initiate teaching of purposeful heading, and characteristics of the soccer ball have been studied as a means to reduce head injury. The best technique is to contract the neck muscles to hold the head rigidly fixed to the trunk, allowing the ball to contact the hairline of forehead.[39] One large US-based soccer organization does not teach purposeful heading to players younger than 10 years,[3] but other soccer authorities or organizations do not adhere to this rule uniformly. Although proper technique is foremost in reducing the risk of concussion from heading the ball, it is also imperative that soccer balls be water resistant, sized appropriately for age, and not hyperinflated.[3,27,41]

Data currently are insufficient to state that soft helmets prevent head injury, and this absence of prospective data, combined with a lack of uniform safety standards and regulations, makes universal support of soft helmets premature at this time.[39] The authors of 1 retrospective cross-sectional study found that use of soft helmets was associated with a reduction in concussions and soft tissue injuries compared with no helmet, without increasing risk of injury to areas not covered by the head gear.[42]

Eye and Other Facial Injuries in Soccer

Soccer is classified as a sport with low-to-moderate risk of eye injury. The American Academy of Pediatrics (AAP) and American Academy of Ophthalmology strongly recommend protective eyewear for all participants in soccer, whereas on the basis of 1 study on ocular injury in collegiate sports, use of eye protection based on the athlete's past ocular history was recommended.[43,44] Protective eyewear should be mandatory for athletes with only 1 functional eye and for those who have had major eye surgery or trauma.[45] Proper protective eyewear includes

polycarbonate lenses that meet the American Society for Testing and Materials (ASTM) F803 standards.[43] Soccer is also associated with orofacial and dental injuries. Use of protective mouth guards has been advocated to reduce the number of these injuries.

FAIR PLAY

If there is low adherence to fair-play policy, injury risk can be greater. It is notable that foul play has been associated with a significant number of contact-related injuries.[12,18] One study of competitors in 9 different sports in 100 US high schools identified 98 066 injuries over a 2-year period that occurred as a direct result of an illegal activity as ruled by a referee or disciplinary committee. Girls' basketball (14%) and girls' (11.9%) and boys' (11.4%) soccer had the highest rates of such injuries, most of which were concussions or other head/facial injuries.[46] There is consensus that proper rule enforcement and limitation of violent contact can reduce the risk of injury. Officials controlling the physicality of the game and emphasis on safe play with respect for one's opponents[27,37] can both play significant roles in reducing contact injuries in soccer.

CONCLUSIONS AND GUIDANCE FOR CLINICIANS

1. Children, adolescents, and young adults can be encouraged to participate regularly in all forms of physical activity, including youth soccer. Soccer can provide a valuable component of fitness and physical activity strategies for young people.
2. Knee-injury risk-reduction programs seem promising, particularly for adolescent and collegiate female players. Research-validated programs are easily accessible at no cost on referenced Web sites. Pediatricians are encouraged to familiarize themselves with these programs and inform their patients on the availability and potential benefits. Additional research is needed to better define knee-injury risk in younger players (younger than 14 years) and to study potential risks (eg, plyometric leaping and impact on open growth plates) to starting prevention exercises in preadolescent players.
3. To reduce soccer-related fatalities, goalposts should be secured in a manner consistent with guidelines developed by the manufacturers and the CPSC.
4. Violent behavior and aggressive infractions of the rules tend to increase the risk of injury and should be strongly discouraged. Pediatricians are encouraged to advocate for the enforcement of all rules and guidelines while strongly promoting sportsmanship and fair play to ensure maximum safety and enjoyment for the athletes.
5. Data have been insufficient to link repetitive heading with permanent cognitive impairment. However, the AAP encourages heading of the ball to only be taught when the child is willing to learn proper technique and has developed coordinated use of his or her head, neck, and trunk to properly contract the neck muscles and contact the ball with the forehead. This guidance is based on consensus of opinion among members of the AAP Council on Sports Medicine and Fitness Executive Committee, because there is currently no valid evidence to support this conclusion.
6. Physicians are encouraged to be aware of and adhere to guidelines regarding the management of concussion and to help educate coaches and athletic trainers using available resources.
7. Protective eyewear is recommended for all participants in soccer, because there is a risk of eye injury, and should be mandatory for athletes with only 1 functional eye or those with a past history of major eye surgery or trauma.

TECHNICAL REPORT

Danielle Laraque, MD, and the Committee on Injury, Violence, and Poison Prevention

Injury Risk of Nonpowder Guns

ABSTRACT. Nonpowder guns (ball-bearing [BB] guns, pellet guns, air rifles, paintball guns) continue to cause serious injuries to children and adolescents. The muzzle velocity of these guns can range from approximately 150 ft/second to 1200 ft/second (the muzzle velocities of traditional firearm pistols are 750 ft/second to 1450 ft/second). Both low- and high-velocity nonpowder guns are associated with serious injuries, and fatalities can result from high-velocity guns. A persisting problem is the lack of medical recognition of the severity of injuries that can result from these guns, including penetration of the eye, skin, internal organs, and bone. Nationally, in 2000, there were an estimated 21840 (coefficient of variation: 0.0821) injuries related to nonpowder guns, with approximately 4% resulting in hospitalization. Between 1990 and 2000, the US Consumer Product Safety Commission reported 39 nonpowder gun–related deaths, of which 32 were children younger than 15 years. The introduction of high-powered air rifles in the 1970s has been associated with approximately 4 deaths per year. The advent of war games and the use of paintball guns have resulted in a number of reports of injuries, especially to the eye. Injuries associated with nonpowder guns should receive prompt medical management similar to the management of firearm-related injuries, and nonpowder guns should never be characterized as toys. *Pediatrics* 2004;114:1357–1361; *nonpowder guns, BB guns, pellet guns, air rifles, paintball guns.*

BACKGROUND

A traditional firearm gun is one that launches a projectile (ie, a bullet) by using the energy generated by burning of gunpowder. Nonpowder guns utilize the power of compressed air to launch a projectile. Nonpowder guns can be classified by the type of projectile they fire, the propulsion mechanism, or the type of barrel.[1–4] The type of projectile can be lead, brass, steel, copper, or, most recently, a paintball. Paintballs are small gelatin projectiles that are 17 mm in diameter, filled with nontoxic, water-soluble paint, and intended to explode on contact with an object.[5,6] This type of projectile is used in war games designed to mark the player with paint when he or she is hit. Air guns have been used since the 16th century[7,8] in warfare and to kill game as large as deer.

The caliber of a projectile refers to its diameter and is measured in hundredths of an inch or millimeters. The caliber affects how much energy the projectile acquires before leaving the muzzle, or the end of the barrel. Tight-fitting missiles, those with little discrepancy between the diameter of the projectile and that of the muzzle, lead to higher velocities. In older nonpowder guns, the projectile was smaller than the barrel size, leading to dissipating of compressed air and an inefficient, low-velocity gun. Technical modifications of these guns have resulted in higher-velocity weapons.[9] Standard pellet guns fire a pellet or spherical ball bearing (BB) with a diameter of less than 0.18 in (4.57 mm). Pellets have several designs, such as wad cutter, sharp pointed, round nosed, and hollow point. Each is suited for a different purpose. Hollow points are used for hunting, and the pellet's diameter increases on impact to cause maximum damage. Ballistic studies have shown that a larger caliber pellet will penetrate the body (eg, skin, bone) at lower velocities because of its increased mass. Skin penetration can be achieved, for example, at a velocity of approximately 331 ft/second with a 0.177-caliber pellet but at 245 ft/second with a 0.22-caliber pellet. Ocular penetration can occur at velocities as low as 130 ft/second.[7,10] Polishing steel pellets with a plastic skirt increases velocity, accuracy, and range and is designed to increase penetration. Typically, high-velocity guns are classified as those with muzzle velocities higher than 350 ft/second (D. Tinsworth, MS, US Consumer Product Safety Commission [CPSC], written communication, November 26, 2001).[7,9,11–13]

Projectiles can be fired by 3 propulsion mechanisms. The spring-piston type is a powerful spring that is cocked manually and released, driving the piston that shoots a stream of air. Use of the spring-piston can result in muzzle velocities between 250 and 350 ft/second. The carbon dioxide–powered gun uses a gas cartridge to generate a propulsive force that can produce muzzle velocities of 350 to 450 ft/second. Muzzle velocities ranging, on average, from 300 to 950 ft/second can be generated depending on the number of times the weapon is pumped, although velocities in excess of 1200 ft/second have been reported in the literature. This range of velocity

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

doi:10.1542/peds.2004-1799
PEDIATRICS (ISSN 0031 4005).

overlaps velocities reached by traditional firearm pistols that have muzzle velocities from 750 ft/second to 1450 ft/second.[1,3,9]

The longer the gun barrel is, the higher the velocity. Gun barrels can be smooth or rifled. Rifled weapons produce a spin in the projectile, giving it more stability in flight. Dieseling of the barrel is achieved when oil placed in the barrel is combusted by the heat generated from friction, leading to an explosion. This is used to increase the speed of the projectile. Piggybacking entails simultaneously loading 2 pellets into the firing chamber, increasing the momentum and energy of the missile.[9] A "zip gun" is a modified gun using homemade powder ammunition.[8] These modifications of nonpowder guns can result in increased ability of these guns to cause serious injury, not unlike traditional powder guns.

EXPOSURE AND INJURY PROFILE

The CPSC estimates that there are approximately 3.2 million nonpowder guns sold yearly.[12–14] Nonpowder guns are sold in many department stores, including toy stores.[9] Eighty percent have muzzle velocities over 350 ft/second, and 50% have muzzle velocities between 500 and 930 ft/second. In 2000, the National Electronic Injury Surveillance System (NEISS), operated by the CPSC, collected information from a nationally representative sample of 100 US hospital emergency departments that included information on nonpowder gun injuries.

According to data from the Centers for Disease Control and Prevention (http://webapp.cdc.gov/sasweb/ncipc/nfirates.html and www.cdc.gov/ncipc/wisqars/nonfatal/datasources.htm) and the CPSC,[12] in 2000 the overall nonfatal age-adjusted rate of injury from BB or pellet guns was 7.71 per 100000 population. In 2000, there were an estimated 21840 (coefficient of variation: 0.0821) nonpowder gun–related injuries treated in emergency departments (D. Tinsworth, MS, CPSC, written communication, November 26, 2001). Of these, 2% occurred in children 0 to 4 years of age; 49% occurred in children 5 to 14 years of age; 33% occurred in those 15 to 24 years of age; and the balance occurred in adults 25 years and older. Approximately 12% of injuries were to the eye; 24% were to the head and neck, excluding the eye; 63% were to extremities; and 1% were to other body areas. With the exception of the age group of 0 to 4 years, most victims were males. Sixty-six percent of injuries were diagnosed as either foreign-body lodgments or puncture wounds. There were no clear seasonal variations in the injury incidence. Nguyen et al[15] provided a review of trends in BB or pellet gun injuries in children and adolescents in the United States from 1985 to 1999 derived from a special study using the NEISS, which focused specifically on injuries associated with penetrating gunshot wounds. On the basis of data from this study, in 1999 an estimated 14313 (95% confidence interval: 12025-16601) children and adolescents had BB or pellet gun–related injuries.

Many articles have been written detailing the clinical manifestations of children injured by nonpowder guns.[3–10,16–31] Some striking observations have been made. Lawrence[3] reported on a series of 10 fatalities, 1 of which was a shot through the medial canthus of the eye in a 6-year-old. The weapon was a carbon dioxide–powered BB pistol. Bond et al[10] described 16 children, 57% of whom required intraoperative treatment, and 19% of whom required other invasive procedures such as arteriogram or ventriculostomy. Thoracic injuries were associated with high morbidity and mortality when penetration of the chest wall occurred. Abdominal wounds were frequently associated with visceral injury and multiple perforations, usually of the small bowel. Peritoneal penetration was associated with a more than 80% chance of visceral injury. Transtracheal and brain injuries were also reported. These authors warn that the wound itself may seem trivial, but if not appreciated for their potential for tissue disruption, nonpowder gun injuries to the head, chest, and abdomen may have catastrophic results. They also note that the pellets from air guns have a propensity to embolize if the missile enters a blood vessel or the heart. The light weight of air gun pellets allows the missile to be swept by the blood flow more readily than heavier, higher-energy projectiles. Friedman et al[7] report that the potential seriousness of pneumatic weapon injury is frequently underestimated. These authors concluded that injuries from air guns should be treated in a manner similar to those from low-velocity powder firearms. Bratton et al[4] reviewed the clinical course of 101 children injured by nonpowder guns between 1988 and 1996 from Cincinnati, Ohio; Kansas City, Missouri; and Seattle, Washington. The case fatality rate for intracranial injuries was 30%, and 56% of patients required at least 1 surgical procedure. Amirjamshidi et al[16] noted that air-gun pellet injuries are rare but catastrophic, with entrance usually through the orbit or the neck and the entry wound being so small that it may be disregarded on physical examination in the emergency department. They concluded that early recognition and correct management of possible complications is important to improve outcomes. Bhattacharyya et al[17] reported on 42 children admitted to a level I pediatric trauma center for air-gun injuries over a 7-year period (1988-1995). They had a mean hospital stay of 7 days (range: 1-136 days) and a mean injury severity score of 8.3. Half of the children underwent operative procedures, and 38% had serious long-term disability. They concluded that these guns are not toys but are weapons, and injuries related to their use should be evaluated and managed in a similar fashion to powder-weapon injuries. These findings were similar to those of Walsh et al.[18] In 1 study, the predominant risk factors for ocular injury from an air gun were lack of adult supervision, use of the gun for a purpose other than target practice, and being at a friend's home or yard.[20] Hearing loss has been reported from nonpowder gun use,[23] and suicides from the use of air guns have been documented.[8,28] Concurrent use of alcohol has been noted also and probably contributes to misuse.

Paintballs used in war games are a relatively new phenomenon.[5,6,21,25] Semiautomatic and fully automatic paintball pistols are available for purchase. The

sport typically involves a team, designated fields, and referees used to ensure fair and "safe" play. Players should be 18 years and older, but younger adolescents are allowed to play with the consent of their parent(s). Private games also occur. The players often wear camouflage, and start-up costs for the weapon, goggles, and paintballs total $100 to $150. The paintballs consist of spherical shells filled with sorbitol, glycol, and food dye. The propulsion mechanism is usually a carbon dioxide canister, and muzzle velocities between 60 and 250 ft/second can be achieved. Given the size of the projectile, the resulting injuries are nonpenetrating. Locally manufactured paintballs are harder than the more expensive imported varieties and may be responsible for the severity of injuries reported in the United States. Importantly, the increasing popularity of war games has been associated with a number of reports in the literature of ocular injuries. These injuries have included but are not limited to hyphemas, commotio retinae, glaucoma, cataracts, choroidal rupture, corneal abrasion, conjunctival laceration, dislocation of the crystalline lens, macular hole, and retinal detachments.[5,6,25,32,33] The visual outcome for many of these injuries is poor. Injuries have occurred even with eye-protective devices (EPDs), but no case of a player injured while properly wearing an EPD meeting the current American Society for Testing and Materials (ASTM) standards has been reported.[6] Some players have sustained injuries to the eye when they have removed their goggles because of fogging. Current antifog inserts with a polycarbonate lens with a urethane-based hydroscopic coating can help prevent fogging. The current ASTM specifications do not involve testing EPDs for their ability to resist fogging but do require manufacturers to attach a warning to EPDs without antifog treatment noting that fogging may occur and recommending the use of an antifog solution. There have been no reported deaths directly related to paintballs, but the CPSC issued a warning on March 24, 2004, because of its investigation of 2 deaths caused by carbon dioxide canisters flying off paintball guns (www.cpsc.gov/CPSCPUB/PREREL/prhtml04/04105.html).

Before 1972, only 2 nonpowder gun–related fatalities were reported in the literature. However, between 1972 and 1982, the decade after the introduction of high-powered air rifles, 10 more fatalities were recorded by the CPSC.[10] The number of deaths per year has increased since then. From 1990 to 2000, the CPSC reported 39 nonpowder gun–related deaths, of which 32 were children younger than 15 years, with an average of 4 deaths per year.[11] The highest number of deaths occurred in 1989, 1990, and 1991.[15] The trends in nonpowder gun fatalities and nonfatal injuries parallel the epidemic of firearm-related injuries and deaths of the past 2 decades.[34]

SAFETY STANDARDS

An ASTM voluntary safety standard was originally published in 1978. The current edition was published in December 1992 (ASTM F589, Standard Consumer Safety Specification for Non-Powder Guns).[35] This standard contains performance requirements to ensure the proper functioning of these products as well as provisions to address instructions, labeling, and marketing. The guns are general-purpose guns not classified as precision, adult, or training guns. For higher-power guns, the minimum labeled age is 16 years, and the potential for serious injury or death is indicated. For lower-power guns, the minimum labeled age is 10 years, and the risk of serious injury, particularly to the eye, is indicated, but not the risk of death. In the pediatric literature as early as 1984, Christoffel et al[36,37] pointed to the dangers of nonpowder guns, noting that they were loosely regulated and could be legally purchased by young adolescents in most jurisdictions. They also emphasized the inadequacy of voluntary standards and proposed stricter regulations.

From June 1 through July 31, 1994, the CPSC conducted a limited study using follow-up telephone investigation of the circumstances of 55 cases of nonpowder gun–related injuries reported to the NEISS. Percentages provided in the analysis were based on national estimates projected from the 55 cases for the 2 months of the survey. Additionally, information on deaths was obtained from the CPSC Death Certificate, In-Depth Investigation, and Injury or Potential Injury Incident files for the period of January 1, 1985, through September 1, 1994. Information on 37 deaths was included (D. Tinsworth, MS, CPSC, written communication, November 26, 2001). Respondents were victims or parents or guardians of victims. The injury epidemiology mirrored that described for the 2000 data, with most injuries occurring in males younger than 16 years. Individuals who fired the guns ranged in age from 8 to 32 years, with most reported to be younger than 16 years. When the gun operator was younger than 16 years, there was no one 18 years or older present at the time of the incident in more than two thirds of the cases. The gun was most often reported to be a rifle and received as a gift, and two thirds were high-powered guns. As reported by the respondents, 51% of the hazard patterns were unintentional shootings, with victims coming into the line of fire during practice, discharges during loading of the gun, or incidents in which the gun "accidentally fired." Fourteen percent were of unknown intent, 7% were intentional shootings, and 28% involved a gun thought to be unloaded, guns that discharged unexpectedly, ammunition that ricocheted, or fingers that became pinched in gun components. Ninety percent of those who died were younger than 16 years. Most fatalities resulted from wounds to the head or chest.

The CPSC report concluded that the effectiveness of age-specific warnings on packaging and instructions needed additional study and that adult supervision was often lacking. It was unclear from the data whether product modification to reduce hazards would be effective.

LEGISLATIVE EFFORTS

Almost 30 states have regulations, ordinances, or laws covering nonpowder guns.[9,38] Two of the strongest are in New York City and New York State. In New York City, air rifles and BB guns are prohibited, and licenses are not available. In New York State, no

purchase or unsupervised use by someone younger than 16 years is permitted, and adult supervision is required at a shooting range or when hunting for someone of this age. Florida also has a strong law similar to the New York State law. In Florida, it is a second-degree misdemeanor for a minor younger than 16 years to use a BB gun, air gun, or gas-operated gun unless an adult is supervising the possession and the minor's parent has consented to such possession.

However, much variability exists, with some states regarding nonpowder guns as firearms and others not.[15] Some state laws do not address nonpowder guns at all. Many authors have called for restrictions in sales and use of nonpowder guns, especially in light of the technologic advances that have resulted in much more powerful and dangerous weapons that are capable of killing and maiming.[9,19,31,39]

SUMMARY/CONCLUSIONS

This technical report is focused mainly on the potential for injury and death associated with the use of nonpowder guns. Although some comments have been made on risk factors for injury, this report is not meant to be an exhaustive review of the behavioral risk factors for injury, nor does the report summarize the literature regarding the psychological implications or effects of the use of these weapons. The data presented do allow the following conclusions:

- Nonpowder guns pose a serious risk of injury, permanent disability, and even death.
- Since the 1980s, the use of high-powered air rifles has been associated with approximately 4 deaths per year.
- The range of muzzle velocities for nonpowder guns overlaps velocities reached by traditional firearms.
- Data suggest that lack of supervision and unstructured use may be risk factors contributing to the incidence of injury from nonpowder guns.
- EPDs can be useful in decreasing, but not fully eliminating, the incidence of ocular injuries associated with paintball use.
- Injuries associated with nonpowder guns should receive prompt medical management similar to the management of firearm-related injuries.
- Nonpowder guns (BB guns, pellet guns, air rifles, paintball guns) are weapons and should never be characterized as toys.

In-line Skating Injuries in Children and Adolescents

ABSTRACT. In-line skating has become one of the fastest-growing recreational sports in the United States. Recent studies emphasize the value of protective gear in reducing the incidence of injuries. Recommendations are provided for parents and pediatricians, with special emphasis on the novice or inexperienced skater.

Since its introduction in 1980, in-line skating has become one of the fastest growing recreational sports for children and teenagers in the United States. An estimated 17.7 million people younger than 18 years participated in this sport in 1996, a 24% increase over the previous year.[1] The sport offers the benefits of aerobic fitness,[2] independent transportation for younger children, the opportunity to play roller hockey or cross-train for other sports, and venues for competition in artistic, speed skating, and endurance events. Entry-level skates now cost less than $20 per pair, a 10-fold decrease in the past decade. The low cost and multiple benefits of participation have allowed the sport to thrive beyond the limits of a "fad," as evidenced by the existence of a professional roller hockey league, in-line speed skating competition at the Pan American Games, trick-skating competition at the Entertainment and Sports Programming Network (ESPN) Extreme Games, several periodicals for enthusiasts, an international skaters association, a formal training program for instructors,[3] and summer training camps.

As the sport has grown, so has the number of participants injured. In 1996, an estimated 76 000 children and teenagers younger than 21 years were injured sufficiently while in-line skating to require emergency department care, compared with about 415 000 bicyclists. The most common reasons cited for injuries during in-line skating were losing one's balance because of a road defect or debris, being unable to stop, out-of-control speeding, or doing a trick.[4] In one study, novice skaters incurred 14% of all injuries requiring treatment.[4] The wrist is the most common site of injury (37% of all injuries), and two thirds of wrist injuries are fractures. Few skaters die. Of a total of 36 who died since 1992, the US Consumer Product Safety Commission Clearinghouse reported that 31 had collided with a motor vehicle.

Wearing proper gear is essential for safe skating. This includes a helmet, wrist guards, knee pads, and elbow pads. Wrist guards are designed to prevent wrist injuries by preventing sudden extreme hyperextension, absorbing some shock of impact, dissipating kinetic forces by forward sliding on their hard volar plates, and preventing local gravel burns. A helmet, elbow pads, and knee pads are recommended for shock absorption.[5–9] Recent research[4] has evaluated the effectiveness of such gear and indicates that wearing wrist guards could reduce the number of wrist injuries by 87%, wearing elbow pads could reduce the number of elbow injuries by 82%, and wearing knee pads could reduce the number of knee injuries by 32%. Although in this study the number of in-line skaters who sustained a head injury was not sufficient to determine the degree of protection afforded by helmets, others[10] have reported that a bicycle helmet or similar approved sports helmet[11] is strongly protective against the occurrence of a head injury to bicyclists in the same physical environment to which a skater is exposed. Helmet use by child and adolescent skaters is required by law in New York and Oregon. Skaters who participate in roller hockey or perform tricks should wear heavy-duty protective gear, including well-constructed wrist guards, knee pads, elbow pads, and a full-head helmet that covers the ears.

"Truck-surfing" or "skitching" refers to skating behind or alongside a vehicle while the skater holds on to the vehicle. This enables a skater to travel at the same velocity as the vehicle. However, it can be very dangerous because the skater cannot slow down fast enough to prevent colliding with the vehicle or being thrown into oncoming traffic or the roadbed if the vehicle suddenly slows, stops, or turns. If the skater falls, his or her enhanced momentum will likely result in a greater force of impact, and consequently, a more severe injury. Several deaths have been caused by skitching.

The design of the skates should match the ability of the skater. Three- or four-wheeled skates are suitable for novice- or intermediate-level skaters, depending on the child's foot size. Five-wheeled skates are high-performance, extremely low-friction skates that should be used only by competitive or long-distance skaters. Skates should fit snugly to allow good, responsive control. Skates, whether rented or owned, should be well maintained: the brake pads should not be worn down, the wheels should be worn symmetrically and turn freely. Skates with expandable shells or interchangeable liners are now available to accommodate the child's growing foot.

Skating skill is not acquired easily or quickly. Good balance and speed control are essential skills to learn. In the past, children acquired skating skills on

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

traditional "quad" skates, rather than in-line skates, but that pattern appears to be changing. The age at which children are ready to use in-line skates safely is not known with certainty because a combination of factors are involved: physical factors (foot size and body strength); skill factors (general athletic ability and large-muscle coordination); and behavioral factors (vigilance in watching the surface for debris and defects, sufficient attention to traffic, judgment). Although most 7- and 8-year-olds can acquire the skills needed to in-line skate, some children may acquire these skills earlier or later. Judgment and ability to avoid obstacles, including bicyclists, pedestrians, and other skaters, are needed. Training may help the novice learn the sport; more than 2000 certified instructors now teach in the United States.

With either type of skate, the novice should preferably learn indoors at a skating rink, where surface conditions, speed, and lighting are controlled without the presence of motor vehicle traffic or other obstacles. Novices particularly need a flat, smooth surface free of debris.

Once a skater can control speed and direction on an indoor rink, he or she is ready to skate on a path or open lot. Hills (even small ones) should be avoided at first. The path selected should be isolated from motor vehicle, bicycle, and pedestrian traffic to the greatest extent possible until the skater is competent enough to avoid such obstacles. Separate trails are advisable where possible. Trail designs have been published, including recommendations for design speed, surface composition, drainage, trail width, and sight distances.[8] Trails should be kept free of sand, dirt, leaves, and twigs, which can become trapped between the wheels and cause a sudden change in velocity with loss of balance. Good drainage is needed so that puddles do not form—water changes the coefficient of friction and results in a sudden change in velocity. Trails should also flatten for at least 30 ft before intersections.[8]

RECOMMENDATIONS

The American Academy of Pediatrics recommends that pediatricians provide the following advice to patients and families concerned with this activity:

1. Parents need to understand both the benefits and risks of in-line skating. Children and their parents should appreciate that injuries are particularly common in novice skaters, roller hockey players, and those performing tricks.
2. Full protective gear needs to be used at all times, including a helmet, wrist guards, knee pads, and elbow pads. The helmet should be certified by the American National Standards Institute (ANSI), the American Society for Testing and Materials (ASTM), the Snell Memorial Foundation, or the Consumer Product Safety Commission. Skaters performing tricks need special heavy-duty protective gear.
3. If skating takes place on the streets, pediatricians should strongly encourage parents, children, and adolescents to use streets that are blocked off or closed to through traffic (eg, dead-end streets or cul-de-sacs).
4. Special attention should be paid to the needs of novice skaters to avoid injuries. They should skate on an indoor or outdoor rink, rather than on a path or street. Inexperienced children should not attempt to do tricks.
5. "Truck-surfing" or "skitching" should be prohibited for all skaters under any circumstance.
6. The type and fit of the skates should be carefully considered when they are purchased or rented and should be appropriate for the child's size, ability, and purpose.
7. Skaters should vigilantly watch for road debris and defects, which may precipitate a loss of balance. They should be trained to react appropriately to these and other rapidly occurring and unpredictable circumstances by learning to stop quickly and fall safely and by avoiding traffic. Instruction in skating by a teacher certified by the International In-Line Skating Association is recommended.
8. Children with large-muscle motor skill or balance problems and those with any uncorrected hearing or vision deficit should skate only in a protected environment. Appropriate areas include a skating rink or outdoor area where the skater is either alone or where no motor vehicle or bicycle traffic occurs and where all other skaters and pedestrians travel in same direction.
9. State legislation that requires helmet use while skating should be encouraged.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Bioethics

Institutional Ethics Committees

ABSTRACT. In hospitals throughout the United States, institutional ethics committees (IECs) have become a standard vehicle for the education of health professionals about biomedical ethics, for the drafting and review of hospital policy, and for clinical ethics case consultation. In addition, there is increasing interest in a role for the IEC in organizational ethics. Recommendations are made about the membership and structure of an IEC, and guidelines are provided for those serving on an ethics committee.

ABBREVIATIONS. IEC, institutional ethics committee; JCAHO, Joint Commission on Accreditation of Healthcare Organizations.

Institutional ethics committees (IECs) initially were proposed to review decisions to limit or withdraw life-sustaining treatment for neurologically devastated or dying adult patients[1,2] and were viewed as a reasonable approach to the complex issues raised by decisions not to treat seriously ill or disabled newborns.[3] IECs have evolved considerably since the 1984 American Academy of Pediatrics statement concerning infant bioethics committees.[4] Rather than being simply a mechanism for implementing federal regulations about treatment of disabled infants and children,[5] IECs help resolve conflicts about treatment decisions through case consultation, provide a forum for discussion of policies relating to institutional ethics, and educate their health care communities about ethical concepts. The Academy supports the availability of an IEC as an important mechanism for the discussion and resolution of ethical issues raised in the individual and institutional provision of patient care.

IECs traditionally have been involved in clinical ethics and have an emerging role in organizational ethics. Recognizing that the development of an IEC is a process, this statement discusses 3 typical roles for an IEC: 1) case consultation; 2) the drafting and review of institutional policy; and 3) the education of health care professionals, patients, and other health care employees. The statement also describes the membership and structure of an IEC. Finally, the statement advises physicians and other health care professionals about their participation as IEC members or as members of an ethics consultation team.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

THE ROLES OF AN IEC IN CLINICAL ETHICS

Case Consultation

For the majority of physician-patient encounters in pediatrics, the necessary scope, value, and desirability of the anticipated medical intervention is shared among physician, patient, and family. Problems tend to arise when no one intervention is clearly preferable, when there are conflicts about the value of an intervention, or when communication breaks down. As a result, parents, children, physicians, and others may experience uncertainty or conflict over how to respond to the situation. An IEC may be asked to help when uncertainty or conflict exists, when questions of moral, legal, or economic justification are raised, when problems of communication seem to be impeding patient care, or when it is simply unclear whom to ask for advice. In this role, the IEC or a subset of members constituting a "consultation team" may be requested to review the clinical situation and offer suggestions for resolution of the problem.[6–8]

The potential importance of the IEC's consultative role has been recognized in numerous ways, including the following: 1) case law suggesting that IEC deliberations may serve as evidence in court[9–11]; 2) state proposals to establish an IEC as an alternative to judicial review[12,13]; and 3) the requirement of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) that every health care organization have an established mechanism to address conflicts—a requirement most often met by establishing an IEC.[14]

The Academy recognizes that there are a range of acceptable approaches to the many issues that need to be considered in providing an ethics consultation service. An IEC that is engaged in providing ethics consultations should have a policy and procedure statement that includes the following: who can request a consultation, how the IEC is contacted, who responds to the request, how the consultation is conducted, who is to be included in the consultation, proper notification of affected persons, protection of patient confidentiality, how the consultation is documented, whether in some circumstances an ethics consultation is required, and the advisory nature of the consultant's recommendations. Information about the availability and process of ethics consultation should be widely distributed to patients, parents, family members, physicians, nurses, and other individuals who may have reason to call on the consultative services of the IEC.

The 2 characteristic features of an ethics consultation that distinguish it from an informal request for

advice or a case-based educational session are the involvement of a patient, family, or both and the documentation in a patient's medical record. If an ethics consultation is deemed inappropriate in favor of a case-based educational session, it may be appropriate for the patient, family, or both to be informed of the session and invited to participate. If hospital staff who are not involved in the patient's care will attend the session, the prior consent of the patient, family, or both for the disclosure of confidential information should be obtained, or the case should be presented while maintaining confidentiality. Acceptable approaches may vary among institutions and even from case to case. However, the following guidelines should apply to providing ethics consultation to ensure fairness and accountability:

1) Any patient, parent or guardian, or family member should be able to initiate an ethics consultation.
2) The patient and parent or guardian should be able to refuse to participate in an ethics consultation.
3) The refusal of a patient or parent or guardian to permit an ethics consultation should not obstruct the ability of an ethics committee to provide consultation services to physicians, nurses, and other concerned staff.
4) Any physician, nurse, or other health care provider who is involved in the care of the patient should be able to request an ethics consultation without fear of reprisal.
5) The process of consultation should be open to all persons involved in the patient's care, yet conducted in a manner that respects patient and family confidentiality.
6) Anonymous requests for consultation should not be accepted in the absence of an identified person who is willing to speak to the issue being raised.
7) The primary care pediatrician should be invited to participate in the consultation to support existing physician-family relationships.

Three models of prospective case consultation generally have been used: 1) an individual consultant who reports on a periodic basis to the entire committee; 2) a small team of committee members; or 3) a meeting of the entire committee. Each model has advantages and disadvantages. In some circumstances, consultation provided by a single person from the IEC may suffice. Although an individual consultant may respond in a timely and flexible manner, such an approach risks losing the diversity and range of perspectives offered by a group. In most situations, small consultation teams made up of individuals of varying personal and professional backgrounds are recommended to balance a timely and flexible response with the value of diverse points of view. The skills and knowledge necessary to participate as a member or leader of such a consultation team varies with one's role in the process.

IECs and their members should attend to the following concerns in developing a reasonable policy and procedure for ethics consultation. First, IECs must concern themselves with questions of procedural fairness and confidentiality. They must have a mechanism for involving or advising patients and others who are the subjects of consultation, and they must respect the privacy and confidentiality of all persons affected by all aspects of IEC consultation. Second, IECs must have means of keeping current with relevant basic bioethics and health law, including information relevant to infants, children, and adolescents, to avoid giving incorrect advice or supporting questionable actions; they must know when to seek further consultation or review (from "authorities" in ethics, medicine, or law) and when judicial involvement should be sought. Finally, a consultation service should report to the IEC, and there should be an IEC mechanism for quality review and improvement of ethics consultations. Failure to develop and then follow reasonable polices and procedures for ethics consultation violates JCAHO standards. Furthermore, these policies and procedures must be communicated to all patients, parents or guardians, and hospital personnel.

The quality of an ethics consultation rests on the IEC's ability to provide a forum for open discussion of the medical, moral, and legal issues surrounding a difficult situation. On occasion, a request for an ethics consultation is motivated by a desire to bring the perceived authority of an IEC to bear on a difference of opinion or conflict, usually with the hope that the IEC will support the position of the person requesting the consultation. The authority, whether institutional, moral, or legal, of an ethics consultant and an IEC is limited.[15] The Academy supports the view that the recommendations from an ethics consultation are advisory only, with all parties to a disagreement taking full responsibility for their own actions. Although the interpretation and application of case law and state regulations may be part of an ethics consultation, the mere fact that an IEC was involved in a case is of uncertain value in providing legal protection to the participants. Improved communication, clarification of differences and available options, and careful documentation of the decisional process may well reduce the potential for future legal action.[16–18] Finally, all ethics consultations should be documented in the committee records, and, in most cases, a summary of the consultation should be briefly, yet completely, included in the patient's medical record. The form and extent of chart documentation of ethics consultations may vary depending on local hospital regulations and requirements.

Policy Development

In addition to involvement in case consultation and educating patients, families, and staff members about ethical issues, the functions of an IEC generally include the drafting and review of institutional policy and procedures. Policies for the limitation or withdrawal of various treatments, such as cardiopulmonary resuscitation or fluid and nutrition, often have been drafted with IEC involvement. The IEC also may be involved in drafting other policies with ethical import, such as the ability of hospital employees to object to taking care of certain patients, the resolution of conflict, and the statement on institu-

tional business ethics now required by JCAHO.[19] The IEC may not only respond to administrative requests, but may also proactively identify issues with ethical ramifications that warrant an institutional policy and procedure.

Ethics Education

An IEC should have a major role in educating all health care professionals, employees, and administrative staff in the ethical foundations of patient care and institutional relationships. Such education can occur as traditional didactic presentations, as ad hoc discussions about common clinical situations, or as one aspect of clinical case consultation. Whenever possible, students and house officers should be included in these educational opportunities. Most important, an IEC should engage in continuing education and ongoing training to ensure the highest quality clinical ethics consultations.

THE ROLE OF AN IEC IN ORGANIZATIONAL ETHICS

Recent trends in the financing and provision of health care have raised concerns about the impact of institutional commitments such as managed-care contracts, integrated systems, and performance incentives on the care of patients. IECs are being looked to in some institutions as a venue within which these concerns might be addressed. Including organizational ethics in the purview of the IEC raises specific questions about its structure, function, and member qualifications.[20,21] The IEC should establish standards of membership, process, and self-improvement specific to organizational ethics issues and to the organizational structure of its home institution. In addition, the IEC should establish procedures for the evaluation and quality improvement of committee functions, process, and success in meeting institutional expectations. One approach is to establish an organizational ethics subcommittee of the IEC that includes additional representatives from administration and finance, along with persons committed to developing the requisite knowledge and skills in business ethics. Processes that organizational ethics teams commonly use to carry out their mission mirror those of clinical ethics: education, policy development, and case consultation.

MEMBERSHIP AND STRUCTURE OF AN IEC

The membership of an IEC should be multidisciplinary with sufficient knowledge and experience to address the range of ethical issues brought to the committee. The ability of a larger committee to encompass a diverse range of perspectives and expertise argues in favor of an IEC retaining overall responsibility for functions such as ethics consultation that are delegated to an individual or a smaller team. Also, the required knowledge and experience depend on the task at hand; that is, there are likely to be differences in the skills needed to draft a policy on organizational ethics, to develop a policy addressing the withdrawal of life-sustaining treatment, or to perform a clinical ethics consultation.

Diversity of IEC membership benefits from community representation, while recognizing the impossibility of including all points of view and the potential for inappropriate generalization in considering any individual "representative" of his or her class, race, gender, or professional group. As medical technology and information become more complex and ethical issues expand to encompass resource allocation and business practices, an IEC may need to seek and incorporate the advice of consultants. The IEC size necessary to include a sufficient diversity of personal, community, and professional views may hinder the IEC's efficiency. It thus may be appropriate for the larger IEC to delegate certain tasks to smaller subgroups (such as providing ethics consultation or drafting specific policies) while retaining the authority for coordination, oversight, and approval of activities of the subcommittees.

Two important issues concerning IEC structure are: 1) the participation of the hospital attorney or risk manager in the IEC; and 2) whether there are 1 or more IECs within a single institution. First, the hospital attorney or risk manager may experience a conflict of interest between a duty to protect the institution and a duty to protect the patient's interest. Such conflicts should be recognized prospectively, and, in some circumstances, the consultation team may choose to restrict the hospital attorney, risk manager, or other administrators to function as ex officio advisors on specific legal or administrative matters. Many IECs have found that the inclusion of nonhospital attorneys familiar with ethical issues is beneficial. In addressing organizational ethics issues, their membership may be essential.

Second, a single multidisciplinary IEC should have authority over all IEC subcommittees addressing consultative, educational, nursing, pediatric, or administrative concerns. The existence of special interest ethics committees, such as an infant care review committee or nursing ethics committee, undermines the diverse multidisciplinary context that is the strength of an IEC. The establishment of multiple IECs may indicate that the process and deliberations of one IEC are not inclusive. Although an institutional review board functions independently to ensure the protection of human subjects in research, it is advisable for an IEC and an institutional review board to establish a mechanism of communication. An IEC may fulfill its functions whether it reports to the medical staff, hospital administration, or board of directors; however, as some ethical issues may involve conflicts between the clinical, administrative, and financial commitments of an institution, reporting to the institutional board of directors may be advantageous in these cases.

At institutions with academic affiliations, the IEC may exist with an academic bioethics program engaged in teaching, research, and ethics consultation. Nevertheless, the IEC should retain oversight within an institution for ethics consultation, policy review, and education when these functions have been delegated to such programs.

SERVING ON AN IEC

Ideally, the members of an IEC encompass a wide range of clinical experiences, personal backgrounds, and professional perspectives, combined with personal integrity and a willingness to discuss and debate the ethical issues raised in the provision of health care. Integrity, diversity, and shared interest, however, do not guarantee that the members of an IEC collectively will have sufficient knowledge and experience in such areas as clinical ethics, health policy, law, communication, and group process. Accordingly, IEC membership requires a commitment to acquire, and then maintain, the knowledge sufficient to address the complex issues faced by an IEC. Each IEC should establish a continuing education program designed to assist IEC members in fulfilling the stated mission of the IEC, especially as new issues emerge.[22,23] When asked to be a member of an IEC, a pediatrician, pediatric subspecialist, or pediatric surgeon should assess his or her commitment to acquiring and then maintaining a sufficient level of knowledge in bioethics appropriate to the tasks of the IEC. A prospective IEC member should be comfortable with the committee's general mission statement, policies, and operation and the required responsibilities with respect to these functions.

If a pediatrician, pediatric subspecialist, or pediatric surgeon is involved in ethics consultation, clinical experience alone is insufficient to engage competently in clinical ethics consultation. An experienced clinician may possess the necessary medical and technical knowledge that often needs clarification during a consultation. An experienced clinician may also possess considerable skill in talking with patients and families about the difficult practical and moral problems faced in complex and, at times, uncertain situations. In addition, however, clinical experience must be supplemented with a basic knowledge of ethical theory, health policy, law, and clinical ethics literature. Performing an ethics consultation requires advanced knowledge of the aforementioned issues along with additional knowledge and skill in communication, group leadership, individual and group dynamics, techniques of mediation, and self-awareness.[24–27] An IEC should permit different levels of member involvement, ranging from simply attending general committee meetings, discussing and drafting institutional policy, or participating in ethics consultation, to leading an ethics consultation team, depending on the skills and experience of each member.

If engaged in clinical ethics consultation, it is reasonable to ask what one's legal liability might be in offering this service. An IEC should clarify the extent to which IEC proceedings are discoverable and whether its members are covered by liability insurance. The question of legal liability is difficult to answer except in general terms. Responsibility increases with authority, so it is generally "riskier" for IECs to act on their own or to mandate or require actions by others than to give advice and make recommendations. However, even IECs whose function is strictly advisory or educational can wield great apparent authority within an institution. IECs unquestionably have a responsibility to persons affected by their deliberations. Furthermore, the actual policies of an IEC are less important than the manner in which those policies are executed and the IEC's success in educating the hospital community, including patients and their families, about the availability and process for clinical ethics consultation. The likelihood that IEC members will be held legally liable for the actions arising from a consultation is, practically speaking, remote. Nevertheless, IECs and their members have an important opportunity to help set the standards for their own work by careful attention to continuing education, preparation, policy, procedure, and documentation.[28]

RECOMMENDATIONS

1. Membership on an IEC should be diverse and reflect different perspectives within the hospital and general community.
2. An IEC should have responsibility within an institution for clinical ethics consultation, review of policies, and education of professional, administrative, and support staff about ethical issues, regardless of whether these functions are delegated to other subcommittees or programs.
3. An IEC that is engaged in clinical ethics consultations should have policies and procedures that conform to ethical principles of fairness and confidentiality.
4. An IEC should establish continuing education and training programs that assure that IEC members are qualified to perform their specific duties within the IEC.
5. Independent ethics committees, such as an infant care review committee, should be dissolved or restructured to report to the larger IEC.
6. IECs within a general hospital setting should ensure an adequate degree of multidisciplinary expertise for addressing ethical issues specific to pediatrics.

Insurance Coverage of Mental Health and Substance Abuse Services for Children and Adolescents: A Consensus Statement

ABBREVIATIONS. SCHIP, State Children's Health Insurance Program; CPT, Current Procedural Terminology.

Mental health needs of children and adolescents are increasing while access to behavioral health, mental health, and substance abuse services is decreasing. Such services include preventive interventions, early identification, assessment and diagnosis, case management, outpatient treatment, hospitalization, home-based treatment, comprehensive drug and alcohol treatment, and residential and hospital psychiatric treatment. In the past 20 years, the rate of psychosocial problems identified in children in primary care has increased from 7% to 18%.[1] It is currently estimated that at least 13 million children are in need of mental health or substance abuse services,[2] yet attempts to restrain health costs have resulted in decreased availability of mental health and substance abuse services for children and adolescents. This decrease is attributable to benefits packages that provide limited mental health services or carve out plans, in which behavioral health care may be carved out (not included) or contracted for separately, making mental health services more difficult to obtain. This decrease is occurring despite increasing evidence of the effectiveness of specific mental health and substance abuse services.[3] In the general health care sector, primary care clinicians are being pressured to see more patients in less time and, therefore, have less time to address psychosocial issues.

Concern regarding the deterioration of clinical mental and behavioral health and substance abuse services for children and adolescents resulted in an unprecedented meeting of representatives from professional organizations who care for the mental health needs of children. These organizations reached consensus on the issues outlined in this statement.

To rectify the present shortage of mental health services, a commitment must be made to increase resources in both the private and public sectors. Without this increase, current and future needs will not be met. Although specific long-term economic benefits are difficult to calculate, children and adolescents who receive early intervention and care may avoid needing costly treatment in the future. In economic terms, immediate improvements in the mental health of children and adolescents are reflected in increased parent work productivity, less parent absenteeism, and less use of general medical services. More importantly, in the long-term, preventive efforts and early treatment of behavioral problems and mental disorders in childhood result not only in changes in behavior but also in changes in the brain. The potential impact of early intervention on instances of violence and the number of incarcerated juveniles and young adults is great. Even a modest reduction in negative outcomes of youth will more than compensate for the increased health care costs at this time.[4] Certainly, for children and families, the avoidance of problems and associated misery is a worthwhile goal in a humane society.

To improve mental health services, it is important to address 3 issues: access, coordination, and monitoring. These issues should be considered from the standpoint of needs for preventive interventions, direct mental health and substance abuse services, and coordinated multiservice care.

ACCESS

Traditional mental health care systems, which were limited at best, have recently been further disrupted by the change to a managed care system. In the past, primary care clinicians could refer patients with mental disorders to appropriate mental health clinicians. Parents and school personnel, when needed, could also obtain direct access to mental health clinicians. This arrangement increased the chances of the family obtaining the services needed and increased the likelihood of communication among professionals.

Many current behavioral health carve out programs make mental health services much more difficult for families to obtain. In many cases, clinicians and families must depend on external screening processes in which decisions for approval are based almost exclusively on preset guidelines for adults, not children. There is no direct contact between the referring physician and the professional provider during the referral process. It is difficult for families to obtain services because of obstacles, such as an absence of criteria for approving services that meet the needs of children, copayments that are higher for behavioral health services than those for other medical services, more limited yearly and lifetime caps, and limited panels of qualified mental health care professionals experienced in treating children.

Limiting the ability of primary care clinicians to provide preventive services further worsens the situation. Primary care clinicians do not receive ade-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

quate reimbursement for preventive efforts, such as addressing psychosocial problems, and they are pressured to see more patients in less time. As a result, they have less time to develop strong, ongoing relationships with families and are less likely to identify mental health and substance abuse problems.

The low number of qualified child mental health and substance abuse clinicians contracting with behavioral health management further limits access.[5] Clinicians experience difficulties in establishing credentials on multiple professional panels. There are obstacles in obtaining approval for adequate levels and quantity of services to care appropriately for their patients. In addition, payment for services to children, adolescents, and their families is inadequate, and administrative practices are burdensome. These factors result in a decrease in available facilities and a disincentive for professionals and those in training to enter or remain in the field.

To address the issues, the following recommendations are proposed:

- Parity should be established between medical health services and mental and behavioral health and substance abuse services.
- The State Children's Health Insurance Program (SCHIP), which has provided additional resources for children's health care and has allowed for flexibility in the distribution of resources, should be supported and expanded to include coverage for mental and behavioral health and substance abuse services.
- The number of qualified child mental health and substance abuse clinicians should be increased through support for training programs, better recruitment into these programs, and job incentives.
- Managed care and behavioral health organizations should be required to provide adequate panels of culturally competent clinicians who are qualified to address child and adolescent mental and behavioral health and substance abuse needs.
- Competent, licensed providers with training and expertise in providing services to children should be equally included on panels, without limitations to specific disciplines.
- Professionals need to be accessible and available to families within a reasonable distance and time frame.
- Services provided by clinicians in alternative sites, such as schools, homes, and centers, must be reimbursed.
- Families and purchasers of health care plans need to be clearly informed about the adequacy of the health care coverage they are considering. The health plan should specifically identify mental health services provided to children, including child and adolescent psychopharmacology, child and adolescent psychological and neuropsychological assessments, child and adolescent psychotherapy, behavioral medicine (eg, pain management, chronic illness management, eating disorders), and substance abuse programs.
- The processes required for children and adolescents to receive mental and behavioral health and substance abuse services should be simplified, shortened, and unified. For clinicians, this should include a universal credential verification process and a universal treatment authorization form. For families, it should include a simplified authorization and appeals process.
- There should be no exclusions for diagnostic categories, chronic disorders, and preexisting conditions (chronic illness and developmental disabilities).
- Reimbursements need to compensate clinicians adequately for the services provided.
- Administrative practices need to be revised to reduce the practitioner's administrative burden.

COORDINATION

Although coordination of care is critical in all types of health care treatment, it is particularly important for mental heath services. Many sectors of a community, including schools, social services, and the justice system, are involved with children and adolescents with mental health and substance abuse problems. For services to be effective and efficient and meet family needs, service professionals must communicate and coordinate with each other. At a time when all sectors are attempting to cut costs, there is a tendency to try to shift responsibilities from one sector to another. As a result, divisions of responsibilities are not always clear. Often, families are caught in the middle and receive no information or conflicting information as to who can best address the child's needs. This lack of organization often results in agencies working inefficiently and sometimes with different purposes. Nowhere is this more evident than with children who have severe and multiple conditions that require coordinated, multiple services.

To address the issues, the following recommendations are proposed:

- Families must be centrally involved in the coordination of care for their children and adolescents. Services provided that address family issues should be reimbursed adequately.[6]
- A seamless system of care must be established within and across sectors that includes mechanisms to promote communications and referrals among professionals such that children and families receive appropriate services regardless of how and where they seek help and irrespective of the nature of their problems.[7]
- Clinicians must be compensated for case management and coordination efforts (ie, compensation of counseling Current Procedural Terminology [CPT] codes and consultation CPT codes). Contracts should include compensation for interpretive and indirect services, such as staff conferences, consultation between clinicians, and contacts with professionals in other sectors, such as schools and law enforcement.
- Mechanisms for apportionment of costs and reimbursements must be established for complex cases that involve multiple agencies.

MONITORING

For economic competition to work to improve health services, families and purchasers of health care plans need to be informed about the quality of the services provided. This issue has always been complex, because quality includes the availability of a spectrum of qualified services, the quality and appropriateness of care provided, and the responsiveness of services to concerns raised by professionals or families. As direct recipients of services, families need information about the services provided and guidelines by which to evaluate this information. Families need mechanisms to communicate their comments and experiences to those who purchase health care plans, most commonly their employers. The purchasers also need uniform and accurate information about plans that provide health care services. As programs have multiplied and diversified, it has become difficult for all to determine the quality of services offered and for appropriate regulatory agencies to hold them accountable.

To address the issues, the following recommendations are proposed:

- Clinician professional organizations and provider plans should be encouraged to better define and use evidence-based care in mental and behavioral health and substance abuse services for children, adolescents, and families. Empirically supported assessments and treatments should include level of care criteria, best practices, and monitoring of incremental expectations for progress. Research on quality of care and outcomes effectiveness should also be enhanced by these groups.
- Public and private sectors should develop mechanisms for system accountability in the cost-effectiveness of service calculations, including consideration of administrative costs.
- Mechanisms to provide user-friendly information to families and purchasers regarding the availability, adequacy, and quality of mental and behavioral health and substance abuse services must be developed.
- Simplified and timely internal and independent external appeals processes should be developed by health plans and mental health care management programs. Families should be included on such panels.

The decreasing availability of health care services to meet the mental health needs of children and adolescents is a serious and worsening problem. Action must be taken to curb this decrease. Issues that negatively impact the access, coordination, and monitoring of such services must be addressed. Improvements in these services will have a positive impact not only on the health and well-being of children and adolescents but on society as well.

Intensive Training and Sports Specialization in Young Athletes

ABSTRACT. Children involved in sports should be encouraged to participate in a variety of different activities and develop a wide range of skills. Young athletes who specialize in just one sport may be denied the benefits of varied activity while facing additional physical, physiologic, and psychologic demands from intense training and competition.

This statement reviews the potential risks of high-intensity training and sports specialization in young athletes. Pediatricians who recognize these risks can have a key role in monitoring the health of these young athletes and helping reduce risks associated with high-level sports participation.

There appear to be increasing numbers of children who specialize in a sport at an early age, train year-round for a sport, and/or compete on an "elite" level. Media coverage of national and international competition in sports such as gymnastics, figure skating, swimming, diving, and tennis has focused attention on a number of very talented but very young competitors. The successes of young athletes can serve as a powerful inducement for others to follow. Most Olympic sports have selection processes that attempt to identify future champions and initiate specialized training—often before the prospect finishes elementary school. The lure of a college scholarship or a professional career can also motivate athletes (and their parents) to commit to specialized training regimens at an early age. The low probability of reaching these lofty goals does not appear to discourage many aspirants.

To be competitive at a high level requires training regimens for children that could be considered extreme even for adults. The ever-increasing requirements for success creates a constant pressure for athletes to train longer, harder, more intelligently, and, in some cases, at an earlier age. The unending efforts to outdo predecessors and outperform contemporaries are the nature of competitive sports. The necessary commitment and intensity of training raises concerns about the sensibility and safety of high-level athletics for any young person.

Adverse consequences from intense training and competition have been reported in the lay and medical literature.[1,2] Many pediatricians can cite examples of undesirable outcomes from sports participation involving patients in their own practices. Unfortunately, anecdotal reports and case studies are insufficient grounds for drawing conclusions about the safety of intense training or high-level competition.

The short-term and long-term health consequences of such training in young athletes need to be further investigated. Physical, physiologic, and psychologic tolerances to stress in children have been studied in laboratory settings and can be defined by observing the threshold for injury in clinical settings. Unfortunately, this information is difficult to directly apply to the specific clinical scenarios of concern to the pediatrician. Studying the risks of "specialized," "intensely trained," or "elite" athletes is hampered by the lack of clear definitions of these at-risk populations. Even if a study group could be defined, the level of variation between sports, individuals, and training regimens creates further methodologic challenges for investigators.

Despite recognized inadequacies of current information, pediatricians can still help safeguard their young athletic patients by being aware of potential problems associated with intense training. Because pediatricians serve as the primary medical contact for most young athletes, they may have the best opportunity to recognize, treat, and monitor injuries or illnesses resulting from strenuous training. To respond to parental concerns and to more effectively monitor the child athlete engaged in intensive training, increased awareness of the following issues is suggested.

CARDIAC

Child athletes have superior cardiac functional capacity compared with nonathletes. Nonetheless, there is some cause for caution. Data obtained from studies using animals and humans indicate that myocardial function can be depressed, at least transiently, after intense exercise. Echocardiographic studies have indicated a transient decrease in left ventricular contractility after extremes of athletic competition (ie, 24-hour ultramarathon runs).[3]

A limited number of studies have failed to identify an adverse effect of intense endurance training on the heart of the child athlete. In these investigations, no differences in resting echocardiograms or electrocardiograms have been observed between trained prepubertal runners and nonathletes.[4,5] Rost studied a group of young swimmers longitudinally with echocardiograms over a 10-year period. Cardiac volume and chamber size exceeded those of nonathletic children.[6] The effects of sustained submaximal exercise on cardiac function are similar in children and adults.[7] Evaluation of cardiac function before and immediately after a 4-km road race by echocardio-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

grams in run-trained boys ages 9 to 14 years showed no evidence of change in left ventricular contractility.[8]

Based on these limited data, currently there is no indication that intense athletic training of the child athlete results in injury to the heart. However, closer study of the cardiac characteristics of children training at elite levels is necessary before this conclusion can be verified. Careful assessment of cardiovascular status (heart murmurs, abnormal rhythms) remains important in ongoing medical care of the child athlete.

MUSCULOSKELETAL INJURY AND GROWTH

With low or absent physical activity, muscle tissue becomes atrophic, and bone mineral content decreases. An increase in physical activity stimulates musculoskeletal growth and repetitive stress can stimulate positive adaptive responses in musculoskeletal structures. However, excessive stress or overload can lead to tissue breakdown and injury. To realize maximum gains, athletes must correctly identify and train just below the threshold for injury.

Overuse injuries (tendinitis, apophysitis, stress fractures) can be consequences of excessive sports training in child and adult athletes. Certain aspects of the growing athlete may predispose the child and adolescent to repetitive stress injuries such as traction apophysitis (Osgood-Schlatter disease, Sever disease, medial epicondylitis [Little League elbow]), injuries to developing joint surfaces (osteochondritis dissecans), and/or injuries to the immature spine (spondylolysis, spondylolisthesis, vertebral apophysitis).[9]

Because of the potential for long-term growth disturbances, injuries to epiphyseal growth centers are a particular concern for young athletes. Because the physeal plate may be weaker than surrounding ligamentous structures, external stress may disrupt a growth plate rather than damaging a ligament or related soft-tissue structure. Physeal fractures can result in growth arrest or deformity of long bones. Fortunately, there is no evidence that epiphyseal fractures or growth complications caused by epiphyseal injuries are seen disproportionately in children who participate in organized sports or higher levels of competition.

The long-term effects of repetitive microtrauma to the epiphysis is still under investigation. Damage to the distal radial epiphysis with subsequent alterations in radial-ulnar growth has been described in highly competitive gymnasts.[10] Epiphyseal injuries to the long bones of prepubertal children involved in distance running and other weight-bearing sports (that might potentially affect development of stature) have not been described. Similarly, cross-sectional and longitudinal studies describing growth in child athletes indicate that size and rate of growth of athletes are not negatively influenced by intensive training and competition.[11] Short stature in gymnasts has been considered most likely a consequence of genetic and physique preselection rather than a result of training, although some have concluded that training starting before and maintained throughout puberty can alter growth rates.[12]

NUTRITION

Proper nutrition is critical for both good health and optimal sports performance. For child athletes, an adequate diet is critical because nutritional needs are increased by both training and the growth process. Young athletes and their parents are frequently unaware of the appropriate components of a training diet. The following 4 areas are of particular concern.

Total Caloric Intake

Athletic training creates a need for increased caloric intake, and requirements relative to body size are higher in growing children and adolescents than at any other time in life. In child athletes, the energy intake must be increased beyond the needs of training to maintain adequate growth. Children who engage in sports in which slenderness is considered important for optimizing performance (ie, gymnastics, ballet dancing) may be at risk for compromising their growth. A risk for pathologic eating behaviors also may be increased in children participating in sports where leanness is rewarded.

Balanced Diet

Balance, moderation, and a variety of food choices should be promoted. The Food Guide Pyramid can be used to plan a diet that is balanced and provides sufficient nutrients and calories for both growth and training needs. Athletes who focus on particular dietary constituents (such as carbohydrates) at the expense of a well-rounded diet may potentially compromise their performance as well as their health.

Iron

The body's requirement for iron is greater during the growing years than at any other time in life. Adequate iron stores are important to the athlete to provide adequate oxygen transport (hemoglobin), muscle aerobic metabolism (Krebs' cycle enzymes), and cognitive function. However, athletes often avoid eating red meat and other iron-containing foods. Moreover, sports training itself may increase body iron losses.

Calcium

Inadequate calcium intake is common in athletes, presumably because of their concern about the fat content in dairy foods. Normal bone growth, and possibly, prevention and healing of stress fractures, are contingent on sufficient dietary calcium.

SEXUAL MATURATION

Athletic girls tends to experience menarche at a later age than nonathletic girls, leading to concern that intensive sports training might delay sexual maturation. The average age of menarche in healthy North American girls is 12.3 to 12.8 years, while that of athletes in a wide variety of sports is typically 1 to 2 years later. Undernutrition, training stress, and low levels of body fat have been hypothesized to account for this delay. Alternatively, it is possible that the

later age of menarche in athletes simply reflects a preselection phenomenon.[13] Girls who have narrow hips, slender physiques, long legs, and low levels of body fat—advantageous characteristics in many girls' sports—are more likely to experience later menarche regardless of sports participation.

Secondary amenorrhea, or cessation of menstrual cycles after menarche, can occur as a result of intense athletic training. Prolonged amenorrhea may cause diminished bone mass from the associated decrease in estrogen secretion, augmenting the risk for stress fractures and the potential for osteoporosis in adulthood. Efforts to improve nutrition or diminish training volume in these girls may permit resumption of menses and diminish these risks.

Studies of males have indicated no evidence of an adverse effect on sexual maturation related to sports training. Progression of Tanner stages of pubertal development has not been observed to be retarded in athletic compared with nonathletic adolescents.[11]

PSYCHOSOCIAL DEVELOPMENT

Considerable research has addressed anxiety and stress that affect children who engage in competitive sports but little data exist about the effects of more intense or sustained training on young athletes. Anecdotal reports suggest risks of "burnout" from physical and emotional stress, missed social and educational opportunities, and disruptions of family life. Unrealistic parental expectations and/or exploitation of young athletes for extrinsic gain can contribute to negative psychological consequences for elite young athletes. Survey studies suggest, however, that while such adverse effects occur, they are experienced by only a small minority of intensely training athletes.[13] Most athletes find elite-level competition to be a positive experience.

Research supports the recommendation that child athletes avoid early sports specialization. Those who participate in a variety of sports and specialize only after reaching the age of puberty tend to be more consistent performers, have fewer injuries, and adhere to sports play longer than those who specialize early.[15]

HEAT STRESS

Child athletes differ from adults in their thermoregulatory responses to exercise in the heat.[16] They sweat less, create more heat per body mass, and acclimatize slower to warm environments. As a result, child athletes may be more at risk for heat-related injuries in hot, humid conditions. It is particularly critical that coaches, parents, and young athletes are aware of signs of heat injury. They also should be aware that limiting sports play and training in hot, humid conditions and ensuring adequate fluid intake can prevent heat injury.

RECOMMENDATIONS

Although many concerns surround intense sports competition in children, little scientific information is available to support or refute these risks. Nonetheless, it is important to make efforts to assist young athletes in avoiding potential risks from early excessive training and competition. The following guidelines are suggested keeping in mind 1) the importance of assuring safe and healthy sports play for children, 2) the need to provide practical and realistic guidelines, and 3) the limited research basis for making such recommendations.

1. Children are encouraged to participate in sports at a level consistent with their abilities and interests. Pushing children beyond these limits is discouraged as is specialization in a single sport before adolescence.
2. Pediatricians should work with parents to ensure that the child athlete is being coached by persons who are knowledgeable about proper training techniques, equipment, and the unique physical, physiologic, and emotional characteristics of young competitors.
3. In the absence of prospective markers of excessive physical stress, physicians and coaches should strive for early recognition and prevention and treatment of overuse injuries (tendinitis, apophysitis, stress fractures, "shin splints"). Child athletes should never be encouraged to "work through" such injuries. Treatment recommendations for overuse injuries that include only "rest" or cessation of the sport are unlikely to be followed by the committed child athlete and are unlikely to adequately address the risk of further injury.
4. The conditions of child athletes involved in intense training should be monitored regularly by a pediatrician. Attention should be focused on serial measurements of body composition, weight, and stature; cardiovascular findings; sexual maturation; and evidence of emotional stress. The pediatrician should be alert for signs and symptoms of overtraining, including decline in performance, weight loss, anorexia, and sleep disturbances.
5. The intensely trained, specialized child athlete needs ongoing assessment of nutritional intake, with particular attention to total calories, a balanced diet, and intake of iron and calcium. Serial measurements of body weight are particularly important in ensuring the adequacy of caloric intake and early identification of pathologic eating behaviors.
6. The child athlete, family, and coach should be educated by the pediatrician about the risks of heat injury and strategies for prevention.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Guidance for the Clinician in Rendering Pediatric Care

Clinical Report—Intimate Partner Violence: The Role of the Pediatrician

abstract

The American Academy of Pediatrics and its members recognize the importance of improving the physician's ability to recognize intimate partner violence (IPV) and understand its effects on child health and development and its role in the continuum of family violence. Pediatricians are in a unique position to identify abused caregivers in pediatric settings and to evaluate and treat children raised in homes in which IPV may occur. Children exposed to IPV are at increased risk of being abused and neglected and are more likely to develop adverse health, behavioral, psychological, and social disorders later in life. Identifying IPV, therefore, may be one of the most effective means of preventing child abuse and identifying caregivers and children who may be in need of treatment and/or therapy. Pediatricians should be aware of the profound effects of exposure to IPV on children. *Pediatrics* 2010;125:1094–1100

INTIMATE PARTNER VIOLENCE: DEFINITION AND EPIDEMIOLOGY

The Centers for Disease Control and Prevention defines intimate partner violence (IPV) as a pattern of coercive behaviors that may include repeated battering and injury, psychological abuse, sexual assault, progressive social isolation, deprivation, and intimidation.[1] These behaviors are perpetrated by someone who is or was involved in an intimate relationship with the victim. Traditionally, research has focused on the subset of IPV that is partner violence against women. It has long been recognized, however, that partner violence against men is a substantial concern as well.[2] IPV occurs in heterosexual relationships and although the research is limited, it is also known to occur in lesbian, gay, bisexual, and transgender relationships.[3]

Patterns of dating violence behavior often start early. Adolescents have a particularly high risk of IPV. Approximately 1 in 5 female high school students report being physically and/or sexually abused by a dating partner.[4] A study of college students revealed that nearly half of them had been the victim of emotional, sexual, and/or physical violence by a partner.[5] Females 16 to 24 years of age are more vulnerable to IPV than any other age group.[3] Given the complexities and unique dynamics in the teenaged population, further discussion of IPV in adolescent relationships is beyond the scope of this report. Information on adolescent dating violence is available from the Centers for Disease Control and Prevention.[6]

It is estimated that approximately 1.5 million women and 830 000 men are physically or sexually assaulted by an intimate partner annually in

the United States.[7] Many of these victims are victimized more than once, which raises estimates of event incidence to approximately 4.8 million women and 2.9 million men assaulted annually in the United States. When considering additional and more common forms of IPV, such as emotional and psychological abuse, it is believed that 1 in 3 women worldwide will be abused in her lifetime.[8] In 2004, IPV resulted in 1544 deaths in the United States; 75% of the victims were women.[9]

IPV AND THE CHILD

As children develop and grow in a home in which they are exposed to IPV, they face not only the risk of becoming involved in an abusive act but also the risk of significant psychosocial trauma from exposure to abusive events. Each of these risks will be considered separately.

The Child as a Victim of Abuse

Children can become the victims of IPV-related abuse even before birth. Pregnancy may increase a woman's risk of being abused, and it is estimated that 3% to 19% of pregnant women are the victims of IPV.[10] Abuse during pregnancy has been associated with several poor health outcomes for the infant, including preterm labor,[11] low birth weight,[11] intracranial injury,[12] and neonatal death.[13] Rivara et al[14] reported increased health care utilization and costs for children whose mothers have experienced IPV, even when the violence stops before the infant's birth.

The co-occurrence of child abuse and IPV is well documented, and study results have indicated that in 30% to 60% of families in which either child maltreatment or IPV is occurring, the other form of violence also is being perpetrated.[15] One study revealed that if IPV was occurring in the home during the first 6 months of child-rearing, physical child abuse was 3.4 times more likely, and child psychological abuse or child neglect was twice as likely up to the child's fifth year.[16] In many of the studies that examined the co-occurrence of child abuse and IPV, child maltreatment was preceded by IPV. IPV has been called the leading precursor of child maltreatment. Identifying and intervening on behalf of a caregiver who is experiencing IPV, therefore, may be an effective means of preventing child abuse and neglect.[14]

It is also important to remember that children may become the collateral victims of IPV. A child may become the victim of abuse by simply being held in a caregiver's arms while he or she is battered. Older children may be harmed while mediating a crisis or defending the abused caregiver.[17]

The Child Exposed to Abuse

Exposure in the home to IPV as a child is associated with a multitude of behavioral and mental health consequences. It is estimated that millions of children are exposed to IPV each year,[18] and pediatricians should be aware of the profound effects on children who are exposed to such violence.[19,20] A clinical report from the American Academy of Pediatrics (AAP) provides guidance to the clinician on understanding the behavioral and emotional consequences of child maltreatment, including exposure to IPV.[21]

Perhaps the most compelling data to detail the impairment associated with exposure to IPV has come from the Adverse Childhood Experiences study. The original study assessed the effects of abuse and household dysfunction during childhood on long-term health and quality-of-life outcomes.[22] A subanalysis of these data by Dube et al[23] demonstrated that adults who were exposed to IPV as children were 6 times more likely to be emotionally abused, 4.8 times more likely to be physically abused, and 2.6 times more likely to be sexually abused than children who were not exposed to IPV. The behavioral effects of exposure to IPV can be long-reaching, and the medical effects can be profound. Exposure to IPV, along with other adverse childhood experiences, has been shown to be associated significantly with many risk factors for the leading causes of death in adulthood, including smoking, severe obesity, physical inactivity, depression, and suicide attempts.[24]

Children of abused caregivers demonstrate significantly more internalizing behaviors, including anxiety, depression, withdrawal, and somatic complaints, as well as externalizing behaviors, including attention problems, aggressive behavior, and rule-breaking actions, than do children of nonabused caregivers.[24,25] These children frequently have social functioning difficulties and trouble establishing and maintaining relationships with their peers. They may be more likely to be aggressive with peers and demonstrate cruelty, bullying, and meanness to others.[26] Academic performance may be poor. As adolescents, they may adopt the same dynamic of violence in their own dating or peer relationships. Stress and anxiety can persist long after the trauma of IPV exposure, and many children exhibit symptoms consistent with posttraumatic stress disorder. Ultimately, some of these children become abusers themselves.[27]

Given the significant overlap between IPV and child maltreatment, practitioners may wonder when a report to child protective services is appropriate. Individual states have differing requirements for reporting concerns of children exposed to IPV on the basis of age of the child, relationship of the child to the perpetrator of the violence, and physical proximity of the child to

the violent act. When a report is mandated, the practitioner should inform the caregiver of the practitioner's responsibility to report. In many situations, it is helpful for the caregiver to file a report as well; doing so may lessen later accusations of "failure to protect." When making this decision, as every decision relevant to IPV situations, the safety needs of both the caregiver and the child should be taken into consideration. The Family Violence Prevention Fund offers recommendations for pediatricians in states without specific reporting requirements for children exposed to IPV.[28] These requirements include an inquiry about direct injury to the child, an assessment of potential for danger (threats, weapons, substance abuse), an assessment of the caregiver's ability to plan for the child's safety, and an assessment of support and connections to community resources.

ASSESSMENT FOR IPV

It is clear that IPV is a pediatric issue. Plans for identification and resources to incorporate into a response are important considerations for the pediatrician.

Whom to Ask?

Assessment for IPV may be approached in a universal or "case-finding" manner. There is insufficient evidence at this time to support one approach over another. Some experts advocate a case-finding approach to IPV detection. Using this approach, only caregivers with specific signs, symptoms, or risk indicators for abuse are asked about exposure to IPV. Pediatricians need to be aware that most abused caregivers will seek care for their children but not for themselves, which makes the pediatric setting an ideal place to be alert to the presence of IPV.[29] Although a caregiver may present with overt signs of injury, such as facial bruising, it is much more likely that the signs of abuse will be subtle—depression, anxiety, failure to keep medical appointments, reluctance to answer questions about discipline in the home, or frequent office visits for complaints not borne out by the medical evaluation of the child. In fact, most of the time, indicators of abuse are absent altogether.

Because of this situation, some experts advocate "universal screening"—asking all caregivers about IPV regardless of clinical indicators. Assessing for IPV at every patient encounter in the pediatric setting has been demonstrated to significantly increase the number of victims who are identified.[30,31] It remains unknown whether there are potential benefits and risks of conducting assessments on a universal basis. The US Preventive Services Task Force found that, although screening increases identification of abuse, there is insufficient evidence to recommend for or against universal IPV assessments because no evidence exists that universal IPV assessments reduce morbidity or mortality of the abused caregiver.[32] Future research is necessary to explore effective interventions for IPV and to determine potential harms and benefits of universal IPV assessments. While these studies are being performed, it seems reasonable to incorporate early and repeated questioning regarding IPV as part of anticipatory guidance while remaining mindful of clinical presentations that suggest risk.

How to Ask?

Approaching the subject of IPV may be uncomfortable for both the pediatrician and the caregiver. Many studies have examined the barriers that pediatricians and caregivers face during an assessment for IPV. Common barriers that pediatricians experience include limited time, lack of education/experience with IPV, absence of resources to assist caregivers who have experienced IPV, and a fear of offending or angering the caregiver.[33] Caregivers may have attitudes and beliefs that make them reluctant to disclose IPV, including shame, fear that disclosure will escalate the abuse, or a desire to protect the abuser.[34] Other barriers that inhibit disclosure include the fear that a disclosure will result in a report to child protective services, a perceived lack of provider empathy, or the concern that a child's health care needs are the priority over those of the caregiver.[35] Intrinsic characteristics of the provider/caregiver dynamic, including race and gender, may negatively influence a caregiver's comfort level when being assessed for IPV.[36] Pediatricians should be aware of these barriers and how they may influence the process of conducting IPV assessments.

Two primary approaches to conducting assessments for IPV have been identified: verbally administered assessments and self-administered assessments, including written, computerized, and tape-recorded surveys.[37] Most literature suggests that verbally administered assessments (face-to-face interviews) are associated not only with lower detection rates[38–40] but also, as some have reported, less patient comfort.[41] Studies that directly compared verbal and self-administered assessments revealed that women significantly preferred self-administered assessments.[42,43] Not only are self-administered assessments preferred, but they may overcome many of the barriers described previously. It is imperative that verbal follow-up is provided if a patient discloses abuse on a self-administered assessment. It is likely that there is not a "1-size-fits-all" screening method. The type of assessment used will depend on many factors, such as type of clinical environment, resources avail-

able, and acceptability to practitioners and parents/caregivers. Several simple screening tools exist, many of which have been well validated and can be incorporated easily into a pediatric setting.[44–46]

If IPV is detected, or if the pediatrician has concerns that IPV may be occurring in the home, further questioning is warranted. The pediatrician should explore the topic with the caregiver in a sympathetic and sensitive manner. The interview should be conducted in a private setting away from all children, family, friends, and the suspected abuser. It is important to remember that even very young children may be affected by the discussion of IPV. The pediatrician should gently introduce the topic in a way that assures the caregiver that the conversation is confidential (if allowed by law), the problem is acknowledged, other resources for help are accessible, and his or her wishes about further disclosure or referral will be respected. These introductory statements can be developed and reviewed in advance for appropriateness with local violence advocacy groups. The Appendix provides nonjudgmental introductory statements that may be helpful in focusing the topic and setting the caregiver at ease.

It is appropriate to document all IPV assessments, although health care professionals must be aware that an abuser may have access to the child's and/or caregiver's health records. A generic statement indicating that an IPV assessment has taken place and resources have been offered per practice protocol provides documentation that inquiry has occurred but does not specify whether a caregiver has disclosed abuse or not.

REFERRALS/SAFETY PLANS

The Family Violence Prevention Fund has published a pediatric guideline for managing situations of IPV.[28] A free training video is available on its Web site (http://fvpfstore.stores.yahoo.net/screentoenda.html). Ideally, a protocol or action plan that has been developed with the input of local shelters, rape crisis centers, and victim advocacy groups should exist. Because of time constraints in a busy office practice or acute care setting, an interdisciplinary approach to IPV is most appropriate. The American Medical Association recognizes that optimal care for the caregiver in an abusive relationship depends on the physician's working knowledge of community resources that can provide safety, advocacy, and support.[47] Pediatricians are encouraged to partner with obstetricians, prenatal clinic nurses and social workers, hospital nurses and social workers, public health administrators, and early childhood education programs to coordinate a community response to the issue of IPV. The American Medical Association and many state medical associations provide directories of agencies that provide services or information about all forms of family violence. A national toll-free hotline (800-799-SAFE) is available to anyone who needs information about local resources on IPV. Additional resources may be accessed at the Family Violence Prevention Fund's Web site (www.endabuse.org/health). The AAP also provides resources to pediatricians on dating violence through the Connected Kids program (www.aap.org/connectedkids).

Pediatricians must understand the dynamics of abusive relationships. Zink et al[48] have suggested that physicians understand the transtheoretical model, known as "stages of change," to help patients with behavior changes and more effectively address the issue of IPV. It has been suggested that the risk of injury and/or death increases at the time a caregiver discloses abuse and attempts to leave his or her abusive partner. Thus, the process of disclosure is naturally very frightening and may not occur unless the caregiver feels that he or she is not in significant jeopardy. Unlike the situation with child maltreatment, there are no mandated state agencies that step in and act to ensure a caregiver's safety during this process. Few states have passed laws that mandate reporting of suspected IPV for individuals being treated by the health care professional, and few states have laws requiring health care professionals to report IPV if it is suspected or discovered during an evaluation of the child. Knowledge of existing state laws for reporting partner violence is essential.* A compilation of these laws is available for public access.[32] In addition, pediatricians should be aware of their state laws regarding the reporting of children exposed to IPV and how it may influence their practice of inquiry for IPV. An updated database of these laws is available through the Child Welfare Information Gateway.[49]

It is important to use discretion when providing printed information about partner violence to patients or their caregivers. If the information is discovered by the abuser, the victim may be at increased risk of violence. If the caregiver feels safe, information about legal and crisis counseling and shelters can be provided in written form. Written plans may be completed by the caregiver to facilitate ongoing safety, and many templates are available for use.[50,51] Because of the strong association between homicide in the home and the presence of both guns and partner violence, it could be life-saving to help an abused caregiver to recognize the value in removing firearms from the home, if it can be accom-

*For additional information and assistance with state laws and related advocacy issues, please contact the AAP Division of State Government Affairs.

plished safely. The possible role of substance abuse contributing to IPV should be considered. Pediatricians also need to be sensitive to ethnic and cultural attitudes about violence specifically toward women, not because such attitudes are acceptable but because they may have a profound influence on the willingness of women to discuss this problem.

Pediatricians can provide education to agencies that deal with IPV about the risk of maltreatment to children whose caregivers are abused. Every reasonable effort should be made to assess risk of harm and lethality in the home and to protect children from a potentially dangerous environment. Counseling should be secured for children who have been exposed to IPV. Such treatment may be provided in groups or individually, but the focus should be on understanding violence and how to avoid it.

CONCLUSIONS

The evidence is overwhelming that children who are exposed to IPV are at risk of child maltreatment and both short-term and long-term medical, behavioral, and mental health problems. The Institute of Medicine recommends several core competencies on family violence for health care professionals.[52] These core competencies include training on the identification, assessment, and documentation of abuse; knowledge of interventions to ensure victim safety; recognition of culture and values as factors that affect IPV; understanding of applicable legal responsibilities; and violence prevention. Pediatricians who possess knowledge and skills in these areas will be in a position to intervene when IPV is present and provide more effective health care to children and their families.

GUIDANCE FOR THE CLINICIAN

1. Residency training programs and continuing medical education program leaders are encouraged to incorporate education on IPV and its implications for child health into the curricula of pediatricians and pediatric subspecialists.
2. Pediatricians should remain alert to the signs and symptoms of exposure to IPV in caregivers and children and should consider attempts to identify evidence of IPV either by targeted screening of high-risk families or universal screening.
3. When caregivers are asked about IPV, it is ideal to have a plan in place to respond to affirmative screens.
4. Pediatricians are encouraged to intervene in a sensitive and skillful manner and attempt to maximize the safety of caretakers and child victims.
5. Pediatricians should be cognizant of applicable IPV laws in their state, particularly as they relate to reporting abuse or concerns of children exposed to IPV.
6. Pediatricians are encouraged to support local and national multidisciplinary efforts to recognize, treat, and prevent IPV.

APPENDIX: SUGGESTED STATEMENTS TO INTRODUCE THE TOPIC OF IPV

"We all have disagreements at home. What happens when you and your partner disagree?"

"Is there shouting, pushing, or shoving? Does anyone get hurt?"

"Has your partner ever threatened to hurt you or your children?"

"Do you ever feel afraid of your partner?"

"Has anyone forced you to have sex in the last few years?"

Technical Report: Knee Brace Use in the Young Athlete

ABSTRACT. This statement is a revision of a previous statement on prophylactic knee bracing and provides information for pediatricians regarding the use of various types of knee braces, indications for the use of knee braces, and the background knowledge necessary to prescribe the use of knee braces for children.

BACKGROUND

Pediatricians are appropriately becoming more involved in the care of young athletes. The knee is one of the most commonly injured joints in athletes. The correct care of knee injuries is an important part of any sports medicine or general pediatrics practice and may include the use of braces. Therefore, the pediatrician should be knowledgeable about knee bracing. This statement is an update of a previous statement on prophylactic knee bracing[1] and includes information for pediatricians regarding the use of various types of knee braces, indications for the use of knee braces, and the background knowledge necessary to prescribe the use of knee braces for children.

Acute and overuse injuries to the knee are seen as a result of participation in virtually all athletic activities. Injuries to the ligamentous structures of the knee in the young athlete are becoming more common. The medial collateral and anterior cruciate ligaments are prime stabilizers of the knee and can be injured when direct or indirect forces are applied to the knee. In a growing child, the distal femoral physis is subject to these same forces and may also be injured. In the skeletally immature child, acute trauma to the knee is most likely to cause injury to these 2 ligaments and/or to the distal femoral physis. Patella subluxation, dislocation, or tracking abnormalities can occur as a result of mechanical predisposition as well as direct or indirect stress to the knee. Cumulative microtrauma or overuse can lead to patellofemoral disorders or apophysitis of the tibial tuberosity (Osgood-Schlatter disease), which are common in adolescents.

TYPES OF KNEE BRACES

Various types of braces have been designed to provide symptomatic relief and diminish the effects of injury to the knee. The 4 categories of knee braces are knee sleeves, prophylactic knee braces, functional knee braces, and postoperative or rehabilitative knee braces (Table 1).[2,3] Although patients often report benefits from wearing braces,[4,5] these benefits have not been verified by scientific investigation.[2,4]

The ideal knee brace in any of the 4 categories would produce a synergism with the inherent knee stabilizers, both muscular and ligamentous, throughout the normal range of motion. It would increase resistance to injury from valgus, varus, rotational, or anterior-posterior translation forces. The ideal brace would not interfere with normal knee function or increase the risk of injury to other parts of the lower extremity or to other players.

Knee Sleeves

Knee sleeves are expandable, slip-on devices usually made of neoprene with a nylon cover. They increase warmth, provide even compression, and may enhance proprioception.[6] Knee sleeves may provide a feeling of support to the knee. Plain knee sleeves may be used to treat postoperative knee effusions[6] and patellofemoral syndrome.[6] Used in this capacity, the purpose of a knee sleeve is to decrease knee pain.[7,8] When a knee pad is added, it provides protective cushioning to the patella and anterior knee.

The knee sleeve may be modified to include an opening for the patella, 1 or more movable straps, or a buttress. The buttress may be circular, C-shaped, J-shaped, or H-shaped. With these modifications, the knee sleeve is often referred to as an extensor mechanism counterforce brace and is used to treat patellofemoral joint disorders, including patella subluxation, patella dislocation, and patellofemoral syndrome, all of which are very common in athletes.[9] The pathophysiology of patellofemoral syndrome is unclear,[10] but it has been postulated to occur as a result of abnormal tracking of the patella on the femoral trochlear groove.[2,6] The knee sleeve helps compress the tissue and limits patella movement.[6] The extensor mechanism braces are designed to apply a medially directed force to the lateral patella, thereby improving patellofemoral tracking and decreasing the likelihood of lateral patella subluxation or dislocation. Used in this capacity, they may be of benefit in the athlete with an unstable patella.[11] These braces may also contain a lateral hinge that incorporates an extension stop.[2,5,7]

When a strap is placed inferior to the patella, it may be used to treat Osgood-Schlatter disease and patellar tendonitis.[6] This infrapatellar band is used to decrease the traction forces at the tibia tuberosity for patients with Osgood-Schlatter disease and on the patellar tendon for patients with patellar tendonitis.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Table 1. Knee Braces and Indications for Use in the Young Athlete*

Brace Category	Indication	Comments
Knee Sleeves†		
 Plain sleeve	Postoperative knee effusions; patellofemoral syndrome	Insufficient for treatment of an unstable knee. Should only be worn during sports activities if swelling occurs. Simple to fit and inexpensive.
 Sleeve with knee pad	Protection and padding of the anterior knee	
 Sleeve with buttress	Patella subluxation, patella dislocation; patellofemoral syndrome	Improves patellofemoral tracking.
 Sleeve with strap	Osgood-Schlatter disease; patella tendonitis	Decreases traction forces on the tibia tuberosity and patella tendon.
Knee Braces		
 Prophylactic brace	Protect medial collateral ligament and anterior cruciate ligament, especially in contact sports	Insufficient evidence to use in the young athlete.
 Functional brace†	Tears of anterior cruciate, posterior cruciate, medial collateral, and lateral collateral ligaments	Intended to prevent reinjury. Not to be used prophylactically.
 Postoperative or rehabilitative brace†	Nonsurgical injury to and after surgical repair of anterior cruciate, posterior cruciate, medial collateral, lateral collateral ligaments, medial and lateral meniscus; or nondisplaced epiphyseal fracture	Can be adjusted for swelling, removed for examinations or icing, and adjusted to allow movement in a controlled range.

*Knee brace images reprinted with permission from djOrthopedics, LLC.
†The use of knee sleeves and functional and postoperative or rehabilitative braces has been accepted clinically on the basis of subjective experience and has not been supported by scientific evidence.

It is important to remember that knee sleeves do not provide ligamentous support and, therefore, are insufficient for the treatment of an unstable knee.[11] Knee sleeves can cause swelling by retaining heat around the knee or by obstructing venous and lymphatic return below the sleeve. They should only be worn during sports activities if these complications occur.[11] The use of these sleeves should be combined with quadriceps and hamstring flexibility, stretching, and strengthening exercises as well as correction of biomechanical dysfunction of the hip, ankle, or foot and improved sports technique.[6,7,9] Scientific evidence of benefits of the knee sleeve is lacking[3,10,12–14]; however, patients report benefits that exceed objective effects noticed by researchers.[2–4] Knee sleeves are relatively simple to fit and inexpensive.[6]

Prophylactic Knee Braces

Prophylactic knee braces[15–17] are braces with unilateral or bilateral bars, hinges, and adhesive straps. The deformable metal of these braces can absorb some of the impact and decrease the force applied to the medial collateral ligament by 10% to 30%.

Prophylactic knee braces are intended to protect (prevent or reduce the severity of injury to) the medial collateral ligament from valgus stress applied to the lateral aspects of the extended weight-bearing leg during contact sports. Some studies indicate they may also protect the anterior cruciate ligament from rotational stress in the same situation. In football, offensive linemen, defensive linemen, linebackers, and tight ends most commonly wear lateral knee stabilizers. Despite anecdotal reports of success, scientific studies have not universally shown that prophylactic knee braces significantly reduce knee injuries.[15–18] Thus, there is insufficient evidence to recommend prophylactic knee bracing in the young athlete.[1–3,7,15–18]

Functional Braces

Functional braces are generally made from a metallic plastic composite with medial and lateral vertical hinges and a variable stop to limit hyperextension. There are 2 types of functional braces: the hinge-postshell and hinge-poststrap models. The rigid shell or straps and hinges provide resistance to deformation. Hinges may be polyaxial to mimic the changing center of motion of the flexing knee. The hinge-postshell model theoretically provides improved tibial displacement control, greater rigidity, enhanced durability, and better soft tissue contact.[7] The upright of a functional brace should be the maximum length comfortable to the athlete.[7,19]

A functional brace is designed to enhance the stability of an unstable knee (usually after an anterior cruciate ligament injury with or without other injuries to the menisci, collateral ligaments, or bone contusion) when rotational and anteroposterior forces are applied. They may be used for 6 to 12 months after anterior cruciate ligament reconstruction[19] to reduce the strain on an anterior cruciate ligament graft.[7,20,21] They are intended to reduce the risk of future injuries without significantly impairing function.

Functional braces are most commonly used by the skeletally immature athlete with an anterior cruciate-deficient knee (awaiting skeletal maturation), the anterior cruciate-deficient athlete who is awaiting surgical reconstruction, and the anterior cruciate-deficient athlete who is not a surgical candidate. This type of brace may also be used during the healing phase of a medial or lateral collateral ligament injury or as a supplement to surgery[21] and rehabilitation to prevent reinjury. Functional anterior cruciate ligament braces may prevent hyperextension; however, their control of rotational forces is less efficient,[2,11,21] so the unstable knee is still at risk of subluxation or shifting, which may lead to meniscal or chondral injury.

There is a lack of scientific evidence that these braces are helpful at the level required for athletic participation.[2,7,19,22–25] However, patients report a positive subjective response, claiming an increase in knee stability, pain attenuation, performance enhancement, and confidence during athletics with brace use.[2,7,22–24] There is probably no difference in effectiveness between off-the-shelf models and custom-made braces.[9,18,23,26] Brace wearers have higher energy expenditures than do nonwearers.[22] Current experimental evidence suggests that functional knee braces do not significantly affect performance.[27]

Lower extremity muscle strengthening, flexibility, and ultimately, improvement and refinement of athletic techniques are more important than functional bracing in treating ligamentous knee injuries.[7,20] Functional braces will never substitute for proper rehabilitation and surgical procedures when necessary.[9]

Postoperative or Rehabilitative Braces

The postoperative or rehabilitative knee brace consists of foam liners that surround the calf, thigh, and knee; full-length medial and lateral rigid bars with hinges at the knee that can be adjusted to allow a controlled range of motion; and 6 to 8 nonelastic straps that hold the brace in place. These braces are prefabricated (off-the-shelf) and adjustable in size.

The postoperative or rehabilitative brace can be used to protect injured ligaments and control knee flexion and extension angles during the initial healing period[2] as part of the treatment program for an injured anterior cruciate ligament, posterior cruciate ligament, medial collateral ligament, lateral collateral ligament, or medial or lateral meniscus. These are most often used during crutch-assisted ambulation immediately after meniscal and/or cruciate ligament injury or surgery. They are used for a short period of time (2–8 weeks) after the acute injury or surgery. The value of a rehabilitative brace as opposed to a cast or splint includes the ability to adjust the brace for swelling, the ability to remove the brace for serial examinations or icing, and the ability to allow for movement in a controlled range of motion.

Pediatricians may order a postoperative brace for the treatment of nonsurgical ligamentous injuries or nondisplaced epiphyseal fractures. There are very little data on the clinical performance of rehabilita-

tive braces.[2,20,28–30] They are accepted clinically on the basis of their subjective performance.

PRESCRIBING KNEE BRACES

Prescribing any knee brace requires an accurate diagnosis of the injury, an appreciation and knowledge of the benefits and limitations of a brace, and an understanding of the physical demands and risks of the given sport. Knee sleeves with or without straps and buttresses can be prescribed for problems with patellar instability, patellofemoral pain, patellar tendonitis, or Osgood-Schlatter disease. Because prophylactic knee braces have not been proven to be cost-effective, pediatricians should not prescribe them. Functional braces may help prevent further injuries to a previously injured knee and may help protect a surgically repaired knee. Functional braces are not recommended for prophylaxis. Postoperative or rehabilitative braces are generally used for acute knee ligament or growth plate injuries or after surgical repair of an anterior cruciate ligament or meniscus.

Even when use of a knee brace is indicated, the brace alone is not sufficient to treat or protect the injured knee. The brace is only 1 component of injury rehabilitation, along with therapeutic exercises, such as flexibility, joint mobilization, strengthening, and proprioceptive retraining.

Brace designs will continue to evolve with lighter and stronger materials, more physiologic and durable hinges, and attachment systems that do not excessively compress the musculature or irritate the skin. Better ability to test the effectiveness of these braces will be rewarding.

SUMMARY

When prescribing the use of knee braces, pediatricians should establish an accurate diagnosis of the injury, consider the spectrum of treatment options, and understand the classifications, benefits, limitations, indications, and cost of any brace prescribed.

There is insufficient scientific evidence to recommend the use of prophylactic knee braces for the pediatric athlete, and available studies do not support the prescribing of most knee braces. However, the use of knee sleeves, functional braces, and postoperative braces has been accepted clinically on the basis of subjective performance. If used, knee braces should complement, rather than replace, rehabilitative therapy and required surgery.

CLINICAL REPORT

Lactose Intolerance in Infants, Children, and Adolescents

Guidance for the Clinician in Rendering Pediatric Care

Melvin B. Heyman, MD, MPH, for the Committee on Nutrition

ABSTRACT

The American Academy of Pediatrics Committee on Nutrition presents an updated review of lactose intolerance in infants, children, and adolescents. Differences between primary, secondary, congenital, and developmental lactase deficiency that may result in lactose intolerance are discussed. Children with suspected lactose intolerance can be assessed clinically by dietary lactose elimination or by tests including noninvasive hydrogen breath testing or invasive intestinal biopsy determination of lactase (and other disaccharidase) concentrations. Treatment consists of use of lactase-treated dairy products or oral lactase supplementation, limitation of lactose-containing foods, or dairy elimination. The American Academy of Pediatrics supports use of dairy foods as an important source of calcium for bone mineral health and of other nutrients that facilitate growth in children and adolescents. If dairy products are eliminated, other dietary sources of calcium or calcium supplements need to be provided.

INTRODUCTION

SIGNIFICANT CHANGES IN our knowledge and approach toward lactose intolerance have occurred over the past quarter century, since the first statement on lactose intolerance was published by the American Academy of Pediatrics Committee on Nutrition.[1] Lactose ingestion in certain susceptible individuals can cause abdominal symptoms that are variable and can be treated with dietary restriction or enzyme replacement, depending on the amount of lactose consumed and the degree of lactase deficiency. Pediatricians and other pediatric care providers should maintain awareness of the benefits and controversies related to the consumption of dietary milk products and milk-based infant formula. The lactose content of milk often influences, correctly or not, the ultimate decision about the use or continuation of milk in the diet. Milk and dairy-product avoidance has a negative effect on calcium and vitamin D intake in infants, children, and adolescents. Other nutrients such as protein make dairy products an important source of nutrition for growing children. This revised statement will update the initial statement of 1978 while incorporating changes from the 1990 supplement[2] and current state-of-the-art relating to lactose intolerance. Recommendations regarding dietary calcium have been updated recently.[3]

Lactose, a disaccharide that comprises the monosaccharides glucose and galactose, is the primary carbohydrate found exclusively in mammalian milk. Absorption of lactose requires lactase activity in the small intestinal brush border to split the bond linking the 2 monosaccharides. A β-galactosidase termed "lactase-phlorizin hydrolase" (lactase) accounts for most of the lactase activity in the intestinal

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

mucosa.[4] Lactase is found in the small intestine and localized to the tips of the villi, a factor of clinical importance when considering the effect of diarrheal illness on the ability to tolerate milk.

Milk intolerance may be attributed to either the lactose or the protein content. Lactose intolerance can occur among infants and young children with acute diarrheal disease, although the clinical significance of this is limited except in more severely affected children. Symptoms of lactose intolerance are relatively common among older children and adolescents; however, associated intestinal injury is infrequently seen. Lactose intolerance is a distinct entity from cow milk–protein sensitivity, which involves the immune system and causes varying degrees of injury to the intestinal mucosal surface. Cow milk–protein intolerance is reported in 2% to 5% of infants within the first 1 to 3 months of life, typically resolves by 1 year of age, and is not the subject of this statement.[5,6]

DEFINITIONS

Following are definitions of terms used in the remainder of this statement:

- Lactose intolerance is a clinical syndrome of 1 or more of the following: abdominal pain, diarrhea, nausea, flatulence, and/or bloating after the ingestion of lactose or lactose-containing food substances. The amount of lactose that will cause symptoms varies from individual to individual, depending on the amount of lactose consumed, the degree of lactase deficiency, and the form of food substance in which the lactose is ingested.
- Lactose malabsorption is the physiologic problem that manifests as lactose intolerance and is attributable to an imbalance between the amount of ingested lactose and the capacity for lactase to hydrolyze the disaccharide.
- Primary lactase deficiency is attributable to relative or absolute absence of lactase that develops in childhood at various ages in different racial groups and is the most common cause of lactose malabsorption and lactose intolerance. Primary lactase deficiency is also referred to as adult-type hypolactasia, lactase nonpersistence, or hereditary lactase deficiency.
- Secondary lactase deficiency is lactase deficiency that results from small bowel injury, such as acute gastroenteritis, persistent diarrhea, small bowel overgrowth, cancer chemotherapy, or other causes of injury to the small intestinal mucosa, and can present at any age but is more common in infancy.
- Congenital lactase deficiency is extremely rare; teleologically, infants with congenital lactase deficiency would not be expected to survive before the 20th century, when no readily accessible and nutritionally adequate lactose-free human milk substitute was available.
- Developmental lactase deficiency is now defined as the relative lactase deficiency observed among preterm infants of less than 34 weeks' gestation.

Primary Lactase Deficiency

Approximately 70% of the world's population has primary lactase deficiency.[7,8] The percentage varies according to ethnicity and is related to the use of dairy products in the diet, resulting in genetic selection of individuals with the ability to digest lactose (Table 1). In populations with a predominance of dairy foods in the diet, particularly northern European people, as few as 2% of the population has primary lactase deficiency. In contrast, the prevalence of primary lactase deficiency is 50% to 80% in Hispanic people, 60% to 80% in black and Ashkenazi Jewish people, and almost 100% in Asian and American Indian people.[9–11] The age of onset and its prevalence differ among various populations. Approximately 20% of Hispanic, Asian, and black children younger than 5 years of age have evidence of lactase deficiency and lactose malabsorption,[12] whereas white children typically do not develop symptoms of lactose intolerance until after 4 or 5 years of age. Recent molecular studies of lactase-phlorizin hydrolase (lactase) have correlated the genetic polymorphism of messenger RNA expression with persistence of lactase activity, demonstrating early loss (at 1–2 years of age) of messenger RNA expression and enzyme activity in Thai children and late (10–20 years of age) loss of activity in Finnish children.[11,13] The clinical relevance of these observations is that children with clinical signs of lactose intolerance at an earlier age than is typical for a specific ethnic group may warrant an evaluation for an underlying cause, because primary lactase deficiency would otherwise be unusual at such a young age. Although primary lactase deficiency may present with a relatively acute onset of milk intolerance, its onset typically is subtle and progressive over many years. Most lactase-

TABLE 1 **Prevalence of Acquired Primary Lactase Deficiency[69]**

Examples of groups among whom lactase deficiency predominates (60%–100% lactase deficient)
Near East and Mediterranean: Arabs, Ashkenazi Jews, Greek Cypriots, Southern Italians
Asia: Thais, Indonesians, Chinese, Koreans
Africa: South Nigerians, Hausa, Bantu
North and South America: black Americans, Latinas, Eskimos, Canadian and American Indians, Chami Indians
Examples of groups among whom lactase persistence predominates (2%–30% lactase deficient)
Northern Europeans
Africa: Hima, Tussi, Nomadic Fulani
India: individuals from Punjab and New Delhi

deficient individuals experience onset of symptoms in late adolescence and adulthood.

Reports that focus on clinical symptoms of lactase deficiency are prone to subjectivity, confounding clinical diagnosis. For instance, when lactase-deficient adults were given 2 glasses of milk or 2 glasses of lactose-hydrolyzed milk per day in a double-blind, crossover study, no statistical differences in symptoms of lactose intolerance were found regardless of whether the individual described himself or herself as lactose intolerant.[14] Even lactose-intolerant adults may find that 1 glass of milk or a scoop of ice cream is tolerated, whereas an additional glass of milk or other milk product may produce symptoms. Because of the variation of dairy intake in each individual's diet and in the amount of lactose contained in different products, symptoms may vary and be modified by diet and by milk-containing foods (see "Management"). For these reasons, dietary history is an unreliable means to confirm or exclude the diagnosis of lactose intolerance.

Secondary Lactase Deficiency

Secondary lactase deficiency implies that an underlying pathophysiologic condition is responsible for the lactase deficiency and subsequent lactose malabsorption. Etiologies include acute infection (eg, rotavirus) causing small intestinal injury with loss of the lactase-containing epithelial cells from the tips of the villi. The immature epithelial cells that replace these are often lactase deficient, leading to secondary lactose deficiency and lactose malabsorption, although several reports indicate that lactose malabsorption in most children with acute gastroenteritis is not clinically important.[15] Several recent studies and a meta-analysis found that children with rotaviral (and other infectious) diarrheal illnesses who have no or only mild dehydration can safely continue human milk or standard (lactose-containing) formula without any significant effect on outcome, including hydration status, nutritional status, duration of illness, or success of therapy.[16–18] However, in the at-risk infant (eg, younger than 3 months or malnourished) who develops infectious diarrhea, lactose intolerance may be a significant factor that will influence the evolution of the illness. Giardiasis, cryptosporidiosis, and other parasites that infect the proximal small intestine often lead to lactose malabsorption from direct injury to the epithelial cells by the parasite. Secondary lactase deficiency with clinical signs of lactose intolerance can be seen in celiac disease, Crohn disease, and immune-related and other enteropathies and should be considered in these children. Diagnostic evaluation should be directed toward these entities when secondary lactase deficiency is suspected and an infectious etiology is not found.

Young infants with severe malnutrition develop small intestinal atrophy that also leads to secondary lactase deficiency.[19] Although uncommon in the United States, malnutrition is associated with lactose malabsorption and carbohydrate intolerance in developing countries.[20] Lactose malabsorption has also been associated with poor growth in these countries.[21] Most infants and children with malabsorption attributable to malnutrition are able to continue to tolerate dietary carbohydrates, including lactose.[22] However, the World Health Organization recommends avoidance of lactose-containing milks in children with persistent postinfectious diarrhea (diarrhea lasting more than 14 days) when they fail a dietary trial of milk or yogurt.[23]

Treatment of secondary lactase deficiency and lactose malabsorption attributable to an underlying condition generally does not require elimination of lactose from the diet but, rather, treatment of the underlying condition. Once the primary problem is resolved, lactose-containing products can often be consumed normally, and these excellent sources of calcium and other nutrients need not be unnecessarily excluded from the diet.

Developmental (Neonatal) Lactase Deficiency

In the immature gastrointestinal tract, lactase and other disaccharidases are deficient until at least 34 weeks' gestation.[24] One study in preterm infants reported benefit from use of lactase-supplemented feedings or lactose-reduced formulas,[25] and the use of lactose-containing formulas and human milk does not seem to have any short- or long-term deleterious effects in preterm infants.[26] Up to 20% of the dietary lactose may reach the colon in neonates and young infants. Bacterial metabolism of colonic lactose lowers the fecal pH (5.0–5.5 is normal), which has a beneficial effect, favoring certain organisms (eg, *Bifidobacterium* and *Lactobacillus* species) in lieu of potential pathogens (*Proteus* species, *Escherichia coli*, and *Klebsiella* species) in young infants. Antimicrobial agents may also affect this colonization.

Congenital Lactase Deficiency

Congenital lactase deficiency is a rare disorder that has been reported in only a few infants.[27,28] Affected newborn infants present with intractable diarrhea as soon as human milk or lactose-containing formula is introduced. Small intestinal biopsies reveal normal histologic characteristics but low or completely absent lactase concentrations.[29,30] Unless this is recognized and treated quickly, the condition is life-threatening because of dehydration and electrolyte losses. Treatment is simply removal and substitution of lactose from the diet with a commercial lactose-free formula.

DIAGNOSIS

Symptoms of lactose intolerance, including abdominal distention, flatulence, abdominal cramping, and (ultimately) diarrhea, are independent of the cause of lactose malabsorption and are directly related to the quantity of ingested lactose. These symptoms are not necessarily

correlated with the degree of intestinal lactase deficiency. Malabsorbed lactose generates an osmotic load that draws fluid and electrolytes into the intestinal lumen, leading to loose stool. The onset of diarrhea and other symptoms is related to the amount of lactose that is not absorbed. As little as 12 g of lactose (the amount of lactose in an 8-oz glass of milk) may be sufficient to cause symptoms in children with chronic abdominal pain.[31] In addition, unabsorbed lactose is a substrate for intestinal bacteria, especially in the colon. Bacteria metabolize lactose, producing volatile fatty acids and gases (methane, carbon dioxide, and hydrogen), leading to flatulence. The fatty acids lower the fecal pH, making the fecal pH test a nonspecific but sometimes helpful marker for lactose (or other carbohydrate) malabsorption. When sufficient intestinal gas is produced by the bacterial metabolic processes to cause stimulation of the intestinal nervous system by intestinal distention, visceral (abdominal) cramping results.

Initial studies using lactose hydrogen breath tests documented lactose malabsorption in up to 40% of children and adolescents presenting with abdominal pain.[32] However, recent studies suggest that the prevalence of abdominal symptoms related to lactose intolerance documented by hydrogen breath tests is variable and ranges from 2% in Finnish children to 24% in southern US children.[33,34]

A good clinical history often reveals a relationship between lactose ingestion and symptoms. When lactose intolerance is suspected, a lactose-free diet can be tried (Tables 2 and 3).[35] During a diagnostic lactose-free diet, it is important that all sources of lactose be eliminated, requiring the reading of food labels to identify "hidden" sources of lactose. Generally, a 2-week trial of a strict lactose-free diet with resolution of symptoms and subsequent reintroduction of dairy foods with recurrence of symptoms can be diagnostic. In more-subtle cases, the hydrogen breath test is the least invasive and most helpful test to diagnose lactose malabsorption. The test has been shown to be more reliable than history, because some patients think they are lactose intolerant when they prove not to be, and others prove to be lactose intolerant (lactose malabsorbers) when they think they are not.[36,37] The test is performed by administration of a standardized amount of lactose (2 g/kg, up to a maximum of 25 g, equivalent to the amount of lactose in 2 8-oz glasses of milk) after fasting overnight and then measuring the amount of hydrogen in expired air over a 2- to 3-hour period. An increase (>20 ppm) in the hydrogen expired after approximately 60 minutes is consistent with lactose malabsorption. Factors that may produce false-negative or false-positive results include conditions affecting the intestinal flora (eg, recent use of antimicrobial agents), lack of hydrogen-producing bacteria (10%–15% of the population), ingestion of high-fiber diets before the test, small intestinal bacterial overgrowth, or intestinal motility disorders. A pediatric gastroenterologist should be consulted to interpret the results of this test.

TABLE 2 **Lactose and Calcium Content of Common Foods[70,71]**

Dairy Products	Calcium Content, mg	Lactose Content, g
Yogurt, plain, low fat, 1 cup	448	8.4
Milk, whole (3.25% fat), 1 cup	276	12.8
Milk, reduced fat, 1 cup	285	12.2
Ice cream, vanilla, 1/2 cup	92	4.9
Cheddar cheese, 1 oz	204	0.07
Swiss cheese, 1 oz	224	0.02
Cottage cheese, creamed (small curd), 1 cup	135	1.4

TABLE 3 **Hidden Sources of Lactose[72]**

Bread and other baked goods
Processed breakfast cereals
Mixes for pancakes, biscuits, and cookies
Instant potatoes, soups, and breakfast drinks
Margarine
Nonkosher lunchmeats
Salad dressings
Candies and other snacks

The older lactose-tolerance test was previously relied on as the primary test of lactose malabsorption before the breath hydrogen test became available. Lactose intolerance was diagnosed by onset of symptoms and/or positive test results after ingestion of a standard lactose dose (2 g/kg of body weight or 50 g/m^2 of body surface area; maximum 50 g in a 20% water solution). If the maximum increase in blood glucose concentration was less than 26 mg/dL after a lactose-tolerance test dose, lactose malabsorption was diagnosed. The lactose-tolerance test is not sensitive enough to determine if a subject is malabsorbing some lactose. It is also often falsely positive because of lack of an increase of blood glucose concentration attributable to normal insulin response to the carbohydrate load. Given the high rate of false-negative and false-positive results, this test should not be used and has been replaced by the hydrogen breath test.

Other tests are available in consultation with a pediatric gastroenterologist to diagnose lactose intolerance. If an underlying cause for secondary lactose intolerance is suspected, testing for intestinal etiologies includes stool examination, particularly for parasites affecting the upper gastrointestinal tract such as *Giardia lamblia* and *Cryptosporidia* species, and blood tests for celiac disease (ie, total immunoglobulin A concentration and antitissue transglutaminase antibody[38,39]) or immunodeficiency (quantitative immunoglobulins). Intestinal biopsy may be needed to uncover an underlying gastrointestinal mucosal problem that is causing the lactose malabsorption. Biopsies can yield direct measurement of disaccharidase concentrations to document lactase deficiency directly and assess the status of the other

brush-border disaccharidases (sucrase, maltase, isomaltase), which may also be deficient under various circumstances. However, intestinal lactase concentrations do not seem to correlate well with symptoms of lactose intolerance.[40]

Newer tests may eventually yield additional detailed information pertaining to the prevalence and significance of lactose intolerance.[41] For example, the [^{13}C]lactose breath test is being considered as a test to augment the accuracy of the breath hydrogen test but is still primarily an investigational tool.[42,43]

In infants with diarrhea in whom lactose (or other carbohydrate) intolerance is suspected, stool can be screened for malabsorbed carbohydrate by testing fecal pH, which decreases with carbohydrate malabsorption as a result of the formation of volatile fatty acids. It should be remembered that fecal pH will normally be lower (5.0–5.5) in infants compared with older children and adolescents because of the physiologic overload of lactose in their diets, which in turn helps to favor growth of *Lactobacillus* species in the colon. Fecal reducing substances can also be measured and become positive by excretion of a reducing sugar in the stools. Reducing sugars include lactose, glucose, fructose, and galactose but not sucrose. Because some patients may only malabsorb enough carbohydrates, such as lactose, to lower the fecal pH but not increase excretion of carbohydrate in the stool, the pH test is a more sensitive test for carbohydrate malabsorption.

MANAGEMENT

When children are diagnosed with lactose intolerance, avoidance of milk and other dairy products will relieve symptoms. However, those with primary lactose intolerance have varying degrees of lactase deficiency and, correspondingly, often tolerate varying amounts of dietary lactose. Lactose-intolerant children (and their parents) should realize that ingestion of dairy products resulting in symptoms generally leads to transient symptoms without causing harm to the gastrointestinal tract (as compared with celiac disease or allergic reactions, including milk-protein intolerance, that can lead to ongoing inflammation and mucosal damage). Although lactose malabsorption does not predispose to calcium malabsorption,[44] avoidance of milk products to control symptoms may be problematic for optimal bone mineralization. Children who avoid milk have been documented to ingest less-than-recommended amounts of calcium needed for normal bone calcium accretion and bone mineralization.[45,46]

Lactose-free and lactose-reduced milks (and lactose-free whole milk for children younger than 2 years) are widely available in supermarkets and can be obtained with WIC (Special Supplemental Nutrition Program for Women, Infants, and Children) vouchers. Although lactose-free milk is more expensive than regular milk, some major chain stores sell less-expensive lactose-free milk under their own brand names.

Beyond infancy, substitutes for cow milk based on rice, soy, or other proteins are readily available and are generally free of lactose, although the nutrient content of most of these milks is not equivalent to cow milk. Other mammalian milks, including goat milk, are not free of lactose. Tolerance to milk products may be partial, so that dietary maneuvers alone may help avoid symptoms in some individuals. Small amounts of lactose in portions of 4 to 8 oz spaced throughout the day and consumed with other foods may be tolerated with no symptoms.[47–51] Some children are able to drink 1 to 2 glasses of milk each day without difficulty but cannot tolerate more without developing symptoms.[14] Many lactose-intolerant individuals who are intolerant of milk can tolerate milk chocolate[52] and/or yogurt (plain better than flavored), because the bacteria in the yogurt partially digest the lactose into glucose and galactose before consumption.[53,54] In addition, yogurt's semisolid state slows gastric emptying and gastrointestinal transit, resulting in fewer symptoms of lactose intolerance.[55] Furthermore, ingestion of other solid foods delays gastric emptying, providing additional time for endogenous lactase to digest dietary lactose. Aged cheeses tend to have lower lactose content than other cheeses and, thus, may also be better tolerated. Finally, oral lactase-replacement capsules or predigested milk or dairy products with lactase are readily available and will often permit a lactose-intolerant individual to be able to take some or all milk products freely.[56] Because the vitamin D content in milk-substitute products varies, labels must be checked to verify the vitamin D content of individual brands.

Even among population groups with significant lactose intolerance, the importance of dietary dairy products has been stressed. For example, the National Medical Association recently recommended that black people consume 3 to 4 servings per day of low-fat milk, cheese, and/or yogurt and that lactose-free milk be used as an alternative for those who are intolerant of these other products to help reduce the risk of nutrient-related chronic diseases such as hypertension and diabetes.[57]

Milk and dairy products are often well tolerated by many children with underlying inflammatory conditions of the intestines, including Crohn disease and ulcerative colitis, in whom the prevalence of lactose intolerance does not seem to be any greater than in the general population.[58–61]

Lactose-Free Formulas

In developed countries, even in the case of acute gastroenteritis, enough lactose digestion and absorption are preserved so that low-lactose and lactose-free formulas have no clinical advantages compared with standard lactose-containing formulas except in severely undernourished children, in whom lactose-containing formu-

las may worsen the diarrhea and lactose-free formulas may be advantageous.[62] Breastfed infants should be continued on human milk in all cases.[57] This has also been reviewed recently in the American Academy of Pediatrics' practice guideline for acute gastroenteritis.[63] The use of lactase in formulas for preterm infants has been noted above. Although lactose-free cow milk–protein-based formulas are readily available and popular, no studies have documented that these formulas have any clinical impact on infant outcome measures including colic, growth, or development.[64]

Lactose, Calcium Absorption, and Bone Mineral Content

Recent evidence indicates that dietary lactose enhances calcium absorption and, conversely, that lactose-free diets result in lower calcium absorption.[65] Thus, lactose intolerance (and lactose-free diets) theoretically may predispose to inadequate bone mineralization, a problem now recognized in many other disorders affecting pediatric patients.[45,46] The effects of lactose-free diets in childhood on long-term bone mineral content and risk of fractures and osteoporosis with aging remains to be clarified. Calcium homeostasis is also affected by protein intake, vitamin D status, salt intake, and genetic and other factors, making long-term studies essential to determine the risks of each or all of these to bone health. Recent studies suggest that in the future, genetic testing may be useful for identifying individuals at increased risk of lactase deficiency and consequent diminished bone mineral density,[66] potentially allowing early intervention with dietary manipulation or nutrient supplementation. Recent research has even suggested that gene-replacement therapies might someday be available for susceptible individuals.[67]

SUMMARY

Lactose intolerance has been recognized for many years as a common problem in many children and most adults throughout the world. Although rarely life-threatening, the symptoms of lactose intolerance can lead to significant discomfort, disrupted quality of life, and loss of school attendance, leisure and sports activities, and work time, all at a cost to individuals, families, and society. Treatment is relatively simple and aimed at reducing or eliminating the inciting substance, lactose, by eliminating it from the diet or by "predigesting" it with supplemental lactase-enzyme replacement. Calcium must be provided by alternate nondairy dietary sources or as a dietary supplement to individuals who avoid milk intake.

CONCLUSIONS

1. Lactose intolerance is a common cause of abdominal pain in older children and teenagers.
2. Lactose intolerance attributable to primary lactase deficiency is uncommon before 2 to 3 years of age in all populations; when lactose malabsorption becomes apparent before 2 to 3 years of age, other etiologies must be sought.
3. Evaluation for lactose intolerance can be achieved relatively easily by dietary elimination and challenge. More-formal testing is usually noninvasive, typically with fecal pH in the presence of watery diarrhea and hydrogen breath testing.
4. If lactose-free diets are used for treatment of lactose intolerance, the diets should include a good source of calcium and/or calcium supplementation to meet daily recommended intake levels.
5. Treatment of lactose intolerance by elimination of milk and other dairy products is not usually necessary given newer approaches to lactose intolerance, including the use of partially digested products (such as yogurts, cheeses, products containing *Lactobacillus acidophilus*, and pretreated milks[56,68]). Evidence that avoidance of dairy products may lead to inadequate calcium intake and consequent suboptimal bone mineralization makes these important as alternatives to milk. Dairy products remain principle sources of protein and other nutrients that are essential for growth in children.

CLINICAL REPORT

"Late-Preterm" Infants: A Population at Risk

Guidance for the Clinician in Rendering Pediatric Care

William A. Engle, MD, Kay M. Tomashek, MD, Carol Wallman, MSN, and the Committee on Fetus and Newborn

ABSTRACT

Late-preterm infants, defined by birth at 34⁰⁄₇ through 36⁶⁄₇ weeks' gestation, are less physiologically and metabolically mature than term infants. Thus, they are at higher risk of morbidity and mortality than term infants. The purpose of this report is to define "late preterm," recommend a change in terminology from "near term" to "late preterm," present the characteristics of late-preterm infants that predispose them to a higher risk of morbidity and mortality than term infants, and propose guidelines for the evaluation and management of these infants after birth.

INTRODUCTION

Infants born at 34⁰⁄₇ through 36⁶⁄₇ weeks' gestation, or "late-preterm" infants, are often the size and weight of some term infants (born at 37⁰⁄₇–41⁶⁄₇ weeks' gestation). Because of this fact, late-preterm infants may be treated by parents, caregivers, and health care professionals as though they are developmentally mature and at low risk of morbidity. They are often managed in newborn level 1 (basic) nurseries or remain with their mother after birth.[1]

Late-preterm infants are physiologically and metabolically immature.[2–8] As a consequence, late-preterm infants are at higher risk than are term infants of developing medical complications that result in higher rates of mortality and morbidity during the birth hospitalization.[6–8] In addition, late-preterm infants have higher rates of hospital readmission during the neonatal period than do term infants.[2,4,7–9] During the last 15 years, the proportion of all US births that were late preterm increased from 7.3% in 1990 to 9.1% in 2005.[10] In 2005, late-preterm births accounted for more than 70% of all preterm births (<37 weeks' gestation), or approximately 377 000 infants.[10–12] In fact, much of the increase in the preterm birth rate in recent years can be attributed to increases in late-preterm births.[12,13]

The reason for the increase in late-preterm births during the last decade is not well understood. One hypothesis is that it may be attributable, in part, to increased use of reproductive technologies and, as a result, an increase in multifetal pregnancies.[11,14–16] Another hypothesis is that advances in obstetric practice have led to an increase in surveillance and medical interventions during pregnancy.[11,14–17] As a result, fetuses considered to be at risk of stillbirth, including those with intrauterine growth restriction, fetal anomalies, and intrapartum asphyxia, may be identified earlier, which results in more deliveries at 34 to 36 weeks' gestation. For example, between 1989 and 2003, the use of electronic fetal monitoring and prenatal ultrasonography increased substantially from 68.1% to 85.4% and 47.6% to 67%, respectively.[10] Rates of labor induction and cesarean delivery also in-

Late-preterm gestation is defined by medical convention as 34⁰⁄₇ weeks (239 days) through and including 36⁶⁄₇ weeks (259 days) after the beginning of the mother's last normal menstrual period. This is indicated in days with a red background. For comparison, term gestation spans from 37⁰⁄₇ weeks (260 days) through and including 41⁶⁄₇ weeks (294 days) after the beginning of the mother's last normal menstrual period, which is indicated in days with an aqua background.

[a] Completed week of gestation indicates the number of 7-day intervals that have passed since the beginning of the mother's last normal menstrual period. For example, the first completed week occurs after 1 seven-day interval (0⁶⁄₇th week or 7 days) has passed. The 37th completed week occurs after 37 seven-day intervals (36⁶⁄₇ weeks or 259 days) have passed.

[b] Fraction of a week indicates the days of each gestational week as a fraction. For example, the first day of gestation is the first day of the mother's 36⁰⁄₇th week of gestation and ends on the 36⁶⁄₇th week of gestation.

[c] Statistical day indicates that the first day of the mother's last menstrual period begins as day 0 and is not complete until the beginning of day 1.

[d] This statistical view of gestational age differs by 1 day from the conventional medical count of days, which indicates that the first day of the mother's last menstrual period begins as day 1. This important difference is indicated by the statistically defined days that have a gray background and conventionally defined days having no background or a red or aqua background.

creased during the last decade.[10,11] It is important to note, however, that the increased intensity of care provided to pregnant women has been accompanied by significant reductions in stillbirths, perinatal mortality, and births beyond 40 weeks' gestation.[11,14]

It is important to understand why these infants are being born early as well as the unique problems that this growing population of infants may experience. A clearer understanding of the underlying risk factors, associated etiologies, and their relative effects on delivery at 34⁰⁄₇

through 36⁶⁄₇ weeks' gestation on the mother and fetus is needed to develop interventions to prevent unnecessary late-preterm births and to improve the management of infants who are born late preterm. Thus, additional research is needed to determine the gestational age at delivery that optimally balances the risk of fetal morbidity or death against risks associated with late-preterm birth for both the mother and the fetus.

The purpose of this report is to define "late preterm," recommend a change in terminology to "late preterm" from the previously used "near term," describe the medical complications and health risks commonly encountered by late-preterm infants, suggest guidelines to identify and manage these complications and risks during the birth hospitalization and after discharge, and identify gaps in knowledge concerning the medical and developmental outcomes of these infants.

DEFINITION OF LATE PRETERM

The gestational age attributed to a newborn infant can be confusing, because the first day of a mother's last normal menstrual period is counted as either day 0 or day 1 depending on whether a statistical or conventional medical definition, respectively, is used. This difference in definition of gestational age accounts for a 1-day variation among data systems when determining the chronologic age of a newborn infant on the first day after birth (Table 1). The day of birth is counted as day 1 when using the conventional medical definition and day 0 when using the statistical definition. The use of conventional medical terminology is illustrated in the definitions of gestational age recommended by the American Academy of Pediatrics, the American College of Obstetricians and Gynecologists, and the World Health Organization.[18–20] For example, "preterm" is defined as birth that occurs on or before the end of the last day of the 37th completed week (ie, 36⁶⁄₇ weeks' gestation) after the onset of the mother's last menstrual period, which equates to 259 days in common medical terminology. The statistical definition for the last day of the 37th completed week of gestation is 258 days. Understanding these definitions is complicated further by financial systems that define the first day of age as delivery before 12:00 AM (midnight) and the subsequent day beginning immediately after 12:00 AM.

The use of the term "completed week" is also confusing. Completed weeks of gestation are defined by the number of 7-day intervals after the first day of the last menstrual period (Table 1).[5,20] For example, the end of the 37th completed week of gestation is 36⁶⁄₇ weeks' gestation, because 37 seven-day intervals (259 days) have transpired. To further clarify, the end of the 37th completed week is not 37⁶⁄₇ weeks' gestation; the beginning of the 38th week of gestation is designated as 37⁰⁄₇ weeks' gestation (260 days).[5,20]

A variety of terms have been used to describe preterm infants born at a number of different intervals between 32 and 37 weeks' gestation ("late preterm," "near term," "marginally preterm," "moderately preterm," "minimally preterm," and "mildly preterm").[2,6,12,21] In contrast, preterm, term, and postterm are mutually exclusive categories that have each been defined precisely according to week and day of gestation (counting the first day as day 1) by the American Academy of Pediatrics, the American College of Obstetricians and Gynecologists, and the World Health Organization (Fig 1).[18,19] As previously described, "preterm" is defined as a birth that occurs on or before the end of the last day of the 37th week (259th day) after the onset of the mother's last menstrual period. "Term" is defined as a birth that occurs on the first day (260th day) of the 38th week through the end of the last day of the 42nd week (294th day) after the onset of the last menstrual period (Table 1). "Postterm" describes the birth of an infant that occurs on or after the first day (295th day) of the 43rd week after the onset of the last menstrual period.

The 2005 workshop "Optimizing Care and Outcome of the Near-Term Pregnancy and the Near-Term Newborn Infant" sponsored by the National Institutes of Health recommended that infants born at 34⁰⁄₇ through 36⁶⁄₇ weeks' gestation after the onset of the mother's last menstrual period be referred to as late preterm to emphasize that these infants are preterm and, as such, are at risk of immaturity-related medical complications (Tables 2 and 3).[5] Furthermore, use of the term "near term," which connotes that the infant is almost term and,

therefore, almost fully mature, should be discouraged, because it might lead health care professionals to underestimate the inherent risks to these infants.[5,20]

Workshop members acknowledged that the definition of "late preterm" was arbitrary.[5] The day after the end of the 34th completed week of gestation (ie, 239th day or 34⁰⁄₇ weeks' gestation after the onset of the mother's last menstrual period) was recommended as the lower limit, because it is frequently used as a cutoff point for obstetric decision-making, as a criterion for admission to a level 2 or 3 NICU, and for epidemiologic and clinical research. The upper limit of gestational age for prematurity was previously established as 36⁶⁄₇ weeks' gestation (259th day after the onset of the mother's last menstrual period). Thus, it was recommended that this same upper limit be applied to the late-preterm category of infants.

DEVELOPMENTAL AND PHYSIOLOGIC IMMATURITY OF LATE-PRETERM INFANTS

Late-preterm infants have not been studied frequently, and understanding of the developmental biology and mechanisms of disease experienced by these infants is largely incomplete.[2,5,7,8,22–30] Management strategies, therefore, are based on general principles, clinical experience, and extrapolation from knowledge of very preterm and term infants. Recently, descriptive studies that detailed the epidemiology, medical problems, and risk of mortality experienced by late-preterm infants have stimulated interest in exploring the comparative biology and basic mechanisms of disease in these infants.[2–8] Several important factors that may predispose late-preterm infants to medical conditions associated with immaturity, such as respiratory distress, apnea, temperature instability, hypoglycemia, hyperbilirubinemia, and poor feeding, are reviewed briefly in this report. However, a comprehensive review of the physiologic and functional deficits that predispose late-preterm infants to these conditions is beyond the scope of this report.[5]

After birth, infants with fetal lung structure and immature functional capacity are at greatest risk of respiratory distress, need for oxygen and positive-pressure ventilation, and admission for intensive care.[2,31–33] From 34⁰⁄₇ through 36⁶⁄₇ weeks' gestation, terminal respiratory units of the lung evolve from alveolar saccules lined with both cuboidal type II and flat type I epithelial cells (terminal sac period) to mature alveoli lined primarily with extremely thin type I epithelial cells (alveolar period).[34,35] During the alveolar period, pulmonary capillaries also begin to bulge into the space of each terminal sac, and adult pool sizes of surfactant are attained.[36] Functionally, this immature lung structure may be associated with delayed intrapulmonary fluid absorption, surfactant insufficiency, and inefficient gas exchange.[24,25]

Apnea occurs more frequently among late-preterm infants than term infants. The incidence of apnea in

late-preterm infants is reported to be between 4% and 7%,[28,31,37,38] compared with less than 1% to 2% at term.[38,39] It is notable that the frequency of apneic events at term was determined by using data from cardiopulmonary monitoring of healthy infants in their homes. Apneic events were inapparent to caregivers and resolved spontaneously. The predisposition to apnea in late-preterm infants is associated with several underlying factors including increased susceptibility to hypoxic respiratory depression, decreased central chemosensitivity to carbon dioxide, immature pulmonary irritant receptors, increased respiratory inhibition sensitivity to laryngeal stimulation, and decreased upper airway dilator muscle tone.[31,38,40–42] It is also suspected that late-preterm infants may be at higher risk of centrally mediated apnea, because their central nervous systems are developmentally immature (ie, fewer sulci and gyri, less myelin) and their brains are approximately two thirds the size of a term infant's brain.[30]

Little is known about cardiovascular physiology and pathobiology in late-preterm infants; it is generally believed that structural and functional immaturity restricts the amount of cardiovascular reserve that is available during times of stress.[43,44] Immature cardiovascular function also may complicate recovery of the late-preterm infant with respiratory distress because of delayed ductus arteriosus closure and persistent pulmonary hypertension.[45]

An infant's response to cold exposure after birth is related to gestational age and is affected by the physical size, the amount of mature brown and white adipose tissue, and maturity of the hypothalamus.[46–48] Brown-fat accumulation and maturation and concentrations of hormones responsible for brown-fat metabolism (eg, prolactin, leptin, norepinephrine, triiodothyronine, cortisol) peak at term.[49,50] Thus, late-preterm infants have less white adipose tissue for insulation, and they cannot generate heat from brown adipose tissue as effectively as infants born at term. In addition, late-preterm infants are likely to lose heat more readily than term infants,

because they have a larger ratio of surface area to weight and are smaller in size.

Hypoglycemia may affect fasting newborn infants of all gestational ages because of insufficient metabolic responses to the abrupt loss of the maternal glucose supply after birth.[51–55] The incidence of hypoglycemia is inversely proportional to gestational age. Within the first 12 to 24 hours after birth, concentrations of enzymes that are essential for hepatic gluconeogenesis and hepatic ketogenesis rapidly increase. Thereafter, hypoglycemia typically resolves. Preterm infants are at increased risk of developing hypoglycemia after birth, because they have immature hepatic glycogenolysis and adipose tissue lipolysis, hormonal dysregulation, and deficient hepatic gluconeogenesis and ketogenesis. Blood glucose concentrations among preterm infants typically decrease to a nadir 1 to 2 hours after birth and remain low until metabolic pathways can compensate or exogenous sources of glucose are provided.[51,54] Carbohydrate metabolism among late-preterm infants is not well understood. However, immature glucose regulation likely occurs in late-preterm infants, because hypoglycemia that requires glucose infusion during the initial birth hospitalization occurs more frequently than in term infants.[2]

Jaundice and hyperbilirubinemia occur more commonly and are more prolonged among late-preterm infants than term infants, because late-preterm infants have delayed maturation and a lower concentration of uridine diphosphoglucuronate glucuronosyltransferase.[21,56] Late-preterm infants are 2 times more likely than term infants to have significantly elevated bilirubin concentrations and higher concentrations 5 and 7 days after birth.[21]

Late-preterm infants also have immature gastrointestinal function[57,58] and feeding difficulties that predispose them to an increase in enterohepatic circulation, decreased stool frequency, dehydration, and hyperbilirubinemia.[59–68] Feeding during the birth hospitalization may be transiently successful but not sustained after discharge. Feeding difficulties in late-preterm infants that are associated with relatively low oromotor tone, function, and neural maturation also predispose these infants to dehydration and hyperbilirubinemia.[30,67–69]

MORBIDITY AND MORTALITY AMONG LATE-PRETERM INFANTS

Late-preterm infants are at increased risk of neonatal morbidity compared with term infants. During the initial birth hospitalization, late-preterm infants are 4 times more likely than term infants to have at least 1 medical condition diagnosed and 3.5 times more likely to have 2 or more conditions diagnosed.[2] Late-preterm infants are more likely than term infants to be diagnosed during the birth hospitalization with temperature instability,[2] hypoglycemia,[2] respiratory distress,[2,24,33,70,71] apnea,[38,42] jaundice,[2] and feeding difficulties[2] (Table 2). During the first month after birth, late-preterm infants are also more likely than term infants to develop hyperbilirubinemia[21,60,72,73] and to be readmitted for hyperbilirubinemia[3,59,64] and non–jaundice-related diagnoses such as feeding difficulties and "rule-out sepsis."[3]

Some of the reported increase in morbidity among late-preterm infants may be attributable to observation and detection bias, because a clinician's threshold to monitor late-preterm infants for medical complications may be lower than their threshold for term infants. For example, a hospital-based study found that late-preterm infants were evaluated for possible sepsis 3 times as often as term infants, and the majority of evaluated late-preterm infants received antibiotic treatment, whereas term infants did not.[2] However, studies have also found that late-preterm infants are at increased risk of developing more severe illness than term infants.[2,24,70] One study of all California singleton live births who survived to 1 year of age found that infants born at 34 to 36 weeks' gestation were 3 to 9 times more likely to require mechanical ventilation than infants born at 38 weeks' gestation.[70] Late-preterm infants are also more likely than term infants to have longer initial hospital stays and to be admitted to the NICU.[2,3,33,70] One large cohort study found that 88% of infants born at 34 weeks' gestation, 54% of infants born at 35 weeks' gestation, 25% of infants born at 36 weeks' gestation, 12% of infants born at 37 weeks' gestation, and 2.6% of infants born at 38 through 40 weeks' gestation were admitted to a NICU.[3]

Severity of illness is also reflected in the increased risk of mortality among late-preterm infants compared with term infants in the United States.[6,10] In 2002, the neonatal mortality rate (deaths among infants 0–27 days' chronologic age) for late-preterm infants was 4.6 times higher than the rate for term infants (4.1 vs 0.9 per 1000 live births, respectively). This difference in neonatal mortality has widened slightly since 1995, when there was a fourfold difference in rates between late-preterm and term infants (4.8 vs 1.2 per 1000 live births, respectively). The infant mortality rate was also higher among late-preterm infants than term infants in 2002 (7.7 vs 2.5 per 1000 live births, respectively). This threefold difference has remained relatively constant since 1995, at which time the infant mortality rate was 9.3 per 1000 live births among late-preterm infants and 3.1 per 1000 live births among term infants.

Several case-control studies designed to evaluate risk factors for neonatal hospital readmission after the birth hospitalization have identified late-preterm birth as a significant risk factor.[62,63,65,68,74] Studies that compared neonatal hospital readmission rates among late-preterm infants and other groups of infants, including term infants, have found that late-preterm infants are more likely to be readmitted than are term infants (Table 3).[3,4,8,24,59] A large study in the United Kingdom found that infants born at 35 through 37 weeks' gestation were

1.7 times more likely to be readmitted during the neonatal period than were infants born at 38 through 40 weeks' gestation (adjusted odds ratio: 1.7; 95% confidence interval: 1.2–2.6).[4] A retrospective cohort study of all newborn infants who survived to discharge at 7 hospitals within a large managed care organization found that 4.4% of all late-preterm infants were readmitted within 2 weeks after the birth hospitalization, compared with 3.0% of infants less than 34 weeks' gestation and 2.0% of infants born at or after 37 weeks' gestation.[3] Late-preterm infants who were never admitted to the NICU were at the highest risk of rehospitalization. This study also found that having a home visit or a scheduled outpatient visit within 72 hours after discharge was associated with a decreased risk of rehospitalization. In addition, a population-based study found that late-preterm infants who were not admitted to the NICU after birth were 2 to 3 times more likely than term infants to be rehospitalized for hyperbilirubinemia.[59]

Late-preterm infants with short NICU stays may be at increased risk of hospital readmission after the birth hospitalization compared with all other NICU survivors. A study that assessed outcomes among all newborn infants discharged alive from 6 NICUs within a large managed care organization found that preterm infants of 33 to 36 weeks' gestation with a hospital stay of less than 4 days had higher hospital readmission rates than all other groups, including the most preterm group.[66] The reason for readmission for the majority of these late-preterm infants was jaundice (71%), followed by suspected sepsis (20%) and feeding difficulties (16%).

Late-preterm infants who are discharged early (<2-night hospital stay) from the hospital after a vaginal delivery may be at increased risk of neonatal morbidity compared with term infants who are discharged early.[8] A population-based study that compared rates of postdischarge neonatal morbidity between singleton late-preterm and term infants who were discharged early found that 4.3% and 2.7% of infants, respectively, were either readmitted or had an observational stay; 3.5% and 2.0%, respectively, were readmitted. Jaundice and infection accounted for 77.1% of readmissions among late-preterm infants and 60.3% of readmissions among term infants. In this study, breastfed late-preterm infants were 1.8 times more likely to require hospital-related care and 2.2 times more likely to be readmitted than breastfed term infants. In contrast, there was no difference in need for subsequent hospital-related care or readmission between nonbreastfed late-preterm and term infants.

Several factors have been identified to be associated with an increased risk of hospital readmission, an observational hospital stay, or severe morbidity among late-preterm infants. A population-based cohort study of healthy, singleton late-preterm infants delivered vaginally in Massachusetts hospitals between 1998 and 2002 found that 6.1% received hospital care after the birth hospitalization or died during the neonatal period.[7] Risk factors for requiring hospital care or experiencing morbidity included being the first born, being breastfed at discharge, having a mother who had labor and delivery complications, being a recipient of public insurance at delivery, or being of Asian/Pacific Island descent.[7,9]

Although it is known that late-preterm infants are at increased risk compared with term infants for infant mortality, morbidity during the initial birth hospitalization, and neonatal morbidity that requires hospital readmission, the long-term health consequences of being born late preterm are not yet known.[75] Small clinical reports that compared late-preterm infants with term infants suggested a higher risk of cerebral palsy,[76] speech disorders,[77,78] neurodevelopmental handicaps,[78] behavioral abnormalities,[79] and competence (behavioral, scholastic, social, and global).[75,79–81] Given that late-preterm infants are born before their nervous systems have fully developed, large population studies that evaluate long-term neurodevelopmental and behavioral outcomes of these children are needed.[75]

The emotional, personal, and financial costs to individuals, family, and society associated with late-preterm births have not been sufficiently described.[82] A conservative estimate for the long-term medical, educational, and productivity costs associated with the birth of all infants before 37 weeks' gestation is approximately $51 600 for each infant or a total cost of $26.2 billion in 2005 dollars. Individual late-preterm infants, on average, require fewer financial and other resources than infants who are born more preterm. However, the total resources and costs associated with late-preterm birth are likely to be a relatively substantial part of the total cost of all preterm births, because the population of late-preterm infants is significantly larger than the population of infants who are born before 34 weeks' gestation.

Collaborative counseling by neonatal and obstetric clinicians about fetal, neonatal, and maternal outcomes is warranted when maternal or fetal conditions indicate the necessity for late-preterm birth. The obstetric clinician can discuss the indications for the delivery and the risks inherent in delaying delivery. The neonatal clinician can provide the family with gestational age-specific outcome information and help prepare the family for the newborn infant's anticipated course in the nursery. Collaborative counseling allows the family to be fully informed and to participate in decision-making. Under emergent conditions, the time to provide such counseling may not exist.

SUMMARY

1. Late-preterm infants are immature.
    a. Infants born at 34 0/7 through 36 6/7 weeks' gestation (239–259 days since the first day of the last

menstrual period) should be referred to as "late preterm."

   b. Late-preterm infants are physiologically immature and have limited compensatory responses to the extrauterine environment compared with term infants.

2. Late-preterm infants are at a greater risk of morbidity and mortality than are term infants.

   a. During the birth hospitalization, late-preterm infants are more likely than are term infants to be diagnosed with temperature instability, hypoglycemia, respiratory distress, apnea, jaundice, or feeding difficulties.

   b. During the first month after birth, late-preterm infants are more likely than term infants to be rehospitalized for jaundice, feeding difficulties, dehydration, and suspected sepsis.

3. Risk factors that have been identified for rehospitalization or neonatal morbidity among late-preterm infants include being the first born, being breastfed at discharge, having a mother who had labor and delivery complications, being a recipient of public insurance at delivery, and being of Asian/Pacific Island descent.

4. Collaborative counseling by both obstetric and neonatal clinicians about the outcomes of late-preterm births is warranted unless precluded by emergent conditions.

Gaps in Knowledge, Clinical Implications, and Research Implications for Late-Preterm Births

The following are areas in which knowledge and research need to be expanded:

1. causes for delivery and short-term fetal, neonatal, and maternal outcomes;
2. developmental immaturity and mechanisms of disease in late-preterm infants;
3. identification tools, educational programs, and screening strategies to identify risk factors and prevent potential medical complications of late-preterm births;
4. recommendations for discharge, early follow-up evaluation, and treatment for jaundice, poor feeding, dehydration, and other complications in late-preterm infants; and
5. long-term medical, neurologic, and developmental outcomes for late-preterm infants.

Recommended Minimum Criteria for Discharge of Late-Preterm Infants

Discharge criteria for late-preterm infants have similarities to criteria developed for both high-risk infants and healthy term infants.[82] Because late-preterm infants are at greater risk of neonatal morbidity and mortality than are term infants, parents of late-preterm infants may need special instruction and guidance before hospital discharge and closer follow-up after discharge. Late-preterm infants who have risk factors for morbidity that requires hospital care (ie, hospital readmission), such as those who are breastfed or are first born, are most vulnerable. It is especially important to educate first-time mothers of late-preterm infants how to evaluate feeding success and what signs to look for to detect dehydration and hyperbilirubinemia. In some circumstances, this education may require a longer birth hospitalization.

Recommended criteria for discharge of late-preterm infants are intended to reflect evidence of physiologic maturity; feeding competency; thermoregulation; maternal education; assessment and planned interventions for medical, family, environmental, and social risk factors; and follow-up arrangements.

Minimum discharge criteria for late-preterm infants are as follows:

1. Accurate gestational age has been determined.[83,84]
2. Timing of discharge is individualized and based on feeding competency, thermoregulation, and absence of medical illness and social risk factors (see below). Late-preterm infants usually are not expected to meet the necessary competencies for discharge before 48 hours of birth.[85]
3. A physician-directed source for continued medical care (ie, medical home) has been identified, with a follow-up visit arranged for 24 to 48 hours after hospital discharge. Additional visits may be indicated until an established and maintained pattern of weight gain has been demonstrated.[86,87]
4. Vital signs should be documented as being within reference ranges and stable for the 12 hours preceding discharge, including a respiratory rate of less than 60 breaths per minute, a heart rate of 100 to 160 beats per minute, and axillary temperature of 36.5 to 37.4°C (97.7–99.3°F) measured in an open crib with appropriate clothing.[85]
5. At least 1 stool has been passed spontaneously.[85]
6. Twenty-four hours of successful feeding, either at the breast or with a bottle, and the ability to coordinate sucking, swallowing, and breathing while feeding has been demonstrated. Any infant with a weight loss of more than 2% to 3% of birth weight per day or a maximum of 7% of birth weight during the birth hospitalization should be assessed for evidence of dehydration before discharge.[85,88–90]
7. A formal evaluation of breastfeeding, including observation of position, latch, and milk transfer, has been undertaken and documented in the chart by trained caregivers at least twice daily after birth.[90,91]

8. A feeding plan has been developed and is understood by the family.[86]
9. A risk assessment for the development of severe hyperbilirubinemia has been performed and appropriate follow-up has been arranged.[88]
10. Physical examinations of the infant reveal no abnormalities that require continued hospitalization.[85]
11. There is no evidence of active bleeding at the circumcision site for at least 2 hours.[85]
12. Maternal and infant test results are available and have been reviewed, including blood test results for maternal syphilis and hepatitis B surface-antigen status; cord or infant blood type and direct Coombs test results, as clinically indicated; and results of screenings performed in accordance with state regulations, including screening for HIV infection.[85,92]
13. Initial hepatitis B vaccine has been administered or an appointment has been scheduled for its administration, and the importance of immunizations has been stressed.[85]
14. Metabolic and genetic screenings have been performed in accordance with state requirements. If a newborn screening is performed before 24 hours of milk feeding, a system for repeating the screening must be in place in accordance with state policy.[93]
15. A car safety seat study completed by a trained professional to observe for apnea, bradycardia, or oxygen desaturation has been passed.[94]
16. Hearing assessment has been performed and the results have been documented in the medical chart. Results have been discussed with family or caregivers. If follow-up is needed, follow-up plans have been outlined.[95]
17. Family, environmental, and social risk factors have been assessed. When risk factors are identified, the discharge should be delayed until they are resolved or a plan to safeguard the infant is in place. Such risk factors may include but are not limited to:
    a. untreated parental substance use or positive toxicology test results in the mother or newborn infant;
    b. history of child abuse or neglect;
    c. mental illness in a parent in the home;
    d. lack of social support, particularly for single, first-time mothers;
    e. homelessness, particularly during this pregnancy;
    f. ongoing or established risk of domestic violence; or
    g. adolescent mother, particularly if other risk factors are present.[85]
18. The mother and caregivers have received information or training or have demonstrated competency in the following:
    a. infant's hospital course and current condition;
    b. expected pattern of urine and stool frequency for the breastfeeding or formula-fed neonate (verbal and written instruction is recommended);
    c. umbilical cord, skin, and newborn genital care;
    d. hand hygiene, especially as a means to reduce the risk of infection;
    e. use of a thermometer to assess an infant's axillary temperature;
    f. assessment and provision of appropriate layers of clothing;
    g. identification of common signs and symptoms of illness, such as hyperbilirubinemia, sepsis, and dehydration;
    h. assessment for jaundice;
    i. provision of a safe sleep environment, including positioning the infant on his or her back during sleep[96];
    j. newborn safety issues including car safety seat use, need for smoke/fire alarms, and hazards of secondhand tobacco smoke and environmental pollutants;
    k. appropriate responses to a complication or an emergency; and
    l. sibling interactions and appropriate inclusion in care responsibilities.

Lawn Mower-Related Injuries to Children

ABSTRACT. Lawn mower-related injuries to children are relatively common and can result in severe injury or death. Many amputations during childhood are caused by power mowers. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries.

ABBREVIATION. ANSI/OPEI, American National Standards Institute and Outdoor Power Equipment Institute.

BACKGROUND

Each year in the United States, approximately 9400 children younger than 18 years receive emergency care for lawn mower-related injuries. Although most of these injuries occur to older children and adolescents, about one fourth are to children younger than 5 years. Males account for approximately three fourths of these injuries. Ride-on mowers and other power mowers account for 21% and 23% of pediatric mower-related injuries, respectively.[1] More than 7% of pediatric mower-related injuries require hospitalization, which is approximately twice the hospitalization rate for consumer product-related injuries overall. Amputations and avulsions account for 7% of pediatric mower-related injuries.[1] Power lawn mowers caused 22% of the amputation injuries among children admitted to one regional level 1 trauma center.[2] Additional details regarding pediatric lawn mower-related injuries are available in the technical report available online.[3]

PREVENTION OF INJURY

Prevention of lawn mower-related injuries can be achieved by 1) design changes of lawn mowers to enhance safety, 2) appropriate age and maturity guidelines for mower operation, and 3) education of parents, other child caregivers, and children regarding the hazards associated with lawn mowers. Details are included in the technical report available online.[3]

Age and Maturity Guidelines for Lawn Mower Operation

No age-specific criteria for use of lawn mowers have been established by the industry or government. However, children should not operate lawn mowers until they have displayed appropriate levels of judgment, strength, coordination, and maturity necessary for their safe operation. They should also receive a period of operational training, safety instruction, and supervision by an adult before they are allowed to operate a mower by themselves. Because of the complexities involved in safe operation, a prudent guideline for the minimum age for operation of lawn mowers by children is at least 16 years for ride-on mowers and at least 12 years for walk-behind power mowers and hand mowers.

A patient safety sheet for distribution to families is available online.

RECOMMENDATIONS

1. Young children must not be allowed to play in or be adjacent to areas where lawn mowers are being used. Children younger than 6 years should be kept indoors during mowing.
2. Children must not be allowed to ride as passengers on mowers or to be towed behind mowers in carts or trailers. They should not be permitted to play on or around the mower when it is in use or in storage.
3. Children should not operate lawn mowers until they have displayed the necessary levels of judgment, strength, coordination, and maturity. They should also be educated in mower operation and safety and be supervised by an adult before they are allowed to operate a mower by themselves. Most children will not be ready to operate a walk-behind power mower or hand mower until at least 12 years of age or a ride-on mower until at least 16 years of age.
4. Additional research regarding the circumstances and contributing factors of lawn mower-related injuries is needed, especially injuries involving mower instability or situations in which a person has been run over or backed over.
5. Strengthening of the voluntary standard of the American National Standards Institute and Outdoor Power Equipment Institute (ANSI/OPEI B71.1) is needed, for example, by requiring manufacturers to design ride-on lawn mowers that will not mow in reverse, with a manual override option. If adequate levels of safety cannot be achieved voluntarily, a mandatory federal safety standard may be necessary.
6. Designs for mower controls should continue to be improved for ease of operation and to minimize inadvertent control contact and unintended operation.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

P² Online version of this article contains a PDF of "Parent Pages," which can be used as a handout for patient education.

PEDIATRICS (ISSN 0031 4005).

7. Evaluation is needed of the effectiveness of education programs and curricula for lawn mower operators, as well as the effectiveness of public awareness and education initiatives regarding lawn mower safety.

Technical Report: Lawn Mower-Related Injuries to Children

ABSTRACT. In the United States, approximately 9400 children younger than 18 years receive emergency treatment annually for lawn mower-related injuries. More than 7% of these children require hospitalization, and power mowers cause a large proportion of the amputations during childhood. Prevention of lawn mower-related injuries can be achieved by design changes of lawn mowers, guidelines for mower operation, and education of parents, child caregivers, and children. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. *Pediatrics* **2001; 107(6). ABBREVIATIONS. CPSC, US Consumer Product Safety Commission; ANSI/OPEI, American National Standards Institute and Outdoor Power Equipment Institute.

BACKGROUND

In the United States, an estimated 68 000 injuries related to lawn mowers (including hand mowers, walk-behind power mowers, and ride-on power mowers, but excluding garden tractors) were treated annually in hospital emergency departments from 1990 through 1999. Approximately 14% of these injuries occur to children younger than 18 years, accounting for an estimated 9400 injuries annually.[1] Ride-on mowers and other power mowers account for 21% and 23% of pediatric mower-related injuries, respectively. The type of lawn mower is not specified in 54% of cases, and hand mowers account for 2% of mower-related injuries to children.[1] Twenty-four percent of pediatric mower-related injuries occur in children younger than 5 years; 36% occur in 5- to 12-year-olds; and 40% occur in 13- to 17-year-olds. The age distribution of these injuries is bimodal, with peaks around 2 and 15 years. Males account for approximately three fourths of these injuries.[1] More than 7% of pediatric mower-related injuries require hospitalization,[1] which is approximately twice the hospitalization rate for consumer product-related injuries overall. Lacerations account for 41% of pediatric mower-related injuries, followed by soft-tissue injuries such as sprains, strains, contusions, and abrasions (20%); burns (14%), fractures, and dislocations (11%); amputations and avulsions (7%); and foreign bodies (3%). Body parts that may be injured include the hands and fingers (31%), legs (19%), feet and toes (18%), head (18%), and arms (7%).[1] Power lawn mowers caused 22% of the amputation injuries among children admitted to one regional level 1 trauma center.[2]

INJURIES RELATED TO RIDE-ON MOWERS

In the United States, ride-on mowers (including riding mowers, lawn tractors, and garden tractors) are commonly used for mowing lawns and fields. An estimated 10.3 million of these mowers were in operation in 1992.[3] They are larger, more powerful, and more mechanically complex to operate than walk-behind lawn mowers. As a consequence, the risk of injury and possible death to children from these vehicles is high compared with that from walk-behind mowers.

In the United States between 1991 and 1993, an estimated 26 800 injuries related to ride-on mowers were treated annually in hospital emergency departments, representing an annual injury rate of 2.6 injuries per 1000 ride-on mowers.[3] This injury rate is more than 3 times greater than that for walk-behind power mowers. In contrast to the decline in the annual injury rate for walk-behind power mowers, the injury rate for ride-on mowers showed no significant change during the 11-year period from 1983–1993.[4] Twenty percent of injuries related to ride-on mowers occur in children 15 years or younger, and approximately 12% of these children require hospitalization.[5] The hospitalization rate is 9% for all ages. Two thirds of the injuries occur when mowers are in use (during mowing, driving, or operating attachments); the remainder of injuries occur when mowers are being maintained or repaired, loaded or unloaded, or played on when not in use. More than half of all injuries related to ride-on mowers occur to operators, and 9% of the injured operators are 14 years or younger. The rate of injury for 5- to 14-year-old operators is more than twice that for 15- to 64-year-olds.[5] Approximately 8% of deaths related to ride-on mowers involve passengers or bystanders, whose average ages are 6 and 4 years, respectively.[5] Infants and children younger than 6 years and children and adolescents 6 to 15 years of age each accounted for 6% of all deaths related to ride-on mowers from 1987 through 1990.[6] The 1993 US Consumer Product Safety Commission (CPSC) report[5] on ride-on mower hazards identified 4 key injury mechanisms: loss of mower stability, blade contact, layout and function of the mower controls (ie, location on mower), and running over or backing over young children.

Approximately 13% of injuries that occur during ride-on mower use are associated with loss of mower stability, accounting for an estimated 2200 injuries annually. Approximately 20% of these injuries require hospitalization.[5] Since July 1987, the lawn

mower voluntary standard of the American National Standards Institute and Outdoor Power Equipment Institute (ANSI/OPEI B71.1)[7] has addressed ride-on mowers tipping over as a result of sudden traction after quick release of the clutch. This standard states that the wheels of the mower cannot lift more than 10° off of level ground when there is a quick release of the clutch. Turning stability is also addressed in the current standard,[8] stating that wheel lift-off will not exceed 5° when the mower performs a maximum turn maneuver while traveling at maximum governed speed on level ground. In 1994, the CPSC abandoned efforts to develop a dynamic stability test on a slope for ride-on mowers.[9]

Approximately 12% of injuries that occur during ride-on mower use are associated with blade contact, accounting for an estimated 2000 injuries per year. Approximately 10% of these injuries require hospitalization.[5] Since July 1987, the lawn mower voluntary standard[7] has required an operator-presence control device on ride-on mowers that automatically stops the blades if the operator leaves the operating position. This type of safety device, often called a "dead man control," is also required on rotary walk-behind power mowers.[10]

Approximately 7% of injuries that occur during ride-on mower use are associated with problems in the layout and function of mower controls that can, for example, result in inadvertent control contact and unintended operation. These problems account for an estimated 1200 injuries per year, and about 14% of these injuries require hospitalization.[5]

Approximately 5% of injuries that occur during ride-on mower use (an estimated 850 injuries annually) and 7% of deaths related to ride-on mowers occur when a person is run over or backed over. Approximately 85% of these injuries occur in children between 15 months and 10 years of age while they are playing in the area being mowed (76% of cases) or after they fall from or jump off of a mower (24%). One third of injured individuals require hospitalization for treatment of serious injuries from blade contact.[5] Injuries from back overs occur approximately twice as often as injuries from run overs.[9] Ride-on mowers can be designed to disengage the blades when the mower is backing up, preventing the machine from mowing in reverse. This feature could help reduce the number of injuries from back overs involving blade contact. A manual switch can be provided to override this feature, but the default setting would be reactivated when the mower is shifted out of reverse.

INJURIES RELATED TO WALK-BEHIND MOWERS

In 1992, there were an estimated 44.2 million walk-behind mowers in use. The annual injury rate was 0.7 per 1000 mowers in use during the years 1983 through 1993, and there was a significant decline in this rate during this time period that resulted in a decrease of 3100 injuries per year.[4] The mean age of children with injuries from walk-behind power mowers is 9 years, and 74% are male. Almost 5% of children who experience injuries from walk-behind power mowers require hospitalization.[1] Among children, a statistically significant association exists between injury to the hands and fingers or feet and toes and walk-behind power mowers when compared with other types of mowers. There is also an association between walk-behind power mowers and amputation or avulsion injuries, and a strong association between these mowers and burns.[1]

PREVENTION OF INJURY

Lawn mower-related injuries to children are relatively common and can result in severe injury and death. Prevention of these injuries can be achieved by 1) design changes of lawn mowers to enhance safety, 2) appropriate age and maturity guidelines for mower operation, and 3) education of parents, other child caregivers, and children regarding the hazards associated with lawn mowers.

Lawn Mower Safety Design

The science of injury prevention recognizes that the most effective prevention strategies are those that do not require frequent human action and vigilance.[11] Therefore, automatic protection provided by safe product design offers the best solution for prevention of lawn mower-related injuries. Changes to the voluntary standard ANSI/OPEI B71.1 and improvements in ride-on mower design led to significant decreases in injury rates related to blade contact and control layout during the period from 1983 through 1993. However, similar declines did not occur in injury rates related to mower instability and incidents that involved running over or backing over a person.[4] These findings indicate a need for additional evaluation of the circumstances of injury for those cases and development and implementation of design changes to ride-on lawn mowers to prevent those injuries. A mandatory standard for rotary walk-behind power lawn mowers[10] went into effect in July 1982, and a significant decline in the annual injury rate related to these machines subsequently occurred.[4]

Age and Maturity Guidelines for Lawn Mower Operation

No age-specific criteria for use of lawn mowers have been established by the industry or government. However, children should not operate lawn mowers until they have displayed appropriate levels of judgment, strength, coordination, and maturity necessary for their safe operation. They should also receive a period of operational training, safety instruction, and supervision by an adult before they are allowed to operate a mower by themselves. Because of the complexities involved in safe operation, a prudent guideline for the minimum age for operation of lawn mowers by children is at least 16 years for ride-on mowers and at least 12 years for walk-behind power mowers and hand mowers.

Education

In 1985, a curriculum[12] was developed by the American Red Cross to provide children 12 years and older with the knowledge and skills for safe operation of power lawn mowers, but no evaluation

of the effectiveness of this curriculum has been done to determine if mower-related injuries decreased as a result. Lawn mower operators, parents, and other child caregivers also should be educated about the hazards that lawn mowers present to children and how to prevent these injuries.

OPPORTUNITIES FOR PREVENTION

The following are important opportunities for prevention of lawn mower-related injuries available to pediatricians, researchers, the public health community, manufacturers, and others:

1. Additional research regarding the circumstances and contributing factors of lawn mower-related injuries is needed, especially injuries involving mower instability or situations in which a person has been run over or backed over.
2. Strengthening of the voluntary standard (ANSI/OPEI B71.1) is needed, for example, by requiring manufacturers to design ride-on lawn mowers that will not mow in reverse, with a manual override option. If adequate levels of safety cannot be achieved voluntarily, a mandatory federal safety standard may be necessary.
3. Designs for mower controls should continue to be improved for ease of operation and to minimize inadvertent control contact and unintended operation.
4. Young children must not be allowed to play in or be adjacent to areas where lawn mowers are being used. Children younger than 6 years should be kept indoors during mowing.
5. Children must not be allowed to ride as passengers on mowers or to be towed behind mowers in carts or trailers. They should not be permitted to play on or around the mower when it is in use or in storage.
6. Children should not operate lawn mowers until they have displayed the necessary levels of judgment, strength, coordination, and maturity. They should also be educated in mower operation and safety and be supervised by an adult before they are allowed to operate a mower by themselves. Most children will not be ready to operate a walk-behind power mower or hand mower until at least 12 years of age or a ride-on mower until at least 16 years of age.
7. Evaluation is needed of the effectiveness of education programs and curricula for lawn mower operators, as well as the effectiveness of public awareness and education initiatives regarding lawn mower safety.

Advice pediatricians may provide to parents is specified in the accompanying policy statement,[13] along with a patient education sheet for duplication and distribution.

abstract

Learning disabilities, including reading disabilities, are commonly diagnosed in children. Their etiologies are multifactorial, reflecting genetic influences and dysfunction of brain systems. Learning disabilities are complex problems that require complex solutions. Early recognition and referral to qualified educational professionals for evidence-based evaluations and treatments seem necessary to achieve the best possible outcome. Most experts believe that dyslexia is a language-based disorder. Vision problems can interfere with the process of learning; however, vision problems are not the cause of primary dyslexia or learning disabilities. Scientific evidence does not support the efficacy of eye exercises, behavioral vision therapy, or special tinted filters or lenses for improving the long-term educational performance in these complex pediatric neurocognitive conditions. Diagnostic and treatment approaches that lack scientific evidence of efficacy, including eye exercises, behavioral vision therapy, or special tinted filters or lenses, are not endorsed and should not be recommended. *Pediatrics* 2009;124:837–844

BACKGROUND

Reading is the process of extracting meaning from written symbolic characters. In elementary school, a large amount of time and effort is devoted to the complicated task of learning to read. Because of the difficulties that some children experience with learning to read, Congress mandated that the Eunice Kennedy Shriver National Institute of Child Health and Human Development assemble a national panel of educators and scientists to review the literature to research the optimal methods of teaching children to read. The 2000 report of the National Reading Panel titled "Teaching Children to Read: An Evidence-Based Assessment of the Scientific Research Literature on Reading and Its Implications for Reading Instruction"[1] linked research findings with recommendations for specific approaches to teaching reading to all children.

Learning disabilities remain a concern for the children and families involved and for the public. The inability to read and comprehend is a major obstacle to learning, which may have long-term educational, social, and economic consequences. Depending on the definition chosen, 5% to 17.5% of people in the United States have a learning disability, with an estimated 2.6 million children aged 6 to 11 years affected.[2] Learning disabilities often prevent children from reaching their full potential. They may cause children to have difficulty learning to listen,

speak, read, spell, write, reason, concentrate, solve mathematical problems, and organize information. These children may also have difficulty mastering social skills or motor coordination. Learning difficulties are frequently associated with and complicated by attention-deficit/hyperactivity disorder.[2] Left untreated, learning difficulties may lead to frustration, low self-confidence, and poor self-esteem and substantially increase the risk of developing psychological and emotional problems.[3]

Approximately 80% of people with learning disabilities have dyslexia.[2,4–7] The terms "reading disability" and "dyslexia" are often used interchangeably in the literature.[8] Dyslexia is a primary reading disorder and results from a written word processing abnormality in the brain.[2,4] It is characterized by difficulties with accurate and/or fluent sight word recognition and by poor spelling and decoding abilities. These difficulties are unexpected in relation to the child's other cognitive skills. Dyslexia has been identified as having a strong genetic basis.[2,8,9] Recent genetic-linkage studies have identified many loci at which dyslexia-related genes are encoded. Approximately 40% of siblings, children, or parents of an affected individual will have dyslexia. Although dyslexia is often inherited, it may exist in the absence of a family history. Dyslexia can be mild or severe, occurs throughout the world, seems to affect boys more than girls,[10] involves children with all levels of intelligence, and can persist for a lifetime.[2,4,5,8,11,12] Dyslexia is identified in some people early in their lives but in others is not diagnosed until much later, when more complex reading and writing skills are required. People with dyslexia can be very bright and may be gifted in math, science, the arts, or even in unexpected areas such as writing.[12] Dyslexia should be separated from other secondary forms of reading difficulties caused by visual or hearing disorders, mental retardation, and experiential or instructional deficits.[2,8] Early reading difficulties may be caused by experiential and instructional deficits.[8] It is important to identify and address such causes of secondary reading difficulties.[5,8]

Oral language development has been found to play a critical role in learning to read.[1] Unlike speaking, reading and writing do not develop naturally and require active learning. Reading is more difficult than speaking, because children must be aware of the sound structure in spoken language and then break the alphabetic code to acquire the sound/symbol connection.

English is a phonemically complex language in which the 26 letters of the alphabet create 44 sounds, or phonemes, in approximately 70 letter combinations.[6,7,13] The phonemic complexity of an alphabet-based language corresponds to the prevalence of dyslexia, pointing to the linguistic origin of dyslexia.[8,14] Reading involves the integration of multiple factors related to a person's experience, ability, and neurologic functioning. Most people with dyslexia have a neurobiological deficit in the processing of the sound structure of language, called a phonemic deficit,[1,2,4–8,11,13,15] which exists despite relatively intact overall language abilities.[2,4–7] Children with more severe forms of dyslexia may have a second deficit in naming letters, numbers, and pictures, creating a double deficit,[8,16] or they may have problems with their attention or working memory.[8] Other children may have trouble orienting, recognizing, and remembering letter combinations.[8,17] This difficulty may be a neuromaturational delay that improves with development. Importantly, the definition of dyslexia does not include reversal of letters or words or mirror reading or writing, which are commonly held misconceptions.[8,12,14]

Research has shown that most children and adults with reading disabilities experience a variety of problems with language[1,2,4–8,11,13] that stem from altered brain function.[2,4,8,18–29] There is solid scientific evidence that supports the neurologic basis for the phonological coding deficit theory of reading disabilities.[2,4–8,18–29] Scientific research using functional MRI studies and positron emission tomography scans has shown that reading takes place predominantly in left-hemisphere sites including the inferior frontal, superior temporal, parietotemporal, and middle temporal-middle occipital gyri in typical readers. Children with dyslexia, on the other hand, use different areas of the brain when reading.[2,4,18–29] People with dyslexia demonstrate a dysfunction in the left-hemisphere posterior reading systems and show compensatory use of the inferior frontal gyri of both hemispheres and the right occipitotemporal area.[2,4,18–29] People with dyslexia have an abnormality in the word-analysis pathways that interferes with their ability to convert written words into spoken words. These dyslexia-specific brain abnormalities have been shown to improve after successful phonologically based intervention.[19,28,29]

THE ROLE OF THE VISUAL SYSTEM AND THE EYES

Visual processing is a higher cortical function.[8,30] Decoding and interpretation of retinal images occur in the brain after visual signals are transmitted from the eyes. Reading print involves adequate vision and the neurologic ability to identify what is seen. Although vision is fundamental for reading, the brain must interpret the incoming visual images. Historically, many theories have implicated defects in the visual system as a cause of dys-

lexia. We now know these theories to be untrue. Improved understanding began with a series of related studies that systematically demonstrated that deficits in visual processes, such as visualization, visual sequencing, visual memory, visual perception, and perceptual-motor abilities, were not basic causes of reading difficulties.[8] Difficulties in maintaining proper directionality have been demonstrated to be a symptom, not a cause, of reading disorders.[8,30,31] Word reversals and skipping words, which are seen in readers with dyslexia, have been shown to result from linguistic deficiencies rather than visual or perceptual disorders.[8]

Specific reading disability in a small subset of patients with dyslexia has been attributed by some researchers to a deficit in the magnocellular visual system.[32–35] The visual system comprises 2 parallel systems: the magnocellular system and the parvocellular system.[32] The magnocellular system responds to high temporal frequency and object movement, and the parvocellular system is sensitive to low-frequency and fine spatial details.[32] It has been proposed that a magnocellular system deficit produces a visual trace of abnormal longevity that creates a masking effect and causes visual acuity blurring when reading connected text in some children with dyslexia.[35] There are study results that support this theory[32–35] and others that refute it.[36–44] Many researchers have concluded that magnocellular system deficits and associated visual trace persistence are not a significant cause of specific reading disability.[8,36–43] At the present, there is insufficient evidence to base any treatment on this possible deficit.

Short-duration, high-velocity, small jumping eye movements called saccades are used for reading. Readers with dyslexia characteristically have saccadic eye movements and fixations similar to the beginning reader but show normal saccadic eye movements when content is corrected for ability.[30,31] The saccadic patterns seen in readers with dyslexia seem to be the result, not the cause, of their reading disability.[30,31,45,46] Decoding and comprehension failure, rather than a primary abnormality of the oculomotor control systems, is responsible for slow reading, increased duration of fixations, and increased backward saccades.[46] Children with dyslexia often lose their place while reading because they struggle to decode a letter or word combination and/or because of lack of comprehension, not because of a "tracking abnormality." Improving reading has been shown to change saccadic patterns, but there has been no evidence to suggest that saccadic training results in better reading. Finally, children with saccadic disorders do not show an increased likelihood of dyslexia.[47] As indicated above, dyslexia is not correlated with eye or eye-movement abnormalities.[8,30,31,45–59]

Other conditions may affect reading. Convergence insufficiency and poor accommodation, both of which are uncommon in children, can interfere with the physical act of reading but not with decoding.[14] Thus, treatment of these disorders can make reading more comfortable and may allow reading for longer periods of time but does not directly improve decoding or comprehension.[14]

Numerous studies have shown that children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions.[8,30,31,45,46,48–59] Specifically, subtle eye or visual problems, including visual perceptual disorders, refractive error, abnormal focusing, jerky eye movements, binocular dysfunction, and misaligned or crossed eyes, do not cause dyslexia.[8,30,31,45,46,48–59] In summary, research has shown that most reading disabilities are not caused by altered visual function.[8,30,31,45,46,48–59]

Many children with reading disabilities enjoy playing video games, including handheld games, for prolonged periods. Playing video games requires concentration, visual perception, visual processing, eye movements, and eye-hand coordination. Convergence and accommodation are also required for handheld games. Thus, if visual deficits were a major cause of reading disabilities, children with such disabilities would reject this vision-intensive activity.

EARLY DETECTION

A family history of learning disabilities should keep parents, teachers, and physicians alert to this possibility. A history of delay or difficulty in developing speech and language, learning rhymes, or recognizing letters and sound/symbol connections may be an early indication of dyslexia.[2,4,5,8] Parents or teachers may detect early signs of learning difficulties in preschool-aged children; however, in most cases, learning disabilities are not discovered until children experience academic difficulties in elementary school.[2,4] The child may have difficulty with reading, spelling, handwriting, remembering words, or performing mathematical computation. Because remediation is more effective during the early years, prompt diagnosis is important.[1,2,4–8,13,15,60] The effect that dyslexia has may be different for each person and depends on the severity of the condition and the effectiveness and timeliness of instruction or remediation.

THE ROLE OF EDUCATION

The educational system has the triple responsibility of early detection, evaluation, and treatment of chil-

dren with learning disabilities. Elementary school teachers are often the first to detect learning difficulties. Assessments for difficulties with alphabet recognition in kindergarten and difficulties with phonemic awareness and rapid naming in kindergarten and first grade can predict many of those who will have difficulty learning to read.[1,2,5–8,13,15] Because early reading difficulties may be caused primarily by experiential and instructional deficits, there are 2 approaches that can be used in the young underachieving child.[8] In the traditional approach, the child would need to show significant underachievement before referral, assessment, and remediation. In the response-to-intervention method, the child will be placed directly in an educational intervention program when he or she first experiences academic difficulties. Only the children who do not show significant improvement with both the group-intervention first-tier program and second-tier targeted intensive individual intervention will undergo a full educational assessment.[8,61,62] Ideally, the response-to intervention approach will allow earlier identification of learning disabilities than the "wait-to-fail" situation that occurs when an ability achievement discrepancy formula is used to determine if a student qualifies for an evaluation of a learning disability.[62]

Because dyslexia is a language-based disorder, treatment should be directed at this etiology.[1,2,4–8,13,15,60] Most students with dyslexia require highly structured, intensive, individualized instruction by a teacher or educational therapist who was specially trained explicitly in teaching the application of phonics.[1,2,4–8,13,15] Longitudinal data indicate that systematic phonics instruction results in more favorable outcomes for readers with disabilities than does a context-emphasis (whole-language) approach.[1,4,8,13,15,60] The critical elements of effective intervention include individualization, feedback and guidance, ongoing assessment, and regular ongoing practice.[4]

Remediation programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension.[1,4–8,13,15] The approach to learning decoding skills begins with explicit instruction in recognizing spoken sounds (phonemic awareness), becoming aware of rhyme, learning the alphabetic code, memorizing sight words, and studying phonics and spelling.[6–8] A child must first accurately decode a word before it can be read fluently.[4,6–8] The home is the ideal setting for practice and reinforcement. Just as an athlete must practice to optimize his or her skills, the child should read aloud to a parent or tutor each day to practice decoding, memorize new sight words, and develop greater fluency by rereading of previously decoded and memorized words.[4] Fluency forms the bridge between decoding and comprehension.[4,6–8] Comprehension is gained through fluency training, vocabulary instruction, and active reading comprehension.[4] Techniques that enhance active reading comprehension include prediction, summarization, visualization, clarification, critical thinking, making inferences, and drawing conclusions.[2,4,6–8,13] Because people with dyslexia have a persistent problem and continue to have slower reading throughout their lives, accommodations and modifications may be necessary in addition to remediation.[2,4] Examples of accommodations include extra time, shortened assignments, a separate quiet room for taking tests, testing alternatives, computers, spell checkers, tape recorders, lecture notes, recorded books, and tutors.[2,4,11]

A MULTIDISCIPLINARY APPROACH

The diagnosis and treatment of learning disabilities depend on the collaboration of a team that may include educators; educational remediation specialists; audiologists; speech, physical, and occupational therapists; teachers for the visually impaired; psychologists; and physicians. Children with learning disabilities should undergo assessments of their health, development, hearing, and vision and, when appropriate, medical and psychological interventions for associated and related treatable conditions.[63]

A formal evidence-based evaluation is needed to discover whether a child has a learning disability. Educational psychologists and neuropsychologists diagnose learning disabilities by performing appropriate testing as part of an educational assessment of the child's abilities and disabilities. A formal assessment for learning disabilities should include evaluation of cognition, memory functions, attention, intellectual ability, information processing, psycholinguistic processing, expressive and receptive language function, academic skills, social-emotional development, and adaptive behavioral functioning. These results are used to develop an individualized education plan (IEP), which includes evidence-based educational remediations, accommodations, and modifications.[2,4,7,13] Educational therapists or educators with specialized training in learning disabilities play a key role by designing and implementing remedial programs and monitoring the student's progress.

Audiologists can identify hearing problems. Speech therapists can evaluate and treat underlying oral language difficulties often associated with dyslexia and help students learn phonological awareness. Physical and occupational therapists do not treat dyslexia but do treat fine and gross motor difficulties or sensory problems that may be associated with learning disabilities. Children with low vision and learning disabilities may benefit from having a

teacher of the visually impaired. Psychiatrists, psychologists, neurologists, and specialty-trained pediatricians can diagnose associated comorbid conditions. Psychiatrists, clinical psychologists, licensed clinical social workers, or licensed mental health counselors can provide strategies to help children adapt to their disabilities and provide therapy to address concurrent psychological disorders. Psychiatrists, neurologists, or specialty-trained pediatricians may prescribe medications. The role of other physicians will be elaborated in a later section of this statement.

THE ROLE OF PARENTS

Parental participation in a child's education is of utmost importance. Families with a history of dyslexia should observe their children for early language difficulties. Reading to their preschool-aged child and having their child read to them as soon as he or she is able allows parents to detect early signs of learning difficulties. Parents should collaborate with early elementary school teachers to monitor their child for academic struggles. Parents need to serve as the child's advocate, speaking with the child's teacher, pediatrician, and other professionals; requesting an educational evaluation; and coordinating remediation and other treatment. By educating themselves in the areas of learning disabilities, available services, and state education rules and regulations, parents will increase their effectiveness as the child's advocate. After a child has been diagnosed with a learning disability, an individualized educational plan or a Section 504 plan may be created. Parents should work with educators to ensure that the school provides the proper remediation and accommodations. Children with dyslexia should read aloud to their parents frequently. Parents should help with practice and reinforcement at home in a supportive and nurturing environment with adequate opportunity for their child to participate in activities in which he or she excels. As the child gets older, parents should help their child use recommended alternative learning strategies such as books on tape or computers. Parents should continue to monitor their child's progress and advocate for their child when necessary.

Because of the complex nature of learning disabilities, including dyslexia, there are no simple remedies. Teaching children with dyslexia and learning disabilities can be a challenge for educators and parents. With proper remediation, accommodations, and support, children with dyslexia and learning disabilities can succeed.

THE ROLE OF THE PHYSICIAN

Physicians, including pediatricians, family physicians, otolaryngologists, neurologists, ophthalmologists, mental health professionals, and other relevant medical specialists, may participate in the comprehensive care of children with learning disabilities including dyslexia. Pediatricians should not diagnose learning disabilities[63] but should inquire about the child's educational progress and be vigilant in looking for early signs of evolving learning disabilities.[63] When a child has suspected learning difficulties, the pediatrician or family physician should first assess the child for medical problems that could affect the child's ability to learn and refer him or her for further evaluation if deemed appropriate.[63,64]

Pediatricians and family physicians have an extremely important function in acting as a medical home by helping parents decide whether further evaluations are needed and in coordinating care for the child after a diagnosis has been made.[63,64] Primary care physicians who have a strong role in assisting school districts should only recommend evidence-based treatments and accommodations. Pediatricians and family physicians should provide information and support to parents on learning disabilities and their treatment and should dispel the myths surrounding these disorders.[30] This should include discussion regarding the lack of efficacy of vision therapy and other "alternative treatments" with the parents.[30] Parents need to be informed that dyslexia is a complex disorder and that there are no quick cures. The American Academy of Pediatrics has information for families on what parents need to know about learning disabilities.[65] The primary care physician should compile and provide a resource list of local specialists from whom the child can obtain proper help and from whom the family members can learn to become advocates for the child.[63]

The Individuals With Disabilities Education Act, Section 504 of the Rehabilitation Act, and the Americans With Disabilities Act define the rights of students with dyslexia and other specific learning disabilities.[66,67] These acts allow parents to request a formal educational evaluation by the school district to determine eligibility for special education and related services. Information for pediatricians on this legislation and its associated rights and procedures is available from the American Academy of Pediatrics.[63,64] Physicians can refer parents of children with learning disabilities to their state's parent training and information center. These parent-directed centers provide information and technical assistance to parents and professionals regarding family and student rights and responsibilities in special education.

For all children, primary care physicians should perform hearing and vision screenings according to national standards[68] so that hearing, ocular, and visual disorders are identified as early as possible. Periodic eye and vi-

sion screenings can identify children who have reduced visual acuity or other visual disorders. Vision screening with nonletter symbols may be necessary for testing children with dyslexia or other learning disabilities.

Children who do not pass vision screening should be referred to an ophthalmologist with experience in the care of children.[68] In addition, the recommended routine pediatric vision screenings are unlikely to disclose near-vision problems such as convergence insufficiency, accommodative insufficiency, and significant hyperopia. Children with suspected learning disabilities in whom a vision problem is suspected by the child, parents, physicians, or educators should be seen by an ophthalmologist with experience in the assessment and treatment of children, because some of these children may also have a treatable visual problem that accompanies or contributes to their primary reading or learning dysfunction.[30,45,58] Treatable ocular conditions can include strabismus, amblyopia, convergence and/or focusing deficiencies, and refractive errors. Missing these problems could cause long-term consequences from assigning these patients to incorrect treatment categories.

The ophthalmologist should identify and treat any significant visual defect according to standard principles of treatment.[69,70] Strabismus, amblyopia, and refractive errors may require glasses, eye patching, eye drops, or eye-muscle surgery. Symptomatic convergence insufficiency can be treated with near-point exercises, prism-convergence exercises, or computer-based convergence exercises. Most of these exercises can be performed at home, and extensive in-office vision therapy is usually not required.[71–73] Alternatively, for other patients, reading glasses with base-in prism[73] or minus-lenses can be used as treatment. Treating convergence insufficiency can make reading more comfortable but does not improve the decoding or understanding of reading.[14] If no ocular or visual disorder is found, the child needs no further vision assessment or management. The ophthalmologist should not diagnose learning disabilities but should provide information on learning disabilities and reinforce the need for additional medical, psychological, educational, or other appropriate evaluation or services. In addition, the ophthalmologist should discuss the lack of efficacy of vision therapy and other "alternative treatments" with the parents. The American Academy of Ophthalmology has a patient-education brochure for families titled "Learning Disabilities."[74] The ophthalmologist, when necessary, should compile and provide a resource list of local specialists who can help obtain proper help for the child.[69]

CONTROVERSIES

Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of controversial and scientifically unsupported alternative treatments, including vision therapy.* Scientific evidence of effectiveness should be the basis for treatment recommendations.[4,45,60] Treatments that have inadequate scientific proof of efficacy should be discouraged. Ineffective, controversial methods of treatment such as vision therapy may give parents and teachers a false sense of security that a child's learning difficulties are being addressed, may waste family and/or school resources, and may delay proper instruction or remediation.[45]

Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems, including abnormal focusing, jerky eye movements, misaligned or crossed eyes, binocular dysfunction, visual-motor dysfunction, visual perceptual difficulties, or hypothetical difficulties with laterality or "trouble crossing the midline" of the visual field, cause learning disabilities.[8,30,31,45,46,48–59] Statistically, children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions.[8,30,31,45,46,48–59] Because visual problems do not underlie dyslexia, approaches designed to improve visual function by training are misdirected.[31,47,56,57,69,78] Other than convergence-insufficiency treatment,[70–73,79,81,95,96] scientific evidence does not support the assumption that vision therapy is capable of correcting subtle visual defects,† nor does it prove eye exercises or behavioral vision therapy to be effective direct or indirect treatments for learning disabilities.‡ Detailed review of the literature supporting vision therapy reveals that most of the information is poorly validated, because it relies on anecdotes, poorly designed studies, and poorly controlled or uncontrolled studies.§ Their reported benefits can often be explained by the placebo effect or by the traditional educational remedial techniques with which they are usually combined.[30,45,46,55,57,58,78,79] There is currently no evidence that children who participate in vision therapy are more responsive to educational instruction than are children who do not participate.‖ Thus, current evidence is of poor scientific quality and does not provide adequate scientific evidence that vision training is a necessary primary or adjunctive therapy.¶

Tinted lenses and filters have been suggested to treat visual perceptual dysfunctions that lead to visual distortion caused by sensitivities to particular wavelengths of light but not to treat language-based dyslexia.[97] Scrutiny of published study results that advocated the use of these therapies to treat dyslexia have shown serious flaws in their methods and have not been sufficiently well controlled to support this assertion.[30,70,84,85,88] There have also been many inconsistencies in the results,[89,98,99] with some studies showing some partial positive results[100–106] and others showing negative results.[84,86,90–94] The method used to select the lens or filter color has been highly variable,[89,104,106] the color selection has also shown considerable variability,[104] and the test-retest consistency has been poor.[107] Many of the studies that have been cited as proof of Irlen-lens efficiency have actually been inconclusive after deeper analysis. The evidence does not support the effectiveness of tinted lenses and tinted filters in these patients because of the weaknesses in methodology and statistics, variability in techniques in the trials, and the largely negative results.[8,30,45,70,76,83–94,107]

RECOMMENDATIONS

1. Children who exhibit signs of learning disabilities should be referred as early in the process as possible for educational, psychological, neuropsychological, and/or medical diagnostic assessments.
2. Children with learning disabilities should receive appropriate support and individualized evidence-based educational interventions combined with psychological and medical treatments as needed.
3. Families of children with suspected learning disabilities should receive information about state and local parent support programs.
4. Pediatricians and family physicians should perform periodic eye and vision screening for all children according to national standards and refer those who do not pass screening to ophthalmologists who are experienced in the care of children.
5. Children with a suspected or diagnosed learning disability in which vision is felt to play a role by parents, the child, educators, or physicians should be referred to an ophthalmologist with experience in the care of children, because routine pediatric vision screening is not designed to detect near-vision problems.
6. Ophthalmologists should identify and treat any significant ocular or visual disorder found to be present.
7. Primary care physicians should only recommend evidence-based treatments and accommodations to school districts.
8. Diagnostic and treatment approaches for dyslexia that lack scientific evidence of efficacy such as behavioral vision therapy, eye-muscle exercises, or colored filters and lenses are not endorsed or recommended.

SUMMARY

Dyslexia and learning disabilities are complex problems that have no simple solutions. The most widely accepted view is that dyslexia is a language-based disorder. The American Academy of Pediatrics, the American Academy of Ophthalmology, the American Association for Pediatric Ophthalmology and Strabismus, and the American Association of Certified Orthoptists strongly support the need for early diagnosis and educational intervention.

Recommendations for multidisciplinary evaluation and management must be based on evidence of proven effectiveness that is demonstrated by objective scientific methodology.[4,45,60] It is important that any therapy for learning disabilities be scientifically established to be valid before it can be recommended for treatment.[60]

Currently, there is no adequate scientific evidence to support the view that subtle eye or visual problems cause learning disabilities.[8,30,31,45,46,48–59] Furthermore, the evidence does not support the concept that vision therapy or tinted lenses or filters are effective, directly or indirectly, in the treatment of learning disabilities.# Thus, the claim that vision therapy improves visual efficiency cannot be substantiated. Diagnostic and treatment approaches that lack scientific evidence of efficacy are not endorsed or recommended.

With early recognition and individualized, interdisciplinary management strategies, children with learning disabilities can enjoy successful academic experiences.

Joint Technical Report—Learning Disabilities, Dyslexia, and Vision

abstract

FREE

Learning disabilities constitute a diverse group of disorders in which children who generally possess at least average intelligence have problems processing information or generating output. Their etiologies are multifactorial and reflect genetic influences and dysfunction of brain systems. Reading disability, or dyslexia, is the most common learning disability. It is a receptive language-based learning disability that is characterized by difficulties with decoding, fluent word recognition, rapid automatic naming, and/or reading-comprehension skills. These difficulties typically result from a deficit in the phonologic component of language that makes it difficult to use the alphabetic code to decode the written word. Early recognition and referral to qualified professionals for evidence-based evaluations and treatments are necessary to achieve the best possible outcome. Because dyslexia is a language-based disorder, treatment should be directed at this etiology. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension. Most programs include daily intensive individualized instruction that explicitly teaches phonemic awareness and the application of phonics. Vision problems can interfere with the process of reading, but children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions. Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems cause or increase the severity of learning disabilities. Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of scientifically unsupported vision-based diagnostic and treatment procedures. Scientific evidence does not support the claims that visual training, muscle exercises, ocular pursuit-and-tracking exercises, behavioral/perceptual vision therapy, "training" glasses, prisms, and colored lenses and filters are effective direct or indirect treatments for learning disabilities. There is no valid evidence that children who participate in vision therapy are more responsive to educational instruction than children who do not participate. *Pediatrics* 2011;127:e818–e856

INTRODUCTION

Reading is the complex process of extracting meaning from abstract written symbols. In modern societies, reading is the most important way to access information, and in today's Western society, literacy is a prerequisite for success. In elementary school, a large amount of time and effort is devoted to the complicated process of learning to read. Because of the difficulties encountered in teaching some children to read, Congress mandated that the Eunice Kennedy Shriver National

Institute of Child Health and Human Development assemble a national panel of educators and scientists to research the optimal methods of teaching children to read. The 2000 report of the National Reading Panel, titled *Teaching Children to Read: An Evidence-Based Assessment of the Scientific Research Literature on Reading and Its Implications for Reading Instruction*,[1] linked research findings with recommendations for specific approaches to teaching reading to all children. The panel concluded that existing evidence supported early explicit instruction in phonemic awareness, phonics-based reading programs, and guided oral reading to improve fluency.

Learning disabilities may interfere with children reaching their full potential. The inability to read and comprehend is a major obstacle to learning that may have long-term educational, social, and economic implications. Teaching children with reading difficulties is a challenge for the student, parents, and educators. Therefore, the causes and treatment of reading disorders have been the subject of considerable thought and study.

This report discusses how we learn to read, the phonologic model, the recognition and treatment of reading difficulties, visual function and reading, the magnocellular deficit theory, colored lenses and overlays, vision therapy, and the roles of the pediatrician and ophthalmologist.

BACKGROUND

History

In 1877, Kussmal[2,3] first described a case of acquired word blindness in an adult alexic patient with a parietal lobe lesion. Hinshelwood,[2,4] an ophthalmologist from Scotland, studied and described an adult with word blindness in 1895. In 1903, an autopsy of this patient revealed abnormalities in the left angular gyrus immediately posterior to Wernicke's area.[4] Morgan,[2,5] a general practitioner from England, published the first case of a child with congenital word blindness in 1896. Subsequently, Hinshelwood turned his attention to both congenital and acquired word blindness. He credited the term "dyslexia" to Berlin.[6] In 1917, he highlighted the potentially inherited aspect of reading disability. Hinshelwood estimated that 1 in 1000 students in elementary schools might have word blindness and postulated that the primary disability was in visual memory for words and letters. He strongly advocated intensive, individualized personal instruction.[2,4]

Beginning in the 1920s, Orton,[2,7,8] a neuropsychiatrist, demonstrated a hereditary component for reading disabilities in children. His studies led to an expanded definition of reading disabilities that was much broader than Hinshelwood's and included a graded series of all degrees of severity of disability. This more liberal definition increased the presumed prevalence to more than 10% of schoolchildren. IQ testing revealed that these children scored near or above average. In 1925, Orton attributed dyslexia to a problem in the visual system, which suggests that an apparent dysfunction from "mixed cerebral dominance" caused problems in visual perception and visual memory, characterized by perception of letters and words in reverse.

The theory that visual dysfunction caused dyslexia led to a proliferation of training programs developed for visual-perceptual and/or visual-motor disabilities. In the 1960s, those prominent in developing and promoting these programs included Kephart, Frostig, Getman, Barsch, Dorman, and Delacato. Research into the programs revealed that, although these programs were sometimes effective in improving perceptual and/or perceptual-motor development, they were ineffective in improving academic performance.[9–12] Although the use of perceptual and perceptual-motor training by educators persisted for a time, by the mid-1980s its use had waned considerably.

Attempts at improved understanding of dyslexia led to the rejection of the visual theories. This process began with a series of related studies that systematically evaluated traditional and widely accepted etiologic conceptualizations, such as Orton's optical reversibility theory,[7] Hermann's spatial confusion theory,[13] and other theories that implicated deficits in visual processes, such as visualization, visual sequencing, and visual memory, as basic causes of reading difficulties.[14,15]

Although Orton attributed dyslexia to visual dysfunction, he was the first to advocate intensive phonics instruction, sound-blending, and multisensory training.[2,8] Orton's work served as the stimulus for Gillingham and Stillman,[16] who also emphasized multisensory training. Subsequently, the Orton-Gillingham phonics techniques have served as the basis for many remediation programs. The International Dyslexia Society, formerly the Orton Dyslexia Society, provides information and resources to professionals and parents regarding reading disabilities.

Learning Disabilities

Learning disabilities constitute a diverse group of disorders in which children who generally possess at least average intelligence have problems processing information or generating output. Learning disabilities can affect neurocognitive processes and may manifest as an imperfect ability to listen, speak, read, spell, write, reason, concentrate, solve mathematical problems, or organize information. Some children may have associated difficul-

ties with motor coordination. Learning difficulties can be associated with and complicated by attention-deficit/hyperactivity disorder (ADHD),[17,18] oppositional defiant disorder, obsessive compulsive disorder, anxiety, or depression.[19] Problems in self-regulatory behaviors, social perception, and social interaction may exist with learning disabilities but do not, by themselves, constitute a learning disability. Although learning disabilities may occur concomitantly with other disabilities (eg, sensory impairment, intellectual disability, serious emotional disturbance) or with extrinsic influences (eg, cultural differences, insufficient or inappropriate instruction), they are not the result of those conditions or influences.[20] Results of recent studies suggest that approximately 20% of the population has some degree of a learning disability.[21] In 2007, 2.7 million public school students (5.5% of all students in public schools) were identified as having learning disabilities and were eligible to receive educational assistance under the Individuals With Disabilities Education Act (IDEA).[22]

Specific learning disabilities include dyslexia (reading disability), dysgraphia (writing disability), and dyscalculia (mathematics disability). Although not included in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*[23] as a specific learning disability, nonverbal learning disability comprises difficulties with social interactions, interpersonal skills, nonverbal problem-solving, visuospatial skills, motor skills, reading comprehension, and mathematics and often coexists with strengths in verbal skills and with fluent and accurate reading.[23] Autism spectrum disorder, although not a specific learning disability, certainly affects learning, because people with autism have difficulties with verbal and nonverbal communication, social interactions, and motor function and may show inappropriate response to sensory information.[23]

Dyslexia

Difficulties in reading are found in a diverse group of conditions that include dyslexia and secondary forms of reading difficulties caused by visual or hearing disorders, intellectual disability, experiential and/or instructional deficits, and other problems.[14,24–26] Dyslexia is defined as a primary reading disorder that is separate from secondary forms.[14,24–26] The terms "specific reading disability," "reading disability," "reading disorder," and "dyslexia" are often used interchangeably in the literature.[14] The term "dyslexia" is derived from Greek and means "difficulty with reading words." Dyslexia is often unexpected in relation to the child's other cognitive abilities. It is a receptive language-based learning disability that is characterized by difficulties with decoding, fluent word recognition, and/or reading-comprehension skills. These difficulties typically result from a deficit in the phonologic component of language that makes it difficult to use the alphabetic code to decode the written word. Secondary consequences may include reduced reading experience that can impede growth of vocabulary, written expression, and background knowledge.[27] A common misconception is that dyslexia is a problem of letter or word reversals. Reversals of letters or words and mirror writing occur normally in early readers and writers. Children with dyslexia are not unusually prone to reversals. Although they do occur, reversal of letters or words, or mirror writing, is not included in the definition of dyslexia.[14,28,29] People with dyslexia may be very creative and bright. In many cases, their high-level thinking is unaffected, and they may be gifted in mathematics, science, the arts, or even in unexpected areas such as writing.[28] People with dyslexia read slowly, but not all people who read slowly have dyslexia.

Approximately 80% of people with learning disabilities have dyslexia, which makes it the most common learning disability.[24,25,30–35] Depending on the definition chosen, the prevalence of reading disability is approximately 5% to 20% of school-aged children in the United States.[21,24,31,34] Reading disabilities seem to affect males slightly more than females,[36–38] although schools identify boys with them twice as often as girls.[22,31] Both environmental and genetic influences affect the expression of dyslexia.[39] Dyslexia has been identified as having a strong genetic basis.[14,24–26,30,31,40,41] Approximately 40% of siblings, children, or parents of an affected person will have dyslexia. Although dyslexia may be inherited, it may also exist in the absence of a family history. Results of family and twin studies have suggested that 50% of the problems in performance can be accounted for by heritable factors; environmental influences are greater in children with lower IQ scores.[42]

Reading ability and reading disability occur along a continuum; reading disability is represented within the lower tail of a normal bell-shaped distribution of reading ability.[21] The lower tail is actually composed of reading difficulties from both primary dyslexia and secondary causes. Dyslexia is a lifelong condition that varies in degrees of severity. Most children with reading disabilities have relatively mild reading disabilities, and a smaller number of them have more severe reading disabilities.[21,30] Because reading skills occur on a continuum with no clear distinction between typical readers and readers with dyslexia, some experts assert that the term "dyslexia" should be reserved for the 2% to 5% with the most severe reading deficits.[43]

Dyslexia occurs at all levels of intelligence and is a persistent problem that does not represent a transient developmental lag.* Children with poor oral language skills in kindergarten often become poor readers. Over time, good readers and poor readers without intervention tend to maintain their relative positions along the spectrum of reading ability. Children who get off to a poor start in reading rarely catch up on their own. A poor reader in 1st grade will almost invariably stay a poor reader; more than 88% of these children display similar difficulties at the end of 4th grade.[35,44,50] Seventy-four percent of those children identified in 3rd grade as reading disabled will remain so in the 10th grade.[30,34,43,51] Readers with dyslexia must expend more attention, concentration, and energy on the task, which makes reading unpleasant, tiring, and difficult.[39] Students who cannot read well read less. Lost practice opportunities make it difficult to acquire even average levels of reading fluency. Both inaccurate reading and diminished reading practice cause slow growth of fluent word-identification skills and vocabulary growth. The vocabularies and concept knowledge of children who read less will plateau as their reading peers improve.[52] The consequences of a slow start in reading become monumental as they accumulate exponentially over time.[35] In the later grades, when children switch from learning to read to reading to learn, reading-impaired children are prevented from fully exploring science, history, literature, mathematics, and the wealth of information that is presented in print. With interventions, people with dyslexia may learn to read accurately, but they have a persistent problem with fluency and continue to read slowly and not automatically throughout their lives.[39] The fluency deficit is problematic for older children, who are expected to read increasingly sophisticated texts.[53]

Many children with reading disability are observed to grow ashamed as they struggle with skills that their classmates master easily. This shame may cause a loss of motivation to learn to read that can further compound the situation. Untreated or poorly treated dyslexia may lead to frustration, low self-confidence, and poor self-esteem, which substantially increases the risk of developing psychological and emotional problems.[19,30]

Approximately 15% of students with reading disability also have ADHD, whereas approximately 35% of students with disorders of attention also have reading disability.[19,24,30,54] However, the 2 disorders are distinct and separable.

Dysgraphia is a learning disability that affects writing abilities. Disorders of written expression can manifest themselves as difficulty with spelling and problems putting thoughts on paper. The spelling deficits in dysgraphia may be oral and/or written. Dysgraphia can also manifest itself as difficulty with writing motor coordination or poor handwriting. Dysgraphia is the learning disability that most frequently co-occurs with dyslexia because of their directly related phonemic base. Decoding breaks the code receptively and encoding (spelling) puts it back together expressively.

Phonologic Model

Currently, the most accepted model for the acquisition of the ability to read is the phonologic model. Phonologic awareness is the sensitivity to the sound structure of oral speech and phonemic awareness is the understanding that speech can be segmented or broken into individual sounds that signal differences in meaning, whereas phonics is the understanding that segmented units of speech can be represented by printed forms.[55] Phonologic awareness is the basis for scaffolding written language onto oral language.[55]

Phonemes are the speech sounds that enable us to tell 1 word from another. For example, "pet" and "bet" are distinguished by the sounds of their initial consonant; thus, changing the "p" to "b" changes the meaning of the word.[56] Coarticulation is the merging and overlapping of sounds into a sound "bundle," which makes oral communication much more efficient.[55] To make normal conversation possible, 8 to 10 phonemes per second are strung together and blended so thoroughly that it is often impossible to separate them. A written word like "cat" has 3 letter-sound units, although the ear hears only 1 sound, not 3, when the word "cat" is spoken aloud.

Oral language development has been found to play a critical role in learning to read.[1,35,57–59] Oral language acquisition is preprogrammed into human development; a drive for expression through organized vocalization seems innate to infant development, although specific languages need to be acquired. On the other hand, writing, an artificially designed use of abstract symbols to represent language, is an acquired skill.[34] English uses an alphabetic system in which each letter is a symbol that is an abstract building block of that language's phonemes (sounds). English is a phonemically complex language in which the 26 letters of the alphabet create 44 sounds or phonemes in approximately 70 letter combinations.[32,33,60] The phonemic complexity of a language corresponds to the prevalence of dyslexia, which points to the linguistic origin of dyslexia.[14,29] Manifestations of dyslexia are often worse in English because of the greater number of inconsistencies and exceptions within the English lan-

*Refs 14, 20, 24–26, 28–31, 34, 35, and 44–49.

guage, but dyslexia is confined neither to the United States nor to English speakers.[14]

Learning to read and write is a complex process that requires active learning. Reading is more difficult than speaking, because children must be aware of the sound structure in spoken language and then break the alphabetic code to acquire the sound/symbol connection. Developing this awareness is not automatic, because phonemes are not separated in speech. To decode a written word, the sounds must be broken apart. Unless the child can convert the printed characters into the phonetic code, these letters remain a mystery of lines and circles that are devoid of linguistic meaning.[34] According to Moats[61] and the American Federation of Teachers, teaching reading is rocket science!

Reading comprises decoding, fluency, and comprehension and requires adequate memory and sustained attention. The foundation for reading is decoding. Decoding, or word attack, is the ability to sound out words. Poor decoding is the core characteristic of poor reading. Most people with dyslexia have a neurobiological deficit in the processing of the sound structure of language, called a phonemic deficit, which impairs decoding and prevents word identification.† The ability to learn to decode print is determined primarily by phonologic skills such as phonologic awareness, facility in alphabetic mapping, name encoding and retrieval, and verbal memory.[14] The reader with dyslexia experiences difficulty in decoding and identifying words because of a specific impairment in the neural representation, storage, retrieval, and coding of phonemes.‡ Children with dyslexia often experience even more difficulty with spelling (dysgraphia) because of imperfectly stored representations of words, although not all children with poor spelling skills have dyslexia.

Children with more severe forms of dyslexia may have a second deficit in rapid automatic naming that causes slow naming of letters, numbers, and pictures, which creates a double deficit.[14,31,66–69] Other children with severe forms of dyslexia may have problems with their short-term working memory or attention or an additional comprehension deficit.[70] Some children with reading difficulties also experience a deficit in orthographic skills, which are defined as difficulties with letter/number orientation recognition and memory, although these skills may improve with development.[14,71]

A child must first accurately decode a word before it can be read fluently. Fluency is the ability to read connected text with expression rapidly, smoothly, effortlessly, and automatically with little conscious attention to decoding. An inexperienced reader will use the phonetic method to sound out most words and consequently will read slowly. No fluent reader uses phonics routinely. Poor decoders are stuck on the task of trying to sound out words to make sense of the text.[52] The next task for the beginning reader is to move from the early phases of "sounding out" words to the more skilled phase in which word recognition occurs almost instantly. Word recognition is the ability to read words without sounding them out.[52] Experienced readers use the whole-word method and will quickly recognize most words as individual units. Average readers require 4 to 14 exposures to a word before it becomes a sight word,[32,33] whereas students with learning disabilities may need up to 40 exposures.[33,72] Fluent reading requires automatic phonemic decoding and word recognition.[1,24,25,31–34,64] Although the ability to read words accurately is a necessary skill, reading speed and fluency become critical factors in ensuring that children gain comprehension. Fluency forms the bridge between decoding and comprehension.[34]

Comprehension is impaired without efficient automatic word-recognition skills.[55] If reading is slow and labored because of decoding difficulties and requires a large portion of their available conscious attention, children do not have enough attentional capacity and cognitive energy to remember what they have read, much less relate the ideas to their own background knowledge.[32–34,64] Current theory maintains that the deficit in lower-order phonologic linguistic decoding function blocks access to the usually intact higher-order cognitive and linguistic functions.[15,24,25,30–35] Thus, it is difficult to apply general intelligence and reasoning, vocabulary, and syntax to the reading endeavor to obtain comprehension.[24,25,34] In some cases, however, other children can show comprehension difficulties in the absence of word-recognition problems. Vocabulary acquisition in a child with dyslexia often may not keep pace with that of a child's peers, because the less a child reads, the fewer the new words to which the child is exposed. In addition to decoding deficiencies, inadequate vocabulary, verbal reasoning, attention, memory, and limitations in background knowledge also can cause reading-comprehension difficulties. Thus, any or all of these problems can interfere with the ultimate purpose of reading, which is comprehension.[34]

Neurobiology

Dyslexia is currently believed to be neurobiological in origin, which means that the problem is located physically in the brain. There is strong scientific evidence that supports the neurobiological basis for the phonologic-coding–

†Refs 1, 14, 15, 20, 24–26, 30–35, 43, 46–49, 55, 60, and 62–65.

‡Refs 1, 24, 25, 31–34, 39, 46–49, and 64.

deficit theory of dyslexia.§ Both anatomical and brain-imagery studies have revealed differences in the way the brain of a person with dyslexia develops and functions. Neuroanatomical changes, microarchitectural distortion, and MRI findings in language-related areas have been observed in the brains of patients with dyslexia, including the absence of the normal asymmetry in the language areas of the brain and similar volume in the left and right planum temporale; normally, the left planum temporale is larger.[86–88] Functional MRI and positron emission tomography (PET) scans measure changes in metabolic activity and blood flow during cognitive tasks in specific brain regions. In typical readers, functional MRI and PET-scan studies have shown that reading takes place predominantly in left-hemisphere sites including the inferior frontal (Broca) area, which is associated with articulation, naming, and silent reading; 2 areas in the posterior brain regions—the parietal temporal region, which serves word analysis, and the left occipitotemporal area, which is involved in word-form and fluent reading; and the posterior inferior temporal cortex, which is associated with lexical retrieval. Children with dyslexia, on the other hand, use different areas of the brain when reading.‖ People with dyslexia have demonstrated a dysfunction in the left-hemisphere posterior reading systems and have shown compensatory use of the inferior frontal gyri of both hemispheres and the right occipitotemporal word-form area.¶ These studies have demonstrated that dyslexia is an abnormality in the word-analysis pathways of the brain that interferes with its ability to convert written words into spoken words. It is postulated that this abnormality is causal, not a result of poor reading experience. Functional MRI studies have also shown brain plasticity in that the dyslexia-specific brain-activation profile improves after successful evidence-based phonologic remedial intervention.[48,80,85]

White-matter abnormalities have also been detected in association with dyslexia. In people with dyslexia, white-matter organization seems to be weaker in the left posterior brain region and seems to project too weakly within the primary reading pathways of the linguistic left hemisphere and too strongly between hemispheres.[53] White-matter pathways of the brain may be characterized by diffusion tensor imaging that provides a quantitative index of the organization of large myelinated axons that constitute the long-range connections of brain networks. Young children are able to undergo diffusion tensor imaging.

Recent genetic-linkage studies have identified many loci at which dyslexia-related genes are encoded. Four candidate genes have been implicated in neural migration, axonal growth, and brain development.[89] These brain changes seem to cause phonologic and auditory processing abnormalities.[89]

RECOGNITION AND TREATMENT

Dyslexia is a disorder that affects people of all ages, but its symptom profile changes over time.[81,90] Because dyslexia is both familial and heritable, affected younger siblings can often be identified earlier. A child should be observed for early indications of dyslexia if he or she has a family history of learning disabilities or has a history of other factors that may be predictive of learning disabilities including hearing, language, or speech problems; preterm birth; low birth weight; fetal exposure to drugs or alcohol; infections of the central nervous system; severe head injuries; cognitive difficulties; or developmental delay.[28] An early history of language difficulties such as delay or difficulty in developing speech and language, learning rhymes, or recognizing letters and sound/symbol connections, may be an early indication of dyslexia.[14,24,34,35,58,62,81] Parents or teachers may detect early warning signs of learning difficulties in preschool-aged children, and early evaluation and intervention should be considered. It is not in the child's best interest to "wait and see" or hope that the child will "grow out of" his or her problems.[91]

However, in many cases, learning disabilities are not discovered until children experience academic difficulties in elementary school.[24,25,34,81] Many parents who had noticed that their child was exhibiting learning difficulties waited a year or more before acknowledging that their child might have a problem and seeking assistance. In elementary school, a child with reading disabilities may show difficulty with remembering words, reading, spelling, handwriting, or writing speed. Teachers are in a position to identify reading problems before they progress significantly. Early identification of children in early grades who are showing delays or difficulties should be a high priority for elementary school teachers. Teachers need to have a strong understanding of the result of research in reading theory and practice to become well versed in reading development and assessment.[33] At all grade levels, teachers must understand the course and the role of instruction in optimizing literacy development. After initial school interventions have been unsuccessful, evaluation for learning disabilities should be considered for all children who present with school diffi-

culties, even if reading difficulty is not the chief complaint.[34]

Parents should read aloud to their children to help develop language skills beginning as early as 6 months of age.[92] Educational experts indicate that reading aloud to children is the single most important activity for parents and caregivers to do to prepare children to learn to read.[33,35] Comprehensive beginning reading instruction is the best educational prevention for reading problems.

The best current approach to the problem of reading failure is to allocate resources for prevention and early identification. The beneficial effects of early identification and intervention are apparent in many studies.[35] In the elementary grades, reading screening should be performed yearly and early in the school year. Assessments for difficulties with alphabet recognition, phonemic awareness and rapid naming in kindergarten,[57,93] adding word identification fluency in 1st grade, and adding oral reading fluency in 2nd grade can predict many of those who will have difficulty learning to read.# Prevention and early phonologic awareness intervention programs in kindergarten through 2nd grade can increase reading skills in many poor readers to average reading levels. Torgesen reviewed many studies on early intervention and found that when intervention began in the 1st grade, the expected incidence of reading disability of 12% to 18% was reduced substantially to 1.6% to 6%.[94] If reading-impaired children receive effective phonologic training in kindergarten and 1st grade, they will have significantly fewer problems in learning to read on grade level than do children who are not identified or helped until 3rd grade.** Children identified as reading disabled after 2nd grade rarely catch up to their peers.[43] Waiting for failure decreases the chances of interventional success. Results of longitudinal studies have shown that when intervention is delayed until 3rd grade or 9 years of age (the average age at which these children receive services), then approximately 74% of these children will continue to have difficulties learning to read through high school.[30,34,43,51] Gains are maintained for at least 1 or 2 years by approximately 50% of children after they return to the school's standard curriculum. These children who retain their benefits improve from year to year, but they do not further catch up to typical readers.[53]

Dyslexia is most often identified in the primary grades, but it is not diagnosed in some students until later during middle or high school, when more complex reading and writing skills are required. In early elementary school, some children compensate by using other strengths until the educational demands increase and make the reading disability more evident. Reading problems diagnosed in the 4th grade or beyond may be secondary to poor word recognition, a combination of poor word recognition and poor comprehension skills, or solely attributable to poor comprehension skills. Late emerging reading disabilities often go undetected in schools. Approximately 10% of children with dyslexia have good word-reading skills but have poor listening and reading-comprehension skills. Poor comprehension skills are often attributable to working-memory, semantic, and syntactic difficulties. Deficits in phonologic coding continue to characterize readers with dyslexia even in adolescence and adulthood.[34] Older children and adults may learn to read words accurately, but they will not be as fluent or automatic, which results in a slower reading rate.†† Although older children and adults can be taught to read, the time and expense of doing so is enormous.[34] Poor comprehension skills also persist and will impair the ability to learn in general.

Difficulties in early reading may be caused by experiential and instructional deficits in addition to primary dyslexia. Some children enter school with experiential deficits in oral language skills and general knowledge as well as delayed phonologic skills.[35] Experiential risk factors include being raised in a high-poverty environment or in a home in which English is the second language or having limited exposure to oral or written language. It is important to recognize these children, differentiate them from children with true dyslexia, and provide proper remediation for them.

The IDEA, Section 504 of the Rehabilitation Act, and the Americans With Disabilities Act (ADA) define the rights of students with dyslexia and other specific learning disabilities.[95–98] The IDEA defines a child with a disability as someone who has any of 13 disabling conditions, including learning disabilities, and who need special education and related services because of the disability. The IDEA guarantees each child a free, appropriate public education tailored to his or her individual needs and allows parents to request a formal educational evaluation by the school district to determine if a child has a disability and qualifies for special education and related services. It allows parental access to all meetings and paperwork, transition planning, and related services. The IDEA also provides funding for special education services.[96] People with a physical or mental impairment that substantially restricts 1 or more major life activities are eligible for services under Section

504 of the Rehabilitation Act of 1973.[97] This act protects the civil rights of students with disabilities and attempts to remove barriers to allow them to participate freely. Students who do not have 1 of the 13 included disabilities or meet the severity criteria but still require some assistance to be able to participate fully in school may be a candidate for a Section 504 plan. Some schools use Section 504 to support learning-disabled students who need only accommodations. Children with ADHD who do not need more comprehensive special education support also are frequently served under this law. The ADA protects people who have a physical or mental impairment that restricts 1 or more major life activities from discrimination. Because learning is considered such an activity under the ADA, students served under the IDEA also are covered by this law.[99] Congress recently passed the ADA Amendments Act of 2008, which became effective in 2009. It expanded the list of major life activities to include reading, thinking, and concentrating.[99] As a result, more people with learning disabilities are now able to satisfy the definition of disability, gain access to reasonable accommodations, and be protected from discrimination.

The latest revision of the IDEA, the federal law that governs special education, offers 2 approaches that can be used in the young underachieving child.[14] The first method is called the response-to-intervention (RTI) method and is designed primarily for the elementary school grades. RTI is a multitiered approach to the early identification and support of students with learning and behavior needs. The RTI process begins with high-quality instruction and screening of all children in kindergarten to identify any child who exhibits the early signs of potential reading difficulties. In the RTI method, the child will be placed directly in an educational intervention program when he or she first experiences academic difficulties. Struggling learners are provided with interventions at increasing levels of intensity to accelerate their rate of learning. The individual student's progress is closely monitored to assess both the learning rate and level of performance. Educational decisions about the intensity and duration of interventions are based on the individual student's response to instruction. Only the children who do not show significant improvement with the first-tier group intervention program and the second-tier targeted intense individual intervention program will undergo a full diagnostic educational assessment.[14,100,101] The majority of these students undergoing educational assessment will likely be identified as reading disabled and qualify for special education services. Ideally, this approach will allow earlier and more effective identification and treatment than the traditional method in which the child must show persistent poor academic achievement for a few years before referral, assessment, and remediation. A "wait-to-fail" situation can occur when an ability-achievement discrepancy formula is used to determine if a student qualifies for a formal diagnostic assessment for a learning disability.[35,43,65,100,101] Thus, the student has suffered the academic and emotional strains of failure for 2 to 3 years before potentially effective instruction can begin.

At all ages, dyslexia is a clinical diagnosis.[81] A formal evaluation is needed to discover whether a person has a learning disability. The assessment techniques should be evidence based.[102,103] Although many schools still use a discrepancy formula to qualify students for special education, there is an emerging consensus among researchers and clinicians that the dependence on a discrepancy between IQ and reading achievement for a diagnosis of dyslexia has outlived its usefulness except in limited circumstances.[34,44,104] There is no single standardized test used to make the diagnosis of dyslexia. Because the hallmark of dyslexia is the presence of a phonologic deficit in the context of relatively intact overall language abilities, the diagnosis of dyslexia can be far more specific.[34] Indicators of phonologic difficulties can be detected by a child's history, by observation, and/or by specific tests. Furthermore, dyslexia is not diagnosed with testing in the areas of vision, sensory-motor skill, or auditory processing, and it is not determined solely by medical screening or psychological/IQ testing alone.[105]

A comprehensive evaluation is necessary to determine the appropriate diagnosis for children who present with reading weaknesses. Comprehensive evaluation in all areas of the suspect disability should be conducted. Such evaluation is multifaceted and generally involves interviews with the child and family; questionnaires and rating scales completed by parents, teachers, and the student; social, developmental, medical, and educational histories; observation of the child in the classroom; and evaluation of test data.[26] The testing can be conducted by trained school or outside specialists. The composition of testing by a school psychologist varies according to state and school district. An evaluation by a developmental/behavioral pediatrician, school psychologist, educational psychologist, clinical psychologist with special training in learning assessments, or neuropsychologist consists of a battery of tests that will provide information on a child's overall abilities, particularly learning style, information-processing abilities, academic skills, and describing areas of strength and weakness. The assess-

ment may include information provided by parents; health and developmental history; knowledge of any previous medical conditions; behavioral rating scales completed by parents, teachers, and, if appropriate, the student; school observations; review of school records; evaluation of intellect, memory, attention, and concentration; perceptual and sensory skills; executive skills; language; academic achievement; motor skills; social-emotional and behavioral components; and adaptive levels. Such an evaluation traditionally has included critical underlying language skills that are closely linked to dyslexia, including receptive-listening skills; expressive-language skills; phonologic skills, including phonemic awareness and rapid naming of letters and names; vocabulary; reading accuracy; fluency; and comprehension. A student's ability to read lists of words in isolation, as well as words in context, should also be assessed. School assessments are usually performed to determine if a child qualifies for special education programs or therapies. These assessments focus on achievement and the skills needed for academic success.

If the focus of the studies is on educational issues as well as on a broader assessment of brain function, the assessment is called a "neuropsychological" evaluation. Neuropsychologists with a special competency in the area of pediatrics can perform extensive evaluations that can lead to a comprehensive understanding of the child's cognitive and emotional processes and provide the gold standard for a learning-disability evaluation. Neuropsychologists can diagnose learning or behavior disorders caused by altered brain function or development. In addition to test data, the assessment also involves a review of the relevant medical, psychiatric, educational, speech-language, occupational therapy, and school-related records (ie, Section 504 plans and individualized education plans [IEPs]). Parents, teachers, and treating professionals are interviewed for their presenting concerns. Neuropsychologists assess intellect, memory, attention and concentration, perceptual and sensory skills, executive skills, language, academic achievement, motor skills, social-emotional and behavioral components, regulatory capacities, adaptive levels, and other neuropsychological phenomena to illuminate the neurocognitive underpinnings of specific learning disabilities as well as their subtypes. This information is critical in identifying the specific deficits relative to the reading weaknesses as well as other comorbid variables that are also involved. These variables can include coexisting attention and concentration disorders, executive-functioning weaknesses, and social-emotional factors (ie, anxiety, depression, and oppositional features). Such information helps to identify whether attentional and/or emotional issues might be contributing to or resulting from learning difficulties.[19] Because neuropsychological evaluation is driven by an understanding of the brain systems involved in different academic functions, it can illuminate learning disorders, allow predictions to be made about future difficulties a child may encounter so that preemptive interventions can be initiated, and bring to light comorbid conditions that may not yet have become apparent. The determination of the underlying causes of the disorder and comorbid conditions will clarify the types of interventions from which the child is most likely to benefit and will provide a road map on which evidence-based interventions and accommodations are based across home and school environments. Referring professionals and parents are provided with a detailed written report of test findings, the diagnosis, treatment recommendations, accommodations, and referral suggestions.

After a comprehensive school evaluation, a learning disability will be diagnosed formally in some students. Under the IDEA, a "child with a disability" is one who is eligible for special education and related services. Eligibility for special education is determined by the IEP team. The evaluation is necessary for developing a proper treatment plan and should also identify the different instructional methods that are most beneficial at various stages of reading development for each child.[55,59,104] To outline the educational goals and services that the student needs to be successful, an IEP contract is developed. The IEP will describe goals and objectives; outline what services will be needed, including specific remedial interventions, accommodations, modifications, and which type of program would be best; and set guidelines to measure future educational progress. After there is agreement by the school professionals and parents, the services that the school system will provide are listed in the IEP. The IEP contract must be signed by the school professionals and parents before it can be implemented. The IEP is reviewed on an annual basis and, if necessary, revised for the next school year. Addendum IEPs can be held if issues in the initial IEP need to be changed or modified during the school year. Every 3 years, the child will undergo comprehensive reevaluation. Alternatively, parents may obtain an independent educational evaluation. If parents obtain an independent educational evaluation on their own and it meets the school's criteria, those results and recommendations must be considered by the IEP team. The IEP team would still need to determine if the disability and its severity qualify to obtain special education and related services in school. Children with less

severe disabilities who do not qualify for school services may still benefit from remediation and other therapies outside of school at the parents' expense.

Many struggling students will not show severe enough difficulties on evaluation to receive a diagnosis of a learning disability and will not be eligible for special education and related services. These students still may need targeted reading assistance to be able to participate fully in school and may be a candidate for a Section 504 plan. The evaluation information may be used to decide what educational accommodations may be needed in a regular education program. In that case, a Section 504 plan will be written that describes the areas of difficulty and lists the accommodations that will be provided in the regular classroom.

The diagnosis and treatment of a child who has learning disabilities depend on the ongoing, coordinated collaboration of a multidisciplinary team that may consist of educators, educational remediation specialists, special services, psychologists, and physicians. Speech therapists can evaluate and treat underlying oral language difficulties often associated with dyslexia or help students learn phonemic awareness. Physical and occupational therapists do not treat dyslexia but do treat fine motor, gross motor, balance, proprioceptive, and sensory-processing disorders that may coexist in some children with learning disabilities.[19] A vision specialist for the visually impaired may benefit children with dyslexia who have low vision. Physicians, including general pediatricians, developmental/behavioral pediatricians, family physicians, neurologists, ophthalmologists, otolaryngologists, mental health professionals, and other appropriate medical specialists may assist in diagnosing and treating any associated health problems if they are present in these patients. Clinical psychologists or other mental health providers, including developmental/behavioral and neurodevelopmental pediatricians, can provide strategies to help children better cope with social challenges that may be associated with learning disabilities. Psychiatrists, developmental/behavioral pediatricians, neurodevelopmental pediatricians, or general pediatricians with special expertise may prescribe medications or conduct therapy to improve comorbid psychological disorders.

Treatment for dyslexia consists of using educational tools to enhance the ability to read. Educational therapists or educators who have been specially trained in learning disabilities develop and implement intervention plans for children with learning disabilities and dyslexia. An appropriate treatment plan will focus on strengthening the student's weaknesses while using the strengths. Because many students with learning disabilities receive most of their instruction in general education class, teachers need to be trained on the instructional strategies essential to success for these students.[22] Many children with dyslexia do well in small group instruction of matched students, whereas others need one-on-one help so that they can move forward at their own pace. The instruction must be intensive enough and continue long enough to have a positive effect that will endure.[105] If a student with dyslexia has an outside academic therapist, the therapist should work closely with the child's classroom teachers.

The critical elements for effective intervention include individualization, feedback and guidance, ongoing assessment, and regular ongoing practice.[34] Remediation, educational accommodation, and modification are used as techniques for overcoming dyslexia and the educational deficits that it causes.[24,30,33,34,55,60,63,81] The management of dyslexia demands a lifespan perspective; early on, the focus is on remediation.[34] Remedial interventions should be aimed at the specific needs of the child and viewed as a dynamic process. Because dyslexia is a language-based disorder, treatment should be directed at this etiology.‡‡ Reading instruction should be explicitly taught, which means that children are not expected to infer key skills or knowledge.[34] Students who are easily confused are more likely to be successful when teachers demonstrate and clearly explain what they need to learn.[58] Most children with dyslexia need help from a teacher, tutor, or therapist who has been specially trained in using a multisensory, structured language approach. It is important for these children to be taught by a sequenced systematic and explicit method that involves several senses (hearing, seeing, touching) at the same time.[107] Highly structured daily intensive individualized instruction by an educational therapist or skilled teacher specially trained in explicitly teaching phonemic awareness and the application of phonics is the foundation for remedial programs.§§ In addition, students with dyslexia often need a great deal of structured practice and immediate, corrective feedback to develop automatic word-recognition skills. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension.|||| The approach to learning decoding begins with detailed instruction in phonemic awareness and then progresses to sound-symbol association (alphabetic principle), phonics, awareness of rhyme, and word segmentation. Phonics is the system of instruction used to teach children

‡‡Refs 1, 14, 24, 25, 30–35, 43, 55, 60, 63–65, 81, and 106.

§§Refs 1, 14, 24, 25, 30–35, 55, 60, and 63–65.

||||Refs 1, 14, 32–35, 43, 55, 60, 63–65, and 81.

the connection between letters and sounds. Longitudinal data indicate that systematic phonics instruction results in more favorable outcomes for readers with disabilities than does a context-emphasis (whole-language) approach.¶¶ Later, syllable instruction, morphology, memorization of sight words, spelling, syntax, and semantics are taught.[55] A child must first accurately decode a word before it can be read fluently, but accuracy does not spontaneously evolve into fluency. Sight words need to be memorized, and speeded word-repetition drills should be performed. Daily fluency practice involves repeated guided oral reading of a large amount of text at the child's independent reading level. Practicing reading aloud makes feedback possible. Fluency forms the bridge between decoding and comprehension.[34] Comprehension is gained through fluency training, vocabulary instruction, and active reading comprehension.[34,35] Techniques that enhance active reading comprehension include prediction, summarization, visualization, clarification, critical thinking, making inferences, and drawing conclusions.[14,24,25,33–35,60,63,65] To further gain comprehension, these activities should be combined with other activities to improve language development.[24,25,32–34,55,60,63,64] The brain learns best by practice, and practice is the key to learning to read.

Schools can implement academic accommodations and modifications to help students with dyslexia succeed. Because people with dyslexia have a persistent problem and continue to read slowly throughout their life, it often becomes necessary to adapt the learning environment.[24,25,34,81] Accommodations allow access to higher-level thinking and reasoning strengths. Examples can include preferential seating, extra time for assignments and tests, shortened or modified assignments, help taking notes, lecture notes, computers for writing, a separate quiet room for taking tests, extra assistance using computers, spell checkers, a line guide, or tutors. Reading can be bypassed by using tape recorders, recorded books, text-reading computer programs, lecture tapes, taped tests, or other testing alternatives.[24,25,34,47,81]

Many good software programs currently exist and are affordable. Text-reading software programs provide an excellent opportunity for students with dyslexia to keep up with reading assignments. They are also helpful with written examinations and handouts provided by the teacher. A portable scanner can easily scan written material in the classroom and at home and be used with these programs. The text-reading rate can be adjusted to assist with comprehension, and spaces can be created to write notes in the text. Text-reading software is also designed to be used with writing software to allow a student's writing to be read aloud. The software includes phonetic spelling assistance and intelligent word-prediction features that can address the dysgraphia that often co-occurs with dyslexia. These programs should be a key component of an educational plan, especially for older students. They provide relief, promote self-esteem, and are fun to use. Ongoing appropriate reading remediation should continue along with these compensatory techniques.

Parental participation in a child's education is of utmost importance but may be more difficult if the parents are functionally illiterate. The home is an ideal setting for practice and reinforcement.[34] Children should read aloud to their parents using fun, easy-to-read books. Reading aloud will alert parents if a problem exists. Children who avoid reading are most in need of practice. Parents should help with practice and reinforcement at home with opportunities to check fluency and comprehension via interactive reading experiences. Reading practice at home should be conducted in a supportive and nurturing environment with adequate opportunity for the child to participate in other activities in which he or she excels. As the child gets older, parents should help the child use recommended alternative learning strategies such as books on tape or computers.

Parents should provide ongoing feedback to remediating specialists and should be given the opportunity to ask questions to maximize educational outcomes. Parents need to serve as the child's advocate by speaking with the child's teacher, pediatrician, and other professionals; requesting an educational evaluation; and coordinating remediation and other treatment. By educating themselves in the areas of learning disabilities, available services, and state education rules and regulations, parents will increase their effectiveness as the child's advocate. Parents should work with educators to ensure that the school provides the proper remediation and accommodations and should continue to monitor their child's progress and advocate for their child when necessary.

The teaching of children with dyslexia and learning disabilities is a challenge for educators and parents; however, with proper remediations, educational accommodations, and support, children with dyslexia and learning disabilities can overcome obstacles to improve their reading and writing. Children with extreme deficits in basic reading skills or those with the double deficit of phonologic and rapid automatic naming difficulties are much more difficult to remediate than children with mild or moderate deficits.[30]

¶¶Refs 1, 14, 30, 34, 60, 63, 65, 81, and 106.

The prognosis depends on the severity of the disability; specific patterns of strengths and weaknesses of the individual child; and the appropriateness, amount, intensity, and timing of the intervention.[34] The instruction must be intensive enough and continue long enough to have a positive effect that will endure.[105] Early identification and treatment are the keys to helping children with dyslexia, because children 8 years and younger are more likely to show improvement.

A potential goal in the treatment of dyslexia will be its prevention. Brain measures, such as studies of longitudinal event-related potentials, have shown impressive relations between brain responses at infancy and later language and reading success or failure. In the future, a combination of behavioral and brain measures, perhaps together with genetic and familial information, may enhance the certainty with which dyslexia can be predicted and promote the possibility of preventive intervention that would allow many more children to succeed at learning to read.[53]

ROLE OF THE PEDIATRICIAN AND PRIMARY CARE PHYSICIAN

Pediatricians and primary care physicians can serve a number of important functions for children with dyslexia and their family members. Developmental screening as early as 30 to 48 months may identify language or learning concerns. During well-child visits, physicians should inquire about the child's educational progress and be vigilant in looking for early signs of evolving learning disabilities. General pediatricians should not diagnose learning disabilities but may discuss the possibility with parents.[108] When a child has suspected learning difficulties, the pediatrician or family physician should first assess the child for medical problems that could affect the child's ability to learn and refer him or her for further evaluation if deemed appropriate.[98,108] The physician should take a complete medical history, including determination of maternal drug or alcohol use, neonatal/birth problems, genetic syndromes, and congenital anomalies. Additional medical history should include detection of medical problems (such as chronic or persistent otitis media, asthma, thyroid problems, or any chronic disease that may have caused school absences); neurologic problems (such as seizure disorder, head trauma, history of central nervous system infection, or lead poisoning); developmental, behavioral, emotional, or psychiatric problems (anxiety, depression, obsessive compulsive disorder, or oppositional defiant disorder); ADHD; or autism spectrum disorder. Specific questions on language acquisition and learning should include history of speech delay, speech difficulties, or articulation problems; difficulties in learning letters or phonics; lack of reading readiness; poor instruction; overall academic achievement; and visual difficulties. A family history of speech and language problems, learning disabilities, or functional illiteracy should also be noted. A social history should be taken, and alcohol use, drug use, cultural differences, or poverty for the child or the family should be noted. A complete physical examination to evaluate the child's overall medical and neurologic condition and a psychological, emotional, and behavioral evaluation should be performed. An assessment of the child's activity level, attention span, alertness, cooperation, and ability to communicate should be noted.

Primary sensory impairments should be ruled out by hearing and vision screenings. For all children, primary care physicians should perform hearing and vision screenings according to national standards so that hearing, ocular, and visual disorders are identified as early as possible.[109] Periodic eye and vision screenings can identify most children who have reduced visual acuity or other visual disorders. Vision screening with nonletter symbols may be necessary for testing children with dyslexia or other learning disabilities.[110]

Children who do not pass vision screening should be referred to an ophthalmologist who has experience with the care of children.[109,110] In addition, the recommended routine pediatric vision screenings are unlikely to disclose near-vision problems such as convergence insufficiency, accommodative insufficiency, and significant hyperopia. Children with suspected learning disabilities in whom a vision problem is suspected by the child, parents, physicians, or educators should be seen by an ophthalmologist who has experience with the assessment and treatment of children, because some of these children may also have a treatable visual problem that accompanies or contributes to their primary reading or learning dysfunction.[110–113] Treatable ocular conditions can include strabismus, amblyopia, convergence and/or focusing deficiencies, and refractive errors. Missing these problems could cause long-term consequences from assigning these patients to incorrect treatment categories.

Pediatricians and primary care physicians play an extremely important function in acting as a medical home by helping parents decide whether further evaluations are needed and in coordinating care for the child after a diagnosis has been made.[98,108] A child should receive medical and psychological interventions as appropriate for diagnosed conditions.[108] If the pediatrician believes that the child has not received a proper assessment at school, then the pediatrician should refer the

child for an outside independent educational evaluation by an educational psychologist, clinical psychologist with special training in learning assessments, neuropsychologist, developmental/behavioral pediatrician, neurodevelopmental pediatrician, or neurologist with appropriate expertise. Referral to an educational psychologist for psychoeducational assessment for the purpose of identifying special needs should be considered if the primary issue is the child's educational performance or learning problems. For patients with complex or long-standing educational problems that have been difficult to remediate, referral to a neuropsychologist, developmental/behavioral pediatrician, neurodevelopmental pediatrician, or neurologist with appropriate expertise should be considered for a more in-depth evaluation of brain function to asses overall cognitive, emotional, and behavioral functioning. A child should be referred to a neuropsychologist for problems such as learning, attention, behavior, socialization, or emotional control; a disease or developmental problem that affects the brain; or a brain injury from an accident or birth trauma. Pediatricians and primary care physicians should compile and provide a resource list of local specialists from whom the child can obtain proper help and from whom the family members can learn to become advocates for the child.[108] Pediatricians and primary care physicians should provide information and support to parents on learning disabilities and their treatment and should dispel the myths surrounding these disorders.[111] When parents inquire about a new technique or treatment concept, physicians should be ready to discuss the treatment and the current knowledge about its efficacy.[26] This discussion should include providing the parents with information regarding the lack of proven efficacy of vision therapy and other "alternative treatments."[111] Parents need to be informed that dyslexia is a complex disorder and that there are currently no quick cures. The American Academy of Pediatrics has information for families on what parents need to know about learning disabilities.[114]

Pediatricians and primary care physicians should be familiar with the IDEA, Section 504 of the Rehabilitation Act, and the ADA, because these acts define the rights of students with dyslexia and other specific learning disabilities.[95–97] The IDEA allows parents to request a formal educational evaluation by the school district to determine eligibility for special education.[96] Information for pediatricians on this legislation and its associated rights and procedures is available from the American Academy of Pediatrics.[98,108] Physicians can refer parents of children with learning disabilities to their state's parent training and information center. These parent-directed centers provide information and technical assistance to parents and professionals about family and student rights and responsibilities in special education.

Physicians who have a strong role in assisting school districts should recommend only evidence-based treatments and accommodations. They should also discourage school districts and parents from pursuing treatments that are not evidence based, because they are likely to waste time and resources.

THE EYES AND VISION

Visual Acuity and Refraction

Books for beginning readers usually have very large print of approximately 20/200 to 20/100 size. Good visual clarity and resolution are necessary to discern small print. There is no evidence that children with moderate myopia, moderate hyperopia, or moderate astigmatism have any greater difficulty in learning to read than do other children. Small amounts of hyperopia are normal in young children and are usually of no pathologic significance. The average refraction of white children in the United States is nearly 2.00 diopters (D) of hyperopia in the first 5 years of life and then gradually decreases into adolescence.[115] (A diopter is the unit of measurement of the refractive power of lenses equal to the reciprocal of the focal length measured in meters.) Nonmyopic significant refractive errors are present in 10% of children younger than 12 years. Children with uncorrected myopia will have reduced distance visual acuity and, thus, have difficulties with reading the board at school but no difficulty with near vision. Despite the condition, children with myopia have been found to be average to above-average students. Early optometric studies that have indicated increased hyperopia in children with reading difficulties are of limited significance, because the studies did not have control groups and were generally unreliable because they were performed without cycloplegia.[116] Before diagnosis and treatment, children with uncorrected high hyperopia may be uninterested in books and near tasks and secondarily experience difficulty starting to read, but they do not have an increased likelihood of true dyslexia.[115] There is no correlation between reading performance and any specific type of refractive error, including hyperopia or a need for glasses.[111]

Amblyopia causes reduced visual acuity and susceptibility to the crowding phenomenon, a difficulty with distinguishing letters in close proximity to one another, but only in the amblyopic eye/visual system. In children with amblyopia, fixation is usually performed with the fellow, nonamblyopic eye/visual system. In 1 study, microstrabismic amblyopia was associated with slower reading rates but not with dyslexia.[117] Nystagmus, bilateral cataracts, and retinal or optic nerve prob-

lems can interfere with visual acuity. Children with severe visual impairment are able to learn to read with assistance from spectacle correction for refractive errors and low-vision appliances. In general, ocular disease does not affect the ability of children to learn to read. Furthermore, children who are blind are able to learn to read using Braille. Vision impairment, in itself, has not been shown to be a predictor of reading disability.[58]

Saccades and Fixations

The eye movements used in reading are not similar to a typewriter typing. Smooth pursuit or tracking eye movements are not used in reading.[136] Reading uses saccades that are short-duration, high-velocity, small jumping eye movements. Reading uses both forward (rightward in English) saccades (85% of saccades) and backward or regression (leftward in English) saccades (15% of saccades).[118,119] Scanning a line of text in English involves a sequence of rightward and leftward saccades. The saccade length depends on the ability to recognize letters, the difficulty of the text, and the length of the word before the saccade. Experienced readers use longer saccades of approximately 2 degrees or 8 letters of average-sized print text.[120] Backward saccades are used for verification and comprehension, increase with the difficulty of the text, and are also used to jump to the next line. Early readers use more backward saccades. Visual perception is suppressed during saccades. Visual information is perceived during foveal fixations, which constitute 90% of our reading time.[111,118] Fixations may last 45 to 450 milliseconds and average 180 milliseconds. The duration of a fixation varies with the difficulty of the text being read.[118] When fixated, the eye rests on a content word and takes in a span of approximately 7 to 9 letters to the right of fixation and 3 to 4 letters to the left before it jumps over to the next fixation point. More letters are processed to the right of fixation if the eye is scanning from left to right, as in English, and the opposite would be true for reading a language than is scanned from right to left.

Early anecdotal publications in the optometric literature in the 1950s reported a possible oculomotor deficit that disrupted the normal saccadic reading pattern. In contrast, many studies subsequently have demonstrated that ocular coordination and motility are normal in children with dyslexia.[121–129] No difference was found between adults with dyslexia and controls on measures of saccadic accuracy and saccadic latency.[130] Readers with dyslexia have shown saccadic eye movements and fixations similar to those of the beginning reader and have shown normal saccadic eye movements when content is corrected for ability.[111,122] Improving reading has been shown to change saccadic patterns, but there is no evidence to suggest that saccadic training results in better reading. Readers with dyslexia have shown normal sequential saccadic tracking in tasks other than reading and oculomotor functioning.[125] Simulated saccadic "abnormalities" can be created by giving normal readers overly complex material or material in a new language.[122] Results of 3 studies by Rayner et al[131–133] were consistent with visual/linguistic-control models of eye-movement control and inconsistent with visual/oculomotor-control models. The saccadic patterns seen in readers with dyslexia appear not as a cause but as a result of their reading disability.## Decoding and comprehension difficulties, rather than a primary abnormality of the oculomotor control systems, are responsible for slow reading, increased duration of fixations, and increased backward saccades.[136] Children with dyslexia often lose their place while reading because they struggle to decode a letter or word combination and/or lack attention or comprehension, not because of a "tracking abnormality." Children with saccadic disorders, Duane syndrome, Moebius syndrome, and abnormal eye movements such as those with congenital motor nystagmus have shown the ability to learn to read fluently.[137] Dyslexia is no more frequent in these children with significant eye-movement disorders than in the general population.[137] Problems such as nystagmus interfere with foveal fixation time, yet affected children have not shown an increased likelihood of dyslexia. Thus, dyslexia is not the result of oculomotor deficits but, rather, the result of more central processing problems.[125]

Accommodation

Accommodation is the ability to focus accurately at near and is necessary for reading at near. Accommodative amplitudes are maximal in childhood and decrease naturally with age. The average amplitude of accommodation in children younger than 10 years is 14 D, which corresponds with a near point of accommodation of 2 to 3 in. Fifty percent, or 7 D, is available for sustained near activity; thus, young children can read comfortably at 6 in for a prolonged time. In the pediatric population, the incidence of accommodative insufficiency is low.[138,139] If it is present, symptoms can include discomfort or blurry or moving vision. Findings of accommodative insufficiency may include decreased visual acuity at near, a remote monocular near point, accommodative lag, and either esophoria or exophoria. Decreased accommodation has been associated with uncorrected high hyperopia, nonspecific viral illness, local ocular trauma, many medications, and functional problems.[138] There is no proof that

##Refs 14, 111, 112, 116, 118–128, and 134–136.

there is a difference in accommodative ability between normal and abnormal readers.[111] Difficulties in accommodation do not interfere with decoding but can interfere with the child's ability to concentrate on print for a prolonged period of time.[29]

The vergence system works to maintain fusion so that the eyes remain aligned on a visual target. Convergence is the inward turning of the eyes and is used for near reading. Various authors define convergence insufficiency differently. The diagnosis of convergence insufficiency is based on a remote near point of convergence or difficulty in sustaining convergence combined with asthenopic symptoms (sensations of visual or ocular discomfort) at near. The presence of 500 seconds of arc of stereopsis is required. These findings should be accompanied by a low convergence fusional amplitude, and/or a large exophoria or intermittent exotropia at near with a smaller exophoria, orthophoria, or esophoria at the distance. These latter findings alone do not constitute the diagnoses of convergence insufficiency, because they may be present with good convergence.[140,141] Of these findings, the most important are the ability to obtain and maintain convergence. The diagnosis of convergence insufficiency is relevant only if there are multiple findings accompanied by significant symptoms. Lack of sleep, illness, and anxiety are known to aggravate the problem. Older children, teenagers, and adults may become symptomatic because of large amounts of demanding near work and reading while fatigued. Patients typically present as teenagers or young adults with gradually increasing complaints of discomfort, eyestrain, headache, blurred vision, or diplopia during extended periods of studying.

The prevalence of convergence insufficiency has been reported to be in approximately 3% to 5% of the population. However, because of the differences in diagnostic criteria, some studies report the prevalence as being as low as 0.3% to 0.8%,[142,143] whereas a retrospective study of 8- to 12-year-olds in which findings alone were used classified 51% of the children with possible convergence insufficiency.[144] This classification system is obviously not valid, because it leads to classifying many normal children as abnormal. The disorder is much less common in children younger than 10 years. The incidence of ADHD was reported in 1 study to be increased in children with convergence insufficiency,[145] but additional analysis has revealed that the reported incidence was actually average when compared with large studies in which the prevalence of ADHD was evaluated.[17,18] Convergence amplitudes have not been correlated with reading comprehension.[146] A study of 735 children found no significant difference in school achievement for children who showed convergence insufficiency and those who did not.[147] Convergence insufficiency can interfere with a child's ability to concentrate on print for a prolonged period of time but does not interfere with decoding.[29]

Binocular Vision

True orthophoria—perfectly straight eyes—occurs rarely; most people demonstrate a small asymptomatic phoria, a latent deviation usually esophoria or exophoria, that should be considered a normal variant. A study of more than 3000 unselected students revealed a near phoria in most children. Several studies have investigated the connection between reading ability and the binocular and accommodative status of unselected children. No causal relationship was found between normal variants and reading/writing difficulties.[113] Manifest strabismus, known as tropias (eg, esotropia and exotropia), also has not been associated with dyslexia.[116,148]

Visual Processing

Processing of visual input is a higher cortical function.[14,15,111] Decoding and interpretation of retinal images occur in the brain after visual signals are transmitted from the eyes. Although vision is necessary for reading, it is the brain that must perform the complex function of interpreting the incoming visual images. Historically, many theories have implicated the visual system in the causation of dyslexia. The demise of these theories began in the 1980s with a series of related studies that systematically evaluated deficits in visual processes such as visualization, visual sequencing, and visual memory as basic causes of reading difficulties.[14,15] Visual theories of reading disability have become less and less popular, because only a few children who are poor readers actually suffer from perceptual malfunctions. Robinson and Schwartz[149] found no correlation between visual-perceptual abilities and reading ability. Larsen et al[150] found no differences in visual perception between normal and learning-disabled children. Larsen and Hammill[151] found no predictive relationship between standardized tests of visual perception and reading ability in their review of 60 studies. Morrison et al[152] found no perceptual deficits in children with reading disabilities. In short, visual skills do not reliably distinguish children who differ in reading ability.*** In their review in 2004, Vellutino et al[14] found no statistically significant differences in the studies between poor and normal readers on measures evaluating visual recognition and visual recall of letters and words. Visual deficits of the types from the early literature were found to be no more prevalent in poor readers than they

***Refs 2, 9–12, 14, 15, 116, 119–128, 134, 135, 137, and 149–151.

were in normal readers. In many studies that compared poor and normal readers, few significant differences were found on measures of visual processing ability when the influence of verbal coding was controlled.[14] Difficulties in maintaining proper directionality have been demonstrated to be a symptom, not a cause, of reading disorders.[14,15,111,122] Word reversals and skipping words and lines were attributable to linguistic deficiencies and not visual or perceptual disorders.[14,15,59]

In summary, vision problems can interfere with the process of reading; however, vision problems are not the cause of dyslexia. Significant refractive errors can make reading more difficult. Convergence insufficiency and poor accommodation, both of which are uncommon in children, can interfere with the physical act of reading but not with decoding and word recognition.[29] Thus, treatment of these disorders can make reading more comfortable and may allow reading for longer periods of time but does not directly improve decoding or comprehension.[29] If reading impairment is attributable solely to a visual problem, improvement in school performance should be observed once the problem is corrected.[153] Other than the need for long-term optical correction, these problems generally do not require extended treatment programs.

Many children with reading disabilities enjoy playing video games, including handheld games, for prolonged periods. Playing video games requires concentration, visual perception, visual processing, eye movements, and eye-hand coordination. Convergence and accommodation are also required for handheld games. Thus, if visual deficits were a major cause of reading disabilities, these children would reject this vision-intensive play activity.

ROLE OF THE OPHTHALMOLOGIST

Because routine pediatric vision screening is not designed to detect problems with near vision, children with suspected or diagnosed learning disabilities should undergo a comprehensive pediatric medical eye examination by an ophthalmologist who has experience with the assessment and treatment of children, because some children may also have a treatable visual problem along with their primary reading or learning dysfunction.[110–113,154] The medical history should include detection of any medical condition that could interfere with the child's ability to learn or a chronic medical illness that could cause school absences or difficulties concentrating or learning. The ocular history should include any eye or vision complaints that may make it difficult for the child to concentrate on reading for extended periods of time. It is important for the ophthalmologist to recognize that healthy children often have visual complaints from normal visual phenomena such as physiologic diplopia and relaxation of accommodation.[112,155] Also, most children (82%) who complain of eyestrain and headaches have a normal eye examination, whereas children with refractive error (78%), amblyopia (68%), or strabismus (58%) are free of eyestrain, which makes these complaints a poor marker of eye conditions in young children.[156]

The ophthalmologist should perform a complete dilated eye examination, including cycloplegic refraction. Cycloplegia with either 1% or 2% cyclopentolate is necessary for accurate refraction in young children. The strength should be based on the child's weight, iris coloration, and dilation history. In eyes with heavily pigmented irides, adjunctive agents such as tropicamide and/or phenylephrine hydrochloride may be necessary to achieve maximal cycloplegia and pupillary dilation. Vision testing with nonletter symbols may be necessary and may be especially important for testing children with dyslexia or other learning disabilities. The eye examination should place special importance on the detection of undiagnosed vision impairment by assessing visual acuity at the distance and near, significant refractive errors, amblyopia, or strabismus.

Strabismus, amblyopia, and refractive errors may require glasses, eye patching, eye drops, convergence training, prisms, or eye muscle surgery in accordance with standard principles of treatment.[110,157,158] In school-aged children without strabismus or amblyopia, correction of myopia should be considered approximately at −0.75 D or greater, astigmatism at 1.00 D to 1.50 D or greater, hyperopia at +4.00 D to +4.50 D or greater, anisometropic myopia at 2.00 D or greater, anisometropic hyperopia at 1.50 D or greater, and anisometropic astigmatism at 1.50 D to 2.00 D or greater.[110,159] Myopia and astigmatism are fully corrected, whereas high hyperopia is often undercorrected by up to 50% but no more than 3.00 D, depending on the clinical situation.[110] These guidelines should be adjusted on the basis of the patient's visual needs and symptoms, such as asthenopia and reduced visual acuity or lack of symptoms. Children with developmental delay or Down syndrome often hypoaccommodate and may benefit from spectacle correction at lower thresholds.[159]

A careful external ocular examination should be performed to determine if the child has problems such as dry eyes, blepharitis, or ocular allergies that could cause eye irritation that can secondarily interfere with his or her ability to concentrate and learn. Finally, a dilated retinal evaluation should be performed. Retinal or optic nerve problems can lead to strabis-

mus, amblyopia, reduced visual acuity, and, rarely, photophobia.

Emphasis should be placed on the evaluation of ocular alignment, binocular function, stereopsis, accommodation, and convergence. Ocular alignment is assessed by using the corneal light reflection, the binocular red-reflex (Bruckner) test, cover/uncover, and alternate-cover tests in primary gaze with accommodative targets at distance and near when feasible; cover testing is most important. If an ocular misalignment is detected, multiple measurements of the ocular deviation using prisms in 1 or more fields of gaze at distance and/or at near is necessary. Ocular versions and ductions should be evaluated. Stereoacuity can be evaluated with the random dot E, Lang, or stereo fly test, whereas fusion can be tested with the Worth 4-dot test or Bagolini lenses. These tests can be performed at both near and distance when necessary.

Near visual acuity should be assessed in the evaluation of accommodation. The monocular near point of accommodation can be measured by conventional push-up technique using a ruler, Clark stick, or Costenbader accommodometer.[160] Before cycloplegia, dynamic retinoscopy can provide a rapid assessment of accommodative function and may be helpful in evaluating a child with high hyperopia, accommodative lag, or possible accommodative insufficiency. The accommodative facility can be assessed by alternately applying −2.00 and +2.00 lenses while the child reads monocularly. Symptomatic accommodative infacility may cause difficulty in shifting from far to near and near to far. The accommodative amplitude can be assessed by using increasing minus lenses while the child reads monocularly. Symptomatic accommodative insufficiency can cause blurry vision and discomfort, which can contribute to difficulties in concentrating on print for prolonged periods of time. Symptomatic accommodative insufficiency with a near point of accommodation well outside established norms can be treated with reading glasses or bifocals; it must be emphasized, however, that this condition is rare; hence, bifocals are rarely needed by children. Treatment of accommodation difficulties can make reading more comfortable but does not improve decoding or comprehension.[29]

The near point of convergence should be tested by using an accommodative target and measured with a ruler. Distance- and near-convergence amplitudes can be measured by using a base-out horizontal prism bar or rotary prism while the child is reading. Symptomatic convergence insufficiency can cause discomfort, eyestrain, blurry vision, diplopia, and headache, which can contribute to limited fluency by interfering with the child's ability to concentrate on print for a prolonged period of time. Symptomatic convergence insufficiency is a treatable condition. To improve reading comfort, it can be treated with near-point exercises, prism convergence exercises, or computer-based convergence exercises. Home computer-based convergence exercises are a newer method of treatment, and many children enjoy using the computer program. Over the years, orthoptic therapy has been adapted into simple visual tasks that can be taught in the office and conducted by the patient at home. Near-point convergence exercises generally consists of push-up exercises using an accommodative target of letters, numbers, or pictures; push-up exercises with additional base-out prisms; jump-to-near-convergence exercises; stereogram convergence exercises; recession from a target; and maintaining convergence for 30 to 40 seconds.[140,161,162] Generally, children are reevaluated in the office on a monthly basis.[140,161] Intensive in-office vision therapy is effective but not required.[161,163–165] Alternatively, for other patients, reading glasses with base-in prism or occlusion during reading can be used to treat the symptoms of diplopia but not the underlying convergence insufficiency.[140] The treatment of convergence insufficiency can help reading become more comfortable and may allow reading for longer periods of time, but this approach does not directly improve decoding or comprehension.[29]

In summary, the ophthalmologist should identify and treat any significant visual defect according to standard principles of treatment.[110,153,158,166] If no ocular or visual disorder is found, the child needs no further vision treatment. The ophthalmologist should not diagnose learning disabilities but should provide information on learning disabilities and reinforce the need for additional medical, psychological, educational, or other appropriate evaluation or services.[153,167] The ophthalmologist, when necessary, should compile and provide a resource list of local specialists to assist in obtaining proper help for the child.[167] In addition, the ophthalmologist should dispel myths surrounding these disorders and discuss the lack of proven efficacy of vision therapy and other alternative treatments with the parents. The American Academy of Ophthalmology and American Academy of Pediatrics have patient-education brochures for families on learning disabilities.[114,168]

SCIENTIFIC RESEARCH AND DISSEMINATION TO THE PUBLIC

Science advances by a process of modification. A continuous process of research and testing needs to take place to show that a treatment has demonstrable effect and benefits and to compare effectiveness between treat-

ments. Over the last 50 years, progress in medicine has been based on controlled studies. Evidence-based medicine (EBM) categorizes different types of clinical evidence and ranks them according to the strength of their freedom from various biases. The "evidence pyramid" ranks testimonials, anecdotes, case reports, and case studies as poor sources of scientific information. Alternative medicine makes most of its claims by unsubstantiated testimonials.

EBM is the use of the most reliable current evidence to make treatment decisions. The practice of EBM integrates individual clinical expertise with the best available external clinical evidence from systematic research.[169] EBM is open to new evidence and revised conclusions. To use EBM, the physician should investigate the medical literature efficiently, read the methodology section to evaluate the quality of the evidence to determine the validity of the study, and, lastly, evaluate the results. The issue of validity speaks to the "truthfulness" of the information. Properly performed scientific studies offer the possibility of validity. Critical appraisal is a systematic process used to identify the strengths and weaknesses of a research article to assess the usefulness and validity of its findings. If the study is not valid, the data are not useful.[170] The physician must not take the conclusion seriously until the appropriateness of the study design, methodology, and statistical analysis have been critically evaluated. Thus, a physician cannot read the study abstract alone and be confident of the conclusion. Serious scientific, methodologic, and statistical flaws noted in some study reports that invalidated their conclusions are discussed in "Controversial Theories and Therapies."

Many types of statistical bias or other problems can be present in published scientific study reports. A positive ascertainment bias leads us to remember only positive results and positive studies. Positive studies are more likely to be published than are negative studies because of publication bias. Nonrandom sampling leads to difficulties generalizing the data. Selection bias includes self-selection, subject prescreening, and attrition. Manipulation of the data by rejection of "bad data" or "outliers" leads to biased data. Preliminary positive results in smaller studies often are not repeatable in larger randomized, placebo-controlled, double-blinded studies. A study with more preliminary supporting evidence is more plausible than one with weak or no previous supporting evidence. False-positive results are more likely in clinical trials that examine highly improbable hypotheses compared with hypotheses with a stronger basis in science.[171,172]

The Hawthorne effect may occur and bias the research when the experimental subjects change their behavior as a result of being observed, not in response to any particular experimental manipulation. The multiplicity problem may occur when the more often a hypothesis is tested, the more likely a positive result will be obtained. Similarly, when a lot of data are collected without a specific hypothesis in advance, some pattern will likely be found. An advanced hypothesis and appropriate statistical methodologies to control the probability of false-positive findings are essential for demonstrating credible scientific findings.

In poor research, the results or the conclusions may be skewed or biased to seem to be consistent with hypotheses proposed. Confirmation bias occurs when experiments are designed to seek confirmatory evidence instead of trying to disprove the hypothesis. Conclusions may be misleading or artificially inflated when data-derived, posthoc subgroup analysis is performed; new statistically significant outcomes are introduced for publication; nonsignificant primary outcomes are omitted from reports; or statistically significant secondary outcomes are upgraded to primary end points.[173]

Poorly conducted research may produce false-positive or false-negative results. Studies that do not control for the placebo effect may produce false-positive results. Studies with controls and "no-treatment groups" are necessary to evaluate the size of the placebo effect. The placebo effect may be a large portion of the positive responders.

The public is largely uninformed about the hallmarks of good research. The finding of an association is not a finding of cause and effect. There should be documented objectivity associated with research, and, when possible, there should be replication. Good research is rigorous and objective and requires peer review. Research findings should be tested and scrutinized from many angles by multiple, unrelated researchers. Ideally, a study of efficacy compares a treatment with a placebo or another treatment by using a double-masked controlled trial and well-defined protocol. Reports should describe enrollment procedures, eligibility criteria, clinical characteristics of the patients, methods for diagnosis, randomization method, definition of treatment, control conditions, and length of treatment. Standardized outcomes and appropriate statistical analyses should be used. Age-matched control groups are important in learning-disability studies.[112] Good baseline similarities of the population and the medical condition is necessary to compare like with like. All associated conditions or treatments should be controlled. The comparison groups must be the same except for the factor that is being studied. Large-scale stud-

ies provide more reliable conclusions by reducing the margin of error. The strongest evidence for therapeutic interventions is provided by carefully designed large-scale, randomized, double-blinded, placebo-controlled trials that involve good baseline similarities of patient population and medical condition with an adequate follow-up time and low study participant attrition rate.[170]

From a scientific perspective, "healthy skepticism" should be adopted by the research community[174] and the public. Scientists hesitate to accept research results unless they can demonstrate a statistical probability of more than 95% that the observations are not attributable to chance. The research community is willing to embrace a theory only when there is substantial convergent evidence from multiple sources. It often takes years to convince the research community that a theory has merit, but it frequently takes no time at all to convince the public.

The media now play a major role in providing information or misinformation on new scientific developments to the public. They may report claims by a tiny minority and place them on equal footing with the majority opinion or report claims before any research. Some scientists report their claims directly to the media, which circumvents the normal process of scientific review and debate. Public health messages are inadequate or distorted when journalists ignore complexities or fail to provide context.[175] The result is that a large share of the science seen by the public is flawed because of minimal or distorted scientific facts. This public information can influence the behavior of clinicians and patients. Media hype of the overstated findings of poorly designed research may change behavior and harm public welfare.[176]

In 1984, Levine[128] stated that pediatricians (and ophthalmologists) must serve as scientific consumer advocates and help parents, teachers, and the community at large to evaluate claims and insist on hard evidence regarding diagnostic and therapeutic modalities. Although it is prudent to be skeptical, especially with regard to prematurely disseminated therapies, it is important to also remain open-minded. Aggressive marketing, dramatic presentations, loosely reviewed journal articles, and fervent anecdotal reports of cure may convince school personnel and parents that visual training is the answer. Levine warned that in such cases, the pediatrician may be bypassed and considerable family and community resources may be diverted toward unsubstantiated interventions.

Helveston[177] stated that it has become traditional in medicine for new and unproven treatments to be evaluated under a protocol by qualified investigators on patients who give informed consent after the risks and benefits have been explained. The work is often performed at no charge, and results are reported for peer review. Only when the aforementioned criteria are met and it is shown that treatment is effective is treatment customarily offered on an unrestricted basis. According to Helveston, the use of tinted lenses or filters and vision therapy for learning disabilities does not follow these standards.

Silver[178,179] has written many articles on controversial therapies including vision therapy. He stated that a treatment approach can be considered suspect if the approach is proposed to the public before any research results are available or preliminary research has not been replicated; the proposed approach goes beyond what research data support; the approach is used in an isolated way when a multimodal assessment and treatment approach is needed; the treatment approach is being commercially promoted before the research shows any support for the proposed treatment; or there is clear research evidence showing that the approach does not work, yet the approach is still advertised commercially.

Kennedy et al[180] stated that unvalidated treatments often claim to be effective against a range of disorders with different symptoms and etiologies. Worrall[181] recommended that the public be suspicious of any therapy that claims to treat a large number of illnesses. He stated that the chronic nature of learning disabilities offers the ideal environment for fraud and quackery. He noted that parents often abandon common sense in their quest to help their struggling children and become easy prey for therapists who promise a cure.[181,182] Thus, the public must learn to carefully evaluate the information received in the face of aggressive promotion.

CONTROVERSIAL THEORIES AND THERAPIES

Magnocellular Deficit Theory

There is continuing interest in low-level impairments of the visual system as an etiologic factor in dyslexia. The visual system is composed of 2 parallel systems: the magnocellular (large-celled) (transient) system and the parvocellular (small-celled) (sustained) system.[183] The magnocellular system responds to high temporal frequency and object movement, and the parvocellular system is sensitive to low-frequency and fine spatial details.[183] The magnocellular component of the visual system is important for timing visual events and controlling eye movements when reading.[183,184] It is postulated that the magnocellular system suppresses the parvocellular system at the time of each saccade. This suppression terminates the activity in the parvocellular system to prevent ac-

tivity elicited during a fixation from lingering into that from the next fixation. The magnocellular deficit theory of dyslexia proposes that without this suppression, the parvocellular activity from different fixations would be confused, which would result in a failure to keep separate neural activity elicited during different fixations. Specific reading disability in a small subset of patients with dyslexia has been attributed to a deficit in the magnocellular visual system.[183–187]

In 1983, Breitmeyer[183] proposed that reading disability is an expression of the disruptive effects of a temporal processing deficit in the magnocellular system. Stein and Walsh[184,187] suggested that this deficit in the inhibitory function of the magnocellular system produces a visual trace of abnormal longevity that creates masking effects along with visual acuity problems when reading connected text. This visual trace could be responsible for complaints of visual distortion and moving print in some people with dyslexia. Selective disruption of the magnocellular pathway via the posterior parietal cortex in certain people with dyslexia could lead to deficiencies in visual processing, visuospatial attention, and abnormal binocular control. Reading errors have been attributed to instabilities in binocular vision that result from destabilization of binocular eye position. However, eye-movement recordings have shown that poor readers and age-matched normal readers have comparable stabilities in binocular fixation. In another article, Stein and Walsh[187] concluded that people with dyslexia may be unable to process fast incoming sensory information adequately in the phonological, visual, and motor systems.

In 1991, Livingstone et al[186] found that disabled readers had abnormally long visual evoked-potential latencies in conditions of low contrast or with rapid changes of the stimulus. It was concluded that the temporal deficits were attributable to a defective magnocellular visual pathway, because this pathway preferentially responds at higher temporal rates and lower contrasts. This finding was not reproduced in a larger study by Victor et al,[188] who concluded that it was unlikely that a simple loss of magnocellular function readily manifest in the visual evoked potential is causally and specifically related to dyslexia. Also in opposition to Livingstone et al, May et al[189] found that the latency periods were shortened under low spatial frequency conditions. In 1993, Lehmkuhle et al[185] noted the lack of change in the latency of the visual evoked potential in reading-disabled children compared with the increased latency noted in children without a reading disability by using low spatial frequency target and high-frequency flicker fields. Their conclusion was that it is possible that a defect in the magnocellular pathway creates a timing disorder that precludes rapid and smooth integration of detailed visual information necessary for efficient reading. A letter to the editor from Victor[190] interpreted the findings of Lehmkuhle et al as showing that the equalization of the responses of normal readers and reading-disabled subjects with the addition of the flickering background reflects not only an increase in response latency in subjects with no reading disability but also a statistically insignificant shortening of response latency in reading-disabled subjects. Victor further stated that this finding defies a simple interpretation in terms of a loss of the magnocellular input.

Most of the evidence supporting the magnocellular theory comes from contrast-sensitivity and functional MRI studies on visual movement processing.[183–187] The studies supporting this theory are outnumbered by studies that have found no loss of contrast-sensitivity and other studies that have found contrast-sensitivity reductions or other findings inconsistent with a magnocellular deficit.[188–201] Thus, the evidence in support of the magnocellular theory is equivocal at best. Amitay et al[191] found that although some (6 of 30) subject with dyslexia showed impaired magnocellular function, they consistently showed impaired performance in auditory and nonmagnocellular visual tasks. Amitay et al hypothesized that the magnocellular pathway deficit is part of a more generalized deficit in fast temporal processing of visual, auditory, and perceptual information. Hutzler et al[129] suggested that pathologic abnormality in the magnocellular system may coexist with dyslexia but that it is not causal. Skoyles and Skottun[202] calculated that more people without dyslexia have magnocellular deficits than those with dyslexia, which challenges the view that dyslexia is the result of a magnocellular deficit. Many researchers have concluded that magnocellular system deficits and associated visual trace persistence are not significant causes of specific reading disability.[14,188–190,192–203]

Some study results involving tinted lenses, tinted filters, or occlusion seem to support the magnocellular theory,[183–187,204] and others refute it.[188–201,205] Iovino et al[204] evaluated 60 children with reading disability and comorbid conditions involving mathematics and ADHD in 1998. Reading accuracy, word-decoding rate, and reading comprehension were assessed by using red, blue, and no overlay. Colored overlays did not differentially affect the reading performance of subjects with and without reading disabilities. However, blue transparencies significantly improved reading comprehension in all groups but reduced the reading rate. The authors noted that these find-

ings indicated that the magnocellular deficit theory may need to be reexamined. This result is important, because Breitmeyer, an author of the Iovino et al report, was also one of the authors who originally proposed the magnocellular deficit theory of dyslexia. Their alternative hypothesis involved the facilitation of attention. At the present time, there is insufficient evidence to base any treatment on this possible deficit.[203]

Colored Lenses and Overlays

At a national meeting in 1983, Irlen[206] proposed treatment with tinted lenses for a specific group of adults with reading problems, which she originally called the "scotopic sensitivity syndrome" (SSS) (now also called the Irlen syndrome or the Meares-Irlen syndrome). Before any supporting research, SSS was featured twice on the television program *60 Minutes*. On the program, it was stated that specially prescribed tinted lenses may be an effective method for the treatment of a variety of reading disorders, including dyslexia.[177] This national exposure led to great interest in the treatment. The initial claims of Irlen were based on observations, students' anecdotal accounts, and no formal experimentation. Supporters of the Irlen syndrome contend that the syndrome affects, to some degree, 12% to 15% of the general population and 45% of those with learning problems. People with this syndrome are thought to suffer from perceptual dysfunctions that cause visual distortion, light sensitivity, visual stress, and visual fragmentation from sensitivities to particular wavelengths of light not attributable to ocular conditions. This syndrome is postulated to interfere with overall attention, performance, fluency, and comprehension and create symptoms similar to learning disabilities. Proposed reading problems can include slow reading rate, poor comprehension, misreading words, skipping words and lines, reading in dim light, shortened reading times, and avoidance of reading. Writing problems can include slanted writing, unequal spacing, misaligning numbers, and errors while copying. General symptoms can include headaches, nausea, fatigue, burning eyes, and tearing. The *Irlen International Newsletter*[207] has reported that the Irlen syndrome should often be expected within the following clinical composites: bipolar spectrum disorder, sensory integration disorder, ADHD, anxiety disorders, school phobia, cranial cerebral trauma, visual dyslexia, tic disorders, reactive attachment disorders, migraines, mood disorder spectrum, recurrent automobile accidents, excessive daytime fatigue, and irritable bowel syndrome.

The Irlen method uses colored lenses and filters to reduce the offending wavelengths and correct these perceptual dysfunctions but does not treat children or adults with language deficiencies, dyslexia, specific learning disabilities, or attention deficit (Helen Irlen, MA., LMFT, personal communication, July 17, 2007). In addition to helping people read better, tinted lenses have been credited by multiple Irlen International newsletters with helping those who suffer from light sensitivity, discomfort, and distortions associated with a wide variety of different problems, including head injuries, concussions, whiplash, perceptual problems, neurologic impairment, memory loss, language deficits, headaches (including migraine), autoimmune disease, fibromyalgia, macular degeneration, cataracts, retinitis pigmentosa, complications from laser-assisted in situ keratomileusis (LASIK) and radial keratotomy, depression, seasonal depression, chronic anxiety, schizophrenia, multiple sclerosis, Asperger syndrome, and others.[207]

A multitude of different models have been used to explain the apparent "visual stress" and perceptual distortions that seem to occur in people with SSS. Currently, the magnocellular dysfunction theory and cortical excitability are being considered. Although the basis of SSS is unknown and the syndrome may not exist, interest in colored filters or overlays as a treatment for dyslexia persists and promotion continues.

Although Irlen and proponents of her method routinely refer to SSS as though it were an accepted medical syndrome, many experts question its validity.[177,208,209] It is interesting that the January 2006 *Irlen International Newsletter* stated that 1 reason that the problem of SSS escapes ophthalmologists is that ophthalmologists typically test under dim-light conditions.[207] In 1990, Helveston[177] stated that there is no evidence that SSS exists and also that there is no basis to use the word "scotopic," because the photopic system is used for reading. He also noted that reports of successful treatment of reading disorders using tinted lenses are based on anecdotal information and testimonials.[177] For many, the problem goes far beyond that of semantics. Hoyt[209] and others have maintained that SSS is not a recognized medical syndrome and consists merely of a group of vague and nonspecific symptoms derived from anecdotal accounts. To this day, there are no clearly established criteria for SSS. The only defining characteristic is a reported benefit of colored filters while reading.[208]

In 1990, the *Journal of Learning Disabilities* published 3 articles in a special series on use of the Irlen technique. A preface was written by Wiederholt,[210] the editor in chief, who noted that the Irlen techniques had received extensive media coverage without having data-based, experimentally controlled studies to validate either the syndrome or the treatment ap-

proach. He stated that the consulting editors who reviewed the studies for publication noted significant scientific and methodologic flaws that created a significant controversy as to whether the studies should be published in the journal. He further stated that on the basis of these 3 studies and the literature before 1990, the validity of the Irlen technique still had not been established.

These 3 studies were then reviewed in the journal by Parker,[176] Solan,[211] and Hoyt.[209] In their reviews of these 3 Irlen-filter studies, Parker, Solan, and Hoyt noted serious methodologic flaws. Parker concluded that the findings could not be considered statistically or scientifically valid. Because firm conclusions could not be drawn, Hoyt recommended a long-term (over 1-year) prospective multicenter trial with carefully constructed control groups of children with learning disabilities who have an ophthalmic or optometric examination at the study's onset and at least yearly thereafter.

The first article in the series was by Robinson and Conway,[212] who studied poor readers with symptoms of scotopic sensitivity. For the first 3 months, the study subjects used an "intermediate" set of lenses based on the student's first preference, then followed by use of "optimum" lenses for the next 9 months. Optimum color lenses were identified after a 2-hour diagnostic procedure that involved up to 130 colors. The use of the intermediate colors was expected to act as a "semiplacebo." The authors concluded that comprehension and accuracy but not reading rate improved using the optimum color lenses.[212] In his review of the study, Parker stated that the use of age scores was a major flaw, the improvement in all reading measures seemed developmental, and the treatment with the optimum lenses seemed to have no greater effect than the semiplacebo. He also noted that the study only had a 50/50 chance of obtaining a statistically significant finding because of the small study size (which was actually the best of the 3 studies).[176] Furthermore, no control group was used,[176,209] and 12 of the 44 subjects reported changes in remedial coaching, degree of assistance, or an alteration in the learning/supportive environment. Hoyt[209] and Solan[211] noted that the study authors stated that the participants had undergone optometric or ophthalmic examination within the year but did not provide the results. Because of the many weaknesses in this study, the conclusion is not valid.

The second study was by O'Connor et al[213] of 105 students from grades 2 to 6 who were reading below grade level. Students who displayed definite scotopic symptoms using the Irlen Differential Perceptual Schedule and displayed marked improvement in reading performance with a particular colored overlay were classified as scotopic. Students who did not show scotopic signs were classified as nonscotopic. Thirteen subjects were dropped from the study, because although they had scotopic complaints, they did not show any preference for color and showed no symptomatic or reading improvement with the colored overlays. Ninety-two children continued in the 1-week study.[213] The article's conclusion stated that reading rate, accuracy, and comprehension were significantly improved when the scotopic children read with the preferred colored overlay. In his review, Parker noted that the study was very short, and the subjects were divided into small groups, randomly and in an idiosyncratic manner.[176] The small group size diminished the study's statistical significance.[176] Reading measures varied between improvement, no change, and regression in 4 of 5 groups. The improvement in some of the subjects in the placebo-filter groups may have been attributable to the placebo effect.[209] The finding of regression may have been attributable to the unreliability or variability of the reading assessments. Solan noted that the improvement in reading was equivocal[211] and that the use of grade-equivalent scores was misleading.[176,211] Solan also noted that there was no optometric pretesting.[211] Most importantly, this study was highly flawed, because the children underwent biased selection.[209,211] Dropping the 13 subjects in the study led Parker to explain that using the same or similar measures to define the treatment group and to assess the effects of treatment is "criterion contamination."[176] On the basis of examination of the methodology of this study, the conclusion is not valid.

The third study, by Blaskey et al,[214] included 40 participants from the ages of 9 to 51 years who were self-referred for a study on Irlen treatment. Thirty-eight of these participants were found to have optometric problems. The study then included only subjects who tested positive for both SSS symptoms and vision problems. Thirty of the 38 originally chose to participate, but only 22 completed the study. The subjects were assigned to an Irlen-treatment, vision-therapy, or control group. The subjects underwent pretreatment and posttreatment optometric and reading tests. The Irlen-treatment group used Irlen lenses for 2 weeks and placebo lenses for 2 weeks, in random order. Three of 11 in the Irlen-treatment group preferred the placebo filter. Subjects in the Irlen-filter group noted a reduction in SSS symptoms, but no reading improvement or change in optometric testing results was noted. Three of 11 in the vision-therapy group dropped out. The remaining subjects in the vision-therapy group showed a

reduction in SSS symptoms and improvement in optometric testing but improvement on only 1 of 4 reading subtests. Five of the 8 control subjects dropped out. The remaining control group was too small to be of any significance, but it was stated that they showed no change in vision status or symptoms or on any of the reading measures. Authors of past studies have remarked that the symptoms of SSS seem similar to convergence insufficiency.[209,211,213] This group with Irlen symptoms showed a high percentage of convergence and accommodative dysfunction, which challenges the claim that the symptoms of SSS are not attributable to vision abnormalities.[211,213] This finding highlighted the need for a formal definition of SSS. The main flaws in this study were that multiple treatments were given to the Irlen-treatment group and the unacceptably large loss of subjects. Parker[176] challenged the statistics in the study and stated that the probability of finding a statistically significant result when none existed was unacceptably high, which invalided the study.

Serious methodologic flaws have continued to be noted in subsequent SSS studies. In 1991, Evans and Drasdo[215] criticized the literature for having no sound theoretical basis for SSS and for the unscientific testing of precision tints. Robinson[216] reviewed the literature concerning tinted lenses and filters up to 1993. He reported that authors of some studies that used anecdotal comments and questionnaires reported improvements in symptoms of visual distortion. Although those survey studies have produced a high rate of positive anecdotal comments, they have not been supported by significant gains of reading achievement in controlled studies. The few noncontrolled studies that he reviewed showed evidence of inconsistent improvement in variable subskill areas of reading. One study showed initial positive gains in reading that were not sustained at retesting. Another study claimed that the positive effects may have been confounded with other remedial interventions given at the same time. In many studies with positive results, the effect of heightened expectations cannot be eliminated because of the lack of a control group. Robinson also noted that some studies with positive results were unable to be duplicated. Many studies found no significant improvement in reading when using colored filters. Robinson concluded in his review that improved print clarity may make the learning of word-attack skills more effective but will not teach such skills and must be accompanied by reading instruction when needed.[208,216]

Menacker et al[217] performed a cohort study (the results of which were published in 1993) using 6 different colored lenses, 1 neutral-density lens, and an empty spectacle frame and showed no reading-performance change or preferred tint among disabled readers.

In 1994, Wilkins et al[218] conducted the first double-masked placebo-controlled study to test the effect of colored filters on symptoms of SSS and reading performance.[218] Subjects who experienced headaches or eye strain in addition to reading difficulties were chosen. Both the precision-tint and placebo-control groups showed a reduction in symptoms of SSS, but a larger effect occurred in the group that used prescribed colored filters. Although the contribution of placebo effects was not entirely ruled out, this study's results suggested that some of the effects of colored lenses may not be entirely attributable to placebo. Although symptoms were reduced in this study, reading rate, accuracy, and comprehension were not affected by either the prescribed or placebo filters.

The study by Robinson and Foreman[219] in 1999 also highlighted the need for proper control procedures. This study measured the effect of Irlen filters on reading performance as well as students' perception of their academic ability. The study included a control group (no SSS and no filter) and 3 experimental groups (placebo, blue, and precision filters). All 4 groups showed increased accuracy and reading comprehension, and the 3 experimental groups, including the placebo group, demonstrated significantly more improvement than the controls. Subjects also perceived an improvement in their SSS symptoms regardless of whether they were wearing placebo tints, blue tints, or prescribed tints.[219] This study revealed a likely placebo effect not only on subjective symptoms but on actual reading performance.[208,219]

In 2002, Bouldoukian et al[220] reported on subjects who experienced SSS symptoms while reading and concluded that colored overlays improved reading speed. However, the results also revealed that greater than one-third of the subjects preferred the control filter and, overall, the subjects were not significantly more likely to prefer their colored overlay than the control filter.

Spafford et al[221] found that contrast reduction, but not lens color, permitted poor readers to be diagnostically differentiated from proficient readers. Lightstone et al[222] stated that the choice of color must be child-specific and requires trial and error. Multiple different methods have been used to select the lens or filter color.[218,223–225] Color selection has shown considerable variability[224] and poor test-retest consistency.[226] Also, the tint selected needed to be changed in up to 25% of subjects within 1 year in a study by

Stone.[227] In a study by Croyle, the blue background provided improvement in the reading rate in low-contrast conditions, whereas the blue background had a slight deteriorative effect under high-contrast conditions.[228] Solan et al[229] found that comprehension of poor readers was improved by using blue filters, whereas Christenson et al[230] found no significant difference in reading comprehension or reading rate when using blue filters. Iovino et al[205] found that blue transparencies significantly improved reading comprehension but reduced reading rate. In a study of yellow filters by Ray et al,[231] the conclusion stated that there was improvement in accommodation, convergence, and reading rates, but deeper analysis of the statistics revealed a question of significance.

Among the numerous criticisms of Irlen's treatment is the argument that precision tints are highly susceptible to placebo effects. By relying on anecdotal accounts or experiments that lack adequate placebo controls, interpretations of findings are speculative at best. Controlling for placebo effects requires, among other things, the inclusion of placebo filters of similar color to precision tints but outside the effective range of chromaticity. Such filters have been successfully produced but have rarely been implemented in Irlen-lens research. Many studies include control groups, but they are typically composed of children who use no filters during testing and who report no symptoms of SSS. Although this is a form of control, it does not adequately control for the possibility of placebo effects.[208] Results are inconclusive when placebo filters are not implemented.[208]

More recent published studies advocating the use of these therapies to treat reading difficulties have continued to have serious flaws in their methods, including biased sample selection, small sample size, biased interpretation, heightened expectations, combination with traditional remediation techniques, and insufficient control for the placebo effect to support the assertion.††† Some studies have claimed to detect some improvement in a few patients in 1 reading subskill but not in other areas. However, improvements in reading subskills do not necessarily translate into improvements in reading. Overall, study results have been inconsistent[208,216,223,232]; many studies have shown that colored overlays and filters are ineffective,[205,214,217,233–235] but a few studies have reported partial positive results.[212,213,218,222,224,231] Many unreported studies have shown no effect of colored filters on measures of either reading performance or SSS symptoms. Also, many of the studies cited as proof of Irlen-lens efficiency actually have been found to be inconclusive after deeper analysis. Not only are some findings less meaningful than they first appear, the large variability in the methodology, techniques, and largely negative results does not support the effectiveness of tinted lenses and tinted filters in these patients.‡‡‡

Contrary to the broad claims of many Irlen-treatment proponents that the syndrome is highly prevalent in the reading-disabled population, the efficacy, if any, of this approach seems to be limited to a small subgroup of children with reading problems. The positive evidence for the effects of colored overlays and filters on reading performance is limited. Worrall et al[182] noted that the studies indicated that fewer than 5% of readers who experience discomfort benefit from a change in contrast, brightness, or color on the page beyond what would be expected from a placebo treatment alone. Thus, colored filters and lenses may be ineffective, except that they act as a placebo. In 1999, Evans[237] explained that treating visual problems or perceptual symptoms will likely alleviate only the "visual component" of reading problems and will not impact the phonologic deficits underlying most cases of reading disabilities. Thus, even proponents of precision tints have maintained that although an improvement in print clarity may facilitate the process of learning to read, it is not enough to lead to spontaneous improvements in word-recognition skills and other complex elements of reading; therefore, remediation for underlying reading problems will still be required.[208] Rooney[238] advised the education community not to embrace SSS and its treatment for learning disabilities and dyslexia.

With nothing but a small amount of anecdotal evidence, CBS reported Irlen's claims to the public and circumvented the normal process of scientific review and debate. Despite the continued lack of definitive evidence of its effectiveness, colored lenses and filters continue to be promoted. Since 1990, the medical community has recommended that Irlen promoters design and perform rigorous prospective, masked, controlled scientific studies to document the effectiveness of their method. Scientifically, the burden of proof is on the developers and promoters of the Irlen method to provide strong evidence to show that their diagnosis is valid and their treatments are beneficial. Contrary to usual scientific practice, 1 Irlen center director stated that it is equally the responsibility of others to carry out this validation research.[177]

Behavioral Optometry

Skeffington was the director of education of the Optometric Extension Program from 1928 to 1976.[239] The Skeffin-

†††Refs 111, 166, 176, 208, 209, and 215.

gton near-point stress model is the basis for much of behavioral optometry.[240] His theories were derived exclusively from his and his collaborators' (Harmon and Renshaw) clinical experience and never independently refereed or formally debated outside the Optometric Extension Program.[239] Skeffington's model states that binocular anomalies and refractive errors are not primary conditions but products of underlying near-point stress. The model states that near-work stress causes underaccommodation and overconvergence. Esophoria usually develops, but sometimes exophoria or myopia develops from the stress. The model further states that this esophoria is best treated preventively. Harmon's theories concern reading posture.

Skeffington recommends an examination using 21 procedures for every patient in a standard sequence.[241] The results of each test are then noted to be higher or lower than an "expected" value.[242] The "expected value" is an "ideal value," not a norm.[242] The Optometric Extension Program "expected value" for ocular alignment at near for children is 6 prism diopters of exophoria. Most people free from ocular symptoms have small amounts of latent strabismus (esophorias or exophorias) that should be considered physiologic. Ophthalmologic and optometric clinical studies have shown that the average near ocular alignment is approximately 1 prism diopter of exophoria.[243–246] Using diagnostic criteria that are not valid such as the developmental optometric "expected values" will lead to misdiagnosis of many conditions. Many children with typical latent strabismus have been labeled by developmental optometrists as abnormal and diagnosed with near-point stress and a "relative esophoria" if they show physiologic lower values of exophoria than their "expected value."

A recent model of vision, considerably different than the traditional optometric model, proposed by Scheiman[247] divides evaluation and treatment into 3 categories: (1) visual acuity, refraction, and eye health disorders; (2) visual efficiency skills of accommodation, binocularity, and ocular motility; and (3) visual information-processing skills of visual discrimination, visual closure, visual memory, visualization, visual-motor integration, and figure-ground perception.

The optometric literature has implicated accommodative spasm, accommodative insufficiency, ill-sustained accommodation, accommodative inertia, and binocular dysfunction as being linked with reading disorders.[111,113,116,247–250] The authors of most of these studies claim that patients experience visual symptoms that lead to degradation in reading performance.[249–252] Accommodative disorders are implicated in causing print blurring, daydreaming, decreased attention span, increased heart and respiratory rate, and poor posture.[253–256] Grisham et al[257] reported an increased incidence of various symptoms in slower readers but could not show a significant difference in reading ability between readers with normal and abnormal binocular function. There is no proof of cause and effect between decreased binocular function and symptoms or between symptoms and poor reading. Other studies have been unable to find an increase in the incidence of binocular disorders in children with reading difficulties or an association between motility disorders and reading ability.[124,126,127]

Training Glasses

"Training" or "developmental" lenses are low-plus power glasses to be used for reading to relieve stress. They are frequently used in conjunction with vision training. Behavioral optometrists believe that training lenses help the visual system develop and mature normally. Skeffington[240] stated that they are best prescribed preventively before a visual problem is identified. Hendrickson stated that every child would benefit from the use of "learning glasses" in the classroom.[258] It has been argued that treatment of accommodative dysfunctions with low-power reading lenses will eliminate secondary problems and their associated symptoms and thereby improve reading efficacy.[259,260] Although they do not provide best-distance visual acuity, they are used to teach the eyes to relearn distance-vision skills that have atrophied. They generally have a power of +0.50 to +1.00 D, and some incorporate bifocals or prisms. Practitioners have followed several highly variable methods to establish the dioptric value of the near correction.[261,262]

Greenspan[253] showed improvement in pencil-and-paper visual tasks and reading posture with the low-plus lenses. Keller and Amos[263] critically reviewed Greenspan's data and found the effect of the developmental lenses to be insignificant. Keller and Amos also noted that if there is an effect, it would imply some unique property of the +0.50 D lens regardless of the patients' refractive error. A study by Barry and Cochran[264] compared plano (no power) and +0.50 D lenses near prescriptions in young adults and found no significant difference in visual performance. Wildsoet and Foo[265] compared 13 children who wore plano lenses and low-power (+0.50 to +1.00 D) training lenses for 6 to 15 months and found no significant difference in reading comprehension. Beauchamp[266] discussed the issue of overprescription of spectacles in his review of vision training in 1986. The justification and benefit for routine in-

tegration of costly spectacles into the program is unsupported and often not discussed. Beauchamp stated that spectacles are provided to the vast majority of children undergoing optometric vision training despite the demonstrably low incidence of ocular motility or refractive deficits.[124,126,127,266,267] Blika[124] found that one third of children in his study had unnecessary glasses, and many had improper prescriptions.

Olitsky and Nelson[111] stated that there is no proof that there is a difference in accommodative ability between normal and abnormal readers and that there was no correlation between reading performance and any specific type of refractive error, including hyperopia or a need for glasses. Olitsky and Nelson noted that the very low power of the reading glasses or bifocals that are often prescribed throws further doubt on their usefulness in a child who often shows large amplitudes of accommodative ability.[111] In a critical review of the behavioral optometric literature before 2000 for the UK College of Optometrists, Jennings[239] declared that the literature revealed no convincing experimental evidence of any benefits from a low-plus prescription.

Vision Therapy

Vision therapy is an attempt to correct or improve ocular, visual processing, and visual-perceptual disorders. A task force representing the College of Optometrists in Vision Development, the American Optometric Association, and the American Academy of Optometry formulated the following policy statement: "Optometric intervention for people with learning related vision problems consists of lenses, prisms, and vision therapy. Vision therapy does not directly treat learning disabilities or dyslexia. Vision therapy is a treatment to improve visual efficiency and visual processing, thereby allowing the person to be more responsive to educational instruction."[268] A vision-therapy program consists of in-office and at-home exercises performed over weeks to months and may include training glasses.

Developmental optometrists divide vision therapy into 2 broad categories: classic orthoptic techniques and behavioral or perceptual vision therapy. Orthoptic techniques are used to correct accommodative and convergence dysfunctions as well as heterophorias and refractive errors that might be responsible for asthenopic symptoms (eye fatigue and discomfort often aggravated by close work). In behavioral vision therapy, eye-movement and eye-hand coordination training techniques are used to improve learning efficiency by improving visual processing skills. These visual processing skills include visual-spatial orientation skills, visual discrimination, visual closure, visual memory, and visual-motor integration. Behavioral vision therapists claim to improve the efficiency of eye movements to improve scanning and locating. Behavioral vision therapy is based on the premise that differences in children's visual-perceptual-motor abilities exist and that these perceptual-motor abilities influence cognitive and adaptive skills such as reading, writing, and motor activities used in activities of daily living. It has been recommended to improve visual skills and processing in the belief that they will improve learning disabilities, including speech and language disorders, and nonverbal learning disorders.[112]

Vision-Therapy Literature Review

Two major reviews of the vision-training literature were undertaken by Keogh, a professor of special education, in 1974 and again in 1985 with Pelland[267,269] to answer the questions of what optometric vision training is and for whom vision training is appropriate and effective. In 1974, Keogh[269] stated that the research on vision theory was sparse, fragmented, and, for the most part, methodologically flawed, and that the professional literature was characterized more by opinion than evidence. The 1974 review concluded with the observation that there was a lack of substantive and comprehensive evidence on which to make decisions about program effects and called for research to specify child and program characteristics that contribute to intervention outcomes.

Keogh stated that, in the 10 years after her first review, behavioral optometrists continued to offer and expand vision training to learning- and reading-disabled pupils, which led to her second review. She noted in her 1985 review that the necessary and sufficient components of vision training are unspecified and, thus, untested. Keogh and Pelland[267] stated that after detailed review of more than 35 program descriptions, there was not a single prototypic program model, which led to the comment that there were almost as many training programs as there were vision trainers. They noted that the variation in vision-training programs was so great that it was extraordinarily difficult to draw inferences about the effectiveness of the procedures. Furthermore, it seemed paradoxical that vision training was being recommended and used for a broad range of problems including preventive treatment.

Keogh and Pelland also noted that the nature of the relationship between vision, reading, and learning problems continues to be a troublesome theoretical question that has not been well answered by optometrists involved in vision training. Although much of the research basis for behavioral optometrists' interpretation was completed before 1975, in general, optometrists accept a link between poor reading

and convergence inefficiencies, farsightedness, and near and distance phorias. Thus, many optometrists argue in favor of vision therapy for problems of convergence, accommodation, ocular motility, and binocular fusion. Keogh and Pelland reported that most of the reviewed studies did not meet rigorous research standards. In most of the reported studies the data were ambiguous with equivocal findings so that the importance of visual efficacy was undeterminable. They declared that to focus on a single aspect of learning problems and to interpret an association or relationship as if it has causal implications goes beyond the evidence.[267]

Keogh and Pelland stated that if visual processing problems are not the cause of many reading problems, vision training to improve visual efficiency is not the treatment of choice. They found little definitive evidence for the effectiveness of vision therapy even when the results were aggregated across studies and concluded that using this treatment would lead to wasteful and ineffective intervention efforts. They concluded that it is imperative that vision-training research receive systematic and rigorous testing and that the research be reported for review in a broader scientific arena.[267]

In 1984, Metzger and Werner[116] reviewed the ophthalmologic, optometric, and psychological literature on the use of visual training for reading disabilities. They found that refractive abnormalities, ocular motor abnormalities, and perceptual capabilities did not differ between reading-disabled children and those with no reading disability. In their review, they noted significant flaws in experimental methodology that supports the visually based hypotheses. They also found that visual-motor-perceptual training programs produced no further improvement in reading ability for affected children when compared with those in control groups.[116] Levine,[128] in his commentary on their article, remarked on the poor methodology in the reviewed studies, researchers having a vested interest, narrow interpretation of the findings, and an initial preconception that a factor in isolation causes reading disability. He recommended properly designing research on the use of vision training for learning disabilities.

In 1987, Beauchamp and Kosmorsky[122] extensively reviewed the interdisciplinary literature for the history of dyslexia and its relationship to neuropathology and eye movements. They concluded that eye movements are not the controlling factor in dyslexia or learning disabilities but are secondary to the comprehension difficulties. In addition, they concluded that approaches designed to improve visual perception by training are misdirected, because visual-perceptual problems do not underlie dyslexia. Their literature review revealed that visual-perceptual training seems to be ineffective and that controlled evidence for treatment efficacy has been found to be conceptually flawed, scant, and contradictory.

Complementary Therapy Assessment: Vision Therapy for Learning Disabilities was published in 2001 by the American Academy of Ophthalmology.[112] This report reviewed the literature on vision therapy for reading disabilities and concluded that there seems to be no consistent scientific evidence that supports behavioral vision therapy, orthoptic vision therapy, or colored overlays and lenses as effective treatments for learning disabilities. No well-performed randomized controlled trials (level I evidence) were found in the literature. The vision-therapy studies have shown an absence of a standard definition of the techniques that constitute vision therapy. Children included in the studies had been diagnosed with learning disabilities by using different criteria and may have been misdiagnosed or may have had additional conditions that confounded the findings. Furthermore, during a course of vision therapy, children were simultaneously receiving continued and even enhanced instruction in a standard or remedial educational setting and undergoing natural maturational changes. The results of subsequent studies have been inconsistent and have failed to reproduce many of these findings. The American Academy of Ophthalmology recommended that appropriately designed and methodologically rigorous scientific studies with a team approach using multidisciplinary educational specialists be conducted to assess the effectiveness of vision therapy.[112]

The Institute for Clinical Systems Improvement technology assessment report on vision therapy was published in 2003.[270] The Institute for Clinical Systems Improvement reports are designed to assist clinicians by providing a scientific assessment, thorough search, review, and analysis of medical literature of the safety and efficacy of medical technologies. The reports classify and grade references by their level of evidence. Two ophthalmologists and 2 optometrists were included on the panel on the topic of vision therapy. Their conclusions were that the studies of vision therapy are predominantly poor-quality case series that provided inadequate scientific evidence to enable a conclusion to be reached about the efficacy of vision therapy for patients with learning disabilities, amblyopia, strabismus, convergence insufficiency, or accommodative disorders. The committee encouraged masked, randomized, controlled trials of vision therapy for these potential uses. They recommended that these trials include clearly defined patient populations, control

groups, clearly defined treatment programs, relevant outcome measures, and adequate patient follow-up to determine if any observed benefits are maintained.[270]

Rawstron et al[271] published a literature review of eye exercises in 2005. The review concluded that the results of small controlled trials and many case reports support the use of eye exercises in the treatment of convergence insufficiency but that there is no clear scientific evidence published in the literature to support the use of eye exercises in the remainder of the areas reviewed, including learning disabilities and dyslexia.

A 2005 Association for Research in Vision and Ophthalmology abstract by optometrists Sampson et al[272] discussed a randomized, masked, and controlled study of 96 suboptimally achieving children who showed visual information-processing delay and normal auditory/verbal language development. The experimental group underwent a visual training program designed to be typical of programs used in pediatric optometric practice. The control group received a placebo program that provided similar amounts of individual time with the children. Diagnostic educational testing took place before the study, at the conclusion, and 6 months after the completion of the programs. Both groups made significantly greater postintervention progress on most variables compared with that expected had no intervention occurred. Results for the entire group showed no significant between-group differences for all educational tests. Thus, results for the entire group did not provide evidence to support efficacy of the visual training program under investigation, which suggests that a placebo effect was responsible for much of the demonstrated improvement.

In 2005, the Convergence Insufficiency Treatment Group published data from a small, masked, placebo-controlled, multicenter, randomized clinical trial that showed that patients treated with office-based vision therapy improved more than those treated with minimally intensive home-based pencil push-up exercises or placebo.[165] The study used both findings and a symptom score. Eight of the 15 patients, or 53% of the patients treated with office-based vision therapy, were considered symptomatically "cured."[165] Kushner,[161] in his accompanying editorial, surveyed 20 pediatric ophthalmologists and 15 orthoptists who treat convergence insufficiency. His survey revealed that most pediatric ophthalmologists and orthoptists do not use unmonitored home treatment with pencil push-ups. Generally, orthoptic therapy prescribed by pediatric ophthalmologists and orthoptists consists of push-up exercises using an accommodative target of letters, numbers, or pictures; push-up exercises with additional base-out prisms; jump-to-near-convergence exercises; stereogram convergence exercises; and recession from a target. The exercises are performed at home, and the children are reevaluated in the office on a monthly basis. Kushner retrospectively reviewed his last 20 patients with convergence insufficiency treated with these orthoptic techniques. Sixteen of his 20 patients (80%) reported complete resolution of symptoms and were objectively "cured" using the same criteria as in the study.[160] The Convergence Insufficiency Treatment Group study showed that convergence insufficiency can be improved with in-office vision therapy, but the accompanying editorial revealed that properly prescribed and monitored home treatment is also very effective.[161,165]

The Convergence Insufficiency Treatment Group[163] published a larger second study in 2008, which was a randomized clinical trial comparing home-based pencil push-up exercises, home computer vergence therapy, office-based orthoptic vision therapy with home reinforcement, and office-based placebo therapy with home reinforcement in 221 children in a 12-week study. Symptomatic improvement was noted in 43% of the home-based pencil push-up exercises group, 33% of the home computer vergence therapy group, 75% of the office-based vision therapy with home reinforcement group, and 35% of the office-based placebo therapy with home reinforcement group. The Convergence Insufficiency Treatment Group study showed better improvement with intensive office-based vergence/accommodative and home reinforcement therapy compared with less intensive home treatments or placebo. Wallace,[164] in his accompanying editorial, noted that neither home-based treatment group used in this study was an ideal comparison group, because fewer actual hours of treatment were received, and the home therapy was less intensive. Granet,[273] a site principle investigator for the study, wrote a letter to the editor concerning the methodology of the study. He stated that the difference between treatment groups could have easily been affected if the time in true treatment had been equalized.

Another major criticism of the 2 studies is the definition of convergence insufficiency. The criteria for study inclusion was a near exophoria at least 4 prism diopters greater than at far, a receded near point of convergence, insufficient positive fusional vergence at near or minimum positive fusional vergence, and a minimum symptom score. Using these diagnostic criteria may overestimate convergence insufficiency. Although the convergence-insufficiency symptom survey has undergone validation,[274] many of the symptoms in their symptom-scoring system are too vague and repetitive. Two examples are: (1) Do your eyes

hurt when reading or doing close work? and (2) Do your eyes ever feel sore when reading or doing close work? Also, many of the symptoms used in the symptom score are nonspecific. Two examples are: (1) Do you read slowly? and (2) Do you have trouble remembering what you have read? Using this symptom survey, many people without convergence insufficiency may have a symptom score that qualifies them for the study. Finally, the use of symptoms in children may be unreliable. In a separate study, complaints such as eyestrain and headaches have been found to be poor markers of eye conditions in young children.[156]

The apparent superiority of office-based orthoptic vision therapy over home-based exercises in these 2 studies is not as strong as it first seemed. This problem was noted in the editorials[161,164] that accompanied both the 2005 and 2008 convergence-insufficiency treatment studies and also in a letter to the editor by Granet.[273] The major weakness of these studies was that the study groups were not appropriately chosen to provide a proper comparison. Treatment with minimally intensive pencil push-ups is not representative of the standard of care and, thus, does not provide the appropriate comparison. The comparison group should consist of the home exercise methods that are frequently prescribed by pediatric ophthalmologists or orthoptists and should be for the same number of hours and intensity as the in-office vision therapy. Sethi,[275] in his letter to the editor, noted that sustained convergence should have been stressed in performing the home pencil push-up exercises. Methodologically, the 2008 study is weakened, because it included 2 different variables and compared different treatments and 2 different intensities of treatment.

Jennings[239] reviewed behavioral vision-therapy studies for the UK College of Optometrists. His report on the evaluation of the theory and practice of behavioral optometry was published in 2000. In his review he noted that many studies showed methodologic and statistical weaknesses. He commented that careful study design is essential, because with training and practice, perceptual judgments improve. This improvement would be greatest if the patient is encouraged and reinforced. He also questioned whether improvement on the training task would transfer to routine activities. He concluded that the merits of vision therapy are extremely difficult to assess and that there is a lack of controlled studies to support behavioral management strategies. Jennings' conclusion was that behavioral optometric therapies do not satisfy evidence-based scrutiny.

On behalf of the UK College of Optometrists, Barrett[276] in 2009 reviewed studies of vision therapy published since the Jennings report in 2000. Barrett remarked that the theory and practice of behavioral optometry remain controversial, especially when considered from the perspective of the traditional optometrist. This is because many of the patients that behavioral optometrists are treating would not exhibit any abnormality under clinical assessment using traditional optometric approaches. Barrett reviewed evidence in 10 categories: accommodative/vergence disorders; underachieving child; prisms for near binocular disorders and for producing postural change; near-point stress and low-plus prescriptions; low-plus lenses at near-to-slow myopia progression; therapy to reduce myopia; therapy of amblyopia and strabismus; training central and peripheral awareness and syntonics; sports vision therapy; and neurologic disorders and neurorehabilitation after trauma/stroke. Barrett found that vision therapy for convergence insufficiency seemed to have some benefits but that further large-scale controlled trials that used proper controls were needed. He reported that vision therapy cannot currently be considered as an evidence-based treatment for reading or learning disorders. He declared that the large majority of behavioral management techniques were to be considered unproven until more rigorous trials were undertaken. His report concluded that the continued absence of rigorous scientific evidence from well-designed trials to support behavioral management approaches, and the paucity of controlled trials in particular, represented a major challenge to the credibility of the theory and practice of behavioral optometry. Barrett's final conclusion was that these approaches were not evidence-based and could not be advocated.[276]

A 2009 article in *Optician Online* commented on Barrett's study. The clinical editor of *Optician Online* stated that although some practitioners may be convinced from their own experience of the effectiveness of behavioral optometry, the lack of sound evidence-based research supporting this stance will always leave it open to the criticism that all it does is pay attention to a perceived problem and thereby influence its expression. The editor contended that it seemed less than ethical to charge for such interventions under a cloak of clinical practice until good evidence for the techniques exists.[277]

Summary on Vision Therapy

Some optometrists attribute reading disabilities or a portion of them to 1 or more subtle ocular or visual abnormalities. The basic tenet of their hypothesis is that children with reading disorders have an increased incidence of vision abnormalities. The College of Optometrists in Vision Development estimates that more than 60% of prob-

lem learners have undiagnosed vision problems that contribute to their difficulties. This claim has not been scientifically established. Many children without vision problems have been labeled as abnormal, because typical physiologic latent strabismus is not taken into account. Optometrists also claim that visual dysfunction in children impairs their ability to respond to the specific instruction intended to remedy the disability. However, the association of binocular and other vision anomalies with learning disabilities, as well as the significance of any association, has not been scientifically demonstrated. Thus, the nature of the relationship between vision problems and reading and learning problems continues to be a troublesome theoretical question that has not been answered adequately by optometrists involved in vision training.[267] Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems, including abnormal focusing, jerky eye movements, misaligned or crossed eyes, visual-motor dysfunction, binocular dysfunction, perceptual dysfunctions, or hypothetical difficulties with laterality or "trouble crossing the midline" of the visual field, cause or increase the severity of learning disabilities.§§§ Statistically, children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions.|||||| Visual problems may coexist with dyslexia but seem to be present with the same incidence as in the population in general; furthermore, no consistent relationship between visual function and academic performance and reading ability has been shown.¶¶¶ Although it is important to have adequate eyesight and ocular motility to read with the greatest efficiency, subtle or severe eye defects do not cause decoding or comprehension difficulties.

Because visual problems do not underlie dyslexia, approaches designed to improve visual function by training are misdirected.[122,128,137,153,266,267] Optometric vision training is based on the premise that reading is primarily a visual task. Many authors in the optometric literature proclaim the usefulness of vision therapy for reading and learning disabilities. Proponents of vision therapy claim that treatment of these visual abnormalities will help children with learning disabilities be more responsive to educational instruction, but this hypothesis has not been proven scientifically. Also, many of the abnormalities that are said to cause problems with reading are undefined and unspecified, which makes evaluation of the claims of successful treatment difficult to analyze. It is even more difficult to determine any possible benefit of vision therapy when used "preventively."

Over the last 35 years, many reviews of the literature that optometry uses to support vision therapy have been performed. Reviews of the vision-therapy literature revealing a lack of scientific support have been performed by researchers in reading and education, pediatricians, and ophthalmologists. Many of the detailed reviews that scientifically questioned the credibility of the theory and practice of vision therapy have been performed recently by optometrists.[181,182,239,270,276] Detailed review of the vision-therapy literature has revealed significant weaknesses, because most of the information has been of poor statistical and scientific quality. Many claims supporting vision therapy are old or found in newsletters, flyers, books without research, or nonedited or loosely reviewed publications. Many of the references used to support the claims in these articles do not relate directly to the topic. Often, a variety of criteria have been used in diagnosing subjects included in the study, and a variety of treatment programs have been used within a study. In addition, the investigator often has a vested interest in the outcome of the study. Many of the studies that support vision therapy use small numbers, and they typically rely on case studies, self-reports, anecdotal information, and testimonials. Studies have been poorly designed, failed to "mask" the investigator, and used inadequate or poor controls so that bias and placebo effects may have confounded the results.### In general, these research methods and references show poor scientific validation.[62,112,270,271]

Scientific evidence does not support the claims that visual training, muscle exercises, ocular pursuit-and-tracking exercises, behavioral/perceptual vision therapy, training glasses, prisms, and colored lenses and filters are effective direct or indirect treatments for learning disabilities.**** There is no valid evidence that children who participate in vision therapy are more responsive to educational instruction than children who do not participate.†††† The reported benefits of vision therapy, including nonspecific gains in reading ability, can often be explained by the placebo effect, increased time and attention given to students who are poor readers, maturation changes, or the traditional educational remedial techniques with which they are usually combined.‡‡‡‡

Other than convergence-insufficiency treatment, the optometric claims that vision therapy improves visual efficiency cannot be substantiated. Treatment of convergence insufficiency helps the reader maintain visual effort for prolonged reading, but treatment of convergence insufficiency by any method is not a treatment for dyslexia. These ineffective, controversial methods of treatment may give parents and teachers a false sense of security that a child's reading difficulties are being addressed, may waste family and/or school time and resources, and may delay proper instruction or remediation.

Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of scientifically unsupported vision-based diagnostic and treatment procedures.§§§§ Despite the continued lack of definitive evidence of its effectiveness, vision training for improving visual efficiency and visual processing has been widely used, at great cost, over the last half-century in many thousands of children with learning disabilities and also as a "preventive treatment." During these years, the medical and educational communities have recommended designing and performing rigorous prospective, masked, controlled scientific studies to document the effectiveness of vision therapy. The burden of proof is on the promoters of vision therapy to provide strong evidence to show that their testing methods are valid, that an association exists between visual dysfunction and learning disabilities, and that their treatments are beneficial. Outcome studies documenting effective results using EBM are necessary before vision therapy can be recommended. Continuing critical literature review will ensure that the best evidence is disseminated and poor-quality studies are subject to proper scrutiny.

MANAGEMENT SUMMARY

Parents should read aloud to their children to help develop language skills. If early warning signs of learning difficulties are detected in preschool-aged children by parents or teachers or during developmental surveillance or screening, the primary care provider should refer the child for early evaluation and intervention. Cost-effective prevention, early identification, and early phonologic awareness intervention programs in kindergarten through 2nd grade should be encouraged. Early identification of children who show delays or difficulties should be a high priority for elementary school teachers. Evaluation for learning disabilities should be considered for all children who present with school difficulties, even if reading difficulty is not the chief complaint.[34] A child with suspected learning disabilities should be placed into remediation and be referred as early as possible for educational evaluation.

A multidisciplinary team consisting of educators, educational remediation specialists, special service professionals, psychologists, and pediatric specialists in neurodevelopmental disabilities or developmental and behavioral pediatrics should be called on to diagnose and treat suspected learning disabilities in children. Making the correct diagnosis of the specific type of learning disability along with any comorbid conditions is of paramount importance before any therapeutic regimen can be prescribed.[167] To outline the educational goals and services that the student needs to be successful, an IEP contract should be developed. The IEP should describe what services will be needed, including specific remedial interventions and accommodations, and which type of program would be best and should set guidelines for measuring future educational progress.

The remedial program should be individualized. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension.¶¶¶¶ Most programs include daily intensive individualized instruction to explicitly teach phonemic awareness and the application of phonics.#### Later, syllable instruction, morphology, memorization of sight words, spelling, syntax, and semantics are taught.[55] Comprehension is gained through fluency training, vocabulary instruction, and active reading comprehension.[34,35] Practice-reading aloud at home is essential. Because people with dyslexia have a persistent problem and continue to read slowly throughout their life, it often becomes necessary to adapt the learning environment.[24,25,34,81] Schools can implement academic accommodations and modifications to help students with dyslexia succeed.

Children with learning disabilities and possible visual problems suspected by their parents, teachers, or physician should be seen by an ophthalmologist who has experience with the assessment and treatment of children, because some of these children may also have a treatable visual problem along with their primary reading or learning dysfunction.[110–113,154] Treatable ocular conditions include strabismus, amblyopia, convergence and/or focusing deficiencies, and refractive errors. The ophthalmologist should identify and treat any significant visual defect according to standard principles of treatment.[110,113,153,166] The primary care pediatrician and ophthalmologist should not diagnose learning disabilities but should provide information on learning disabili-

¶¶¶¶Refs 1, 14, 32–35, 43, 55, 60, 63–65, and 81.

ties and reinforce the need for additional medical, psychological, educational, or other appropriate evaluation or services.[167] In addition, the primary care pediatrician and ophthalmologist should discuss the lack of proven efficacy of vision therapy and other alternative treatments with the parents. Finally, the public must learn to carefully evaluate the information that they receive in the face of aggressive promotion.

CONCLUSIONS

Underachievement is not synonymous with specific learning disability.[279] Learning disabilities arise from neurologic differences in brain structure and function that affect the brain's ability to store, process, or communicate information. The consensus of educators, psychologists, and medical specialists is that children who exhibit signs of learning disabilities should be referred as early as possible for educational, psychological, neuropsychological, and/or medical diagnostic assessments, because the beneficial effects of early identification and intervention are apparent in many studies. Children diagnosed with learning disabilities should receive appropriate support and individualized evidence-based educational interventions combined with psychological, medical, and visual treatments as needed.

Reading difficulties constitute a diverse group of problems that include dyslexia and secondary forms of reading difficulties caused by visual or hearing disorders, intellectual disability, experiential and/or instructional deficits, and other problems.[14,24–26] Missing these problems could cause long-term consequences from assigning these patients to incorrect treatment categories. Dyslexia is a primary receptive language-based reading disorder secondary to a neurobiological deficit in the processing of the sound structure of language called a phonemic deficit that makes it difficult to use the alphabetic code. Because of our rudimentary knowledge of learning disabilities, including dyslexia, there currently are no simple remedies. Because dyslexia is a language-based disorder, treatment should be directed at this etiology.***** The prognosis depends on the severity of the disability, the specific patterns of strengths and weaknesses, and the appropriateness, amount, intensity, and timing of the intervention. Early recognition and individualized, interdisciplinary management strategies are the keys to helping children with dyslexia. Early intervention with intense, explicit instruction is critical for helping students ameliorate the lifelong consequences of poor reading.

Visual problems do not cause dyslexia. Scientific evidence does not support the efficacy of eye exercises, behavioral/perceptual vision therapy, training glasses, or special tinted filters or lenses in improving the long-term educational performance in these complex pediatric neurocognitive conditions. Recommendations for multidisciplinary evaluation and management must be based on evidence of proven effectiveness demonstrated by objective scientific methodology.[106,112,239,270,276] It is important that any therapy for learning disabilities be scientifically established to be valid before it can be recommended for treatment.[106] Because vision therapy is not evidence based, it cannot be advocated.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Substance Abuse and Committee on Adolescence

Legalization of Marijuana: Potential Impact on Youth

ABSTRACT. As experts in the health care of children and adolescents, pediatricians may be called on to advise legislators concerning the potential impact of changes in the legal status of marijuana on adolescents. Parents, too, may look to pediatricians for advice as they consider whether to support state-level initiatives that propose to legalize the use of marijuana for medical purposes or to decriminalize possession of small amounts of marijuana. This policy statement provides the position of the American Academy of Pediatrics on the issue of marijuana legalization, and the accompanying technical report (available online) reviews what is currently known about the relationship between adolescents' use of marijuana and its legal status to better understand how change might influence the degree of marijuana use by adolescents in the future. ***Pediatrics*** **2004;113:1825–1826;** ***marijuana, legalization, substance abuse, decriminalization.***

INTRODUCTION

Substance abuse by adolescents is an ongoing concern of pediatricians. Marijuana is the illicit substance most commonly abused by adolescents.[1] Any change in the legal status of marijuana, even if limited to adults, could affect the prevalence of use among adolescents.[2] For example, tobacco and alcohol products, both legal for adults 18 and 21 years of age, respectively, are the psychoactive substances most widely abused by adolescents.

Marijuana currently is classified by the US Drug Enforcement Agency as a schedule I drug, which means that it has a high potential for abuse, has no currently accepted medical use in the United States, and lacks accepted safety for use under supervision by a physician. Rigorous scientific research to determine whether marijuana, especially cannabinoids, has any potential therapeutic effect is just beginning. In contrast, the significant neuropharmacologic, cognitive, behavioral, and somatic consequences of acute and long-term marijuana use are well known and include negative effects on short-term memory, concentration, attention span, motivation, and problem solving, which clearly interfere with learning; adverse effects on coordination, judgment, reaction time, and tracking ability, which contribute substantially to unintentional deaths and injuries among adolescents (especially those associated with motor vehicles); and negative health effects with repeated use similar to effects seen with smoking tobacco.[3]

More information, including historical perspectives on the legal status of marijuana as well as concerns surrounding medicinal use of marijuana, is available in the accompanying technical report (available online).[2]

RECOMMENDATIONS

1. The American Academy of Pediatrics opposes the legalization of marijuana.
2. The American Academy of Pediatrics supports rigorous scientific research regarding the use of cannabinoids for the relief of symptoms not currently ameliorated by existing legal drug formulations.

Legalization of Marijuana: Potential Impact on Youth

ABSTRACT. This technical report provides historical perspectives and comparisons of various approaches to the legal status of marijuana to aid in forming public policy. Information on the impact that decriminalization and legalization of marijuana could have on adolescents, in addition to concerns surrounding medicinal use of marijuana, are also addressed in this report. Recommendations are included in the accompanying policy statement. *Pediatrics* 2004;113:e632–e638. URL: http://www.pediatrics.org/cgi/content/full/113/6/e632; *marijuana, legalization, substance abuse, decriminalization.*

ABBREVIATIONS. AAP, American Academy of Pediatrics; IOM, Institute of Medicine.

BACKGROUND

Over the last 40 years, the legal status of marijuana has been debated vigorously. Proponents of policies that would permit individual possession of small amounts of marijuana argue that it is a safe drug and that criminal sanctions against personal use and possession represent at worst excessively harsh and at best unnecessary penalties. Echoing these sentiments, editors of *The Lancet* have concluded that "cannabis per se is not a hazard to society but driving it further underground may well be."[1] Advocates for legalization also point out that the morbidity, mortality, and economic costs to society associated with alcohol and tobacco use in the United States dwarf those associated with marijuana use.

Those opposing liberalization of current laws counter that marijuana is not a benign drug, especially in light of new psychopharmacologic information demonstrating that marijuana shares many features with other illicit drugs. They also contend that legalization or decriminalization of personal use of marijuana likely would trigger a substantial increase in use, with foreseeable increases in the social, economic, and health costs.

Most recently, the debate has focused on the medical use of marijuana (that is, the use of smoked marijuana to treat a variety of medical conditions). Eight states (Alaska, Arizona, California, Colorado, Maine, Nevada, Oregon, and Washington) have passed ballot initiatives that provide for medical use of marijuana under certain circumstances; one other state (Hawaii) has enacted state legislation permitting medical marijuana use.[2] The federal government has opposed vigorously any efforts to permit physicians to prescribe marijuana for medical purposes, an approach characterized by the former editor of the *New England Journal of Medicine* as "misguided, heavy-handed, and inhumane."[3]

Controversy regarding marijuana is not limited to the United States. Australia has decriminalized the use of marijuana in some territories, and Canada[4] as well as Switzerland and other European countries[5] are reconsidering their approach to marijuana. However, the most widely publicized approach to regulation of marijuana is that of The Netherlands. Under a complex system of "law-on-the-books" and "law-in-action," Dutch law permits personal use of marijuana but outlaws possession.[6]

Pediatricians, too, are not of one mind in their views regarding the legal status of marijuana. In a periodic survey of fellows of the American Academy of Pediatrics (AAP) conducted in 1995,[7] only a minority (18%) favored legalization, and 26% believed that possession or sale should be a felony; 31% felt that marijuana should be available by prescription for medical purposes to a certain class of patients, and 24% believed that marijuana should remain illegal but penalties for personal possession should be reduced or eliminated.

Since the periodic survey was conducted, much more has been learned about the psychopharmacologic properties of marijuana. Scientists have demonstrated that the emotional stress caused by withdrawal from marijuana is linked to corticotropin-releasing factor, the same brain chemical that has been linked to anxiety and stress during opiate, alcohol, and cocaine withdrawal.[8] Others report that tetrahydrocannabinol, the active ingredient in marijuana, stimulates release of dopamine in the mesolimbic area of the brain, the same neurochemical process that reinforces dependence on other addictive drugs.[9] Current scientific information about marijuana has been summarized in the AAP policy statement "Marijuana: A Continuing Concern for Pediatricians."[10] Some of the significant neuropharmacologic, cognitive, behavioral, and somatic consequences of acute and long-term marijuana use are well known and include negative effects on short-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

term memory, concentration, attention span, motivation, and problem solving, which clearly interfere with learning; adverse effects on coordination, judgment, reaction time, and tracking ability, which contribute substantially to unintentional deaths and injuries among adolescents (especially those associated with motor vehicles); and negative health effects with repeated use similar to effects seen with smoking tobacco. Three recent studies[11–13] demonstrate an association between marijuana use and the subsequent development of mental health problems; however, a small study of 56 monozygotic cotwins discordant for marijuana use did not find any such associations.[14]

DEFINITION OF TERMS

There are 3 general policy perspectives concerning the status of marijuana in the United States: prohibition, decriminalization, and legalization. Prohibition describes current federal policy toward marijuana use, which seeks to minimize or prevent use of marijuana with strong legal sanctions and aggressive interdiction of supply routes. Decriminalization and depenalization (used interchangeably in this report) refer to the elimination, reduction, and/or nonenforcement of penalties for the sale, purchase, or possession of marijuana although such activities remain illegal. Under decriminalization, penalties for use or distribution are at least possible theoretically, and advertising would be banned. Legalization, one step beyond decriminalization, would fundamentally change the status of marijuana in society. It is an acknowledgment that the government has no fundamental interest in an individual's use of a drug, although it may still seek to regulate its sale, distribution, use, and advertisement to safeguard the public's health. Such is the case with alcohol and tobacco. Of the 3 approaches, only the prohibitionist approach has reducing or limiting drug use as its explicit goal.

HISTORICAL PERSPECTIVES ON DRUG POLICIES IN THE UNITED STATES

Important perspectives on how changing the status of marijuana could affect use by adolescents can be gleaned from an examination of this country's experience with drugs over the last 200 years. During the 19th century, opiate drugs were legal and widely available. Opium use was common, especially among middle-class white women.[15] Use of morphine also was extensive, and heroin was marketed as a "sedative for coughs." Cocaine, which routinely was added to patent medicines and beverages, also was legal; it was prized for its local anesthetic effect and its ability to counteract the effects of morphine. The national opiate addiction rate increased from 0.72 per 1000 in 1840 to 4.59 per 1000 in the 1890s, thereafter beginning a sustained decline.[16(p28)]

Another wave of drug use began in the mid-1960s as enforcement of marijuana laws by police became lax and adolescent and layperson perceptions of the risk of regular use declined. Officials from the US Drug Enforcement Agency expressed the view that the fight against marijuana detracted from the more important work of combating heroin use.[16(p174)] Drug incarcerations per 1000 arrests began to drop in 1960 and remained low through 1979. The Carter administration (1977–1981) proposed removing criminal sanctions for possessing small amounts of marijuana.[16(p175)] In 1975, 6% of high school seniors reported using marijuana daily during the previous 30 days. By 1978, the same year during which perceived risk of regular use of marijuana reached its lowest point ever, 10.7% of high school seniors reported using the drug daily.[17]

Drug use in America tends to follow cycles, often with one generation having to relearn the experiences of previous ones. Ninety years after the first cocaine epidemic, cocaine use began to increase in the 1970s and escalated substantially from 1980 to 1995. Because it had been so long since the previous epidemic, cocaine was perceived to be a safe drug. In a chapter on cocaine in the 1980 edition of a prominent textbook of psychiatry, the authors wrote: "If it is used no more than two or three times a week, cocaine creates no serious problems."[18] In 1977, 10% of 18- to 25-year-olds had used cocaine; that proportion doubled to 20% in 1979. By 1985, one third of 18- to 25-year-olds had used cocaine, as had 17.3% of 12th graders.[15] Only with subsequent widespread publicity about the health risks and addictive properties of cocaine and the epidemic of crack cocaine did cocaine use among young people begin to wane.

US AND INTERNATIONAL EXPERIENCES WITH MARIJUANA LEGALIZATION AND DEPENALIZATION

Because to our knowledge no country has completely legalized the sale, possession, and advertising of marijuana, there are no studies that examine the effect of legalization on marijuana use by young people. Hence, we examine data on adolescents' use of marijuana in states and countries that have, to a greater or lesser extent, decriminalized use and possession of this drug.

Analyzing data from the annual Monitoring the Future survey, Johnston et al[19] concluded that decriminalization of marijuana in a number of states from 1975 to 1980 apparently had no effect on high school students' beliefs and attitudes about marijuana or on their use of the drug during those years. In contrast, Chaloupka et al,[20] analyzing data from the 1992–1994 Monitoring the Future surveys, found that "youths living in decriminalized states are significantly more likely to report currently using marijuana and may consume more frequently."

There are several possible explanations for these disparate findings. Although the study by Johnston et al did not find any effect of decriminalization, baseline marijuana use was higher in states that changed their laws compared with states that did not, although the subsequent rate of increase in all states was the same. It is possible that the higher baseline rates of use in the states that decriminalized marijuana use may have reflected a more lax or tolerant approach to marijuana use before decriminalization. Hence, decriminalization would not have resulted in any significant lessening of enforcement,

rettes (defined as those smoked by >5% of 8th, 10th, and 12th graders in 1998) in youth-oriented magazines increased from 1995 to 2000, as did expenditures for adult brands in youth-oriented magazines.[33] The Supreme Court recently struck down several Massachusetts regulations aimed at protecting schoolchildren from tobacco advertising (including bans on tobacco ads within 1000 feet of a school or playground). "The state's interest in preventing underage tobacco use is substantial and even compelling, but it is no less true that the sale and use of tobacco by adults is a legal activity," wrote Justice Sandra Day O'Connor for the majority. She continued, ". . . tobacco retailers and manufacturers have an interest in conveying truthful information about their products to adults, and adults have a corresponding interest in receiving truthful information about tobacco products."[34] Presumably, these same interests in regard to advertising for marijuana products also would be protected.

DiFranza[35] has demonstrated that both the states and the federal government are poorly enforcing the Synar Amendment, which requires states to control the sale of tobacco products to those younger than 18 years. Legalization of marijuana for adults but not adolescents would necessitate additional law enforcement burdens on a system that currently is not meeting its regulatory obligations.

Similarly, the alcoholic-beverage industry continues to portray drinking in terms that clearly appeal to young people. Drinking is associated with being sexy, popular, and fun and as an ideal means to "break the ice" in social settings.[36] These portrayals are extremely enticing to adolescents, who are in the process of developing their own identities as well as refining their social skills. One can speculate that distributors of marijuana quickly would recognize the profitability of portraying marijuana in a similar manner (thereby maximizing sales), all the while protesting that their marketing attempts seek only to induce adults to change brands.

How adolescents would perceive a change in the legal status of marijuana, even if only for adults, also is difficult to determine. However, recent studies have shown that prevalence of adolescent marijuana use is inversely proportional to the perceived risk associated with use (Fig 1).[37] The proportion of 12th graders who reported using marijuana in the past 30 days peaked in 1978 and again in 1997, exactly the years in which the perceived risk of regular use was at its lowest.

Some research suggests that legal sanctions may

Fig 1. Marijuana: trends in perceived availability, perceived risk of regular use, and prevalence of use in past 30 days for 12th graders

influence the initial decision to use drugs and that this influence diminishes as drug use by individuals progresses.[38] If so, it is the youngest adolescents (those who have not yet tried marijuana or are in the experimentation phase) who would be affected most by changes in marijuana laws. Age at first use is, in turn, a risk factor for problem use in the future.[39]

Moral development in children and adolescents assumes a developmental trajectory. Early adolescents have a concrete approach to morality: laws are obeyed to avoid punishment. As such, young adolescents would be most susceptible to the deterrent effects of drug laws. This deterrent effect could disappear or lessen with legalization of marijuana. Once adolescents gain the ability to think abstractly, challenges to the apparent hypocrisy of "do as I say, not as I do" can be anticipated.

Parental drug use is an important influence on adolescents' drug use.[40] Recent data indicate that easy household access to illicit substances is associated with greater risk of marijuana use among both younger and older adolescents.[41] Some adults may choose not to use marijuana (however they may feel about the law), because the potential risk of criminal sanctions outweighs any perceived benefit from using the drug. With the demise of legal sanctions against use, some parents may choose to begin using marijuana, acting as an important new source of exposure for their adolescents. Parental use of marijuana in the last year is associated with their adolescent's use during the same period.[42]

Availability of marijuana, which might increase if the drug were legalized, clearly has been shown to affect adolescents' use. Adolescents who have been offered marijuana are 7 times more likely to use it than are those who have not been offered marijuana. Similarly, those who report that marijuana is easy to get are approximately 2.5 times more likely to use it than those who consider it hard to get.[43]

Marijuana is cheap and easy to produce; if it were legalized, its price likely would decrease below current levels. Work by Pacula et al[44] in the United States and Williams[45] in Australia demonstrates clearly that a decrease in the price of marijuana is associated with a significant increase in the prevalence of use among adolescents.

Some advocates for the legalization of marijuana argue that it is safer than alcohol. They suggest that increased use of marijuana by young people might have a positive effect if some adolescents switched from alcohol to marijuana (a substitution effect). This theory cannot be supported by recent studies on adolescent marijuana and alcohol use that incorporated the price of marijuana into the analysis. These studies conclude that an increase in use of marijuana by adolescents would result in an increased use of alcohol (ie, that the 2 drugs are economic complements).[46]

From a public health perspective, even a small increase in use, whether attributable to increased availability or decreased perception of risk, would have significant ramifications. For example, if only an additional 1% of 15- to 19-year-olds in the United States began using marijuana, there would be approximately 190 000 new users.[47]

COMPARISONS BETWEEN MARIJUANA, ALCOHOL, AND TOBACCO

Proponents of legalization of marijuana argue that in terms of costs to society, both financial and health-related, alcohol and tobacco cause far more harm than does marijuana. They argue that classifying a relatively benign drug (marijuana) as schedule I and vigorously prosecuting its sale and possession while permitting the legal use of substances that cause far more damage are inconsistent and illogical practices or policies. That alcohol and tobacco cause far more harm in our society than marijuana is undeniable, but it does not follow logically that yet a third addictive psychoactive drug (marijuana) should be legalized. Many of the harms associated with alcohol and tobacco use stem from the widespread acceptability, availability, and use of these substances. Still other harms result from lax enforcement of current laws regulating their use or sale, especially to underage youth. Rather than legalizing marijuana, an equally compelling approach would be vigorously enforcing current regulations regarding sale and use of alcohol and tobacco products to minimize health-related problems attributable to their consumption. Recent examples include lowering the blood alcohol concentration that defines whether an individual is driving while intoxicated to 0.08 mg/dL (0.02 mg/dL for youth), limiting or banning smoking in public places, and banning cigarette advertisements targeted toward young people.

SUMMARY

Several recent studies concerning American adolescents, the Dutch experience with decriminalization (from 1984 to 1992), and the relationship between cheaper marijuana and use by adolescents suggest that decriminalization increases marijuana use by adolescents. Because no country has legalized use of marijuana outright, there are no studies available to evaluate the potential effect of legalization in the United States. Legalization of marijuana could decrease adolescents' perceptions of the risk of use and increase their exposure to this drug. Furthermore, data concerning adolescents' use of the 2 drugs that are legal for adults (alcohol and tobacco) suggest strongly that legalization of marijuana would have a negative effect on youth. Alcohol and tobacco are the drugs most widely abused by adolescents, although their sale to adolescents (younger than 18 years for tobacco and younger than 21 years for alcohol) is illegal. Research demonstrates that manufacturers of alcohol and tobacco market their products to young people, and the recent Supreme Court decision and experience with the Synar Amendment suggest that, if marijuana were legalized, restrictions on the sale and advertising of the substance to young people would prove daunting. Finally, two in-depth reviews of medical marijuana conclude that future research should focus on the medical use of cannabinoids, not smoked marijuana.

The Lifelong Effects of Early Childhood Adversity and Toxic Stress

abstract

FREE

Advances in fields of inquiry as diverse as neuroscience, molecular biology, genomics, developmental psychology, epidemiology, sociology, and economics are catalyzing an important paradigm shift in our understanding of health and disease across the lifespan. This converging, multidisciplinary science of human development has profound implications for our ability to enhance the life prospects of children and to strengthen the social and economic fabric of society. Drawing on these multiple streams of investigation, this report presents an ecobiodevelopmental framework that illustrates how early experiences and environmental influences can leave a lasting signature on the genetic predispositions that affect emerging brain architecture and long-term health. The report also examines extensive evidence of the disruptive impacts of toxic stress, offering intriguing insights into causal mechanisms that link early adversity to later impairments in learning, behavior, and both physical and mental well-being. The implications of this framework for the practice of medicine, in general, and pediatrics, specifically, are potentially transformational. They suggest that many adult diseases should be viewed as developmental disorders that begin early in life and that persistent health disparities associated with poverty, discrimination, or maltreatment could be reduced by the alleviation of toxic stress in childhood. An ecobiodevelopmental framework also underscores the need for new thinking about the focus and boundaries of pediatric practice. It calls for pediatricians to serve as both front-line guardians of healthy child development and strategically positioned, community leaders to inform new science-based strategies that build strong foundations for educational achievement, economic productivity, responsible citizenship, and lifelong health. *Pediatrics* 2012;129:e232–e246

INTRODUCTION

Of a good beginning cometh a good end.

John Heywood, *Proverbs* (1546)

The United States, like all nations of the world, is facing a number of social and economic challenges that must be met to secure a promising future. Central to this task is the need to produce a well-educated and healthy adult population that is sufficiently skilled to participate effectively in a global economy and to become responsible stakeholders in a productive society. As concerns continue to grow about the quality of public education and its capacity to prepare the nation's future workforce, increasing investments are being made in

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

the preschool years to promote the foundations of learning. Although debates about early childhood policy focus almost entirely on educational objectives, science indicates that sound investments in interventions that reduce adversity are also likely to strengthen the foundations of physical and mental health, which would generate even larger returns to all of society.[1,2] This growing scientific understanding about the common roots of health, learning, and behavior in the early years of life presents a potentially transformational opportunity for the future of pediatrics.

Identifying the origins of adult disease and addressing them early in life are critical steps toward changing our current health care system from a "sick-care" to a "well-care" model.[3–5] Although new discoveries in basic science, clinical subspecialties, and high-technology medical interventions continue to advance our capacity to treat patients who are ill, there is growing appreciation that a successful well-care system must expand its scope beyond the traditional realm of individualized, clinical practice to address the complex social, economic, cultural, environmental, and developmental influences that lead to population-based health disparities and unsustainable medical care expenditures.[2,6,7] The science of early childhood development has much to offer in the realization of this vision, and the well-being of young children and their families is emerging as a promising focus for creative investment.

The history of pediatrics conveys a rich narrative of empirical investigation and pragmatic problem solving. Its emergence as a specialized domain of clinical medicine in the late 19th century was dominated by concerns about nutrition, infectious disease, and premature death. In the middle of the 20th century, as effective vaccines, antibiotics, hygiene, and other public health measures confronted the infectious etiologies of childhood illness, a variety of developmental, behavioral, and family difficulties became known as the "new morbidities."[8] By the end of the century, mood disorders, parental substance abuse, and exposure to violence, among other conditions, began to receive increasing attention in the pediatric clinical setting and became known as the "newer morbidities."[9] Most recently, increasingly complex mental health concerns; the adverse effects of television viewing; the influence of new technologies; epidemic increases in obesity; and persistent economic, racial, and ethnic disparities in health status have been called the "millennial morbidities."[10]

Advances in the biological, developmental, and social sciences now offer tools to write the next important chapter. The overlapping and synergistic characteristics of the most prevalent conditions and threats to child well-being—combined with the remarkable pace of new discoveries in developmental neuroscience, genomics, and the behavioral and social sciences—present an opportunity to confront a number of important questions with fresh information and a new perspective. What are the biological mechanisms that explain the well-documented association between childhood adversity and adult health impairment? As these causal mechanisms are better elucidated, what can the medical field, specifically, and society, more generally, do to reduce or mitigate the effects of disruptive early-life influences on the origins of lifelong disease? When is the optimal time for those interventions to be implemented?

This technical report addresses these important questions in 3 ways. First, it presents a scientifically grounded, ecobiodevelopmental (EBD) framework to stimulate fresh thinking about the promotion of health and prevention of disease across the lifespan. Second, it applies this EBD framework to better understand the complex relationships among adverse childhood circumstances, toxic stress, brain architecture, and poor physical and mental health well into adulthood. Third, it proposes a new role for pediatricians to promote the development and implementation of science-based strategies to reduce toxic stress in early childhood as a means of preventing or reducing many of society's most complex and enduring problems, which are frequently associated with disparities in learning, behavior, and health. The magnitude of this latter challenge cannot be overstated. A recent technical report from the American Academy of Pediatrics reviewed 58 years of published studies and characterized racial and ethnic disparities in children's health to be extensive, pervasive, persistent, and, in some cases, worsening.[11] Moreover, the report found only 2 studies that evaluated interventions designed to reduce disparities in children's health status and health care that also compared the minority group to a white group, and none used a randomized controlled trial design.

The causal sequences of risk that contribute to demographic differences in educational achievement and physical well-being threaten our country's democratic ideals by undermining the national credo of equal opportunity. Unhealthy communities with too many fast food franchises and liquor stores, yet far too few fresh food outlets and opportunities for physical activity, contribute to an unhealthy population. Unemployment and forced mobility disrupt the social networks that stabilize communities and families and, thereby, lead to higher rates of violence

and school dropout. The purpose of this technical report is to leverage new knowledge from the biological and social sciences to help achieve the positive life outcomes that could be accrued to all of society if more effective strategies were developed to reduce the exposure of young children to significant adversity.

A NEW FRAMEWORK FOR PROMOTING HEALTHY DEVELOPMENT

Advances in our understanding of the factors that either promote or undermine early human development have set the stage for a significant paradigm shift.[12] In simple terms, the process of development is now understood as a function of "nature dancing with nurture over time," in contrast to the longstanding but now outdated debate about the influence of "nature versus nurture."[13] That is to say, beginning prenatally, continuing through infancy, and extending into childhood and beyond, development is driven by an ongoing, inextricable interaction between biology (as defined by genetic predispositions) and ecology (as defined by the social and physical environment)[12,14,15] (see Fig 1).

Building on an ecological model that explains multiple levels of influence on psychological development,[16] and a recently proposed biodevelopmental framework that offers an integrated, science-based approach to coordinated, early childhood policy making and practice across sectors,[17] this technical report presents an EBD framework that draws on a recent report from the Center on the Developing Child at Harvard University to help physicians and policy makers think about how early childhood adversity can lead to lifelong impairments in learning, behavior, and both physical and mental health.[1,6]

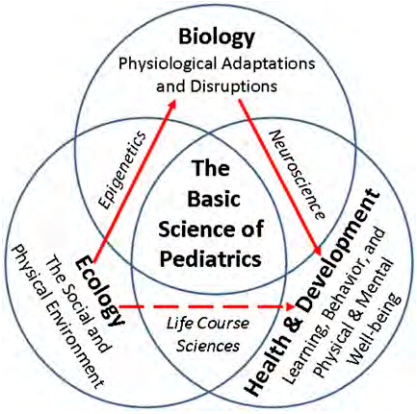

FIGURE 1

The basic science of pediatrics. An emerging, multidisciplinary science of development supports an EBD framework for understanding the evolution of human health and disease across the life span. In recent decades, epidemiology, developmental psychology, and longitudinal studies of early childhood interventions have demonstrated significant associations (hashed red arrow) between the ecology of childhood and a wide range of developmental outcomes and life course trajectories. Concurrently, advances in the biological sciences, particularly in developmental neuroscience and epigenetics, have made parallel progress in beginning to elucidate the biological mechanisms (solid arrows) underlying these important associations. The convergence of these diverse disciplines defines a promising new basic science of pediatrics.

Some of the most compelling new evidence for this proposed framework comes from the rapidly moving field of epigenetics, which investigates the molecular biological mechanisms (such as DNA methylation and histone acetylation) that affect gene expression without altering DNA sequence. For example, studies of maternal care in rats indicate that differences in the quality of nurturing affect neural function in pups and negatively affect cognition and the expression of psychopathology later in life. Moreover, rats whose mothers showed increased levels of licking and grooming during their first week of life also showed less exaggerated stress responses as adults compared with rats who were reared by mothers with a low level of licking and grooming, and the expression of mother-pup interactions in the pups has been demonstrated to be passed on to the next generation.[18–22] This burgeoning area of research is challenging us to look beyond genetic predispositions to examine how environmental influences and early experiences affect when, how, and to what degree different genes are actually activated, thereby elucidating the mechanistic linkages through which gene-environment interaction can affect lifelong behavior, development, and health (see Fig 1).

Additional evidence for the proposed framework comes from insights accrued during the "Decade of the Brain" in the 1990s, when the National Institutes of Health invested significant resources into understanding both normal and pathologic neuronal development and function. Subsequent advances in developmental neuroscience have begun to describe further, in some cases at the molecular and cellular levels, how an integrated, functioning network with billions of neurons and trillions of connections is assembled. Because this network serves as the biological platform for a child's emerging social-emotional, linguistic, and cognitive skills, developmental neuroscience is also beginning to clarify the underlying causal mechanisms that explain the normative process of child development. In a parallel fashion, longitudinal studies that document the long-term consequences of childhood adversity indicate that alterations in a child's ecology can have measurable effects on his or her developmental trajectory, with lifelong consequences for educational achievement, economic productivity, health status, and longevity.[23–27]

The EBD framework described in this article presents a new way to think about the underlying biological mechanisms that explain this robust link between early life adversities (ie, the

new morbidities of childhood) and important adult outcomes. The innovation of this approach lies in its mobilization of dramatic scientific advances in the service of rethinking basic notions of health promotion and disease prevention within a fully integrated, life span perspective from conception to old age.[6] In this context, significant stress in the lives of young children is viewed as a risk factor for the genesis of health-threatening behaviors as well as a catalyst for physiologic responses that can lay the groundwork for chronic, stress-related diseases later in life.

Understanding the Biology of Stress

Although genetic variability clearly plays a role in stress reactivity, early experiences and environmental influences can have considerable impact. Beginning as early as the prenatal period, both animal[28–30] and human[31,32] studies suggest that fetal exposure to maternal stress can influence later stress responsiveness. In animals, this effect has been demonstrated not only in the offspring of the studied pregnancy but also in subsequent generations. The precise biological mechanisms that explain these findings remain to be elucidated, but epigenetic modifications of DNA appear likely to play a role.[31,33,34] Early postnatal experiences with adversity are also thought to affect future reactivity to stress, perhaps by altering the developing neural circuits controlling these neuroendocrine responses.[34,35] Although much research remains to be performed in this area, there is a strong scientific consensus that the ecological context modulates the expression of one's genotype. It is as if experiences confer a "signature" on the genome to authorize certain characteristics and behaviors and to prohibit others. This concept underscores the need for greater understanding of how stress "gets under the skin," as well as the importance of determining what external and internal factors can be mobilized to prevent that embedding process or protect against the consequences of its activation.

Physiologic responses to stress are well defined.[36–38] The most extensively studied involve activation of the hypothalamic-pituitary-adrenocortical axis and the sympathetic-adrenomedullary system, which results in increased levels of stress hormones, such as corticotropin-releasing hormone (CRH), cortisol, norepinephrine, and adrenaline. These changes co-occur with a network of other mediators that include elevated inflammatory cytokines and the response of the parasympathetic nervous system, which counterbalances both sympathetic activation and inflammatory responses. Whereas transient increases in these stress hormones are protective and even essential for survival, excessively high levels or prolonged exposures can be quite harmful or frankly toxic,[39–41] and the dysregulation of this network of physiologic mediators (eg, too much or too little cortisol; too much or too little inflammatory response) can lead to a chronic "wear and tear" effect on multiple organ systems, including the brain.[39–41] This cumulative, stress-induced burden on overall body functioning and the aggregated costs, both physiologic and psychological, required for coping and returning to homeostatic balance, have been referred to as "allostatic load."[38,42–44] The dynamics of these stress-mediating systems are such that their overactivation in the context of repeated or chronic adversity leads to alterations in their regulation.

The National Scientific Council on the Developing Child has proposed a conceptual taxonomy comprising 3 distinct types of stress responses (in contrast to the actual stressors themselves) in young children—positive, tolerable, and toxic—on the basis of postulated differences in their potential to cause enduring physiologic disruptions as a result of the intensity and duration of the response.[17,45] A positive stress response refers to a physiologic state that is brief and mild to moderate in magnitude. Central to the notion of positive stress is the availability of a caring and responsive adult who helps the child cope with the stressor, thereby providing a protective effect that facilitates the return of the stress response systems back to baseline status. Examples of precipitants of a positive stress response in young children include dealing with frustration, getting an immunization, and the anxiety associated with the first day at a child care center. When buffered by an environment of stable and supportive relationships, positive stress responses are a growth-promoting element of normal development. As such, they provide important opportunities to observe, learn, and practice healthy, adaptive responses to adverse experiences.

A tolerable stress response, in contrast to positive stress, is associated with exposure to nonnormative experiences that present a greater magnitude of adversity or threat. Precipitants may include the death of a family member, a serious illness or injury, a contentious divorce, a natural disaster, or an act of terrorism. When experienced in the context of buffering protection provided by supportive adults, the risk that such circumstances will produce excessive activation of the stress response systems that leads to physiologic harm and long-term consequences for health and learning is greatly

reduced. Thus, the essential characteristic that makes this form of stress response tolerable is the extent to which protective adult relationships facilitate the child's adaptive coping and a sense of control, thereby reducing the physiologic stress response and promoting a return to baseline status.

The third and most dangerous form of stress response, toxic stress, can result from strong, frequent, or prolonged activation of the body's stress response systems in the absence of the buffering protection of a supportive, adult relationship. The risk factors studied in the Adverse Childhood Experiences Study[23] include examples of multiple stressors (eg, child abuse or neglect, parental substance abuse, and maternal depression) that are capable of inducing a toxic stress response. The essential characteristic of this phenomenon is the postulated disruption of brain circuitry and other organ and metabolic systems during sensitive developmental periods. Such disruption may result in anatomic changes and/or physiologic dysregulations that are the precursors of later impairments in learning and behavior as well as the roots of chronic, stress-related physical and mental illness. The potential role of toxic stress and early life adversity in the pathogenesis of health disparities underscores the importance of effective surveillance for significant risk factors in the primary health care setting. More important, however, is the need for clinical pediatrics to move beyond the level of risk factor identification and to leverage advances in the biology of adversity to contribute to the critical task of developing, testing, and refining new and more effective strategies for reducing toxic stress and mitigating its effects as early as possible, before irrevocable damage is done. Stated simply, the next chapter of innovation in pediatrics remains to be written, but the outline and plot are clear.

Toxic Stress and the Developing Brain

In addition to short-term changes in observable behavior, toxic stress in young children can lead to less outwardly visible yet permanent changes in brain structure and function.[39,46] The plasticity of the fetal, infant, and early childhood brain makes it particularly sensitive to chemical influences, and there is growing evidence from both animal and human studies that persistently elevated levels of stress hormones can disrupt its developing architecture.[45] For example, abundant glucocorticoid receptors are found in the amygdala, hippocampus, and prefrontal cortex (PFC), and exposure to stressful experiences has been shown to alter the size and neuronal architecture of these areas as well as lead to functional differences in learning, memory, and aspects of executive functioning. More specifically, chronic stress is associated with hypertrophy and overactivity in the amygdala and orbitofrontal cortex, whereas comparable levels of adversity can lead to loss of neurons and neural connections in the hippocampus and medial PFC. The functional consequences of these structural changes include more anxiety related to both hyperactivation of the amygdala and less top-down control as a result of PFC atrophy as well as impaired memory and mood control as a consequence of hippocampal reduction.[47] Thus, the developing architecture of the brain can be impaired in numerous ways that create a weak foundation for later learning, behavior, and health.

Along with its role in mediating fear and anxiety, the amygdala is also an activator of the physiologic stress response. Its stimulation activates sympathetic activity and causes neurons in the hypothalamus to release CRH. CRH, in turn, signals the pituitary to release adrenocorticotropic hormone, which then stimulates the adrenal glands to increase serum cortisol concentrations. The amygdala contains large numbers of both CRH and glucocorticoid receptors, beginning early in life, which facilitate the establishment of a positive feedback loop. Significant stress in early childhood can trigger amygdala hypertrophy and result in a hyperresponsive or chronically activated physiologic stress response, along with increased potential for fear and anxiety.[48,49] It is in this way that a child's environment and early experiences get under the skin.

Although the hippocampus can turn off elevated cortisol, chronic stress diminishes its capacity to do so and can lead to impairments in memory and mood-related functions that are located in this brain region. Exposure to chronic stress and high levels of cortisol also inhibit neurogenesis in the hippocampus, which is believed to play an important role in the encoding of memory and other functions. Furthermore, toxic stress limits the ability of the hippocampus to promote contextual learning, making it more difficult to discriminate conditions for which there may be danger versus safety, as is common in posttraumatic stress disorder. Hence, altered brain architecture in response to toxic stress in early childhood could explain, at least in part, the strong association between early adverse experiences and subsequent problems in the development of linguistic, cognitive, and social-emotional skills, all of which are inextricably intertwined in the wiring of the developing brain.[45]

The PFC also participates in turning off the cortisol response and has an important role in the top-down

regulation of autonomic balance (ie, sympathetic versus parasympathetic effects), as well as in the development of executive functions, such as decision-making, working memory, behavioral self-regulation, and mood and impulse control. The PFC is also known to suppress amygdala activity, allowing for more adaptive responses to potentially threatening or stressful experiences; however, exposure to stress and elevated cortisol results in dramatic changes in the connectivity within the PFC, which may limit its ability to inhibit amygdala activity and, thereby, impair adaptive responses to stress. Because the hippocampus and PFC both play a significant role in modulating the amygdala's initiation of the stress response, toxic stress–induced changes in architecture and connectivity within and between these important areas might account for the variability seen in stress-responsiveness.[50] This can then result in some children appearing to be both more reactive to even mildly adverse experiences and less capable of effectively coping with future stress.[36,37,45,51]

Toxic Stress and the Early Childhood Roots of Lifelong Impairments in Physical and Mental Health

As described in the previous section, stress-induced changes in the architecture of different regions of the developing brain (eg, amygdala, hippocampus, and PFC) can have potentially permanent effects on a range of important functions, such as regulating stress physiology, learning new skills, and developing the capacity to make healthy adaptations to future adversity.[52,53] As the scientific evidence for these associations has become better known and has been disseminated more widely, its implications for early childhood policy and programs have become increasingly appreciated by decision makers across the political spectrum. Notwithstanding this growing awareness, however, discussions about early brain development in policy-making circles have focused almost entirely on issues concerned with school readiness as a prerequisite for later academic achievement and the development of a skilled adult workforce. Within this same context, the health dimension of early childhood policy has focused largely on the traditional components of primary pediatric care, such as immunizations, early identification of sensory impairments and developmental delays, and the prompt diagnosis and treatment of medical problems. That said, as advances in the biomedical sciences have generated growing evidence linking biological disruptions associated with adverse childhood experiences (ACE) to greater risk for a variety of chronic diseases well into the adult years, the need to reconceptualize the health dimension of early childhood policy has become increasingly clear.[1,6] Stated simply, the time has come to expand the public's understanding of brain development and shine a bright light on its relation to the early childhood roots of adult disease and to examine the compelling implications of this growing knowledge base for the future of pediatric practice.

The potential consequences of toxic stress in early childhood for the pathogenesis of adult disease are considerable. At the behavioral level, there is extensive evidence of a strong link between early adversity and a wide range of health-threatening behaviors. At the biological level, there is growing documentation of the extent to which both the cumulative burden of stress over time (eg, from chronic maltreatment) and the timing of specific environmental insults during sensitive developmental periods (eg, from first trimester rubella or prenatal alcohol exposure) can create structural and functional disruptions that lead to a wide range of physical and mental illnesses later in adult life.[1,6] A selective overview of this extensive scientific literature is provided below.

The association between ACE and unhealthy adult lifestyles has been well documented. Adolescents with a history of multiple risk factors are more likely to initiate drinking alcohol at a younger age and are more likely to use alcohol as a means of coping with stress than for social reasons.[54] The adoption of unhealthy lifestyles as a coping mechanism might also explain why higher ACE exposures are associated with tobacco use, illicit drug abuse, obesity, and promiscuity,[55,56] as well as why the risk of pathologic gambling is increased in adults who were maltreated as children.[57] Adolescents and adults who manifest higher rates of risk-taking behaviors are also more likely to have trouble maintaining supportive social networks and are at higher risk of school failure, gang membership, unemployment, poverty, homelessness, violent crime, incarceration, and becoming single parents. Furthermore, adults in this high-risk group who become parents themselves are less likely to be able to provide the kind of stable and supportive relationships that are needed to protect their children from the damages of toxic stress. This intergenerational cycle of significant adversity, with its predictable repetition of limited educational achievement and poor health, is mediated, at least in part, by the social inequalities and disrupted social networks that contribute to fragile families and parenting difficulties.[7,58,59]

The adoption of unhealthy lifestyles and associated exacerbation of socioeconomic inequalities are potent

risk factors for poor health. Up to 40% of early deaths have been estimated to be the result of behavioral or lifestyle patterns,[3] and 1 interpretation of the ACE study data is that toxic stress in childhood is associated with the adoption of unhealthy lifestyles as a coping mechanism.[60] An additional 25% to 30% of early deaths are thought to be attributable to either inadequacies in medical care[3] or socioeconomic circumstances, many of which are known to contribute to health care–related disparities.[61–67]

Beyond its strong association with later risk-taking and generally unhealthy lifestyles, it is critically important to underscore the extent to which toxic stress in early childhood has also been shown to cause physiologic disruptions that persist into adulthood and lead to frank disease, even in the absence of later health-threatening behaviors. For example, the biological manifestations of toxic stress can include alterations in immune function[68] and measurable increases in inflammatory markers,[69–72] which are known to be associated with poor health outcomes as diverse as cardiovascular disease,[69,70,73] viral hepatitis,[74] liver cancer,[75] asthma,[76] chronic obstructive pulmonary disease,[77] autoimmune diseases,[78] poor dental health,[72] and depression.[79–81] Thus, toxic stress in early childhood not only is a risk factor for later risky behavior but also can be a direct source of biological injury or disruption that may have lifelong consequences independent of whatever circumstances might follow later in life. In such cases, toxic stress can be viewed as the precipitant of a physiologic memory or biological signature that confers lifelong risk well beyond its time of origin.[38,42–44]

Over and above its toll on individuals, it is also important to address the enormous social and economic costs of toxic stress and its consequences for all of society. The multiple dimensions of these costs extend from differential levels of civic participation and their impacts on the quality of community life to the health and skills of the nation's workforce and its ability to participate successfully in a global economy. In the realm of learning and behavior, economists argue for early and sustained investments in early care and education programs, particularly for children whose parents have limited education and low income, on the basis of persuasive evidence from cost-benefit analyses that reveal the costs of incarceration and diminished economic productivity associated with educational failure.[82–86] In view of the relatively scarce attention to health outcomes in these long-term follow-up studies, the full return on investments that reduce toxic stress in early childhood is likely to be much higher. Health care expenditures that are paying for the consequences of unhealthy lifestyles (eg, obesity, tobacco, alcohol, and substance abuse) are enormous, and the costs of chronic diseases that may have their origins early in life include many conditions that consume a substantial percentage of current state and federal budgets. The potential savings in health care costs from even small, marginal reductions in the prevalence of cardiovascular disease, hypertension, diabetes, and depression are, therefore, likely to dwarf the considerable economic productivity and criminal justice benefits that have been well documented for effective early childhood interventions.

In summary, the EBD approach to childhood adversity discussed in this report has 2 compelling implications for a full, life span perspective on health promotion and disease prevention. First, it postulates that toxic stress in early childhood plays an important causal role in the intergenerational transmission of disparities in educational achievement and health outcomes. Second, it underscores the need for the entire medical community to focus more attention on the roots of adult diseases that originate during the prenatal and early childhood periods and to rethink the concept of preventive health care within a system that currently perpetuates a scientifically untenable wall between pediatrics and internal medicine.

THE NEED FOR A NEW PEDIATRIC PARADIGM TO PROMOTE HEALTH AND PREVENT DISEASE

In his 1966 Aldrich Award address, Dr Julius Richmond identified child development as the basic science of pediatrics.[87] It is now time to expand the boundaries of that science by incorporating more than 4 decades of transformational research in neuroscience, molecular biology, and genomics, along with parallel advances in the behavioral and social sciences (see Fig 1). This newly augmented, interdisciplinary, basic science of pediatrics offers a promising framework for a deeper understanding of the biology and ecology of the developmental process. More importantly, it presents a compelling opportunity to leverage these rapidly advancing frontiers of knowledge to formulate more effective strategies to enhance lifelong outcomes in learning, behavior, and health.

The time has come for a coordinated effort among basic scientists, pediatric subspecialists, and primary care clinicians to develop more effective strategies for addressing the origins of social class, racial, and ethnic disparities in health and development. To this end, a unified, science-based approach to early childhood policy and practice across multiple sectors (including primary health care, early

care and education, and child welfare, among many others) could provide a compelling framework for a new era in community-based investment in which coordinated efforts are driven by a shared knowledge base rather than distracted by a diversity of traditions, approaches, and funding streams.

Recognizing both the critical value and clear limitations of what can be accomplished within the constraints of an office visit, 21st century pediatrics is well positioned to serve as the primary engine for a broader approach to health promotion and disease prevention that is guided by cutting-edge science and expanded in scope beyond individualized health care.[88,89] The pediatric medical home of the future could offer more than the early identification of concerns and timely referral to available programs, as enhanced collaboration between pediatricians and community-based agencies could be viewed as a vehicle for testing promising new intervention strategies rather than simply improving coordination among existing services. With this goal in mind, science tells us that interventions that strengthen the capacities of families and communities to protect young children from the disruptive effects of toxic stress are likely to promote healthier brain development and enhanced physical and mental well-being. The EBD approach proposed in this article is adapted from a science-based framework created by the Center on the Developing Child at Harvard University to advance early childhood policies and programs that support this vision (see Fig 2).[1] Its rationale, essential elements, and implications for pediatric practice are summarized below.

Broadening the Framework for Early Childhood Policy and Practice

Advances across the biological, behavioral, and social sciences support 2 clear and powerful messages for leaders who are searching for more effective ways to improve the health of the nation.[6] First, current health promotion and disease prevention policies focused largely on adults would be more effective if evidence-based investments were also made to strengthen the foundations of health in the prenatal and early childhood periods. Second, significant reductions in chronic disease could be achieved across the life course by decreasing the number and severity of adverse experiences that threaten the well-being of young children and by strengthening the protective relationships that help mitigate the harmful effects of toxic stress. The multiple domains that affect the biology of health and development—including the foundations of healthy development, caregiver and community capacities, and public and private sector policies and programs—provide a rich array of targeted opportunities for the introduction of innovative interventions, beginning in the earliest years of life.[1]

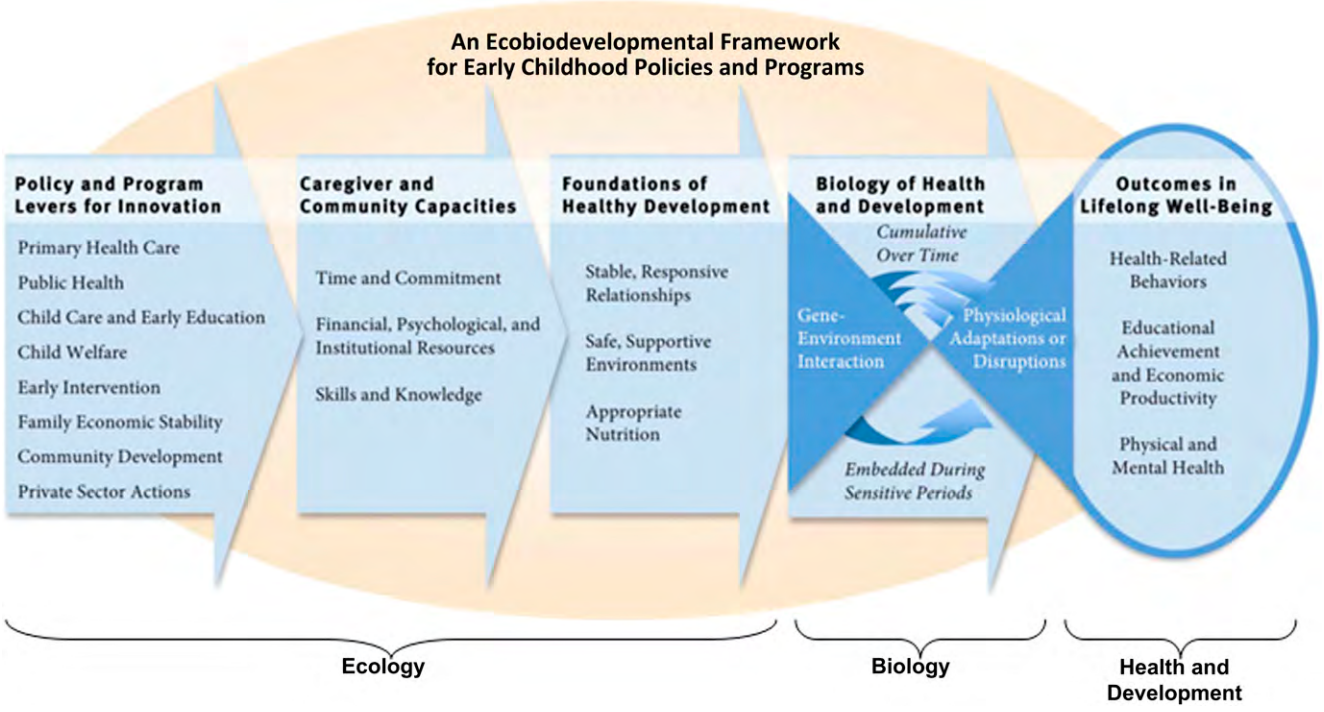

FIGURE 2
An ecobiodevelopmental framework for early childhood policies and programs. This was adapted from ref 1. See text for details.

The biology of health and development explains how experiences and environmental influences get under the skin and interact with genetic predispositions, which then result in various combinations of physiologic adaptation and disruption that affect lifelong outcomes in learning, behavior, and both physical and mental well-being. These findings call for us to augment adult-focused approaches to health promotion and disease prevention by addressing the early childhood origins of lifelong illness and disability.

The foundations of healthy development refers to 3 domains that establish a context within which the early roots of physical and mental well-being are nourished. These include (1) a stable and responsive environment of relationships, which provides young children with consistent, nurturing, and protective interactions with adults to enhance their learning and help them develop adaptive capacities that promote well-regulated stress-response systems; (2) safe and supportive physical, chemical, and built environments, which provide physical and emotional spaces that are free from toxins and fear, allow active exploration without significant risk of harm, and offer support for families raising young children; and (3) sound and appropriate nutrition, which includes health-promoting food intake and eating habits, beginning with the future mother's preconception nutritional status.

Caregiver and community capacities to promote health and prevent disease and disability refers to the ability of family members, early childhood program staff, and the social capital provided through neighborhoods, voluntary associations, and the parents' workplaces to play a major supportive role in strengthening the foundations of child health. These capacities can be grouped into 3 categories: (1) time and commitment; (2) financial, psychological, social, and institutional resources; and (3) skills and knowledge.

Public and private sector policies and programs can strengthen the foundations of health through their ability to enhance the capacities of caregivers and communities in the multiple settings in which children grow up. Relevant policies include both legislative and administrative actions that affect systems responsible for primary health care, public health, child care and early education, child welfare, early intervention, family economic stability (including employment support for parents and cash assistance), community development (including zoning regulations that influence the availability of open spaces and sources of nutritious food), housing, and environmental protection, among others. It is also important to underscore the role that the private sector can play in strengthening the capacities of families to raise healthy and competent children, particularly through supportive workplace policies (such as paid parental leave, support for breastfeeding, and flexible work hours to attend school activities and medical visits).

Defining a Distinctive Niche for Pediatrics Among Multiple Early Childhood Disciplines and Services

Notwithstanding the important goal of ensuring a medical home for all children, extensive evidence on the social determinants of health indicates that the reduction of disparities in physical and mental well-being will depend on more than access to high-quality medical care alone. Moreover, as noted previously, experience tells us that continuing calls for enhanced coordination of effort across service systems are unlikely to be sufficient if the systems are guided by different values and bodies of knowledge and the effects of their services are modest. With these caveats in mind, pediatricians are strategically situated to mobilize the science of early childhood development and its underlying neurobiology to stimulate fresh thinking about both the scope of primary health care and its relation to other programs serving young children and their families. Indeed, every system that touches the lives of children—as well as mothers before and during pregnancy—offers an opportunity to leverage this rapidly growing knowledge base to strengthen the foundations and capacities that make lifelong healthy development possible. Toward this end, explicit investments in the early reduction of significant adversity are particularly likely to generate positive returns.

The possibilities and limitations of well-child care within a multidimensional health system have been the focus of a spirited and enduring discussion within the pediatric community.[88,90,91] Over more than half a century, this dialogue has focused on the need for family-centered, community-based, culturally competent care for children with developmental disabilities, behavior problems, and chronic health impairments, as well as the need for a broader contextual approach to the challenges of providing more effective interventions for children living under conditions of poverty, with or without the additional complications of parental mental illness, substance abuse, and exposure to violence.[10] As the debate has continued, the gap between the call for comprehensive services and the realities of day-to-day practice has remained exceedingly difficult to reduce. Basic recommendations for routine developmental screening and referrals to appropriate community-based services have been particularly difficult

to implement.[92] The obstacles to progress in this area have been formidable at both ends of the process—beginning with the logistical and financial challenges of conducting routine developmental screening in a busy office setting and extending to significant limitations in access to evidence-based services for children and families who are identified as having problems that require intervention.

Despite long-standing calls for an explicit, community-focused approach to primary care, a recent national study of pediatric practices identified persistent difficulties in achieving effective linkages with community-based resources as a major challenge.[92] A parallel survey of parents also noted the limited communication that exists between pediatric practices and community-based services, such as Supplemental Nutrition Program for Women, Infants, and Children; child care providers; and schools.[93] Perhaps most important, both groups agreed that pediatricians cannot be expected to meet all of a child's needs. This challenge is further complicated by the marked variability in quality among community-based services that are available—ranging from evidence-based interventions that clearly improve child outcomes to programs that appear to have only marginal effects or no measurable impacts. Thus, although chronic difficulty in securing access to indicated services is an important problem facing most practicing pediatricians, the limited evidence of effectiveness for many of the options that are available (particularly in rural areas and many states in which public investment in such services is more limited) presents a serious problem that must be acknowledged and afforded greater attention.

At this point in time, the design and successful implementation of more effective models of health promotion and disease prevention for children experiencing significant adversity will require more than advocacy for increased funding. It will require a deep investment in the development, testing, continuous improvement, and broad replication of innovative models of cross-disciplinary policy and programmatic interventions that are guided by scientific knowledge and led by practitioners in the medical, educational, and social services worlds who are truly ready to work together (and to train the next generation of practitioners) in new ways.[88,89] The sheer number and complexity of underaddressed threats to child health that are associated with toxic stress demands bold, creative leadership and the selection of strategic priorities for focused attention. To this end, science suggests that 2 areas are particularly ripe for fresh thinking: the child welfare system and the treatment of maternal depression.

For more than a century, child welfare services have focused on physical safety, reduction of repeated injury, and child custody. Within this context, the role of the pediatrician is focused largely on the identification of suspected maltreatment and the documentation and treatment of physical injuries. Advances in our understanding of the impact of toxic stress on lifelong health now underscore the need for a broader pediatric approach to meet the needs of children who have been abused or neglected. In some cases, this could be provided within a medical home by skilled clinicians with expertise in early childhood mental health. In reality, however, the magnitude of needs in this area generally exceeds the capacity of most primary care practice settings. A report from the Institute of Medicine and National Research Council[15] stated that these needs could be addressed through regularized referrals from the child welfare system to the early intervention system for children with developmental delays or disabilities; subsequent federal reauthorizations of the Keeping Children and Families Safe Act and the Individuals with Disabilities Education Act (Part C) both included requirements for establishing such linkages. The implementation of these federal requirements, however, has moved slowly.

The growing availability of evidence-based interventions that have been shown to improve outcomes for children in the child welfare system[94] underscores the compelling need to transform "child protection" from its traditional concern with physical safety and custody to a broader focus on the emotional, social, and cognitive costs of maltreatment. The Centers for Disease Control and Prevention has taken an important step forward by promoting the prevention of child maltreatment as a public health concern.[95,96] The pediatric community could play a powerful role in leading the call for implementation of the new requirement for linking child welfare to early intervention programs, as well as bringing a strong, science-based perspective to the collaborative development and implementation of more effective intervention models.

The widespread absence of attention to the mother-child relationship in the treatment of depression in women with young children is another striking example of the gap between science and practice that could be reduced by targeted pediatric advocacy.[97] Extensive research has demonstrated the extent to which maternal depression compromises the contingent reciprocity between a mother and her young child that is essential for healthy cognitive, linguistic, social, and emotional development.[98] Despite that well-documented observation, the treatment of depression in women with

young children is typically viewed as an adult mental health service and rarely includes an explicit focus on the mother-child relationship. This serious omission illustrates a lack of understanding of the consequences for the developing brain of a young child when the required "serve and return" reciprocity of the mother-child relationship is disrupted or inconsistent. Consequently, and not surprisingly, abundant clinical research indicates that the successful treatment of a mother's depression does not generally translate into comparable recovery in her young child unless there is an explicit therapeutic focus on their dyadic relationship.[98] Pediatricians are the natural authorities to shed light on this current deficiency in mental health service delivery. Advocating for payment mechanisms that require (or provide incentives for) the coordination of child and parent medical services (eg, through automatic coverage for the parent-child dyad linked to reimbursement for the treatment of maternal depression) offers 1 promising strategy that American Academy of Pediatrics state chapters could pursue. As noted previously, although some medical homes may have the expertise to provide this kind of integrative treatment, most pediatricians rely on the availability of other professionals with specialized skills who are often difficult to find. Whether such services are provided within or connected to the medical home, it is clear that standard pediatric practice must move beyond screening for maternal depression and invest greater energy in securing the provision of appropriate and effective treatment that meets the needs of both mothers and their young children.

The targeted messages conveyed in these 2 examples are illustrative of the kinds of specific actions that offer promising new directions for the pediatric community beyond general calls for comprehensive, family-centered, community-based services. Although the practical constraints of office-based practice make it unlikely that many primary care clinicians will ever play a lead role in the treatment of children affected by maltreatment or maternal depression, pediatricians are still the best positioned among all the professionals who care for young children to provide the public voice and scientific leadership needed to catalyze the development and implementation of more effective strategies to reduce adversities that can lead to lifelong disparities in learning, behavior, and health.

A great deal has been said about how the universality of pediatric primary care makes it an ideal platform for coordinating the services needed by vulnerable, young children and their families. In this respect, the medical home is strategically positioned to play 2 important roles. The first is to ensure that needs are identified, state-of-the-art management is provided as indicated, and credible evaluation is conducted to assess the effects of the services that are being delivered. The second and, ultimately, more transformational role is to mobilize the entire pediatric community (including both clinical specialists and basic scientists) to drive the design and testing of much-needed, new, science-based interventions to reduce the sources and consequences of significant adversity in the lives of young children.[99] To this end, a powerful new role awaits a new breed of pediatricians who are prepared to build on the best of existing community-based services and to work closely with creative leaders from a range of disciplines and sectors to inform innovative approaches to health promotion and disease prevention that generate greater effects than existing efforts.

No other profession brings a comparable level of scientific expertise, professional stature, and public trust—and nothing short of transformational thinking beyond the hospital and office settings is likely to create the magnitude of breakthroughs in health promotion that are needed to match the dramatic advances that are currently emerging in the treatment of disease. This new direction must be part of the new frontier in pediatrics —a frontier that brings cutting-edge scientific thinking to the multidimensional world of early childhood policy and practice for children who face significant adversity. Moving that frontier forward will benefit considerably from pediatric leadership that provides an intellectual and operational bridge connecting the basic sciences of neurobiology, molecular genetics, and developmental psychology to the broad and diverse landscape of health, education, and human services.

SUMMARY

A vital and productive society with a prosperous and sustainable future is built on a foundation of healthy child development. Health in the earliest years—beginning with the future mother's well-being before she becomes pregnant—lays the groundwork for a lifetime of the physical and mental vitality that is necessary for a strong workforce and responsible participation in community life. When developing biological systems are strengthened by positive early experiences, children are more likely to thrive and grow up to be healthy, contributing adults. Sound health in early childhood provides a foundation for the construction of sturdy brain architecture and the achievement of a broad range of skills and learning capacities. Together these constitute the building blocks for a vital and sustainable society that invests in its

human capital and values the lives of its children.

Advances in neuroscience, molecular biology, and genomics have converged on 3 compelling conclusions: (1) early experiences are built into our bodies; (2) significant adversity can produce physiologic disruptions or biological memories that undermine the development of the body's stress response systems and affect the developing brain, cardiovascular system, immune system, and metabolic regulatory controls; and (3) these physiologic disruptions can persist far into adulthood and lead to lifelong impairments in both physical and mental health. This technical report presents a framework for integrating recent advances in our understanding of human development with a rich and growing body of evidence regarding the disruptive effects of childhood adversity and toxic stress. The EBD framework that guides this report suggests that many adult diseases are, in fact, developmental disorders that begin early in life. This framework indicates that the future of pediatrics lies in its unique leadership position as a credible and respected voice on behalf of children, which provides a powerful platform for translating scientific advances into more effective strategies and creative interventions to reduce the early childhood adversities that lead to lifelong impairments in learning, behavior, and health.

CONCLUSIONS

1. Advances in a broad range of interdisciplinary fields, including developmental neuroscience, molecular biology, genomics, epigenetics, developmental psychology, epidemiology, and economics, are converging on an integrated, basic science of pediatrics (see Fig 1).
2. Rooted in a deepening understanding of how brain architecture is shaped by the interactive effects of both genetic predisposition and environmental influence, and how its developing circuitry affects a lifetime of learning, behavior, and health, advances in the biological sciences underscore the foundational importance of the early years and support an EBD framework for understanding the evolution of human health and disease across the life span.
3. The biology of early childhood adversity reveals the important role of toxic stress in disrupting developing brain architecture and adversely affecting the concurrent development of other organ systems and regulatory functions.
4. Toxic stress can lead to potentially permanent changes in learning (linguistic, cognitive, and social-emotional skills), behavior (adaptive versus maladaptive responses to future adversity), and physiology (a hyperresponsive or chronically activated stress response) and can cause physiologic disruptions that result in higher levels of stress-related chronic diseases and increase the prevalence of unhealthy lifestyles that lead to widening health disparities.
5. The lifelong costs of childhood toxic stress are enormous, as manifested in adverse impacts on learning, behavior, and health, and effective early childhood interventions provide critical opportunities to prevent these undesirable outcomes and generate large economic returns for all of society.
6. The consequences of significant adversity early in life prompt an urgent call for innovative strategies to reduce toxic stress within the context of a coordinated system of policies and services guided by an integrated science of early childhood and early brain development.
7. An EBD framework, grounded in an integrated basic science, provides a clear theory of change to help leaders in policy and practice craft new solutions to the challenges of societal disparities in health, learning, and behavior (see Fig 2).
8. Pediatrics provides a powerful yet underused platform for translating scientific advances into innovative early childhood policies, and practicing pediatricians are ideally positioned to participate "on the ground" in the design, testing, and refinement of new models of disease prevention, health promotion, and developmental enhancement beginning in the earliest years of life.

National Athletic Trainers' Association Position Statement: Lightning Safety for Athletics and Recreation

Katie M. Walsh, EdD, ATC-L*; Brian Bennett, MEd, ATC†; Mary Ann Cooper, MD‡; Ronald L. Holle, MS§; Richard Kithil, MBA¶; Raul E. López, PhD§

*East Carolina University, Greenville, NC; †The College of William and Mary, Williamsburg, VA; ‡The University of Illinois at Chicago, Chicago, IL; §National Severe Storms Laboratory, Norman, OK; ¶The National Lightning Safety Institute, Louisville, CO

Objective: To educate athletic trainers and others about the dangers of lightning, provide lightning-safety guidelines, define safe structures and locations, and advocate prehospital care for lightning-strike victims.

Background: Lightning may be the most frequently encountered severe-storm hazard endangering physically active people each year. Millions of lightning flashes strike the ground annually in the United States, causing nearly 100 deaths and 400 injuries. Three quarters of all lightning casualties occur between May and September, and nearly four fifths occur between 10:00 AM and 7:00 PM, which coincides with the hours for most athletic or recreational activities. Additionally, lightning casualties from sports and recreational activities have risen alarmingly in recent decades.

Recommendations: The National Athletic Trainers' Association recommends a proactive approach to lightning safety, including the implementation of a lightning-safety policy that identifies safe locations for shelter from the lightning hazard. Further components of this policy are monitoring local weather forecasts, designating a weather watcher, and establishing a chain of command. Additionally, a flash-to-bang count of 30 seconds or more should be used as a minimal determinant of when to suspend activities. Waiting 30 minutes or longer after the last flash of lightning or sound of thunder is recommended before athletic or recreational activities are resumed. Lightning-safety strategies include avoiding shelter under trees, avoiding open fields and spaces, and suspending the use of land-line telephones during thunderstorms. Also outlined in this document are the prehospital care guidelines for triaging and treating lightning-strike victims. It is important to evaluate victims quickly for apnea, asystole, hypothermia, shock, fractures, and burns. Cardiopulmonary resuscitation is effective in resuscitating pulseless victims of lightning strike. Maintenance of cardiopulmonary resuscitation and first-aid certification should be required of all persons involved in sports and recreational activities.

Key Words: lightning, policies and procedures, lightning casualties, severe-storm hazards, environmental hazards, emergency action plan, thunderstorms, lightning-safety policy, athletics, recreation

Over the past century, lightning has consistently been 1 of the top 3 causes of weather-related deaths in this country.[1,2] It kills approximately 100 people and injures hundreds more each year.[2ï 5] Lightning is an enormous and widespread danger to the physically active population, due in part to the prevalence of thunderstorms in the afternoon to early evening during the late spring to early fall and a societal trend toward outdoor physical activities.[2,3,6] Certain areas of the United States have higher propensities for thunderstorm activity, and thus, higher casualty rates: the Atlantic seaboard, southwest, southern Rocky Mountains, and southern plains states.[2,7]

Worldwide, approximately 2000 thunderstorms and 50 to 100 lightning flashes occur every second.[8] In 1997, the National Lightning Detection Network recorded nearly 27 000 000 cloud-to-ground lightning strikes in the United States (Christoph Zimmerman, Global Atmospherics, Inc, Tucson, AZ, unpublished data). Many of these strikes caused fires, power outages, property damage, loss of life, and disabling injuries. Property damage from lightning is estimated to cost $5 000 000 000 to $6 000 000 000 annually in this country.[9] While print and television news reports of lightning-strike incidents to recreational athletes are frequent during the thunderstorm season, many people are unsure about what to do and where to go to improve their safety during thunderstorms. It is incumbent on all individuals, particularly those who are leaders in athletics and recreation, to appreciate the lightning hazard, learn the published lightning-safety guidelines, and act prudently, wisely, and in a spirit that will encourage safe behavior in others.

The guidelines presented in this article govern all outdoor activities, as well as indoor swimming-pool activities. The purpose of this position statement is to recommend lightning-safety policy guidelines and strategies and to educate athletic trainers and others involved with athletic or recreation activities about the hazards of lightning.

RECOMMENDATIONS

1. Formalize and implement a comprehensive, proactive lightning-safety policy or emergency action plan specific to lightning safety.[1,7,10–14] The components of this policy should include the following:
   A. An established chain of command that identifies who is to make the call to remove individuals from the field or an activity.
   B. A designated weather watcher (ie, a person who actively looks for the signs of threatening weather and notifies the chain of command if severe weather becomes dangerous).
   C. A means of monitoring local weather forecasts and warnings.
   D. A listing of specific safe locations (for each field or site) from the lightning hazard.
   E. The use of specific criteria for suspension and resumption of activities (refer to recommendations 4, 5, and 6).
   F. The use of the recommended lightning-safety strategies (refer to recommendations 7, 8, and 9).
2. The primary choice for a safe location from the lightning hazard is any substantial, frequently inhabited building. The electric and telephone wiring and plumbing pathways aid in grounding a building, which is why buildings are safer than remaining outdoors during thunderstorms. It is important not to be connected to these pathways while inside the structure during ongoing thunderstorms.
3. The secondary choice for a safer location from the lightning hazard is a fully enclosed vehicle with a metal roof and the windows closed.[1,7,10,11,13,14] Convertible cars and golf carts do not provide protection from lightning danger. It is important not to touch any part of the metal framework of the vehicle while inside it during ongoing thunderstorms.
4. Seeking a safe structure or location at the first sign of lightning or thunder activity is highly recommended. By the time the flash-to-bang count approaches 30 seconds (or is less than 30 seconds), all individuals should already be inside or should immediately seek a safe structure or location.[1,13–15] To use the flash-to-bang method, the observer begins counting when a lightning flash is sighted. Counting is stopped when the associated bang (thunder) is heard. Divide this count by 5 to determine the distance to the lightning flash (in miles). For example, a flash-to-bang count of 30 seconds equates to a distance of 6 miles (9.66 km).
5. Postpone or suspend activity if a thunderstorm appears imminent before or during an activity or contest (regardless of whether lightning is seen or thunder heard) until the hazard has passed. Signs of imminent thunderstorm activity are darkening clouds, high winds, and thunder or lightning activity.
6. Once activities have been suspended, wait at least 30 minutes after the last sound of thunder or lightning flash before resuming an activity or returning outdoors.[1,13–15] A message should be read over the public address system and lightning-safety tips should be placed in game programs alerting spectators and competitors about what to do and where to go to find a safer location during thunderstorm activity.[13,15]
7. Extremely large athletic events are of particular concern with regard to lightning safety. Consider using a multidisciplinary approach to lessen lightning danger, such as integrating weather forecasts, real-time thunderstorm data, a weather watcher, and the flash-to-bang count to aid in decision making.
8. Avoid being in contact with, or in proximity to, the highest point of an open field or on the open water. Do not take shelter under or near trees, flag poles, or light poles.[1,8,10,13–15]
9. Avoid taking showers and using plumbing facilities (including indoor and outdoor pools) and land-line telephones during thunderstorm activity.[1,8,10,13–15] Cordless or cellular telephones are safer to use when emergency help is needed.
10. Individuals who feel their hair stand on end or skin tingle or hear crackling noises should assume the lightning-safe position (ie, crouched on the ground, weight on the balls of the feet, feet together, head lowered, and ears covered). Do not lie flat on the ground.[1,8,10,13–15]
11. Observe the following basic first-aid procedures, in order, to manage victims of lightning strike[16]:
    A. Survey the scene for safety. Ongoing thunderstorms may still pose a threat to emergency personnel responding to the situation.
    B. Activate the local emergency management system.
    C. Move the victim carefully to a safer location, if needed.
    D. Evaluate and treat for apnea and asystole.
    E. Evaluate and treat for hypothermia and shock.
    F. Evaluate and treat for fractures.
    G. Evaluate and treat for burns.
12. All persons should maintain current cardiopulmonary resuscitation (CPR) and first-aid certification.
13. All individuals should have the right to leave an athletic site or activity, without fear of repercussion or penalty, in order to seek a safe structure or location if they feel they are in danger from impending lightning activity.[13,15]

BACKGROUND

Lightning-Flash Development

Within a developing thunderstorm cloud, updrafts promote the collision of rising and descending ice and water particles, and the positive and negative charges are separated into distinct layers. Positive charges are taken via updrafts to the top of the cloud, while negative charges accumulate in the bottom of the cloud, creating the equivalent of a giant atmospheric battery.[8]

A cloud-to-ground lightning flash is the product of the buildup and discharge of static electric energy between the charged regions of the cloud and the earth. The negatively charged lower region of the cloud induces a positive charge on the ground below. The tremendous electric forces between these 2 opposite charges initiate the lightning flash, which begins as a barely visible step leader moving in a series of steps downward from the cloud. Various objects on the ground (trees, chimneys, people, etc) can produce positively charged, upward streamers. The connection of the step leader with an upward streamer determines the connection point on the ground. After contact, a bright return stroke propagates upward from the ground, while electrons move downward toward the earth.[8] This entire phenomenon happens in less than a fraction of a second,[8] but a large amount of charge is transferred to the earth from the cloud.

Most lightning flashes have several return strokes, separated by only 0.004 to 0.005 seconds.[8] The human eye can barely

resolve the intervals between the strokes that cause the lightning flash to appear to flicker. A lightning flash is essentially a brief spark, similar to that received from touching a doorknob after walking across a carpeted room. The lightning channel is approximately 2.54 cm (1 inch) in diameter and averages 4.83 to 8.05 km (3 to 5 miles) in vertical height but can be 9.66 km (6 miles) or higher.[8] Cloud-to-ground lightning flashes typically have peak currents ranging from 10 000 to 200 000 ¡ , and the electric potential between the cloud and ground can be 10 000 000 to 100 000 000 V.[8]

Thunder is created when lightning quickly heats the air around it, sometimes to temperatures greater than approximately 27 800ÁC (50 000ÁF), which is about 5 times hotter than the surface of the sun.[8] The rapidly heated air around a lightning channel explodes, which in turn creates the sound we hear as a clap of thunder.[8] The audible range of thunder is about 16.09 km (10 miles) but can be more or less depending on local conditions.[1] Heat lightning is intracloud or intercloud lightning that is too distant for the accompanying thunder to be heard.[8] Although it is possible to have lightning without thunder, thunder never occurs in the absence of lightning.

Lightning Casualty Demographics

On average, lightning kills approximately 100 people each year in this country, while many hundreds more are injured.[2ï5] The death toll from lightning for 1940 to 1973 was greater than that from tornadoes and hurricanes combined.[17] Ninety-two percent of lightning casualties occur between May and September, while July has the greatest number of casualties.[2,3,7,18] Furthermore, 45% of the deaths and 80% of the casualties occurred in these months between 10:00 AM and 7:00 PM,[2,3,7,8] which coincides with the most likely time period for athletic or recreational events. For these reasons, it is accurate to say that lightning is the most dangerous and frequently encountered severe-storm hazard that most people experience each year.[10,11]

The statistics on lightning casualty demographics compiled from the National Oceanographic and Atmospheric Administration publication *Storm Data* for the state of Colorado over the last few decades demonstrate an increase in the number of lightning casualties in persons involved in sports and outdoor recreation.[7,10,18,19] Fifty-two percent of lightning casualties were people involved in outdoor recreation.[7,18] In addition, these authors noted that the highest number of casualties from lightning was recorded in recreational and sports activities for each year of the study.[18] During the 1960s, more than 30% of lightning casualties occurred during outdoor recreation activities; during the 1970s, that figure rose to 47%.[17] Furthermore, the rate of increase of lightning casualties during sports was higher than the general United States population rate of increase during the same time period.[7,18]

Lightning casualty statistics from Colorado demonstrate that the most common sites for fatalities were open fields (27%), near trees (16%), and close to water (13%).[7,8,18] Statistics from the country as a whole mimic the numbers from Colorado. Open fields, ballparks, and playgrounds accounted for nearly 27% of casualties, and under trees (14%), water-related (8%), and golf-related (5%) deaths associated with lightning followed.[19] All these fatalities had 1 common denominator: being near the highest object or being the tallest object in the immediate area. This single factor accounted for 56% of all fatalities from Colorado. Thus, it is imperative to avoid high ridges and high points on the terrain, and conversely, it is important to seek low-lying points on the terrain.[1,3,8,13ï15]

The height above ground has been demonstrated to play a prominent role in determining the strike probability. Therefore, it is important to understand why minimizing vertical height is critical in decreasing the chances of becoming a victim of lightning. Warning signs of a high electromagnetic field and imminent lightning strike include hair standing on end and sounds similar to bacon sizzling or cloth tearing.[8] If these conditions occur, a cloud-to-ground lightning flash could strike in the immediate area. Therefore, one should immediately crouch in the lightning-safe position: feet together, weight on the balls of the feet, head lowered, and ears covered.[1] This position is intended to minimize the probability of a direct strike by both lowering the personôs height and minimizing the area in contact with the surface of the ground. Taller objects are more likely to be struck (but not always) because their upward streamer occurs first, so that it is closer in proximity to the step leader coming downward from the cloud.

The ultimate message is that individuals in dangerous lightning situations should never wait to seek a safe location and pursue safety measures. It is important to be proactive by having all individuals inside a safe structure or location long before the lightning is close enough to be threatening.

Mechanisms of Lightning Injury

Injury from lightning can occur via 5 mechanisms.[16] A direct strike most commonly occurs to the head, and lightning current enters the orifices. This mechanism explains why eye and ear injuries in lightning-strike victims are abundantly reported in the literature.[16] The shock wave created by the lightning channel can also produce injuries, such as rupture of the tympanic membrane, a common clinical presentation in the lightning-strike victim.[16,23,24] Recommending that individuals cover their ears while in the lightning-safe position may help to mitigate this type of injury.

The second mechanism, contact injury, occurs when the lightning victim is touching an object that is in the pathway of a lightning current.[16] Side flash, the third mechanism, occurs when lightning strikes an object near the victim and then jumps from that object to the victim. This is the main danger to a person who is sheltered under an isolated, tall tree.[6] An upward streamer is triggered by the tree but when this connects with the step leader, the resulting stroke jumps to the victim, who represents an additional pathway to ground.

The fourth mechanism, a step voltage or ground current, occurs when the lightning current flowing in the ground radiates outward in waves from the strike point. If 1 of the individualôs feet is closer to the strike than the other, a step voltage is created.[6,16] Humans are primarily salt minerals in an aqueous solution, and a lightning current preferentially travels up from the earth through this solution (that is, the person) rather than through the ground. The greater the differential step voltage (ie, the greater the distance between the 2 feet), the greater the likelihood of injury. Placing oneôs feet close together while in the crouched position and not lying flat on the ground are crucial in reducing the likelihood of injury from a step voltage or ground current.

Blunt injury is the fifth mechanism for lightning-strike injuries. Lightning current can cause violent muscular contractions that throw its victims many meters from the strike point.

Explosive and implosive forces created by the rapid heating and cooling by the lightning current are also enough to produce traumatic injuries.[16]

Common Effects of Lightning Injury

While lightning kills nearly 100 people annually in this country, the protracted suffering of the survivors should not be underestimated. Although the only acute cause of death from lightning injury is cardiac arrest,[20] the anoxic brain damage that can occur if the person is not rapidly resuscitated can be devastating. In addition, even for the survivor who did not sustain a cardiac arrest, permanent sequelae can include common brain-injury symptoms such as deficits in short-term memory and processing of new information, as well as severe and ongoing headaches, hyperirritability, sleep disturbances, and distractibility.[21,22] Others may develop chronic pain syndromes or absence-type seizures. Frequently, survivors are unable to return to their previous level of function. They may not be able to continue in their jobs or in their educational pursuits and may be permanently disabled.

Components of a Lightning-Safety Policy

The purpose of formalizing a policy on lightning safety is to provide written guidelines for safety during lightning storms. Ninety-two percent of National Collegiate Athletic Association Division I athletics departments responding to a survey did not have a formal, written lightning-safety policy.[12] The best means of reducing the lightning hazard to people is to be proactive. Athletic and recreational personnel should formalize and implement an emergency action plan specific to lightning safety before the thunderstorm season.[1,11,13ï 15] Dissemination of the plan is paramount, so that all persons will know what to do and where to go to improve their own safety during thunderstorms. The 6 components of a lightning-safety policy or emergency action plan for lightning are discussed in the following paragraphs.

The first component in an emergency action plan or policy for lightning safety is the establishment of a specific chain of command that identifies the person who has the authority to remove participants from athletic venues or activities. The second is to appoint a weather watcher who actively looks for signs of developing local thunderstorms, such as high winds, darkening clouds, and any lightning or thunder.

The third element of a lightning-safety policy is the stipulation for monitoring local weather forecasts. One method is to use weather radios that broadcast information on daily forecasts and approaching storm systems. Weather radios are an excellent informational tool for general storm movement and strength. While this information is extremely important in decision making, the National Weather Service does not broadcast information on specific storm cells or lightning. Therefore, in addition to monitoring weather radios, it is essential that the weather watcher be on constant lookout for conditions in the immediate vicinity of the athletic event and compare these conditions with the weather radio information.

When a local area is placed under a severe-storm watch or warning by the National Weather Service, weather radios can be programmed to give audible alert tones. A watch indicates conditions are favorable for severe weather; a warning means severe weather has been detected in the locale, and all persons should take the necessary precautions to preserve their own safety. If severe storms are in the vicinity, all individuals should more intently monitor thunderstorm activity, such as severity and direction of movement of the storm. It may also mean that steps should be taken to remove athletes from the field or perhaps to postpone or suspend athletic or recreational activities during the event or before the storm begins.

Safe Locations

The fourth aspect of a lightning-safety policy, defining and listing safe structures or locations to evacuate to in the event of lightning, is of utmost importance. While there are reports of people being injured by lightning inside buildings,[8] evacuating to a substantial building can considerably lower the risks of lightning injury compared with those of remaining outside during the thunderstorm. The lightning-safety policy should identify the safe structure or location specific to each venue. This information will enable individuals to know where to go in advance of any thunderstorm situation and appreciate how long it takes to get to the specific safe location from each field or event site.

The primary choice for a safe structure is any fully enclosed, substantial building.[1,3,8,13ï 15] Ideally, the building should have plumbing, electric wiring, and telephone service. The lightning current is more likely to follow these pathways to ground, which aids in electrically grounding the structure.[8] If a substantial building is not available, a fully enclosed vehicle with a metal roof and the windows completely closed is a reasonable alternative.[1,3,13ï 15] It is not the rubber tires that make the vehicle safe but the metal enclosure that guides the lightning current around the passengers, rather than through them. Do not touch any part of the metal framework while inside the vehicle.[8] Convertible vehicles and golf carts do not provide a high level of protection and cannot be considered safe from lightning.

Unsafe Locations

Unfortunately, those properties that serve to define a safe structure and improve the safety of its inhabitants also present a potential risk. Lightning current can enter a building via the electric or telephone wiring. It can also enter via a ground current through the incoming plumbing pipelines. This condition makes locker-room shower areas, swimming pools (indoor and outdoor), telephones, and electric appliances unsafe during thunderstorms because of the possible contact with current-carrying conduction. While such reports are rare, people have been killed or injured by lightning in their homes while talking on the telephone, taking a shower, or standing near household appliances such as dishwashers, stoves, or refrigerators.[1,3,8,13ï 15]

From 1959 through 1965, lightning killed 4 people and injured 36 others while they were talking on the telephone. These numbers comprised 0.42% (n = 960) of deaths and 2.1% (n = 1736) of injuries for the period.[5] Studying reports from *Storm Data*, researchers found that between 1959 and 1994, 2.4% of lightning casualties were telephone related.[2] Because they are not connected directly to a land-line phone, cellular and cordless telephones are reasonably safe alternatives for summoning help during a thunderstorm. It should be noted that injury from acoustic damage can occur via explosive static from the earpiece caused by a nearby lightning strike.

Even though a swimming pool may be indoors and apparently safe, it can be a dangerous location during thunderstorms.[25] The current can be propagated through plumbing and electric connections via the underwater lights and drains of most swimming pools. Lightning current can also enter the building, either into the electric wiring inside the building or through underground plumbing pipelines that enter the building.[8] If lightning strikes the building or ground nearby, the current will most likely follow these pathways to the swimmers through the water. Thus, indoor-pool activities are potentially dangerous and should be avoided during thunderstorms.[25]

Small structures, such as rain or picnic shelters or athletic storage sheds, are generally not properly protected and should be avoided during thunderstorms. These locations may actually increase the risk of lightning strike via a side flash and cause injury to the occupants.

Criteria for Postponement and Resumption of Activities

The fifth component of any lightning-safety policy is to clearly describe criteria for both the suspension and resumption of athletic or recreational activities. Various technologies currently on the market propose to assist in determining when lightning is in the immediate area. Within the developing area of this lightning technology, data-based research is insufficient to either support or dispute companiesô claims regarding establishing when one is in danger of a lightning strike. Therefore the National Athletic Trainersô Association promotes the flash-to-bang standard to warn people of imminent lightning danger. The flash-to-bang method is the easiest and most convenient means for determining the distance to a lightning flash and can also be used to determine when to suspend or postpone activities. The flash-to-bang method is based on the fact that light travels faster than sound, which travels at a speed of approximately 1.61 km (1 mile) every 5 seconds.[1,8,13,14] To use the flash-to-bang method, begin counting on the lightning flash, and stop counting when the associated clap of thunder is heard. When storms have a high flash rate, it is important to correlate a specific flash with the thunder it produced. Divide the time to thunder (in seconds) by 5 to determine the distance (in miles) to the lightning flash.[1,8,13,14] For example, an observer obtains a count of 30 seconds from the time he or she spots the flash to when the thunder is heard. Thirty divided by 5 equals 6; therefore, that lightning flash was 6 miles (9.66 km) from the observer.

The 30-second rule is not an arbitrary guideline. Lõpez and Holle[26] studied storms in Oklahoma, Colorado, and Florida and found that in larger thunderstorms, the distance between successive flashes can be up to 6 miles (9.66 km) (ie, a flash-to-bang count of 30 seconds) in approximately 80% of the flash pairs. The authors also found the distance between successive flashes may be as great as 9 miles (14.48 km) or more, depending on local geography and atmospheric conditions. If a flash-to-bang count of 30 seconds is observed, the next flash could conceivably be at the observerôs location.

Another important factor to consider when using the flash-to-bang method is that, although a relatively rare occurrence, lightning has been reported to strike 16.09 km (10 miles) or more from where it is raining.[1] Therefore, a flash-to-bang count of at least 30 seconds is strongly recommended as a determinant of when to suspend or postpone athletic or recreational activities.[13ï15] As the flash-to-bang count approaches 30 seconds, all persons should be seeking, or already inside, a safe structure or location. This is the minimal guideline when using the flash-to-bang method to halt athletic or recreational activities. Seeking a safe location at the first sign of thunder or lightning activity is also highly recommended.

Another facet of the lightning-safety policy is embodied in the ñ30ï 30 ruleò (Table 1), which relies on the flash-to-bang method. If a game, practice, or other activity is suspended or postponed due to lightning activity, it is important to establish strict criteria in the lightning-safety policy for resumption of activities. Waiting at least 30 minutes after the last lightning flash or sound of thunder is recommended.[13ï15] When storm reports and flash data at the time of death or injury were compared, researchers found that the end of the storm, when the flash-rate frequency began to decline, was as deadly as the middle of the storm, when the lightning flash rate was at its peak. The authors postulated that once the flash rate begins to decline, people do not perceive the thunderstorm as dangerous and are struck by lightning when they return outdoors prematurely.[1] An important adage for athletic trainers, coaches, and officials to remember is, ñif you see it (lightning) flee it, if you hear it (thunder), clear it.ò

The 30-minute rule can also be explained in another way. A typical thunderstorm moves at a rate of approximately 40.23 km (25 miles) per hour. Experts believe that 30 minutes allow the thunderstorm to be about 16.09 to 19.31 km (10 to 12 miles) from the area, minimizing the probability of a nearby, and therefore dangerous, lightning strike.[15] Blue sky in the local area or a lack of rainfall are not adequate reasons to breach the 30-minute return-to-play rule. Lightning can strike far from where it is raining, even when the clouds begin to clear and show evidence of blue sky.[1] This situation is often referred to as a ñbolt out of the blue.ò Each time lightning is observed or thunder is heard, the 30-minute clock should be reset.

Obligation to Warn

The recommendation for reading lightning-safety messages over public address systems and placing placards conspicuously around each venue resulted from a fatal lightning strike in Washington, DC, in May 1991.[27] During a high school lacrosse game, a dangerous thunderstorm swept into the local area, and the game was suspended. Lightning killed 1 young person and injured 10 others who sought refuge under a tree. Many people stated that they did not know what to do or where to go to protect themselves from the dangers of lightning.

According to the basic principles of tort law, an individual has a duty to warn others of dangers that may not be obvious to a guest or subordinate of that person.[28] Black et al[29] defined the legal principle of ñforeseeabilityò as ñthe ability to see or

Table 1. The 30-30 Rule[15]

Criteria for suspension of activities	By the time the flash-to-bang count approaches 30 seconds, all individuals should already be inside a safe shelter.
Criteria for resumption of activities	Wait at least 30 minutes after the last sound (thunder) or observation of lightning before leaving the safe shelter to resume activities.

know in advance, eg, reasonable anticipation, that harm or injury is a likely result from certain acts or omissions.ò With regard to dangerous lightning situations, it could be argued that an institution (or athletic department) has the duty to warn spectators, invited guests, and participants if conditions are such that lightning activity may be an imminent danger in the immediate area. Whereas lightning is understood by all to be a dangerous phenomenon, the importance of seeking safe shelter and the specific time that one should vacate to safety are generally not known. Based on research presented in this article regarding the number of lightning casualties resulting from the erroneous tendency of people to seek shelter under trees, it would be wise for an organization to promote lightning safety to its clientele and participants, including a list of specific safe locations or structures.

Warnings should be commensurate with the age and understanding of those involved. Announcements should be repeated over the public address system and colorful notices and safety instructions both placed in the event programs and posted in visible, high-traffic areas. Safety instructions should include the location of the nearest safe shelter, similar to airline pocket diagrams of nearest emergency exits. Being proactive with regard to the lightning threat demands not putting individuals at risk if a hazardous situation could have been prevented. If thunderstorm activity looks menacing before or during an event, consider canceling or postponing the event until the complete weather situation can be ascertained and determined to no longer be a threat. The first lightning flash from the thunderstorm cloud and storms that produce only a few flashes still pose a potential threat and should be treated as such. Every cloud-to-ground lightning flash is dangerous and potentially deadly and should not be taken lightly or viewed complacently. Therefore, it is the recommendation of the National Athletic Trainersô Association to postpone or suspend athletic and recreational activities before their onset, if thunderstorm activity appears imminent.

Prehospital Care of Victims

If a lightning-strike victim presents in asystole or respiratory arrest, it is critical to initiate CPR as soon as safely possible.[23] Because lightning-strike victims do not remain connected to a power source, they do not carry an electric charge and are safe to assess.[30] However, during an ongoing thunderstorm, lightning activity in the local area still poses a deadly hazard for the medical team responding to the incident. The athletic trainer or other medical personnel should consider his or her own personal safety before venturing into a dangerous situation to render care.

If medical personnel assume the risk of entering a dangerous lightning situation to render care, the first priority should be to move the victim to a safe location. In this way, a hazardous situation can be neutralized for the athletic trainer, as well as the victim. It is unlikely that moving a victim to an area of greater safety for resuscitation will cause any serious injury to the victim.[16] The primary and secondary survey of the victimôs condition can then be conducted once safety is reached.

It is not uncommon to find a lightning-strike victim unconscious, with fixed and dilated pupils and cold extremities and in cardiopulmonary arrest. Case studies of individuals with prolonged apnea and asystole after a lightning strike have demonstrated successful resuscitations using CPR.[23,24,31] Once stopped, the heart will most likely spontaneously restart, but breathing centers in the brain may be damaged. Respiratory arrest lasts longer than cardiac arrest, leading to secondary asystole from hypoxia.[16] Therefore, the basic principle of triage, ñtreat the living first,ò should be reversed in cases involving casualties from a lightning strike. It is imperative to treat those persons who are ñapparently deadò first by promptly initiating CPR. See Table 2 for quick-reference guidelines in evaluating and treating victims of lightning strike.

Table 2. Recommended Prehospital Care for Treating Lightning-Strike Victims[16]

Perform the following steps in order:

1. Survey the scene for safety.
2. Activate the local emergency management system.
3. Carefully move the victim to a safe area, if needed.
4. Evaluate and treat for apnea and asystole.
5. Evaluate and treat for hypothermia and shock.
6. Evaluate and treat for fractures.
7. Evaluate and treat for burns.

CONCLUSIONS

Due to its pervasiveness during the times that most athletic events occur, lightning is a significant hazard to the physically active population. Lightning-casualty statistics show an alarming rise in the number of lightning casualties in recreational and sports settings in recent decades.[2,3,9] Each person must take responsibility for his or her own personal safety during thunderstorms.[10] However, because people are often under the direction of others, whether they are children or adults participating in organized athletics, athletic trainers, coaches, teachers, and game officials must receive education about the hazards of lightning and become familiar with proved lightning-safety strategies. A policy is only as good as its compliance and unwavering, broad-based enforcement.

It is important to be much more wary of the lightning threat than the rain. Lightning can strike in the absence of rain, as well as from apparently clear blue skies overhead, even though a thunderstorm may be nearby. The presence of lightning or thunder should be the determining factor in postponing or suspending games and activities, not the amount of rainfall on the playing field. Lightning should be the only critical factor in decision making for athletic trainers, umpires, officials, referees, and coaches.

Athletic trainers, umpires, officials, referees, coaches, teachers, and parents can make a difference in reducing the number of lightning casualties if they (1) formalize and implement a lightning-safety policy or emergency action plan specific to lightning safety; (2) understand the qualifications of safe structures or locations, in addition to knowing where they are in relation to each athletic field or activity site; (3) understand the 30ï 30 rule as a minimal determinant of when to suspend activities and follow it; being conservative and suspending activities at the first sign of lightning or thunder activity is also prudent and wise; (4) practice and follow the published lightning-safety guidelines and strategies; (5) and maintain CPR and standard first-aid certification.

CLINICAL REPORT

Long-term Follow-up Care for Pediatric Cancer Survivors

Guidance for the Clinician in Rendering Pediatric Care

AMERICAN ACADEMY OF PEDIATRICS
Section on Hematology/Oncology
CHILDREN'S ONCOLOGY GROUP

ABSTRACT

Progress in therapy has made survival into adulthood a reality for most children, adolescents, and young adults diagnosed with cancer today. Notably, this growing population remains vulnerable to a variety of long-term therapy-related sequelae. Systematic ongoing follow-up of these patients, therefore, is important for providing for early detection of and intervention for potentially serious late-onset complications. In addition, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care to promote risk reduction for health problems that commonly present during adulthood. Both general and subspecialty pediatric health care providers are playing an increasingly important role in the ongoing care of childhood cancer survivors, beyond the routine preventive care, health supervision, and anticipatory guidance provided to all patients. This report is based on the guidelines that have been developed by the Children's Oncology Group to facilitate comprehensive long-term follow-up of childhood cancer survivors (www.survivorshipguidelines.org). *Pediatrics* 2009;123:906–915

INTRODUCTION

Cancer is diagnosed in approximately 12 400 children and adolescents younger than 20 years each year in the United States.[1] Before 1970, almost all children with cancer died as a result of their primary disease. However, rapid improvements in multimodal treatment regimens (chemotherapy, radiation therapy, and surgery), coupled with aggressive supportive-care regimens, have resulted in survival rates that continue to increase at a fast pace. The current overall survival rate for childhood malignancies is estimated at 79%.[2] This translates into approximately 300 000 childhood cancer survivors now in the United States, many of whom may seek ongoing care from pediatricians and other pediatric subspecialty providers.[3] As the number of childhood cancer survivors continues to grow, there is a concomitant increase in the number of survivors being cared for in the primary care setting. The Childhood Cancer Survivor Study (CCSS), the largest and most extensively characterized cohort of 5-year childhood cancer survivors in North America, reported that survivors receive most of their care from primary care providers.[4] Furthermore, the proportion of survivors reporting a cancer-related visit decreases with increasing time from cancer diagnosis. Thus, the general pediatrician is likely to have an increasingly vital role in caring for this rapidly growing population.

Cancer and its treatment may result in a variety of physical and psychosocial effects that predispose childhood cancer survivors to excess morbidity and early mortality when compared with the general population.[5–12] Virtually every organ system can be affected by the chemotherapy, radiation, and/or surgery required to achieve cure of pediatric malignancies. Late complications of treatment may include problems with organ function, growth and development, neurocognitive function and academic achievement, and the potential for additional cancers. Cancer and its treatment also have psychosocial consequences that may adversely affect family/peer relationships, vocational and employment opportunities, and insurance and health care access. A child's life is forever changed when touched by the cancer experience, and it is critical to assist the child and his or her family with rehabilitation into a society that places high value on good health and proper performance. Moreover, late effects after childhood cancer are common. Two of every 3 childhood cancer survivors will develop at least 1 late-onset therapy-related complication;

in 1 of every 4 cases, the complication will be severe or life-threatening.[13] Childhood cancer survivors, therefore, require ongoing comprehensive long-term follow-up care to optimize long-term outcomes by successfully monitoring for and treating the late effects that may occur as a result of previous cancer therapies.

Because health risks associated with cancer are unique to the age at treatment and specific therapeutic modality, follow-up evaluations and health screening should be individualized on the basis of treatment history. To facilitate comprehensive and systematic follow-up of childhood cancer survivors, the Children's Oncology Group (COG) organized exposure-based health screening guidelines. This clinical report presents the pediatrician with guidance in providing high-quality long-term follow-up care and health supervision for survivors of pediatric malignancies by incorporating long-term follow-up guidelines developed by the COG into their practice[14] and by maintaining ongoing interaction with pediatric oncology subspecialists to facilitate communication regarding any changes in follow-up recommendations specific to the childhood cancer survivors under their care.

METHODS: DEVELOPMENT OF LONG-TERM FOLLOW-UP GUIDELINES

The COG is a cooperative clinical trials group supported by the National Cancer Institute with more than 200 member institutions. In January 2002, at the request of the Institute of Medicine, a multidisciplinary panel within the COG initiated the process of developing comprehensive risk-based, exposure-related recommendations for screening and management of late treatment-related complications potentially resulting from therapy for childhood cancers. The resulting comprehensive resource, the COG's *Long-term Follow-up Guidelines for Survivors of Childhood, Adolescent, and Young Adult Cancers* (COG LTFU guidelines),[14] is designed to raise awareness of the risk of late treatment-related sequelae to facilitate early identification and intervention for these complications, standardize follow-up care, improve quality of life, and provide guidance to health care professionals, including pediatricians, who supervise the ongoing care of childhood cancer survivors.

The methodology used in developing these guidelines has been described elsewhere.[15] Briefly, evidence for development of the COG LTFU guidelines was collected by conducting a complete search of the medical literature for the previous 20 years via Medline. After the screening recommendations were developed, a multidisciplinary panel (including experts from pediatric oncology and other pediatric subspecialties, nursing, radiation oncology, behavioral medicine, and patient advocacy) reviewed and revised the guidelines. A panel of experts in the late effects of childhood and adolescent cancer treatment then reviewed and scored the guidelines by using a modified version of the National Comprehensive Cancer Network "Categories of Consensus" system.[16] Each score reflects the strength of data from the literature linking specific late complications with therapeutic exposures, coupled with an assessment of the appropriateness of screening recommendations on the basis of collective clinical experience of the expert panel. The COG LTFU guidelines, therefore, are a hybrid of evidence-based and consensus-driven approaches to guideline development. Task forces within the COG monitor the literature on an ongoing basis and provide recommendations for guideline revision as new information becomes available. These task forces include general pediatricians and other primary care providers to incorporate a primary care perspective and facilitate effective dissemination of these guidelines into the "real-world" setting. Table 1 provides a summary of selected treatment exposures and associated late effects according to organ system as outlined in the COG LTFU guidelines. Fig 1 provides an example of an exposure-based recommendation from the COG LTFU guidelines.

The COG LTFU guidelines are designed for use in asymptomatic survivors presenting for routine health maintenance at least 2 years after completion of therapy.[15] They are not designed for disease-related surveillance, which generally continues under the guidance of the treating oncologist throughout the period when the patient remains at risk of relapse from his or her primary disease. This period of risk varies depending on diagnosis and is generally highest in the first few years, with the risk decreasing significantly as time from diagnosis lengthens.

CLINICAL APPLICATION OF THE COG LTFU GUIDELINES

Malignancies that present in the pediatric age range encompass a spectrum of diverse histologic subtypes that have been managed with heterogeneous and evolving treatment approaches. Over the last 20 years, treatment protocols for localized and biologically favorable presentations of pediatric cancers have been modified substantially to reduce the risk of therapy-related complications. Conversely, therapy has been intensified for many advanced and biologically unfavorable pediatric cancers to optimize disease control and long-term survival. Thus, not all childhood cancer survivors have similar risks of late treatment effects, including those with the same diagnosis. The diversity and potential interplay of factors contributing to cancer-related morbidity are illustrated in the case presentations summarized in Table 2. In general, the risk of late effects is directly proportional to the intensity of therapy required to achieve and maintain disease control. Longer treatment with higher cumulative doses of chemotherapy and radiation, multimodal therapy, and relapse therapy increases the risk of late treatment effects. Specifically, the risk of late effects is related to the type and intensity of cancer therapy (eg, surgery, radiation therapy, chemotherapy, hematopoietic stem cell transplantation) and the patient's age at the time of treatment. Chemotherapy most often results in acute effects, some of which may persist and cause problems as the survivor ages. Many radiation-related effects on growth and development, organ function, and carcinogenesis may not manifest until many years after cancer treatment. The young child is especially at risk of delayed treatment toxicity affecting linear growth, skeletal maturation, intellectual function, sexual develop-

TABLE 1 Potential Late Effects of Selected Therapeutic Interventions for Childhood Cancer According to Organ System

Organ System	Therapeutic Exposures			Potential Late Effect
	Chemotherapy	Radiation Therapy Field	Surgery	
Skin	—	All fields	—	Dysplastic nevi; skin cancer
Ocular	Busulfan; corticosteroids	Cranial; orbital/eye; TBI	Neurosurgery	Cataracts; retinopathy (XRT doses ≥ 30 Gy only); ocular nerve palsy (neurosurgery only)
Auditory	Cisplatin; carboplatin (in myeloablative doses only)	≥30 Gy to: cranial, ear/infratemporal, nasopharyngeal	—	Sensorineural hearing loss; conductive hearing loss (XRT only); Eustachian tube dysfunction (XRT only)
Dental	Any chemotherapy before development of secondary dentition	Head and neck fields that include the oral cavity or salivary glands (eg, cranial, oropharyngeal, mantle, TBI)	—	Dental maldevelopment (tooth/root agenesis, microdontia, enamel dysplasia); periodontal disease; dental caries; osteoradionecrosis (XRT doses ≥ 40 Gy)
Cardiovascular	Anthracycline agents (eg, doxorubicin, daunorubicin)	Chest (eg, mantle, mediastinal); upper abdominal	—	Cardiomyopathy; congestive heart failure; arrhythmia; subclinical left ventricular dysfunction; XRT only: valvular disease, atherosclerotic heart disease, myocardial infarction, and pericarditis, pericardial fibrosis
Pulmonary	Bleomycin; busulfan; carmustine; lomustine	Chest (mantle, mediastinal, whole lung); TBI	Pulmonary resection; lobectomy	Pulmonary fibrosis; interstitial pneumonitis; restrictive/obstructive lung disease; pulmonary dysfunction
Breast	—	Chest (mantle, mediastinal, axillary, whole lung, TBI)	—	Breast tissue hypoplasia; breast cancer (XRT doses ≥ 20 Gy)
Gastrointestinal	—	Abdominal, pelvic (doses ≥ 30 Gy)	Laparotomy; pelvic/spinal surgery	Chronic enterocolitis; gastrointestinal tract strictures; adhesions/obstruction; fecal incontinence; colon cancer (XRT only; doses ≥ 30 Gy)
Liver	Antimetabolites (mercaptopurine, thioguanine, methotrexate)	Abdominal (doses ≥ 30 Gy)	—	Hepatic dysfunction; veno-occlusive disease (VOD); hepatic fibrosis, cirrhosis; cholelithiasis
Renal	Cisplatin; carboplatin; ifosfamide; methotrexate	Abdominal (including kidney)	Nephrectomy	Glomerular toxicity; tubular dysfunction; renal insufficiency; hypertension
Bladder	Cyclophosphamide; ifosfamide	Pelvic (including bladder); lumbar-sacral spine	Spinal surgery; cystectomy	Hemorrhagic cystitis; bladder fibrosis; dysfunctional voiding; neurogenic bladder; bladder malignancy (cyclophosphamide, XRT)
Sexual/reproductive				
Males	Alkylating agents (eg, busulfan, carmustine, lomustine, cyclophosphamide, mechlorethamine, melphalan, procarbazine)	Hypothalamic-pituitary; testicular; pelvic; TBI	Pelvic/spinal surgery; orchiectomy	Delayed/arrested puberty; hypogonadism; infertility; erectile/ejaculatory dysfunction
Females	Alkylating agents (eg, busulfan, carmustine, lomustine, cyclophosphamide, mechlorethamine, melphalan, procarbazine)	Hypothalamic-pituitary; pelvic; ovarian; lumbar-sacral spine; TBI	Oophorectomy	Delayed/arrested puberty; premature menopause; infertility; uterine vascular insufficiency (XRT only); vaginal fibrosis/stenosis (XRT only)

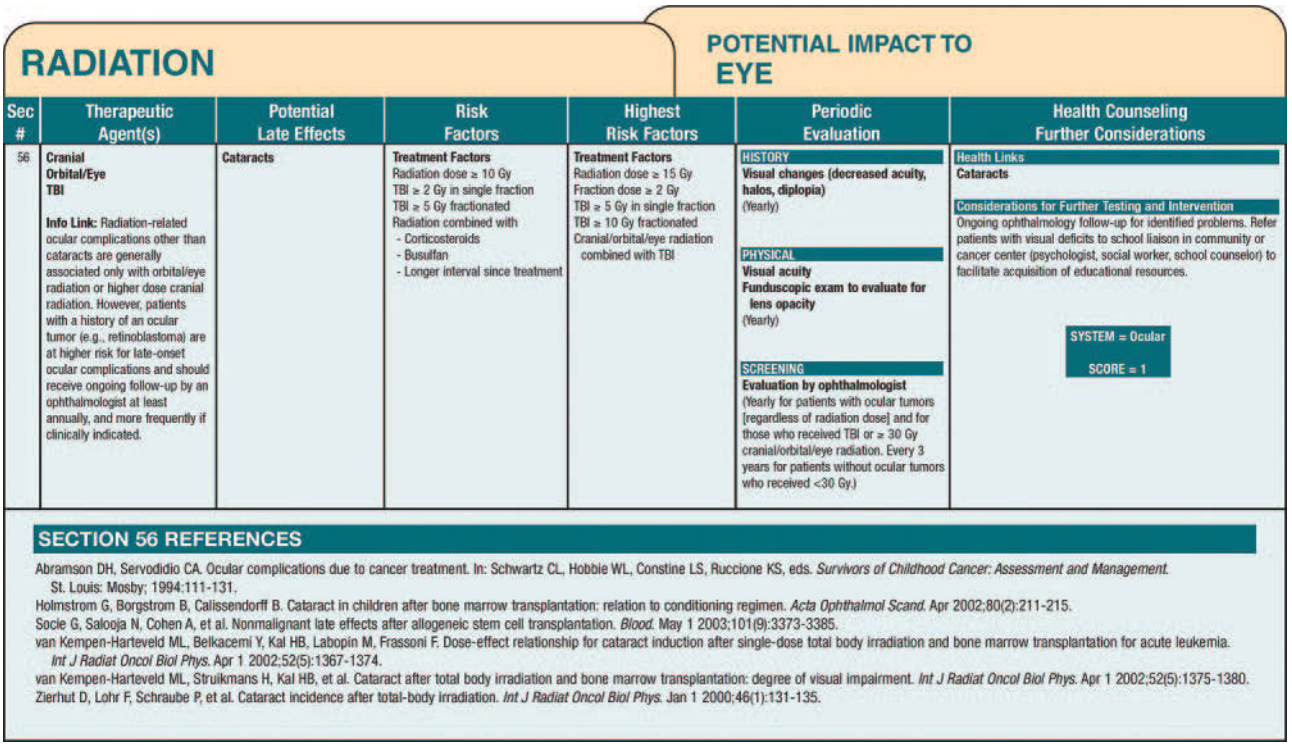
TABLE 1 Continued

Organ System	Therapeutic Exposures			Potential Late Effect
	Chemotherapy	Radiation Therapy Field	Surgery	
Endocrine/metabolic	—	Hypothalamic-pituitary; neck (thyroid)	Thyroidectomy	Growth hormone deficiency; precocious puberty; hypothyroidism; thyroid nodules/cancer; XRT doses ≥ 40 Gy: hyperprolactinemia, central adrenal insufficiency, gonadotropin deficiency, and hyperthyroidism
Musculoskeletal	Corticosteroids; methotrexate	—	—	Osteopenia/osteoporosis; osteonecrosis
	—	All fields	—	Reduced/uneven growth; reduced function/mobility; hypoplasia, fibrosis; radiation-induced fracture (doses ≥ 40 Gy); scoliosis/kyphosis (trunk fields only); secondary benign or malignant neoplasm
	—	—	Amputation; limb sparing	Reduced/uneven growth; reduced function/mobility
Neurocognitive	Methotrexate (intrathecal administration or IV doses ≥ 1000 mg/m^2); cytarabine (IV doses ≥ 1000 mg/m^2)	Cranial; ear/infratemporal; total body irradiation	Neurosurgery	Neurocognitive deficits (executive function, attention, memory, processing speed, visual motor integration); learning deficits; diminished IQ
Central nervous system	Methotrexate, cytarabine (intrathecal administration or IV doses ≥ 1000 mg/m^2)	Doses ≥ 18 Gy to: cranial, orbital/eye, ear/infratemporal, nasopharyngeal	Neurosurgery	Leukoencephalopathy (spasticity, ataxia, dysarthria, dysphagia, hemiparesis, seizures [chemotherapy and XRT]); motor and sensory deficits; cerebrovascular complications (stroke, Moya Moya, occlusive cerebral; vasculopathy [XRT and surgery]) Brain tumor (any XRT dose)
Peripheral nervous system	Plant alkaloids (vincristine, vinblastine); cisplatin, carboplatin	—	Spinal surgery	Peripheral sensory or motor neuropathy
Immunologic		Abdomen, left upper quadrant, spleen (doses ≥ 40 Gy)	Splenectomy	Life-threatening infection related to functional or anatomic asplenia (note: functional asplenia can also occur as a consequence of active chronic graft-vs-host disease after hematopoietic stem cell transplant)
Psychosocial	Any	Any	Any	Social withdrawal; educational problems; depression; anxiety; posttraumatic stress

This table briefly summarizes potential late effects for selected therapeutic exposures only; the complete set of long-term follow-up guidelines from the Children's Oncology Group, including screening recommendations, is available at www.survivorshipguidelines.org. XRT indicates radiation therapy; TBI, total body irradiation; IV, intravenous.

ment, and organ function. Because pediatricians provide care across a continuum of developmental periods, they must also recognize that childhood cancer survivors face unique vulnerabilities related to their age at diagnosis and treatment.

Risk-based care involving a systematic plan for lifelong screening, surveillance, and prevention that incorporates risks on the basis of previous cancer, cancer therapy, genetic predispositions, lifestyle behaviors, and comorbid health conditions is recommended for all survivors.[10,17] Information critical to the coordination of risk-based care includes the date of cancer diagnosis, cancer histology, organs/tissues affected by cancer, and specific treatment modalities such as surgical procedures, chemotherapeutic agents and radiation treatment fields and doses, and history of bone marrow or stem cell transplant and blood-product transfusion. Knowledge of cumulative chemotherapy dosages (eg, for anthracycline agents), or dose intensity of administration (eg, for methotrexate), also is important in estimating risk and screening frequency. This pertinent clinical information can be organized into a treatment summary that interfaces with the COG LTFU guidelines to



RADIATION

POTENTIAL IMPACT TO EYE

Sec #	Therapeutic Agent(s)	Potential Late Effects	Risk Factors	Highest Risk Factors	Periodic Evaluation	Health Counseling Further Considerations
56	**Cranial** **Orbital/Eye** **TBI** **Info Link:** Radiation-related ocular complications other than cataracts are generally associated only with orbital/eye radiation or higher dose cranial radiation. However, patients with a history of an ocular tumor (e.g., retinoblastoma) are at higher risk for late-onset ocular complications and should receive ongoing follow-up by an ophthalmologist at least annually, and more frequently if clinically indicated.	**Cataracts**	**Treatment Factors** Radiation dose ≥ 10 Gy TBI ≥ 2 Gy in single fraction TBI ≥ 5 Gy fractionated Radiation combined with - Corticosteroids - Busulfan - Longer interval since treatment	**Treatment Factors** Radiation dose ≥ 15 Gy Fraction dose ≥ 2 Gy TBI ≥ 5 Gy in single fraction TBI ≥ 10 Gy fractionated Cranial/orbital/eye radiation combined with TBI	**HISTORY** **Visual changes (decreased acuity, halos, diplopia)** (Yearly) **PHYSICAL** **Visual acuity** **Funduscopic exam to evaluate for lens opacity** (Yearly) **SCREENING** **Evaluation by ophthalmologist** (Yearly for patients with ocular tumors [regardless of radiation dose] and for those who received TBI or ≥ 30 Gy cranial/orbital/eye radiation. Every 3 years for patients without ocular tumors who received <30 Gy.)	**Health Links** **Cataracts** **Considerations for Further Testing and Intervention** Ongoing ophthalmology follow-up for identified problems. Example of an exposure-based recommendation from the COG LTFU guidelines. (Reproduced with permission from the Children's Oncology Group. *Long-term Follow-up Guidelines for Survivors of Childhood, Adolescent, and Young Adult Cancers*. Version 3.0. Arcadia, CA: Children's Oncology Group; 2008:73.)

facilitate identification of potential late complications and recommended follow-up care (Fig 2). Because of the diversity and complexity of pediatric cancer therapies, the treating pediatric oncology center represents the optimal resource for this treatment information. Furthermore, the need for ongoing, open lines of communication between the pediatric cancer center and the primary care provider is critical.

TABLE 2 Examples of 2 Survivors: Factors Contributing to Cancer-Related Morbidity

Factor	Example 1: Leukemia	Example 2: Solid Tumor
Host	3-y-old white male	16-y-old black female
Tumor	Acute lymphoblastic leukemia, B lineage, average risk, without CNS involvement	Embryonal rhabdomyosarcoma of the chest wall, stage II
Treatment	Vincristine; corticosteroids; antimetabolites (PO, IV, intrathecal); asparaginase; cyclophosphamide (moderate dose); doxorubicin (low dose)	Vincristine; dactinomycin; chest radiation (36 Gy)
Potential late effects	Peripheral neuropathy; osteopenia/osteoporosis; osteonecrosis; cataracts; hepatic dysfunction; renal insufficiency; neurocognitive deficits; leukoencephalopathy; hemorrhagic cystitis, bladder malignancy; secondary myelodysplasia or myeloid leukemia; gonadal dysfunction; cardiomyopathy, congestive heart failure, arrhythmia; dental maldevelopment, periodontal disease, excessive dental caries	Peripheral neuropathy; cardiac complications (cardiomyopathy, congestive heart failure, arrhythmia, subclinical left ventricular dysfunction, valvular disease, atherosclerotic heart disease, myocardial infarction, pericarditis, pericardial fibrosis); pulmonary complications (fibrosis, interstitial pneumonitis, restrictive/obstructive lung disease); esophageal stricture; breast tissue hypoplasia; breast cancer; scoliosis/kyphosis; shortened trunk height; secondary benign or malignant neoplasms in radiation field
Genetics/familial	Diabetes mellitus, type 2	Hypertension; early coronary artery disease
Comorbid conditions	Obesity	Hypertension
Health behaviors	Sedentary lifestyle	Smoker
Aging	Bone mineral density (osteoporosis)	Cardiomyopathy

CNS indicates central nervous system; PO, oral; IV, intravenous.

Arcadia, CA: Children's Oncology Group; 2008:Appendix 1.)

Coordination of risk-based care for childhood cancer survivors requires a working knowledge about cancer-related health risks and appropriate screening evaluations or access to a resource that contains this information. Individualized recommendations for long-term follow-up care of childhood cancer survivors can be customized from the COG LTFU guidelines on the basis of each patient's treatment history, age, and gender into a "survivorship care plan" that is ideally developed by, or in coordination with, the pediatric oncology subspecialist. In addition, the COG LTFU guidelines provide information to assist with risk stratification, allowing the health care provider to address specific treatment-related health risks that may be magnified in individual patients because of familial or genetic predisposition, sociodemographic factors, or maladaptive health behaviors. The patient education materials (known as "health links") that accompany the COG LTFU guidelines are specifically tailored to enhance health supervision and promotion in this population by providing simplified explanations of guideline-specific topics in lay language.[18] The COG LTFU guidelines, associated patient education materials, and supplemental resources to enhance guideline application, including clinical summary templates, can be downloaded from www.survivorshipguidelines.org. A Web-based platform that will allow online generation of therapeutic summaries with simultaneous output of patient-specific guidelines on the basis of exposure history, age, and gender is currently under development.[19]

DISCUSSION/RECOMMENDATIONS

Pediatricians are uniquely qualified to deliver ongoing health care to childhood cancer survivors, because they are already familiar with health maintenance and supervision for healthy children and adolescents and also provide care for patients with complex chronic medical conditions. The concept of the "medical home" has been endorsed by the American Academy of Pediatrics as an effective model for coordinating the complex health care requirements of children with special needs, such as childhood cancer survivors, to provide care and preventive services that are accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective.[20,21] Within this framework, the pediatrician is able to view the cancer survivor in the context of the family and to assist not only the survivor but also the parents and siblings in adapting to the "new normal" of cancer survivorship. The focus of care for the childhood cancer survivor seen in the general pediatric practice is not the cancer from which the patient has now recovered but, rather, the actual and potential sequelae of cancer and its therapy. Childhood cancer survivors are at a substantially increased risk of morbidity and mortality when compared with the general population.[5–12] Their follow-up evaluations should be individualized on the basis of their treatment history and may include screening for such potential complications as thyroid or cardiac dysfunction, second malignant neoplasms, neurocognitive difficulties, and many others.[13] The COG LTFU guidelines should be used to guide development of individualized follow-up plans for each patient on the basis of his or her particular risk of late complications, which should be developed through a shared partnership that includes the general pediatric and pediatric oncology subspecialty providers, the child, and the family. The COG LTFU guidelines can assist the clinician in maintaining a balance between overscreening (which could potentially cause undue fear of unlikely but remotely plausible complications as well as higher medical costs resulting from unnecessary screening) and underscreening (which could miss potentially life-threatening complications, thus resulting in lost opportunities for early intervention that could minimize morbidity). Ultimately, as with all clinical practice guidelines, decisions regarding specific screening and ongoing clinical management for individual patients should be tailored to take all relevant factors (such as therapeutic exposures, medical and psychosocial history, and comorbidities) into consideration.

The pediatrician must also be aware that the childhood cancer experience is unique in that some survivors, given their young age at diagnosis, may not remember their cancer diagnosis or the treatment that they received. For others, parents may not have told the child about his or her cancer history. Therefore, it is not surprising that when childhood cancer survivors have been questioned regarding knowledge of their diagnosis and treatment, important deficits have been identified.[22] The pediatrician may need to request a cancer treatment summary and "survivorship care plan" from the pediatric oncology center if one is not provided at the time that the child transitions back to the primary care setting. Many pediatric oncology centers offer ongoing multidisciplinary follow-up care for childhood cancer survivors on an annual, 1-time, or as-needed basis. Some follow-up clinics are comprehensive and offer ongoing care and risk-based screening for childhood cancer survivors, and other follow-up clinics are consultative in nature and develop risk-based recommendations for ongoing follow-up (included in survivorship care plans) that can be conducted in the primary care setting. In any case, the components of a survivorship care plan should include recommendations for late-effects screening generated from the COG LTFU guidelines on the basis of therapeutic exposures, identification of the provider(s) who will be coordinating the indicated screening evaluations, and identification of the provider(s) responsible for communicating and explaining the results to the patient and/or caregivers.

In addition to screening for late effects on the basis of previous therapeutic exposures, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care in this population. Oeffinger and colleagues[13] have shown that survivors of childhood cancer have a high rate of chronic health conditions when followed long-term. For this reason, it is essential for the pediatrician to provide anticipatory guidance regarding health promotion and disease prevention aimed at minimizing the risk of future morbidity and mortality. For example, survivors who are at risk of obesity, cardiovascular disease, and osteoporosis should be counseled re-

garding the importance of eating a well-balanced diet (high in calcium, low in fat) and participating in regular exercise. The COG LTFU guidelines can be used to facilitate targeted education regarding health promotion. In addition to the verbal counseling completed in the office setting, survivors should also receive written and/or Web-based educational material that can be used to further reinforce their knowledge about their risks for specific late effects. These written and Web-based health education materials are called health links and are available with the COG LTFU guidelines at www.survivorshipguidelines.org. They can be printed for distribution in the primary care office setting and are available for viewing by patients and their caregivers on the Internet.[18]

Again, it must be emphasized that the pediatrician is not alone in caring for the childhood cancer survivor. There are numerous multidisciplinary long-term follow-up programs for childhood cancer survivors, and most of these programs will work collaboratively with pediatricians to assist with the development of individualized survivorship care plans. Depending on geographic location, insurance coverage, and other considerations, some patients may return to the primary oncology center for annual or periodic visits, and their long-term follow-up care may be partially or entirely accomplished through these specialized centers, with the pediatrician providing the primary pediatric health care for those patients. However, for many survivors, long distances or other barriers may make specialized long-term follow-up impractical, and the pediatrician is often called on to provide both long-term follow-up and primary care for childhood cancer survivors in the community setting. Telephone consultation with the primary oncology team or associated long-term follow-up center is generally available to facilitate this ongoing care. For survivors who are identified as having chronic health problems as a result of their previous cancer therapy, the pediatrician can also work with the primary oncology center to obtain assistance with referrals to subspecialists knowledgeable in issues related to childhood cancer survivorship. In addition, a listing of COG-affiliated subspecialty survivorship clinics is available (www.childrensoncologygroup.org). These clinics are also excellent venues for pediatric residents to learn about the unique health care needs of childhood cancer survivors and of the long-term therapy-related risks that they continue to face across their life span; however, there are currently no formal mechanisms for including cancer survivorship in the training of medical students or pediatric residents.
