Steering Committee on Quality Improvement and Management

Classifying Recommendations for Clinical Practice Guidelines

ABSTRACT. Clinical practice guidelines are intended to improve the quality of clinical care by reducing inappropriate variations, producing optimal outcomes for patients, minimizing harm, and promoting cost-effective practices. This statement proposes an explicit classification of recommendations for clinical practice guidelines of the American Academy of Pediatrics (AAP) to promote communication among guideline developers, implementers, and other users of guideline knowledge, to improve consistency, and to facilitate user understanding. The statement describes 3 sequential activities in developing evidence-based clinical practice guidelines and related policies: 1) determination of the aggregate evidence quality in support of a proposed recommendation; 2) evaluation of the anticipated balance between benefits and harms when the recommendation is carried out; and 3) designation of recommendation strength. An individual policy can be reported as a "strong recommendation," "recommendation," "option," or "no recommendation." Use of this classification is intended to improve consistency and increase the transparency of the guideline-development process, facilitate understanding of AAP clinical practice guidelines, and enhance both the utility and credibility of AAP clinical practice guidelines. ***Pediatrics*** **2004;114:874–877;** ***practice guidelines, evidence-based, recommendation, classification system.***

ABBREVIATION. AAP, American Academy of Pediatrics.

INTRODUCTION

Clinical practice guidelines are intended to reduce inappropriate variations in clinical care, minimize harm, promote cost-effective practice, and produce optimal health outcomes for patients. Evidence-based guidelines use a systematic process to select and review scientific evidence to develop policy. In a clinical practice guideline, policy is stated in terms of recommendations. Recommendations are the guideline components that are intended to influence practitioner and patient behavior.

The contemporary, evidence-based approach to guideline development differs from other methods of creating policy in several ways, including:

1. The high level of rigor with which the evidence in support of a policy is identified, appraised, and summarized, and
2. The explicit linkage between recommendations and the evidence that supports them.

Like all scientists, evidence-based guideline developers define their methods first and then allow their methods to lead to the results rather than deciding first on the outcome.

A variety of systems have been used to convey information to guideline readers regarding the quality of evidence that supports a given recommendation and the strength assigned to the recommendation by guideline developers. A large number of numeric and alphabetic codes contribute to general confusion about the meaning of these scales. A recent evidence report prepared by the Agency for Healthcare Research and Quality found 121 scales, checklists, or other types of instruments for rating evidence quality.[1]

The American Academy of Pediatrics (AAP) develops clinical practice guidelines internally through various entities and in collaboration with other organizations and also considers for endorsement guidelines developed by external organizations. Clearly, the method used to classify recommendations in clinical practice guidelines should be consistent and explicit. A unified approach will facilitate communication between guideline developers and users and promote appropriate interpretation and application of guidelines by clinicians.

The objective of this statement is to describe a system for defining recommendation strength for AAP evidence-based practice guidelines that is clear, informative, and helpful to users. A common current approach to indicate the strength of a recommendation is to append a term to describe the "level of consensus" or, in some instances, fervor achieved. Because this judgment may not reflect unanimity of the development team and can be influenced disproportionately by vociferous or persuasive team members, it represents a lapse in an otherwise explicit system to link guideline statements to the strength of evidence and recommendation.

The proposed system was derived from existing systems that support the principle of using explicit criteria for guideline development. This system is intended for use by the AAP in the process of developing evidence-based clinical practice guidelines. This statement describes 3 sequential processes in evidence-based policy setting: 1) determination of evidence quality in support of a proposed recom-

DOI: 10.1542/peds.2004-1260
PEDIATRICS (ISSN 0031 4005).

mendation; 2) evaluation of the balance between anticipated benefits and harms when the recommendation is carried out; and 3) designation of recommendation strength.

CLASSIFICATION PROCEDURE

1. Assess Evidence Quality: Individual and Aggregate

Quality appraisal of individual studies examines both the type of study and the rigor of the investigator's adherence to methodologic principles. Evidence quality refers to "the extent to which all aspects of a study's design and conduct can be shown to protect against systematic bias, nonsystematic bias, and inferential error."[2] Systematic errors include selection bias and confounding, in which values tend to be inaccurate in a particular direction. Nonsystematic errors are attributable to chance. Inferential errors result from problems in data analysis and interpretation, such as choice of the wrong statistical measure or wrongly rejecting the null hypothesis.

Highest-quality evidence for therapeutic interventions comes from well-designed and well-conducted randomized, controlled trials performed on a population similar to the guideline's target population. The lowest-quality evidence is derived from case reports, reasoning from first principles of pathophysiology, and expert opinion based on ill-defined "clinical experience." Intermediate-quality evidence is associated with a randomized, controlled trial with "nonfatal flaws" or methodologic limitations (for example, one performed on a group from a population different from the target population, therefore requiring that findings be extrapolated) or with an observational design such as a case-control or cohort study. For studies of diagnostic tests, the representativeness of the population studied, the adequacy of the description of the test, the appropriateness of the reference standard against which the test is compared, and the methods used to avoid bias in interpretation of results (such as blinded comparison with the reference standard) are criteria for judging quality.[3]

After systematically reviewing the literature for studies that bear on a policy decision, evidence-based guideline developers must carefully review each study, extract the findings, and appraise both the quality of the study design and its execution. The specific quality criteria applied depend on the design and type of study. For example, appraisal of controlled trials requires consideration of the adequacy of randomization and blinding and loss to follow-up; assessing case-control studies requires consideration of the appropriateness of matching cases and controls.

Next, guideline developers must consider the quality of the aggregate of studies that bear on the issue. Judging the strength of a body of evidence requires careful consideration of the consistency of the results of individual studies, the magnitude of the effect that the studies detect, and the individual and aggregate sample sizes of these studies.[1]

2. Assess Anticipated Balance Between Benefits and Harms

The anticipated benefit, harm, risk, and cost of adherence to a guideline recommendation constitute the second factor that influences the strength of a recommendation. Guyatt et al[4] suggest looking at the clarity of the balance between benefits and harms. When the evidence indicates a clear benefit not offset by important harms or costs or a clear harm not mitigated by important benefit, stronger recommendations are possible. On the other hand, when the magnitude of the benefit is small or benefits are present but offset by important adverse consequences, the equilibrium between benefits and harms prevents a strong recommendation. A clear preponderance of benefit or harm supports stronger statements for or against a course of action. When the benefit-harm assessment is balanced, no matter how good the studies, practitioners should be offered options rather than recommendations. Such cases mirror the situation described by Bass,[5] in which "there is adequate evidence at hand to support those who wish to treat...yet the evidence is not so overwhelming as to suggest that those who do not choose to use this form of therapy are in error."

3. Assign Recommendation Strength

Recommendation strength communicates the guideline developers' (and the sponsoring organizations') assessment of the importance of adherence to a particular recommendation and is based on both the quality of the supporting evidence and the magnitude of the potential benefit or harm. The proposed classification defines 4 levels of policy (strong recommendation, recommendation, option, and no recommendation) based on:

- Four levels of aggregate evidence quality: A, B, C, and D (see Fig 1);
- Two benefit-harm assessments: clear (ie, substantial) preponderance of benefit or harm versus a relative balance of benefits and harms; and
- A category for recommendation under exceptional situations in which evidence cannot be obtained but clear benefits or harm are evident.

Because guideline recommendations are prescriptive or proscriptive (constraining variation in practice), guideline developers must follow an approach that has a high likelihood of doing more good than harm. The more restrictive the guidance (strong recommendation), the more certain the guideline developers and endorsers must be of its correctness. The AAP believes that its policy makers should be cautious about classifying a recommendation as strong, lest they jeopardize their credibility by making statements that do not stand up to scientific scrutiny. Most recommendations are likely to be just that: recommendations.

When the evidence is of low quality and the benefit-harm equilibrium is balanced, guideline developers generally should not constrain the clinician's discretion by making a recommendation but instead should designate acceptable alternatives as options.

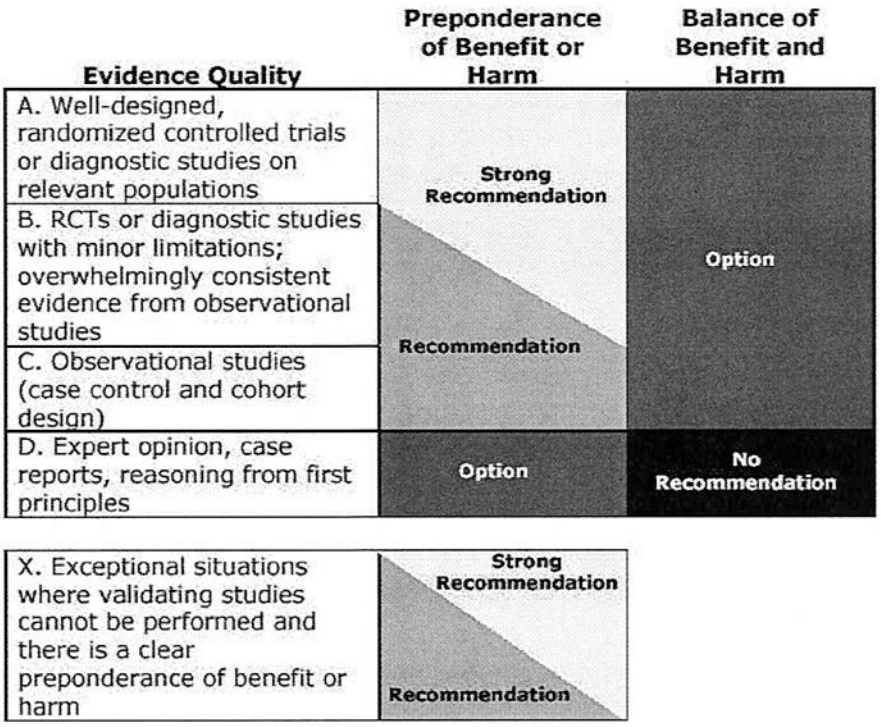

Fig 1. Integrating evidence quality appraisal with an assessment of the anticipated balance between benefits and harms if a policy is carried out leads to designation of a policy as a strong recommendation, recommendation, option, or no recommendation.

Although options do not direct clinicians' actions toward one activity or another, they may place boundaries by delineating appropriate alternative practices.

When the evidence is scant and the balance of benefit and harm is unknown, as for example with some complementary and alternative medicine practices, no recommendation regarding therapy may be possible. Stating that no recommendation is possible provides information but little direction to the clinician. No-recommendation statements are therefore of limited utility and should be discouraged. In some cases, guideline developers still may be able to make policy or offer options based on evidence. For example, although there may be no evidence of effectiveness of a complementary and alternative medicine practice, developers may be able to recommend that clinicians should inquire about use of complementary and alternative medicine and counsel about potential interactions. In other circumstances, guideline developers might suggest individualization on the basis of risk and values.

In some cases, a recommendation or strong recommendation may be made when analysis of the balance of benefits and harms demonstrates an exceptional preponderance of benefit or harm and it would be unethical to perform clinical trials to "prove" the point. These are almost exclusively situations of a medical (not social or political) nature. For example, the anticipated benefit of a recommendation for prescribing anthrax prophylaxis to exposed patients clearly outweighs the expected harms and calls for a strong recommendation, although studies do not exist to support the practice. Such situations with poor evidence but a highly unbalanced benefit-harm equation must be unmistakably differentiated from other circumstances in which high-quality evidence supports strong recommendations. Requiring the authors to explicitly state the benefit-harm proposition opens it up for constructive debate.

INTERPRETING GUIDELINE RECOMMENDATIONS

How should a clinician interpret recommendations from the AAP in light of the proposed criteria for guideline recommendations? Guidelines are never intended to overrule professional judgment; rather, they may be viewed as a relative constraint on individual clinician discretion in a particular clinical circumstance. Less frequent variation in practice is expected for a strong recommendation than might be expected with a recommendation. Options offer the most opportunity for practice variability.[6] Clinicians should always act and make decisions on behalf of their patients' best interests and needs regardless of guideline recommendations. Guidelines represent the best judgment of a team of experienced clinicians and methodologists addressing the scientific evidence for a particular clinical topic.

A strong recommendation means that the committee believes that the benefits of the recommended approach clearly exceed the harms of that approach (or, in the case of a strong negative recommendation, that the harms clearly exceed the benefits) and that the quality of the evidence supporting this approach is either excellent or impossible to obtain. Clinicians should follow such guidance unless a clear and compelling rationale for acting in a contrary manner is present.

A recommendation means that the committee believes that the benefits exceed the harms (or, in the case of a negative recommendation, that the harms exceed the benefits), but the quality of the evidence on which this recommendation is based is not as

strong. Clinicians also generally should follow such guidance but also should be alert to new information and sensitive to patient preferences.

An option means either that the evidence quality that exists is suspect or that well-designed, well-conducted studies have demonstrated little clear advantage to one approach versus another. Options offer clinicians flexibility in their decision-making regarding appropriate practice, although they may set boundaries on alternatives. Patient preference should have a substantial role in influencing clinical decision-making, particularly when policies are expressed as options.

No recommendation is made when there is both a lack of pertinent evidence and an unclear balance between benefits and harms. Clinicians should feel little constraint in their decision-making when addressing areas with insufficient evidence. Patient preference should have a substantial role in influencing clinical decision-making.

The AAP believes that adoption of an explicit, consistent classification of recommendations will facilitate communication between the AAP entities that develop guidelines (committees, sections, and task forces and the board of directors) and pediatricians who apply them to clinical practice. We recognize that any classification system may be considered by payors in making reimbursement decisions. This classification is intended only to increase transparency and to enhance the utility and credibility of AAP clinical practice guidelines. Direct linkage of this classification to reimbursement decisions would be overly simplistic, because recommendation strength is one of many factors that should be considered in developing reimbursement policy. Experience and new knowledge will likely require periodic revision of the proposed classification system.

FREE

Results of new research indicate that, contrary to previous thinking, youth do not have less effective thermoregulatory ability, insufficient cardiovascular capacity, or lower physical exertion tolerance compared with adults during exercise in the heat when adequate hydration is maintained. Accordingly, besides poor hydration status, the primary determinants of reduced performance and exertional heat-illness risk in youth during sports and other physical activities in a hot environment include undue physical exertion, insufficient recovery between repeated exercise bouts or closely scheduled same-day training sessions or rounds of sports competition, and inappropriately wearing clothing, uniforms, and protective equipment that play a role in excessive heat retention. Because these known contributing risk factors are modifiable, exertional heat illness is usually preventable. With appropriate preparation, modifications, and monitoring, most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. *Pediatrics* 2011;128:e741–e747

INTRODUCTION

The American Academy of Pediatrics recognizes that appropriate and sufficient regular physical activity plays a significant part in enhancing and maintaining health.[1–7] However, special consideration, preparation, modifications, and monitoring are essential when children and adolescents are engaging in sports or other vigorous physical activities in warm to hot weather. Exertional heat illness, including heat exhaustion and heat stroke, might occur even in a temperate environment, but the risk is highest when children and adolescents are vigorously active outdoors in hot and humid conditions. Severe exertional heat injury or heat stroke is associated with significant morbidity and mortality, especially if diagnosis is delayed and appropriate medical management is not initiated promptly. The Appendix contains definitions of the heat-illness–related terms used in this statement.

Researchers have previously suggested that children are less effective in regulating body temperature, incur greater cardiovascular strain, and have lower exercise tolerance during exercise in the heat compared with adults.[8–13] However, more recent studies, in which both groups were exposed to *equal* relative intensity exercise workloads and environmental conditions while minimizing dehydration, have compared 9- to 12-year-old boys and girls to *similarly* fit and heat-acclimatized adults. These newer findings indicate that children and adults have similar rectal and skin temperatures, cardiovascular re-

sponses, and exercise-tolerance time during exercise in the heat.[14–17] Accordingly, modifiable evidence-based determinants of exertional heat-illness risk in youth should be the focus of prevention measures.

Current or recent illness increases the challenge of participating in physical activity safely in the heat because of the potential negative residual effects on hydration status and regulation of body temperature. This is especially true for illnesses that involve gastrointestinal distress (eg, vomiting, diarrhea) and/or fever. Notable chronic clinical conditions and medications that contribute to decreased exercise-heat tolerance and increased exertional heat-illness risk include diabetes insipidus,[18] type 2 diabetes mellitus,[19] obesity,[20,21] juvenile hyperthyroidism (Graves disease),[22] cystic fibrosis,[23] and anticholinergic drugs or certain other medications that affect hydration or thermoregulation (eg, a dopamine-reuptake inhibitor to treat attention-deficit/hyperactivity disorder or enhance performance[24] or diuretics). Any other chronic or acute medical condition[25] or injury[26] that adversely affects water-electrolyte balance, thermoregulation, and exercise-heat tolerance warrants particular concern as well. Sickle cell trait should also be considered a possible contributing clinical risk/complicating factor for vascular dysfunction, exertional rhabdomyolysis, and collapse related to red blood cell sickling in youth during strenuous physical activity in the heat.[27–29] A previous episode of heat stroke, however, generally does not seem to have long-term negative effects on thermoregulation, exercise-heat tolerance, or exertional heat-illness risk, especially for those who received prompt cooling therapy.[30]

POLICY AND RECOMMENDATIONS

Most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. With appropriate preparation, modifications, and monitoring, exertional heat illness is usually preventable. Table 1 summarizes key heat-illness risk factors during sports and other physical activity and recommended responses (actions) for reducing physiologic strain and improving safety and activity tolerance. As heat and humidity increase and as additional other exertional heat-illness risk factors such as those listed in Table 1 are present, the

TABLE 1 Key Exertional Heat-Illness Risk Factors During Exercise, Sports, and Other Physical Activities and Recommended Responses (Actions) for Reducing Physiologic Strain and Improving Activity Tolerance and Safety

Risk factors
Hot and/or humid weather
Poor preparation
Not heat-acclimatized
Inadequate prehydration
Little sleep/rest
Poor fitness
Excessive physical exertion
Insufficient rest/recovery time between repeat bouts of high-intensity exercise (eg, repeat sprints)
Insufficient access to fluids and opportunities to rehydrate
Multiple same-day sessions
Insufficient rest/recovery time between practices, games, or matches
Overweight/obese (BMI ≥ 85th percentile for age) and other clinical conditions (eg, diabetes) or medications (eg, attention-deficit/hyperactivity disorder medications)
Current or recent illness (especially if it involves/involved gastrointestinal distress or fever)
Clothing, uniforms, or protective equipment that contribute to excessive heat retention
Actions[a]
Provide and promote consumption of readily accessible fluids at regular intervals before, during, and after activity
Allow gradual introduction and adaptation to the climate, intensity, and duration of activities and uniform/protective gear
Physical activity should be modified
Decrease duration and/or intensity
Increase frequency and duration of breaks (preferably in the shade)
Cancel or reschedule to cooler time
Provide longer rest/recovery time between same-day sessions, games, or matches
Avoid/limit participation if child or adolescent is currently or was recently ill
Closely monitor participants for signs and symptoms of developing heat illness
Ensure that personnel and facilities for effectively treating heat illness are readily available on site
In response to an affected (moderate or severe heat stress) child or adolescent, promptly activate emergency medical services and rapidly cool the victim

With any of these risk factors or other medical conditions[25] adversely affecting exercise-heat safety present, some or all of the actions listed may be appropriate responses to reduce exertional heat-illness risk and improve well-being.

[a] As environmental conditions become more challenging (heat and humidity increase) and as additional other listed risk factors are present, the possible actions to improve safety become more urgent. Note that each listed action does not necessarily correspond or apply to any particular or every listed risk factor.

actions for improving safety become more urgent. Likewise, as the number of risk factors for exertional heat illness increases, the maximum environmental heat and humidity level for safe exercise, sports participation, or other physical activities will decrease.

Operationally, pediatricians, coaches, and administrators need to make appropriate recommendations and "on-the-field" decisions to improve safety and minimize exertional heat-illness risk for a team or event as a whole. However, given individual variations in health status, conditioning, or other circumstances, some participants might not require the same heightened concern as other young athletes who might need implementation of additional exertional heat-illness prevention measures and closer monitoring in the same or a less challenging environment. For instance, even with a heat index of 95°F (35°C), a very fit, well-hydrated, rested, healthy 12-year-old who is acclimatized to the hot and humid conditions can likely safely compete in a soccer game without significant risk to his or her well-being or safety. On the other hand, with a heat index of only 85°F (29.4°C), an overweight high school football player who recently recovered from diarrhea and is running wind sprints at the end of the second 3-hour workout on an unusually warm first day of preseason football is much more likely to be at risk of overheating and exertional collapse. These examples also underscore the infinite number of scenarios that can alter individual exertional heat-illness risk. Therefore, it is extremely difficult to impose appropriate universal measures for maintaining optimal safety for all children and adolescents while sensibly allowing sports participation and other physical activities to continue. Although Table 1 can be used to help guide the decision-making process in taking appropriate prevention measures, considerably more research is needed to examine core body-temperature responses and exertional heat-illness risk with children and adolescents in different environmental conditions during various practice,[31] competition,[32] and other physical activity scenarios.[33] With such empirical information, appropriate sport- and activity-specific "heat safety grids" and field evidence-based prevention, participation, and cancellation guidelines can be developed.

Community pediatricians can be instrumental in improving heat safety for children and adolescents engaged in youth sports and other physical activities by actively participating as school team physicians or on school wellness committees or health councils; on school boards; on local, regional, or national sport or sports medicine advisory committees; or in local parks and recreation programs to educate youth and parents and to guide coaches and administrators in developing and implementing effective exertional heat-illness prevention and management strategies. However, field evidence is not currently sufficient to optimally guide pediatricians, coaches, administrators, and youth sport governing bodies in making the most appropriate and advantageous modifications to play and practice specific to heat safety or deciding when to cancel activities altogether if necessary. Accordingly, parents, teachers, coaches, athletic trainers, and pediatricians as well as youth sports governing bodies and administrators should always emphasize and use suitable prevention strategies, to the best of their ability, to improve safety and appropriately minimize the risk of exertional heat illness for all children and adolescents during exercise, sports participation, and other physical activities in warm to hot weather. To this end, the American Academy of Pediatrics recommends the following.

1. Community and team/school physicians as well as athletic directors, community parks and recreation programs, and youth sport governing bodies should emphasize comprehensive awareness, education, and implementation of effective exertional heat-illness risk-reduction strategies to coaches and their staff, athletic trainers, teachers, administrators, and others who oversee or assist with exercising children and adolescents and youth sports, especially for those involved with youth and preseason high school American football.
2. Trained personnel and facilities capable of effectively treating all forms of heat illness, especially exertional heat stroke by rapidly lowering core body temperature, should be readily available on site during all youth athletic activities and community programs that involve vigorous physical activity and are held in the heat.
3. Children and adolescents should be regularly educated on the merits of proper preparation, ample hydration, honest reporting, and effectively managing other factors under their control, such as recovery and rest, which will directly affect exercise-heat tolerance and safety.
4. Each child and adolescent should be given the opportunity to gradually and safely adapt to preseason practice and conditioning, sport participation, or other physical activity in the heat by appropriate and progressive acclimatization. This process includes graduated exposure (typically over a 10- to 14-day period) to the environment, intensity, duration, and volume of physical activity and to the insulating and metabolic effects of

wearing various uniform and protective-equipment configurations. Specific guidelines for American youth football are available[34,35] and can be used as a basis for developing other youth sports-acclimatization and practice-modification/monitoring strategies.

5. Sufficient, sanitary, and appropriate fluid should be readily accessible and consumed at regular intervals before, during, and after all sports participation and other physical activities to offset sweat loss and maintain adequate hydration while avoiding overdrinking. Generally, 100 to 250 mL (approximately 3–8 oz) every 20 minutes for 9- to 12-year-olds and up to 1.0 to 1.5 L (approximately 34–50 oz) per hour for adolescent boys and girls is enough to sufficiently minimize sweating-induced body-water deficits during exercise and other physical activity as long as their preactivity hydration status is good. Preactivity to postactivity body-weight changes can provide more specific insight to a person's hydration status and rehydration needs. Although water is often sufficient to maintain adequate hydration, long-duration (eg, ≥1-hour) or repeated same-day sessions of strenuous exercise, sport participation, or other physical activity might warrant including electrolyte-supplemented beverages that emphasize sodium to more effectively optimize rehydration.[36–40] This is especially justified in warm- to hot-weather conditions, when sweat loss is extensive.
6. Exercise, sport participation, and other physical activity should be modified for safety in relation to the degree of environmental heat stress: air temperature, humidity, and solar radiation, as indicated by the heat index or wet-bulb globe temperature (WBGT), for those with access to such a device. Effective modifications include lowering the intensity and/or shortening the activity duration and increasing the frequency and duration of breaks, which would preferably be in the shade. Individual medical conditions[25] and other risk factors identified by a preparticipation physical examination or as indicated by a more recent change in health status that could lower tolerance for exercise in the heat and increase risk for exertional heat illness should also prompt these and additional modifications (see Table 1).
7. Any child or adolescent should avoid or limit exercise, sport participation, or other physical activity in the heat if he or she is currently ill or is recovering from an illness, especially those involving gastrointestinal distress (eg, vomiting, diarrhea) and/or fever.
8. Supervisory staff such as coaches, athletic trainers, physical education teachers, and playground aides should receive appropriate training and closely monitor all children and adolescents at all times during sports and other physical activity in the heat for signs and symptoms of developing heat illness. Any significant deterioration in performance with notable signs of struggling, negative changes in personality or mental status, or other concerning clinical markers of well-being, including pallor, bright-red flushing, dizziness, headache, excessive fatigue, vomiting, or complaints of feeling cold or extremely hot, should be sufficient reason to immediately stop participation and seek appropriate medical attention for those affected. First aid for evolving heat illness should not be delayed. Anyone experiencing exertional heat illness should not return to practice or competition, recreational play, or other physical activity for the remainder of the current session, game/match, or play/activity period.
9. An emergency action plan with clearly defined written protocols should be developed and in place ahead of time. Emergency medical services (EMS) communication should be activated immediately for any child or adolescent who collapses or exhibits moderate or severe central nervous system dysfunction or encephalopathy during or after practice, competition, or other physical activity in the heat, especially if the child or adolescent is wearing a uniform and/or protective equipment that is potentially contributing to additional heat storage. Although treatment should not be delayed pending core body-temperature verification, when feasible, rectal temperature should be promptly checked by trained personnel and, if indicated (rectal temperature > 40°C [104°F]), on-site whole-body rapid cooling using proven techniques should be initiated without delay.[41–44] This process includes promptly moving the victim to the shade, immediately removing protective equipment and clothing, and cooling by cold- or ice-water immersion (preferred, most effective method) or by applying ice packs to the neck, axillae, and groin and rotating ice-water–soaked towels to all other areas of the body until rectal temperature reaches just under 39°C (approximately 102°F) or the victim shows clinical improvement. If rectal temperature cannot be assessed

in a child or adolescent with clinical signs or symptoms suggestive of moderate or severe heat stress, appropriate treatment should not be delayed. Prompt rapid cooling for 10 to 15 minutes and, if the child or adolescent is alert enough to ingest fluid, hydration should be initiated by attending staff while awaiting the arrival of medical assistance.

10. To improve athlete safety and performance, youth sports governing bodies, tournament directors, and other event administrators should provide adequate rest and recovery periods of 2 hours or *more* between same-day contests in warm to hot weather to allow sufficient recovery and rehydration.[45,46]
11. In conditions of extreme heat or humidity when children or adolescents can no longer maintain thermal balance, safety should be the priority, and outdoor contests and practice sessions should be canceled or rescheduled to cooler times, even if it means playing or practicing very early in the day or later in the evening.

APPENDIX: DEFINITIONS

Heat stress: High air temperature, humidity, and solar radiation that lead to perceived discomfort and physiologic strain when children and adolescents are exposed to such environmental conditions, especially during vigorous exercise and other physical activity.

Exertional heat illness: A spectrum of clinical conditions that range from muscle (heat) cramps, heat syncope, and heat exhaustion to life-threatening heat stroke incurred as a result of exercise or other physical activity in the heat.

Heat exhaustion: Moderate heat illness, characterized by the inability to maintain blood pressure and sustain adequate cardiac output, that results from strenuous exercise or other physical activity, environmental heat stress, acute dehydration, and energy depletion. Signs and symptoms include weakness, dizziness, nausea, syncope, and headache; core body temperature is $<$104°F (40°C).

Exertional heat stroke: Severe multisystem heat illness, characterized by central nervous system abnormalities such as delirium, convulsions, or coma, endotoxemia, circulatory failure, temperature-control dysregulation, and, potentially, organ and tissue damage, that results from an elevated core body temperature ($>$104°F [$>$40°C]) that is induced by strenuous exercise or other physical activity and typically (not always) high environmental heat stress.

Heat injury: Profound damage and dysfunction to the brain, heart, liver, kidneys, intestine, spleen, or muscle induced by excessive sustained core body temperature associated with incurring exertional heat stroke, especially for those victims in whom signs and/or symptoms are not promptly recognized and are not treated effectively (rapidly cooled) in a timely manner.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

CLINICAL REPORT

Clinical Genetic Evaluation of the Child With Mental Retardation or Developmental Delays

Guidance for the Clinician in Rendering Pediatric Care

John B. Moeschler, MD, Michael Shevell, MD, and the Committee on Genetics

ABSTRACT

This clinical report describes the clinical genetic evaluation of the child with developmental delays or mental retardation. The purpose of this report is to describe the optimal clinical genetics diagnostic evaluation to assist pediatricians in providing a medical home for children with developmental delays or mental retardation and their families. The literature supports the benefit of expert clinical judgment by a consulting clinical geneticist in the diagnostic evaluation. However, it is recognized that local factors may preclude this particular option. No single approach to the diagnostic process is supported by the literature. This report addresses the diagnostic importance of clinical history, 3-generation family history, dysmorphologic examination, neurologic examination, chromosome analysis (≥650 bands), fragile X molecular genetic testing, fluorescence in situ hybridization studies for subtelomere chromosome rearrangements, molecular genetic testing for typical and atypical presentations of known syndromes, computed tomography and/or magnetic resonance brain imaging, and targeted studies for metabolic disorders.

INTRODUCTION

The purpose of this clinical report of the American Academy of Pediatrics (AAP) Committee on Genetics is to describe an optimal clinical genetics evaluation of the child with developmental delays or mental retardation (DD/MR). Developmental surveillance is an integral component of a primary care medical home, and much is written about the importance of early identification and referral of children with developmental delays. For example, in "Developmental Surveillance and Screening of Infants and Young Children," the AAP Committee on Children With Disabilities discusses the importance of early identification and referral of infants with developmental delays by the primary care pediatrician and the importance of the pediatrician's responsibility to "determine the cause of delays or refer to appropriate consultant for determination."[1] No AAP statement has addressed the elements that constitute an optimal diagnostic evaluation of the infant or young child with DD/MR. This clinical report focuses on the diagnostic evaluation once the primary care pediatrician or other health care professional determines that there is a developmental delay. The goal of this diagnostic evaluation is to identify the etiology of the disability, including any medical genetic cause. The medical genetics diagnostic evaluation takes place within the context of a comprehensive evaluation of a child's neurodevelopmental status, which is designed to address

the child's developmental management needs and guide the etiologic evaluation process.[2–5] The primary care pediatrician has a role in determining whether neurologic, developmental pediatrics, audiologic, or ophthalmologic evaluations, as well as other rehabilitative services, are needed in the child's neurodevelopmental diagnosis. Many primary care pediatricians will initiate aspects of the diagnostic evaluation; others will seek specialty consultation before embarking on the diagnostic evaluation. It is appropriate for the individual pediatrician to determine the diagnostic approach that is optimal for a particular child and family.

The type of developmental delay identified is an important preliminary step, because such typing influences the path of investigation that is undertaken later. The focus of this report is the child with cognitive developmental delays rather than those with motor delays or language delays solely. Such delays require accurate documentation using norm-referenced and age-appropriate standardized measures of development by experienced pediatricians or developmental specialists whenever feasible.[6,7] The term "developmental delay" is usually reserved for younger children (typically younger than 5 years), and the term "mental retardation" is usually applied to older children when IQ testing is valid and reliable.[8] Children with developmental delays are those who present with delays in the attainment of developmental milestones at the expected age. Developmental delays imply deficits in learning and adaptation,[2] which may be significant and predict later cognitive or intellectual disability. However, delays in development, especially those that are mild, may be transient and lack predictive reliability for mental retardation or other developmental disabilities.

Mental retardation (often referred to as "intellectual disability" and "cognitive disability") is a lifelong disability that presents in infancy or the early childhood years but cannot be diagnosed until the child is older than 5 years, when standardized measures of intelligence become reliable and valid. The American Association on Mental Retardation defines mental retardation by measures of 3 domains: intelligence (IQ), adaptive behavior, and systems of supports. Thus, one cannot rely solely on the measure of IQ to define mental retardation.[9]

The prevalence of developmental delay is estimated at 1% to 3% based on the rate often quoted for mental retardation.[2] However, this may be an overestimate.[10,11] The US Department of Education data from 1993 indicated a rate of 1.14%, although there are state-to-state variations in rates.[12] Developmental disabilities, taken together, affect 5% to 10% of all children.[13]

Developmental surveillance is one important component of a primary care medical home. The AAP Committee on Children With Disabilities states: "All infants and young children should be screened for developmental delays. Screening procedures should be incorporated into the ongoing health care of the child as part of the provision of a medical home, as defined by the Academy."[1] Developmental screening or surveillance identifies those who may need further evaluation and referral for services. Of those who are screened and identified with developmental delays, only a subset of the whole will be diagnosed with developmental delays that indicate the presence of a cognitive disability and for which this suggested diagnostic evaluation is warranted. The proportion of children who will have developmental delays detected on screening depends on the psychometric characteristics of the screening method used, including sensitivity and specificity of the screening test.[14]

The diagnosis of mental retardation cannot be made accurately or reliably until the child is at least 5 years of age; therefore, many children will continue with the diagnosis of developmental delay until 5 years or older. Thus, developmental delay might be considered as a set of symptoms and signs (a "phenotype") for which a variety of etiologies are known.

This clinical report will not address the etiologic evaluation of young children who are diagnosed with cerebral palsy, autism, or a single-domain developmental delay (gross motor delay or specific language impairment). Some children present with both developmental delay and features of autism. In such cases, the judgment of the clinical geneticist will be important in determining the evaluation of the child depending on the primary neurodevelopmental diagnosis. It is recognized that the determination that an infant or young child has a cognitive disability can be a matter of clinical judgment, and it is important for the pediatrician and consulting clinical geneticist to discuss this before deciding on the best approach to the diagnostic evaluation.

Pediatricians are key in the process that ultimately leads to making a diagnosis of DD/MR. Pediatricians often are charged with explaining the etiology of the child's DD/MR to the family as one role in providing a medical home.[1] The primary care pediatrician, by providing the medical home, is key in translating diagnostic results to help families develop an integrated, anticipatory plan including health care, education, and eventual transition planning.[15]

The yield of etiologic evaluations of children with DD/MR vary widely (10% to 81%).[2–5] The wide variation reflects many factors, such as study population differences, extent of the diagnostic evaluation, era during which the study was completed, and improving diagnostic technologic advances over time. There is also wide variation in the category of reported causes of mental retardation: 18.6% to 44.5% of cases have exogenous causes, such as teratogen exposure or infection, and 17.4% to 47.1% have genetic causes.[11,16–18]

For the purposes of this clinical report, we have adopted the definition of "etiology" proposed by Schaefer and Bodensteiner[19]: "a specific diagnosis [is]

that [which] can be translated into useful clinical information for the family, including providing information about prognosis, recurrence risks, and preferred modes of available therapy." For example, agenesis of the corpus callosum is a finding or sign and not a diagnosis, whereas Down syndrome is a clinical diagnosis, and when confirmed by a routine chromosome study, there is certainty that the clinical diagnosis is correct and indication as to how the patient came to have trisomy 21 (eg, nondisjunction versus translocation).

Pediatricians are expected to know the elements that constitute an optimal clinical genetics diagnostic evaluation for the cause of DD/MR. Families of children with DD/MR expect and deserve to know, whenever possible, the underlying etiology of their child's diagnosis. Pediatricians often refer such patients to consultants, including clinical geneticists, to assist with diagnosis and management and would benefit from knowing what represents an optimal evaluation. Knowing what is likely to be involved in the clinical genetics diagnostic evaluation will assist pediatricians in preparing the family for what to expect during the course of the evaluation and in integrating a diagnosis into the care provided to the child and family (Table 1).

Recently, the American College of Medical Genetics[3] and the American Academy of Neurology and Child Neurology Society[2] published statements on the evaluation of children with DD/MR. This clinical report will refer to these statements and to more recent literature to support this description of an optimal medical genetics evaluation for DD/MR. The AAP recognizes that the evaluation of a child is tailored to the specific facts of that child's situation as defined by the child, family, and referring pediatrician and that the consulting clinical geneticist will use clinical judgment in devising the most appropriate diagnostic evaluation schema. As Curry et al[3] stated, "there was no uniform consensus regarding the 'right' or 'wrong' approach. No unifying or single algorithm was found appropriate for every patient or every situation. A large number of variables currently affect the physician's evaluation process." And although Shevell et al[2] suggested a diagnostic algorithm, they acknowledge that there are few systematic studies of the process of evaluation. Cost savings are documented[20] when the evaluation process suggested by Shevell et al[2] is used, compared with that of a group of specialists not following a particular process; the diagnostic rate was no different. The AAP Committee on Genetics favors an approach modified from that suggested by van Karnebeek et al,[4] because it emphasizes the importance of the clinical history, family history, and diagnostic skill of the clinical geneticist (Fig 1).

TABLE 1 **What Families Might Expect From the Clinical Genetics Evaluation**

Before visit	Request for child's medical charts; neurodevelopmental test results; all medical test results; copies of MRI, CT, or other imaging studies
	Request to bring photographs of child and family members
	Asked about the family history
	Asked to set aside sufficient time for prolonged consultation
At the visit	Clarify the purpose of the visit
	Review the child's medical history and neurodevelopmental status
	Review family history (≥3 generations)
	Complete physical and neurologic examinations
	Geneticist's initial impressions discussed
After the visit	Clinical photographs
	Laboratory studies (blood and/or urine tests)
	Arrangements for MRI or CT studies
	Arrangements for other consultations (eg, neurology, developmental pediatrics, ophthalmology, etc)
	Arrangements for ongoing communication and follow-up visits

EXPECTED OUTCOMES OF A MEDIAL GENETICS EVALUATION

There is no systematic study of the benefits (or harms) of a comprehensive evaluation of the child with DD/MR. However, there are recurring statements of likely benefits for parents and patients in the literature.[3,21–24] For example, Shevell[21] indicated that the "etiologic diagnosis in the young child has immediate implications with respect to recurrence risks and therapeutic imperatives, possessing the potential to modify management and expected outcomes" and that "future medical challenges and the actual prognosis for the disabled child can be more accurately addressed." The family of a child with DD/MR often experiences the feeling of a loss of control,[25] and a diagnosis can contribute to the family feeling in control once more. "As physicians we have experience with other children who have the same disorder, access to management programs, knowledge of the prognosis, awareness of research on understanding the disease and many other elements that when shared with the parents will give them a feeling that some control is possible"[23] (Table 2).

KEY COMPONENTS OF THE GENETICS EVALUATION

The referring pediatrician and the family will benefit from knowing what to expect from the medical genetics consultation and evaluation. The approach to a child with DD/MR includes the clinical history (including prenatal and birth histories), family history and construction of a pedigree of 3 generations or more, and physical and neurologic examinations, emphasizing the examination for minor anomalies and neurologic or behavioral signs that might suggest a specific recognizable syndrome or diagnosis (Table 3). After this clinical consultation, judicious use of laboratory tests, imaging, and

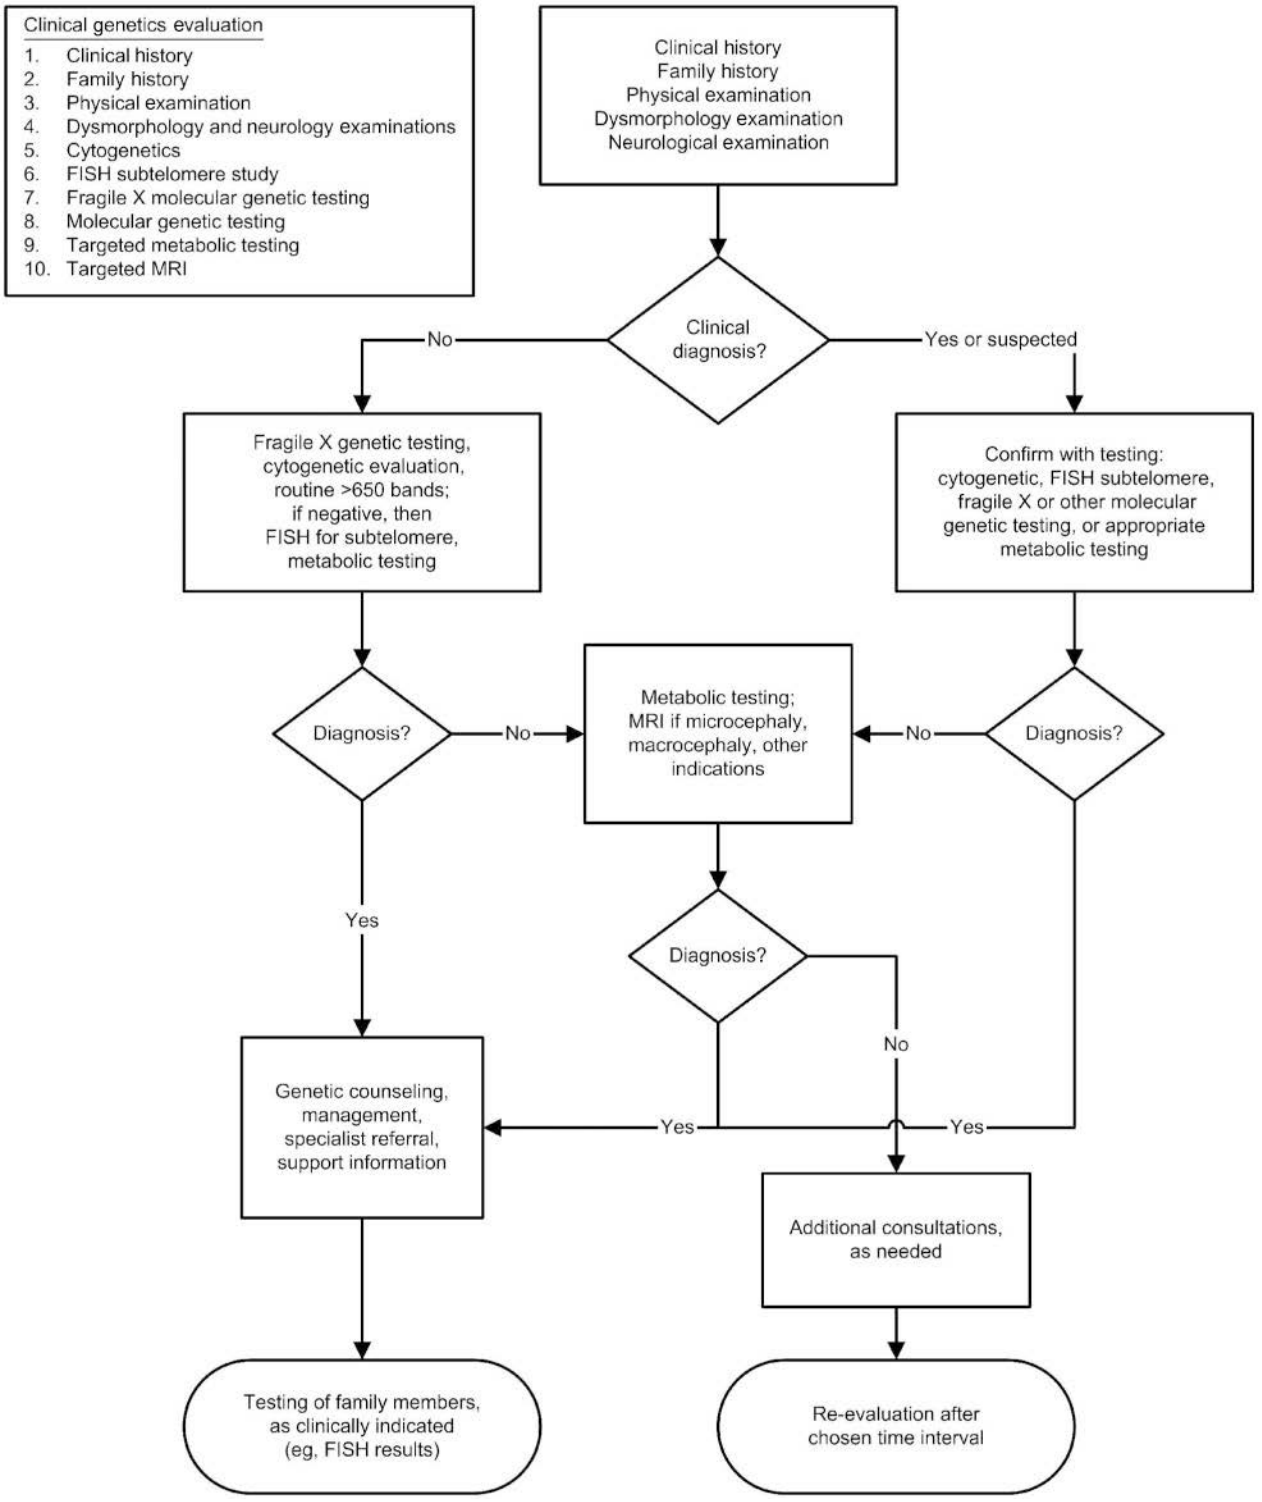

FIGURE 1
Approach to the clinical genetics evaluation for DD/MR.

other consultant services can be anticipated with most patients.

Family History

An optimal medical genetics evaluation starts with a comprehensive history and physical examination, including a 3-generation family history with particular attention to family members with mental retardation, developmental delays, psychiatric diagnoses, congenital malformations, miscarriages, stillbirths, and early childhood deaths. The medical and family history allows for the clinical geneticist to suspect an etiology and helps in

TABLE 2 **Expected Benefits of Evaluation for DD/MR[3]**

For parents	Questions addressed
	What is the cause of my child's delays?
	How did this happen?
	Are there medical complications?
	What can we expect in the future?
	Is there treatment?
	Will this happen again in future children?
	Can it be prevented in future children?
	Can we test for it in future pregnancies?
	Are others in my family at risk?
	How can I learn more?
	What support resources are available?
For pediatricians	Clarification of etiology, prognosis, genetic mechanism(s), recurrence risks, treatment options
	Avoidance of unnecessary tests
	Information regarding management or surveillance and family support
	Research/treatment protocols
	Co-management of appropriate patients

TABLE 3 **Selected Clinical Findings or Laboratory Abnormalities Suggesting a Metabolic Disorder[3]**

Failure of appropriate growth
Recurrent unexplained illness
Seizures
Ataxia
Loss of psychomotor skills
Hypotonia
"Coarse" appearance
Eye abnormalities (cataracts, ophthalmoplegia, corneal clouding, abnormal retina)
Recurrent somnolence/coma
Abnormal sexual differentiation
Arachnodactyly
Hepatosplenomegaly
Metabolic/lactic acidosis
Hyperuricemia
Hyperammonemia
Low cholesterol
Structural hair abnormalities
Unexplained deafness
Bone abnormalities (dysostosis, occipital horns, punctuate calcifications)
Skin abnormalities (angiokeratoma, "orange-peel" skin, ichthyosis)

guiding the diagnostic evaluation; it does not stand alone and is important only in the context of the clinical examination. The family history can help in suggesting a diagnosis, particularly when other family members are affected similarly. This is important especially in the case of male patients who have male relatives with DD/MR, related through females who are not mentally retarded. Such a pedigree suggests an X-linked genetic cause of DD/MR and requires special attention (see section on fragile X testing later in this report).

The Dysmorphologic Examination

Pediatricians and families can expect that an optimal clinical genetics evaluation will include a thorough examination for minor anomalies that might suggest an etiology or contribute to the recognition of a particular diagnostic pattern—a dysmorphologic examination.[26–28] Schaefer and Bodensteiner[19] state that the "association of mental retardation and congenital malformations has long been recognized" and that "a necessary component of the evaluation of the child with idiopathic mental retardation is a comprehensive dysmorphologic examination."

Several studies of etiology of mental retardation suggest that the dysmorphologic examination and syndrome recognition by an experienced clinical geneticist is the critical diagnostic modality. An early study of the co-occurrence of mental retardation and minor anomalies was that of Smith and Bostian.[29] The authors examined 50 children with mental retardation of unknown cause for the numbers and kinds of minor anomalies; controls consisted of 100 children without mental retardation. They found that 42% of the children with DD/MR had 3 or more minor anomalies, compared with none of the controls. They concluded that the etiology of the mental retardation was abnormal development of the central nervous system (CNS) heralded by the presence of the minor anomalies on the surface examination. Hunter[18] completed a retrospective study of the diagnostic evaluation of 411 children with mental retardation referred to a university-based genetics center between 1986 and 1997. He found that "physical findings in the patient were the most important factors in determining whether or not a diagnosis was made. . . A diagnosis was significantly more likely when a patient was noted to have an unusual appearance (sic) and, although the numbers are small, the presence of a major malformation did not increase the diagnostic rate. Half the diagnoses were made on the basis of a key finding (eg, velopharyngeal incompetence) or the Gestalt of the patient."

In a prospective study of patients referred to a university hospital clinical genetics center in Amsterdam, Netherlands, for diagnostic evaluation for DD/MR, van Karnebeek et al[5] studied 281 children prospectively and made etiologic diagnoses in 150 (54%). One third of these diagnoses were made on the basis of history and examination alone; in another one third, history and examination provided essential clues to the diagnosis, later confirmed by additional studies; and laboratory studies alone provided diagnoses in the remaining one third. For example, in patients with Prader-Willi syndrome, these authors felt the history and examination were contributory to the diagnosis and the molecular genetic analysis was essential for the diagnosis. Using these definitions, they found that the dysmorphologic examination was contributory to the diagnosis in 79% of cases and essential in 62%. This study found that on the basis of clinical history alone, a diagnosis could be estab-

lished in 1 of 20 patients, and on the basis of physical examination alone, a diagnosis could be established in 1 of 30 patients. On the basis of history and examination together, a diagnosis was made in 1 of 3 patients. In addition, the clinical history and examination provided essential guidance to the clinician regarding which additional investigations should be performed. The additional investigations (laboratory and consultation) allowed for diagnosis in another one third of the patients in the study.

Similarly, Battaglia and Carey[30] found that a "pathogenetic diagnosis" could be identified in 80% of all patients; of these, half were diagnosed by history and physical examination alone. Majnemer and Shevell[7] found that a diagnosis was made in 63.3% of patients with "global developmental delays"; of this total, the diagnosis was made by history and physical examination alone in 18.4%. Shevell et al[22] studied 99 children with global developmental delays prospectively, and in 44, an etiology was determined. Of these 44, 15 (38.6%) had diagnoses made by history and physical examination alone. It is emphasized that Wood lamp examination for neurocutaneous disorders, such as tuberous sclerosis, is an essential component of the diagnostic evaluation. Thus, the dysmorphologic examination by the experienced clinical geneticist is a key element of the diagnostic evaluation.

Neurologic Examination

Like the dysmorphologic examination, the neurologic examination (defined as the physical examination focused on detecting neurologic abnormalities) is considered essential in the evaluation of every child with DD/MR. However, there are few systematic studies of the utility of the neurologic examination in establishing a diagnosis. For example, in their review, Majnemer and Shevell[7] included in this category the utility of electroencephalography (EEG) and neuroimaging by computed tomography (CT) or magnetic resonance imaging (MRI). The role of the neurologic examination itself is addressed by van Karnebeek et al[4] in their systematic review. They included 5 studies that addressed the neurologic examination alone[18,31–34] and reported that the total yield of etiologic diagnoses in all studies was 42.9%, which means that 42.9% of patients presenting with DD/MR had abnormalities, which typically included cerebral palsy, muscle weakness, spasticity, paresis, and microcephaly. Finding such abnormalities on neurologic examination assisted in determining the need for additional studies, such as EEG, neuroimaging or molecular genetic testing, or referral to other specialists.

Cytogenetic Studies

Cytogenetic studies in the evaluation of children with DD/MR are to be expected in all children for whom the etiology of DD/MR is unknown. The reported frequency of chromosome anomalies detected by high-resolution karyotyping (ie, ≥650 bands) in patients evaluated for DD/MR varies between 9% and 36%.[35] In a recent review of the frequency of cytogenetic abnormalities in the evaluation of patients with mental retardation by van Karnebeek et al,[5] the authors found the median frequency of detected chromosome abnormalities was nearly 1 in 10 patients investigated. Their review noted a wide range of reported frequencies of chromosome abnormalities causing mental retardation—from 2% to 50% depending on the variation in the study design among published reports. They found that chromosome abnormalities were present in all categories of mental retardation (mild to profound) and in both genders. The authors concluded that cytogenetic studies are a "valuable diagnostic technique" in the evaluation of children with DD/MR. In a recent prospective study of the etiology of mental retardation in which karyotyping was performed in 266 children in Amsterdam, van Karnebeek et al[31] found that 21 children (8.3%) had abnormalities (8 numerical, 13 structural). These authors found that there was a relationship between the number of minor anomalies and the likelihood of a chromosomal abnormality: a higher number of anomalies (more than 6) indicated a significantly higher likelihood to find a chromosomal abnormality. They concluded that all patients with no known cause for the DD/MR should have chromosome analysis performed.

Likewise, a review by Shevell et al[2] reported the range of chromosomal abnormalities found on routine cytogenetic analysis to be 2.93% to 11.6%, with a median of 3.7%. They concluded that "routine cytogenetic testing is indicated in the evaluation of the child with developmental delay even in the absence of dysmorphic features or clinical features suggestive of a syndrome." They cite Graham and Selikowitz,[36] who found that 4 of 10 patients with mental retardation attributable to chromosomal abnormalities had no dysmorphic features. Curry et al[3] state that "chromosome analysis in the individual with mental retardation is generally regarded as a mainstay in the overall evaluation process." van Karnebeek et al[4] found that approximately 10% of all patients with DD/MR had a chromosomal abnormality and recommended routine karyotyping in all patients for whom the etiology of the DD/MR was unknown. It is key that the cytogenetic study be reviewed by the clinical geneticist during the evaluation of a particular child. At times, a clinical geneticist may request a second chromosomal analysis for a number of reasons, ranging from high clinical suspicion of a certain chromosomal diagnosis to a desire to have a chromosomal study of sufficient bands to find smaller rearrangements, such as a 700-band study. Thus, pediatricians and families can anticipate that a routine chromosome analysis will be recommended for those patients in whom an etiology is not recognized after the clinical history and examination.

Submicroscopic Subtelomeric Rearrangements

Approximately half of all structural chromosomal abnormalities ("segmental aneusomies") include the telomere of the chromosome. A test for the absence of the functional end of the chromosome (subtelomere region) will effectively evaluate many potential abnormalities of that chromosome and, thus, the cause of the DD/MR. Many deletions of the telomeres are visible by standard techniques, and the syndromes caused by such deletions are often clinically recognizable (eg, cri-du-chat syndrome, which is caused by the deletion of the telomere of the short [p] arm of chromosome 5). However, deletions of other subtelomeric regions lead to a phenotype that is not recognized easily, and the deletions often go undetected by routine karyotyping.

Recently, fluorescence in situ hybridization (FISH) techniques have been applied to examine the subtelomeric regions of each chromosome for abnormalities that are known to cause mental retardation.[37–44] Since a complete set of FISH probes has become available clinically, the utility of these probes has been demonstrated by the numerous reports of patients with mental retardation who have had a previously normal routine karyotype, suggesting that subtelomeric abnormalities (deletions or duplications of chromosome regions) are second only to Down syndrome as the most common cause of mental retardation.[41,45] Some deletions and duplications of clinically significant chromosome material at the telomeres are not visible by standard karyotype analytic techniques; these are often referred to as "cryptic" subtelomeric chromosome anomalies (ie, they are not detectable by routine cytogenetic testing). The newer FISH techniques have allowed more sensitive analysis of the telomeres for clinically significant abnormalities.

The application of the FISH technique to examine the subtelomere region of each chromosome has led to the recognition that approximately 7.4% of children with moderate to severe mental retardation who have had normal results of routine chromosome analysis have an abnormality detected (either a deletion or duplication, sometimes both) by the FISH technique to explain their mental retardation. Also, 0.5% of children with mild mental retardation of previously unknown etiology have been found to have cryptic telomere rearrangements as the etiology.[41,45] Only a few subtelomeric syndromes have been delineated to date (Table 4).

Most subtelomeric abnormalities detected by FISH cause mental retardation syndromes that have not been fully delineated, thus making recognition and selection of patients for such testing challenging and counseling families regarding the natural history of their child's diagnosis difficult.

There have been apparent subtelomere deletions detected by FISH techniques that have been proven to be benign familial "variations" and not the cause of the child's DD/MR. Such "false positives" are thought to be rare[31] but complicate the evaluation of patients and their families by requiring parental samples for confirmation.

TABLE 4 **Recognizable Syndromes Caused by Subtelomeric Abnormalities Detected by FISH Technique**

Chromosome Syndrome	Key Features
1pter deletion	Growth retardation; mental retardation; seizures; visual problems; large anterior fontanelle; asymmetric and low-set, dysplastic ears; deep-set eyes; depressed nasal bridge; pointed chin; and fifth finger clinodactyly[72,73]
1p36.3 deletion	Ebstein anomaly; mental retardation[72–74]
1qter deletion	Microcephaly; growth and mental retardation; corpus callosum abnormalities; cardiac anomalies; hypospadias; characteristic facial features[75]
22qter deletion	Developmental delay; hypotonia; absent speech; and normal growth or somatic overgrowth[76–79]

Biesecker[45] reviewed 14 studies involving 1718 subjects who were selected on the basis of mental retardation, growth retardation, major and minor anomalies, exclusion of known diagnosis, and familial versus sporadic occurrence. It is notable that even with the variation in subject selection criteria from study to study, there was a relatively constant yield of subtelomere abnormalities detected by FISH of approximately 6%. The presence of major and minor physical anomalies did not affect the yield; however, the yield was higher among familial cases compared with sporadic cases. de Vries et al[47] have proposed a 5-item checklist designed to increase the yield of FISH subtelomere studies; using a score of ≥ 3 as a cutoff for subtelomere testing, the authors note that approximately 20% of cases could be excluded from testing without missing a subtelomeric case.

Thus, when the standard karyotype is normal, a FISH study for subtelomere rearrangements is an important diagnostic component in the evaluation of the child with DD/MR.

The use of microarray comparative genomic hybridization in the evaluation of children with DD/MR might be considered best as "emerging technology."[47] This methodology promises to detect abnormal copy numbers of DNA sequences—deletions and duplications of very small segments of the entire chromosomes. Currently, this testing technique samples many known clinically important loci simultaneously in addition to the subtelomeres and pericentric regions of all chromosomes. Some clinical geneticists have begun to take advantage of this testing technique in patients with undiagnosed DD/MR because it is an efficient method for subtelomere testing and can be used to confirm clinical suspicion on certain diagnoses (eg, Williams syndrome). It appears that this method will increase the clinician's ability to determine the cause of DD/MR, particularly in cases with minor anomalies. There are currently insufficient published reports of the use of this technology in the evaluation of the child with DD/MR. At the time of

this writing, a few clinical laboratories are offering this type of testing.

Molecular Genetic Diagnostic Testing and Fragile X Syndrome

Molecular genetic diagnostic testing is used to establish the genetic etiology for DD/MR when the diagnosis is considered established clinically (eg, a girl who fulfills established clinical diagnostic criteria for typical Rett syndrome) or suspected clinically (a young boy with nonspecific mental retardation suspected to have fragile X syndrome).

Fragile X Syndrome

Fragile X syndrome is said to be the most common genetic cause of DD/MR,[2] yet reviews suggest that only approximately 2.0% of patients with mental retardation (both genders) will be found to have a mutation in this gene (with prevalence ranging from 0% to 28.6%).[4] In their comprehensive review of the literature, van Karnebeek et al[4] found that those with more significant mental retardation are more likely to have positive results of fragile X testing (4.1%), compared with those with milder delays or borderline intelligence testing results (1.0%). In a large study of unselected school-aged patients with mental retardation, de Vries et al[48,49] reported a prevalence of fragile X diagnosed by molecular genetic testing to be 0.7%, with a higher prevalence among boys (1.0% for boys, 0.3% for girls). There have been a number of studies using clinical checklists aimed at improving identification of patients for whom fragile X testing is warranted. For example, de Vries et al[49] found that a 7-item clinical checklist increased the molecular genetic diagnostic yield to 7.6% without the loss of cases identified. This checklist included positive family history of mental retardation, long jaw or high forehead, large and/or protuberant ears, hyperextensible joints, soft and velvety palmar skin with redundancy on the dorsum of the hands, testicular enlargement, and behaviors of initial shyness and lack of eye contact followed by friendliness and verbosity. Other checklists designed to increase the efficiency of fragile X genetic testing have been used with results that are generally positive.[50–54] However, the design of such checklists varies, and comparisons among them are difficult. Generally, they included male gender, a positive family history for mental retardation, and absence of microcephaly.

At a consensus conference convened by the American College of Medical Genetics, it was recommended that fragile X testing be "strongly considered in both males and females with unexplained mental retardation especially in the presence of a positive family history, a consistent physical and behavioral phenotype and absence of major structural abnormalities."[3] Likewise, the Child Neurology Society and American Academy of Neurology advise in a practice parameter that fragile X testing be "considered in the evaluation of the child with global developmental delay" and that "clinical preselection may narrow the focus of who can be tested without sacrificing diagnostic yield."[2] van Karnebeek et al[4] recommend that all boys with unexplained mental retardation have molecular genetic testing for fragile X syndrome but caution that routine testing of girls is not warranted unless there are indications of increased risk (eg, a positive family history).

Pediatricians and families can expect that clinical geneticists are likely to recommend testing for fragile X syndrome in any child with undiagnosed DD/MR, particularly if there are findings in the history or examination suggestive of this diagnosis. Molecular genetic testing for fragile X is highly sensitive and specific and is considered the diagnostic standard for fragile X syndrome.[55]

Other Molecular Genetic Testing

There are situations in which the clinical geneticist may establish a clinical diagnosis and use genetic testing to confirm it (much in the same way that the clinical diagnosis of Down syndrome is confirmed by karyotyping). In addition to confirming the clinical diagnosis, genetic testing may be important for describing the genetic mechanism for the diagnosis and for improving the precision of genetic counseling. For example, Angelman syndrome might be attributable to one of several genetic mechanisms (interstitial deletion of the critical region of chromosome 15q, uniparental disomy, an imprinting mutation, or a mutation in the gene *UBE3A*), the knowledge of which becomes important for genetic counseling as well as for confirming the clinical diagnosis.[56]

In other situations, the clinical geneticist may consider molecular genetic testing for the patient who presents with "atypical features" of a known syndrome, as is the case for those suspected to have a mutation in the *MECP2* gene, which causes Rett syndrome in patients who do not fulfill the diagnostic criteria. There are now case reports of girls with milder presentations consistent with DD/MR who have mutations in *MECP2*[57] as well as males with X-linked mental retardation syndromes.[58] (Also see Laumonnier et al[59] for discussion of *NGLN4* gene mutations and X-linked mental retardation and autism.) Thus, in certain circumstances, the clinical geneticist may suggest testing for *MECP2* mutations when the patient does not fulfill the clinical diagnostic criteria for the syndrome in question (in this example, Rett syndrome) but when deemed appropriate to address the question of an "atypical presentation" of the known clinical syndrome. There is not yet sufficient data to suggest that this be part of the optimal genetics evaluation, but it does serve as a example of a likely trend in clinical genetics.

MRI and CT

The literature does not indicate universal agreement on the role that brain imaging by CT or MRI plays in the

evaluation of children with DD/MR. Recommendations range from performing brain imaging on all patients with DD/MR[60] to performing it only on those with indications on clinical examination.[4] Major or minor malformations of the brain are known to be an important finding in patients with DD/MR. The finding of a brain abnormality may lead to the recognition of the specific cause for a particular child's DD/MR in the same way that a dysmorphologic examination might lead to a clinical diagnosis. However, like other major or minor anomalies noted on physical examination, abnormalities on brain imaging typically are not sufficient for determining the cause of the DD/MR; the cause of the brain anomaly is often unknown. Thus, although a CNS anomaly (often called "CNS dysgenesis") is a useful finding (and considered, according to the definition by Schaefer and Bodensteiner,[19] a useful "diagnosis"), it is frequently not an etiologic or "syndrome" diagnosis. This distinction is not always made in the literature on the utility of MRI in the evaluation patients with DD/MR.

Early studies of the use of CT in the evaluation of patients with idiopathic mental retardation[61] indicated a low diagnostic yield or the nonspecific finding of "cerebral atrophy," which did not contribute to clarifying the cause of the mental retardation.[62] Later studies that used MRI to detect CNS abnormalities suggested that MRI is more sensitive than CT, with increased yield.[2,63] The rate of abnormalities detected on imaging varies widely in the literature as a result of many factors such as subject selection criteria and method of imaging (CT, MRI, whether quantitative methods were used). Schaefer and Bodensteiner,[60] in their literature review, found reported ranges of abnormalities from 9% to 80% of those patients studied. Shevell et al[2] reported a similar range of findings in their review.[2] For example, in 3 studies of a total of 329 children with developmental delay in which CT was used in almost all patients and MRI was used in a small sample, a specific cause was determined in 31.4%,[7] 27%,[22] and 30% of the children.[64] In their systematic review, van Karnebeek et al[4] reported on 9 studies of the use of MRI in children with mental retardation. The mean rate of abnormality found was 30%, with a range of 6.2% to 48.7%, and more abnormalities were found in children with moderate to profound mental retardation versus borderline to mild mental retardation (means of 30% and 21.2%, respectively). These authors also noted that none of the studies reported on the value of the absence of any neuroradiologic abnormality for a diagnostic workup and concluded that the "value for finding abnormalities or the absence of abnormalities must be higher" than the 30% mean rate implies.

If neuroimaging is performed in only selected cases with abnormal head circumference or an abnormal focal neurologic finding, the rate of abnormalities detected is increased. Shevell et al[22] reported that the percentage of abnormalities was 13.9% if performed on a "screening basis" but increased to 41.2% if performed on an "indicated basis." In their practice parameter, the American Academy of Neurology and Child Neurology Society[2] discussed other studies on smaller numbers of patients that showed similar results, which led to the recommendation that "neuro-imaging is a recommended part of the diagnostic evaluation," particularly should there be abnormal findings on examination (microcephaly, focal motor findings), and that MRI is preferable to CT. However, in the American College of Medical Genetics consensus conference report,[3] the authors state that neuroimaging by CT or MRI in the normocephalic patient without focal neurologic signs should not be considered "standard of practice" or mandatory. These authors felt that the decisions regarding "cranial imaging will need to follow (not precede) a thorough assessment of the patient and the clinical presentation."

In contrast, van Karnebeek et al[4] found that MRI alone leads to an etiologic diagnosis in a much lower percentage of patients studied. They cited Kjos et al,[65] who reported diagnoses in 3.9% of patients who had no known cause for their mental retardation and followed no progressive or degenerative course. Bouhadiba et al[66] reported diagnoses in 0.9% of patients with neurologic symptoms, and in 4 additional studies, no etiologic or syndrome diagnosis on the basis of neuroimaging alone was found.[18,62,64,67] The authors of 3 studies reported the results of unselected patients: Majnemer and Shevell[7] reported a diagnosis by this type of investigation in 0.2% of patients, Stromme[34] reported a diagnosis in 1.4% of patients, and van Karnebeek et al[31] reported a diagnosis in 2.2% of patients.

Abnormal findings on MRI are seen in approximately 30% of patients with DD/MR. However, MRI leads to an etiologic or syndrome diagnosis in 0% to 3.9% of patients studied. The value of a negative MRI result in leading to a diagnosis has not been studied. In addition, MRI in the young child with DD/MR invariably requires sedation or anesthesia to immobilize the child to accomplish the study. Although this poses a small risk for the child, it merits appropriate consideration by the clinicians and family.[60] Thus, although MRI is often useful in the evaluation of the child with DD/MR, it is not a mandatory study and has a higher diagnostic yield when indications exist (eg, microcephaly, focal motor findings on neurologic examination).

Metabolic Studies

Inborn errors of metabolism are a rare cause of DD/MR (approximately 1%), particularly when there are no other signs or symptoms suggestive of a metabolic disorder. Although rare, the effect of proper diagnosis and treatment of a metabolic disorder on the patient's prognosis may be substantial.

Shevell et al[2] found that "routine metabolic screen-

ing" of patients with DD/MR has a diagnostic yield of less than 1% and that a stepwise evaluation (on the basis of clinical indicators) will increase the diagnostic yield (on the basis of the single report of Papavasiliou et al[68]). Curry et al[3] found an "extremely low yield for unselected metabolic screening" and concluded that metabolic testing should be selective and "targeted at the suspected category of disorder" on the basis of the history and examination. In their systematic literature review, van Karnebeek et al[4] identified 16 studies that addressed the metabolic evaluation of patients with DD/MR. They reported diagnostic yield from metabolic studies of 0.2% to 8.4%, with a median of 1.0% of patients. The higher rates were from countries in which a specific metabolic disorder is common (eg, aspartylglycosaminuria in Finland) or from a study that included targeted screening of highly inbred populations. van Karnebeek et al[4] also found that comparison between studies was not possible given the lack of uniformity of metabolic testing from study to study.[4] These authors suggest that the need for any metabolic studies be determined by the history and examination findings and that, to standardize and study the approach, checklists be used to guide the metabolic evaluation of patients with DD/MR. Hunter[18] accepted "a metabolic screen . . . in any child under a year of age or who showed apparent deterioration" in his review of his center's evaluation process. Hunter reported that 37.5% of his patient sample had a metabolic screening of urine amino acids, mucopolysaccharides, nitroprusside, ketones, reducing substances, phenylhydrazide, and ferric chloride, and 7.1% had an organic acid screening. Using criteria that screening was justified if there were signs of a specific biochemical disease or the child had unexplained mental retardation and was younger than 1 year or there was evidence of apparent deterioration, Hunter[18] concluded that 75.3% of the metabolic screens and 69% of the organic acid studies were unnecessary. van Karnebeek et al[5] stated that "metabolic studies should not be performed as the first diagnostic study in each child, but in the absence of clues for other causes the yield is still of sufficiently high level to allow testing." Thus, there is a range of expert opinion regarding what constitutes the optimal metabolic screening pathway for patients who present with nonspecific DD/MR. More study in this area is needed.

Routine metabolic screening of all patients with DD/MR is not required; targeted metabolic studies are expected in patients on the basis of findings in the history or examination or if the clinical geneticist judges them necessary. Curry et al[3] have listed selected clinical findings or laboratory abnormalities that may indicate the need for further metabolic investigations (Table 3). Even in the absence of such indicators, some experts recommend routine metabolic testing of patients with nonspecific DD/MR.

Tandem mass spectrometry for screening for inborn errors of metabolism in newborn infants is an example of a recent technology that may affect the ability to screen patients with DD/MR for inborn errors of metabolism. Many metabolic conditions appear to be identifiable with relatively little cost[69,70] and a small sample of blood. However, there is insufficient literature on the clinical application at this time to judge its appropriateness in the evaluation of the child with DD/MR. Because the technology is used for newborn screening programs, the clinical utility in other settings, such as the evaluation of children who might be clinically symptomatic, is being discussed.[69,71] Studies addressing the optimal metabolic evaluation of patients with DD/MR are needed.

SUMMARY

The aim of this clinical report was to describe what pediatricians and patients can anticipate as an optimal clinical genetics evaluation of the child with DD/MR (Table 5) and the anticipated benefits and outcome of such an evaluation. The literature supporting the clinical genetics diagnostic evaluation has been provided, as has a description of what pediatricians and families can anticipate. It is important to note that many patients will not have an etiologic diagnosis as a result of a complete diagnostic consultation. These patients and families deserve occasional reevaluations by the clinical geneticist as new diagnostic testing becomes available that might address the etiology of the child's DD/MR. The interval between diagnostic evaluations or the indications for reconsidering the evaluation timing (eg, new signs or symptoms) are topics that have not been systematically studied. It is important that the consulting clinical geneticist, primary care pediatrician (medical home), and family discuss the interval between evaluations and any signs or symptoms that might prompt an earlier return to the clinical geneticist.

COMMITTEE ON GENETICS, 2005–2006

Clinical Policy: Evidence-Based Approach to Pharmacologic Agents Used in Pediatric Sedation and Analgesia in the Emergency Department

From the EMSC Grant Panel (Writing Committee) on Pharmacologic Agents Used in Pediatric Sedation and Analgesia in the Emergency Department

Sharon E. Mace, MD, Chair, American College of Emergency Physicians (ACEP)
Isabel A. Barata, MD (ACEP)
Joseph P. Cravero, MD (American Society of Anesthesiologists)
William C. Dalsey, MD (ACEP)
Steven A. Godwin, MD (ACEP)
Robert M. Kennedy, MD (American Academy of Pediatrics)
Kelly C. Malley, CPNP, RN (Emergency Nurses Association)
R. Lawrence Moss, MD (American Pediatric Surgical Association)
Alfred D. Sacchetti, MD (ACEP)
Craig R. Warden, MD, MPH (ACEP)
Robert L. Wears, MD, MS, Methodologist (ACEP)

Other members of the EMSC Grant Panel included:
John A. Brennan, MD (ACEP Board Liaison)
Rhonda R. Whitson, RHIA (Clinical Policies Manager, ACEP)
Heather Crown, MRC (EMSC, Public Policy and Partnerships Specialist)
Dan Kavanaugh, MSW (EMSC Program Director)
Susan Eads Role, JD, MSLS (EMSC, Public Policy and Partnerships Director).

This clinical policy was developed by a multidisciplinary panel and supported in part by grant 02-MCHB-48A from the Department of Health and Human Services (DHHS), Health Resources and Services Administration, Maternal and Child Health Bureau, Emergency Medical Services for Children Program in cooperation with the US Department of Transportation (DOT), National Highway Traffic Safety Administration. The contents are the sole responsibility of the authors and do not necessarily represent the official views of DHHS or DOT.

Policy statements and clinical policies are the official policies of the American College of Emergency Physicians and, as such, are not subject to the same peer review process as articles appearing in the journal. Policy statements and clinical policies of ACEP do not necessarily reflect the policies and beliefs of Annals of Emergency Medicine *and its editors.*

Approved by the ACEP Board of Directors, April 19, 2004.

Endorsed by the following organizations: American Academy of Pediatrics, American Pediatric Surgical Association, and Emergency Nurses Association.

This document is being simultaneously published in the Journal of Pediatric Surgery *and the* Journal of Emergency Nursing.

[*Ann Emerg Med.* 2004;44:342-377.]

INTRODUCTION

The appropriate management of pain and anxiety in the emergency department (ED) is a significant facet of emergency care for all patients, including pediatric patients. The administration of drugs for the purpose of reducing or eliminating pain and awareness or providing sedation is an essential component of emergency medicine practice and is a requirement of emergency medicine training programs.[1-3] Proactively addressing pain and anxiety may improve quality of care and patient satisfaction by facilitating interventional procedures and minimizing patient suffering.

Effective and safe procedural sedation requires the selection of appropriate drugs, given in appropriate doses, on selected patients, and in the proper environment. The logistics of procedural sedation in the ED and the hospital has been documented elsewhere.[1,4] There are a variety of drugs available for use in procedural sedation and analgesia. Selection of a particular drug is dependent on many variables, including patient characteristics, the procedure to be performed, and clinician experience. For example, sedation of children with American Society of Anesthesiologists (ASA) status III or IV has been associated with a higher rate of oxygen desaturation and airway difficulties than children with ASA status I or II.[5]

This clinical policy focuses on the use of medications to achieve sedation and analgesia in pediatric patients undergoing procedures in the ED. Specific sedation and analgesia drugs focused on in this document are: etomidate, fentanyl/midazolam, ketamine, methohexital, pentobarbital, and propofol. These 6 drugs represent sedation and analgesia agents used in the ED.

Procedural sedation is defined as the technique of administering sedatives or dissociative agents with or

without analgesics to induce a state that allows the patient to tolerate unpleasant procedures while maintaining cardiorespiratory function.[1] Procedural sedation is generally combined with analgesia to minimize pain whenever the procedure is uncomfortable or painful. The goal of procedural sedation and analgesia is to create a depressed level of consciousness while the patient concurrently maintains his or her own airway and oxygenation without assistance. The Joint Commission on Accreditation of Healthcare Organizations (JCAHO), the ASA, and the American Academy of Pediatrics (AAP) have defined the levels of sedation and analgesia.[4,6,7]

Moderate sedation/analgesia, formerly "conscious sedation," is a drug-induced depression of consciousness during which patients respond purposefully to verbal or light tactile stimulation while generally maintaining protective airway reflexes.[4,7,8] Deep sedation/analgesia is a drug-induced depression of consciousness in which patients are not easily aroused and may need airway and ventilatory assistance, although they purposefully respond to repeated or painful stimulation.[4,7,8] General anesthesia is a drug-induced loss of consciousness during which patients are not arousable and often have impaired cardiorespiratory function needing support.[4,8] Because individuals vary in their response to medications, and sedation for analgesia is a continuum, the practitioner providing sedation and analgesia needs to be proficient in airway management and cardiovascular support.[1,4,7,8] Guidelines for monitoring patients under moderate sedation, deep sedation, and anesthesia have been recommended.[1,4,7,8] Furthermore, whenever moderate or deep sedation is given, the standards for anesthesia care are applicable.[6]

This policy is not intended to be all encompassing and is a guideline. It represents evidence for answering important questions about critical diagnostic and management issues. Recommendations in this policy are not intended to represent the only diagnostic and management options that the emergency physician can consider. The authors clearly recognize the importance of the individual physician's judgment. Rather, this guideline defines for the physician those strategies for which medical literature exists to provide support for answers to the critical questions addressed in this policy.

METHODOLOGY

This policy provides an evidence-based approach to pediatric procedural sedation and analgesia and was created after careful review and critical analysis of the peer-reviewed literature. Multiple MEDLINE searches were done on each of the 6 drugs (etomidate, fentanyl/midazolam, ketamine, methohexital, pentobarbital, and propofol). The drug names were then combined with a search expression designed to identify adverse effects, apnea, vomiting/aspiration, laryngospasm, and hypotension. Finally, the results were limited to English-language studies published between 1966 and 2002 that examined human subjects aged 1 to 18 years. Variants on this search strategy, limiting results to clinical trials or to review articles, were also run.

Searches were done for pre-1966 articles by drug name and were limited to English-language studies; however, no studies from this search were selected for further scrutiny.

Several additional searches were done crossing specific drugs or drug combinations with the terms "conscious sedation" or "procedural sedation" or "procedures." A search of other relevant materials, such as textbooks and reference databases, identified 3 additional papers that were not indexed by drug name. A final set of searches was performed that did not use any specific drug names, but was limited to publication dates from 1966 to 2002, human subjects, subjects aged 1 to 18 years, and conscious sedation or pediatric sedation. A manual search was performed in the peer-reviewed emergency medicine literature for pertinent articles published in 2003.

References obtained on the searches were reviewed by panel members (title and abstract, where available) for relevance before inclusion in the pool of studies to be reviewed. Abstracts and articles were reviewed by subcommittee members, and pertinent articles were selected. These articles were evaluated, and those addressing the questions considered in this document were chosen for grading. Subcommittee members also supplied references from bibliographies of initially selected articles or from their own files.

All publications were graded by at least 2 of the subcommittee members into 1 of 3 categories of strength of evidence. Some articles were downgraded on the basis of a standardized formula that considers the size, age, and location of the study population, methodology, validity of conclusions, and potential sources of bias (Appendix A).

During the review process, all articles were given a baseline "strength of evidence" by the subcommittee members according to the following criteria:

Strength of evidence Class I–Interventional studies including clinical trials, observational studies including prospective cohort studies, aggregate studies including meta-analyses of randomized clinical trials only.

Strength of evidence Class II–Observational studies including retrospective cohort studies, case-controlled

studies, aggregate studies including other meta-analyses.

Strength of evidence Class III–Descriptive cross-sectional studies, observational reports including case series and case reports, consensus studies including published panel consensus by acknowledged groups of experts.

Strength of evidence Class I and II articles were then rated on elements the subcommittee members believed were most important in creating a quality work. Class I and II articles with significant flaws or design bias were downgraded on the basis of a set formula (Appendix B). Strength of evidence Class III articles were downgraded if they demonstrated significant flaws or bias. Articles downgraded below strength of evidence Class III were given an "X" rating and were not used in formulating recommendations in this policy. An Evidentiary Table was constructed and is included at the end of this policy.

Most of the studies included in this guideline lacked a standardized validated scoring system for evaluation of efficacy. In addition, the endpoints differed among the various studies. For many studies, efficacy was defined as the completion of the procedure without any measurement of the degree of sedation. When this occurred, the panel noted "efficacy was not addressed." When a success/failure rate was given, efficacy was graded as Class III. When there was a quantitative measure of sedation, efficacy was given a higher grade (Class I or II) depending on the overall assessment.

In considering the question of safety with respect to the administration of the various drugs included in this clinical policy, the panel recognized that there is not sufficient power in the peer-reviewed literature to document true "safety" for any of the agents involved in any setting, including the operating suite, because critical incidents of very low frequency would require patient cohorts of thousands to be fully evaluated. Lacking this type of data, the panel considered all of the available information from studies that took place in an ED or analogous venue and graded safety on the basis of the available data. More conclusive statements concerning the safety of pediatric sedation with respect to specific agents will await future studies.

Recommendations regarding patient management were then made according to the following criteria:

Level A recommendations. Generally accepted principles for patient management that reflect a high degree of clinical certainty (ie, based on strength of evidence Class I or overwhelming evidence from strength of evidence Class II studies that directly address all the issues).

Level B recommendations. Recommendations for patient management that may identify a particular strategy or range of management strategies that reflect moderate clinical certainty (ie, based on strength of evidence Class II studies that directly address the issue, decision analysis that directly addresses the issue, or strong consensus of strength of evidence Class III studies).

Level C recommendations. Other strategies for patient management based on preliminary, inconclusive, or conflicting evidence, or in the absence of any published literature, based on panel consensus.

There are certain circumstances in which the recommendations stemming from a body of evidence should not be rated as highly as the individual studies on which they are based. Factors such as heterogeneity of results, uncertainty about effect magnitude and consequences, strength of prior beliefs, and publication bias, among others, might lead to such a downgrading of recommendations.

Expert review comments were received on an earlier draft of this document from members of the AAP, the American Pediatric Surgical Association, the ASA, the Emergency Nurses Association, and the American College of Emergency Physicians. Their responses were used to further refine and enhance this policy.

Scope of Application. This policy is intended for physicians administrating procedural sedation and analgesia to pediatric patients in hospital-based EDs.

Inclusion Criteria. This policy applies to patients between the ages of 1 to 18 years who are in a hospital ED and have conditions necessitating the alleviation of anxiety, pain, or both.

Exclusion Criteria. This policy excludes: (1) children younger than 1 year, (2) patients receiving analgesia to treat pain without concomitant sedative use, (3) intubated patients, and (4) inhalational anesthetics.

CRITICAL QUESTIONS

Etomidate

Etomidate is an imidazole derivative that acts as a hypnotic without analgesic properties and has a favorable hemodynamic profile in both adults and children.[9-11] There are limited data available on the use of etomidate in procedural sedation.

There were 56 articles reviewed. The articles that described the use of etomidate for procedural sedation in a setting compatible to the ED were then included. A total

of 4 ED-based studies were included. In addition, 4 studies evaluating the presence of adrenal suppression and 3 studies looking at myoclonus and/or pain with injection in patients receiving etomidate were included.

I. Is etomidate effective for providing procedural sedation in children in the ED?

Four recent studies have been published regarding the performance of etomidate as a procedural agent specifically in the ED. The literature does not clearly address the need for the use of analgesia with etomidate, thus no recommendation can be made in this document. In a retrospective review of 53 children (25 <10 years), Dickinson et al[12] described the drug's use in the reduction of pediatric orthopedic procedures. The authors found an 83% procedural success rate after the first attempt. After an initial retrospective pilot study of 9 patients, Ruth et al[13] designed a descriptive, prospective feasibility study that specifically evaluated complications arising from intravenous etomidate in 51 patients. Physician assessments reported a 98% (59/60) satisfaction with adequate sedation. This study included only 18 children aged 5 to 18 years with the predominance of pediatric sedation performed for fracture reduction. The authors reported that 98% (50/51) of the patients reached adequate sedation, and procedural success was reported in 92% (47/51) of the patients. In a retrospective observational study performed by Vinson and Bradbury[14] of 150 procedures, 11% (15/134) of patients enrolled were children aged 6 to 17 years. Moderate sedation was documented in 32% (48/150) of the procedures, and deep sedation was induced in 68% (102/150) of the procedures as measured by the Aldrete Postanesthetic Recovery Score. The authors reported that 11% (16/150) of the procedures required additional doses of medication to complete the procedure, with 9% (13/150) receiving 2 doses and 2% (3/150) requiring 3 doses. These results are complicated by the 23% (34/150) of procedures that used adjunctive medications including opiates, benzodiazepines, or both. In the 113 patients receiving etomidate only, the authors could identify no proportional increase in depth and duration of sedation with increasing mean etomidate doses.

Another smaller retrospective chart review of 46 adults and 2 children identified 8.3% (4/48) of patients with procedural failure.[15] Each of the retrospective studies have been criticized because of the inherent flaws associated with their incomplete data sets.

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. None specified.

Level C recommendations. Etomidate is an effective agent for procedural sedation in the pediatric patient population within the ED.

II. Is etomidate safe for providing procedural sedation in children in the ED?

Dickinson et al[12] documented side effects including 0.7% (1/153) of patients with nausea and 0.7% (1/153) of patients requiring a fluid bolus for transient hypotension. There were no reported incidences of patients who required assisted ventilation of any kind. Adverse events captured by Ruth et al[13] included brief desaturations requiring face-mask oxygen supplementation in 9.8% (5/51), myoclonus in 7.8% (4/51), vomiting in 1.9% (1/51), pain with injection in 1.9% (1/51), and a less than 30-second episode of desaturation-induced bradycardia that was "immediately" corrected with face-mask oxygen supplementation in 1.9% (1/51). The authors fail to further describe the pediatric age distribution, and no specific pediatric issues received comment. Vinson and Bradbury[14] described oxygen desaturation in 5 adults (N=150; 3.3%) that was treated with face-mask oxygen supplementation. Of these 5 patients, 4 (N=150; 2.7%) also received bag-assisted ventilation. The 5 patients needing supplemental face-mask oxygen all received higher doses of etomidate (0.23 mg/kg) and were older than 55 years; 2 (N=150; 1.3%) patients had emesis. A follow-up questionnaire revealed that 95% (114/120) of responders stated they would be "extremely" willing to have etomidate again. Keim et al[15] found 21% (10/48) of patients with adverse reactions. Respiratory complications occurred in 4% (2/48) of patients, with 1 patient developing transient apnea requiring bag-valve-mask ventilation, whereas another patient required a nonrebreather mask for oxygen desaturation below 90%. In addition, 4% (2/48) of patients developed emesis, and procedure failure was documented in 8% (4/48) of patients.

In a study by McDowell et al,[16] the etomidate group was associated with more episodes of vomiting (9.9%; 10/101) and agitation (4%; 4/101) compared with 603 reviewed charts of patients receiving propofol (0.5% [3] and 1.2% [7], respectively). The etomidate group did experience significantly less hypoxia (oxygen saturation <94%; 2% [2/101]) than the propofol group (15.7% [95/603]). Myoclonus was also noted in 18% (18/101) of the etomidate group.

Although trials investigating etomidate-induced adrenal suppression in procedural sedation are not available, numerous studies have demonstrated cortisol depression for up to 24 hours with as little as a single dose of etomidate. However, the levels consistently remain in the normal range with no clinically significant sequelae.[17-20]

Pain with injection and myoclonus are also commonly reported side effects associated with etomidate.[13,16,21] Pain with injection occurred in 1.9% (1/51) of patients in the study by Ruth et al[13] (patients were also given analgesics), and in 17% (5/29) of patients in the study by Helmers et al.[21] Myoclonus was noted in 7.8% (4/51),[13] 17.8% (18/101) (versus 0% [0/267] for ketamine and 0% [0/603] for propofol),[16] and 37.9% (11/29)[21] of patients. When present, myoclonus usually lasts less than 1 minute but can resemble seizure activity and can be decreased by the coadministration of other drugs. These tremors are benign and not epileptiform activity.[21,22]

One study has evaluated etomidate's ability to induce electroencephalogram burst suppression to facilitate intubation in the presence of increased intracranial pressure. A significant reduction in intracranial pressure was observed during tracheal manipulation, with minimal effects on cerebral perfusion pressure.[22]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. None specified.

Level C recommendations. Etomidate is a safe agent for procedural sedation in the pediatric patient population within the ED.

Fentanyl/Midazolam

Fentanyl is an opiate that is 100 times more potent than morphine. Opiates are powerful analgesics that also produce varying amounts of sedation and reduce anxiety through direct action on opiate receptors.[9] Fentanyl is active within 2 to 3 minutes of intravenous administration, with a duration of action of 20 to 30 minutes.[23]

Midazolam is a short-acting benzodiazepine. Benzodiazepines produce sedation, anxiolysis, and antegrade amnesia through direct action on a benzodiazepine receptor. Benzodiazepines have no analgesic properties. Midazolam is active within 2 to 3 minutes of intravenous administration, with a duration of approximately 30 minutes.[24]

Twenty-eight articles concerning the parenteral use of fentanyl and midazolam were reviewed. After grading, 14 articles were included in this analysis. These articles include several ED-based clinical studies and some studies involving only adults.

III. Are fentanyl and midazolam effective for providing procedural sedation in children in the ED?

Fentanyl and midazolam are widely used and effective agents for sedation and analgesia in the pediatric population. The efficacy of intravenous fentanyl and midazolam is reported to be high, ranging from 91% to 100%.[25-28] It has been found to be of similar efficacy when compared with alternative agents. The analgesic and sedative effects of fentanyl may be increased when combined with a benzodiazepine.[29]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Intravenous use of fentanyl and midazolam is effective for pediatric sedation during painful procedures in the ED.

Level C recommendations. None specified.

IV. Is the use of fentanyl and midazolam safe for providing procedural sedation for painful procedures in children in the ED?

The primary adverse effect of opiates is respiratory depression and resultant hypoxia and/or apnea. Additional side effects include nausea, vomiting, and pruritis.

In rare cases, chest wall rigidity, in addition to hypoxia from respiratory depression, is reported when fentanyl is given in moderate-to-large doses or with rapid administration.[30] The effects of fentanyl may be reversed with naloxone or naltrexone.[31]

The primary adverse effects of midazolam are respiratory depression, paradoxical excitement, and occasional hypotension.[32] The effects of midazolam may be reversed by flumazenil.

The use of opiates and benzodiazepines together is widely reported to produce a synergistic response of both the desired effects and adverse side effects.[33] In 2 adult studies, the risk of respiratory depression and apnea was increased (92% versus 50% and 63% versus 3%) when fentanyl was administered in conjunction with midazolam.[34,35] The strong respiratory depressant effect of the fentanyl and midazolam combination was further underscored by McQuillen and Steele[31] and Kennedy et al,[29] who both reported an increased risk of respiratory depression. However, 2 retrospective case series refute the assertion that fentanyl and midazolam in combination are more dangerous than either agent alone.[24,32] Two randomized trials did not find a significantly increased risk for fentanyl

and midazolam in combination, but both of these studies were very small.[25,26] In Pena and Krauss'[23] large prospective series of 1,180 patients, the authors found no increased risk of respiratory depression with fentanyl and midazolam compared with other agents. The disparity in these findings may be related to the method used to assess respiratory depression or monitor for serious adverse events. Most studies report very low incidences of apnea or serious adverse events (0% to 2%), with much higher frequencies of decreased pulse oximetry or increases in end-tidal carbon dioxide ($ETCO_2$). When these occurred, the patients usually responded to verbal stimulation, repositioning, or other minor interventions. Rarely did patients require bag-valve-mask ventilation or intubation.

The incidence of serious respiratory events is quite low for pediatric sedation with fentanyl and midazolam. Of 334 patients reported by Graff et al,[32] 11% had minor respiratory events and 2 required naloxone. No patients required ventilatory assistance. Hostetler and Barnard[33] reported transient hypoxia in 15% of 28 children receiving fentanyl and midazolam and no life-threatening events. Other reports similarly found that approximately 10% to 20% of patients had a mild respiratory event requiring oxygen or stimulation, while the need for respiratory assistance was rare, and the incidence of life-threatening events was near zero.[23,26,29,32] One case report of a respiratory arrest in an unmonitored 13-month-old child receiving fentanyl and midazolam serves as a reminder that these drugs do have potentially life-threatening consequences and that close monitoring and emergency backup measures are essential.[36]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. The combination of fentanyl and midazolam appears to result in a greater risk of respiratory depression; therefore, the clinician should take particular care to monitor the patient for signs of respiratory depression and should have appropriate training and support to treat apnea.

Level C recommendations. None specified.

Ketamine

Ketamine is a sedative-analgesic medication for procedural sedation.[9] It has a unique mechanism of action based on N-methyl-D-aspartate glutamate receptor antagonism and is classified as a dissociative agent allowing potent sedation, analgesia, and amnesia during painful procedures. Onset of sedation-analgesia is rapid by either intravenous or intramuscular administration. Twenty-nine articles concerning the parenteral use of ketamine in an ED were reviewed. After grading, 19 articles were included in this analysis. There were no ED-based studies of ketamine for imaging sedation.

V. Is ketamine effective for providing procedural sedation in children in the ED?

A partially blinded, randomized, controlled trial of intravenous propofol/fentanyl (1 mg/kg initially with smaller aliquots and 1 to 2 μg/kg aliquots, respectively) versus ketamine/midazolam (1 to 2 mg/kg and 0.05 mg/kg aliquots, respectively) for orthopedic procedural sedation in children aged 3 to 18 years showed ketamine/midazolam to have statistically better but questionable clinical significance, improved Observation Score of Behavioral Distress–Revised (OSBD-R) scores during manipulation (0.278 versus 0.084 [Δ0.194; 95% confidence interval (CI) 0.048 to 0.340; P=.008]), and equivalent orthopedic, nursing, and parental satisfaction scores.[37] Intravenous ketamine/midazolam (1 mg/kg and 0.1 mg/kg, respectively) was superior to intranasal midazolam (0.5 mg/kg) in patients undergoing laceration repair for sedation onset and consistency of effect. At 30 minutes, the average sedation score was 2.4 versus 3.5 (P<.001), and the average sedation visual analog scale (VAS) score was 1.8 versus 3.8 (P<.001). Physician and parental satisfaction was rated "excellent or good" in 88% versus 54% (P=.006) and 92% versus 65% (P=.02), respectively.[38] Intramuscular ketamine (4 mg/kg) was superior to intramuscular meperidine/promethazine/chlorpromazine in a study of patients undergoing wound repair, burn care, or lumbar puncture, demonstrating a mean OSBD-R score of 2.7 versus 9.8 (P<.003).[39] Ketamine/midazolam was superior to fentanyl/midazolam for procedural sedation for orthopedic procedures demonstrating a mean OSBD-R score of 1.12 versus 2.70 (P≤.0001).[29] In these 3 Class I studies, the efficacy of ketamine for "adequacy of sedation" to complete the procedure was 100%.

Low-dose intramuscular ketamine (2.5 mg/kg) was shown to be superior to intranasal midazolam in laceration repair: 100% versus 70% were rated as "cooperative" or "intermittently crying" during repair (P<.01).[40] Several prospectively designed, single treatment arm studies have also shown that ketamine has a high efficacy rate and high provider and parental satisfaction.[41-43] (See Evidentiary Table for comparisons.)

Patient Management Recommendations

Level A recommendations. Ketamine is effective either as a sole agent or in combination with a benzodiazepine for brief painful procedures in children.

Level B recommendations. None specified.

Level C recommendations. None specified.

VI. Is ketamine safe for providing procedural sedation in children in the ED?

Two Class I studies for safety, either comparing ketamine/midazolam to fentanyl/midazolam or ketamine with or without midazolam, have demonstrated a good safety profile for ketamine in procedural sedation in children.[29,44] Kennedy et al[29] found that, for ketamine/midazolam versus fentanyl/midazolam, in 260 cases patients had an incidence of hypoxemia of 6% versus 24% during sedation (*P*=.001), required breathing cues 1% versus 12% of the time (*P*=.001), required an airway maneuver 6% versus 11% of the time (*P*=NS), and required bag-valve-mask ventilatory support 2% versus 0% of the time (*P*=NS). A small pilot study of 20 pediatric patients undergoing ketamine sedation and using sidestream $ETCO_2$ monitoring demonstrated no evidence of hypoventilation.[45] In a study of 266 sedations, of which 137 received midazolam, Wathen et al[44] found that the rates of adverse effects in the ketamine versus ketamine/midazolam groups of recovery agitation were 7.1% versus 6.2% (Δ0.8 [95% CI −5.3 to 7.0]); Spo_2 less than 90% in 1.6% versus 7.3% (Δ −5.7% [95% CI −5.7% to −0.9%]); and emesis in 19.4% versus 9.6% (Δ9.8% [95% CI 1.4% to 18.2%]). For patients older than 10 years, recovery agitation was 5.7% versus 35.7% (Δ −30.0% [95% CI −49.3% to −10.7%]). Several large and moderate-sized Class II studies confirm that ketamine is very safe when used with adequate monitoring and resuscitation equipment for procedural sedation in children in the ED. There was no evidence of clinically evident aspiration in any of these studies.[23,37,38,40-43,46-52] Specifically, the incidence of laryngospasm is very low: 1/108 (0.9%) in 1 prospective cohort study[52] and 1.4% in a large (1,022 patients) retrospective cohort study.[50] However, a study of pediatric patients undergoing gastroenterology procedures (generally, esophagogastroduodenoscopy and/or colonoscopy) performed in a gastroenterology suite or in the pediatric ICU found transient laryngospasms occurred in 8.2% of patients. The only predictor of laryngospasm was decreasing age (13.9% in children <6 years versus 3.6% in children ≥6 years). Nearly half the patients in this study were ASA status III or greater.[53]

Of note, despite some concern for the use of ketamine for sedation for procedures involving the oropharyngeal and upper aerodigestive tract, several studies have evaluated this issue. A retrospective, uncontrolled comparison in esophageal foreign body removal using ketamine/midazolam versus fentanyl/midazolam showed hypoxemia in 10.7% (95% CI 6.6% to 14.8%) versus 15.4% (95% CI 8.6% to 22.2%) of patients; stridor in 1.8% (95% CI 0% to 3.6%) versus 0% (95% CI 0% to 1.9%) of patients; and bag-valve-mask ventilatory support in 3.6% (95% CI 1.1% to 6.1%) versus 3.8% (95% CI 0.2% to 7.4%) of patients.[33] Another prospective, nonrandomized study of intramuscular ketamine/midazolam for dental procedural sedations in the ED showed Spo_2 greater than 96% and no adverse airway events in all patients, and emesis in only 2 (4.8%) patients.[43]

Patient Management Recommendations

Level A recommendations. Ketamine can be safely used for procedural sedation in children in the ED, but may require head positioning, supplemental oxygen, occasional bag-valve-mask ventilatory support, and measures to address laryngospasm.

Level B recommendations. None specified.

Level C recommendations. None specified.

VII. Does the addition of midazolam as an adjunct to ketamine for procedural sedation for children in the ED reduce recovery agitation or vomiting?

In many centers, ketamine is administered along with a benzodiazepine (usually midazolam) to reduce the incidence of unpleasant recovery agitation, hallucinations, or "bad dreams."

Two Class I studies have shown that midazolam does not decrease the incidence of recovery agitation when used with ketamine. Wathen et al[44] found that the incidence of recovery agitation in the ketamine versus ketamine/midazolam groups was 7.1% versus 6.2% (Δ0.8 [95% CI −5.3% to 7.0%]). In addition, in the age group greater than 10 years of age, the incidence of recovery agitation was increased in the ketamine/midazolam group 5.7% versus 35.7% (Δ −30.0% [95% CI −49.3% to −10.7%]). The incidence of emesis was decreased in the ketamine/midazolam group: 19.4% versus 9.6% (Δ9.8% [95% CI 1.4% to 18.2%]). Sherwin et al[46] demonstrated no difference between the ketamine and ketamine/midazolam treatment groups in the incidence of recovery agitation (VAS 5 mm [interquartile range 3 mm to 14 mm] versus 4 mm [interquartile range 2 mm to 19 mm]; *P*=.70), and the incidence of emesis 12% versus 2% (Δ −10% [95% CI −20% to 0%]; *P*=.058).

Patient Management Recommendations

Level A recommendations. The addition of midazolam as an adjunct to ketamine for procedural sedation for children in the ED does not decrease the incidence of emergent reactions.

Level B recommendations. The addition of midazolam as an adjunct to ketamine for procedural sedation for children decreases the incidence of emesis.

Level C recommendations. None specified.

Methohexital

Methohexital is a rapid-acting barbiturate that produces its effect through direct stimulation of the gamma-aminobutyric acid receptor.[9] As a barbiturate, methohexital may be described as a pure sedative. As such, most of its applications are for sedation for painless diagnostic studies. A review of methohexital use in pediatric patients for procedural sedation was performed. A total of 50 articles were reviewed; however, only articles describing methohexital use for procedural sedation compatible to ED practice were included in the analysis. Those articles describing methohexital effectiveness as part of an induction process for general anesthesia in the operating room were excluded from analysis except for a single study describing only the hemodynamic parameters in children after a rectal dose commonly used in the ED. There were 6 articles selected for inclusion in this analysis.

VIII. Is methohexital effective for providing procedural sedation in children in the ED?

In all but 1 of the studies, the patients underwent sedation with methohexital for computed tomography (CT) or magnetic resonance imaging (MRI) scan studies.[54-58] In the remaining study, the patients underwent oncology-related procedures such as lumbar punctures, in which local anesthesia was used.[59]

Three different routes were described for methohexital administration (ie, intravenous, intramuscular, rectal) for CT scans.[54-59] For all of the studies examining use for CT or MRI sedation, methohexital demonstrated efficacy from 92% to 100% as determined by cooperation with study and quality of study obtained.[56-59] For the intravenous route, Class II and Class III data exist supporting efficacy of 99% to 100% for methohexital as determined by the ability to complete either CT studies or hematology/oncology procedures.[57,59] For the intramuscular routes, a single Class II study documented 92% efficacy for ability to complete CT scan.[58] For rectal administration, a single Class I study demonstrated 95% efficacy.[56] Efficacy was defined on 2 separate 3-point scales, 1 examining the need for restraint and the other motion artifacts on the CT scan. Doses of methohexital described included 1 mg/kg intravenously, 10 mg/kg intramuscularly, and 25 mg/kg rectally.

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Methohexital administered by either the intravenous, intramuscular, or rectal routes can provide effective sedation for children undergoing painless diagnostic studies.

Level C recommendations. None specified.

IX. Is methohexital safe for providing procedural sedation in children in the ED?

As a barbiturate, methohexital has the potential to produce hypotension, hypoventilation, and apnea in children in whom it is administered.[54-59] Safety documentation was demonstrated through prospective monitoring of children undergoing sedation with methohexital. Continuous cardiac monitoring, pulse oximetry, and intermittent blood pressure monitoring were all used to document the safety of this medication.

Regardless of the route of administration, methohexital has the capacity to produce hypoventilation leading to hypoxia. The incidence of hypoxia with methohexital ranged from 1% to 6%.[55-57,59] In all but 1 of the studies, the hypoxia was resolved through repositioning of the patient or administration of supplemental oxygen.[55-57] In the only grade I study, 3 out of 100 patients required bag-valve-mask ventilation support, although this was performed as required by a sedation protocol and not at the discretion of the managing clinician.[56] No child demonstrated adverse affects from the hypoxia, and none required endotracheal intubation. Transient hypotension was noted in up to 17% of 1 group of patients when administered intravenously.[59] When studied echocardiographically, rectal administration was found to produce clinically insignificant hemodynamic effects.[54]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Methohexital can be safely used for procedural sedation but may require head positioning, supplemental oxygen, and occasional bag-valve-mask ventilatory support.

Level C recommendations. None specified.

Pentobarbital

Pentobarbital is a short-acting barbiturate used to facilitate obtaining diagnostic studies such as CT and MRI

scans of children.[9] Barbiturates function at the gamma-aminobutyric acid receptor complex and produce a central nervous system depressant effect. Pentobarbital is a pure sedative agent. There were 14 articles reviewed and 11 studies included for this analysis. Most studies were done in fasted patients undergoing painless, diagnostic procedures.

X. Is pentobarbital effective for providing procedural sedation in children in the ED?

In the 11 studies included, pentobarbital was given intravenously, except in 1 study in which it was given orally.[60] Greenberg et al,[61] using 6 mg/kg of pentobarbital divided in 3 doses to a maximum of 200 mg, found that 8% (8 children out of 100) of patients were not successfully sedated (were unable to complete their diagnostic study). The children who were not successfully sedated were either 12 years or older (characteristics of older children that required sedation were not defined in this article) or weighed greater than 50 kg, which may reflect the 200-mg maximum dose in this study. Best results were seen in children younger than 8 years.

When using pentobarbital for pediatric sedation, higher success rates of 99% or greater were found by Karian et al,[62] Mason et al,[63] and Strain et al.[64]

Mason et al,[63] in a nonblinded prospective study of 1,070 children, compared the use of intravenous pentobarbital alone and a combination of pentobarbital and midazolam and found no beneficial effect by adding midazolam. The success rate of the pentobarbital alone group was 99.5% compared with 99.8% in the pentobarbital-midazolam group. The use of midazolam increased time to sedation (pentobarbital-midazolam 8.0±4.4 minutes versus pentobarbital 6.5±4.4 minutes) and also prolonged the time to discharge by approximately 14 minutes when used in conjunction with pentobarbital (pentobarbital-midazolam 120±32 minutes versus pentobarbital 106±34 minutes).

Moro-Sutherland et al[65] compared the efficacy of intravenous midazolam to intravenous pentobarbital when used for sedation of 55 pediatric patients undergoing CT imaging of the head in the ED and found that pentobarbital had a 97% success rate compared with a 19% success rate for midazolam.

In a study by Kain et al[66] of 58 pediatric patients, group 1 received 1 to 2 mg/kg of propofol followed by propofol infusion, and group 2 received 1 to 3 mg/kg of thiopental followed by a 2- to 3-mg/kg pentobarbital bolus and supplemental doses of 1 to 2 mg/kg of thiopental were administered to maintain sedation. Time to recovery in group 1 was 19±7 minutes versus 35±20 minutes in group 2. Time to discharge in group 1 was 24±6 minutes versus 40±11 minutes in group 2. Pentobarbital had a greater recovery time and longer time to discharge than propofol; however, adverse reactions were not addressed in this study.

Rooks et al,[60] in a study of 675 pediatric patients, compared the use of oral pentobarbital at an average dose of 4 mg/kg to oral chloral hydrate at an average dose of 50 mg/kg and found similar time to sedation (pentobarbital 19±14 minutes and choral hydrate 16±11 minutes), time to discharge (pentobarbital 100±35 minutes and chloral hydrate 103±36 minutes), length of sedation (pentobarbital 81±34 minutes and chloral hydrate 81±34 minutes), and adverse reactions in both groups (pentobarbital 1.6 % and chloral hydrate 1.7%). Adverse reactions were reported in 5 (1.6%) patients in the oral pentobarbital group versus 6 (1.7%) patients in the chloral hydrate group. In the pentobarbital group, 1 patient vomited after the second dose of pentobarbital, 1 patient who received 6 mg/kg had prolonged sedation with discharge after 5 hours, 1 patient had decrease in oxygen saturation level (patient had a history of severe gastroesophageal reflux) and required suctioning and airway repositioning, 1 patient had inspiratory and expiratory wheezing and responded to albuterol (patient had preexisting respiratory condition), and 1 patient had a paradoxical reaction. One delayed event occurred in the oral pentobarbital group 4 hours after discharge when the patient had an episode of perioral cyanosis and was observed in the ED for 4 hours and discharged. In the chloral hydrate group, there were 4 patients with mild decrease in oxygen saturation. Of these 4, 2 patients required airway repositioning and 1 required bag-valve-mask ventilation. Other adverse reactions included irritability and hyperactivity lasting 30 minutes, and 1 episode of vomiting.

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Pentobarbital alone is effective in producing cooperation for painless diagnostic procedures. Best sedation results are seen in children younger than 8 years.

Level C recommendations. None specified.

XI. Is pentobarbital safe for providing procedural sedation in children in the ED?

Transient respiratory depression to oxygen saturation less than 10% below the baseline has been reported from

1.2% to 7.5% of pediatric patients undergoing sedation with pentobarbital, although in most cases oxygen desaturation responded to interventions such as head positioning or supplemental oxygen.[60-64,67,68]

In a study by Sanderson[69] using a pentobarbital average dose of 4.6 mg/kg, there was a 14% rate of complications, including desaturation, vomiting, increased airway secretions, airway obstruction, coughing, and bronchospasm.

Emergence reactions were documented in 4 separate studies.[60,61,63,68] Hyperactivity was noted by Slovis et al[68] and Greenberg et al[61] in 5% (17/357) to 7% (7/100) of children sedated with pentobarbital. Slovis et al[68] also reported an even higher rate of 8.4% in children older than 8 years. However, Greenberg et al[61] noted that this only led to sedation failure in 1 child out of 100. Rooks et al[60] and Mason et al[63] described a paradoxical reaction as a patient experiencing sustained inconsolability and severe irritability and combativeness for more than 30 minutes after the administration of pentobarbital or after awakening from the sedation. A paradoxical reaction occurred in less than 0.01% (1/317) of children in the oral pentobarbital group in the study by Rooks et al,[60] and in 1.5% (10/640) of children in the intravenous pentobarbital group in the study by Mason et al.[63] Emesis was reported in 0.53% to 1% of the patients.[61,63,67] One study reported a 3% incidence of coughing that led to a 1% failure rate.[61]

The duration of action is variable, the average induction time is 6 minutes, and the duration of sedation is up to 106 minutes, but most patients are alert within 30 to 60 minutes of administration.[63,65] Greenberg et al[61] found a 2% prolonged sedation rate of greater than 120 minutes when the maximum suggested dose was exceeded.

Slovis et al[68] performed a 24-hour follow-up of pediatric patients aged 12 months and older who had been sedated for MRI by using 3 mg/kg of pentobarbital alone or followed by 1 μg/kg of fentanyl if the patient was not asleep 5 minutes after the administration of pentobarbital; the study found that 19% of children slept for more than 8 hours. The multiple-dose regimen of pentobarbital had a significant short-term effect on children aged younger than 8 years, with 35% sleeping longer than 8 hours after the MRI.

Bloomfield et al[70] found greater recovery time (range 0 to 67 minutes) for pentobarbital compared with propofol (range 1 to 18 minutes); however, the pentobarbital group had fewer adverse reactions, less decrease in pulse rate, and less transient decrease in oxygen saturation than propofol.

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Pentobarbital can be safely used for procedural sedation but may require head positioning, supplemental oxygen, and occasional bag-valve-mask ventilatory support.

Level C recommendations. None specified.

Propofol

Propofol is a highly lipid-soluble alkyl phenol sedative agent.[9] Operating through an interaction with the gamma-aminobutyric acid receptor system, propofol is proposed to prolong the duration of contact between gamma-aminobutyric acid and its receptor site. This action promotes an extended chloride influx into the neuron, leading to hyperpolarization of the neuronal cell membrane.[71]

Propofol is classified as a pure sedative. Unlike other pure sedatives, because of its potency propofol has been used for both painful and painless procedures. For painless diagnostic studies such as MRI or CT scans, propofol is generally used alone. For painful procedures, it is frequently combined with a short-acting potent opiate analgesic, although it has been used alone for painful procedures.[37,72]

A total of 63 articles were reviewed; however, only articles describing propofol use for procedural sedation compatible to ED practice were included in the analysis. Although propofol has an extensive history of safe and effective use in general anesthesia, articles describing its use as an induction agent in the operating room or in combination with inhalation agents were not selected. Articles describing propofol's use for brief procedures, such as lumbar puncture for intrathecal medications or bone marrow biopsies, were included. Although these are not necessarily ED procedures, the manner in which propofol was used to facilitate a brief painful activity was considered consistent with how the drug may be used in the ED. There were 14 articles selected for inclusion in the analysis.

XII. Is propofol effective for providing procedural sedation in children in the ED?

In all instances, propofol was administered intravenously. For short procedures, propofol was administered as a bolus followed by additional doses as needed to maintain cooperation.[37,73-76] For longer procedures, propofol treatment was initiated with an intravenous bolus, with sedation maintained through a continuous infusion.[66,70,72,77-82]

Of the studies included in the analysis, 12 described propofol's efficacy in providing cooperation for an intended procedure. One study with Class I and 1 with Class III evidence used the 6-point Ramsay scoring system in documenting propofol's efficacy.[72,82] In these studies, propofol produced mean sedation levels of 5.5[72] and 5.6.[82] In 1 of these studies, propofol was paired with a fixed dose of an opiate.[72] A second study with Class I evidence again combined propofol with an opiate but used the OSBD-R scoring system to rate the efficacy of this combination for orthopedic procedures.[37] Propofol's sedation score was 0.278 in this system, in which a score of 0 represents no distress, whereas 23.5 represents maximal distress. Another study with Class II evidence used radiologists' objective assessments of lack of motion artifacts in MRI scans and showed good efficacy for children sedated with propofol, with mean quality scores of 9.0 out of 10.[66]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Propofol combined with opiate agents is effective in producing cooperation for painful therapeutic or diagnostic studies.

Level C recommendations. Propofol alone, without the concomitant use of opiate agents, is likely to be effective in producing sedation for painless diagnostic studies in ED patients.

XIII. Is propofol safe for providing procedural sedation in children in the ED?

In addition to its sedative hypnotic properties, propofol also has the potential to produce hypoventilation and apnea. Because of the monitoring practices used with procedural sedation, Class I prospective data are available concerning propofol's respiratory depression effects. The specific definition of hypoxia varied between studies, with some regarding pulse oximetry levels below 95% as hypoxia whereas others did not consider a patient hypoxic until saturations decreased below 90%.

If definitions of hypoxia or hypoventilation are accepted as study specific, then 7 studies with Class I to III evidence indicate that this occurs in 2% to 31% of patients sedated with a propofol bolus and infusion.[37,66,70,72,78,79,82] In all but 1 of the studies, the hypoxia responded to minimal interventions such as head repositioning or supplemental oxygen. In 1 Class I study, oxygen desaturation occurred in 11.6% of patients, with no intervention required aside from supplemental oxygen.[72] In another Class I study, the desaturation rate was 31% but was again transient, responding to jaw thrusts or supplemental oxygen.[37] In a single Class III study using high doses of propofol in an ICU setting, 20% of patients experienced hypoxia and 19% of patients required bag-valve-mask ventilation.[82] This study was in marked contrast to data in all other studies, in which the highest incidence of bag-valve-mask ventilation was 2.5%. In the 2 studies evaluating propofol use for painless diagnostic sedation for MRI scans, the incidence of hypoxia was 5% to 10%.[66,70]

Propofol also had hemodynamic effects associated with decreased peripheral vascular resistance when administered intravenously. Clinically insignificant transient decreases in blood pressure are reported in some patients, although in none of these patients was any intervention required.[37,77,78,81,82]

Because of the hydrophobic nature of propofol, it must be delivered in a lipophylic suspension. Such vehicles can produce pain on injection of the drug. Clinical measures described to limit this effect include pretreatment of the vein with lidocaine and rapid infusion rates of normal saline solution with a slow injection of propofol.[74,82]

Patient Management Recommendations

Level A recommendations. None specified.

Level B recommendations. Propofol combined with opiate agents can be safely used for procedural sedation but may require head positioning, supplemental oxygen, and occasional bag-valve-mask ventilatory support.

Level C recommendations. Propofol alone, without the concomitant use of opiate agents, can be safely used for procedural sedation but may require head positioning, supplemental oxygen, and occasional bag-valve-mask ventilatory support.

Evidentiary Table.

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Guldner et al[10]	Retrospective pediatric rapid sequence intubation study in ED; intravenous dosing of etomidate with median dose 0.32±0.12 mg/kg; adjunctive medications included atropine in 78/105 (74%), lidocaine in 62/105 (59%), morphine in 3/105 (3%), and midazolam in 7/105 (7%); 105 charts; average age 3±2.9 y	The authors describe a slight increase in blood pressure; no episodes of myoclonus or seizure activity noted; there were no reported episodes of adrenal suppression determined either clinically or with laboratory testing as a result of etomidate administration	Design was retrospective; the main clinical endpoint was adrenal suppression	The authors note very little hemodynamic changes with the use of etomidate	Efficacy was not objectively measured	III
Sokolove et al[11]	Retrospective pediatric study evaluating rapid sequence intubation at 2 academic centers of both hospital and ED patients; etomidate IV dosing with mean dose of 0.37 mg/kg; adjunctive medications included lidocaine in 58/100 (58%), atropine in 37/100 (37%), and benzodiazepines in 9/100 (9%); 100 patients aged <10 y	Etomidate resulted in a mean blood pressure decrease of 1% during rapid sequence intubation; clinically important adrenal suppression was defined as the need for exogenous corticosteroid replacement for suspected adrenal insufficiency during the hospital course; inpatient records were available on 99 patients, and none of these patients received corticosteroids for suspected adrenal suppression	Design; only endpoints of study were hypotension and adrenal suppression; all patients were intubated	Based on a low incidence of hypotension and no important adrenal suppression	Efficacy was not objectively measured	III
Dickinson et al[12]	Retrospective descriptive study in a university-based ED; 53 charts of children aged <18 y; all patients received IV etomidate (most received 0.1 to 0.2 mg/kg) and an IV opioid; a single etomidate dose was required in 40/53 (75%) patients and a second dose was necessary in 9/53 (17%) patients; 4/53 (7.5%) patients also received a dose of midazolam; 0.2-mg/kg initial bolus	There were no major adverse effects; 1 patient reported nausea, and another was given a fluid bolus for transient hypotension; no patient required ventilatory assistance; measure of efficacy was procedural success	Retrospective design; selection bias; documentation concerns as demonstrated by no reported cases of myoclonus	Results suggest that etomidate may be used safely in children, but the authors warn that further larger prospective studies are indicated	III	III
Ruth et al[13]	2-phase feasibility study: retrospective pilot followed by a prospective descriptive study performed in a university-based ED; IV dosing in 9 patients in the pilot phase and in 51 patients in the prospective phase; a mean of 1.6 doses were required to complete procedures (range 1–3 doses); initial etomidate bolus used was 0.1 mg/kg; 18 patients included aged 1–25 y	Procedural success was achieved in 56/60 (93%) patients, with adequate sedation as documented by the physician in 59/60 (98%) patients; 12 complications were reported including oxygen desaturation below 90% (5), myoclonus (4), vomiting (1), pain with injection (1), and a "brief" bradycardic episode; none of the patients required ventilatory assistance	13 patients had missing nursing records, and another 4 patients lacked depth of sedation information	Etomidate administered IV for procedural sedation in the ED was both effective and safe in this group of patients	III	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Vinson and Bradbury[14]	Retrospective observational study in 3 affiliated suburban EDs; chart review performed with prospective questionnaire sent to patients, with 120 (90%) completed; IV etomidate dosing with mean cumulative dose of 0.2 mg/kg; 134 total patients enrolled aged 6–93 y; 3 patients were aged 6–12 y and 12 patients included were aged 13–17 y	Moderate sedation was achieved in 48 (32%) patients, and deep sedation induced in 102 (68%) patients as measured by the Aldrete Postanesthetic Recovery Score; 5 (4.7%) of 7 adverse reactions were the result of oxygen desaturation requiring face mask oxygen; 4/5 also received bag-assisted ventilation; each of these patients were >55 y and had received relatively higher doses of etomidate, 0.23 mg/kg compared with 0.19 mg/kg in the nonrespiratory-compromised patients; no intubations; 2 patients experienced emesis; 114 (94%) responders stated they would be "extremely" willing to have this medication again	Design; few pediatrics; no standardized dosing; adjunctive medications given in 23% of procedures; only patients meeting ASA status I or II were candidates for procedural sedation; some patients were entered into the study more than once	The authors concluded that etomidate appears to be a brief, safe, and effective drug for emergency procedural sedation; however, the power of the study is not enough to evaluate incidence of all complications	III	III
Keim et al[15]	Retrospective chart review in a university-based ED; the charts of 46 adults and 2 children, all receiving IV dosing were reviewed; mean initial dose of etomidate was 13 mg	10/48 (21%) of patients had adverse reactions; 1 (2%) patient had transient apnea requiring bag-valve-mask ventilation (this patient had multiple doses of analgesics as well); 1 (2%) patient required a nonrebreather for a desaturation <90%; emesis in 2 (4%) patients; anxiety in 2 (4%) patients; 4 (8%) patients had failed procedures	Design; limited pediatric patients; not an etomidate-only study, so some adverse side effects may be related to other sedatives and analgesics; documentation concerns as demonstrated by no reported cases of myoclonus	The authors conclude that although further study is indicated, etomidate holds promise as a procedural agent in the ED; the authors further stressed the need for adequate monitoring in the ED when using agents that may induce deep sedation	III	III
McDowell et al[16]	Retrospective review of 971 pediatric oncology patients at a university hospital; 101 received IV etomidate (0.3 mg/kg) combined with either fentanyl or alfentanil for brief diagnostic or therapeutic procedures; all patients were <19 y	Etomidate was effective as defined by procedural success but was associated with more episodes of vomiting (9.9%) and agitation (4%) compared with propofol (0.5%) and (1.2%), respectively	Retrospective design; all 101 etomidate patients received narcotics for analgesia that could confound both the efficacy and safety data	Etomidate is an effective agent but had more vomiting and agitation when compared with propofol; however, propofol had a greater incidence of hypoxia (15.7%) than etomidate (2%)	Efficacy was not objectively measured	III
Schenarts et al [17]	Prospective randomized controlled trial; included 10 etomidate and 8 control (midazolam) patients; each had a 4-h, 12-h, and 24-h cosyntropin stimulation test performed after standard drug administration during rapid sequence intubation induction in the ED; patients were ≥18 y, with a mean age of 58.4 y	Although a significant decrease in the normal adrenal response was noted at the 4-h level, all measured levels remained within normal levels throughout the study process; at 12 h, levels were no longer affected by the single 0.3-mg/kg induction dose	Study design does not evaluate clinical significance of brief adrenal suppression; no pre-induction cortisol levels were obtained; 13 additional patients were excluded	The authors concluded that, although a single dose of etomidate resulted in a decrease in normal adrenal response, adrenocortical levels remained in a normal laboratory range	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Absalom et al[18]	Prospective randomized trial; adrenocortical function of 35 critically ill patients was evaluated at pre-induction of general anesthesia in operating room with etomidate or thiopentone and after 24 h; each patient with an ASA status $\geq$III and aged $\geq$16 y	The etomidate group was significant for more patients with an ACTH-stimulated cortisol increment $<$200 nmol/L; however, cortisol levels were never documented as low during the study	Number of patients aged 16–18 y not given; no baseline ACTH stimulation performed before induction; only 3 cortisol levels obtained; study power may be too small to show a significant difference	No significant difference between pre- and post-ACTH cortisol levels; significance of findings of the smaller ACTH-stimulated increment unclear	Efficacy was not objectively measured	III
Allolio et al[19]	Prospective controlled trial; 29 patients undergoing general anesthesia induction were randomly assigned to etomidate or thiopentone, and ACTH and cortisol levels were measured up to 240 min after induction	The etomidate group had a significantly higher ACTH level and a significantly lower cortisol level; cortisol levels remained in a normal range	All patients were aged >14 y	The authors conclude that etomidate is safe for minor surgeries, but the adrenal suppression may cause problems for patients who require a greater adrenal response	Efficacy was not objectively measured	III
Allolio et al[20]	Prospective controlled trial evaluating the effect of a single induction dose of IV etomidate or thiopentone on adrenocortical function up to 210 min after induction; included 14 patients undergoing induction for general anesthesia; patient aged 14–74 y; with mean age for etomidate group of 45.5$\pm$16.1 y	ACTH levels were elevated in the etomidate group but not to significant levels compared with the thiopentone group; demonstrated suppression of cortisol levels compared with thiopentone dosing	Time of day not noted	Authors found that despite inhibition of 11 β-hydroxylase after etomidate induction, no other comparable blockade of other enzymes in the corticosteroid-synthetic pathway could be demonstrated; confirmed previous data demonstrating suppression of cortisol levels with single etomidate dosing	Efficacy was not objectively measured	II
Helmers et al[21]	Prospective double-blind controlled trial to determine if IV injection of droperidol or fentanyl before etomidate could attenuate side effects of pain and myoclonus; 83 patients aged 14–78 y with ASA status I, II, and III were enrolled; a severity score was assigned to pain and involuntary movements; operating room study	The incidence of pain on delivery in patients was: etomidate+normal saline solution 17% (5/29), etomidate+droperidol 16.7% (4/24), etomidate+fentanyl 18.5% (5/27); the incidence of myoclonus in patients was: etomidate+normal saline solution 37.9% (11/29), etomidate+droperidol 14.3% (3/24), etomidate+fentanyl 12.5% (3/24) ($P<.05$ for the groups using etomidate+another drug vs etomidate alone)	Not a sedation study; evaluated side effects during initial induction only; potential bias in scoring of pain and myoclonus	Both fentanyl and droperidol showed a significant difference in attenuating myoclonus after etomidate administration	Efficacy was not objectively measured	II

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Modica and Tempelhoff[22]	Prospective observational study; included 8 patients meeting ASA III–IV status with space occupying lesions and undergoing surgery; IV dosing; ages 18–71 y; anesthesia was induced with 0.2-mg/kg of etomidate followed by a 20-mg/min infusion	All patients monitored during induction with IV etomidate for EEG burst suppression and changes in intracranial pressure; the etomidate bolus required to reach burst suppression was 1.28±0.11 mg/kg	No pediatric patients; small study size	Etomidate did result in significant reduction in intracranial pressure during intubation	Efficacy was not objectively measured	II
Pena and Krauss[23]	Prospective case series of 1,180 patients aged <21 y requiring procedural sedation in pediatric ED of large urban hospital using standard sedation record; midazolam and fentanyl used in 391, IV midazolam in 67, oral midazolam in 62, IN midazolam in 3; remainder used a variety of other drugs and combinations; 180 patients had IM ketamine/midazolam (3.30±0.80 mg/unknown); 40 patients had IV ketamine/midazolam (1.31±0.45 mg/unknown)	For fentanyl/midazolam: adverse event rate was 2.3%, with no serious or life-threatening complications; complications included oxygen desaturation in 10 (0.8%), paradoxical reaction in 7 (0.6%), emesis in 3 (0.25%), requirement for supplemental oxygen in 2 (0.17%); no significant differences between regimens; for ketamine/midazolam: 1.8% experienced adverse event (1 laryngospasm, 2 desaturations, 1 emesis)	Wide variety of agents and techniques; efficacy not measured; authors conclude that fentanyl/midazolam does not have increased rate of respiratory complications, but data show OR of 2.94 (95% CI 0.93–10.29, *P*=.070); small sample size for ketamine, selection bias, single center	Procedural sedation (fentanyl/midazolam or ketamine/midazolam) can be safely administered in pediatric ED by pediatric emergency physician; adverse event rate is low	Efficacy was not objectively measured	III
Sievers et al[24]	Prospective case series of 24 patients undergoing 70 pediatric oncology procedures using IV midazolam with (59%) or without (41%) morphine or fentanyl; mean age 7.83±4.44 y (range 1.5–15.5 y); pediatric oncology clinic treatment room	Anxiety scores were highest on entry into treatment room and lowered during the procedure to levels approaching preprocedure baseline; restraint requirements were: much (20%), some (35%), none (45%); 13% experienced desaturation (oxygen saturation <90%), 14% required verbal stimulation, and 3% required oxygen; no patients required assisted ventilation or intubation; no serious complications; amnesia complete in 62%, partial in 28%	Sample size too small to make conclusions about adverse events; small sample size precludes conclusion that adding fentanyl to midazolam does not increase respiratory complications	Midazolam alone can cause respiratory depression in absence of narcotics; hypoxemia is dose related and subject to marked individual variation; observation period of 60 min after procedure appeared sufficient	III	III
Sandler et al[25]	Prospective, randomized crossover trial of midazolam vs fentanyl as premedication for painful oncology procedures; pediatric oncology clinic treatment room; mean age 10.04±5.01 y (range 3.33–18.77 y); 86 procedures on 27 patients	No serious adverse events in either group; no episodes of oxygen desaturation <90%; efficacy (defined as patient/parent satisfaction) good in both groups; amnesia 91% for midazolam, 28% for fentanyl; patients/parents preferred midazolam 72% to 28%; OSBD scores increased from first procedure to last and decreased slightly for those choosing fentanyl	Small sample size; nonblinded assessment	Both agents are effective; patients and families prefer midazolam probably because of amnestic effects	II	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Hart et al[26]	Prospective, randomized, blinded experimental trial in 42 children requiring painful ED procedures treated with (1) fentanyl, (2) fentanyl-midazolam, or (3) MPC; all patients monitored for safety with $ETCO_2$ and pulse oximetry; efficacy was measured by objective clinical signs and subjective scale by blinded observers; mean age 4.8±2.0 y (range 2–11 y)	Pain was measured by the 10-point scale of Broadman et al[83]; anxiety was measured using the author's 4-point scale; sedation was measured by the author's 5-point scale; author states that all scales were previously published and research assistants were trained in the use of scales; all equally efficacious; subclinical respiratory depression by hypoxemia or elevated $ETCO_2$ in 20% fentanyl, in 23% fentanyl-midazolam and in 11% MPC; prolonged sedation with MPC	The small sample size limits conclusions especially for safety concerns; the clinical relevance of documented transient hypercarbia in the absence of hypoxemia is not clear; the absence of any significant clinical events leaves the $ETCO_2$ data difficult to interpret	The new technique of noninvasive $ETCO_2$ monitoring may be a useful monitoring tool in the pediatric ED; fentanyl and midazolam cause a high incidence of subclinical respiratory depression	II	II
Kovoor et al[27]	Prospective observational case series of 1,344 adults requiring 2–3-h electrophysiologic studies for cardiac arrhythmias; efficacy data are included on 775 patients and safety data on 1,344 patients; cardiac catheterization lab	No serious complications; insignificant changes in respiratory rate, oxygen saturation, $ETCO_2$, and blood pressure; upper airway obstruction defined as snoring increases; increases in $ETCO_2$ or clinical evidence of upper airway obstruction occurred in 42%; restlessness occurred in 20%; 0.3% required conversion to general anesthesia for apnea or severe restlessness; efficacy in the sedation group was measured against those who had the study without sedation; in the sedated group vs the unsedated: no distress 74% vs 42%; moderate distress 24% vs 50%; extreme distress 2% vs 8%	All data are from adults; study was of continuous infusion of drugs rather than bolus for short procedure; procedure is 2–3-h electrophysiologic study primarily; this requires anxiolysis but not significant analgesia or sedation; applicability of these results to short painful procedures in children is questionable; no comparison group was used; observers of efficacy were not blinded	Continued infusion of fentanyl/midazolam can be safe and effective for adult electrophysiologic studies	III	III
Wright et al[28]	Retrospective case series of midazolam use in 389 patients in adult ED	Serious adverse event rate 1%; all serious adverse events associated with use of opiate drugs in addition to midazolam; efficacy defined as the procedure being accomplished and the physician not noting a problem	All adult patients; no standardized evaluation form	Midazolam is safe and effective when used in the ED in adult patients	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Kennedy et al[29]	Prospective, single-blind, randomized, controlled trial of ketamine/midazolam vs fentanyl/midazolam in 260 patients, aged 5–15 y requiring orthopedic procedures in ED; ASA status I–II; videotaped blinded assessment of adequacy of sedation; safety assessed by objective monitoring; efficacy assessed by 9-point facial affective scale, parents 10-cm VAS, orthopedist satisfaction VAS, and OSBD-R scored by blinded observers and blinded treating physicians; midazolam ≤0.1 mg/kg, maximum 2.5 mg every 3 min until sedated; fentanyl ≤0.5 μg/kg every 3 min until decrease response to verbal/painful stimuli vs ketamine ≤0.5 mg/kg every 3 min (up to 2 mg/kg) + glycopyrrolate 5 μg/kg up to 250 μg	Safety: hypoxia occurred in 6% of patients in the ketamine/midazolam group vs 25% of patients in the fentanyl/midazolam group, breathing cues needed 1% vs 12%, oxygen required 10% vs 20%; 2 patients in ketamine/midazolam group required assisted mask ventilation vs 0 in fentanyl/midazolam group; Efficacy: ketamine/midazolam had better efficacy measured by lower distress scores during procedure and increased orthopedic physician satisfaction; ketamine/midazolam had more vomiting in 2 wk after procedure (4% vs 0%); OSBD-R 1.08±1.12 vs 2.70±2.16 (P≤.0001), parental pain VAS 4.21±3.30 vs 5.55±3.33 (P=.004), parental anxiety 4.48±3.26 vs 5.49±3.26 (P=.02), orthopedic satisfaction 8.71±2.21 vs 9.61±0.78 (P=.0001), equal induction time of 13 min, recovery time 113.7±36.9 min vs 127.6±56.2 min (P=.02), hypoxia 24% vs 6% (P=.001), breathing cues 12% vs 1% (P=.001), airway maneuver 11% vs 6% (P=NS), and bag-valve-mask 0% vs 2% (P=NS)	Study examined only orthopedic procedures; age range 5–15 y; results may not apply to younger patients; single-blind study	Well-done randomized controlled trial; ketamine/midazolam is more efficacious for sedation than fentanyl/midazolam for orthopedic procedures with less hypoxia and airway maneuvers; ketamine/midazolam is associated with fewer respiratory complications, but respiratory support may be needed with either regimen; vomiting in weeks following slightly more common with ketamine/midazolam (4% vs 0%)	I	I
Bauman et al[30]	Retrospective case series of randomly selected charts (convenience sample) (64/243) of sedation for lumbar puncture and BM biopsy in an outpatient oncology population; administered by pediatric critical care physician or anesthesiologist; nonstandardized treatments included multiple drug regimens; no data on fentanyl or midazolam use in absence of other agents; average age 6.6 y (range 3 mo to 15 y)	4/64 (6.25%) complications: 1/64 (1.6%) desaturation, 1/64 (1.6%) apnea, 1/64 (1.6%) hypotension, and 1/64 (1.6%) prolonged sedation; all complications were reversible and not serious; all procedures were completed; no complications with fentanyl/propofol	Very small study with small numbers in each group and much heterogeneity within each group; multiple agents used; difficult to glean efficacy or safety data about fentanyl and midazolam alone; retrospective descriptive study with no uniformity of data collection or observation of patients between groups	A fentanyl/propofol combination can be used in the pediatric population	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
McQuillen and Steele[31]	Prospective case series of 106 children undergoing ED sedation for painful procedures; patients assessed with $ETCO_2$ monitoring; mean age 6.8 y (range 1.2–16.6 y)	Mean increase in $ETCO_2$ during sedation was: for all sedation combined 6.7 (95% CI 5.8–7.5 mm Hg), for midazolam alone 3.2 (95% CI 2.2–4.2 mm Hg), for midazolam and ketamine 5.4 (95% CI 4.5–6.4 mm Hg), and for midazolam and opiate 8.8 (95% CI 7.4–10.2 mm Hg); percentage of patients with increased $ETCO_2$ >10 mm Hg: for all sedation combined 19% (95% CI 0%–60%), for midazolam alone 9% (95% CI 3%–22%), for midazolam and ketamine 35% (95% CI 21%–50%), and for midazolam and opiate 50% (95% CI 13%–99%); all drug combinations used increased $ETCO_2$, but midazolam and fentanyl increased it to a greater degree than other agents	Did not measure efficacy; assessment not blinded; clinical significance of increased $ETCO_2$ not clear	$ETCO_2$ can be used as a monitoring adjunct in patients requiring sedation in the pediatric ED; midazolam/fentanyl causes more CO_2 retention than other commonly used agents	Efficacy was not objectively measured	III
Graff et al[32]	Retrospective observational study of fentanyl and midazolam for 334 children undergoing orthopedic procedures (retrospective grading of depth of sedation); mean age 8.4±3.75 y; pediatric ED of large urban children's hospital	11% with some respiratory event (37 patients), with 2 patients requiring naloxone; 10% needed airway positioning or stimulation, but none required ventilation or intubation	Efficacy was not rigorously measured; this is the primary weakness of this study; retrospective study with no comparison group	Fentanyl and midazolam can be safely used for ED treatment of orthopedic injuries; close monitoring of respiratory status is essential	Efficacy was not objectively measured	II
Hostetler and Barnard[33]	Retrospective case series comparing ketamine/midazolam to fentanyl/midazolam in 93 children undergoing esophageal foreign body removal in the ED over a 2-y period; 57 (61.2%) of the 93 patients received ketamine/midazolam, 28 (30.1%) received fentanyl/midazolam, 5 (5.4%) received general anesthesia, and 3 (3.2%) received other; per protocol, midazolam was dosed initially at 0.05–0.1 mg/kg followed by 0.05-mg/kg subsequent doses; ketamine was given initially in 1–2-mg/kg IV doses followed by 0.5–1.0-mg/kg doses; fentanyl was given in 1–2-μg/kg IV doses initially, followed by 0.5–1.0-μg/kg; mean age 39.3± 33.9 mo (range 3–168 mo)	Comparing ketamine/midazolam vs fentanyl/midazolam: mean procedure time 4.8 min (95% CI 3.7–6.0) vs 7.0 min (95% CI 5.1– 8.9); mean length of stay 3.6 h (95% CI 3.3–3.9) vs 5.7 h (95% CI 3.0–8.3); transient hypoxia 10.7% (95% CI 6.6–14.8) vs 15.4% (95% CI 8.6–22.2); stridor 1.8% (95% CI 0–3.6) vs 0 (95% CI 0–1.9); and bag-valve-mask 3.6% (95% CI 1.1–6.1) vs 3.8% (95% CI 0.2–7.4)	Retrospective data collection and uncontrolled comparison; small sample size; removal of esophageal foreign body may cause hypoxia unrelated to sedation/analgesia	Ketamine/midazolam and fentanyl/midazolam are safe and effective for foreign body removal in children; recovery time appears longer for fentanyl/midazolam than for ketamine/midazolam	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Bailey et al[34]	Randomized, blinded, prospective experimental trial of drug administration to 12 healthy adult volunteers to evaluate safety profile	Midazolam alone produced no significant respiratory effects; fentanyl alone produced hypoxemia in 50% of subjects, hypoxemic episodes were defined as Spo_2 <90% and lasting ≥10 s; decreased ventilatory response to CO_2, and apnea in 0%; combination of fentanyl and midazolam produced hypoxemia in 92%, decreased ventilatory response to CO_2 similar to but no worse than fentanyl, and apnea in 50%	Small sample size for safety study limits conclusions; study done in adults; it is not clear how dosage, adverse effect profile, and responses to decreased ventilatory response to CO_2 will affect children in the clinical setting; study of drug effect in healthy volunteers with no painful stimulus may be difficult to translate to children undergoing painful procedures	Combination of fentanyl and midazolam markedly increase risk of hypoxia and apnea in comparison to either agent alone	Efficacy was not objectively measured	III
Milgrom et al[35]	Randomized, blinded, placebo-controlled trial of midazolam, fentanyl, and methohexital in various combinations in 207 adults undergoing dental procedure (molar extraction); university dental clinic	Midazolam fentanyl combination resulted in greater efficacy but increased level of sedation and complications; efficacy measures included observer-reported sedation score and self-reported pain and anxiety scores; apnea in 63% of midazolam and fentanyl and in 3% midazolam alone	All adult data but well-done study of drug use in painful procedures	High rate of apnea in combination group does not justify its use based on small increase in sedation effect	II	II
Yaster et al[36]	Case report	Respiratory arrest in a 13-month-old toddler receiving midazolam and fentanyl	Anecdotal	Midazolam and fentanyl are respiratory depressants	X	X
Godambe et al[37]	Prospective, partially blinded, randomized (videotaped) controlled trial in convenience sample of patients; ASA status I–III for orthopedic procedures in ED; 59 patients given IV propofol (1 mg/kg initially with smaller aliquots)/ fentanyl (1–2-μg/kg aliquots) vs 54 patients given ketamine (1–2-mg/kg)/midazolam (0.05 mg/kg aliquots); measurement of sedation and recovery times; use of OSBD-R and Likert satisfaction scores for orthopedist and nurse, and VAS for parents; 113 patients aged 3.1–16.3 y (median 9.0 y)	Total sedation and recovery time for propofol/fentanyl vs ketamine/midazolam 38.9 min vs 62.1 min (P<.0001) and 54.2 min vs 20.8 min (P<.0001), respectively; transient desaturation (responsive to jaw thrust or head repositioning or supplemental oxygen) occurred in 18/59 (31%) of propofol/fentanyl patients vs 4/54 (7%) of ketamine/midazolam patients (P=.002); mean OSBD-R during manipulation for propofol/ fentanyl vs ketamine/ midazolam 0.278 on scale of 0–23.5, with 0 representing no distress, vs 0.084 (P=.787); for propofol/fentanyl vs ketamine/ midazolam: orthopedic satisfaction 4.85 vs 4.93 (P=.245), nurse satisfaction 4.85 vs 4.95 (P=.173), and parental VAS 8.7 vs 13.0 (P=.380)	No significant limitations; partially blinded only; loss of videotaping in 3 patients	Both propofol and ketamine are safe and effective for ED orthopedic procedures; propofol/fentanyl had significantly shorter sedation times and longer recover times than ketamine/midazolam and equivalent satisfaction scores; there were significantly more transient desaturations with propofol/fentanyl than with ketamine/ midazolam	I	I

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Acworth et al[38]	Single-blinded (sedation assessment), randomized, controlled trial; ketamine 1 mg/kg/midazolam 0.1 mg/kg IV vs IN midazolam 0.4 mg/kg; laceration repair and foreign body removal; VAS (author's sedation scoring system); age 6 mo to 12 y; ED study; total of 53 patients	"Adequate" sedation in 27/27 vs 24/26 (P=NS), onset 2.0 min vs 7.3 min ($P<.001$), time to discharge 97.9 min vs 79.0 min (P=.02), average sedation score at 30 min: 2.4 vs 3.5 (Δ1.1, 95% CI 0.7–1.4, $P<.001$), average VAS (author's scoring system used) at 30 min: 1.8 vs 3.8 (Δ2.0, 95% CI 1.1–2.9, $P<.001$), overall VAS 2.1 vs 4.5 (Δ2.4, 95% CI 1.1–3.6, P=.001); physician satisfaction "excellent/good" 88% vs 54%, P=.006, parental satisfaction "excellent/good": 92% vs 65%, P=.02; one significant adverse event: saturation <90% in the ketamine group	Treating physician and nurse not blinded; small study for adverse events	IV ketamine/midazolam superior to IN midazolam in sedation onset, time to discharge, sedation scores, and physician and parental satisfaction	II	II
Petrack et al[39]	Double-blinded randomized, controlled trial 12 h/d with research assistant; patients aged 6 mo to 6 y requiring sedation for wound repair, burn care, or lumbar puncture; randomized to ketamine 4 mg/kg/atropine 0.01 mg/kg IM vs meperidine 2 mg/kg/promethazine 1 mg/kg/chlorpromazine 1 mg/kg IM; ED study; total of 27 patients	15 patients received ketamine vs 12 received MPC; ages 31±20 mo vs 39±22 mo, onset of sedation 3 min vs 18 min ($P<.01$), duration 82 min vs 97 min (P=.15), time to discharge 85 min vs 113 min (P=.01), and mean OSBD-R score 2.7 (95% CI 0.4–4.9) vs 9.8 (95% CI 4.9–14.6, $P<.003$); there were no significant adverse effects seen in either group	Small numbers for adverse effects; patients only recruited 12 h/d	Ketamine is superior to MPC in time of onset of sedation, time to discharge, and mean OSBD-R score; the durations of sedation were similar	I	X
McGlone et al[40]	Prospective nonrandomized comparison of IM ketamine 2.5 mg/kg + atropine (additional 1 mg/kg given prn) versus IN midazolam 0.5 mg/kg for laceration repair age 12 mo to 7 y; used nonvalidated, simple 4-point behavior scales; ED study; 102 patients, average age 3.6 y	For ketamine vs midazolam: during anesthetic injection 96% vs 38% and during suturing 100% vs 70% patients were cooperative/intermittent crying ($P<.01$); 18% vs 8% had vomiting (P=.234), median Spo_2 97% for both, recovery behavior quiet or mild agitation in 92% vs 86% (P=.44)	Nonblinded alternating of sedative	IM ketamine 2.5 mg/kg more effective than IN midazolam for suturing	III	II
Dachs and Innes[41]	Prospective nonrandomized study; patients aged 18 mo to 8 y; brief painful procedures; IV ketamine 1–1.5 mg/kg±atropine; ED study; 30 patients	Median age 38 mo, 90% laceration repair, local anesthesia used in 52%; 1mg/kg dose resulted in 6/11 (54%) patients requiring additional ketamine, dose increased to 1.5 mg/kg during study, 1.5 mg/kg dose resulted in 1/18 (5.5%) patients requiring additional ketamine; all patients were unresponsive to painful stimulation (endpoint); Spo_2 >93% on room air for all patients; telephone follow-up in 96.6%: 1 patient vomited in recovery, 1 at home, 9 with ataxia for 0.5–2 h and no nightmares	Small sample size, nonblinded outcome assessments	IV ketamine at 1.5 mg/kg effective for procedural sedation	III	II

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
McCarty et al[42]	Prospective cohort of patients aged 12 mo to 11 y undergoing orthopedic procedures using ketamine by standard protocol; emergency physician monitored sedation along with nurse while orthopedist did reduction and measured sedation with CHEOPS; 99 received 2 mg/kg IV ketamine and 15 received 4 mg/kg IM ketamine; ED study; total 114 patients	Average onset to reduction for IV: 96 s (20 s to 5 min) and IM: 4 min 42 s (60 s to 15 min); average CHEOPS score 6.4 (5–10) and all had adequate sedation for reduction; emesis in 8 (7%), nausea in 5 (4%), ataxia in 8 (7%), and dysphoria in 1 (1%); time to discharge IV: 84 min (22–215 min), IM: 90 min (60–130 min)	Nonrandomized study; small numbers for serious adverse effects	IV and IM ketamine allowed adequate sedation for fracture and/or joint reduction without serious adverse effects; IV ketamine has a rapid onset of action, both IV and IM ketamine have a fairly prolonged recovery time	II	II
Pruitt et al[43]	Prospective, single-arm trial of IM ketamine 3 mg/kg/ midazolam 0.05 mg/kg/ glycopyrrolate for lacerations/dental procedures in patients aged 1–7 y; additional ketamine 1 mg/kg prn; nonvalidated, simple behavior scales during procedure and recovery (Spo_2, etc); ED study; 42 patients (average age 2.7 y)	Onset average 4.8 min (3–10 min); recovery average 76 min (50–120 min); 26/37 patients cooperative/ sleeping; 11/37 patients intermittently crying/ fighting, 5/11 got additional 1 mg/kg of ketamine; heart rate increased 18%, respiratory rate increased 13%, Spo_2 >96% in all; no airway adverse events; emesis in 2 patients	Nonrandomized trial; small number of patients to assess frequency of major adverse events	IM ketamine/ midazolam/ glycopyrrolate safe and effective	III	II
Wathen et al[44]	Double-blind randomized, controlled trial of patients aged 4.5 mo to 16 y requiring sedation, ASA status I–II; received ketamine 1 mg/kg/ glycopyrrolate 5 μg/kg IV±midazolam 0.1 mg/kg IV; videotaped blinded assessment using OSBD-R; ED study; 266 patients	129 had ketamine alone, 92% fracture reduction or wound repair; total sedation time: 78 min (60–100 min) vs 75 min (60–95 min), Δ3 (95% CI −5 to 10), recovery agitation 7.1% vs 6.2%, Δ0.8 (95% CI −5.3 to 7.0); desaturations 1.6% vs 7.3%, Δ −5.7% (95% CI −5.7% to −0.9%); emesis: 19.4% vs 9.6%, Δ9.8% (95% CI 1.4%–18.2%); for patients >10 y: recovery agitation 5.7% vs 35.7%, Δ–30.0% (95% CI −49.3% to −10.7%)	None	Adding midazolam to ketamine does not increase sedation time, does not decrease recovery agitation; increases recovery agitation in patients >10 y, but decreases emesis	I	I
Kim et al[45]	Pilot study of sidestream $ETCO_2$ monitoring for consecutive patients aged 12 mo to 15 y ASA status I–II receiving IV ketamine (1.5 mg/kg)/atropine 0.01 mg/kg, minimum 0.1 mg, maximum 0.5 mg for procedural sedation; ED study; total of 27 patients	20 of 27 patients in whom $ETCO_2$ monitoring was attempted had usable data; no significant change in $ETCO_2$ and Spo_2; no $ETCO_2$ >47 mm	Selected small pilot study	Ketamine appears to not induce hypoventilation	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Sherwin et al[46]	Double-blind randomized, controlled trial; patients aged 12 mo to 15 y undergoing short, painful procedure in ED; ketamine 1.5 mg/kg/atropine 0.01 mg/kg IV±midazolam 0.05 mg/kg up to 2 mg; 0–100 mm VAS (author's scoring system used) for agitation; 104 patients	53 patients received midazolam; recovery agitation VAS (author's scoring system used) 4 mm (IQR 2–19 mm) vs 5 mm (IQR 3–14 mm), *P*=.70; adequate sedation 100% vs 100%, *P*=1.00; recovery 61 min (40–98 min) vs 64 min (44–79 min) *P*=.57; airway complication 4% vs 2%, *P*=1.00; emesis 2% vs 12% (Δ–10%, 95% CI −20% to 0%, *P*=.058)	None	Midazolam does not decrease recovery agitation when ketamine is used for sedation; there is a strong trend to less emesis	I	II
Holloway et al[47]	Retrospective chart review of all children who received ketamine over a 20-mo period, primarily for laceration repair; no standardized sedation record; follow-up parent standardized interview regarding: adverse effects, mean 5 mo (range 1 wk to 14 mo) postsedation; ED study; 100 patients	78% of patients had wound repair, all IM, mean dose 5.5 mg/kg (range 3.65–8.91 mg/kg); no admissions or "airway problems" noted; vomiting during recovery in 14%, after discharge in 12%; agitation/nightmares in 2%, "unusual behavior" in 4%	Retrospective review; no standardized sedation records	Ketamine is safe when administered IM for short painful procedures	Efficacy was not objectively measured	III
Hostetler and David[48]	Prospective cohort of patients aged 6 mo to 18 y; received ketamine 0.5 to 1.5 mg/kg/midazolam 0.035 to 0.05 mg/kg/atropine 0.01 mg/kg IV and prehypnotic suggestion; sedative redosing with ketamine 0.5–1.0 mg/kg IV; 1 physician and nurse monitored sedation, and second physician did procedure; ED study; 301 eligible patients recruited	68.8% of patients for orthopedic procedures, 20.6% for wound care, and 10.6% other; 205 patients aged <10 y, 96 aged ≥10 y; physician and nurse evaluation of behavioral reaction κ=0.77; for patients aged <10 y: 7/205, 3.4% (95% CI 0.9%–5.9%) had mild reaction, 2/205, 1.0% (95% CI 0%–2.4%) had severe reaction; for patients aged ≥10 y: 2/96, 2.1% (95% CI 0%–5.0%) had mild reaction, 4/96, 4.2% (95% CI 0%–8.2%) had severe reaction; 13.2% of 167 patients followed up had nighttime awakening; overall 97.5% of parents were satisfied, 98.1% for patients not having behavioral reaction, 80.0% for patients suffering behavioral reaction	Behavioral reaction measurement not validated; not randomized or blinded; phone follow-up for approximately 50% of the patients	There is a low rate of mild or severe behavioral reaction to ketamine with a moderate number suffering nighttime awakening; there is good parental satisfaction with ketamine sedation	Efficacy was not objectively measured	II

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Green et al[49]	Retrospective cohort study of children aged <15 y receiving IM ketamine in 2 EDs following a treatment protocol; used multiple logistic regression to test predictor variables (ie, age, sex, ASA status, quantity of first ketamine dose, number of doses) for adverse events; protocol dictated initial IM dose of 4 mg/kg with repeat allowed in 5–10 min of another IM dose of 2–4 mg/kg; 1,022 patients	No association of risk factors for airway complications; emesis increased with age: OR 1.25/y (95% CI 1.17–1.34, $P<.001$); recovery agitation associated with ASA status >I: OR 3.05 (95% CI 1.65–7.30, $P=.004$) and decreasing age: OR 0.79 (95% CI 0.69–0.89, $P<.001$)	Retrospective data collection	Recovery agitation associated with higher ASA status but decreasing age; emesis is associated with increasing age; effects are not large and may not be clinically important	Efficacy was not objectively measured	II
Green et al[50]	9-y retrospective cohort study of children aged <15 y receiving IM ketamine in 2 EDs following a treatment protocol; some prospective data collection for sedation (42% of cases), supplemented by chart review; unvalidated outcome measures; protocol dictated initial IM dose of 4 mg/kg with repeat allowed in 5–10 min of another IM dose of 2–4 mg/kg; 1,022 patients	4.4% of the patients were ASA status >II, 86.5% for wound and orthopedic procedures, 4% were critical care procedures; "adequate" sedation in 98%, 215 patients required >1 dose; adverse events included airway complications in 1.4% without intubation or sequelae, emesis without evidence of aspiration in 6.7%, mild recovery agitation in 17.6%, moderate-to-severe agitation in 1.6%, and no hospitalizations due to ketamine; median time from ketamine administration of a single dose to discharge was 110 min	Retrospective series, <50% compliance with data collection form; nonblinded and unvalidated outcome measures	Ketamine in this very large cohort has a low rate of significant adverse events without serious sequelae	Efficacy was not objectively measured	II
Green et al[51]	9-y retrospective cohort study of all children aged <15 y who received IV ketamine for procedural sedation using treatment protocol at 2 centers; initial dose 1.5±0.5 mg/kg, total dose 2.5±1.6 mg/kg, 31% received midazolam; ED study; 156 patients, average age 6.3±3.2 y	81% of patients for orthopedic or wound management, 6% for endotracheal intubation and 13% miscellaneous, 17 with ASA status III–IV; adverse events: 1 with apnea with rapid IV infusion, 1 with respiratory depression requiring jaw thrust only, and 6 with emesis without evidence of aspiration; median recovery time 103 min (IQR 76–146 min)	Mixed indications for use of IV ketamine; retrospective data collection; not blinded	IV ketamine appears safe even in high-risk patients	Efficacy was not objectively measured	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Green et al[52]	Prospective uncontrolled cohort, age 14 mo to 13 y requiring sedation for painful procedures; protocol: IM ketamine 4 mg/kg; unvalidated sedation assessment; ED study; 108 patients, mean age 54 mo	75% of patients with lacerations, 9.3% orthopedic procedures; 86% procedures completed without local anesthesia, 7% received local, 3% needed additional ketamine; onset by 5 min in 83%, recovery mean 82±33 min, recovery behavior quiet in 80%, mild agitation in 17%, moderate agitation in 3%, pronounced agitation in 1%, laryngospasm in 1 after study completed, and emesis in 6	Uncontrolled unvalidated trial; unblinded outcome measures; small sample size for safety	Ketamine is effective for brief painful procedures with a low rate of adverse effects	III	II
Green et al[53]	Retrospective 5-y cohort of non-ED patients, ages <1 mo to 21 y, receiving IV ketamine/midazolam to facilitate gastrointestinal procedures (86% esophagoscopy); median ketamine dose 1.3 mg/kg, 46% patients ASA status ≥III	636 patients given ketamine, 86% for esophagoscopy; laryngospasms noted in 8.2% overall, and in 14% of preschoolers; median lowest oxygen saturation, if recorded, with laryngospasms was 70% (range 30%–89%); 37% received positive pressure ventilation	Retrospective design with no comparison group; the main clinical efficacy endpoint was accomplishment of procedure; safety endpoints were adverse cardiopulmonary events that were not routinely recorded (eg, lowest oxygen saturation, presence/absence of laryngospasm)	Authors conclude no adverse outcomes attributable to ketamine	Efficacy was not objectively measured	X
Forbes et al[54]	Prospective observational study to examine hemodynamic effects of rectal methohexital (25 mg/kg) through echocardiography in operating room; the study included 12 patients aged 32.4±3.8 mo	Methohexital had increased heart rate but had no effect on other parameters; no arterial desaturation or apnea	Study did not effectively examine apnea or desaturation but only echocardiographic effects	Rectal methohexital has minimal hemodynamic effects	Efficacy was not objectively measured	III
Manuli and Davies[55]	Retrospective study of CT and MRI patients; non-ED study; 25 mg/kg of methohexital given rectally; 94 patients aged 25±2 mo	Sleep was induced in 81% of children; 1% desaturation rate	Retrospective nature and methods prevented valid conclusions on efficacy; deduced from chart	Rectal methohexital is safe	Efficacy was not objectively measured	II
Pomeranz et al[56]	Prospective observational study of ED patients undergoing CT scan; 25 mg/kg of methohexital given rectally; efficacy was determined with 2 separate measures: a 3-point scale recorded the need for restraints to complete the CT study while another scale recorded the quality of the CT scan as determined by the presence of motion artifact; 100 patients with average age of 24 mo	95% efficacy; 3% required bag-valve-mask ventilatory support briefly, no endotracheal intubations, 2 head repositionings, and 2 given nasal oxygen	None; complications may not be as severe as noted because bag-valve-mask ventilatory support was by protocol	Methohexital safe and effective for CT scanning	I	I

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Sedik[57]	Retrospective and prospective observational study; IV methohexital in ED patients for CT scans; used a dosing range of 0.5–2 mg/kg; efficacy was determined by the ability to complete the CT scan; 55 patients; 2-phase study—phase 1 patient age: 28±24 mo; phase 2 patient age: 27±17 mo	1% of patients had oxygen saturation <93%, and 1% had a failure rate of sedation	Part of the study was done retrospectively, although the prospective portion compensates	Methohexital is safe and effective with brief duration of action	II	II
Varner et al[58]	Prospective observational study of 10 mg/kg IM methohexital for CT studies; 2 different strengths examined (3.5% and 5%); efficacy was determined by the ability to complete the CT scan; non-ED study with 50 patients aged 2 mo to 5 y	Efficacy data only, 92% effective for CT	Safety data are not well documented, although no apnea was noted	Methohexital is effective at 10 mg/kg	II	Safety was not objectively measured
Schwanda et al[59]	Retrospective observational study of hematology/oncology patients; 1 mg/kg IV methohexital; efficacy was determined by the ability to complete hematology/oncology procedure; because the drug was titrated by the physician to the endpoint of cooperation with the procedure, the drug was 100% effective; 132 procedures in 33 patients aged 8.3±5 y	100% effective; 1.5% needed bag-valve-mask ventilatory support, 17% had decreased blood pressure, 5.3% had complications with intervention	Safety data were prospectively collected and are grade II; the efficacy data were collected through chart review and should be regarded as grade III; not truly reflective of ED patients; the use for lumbar punctures may be of some value	Slightly higher complication rate than reported in other studies	III	II
Rooks et al[60]	Prospective, nonblinded study; 317 children in pentobarbital group; 358 children in chloral hydrate group; total of 675 patients; comparison of oral pentobarbital to oral chloral hydrate; pentobarbital at dose of 4 mg/kg/dose; chloral hydrate at dose of 50 mg/kg/dose; radiology study; patients in the oral pentobarbital group were sedated for MRI (230 patients), CT (85 patients), nuclear medicine (1 patient), and interventional radiology (1 patient) procedures. In the chloral hydrate group the breakdown was as follows: MRI (268 patients), CT (87 patients), nuclear medicine (1 patient), and interventional radiology (2 patients) procedures	Oral pentobarbital: time to sedation 19±14 min; time to discharge 100±35 min; length of sedation 81±34 min; adverse reactions 1.6%; sedation was unsuccessful in 1 patient (0.3%) in the oral pentobarbital group; Oral chloral hydrate: time to sedation 16±11 min; time to discharge 103±36 min; length of sedation 81±34 min; adverse reactions 1.7%; sedation was unsuccessful in 1 patient (0.3%) in the chloral hydrate group	Radiology study, fasted patients	Similar time to sedation, time to discharge, length of sedation, and adverse reactions	II	II

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Greenberg et al[61]	Prospective, nonblinded study included 100 children; pentobarbital dose 6 mg/kg in 3 divided doses to a maximum of 200 mg; age range 2–15 y with a mean age of 6.8 y; radiology department study; all patients had MRI	8% (8 children out of 100) that failed were either $\geq$12 y or weight was >50 kg; side effects: 7% hyperactivity, 6% oxygen desaturation, 3% cough, 2% prolonged sedation, 1% vomiting	Routine and fasted studies	The success rate was good, it could be improved if the use was limited to children $<$12 y and weighing $<$50 kg	II	II
Karian et al[62]	Retrospective study included 1,665 children; children aged $<$1 y were sedated with chloral hydrate (50–100 mg/kg) or oral pentobarbital (4–8 mg/kg); children aged >1 y received IV sedation, pentobarbital IV 2–6 mg/kg, fentanyl 1–2 μg/kg if required; midazolam dose of 0.05 mg/kg IV or 0.5–0.75 mg/kg orally; 216 patients were >10 y; radiology study—1,665 pediatric patients had sedation for various radiology studies, of these 1,110 had a scan (302 MRI, 179 CT), 675 patients received IV contrast	Paradoxical reaction in 1.2% and decreased oxygen saturation in 0.5% of patients who recovered with head positioning; sedation failure rate of 1%	Radiology study; fasted patients; multiple drug regimens	Pentobarbital has a low sedation failure and few adverse reactions	III	II
Mason et al[63]	Prospective, nonblinded; study included 1,070 children; pentobarbital compared with combination of pentobarbital and midazolam; pentobarbital group received 2–6 mg/kg IV; pentobarbital-midazolam group received an initial 0.1 mg/kg of IV midazolam followed after 1 min by 2–6 mg/kg IV pentobarbital; in both groups, all pentobarbital was titrated to effect in standardized 1–2 mg/kg doses; age in pentobarbital group: 3.3$\pm$2.5 y; age in pentobarbital/midazolam group: 4.3$\pm$2.7 y; radiology study; pentobarbital group: MRI 482 (75%), CT 120 (19%), nuclear medicine 22 (3%), and MRI combined with CT 16 (3%); pentobarbital-midazolam group: MRI 340 (79%), CT 65 (15%), nuclear medicine 20 (5%), MRI combined with CT 5 (1%)	The success rate of the pentobarbital alone group was 99.5% vs 99.8% in the pentobarbital-midazolam group; the use of midazolam increased time to sedation (pentobarbital-midazolam 8.0$\pm$4.4 min vs pentobarbital 6.5$\pm$4.4 min) and also prolonged the time to discharge by approximately 14 min when used in conjunction with pentobarbital (pentobarbital-midazolam 120$\pm$32 min vs pentobarbital 106$\pm$34 min)	Radiology study; fasted patients	No beneficial effect by adding midazolam to pentobarbital; it actually increased the time to sedation and the time to discharge	II	I

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Strain et al[64]	Prospective, nonrandomized, nonblinded, no comparison group; study included 225 children; 2–6 mg/kg were given in the following manner: 2.5 mg/kg IV and patient is observed for disconjugate eye movement, yawning, quiet sleep, or a slowed respiratory rate, wait 30 s then if still active give 1.25 mg/kg, wait 30 s, then the remaining dose of 1.25 mg/kg was given if the patient did not become quiet over the next 30–60 s; occasionally an additional dose of 1 mg/kg was given to a total dose of 6 mg/kg; the patients received a mean dose of 4.5 mg/kg; 25% of patients aged 6 wk to 6 mo; 30% of patients aged 6 mo to 1 y; 30% of patients aged 1–3 y; upper age limit not given; radiology study—sedation for CT imaging	7.5% transient desaturation to ≤80%: oxygen normalized spontaneously in 14 patients (sample size 225) and 2 patients needed head positioning; sedation failure rate <1%	Radiology study; fasted patients	IV nembutal is safe, effective, and efficient form of sedation for pediatric CT imaging	II	II
Moro-Sutherland et al[65]	Prospective, randomized, nonblinded; study included 55 children aged 6 mo to 6 y; compared pentobarbital vs midazolam; standardized dose of midazolam: total dose 0.2 mg/kg (maximum dose 7.5 mg); pentobarbital: total dose of 5 mg/kg (maximum dose 100 mg); protocol for the administration of midazolam: IV midazolam 0.2 mg/kg drawn up, 0.1 mg/kg IV over 2 min, wait 2 min, 0.05 mg/kg IV over 2 min, wait 2 min, 0.05 mg/kg IV over 2 min; dose titrated against response; protocol for the administration of pentobarbital: IV pentobarbital 5 mg/kg drawn up, 2.5 mg/kg IV over 30 s, wait 1 min, 1.25 mg/kg IV over 30 s, wait 1 min, 1.25 mg/kg IV over 30 s, dose titrated against response, average dose was 3.75 mg/kg; radiology study—sedation for head CT	With pentobarbital, 97% of patients scanned successfully; induction time 6 min, duration of sedation 86 min; with midazolam, 19% of patients scanned successfully; mild oxygen desaturation, oxygen saturation >90%	Radiology study; fasted patients; only 55 patients; not blinded to outcomes	IV pentobarbital is more effective than IV midazolam for sedation of children requiring CT imaging	II	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Kain et al[66]	Prospective, randomized, nonblinded controlled trial comparing propofol with a combination of thiopental and pentobarbital for MRI studies in radiology suite; study included 58 patients; 29 patients received 1–2 mg/kg of propofol followed by propofol infusion 5.4 mg/kg/h, and second group received 1–3 mg/kg of thiopental followed by a pentobarbital bolus of 2–3 mg/kg, and supplemental doses of 1–2 mg/kg of thiopental; ages 11 mo to 6.5 y; radiology study—MRI of the brain or spine	Time to recovery in propofol group was 19±7 min vs 35±20 min in thiopental/pentobarbital group; time to discharge in propofol group was 24±6 min vs 40±11 min in thiopental/pentobarbital group; for propofol group: 5% pulse oximetry level desaturation <90% and 4% for thiopental/pentobarbital group with all events responding spontaneously or to head repositioning; all studies were completed, and the average MRI quality score was comparable in both groups	Radiology study; fasted patients; sample size is a minor limitation	Propofol and pentobarbital are safe for use in painless diagnostic studies; propofol and pentobarbital had similar desaturation levels; pentobarbital had longer recovery time and longer time to discharge than propofol	II	III
Egelhoff et al[67]	Retrospective, observational study; study included 6,006 children; oral choral hydrate was given to infants aged <18 mo, the initial dose was usually 50–75 mg/kg with additional doses of 25–50 mg/kg up to 100 mg/kg as needed; nembutal (3–8 mg/kg) was started at 3 mg/kg in children >18 mo; fentanyl was added if painful procedure at a dose of 1 μg/kg up to 3 μg/kg; patient ages: 1 d to 18 y; radiology study; imaging studies included CT, sonography, MRI, special procedures, and nuclear medicine (actual number of patients included in each group was not specified)	Sedation failure rate was 1%; 0.06% required overnight hospitalization; transient respiratory depression to oxygen saturation <10% below the baseline despite repositioning; vomiting in <0.53% of patients; irritability in 0.21% of patients	Radiology study; fasted patients; 3 different drug regimens were used: chloral hydrate, pentobarbital, and pentobarbital with fentanyl	This study looked mainly at the use of chloral hydrate and pentobarbital alone or pentobarbital in combination with fentanyl; however, additional drugs were used including but not limited to diazepam and midazolam; the sedation failure rate was 1% and the rate of complications was low	III	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Slovis et al[68]	Prospective study; study included 549 children, above or below 8 y; 70% <8 y, of those 48% were <4 y; multiple drug regimens: chloral hydrate, pentobarbital, midazolam, diazepam, and with any of these drugs fentanyl was used for enhancement; dosing: oral chloral hydrate either 50 mg/kg or 75 mg/kg given depending on weight, age, and length of examination, up to a maximum of 1,000 mg, age <12 mo, optional use at age 12–18 mo; IV pentobarbital 3 mg/kg for ≥12 mo, 1 μg/kg fentanyl given if not asleep 5 min after pentobarbital; IV fentanyl 1 μg/kg at any age, used mostly for pain; IV midazolam 0.2–0.3 mg/kg × 2, with 2–5 min between doses, use for children aged ≥8 y; oral diazepam 5–10 mg in children aged >5 years, used on anxious older children in MRI; radiology study; imaging procedures included MRI (1,202 patients), CT (1,238 patients), nuclear medicine (162 patients), ultrasound (9 patients), diagnostic imaging (6 patients), and special procedures (240 patients)	With pentobarbital 8.4% hyperactivity in children >8 y and 19% sleeping for >8 h; if multiple doses of pentobarbital were used, there was a significant short-term effect on children <8 y, with 35% sleeping >8 h after the MRI; among 2,857 patients sedated in a 12-mo period, there were 40 failures (1.4%), complications (all minor) in 142 (5%); among the 2,857 patients, 1,202 had an MRI, with 26 failures (2.2%) including hyperactivity and vomiting, and 1,238 had a CT	Radiology study; fasted patients	Hyperactivity was found only in those children who received pentobarbital; the association of pentobarbital with hyperactivity was statistically significant for all ages when compared with drug regimens not containing pentobarbital	II	II
Sanderson[69]	Retrospective study; study included 149 children aged 3 mo to 7 y and 3 mo; children undergoing abdominal CT scan with oral contrast media, therefore not NPO; 141 patients received pentobarbital as the only sedative agent (94.6%), 8 patients (5.4%) required supplemental sedation with midazolam, with 1 patient requiring both midazolam and fentanyl; pentobarbital average dose 4.6 mg/kg; midazolam average dose 0.18 mg/kg (range 0.13–0.27); fentanyl was given to 1 patient at a dose of 2 μg/kg; radiology department	Abdominal CT with oral contrast was completed in all patients; 14% complication rate: desaturation, vomiting, airway secretions, airway obstruction, coughing, and bronchospasm	Retrospective study; radiology department; abdominal CT, however, patients were not NPO and had received oral contrast 45 min before the scan	Pentobarbital was an effective sedation agent with abdominal CT scan completed in all patients; complication rate was high (14.7%); some of the complications included desaturation, vomiting, and cough	III	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Bloomfield et al[70]	Prospective, randomized, controlled, nonblinded trial; pentobarbital compared with propofol; dosing: pentobarbital IV in successive boluses of 2.5 mg/kg to a maximum of 7.5 mg/kg; propofol IV 2 mg/kg (with supplemental 1-mg/kg boluses) followed by continuous infusion of 6–10 mg/kg/h; efficacy was determined by the ability to complete MRI study; MRI patients, radiology study; pentobarbital group mean age 4 y; propofol group mean age 5 y; age range 2–11 y; 61 total patients, 31 propofol cases and 30 pentobarbital cases	There was no significant difference in the responses between the propofol and pentobarbital groups; however, the propofol group had a greater decrease in pulse rate and 3/31 (10%) patients had transient decreases in oxygen saturation $<90\%$, with all responding to head repositioning, compared with the pentobarbital group that had 0 decrease in pulse oximetry levels $<90\%$; the propofol group had a faster recovery than the pentobarbital group; the propofol group average time to arousal was 5 min and time to discharge 12.5 min; in the pentobarbital group, the average time to arousal was 21.5 min and time to discharge 34 min; both 100% effective	Radiology study; fasted patients; some difficulties with early randomization	Both propofol and pentobarbital are safe and effective for sedation for painless diagnostic studies, but require careful patient selection and diligent monitoring; pentobarbital had less decrease in pulse rate and less transient desaturation but had greater recovery time than propofol	II	II
Havel et al[72]	Prospective, blinded, randomized, controlled trial comparing IV midazolam and propofol for painful procedures in the ED; 46 patients in midazolam group: 0.1 mg/kg; 43 patients in propofol group: bolus 1 mg/kg, infusion 4–6 mg/kg/h; total of 89 patients; aged 9.0 ± 3.8 y in propofol group, and 8.6 ± 4.2 y in midazolam group	11.6% had oxygen saturation below 93%; no interventions were needed aside from oxygen; mean sedation 5.5/6 on Ramsay Sedation Scale	Sample size is only a minor limitation	Propofol is effective and safe; shorter recovery time than midazolam	I	I
Skokan et al[73]	Prospective observational study of ED procedures; 1-mg/kg dose followed by 0.5-mg/kg boluses; mean age 7.4 y; 40 patients	Oxygen administered by 2/3 physicians regardless of pulse oximetry levels; all patients received opiate as well; 30% required supplemental oxygen; 1 (2.5%) patient required brief bag-valve-mask ventilation; 100% rated sedation as excellent	Data collection very unclear; multiple variations in delivery and recording of information	Propofol is safe and effective for use in ED procedures	III	III
Hertzog et al[74]	Prospective observational study of propofol for oncology procedures in a pediatric ICU–affiliated procedural unit; 2-mg/kg bolus and additional intermittent bolus injections; efficacy was determined by the ability to complete hematology/oncology procedure; ages 7.5 ± 4.3 y; 50 cases	4 (8%) transient pulse oximetry levels $<92\%$, 1 patient required bag-valve-mask ventilation, 2 cases of transient apnea; 100% effective	No significant limitation	Propofol reasonable option for procedural sedation in pediatric ICU	Efficacy was not objectively measured	II

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Guenther et al[75]	Prospective observational study of procedural patients managed in a pediatric ED–associated sedation unit; patients electively scheduled for unit from multiple outpatient sources, most commonly hematology/ oncology; protocol delivered propofol with fentanyl as 1–2 μg/kg; fentanyl initially, followed by 1 mg/kg of propofol; subsequent doses of 0.5 mg/kg administered at discretion of pediatric emergency physician managing sedation; mean dose 3.9 mg/kg of propofol; total of 87 patients underwent 291 separate sedations; efficacy defined as successful completion of procedure; 100% procedures successfully completed; median age 6 y	7% of children had transient desaturation below 90%, 4% partial airway obstruction requiring jaw thrust, 1% required transient bag-valve-mask assisted ventilation; transient decrease in systolic blood pressure noted with no clinical impact noted in almost all cases	Patients preselected and scheduled; success defined as completion of procedure with no adverse events	Propofol safe and effective for administration by pediatric emergency physicians in an ED-associated sedation unit	II	II
Bassett et al[76]	Prospective observational study of consecutive patients sedated with propofol in a pediatric ED; protocol delivered propofol with fentanyl as 1–2 μg/kg; fentanyl initially, followed by 1 mg/kg of propofol; subsequent doses of 0.5 mg/kg administered at discretion of pediatric emergency physician managing sedation; supplemental oxygen was applied to patients per protocol; mean dose 2.9 mg/kg of propofol; total of 392 patients underwent 393 separate sedations; median age 8 y	5% of children had transient desaturation below 90%, 3% partial airway obstruction, 0.8% required transient bag-valve-mask assisted ventilation; clinically insignificant transient decrease in systolic blood pressure noted in 84% of patients (median decrease 10.5 mm Hg); 6% demonstrated transient bradycardia with no clinical impact	No observations or definition of efficacy contained; conclusion that propofol is efficacious is stated and implied in lack of data that no procedures were not successfully completed	Propofol safe and effective when administered in ED setting	II	III
Jayabose et al[77]	Retrospective review of prospectively collected data on patients undergoing painful cancer-related procedures in an oncologic procedure unit; dosing varied depending on combination with other drugs; when only propofol was used the dosing was 25 mg/kg/min; age 2–15 y; 52 patients, 335 procedures	6 episodes of hypoxia <94%; no endotracheal tube intubations; efficacy on a unique scoring system was 93% for propofol only (160 episodes)	Some use of fentanyl, midazolam, and other agents	Propofol is safe and effective for use in patients undergoing painful procedures	III	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Keidan et al[78]	Prospective, randomized, controlled trial of propofol vs propofol/remifentanil for bone marrow biopsy in outpatient clinic; 3-mg/kg bolus infusion of 18 mg/kg/h; 36 pure propofol patients; propofol group mean age 8.4±4.8 y; propofol/remifentanil group mean age 9±5 y; 77 total patients	4 (11%) saturation <90%	May not be able to extrapolate from ASA III patients to ED	Propofol combined with remifentanil is better than propofol alone	Efficacy was not objectively measured	II
Levati et al[79]	Prospective observational study of MRI patients in radiology suite; origin of patients from multiple clinical areas; 3.7- to 5.4-mg/kg propofol bolus (lower dose in weight >10 kg), 7.1- to 10.1-mg/kg/h infusion; efficacy was determined by the ability to complete MRI study; ages 2 wk to 11 y; 84 patients	No apnea, 5 (6%) $ETCO_2$ elevation, 1 hypoxia <97%; 100% effective	Some variation in monitoring in some patients	Propofol is useful and safe for painless diagnostic study such as MRI	II	II
Merola et al[80]	Retrospective review of anesthesia records of sedation for MRI; compared with chloral hydrate; unclear to what extent data were prospectively collected; 2 mg/kg bolus drip 80–140 μg/kg/min (4.8–8.4 mg/kg/h); efficacy was determined by the ability to complete MRI study; ages 1 mo to 17 y; 318 propofol sedations; 455 total patients	No adverse outcomes documented; defined as pulse oximetry levels <94%	Unclear methods of data collection and documentation of adverse events	Propofol is reliable and safe	III	III
Scheiber et al[81]	Retrospective chart review of prospectively collected data in children undergoing radiation therapy in radiology suite; sedated with 3.4 mg/kg bolus IV propofol, 7.6 mg/kg/h infusion; efficacy was determined by the ability to complete radiation therapy; mean age 30±7.8 mo; 11 patients underwent 155 sedative procedures	No saturation <92% on room air	Results not clearly documented; mean pulse oximetry levels reported; effective treatment	Sedation with propofol excellent method for radiotherapy	III	III

Evidentiary Table (continued).

Study	Design	Findings	Limitations	Conclusions	Grade (Efficacy)	Grade (Safety)
Vardi et al[82]	Prospective, randomized, controlled trial of propofol vs ketamine for procedures in pediatric ICU; propofol dose 2.5–3 mg/kg bolus 12 mg/kg/h; ketamine dose 2 mg/kg plus midazolam 0.1 mg/kg plus fentanyl 2 μg/kg; mean age 7.25±5.73 y; 58 patients	For propofol sedation 9.6/10 scale and 5.6/6 on Ramsay Scale; for ketamine sedation 9.3/10 scale and 5.3/6 on Ramsay scale; for propofol: head repositioning 12 (20%), apnea requiring bag-valve-mask ventilation 10 (19%), no endotracheal tube intubations; for ketamine: airway repositioning 7 (14%), apnea 3 (6%), intubations 1 (2%)	May not be able to extrapolate from critically ill patients to stable ED patients	Both propofol and ketamine are safe and effective in pediatric ICU setting	III	III

abstract

FREE

The use of cochlear implants is increasingly common, particularly in children younger than 3 years. Bacterial meningitis, often with associated acute otitis media, is more common in children with cochlear implants than in groups of control children. Children with profound deafness who are candidates for cochlear implants should receive all age-appropriate doses of pneumococcal conjugate and *Haemophilus influenzae* type b conjugate vaccines and appropriate annual immunization against influenza. In addition, starting at 24 months of age, a single dose of 23-valent pneumococcal polysaccharide vaccine should be administered. Before implant surgery, primary care providers and cochlear implant teams should ensure that immunizations are up-to-date, preferably with completion of indicated vaccines at least 2 weeks before implant surgery. Imaging of the temporal bone/inner ear should be performed before cochlear implantation in all children with congenital deafness and all patients with profound hearing impairment and a history of bacterial meningitis to identify those with inner-ear malformations/cerebrospinal fluid fistulas or ossification of the cochlea. During the initial months after cochlear implantation, the risk of complications of acute otitis media may be higher than during subsequent time periods. Therefore, it is recommended that acute otitis media diagnosed during the first 2 months after implantation be initially treated with a parenteral antibiotic (eg, ceftriaxone or cefotaxime). Episodes occurring 2 months or longer after implantation can be treated with a trial of an oral antimicrobial agent (eg, amoxicillin or amoxicillin/clavulanate at a dose of approximately 90 mg/kg per day of amoxicillin component), provided the child does not appear toxic and the implant does not have a spacer/positioner, a wedge that rests in the cochlea next to the electrodes present in certain implant models available between 1999 and 2002. "Watchful waiting" without antimicrobial therapy is inappropriate for children with implants with acute otitis media. If feasible, tympanocentesis should be performed for acute otitis media, and the material should be sent for culture, but performance of this procedure should not result in an undue delay in initiating antimicrobial therapy. For patients with suspected meningitis, cerebrospinal fluid as well as middle-ear fluid, if present, should be sent for culture. Empiric antimicrobial therapy for meningitis occurring within 2 months of implantation should include an agent with broad activity against Gram-negative bacilli (eg, meropenem) plus vancomycin. For meningitis occurring 2 months or longer after implantation, standard empiric antimicrobial therapy for meningitis (eg, ceftriaxone plus vancomycin) is indicated. For patients with meningitis, urgent evaluation by an otolaryngologist is indicated for consideration of imaging and surgical exploration. *Pediatrics* 2010; 126:381–391

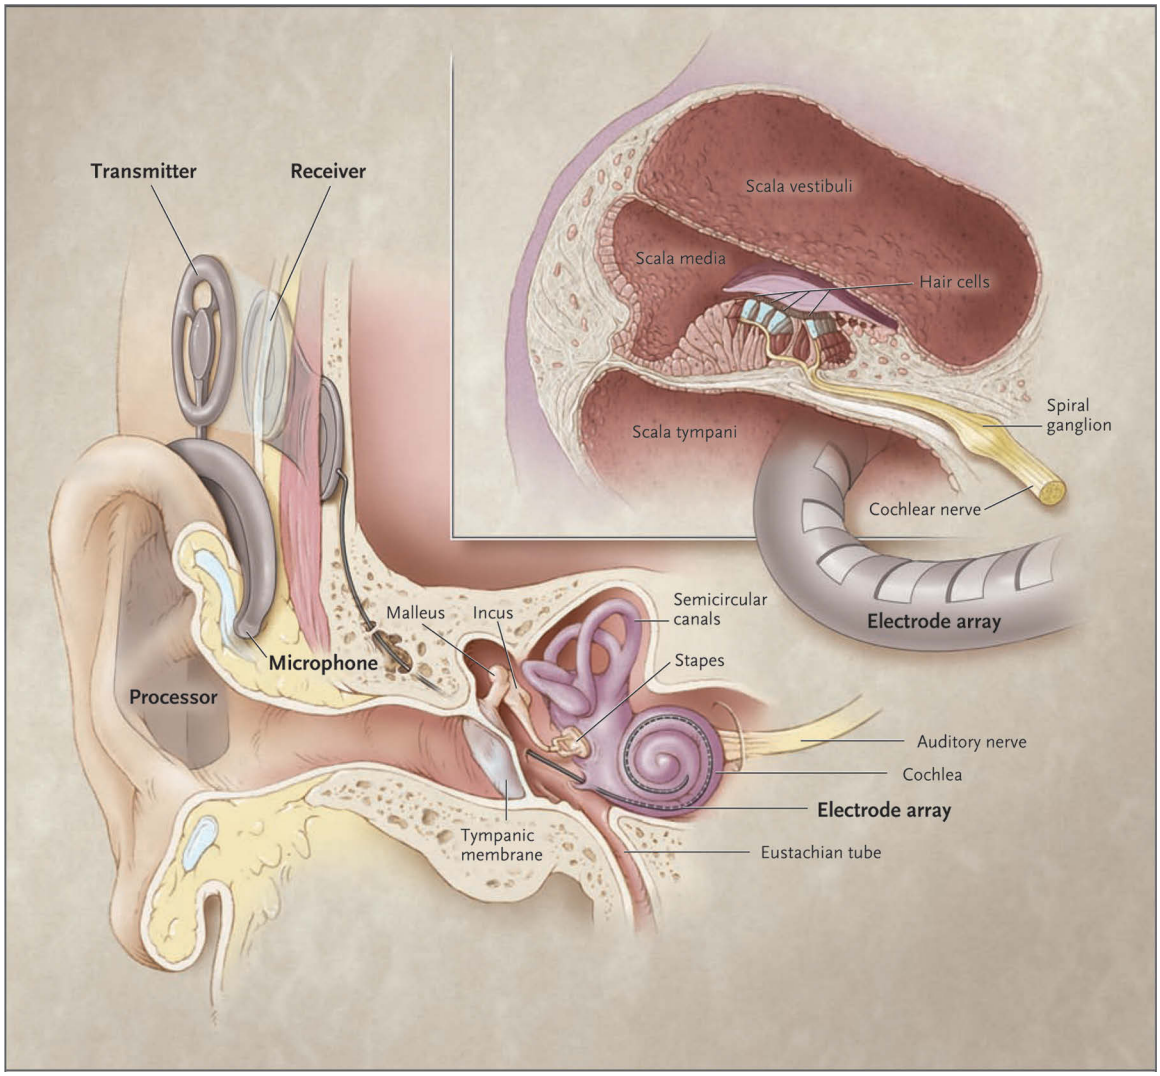

FIGURE 1

Diagram of the implanted cochlear device. External devices pick up, process, and transmit the sound across the skin to a receiver-stimulator implanted in bone. The receiver sends the code down a bundle of wires that passes through the middle ear and continues as the electrode array that is threaded into the cochlea. (Reprinted with permission from Papsin BC, Gordon KA. *N Engl J Med.* 2007;357[23]:2380–2387. Copyright © 2007 Massachusetts Medical Society. All rights reserved.)

BACKGROUND

A cochlear implant is an implanted electronic hearing device designed to produce useful hearing sensations to a person who is profoundly deaf or severely hard of hearing by electrically stimulating nerves inside the inner ear. The implant consists of an external portion that sits behind the ear and internal components that are surgically placed under the skin and inserted in the cochlea (Fig 1).[1,2] Cochlear implants are increasingly being used as a treatment for hearing loss. By the end of 2005, nearly 15 000 children and 22 000 adults in the United States and nearly 100 000 people worldwide had received cochlear implants for treatment of hearing loss.[2] In another important trend, some adults and children are now receiving bilateral cochlear implants.[1] Approximately 1 million people in the United States are potential candidates for cochlear implants. The current minimum age for placement of cochlear implants approved by the US Food and Drug Administration (FDA) is 1 year, although implants have been placed successfully in infants younger than 1 year with profound hearing loss.[3–5] It is increasingly likely that a primary care pediatrician will have 1 or more children with a cochlear implant in his or her practice. Potential infectious complications of cochlear implants include postoperative wound and device-related infections and bacterial meningitis. In children with cochlear implants, an episode of acute otitis media may lead to inner-ear infection, device infection, device extrusion, device

TABLE 1 Acute Otitis Media in Children With Cochlear Implants

Reference (Year)	Study Design	No. of Patients Evaluated	No. of Patients With ≥1 Episode of Acute Otitis Media in Implanted Ear (Total No. of Episodes That Occurred in Either or Both Ears)	Age at Implantation (Mean Age at Implantation), y	Length of Follow-up Time After Implantation (Mean), y	Time Interval From Implantation to Acute Otitis Media, Range (Mean), mo	Management	No. of Episodes of Meningitis

failure, and/or meningitis. Thus, there is a need for guidelines for prevention, recognition, and management of cochlear implant–related infections, acute otitis media, and bacterial meningitis in children with cochlear implants.

Postoperative Wound Infections

Postoperative surgical site infection has been reported in 1% to 12% of patients who have undergone cochlear implantation.[6,7] Major infections may have serious consequences, including loss of the implant, and may occur more frequently in pediatric patients.[6] In 1 case series, 8 of 9 patients with device exposure (ie, an opening in the skin overlying the device as a result of wound infection and resultant wound dehiscence) ultimately required device removal, compared with 3 of 17 patients with a wound infection without device exposure.[7] Although the use of prophylactic perioperative antimicrobial agents has varied among centers and surgeons, the FDA recommended in 2003 that "[h]ealth care providers should consider prophylactic antibiotic treatment perioperatively in children receiving cochlear implants."[8] This recommendation was made to reduce the risk of meningitis that occurs in the immediate postoperative period, but it is possible that the use of prophylactic antimicrobial agents may also reduce the rate of occurrence of postoperative wound infection, acute otitis media, and implant infection. Patients with suspected postoperative wound infections should be referred urgently to the surgeon who performed the implant.

Acute Otitis Media in Cochlear Implant Recipients

With an increasing number of children younger than 3 years receiving cochlear implants, primary care providers are likely to be confronted with children with cochlear implants who present with acute otitis media. Rates of morbidity associated with acute otitis media may be higher in children with cochlear implants than in other children, because the surgically placed electrode traverses the middle ear to the inner ear through the cochlear wall (cochleostomy) or the round window membrane (Fig 1). Although the opening created between the middle and inner ear is generally sealed with fascia or other material, it remains a potential route for acute otitis media–causing bacteria in the middle ear to spread to the inner ear. Inner-ear infection can result in severe symptoms including hearing loss attributable to damage to auditory primary afferent neurons, vestibular dysfunction, and meningitis. In addition, inner-ear infection can result in loss of the implant because of implant contamination or implant malfunction related to ossification of the cochlea.

Published data concerning the incidence and prognosis of acute otitis media in children with implants are limited (Table 1).[9–13] Theoretically, in the initial months after placement of a cochlear implant, the risk of complications associated with an episode of acute otitis media may be higher if the cochleostomy, the communication between the middle and inner ear created during implantation, has not healed. An animal model has demonstrated that acute otitis media induced within 2 weeks after cochlear implantation may result in severe cochlear damage.[14] However, postmortem study of the temporal bone of implant recipients 2 to 10 years after implantation demonstrated that the opening in the round window around the electrode was sealed with fibrous tissue.[15]

In the only prospective study of acute otitis media in implant recipients, Luntz et al[9,16] studied 60 children whom

they categorized as otitis media prone (on the basis of previous history of frequent otitis media; $n = 34$; mean age at cochlear implant: 48 months) and non–otitis media prone ($n = 26$; mean age at cochlear implant: 35 months). Preoperatively, the otitis media–prone group underwent ventilation-tube placement with or without adenoidectomy and, in some cases, additional measures. Patients were required to have a normal tympanic membrane and no drainage via the ventilation tube for at least 2 weeks before implantation. With a mean follow-up period of 20 months after implantation, at least 1 episode of acute otitis media had occurred in 15 (44%) of the 34 otitis media–prone children and 2 (8%) of the non–otitis media–prone children. Six (10%) children with implants, 5 of whom were in the otitis media–prone group, had an episode of acute otitis media within 1 month of implantation, a finding that supports the assertion that children are at highest risk of acute otitis media during the immediate postoperative period. All these episodes of acute otitis media were treated successfully with oral antimicrobial agents, typically amoxicillin/clavulanate. Thirteen patients developed acute otitis media later than 1 month after implantation; all of them had installation of a new ventilation tube to establish middle-ear drainage, unless the patient had a preexisting ventilation tube, and were treated initially with oral antimicrobial therapy. Six children required hospitalization and administration of intravenous antimicrobial therapy because of failure of oral antimicrobial agents and, in 2 of these 6 children, acute mastoiditis.

Four retrospective studies of acute otitis media in children with implants have been reported. In 3 studies, the severity or outcome of acute otitis media was found to be satisfactory when using standard treatments (Table 1).[10,11,13] In contrast, the fourth study[12] revealed that patients with implants were more likely to require intravenous antimicrobial therapy and a myringotomy.[12] Furthermore, of the 11 episodes of acute otitis media reported in this study, 7 patients underwent surgical treatment for mastoiditis. No child in any of the 4 series was reported to have developed bacterial meningitis. Although these reports provide useful insight, they contain significant limitations, including the retrospective design, possibly leading to identification and inclusion of only the more severe acute otitis media episodes. Another limitation is the lack of report of pathogens causing acute otitis media episodes.

That no cases of bacterial meningitis were reported in these case series of children with acute otitis media is not surprising, given the small number of cases in these series and a reported incidence of *Streptococcus pneumoniae* meningitis in children with cochlear implants of 138 cases per 100 000 person-years.[17] However, in a study of bacterial meningitis in children with implants, for the subgroup of children with bacterial meningitis that occurred at least 30 days after implant surgery (and for whom clinical information was available concerning the presence of acute otitis media), acute otitis media was present in 13 (50%) of 26 patients at the time of presentation with meningitis (although whether acute otitis media was in the same ear as the implant was not reported).[17,18] These findings indicate that, at least in some cases, there may be a causal relationship between acute otitis media and bacterial meningitis. Signs of acute otitis media were not reported in any of 9 episodes of bacterial meningitis that presented within 30 days of implantation of a cochlear device. To prevent episodes of acute otitis media after cochlear implantation, surgeons may place tympanostomy tubes before or at the time of implantation in children with a history of recurrent acute otitis media or persistent middle-ear effusion.[16,19] A consensus report prepared by 8 cochlear implant surgeons recommended, on the basis of theoretical considerations and a series of otitis media–related meningitis episodes in adults,[20] avoidance of implantation if middle-ear fluid is present.[21] The surgeons stated that if middle-ear fluid is encountered at the time of implantation, they recommended high-volume irrigation of the middle ear, administration of topical antimicrobial agents into the middle-ear space, and systemic therapy with ceftriaxone.[21]

Bacterial Meningitis in Cochlear Implant Recipients

Factors independent of cochlear implantation may place children with hearing loss at increased risk of bacterial meningitis.[17] Some children have an inner-ear malformation (eg, common cavity malformation) that predisposes them to bacterial meningitis as a complication of middle- and inner-ear infection. For example, a 6-year-old child with Mondini-type malformation and a cochlear implant in the left ear placed 2 years earlier developed rapidly fatal meningitis.[22] Examination of the temporal bones at autopsy showed that acute meningitis was related to right middle-ear infection and suppurative labyrinthitis. The left middle ear on the side of the implant was uninfected. Thus, in this case and in a second case,[23] just having an inner-ear malformation, rather than a cochlear implant, was the risk factor for acute otitis media–related meningitis. Bacterial meningitis in infants is an important cause of acquired deafness, which may lead to cochlear implantation, and preimplant meningitis has been identified as a risk factor for postimplant meningitis.[24]

In most cases of meningitis in patients with an implant, the initial event in the pathogenesis of meningitis is acute otitis media that occurs in the ipsilateral ear, especially when meningitis occurs more than 30 days after surgery. After acute otitis media develops, bacteria can enter the inner ear through an incompletely sealed cochleostomy. Pathways of bacterial access to the cerebrospinal fluid (CSF) from the inner ear include entry into the labyrinth, infiltration of the cochlear turns along the electrode entering the Schuknecht bony channels, and following perineural and/or perivascular pathways into the internal auditory canal to the meninges.[21] In patients with a malformed cochlea in which there is a connection to the subarachnoid space, meningitis also can occur via the cochlear aqueduct. In the absence of a surgical procedure to reduce such risks, these children remain at increased risk of meningitis after cochlear implantation. In addition, as postulated by Arnold et al[21] and studied experimentally by Wei et al,[25] cases of bacterial meningitis in implant recipients may originate via pneumococcal bacteremia with hematogenous seeding of the cochlea, such as at a site of tissue necrosis related to the electrode or positioner (locus minoris resistentiae) with contiguous spread to the CSF and meninges.

In addition, cochlear implants themselves increase the risk of bacterial meningitis, especially during the first 2 months after implantation. In a nested case-control investigation of US children younger than 6 years with cochlear implants and meningitis between 1997 and 2002, 26 children with bacterial meningitis were identified among 4264 children with cochlear implants.[17] During an additional 2 years of follow-up of this cohort, 12 additional episodes of bacterial meningitis were identified.[18] The rate of bacterial meningitis was 189 cases per 100 000 person-years, a more than 30-fold increased risk compared with that in the overall population.[17] In a study in Denmark, the rate of bacterial meningitis was 43 cases per 100 000 person-years in young children with hearing loss (10.4% of the cohort had cochlear implants).[26] In the same study, young children with hearing loss and without a cochlear implant were at a 4.1-fold increased relative risk (95% confidence interval [CI]: 1.5–11.0) for development of bacterial meningitis compared with a group of children without hearing loss. Within the group of children with implants in the US study, the risk of meningitis was significantly higher for patients with a particular implant model (AB-5100H or AB-5100H-11 [Advanced Bionics, Sylmar, CA]) that included a positioner (or a so-called spacer, a wedge that rests in the cochlea next to the electrodes).[17] During the period from 1997 to 2004, only 19% of the cohort of children had a model with a positioner, yet these children accounted for 71% of the children with meningitis. The models with positioners were available beginning in 1999 and were voluntarily recalled in the United States in July 2002. In a multivariate analysis of a case-control study, the odds ratio for meningitis in patients with an implant with a positioner was 4.5 (95% CI: 1.3–17.9). Although the increased risk of meningitis in patients with an implant with a positioner continues beyond 24 months after implantation,[18] to date, elective removal of these implants or their positioners is not recommended,[18,27] and these implants remain in place in many patients. In the same analysis, an additional risk factor for development of meningitis was inner-ear malformation with a CSF leak (odds ratio: 9.3 [95% CI: 1.2–94.5]).

Episodes of meningitis in patients with a cochlear implant may have a fatal outcome. Of 198 cases of postimplant bacterial meningitis in children and adults reported to the FDA, the mortality rate in the 184 cases for which the outcome of infection was known was 16% (Eric Mann, FDA, personal communication, February 7, 2008). Of 38 children who experienced 41 episodes of meningitis reported by Reefhuis et al[17] and Biernath et al,[18] 3 children died.

Streptococcus pneumoniae is the most common pathogen that causes meningitis in children with cochlear implants[17,18] and in patients with an inner-ear malformation that predisposed them to bacterial meningitis.[28] Pathogens associated with bacterial meningitis that occurred within 30 days of implant surgery were *S pneumoniae* in 4 of 9 cases and *Acinetobacter baumannii* (2 cases), *Escherichia coli*, *Haemophilus influenzae* type b, and *Enterococcus* spp in the remainder.[17] Of 25 cases that occurred more than 30 days after implant surgery with an identified pathogen, the etiology was *S pneumoniae* in 80%; nontypeable *H influenzae* in 12%; *H influenzae* type b in 4%; and *Streptococcus pyogenes* in 4%.[17,18] *Neisseria meningitidis* (meningococcus) has not been reported as an etiology of meningitis in children with cochlear implants (although meningococcal meningitis has been reported in 2 children with congenital malformation of the middle ear[26]), and available data do not support cochlear implants as a risk factor for meningitis attributable to *N meningitidis*. As noted earlier, acute otitis media was not noted to be present at the time of diagnosis in any of the cases that occurred during the first 30 days after implantation but was noted in 52% of cases that occurred more than 30 days after implantation.

Use of Pneumococcal and *H influenzae* Type b Vaccines for Prevention of Acute Otitis Media and Meningitis

Immunization of the general population of infants with the primary series of heptavalent pneumococcal conjugate vaccine (PCV7) has resulted in a marked decrease in invasive pneumococcal disease, including meningitis.[29,30] In addition, immunization of infants has resulted in an approximately 7% reduction in episodes of acute otitis media from all etiologies and a 34% reduction in pneumococcal otitis media.[31,32] However, 2 randomized double-blind studies of prevention of acute otitis media in children 1 to 6 years of age identified as otitis prone in which the treatment group received 1 or 2 doses of PCV7 followed 6 months later by a dose of 23-valent pneumococcal polysaccharide vaccine (PPSV23) revealed no effect on the rate or severity of episodes of acute otitis media.[33,34] Although PCV7 results in a reduction in nasopharyngeal colonization with vaccine serotypes, overall carriage of pneumococci is unchanged as a result of colonization with nonvaccine serotypes.[35] PPSV23, licensed for children 2 years of age and older, reduces the incidence of invasive pneumococcal disease but does not prevent pneumococcal colonization or acute otitis media.[36] Therefore, it is uncertain, theoretically, whether PPSV23 in children with implants would prevent meningitis attributable to pneumococcal infections that originate in the middle ear and cause meningitis by contiguous spread of bacteria. There are no data on the efficacy of PCV7 or PPSV23 in prevention of pneumococcal meningitis in children with cochlear implants, but there are immunogenicity data. A single dose of PCV7 in children 14 months through 5 years of age with cochlear implants induced a substantial immune response with mean 12-fold and 7.8-fold increases in anticapsular antibody concentration to the 7 serotypes in the vaccine in children 14 months to 2 years of age and children 2 through 5 years of age, respectively.[37] Among children 2 through 5 years of age, a single dose of PCV7 was more immunogenic than a single dose of PPSV23 for the 7 serotypes in PCV7. PPSV23 was immunogenic in children older than 5 years, adolescents, and young adults; there was a mean 4.2-fold increase in anticapsular antibody concentration to the 7 PCV7 serotypes.[37] The distribution of serotypes of *S pneumoniae* causing meningitis in implant recipients is unknown but is assumed to be the same as in children without cochlear implants. On February 24, 2010, a 13-valent pneumococcal conjugate vaccine (PCV13) was licensed by the FDA on the basis of safety and immunogenicity. This vaccine contains polysaccharides of the 7 serotypes in PCV7 and polysaccharides from 6 additional serotypes. It has not been studied in children with cochlear implants or in children older than 71 months. This vaccine replaces PCV7 for all scheduled doses of PCV7 in infants.[38] In addition, a supplemental dose of PCV13 is recommended for children 14 months through 18 years of age with a cochlear implant.[38]

H influenzae type b conjugate vaccine (Hib) is highly effective for prevention of invasive disease and colonization with this pathogen[39,40] and, presumably, is effective for prevention of acute otitis media attributable to *H influenzae* type b. Cochlear implant recipients have anticapsular antibody concentrations to *H influenzae* type b after immunization that are likely to be protective.[37,41] Hib vaccine does not prevent colonization or infection with non–serotype b strains; most *H influenzae* strains that cause acute otitis media are nontypeable strains, as were the isolates from most cases of *H influenzae* meningitis in implant recipients.[17]

RECOMMENDATIONS

US Preventive Services Task Force Ratings criteria[42] were used to assess the strength of evidence for recommendations. All of the recommendations were classified as "I" indicating insufficient evidence except where a different rating (ie, ratings A, B, C, or D) is noted after the statement (see Appendix).

1. Evaluations and Management Before or During Insertion of Cochlear Implant

- Imaging of the temporal bone/inner ear should be performed before cochlear implantation in all children with congenital deafness and all patients with profound hearing impairment and a history of bacterial meningitis (if not known to have normal hearing before meningitis) to identify those with inner-ear malformations/CSF fistulas or ossification of the cochlea. In patients with inner-ear malformations that are associated with a higher likelihood of CSF fistulas after cochlear implantation (eg, wide vestibular aqueduct syndrome or Mondini malformation), particular attention must be paid to sealing the cochleostomy during the cochlear implant surgery to further lower the risk of developing bacterial meningitis.
- For otitis-prone children or children with persistent middle-ear effusion, tympanostomy tube placement should be considered before cochlear implantation.[9,16,43]

2. Primary and Secondary Prevention of Meningitis and Acute Otitis Media

- All children, including those with severe hearing impairment or infants with profound deafness, should receive all doses of PCV13 (or PCV7 if PCV13 is not yet available) and Hib, according to the routine recom-

mended schedule (ie, a dose of each at 2, 4, 6, and 12–15 months of age, except that a dose of Hib is not needed at 6 months of age if PRP-OMP [PedvaxHIB or ComVax, Merck, Whitehouse Station, NJ] was given for the first 2 doses)[44] (**recommendation A**).

- Starting at 2 years of age and at least 2 months after the last dose of PCV13 (or PCV7 if PCV13 is unavailable), a dose of PPSV23 should be administered to (1) children scheduled for cochlear implantation (or after cochlear implantation if not previously administered) and (2) children with an inner-ear malformation with a CSF communication[45,46] (**recommendation B**). For maximal benefit, administration of the doses of PCV13 and PPSV23 should be completed at least 2 weeks before implant surgery. Children 24 through 71 months of age who have received 2 or fewer previous doses of PCV13 (or PCV7) before 24 months of age should receive 2 doses of PCV13 at least 2 months apart, and those who have received 3 previous doses of PCV13 (or PCV7) should receive 1 dose of PCV13.[47] PPSV23 should be administered 2 months after completion of the PCV13 (PCV7) series. For children older than 71 months who have not received PCV13, administration of 1 dose of PCV13 should be considered. All such children should receive PPSV23 (2 months after PCV13 if PCV13 is administered) if not previously administered (**recommendation B**). Administration of more than 1 dose of PPSV23 to children with cochlear implants is not recommended.
- A single supplemental dose of PCV13 should be administered to children 14 months through 71 months of age who have been fully immunized with PCV7. A supplemental dose is unnecessary if the fourth dose of pneumococcal conjugate vaccine given at 12 months of age or older was PCV13.
- A single dose or supplemental dose of PCV13 may be administered to pediatric patients 6 through 18 years of age who have a cochlear implant or are scheduled to receive a cochlear implant regardless of previous doses of PCV7 and PPSV23.
- When assessing a history of previous immunization with pneumococcal vaccines, care should be exercised to avoid confusing past immunization with other vaccines that could be considered "meningitis vaccines" (ie, Hib and quadrivalent meningococcal polysaccharide or conjugate vaccines) with doses of PCV7 and PPSV23.
- Meningococcal conjugate vaccine should be administered in accordance with routine recommendations,[48–50] but given current data, cochlear implant recipients should not be considered a group at high risk of invasive meningococcal disease. Therefore, children younger than 11 years should not be immunized routinely.
- In most studies, administration of influenza vaccine to healthy children reduced the incidence of episodes of acute otitis media during influenza season.[51–54] To reduce the number of episodes of acute otitis media, annual administration of influenza vaccine with trivalent inactivated vaccine or live attenuated nasal vaccine (if the child has no condition that constitutes a medical contraindication) to patients with a cochlear implant is recommended, and influenza immunization of their household contacts should be strongly considered (**recommendation B**).
- Tympanostomy tube placement also should be considered if recurrent episodes of acute otitis media occur after cochlear implantation.

3. Management of Postoperative Wound Infection or Suspected Cochlear Implant Infection

- Patients with suspected postoperative wound infection or suspected implant infection should be referred urgently to the surgeon who performed the implant procedure. Broad-spectrum antimicrobial therapy that includes an agent or agents with activity against methicillin-susceptible and methicillin-resistant *Staphylococcus aureus* should be initiated.

4. Early Diagnosis of Acute Otitis Media and Meningitis

- Patients and parents should be educated as to symptoms of acute otitis media and meningitis and to seek immediate medical evaluation for acute illness with symptoms possibly attributable to either acute otitis media (eg, fever or earache) or meningitis (eg, fever, headache, vomiting, stiff neck, or change in level of consciousness).
- Clinicians should consider bacterial meningitis in the differential diagnosis of all patients with cochlear implants who present with fever with or without acute otitis media on physical examination, particularly during the first 2 years after implantation in patients with cochlear implants without positioners and indefinitely in patients with cochlear implants placed between 1999 and August 2002 with positioners (Advanced Bionics model AB-5100H or AB-5100H-11).

5. Management of Acute Otitis Media in Children With Cochlear Implants

- Patients with cochlear implants who are diagnosed with acute otitis media should be started urgently on systemic antimicrobial therapy; watchful waiting is inappropriate for these children.[55] Initial empiric treatment

with an oral antimicrobial agent (eg, amoxicillin or amoxicillin/clavulanate, at a dose of 80–90 mg/kg per day) is reasonable if all of the following criteria are fulfilled: (1) the episode occurs 2 or more months after cochlear implantation; (2) the patient does not have an uncorrected Mondini or similar inner-ear malformation or CSF/middle-ear fistula; (3) the patient does not appear severely ill and there is no clinical evidence of mastoiditis or meningitis; and (4) the cochlear implant does not have a spacer/positioner (Advanced Bionics model AB-5100H or AB-5100H-11). Patients with acute otitis media who fulfill these criteria are likely to be at a lower risk of developing inner-ear infection or meningitis complicating acute otitis media. If feasible, middle-ear fluid should be obtained through the tympanostomy tube or a tympanocentesis or myringotomy for culture just before initiation of antimicrobial therapy, but this should not be allowed to cause an undue delay in initiation of antimicrobial therapy. For patients with a cochlear implant who do not meet these criteria (including patients with implants of an unknown type implanted between 1999 and August 2002), initial therapy with a parenteral antimicrobial agent for treatment of acute otitis media (eg, ceftriaxone or cefotaxime) is recommended. Patients with a cochlear implant and acute otitis media should be evaluated by an otolaryngologist if their condition worsens despite 24 hours of antimicrobial therapy. A sample of middle-ear fluid should be obtained for culture, and a myringotomy with or without ventilation placement should be performed to drain the middle ear.

6. Management of Bacterial Meningitis in Patients With a Cochlear Implant

- CSF should be submitted for culture. If present, middle-ear fluid should be obtained and sent for culture. The choice of empiric antimicrobial therapy for meningitis (eg, ceftriaxone or cefotaxime plus vancomycin) is similar to that for children without implants. An exception is for children with the onset of meningitis during the first 2 weeks after cochlear implantation; in such circumstances, causal bacteria may include a broader range of pathogens, including Gram-negative bacilli such as *A baumannii* and Gram-positive bacteria such as *Enterococcus* spp. Selection of a combination of agents that provide broader-spectrum activity against Gram-negative bacilli (eg, meropenem and vancomycin) should be considered. Patients with a cochlear implant and bacterial meningitis should be evaluated urgently by an otolaryngologist for consideration of imaging and surgical exploration.

APPENDIX Grading of Recommendations

Grade	Definition
A	Recommended: there is high certainty that the net benefit is substantial.
B	Recommended: there is high certainty that the net benefit is moderate or there is moderate certainty that the net benefit is moderate to substantial.
C	Recommendation against routinely providing: there may be considerations that support providing the service in an individual patient, and there is at least moderate certainty that the net benefit is small.
D	Recommends against the service: there is moderate or high certainty that the service has no net benefit or that the harms outweigh the benefits.
I	The current evidence is insufficient to assess the balance of benefits and harms of the recommendation. Evidence is lacking, of poor quality, or conflicting, and the balance of benefits and harms cannot be determined.

Modified from the US Preventive Services Task Force recommendations categories (available at: www.ahrq.gov/clinic/uspstf/grades.htm).

APPENDIX A.

*Literature classification schema.**

Design/Class	Therapy†	Diagnosis‡	Prognosis§
1	Randomized, controlled trial or meta-analyses of randomized trials	Prospective cohort using a criterion standard	Population prospective cohort
2	Nonrandomized trial	Retrospective observational	Retrospective cohort Case control
3	Case series Case report Other (eg, consensus, review)	Case series Case report Other (eg, consensus, review)	Case series Case report Other (eg, consensus, review)

*Some designs (eg, surveys) will not fit this schema and should be assessed individually.
†Objective is to measure therapeutic efficacy comparing $\geq$2 interventions.
‡Objective is to determine the sensitivity and specificity of diagnostic tests.
§Objective is to predict outcome including mortality and morbidity.

TECHNICAL REPORT

Communicating With Children and Families: From Everyday Interactions to Skill in Conveying Distressing Information

Marcia Levetown, MD, and the Committee on Bioethics

ABSTRACT

Health care communication is a skill that is critical to safe and effective medical practice; it can and must be taught. Communication skill influences patient disclosure, treatment adherence and outcome, adaptation to illness, and bereavement. This article provides a review of the evidence regarding clinical communication in the pediatric setting, covering the spectrum from outpatient primary care consultation to death notification, and provides practical suggestions to improve communication with patients and families, enabling more effective, efficient, and empathic pediatric health care.

INTRODUCTION/OVERVIEW

Health care communication is a critical, but generally neglected, component of pediatric and pediatric subspecialty practice and training and is a skill that can and must be taught.[1–13] The practicing clinician's ability to communicate openly and with compassion is essential for effective and efficient routine health care; this ability becomes a vital lifeline for parents and children confronted with life-altering and sometimes life-ending conditions.[13–16] The purpose of this report is to provide research-based and practical guidance to enable effective communication with pediatric patients and their families in a number of common settings and situations. Although child abuse, sexuality, divorce, and many other situations are not individually addressed, the principles and approaches discussed apply equally to these situations.

Communication is the most common "procedure" in medicine. Health care communication is different from normal social discourse, because intimate and very private issues are often discussed. These include hopes and fears, developmental concerns, sexuality, and mental health disorders. Painful issues, such as abuse, school failure, drug use, and terminal illness, are also discussed. Communication is the foundation of the therapeutic relationship; it is the basis of fiduciary and ethical obligations of physicians to patients and their families. Effective health care communication is an essential tool for accurate diagnosis[17–19] and for the development of a successful treatment plan,[20–23] correlating with improved patient knowledge,[15,24] functional status,[25,26] adherence to the agreed-on treatment regimen,[20,21,27–32] improved psychological and behavioral outcomes,[15,33–36] and even reduced surgical morbidity.[3,4,37] In the case of distressing news, skillful communication can enable a family to adapt better to a challenging situation,[12,38,39] including a child's unanticipated impairments.[40–43] Poor communication, on the other hand, can prompt lifelong anger[31,42,44–48] and regret,[14,40] can result in compromised outcomes for the patient and family, and can have medicolegal consequences for the practitioner.[49]

WHAT IS COMMUNICATION?

Effective communication is responsive to the needs of the whole patient and family dynamic; it is essential to patient-centered and family centered care, the basic building block of the medical home concept (www.medicalhomeinfo.org) endorsed by the American Academy of Pediatrics (AAP) as a cornerstone of care.[50]

Taking time to build rapport and understand the child and family builds trust, leading to increased reporting of the actual reason for the visit.[51,52] Clearly, improved communication will enhance patient outcomes and satisfaction.[4] There are 3 elements of physician-parent-child communication[53]:

- Informativeness: quantity and quality of health information provided by the physician;
- Interpersonal sensitivity: affective behaviors that reflect the doctor's attention to, and interest in, the parents' and child's feelings and concerns; and
- Partnership building: the extent to which the physician invites the parents (and child) to state their concerns, perspectives, and suggestions during the consultation.

There are 2 types of patient needs to be addressed during the medical interview: cognitive (serving the need to know and understand) and affective (serving the emotional need to feel known and understood). Thus, physicians are expected to have task-related behavior and relational behavior. The first involves asking questions and providing information. The latter includes reflecting feelings and showing respect, concern, and compassion, often by nonverbal means, such as gestures, posture, and eye contact, as well as the use of silence to allow for the processing of emotional responses and the formulation of questions. (An example of a reflective response is, "When you say you don't think you can manage this, what is the hardest thing about Chad's illness for you and your family?") Parent satisfaction with quality of care is substantially influenced by the interpersonal skills of the practitioner, particularly in the case of anxious parents.[53,54]

MEDICAL EDUCATION AND COMMUNICATION

Despite the essential nature of communication in health care, there is little programmatic or curricular emphasis on building interpersonal skills in pediatric service or training. Instead, a preponderance of time is spent on facts and procedures, with minimal attention to feelings, relationships, and continuity of care.[12,34,47,54–60] The AAP, in its policy statement "The New Morbidity Revisited: A Renewed Commitment to the Psychosocial Aspects of Pediatric Care," states that "there is a need to better learn how to elicit information, including using a narrative interview approach, allowing the child, adolescent, and parents to tell their stories," and "there is a need to communicate empathy."[3] The AAP suggests that the teaching of these skills involves supervised practice, feedback, and mentoring.

There is a long history of concern among holistic medical educators and philosophers regarding the loss of empathy related to current medical education methods and role models.[61–66] This concern has led to attempts to measure empathy and to reinforce it during medical education.[67–69] It has been demonstrated in preliminary studies that empathy not only can be extinguished by training but also can be amplified and taught. Empathy affects quality of care and patient satisfaction; physicians who are empathetic have been shown to elicit patient concerns more accurately and address needs more effectively, often enhancing cost efficiency.[70–76]

Unfortunately, studies over the last 15 years do not indicate a trend toward improvement in this area. Despite requirements and recommendations of the American Council for Graduate Medical Education,[77] the Future of Pediatric Education II Task Force,[2] and the long-standing dedication to the child, family, and psychosocial environment by the AAP as manifested in numerous policies and published goals,[3,4,50,78–84] the "informal" or "hidden curriculum" (that which is taught by observing the daily behavior of health care professionals, both good and bad)[85] continues to disproportionately reward "hard" data collection while downplaying the role of the psychosocial, existential, and interpersonal concerns and needs of the patient and family. Such a training emphasis does not enhance the ability of the physician to fully meet the needs of our patients and their families.[86]

The Current Situation

Health care communication is currently learned primarily through trial and error.[1] This may be attributable, in part, to a dearth of skilled mentors. A large national survey published in 2003 indicates that medical school faculty members may, themselves, need communication skills training.[87] Nonphysician mentors who are trained communicators, such as child life therapists,[88] child psychologists (as an example, see Sourkes[89]), and members of the American Academy on Communication in Health Care (AACH [www.aachonline.org]), can help practicing physicians and medical school faculty develop these skills.[55] In the inpatient setting, social workers, advanced practice nurses, psychologists, and chaplains can assist in the provision and modeling of effective communication with children and their families,[90–93] but the practice of depending on numerous caregivers to communicate poses a risk of families being exposed to conflicting information and opinions, often provoking anxiety and confusion. True interdisciplinary teamwork and collaboration can prevent this complication.[43] Regardless of the help available, however, the physician must always play a significant role in the communication process.

Communication Needs

Patients and families expect more accessible information than is commonly provided in virtually every health care setting.[12,31,58,94–98] It is estimated that 35% to 70% of medicolegal actions result from poor delivery of information, failure to understand patient and family perspectives, failure to solicit and incorporate patients' values into the plan of care, and perceptions of desertion.[49,99–104]

Psychosocial and practical/family issues are often overlooked.[52] Closed interviewing techniques, such as asking yes or no questions, may be used by clinicians to control the duration of the interview. Families perceive this style as indicative of a lack of interpersonal interest, sometimes resulting in a reluctance to reveal the true reason for seeking consultation; potential results are treatment failure and poor health outcomes.[56,105–107] Invitations by physicians to the child and family to contribute and to express concerns are nearly always welcomed by parents and do not increase the duration, but do increase the utility, of the encounter.[49,108] Formal

TABLE 1 **Physician "Competencies" for Health Care Communication**

1.	Develop a partnership with the patient
2.	Establish or review the patient's preferences for information
3.	Establish or review the patient's preferences for his or her role in decision making
4.	Ascertain and respond to the patient's ideas, concerns, and expectations
5.	Identify choices (including those suggested by the patient) and evaluate research in relation to the individual patient
6.	Present information and assist the patient to reflect on the impact of alternate decisions with regard to his or her lifestyle and values
7.	Negotiate a decision with the patient
8.	Agree on an action plan and complete arrangements for follow-up

communication training is helpful in developing this skill.[6,35,72,109–116]

Communication Competencies for Physicians

One group identified 8 physician "competencies" that enable "informed shared decision-making" to take place[117] (see Table 1). These competencies, behaviors, and protocols will also result in patient-centered and family-centered interviews, which are key elements in the construction of a medical home.

According to these investigators, such an interview can be accomplished in 10 minutes with adult patients. The triadic nature of pediatric patient interactions would, as always, require more time. The child's preferences and values should be solicited in addition to that of the parents. Sharing of information and responsibility for decision-making must be negotiated.

Effective Methodologies for Teaching Communication Skills

High proportions of physicians at all levels of practice are willing to reveal their discomfort with communication, particularly involving unwelcome information that is likely to upset parents.[118] In response to residents' requests and parents' complaints, Northwestern University's pediatric residency program developed a communication course[9] designed according to the articulated needs of the learners. Provided during the middle of the first year of pediatric residency, training addressed "breaking bad news" and "difficult families." Scenarios were designed with input from the residents. Teaching tools included didactic sessions, interactive discussion, parent-panel discussions (including children who had survived life-threatening illness and bereaved parents), paired role play, and discussion. Although well received, the effect was difficult to evaluate because of the low number of participants.

Use of simulated patients, observation of role models, attendance at camps, support groups, and home visits are also useful in developing a patient-centered and family-centered perspective, resulting in more effective communication skills.

A teaching program for "breaking bad news" in the emergency department (ED) setting using simulated patients and video feedback demonstrated improvement in skills after 2 sessions on the basis of a checklist of desired behaviors, simulated patient feedback, and improved confidence of trainees.[6] A study of a 1-day workshop using scenarios relevant to the PICU also demonstrated statistically significant improvements.[10] Simulated or "standardized patient" programs are, however, expensive.

Other investigators have found measurable success improving communication by using immediate video feedback alone.[7] One innovative program designed for undergraduate medical students used two 2-hour sessions in both inpatient and outpatient settings, interviews with parents, and play with child patients to enable students to better understand family perspectives about communication.[113] Progressive experiences included a small-group discussion about the difficulties of breaking bad news, a video role model followed by a parent panel, and finally, time to meet the child patient. The training was favorably received by student, parent, and patient participants. After the experience, some students reported a profound effect on their attention to the patient and his or her supporters; 18 months after the seminar, 1 student noted he still "keenly felt the influence of his eyes being opened to the myopic view of the medical fraternity" in health care communication.

Another communication workshop to teach pediatric residents how to tell parents about a child's lifelong disability was developed by a parent support group and a pediatrician.[119] In this workshop, the psychosocial dynamics of the interchange are defined/identified, and facilitative behaviors are described. The resident chooses a skill in which he or she feels most deficient and works specifically to improve it in a role-play exercise. The workshop concludes with a debriefing and a review of the interview tape with the parent.

There are several communication skills teaching aids available. The Initiative for Pediatric Palliative Care (www.ippcweb.org) has communication modules, including videotapes for difficult conversations. The AACH has 3- to 5-day intensive training sessions on communication, generally focused on adult patient scenarios, which include videotaped feedback, self-critique, and peer critique. In addition, the AACH provides Web-based, multimedia interactive modules on communication and relational topics (www.aachonline.org). A list of tips, techniques, and resources can also be found in other publications.[120,121]

Unfortunately, efforts to elevate health care communication, empathy, patient-centered and family-centered care as core competencies within the educational process and professional practice have, thus far, failed. Despite the overwhelming evidence of the benefit to patients, physicians, and society, effective communication is not rewarded by academic promotion or financial compensation. In fact, increased attention to communication can be costly to the practitioner in the short term because of inadequate payment for time spent discussing treatment plans and otherwise counseling families. The willingness of students, mentors, and practitioners to exert the time and effort to learn and practice effective and compassionate communication is undoubtedly influenced by these factors. Long-term benefits, such as improved patient outcome and satisfaction, decreased

risk, and greater professional satisfaction, may be harder to quantify and appreciate.

Practitioners' Needs

Practicing physicians' self-assessment of skill level in breaking bad news is often inaccurate and overly self-flattering.[1,122] Practice alone clearly does not result in improved communication skills. When self-assessed skill in this critical area is inadequate, some physicians avoid the discomfort by not engaging in difficult conversations. Less dramatically, given the widespread dissatisfaction with communication, it is clear that most practitioners would benefit from objective assessment of their current communication skills followed by targeted training, regardless of seniority.

Need for Research on Communication Education and Practice

If communication skill training is to be recommended throughout medical training and for continuing education, it is important to understand what techniques are most efficacious, time-efficient, and cost-efficient to achieve the goal of more consistently achieving effective, empathetic, and culturally appropriate communication that meets the needs identified by patients and parents. What timing during the course of education is most likely to result in durable change? Which communication techniques best prevent the anger and dismay that too often lead to suboptimal patient outcomes or malpractice litigation? Finally, what changes in institutional culture or reimbursement mechanisms will reinforce good communication throughout the career of the practitioner? Research on these topics should be a priority, given the central importance of communication in medicine.

CLINICAL PRACTICE ISSUES

Communication With Parents: Ensuring Effective Communication

Factors predictive of effective communication between physicians and patients/parents are the perception of interest, caring, warmth, and responsiveness.[123–125] Parents' most frequent criticisms of health care practice concern relationships with practitioners[53]; these relationships have a dramatic effect on parental satisfaction, recall of instructions and, not surprisingly, treatment adherence.[126,127] Greater trust and a better relationship with the physician have more of an effect on patient recall and satisfaction than written instructions or even the amount of time spent.[128]

Causes of Dissatisfaction

Even with very detailed explanations, parents who feel they are not treated with respect or who have unrecognized or unaddressed fears feel unhappy about the amount of information provided. For instance, being asked to consent to a new aspect of a procedure while standing in the hall the night before surgery caught 1 parent by surprise, coloring her overall satisfaction and perception of the sufficiency of information.[54] Facilitators of improved communication include clear demonstrations of empathy and respect. See Table 2 for additional recommendations.

TABLE 2 Recommended Communication Behaviors for Procedural Interventions

Find a private setting for discussion and decision making
Use language the family can understand
Use visual aids (drawings, models, and radiographs)
Pace the information, providing it in a logical sequence; be prepared to patiently repeat information and answer questions
Recognize emotional distress
Discuss indications, risks, benefits, and all reasonable alternatives (including not doing the procedure at all) and the associated risks and benefits
Discuss specific tubes and drains immediately before surgery
Personalize the information rather than giving it as a rote speech (eg, use the child's name)
Avoid last-minute surprises when feasible
Ask parents and the child (when appropriate) to repeat what they understood in their own words, and clarify information and plans as needed

Data were adapted from Lashley et al.[54]

Audiotapes as Communication Aids

Several articles support the use of audiotapes to allow parents to repeatedly listen to the information, allowing it to soak in, and importantly, enabling dissemination of accurate information to others who could not be present.[129–135] Parents frequently consult others in making health care decisions for their children, ranging from extended family members to other practitioners, other parents, religious leaders, and tribal elders. One study found that tapes made during outpatient encounters were listened to by parents nearly universally; grandparents listened to them more than half the time (52.8%), 70% were listened to more than once, and one third of parents made a copy to keep for themselves. The tapes were found to be helpful >99% of the time.[129] Physician fears of the use of such tapes in medicolegal actions are understandable but, thus far, unfounded. In fact, the tapes often reveal that much more information was shared than either party realized, suggesting that the tapes may even be protective.[136]

What Parents Want to Know: Surgical Procedures and Chronic Conditions

Patients undergoing surgery and their parents often want answers to seemingly "minor" questions.[137] The expected duration of the surgery, the amount of hair to be removed, the location and length of the incision and bandages, location and purpose of intravenous lines and other assorted tubes, and the child's likely appearance after the procedure are sources of concern that, although routine for practitioners, should be prospectively addressed.[54]

Parents consistently state that they need more and clearer information about their children's health status, particularly in the setting of chronic or terminal illness.[50,94,138–142] Parents of chronically ill children want more information about the child's condition, its treatment, and its long-term implications;[94,142–144] they want

that information to be shared with them as soon as it is known.[42]

Parents want advice about their child's behavior and development, genetic implications of the child's condition, and social contact with families in similar situations.[39,142] They would like someone, preferably the physician, to provide oversight of the long-term care plan, including an opportunity for advance care planning and execution of advance directives.[143,145] They want their views and concerns factored into the care plan and to be treated like partners (and often experts) in their child's care.[5,53,54,94,137,142,143] They need affirmation of their efforts and assistance with and recognition of the need to preserve family solidarity and support, including social support, child care, education, and professional services;[94,140,143,146] in some studies, parents report assistance with family and social support as their greatest unmet need.[94,142,143] One proposed solution is to have an annual meeting of the family and physician to discuss the "big picture."[94] In short, parents of chronically ill children want a "medical home" as envisioned by the AAP. When appropriate information is not provided and this style of communication and relationship does not occur, the bitterness can linger for years.[12–14,32,41,42] Physicians who are empathic, well informed, and honest are a source of strength for parents, particularly those struggling to adapt to a difficult situation.

Intraprofessional Communication

Particularly for children living with chronic health conditions, communication between primary care practitioner and specialist is critical for effective and efficient care.[50,147–152] A recent study[153] indicates that pediatric practitioners agree about the importance of such communication but have difficulty putting it into practice. Specific recommendations include timely, systematic information transfer from generalist to specialist at the time of referral, after consultation, and during follow-up visits. A toolkit with practical recommendations and reimbursement strategies can be found at www.medicalhomeinfo.org/tools/toolkits.html. In addition, recognition of the medical home concept and a plan for comanagement and communication should be in place.[50,147,153]

Telemedicine

In the setting of rural health care and limited numbers of pediatric specialists, communication and medical care may be provided via video and audio conferencing. Even in the case of psychiatric illness[154] and chronic illness requiring multispecialty input,[155,156] parents and caregivers found this means of communication nearly as efficacious as in-person communication, particularly when combined with less frequent face-to-face consultations.[155,156] Another application of telemedicine is to provide frequent updates and secure communication for parents and extended families and other practitioners when a child is receiving care in the ICU.[157]

Communication With the Child Patient: Ethical, Relational, Developmental, and Cultural Considerations

Moral, Ethical, and Developmental Obligation to Include Children in Communication About Their Health

There is a moral and ethical obligation to discuss health and illness with the child patient, which is supported by a number of United Kingdom,[158,159] Canadian,[160,161] and US[162,163] laws, policies, and court decisions (eg, *Bellotti vs Baird*, 443 US 622 [1979][164]), indicating an expectation that children will be active participants in their care.[165–167] The principle of self-determination applies to children and adults.[158,168–172] Involving children in communication about their health and in decisions regarding their health care shows respect for their capacities, will enhance their skill in the process of making future health decisions, and enables their essential input into decisions where there is no "right answer" other than the 1 that best meets the needs of the individual child and family.[167,169,173,174] Older children and adolescents should have a significant role in such cases. When the patient and family disagree, the cultural and family values, roles, and structure that have always governed the relationship should be treated with due respect.

Communication as a Developmental, Relational, and Cultural Process

At its core, child health decision making is family-centered decision making.[173] Parents and children themselves are more satisfied and adherence to the treatment regimen is enhanced when the child is addressed in information gathering and in the creation of the treatment plan.[5,78,169,175] However, parents want to be involved in the decision regarding how their children are informed about their health conditions.[150] It is, therefore, important to understand the preexisting parent-child relationship, the family's cultural and idiosyncratic values,[176–178] and the developmental needs of the child, including the desire to participate in his or her own care plan.[178] Simultaneously, determination of the parents' perspectives on providing information to the child is imperative. It is important for parents to understand that research demonstrates improved adherence to the plan and resultant health outcomes when the child is treated as a partner. (For 2 recent reviews of the literature, see Tates and Meeuwesen[175] and Rushforth.[168]) Pediatric health care quality will improve if the child is recognized to have his or her own individual cognitive and emotional needs, is taken seriously, and is considered to be intelligent, capable, and cooperative.[5,137,150,168–170,173,175] Parents and practitioners should decide together whether the child will be present at the informational consultations, whether parents would prefer to tell the child themselves or have another person tell the child, and whether the informing interview will occur with or without the parents present. A recent literature review indicates that children 7 years and older are more accurate than their parents in providing health data that predicts future health outcomes, although they are worse at providing past medical histories.[179] Thus, significant attention to the child's input should be routine

TABLE 3 **Strategies to Engage Children in the Outpatient Setting**

Speak with the child; not at or to him or her
Speak in a private setting
Determine whom the child would like to be present (younger children will generally prefer parents to be present; children who have been abused by family members may need privacy to facilitate disclosure; most adolescents prefer privacy)
Begin with a nonthreatening topic
Listen actively
Pay attention to body language and tone of voice
Use drawings, games, or other creative communication tools
Elicit fears and concerns by reference to self or a third party
Ask the child what he or she would do with 3 wishes or a magic wand

Data were adapted from Lask.[180]

practice. Assisting the child to achieve gradually increased capacity to take responsibility for the maintenance of health and the treatment of illness is a crucial task, specific to pediatric physicians and practitioners.[5,168,169] See Table 3 for helpful strategies to accomplish this goal.

Despite these seemingly simple and cost-effective techniques, recent studies indicate that children are generally passive recipients of medical care, with little opportunity to express their concerns and virtually no attempt to engage them in the creation or implementation of a feasible care plan.[150,181] In 1 study, children 8 to 15 years of age who had cancer perceived that they "occupy a marginal position in consultations . . . their priorities were of little interest to medicine."[150]

Enabling Effective Child Participation

In the past, children of any age were rarely consulted about their own health concerns. In current Western culture, children are highly valued, yet attention to their autonomous needs, especially when the child is not yet an adolescent, remains challenging.[137,150,168,169,173] There are many reasons to include children as active partners in their own health care; however, this rarely happens.[170] Some attribute this situation to the dearth of tools to clarify children's conceptualization of health and illness, to assess their capacity for decision-making, to effectively share information with children, and to assess the outcome of shared decision making on the child patient.[169]

Children can be coached to effectively assume the role of a health partner. One study[5] used brief videos, age-appropriate workbooks, and a short (1- to 2-minute) role-play for the child subjects. Simultaneously, the physician and parents were educated on the importance of the child's participation. The goal was to enable children to raise concerns, ask questions, note information, and participate in the creation and troubleshooting of potential problems with the care plan. Coached children preferred an active role in their care and reported better rapport with the physician, recalling significantly greater amounts of information about their medication regimen than controls (77% vs 47%, respectively). Physicians can encourage the parent to coach the child to be an effective advocate for his or her own health.

The importance of the child possessing effective health communication skills becomes evident when trying to assess and treat a child's subjective symptom, including pain. In the absence of the child's input, it is difficult to understand the nature and severity of the pain; thus, it is nearly impossible to relieve the discomfort effectively and safely. It is well known that the use of patient-controlled analgesia assists with the resolution of pain beyond the dose of medication. The message that the child knows his pain, is in control of his therapy, and is trusted is a powerful therapeutic intervention.[182] Children as young as 4 years of age have used patient-controlled anesthesia effectively.[183]

In many cases, parents mistakenly think that not informing the child is best. Some professionals argue that paternalistic decisions (primarily on the part of the family) to withhold "harmful" information from the child can be justified.[184] This position is not supported in the literature that examines the child's preference for information.[5,150,167–169,181,185–188] One of the most striking was Bluebond-Langner's[189] landmark study of terminally ill children, indicating that children as young as 3 years of age were aware of their diagnosis and prognosis without ever having been told by an adult. She found that adult avoidance of disclosure and denial of difficult information led the child to feel abandoned and unloved. At the same time, the child's response is often to "protect" the "unaware" adults, despite great personal cost; this situation is called mutual pretense and it hurts both parties.[189] By using whatever information they have, children will continually try to make sense of their situations. An incomplete ability to understand does not justify a lack of discussion with a child who desires involvement in his or her care and decision making.

Children often understand more than has been assumed;[168,185] increased experience with information they can understand creates a stable framework on which to add new information, promoting the integration of increasingly complex pieces of information.[169] Children need to have usable information, to be given choices (including their desired level of involvement), and to be asked their opinion, even when their decision will not be determinative.[165] Enhanced understanding provides a sense of control, which in turn mitigates fear, reducing the harms associated with illness and injury. Moreover, if the child is asking about the condition, he or she often already knows something is wrong and is checking to see whom to trust. Children who do not ask should be given the opportunity to receive information, but if they refuse it, information should never be forced on them.

Parents are also apparently harmed in the aftermath of nondisclosure to their children. A study of bereaved parents in Sweden indicates that all those who spoke openly with their children had no regrets, whereas 27% of those who did not speak to their children about dying not only regretted their decision but also suffered from an increased incidence of depression and anxiety as a result.[190] Thus, counseling parents about the benefits of disclosure should be invoked when they are reluctant to speak with their child about illness or death.

Adolescents' Roles in Health Care Communication and Decisional Authority

If adolescents are to be given authority for their health care decisions, they must receive thorough, developmentally appropriate, understandable information,[165] to enable an understanding of the condition, what to expect with various tests and treatments, the range of acceptable and practical alternative care plans, and likely outcomes of each option.[191] Only then can adolescents fully participate as partners in their health care.

Because the ability to comprehend and decide is fluid and variable within and between individuals, the assent given by an informed child or adolescent who can weigh the pros and cons of the proposed intervention should be given progressively greater weight compared with parental permission.[165] However, the child's choice and parents' choices may be discordant. Expecting children to adhere to adult priorities and preferences may be illogical; Ladd and Forman[192] argue that adults' priorities clearly change over the trajectory of adulthood. Thus, if no value set is static, the adolescent's seemingly trivial or superficial judgments may be just as legitimate as any other. They argue that total paternalism toward adolescents' decisions undermines respect for the emerging, autonomous adults they will become and the emotional investment they have in their current values. The values with which adolescents judge their options are applied to an adolescent who holds those values, not to an adult with divergent values. This tolerant model of decision making addresses potentially harmful decisions by giving weight to the adolescent's decision, with the proxy taking the role of educator, discussant, challenger, and shared decision maker.[193] Overriding the adolescent's decision should be undertaken with great trepidation, using the same criteria as are used to override an adult's choice.[192]

Adolescents and Forgoing "Life-Prolonging" Treatments

Children who have undergone treatments for a condition know the burdens of therapy more intimately than the adults trying to help them. Although they may not appreciate all the hoped-for benefits, their input into treatment decisions is clearly critical for a legitimate weighing of the benefit-burden calculus.[186,193–196] When adolescents are able to appreciate the hoped-for benefits, they then also have the capacity to make full-fledged decisions regarding whether to forgo medical interventions. Decisions to forgo life-prolonging treatments made by adolescents have been upheld in courts of law. Landmark cases are described by Traugott and Alpers.[173] Ridgway[197] found that when physicians oppose these decisions, the courts generally decide for the professionals, prompting a caution to physicians to carefully weigh the likely burdens and benefits before going to court to force treatment.

Adolescent Decision Making: Legal and Ethical Issues

By US law, adolescents younger than 18 years (19 years in Nebraska and 21 years in Michigan)[198] cannot make decisions about their health without their parents' permission with some exceptions, notably emancipated minor status. Emancipated minors are persons younger than 18 years who live independent of their parents, who have taken on the responsibilities of an adult, including financial independence, parenthood, or military service, or who are emancipated by court order.[199] Most states recognize "mature minors" by criteria strikingly similar to emancipated minor status.[200] However, both the age of the patient and the conditions vary somewhat from state to state. Adolescents who are neither emancipated nor mature minors are allowed by some state statutes to give legally binding consent for treatments for limited reasons (examples include testing and treatment for sexually transmitted infections, including HIV infection; drug or alcohol abuse; family planning; blood donation; and mental health care) without parental notification.[201]

Cultural Considerations

Minority and non–English-speaking families often have cultural expectations and nuanced understandings of language that, if not understood and attended to, can substantially interfere with effective medical care and may lead to a decrease in health status for their children.[176] The AAP endorses the responsibility of the practitioner to be aware of and to accommodate the needs of such families.[178] At issue are concerns regarding who gets information, who makes decisions, amount of eye contact, forthrightness, and the need for indirect discussion. It is a good idea to be aware of the general cultural norms and taboos of the dominant subcultures attending the practice. Although there are guidelines for what is "culturally competent,"[178,203] none describes any individual family. Rather than assuming that a family will identify itself a certain way or follow cultural "norms," it is generally safer to ask family members about the etiquette for communicating with them. "How should I give your family medical information about Mary?" "With whom do I share information?" "Who makes decisions?" "Are there topics that should not be directly discussed in your family?" Offering to wait until the relevant persons arrive is culturally respectful.

Members of subcultures that are typically passive with authority figures, who are fearful in medical situations, who make decisions that favor the group over the individual, or who have generally low educational levels may have special needs. These needs may include repeated invitations to ask questions, use of long silences during discussions, accommodation of large groups for information dissemination and health-planning discussions, extra time to consult with others when decisions are to be made, and written summaries or tapes of conversations to facilitate understanding through sharing information with others,[129,177] particularly if there is limited English language proficiency. See Table 4 for suggested prompts to elicit culturally related health beliefs, concerns, and practices.

Use of Translators

The availability of trained translators is required by the Joint Commission.[205] Medicaid partially pays for transla-

TABLE 4 **Prompts to Elicit Medically Relevant, Culturally Important Information**

What concerns prompted you to bring your child (use the child's name) for health care?
What behaviors and symptoms are of greatest concern to you?
What do you think caused this problem?
How do you think the illness affects your child?
What have you tried to do to make the illness better? Have you tried any traditional remedies?
Are there any specific dietary, religious, or cultural practices that need to be accommodated?

Data were adapted from De Trill and Kovalcik.[204]

tion services.[206] Well-trained translators are often aware of cultural norms in addition to their language proficiency. Effective use of translators includes the establishment of a framework for collaboration; before the consultation begins, acknowledge the potential for and the desire to prevent cultural missteps. "I may ask you to say some things that you think are not culturally acceptable. If that happens, please let me know and guide me to more appropriately approach these topics." Use of untrained translators, such as bilingual children or other family members who are trying to absorb information and transmit it while emotionally upset, is inappropriate. Nonprofessional hospital employees are also a common source of "translation." Their knowledge of the English language is often limited, their educational levels, even in their own country, may be low, and they too will be assaulted emotionally with confidential and difficult information. There is rarely a debriefing opportunity for these kinds volunteers in the aftermath of the discussion. Use of untrained translators is, therefore also, an unacceptable option.

Bad News

Bad news can be defined as "pertaining to situations where there is a feeling of no hope, a threat to a person's mental or physical well-being, a risk of upsetting an established lifestyle, or where a message is given that conveys to an individual fewer choices in his or her life."[207] An alternate definition is that bad news is information that "results in a cognitive, behavioral, or emotional deficit that persists for some time."[46] Recognition that much of health care communication is actually bad news will improve attention to its delivery. As an example, although the diagnosis of neurofibromatosis type 1 may not seem to the practitioner to be bad news, the variability of the outcome and the lack of predictability of the disease make this diagnosis very difficult for parents.[13]

Similarly, the need for unanticipated blood tests for a needle-phobic child or the disruption of an unexpected overnight hospital stay, the need to take medications for the rest of one's life for a chronic condition, and many other common occurrences are bad news for families. Greater attention to the empathic delivery of bad news will result in improved skills when the stakes escalate, as in terminal conditions. Communication skills will be well honed and practitioner fear and guilt will not predominate when a bereaved parent states "I remember every aspect of what was said and how it was said when the doctor told me that my daughter had cancer."[208]

Pediatric oncologists have significant-to-profound discomfort in discussing prognosis, particularly the impending death of their patients.[1] Bereaved parents of trauma victims[12] have reported being told of the death in the hallway, waiting room, or other public area, implying a lack of training of emergency and surgery personnel. When information is delivered poorly, parents perceive a lack of empathy and respect, and memories of this experience may be etched in the minds of the survivors for the remainder of their lives, compounding and prolonging the grieving process.[14] Given the risks of such permanent damage, there is a moral imperative to ensure that preparation for the effective and empathetic disclosure of bad news is routinely integrated into pediatric training.

Good Ways to Give Bad News

Most of the advice about breaking bad news in general applies to the ICU, ED, and delivery room settings and to the disclosure of terminal illness. The main difference is the time frame and the intensity of emotion, although even parents of chronically ill children who have survived many previous hospitalizations will also often be shocked (and frequently unbelieving) that the child will not recover this time ("We've been told that before, and he is still here").

Many clinicians believe there is no good way to give bad news. However, research with parents whose children had a wide range of diagnoses provides consistent guidance.[15,24,32–35,40–42,46,47,92,209–213] See Table 5 for suggestions for breaking bad news with skill and empathy.

When hearing bad news, parents value a physician who clearly demonstrates a caring attitude and who allows them to talk and to express their emotions.[47] One effective opening to the conversation is to ask, "What do you already know about what is happening to (patient's name)?" Once their ideas are elicited, misperceptions should be corrected. Asking whether they know someone else with this diagnosis or situation and inquiring about their associated experience can be helpful. The latter question assists the physician to be aware of the family's fears and expectations. Pointing out how the child's situation is similar to or different from the previous experience helps parents to better understand the child's likely course.

Parental dissatisfaction with the process of breaking bad news is common. Use of a protocol for breaking bad news can substantially improve the experience.[41] Comprehensive guides for breaking bad news are available.[40] Although needing to inform parents of a chronic, incurable diagnosis may challenge a physician's feelings of competency, parents are most attentive to the affective relationship of their informant, rather than the ability of the informer to "fix it." Parents are able to distinguish the difference between the delivery of the news and the news itself.[32]

One US study in the 1980s[209] found that parents of children with cancer, when hearing the initial diagnosis,

TABLE 5 **Suggestions for "Breaking Bad News" With Skill and Empathy**

Do not disclose bad news over the telephone
Use trained translators as needed
Avoid telling a lone parent without his or her spouse and/or a preferred support person present
Enable the parents to touch the deceased child before or during the interview
Hold or touch the child with obvious care
Recognize that parents are primarily responsible for their child
Show caring, compassion, and a sense of connection to the patient and the family
Pace the discussion to the parents' emotional state; do not overwhelm them with information
Do not use jargon
Elicit parents' ideas of the cause of the problem; ensure they do not blame themselves or others
Name the illness and write it down for the parents
Ask the parents to use their own words to explain what you have just told them to confirm effective transmission of information
Address the implications for the child's future
Acknowledge their emotions and be prepared for tears and a need for time; it is helpful to bring a social worker and/or chaplain to the meeting
Be willing to show your own emotion; aloofness or detachment is offensive
Give parents time to be alone to absorb the information, react, and formulate additional questions
Be able to recommend relevant community-based resources
Provide contacts with other willing families with a similarly affected child
Provide a follow-up plan and make an appointment for the next conversation

Data were adapted from Krahn et al,[15] Fallowfield,[35] Nursey et al,[42] Heller and Solomon,[125] and Woolley et al.[214]

desire less information at that time, preferring an emphasis on establishing trust with new caregivers. Parents' trust of advice is built by acknowledging the grief, anxiety, and fear the family is experiencing and inviting them to share their feelings and ask questions. Gradually sharing additional illness and treatment information, supplemented by written or taped materials, and providing a means to contact the physician when additional questions arise, is also greatly appreciated.[32] Many parents now are asking for e-mail contact and, in some instances, this is a reimbursable service.[215]

When parents (predictably) become upset during the informing interview, acknowledge their grief and fear by waiting until their attention turns back to the discussant, then state (for instance):

"I can see you were not expecting this." (Silence)

"You seem quite upset; I would be, too. (Silence.) Do you know anyone who has had this illness? (Silence.) How did things go for them?"

Facial tissues are essential equipment. Parents want hopeful and positive things said about their child, and an opportunity to touch or hold the child, particularly newborn infants or children from whom they have been separated during a transport. They need recognition by the physician of the child's unique value as an individual first and as an ill or injured person second.[15] Speaking of the child as if he or she "is" the diagnosis is hurtful.

As time progresses, parents also appreciate emotional support and affirmation of their efforts and ability to care for the child. "Your child is lucky to have you for parents! I can't imagine anyone doing a better job than you two!" Harsh or judgmental statements about the child, the parents, or their behaviors are unhelpful.

Communication in the ICU and ED

Bad News in the ED

In the ED, parents often arrive separately from the child. If they are available by telephone, let them know the child is seriously ill/injured, but do not disclose death over the telephone unless the parent is insistent. Suggest they come in as soon as possible and bring their spouse and a close friend with them. Ask them to be careful and to consider letting someone else drive, because they are at an increased risk of having an accident because of their appropriately upset emotional state.

If a child is undergoing resuscitation when the parents arrive at the ED, it may be appropriate to offer the parents the opportunity to be with the child.[216–222] The majority of families offered this option accept and feel much better knowing that "everything was done" and that they were there in the child's last moments of life.[223–228] Parents should know they do not have to go into the resuscitation area if they choose not to; affirmation should be provided indicating that loving and good parents decide either way. If the parents choose to be present, a staff member should be assigned as a dedicated escort. This individual should tell them what they will see and let them know they can leave at any time. Parents should be informed that they will be asked to leave if they interfere with the team's function or seem to be harmed by being there. When in the room, the escort explains the role of each person present, what is being done, then affirms that, despite all that is going on, this is still their child (use the child's name) and that he or she may be able to hear the parent. The escort can suggest the parents touch and speak to the child, assuring him or her of the family's love.

An even more challenging task is to inform families of trauma victims that their previously healthy child is dead.[229] Jurkovich et al[12] studied the experiences of bereaved families of child and adult trauma victims. The findings and recommendations were consistent with those for ICU patients. The most important attributes of the communication, from the parents' perspectives, are the attitude of the informer, clarity of the message, privacy of the conversation, and the ability of the informer to accurately answer parents' questions. Many parents recounted positive experiences, primarily of having caring hospital and prehospital staff. Physicians garnered most of the negative comments. Rank and attire were of minimal concern to these families.

After greeting the parents and escorting them to a private area, have someone who has directly participated in the care of their child speak with them. Sit down and bring tissues. Begin by asking what they know so far. Ask when they saw the child last and what he or she was doing at that time. Explain any factual details that are known about what happened at the scene and what has been done so far in the resuscitation. There are

TABLE 6 **Family Centered Communication and Support in the ICU**

Early (within 24–48 hours of admission) and frequent communication
Indication that the health care team cares for the child as an individual
Practitioners trained in meeting facilitation and conflict management
The use of open-ended questions and reflective explanation
Hopeful but honest and clear communication; acknowledgment of uncertainty
Discussion of likely and hoped-for outcomes
Use of numeric terms when describing probabilities; use of drawings and models
Provide timeframes for improvement and future discussion
Participation of families in clinical bedside rounds, caregiving for their child and ability to stay with their child during invasive procedures
Listen to and involve the nurse, chaplain, and social worker in the information loop
Open visitation, including sibling and pet visitation
Consistent caregivers; if this is not possible, ensure consistency of the message
Prompt informing of parents of transitions, such as a change of location, condition, treatment plan, assignment of attending physician or residents
Shared decision making rather than autonomy; encourage the parents to involve their family, friends, and medical home pediatrician to help them to understand information and make decisions
Written, audiotaped, and computerized education for families (see www.icu-usa.com)
Discussion and support of coping mechanisms, including religious and spiritual values
Initiation of palliative care at the time of admission

Data were adapted from Todres et al,[16] Davidson et al,[228] Robinson et al,[231] and Todres.[232]

TABLE 7 **Coping Strategies of Parents of Critically Ill and Injured Children[16]**

Focus on the positive (hope)
Minimize the significance of the information
Preoccupation with medical details
Support from family, friends, and clergy
Religious faith
Hostility, depression, irritability

2 choices at this point; the first is immediate notification of the death, offering to escort the parents into the room to be with the body, and explaining what was done and that the child's injuries were too severe to survive but reassuring them that everything that could have been done to save the child's life was done.[92] Alternatively, there can be a staged disclosure, initially telling them that the child is very severely injured and at risk of dying, but that everything possible to save him is still being done. Tell them you are going to check on the rescue team's progress, leaving a team member in the room with them; make sure the rescue area is cleaned up and that the child's body is presentable. Leave some of the tubes in place to demonstrate the efforts that were made to save the child's life. Call the chaplain and the social worker if they are not on the scene.[230] Then, go back and inform the parents of the child's death a few minutes later. In the case of sudden, unexpected, and overwhelming illness or death, parents will likely be shocked, highly emotional, angry, and suspicious. This reaction, although difficult to endure as the perceived target of their animosity, is certainly understandable. A parent might blurt:

> "But I put Juanita on the school bus this morning. She can't be dead!"

Offer to take parents in to see their child, and ensure a member of the resuscitation team is available to provide the specifics of what was done and to answer any questions. If feasible, move the body and the family to a private area to maximize privacy and minimize disruption; allow families to have some private time with the body. Ensure an appropriate environment, including a rocking chair, support persons from the family, and a limited number of members of the care team, if desired by the family. Do not rush them. Experience indicates that 2 to 3 hours is the maximum time most families want to remain with the body; 15 to 20 minutes is more common.[93]

Communication in the NICU and PICU

Communication within an NICU or PICU generally involves bad news in a very foreign environment, virtually always with large numbers of unfamiliar health care professionals. Guidelines have been promulgated to suggest important ways to support families of ICU patients.[228] See Table 6 for suggestions with regard to communication.

Understanding how parents cope with bad news may prevent some judgmental conclusions and may assist ICU caregivers to be effective communicators with families. See Table 7 for a list of coping mechanisms, both adaptive and maladaptive, of parents with critically ill children.

The stakes involved in having a child in the ICU and the constant uncertainty make negative reactions understandable.[16] Parental sources of stress include seeing their child in pain, frightened, or sad, and the inability to communicate with the child.[233] Increased attention to the fulfillment of parental needs can improve relations between parents and ICU staff.

Special Communication Considerations in Terminal Illness

No communication is more difficult than telling a parent that his or her child will die. However, in many instances, painful as it is, parents may be hoping doctors will do just that. Parental recognition that one's child is suffering, disproportionate to the likelihood of benefit, is extremely distressing. However, it is a rare parent who will challenge the physician who continues to hold out hope for "cure" or prolonged life. Parents and adult patients expect physicians to recognize and discuss the need to change the goals of care. In 1 study, 45% of parents of critically ill children thought it may be time to stop attempts to treat the illness before the physician brought it up, but none broached the topic.[234] Many physicians, however, wait until they perceive the family or patient is "ready," leading to additional emotional and physical suffering, including a prolonged dying process. Mixed messages from multiple consultants, particularly in the ICU setting, can be extremely confusing and upsetting for families, often leading to poor decision making as the parents (understandably) hold on to the most hopeful messages. Having a clear captain of the care team, one who is evaluating the situation as a whole,

particularly as death nears, is extremely helpful in preventing such problems.

Bad News in the Delivery Room

Despite increasing accuracy and availability of prenatal diagnosis, a pediatrician can be confronted in the delivery room by a child who is too immature to survive or who has anomalies that are incompatible with life; attempts at resuscitation would be inappropriate in these situations.[235] When prematurity is the problem, the parent is generally already aware of this. Introducing oneself and providing "a warning shot" may be helpful.

> "I am Dr. _____ and I am the pediatrician who was called by your physician to care for your infant. My team and I have experience doing everything possible to help premature newborns. Based on your history and our examination, it seems, unfortunately, that your daughter was born too early to survive for very long, no matter what we do. (Pause) I am sorry. I really wish it were different. At this point, we are ensuring her warmth and comfort. (Pause) Does she have a name? Would you like to spend some time with her and hold her?"

Point out the infant's normal features. Important things not to say at his time include asking when the mother noted her premature labor or asking about factors that may have triggered premature delivery. Blaming is unhelpful and unnecessary; avoidance of a recurrence can be accomplished at a future time when the information can be seen as helpful and can be absorbed.

For the near-term child with lethal anomalies, the diagnosis has typically been made before delivery. In this case, it can be helpful for pediatricians to ask parents what they know and provide confirmation of what they see. Goals of care should have already been established; in some settings, a prenatal hospice program may have been set up and available for support during the delivery.[236] If not, or if the diagnosis is unexpected, a "warning shot" is needed, followed by empathic and clear disclosure. Hovering and whispering about the infant only adds to the panic and confusion.

> "I am Dr. ____ and I was asked to help care for your son. He has beautiful hands! And he also appears to have some unusual characteristics. Did you or your obstetrician have any concerns or suspicions that something may have been different about your baby before his birth?"

If the prognosis or diagnosis is not clear, the infant will likely be brought to the NICU for additional evaluation and management.[235] An explanation of what will be done, how long it will take, when the parents can visit, and when more will be known is important. If the child has a clearly lethal anomaly (eg, anencephaly), the child should not be separated from the parents unless that is their preference, and the process of palliative care should begin immediately. Pointing out the normal features of the child and ensuring the parents do not blame themselves for the anomalies are important therapeutic interventions. Asking whether parents wish to bathe or dress their child or have siblings hold their child helps families accept the newborn. If the infant is alive, attend to its comfort with warm blankets and maternal skin contact, if desired. Suggest making a hand mold or print, cutting a lock of hair, or taking photographs. Offer to call a chaplain or the parents' own clergy, if they prefer, to assist them to explore meaning and to help with any rituals.[231] Give them time to be with the infant or the body in a private place for as long as they desire. Offer help to call friends or family if they choose. Ensure bereavement follow-up.

In the NICU and PICU, parents are often asked to participate in the decision-making process regarding the use of "life-prolonging" measures. Little research addresses effective and compassionate ways to communicate about stopping critical care interventions and changing goals of care, although much research documents dissatisfaction with current methods. The usual way of addressing the failure of medical therapy can be very problematic and may generate thoughts or conclusions that are unintended but potentially devastating. Table 8 presents common medical statements, how they may be perceived, and suggests alternatives.

INFORMED CONSENT, COMMUNICATING RISKS, AND BENEFITS OF RESEARCH

Sometimes, when conventional treatment has failed, clinical trails are available. Although parents often state their motives to enroll their child in research are altruism and/or the desire to learn more about their child's disease, it is interesting to note that, when they are in an outpatient setting and less rushed to make a decision, participation rates in clinical trials are lower than in inpatient settings.[237] It is clearly difficult to achieve truly informed consent for medical care or procedures, let alone clinical research, when death is likely; strong emotions govern such situations. The need to explain complex constructs of risks and benefits, randomization, physiology, and often, pharmacology to lay people is daunting. Nevertheless, there is still an obligation to make a valiant effort to obtain truly informed consent. Too often there is a problem of therapeutic misperception, representing that the purpose of the research is to treat the patient rather than benefit future patients.[238] Indeed, therapeutic misperception may sometimes even be fostered by investigators. However, a recent analysis of cancer trials found that there were "insufficient data to conclude" that enrollment in clinical trials resulted in improved outcomes.[239] According to the Institute of Medicine Committee on Clinical Research Involving Children,[240] consent, permission, and assent should be viewed as a process of communication, encouraging questions at the initiation and throughout treatment to assess understanding and ensure lack of coercion in ongoing participation. These recommendations are based in part on 2 other important, recent reports on research ethics.[241,242]

A study of consent for childhood leukemia trials found that not providing information, and lack of understanding of information presented, hampered the achievement of informed consent.[243] For instance, randomization was not mentioned in 17% of cases, and parents did not understand it 50% of the time, despite efforts to explain the concept. Similarly, 18% of parents

TABLE 8 **Methods of Communicating Sensitive Health Care Information and Perceptions of Communication**

Usual Method of Communicating Message	How the Usual Communication May Be Perceived	Alternative Method of Communicating Message
"Do you want us to do CPR?"	"CPR would work if you would allow us to do it"	"Tell me what you know about" CPR. "CPR is most helpful for patients who are relatively healthy, and even then, only 1 of 3 patients survive. Many of Lisa's organs are not working. As you know, she is getting dialysis to clean her blood like her kidneys would have, a breathing machine for her lungs, and medicine to keep her blood pressure up. If her heart were to stop, it would not be because there is a problem with her heart (it is fine), but it would be because she is dying. All of our hearts stop when we die. So pumping on her heart, or "doing CPR" will not make her better. On the other hand, while I would recommend not doing CPR, I am not recommending stopping any other treatment she is receiving at this time. There is still a chance that she may get better. Let's hope for the best, but also plan for the worst. We will need to keep a close watch on her and keep you up to date on how she is doing. Do you have any questions?" "Let's talk again later today so I can update you. Is there anyone else I need to talk to?"
"Let's stop heroic treatment"	"We will provide less than optimal care" (What is heroic about performing invasive, painful, costly, nonbeneficial care?)	"At this time, I think the most heroic thing we can do is to understand how sick Jamal is and stop treatments that are not working for him. I think we should do all we can to ensure his comfort and yours, make sure there are no missed opportunities, and ensure we properly celebrate his life. I will follow your lead on this. Some ideas that have helped other families include getting him home with help for you if you wish, or you may choose to have his friends and your family come here instead and have a party; you can bring his clothes so that he will look like himself, bring in his music or a photo album and relive some of your best memories of him, make a mold of his hand so that you will always have his hand to hold, or anything else that would be a proper celebration of his life."
"Let's stop aggressive treatment"	"We will not be attentive to his needs, including symptom distress and need for comfort"	"We will do all we can to ensure he is as comfortable as possible."
"Aeisha has failed the treatment"	"The patient is the cause of the problem"	"We have tried all the proven treatments and even some experimental ones for Aiesha. Unfortunately, we did not get the results we had hoped for. I wish it were different!"
"We are recommending withdrawal of care for Marisa"	"We are going to abandon her and you"	"Marisa is too ill to get better. We need to refocus our efforts on making the most of the time she has left."
"There is nothing more we can do for Adam"	"We will allow him to suffer, we do not care about him, we only care about fighting the disease"	"We need to change the goals of our care for Adam. At this point we clearly cannot cure him, but that does not mean we can't help him and your family."
"Johnny is not strong enough to keep going"	"Johnny is weak"	"Johnny is a strong boy and he has fought hard with us to beat his disease. Unfortunately, as much as we wish we could, we cannot cure Johnny. At this point, we are hurting him rather than helping, giving him side effects, and keeping him from being at home or taking a trip, or whatever he really wants to do with the time he has left."
"We will make it so Thuy does not suffer"	"We are going to kill Thuy."	"We will do everything we can to make Thuy comfortable."
"We need to stop active treatment for Dwayne"	"We will not take care of him at all"	"The goal of curing Dwayne's disease, despite the best efforts of a lot of smart and hard-working people, is no longer possible. We are so sorry and wish that that were different! I have cared for many children who are as sick as your son. It is very hard on all of us, especially you, his parents and family when the treatments do not work as we had hoped. Many parents like you have agreed to stop efforts to cure when they are not working, as difficult as that is. Would you like me to put you in touch with some of the other parents who have been through this too?"
"Do you want us to stop Bobby's treatment?"	"You are the final arbiter of your child's death"	"Bobby is lucky to have such excellent, loving and selfless parents. I know this is hard; we will get through it together. I am glad you agree with our recommendations to change the goals of care to better meet Bobby's needs. I will let my team know what we have decided."
"I am glad you agree. Will you sign Juan's do-not-resuscitate order?"	"You are signing his death warrant"	"There is no surgery, no medicine, and all the love you clearly feel for Juan will not make him better, he is just too sick. I wish it were different." (Silence) "I will change his orders to make sure he only gets tests and treatments that can help him now."

CPR indicates cardiopulmonary resuscitation.

TABLE 9 **Suggestions to Improve Communication About Clinical Trials**

Ensure the presence of a nurse
Read the consent document with the parents, explicitly soliciting questions and allocating sufficient time to answer them
Provide time to process the information, including taking the consent document home overnight
Provide written and video explanations
Provide information in the family's native language when possible
Provide names and contact information for practioners who can offer independent, competent second opinions
Conduct a daily education conference to allow information to be incrementally processed

Data were adapted from Kodish et al.[244]

lacked understanding of the right to refuse to participate (attempted explanation, 97%) and 20% did not understand the right to withdraw from the study at any time (attempted explanation, 72%).[243] In another study, parents did not understand the existence or details of treatment alternatives.[244] Health literacy is a problem for much of the adult US population, not just parents.[245,246]

Children being offered the opportunity to participate in clinical research trials must be asked their opinion and must give permission to proceed. In fact, the requirement for affirmative child assent is codified in the Current Federal Regulations.[247–249] The opportunity to provide assent implies the ability to dissent as well; dissent must be taken seriously but is not considered to be determinative, when rendered by the child, if the trial holds realistic promise for a beneficial outcome. These concerns and needs must be anticipated as routine and accommodated. Clinical investigators need explicit training regarding how to obtain truly informed consent.[244] Suggestions to help improve communication about clinical trials are in Table 9.

In the setting of research with a potentially terminally ill child, emotions run high. Parental and clinician ability to judge the situation on the objective merits of the alternatives, within the framework of long-held values, is severely challenged and rarely accomplished. An altruistic child may prefer to continue on to benefit others, regardless of his or her own outcome.[195] These children are ideal candidates for research. However, others want desperately to control their destinies and to enjoy the time remaining. Parents' need to sustain life, often at all costs, can blind them to the child's need to enjoy it. It is the clinician's obligation to ensure that the risks and benefits are communicated in an unbiased way, while giving recommendations based on disclosed priorities and experience. Decisions should incorporate the views of the child, parents, and other caregivers who know the child well. Additional research is desperately needed to ensure a process that enables truly informed consent.[240]

Presenting Palliative Care as a Viable Alternative to Research Participation

At such vulnerable times, parents are often told that the "only" alternative to enrollment in experimental therapies is "doing nothing," an alternative that is never attractive and is also never true. Each treatment option should be evaluated based on the likely (not just hoped for) outcomes in this individual child's case, given his or her illness history and comorbidities, and the known and possible burdens and complications, including pain, isolation, fatigue, and missed opportunities. The merits and burdens of pursuing palliative goals of care without further attempts to reverse the disease versus experimental or "innovative" (uncontrolled research) treatment must be clearly explained to ensure that a choice is truly being offered.

Palliative care can be provided concurrently with life-extending measures[81,228] or can be the sole focus of care. Palliative care is intensive care, addressing the whole child within the context of self, family, and community. Palliative care attends to spiritual, physical, emotional, and social needs of the patient while also addressing the needs of parents, siblings, and others affected by the child's illness and ultimate death. Palliative care can facilitate an excellent quality of living in the face of a short life expectancy, ensuring that the child and his or her family live fully, despite being in the shadow of inevitable death.[14,81,121,250] Children can even live longer than expected when effective palliative care is offered because of renewed hope and relief of symptoms that are too often ignored in other treatment paradigms.

Postmortem Communication

Parents are generally supported by family, friends, the community-based medical home pediatrician, and their congregational clergy after the death.[93] However, they often feel cut off from the people with whom they developed an intense bond in the hospital; the last people to assist them to care for their child, the people who guided their initial acknowledgment of their child's death.[234] Even small tokens of continued concern have a huge effect on families. In a study of bereaved survivors of adult patients, a condolence card, signed by direct care providers and mailed 2 weeks after the death, had a profound impact.[251] Ninety-four percent of the recipients still had the card in an easily accessible place 1 year later. One woman whose husband died in the ED stated that the card helped her cope with his unanticipated death, because "at least I know he died among caring people." There is published guidance for physicians about how to write a condolence card,[252] but even a signature will suffice.

Sometimes, especially when practitioners have become extremely close to the patient, attending the memorial or funeral service may be appropriate. This act serves to let the family know that the concern and attachment they perceived were real; it may also allow some healing for the practitioner, who otherwise may "burn out" from the emotional exhaustion of the investment in children who die and their families. Giving oneself permission to love and let go is important, and societal rituals may assist in the resolution of the professionals' grief as well. Families are generally overcome with appreciation when the physician attends the memorial or funeral and can be resentful when they do

not.[125] The AAP endorses an active role for the pediatrician in providing bereavement care.[82]

Autopsies as Communication Opportunities

Particularly if an autopsy is performed, it is advisable to have a postmortem conference with the parents (and sometimes siblings as well) approximately 6 to 8 weeks after the death.[93,253–255] As parents reflect on the whirlwind events of their final days with their child, numerous questions arise. They need a vehicle to have these questions answered efficiently. If an autopsy is performed and there is no opportunity to hear and discuss the results, parents may become suspicious that the medical establishment was "experimenting" on their child.[92,93] Moreover, parents may have requested the autopsy to assist in family planning or to determine the need to do screening procedures on close relatives; thus, they may be awaiting the results anxiously. An in-person meeting allows the treating physician to answer all the family's questions, translate the autopsy findings into understandable lay language, and importantly, to check on the well-being of the parents and siblings. The family and the staff appreciate coordination of the timing of this meeting so all important members of the care team can attend. Long-term follow-up may include an annual card on the child's birthday or anniversary of the death, invitation to annual memorial services at the hospital, or other locally appropriate options.

MEDICAL ERROR DISCLOSURE

Medical errors are increasingly in the public eye. Communication about medical errors is 1 of the most challenging aspects of health care,[256] yet parents exhort caregivers to be forthright and timely in revealing the mishap.[104] Training on how to approach patients and families about the occurrence of a medical error can increase family and patient satisfaction regarding these situations and can substantially decrease the medical malpractice payouts related to such occurrences. (Multiple case studies are available at www.sorryworks.net.)

PHYSICIAN SELF-CARE

Medicine is a challenging and rewarding profession. It requires lifelong learning, not only from books, journals, and courses, but also from attention to interactions with patients and families. Physicians have a difficult job; the responsibility to communicate effectively and efficiently to clarify the diagnosis, consider psychosocial and existential concerns, respect family and other supporters' needs, and to come to an agreed-on plan of care is substantial and can be overwhelming. Allowing time between patients and debriefing conversations with staff, increased physician education on communication, and improved payment for counseling time can help.

SUMMARY

Effective, empathic communication is an essential skill for physicians caring for pediatric patients and their families. It can lead to improved outcomes for children, their families, and physicians themselves. Communication deserves a place at center stage for pediatric education, practice, and research.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

CLINICAL REPORT

Comprehensive Health Evaluation of the Newly Adopted Child

abstract

FREE

Children who join families through the process of adoption often have multiple health care needs. After placement in an adoptive home, it is essential that these children have a timely comprehensive health evaluation. This evaluation should include a review of all available medical records and a complete physical examination. Evaluation should also include diagnostic testing based on the findings from the history and physical examination as well as the risks presented by the child's previous living conditions. Age-appropriate screens should be performed, including, for example, newborn screening panels, hearing, vision, dental, and formal behavioral/developmental screens. The comprehensive assessment can occur at the time of the initial visit to the physician after adoptive placement or can take place over several visits. Adopted children should be referred to other medical specialists as deemed appropriate. The Section on Adoption and Foster Care is a resource within the American Academy of Pediatrics for physicians providing care for children who are being adopted. *Pediatrics* 2012;129:e214–e223

Increasing numbers of children are joining families through adoption. It is estimated that every year, more than 100 000 children are adopted in the United States.[1] Children can be adopted through the national public welfare system, private agencies, existing relationships, or the international process. Regardless of the route or timing of adoption, these children may have a myriad of special health care needs. Numerous studies have demonstrated that many children who enter the foster care system or children adopted domestically or internationally have an increased incidence of physical, developmental, and mental health concerns.[2–5] Although these concerns may be addressed before adoption, many of these issues persist and continue to be significant or do not become apparent until after the time of placement in an adoptive home.

The number of international adoptions has tripled over the past 15 years, with an average of 22 000 adoptees entering the United States each year for the past 4 years.[6,7] Most of these children come from China, Guatemala, Russia, Ethiopia, South Korea, Vietnam, Ukraine, and Kazakhstan.[7] Regardless of their countries of origin, many of these children may have concerns related to infectious diseases and developmental delays.[4,8–13] Several risk factors have been identified that may account for the aforementioned outcomes, including poverty, little or no prenatal care, malnutrition, perinatal and postnatal exposure to bloodborne and environmental toxins and pathogens, and inadequate

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

developmental stimulation and emotional sustenance.[14,15] Children available for adoption are at high risk of having been exposed prenatally to illegal drugs or alcohol.[8,15,16] Before adoption, children may have been directly or indirectly exposed to physical, emotional, or sexual abuse.[8]

Pediatricians have played a significant role in the adoption process, in some cases providing counseling to parents during the preadoption phase and subsequently providing health care for these children. The pediatrician must be aware of the special needs of many of these children to evaluate and treat them appropriately. The pediatrician also needs to become knowledgeable of the resources available to help families integrate the new adoptee into the family unit. The purpose of this statement is to provide the general pediatrician with practical guidance that addresses the initial comprehensive health evaluation of adopted children.

COMPONENTS OF THE INITIAL PLACEMENT EVALUATION

A comprehensive medical evaluation should be completed soon after placement in an adoptive home to confirm and clarify existing medical diagnoses, assess for any previously unrecognized medical issues, discuss developmental and behavioral concerns, and make appropriate referrals.[8] This evaluation should include a thorough review of the medical history, including an assessment of health risks, a developmental assessment, and a complete, unclothed physical examination.[8,9,15,17] The initial health evaluation of an adopted child should be comprehensive in nature, but it is not necessary for this to occur during only one medical visit. Several visits to the pediatrician may be necessary to complete the assessment of the child's history, to review laboratory findings, and to make referrals to medical, developmental, mental health, and dental specialists. Subsequent evaluations, including referrals and laboratory testing, should be undertaken to allow for comprehensive health planning.

The Preadoption Visit

The preadoption visit can be helpful for the adoptive family.[15,17–21] Parents may request the pediatrician review medical records of the child and/or biologicical parents. The pediatrician may be able to use those records to help parents determine additional questions that could clarify a particular health issue and help parents clarify what special needs they are prepared to accept. Some specific issues to address in the medical records include growth trends and a preliminary assessment of developmental progress, and, if available, family history and information about the pregnancy course and childbirth. The pediatrician may offer clarification of medical diagnoses, particularly from international adoptions, that may be more prevalent in particular regions of the world.[17,18,20] Besides medical records, parents may have other materials, such as photos and video, for review. Although these may be informative to confirm or refute what is written in the medical record, they do not provide a conclusive diagnosis. The preadoption visit also allows for counseling on other issues. The issue of closed versus open adoption can be explored with the parents. Open adoption describes a continuum of communication between the birth parents and the adoptive family.[22] Pediatricians should discuss with families the extent of communication between the adoptive family and the biological family and provide needed support by identifying potential and real benefits and drawbacks to the relationship.

Special issues related to nutrition of the child could be addressed. Some families may be interested in breastfeeding their infant, so the pediatrician needs to be familiar and supportive of the option and techniques of induced lactation.[23,24] Finally, providing information about available community support services may ease the transition for the expected family. For further assistance, the primary care physician can consult with the American Academy of Pediatrics (AAP) Section on Adoption and Foster Care.

Initial History and Review of Medical Records

When a child presents for an initial complete adoption evaluation, a review of the current and past medical history must be undertaken, with particular attention to any previous medical findings in the child's medical records. The Electronic Health Record (EHR), using the Health Information Exchange standards, may eventually help facilitate transfer of this medical information. A list of information to be sought from the child's history is provided in Table 1.

A complete medical history, including prenatal history obtained from the mother and genetic history obtained from both parents, is ideal but rarely available.[10] The adoption agency social worker (who should be trained appropriately to do a skilled genetic, medical, and prenatal interview) should take an extensive history from the birth parent(s), if possible, and enter these data into the formal medical record for the future adoptive parent. Perinatal risks, which must include lifestyle-related information about the parent(s) that may affect the fetus at birth or later in development, also should be reviewed.[19,21] Such information includes parental use of alcohol or drugs and history of sexual practices that increase the risk of sexually transmitted infections both in the mother and her

TABLE 1 Review of Medical History/Previous Records

- Birth records should be obtained whenever possible, particularly for children younger than 6 y
  - Prenatal blood and urine test results of biological mother
  - Exposure to medications, illegal substances, alcohol, tobacco
  - Gestational age, birth weight, length, head size; Apgar scores
  - Prenatal concerns, neonatal complications
  - Newborn hearing screening results
  - Results of newborn metabolic screening
- Previous growth points, including head circumference
- History of abuse, physical and sexual; history of neglect
- Reason for placement into adoptive home
  - Voluntary versus involuntary termination of parental rights
- Nutritional history, particularly with respect to iron, calcium, vitamin D, iodine, and other nutrients
  - Assess current dietary habits
  - Determine whether the child has any issues eating textured foods
  - Exercise history
- Developmental milestones, past and present
- Behavioral issues, particularly with respect to socialization, indiscriminate friendliness
- Laboratory test results, radiographic studies, other studies
- Immunizations
  - School records may be sufficient, particularly for older children
  - Original records and adequate timing of doses should be verified with antibody titers
  - Children with no records or records that do not appear to be original or accurate should be reimmunized
- Results (if known) of previous testing for tuberculosis, including treatment
- Chronic medical diagnoses
- Allergies (medication, food, environmental, latex, insect stings)
- Medications (both used acutely and chronically)
- Reports from previous specialists seen
  - Consider having an original translation of records from other countries
- Family history (when available)
  - Vision, hearing deficits
  - Genetic diseases
  - Concerns related to ethnicity (eg, sickle cell anemia, thalassemia, Tay Sachs disease, lactose intolerance)
  - Mental health diagnoses
- Environmental risk factors
  - Lead risks
  - Institutionalization
    - Reason and timing, if known, of placement
    - If known, feeding and sleeping schedule and environment where feeding and sleeping occurred
  - Risks for previous physical, emotional, and sexual abuse
    - Substandard housing, multiple changes in residence
    - Family members using illegal substances or alcohol, domestic violence
  - Passive tobacco exposure, methamphetamines, other illicit substances in the home environment
  - Other environmental toxins, both in the home and in the surrounding community
- Number of prior placements, quality of such care

Notes:

- Children who have been adopted internationally may have neurologic, hematologic, cardiac, and metabolic disorders that were previously overdiagnosed, underdiagnosed, or missed completely.
- Medical records from other countries (if available) may be limited in information, inaccurate, or even falsified.
- For children adopted domestically, there may be issues of confidentiality associated with obtaining records, particularly if the child's name was changed at the time of the adoption. In all cases, physicians should work with families and adoption workers to obtain complete medical records, while also strictly adhering to laws regarding confidentiality of medical information.

partner(s). Physicians and adoption agency social workers should be trained to obtain such information in a manner that is sensitive to the psychological and cultural issues of the families.[25]

Children being adopted from foster care most likely have had fragmented care and limited continuity of medical records. Health care before foster care placement may have been inadequate, with multiple unmet medical needs.[1,19,26]

The AAP recommends a comprehensive health evaluation of all children at the time of entrance into foster care.[26] The medical records from all previous health care providers should be made available for review for the adoptive parents as soon as possible after placement into an adoptive home and before finalization of adoption from foster care. Lack of availability of medical records should not delay the timing of the initial comprehensive health evaluation. Parents, working in collaboration with their legal representative, their pediatrician, and local child welfare and adoption agencies, should obtain the child's complete medical records, including (if possible) developmental, educational, and mental health assessments.[1,27] For children being adopted from foster care, equal emphasis should be placed on review of the medical history and the physical examination of the child.[1,19]

With international placements, medical history may be sparse or inaccurate. The evaluation of a child who has been adopted internationally will depend, to a large degree, on a complete physical examination and comprehensive laboratory screening based on environmental, nutritional, ethnic, and infectious disease risks.[8,28] Pediatricians should take advantage of current literature that specifically addresses issues that may be prevalent for a potential health risk secondary to the child's countries of origin.[17,28,29]

Initial Physical Examination

The initial physical examination, as noted in Table 2, should be comprehensive, with particular attention to systems that have been found to be more "at risk" for adopted children.[1,5,30,31] Care should be used when approaching the newly adopted child, particularly for internationally

TABLE 2 Components of the Comprehensive Physical Examination Pertinent to Adoption

- Vital signs (temperature, pulse, respiratory rate, blood pressure)
- Growth points, including length or height, weight, head circumference (on all children). Data should be plotted on World Health Organization growth charts, along with comparison with any measurements previously obtained. Body mass index should be calculated and plotted.
- Complete physical examination, with emphasis on the following areas:
  - Skin examination
    - Identify infectious diseases, rashes, or infestations, including scabies, lice, and impetigo
    - Identify and document any congenital skin abnormalities, including hemangiomas, nevi, and blue macules of infancy (usually seen in children of Asian, African, or Hispanic ethnicity).
    - Identify and document bruises or scars that may have resulted from previous abuse or previous immunization.
  - Careful genitalia examination (including the anus) should be performed to identify any abnormality suspicious for prior sexual abuse or genital cutting.
    - Testing for sexually transmitted diseases should be performed with any suspicion of abuse.
    - Testing for sexually transmitted diseases should be performed if sexually active.
  - Neurologic examination, with emphasis on developmental and neurologic abnormalities.

adopted children. The child, who may be new to the country, may have never experienced a comprehensive examination and may become anxious. For older international adoptees, it is often helpful to have a translator present to explain what is happening. For all children, one needs to go slowly and be sensitive to the child's cues and provide reassurance.

Growth parameters, including height, weight, and head circumference, should be measured accurately for all children. Ethnically oriented growth charts should be used when available, particularly for international adoptees. If possible, previous measurements should be obtained to assess growth over time, because this may provide an objective assessment of the child's nutritional and medical status.[15,21] Attention should be given to the child's general appearance. Any abnormal features that might be suggestive of a genetic disorder, syndromes (such as fetal alcohol syndrome), or congenital defects should be noted, as should any abnormalities of the skin that may lead to a diagnosis of an infectious disease or are suggestive of previous abuse. A thorough but sensitive examination of the genital area should be performed to identify any abnormality suggestive of previous sexual abuse. Ritual genital cutting should be documented. The timing of this examination may need to be adjusted depending on the child. Children who have been traumatized in the past and are new to their adoptive homes may become anxious and overwhelmed. If the relationship with the adoptive parent is still very new, the child may feel helpless without adequate support. As is expected for any new patient, a comprehensive neurologic examination should be performed.

Referral for Diagnostic Testing

For all children, diagnostic studies appropriate for the evaluation of the child's risk factors should be completed (Table 3). Children born outside of the United States should have all tests that were completed in the country of birth repeated according to US recommendations.[15] Previous laboratory testing may not be verifiable because of concerns about accuracy, appropriate reporting and interpretation, and timing of the tests. Recommendations are also available for children who have lived in foster care.[26] For children who lived in a foster home before finalization of adoption, diagnostic studies do not need to be repeated if the physician can review the results of the diagnostic studies, unless there has been additional risk of infectious disease and environmental exposures. Children being adopted shortly after birth should have accurate verification of the biological mother's prenatal laboratory studies, with testing performed on the child if the information is unavailable or if the accuracy of the records is unclear.

Children who previously lived in conditions of significant poverty, in institutional settings, or in other countries are at particular risk of infectious diseases. Recommendations for screening children adopted internationally are available in the current AAP *Red Book*.[17]

Immunizations

Immunization records should be reviewed carefully, particularly with respect to the immunizations given, the dates, intervals between vaccines, and the age of the child at the time the immunizations were given.[7,17,31] Records for children who have lived in several foster homes may be incomplete. Children who were immunized in an institutional setting may have an inadequate immunologic response because of poor storage of vaccines or vaccines used beyond the expiration date.[32] For children with previous immunizations, vaccines may be repeated for most children using an accelerated immunization schedule.[17] As an alternative, antibody titers may be performed to determine serum immunity for major antigens (see Table 4 for recommended antibody titers). This approach is usually more cost-effective for older children.[28,30] If antibody concentrations are to be obtained, it is important to interpret results in light of the dates of the last vaccine doses and possible persistence of maternal antibodies. An

TABLE 3 Diagnostic Testing

- Infectious diseases (for updates on infectious disease screening, please consult the current AAP *Red Book*[17])
  - Hepatitis B surface antigen (HBsAg), hepatitis C antibody (if from country with high prevalence)
  - HIV 1 and 2 serologic testing
  - Syphilis serologic testing
    - Nontreponemal test (RPR, VDRL, or ART)
    - Treponemal test (MHA-TP, FTA-ABS, or TPPA)
    - For newborn infants, acceptable testing includes biological mother's prenatal laboratory test results.
    - For children adopted internationally, all testing done before adoption should be repeated.
    - For children adopted internationally, the aforementioned bloodborne pathogen tests should be repeated after placement in the adoptive home for 6 mo.
    - If sexual abuse is suspected, the child should be tested for gonorrhea, *Chlamydia*, and other sexually transmitted infections. Testing should include any suspected site of abuse, including the mouth and rectum.
  - Tuberculosis
    - PPD should be placed on all at risk newly adopted children, including those with previous BCG immunization before placement with the adoptive family.
    - For all children adopted internationally, testing must be repeated after placement in the adoptive home for 6 mo.
      - Children who are anergic because of chronic malnutrition may have a negative initial PPD. PPD also evaluates children who were exposed to active cases of tuberculosis just before placement.
    - Interpretation of positive test results should be consistent with the exposure history and nutritional status of the child, as per the guidelines in the *Red Book*. Previous BCG immunization before placement should not be considered to be a contraindication to placement of a PPD in any child. A positive PPD should never be assumed to be secondary to the BCG vaccine.
  - Stool pathogens should be screened for any child who previously lived in inadequate housing, another country, or an institution or has diarrhea. Diarrhea need not be present for children to have parasite infections.
    - Ova and parasites: 3 tests for optimal screening (48–72 h between collection of each specimen)
      - If available, antigen testing for *Giardia* and *Cryptosporidia* species should be obtained.
    - Following treatment of stool parasites, repeat stool studies should be performed to ensure eradication of the parasite.
    - Consider stool bacterial culture if diarrhea is present.
- Anemia, metabolic, and nutritional screening
  - Complete blood cell count with red cell indices
    - Routine anemia screening is indicated for all children 6 mo or older, as well as all children adopted internationally.
    - In children with an absolute eosinophil count exceeding 450 cells/mm^3 and negative stool ova and parasite examinations, consider serologic testing for *Strongyloides* and *Schistosoma* species for children from certain regions.[15]
  - Screening for hemoglobinopathies and blood disorders in children of African, Asian, Hispanic, or Mediterranean ethnicities
    - Sickle cell disease
    - Thalassemia
    - G-6-PD deficiency
  - Blood lead concentration for children up to 6 y of age; older ages if indicated (ie, refugees, at-risk cultural practices)
  - Newborn screening panel (young infants)
  - Rickets screening (calcium, phosphorus, alkaline phosphatase) for children who were institutionalized, have growth delay, or had history of poor vitamin D intake or limited sunlight.
    - Most children are easily treated for this with increased calcium in the diet and a daily multivitamin.
- Testing does not need to be repeated for children adopted from the US foster care system who previously had laboratory studies consistent with the recommendations from the AAP

ART, automated reagin test; BCG, bacille Calmette-Guérin; FTA-ABS, fluorescent treponemal antibody absorption; G-6-PD, glucose-6-phosphate dehydrogenase; MHA-TP, microhemagglutination *Treponema pallidum*; PPD, purified protein derivative; RPR indicates rapid plasma reagin; TPPA, *Treponema pallidum* particle agglutination; VDRL, Venereal Disease Research Laboratory.

acceptable alternative when doubt exists is to reimmunize the child.

Chronic Health Concerns

During the health assessment of an adopted child, health concerns not previously diagnosed may be identified. Following a review of any previous medical testing, it is appropriate to make referrals to pediatric medical subspecialists. The pediatrician should play a key role in coordinating the health care management of adopted children with special health care needs. Although referral is important, one may take into consideration that the child is adapting to a new home, and parents are adapting to the child. Minimizing the number of referrals or at least planning them carefully is critical to ensure successful adjustment and to encourage the family to establish a medical home for ongoing continuity of care.[33]

Hearing and Vision Screening

Hearing and vision screening of children is recommended (Table 5). A child adopted in the newborn period should have an examination of his or her hearing if not performed previously. In many states, routine hearing screenings are performed for all newborn infants. These results should be documented and made a part of the child's permanent medical record. Even if tested in the newborn period, a hearing evaluation should be obtained for any child with a history of recurrent otitis media or developmental delays, including speech delay.[26,34,35]

TABLE 4 Evaluation and Administration of Immunization Status of Adopted Children

- Infectious diseases (for updates on infectious disease screening, please consult the AAP *Red Book*[17])
  - Hepatitis B
    - Test for HBsAb; if negative, give age-appropriate immunization
  - Diphtheria, pertussis, and tetanus toxoids
    - Immunize as appropriate for age. Serologic testing for antitoxoid antibodies 4 wk after dose 1 if severe local reaction.
    - If previously received ≥3 doses, serologic testing for antitoxoid antibody to diphtheria and tetanus toxins before administrating additional doses or administer a single dose of diphtheria and tetanus-containing vaccine, followed by serologic testing 1 mo later for antitoxoid antibody.
  - *Haemophilus influenza* type b (Hib)
    - Age-appropriate immunization
    - If >12 mo of age, serologic testing for Hib immunoglobulin G (IgG) is available
  - Pertussis
    - There is no serologic test routinely available, but may use antibodies to diphtheria or tetanus as a marker that vaccine was previously given.
  - Poliovirus
    - Immunize with inactivated poliovirus vaccine (IPV) per routine schedule
    - An alternative to vaccination would be to perform serologic testing for neutralizing antibody to poliovirus types 1, 2, and 3 or give a single dose of IPV, followed by serologic testing.
  - Measles-Mumps-Rubella (MMR)
    - Immunize with MMR or obtain measles antibody concentration. If positive, give MMR vaccine to protect against mumps and rubella.
    - An alternative would be to perform serologic testing for IgG antibody to vaccine viruses, indicated by the immunization record.
  - Varicella
    - Give age-appropriate immunization if there is not a reliable history of previous disease or serologic evidence of disease by varicella antibody.
  - Pneumococcal
    - Give age-appropriate immunization.
    - If >12 mo of age, serologic testing for IgG for serotypes 7-14

TABLE 5 Other Screening Evaluations

- Hearing
  - Validate newborn screening when available
  - Screen all children if possible, particularly those with risk factors for hearing loss as well as developmental (speech) delays
- Vision
  - Eye examination as appropriate for age
  - Screening for refraction error as of age 3
  - Funduscopic examination for children with birth wt <1500 g
- Dental
  - Referral to dentist for all children 12 mo or older
  - Earlier referral if evidence of dental caries or abuse via the mouth
- Developmental screening/assessment/interventions
  - Timely identification of developmental delays is strongly recommended
  - Risk factors include prematurity, illegal drug and/or alcohol exposure, poor prenatal care, institutionalization
    - Formal referral for all children adopted in the newborn period or beyond with risk factors as listed or other concerns
    - Referral for all children adopted beyond the newborn period with risk factors or concerns about development when appropriate.
    - For children adopted internationally, a speech evaluation within a few weeks of arrival home by a speech therapist fluent in the child's native language is optimal to help reveal gaps in articulation and language processing skills
  - Referrals may be made to the early intervention program for children birth through 35 mo of age
  - Referrals through the school system for children 36 mo and older with establishment of an Individualized Educational Plan (IEP) when appropriate
  - Referral for speech/language, occupational, and physical therapy when indicated
  - Children adopted internationally should be placed in an educational setting with flexible placement based on the child's developmental profile

All children should have an eye examination. Newborn infants should have careful documentation of the red reflex. A funduscopic examination of dilated eyes should be performed by an ophthalmologist for all children with a birth weight <1500 g.[36] Older children should have examination for strabismus and for abnormalities of the fundus, eyelids, and extraocular muscles. Vision screening should be performed for all children 3 years and older.[37–39]

Dental

Any previous dental diagnoses should also be noted, with appropriate referrals to dental specialists. Dental professionals should be informed about previous medical illnesses and malnutrition, as well as periods in which the child lived in an area of the world with no fluoride in the diet. A dental evaluation, as recommended by the AAP[37,39] should be performed for all children 12 months or older, as well as younger children with evidence of dental caries, baby bottle tooth decay, or historical risk factors, including abuse via the mouth (Table 5).

Age Determination

For some international adoptees, questions may arise with respect to the child's accurate date of birth. For children younger than 1 year, a difference of weeks or a few months will not be critical in the long term.[18,31] For older children, age determination may be more important, especially with respect to placement in school and eligibility for special education services.[18,31] There are no accurate or reliable tests for age determination. Malnutrition and deprivation may affect assessments using standard measurements, including radiographic bone age and dental eruption. Onset of puberty may be advanced as a child's nutritional status rapidly improves. It is usually best to delay changing a birth date until at least 12 months after adoption to allow for catch-up growth, as well as prolonged observation of a child's physical and emotional development.[28,31]

Developmental Screening

Developmental screening should be performed using validated screening tools; for the internationally adopted child, it may be a very complicated issue (Table 5). Validated screening tools performed shortly after arrival often may be difficult to interpret. The child usually faces a language barrier, and his or her exposure to the types of materials used for testing may be limited. For these children, early scores may not be predictive of later functioning, as seen in studies by Rutter et al.[40] Several studies have demonstrated significant developmental delays in children as they enter foster care, particularly in speech and language.[2,5,41–43] Likewise, children adopted internationally nearly always demonstrate delays in at least one area of development, with nearly half of the children having global delays.[13,44–46] Children adopted internationally may demonstrate delays in expressive and receptive language that are not solely related to acquisition of a new language.[13,15,39,47] Although "catch-up" development does occur, studies have shown that many children are at increased risk of long-term consequences of developmental delay, depending on the age of adoption and the length of time spent in an institutional setting.[40,46]

Mental Health Review

Children adopted from foster care and children adopted from institutions are at an increased risk of mental health disorders, including socioemotional problems.[4,46] Preplacement factors such as prenatal drug and alcohol exposure, prolonged institutionalization, multiple placements, and previous abuse and neglect contribute significantly to the emotional problems of these children.[27,40,46] When available, pediatricians should take into consideration any history of mental health diagnoses in members of the birth family, watching a child carefully with the use of validated screening tests, such as the Pediatric Symptom Checklist,[48] Brief Infant-Toddler Social Emotional Assessment,[49] or Ages and Stages Questionnaire: Social-Emotional,[50] that can be performed in the pediatric office. Appropriate referrals should be made when such a risk presents itself. Although referrals should be performed at the time of placement for children with a history of abuse or neglect, screening for mental health disorders should take place at all medical visits, particularly at the time of regular health assessments (refer to Table 6).

Issues of Adjustment

Adjustment issues should be addressed at the time of placement into the home. Children may be withdrawn, have temper tantrums, be aggressive or defiant, cry inconsolably, or even have autisticlike behavior as they undergo changes in their family placement.[12] Some children may regress in previously obtained skills. Older, internationally adopted children will likely

TABLE 6 Behavioral and Mental Health Recommendations

- Review behavior, including past and present concerns
  - Adjustment
  - Fostering of positive relationships
  - Aggressive behavior
  - Hyperactive
  - Impulsivity
  - Internalizing behaviors (withdrawal, anxiety)
  - Sleep issues
  - Feeding issues, including overeating or hoarding food
  - Enuresis
- Document psychiatric medications used currently or in the past
- Document any past psychiatric hospitalizations
- Previous violent behavior or animal cruelty
- Sexualizing behaviors
  - Sexual promiscuity or acting out
  - Excessive or inappropriate masturbation
- Substance abuse
  - Tobacco, alcohol, illicit substances
- Suicide
  - Suicide ideology
  - Previous suicide attempts
- Children need to be monitored for issues related to loss and grief, attachment disturbances, posttraumatic stress disorder
  - Children may not admit to previous abuse or neglect until they are secure in an adoptive home
  - Even children placed as newborn infants may have issues related to their history of adoption (ie, identity development) that do not necessarily rise to the level of mental health issues

encounter frustrating language barriers with their adoptive family.[12,15] Even if transitions into an adoptive home are gradual, most children experience grief with the change in their caregivers, peers, and home environment.[12,51] Sleep problems are also common.[12,51] Difficulties in timing, location, duration, and quality of sleep are typical.[12] Feeding problems may present after adoption. Feeding issues may include overeating, hoarding, or food refusal.[12] Pediatricians need to counsel families about potential adjustment issues and encourage them to look for cues that the child may be overwhelmed and help them to develop strategies to promote strong, healthy attachments within the family unit.[52]

Kinship-Specific Issues

Children placed with kin should also receive the same comprehensive evaluation as those living in nonrelative placements. This recommendation applies even if the child has had no interruption in the child's medical home before or after placement. Studies have demonstrated that the incidence of chronic medical problems and mental health concerns in children living in kin foster care are similar to those of children living in nonrelative foster care.[53–55]

Role of Adoption Medical Specialists

Adoption and foster care medicine is an evolving subspecialty within the field of pediatrics. The AAP Section on Adoption and Foster Care provides a mechanism for obtaining information related to enhancing further training for physicians who care for children who have been adopted.

Financial Considerations

The comprehensive assessment of a newly adopted child requires extensive physician time and commitment. Services can be reimbursed on the basis of type of services provided, time spent, and complexity of care.[56] Services such as the preplacement consultation may not be covered by most insurance carriers, but the pediatrician should advise the adoptive parent to seek information from the parent's employer about benefits covered through an adoption subsidy plan or flexible-spending account. Children adopted through the foster care system may have continuation of their Medicaid benefits even after the adoption is finalized. Finally, families may be eligible for the federal adoption tax credit to offset some of the adoption-related costs.

CONCLUSIONS

Children placed for adoption are in need of a comprehensive health evaluation to fully address all of their health and developmental needs. This is best accomplished with the establishment of a medical home for these children. The comprehensive evaluation should include a review of the child's medical history, complete physical examination, and results of necessary diagnostic testing. Important consideration should be given to risks in the child's past, with full attention to infectious diseases and environmental, nutritional, developmental, and mental health issues. Pediatricians play an important role in working with families in identification of children's needs and providing emotional support to help families through the adoption process. Ongoing awareness of the adopted child's history through routine follow-up visits will enable the pediatrician to identify other health issues that may develop and assist families in accessing resources that will help them in the long term.

Summary

This report is the first of a two-part statement from the Advisory Committee on Immunization Practices (ACIP) that updates the strategy to eliminate hepatitis B virus (HBV) transmission in the United States. The report provides updated recommendations to improve prevention of perinatal and early childhood HBV transmission, including implementation of universal infant vaccination beginning at birth, and to increase vaccine coverage among previously unvaccinated children and adolescents. Strategies to enhance implementation of the recommendations include 1) establishing standing orders for administration of hepatitis B vaccination beginning at birth; 2) instituting delivery hospital policies and procedures and case management programs to improve identification of and administration of immunoprophylaxis to infants born to mothers who are hepatitis B surface antigen (HBsAg) positive and to mothers with unknown HBsAg status at the time of delivery; and 3) implementing vaccination record reviews for all children aged 11–12 years and children and adolescents aged <19 years who were born in countries with intermediate and high levels of HBV endemicity, adopting hepatitis B vaccine requirements for school entry, and integrating hepatitis B vaccination services into settings that serve adolescents. The second part of the ACIP statement, which will include updated recommendations and strategies to increase hepatitis B vaccination of adults, will be published separately.

Strategy to Eliminate Hepatitis B Virus Transmission

Hepatitis B virus (HBV) is a bloodborne and sexually transmitted virus. Rates of new infection and acute disease are highest among adults, but chronic infection is more likely to occur in persons infected as infants or young children. Before hepatitis B vaccination programs became routine in the United States, an estimated 30%–40% of chronic infections are believed to have resulted from perinatal or early childhood transmission, even though <10% of reported cases of hepatitis B occurred in children aged <10 years (*1*). Chronically infected persons are at increased lifetime risk for cirrhosis and hepatocellular carcinoma (HCC) and also serve as the main reservoir for continued HBV transmission.

The material in this report originated in the National Center for Infectious Diseases, Rima F. Khabbaz, MD, Director, Division of Viral Hepatitis, John W. Ward, MD, Director; and the National Immunization Program, Anne Schuchat, MD, Director, Immunization Services Division, Lance E. Rodewald, MD, Director.
Corresponding preparer: Eric E. Mast, MD, Division of Viral Hepatitis, National Center for Infectious Diseases, 1600 Clifton Road, NE, MS G-37, Atlanta, GA 30333. Telephone: 404-371-5460; Fax: 404-371-5221; E-mail: emast@cdc.gov.

Hepatitis B vaccination is the most effective measure to prevent HBV infection and its consequences. Since they were first issued in 1982, recommendations for hepatitis B vaccination have evolved into a comprehensive strategy to eliminate HBV transmission in the United States (*2–6*) (Box 1). A primary focus of this strategy is universal vaccination of infants to prevent early childhood HBV infection and to eventually protect adolescents and adults from infection. Other components include routine screening of all pregnant women for hepatitis B surface antigen (HBsAg) and postexposure immunoprophylaxis of infants born to HBsAg-positive women, vaccination of children and adolescents who were not previously vaccinated, and vaccination of unvaccinated adults at increased risk for infection.

To date, the immunization strategy has been implemented with considerable success. Recent estimates indicate that >95% of pregnant women are tested for HBsAg, and case management has been effective in ensuring high levels of initiation and completion of postexposure immunoprophylaxis among identified infants born to HBsAg-positive women (*7*). Hepatitis B vaccine has been successfully integrated into the childhood vaccine schedule, and infant vaccine coverage levels are now equivalent to those of other vaccines in the childhood schedule. During 1990–2004, incidence of acute hepatitis B

BOX 1. Immunization strategy to eliminate transmission of hepatitis B virus (HBV) infection in the United States

- Universal vaccination of infants beginning at birth
- Prevention of perinatal HBV infection through
  - routine screening of all pregnant women for hepatitis B surface antigen (HBsAg), and
  - immunoprophylaxis of infants born to HBsAg-positive women and infants born to women with unknown HBsAg status
- Routine vaccination of previously unvaccinated children and adolescents
- Vaccination of previously unvaccinated adults at increased risk for infection

in the United States declined 75%. The greatest decline (94%) occurred among children and adolescents, coincident with an increase in hepatitis B vaccine coverage. As of 2004, among U.S. children aged 19–35 months, >92% had been fully vaccinated with 3 doses of hepatitis B vaccine (*8*). This success can be attributed in part to the established infrastructure for vaccine delivery to children and to federal support for perinatal hepatitis B prevention programs.

Vaccine coverage among adolescents has also increased substantially. Preliminary data demonstrate that 50%–60% of adolescents aged 13–15 years have records indicating vaccination (with 3 doses) against hepatitis B (CDC, unpublished data, 2003). As of November 2005, a total of 34 states require vaccination for middle-school entry (*9*). Certain programs provide hepatitis B vaccine to youth who engage in behaviors that place them at high risk for HBV infection (i.e., injection-drug use, having more than one sex partner, and male sexual activity with other males), and adolescent hepatitis B vaccination is included as a Health Plan Employer Data Information Set (HEDIS) measure (*10*).

Despite these successes, challenges remain. Even with improvements in the management of pregnant women, only approximately 50% of expected births to HBsAg-positive women are identified (on the basis of application of racial/ethnic-specific HBsAg prevalence estimates to U.S. natality data) for case management, which maximizes timely delivery of postexposure immunoprophylaxis (*11*; CDC, unpublished data, 2004). The need for proper management of women without prenatal care, including HBsAg testing at the time of admission for delivery and administration of the first dose of vaccine to infants <12 hours of birth, is underscored by the higher prevalence of HBsAg seropositivity among these women than among women who are screened prenatally (*12*). Even when maternal HBsAg testing does occur, certain infants of HBsAg-positive mothers do not receive postexposure immunoprophylaxis because of testing errors and lapses in reporting of test results (*13*), and infants of women with unknown HBsAg status at the time of delivery often do not receive a birth dose of vaccine (*14*). Birth dose coverage in 2004 was only 46% (National Immunization Survey, unpublished data, 2004), and coverage has not returned to levels from before July 1999 (54%), when recommendations were made to temporarily suspend administration of hepatitis B vaccines at birth until vaccines that do not contain thimerosal as a preservative became available (*15*). Among adolescents, efforts to prevent HBV transmission are hampered by the low rate of health-care visits in this age group compared with that of young children and the frequency of initiation of high-risk behaviors.

To address these remaining challenges and accelerate progress toward elimination of HBV transmission in the United States, the ACIP has updated the hepatitis B immunization recommendations for infants, children, and adolescents and supplemented the recommendations with strategies for implementation. The recommendations and implementation strategies address prevention of perinatal and early childhood transmission and routine vaccination of children and adolescents. A main focus is on universal infant vaccination beginning at birth, which provides a "safety net" for prevention of perinatal infection, prevents early childhood infections, facilitates implementation of universal vaccination recommendations, and prevents infections in adolescents and adults. The second part of the ACIP statement, which includes updated recommendations and implementation strategies to increase hepatitis B vaccination among unvaccinated adults, will be published separately (*16*).

Major Updates to the Recommendations

This report provides updated recommendations and approaches to address challenges in implementing the strategy to eliminate HBV transmission in the United States. These include the following measures:

- **Improve prevention of perinatal and early childhood HBV transmission.** Implement delivery hospital policies and procedures, case-management programs, and laws and regulations to improve identification of infants born to HBsAg-positive mothers and to mothers with unknown HBsAg status at the time of delivery, ensure administration of appropriate postexposure immunoprophylaxis to these infants beginning at birth, and administer a birth dose of hepatitis B vaccine to medically stable infants who weigh ≥2,000 g and who are born to HBsAg-negative mothers.

- **Improve vaccine coverage of children and adolescents who were not previously vaccinated.** Implement immunization record reviews for all children aged 11–12 years and children and adolescents aged <19 years who were born in countries in which HBV endemicity is high or intermediate (Figure 1 and Box 2); adopt hepatitis B vaccine requirements for school entry; and vaccinate all unvaccinated adolescents in settings that provide health-care services to persons in this age group.

Background

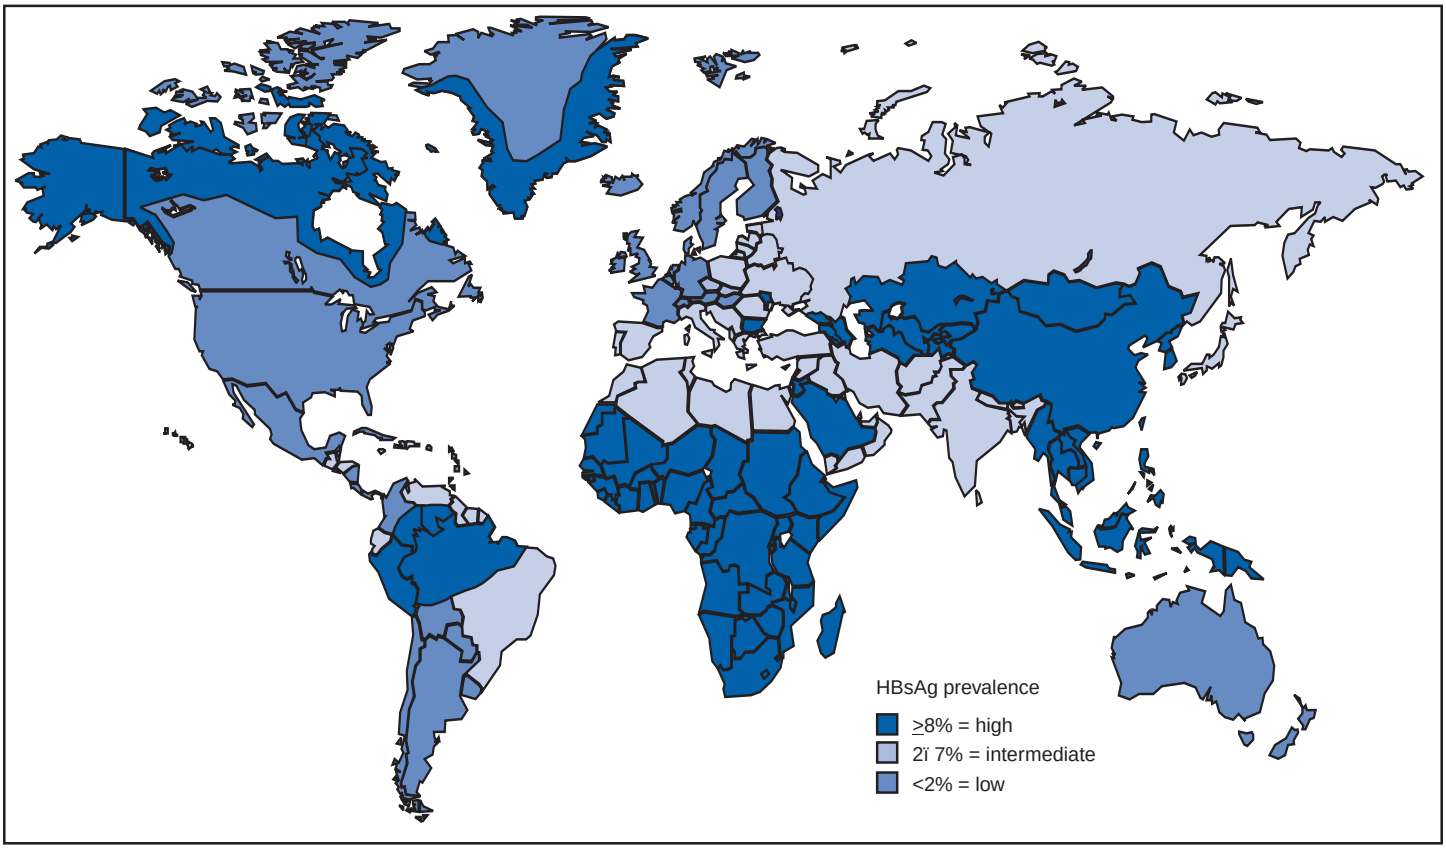
Clinical Features and Natural History of HBV Infection

HBV is a 42-nm DNA virus classified in the *Hepadnaviridae* family. The liver is the primary site of HBV replication. After a susceptible person is exposed, the virus enters the liver via the bloodstream; no evidence exists indicating that the virus replicates at mucosal surfaces. HBV infection can produce either asymptomatic or symptomatic infection. The average incubation period is 90 days (range: 60–150 days) from exposure to onset of jaundice and 60 days (range: 40–90 days) from exposure to onset of abnormal serum alanine aminotransferase (ALT) levels (*17,18*).

The onset of acute disease is usually insidious. Infants and young children (aged <10 years) are typically asymptomatic (*19*). When present, clinical symptoms and signs might include anorexia, malaise, nausea, vomiting, abdominal pain, and jaundice. Extrahepatic manifestations of disease (e.g., skin rashes, arthralgias, and arthritis) also can occur (*20*). The fatality rate among persons with reported acute hepatitis B is 0.5%–1.5%, with highest rates in adults aged >60 years (*21*).

Although the consequences of acute hepatitis B can be severe, the majority of serious sequelae associated with HBV disease occur in persons who are chronically infected. Persons with chronic infection also serve as the major reservoir for continued HBV transmission. Chronic infection occurs in approximately 90% of infected infants, 30% of infected children aged <5 years, and <5% of infected persons aged ≥5 years, with continuing viral replication in the liver and persistent viremia (*19,22–24*). Primary infections also become chronic more fre-

FIGURE 1. Geographic distribution of chronic hepatitis B virus (HBV) infection, 2005*



* For multiple countries, estimates of prevalence of hepatitis B surface antigen (HBsAg), a marker of chronic HBV infection, are based on limited data and might not reflect current prevalence in countries that have implemented routine childhood hepatitis B vaccination. In addition, HBsAg prevalence rates might vary within countries by subpopulation and locality.

BOX 2. Geographic areas with intermediate* and high† hepatitis B virus endemicity

Africa: all countries
South Asia: all countries except Sri Lanka
Western Pacific: all countries and territories except Australia and New Zealand
Middle East: all countries except Cyprus
Eastern Europe: all countries except Hungary
Newly Independent States of the former Soviet Union: all countries
Western Europe: Greece, Italy, Malta, Portugal, and Spain
North America: Alaska Natives and indigenous populations of Northern Canada and Greenland
Central America: Belize, Guatemala, Honduras, and Panama
South America: Argentina, Bolivia, Brazil, Ecuador, Guyana, Suriname, Venezuela, and the Amazonian areas of Colombia and Peru
Caribbean: Antigua and Barbuda, Dominica, Dominican Republic, Grenada, Haiti, Jamaica, Puerto Rico, St. Kitts and Nevis, St. Lucia, St. Vincent and Grenadines, Trinidad and Tobago, and Turcs and Caicos

† HBsAg prevalence of ≥8%.

quently in immunosuppressed persons (e.g., hemodialysis patients and persons with human immunodeficiency virus [HIV] infection) (*23,25,26*). On the basis of data from follow-up studies of persons infected with HBV as infants or young children, approximately 25% of those with chronic infection die prematurely from cirrhosis or liver cancer; the majority remain asymptomatic until onset of cirrhosis or end-stage liver disease (*27–29*).

No specific treatment exists for acute hepatitis B. Persons who have chronic HBV infection require medical evaluation and regular monitoring (*30,31*). Therapeutic agents approved by the Food and Drug Administration (FDA) for treatment of chronic hepatitis B can achieve sustained suppression of HBV replication and remission of liver disease in certain persons (*31*). Periodic screening with alfa fetoprotein or imaging studies has been demonstrated to enhance early detection of HCC (*31*). Chronically infected persons with HCC have been reported to have experienced long-term survival after resection or ablation of small HCCs, and persons who were screened had a substantial survival advantage compared with historic controls (*31*).

Reinfection or reactivation of latent HBV infection has been reported among certain groups of immunosuppressed persons, including renal transplant recipients, HIV-infected patients, bone marrow transplant recipients, and patients receiving chemotherapy (*32–35*). The frequency with which this phenomenon occurs is unknown.

Interpretation of Serologic Markers of HBV Infection

The antigens and antibodies associated with HBV infection include HBsAg and antibody to HBsAg (anti-HBs), hepatitis B core antigen (HBcAg) and antibody to HBcAg (anti-HBc), and hepatitis B e antigen (HBeAg) and antibody to HBeAg (anti-HBe). At least one serologic marker is present during the different phases of HBV infection (Table 1) (*18,36*). Serologic assays are commercially available for all markers except HBcAg because no free HBcAg circulates in blood.

The presence of a confirmed HBsAg result is indicative of ongoing HBV infection. All HBsAg-positive persons should be considered infectious. In newly infected persons, HBsAg is the only serologic marker detected during the first 3–5 weeks after infection, and it persists for variable periods at very low levels. The average time from exposure to detection of HBsAg is 30 days (range: 6–60 days) (*17,18*). Highly sensitive single-

** Negative test result.
[ÀÀ] Positive test result.
[ÄÄ] To ensure that an HBsAg-positive test result is not a false positive, samples with repeatedly reactive HBsAg results should be tested with a licensed (and, if appropriate, neutralizing confirmatory) test.
[ÆÆ]Persons positive for only anti-HBc are unlikely to be infectious except under circumstances in which they are the source for direct percutaneous exposure of susceptible recipients to large quantities of virus (e.g., blood transfusion or organ transplant).
*** Milli-International Units per milliliter.

sample nucleic acid tests can detect HBV DNA in the serum of an infected person 10–20 days before detection of HBsAg (*37*). Transient HBsAg positivity has been reported for up to 18 days after vaccination and is clinically insignificant (*38,39*).

Anti-HBc appears at the onset of symptoms or liver test abnormalities in acute HBV infection and persists for life. Acute or recently acquired infection can be distinguished by the presence of the IgM class of anti-HBc, which is detected at the onset of acute hepatitis B and persists for up to 6 months if the disease resolves. In patients who develop chronic hepatitis B, IgM anti-HBc can persist at low levels during viral replication and can result in positive tests for IgM anti-HBc (*40*). In addition, false-positive IgM anti-HBc test results can occur. Because the positive predictive value is low in asymptomatic persons, for diagnosis of acute hepatitis B, testing for IgM anti-HBc should be limited to persons with clinical evidence of acute hepatitis or an epidemiologic link to a case.

In persons who recover from HBV infection, HBsAg is eliminated from the blood, usually within 3–4 months, and anti-HBs develops during convalescence. The presence of anti-HBs typically indicates immunity from HBV infection. Infection or immunization with one genotype of HBV confers immunity to all genotypes. In addition, anti-HBs can be detected for several months after hepatitis B immune globulin (HBIG) administration. The majority of persons who recover from natural infection will be positive for both anti-HBs and anti-HBc, whereas persons who respond to hepatitis B vaccine have only anti-HBs. In persons who become chronically infected, HBsAg and anti-HBc persist, typically for life. HBsAg will become undetectable in approximately 0.5%–2% of chronically infected persons yearly, and anti-HBs will occur in the majority of these persons (*41–44*).

In certain persons, the only HBV serologic marker detected in serum is anti-HBc. Isolated anti-HBc can occur after HBV infection among persons who have recovered but whose anti-HBs levels have waned or among persons in whom anti-HBs failed to occur. Persons in the latter category include those with circulating HBsAg levels not detectable by commercial assays. These persons are unlikely to be infectious except under circumstances in which they are the source for direct percutaneous exposure of susceptible recipients to substantial quantities of virus (e.g., through blood transfusion or following liver transplantation) (*45*). HBV DNA has been detected in the blood of <5% of persons with isolated anti-HBc (*46*). Typically, the frequency of isolated anti-HBc relates directly to the prevalence of HBV infection in the population. In populations with a high prevalence of HBV infection, isolated anti-HBc likely indicates previous infection, with loss of anti-HBs. For persons in populations with a low prevalence of HBV infection, an isolated anti-HBc result often represents a false-positive reaction. The majority of these persons have a primary anti-HBs response after a 3-dose series of hepatitis B vaccine (*47,48*). Infants who are born to HBsAg-positive mothers and who do not become infected might have detectable anti-HBc for ≤24 months after birth from passively transferred maternal antibody.

HBeAg can be detected in the serum of persons with acute or chronic HBV infection. The presence of HBeAg correlates with viral replication and high levels of virus (i.e., high infectivity) (*49,50*). Anti-HBe correlates with the loss of replicating virus and with lower levels of virus, although reversion to HBeAg positivity has been observed (*44*).

Epidemiology of HBV Infection

Transmission

HBV is transmitted by percutaneous (i.e., puncture through the skin) or mucosal (i.e., direct contact with mucous membranes) exposure to infectious blood or to body fluids that contain blood. All HBsAg-positive persons are infectious, but those who are also HBeAg positive are more infectious because their blood contains high titers of HBV (typically 10^7–10^9 virions/mL) (*49,50*). Although HBsAg has been detected in multiple body fluids, only serum, semen, and saliva have been demonstrated to be infectious (*51,52*). HBV is comparatively stable in the environment and remains viable for ≥7 days on environmental surfaces at room temperature (*53*). HBV at concentrations of $10^{2–3}$ virions/mL can be present on environmental surfaces in the absence of any visible blood and still cause transmission (*53,54*).

For infants and children, the two primary sources of HBV infection are perinatal transmission from infected mothers and horizontal transmission from infected household contacts. Adolescents are at risk for HBV infection primarily through high-risk sexual activity (i.e., sex with more than one partner and male sexual activity with other males) and injection-drug use (*21*). Transmission of HBV via transfusion of blood and plasma-derived products is rare because of donor screening for HBsAg and viral inactivation procedures.

For a newborn infant whose mother is positive for both HBsAg and HBeAg, the risk for chronic HBV infection is 70%–90% by age 6 months in the absence of postexposure immunoprophylaxis (*55–57*). For infants of women who are HBsAg positive but HBeAg negative, the risk for chronic infection is <10% in the absence of postexposure immunoprophylaxis (*58–60*). Rare cases of fulminant hepatitis B among perinatally infected infants also have been reported (*61,62*). Studies suggest that breastfeeding by an HBsAg-

positive mother does not increase the risk for acquisition of HBV infection in the infant (*63*).

Children who are not infected at birth remain at risk from long-term interpersonal contact with their infected mothers. In one study, 38% of infants who were born to HBsAg-positive mothers and who were not infected perinatally became infected by age 4 years (*64*). In addition, children living with any chronically infected persons are at risk for becoming infected through percutaneous or mucosal exposures to blood or infectious body fluids (e.g., sharing a toothbrush, contact with exudates from dermatologic lesions, contact with HBsAg-contaminated surfaces). HBV transmission rates to susceptible household contacts of chronically infected persons have varied (range: 14%–60%) (*65,66*). High rates of infection also have been reported among unvaccinated long-term residents of institutions for the mentally handicapped (*67,68*), and, in rare instances, person-to-person transmission has been reported in child care settings (*69,70*).

Incidence

During 1990–2004, overall incidence of reported acute hepatitis B declined 75%, from 8.5 to 2.1 per 100,000 population. The most dramatic declines occurred in the cohort of children to whom recommendations for routine infant and adolescent vaccination have applied. Incidence among children aged <12 years and adolescents aged 12–19 years declined 94%, from 1.1 to 0.36 and 6.1 to 2.8 per 100,000 population, respectively (Figure 2). Since implementation of routine childhood immunization, an estimated 6,800 perinatal infections and an additional 18,700 infections during the first 10 years of life have been prevented annually in the United States (*71*).

Although infections in infants and children aged <10 years represented <10% of all HBV infections before implementation of childhood immunization programs, childhood infections resulted in an estimated 30%–40% of the chronic HBV infections among persons who acquired their infections in the United States (*1*). In two population-based studies conducted among Asian/Pacific Islander children who were born in the United States before perinatal hepatitis B prevention programs were widely implemented, 61%–66% of the chronic HBV infections occurred in children born to HBsAg-negative mothers (*72,73*). A substantial proportion of these chronic infections would not have been prevented by a selective program of identification and immunization of only infants born to HBsAg-positive mothers.

In addition to declines in incidence among all age groups, racial disparities in hepatitis B incidence among children have been substantially reduced (Figure 3). The reduction of the disparity between Asian/Pacific Islander and other children is consistent with recent observations noting a decline in seroprevalence of HBV infection after successful implementation of routine hepatitis B vaccination among Asians who have recently immigrated to the United States (*74,75*). However, as hepatitis B incidence has declined among U.S.-born children, unvaccinated foreign-born children account for a high proportion of infections. During 2001–2002, of 19 children born after 1991 in whom acute hepatitis B had been verified, eight (42%) were foreign born (*76*).

Prevalence

In the U.S. population, the overall age-adjusted prevalence of HBV infection (including persons with chronic infection and those with previous infection) was 4.9% in the third

National Health and Nutrition Examination Survey (NHANES III, 1988–1994) (*77*). Foreign-born persons (particularly Asian/Pacific Islanders) who have emigrated from countries in which HBV is endemic (Figure 1 and Box 2) contribute disproportionately to the burden of chronic HBV infection in the United States. The prevalence of chronic HBV infection among foreign-born persons immigrating to the United States from Central and Southeast Asia, the Middle East, and Africa varies (range: 5%–15%) and reflects the patterns of HBV infection in the countries and regions of origin for these persons. During 1994–2003, approximately 40,000 immigrants with chronic HBV infection were admitted annually to the United States for permanent residence (*78*; CDC, unpublished data, 2005).

Prophylaxis Against HBV Infection

Hepatitis B Vaccine

HBsAg is the antigen used for hepatitis B vaccination (*79,80*). Vaccine antigen can be purified from the plasma of persons with chronic HBV infection or produced by recombinant DNA technology. Vaccines available in the United States use recombinant DNA technology to express HBsAg in yeast, which is then purified from the cells by biochemical and biophysical separation techniques (*81,82*). Hepatitis B vaccines licensed in the United States are formulated to contain 10–40 μg of HBsAg protein/mL. Since March 2000, hepatitis B vaccines produced for distribution in the United States do not contain thimerosal as a preservative or contain only a trace amount (<1.0 mcg mercury/mL) from the manufacturing process (*83,84*).

Hepatitis B vaccine is available as a single-antigen formulation and also in fixed combination with other vaccines. Two single-antigen vaccines are available in the United States: Recombivax HB® (Merck & Co., Inc., Whitehouse Station, New Jersey) and Engerix-B® (GlaxoSmithKline Biologicals, Rixensart, Belgium). Of the three licensed combination vaccines, one (Twinrix® [GlaxoSmithKline Biologicals, Rixensart, Belgium]) is used for vaccination of adults, and two (Comvax® [Merck & Co., Inc., Whitehouse Station, New Jersey] and Pediarix® [GlaxoSmithKline Biologicals, Rixensart, Belgium]) are used for vaccination of infants and young children. Twinrix contains recombinant HBsAg and inactivated hepatitis A virus. Comvax contains recombinant HBsAg and *Haemophilus influenzae* type b (Hib) polyribosylribitol phosphate conjugated to *Neisseria meningitidis* outer membrane protein complex. Pediarix contains recombinant HBsAg, diphtheria and tetanus toxoids and acellular pertussis adsorbed (DTaP), and inactivated poliovirus (IPV).

HBIG

HBIG provides passively acquired anti-HBs and temporary protection (i.e., 3–6 months) when administered in standard doses. HBIG is typically used as an adjunct to hepatitis B vaccine for postexposure immunoprophylaxis to prevent HBV infection. HBIG administered alone is the primary means of protection after an HBV exposure for nonresponders to hepatitis B vaccination.

HBIG is prepared from the plasma of donors with high concentrations of anti-HBs. The plasma is screened to eliminate donors who are positive for HBsAg, antibodies to HIV and hepatitis C virus (HCV), and HCV RNA. In addition, proper manufacturing techniques for HBIG inactivate viruses (e.g., HBV, HCV, and HIV) from the final product (*85,86*). No evidence exists that HBV, HCV, or HIV ever has been transmitted by HBIG commercially available in the United States. HBIG that is commercially available in the United States does not contain thimerosal.

Vaccination Schedules and Results of Vaccination

Preexposure Vaccination

Infants and Children

Primary vaccination consists of ≥3 intramuscular doses of hepatitis B vaccine (Table 2). Vaccine schedules for infants and children (Tables 3–5) are determined on the basis of immunogenicity data and the need to integrate hepatitis B vaccine into a harmonized childhood vaccination schedule. Although not all possible schedules for each product have been evaluated in clinical trials, available licensed formulations for both single-antigen vaccines produce high (>95%) levels of seroprotection among infants and children when administered in multiple schedules (*87–91*).

The immunogenicity of the combined hepatitis B-Hib conjugate vaccine (Comvax) and the combined hepatitis B-DTaP-IPV vaccine (Pediarix) is equivalent to that of their individual antigens administered separately. However, these vaccines cannot be administered to infants aged <6 weeks; only single-antigen hepatitis B vaccine may be used for the birth dose. Use of 4-dose hepatitis B vaccine schedules, including schedules with a birth dose, has not increased vaccine reactogenicity (*92,93*). Anti-HBs responses after a 3-dose series of hepatitis B-containing combination vaccines among infants who were previously vaccinated at birth with single-antigen hepatitis B vaccine are comparable to those observed after a 3-dose series of combination vaccine without a birth dose (*93*).

* Combined hepatitis Bï *Haemophilus influenzae* type b conjugate vaccine. This vaccine cannot be administered at birth, before age 6 weeks, or after age 71 months.
[À] Combined hepatitis Bï diphtheria, tetanus, and acellular pertussis-inactivated poliovirus vaccine. This vaccine cannot be administered at birth, before age 6 weeks, or at age ≥7 years.
[Ä] Combined hepatitis A and hepatitis B vaccine. This vaccine is recommended for persons aged ≥18 years who are at increased risk for both hepatitis B virus and hepatitis A virus infections.
[Æ] Recombinant hepatitis B surface antigen protein dose.
** Not applicable.
[ÀÀ] Adult formulation administered on a 2-dose schedule.
[ÄÄ] Higher doses might be more immunogenic, but no specific recommendations have been made.
[ÆÆ] Dialysis formulation administered on a 3-dose schedule at age 0, 1, and 6 months.
*** Two 1.0-mL doses administered at one site, on a 4-dose schedule at age 0, 1, 2, and 6 months.

Birth Dose

Hepatitis B vaccine can be administered soon after birth with only minimal decrease in immunogenicity, compared with administration at older ages, and no decrease in protective efficacy (*87*). Administration of a birth dose of hepatitis B vaccine is required for effective postexposure immunoprophylaxis to prevent perinatal HBV infection. Although infants who require postexposure immunoprophylaxis should be identified by maternal HBsAg testing, administering a birth dose to infants even without HBIG serves as a "safety net" to prevent perinatal infection among infants born to HBsAg-positive mothers who are not identified because of errors in maternal HBsAg testing or failures in reporting of test results (*13*). The birth dose also provides early protection to infants at risk for infection after the perinatal period. Administration of a birth dose has been associated with higher rates of on-time completion of the hepatitis B vaccine series (*15,94*). In certain populations, the birth dose has been associated with improved completion rates for all other infant vaccines (*95*), although findings have not been consistent (*15,94*).

Adolescents

Recommended vaccination schedules for adolescents balance available immunogenicity data with the need to achieve compliance with vaccination in this age group (Tables 2 and 5). Both licensed single-antigen hepatitis B vaccines administered intramuscularly at 0, 1, and 6 months produce a >95% sero-protection rate in adolescents. Equivalent seroprotection rates are achieved among adolescents vaccinated at 0, 1–2, and 4 months and 0, 12, and 24 months. The adult (10 µg) dose of Recombivax-HB administered in a 2-dose schedule to children and adolescents aged 11–15 years at 0 and 4–6 months produces antibody levels equivalent to those obtained with the 5-µg dose administered on a 3-dose schedule (*96,97*). However, no data on long-term antibody persistence or protection are available for 2-dose schedules. No combination vaccines containing hepatitis B vaccine antigen are approved for use in adolescents aged 11–17 years.

Nonstandard Vaccine Schedules

No apparent effect on immunogenicity has been documented when minimum spacing of doses is not achieved precisely. Increasing the interval between the first 2 doses has little effect on immunogenicity or final antibody concentration (*98–100*). The third dose confers the maximum level of seroprotection but acts primarily as a booster and appears to provide optimal long-term protection (*101*). Longer intervals between the last 2 doses result in higher final antibody levels but might increase the risk for acquisition of HBV infection among persons who have a delayed response to vaccination. No differences in immunogenicity have been observed when 1 or 2 doses of hepatitis B vaccine produced by one manufacturer are followed by doses from a different manufacturer (*102*).

TABLE 3. Hepatitis B vaccine schedules for newborn infants, by maternal hepatitis B surface antigen (HBsAg) status*

Maternal HBsAg status	Single-antigen vaccine		Single antigen + combination vaccine	
	Dose	Age	Dose	Age

	2	1ï 2 mos	2	2 mos
	3[¶]	6ï 18 mos	3	4 mos
			4[¶]	6 mos (Pediarix) or 12ï 15 mos (Comvax)

* See Table 4 for vaccine schedules for preterm infants weighing <2,000 g.
† Recombivax HB or Engerix-B should be used for the birth dose. Comvax and Pediarix cannot be administered at birth or before age 6 weeks.
§ Hepatitis B immune globulin (0.5 mL) administered intramuscularly in a separate site from vaccine.
¶ The final dose in the vaccine series should not be administered before age 24 weeks (164 days).
** Mothers should have blood drawn and tested for HBsAg as soon as possible after admission for delivery; if the mother is found to be HBsAg positive, the infant should receive HBIG as soon as possible but no later than age 7 days.
†† On a case-by-case basis and only in rare circumstances, the first dose may be delayed until after hospital discharge for an infant who weighs ≥2,000 g and whose mother is HBsAg negative, but only if a physicianõs order to withhold the birth dose and a copy of the motherõs original HBsAg-negative laboratory report are documented in the infantõs medical record.

TABLE 4. Hepatitis B immunization management of preterm infants weighing <2,000 g, by maternal hepatitis B surface antigen (HBsAg) status

Maternal HBsAg status	Recommendation
Positive	Å HBIG* + hepatitis B vaccine (≤12 hrs of birth) Å Continue vaccine series beginning at age 1ï 2 mos according to recommended schedule for infants born to HBsAg-positive mothers (see Table 3). Å Do not count birth dose as part of the vaccine series. Å Test for HBsAg and antibody to HBsAg after completion of the vaccine series at age 9ï 18 mos (i.e., next well-child visit).
Unknown	Å HBIG + hepatitis B vaccine (≤12 hrs of birth) Å Test mother for HBsAg. Å Continue vaccine series beginning at age 1ï 2 mos according to recommended schedule based on the motherõs HBsAg result (see Table 3). Å Do not count birth dose as part of the vaccine series.
Negative	Å Delay first dose of hepatitis B vaccine until age 1 mo or hospital discharge. Å Complete the vaccine series (see Table 3).

* Hepatitis B immune globulin.

Response to Revaccination

A study of infants born to HBsAg-positive mothers who did not respond to a primary vaccine series indicated that all those not infected with HBV responded satisfactorily to a repeat 3-dose revaccination series (*103*). No data suggest that children who have no detectable antibody after 6 doses of vaccine would benefit from additional doses.

Groups Requiring Different Vaccination Doses or Schedules

Preterm infants. Preterm infants weighing <2,000 g at birth have a decreased response to hepatitis B vaccine administered before age 1 month (*104–106*). By age 1 month, medically stable preterm infants, regardless of initial birth weight or gestational age, have a response to vaccination that is comparable to that of full-term infants (*107–110*).

Hemodialysis patients and other immunocompromised persons. Although data concerning the response of pediatric hemodialysis patients to vaccination with standard pediatric doses are lacking, protective levels of antibody occur in 75%–97% of those who receive higher dosages (20-*µ*g) on either the 3- or the 4-dose schedule (*111–114*). Humoral response to hepatitis B vaccination is also reduced in other children and adolescents who are immunocompromised (e.g., hematopoietic stem cell transplant recipients, patients undergoing chemotherapy, and HIV-infected persons) (*115–119*). Modified dosing regimens, including a doubling of the standard antigen dose or administration of additional doses, might increase response rates (*120*). However, data on response to these alternative vaccination schedules are limited (*121*).

Immune Memory

Anti-HBs is the only easily measurable correlate of vaccine-induced protection. Immunocompetent persons who achieve anti-HBs concentrations ≥10 mIU/mL after preexposure vaccination have virtually complete protection against both acute disease and chronic infection even if anti HBs concentrations subsequently decline to <10 mIU/mL (*122–125*). Although immunogenicity is lower among immunocompromised persons, those who achieve and maintain a protective antibody response before exposure to HBV have a high level of protection from infection.

After primary immunization with hepatitis B vaccine, anti-HBs concentrations decline rapidly within the first

TABLE 5. Hepatitis B vaccine schedules for children, adolescents, and adults*

* Children, adolescents, and adults may be vaccinated according to any of the schedules indicated, except as noted. Selection of a schedule should consider the need to optimize compliance with vaccination

À Pediatric/adolescent formulation.

ÆA 2-dose schedule of Recombivax-HB adult formulation (10 Õg) is licensed for adolescents aged 11ï 15 years. When scheduled to receive the second dose, adolescents aged >15 years should be switched to a 3-dose series, with doses 2 and 3 consisting of the pediatric formulation administered on an appropriate schedule.

Ä A 4-dose schedule of Engerix B is licensed for all age groups.

** Adult formulation.

ÀÀ Twinrix may be administered to persons aged ≥18 years at 0, 1, and 6 months.

year and more slowly thereafter. Among children who respond to a primary vaccine series with antibody levels ≥10 mIU/mL, 15%–50% have low or undetectable concentrations of anti-HBs (anti-HBs loss) 5–15 years after vaccination (*126–130*). The persistence of detectable anti-HBs after vaccination, in the absence of exposure to HBV, depends on the level of post-vaccination antibody concentration.

Despite declines in anti-HBs to <10 mIU/mL, nearly all vaccinated persons are still protected against HBV infection. The mechanism for continued vaccine-induced protection is thought to be the preservation of immune memory through selective expansion and differentiation of clones of antigen-specific B and T lymphocytes (*131*). Persistence of vaccine-induced immune memory among persons who responded to a primary childhood vaccine series 13–23 years earlier but then had levels of anti-HBs below 10 mIU/mL has been demonstrated by an anamnestic increase in anti-HBs levels in 67%–76% of these persons 2–4 weeks after administration of an additional vaccine dose (*132,133*). Although direct measurement of immune memory is not yet possible, these data indicate that a high proportion of vaccine recipients retain immune memory and would develop an anti-HBs response upon exposure to HBV.

Studies of cohorts of immunocompetent persons vaccinated as children or infants also indicate that, despite anti-HBs loss years after immunization, nearly all vaccinated persons who respond to a primary series remain protected from HBV infection. No clinical cases of hepatitis B have been observed in follow-up studies conducted 15–20 years after vaccination among immunocompetent vaccinated persons with antibody levels ≥10 mIU/mL. Certain studies have documented breakthrough infections (detected by the presence of anti-HBc or HBV DNA) in a limited percentage of vaccinated persons (*130,131*), but these infections are usually transient and asymptomatic; chronic infections have been documented only rarely (*134*). Breakthrough infections resulting in chronic infection have been observed only among vaccinated infants born to HBsAg-positive women.

Limited data are available on the duration of immune memory after hepatitis B vaccination in immunocompromised persons (e.g., HIV-infected patients, dialysis patients, patients undergoing chemotherapy, or hematopoietic stem cell transplant patients). No clinically important HBV infections have been documented among immunocompromised persons who maintain protective levels of anti-HBs. In studies of long-term protection among HIV-infected persons, breakthrough infections occurring after a decline in anti-HBs concentrations to <10 mIU/mL have been transient and asymptomatic (*135*). However, among hemodialysis patients who respond to the vaccine, clinically significant HBV infection has been documented in persons who have not maintained anti-HBs concentrations of ≥10 mIU/mL (*136*).

Postexposure Prophylaxis

Both passive-active postexposure prophylaxis (PEP) with HBIG and hepatitis B vaccine and active PEP with hepatitis B vaccine alone have been demonstrated to be highly effective in preventing transmission after exposure to HBV (*137–140*). HBIG alone has also been demonstrated to be effective in preventing HBV transmission (*141–144*), but with the availability of hepatitis B vaccine, HBIG typically is used as an adjunct to vaccination.

The major determinant of the effectiveness of PEP is early administration of the initial dose of vaccine. The effectiveness of PEP diminishes the longer it is initiated after exposure (*17,145,146*). Studies are limited on the maximum interval after exposure during which PEP is effective, but the interval is unlikely to exceed 7 days for perinatal (*147*) and needlestick (*140–142*) exposures and 14 days for sexual exposures (*122, 138,139,143,144*).

No data are available on the efficacy of HBsAg-containing combination vaccines when used to complete the vaccine series for PEP, but the efficacy of combination vaccines is expected to be similar to that of single-antigen vaccines because the HBsAg component induces a comparable anti-HBs response.

Perinatal HBV Exposure

Passive-active PEP. PEP with hepatitis B vaccine and HBIG administered 12–24 hours after birth, followed by completion of a 3-dose vaccine series, has been demonstrated to be 85%–95% effective in preventing acute and chronic HBV infection in infants born to women who are positive for both HBsAg and HBeAg (*137*). Although clinical trials have evaluated the efficacy of passive-active PEP with hepatitis B vaccine and HBIG administered only within 24 hours of birth, studies of passive immunoprophylaxis have demonstrated that HBIG provided protection when administered as late as 72 hours after exposure. The majority of clinical trials have evaluated the efficacy of passive-active PEP when the second vaccine dose was administered at age 1 month (*137*). Administration of HBIG plus vaccine at birth, 1 month, and 6 months and at birth, 2 months, and 6 months has demonstrated comparable efficacy in prevention of acute and chronic infection among infants born to women who were both HBsAg and HBeAg positive (Cladd E. Stevens, MD, New York Blood Center, personal communication, 1994).

Infants born to HBsAg-positive/HBeAg-negative mothers who receive passive-active PEP with HBIG and hepatitis B vaccine should have the same high degree of protection as infants born to women who are HBsAg positive/HBeAg positive. However, the efficacy of this regimen has not been examined in controlled clinical trials because the low infection rate would require an unattainable sample size.

Active PEP. Active PEP with hepatitis B vaccine alone (i.e., without HBIG) is frequently used in certain remote areas (e.g., Alaska and the Pacific Islands) where implementation of maternal HBsAg testing is difficult because no access exists to a laboratory. In randomized, placebo-controlled clinical trials, administration of hepatitis B vaccine in a 3- or 4-dose schedule without HBIG beginning ≤12 hours after birth has been demonstrated to prevent 70%–95% of perinatal HBV infections among infants born to women who are positive for both HBsAg and HBeAg (*58,148–152*). Population-based studies in areas with a high endemicity of HBV infection have demonstrated that active postexposure vaccination is highly effective in preventing infection when the first dose is administered soon after birth, the second at age 1–2 months, and the third at age 6–8 months (*153–155*).

Vaccine Safety

Hepatitis B vaccines have been demonstrated to be safe when administered to infants, children, adolescents, and adults. Since 1982, an estimated >60 million adolescents and adults and >40 million infants and children have been vaccinated in the United States.

Vaccine Reactogenicity

The most frequently reported side effects among persons receiving hepatitis B vaccine are pain at the injection site (3%–29%) and fever >99.9° F (>37.7° C) (1%–6%) (*156,157*). However, in placebo-controlled studies, these side effects were reported no more frequently among persons receiving hepatitis B vaccine than among persons receiving placebo (*87*). Administration of hepatitis B vaccine soon after birth has not been associated with an increased rate of elevated temperatures or microbiologic evaluations for possible sepsis in the first 21 days of life (*158*).

Adverse Events

A causal association has been established between receipt of hepatitis B vaccine and anaphylaxis (*159*). On the basis of data from the Vaccine Safety Datalink (VSD) project, the estimated incidence of anaphylaxis among children and adolescents who received hepatitis B vaccine is one case per 1.1 million vaccine doses distributed (95% confidence interval = 0.1–3.9) (*160*).

Early postlicensure surveillance of adverse events suggested a possible association between Guillain-Barré syndrome and receipt of the first dose of plasma-derived hepatitis B vaccine among U.S. adults (*161*). However, in a subsequent analysis of Guillain-Barré syndrome cases reported to CDC, FDA, and vaccine manufacturers, among an estimated 2.5 million adults who received ≥1 dose of recombinant hepatitis B vaccine during 1986–1990, the rate of Guillain-Barré syndrome occurring after hepatitis B vaccination did not exceed the background rate among unvaccinated persons (CDC, unpublished data, 1992). A review by persons with clinical expertise concluded that evidence was insufficient to reject or accept a causal association between Guillain-Barré syndrome and hepatitis B vaccination (*159,162*).

Multiple sclerosis (MS) has not been reported after hepatitis B vaccination among children. However, one retrospective case-control study (*163,164*) reported an association between hepatitis B vaccine and MS among adults. Multiple other studies (*165–168*) have demonstrated no association between hepatitis B vaccine and MS. Reviews of these data by panels of persons with clinical expertise have favored rejection of a causal association between hepatitis B vaccination and MS (*169,170*).

Chronic illnesses that have been reported in rare instances after hepatitis B vaccination include chronic fatigue syndrome (*171*), neurologic disorders (e.g., leukoencephalitis, optic neu-

ritis, and transverse myelitis) (*172–174*), rheumatoid arthritis (*175,176*), type 1 diabetes (*177*), and autoimmune disease (*178*). No evidence of a causal association between these conditions or other chronic illnesses and hepatitis B vaccine has been demonstrated (*159,169,170,179–182*).

Reported episodes of alopecia (hair loss) after rechallenge with hepatitis B vaccine suggest that vaccination might, in rare cases, trigger episodes of alopecia (*183*). However, a population-based study determined no statistically significant association between alopecia and hepatitis B vaccine (*184*).

No evidence exists of a causal association between hepatitis B vaccination, including administration of the birth dose, and sudden infant death syndrome (SIDS) or other causes of death during the first year of life (*185–187*). Infant death rates, including rates of SIDS, declined substantially in the United States during the 1990s, coincident with an increase in infant hepatitis B vaccination coverage from <1% to >90% and implementation of efforts to reduce SIDS through infant sleep positioning and separation from other persons in bed (*188*).

The safety of hepatitis B vaccine and other vaccines is assessed continuously through ongoing monitoring of data from VSD, the Vaccine Adverse Events Reporting System (VAERS), and other surveillance systems. Any adverse events after vaccination should be reported to VAERS; report forms and assistance are available from CDC at telephone 1-800-822-7967 or at http://www.vaers.hhs.gov.

Contraindications and Precautions

Hepatitis B vaccination is contraindicated for persons with a history of hypersensitivity to yeast or to any vaccine component (*92,189–191*). Despite a theoretic risk for allergic reaction to vaccination in persons with allergy to *Saccharomyces cerevisiae* (baker's yeast), no evidence exists that documents adverse reactions after vaccination of persons with a history of yeast allergy.

Persons with a history of serious adverse events (e.g., anaphylaxis) after receipt of hepatitis B vaccine should not receive additional doses. As with other vaccines, vaccination of persons with moderate or severe acute illness, with or without fever, should be deferred until the illness resolves (*192*). Vaccination is not contraindicated in persons with a history of MS, Guillain-Barré syndrome, autoimmune disease (e.g., systemic lupus erythematosis or rheumatoid arthritis), or other chronic diseases.

Pregnancy is not a contraindication to vaccination. Limited data indicate no apparent risk for adverse events to developing fetuses when hepatitis B vaccine is administered to pregnant women (*193*). Current vaccines contain noninfectious HBsAg and should cause no risk to the fetus.

Future Considerations

Implementation of the recommendations and strategies in this document should ultimately lead to the elimination of HBV transmission in the United States. New information will have implications for this effort, and adjustments and changes are expected to occur.

Long-Term Protection and Booster Doses

Studies are needed to assess long-term protection after vaccination and the possible need for booster doses of vaccine. The longest follow-up studies of vaccine protection have been conducted in populations with an initially high endemicity of HBV infection (i.e., ≥8% prevalence of chronic infection) (*130*). Implementation of hepatitis B vaccination programs in populations with a high endemicity of HBV infection has resulted in virtual elimination of new HBV infections by providing vaccine-induced immunity to susceptible persons. In these populations, ongoing exposure of vaccinated persons to persons with chronic HBV infection might complicate future efforts to assess long-term hepatitis B vaccine efficacy. Assessment of efficacy provided by hepatitis B immunization after 15–20 years will require studies among populations that continue to have exposures to HBsAg-positive persons (e.g., communities of immigrants from highly endemic countries, populations of injection-drug users, or health-care workers) and studies among populations with a low prevalence of infection.

Immunization Escape Mutants

Mutations in the S gene of HBV can lead to conformational changes in the *a* determinant of the HBsAg protein, which is the major target for neutralizing anti-HBs. These variants have been detected in humans infected with HBV, and concern has been expressed that these variants might replicate in the presence of vaccine-induced anti-HBs or anti-HBs contained in HBIG (*194,195*). Although no evidence suggests that S gene immunization escape mutants pose a threat to existing programs using hepatitis B vaccines (*196*), further studies and enhanced surveillance to detect the emergence of these variants are high priorities for monitoring the effectiveness of current vaccination strategies.

Recommendations for Hepatitis B Vaccination of Infants, Children, and Adolescents

This section outlines updated ACIP recommendations and associated implementation strategies for hepatitis B vaccina-

tion of infants, children, and adolescents. These recommendations have been summarized (Box 3).

Prevention of Perinatal HBV Infection and Management of Pregnant Women

Recommendations

Prenatal HBsAg Testing

- All pregnant women should be tested routinely for HBsAg during an early prenatal visit (e.g., first trimester) in each pregnancy, even if they have been previously vaccinated or tested.
- Women who were not screened prenatally, those who engage in behaviors that put them at high risk for infection (e.g., injection-drug use, having had more than one sex partner in the previous 6 months or an HBsAg-positive sex partner, evaluation or treatment for a sexually transmitted disease [STD], or recent or current injection-drug use) and those with clinical hepatitis should be tested at the time of admission to the hospital for delivery.
- All laboratories that provide HBsAg testing of pregnant women should use an FDA-licensed or -approved HBsAg test and should perform testing according to the manufacturer's labeling, including testing of initially reactive specimens with a licensed neutralizing confirmatory test. When pregnant women are tested for HBsAg at the time of admission for delivery, shortened testing protocols may be used and initially reactive results reported to expedite administration of immunoprophylaxis to infants.
- Women who are HBsAg positive should be referred to an appropriate case-management program to ensure that their infants receive timely postexposure prophylaxis and follow-up (see Case-Management Programs to Prevent Perinatal HBV Infection). In addition, a copy of the original laboratory report indicating the pregnant woman's HBsAg status should be provided to the hospital where delivery is planned and to the health-care provider who will care for the newborn.
- Women who are HBsAg positive should be provided with or referred for appropriate counseling and medical management (Appendix A). HBsAg-positive pregnant women should receive information concerning hepatitis B that discusses
  - — modes of transmission;
  - — perinatal concerns (e.g., infants born to HBsAg-positive mothers may be breast fed);
  - — prevention of HBV transmission to contacts, including the importance of postexposure prophylaxis for the newborn infant and hepatitis B vaccination for household, sexual, and needle-sharing contacts;
  - — substance abuse treatment, if appropriate; and
  - — medical evaluation and possible treatment of chronic hepatitis B.
- When HBsAg testing of pregnant women is not feasible (i.e., in remote areas without access to a laboratory), all infants should receive hepatitis B vaccine ≤12 hours of birth and should complete the hepatitis B vaccine series according to a recommended schedule for infants born to HBsAg-positive mothers (Tables 2 and 3).

Management of Infants Born to Women Who Are HBsAg Positive

- All infants born to HBsAg-positive women should receive single-antigen hepatitis B vaccine (Table 2) and HBIG

BOX 3. Summary of hepatitis B vaccination recommendations for infants, children, and adolescents

Maternal hepatitis B surface antigen (HBsAg) testing
- All pregnant women should be tested routinely for HBsAg.

Vaccination of infants

At birth
- Infants born to mothers who are HBsAg positive should receive hepatitis B vaccine and hepatitis B immune globulin (HBIG) ≤12 hours of birth.
- Infants born to mothers whose HBsAg status is unknown should receive hepatitis B vaccine ≤12 hours of birth. The mother should have blood drawn as soon as possible to determine her HBsAg status; if she is HBsAg positive, the infant should receive HBIG as soon as possible (no later than age 1 week).
- Full-term infants who are medically stable and weigh ≥2,000 g born to HBsAg-negative mothers should receive single-antigen hepatitis B vaccine before hospital discharge.
- Preterm infants weighing <2,000 g born to HBsAg-negative mothers should receive the first dose of vaccine 1 month after birth or at hospital discharge.

After the birth dose
- All infants should complete the hepatitis B vaccine series with either single-antigen vaccine or combination vaccine, according to a recommended vaccination schedule (see Tables 3 and 4).
- Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of the hepatitis B vaccine series at age 9–18 months.

Vaccination of children and adolescents
- All unvaccinated children and adolescents aged <19 years should receive the hepatitis B vaccine series.

(0.5 mL) ≤12 hours of birth, administered at different injection sites. The vaccine series should be completed according to a recommended schedule for infants born to HBsAg-positive mothers (Table 3). The final dose in the vaccine series should not be administered before age 24 weeks (164 days).

- For preterm infants weighing <2,000 g, the initial vaccine dose (birth dose) should not be counted as part of the vaccine series because of the potentially reduced immunogenicity of hepatitis B vaccine in these infants; 3 additional doses of vaccine (for a total of 4 doses) should be administered beginning when the infant reaches age 1 month (Tables 3 and 4).
- Postvaccination testing for anti-HBs and HBsAg should be performed after completion of the vaccine series, at age 9–18 months (generally at the next well-child visit). Testing should not be performed before age 9 months to avoid detection of anti-HBs from HBIG administered during infancy and to maximize the likelihood of detecting late HBV infection. Anti-HBc testing of infants is not recommended because passively acquired maternal anti-HBc might be detected in infants born to HBV-infected mothers to age 24 months.
  - — HBsAg-negative infants with anti-HBs levels ≥10 mIU/mL are protected and need no further medical management.
  - — HBsAg-negative infants with anti-HBs levels <10 mIU/mL should be revaccinated with a second 3-dose series and retested 1–2 months after the final dose of vaccine.
  - — Infants who are HBsAg positive should receive appropriate follow-up (Appendix A).
- Infants of HBsAg-positive mothers may be breast fed beginning immediately after birth.
- Although not indicated in the manufacturer's package labeling, HBsAg-containing combination vaccines may be used for infants aged ≥6 weeks born to HBsAg-positive mothers to complete the vaccine series after receipt of a birth dose of single-antigen hepatitis B vaccine and HBIG.

Management of Infants Born to Women with Unknown HBsAg Status

- Women admitted for delivery without documentation of HBsAg test results should have blood drawn and tested as soon as possible after admission.
- While test results are pending, all infants born to women without documentation of HBsAg test results should receive the first dose of single-antigen hepatitis B vaccine (without HBIG) ≤12 hours of birth (Tables 2 and 3).
  - — If the mother is determined to be HBsAg positive, her infant should receive HBIG as soon as possible but no later than age 7 days, and the vaccine series should be completed according to a recommended schedule for infants born to HBsAg-positive mothers (Table 3).
  - — If the mother is determined to be HBsAg negative, the vaccine series should be completed according to a recommended schedule for infants born to HBsAg-negative mothers (Table 3).
  - — If the mother has never been tested to determine her HBsAg status, the vaccine series should be completed according to a recommended schedule for infants born to HBsAg-positive mothers (Table 3). Administration of HBIG is not necessary for these infants.
- Because of the potentially decreased immunogenicity of vaccine in preterm infants weighing <2,000 g, these infants should receive both single-antigen hepatitis B vaccine and HBIG (0.5 mL) if the mother's HBsAg status cannot be determined ≤12 hours of birth. The birth dose of vaccine should not be counted as part of the 3 doses required to complete the vaccine series; 3 additional doses of vaccine (for a total of 4 doses) should be administered according to a recommended schedule on the basis of the mother's HBsAg test result (Table 3).

Vaccination of Pregnant Women

- Pregnant women who are identified as being at risk for HBV infection during pregnancy (e.g., having more than one sex partner during the previous 6 months, been evaluated or treated for an STD, recent or current injection-drug use, or having had an HBsAg-positive sex partner) should be vaccinated.
- Pregnant women at risk for HBV infection during pregnancy should be counseled concerning other methods to prevent HBV infection.

Implementation

Delivery Hospital Policies and Procedures

- All delivery hospitals should implement policies and procedures (Box 4) to ensure 1) identification of infants born to HBsAg-positive mothers and infants born to mothers with unknown HBsAg status (see Prenatal HBsAg Testing), and 2) initiation of immunization for these infants). Such policies and procedures should include the following standing orders:
  - — for all pregnant women, review of HBsAg test results at the time of admission for delivery;
  - — for women who do not have a documented HBsAg test result, HBsAg testing as soon as possible after admission for delivery;

BOX 4. Delivery hospital policies and procedures to prevent perinatal HBV transmission

At time of admission for delivery

- Review hepatitis B surface antigen (HBsAg) status of all pregnant women.
- Record maternal HBsAg test results on both labor and delivery record and on infant's delivery summary sheet.
- Perform HBsAg testing as soon as possible on women who
  - do not have a documented HBsAg test result,
  - were at risk for HBV infection during pregnancy (e.g., more than one sex partner in the previous 6 months, evaluation or treatment for a sexually transmitted disease, recent or current injection-drug use, or HBsAg-positive sex partner), or
  - had clinical hepatitis since previous testing.

After delivery

HBsAg-positive mothers and their infants

- Administer single-antigen hepatitis B vaccine and hepatitis B immune globulin (HBIG) to all infants born to HBsAg-positive mothers ≤12 hours after birth and record date and time of administration of HBIG and hepatitis B vaccine in infant's medical record.
- Provide information regarding hepatitis B to HBsAg-positive mothers, including
  - advice that they may breast feed their infants upon delivery;
  - modes of HBV transmission;
  - need for vaccination of their susceptible household, sexual, and needle-sharing contacts;
  - need for substance abuse treatment, if appropriate; and
  - need for medical management and possible treatment for chronic hepatitis B.

Mothers with unknown HBsAg status and their infants

- Administer single-antigen hepatitis B vaccine (without HBIG) to all infants born to mothers with unknown HBsAg status ≤12 hours after birth and record date and time of administration of hepatitis B vaccine on infant's medical record.
- Alert infant's pediatric health-care provider if an infant is discharged before the mother's HBsAg test result is available; if the mother is determined to be HBsAg positive, HBIG should be administered to the infant as soon as possible, but no later than age 7 days.

All mothers and their infants

- Administer a dose of single-antigen hepatitis B vaccine to all infants weighing ≥2,000 g.
- Ensure that all mothers have been tested for HBsAg prenatally or at the time of admission for delivery and document test results.

At time infant is discharged

- Provide infant's immunization record to mother and remind her to take it to the infant's first visit to pediatric health-care provider.
  - identification and management of all infants born to HBsAg-positive mothers;
  - identification and management of all infants born to mothers with unknown HBsAg status; and
  - for all infants, documentation on the infant's medical record of maternal HBsAg test results, infant hepatitis B vaccine administration, and administration of HBIG (if appropriate).
- Delivery hospitals should enroll in the federally funded Vaccines for Children (VFC) program to obtain free hepatitis B vaccine for administration of the birth dose to newborns who are eligible (i.e., Medicaid eligible, American Indian or Alaska Native, underinsured, or uninsured).

Case-Management Programs to Prevent Perinatal HBV Infection

- States and localities should establish case-management programs (Box 5), including appropriate policies, procedures, laws, and regulations, to ensure that
  - all pregnant women are tested for HBsAg during each pregnancy, and
  - infants born to HBsAg-positive women and infants born to women with unknown HBsAg status receive recommended case management.
- The location of these programs and the methods by which they operate will depend on multiple factors (e.g., population density and annual caseload of HBsAg-positive women). Programs may be located in state or local health departments, private health-care systems (e.g., health maintenance organizations), or institutions (e.g., correctional facility systems). Program administrators will need to work with prenatal care providers, delivery hospital staff, pediatric care providers, private health-care systems, and health departments.

Universal Vaccination of Infants

Recommendations

- All infants should receive the hepatitis B vaccine series as part of the recommended childhood immunization schedule (Table 5 and Appendix B). (For recommendations on management of infants born to HBsAg-positive mothers and infants born to mothers with unknown HBsAg status, see Prevention of Perinatal HBV Infection and Management of Pregnant Women.)
- For all medically stable infants weighing ≥2,000 g at birth and born to HBsAg-negative mothers, the first dose of vaccine should be administered before hospital discharge. Only single-antigen hepatitis B vaccine should be used for the birth dose.

BOX 5. Components of case-management programs to prevent perinatal hepatitis B virus infection

Test all pregnant women for hepatitis B surface antigen (HBsAg)

- Health-care providers should test all pregnant women for HBsAg during each pregnancy.
- HBsAg testing should be incorporated into standard prenatal testing panels (e.g., blood type, human immunodeficiency virus) infection, Rh factor, rubella antibody titer, and syphilis infection) used by all health-care providers caring for pregnant women.
- Delivery hospitals should ensure that all pregnant or delivering women have been tested for HBsAg before hospital discharge.
- Reporting of HBsAg test status should be included on hospital-based electronic birth certificates or neonatal metabolic screening requests.

Report and track HBsAg-positive women

- All HBsAg-positive pregnant women and all women of childbearing age with HBsAg-positive laboratory results should be reported to state or local perinatal hepatitis B prevention programs.
- All HBsAg-positive pregnant women should be entered into case-management tracking systems.

Provide prenatal HBsAg testing records to delivery hospitals

- HBsAg test results should be included on all forms (hard copy, electronic) used by practitioners to record and transmit information regarding care during pregnancy.
- For all pregnant women, a copy of the original laboratory report of HBsAg test results should be transferred from the prenatal care provider to the delivery hospital.
- Practitioners should document that HBsAg-positive pregnant women have a copy of the original laboratory report, that a copy of the original laboartory report is transferred from the prenatal care provider to the delivery hospital, and that patients are informed of their HBsAg test status and advised to notify delivery staff.

Identify and manage infants born to HBsAg-positive mothers

- Delivery hospitals should implement policies and procedures to ensure identification and initiation of postexposure immunization of infants born to HBsAg-positive mothers (see Delivery Hospital Policies and Procedures).
- Delivery hospitals should document the date and time of birth and the date and time of administration of hepatitis B immune globulin (HBIG) and hepatitis B vaccine for all infants born to HBsAg-positive mothers.

Identify and manage infants born to mothers without HBsAg test results

- Delivery hospitals should implement policies and procedures to ensure identification and initiation of postexposure immunization of infants born to mothers with unknown HBsAg status at delivery (see Delivery Hospital Policies and Procedures).
- Delivery hospitals should document the date and time of birth, date and time of administration of hepatitis B vaccine, and maternal HBsAg test results for all infants born to mothers with unknown HBsAg status at the time of delivery.

Complete the hepatitis B vaccine series

- Practitioners should document the dates of administration of all doses of the hepatitis B vaccine series for all infants born to HBsAg-positive mothers.

Complete postvaccination testing

- Health-care providers should document the results of testing for HBsAg and antibody to hepatitis B surface antigen (anti-HBs) after completion of the hepatitis B vaccine series for all infants born to HBsAg-positive mothers.

Monitor and evaluate the case management program

- Annually, each program should track
  - — the number of HBsAg-positive pregnant women;
  - — the proportion of infants born to HBsAg-positive women receiving postexposure prophylaxis ≤12 hours of birth, third vaccine dose by age 6 months, and postvaccination serologic testing for HBsAg and anti-HBs;
  - — the number of delivering women with unknown HBsAg status; and
  - — the proportion of infants born to mothers with unknown HBsAg status receiving hepatitis B vaccine within 12 hours of birth.
- Programs should determine reasons for
  - — >10% difference between expected and identified number of HBsAg-positive pregnant women;
  - — <90% completion rates for HBIG and hepatitis B vaccine ≤12 hours of birth, third dose by age 6 months, and postvaccination testing for infants born to HBsAg-positive mothers; and
  - — <90% completion rates for hepatitis B vaccine ≤12 hours of birth for infants born to mothers with unknown HBsAg status.

- On a case-by-case basis and only in rare circumstances, the first dose may be delayed until after hospital discharge for an infant who weighs ≥2,000 g and whose mother is HBsAg negative.
  - — When such a decision is made, a physician's order to withhold the birth dose and a copy of the original laboratory report indicating that the mother was HBsAg negative during this pregnancy should be placed in the infant's medical record.
  - — For infants who do not receive a first dose before hospital discharge, the first dose should be administered no later than age 2 months.
  - — Situations in which the birth dose should not be delayed include any high-risk sexual or drug-using practices of the infant's mother during pregnancy (e.g., having had more than one sex partner during the previous 6 months or an HBsAg-positive sex partner, evaluation or treatment for an STD, or recent or current injection-drug use) and expected poor compliance with follow-up to initiate the vaccine series.
- Preterm infants weighing <2,000 g and born to HBsAg-negative mothers should have their first vaccine dose delayed until 1 month after birth or hospital discharge (Table 4). For these infants, a copy of the original laboratory report indicating that the mother was HBsAg negative during this pregnancy should be placed in the infant's medical record.
- The vaccine series should be completed according to a recommended schedule with either single-antigen vaccine or a combination vaccine that contains the hepatitis B vaccine antigen (e.g., Hib-hepatitis B or DTaP-IPV-hepatitis B) (Table 2). The final dose in the vaccine series should not be administered before age 24 weeks (164 days).
- Administration of 4 doses of hepatitis B vaccine to infants is permissible in certain situations (e.g., when combination vaccines are administered after the birth dose).
- In populations with currently or previously high rates of childhood HBV infection (i.e., Alaska Natives; Pacific Islanders; and immigrant families from Asia, Africa, and other regions with intermediate or high endemic rates of infection [Figure 1 and Box 2]), the first dose of hepatitis B vaccine should be administered at birth and the final dose at age 6–12 months.

Implementation

- All delivery hospitals should implement standing orders for administration of hepatitis B vaccination as part of routine medical care of all medically stable infants weighing ≥2,000 g at birth (Box 4).
- All delivery hospitals should implement policies and procedures for management of infants weighing <2,000 g at birth, including the following:
  - — ensuring initiation of postexposure immunization of infants born to HBsAg-positive mothers and infants born to mothers not screened for HBsAg prenatally (see Prevention of Perinatal HBV Infection and Management of Pregnant Women), and
  - — documentation of maternal HBsAg test results on the infant's medical record.
- Prenatal care education should include information regarding the rationale for and importance of newborn hepatitis B vaccination.
- States are encouraged to adopt regulations or laws that require hepatitis B vaccination for entry into child care and also for entry into kindergarten and/or elementary school to ensure high vaccine coverage among infants and children.

Vaccination of Children and Adolescents Who Were Not Previously Vaccinated

Recommendations

- Hepatitis B vaccination is recommended for all children and adolescents aged <19 years.
- Children and adolescents who have not previously received hepatitis B vaccine should be vaccinated routinely at any age with an appropriate dose and schedule (Tables 2 and 5). Selection of a vaccine schedule should consider the need to achieve completion of the vaccine series. In all settings, vaccination should be initiated even though completion of the vaccine series might not be ensured.

Implementation

- To ensure high vaccination coverage among children and adolescents, the following measures are recommended:
  - — All children aged 11–12 years should have a review of their immunization records and should complete the vaccine series if they were not previously vaccinated or were incompletely vaccinated.
  - — All children and adolescents aged <19 years (including internationally adopted children) who were born in Asia, the Pacific Islands, Africa, or other intermediate- or high-endemic countries (Figure 1 and Box 2) or who have at least one parent who was born in one of these areas should have a review of their immunization records and should complete the vaccine series if they were not previously vaccinated or were incompletely vaccinated.

— States are encouraged to adopt regulations or laws that require hepatitis B vaccination before entry into middle school or its equivalent.
— Vaccination requirements should be considered for older high school students and for students before college entry, when feasible.
— States are encouraged to expand or implement immunization registries to include adolescents.
— Hepatitis B vaccine should be offered to all unvaccinated adolescents in settings that provide health-care services to this age group (Box 6), particularly those who engage in behaviors that place them at high risk for HBV infection.

BOX 6. Health-care settings in which hepatitis B vaccine should be offered to all unvaccinated children and adolescents

Primary care clinics
Substance abuse treatment facilities
Family planning clinics
Institutions for the developmentally disabled
Juvenile correctional facilities
Nonresidential daycare facilities for the developmentally disabled
Sexually transmitted disease clinics
School-based clinics

Acknowledgments

Review of this report was provided by the following persons: R. Palmer Beasley, MD, School of Public Health, University of Texas Health Science Center at Houston, Houston, Texas; F. Blaine Hollinger, MD, Baylor College of Medicine, Houston, Texas; Neal A. Halsey, MD, Johns Hopkins Bloomberg School of Public Health and Johns Hopkins School of Medicine, Baltimore, Maryland; and Craig N. Shapiro, MD, Office of Global Health Affairs, U.S. Department of Health and Human Services, Washington, DC. Allison Greenspan, MPH, Division of Viral Hepatitis, National Center for Infectious Diseases, CDC, provided vital assistance in the preparation of this report.

Appendix A

Case Finding and Management of Hepatitis B Surface Antigen (HBsAg)–Positive Persons During Delivery of Vaccination Services

Chronically infected persons are at high risk for chronic liver disease and are a major reservoir of hepatitis B virus (HBV) infection. Foreign-born persons, especially persons from Africa, Asia, and the Pacific Islands, have high* rates of chronic HBV infection. During delivery of recommended hepatitis B vaccination services (e.g., HBsAg screening of pregnant women and serologic testing to assess susceptibility), vaccination providers will identify persons who are HBsAg positive. These persons require counseling and medical management for chronic HBV infection to reduce their risk for chronic liver disease. Their susceptible household, sexual, and needle-sharing contacts also need to be vaccinated against hepatitis B.

Few programs have been implemented to identify HBsAg-positive persons, provide or refer these persons for appropriate medical management, and provide vaccination to their contacts (*1*). Extending these services to persons identified as HBsAg positive will help prevent serious sequelae in chronically infected persons and enhance vaccination strategies for elimination of HBV transmission. This Appendix addresses case finding and management of persons with chronic HBV infection in the context of vaccine delivery. The recommendations are not intended to represent a comprehensive prevention program for chronically infected persons.

Case Finding in the Context of Vaccination Service Delivery

- All foreign-born persons (including immigrants, refugees, asylum seekers, and internationally adopted children) born in Asia, the Pacific Islands, Africa, and other regions with high endemicity of HBV infection (Box A-1) should be tested for HBsAg, regardless of vaccination status.
  - — For all persons born in high-endemic countries who are applying for permanent U.S. residence, HBsAg screening and appropriate follow-up on the basis of HBsAg test results should be included as part of the required overseas premigration and domestic adjustment-of-visa status medical examination process (*2*). HBsAg-positive persons should be considered eligible for migration and adjustment-of-visa status and counseled and recommended for follow-up medical evaluation and management in U.S. resettlement communities.
  - — Providers should identify children born in high-endemic countries and provide HBsAg testing and follow-up in all settings that provide health care. Retesting of persons who were tested for HBsAg in other countries should be considered.
- Other persons who should be tested for HBsAg as part of vaccination services include
  - — all pregnant women (See Prevention of Perinatal HBV Infection and Management of Pregnant Women),
  - — persons who receive prevaccination testing for susceptibility and who test positive for anti-HBc (See Prevaccination Testing for Susceptibility),
  - — hemodialysis patients, and
  - — nonresponders to vaccination (See Appendix B, Postvaccination Testing for Serologic Response).

BOX A-1. Geographic areas with high* hepatitis B virus endemicity

Africa: all countries except Algeria, Egypt, Lybia, and Tunisia
South Asia: all countries except Afghanistan, Bangladesh, Bhutan, India, Malaysia, Maldives, Nepal, Pakistan, and Sri Lanka
Western Pacific: all countries except Australia, Guam, Japan, and New Zealand
Middle East: Jordan and Saudi Arabia
Eastern Europe and Newly Independent States of the former Soviet Union: Albania, Armenia, Azerbaijan, Bulgaria, Croatia, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Tajikistan, Turkmenistan, and Uzbekistan
Western Europe: Malta
North America: Alaska Natives and indigenous populations in Northern Canada and Greenland
South America: Amazonian areas of Bolivia, Brazil, Columbia, Peru, and Venezuela

* Hepatitis B surface antigen prevalence of ≥8%.

Management of Persons Identified as HBsAg Positive

- All persons with HBsAg-positive laboratory results should be reported to the state or local health department.
- To verify the presence of chronic HBV infection, HBsAg-positive persons should be retested. The absence of immu-

* Hepatitis B surface antigen prevalence of ≥8%.

noglobulin M antibody to HBcAg or the persistence of HBsAg for 6 months indicates chronic HBV infection.

- Persons with chronic HBV infection should be referred for evaluation by a physician experienced in the management of chronic liver disease (*3*). Certain patients with chronic hepatitis B will benefit from early intervention with antiviral treatment or screening to detect hepatocellular carcinoma at an early stage.
- Household, sexual, and needle-sharing contacts of chronically infected persons should be identified. Unvaccinated sex partners and household and needle-sharing contacts should be tested for susceptibility to HBV infection (see Prevaccination Serologic Testing for Susceptibility) and should receive the first dose of hepatitis B vaccine immediately after collection of the blood sample for serologic testing. Susceptible persons should complete the vaccine series using an age-appropriate vaccine dose and schedule (see Tables 2 and 6) Persons who are not fully vaccinated should complete the vaccine series.
- Sex partners of HBsAg-positive persons should be counseled to use methods (e.g., condoms) to protect themselves from sexual exposure to infectious body fluids (e.g., semen or vaginal secretions) unless they have been demonstrated to be immune after vaccination (i.e., anti-HBs ≥10 mIU/mL) or previously infected (anti-HBc positive).
- To prevent or reduce the risk for transmission to others, HBsAg-positive persons should be advised concerning the risks for
  - — perinatal transmission to infants born to HBsAg-positive women and the need for such infants to receive hepatitis B vaccine beginning at birth (see Prevention of Perinatal HBV Infection and Management of Pregnant Women) and
  - — transmission to household, sexual, and needle-sharing contacts and the need for such contacts to receive hepatitis B vaccine.
- HBsAg-positive persons should also be advised to
  - — use methods (e.g., condoms) to protect nonimmune sex partners from acquiring HBV infection from sexual activity until the sex partners can be vaccinated and immunity documented;
  - — cover cuts and skin lesions to prevent the spread of infectious secretions or blood;
  - — refrain from donating blood, plasma, tissue, or semen (organs may be donated to HBV-immune or chronically infected persons needing a transplant); and
  - — refrain from sharing household articles (e.g., toothbrushes, razors, or personal injection equipment) that could become contaminated with blood.
- To protect the liver from further harm, HBsAg-positive persons should be advised to
  - — avoid or limit alcohol consumption because of the effects of alcohol on the liver;
  - — refrain from beginning to take any new medicines, including over-the-counter and herbal medicines, without consulting their health-care provider; and
  - — obtain vaccination against hepatitis A if chronic liver disease is found to be present.
- When seeking medical or dental care, HBsAg-positive persons should be advised to inform those responsible for their care of their HBsAg status so they can be evaluated and their care managed appropriately.
- Other counseling messages:
  - — HBV is not spread by breastfeeding, kissing, hugging, coughing, ingesting food or water, sharing eating utensils or drinking glasses, or casual contact.
  - — Persons should not be excluded from school, play, child care, work, or other settings on the basis of their HBsAg status unless they are prone to biting (*4*).
  - — Involvement with a support group might help patients cope with chronic HBV infection.

Appendix B

Immunization Management Issues

Hepatitis B Vaccine Dose and Administration

- Recommended vaccine doses vary by product, age of recipient, and needs of special populations (see Table 2). Administration of single-antigen or combination vaccine simultaneously with other childhood vaccines produces no clinically significant interference in antibody responses (*1–13*). Although the antigen contents of vaccines differ, vaccines made by different manufacturers are interchangeable, except for the 2-dose schedule used for adolescents aged 11–15 years, for which only Recombivax HB is approved. Combination vaccines are not approved for use as a birth dose because of potential suppression of the immune response to subsequent doses of the *Haemophilus influenzae* type b (Hib) component in Comvax (*14*) and possible decreased immunogenicity of the diphtheria component of Pediarix when administered at birth.
- Hepatitis B vaccine should be administered by intramuscular injection. Injection into the buttock is associated with decreased immunogenicity (*15–18*). Intradermal administration can result in a lower seroconversion rate and final concentration of antibody to hepatitis B surface antigen compared with intramuscular administration; limited data are available to assess long-term protection from this route of administration (*19,20*).
- The anterolateral thigh muscle is the recommended site of administration for neonates (aged <1 month) and infants (aged 1–12 months). For toddlers (aged 1–2 years) and older children, either the anterolateral thigh or the deltoid muscle may be used if the muscle mass is adequate. The deltoid muscle is the preferred site of administration for adolescents.
- For intramuscular injection, the needle should be long enough to reach the muscle mass and prevent vaccine from seeping into subcutaneous tissue, but not so long as to involve underlying nerves and blood vessels or bone (*21*). The appropriate needle length is usually $^5/_8$" for neonates, $^7/_8$"–1" for infants, and $^7/_8$"–1$^1/_4$" for toddlers, older children, and adolescents. A 22- to 25-gauge needle should be used.
- Hepatitis B vaccine administered by any route or site other than intramuscularly in the anterolateral thigh or deltoid muscle should not be counted as valid and should be repeated unless serologic testing indicates that an adequate response has been achieved (see Postvaccination Testing for Serologic Response).
- Hepatitis B vaccine and other vaccines administered during the same visit should be administered in different injection sites. When more than one injection must be administered in the same limb, the anterolateral thigh is usually the preferred site, with injections separated by 1"–2" to avoid overlap in local reactions.
- For persons at risk for hemorrhage (e.g., persons with hemophilia), the risk of bleeding after intramuscular injection can be minimized by use of a 23-gauge (or smaller) needle, application of direct pressure to the injection site for ≥2 minutes, and administration of vaccine immediately after infusion of coagulation factor. Subcutaneous administration of vaccine can be considered for these persons but might result in lower response and an increased local reaction.
- Hepatitis B vaccine should be stored at 35°–46° F (2°–8° C) and should not be frozen.
- A vaccine information statement (VIS) must be provided to recipients of hepatitis B vaccine. The National Childhood Vaccine Injury Act of 1986 (42 U.S.C. § 300aa-26) requires vaccine providers to give a copy of the most current vaccine-specific VIS to all recipients (children or their guardians) of vaccines that are included on the National Vaccine Injury Compensation Program table maintained by the Health Resources and Services Administration (available at http://www. hrsa.gov). Hepatitis B vaccine is included on this table. The most current VIS for hepatitis B vaccine is available at http://www.cdc.gov/nip/publications/vis. Statements in languages other than English are available from the Immunization Action Coalition at http://www.immunize.org.

Hepatitis B Immune Globulin (HBIG) Dose and Administration

- The standard dose of HBIG is 0.5 mL for postexposure prophylaxis of infants born to hepatitis B surface antigen (HBsAg)–positive women and 0.06 mL/kg for all other applications.
- HBIG may be administered simultaneously with hepatitis B vaccine but in a different injection site.
- HBIG is administered by intramuscular injection. For infants, HBIG should be administered intramuscularly

in the anterolateral thigh using a 22–25-gauge needle that is 7/8"–1" in length. For older children and adolescents, an appropriate muscle mass (i.e., deltoid or gluteal) should be chosen in which to deliver the larger volumes of HBIG required for these age groups by using a needle length appropriate for the person's age and size (*21*).
- Vaccination with certain live-virus vaccines (measles, mumps, rubella, and varicella) should be deferred for at least 3 months after administration of HBIG because HBIG can inhibit the response to these vaccines (*21*).
- HBIG should be stored at 35°–46° F (2°–8° C) and should not be frozen.

Unknown or Uncertain Vaccination Status

- A reliable vaccination history is defined as a written, dated record (personal, school, physician, or immunization registry) of each dose of a complete series.
- In the majority of clinical practice settings and in situations when postexposure prophylaxis is indicated (see Appendix C), providers should accept only written and dated records (e.g., personal, school, physician, or immunization registry) as evidence of vaccination. Although vaccinations should not be postponed if records cannot be located, providers should try to locate missing records by contacting previous health-care providers and searching for personally held records.
- Persons whose records cannot be located should be considered susceptible and started or continued on the age-appropriate vaccine schedule.
- Persons who reside in the United States but were vaccinated in other countries should be considered fully vaccinated if they have written documentation of ≥3 doses of vaccine administered at recommended minimum intervals, including the third dose at age ≥24 weeks. If they were not vaccinated according to recommended minimum intervals, they should be revaccinated (see Minimum Dosing Intervals and Management of Persons Who Were Incorrectly Vaccinated). Persons without written documentation of full vaccination should complete the age-appropriate vaccine series.

Interrupted Vaccine Schedules

- When the hepatitis B vaccine schedule is interrupted, the vaccine series does not need to be restarted.
- If the series is interrupted after the first dose, the second dose should be given as soon as possible, and the second and third doses should be separated by an interval of at least 8 weeks.
- If only the third dose is delayed, it should be administered as soon as possible, after age 24 weeks (164 days).
- It is not necessary to restart the vaccine series for infants switched from one vaccine brand to another, including combination vaccines.

Minimum Dosing Intervals and Management of Persons Who Were Incorrectly Vaccinated

- The third dose of vaccine must be administered at least 8 weeks after the second dose and should follow the first dose by at least 16 weeks; the minimum interval between the first and second doses is 4 weeks. In infants, administration of the final dose is not recommended before age 24 weeks (164 days).
- Inadequate doses of hepatitis B vaccine (see Table 2) or doses received after a shorter-than-recommended dosing interval should be readministered.

Accelerated Vaccine Schedules

- The Food and Drug Administration (FDA) has not approved accelerated schedules in which hepatitis B vaccine is administered more than once in a month. If clinicians choose to use an accelerated schedule (i.e., doses at days 0, 7, and 14 days), the patient should also receive a booster dose at least 6 months after the start of the series to promote long-term immunity.

Hemodialysis Patients and Other Immunocompromised Persons

- Standard hepatitis B vaccine doses (see Table 2) are approved by FDA for vaccination of all persons aged <20 years. For hemodialysis patients and other immunocompromised persons, higher doses might be more immunogenic, but no specific recommendations have been made.
- Serologic testing of hemodialysis patients and other immunocompromised persons is recommended 1–2 months after administration of the final dose of the primary vaccine series to determine the need for revaccination (see Postvaccination Testing for Serologic Response). In addition, booster doses of vaccine might be needed (see Booster Doses).

Prevaccination Serologic Testing for Susceptibility

- Because of the low prevalence of HBV infection among infants, children, and adolescents born in the United States, prevaccination testing for susceptibility usually is not indicated for these age groups.
- Prevaccination testing for susceptibility is recommended for unvaccinated household, sexual, and needle-sharing contacts of HBsAg-positive persons.
- Anti-HBc is the test of choice for prevaccination testing.
- Persons tested for anti-HBc and found to be anti-HBc negative are susceptible and should complete the vaccine series.
- Persons found to be anti-HBc positive should be tested for HBsAg. HBsAg testing may be performed on the same specimen collected for anti-HBc testing. If the HBsAg test result is positive, the person should receive appropriate management (see Appendix A).
- In most situations, the first vaccine dose should be administered immediately after collection of the blood sample for serologic testing.

Postvaccination Testing for Serologic Response

Recommendations for postvaccination testing of infants born to HBsAg-positive women are provided in this report (see Management of Infants Born to Women Who Are HBsAg Positive). This section provides recommendations for postvaccination testing of other persons.

- Serologic testing for immunity is not necessary after routine vaccination of infants, children, or adolescents.
- Testing after vaccination is recommended only for the following persons whose subsequent clinical management depends on knowledge of their immune status:
  - — health-care workers;
  - — chronic hemodialysis patients, HIV-infected persons, and other immunocompromised persons (e.g., hematopoietic stem-cell transplant recipients or persons receiving chemotherapy), to determine the need for revaccination and the type of follow-up testing; and
  - — sex partners of HBsAg-positive persons, to determine the need for revaccination and the need for other methods of protection against HBV infection.
- Testing should be performed 1–2 months after administration of the last dose of the vaccine series by using a method that allows determination of a protective level of anti-HBs (≥10 mIU/mL).
- Persons found to have anti-HBs levels of ≥10 mIU/mL after the primary vaccine series are considered to be immune.
  - — Immunocompetent persons have long-term protection and do not need further periodic testing to assess anti-HBs levels.
  - — Immunosuppressed persons might need annual testing to assess anti-HBs levels (see Booster Doses).
- Persons found to have anti-HBs levels of <10 mIU/mL after the primary vaccine series should be revaccinated. Administration of three doses on an appropriate schedule (Table 7), followed by anti-HBs testing 1–2 months after the third dose, is usually more practical than serologic testing after one or more doses of vaccine.
- Persons who do not respond to revaccination should be tested for HBsAg.
  - — If the HBsAg test result is positive, the persons should receive appropriate management (see Appendix B), and any household, sexual, or needle-sharing contacts should be identified and vaccinated (see Appendix A).
  - — Persons who test negative for HBsAg should be considered susceptible to HBV infection and should be counseled about precautions to prevent HBV infection and the need to obtain HBIG postexposure prophylaxis for any known or likely parenteral exposure to HBsAg-positive blood (see Appendix C).

Booster Doses

- Booster doses are not recommended for persons with normal immune status who were vaccinated as infants, children, or adolescents. Serologic testing is not recommended to assess antibody levels in any age group, except in specific circumstances (see Postvaccination Testing for Serologic Response).
- For hemodialysis patients, the need for booster doses should be assessed by annual antibody to hepatitis B survace antigen (anti-HBs) testing. A booster dose should be administered when anti-HBs levels decline to <10 mIU/mL.
- For other immunocompromised persons (e.g., HIV-infected persons, hematopoietic stem cell transplant recipients, and persons receiving chemotherapy), the need for booster doses has not been determined. Annual anti-HBs testing and booster doses when anti-HBs levels decline to <10 mIU/mL should be considered in persons with an ongoing high risk for exposure.

Appendix C

Postexposure Prophylaxis of Persons with Discrete Identifiable Exposures to Hepatitis B Virus (HBV)

This appendix provides recommendations for management of persons who are exposed to HBV through a discrete, identifiable exposure to blood or body fluids that contain blood. Recommendations for management of infants born to mothers who test positive for hepatitis B surface antigen (HBsAg)-positive mothers are provided in this report (see Prevention of Perinatal HBV Transmission and Management of Pregnant Women).

HBsAg-Positive Source

- Unvaccinated persons (Table C-1) or persons known not to have responded to a complete hepatitis B vaccine series should receive both hepatitis B immune globulin (HBIG) and hepatitis B vaccine as soon as possible after exposure (preferably ≤24 hours). For sexual exposures, HBIG should not be administered more than 14 days after exposure. Hepatitis B vaccine may be administered simultaneously with HBIG in a separate injection site. The hepatitis B vaccine series should be completed using the age-appropriate vaccine dose and schedule (see Tables 2 and 3).
- Persons who are in the process of being vaccinated but who have not completed the vaccine series should receive the appropriate dose of HBIG and should complete the vaccine series.
- Children and adolescents who have written documentation of a complete hepatitis B vaccine series and who were did not receive postvaccination testing should receive a single vaccine booster dose.

Source with Unknown HBsAg Status

- Unvaccinated persons (Table C-1) should receive the hepatitis B vaccine series with the first dose initiated as soon as possible after exposure, preferably ≤24 hours. The vaccine series should be completed using the age-appropriate dose and schedule (see Tables 2, 3, and 5).
- Persons who are not fully vaccinated should complete the vaccine series.
- Children and adolescents with written documentation of a complete hepatitis B vaccine series require no further treatment.

TABLE C-1. Guidelines for postexposure immunoprophylaxis of unvaccinated persons who are exposed to blodo or body fluids that contain blood

Cause	Action
Discrete exposure to an HBsAg*-positive source	
Percutaneous (e.g., bite, needlestick) or mucosal exposure to HBsAg-positive blood or body fluids that contain blood	Administer hepatitis B vaccine and hepatitis B immune globulin (HBIG)[À]
Sexual or needle-sharing contact of an HBsAg-positive person	Administer hepatitis B vaccine and HBIG[À]
Victim of sexual assault/abuse by a perpetrator who is HBsAg-positive	Administer hepatitis B vaccine and HBIG[À]
Discrete exposure to a source with unknown HBsAg status	
Victim of sexual assault/abuse by a perpetrator with unknown HBsAg status	Administer hepatitis B vaccine[À]
Percutaneous (e.g., bite or needclestick) or mucosal exposure to blood or body fluids that contain blood from a source with unknown HBsAg status	Administer hepatitis B vaccine[À]

* Hepatitis B surface antigen.
[À] Immunoprophylaxis should be administered as soon as possible, preferably ≤24 hours. Studies are limited on the maximum interval after exposure during which postexposure prophylaxis is effective, but the interval is unlikely to exceed 7 days for percutaneous exposures and 14 days for sexual exposures. The hepatitis B vaccine series should be completed.

Glossary

Terms and Abbreviations Used in This Report

ACIP	Advisory Committee on Immunization Practices
ALT	alanine aminotransferase
Anti-HBc	antibody to hepatitis B core antigen
Anti-HBe	antibody to hepatitis B e antigen
Anti-HBs	antibody to hepatitis B surface antigen
DTaP	diphtheria and tetanus toxoids and acellular pertussis adsorbed
FDA	Food and Drug Administration
HBcAg	hepatitis B core antigen
HBeAg	hepatitis B e antigen
HBIG	hepatitis B immune globulin
HBsAg	hepatitis B surface antigen
HBV	hepatitis B virus
HCC	hepatocellular carcinoma
HCV	hepatitis C virus
Hib	*Haemophilus influenzae* type b
HIV	human immunodeficiency virus
IgM	immunoglobulin M
IPV	inactivated poliovirus
MS	multiple sclerosis
NHANES	National Health and Nutrition Examination Survey
VAERS	Vaccine Adverse Events Reporting System
VSD	Vaccine Safety Datalink

MMWR™

Morbidity and Mortality Weekly Report

Recommendations and Reports December 23, 2005 / Vol. 54 / No. RR-16

Continuing Education Activity Sponsored by CDC

A Comprehensive Immunization Strategy to Eliminate Transmission of Hepatitis B Virus Infection in the United States

Recommendations of the Advisory Committee on Immunization Practices (ACIP) Part 1: Immunization of Infants, Children, and Adolescents

EXPIRATION — December 23, 2008

You must complete and return the response form electronically or by mail by **December 23, 2008**, to receive continuing education credit. If you answer all of the questions, you will receive an award letter for 3.25 hours Continuing Medical Education (CME) credit; 0.3 Continuing Education Units (CEUs); or 3.8 contact hours Continuing Nursing Education (CNE) credit. If you return the form electronically, you will receive educational credit immediately. If you mail the form, you will receive educational credit in approximately 30 days. No fees are charged for participating in this continuing education activity.

INSTRUCTIONS

By Internet

1. Read this *MMWR* (Vol. 54, RR-16), which contains the correct answers to the questions beginning on the next page.
2. Go to the *MMWR* Continuing Education Internet site at http://www.cdc.gov/mmwr/cme/conted.html.
3. Select which exam you want to take and select whether you want to register for CME, CEU, or CNE credit.
4. Fill out and submit the registration form.
5. Select exam questions. To receive continuing education credit, you must answer all of the questions. Questions with more than one correct answer will instruct you to "Indicate all that apply."
6. Submit your answers no later than **December 23, 2008**.
7. Immediately print your Certificate of Completion for your records.

By Mail or Fax

1. Read this *MMWR* (Vol. 54, RR-16), which contains the correct answers to the questions beginning on the next page.
2. Complete all registration information on the response form, including your name, mailing address, phone number, and e-mail address, if available.
3. Indicate whether you are registering for CME, CEU, or CNE credit.
4. Select your answers to the questions, and mark the corresponding letters on the response form. To receive continuing education credit, you must answer all of the questions. Questions with more than one correct answer will instruct you to "Indicate all that apply."
5. Sign and date the response form or a photocopy of the form and send no later than **December 23, 2008**, to
   Fax: 770-488-8555
   Mail: MMWR CE Credit
   Division of Scientific Communications
   Coordinating Center for Health Information and Service, MS K-95
   Centers for Disease Control and Prevention
   1600 Clifton Rd, N.E.
   Atlanta, GA 30333
6. Your Certificate of Completion will be mailed to you within 30 days.

ACCREDITATION

Continuing Medical Education (CME). CDC is accredited by the Accreditation Council for Continuing Medical Education to provide continuing medical education for physicians. CDC designates this educational activity for a maximum of 3.25 hours in category 1 credit toward the AMA Physician's Recognition Award. Each physician should claim only those hours of credit that he/she actually spent in the educational activity.

Continuing Education Unit (CEU). CDC has been approved as an authorized provider of continuing education and training programs by the International Association for Continuing Education and Training. CDC will award 0.3 continuing education units to participants who successfully complete this activity.

Continuing Nursing Education (CNE). This activity for 3.8 contact hours is provided by CDC, which is accredited as a provider of continuing education in nursing by the American Nurses Credentialing Center's Commission on Accreditation.

DEPARTMENT OF HEALTH AND HUMAN SERVICES
CENTERS FOR DISEASE CONTROL AND PREVENTION

Goal and Objectives

This report updates the immunization strategy to eliminate hepatitis B virus (HBV) transmission in the United States. The report includes new recommendations and implementation strategies for immunization of infants, children, and adolescents. The goal of the report is to provide guidance for health-care professionals to implement these recommendations and strategies to prevent perinatal HBV transmission, to promote universal vaccination of infants as part of the routine childhood vaccination schedule, and to promote vaccination of children and adolescents who were not previously vaccinated. Upon completion of this educational activity, the reader should be able to a) identify ways to maintain high hepatitis B surface antigen (HBsAg) screening rates among pregnant women, b) describe the components of a case management program for HBsAg-positive women, c) describe methods to ensure that newborn infants of HBsAg-positive mothers and mothers with unknown HBsAg status receive appropriate immunoprophylaxis, d) describe how to structure programs to increase the number of infants who receive a birth dose of hepatitis B vaccine, e) list ways to increase vaccine coverage among adolescents, and f) identify ways to increase rates of HBsAg screening and hepatitis B vaccination of foreign-born persons.

To receive continuing education credit, please answer all of the following questions.

1. **Components of a health department case-management program to enhance prevention of perinatal hepatitis B virus (HBV) infection should ensure that…(*Indicate all that apply.*)**
   - A. all pregnant women are tested for HBsAg.
   - B. HBsAg-positive women are reported and tracked.
   - C. prenatal HBsAg testing records are received by maternity hospitals before delivery.
   - D. infants born to HBsAg-positive mothers and infants born to mothers with unknown HBsAg status are identified and managed.
   - E. all of the above.

2. **All delivery hospitals should implement standing orders for administration of hepatitis B vaccination before hospital discharge as part of routine medical care to all medically stable infants weighing >2,000 g at birth. (*Choose the one correct answer.*)**
   - A. True.
   - B. False

3. **Which of the following statement(s) regarding HBsAg screening and vaccination of immigrants and international adoptees is true? (*Indicate all that apply.*)**
   - A. All foreign-born persons (including immigrants, refugees, asylum seekers, and internationally adopted children) from Asia, the Pacific Islands, and Africa and other countries with HBsAg prevalence ≥2% should be tested for HBsAg.
   - B. Persons who test positive for HBsAg should receive appropriate follow-up, including counseling, evaluation for chronic liver disease and antiviral treatment, and vaccination of susceptible household and sexual contacts.
   - C. Persons who reside in the United States but who were vaccinated in other countries should be considered fully vaccinated if they have written documentation of at least three doses of vaccine administered at recommended minimum intervals.
   - D. All of the above.

4. **Identify health-care settings in which hepatitis B vaccine should be offered to all unvaccinated adolescents. (*Indicate all that apply.*)**
   - A. Drug treatment facilities.
   - B. Institutions for the developmentally disabled.
   - C. College health clinics.
   - D. Family planning clinics.
   - E. All of the above.

5. **Which of the following statements regarding the hepatitis B vaccination schedule in infants and children are true? (*Indicate all that apply.*)**
   - A. Administration of the final dose to infants is not recommended before age 24 weeks.
   - B. A vaccine series started with a birth dose of single-antigen vaccine cannot be completed with 3 doses of combination vaccine.
   - C. No differences in immunogenicity have been observed when one or two doses of hepatitis B vaccine produced by one manufacturer are followed by dose(s) from a different manufacturer.
   - D. Currently licensed formulations for both single-antigen vaccines have been demonstrated to produce high (>95%) levels of seroprotection among infants, children, and adolescents when administered in different schedules.
   - E. All of the above.

6. **Which of the following statements regarding the management of perinatal HBV exposure are true? (*Indicate all that apply.*)**
   - A. Passive-active prophylaxis with hepatitis B vaccine and HBIG should be administered within 12 hours after birth.
   - B. A vaccine series started with a birth dose of single-antigen vaccine can be completed with three doses of combination vaccine.
   - C. Active postexposure prophylaxis with hepatitis B vaccine alone (i.e., without HBIG) beginning at birth is frequently used in areas where implementation of maternal HBsAg testing is difficult (e.g., in Alaska, Pacific Islands, and developing countries).
   - D. Although rates of perinatal HBV transmission are higher from HBeAg-positive mothers compared with HBeAg-negative mothers, testing of HBsAg-positive pregnant women for HBeAg is not warranted for the management of the infant because postexposure prophylaxis is recommended for all infants born to HBsAg-positive women.
   - E. All of the above.

7. **Which best describes your professional activities:**
   - A. Physician.
   - B. Nurse.
   - C. Health educator.
   - D. Office staff.
   - E. Other.

8. **I plan to use these recommendations as the basis for…(*Indicate all that apply.*)**
   - A. health education materials.
   - B. insurance reimbursement policies.
   - C. local practice guidelines.
   - D. public policy.
   - E. other.

9. **Overall, the length of the journal report was…**
   - A. much too long.
   - B. a little too long.
   - C. just right.
   - D. a little too short.
   - E. much too short.

10. **After reading this report, I am confident I can identify ways to maintain high hepatitis B surface antigen (HBsAg) screening rates among pregnant women.**
    - A. Strongly agree.
    - B. Agree.
    - C. Undecided.
    - D. Disagree.
    - E. Strongly disagree.

11. **After reading this report, I am confident I can describe the components of a case management program for HBsAg-positive women.**
    - A. Strongly agree.
    - B. Agree.
    - C. Undecided.
    - D. Disagree.
    - E. Strongly disagree.

12. After reading this report, I am confident I can describe methods to ensure that newborn infants of HBsAg-positive mothers and mothers with unknown HBsAg status receive appropriate immunoprophylaxis.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

13. After reading this report, I am confident I can describe how to structure programs to increase the number of infants who receive a birth dose of hepatitis B vaccine.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

14. After reading this report, I am confident I can increase vaccine coverage among adolescents.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

15. After reading this report, I am confident I can identify ways to increase rates of HBsAg screening and hepatitis B vaccination of foreign-born persons.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

16. The learning outcomes (objectives) were relevant to the goal of this report.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

17. The instructional strategies used in this report (text, tables, figures, boxes, and appendices) helped me learn the material.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

18. The content was appropriate given the stated objectives of the report.

A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

MMWR Response Form for Continuing Education Credit
December 23, 2005/Vol. 54/No. RR-16

A Comprehensive Immunization Strategy to Eliminate Transmission of Hepatitis B Virus Infection in the United States

Recommendations of the Advisory Committee on Immunization Practices (ACIP)

Part 1: Immunization of Infants, Children, and Adolescents

To receive continuing education credit, you must
1. provide your contact information (**please print or type**);
2. indicate your choice of CME, CME for nonphysicians, CEU, or CNE credit;
3. answer all of the test questions;
4. sign and date this form or a photocopy;
5. submit your answer form by **December 23, 2008**.

Failure to complete these items can result in a delay or rejection of your application for continuing education credit.

Last Name (**print or type**) First Name

Street Address or P.O. Box

Apartment or Suite

City State ZIP Code

Phone Number Fax Number

E-Mail Address

Check One
- ☐ CME Credit
- ☐ CME for nonphysicians Credit

19. The content expert(s) demonstrated expertise in the subject matter.
A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

20. Overall, the quality of the journal report was excellent.
A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

21. These recommendations will improve the quality of my practice.
A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

22. The availability of continuing education credit influenced my decision to read this report.
A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

23. The *MMWR* format was conducive to learning this content.
A. Strongly agree.
B. Agree.
C. Undecided.
D. Disagree.
E. Strongly disagree.

24. Do you feel this course was commercially biased? *(Indicate yes or no; if yes, please explain in the space provided.)*
A. Yes.
B. No.

25. How did you learn about the continuing education activity?
A. Internet.
B. Advertisement (e.g., fact sheet, *MMWR* cover, newsletter, or journal).
C. Coworker/supervisor.
D. Conference presentation.
E. *MMWR* subscription.
F. Other.

Correct answers for questions 1–6.
1. E; 2. A; 3. D; 4. E; 5. A, C, and D; 6. E.

Advisory Committee on Immunization Practices

Membership List, June 2005

Chairman: Myron J. Levin, MD, Professor of Pediatrics and Medicine, University of Colorado Health Sciences Center, Denver, Colorado.

Executive Secretary: Larry Pickering, MD, National Immunization Program, CDC, Atlanta, Georgia.

Members: Jon S. Abramson, MD, Wake Forest University School of Medicine, Winston-Salem, North Carolina; Ban Mishu Allos, MD, Vanderbilt University School of Medicine, Nashville, Tennessee; Guthrie S. Birkhead, MD, New York State Department of Health, Albany, New York; Judith Campbell, MD, Baylor College of Medicine, Houston, Texas; Reginald Finger, MD, Focus on the Family, Colorado Springs, Colorado; Janet Gildsdorf, MD, University of Michigan, Ann Arbor, Michigan; Tracy Lieu, MD, Harvard Pilgrim Health Care and Harvard Medical School, Boston, Massachusetts; Edgar Marcuse, MD, Children's Hospital and Regional Medical Center, Seattle, Washington; Julia Morita, MD, Chicago Department of Health, Chicago, Illinois; Gregory Poland, MD, Mayo Clinic College of Medicine, Rochester, Minnesota; John B. Salamone, National Italian American Foundation, Washington, DC; Patricia Stinchfield, Children's Hospital and Clinics, St. Paul, Minnesota; John J. Treanor, MD, University of Rochester School of Medicine and Dentistry, Rochester, New York; Robin Womeodu, MD, University of Tennessee Health Sciences Center, Memphis, Tennessee.

Ex-Officio Members: James E. Cheek, MD, Indian Health Service, Albuquerque, New Mexico; Wayne Hachey, DO, Department of Defense, Falls Church, Virginia; Geoffrey S. Evans, MD, Health Resources and Services Administration, Rockville, Maryland; Bruce Gellin, MD, National Vaccine Program Office, Washington, DC; Linda Murphy, Centers for Medicare and Medicaid Services, Baltimore, Maryland; George T. Curlin, MD, National Institutes of Health, Bethesda, Maryland; Norman Baylor, MD, Food and Drug Administration, Bethesda, Maryland; Kristin Lee Nichol, MD, Department of Veterans Affairs, Minneapolis, Minnesota.

Liaison Representatives: American Academy of Family Physicians, Jonathan Temte, MD, Clarence, New York, and Richard Clover, MD, Louisville, Kentucky; American Academy of Pediatrics, Margaret Rennels, MD, Baltimore, Maryland, and Carol Baker, MD, Houston, Texas; America's Health Insurance Plans, Andrea Gelzer, MD, Hartford, Connecticut; American College Health Association, James C. Turner, MD, Charlottesville, Virginia; American College of Obstetricians and Gynecologists, Stanley Gall, MD, Louisville, Kentucky; American College of Physicians, Kathleen Neuzil, MD, Seattle, Washington; American Medical Association, Litjen Tan, PhD, Chicago, Illinois; American Pharmacists Association, Stephan L. Foster, PharmD, Memphis, Tennessee; Association of Teachers of Preventive Medicine, W. Paul McKinney, MD, Louisville, Kentucky; Biotechnology Industry Organization, Clement Lewin, PhD, Cambridge, Massachusetts; Canadian National Advisory Committee on Immunization, Monica Naus, MD, Vancouver, British Columbia; Health-Care Infection Control Practices Advisory Committee, Steve Gordon, MD, Cleveland, Ohio; Infectious Diseases Society of America, Samuel L. Katz, MD, Durham, North Carolina, and William Schaffner, MD, Nashville, Tennessee; London Department of Health, David M. Salisbury, MD, London, United Kingdom; National Association of County and City Health Officials, Nancy Bennett, MD, Rochester, New York; National Coalition for Adult Immunization, David A. Neumann, PhD, Bethesda, Maryland; National Immunization Council and Child Health Program, Mexico, Romeo Rodriguez, Mexico City, Mexico; National Medical Association, Dennis A. Brooks, MD, Baltimore, Maryland; National Vaccine Advisory Committee, Charles Helms, MD, PhD, Iowa City, Iowa; Pharmaceutical Research and Manufacturers of America, Damian A. Braga, Swiftwater, Pennsylvania, and Peter Paradiso, PhD, Collegeville, Pennsylvania; and Society for Adolescent Medicine, Amy Middleman, MD, Houston, Texas.

ACIP Hepatitis Vaccines Working Group

Chair: Tracy Lieu, MD, Boston, Massachusetts.

Members: Jon Abramson, MD, Winston-Salem, North Carolina; Beth Bell, MD, Atlanta, Georgia; James E. Cheek, MD, Albuquerque, New Mexico; Anthony Fiore, MD, Atlanta, Georgia; Stephen Feinstone, MD, Bethesda, Maryland; Robert Frenck, MD, Torrance, California; Stanley Gall, MD, Louisville, Kentucky; Janet Gildsdorf, MD, Ann Arbor, Michigan; Steve Gordon, MD, Cleveland, Ohio; Samuel L. Katz, MD, Durham, North Carolina; Edgar Marcuse, MD, Seattle, Washington; Ban Mishu Allos, MD, Nashville, Tennessee; Eric Mast, MD, Atlanta, Georgia; Julia Morita, MD, Chicago, Illinois; William Schaffner, MD, Nashville, Tennessee; Deborah Wexler, MD, Minneapolis, Minnesota.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. rate reported by the Emerging Infections Program[§§] for children aged 0–17 years was 0.24 per 10,000. For children aged 0–4 years and 5–17 years, the rate was 0.66 per 10,000 and 0.04 per 10,000, respectively. During October 30, 2005–January 21, 2006, the preliminary laboratory-confirmed influenza-associated hospitalization rate for children aged 0–4 years in the New Vaccine Surveillance Network[¶¶] was 0.21 per 10,000.

Human Avian Influenza A (H5N1)

No human avian influenza A (H5N1) virus infection has ever been identified in the United States. From December 2003 through February 13, 2006, a total of 169 laboratory-confirmed human avian influenza A (H5N1) infections were reported to WHO from Cambodia, China, Indonesia, Iraq, Thailand, Turkey, and Vietnam.[***] Of these, 91 (54%) were fatal (Table). This represents an increase of two cases and one death in China and two cases and two deaths in Indonesia since February 6, 2006. The majority of infections appear to have been acquired from direct contact with infected poultry. No evidence of sustained human-to-human transmission of H5N1 has been detected, although rare instances of human-to-human transmission likely have occurred (*1*).

[§§] The Emerging Infections Program Influenza Project conducts surveillance in 60 counties associated with 12 metropolitan areas: San Francisco, California; Denver, Colorado; New Haven, Connecticut; Atlanta, Georgia; Baltimore, Maryland; Minneapolis/St. Paul, Minnesota; Albuquerque, New Mexico; Las Cruces, New Mexico; Albany, New York; Rochester, New York; Portland, Oregon; and Nashville, Tennessee.

[¶¶] The New Vaccine Surveillance Network conducts surveillance in Monroe County, New York; Hamilton County, Ohio; and Davidson County, Tennessee.

Notice to Readers

Draft of Applied Epidemiology Competencies

In October 2004, CDC and the Council of State and Territorial Epidemiologists (CSTE) convened a panel to define competencies for applied epidemiology for local, state, and federal government public health epidemiologists. This panel includes representatives from state and local health agencies, academia, private industry, and CDC. The complete draft of defined competencies for all levels of practicing epidemiologists is now available for review and comment at http://www.cste.org/assessment/competencies/indexnew.asp.

Practicing epidemiologists and those employing applied epidemiologists can also submit questions and comments to CSTE by e-mail (competencies@cste.org) through March 17, 2006. After the review period, the panel will consider all information received and revise the competencies for publication.

Errata: Vol. 54, No. RR-16

In the *MMWR Recommendations and Reports*, "A Comprehensive Immunization Strategy to Eliminate Transmission of Hepatitis B Virus Infection in the United States: Recommendations of the Advisory Committee on Immunization Practices (ACIP), Part 1: Immunization of Infants, Children, and Adolescents," the following errors occurred:

On page 8, the last two footnotes in Table 2 should read, "[¶¶]Dialysis formulation administered on a 3-dose schedule **at 0, 1, and 6 months**. [***]Two 1.0-mL doses administered at one site, on a 4-dose schedule **at 0, 1, 2, and 6 months**."

On pages 27–28, in the section titled, "Hepatitis B Immune Globulin (HBIG) Dose and Administration," the second sentence of the third bullet should read, "**For neonates (aged <1 month) and infants (aged 1–12 months)**, HBIG should be administered intramuscularly in the anterolateral thigh using a 22–25-gauge needle. **The appropriate needle length is usually 5/8" for neonates and 7/8"–1" for infants**."

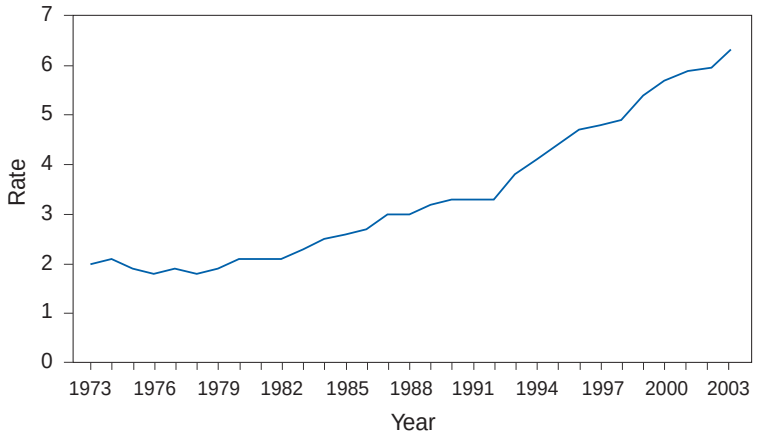
On page 29, second column, the second sentence of the second bullet should read, "Administration of three doses on an appropriate schedule (**Table 5**), followed by anti-HBs testing 1–2 months after the third dose, is usually more practical than serologic testing after one or more doses of vaccine."

Also on page 29, second column, third bullet, the first sub-bullet should read, "— If the HBsAg test result is positive, the persons should receive appropriate management, and any household, sexual, or needle-sharing contacts should be identified and vaccinated (see Appendix A)."

QuickStats

FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Age-Adjusted Death Rates* for Parkinson Disease ð United States, 1973ï 2003À



* Per 100,000 standard U.S. population.
À Coded in accordance with the *International Classification of Diseases, Eighth Revision, Adapted*, during 1973ï 1978 and the *Ninth Revision* during 1979ï 1998. The *Tenth Revision* (codes G20-G21) is now in effect.

Annual U.S. death rates for Parkinson disease increased during 1973ï 2003. Parkinson disease became the 14th leading cause of death in the United States in 2003. This increase might be attributable to multiple factors, including an aging population, greater awareness of the disease, and improved identification of cases.

Confidentiality in Adolescent Health Care (RE9151)

AMERICAN ACADEMY OF PEDIATRICS

This statement was approved as policy by the following organizations: the American Academy of Pediatrics; the American Academy of Family Physicians; the American College of Obstetricians and Gynecologists; NAACOG-The Organization for Obstetric, Gynecologic, and Neonatal Nurses; and the National Medical Associations.

Adolescents tend to underutilize existing health care resources. The issue of confidentiality has been identified, by both providers and young people themselves, as a significant access barrier to health care.

Adolescents in the United States, while generally considered healthy, have a range of problems, including some of such severity as to jeopardize their development and health, their future opportunities and even their lives. To illustrate, there is an urgent need to reduce the incidence of adolescent suicide, substance abuse, and sexually transmitted diseases and unintended pregnancy.

As the primary providers of health care to adolescents, we urge the following principles for the guidance of our professional members and for broad consideration in the development of public policy:

1. Health professionals have an ethical obligation to provide the best possible care and counseling to respond to the needs of their adolescent patients.
2. This obligation includes every reasonable effort to encourage the adolescent to involve parents, whose support can, in many circumstances, increase the potential for dealing with the adolescent's problems on a continuing basis.
3. Parents are frequently in a patient relationship with the same providers as their children or have been exercising decision-making responsibility for their children with these providers. At the time providers establish an independent relationship with adolescents as patients, the providers should make this new relationship clear to parents and adolescents with regard to the following elements:
* The adolescent will have an opportunity for examination and counseling apart from parents, and the same confidentiality will be preserved between the adolescent patient and the provider as between the parent/adult and the provider.
* The adolescent must understand under what circumstances (eg, life-threatening emergency), the provider will abrogate this confidentiality.
* Parents should be encouraged to work out means to facilitate communication regarding appointments, payment, or other matters consistent with the understanding reached about confidentiality and parental support in this transitional period when the adolescent is moving toward self-responsibility for health care.
4. Providers, parents, and adolescents need to be aware of the nature and effect of laws and regulations in their jurisdictions that introduce further constraints on these relationships. Some of these laws and regulations are unduly restrictive and in need of revision as a matter of public policy. Ultimately, the health risks to the adolescent are so impelling that legal barriers and deference to parental involvement should not stand in the way of needed health care.

Reaffirmed 1/93, 11/97 COA, reaffirmed 5/00 COCAN.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

AMERICAN ACADEMY OF PEDIATRICS

Section on Endocrinology and Committee on Genetics

Technical Report: Congenital Adrenal Hyperplasia

ABSTRACT. The Section on Endocrinology and the Committee on Genetics of the American Academy of Pediatrics, in collaboration with experts from the fields of pediatric endocrinology and genetics, developed this policy statement as a means of providing up-to-date information for the practicing pediatrician about current practice and controversial issues in congenital adrenal hyperplasia (CAH), including the current status of prenatal diagnosis and treatment, the benefits and problem areas of neonatal screening programs, and the management of children with nonclassic CAH. The reference list is designed to allow physicians who wish more information to research the topic more thoroughly.

ABBREVIATIONS. CAH, congenital adrenal hyperplasia; 21-OH, 21-hydroxylase; 17-OHP, 17α-hydroxyprogesterone; AF, amniotic fluid; HLA, human leukocyte antigen; ACTH, adrenocorticotropic hormone.

Congenital adrenal hyperplasia (CAH) consists of a family of disorders caused by reduced activity of enzymes required for cortisol biosynthesis in the adrenal cortex. The most common defect is 21-hydroxylase (21-OH) deficiency, which accounts for >90% of all cases of CAH. Classic 21-hydroxylase deficiency is found in about 1:12 000 to 1:15 000 births; the frequency of nonclassic deficiency is unknown, although it may occur in up to 3% of individuals in certain groups. Clinical consequences of 21-OH deficiency arise primarily from overproduction and accumulation of precursors proximal to the blocked enzymatic step. These precursors are shunted into the androgen biosynthesis pathway, producing virilization in the female fetus or infant and rapid postnatal growth with accelerated skeletal maturation, precocious puberty, and short adult stature in both males and females. Approximately 75% of patients with classic 21-OH deficiency also have a defect in their ability to synthesize aldosterone. Such patients, especially undiagnosed male infants, may die during the newborn period of shock resulting from salt wasting.

Recent advances in molecular genetic analysis allow for prenatal diagnosis and treatment of at-risk fetuses. However, controversy remains regarding the efficacy and safety of prenatal intervention that attempts to minimize prenatal virilization in girls. Other controversial issues include the optimal regimen for postnatal treatments and the effects of long-term corticosteroid therapy on final height, sexual function, and fertility. Approximately 20 states include screening for CAH as a part of their newborn screening profiles. The cost-effectiveness of the programs in detecting patients who would not have been diagnosed before clinical manifestation of CAH continues to improve as new standards for levels of 17α-hydroxyprogesterone (17-OHP) in premature infants, very sick infants, and infants younger than 24 hours decrease the rate of false-positive results.

This review is designed to provide current information on prenatal diagnosis and treatment, the status of newborn screening, methods of diagnosis of affected patients and heterozygote carriers, and newer treatment approaches for CAH.

PRENATAL DIAGNOSIS AND TREATMENT

The objective of prenatal diagnosis and treatment of 21-OH deficiency is the prevention of prenatal virilization in affected female infants and the early recognition of the potential for salt wasting in the newborn infant.

Prenatal Diagnosis of 21-OH Deficiency

Prenatal prediction of CAH attributable to classic 21-OH deficiency is possible by using a number of modalities: determination of amniotic fluid (AF) hormone levels, human leukocyte antigen (HLA) typing of chorionic villus cells and/or AF cells, and molecular genetic studies of chorionic villus cells and AF cells. Advances in molecular genetic techniques have made molecular genetic studies the test of choice.

Prenatal diagnosis of CAH was first reported in 1965, based on elevated levels of AF 17-ketosteroids and pregnanetriol.[1] In 1975, the association between an elevated 17-OHP concentration in AF and the birth of an infant with salt-wasting CAH was reported.[2] Subsequent reports have confirmed the usefulness of AF 17-OHP concentrations for the prenatal diagnosis of classic CAH attributable to 21-OH deficiency.[3–13] Although amniocentesis has been performed routinely during the second trimester in women at risk of having an infant with CAH, elevated 17-OHP levels in AF obtained as early as 9 to 13 weeks in pregnancies with an affected fetus have been reported. Androstenedione levels (Δ4), which also are elevated in pregnancies in which the fetus is affected with CAH, provide another diagnostic measurement.

Because the gene for 21-OH has been linked to the HLA system on chromosome 6, prenatal prediction of CAH may be made by HLA typing of cultured AF

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

cells and cultured chorionic villus cells.[5,7,10,13–18] Use of chorionic villus cells permits earlier identification of the affected fetus than is possible with amniocentesis. In a pregnancy in which the fetus has an HLA type identical to that of the index case with 21-OH deficiency, the fetus is predicted to be affected. The fetus that shares 1 parental haplotype with the index case is predicted to be a heterozygous carrier, and the fetus with both haplotypes different from the index case is predicted to be homozygous normal.

The preferred technique for prenatal diagnosis is molecular genetic analysis using DNA extracted from chorionic villus cells or amniocytes for analysis of *CYP21B*, *C4* and HLA class I and II genes.[18–23] Advances in these molecular techniques have made genetic characterization more reliable and rapid,[24] such that in most centers the analysis of fetal *P450c21B* genes from chorionic villus cells or amniocytes has largely replaced hormonal and HLA analysis in the prenatal diagnosis of CAH attributable to 21-OH deficiency.[25] Causative mutations can now be identified on 95% of chromosomes using Southern blot analysis and selective amplification of the *CYP21B* gene by polymerase chain reaction, followed by allele-specific hybridization with oligonucleotide probes for a panel of 9 known *CYP21B* mutations.[26] A newly developed, rapid, allele-specific polymerase chain reaction has been used for prenatal diagnosis.[27] Mutations not detected by this approach can be characterized by direct sequencing of *CYP21B* genes.[28,29] Determination of satellite markers also may be informative. De novo mutations, found in patients with CAH but not in parents, are found in 1% of disease-causing *CYP21B* mutations.[28] Accurate prenatal prediction requires the correct molecular genetic analysis of the index case and molecular genetic analysis and complete hormonal profiling of the parents.

Prenatal Treatment of CAH Attributable to 21-OH Deficiency

Prenatal treatment of CAH to prevent the virilization of an affected female fetus has been considered desirable by a number of investigators.[2,30–33] Because masculinization of the external genitalia begins at about 6 to 7 weeks of gestation (8 to 9 weeks after the last menstrual period),[34,35] suppression of the fetal pituitary-adrenal axis at no later than 6 weeks of gestation theoretically could prevent ambiguity of the external genitalia in the female fetus with classic CAH, whereas therapy after that time would prevent progression of virilization.

Successful prenatal treatment to ameliorate or prevent virilization of a female fetus with classic CAH attributable to 21-OH deficiency was first reported in 1984.[36] In 2 pregnancies at risk for classic salt-wasting CAH, the mothers were treated with hydrocortisone and dexamethasone, respectively. Subsequent amniocentesis demonstrated that both infants were girls and had HLA types identical to those of their affected siblings, and treatment was continued to term. At birth, the external genitalia were normal in the infant whose mother was given dexamethasone and minimally virilized in the infant whose mother received hydrocortisone. Postnatally, the diagnosis of 21-OH deficiency was confirmed in both infants.[36] There are reports of >50 affected female infants in whom prenatal treatment with dexamethasone has been attempted. The dose of dexamethasone has ranged between 0.5 and 2 mg/d in 1 to 4 divided doses. Treatment was begun as early as the 4th week of pregnancy to as late as the 16th week. In some cases, treatment was interrupted for 5 to 7 days before amniocentesis, and, in a few cases, treatment was discontinued at 21 to 26 weeks.[18,21–23,37–53]

Fetal Outcome

Of the total number of cases for which data are available, treatment was considered successful for almost three fourths of the female infants; approximately one third had normal genitalia, and two thirds were described as being mildly virilized with clitoromegaly, partial labial fusion, or both. In slightly more than one fourth of all female infants treated, therapy was unsuccessful, and the infants had marked genital virilization.

The variability of the results has been attributed to a number of factors: inadequate dosage, interruption of treatment, delay in initiating treatment, variability in maternal metabolic clearance, and variability of placental metabolism of the administered glucocorticoid.[23,50] Variability in onset of fetal sexual differentiation and maternal noncompliance to therapy also must be considered.[23,50]

Spontaneous abortion, fetal demise during late pregnancy, intrauterine growth retardation, liver steatosis, hydrocephalus, agenesis of the corpus callosum, and hypospadias with unilateral cryptorchidism[51] have been reported occasionally when mothers received short-term treatment in unaffected pregnancies, as well as in affected pregnancies in which the mother received prolonged corticosteroid treatment. These events generally have not been considered related to the treatment or to the disease itself.[17,45,49,50] In a report of intrauterine growth retardation in an infant treated successfully for CAH, however, it was concluded that intrauterine growth retardation still should be considered "a possible fetal complication of treatment."[46] In long-term follow-up of most infants treated throughout the pregnancy or treated prenatally until midgestation,[17,44–50] development seems to be normal, and growth has been consistent with the family pattern and that of the other affected siblings.[17,41,42,44,45] Rare adverse events, including failure to thrive and psychomotor and psychosocial delay in development, have been observed.[51] Long-term follow-up is limited, however, and detailed neuropsychological evaluations have not been reported.

In a preliminary report, cognitive and behavioral development of young children aged 6 months to 5.5 years treated prenatally with dexamethasone because of risk for CAH was assessed by standard questionnaires completed by the mothers. The development of those children was compared with the development of children from untreated pregnancies at risk for CAH.[52] No significant differences in cognitive abilities or behavior problems were identified.[50] However, the demonstration of an increased

frequency of neurologically silent white matter abnormalities and temporal lobe atrophy in children and adults with CAH indicates that the long-term effects of glucocorticoids on the central nervous system are not fully known and must be evaluated carefully.[54] Although experimental treatment given to animals cannot be directly extrapolated to humans, high doses of dexamethasone administered to rhesus monkeys toward the end of gestation were associated with abnormalities of the fetal brain consisting of neuronal degeneration of hippocampal, pyramidal, and dentate regions.[55] Other animal studies have focused on long-term cardiovascular risks of prenatal dexamethasone treatment. Intrauterine growth retardation, lower kidney weight, oligonephronia, and the development of hypertension in adulthood have been demonstrated in rat pups whose mothers received dexamethasone prenatally.[56–58] These studies underscore the need for careful long-term outcome studies of prenatal dexamethasone treatment, in which treated mothers and infants are followed up to determine possible ill effects in later adult life.

Maternal Complications of Prenatal Treatment

Maternal adverse effects of dexamethasone may be serious and long-lasting.[23,44] Reported adverse effects include edema, excessive weight gain, irritability, nervousness, mood swings, hypertension, glucose intolerance, chronic epigastric pain, gastroenteritis, cushingoid facial features, increased facial hair growth, and severe striae with permanent scarring.[17,18,23,40,44–47,49,50]

In a European survey, adverse effects occurred in approximately one third of women who were treated until delivery and for whom data were available.[48] Marked weight gain, reported in approximately 25%, was the most common problem.[48] The maternal adverse effects prompted decreasing the dosage or discontinuing treatment and may have resulted in nonadherence with therapy and unsatisfactory genital outcome for the infant.[40,49] Transient symptoms of glucocorticoid deficiency on tapering or discontinuing treatment have been reported rarely.[17,41] A recent report indicated that one third of the mothers who received dexamethasone treatment during pregnancy would not elect treatment in a future pregnancy.[51]

Current Recommendations for Prenatal Diagnosis and Treatment

Prenatal diagnosis and treatment is performed most commonly in families with a previously affected child with CAH with a defined genetic defect.

Informed consent, in which the risks of possible maternal adverse effects, variable genital outcome, and possible but presently unknown long-term effects of dexamethasone treatment on the treated children are discussed, should be obtained from all parents seeking genetic counseling before prenatal diagnosis and treatment. Mothers with previous medical or mental conditions that may be aggravated by dexamethasone, such as psychosis, hypertension, overt diabetes, gestational diabetes, or toxemia, should not be treated or should be treated only with extreme caution. Patients should be referred to centers with expertise in the prenatal management of pregnancies at risk for CAH. Treatment should be initiated by the fifth week of gestation with dexamethasone, at a dose of approximately 20 to 25 μg/kg per day, given in 2 or 3 divided doses. Chorionic villus sampling during the 9th to 10th week of gestation for prenatal diagnosis should be performed with karyotyping, and, optimally, *HLA, CYP21B,* and *C4* gene analysis of chorionic villus cells. If chorionic villus sampling is performed during the 10th to 11th week, a small amount of AF can be obtained for hormonal analysis as well, to gain some measure of fetal adrenal suppression. If the fetus is a boy or an unaffected girl, treatment is discontinued. If the fetus is an affected girl, or if prenatal diagnosis by chorionic villus sampling is unsuccessful or not performed, treatment is continued. If necessary, for further clarification, amniocentesis can be performed at 15 weeks with genetic analysis of amniocytes and hormonal determination in the AF. If the fetus is an affected girl, treatment is continued to term. It is important to note that if the mother is receiving treatment with dexamethasone, hormonal analysis of AF is unreliable for prenatal diagnosis. Furthermore, because only 1 of 8 infants will be an affected girl, 7 of 8 infants will be treated unnecessarily for at least 12 weeks.

Maternal monitoring for physical, hormonal, and metabolic changes should begin at the initiation of treatment and should be continued throughout the pregnancy. The serum estriol level to evaluate adequacy of fetal adrenal suppression and the fasting blood glucose level should be determined monthly, and an oral glucose tolerance test should be performed during the second and third trimesters. In the presence of excessive weight gain, increased blood pressure, and glucose intolerance or other adverse effects, prompt intervention should be instituted. Consideration should be given to reducing the dosage of dexamethasone during the second and third trimesters.

Maternal treatment seems to prevent or reduce virilization in approximately 75% of affected female fetuses but has not been uniformly successful in all pregnancies. Its efficacy and safety remain to be fully defined. It should be offered only to patients who have a clear understanding of the possible risks and benefits and who are able to comply with the need for close monitoring throughout pregnancy and the need for long-term follow-up of the infants, children, and adults treated prenatally.

NEONATAL SCREENING

The major objectives of newborn screening for CAH attributable to 21-OH deficiency are to identify infants at risk for the development of life-threatening adrenal crisis and to prevent the incorrect male sex assignment of affected female infants with ambiguous genitalia. The former is particularly important for affected boys whose initial manifestation may be adrenal crisis. In addition, early identification will permit the monitoring and treatment of affected in-

fants and children to prevent postnatal exposure to excessive androgens and the accompanying clinical manifestations. In 1977, newborn screening for 21-OH deficiency became possible after development of the method to measure 17-OHP in a heel-stick capillary blood specimen on filter paper. A pilot newborn screening program was developed in Alaska shortly thereafter. National and regional screening programs now have been developed worldwide, and in almost 20 states.[59–61] Data on >8 million neonates screened are available. The disorder occurs in 1 of 21 000 newborns in Japan, 1 of 10 000 to 16 000 in Europe and North America, and 1 of 300 in Yupik Eskimos of Alaska. About 75% of affected infants have the salt-losing, virilizing form, and 25% have the simple virilizing form of the disorder. The nonclassic form is not detected reliably by newborn screening.

Newborn Screening Procedures and Cost Analysis

Neonatal screening for CAH requires the following procedures for optimal efficiency and effective screening results: 1) early sample collection, ideally between 2 and 3 days of life; 2) immediate and reliable analysis of 17-OHP levels after sample collection; 3) optimally chosen 17-OHP cutoff levels that distinguish affected from unaffected newborns; 4) immediate and clear communication of presumptive positive results to the appropriate health care professional and to family members; and 5) diagnostic confirmation of newborns with positive screening results.

All CAH newborn screening programs use the measurement of 17-OHP in a filter paper blood spot sample obtained by the heel-stick technique as used for newborn screening of other disorders. The concurrent screening test procedures for disorders such as phenylketonuria and congenital hypothyroidism, which were established before the initiation of CAH screening, seem to have influenced the age at which CAH screening samples were collected in many programs. Although most screening samples for CAH had been collected between 3 and 5 days after birth,[59,62] recent practices of early discharge from the nursery and increased numbers of deliveries at birthing centers have resulted in many screening samples being collected at 1 to 2 days after birth. This may result in an increased number of false-positive tests.

The majority of screening programs worldwide use a single screening test without retesting of questionable 17-OHP levels.[62] This single-screen method offers the advantage of expedited results but may cause inaccurate classification in borderline cases. A small number of programs perform a second screening test of the initial sample to confirm borderline cases identified in the first screening.[62] Although relatively time-intensive, this approach provides greater accuracy than the single-screen method. One program (Manitoba, Canada) collects and tests a second sample on request when 17-OHP levels are elevated above the cutoff level in the initial test.[62] A number of programs mandate 2 screenings and routinely obtain and test a second sample.[62–64] In addition to detecting infants with the salt-wasting form of CAH and preventing life-threatening adrenal crisis by using results of the first screening, this approach is optimal for minimizing false-negative results by detecting newborns with the simple virilizing and mild forms of the disorder on the second screening who may not have been identified initially.[59]

Laboratory Screening Assay Methods and Cutoff Levels

Three principal assay techniques are used for the initial screening of CAH in neonates: radioimmunoassay, enzyme-linked immunosorbent assay, and time-resolved fluoroimmunoassay. These assays measure the 17-OHP concentration in a filter paper blood spot sample obtained by the heel-stick technique without prior extraction or purification. The 17-OHP levels measured by direct fluoroimmunoassay are significantly higher than levels measured by radioimmunoassay after extraction. Screening fluoroimmunoassay may overestimate 17-OHP levels in low birth weight infants weighing <1500 g.[65] Although theoretically 17-OHP concentrations in newborns should be comparable regardless of the assay method, there is considerable variation in cutoff levels from one program to another. The 17-OHP cutoff levels that divide positive from negative screening test results have been established at greater than the 99th percentile of the mean level in healthy newborns or on the basis of a normal range established in that program or on the experience of other programs.[62] Other sources of variation include the different antibodies and reagents used in the assay systems, varying thickness and density of the filter paper used for sample collection, and, most significantly, the ethnic background of the reference newborns.

Reliability of Screening Tests

The reliability of each screening program is based on evaluation of both the false-negative and false-positive rates. There have been extraordinarily few false-negative results in newborn screening worldwide.[62] The majority of reported false-positive results have been caused by low birth weight and premature birth, in which the 17-OHP levels are invariably higher. Therefore, separate normative reference levels should be established based on birth weight or gestational age to minimize an otherwise unacceptably high false-positive rate. In 1 study, application of multitiered weight-adjusted 17-OHP cutoff levels compared with a 2-tiered criterion reduced the number of false-positive results requiring immediate follow-up testing by >50%, and the rate was reduced by >90% among low birth weight infants.[65] Two-tier weight-adjusted cutoff levels are being used by many programs with acceptable false-positive rates,[62] but further modification of the test cutoff levels and recall procedures is necessary in programs with persistently high false-positive rates.

As more adequate reference data have been developed, 17-OHP cutoff levels in low birth weight infants have been adjusted, and the false-positive rates in preterm screening populations have improved.[62,65,66] Issues relating to false-positive results, however, including the cost of evaluating false-pos-

itive cases and the undesirable psychological effect on patients' families, continue to be problematic. Therefore, periodic review of 17-OHP cutoff levels is essential to minimize false-positive and false-negative rates and ensure high sensitivity and specificity of neonatal screening tests for CAH. Genotyping for mutations in *CYP21B* causing CAH has been suggested as an adjunct to newborn screening.[67]

DIAGNOSIS

In classic 21-OH deficiency, serum levels of 17-OHP are markedly elevated. However, 17-OHP levels are normally high during the first 2 to 3 days after birth and may range as high as levels found in affected patients. By the third day, however, levels in healthy infants fall, and those in affected infants rise to clearly diagnostic levels. Ill, unaffected infants and premature infants may have elevated levels of 17-OHP. Serum concentrations of testosterone in girls and androstenedione in boys and girls also are elevated in affected infants. Salt losers may have low serum sodium and chloride levels, inappropriately increased urine sodium levels, and elevated levels of serum potassium and serum urea nitrogen. However, hyponatremia and hyperkalemia are usually not present before 7 days of age. Plasma levels of renin are elevated, and the serum aldosterone level is inappropriately low for the renin level.

In the late-onset variant of CAH, basal circulating levels of 17-OHP are not as high as in the classic form and may even be normal, especially if the specimen is not obtained in the morning. Therefore, for initial screening, blood specimens should be obtained between 7:30 and 8:30 AM. Elevated basal 17-OHP levels may suggest the diagnosis, but an adrenocorticotropic hormone (ACTH) test with measurement of serum cortisol and 17-OHP levels is necessary to confirm the diagnosis. A significant rise in the 17-OHP level 60 minutes after an intravenous bolus of 0.25 mg of ACTH (1–24) is diagnostic. The 17-OHP–cortisol ratio is markedly elevated, and there may be a blunted or absent response in cortisol.

TREATMENT

Administration of glucocorticoids inhibits excessive production of androgens and prevents progressive virilization. A variety of glucocorticoids (hydrocortisone, prednisone, dexamethasone) and dosage schedules have been used for this purpose. Most often, hydrocortisone (10–20 mg/m^2 per 24 hours) is administered orally in 3 divided doses. There have been recent problems with consistent dosing with the liquid formulation of hydrocortisone. Tablets may give more reliable levels. Infants usually require 2.5 to 5 mg 3 times daily and children, 5 to 10 mg 3 times daily. The morning dose should be given as early as possible to blunt the early morning corticotropin increase that begins during the predawn hours. Doses must be individualized by monitoring growth, bone age, and hormonal levels. Patients with disturbances of electrolyte regulation (salt losers) and elevated plasma renin activity require a mineralocorticoid and sodium supplementation in addition to the glucocorticoid. Maintenance therapy with fludrocortisone acetate (Florinef) (0.05–0.3 mg daily) and sodium chloride (1–3 g) is usually sufficient to normalize plasma renin activity. Increased doses of glucocorticoid are indicated during periods of stress, such as infection or surgery, for salt-losing and non–salt-losing patients.

Non–salt-losing children, particularly boys, frequently are not diagnosed until 3 to 7 years of age, at which time osseous maturation may be 5 years or more in advance of chronologic age. Institution of treatment slows growth and osseous maturation to more nearly normal rates in some children. In others, especially if the bone age is 12 years or more, spontaneous gonadotropin-dependent puberty may occur as therapy with hydrocortisone suppresses production of adrenal androgens and permits release of pituitary gonadotropins if the appropriate level of hypothalamic maturation is present. This form of superimposed true precocious puberty may be treated with a long-acting potent luteinizing hormone–releasing hormone analog.

Patients with nonclassic 21-OH deficiency do not always require treatment. Many are asymptomatic throughout their lives, or symptoms may develop during puberty, after puberty, or postpartum. Traditionally, therapy with lower amounts of glucocorticoid than those required for patients with classic 21-OH deficiency have been used. Indications for treatment include bone age advancement, severe acne, hirsutism, menstrual irregularity, and infertility.

The protocol for monitoring these patients varies with personal preference. Measurements of 24-hour urinary levels of 17-ketosteroids and pregnanetriol are unnecessary. Serum levels of 17-OHP, androstenedione, testosterone, and renin, measured preferably between 7:30 and 8:30 AM, either before or shortly after taking the morning medication, usually provide adequate indices of control. Recent reports indicate that 17-OHP may be measured reliably and accurately at home using filter paper techniques.[68] Careful monitoring for signs of cortisol and androgen excess, growth and weight gain, pubertal development, and osseous maturation is important.

The administration of glucocorticoid must be lifelong for all patients with classic forms of CAH. More potent glucocorticoids tend to suppress growth more than hydrocortisone. However, after growth is completed, prednisone, given once or twice daily, or dexamethasone, given as a single dose at bedtime, may result in adequate suppression of androgens.

Heterozygous carriers of 21-OH deficiency have been identified by measuring the ratio of 17-OHP to 11-deoxycortisol or cortisol 60 minutes after an intravenous bolus injection of 0.25 mg of ACTH (1–24) and, in families with an affected individual, by HLA genotyping. Molecular characterization, alone or in combination with hormonal measurements and HLA genotyping, should be used when available for genetic counseling.

A number of clinical trials have been designed to evaluate the efficacy of new treatment modalities. These modalities should be considered experimental at this time.

Because it is recognized that patients with Addison's disease are more easily and successfully treated than patients with CAH, adrenalectomy for patients with salt-wasting 21-OH deficiency has been suggested as a possible mode of therapy. This would eliminate the difficult problems of achieving adequate suppression of adrenal androgens without giving excessive glucocorticoid, and without the rapid advancement of bone age and early virilization that occur with inadequate adrenal androgen suppression. Adrenalectomy has been performed for treatment of 21-OH deficiency. Long-term follow-up of a large number of patients will be necessary to determine the safety and efficacy of this mode of therapy.[69]

Preliminary use of a combination of an antiandrogen (to block androgen effect) and an aromatase inhibitor (to block conversion of androgen to estrogen) with a reduced hydrocortisone dose also has been reported.[70,71] Again, long-term studies are required to determine if this regimen will further improve the final outcome. The use of synthetic blockers of the corticotropin-releasing hormone and corticotropin receptors theoretically could provide a pharmacologic adrenalectomy and may provide additional future treatment options.

CAH is a chronic disease requiring lifelong monitoring and treatment. The diagnosis and treatment are complex, requiring specific training and expertise to individualize therapy. Thus, a pediatric endocrinologist ideally should be involved in the management of all children and adolescents with CAH. A high index of suspicion should be present in any infant with ambiguous genitalia and nonpalpable testes, especially in the presence of increased pigmentation of nipples, genitalia, and/or skin creases. A family history of early neonatal deaths or previously affected family members adds to the risk of having CAH. Markedly elevated levels of 17-OHP should prompt immediate evaluation in any newborn infant. Pediatricians should call their state department of health to determine if newborn screening for CAH is available. New molecular techniques permit early prenatal diagnosis and have made possible intervention to prevent prenatal virilization in affected female infants. Early diagnosis through newborn screening may avert salt-losing crises, particularly in affected boys, by permitting early initiation of therapy. Although glucocorticoid therapy is the mainstay of treatment, the outcome has not been optimal and therapeutic regimens vary. New approaches to treatment, including adrenalectomy, combination antiandrogen and aromatase inhibitors, and synthetic blockers of corticotropin-releasing hormone and corticotropin receptors are under investigation. Support for families is available through a national CAH group, The Magic Foundation, 1327 North Harlem Avenue, Oak Park, IL, 60302 (http://www.magicfoundation.org).

A Consensus Statement on Health Care Transitions for Young Adults With Special Health Care Needs

ABSTRACT. This policy statement represents a consensus on the critical first steps that the medical profession needs to take to realize the vision of a family-centered, continuous, comprehensive, coordinated, compassionate, and culturally competent health care system that is as developmentally appropriate as it is technically sophisticated. The goal of transition in health care for young adults with special health care needs is to maximize lifelong functioning and potential through the provision of high-quality, developmentally appropriate health care services that continue uninterrupted as the individual moves from adolescence to adulthood. This consensus document has now been approved as policy by the boards of the American Academy of Pediatrics, the American Academy of Family Physicians, and the American College of Physicians-American Society of Internal Medicine.

INTRODUCTION

Each year in the United States, nearly half a million children with special health care needs cross the threshold into adulthood.[1] One generation ago, most of those with severe disabilities died before reaching maturity; now more than 90% survive to adulthood.[2] Most young people with special health care needs are able to find their way into and negotiate through adult systems of care.[3] However, many adolescents and young adults with severe medical conditions and disabilities that limit their ability to function and result in complicating social, emotional, or behavioral sequelae experience difficulty transitioning from child to adult health care. There is a substantial number whose success depends on more deliberate guidance.[4]

Children grow up within complex living arrangements, communities, and cultures and receive medical care within an equally complex, interlocking set of relationships that includes social services, education, vocational training, and recreation. Clearly, no single approach will work equally well for all young people, and the health care sector cannot work in isolation from the other professionals and networks that impact these young people.[5] By focusing on the health care sector in this policy statement, we do not ignore other critical relationships. Rather, we are acknowledging that physicians have an important role in facilitating transitions to adulthood and to adult health care for young people who are least likely to do it successfully on their own.

The goals of this policy statement are to ensure that by the year 2010 all physicians who provide primary or subspecialty care to young people with special health care needs 1) understand the rationale for transition from child-oriented to adult-oriented health care; 2) have the knowledge and skills to facilitate that process; and 3) know if, how, and when transfer of care is indicated.

WHAT IS MEANT BY "HEALTH CARE TRANSITIONS"?

Transitions are part of normal, healthy development and occur across the life span. Transition in health care for young adults with special health care needs is a dynamic, lifelong process that seeks to meet their individual needs as they move from childhood to adulthood. The goal is to maximize lifelong functioning and potential through the provision of high-quality, developmentally appropriate health care services that continue uninterrupted as the individual moves from adolescence to adulthood. It is patient centered, and its cornerstones are flexibility, responsiveness, continuity, comprehensiveness, and coordination.

Physicians are of special importance in this process because of the frequent contact with many of these young people and the close relationships that often develop with them and their families.

A well-timed transition from child-oriented to adult-oriented health care allows young people to optimize their ability to assume adult roles and functioning. For many young people with special health care needs, this will mean a transfer from a child to an adult health care professional; for many others, it will involve an ongoing relationship with the same provider but with a reorientation of clinical interac-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

tions to mirror the young person's increasing maturity and emerging adulthood.

Whether the transition entails a transfer of care or not, all adults with special health care needs deserve an adult focused primary care physician. This is not to say that the child health specialist will not have an ongoing role. Rather, it is to affirm that just as children receive optimal primary care in a medical practice experienced in the care of children, so too adults benefit from receiving care from physicians who are trained and experienced in adult medicine.[5] Whether or not a transfer of care occurs, successful transition requires communication and collaboration among primary care specialists, subspecialists, young adult patients, and their families.

WHY IS PLANNING FOR TRANSITIONS IMPORTANT NOW?

Healthy People 2010[6] established the goal that all young people with special health care needs will receive the services needed to make necessary transitions to all aspects of adult life, including health care, work, and independent living. Just as the Individuals With Disabilities Education Act of 1997[7] requires a plan for education transition, so too there should be a plan for health care transition. The challenges faced by health care professionals include ensuring age-appropriate care, advocating for improved health insurance coverage, and negotiating adequate compensation for services provided.

Optimal health care is achieved when every person at every age receives health care that is medically and developmentally appropriate. The central rationale for health care transition planning for young people with special health care needs is to achieve this goal by ensuring that adults receive primary medical care from those trained to provide it.

CRITICAL FIRST STEPS TO ENSURING SUCCESSFUL TRANSITIONING TO ADULT-ORIENTED HEALTH CARE

1. Ensure that all young people with special health care needs have an identified health care professional who attends to the unique challenges of transition and assumes responsibility for current health care, care coordination, and future health care planning. This responsibility is executed in partnership with other child and adult health care professionals, the young person, and his or her family. It is intended to ensure that as transitions occur, all young people have uninterrupted, comprehensive, and accessible care within their community.
2. Identify the core knowledge and skills required to provide developmentally appropriate health care transition services to young people with special health care needs and make them part of training and certification requirements for primary care residents and physicians in practice.
3. Prepare and maintain an up-to-date medical summary that is portable and accessible. This information is critical for successful health care transition and provides the common knowledge base for collaboration among health care professionals.
4. Create a written health care transition plan by age 14 together with the young person and family. At a minimum, this plan should include what services need to be provided, who will provide them, and how they will be financed. This plan should be reviewed and updated annually and whenever there is a transfer of care.
5. Apply the same guidelines for primary and preventive care for all adolescents and young adults, including those with special health care needs, recognizing that young people with special health care needs may require more resources and services than do other young people to optimize their health. Examples of such guidelines include the American Medical Association's *Guidelines for Adolescent Preventive Services (GAPS)*,[8] the National Center for Education in Maternal and Child Health's *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*,[9] and the US Public Health Service's *Guidelines to Clinical Preventive Services*.[10]
6. Ensure affordable, continuous health insurance coverage for all young people with special health care needs throughout adolescence and adulthood. This insurance should cover appropriate compensation for 1) health care transition planning for all young people with special health care needs, and 2) care coordination for those who have complex medical conditions.

The authors have indicated they have no financial relationships relevant to this article to disclose.

THE BIRTH of an intersex child prompts a long-term management strategy that involves myriad professionals working with the family. There has been progress in diagnosis, surgical techniques, understanding psychosocial issues, and recognizing and accepting the place of patient advocacy. The Lawson Wilkins Pediatric Endocrine Society and the European Society for Paediatric Endocrinology considered it timely to review the management of intersex disorders from a broad perspective, review data on longer-term outcome, and formulate proposals for future studies. The methodology comprised establishing a number of working groups, the membership of which was drawn from 50 international experts in the field. The groups prepared previous written responses to a defined set of questions resulting from evidence-based review of the literature. At a subsequent gathering of participants, a framework for a consensus document was agreed. This article constitutes its final form.

NOMENCLATURE AND DEFINITIONS

Advances in identification of molecular genetic causes of abnormal sex with heightened awareness of ethical issues and patient advocacy concerns necessitate a reexamination of nomenclature.[1] Terms such as "intersex," "pseudohermaphroditism," "hermaphroditism," "sex reversal," and gender-based diagnostic labels are particularly controversial. These terms are perceived as potentially pejorative by patients[2] and can be confusing to practitioners and parents alike. We propose the term "disorders of sex development" (DSD), as defined by congenital conditions in which development of chromosomal, gonadal, or anatomic sex is atypical.

The proposed changes in terminology are summarized in Table 1. A modern lexicon is needed to integrate progress in molecular genetic aspects of sex development. Because outcome data in individuals with DSD are limited, it is essential to use precision when applying definitions and diagnostic labels.[3,4] It is also appropriate to use terminology that is sensitive to the concerns of patients. The ideal nomenclature should be sufficiently flexible to incorporate new information yet robust enough to maintain a consistent framework. Terms should be descrip-

TABLE 1 **Proposed Revised Nomenclature**

Previous	Proposed
Intersex	DSD
Male pseudohermaphrodite, undervirilization of an XY male, and undermasculinization of an XY male	46,XY DSD
Female pseudohermaphrodite, overvirilization of an XX female, and masculinization of an XX female	46,XX DSD
True hermaphrodite	Ovotesticular DSD
XX male or XX sex reversal	46,XX testicular DSD
XY sex reversal	46,XY complete gonadal dysgenesis

tive and reflect genetic etiology when available and accommodate the spectrum of phenotypic variation. Clinicians and scientists must value the nomenclature's use, and it must be understandable to patients and their families. An example of how the proposed nomenclature could be applied in a classification of DSD is shown in Table 2.

Psychosexual development is traditionally conceptualized as 3 components: "gender identity" refers to a person's self-representation as male or female (with the caveat that some individuals may not identify exclusively with either); "gender role" (sex-typical behaviors) describes the psychological characteristics that are sexually dimorphic within the general population, such as toy preferences and physical aggression; and "sexual orientation" refers to the direction(s) of erotic interest (heterosexual, bisexual, homosexual) and includes behavior, fantasies, and attractions. Psychosexual development is influenced by multiple factors such as exposure to androgens, sex chromosome genes, and brain structure, as well as social circumstance and family dynamics.

Gender dissatisfaction denotes unhappiness with assigned sex. Causes of gender dissatisfaction, even among individuals without DSD, are poorly understood. Gender dissatisfaction occurs more frequently in individuals with DSD than in the general population but is difficult to predict from karyotype, prenatal androgen exposure, degree of genital virilization, or assigned gender.[5–7] Prenatal androgen exposure is clearly associated with other aspects of psychosexual development.[8,9] There are dose-related effects on childhood play behavior in girls with congenital adrenal hyperplasia (CAH), whereby those with the more severe mutations and marked genital virilization play more with boys' toys.[10] Prenatal androgen exposure is also associated with other psychological characteristics such as maternal interest and sexual orientation. It is important to emphasize the separability of sex-typical behavior, sexual orientation, and gender identity. Thus, homosexual orientation (relative to sex of rearing) or strong cross-sex interest in an individual with DSD is not an indication of incorrect gender assignment. Understanding variations in psychosexual development in individuals with DSD requires reference to studies in nonhuman species that show marked but complex effects of androgens on sex differentiation of the brain and on behavior. Outcomes can be influenced by the timing, dose, and type of androgen exposure, receptor availability, and modification by the social environment.[11–14]

Data from rodent studies suggest that sex chromosome genes may also influence brain structure and behavior directly.[15,16] However, studies in individuals with complete androgen insensitivity syndrome (CAIS) do not indicate a behavioral role for Y-chromosome genes, although data are limited.[17] Sex differences in brain structures have been identified across species, some of which coincide with pubertal onset, perhaps suggesting hormonal responsivity.[18–20] The limbic system and hypothalamus, both of which play a role in reproduction, show sex differences in specific nuclei, but it is not clear

TABLE 2 **An Example of a DSD Classification**

Sex Chromosome DSD	46,XY DSD	46,XX DSD
45,X (Turner syndrome and variants)	Disorders of gonadal (testicular) development: (1) complete gonadal dysgenesis (Swyer syndrome); (2) partial gonadal dysgenesis; (3) gonadal regression; and (4) ovotesticular DSD	Disorders of gonadal (ovarian) development: (1) ovotesticular DSD; (2) testicular DSD (eg, SRY^+, duplicate SOX9); and (3) gonadal dysgenesis
47,XXY (Klinefelter syndrome and variants)	Disorders in androgen synthesis or action: (1) androgen biosynthesis defect (eg, 17-hydroxysteroid dehydrogenase deficiency, 5αRD2 deficiency, StAR mutations); (2) defect in androgen action (eg, CAIS, PAIS); (3) luteinizing hormone receptor defects (eg, Leydig cell hypoplasia, aplasia); and (4) disorders of anti-Müllerian hormone and anti-Müllerian hormone receptor (persistent Müllerian duct syndrome)	Androgen excess: (1) fetal (eg, 21-hydroxylase deficiency, 11-hydroxylase deficiency); (2) fetoplacental (aromatase deficiency, POR [P450 oxidoreductase]); and (3) maternal (luteoma, exogenous, etc)
45,X/46,XY (MGD, ovotesticular DSD)		Other (eg, cloacal exstrophy, vaginal atresia, MURCS [Müllerian, renal, cervicothoracic somite abnormalities], other syndromes)
46,XX/46,XY (chimeric, ovotesticular DSD)		

Although consideration of karyotype is useful for classification, unnecessary reference to karyotype should be avoided; ideally, a system based on descriptive terms (eg, androgen insensitivity syndrome) should be used wherever possible. StAR indicates steroidogenic acute regulatory protein.

when these differences emerge. Interpretation of sex differences is complicated by the effect of cell death and synaptic pruning on normal maturation and by effects of experience on the brain. Structure of the brain is not currently useful for gender assignment.

INVESTIGATION AND MANAGEMENT OF DSD

General Concepts of Care

Optimal clinical management of individuals with DSD[21] should comprise the following: (1) gender assignment must be avoided before expert evaluation in newborns; (2) evaluation and long-term management must be performed at a center with an experienced multidisciplinary team; (3) all individuals should receive a gender assignment; (4) open communication with patients and families is essential, and participation in decision-making is encouraged; and (5) patient and family concerns should be respected and addressed in strict confidence.

The initial contact with the parents of a child with a DSD is important, because first impressions from these encounters often persist. A key point to emphasize is that the child with a DSD has the potential to become a well-adjusted, functional member of society. Although privacy needs to be respected, a DSD is not shameful. It should be explained to the parents that the best course of action may not be clear initially, but the health care team will work with the family to reach the best possible set of decisions in the circumstances. The health care team should discuss with the parents what information to share in the early stages with family members and friends. Parents need to be informed about sexual development, and Web-based information may be helpful, provided the content and focus of the information is balanced and sound.

Ample time and opportunity should be made for continued discussion with review of information previously provided.[1]

The Multidisciplinary Team

Optimal care for children with DSD requires an experienced multidisciplinary team that is generally found in tertiary care centers. Ideally, the team includes pediatric subspecialists in endocrinology, surgery, and/or urology, psychology/psychiatry, gynecology, genetics, neonatology, and, if available, social work, nursing, and medical ethics.[22] Core composition will vary according to DSD type, local resources, developmental context, and location. Ongoing communication with the family's primary care physician is essential.[23]

The team has a responsibility to educate other health care staff in the appropriate initial management of affected newborns and their families. For new patients with DSD, the team should develop a plan for clinical management with respect to diagnosis, gender assignment, and treatment options before making any recommendations. Ideally, discussions with the family are conducted by one professional with appropriate communication skills.[24] Transitional care should be organized with the multidisciplinary team operating in an environment that includes specialists with experience in both pediatric and adult practice. Support groups can have an important role in the delivery of care to patients with DSD and their families[25] (see Appendix 1).

Clinical Evaluation

A family and prenatal history, a general physical examination with attention to any associated dysmorphic features, and an assessment of the genital anatomy in comparison to published norms need to be recorded (Table 3). Criteria that suggest DSD include (1) overt genital ambiguity (eg, cloacal exstrophy), (2) apparent female genitalia with an enlarged clitoris, posterior labial fusion, or an inguinal/labial mass, (3) apparent male genitalia with bilateral undescended testes, micropenis, isolated perineal hypospadias, or mild hypospadias with unde-

GA indicates gestational age.

scended testis, (4) a family history of DSD such as CAIS, and (5) a discordance between genital appearance and a prenatal karyotype. Most causes of DSD are recognized in the neonatal period; later presentations in older children and young adults include (1) previously unrecognized genital ambiguity, (2) inguinal hernia in a female, (3) delayed or incomplete puberty, (4) virilization in a female, (5) primary amenorrhea, (6) breast development in a male, and (7) gross and occasionally cyclic hematuria in a male.

Diagnostic Evaluation

Considerable progress has been made with understanding the genetic basis of human sexual development,[35] yet a specific molecular diagnosis is identified in only ~20% of cases of DSD. The majority of virilized 46,XX infants will have CAH. In contrast, only 50% of 46,XY children with DSD will receive a definitive diagnosis.[36,37] Diagnostic algorithms do exist, but with the spectrum of findings and diagnoses, no single evaluation protocol can be recommended in all circumstances. Some tests, such as imaging by ultrasound, are operator dependent. Hormone measurements need to be interpreted in relation to the specific assay characteristics and to normal values for gestational and chronological age. In some cases, serial measurements may be needed.

First-line testing in newborns includes karyotyping with X- and Y-specific probe detection (even when prenatal karyotype is available), imaging (abdominopelvic ultrasound), measurement of 17-hydroxyprogesterone, testosterone, gonadotropins, anti-Müllerian Hormone, and serum electrolytes, and urinalysis. The results of these investigations are generally available within 48 hours and will be sufficient for making a working diagnosis. Decision-making algorithms are available to guide additional investigation.[38] These assessments include human chorionic gonadotropin– and adrenocorticotropin-stimulation tests to assess testicular and adrenal steroid biosynthesis, urinary steroid analysis by gas chromatography mass spectroscopy, imaging studies, and biopsies of gonadal material. Some gene analyses are performed in clinical service laboratories. However, current molecular diagnosis is limited by cost, accessibility, and quality control.[39] Research laboratories provide genetic testing, including functional analysis, but may face restrictions on communicating results.[40]

Gender Assignment in Newborns

Initial gender uncertainty is unsettling and stressful for families. Expediting a thorough assessment and decision is required. Factors that influence gender assignment include diagnosis, genital appearance, surgical options, need for lifelong replacement therapy, potential for fertility, views of the family, and, sometimes, circumstances relating to cultural practices. More than 90% of patients with 46,XX CAH[41] and all patients with 46,XY CAIS assigned female in infancy[42] identify as females. Evidence supports the current recommendation to raise markedly virilized 46,XX infants with CAH as female.[43] Approximately 60% of 5-α-reductase (5αRD2)-deficient patients assigned female in infancy and virilizing at puberty (and all assigned male) live as males.[5] In 5αRD2 and possibly 17β-hydroxysteroid dehydrogenase deficiencies, for which the diagnosis is made in infancy, the combination of a male gender identity in the majority and the potential for fertility (documented in 5αRD2 but unknown in 17β-hydroxysteroid dehydrogenase deficiencies) should be discussed when providing evidence for gender assignment.[5,44,45] Among patients with partial androgen insensitivity syndrome (PAIS), androgen biosynthetic defects, and incomplete gonadal dysgenesis, there is dissatisfaction with the sex of rearing in ~25% of individuals whether raised male or female.[46] Available data support male rearing in all patients with micropenis, taking into account equal satisfaction with assigned gender in those raised male or female but no need for surgery and the potential for fertility in patients reared male.[42] Those making the decision on sex of rearing for those with ovotesticular DSD should consider the potential for fertility on the basis of gonadal differentiation and genital development and assuming that the genitalia are, or can be made, consistent with the chosen sex. In the case of mixed gonadal dysgenesis (MGD), factors to consider include prenatal androgen exposure, testicular function at and after puberty, phallic development, and gonadal location. Individuals with cloacal exstrophy reared female show variability in gender identity outcome, but >65% seem to live as female.[6]

Surgical Management

The surgeon has a responsibility to outline the surgical sequence and subsequent consequences from infancy to adulthood. Only surgeons with expertise in the care of children and specific training in the surgery of DSD should perform these procedures. Parents now seem to be less inclined to choose surgery for less severe clitoromegaly.[47] Surgery should only be considered in cases of severe virilization (Prader III–V) and be performed in conjunction, when appropriate, with repair of the common urogenital sinus. Because orgasmic function and erectile sensation may be disturbed by clitoral surgery, the surgical procedure should be anatomically based to preserve erectile function and the innervation of the clitoris. Emphasis is on functional outcome rather than a strictly cosmetic appearance. It is generally felt that surgery that is performed for cosmetic reasons in the first year of life relieves parental distress and improves attachment between the child and the parents[48–51]; the systematic evidence for this belief is lacking.

Currently, there is inadequate evidence in relation to establishment of functional anatomy to abandon the practice of early separation of the vagina and urethra.[52]

The rationale for early reconstruction is based on guidelines on the timing of genital surgery from the American Academy of Pediatrics,[53] the beneficial effects of estrogen on tissue in early infancy, and the avoidance of potential complications from the connection between the urinary tract and peritoneum via the Fallopian tubes. It is anticipated that surgical reconstruction in infancy will need to be refined at the time of puberty.[54–56] Vaginal dilatation should not be undertaken before puberty. The surgeon must be familiar with a number of operative techniques to reconstruct the spectrum of urogenital sinus disorders. An absent or inadequate vagina (with rare exceptions) requires a vaginoplasty performed in adolescence when the patient is psychologically motivated and a full partner in the procedure. No one technique has been universally successful; self-dilatation, skin substitution, and bowel vaginoplasty each have specific advantages and disadvantages.

In the case of a DSD associated with hypospadias,[57] standard techniques for surgical repair such as chordee correction, urethral reconstruction, and the judicious use of testosterone supplementation apply. The magnitude and complexity of phalloplasty in adulthood should be taken into account during the initial counseling period if successful gender assignment depends on this procedure.[58] At times, this may affect the balance of gender assignment. Patients must not be given unrealistic expectations about penile reconstruction, including the use of tissue engineering. There is no evidence that prophylactic removal of asymptomatic discordant structures, such as a utriculus or Müllerian remnants, is required, although symptoms in the future may indicate surgical removal. For the male who has a successful neophalloplasty in adulthood, an erectile prosthesis may be inserted but has a high morbidity.

The testes in patients with CAIS[35] and those with PAIS, raised female, should be removed to prevent malignancy in adulthood. The availability of estrogen-replacement therapy allows for the option of early removal at the time of diagnosis that also takes care of the associated hernia, psychological problems with the presence of testes, and the malignancy risk. Parental choice allows deferment until adolescence, recognizing that the earliest reported malignancy in CAIS is at 14 years of age.[59] The streak gonad in a patient with MGD raised male should be removed laparoscopically (or by laparotomy) in early childhood.[35] Bilateral gonadectomy is performed in early childhood in females (bilateral streak gonads) with gonadal dysgenesis and Y-chromosome material. In patients with androgen biosynthetic defects raised female, gonadectomy should be performed before puberty. A scrotal testis in patients with gonadal dysgenesis is at risk for malignancy. Current recommendations are testicular biopsy at puberty seeking signs of the premalignant lesion termed carcinoma in situ or undifferentiated intratubular germ cell neoplasia. If positive, the option is sperm banking before treatment with local low-dose radiotherapy that is curative.[60]

Surgical management in DSD should also consider options that will facilitate the chances of fertility. In patients with a symptomatic utriculus, removal is best performed laparoscopically to increase the chance of preserving continuity of the vas deferens. Patients with bilateral ovotestes are potentially fertile from functional ovarian tissue.[35,61] Separation of ovarian and testicular tissue can be technically difficult and should be undertaken, if possible, in early life.

Sex-Steroid Replacement

Hypogonadism is common in patients with dysgenetic gonads, defects in sex-steroid biosynthesis, and resistance to androgens. The timing of initiation of puberty may vary, but this is an occasion that provides an opportunity to discuss the condition and set a foundation for long-term adherence to therapy. Hormonal induction of puberty stimulates replication of normal pubertal maturation to induce secondary sexual characteristics, a pubertal growth spurt, and optimal bone mineral accumulation, together with psychosocial support for psychosexual maturation.[62] Intramuscular depot injections of testosterone esters are commonly used in males; another option is oral testosterone undecanoate, and transdermal preparations are also available.[63–65] Patients with PAIS may require supraphysiologic doses of testosterone for optimal effect.[66] Females with hypogonadism require estrogen supplementation to induce pubertal changes and menses. A progestin is usually added after breakthrough bleeding develops or within 1 to 2 years of continuous estrogen. There is no evidence that the addition of cyclic progesterone is beneficial in women without a uterus.

Psychosocial Management

Psychosocial care provided by mental health staff with expertise in DSD should be an integral part of management to promote positive adaptation. This expertise can facilitate team decisions about gender assignment/reassignment, timing of surgery, and sex-hormone replacement. Psychosocial screening tools that identify families at risk for maladaptive coping with a child's medical condition are available.[67] Once the child is sufficiently developed for a psychological assessment of gender identity, such an evaluation must be included in discussions about gender reassignment. Gender identity development begins before the age of 3 years,[68] but the earliest age at which it can be reliably assessed remains unclear. The generalization that the age of 18 months is the upper limit of imposed gender reassignment should be treated with caution and viewed conservatively. Atypical gender-role behavior is more common in children with DSD than in the general population but should not be taken as an indicator for gender reassignment. In

affected children and adolescents who report significant gender dysphoria, a comprehensive psychological evaluation[69] and an opportunity to explore feelings about gender with a qualified clinician is required over a period of time. If the desire to change gender persists, the patient's wish should be supported and may require the input of a specialist skilled in the management of gender change.

The process of disclosure concerning facts about karyotype, gonadal status, and prospects for future fertility is a collaborative, ongoing action that requires a flexible individual-based approach. It should be planned with the parents from the time of diagnosis.[70] Studies in other chronic medical disorders and of adoptees indicate that disclosure is associated with enhanced psychosocial adaptation.[71] Medical education and counseling for children is a recurrent gradual process of increasing sophistication that is commensurate with changing cognitive and psychological development.[72]

Quality of life encompasses falling in love, dating, attraction, ability to develop intimate relationships, sexual functioning, and the opportunity to marry and raise children, regardless of biological indicators of sex. The most frequent problems encountered in DSD patients are sexual aversion and lack of arousability, which are often misinterpreted as low libido.[73] Health care staff should offer adolescent patients opportunities to talk confidentially without their parents and encourage the participation in condition-specific support groups that enhance the ability of the patient to discuss their concerns comfortably. Some patients avoid intimate relationships, and it is important to address fears of rejection and advise them on the process of building a relationship with a partner. The focus should be on interpersonal relationships and not solely on sexual function and activity. Referral for sex therapy may be needed. Repeated examination of the genitalia, including medical photography, may be experienced as deeply shaming.[74] Medical photography has its place for record keeping and education but should be undertaken, whenever possible, when the patient is under anesthesia for a procedure. Medical interventions and negative sexual experiences may have fostered symptoms of posttraumatic stress disorder, and referral to a qualified mental health professional may be indicated.[75]

OUTCOME IN DSD

As a general statement, information across a range of assessments is insufficient in DSD. The following is based on those disorders for which some evidence base is available. They include CAH, CAIS, and PAIS, disorders of androgen biosynthesis, gonadal dysgenesis syndromes (complete and partial), and micropenis. Long-term outcome in DSD should include external and internal genital phenotype, physical health including fertility, sexual function, and social and psychosexual adjustment, mental health, quality of life, and social participation. There are additional health problems in individuals with DSD, including the consequences of associated problems such as other malformations, developmental delay and intellectual impairment, delayed growth and development, and unwanted effects of hormones on libido and body image.[76]

Surgical Outcome

Some studies suggest satisfactory outcomes from early surgery.[43,46,47,77] Nevertheless, outcomes from clitoroplasty identify problems related to decreased sexual sensitivity, loss of clitoral tissue, and cosmetic issues.[78] Techniques for vaginoplasty carry the potential for scarring at the introitus necessitating repeated modification before sexual function can be reliable. Surgery to construct a neovagina carries a risk of neoplasia.[79] The risks from vaginoplasty are different for high and low confluence of the urethra and vagina. Analysis of long-term outcomes is complicated by a mixture of surgical techniques and

SF1 (NR5A1)	Nuclear receptor TF	184757	9q33	AD/AR	Dysgenetic testis	+/−	Female or ambiguous	More severe phenotypes include primary adrenal failure; milder phenotypes have isolated partial gonadal dysgenesis
SRY	TF	480000	Yp11.3	Y	Dysgenetic testis or ovotestis	+/−	Female or ambiguous	
SOX9	TF	608160	17q24-25	AD	Dysgenetic testis or ovotestis	+/−	Female or ambiguous	Camptomelic dysplasia (17q24 rearrangements; milder phenotype than point mutations)
DHH	Signaling molecule	605423	12q13.1	AR	Dysgenetic testis	+	Female	The severe phenotype of 1 patient included minifascicular neuropathy; other patients have isolated gonadal dysgenesis
ATRX	Helicase (? chromatin remodeling)	300032	Xq13.3	X	Dysgenetic testis	−	Female, ambiguous, or male	α-Thalassemia, mental retardation
ARX	TF	300382	Xp22.13	X	Dysgenetic testis	−	Ambiguous	X-linked lissencephaly, epilepsy, temperature instability
Disorders of gonadal (testicular) development: chromosomal changes involving key candidate genes								
DMRT1	TF	602424	9p24.3	Monosomic deletion	Dysgenetic testis	+/−	Female or ambiguous	Mental retardation
DAX1 (NR0B1)	Nuclear receptor TF	300018	Xp21.3	dupXp21	Dysgenetic testis or ovary	+/−	Female or ambiguous	
WNT4	Signaling molecule	603490	1p35	dup1p35	Dysgenetic testis	+	Ambiguous	Mental retardation
Disorders in hormone synthesis or action								
LHGCR	G-protein receptor	152790	2p21	AR	Testis	−	Female, ambiguous, or micropenis	Leydig cell hypoplasia
DHCR7	Enzyme	602858	11q12-13	AR	Testis	−	Variable	Smith-Lemli-Opitz syndrome: coarse facies, second-third toe syndactyly, failure to thrive, developmental delay, cardiac and visceral abnormalities
StAR (steroidogenic acute regulatory protein)	Mitochondrial membrane protein	600617	8p11.2	AR	Testis	−	Female	Congenital lipoid adrenal hyperplasia (primary adrenal failure), pubertal failure
CYP11A1	Enzyme	118485	15q23-24	AR	Testis	−	Female or Ambiguous	CAH (primary adrenal failure), pubertal failure
HSD3B2	Enzyme	201810	1p13.1	AR	Testis	−	Ambiguous	CAH, primary adrenal failure, partial androgenization caused by dehydroepiandrosterone sulfate

TABLE 5 **Continued**

CYP17	Enzyme	202110	10q24.3	AR	Testis	−	Female, ambiguous, or micropenis	CAH, hypertension caused by corticosterone and 11-deoxycorticosterone (except in isolated 17,20-lyase deficiency)
POR (P450 oxidoreductase)	CYP enzyme electron donor	124015	7q11.2	AR	Testis	−	Male or ambiguous	Mixed features of 21-hydroxylase deficiency, 17α-hydroxylase/17,20-lyase deficiency, and aromatase deficiency; sometimes associated with Antley Bixler craniosynostosis
HSD17B3	Enzyme	605573	9q22	AR	Testis	−	Female or ambiguous	Partial androgenization at puberty, androstenedione/testosterone ratio
SRD5A2	Enzyme	607306	2p23	AR	Testis	−	Ambiguous or micropenis	Partial androgenization at puberty, testosterone/dihydrotestosterone ratio
Anti-Müllerian hormone	Signaling molecule	600957	19p13.3-13.2	AR	Testis	+	Normal male	Persistent Müllerian duct syndrome; male external genitalia, bilateral cryptorchidism
Anti-Müllerian hormone receptor	Serine-threonine kinase transmembrane receptor	600956	12q13	AR	Testis	+	Normal male	
Androgen receptor	Nuclear receptor TF	313700	Xq11-12	X	Testis	−	Female, ambiguous, micropenis, or normal male	Phenotypic spectrum from CAIS (female external genitalia) and PAIS (ambiguous) to normal male genitalia/infertility
46,XX DSD								
Disorders of gonadal (ovarian) development								
SRY	TF	480000	Yp11.3	Translocation	Testis or ovotestis	−	Male or ambiguous	
SOX9	TF	608160	17q24	dup17q24	Not determined	−	Male or ambiguous	
Androgen excess								
HSD3B2	Enzyme	201810	1p13	AR	Ovary	+	Clitoromegaly	CAH, primary adrenal failure, partial androgenization caused by dehydroepiandrosterone sulfate
CYP21A2	Enzyme	201910	6p21-23	AR	Ovary	+	Ambiguous	CAH, phenotypic spectrum from severe salt-losing forms associated with adrenal failure to simple virilizing forms with compensated adrenal function, 17-hydroxyprogesterone
CYP11B1	Enzyme	202010	8q21-22	AR	Ovary	+	Ambiguous	CAH, hypertension caused by 11-deoxycortisol and 11-deoxycorticosterone
POR (P450 oxidoreductase)	CYP enzyme electron donor	124015	7q11.2	AR	Ovary	+	Ambiguous	Mixed features of 21-hydroxylase deficiency, 17α-hydroxylase/17,20-lyase deficiency, and aromatase deficiency; associated with Antley Bixler craniosynostosis
CYP19	Enzyme	107910	15q21	AR	Ovary	+	Ambiguous	Maternal androgenization during pregnancy, absent breast development at puberty, except in partial cases
Glucocorticoid receptor	Nuclear receptor TF	138040	5q31	AR	Ovary	+	Ambiguous	Adrenocorticotropin, 17-hydroxyprogesterone and cortisol; failure of dexamethasone suppression (patient heterozygous for a mutation in CYP21)

OMIM indicates Online Mendelian Inheritance in Man; TF, transcription factor; AD, autosomal dominant (often do novo mutation); AR indicates autosomal recessive; Y, Y-chromosomal; X, X-chromosomal. Chromosomal rearrangements likely to include key genes are included. Modified from Achermann JC, Ozisik G, Meeks JJ, Jameson JL. Genetic causes of human reproductive disease. *J Clin Endocrinol Metab*. 2002;87:2447-2454.

diagnostic categories.[80] Few women with CAIS need surgery to lengthen the vagina.[81]

The outcome in undermasculinized males with a phallus depends on the degree of hypospadias and the amount of erectile tissue. Feminizing genitoplasty as opposed to masculinizing genitoplasty requires less surgery to achieve an acceptable outcome and results in fewer urologic difficulties.[46] Long-term data regarding sexual function and quality of life among those assigned female as well as male show great variability. There are no controlled clinical trials of the efficacy of early (<12 months of age) versus late (in adolescence and adulthood) surgery or of the efficacy of different techniques.

Risk of Gonadal Tumors

Interpretation of the literature is hampered by unclear terminology and effects of normal cell-maturation delay.[82–84] The highest tumor risk is found in TSPY (testis-specific protein Y encoded) positive gonadal dysgenesis and PAIS with intraabdominal gonads, whereas the lowest risk (<5%) is found in ovotestis[85] and CAIS.[83,86] Table 4 provides a summary of the risk of tumor development according to diagnosis and recommendations for management.

Cultural and Social Factors

DSD may carry a stigma. Social and cultural factors, as well as hormonal effects, seem to influence gender role in 5αRD2 deficiency. Gender-role change occurs at different rates in different societies, suggesting that social factors may also be important modifiers of gender-role change.

In some societies, female infertility precludes marriage, which also affects employment prospects and creates economic dependence. Religious and philosophical views may influence how parents respond to the birth of an infant with a medical condition. Fatalism and guilt feelings in relation to congenital malformations or genetic conditions have an influence, whereas poverty and illiteracy negatively affect access to health care.[87]

FUTURE STUDIES

Establishing a precise diagnosis in DSD is just as important as in other chronic medical conditions that have lifelong consequences. Considerable progress has been achieved with molecular studies, as illustrated in Table 5, which summarizes the genes known to be involved in DSD. Use of tissue-specific animal knock-out models, comparative genomic hybridization, and microarray screens of the mouse urogenital ridge will provide benefits in identifying new genes causing DSD.[88] It is essential that the momentum for an international collaborative approach to this task be maintained.

Much remains to be clarified about the determinants of gender identity in DSD. Future studies require representative sampling to carefully conceptualize and measure gender identity, recognizing that there are multiple determinants to consider, and gender identity may change into adulthood. In terms of psychological management, studies are needed to evaluate the effectiveness of information management with regard to timing and content. The pattern of surgical practice in DSD is changing with respect to the timing of surgery and the techniques used. It is essential to evaluate the effects of early versus later surgery in a holistic manner, recognizing the difficulties posed by an ever-evolving clinical practice.

The consensus has clearly identified a major shortfall in information about long-term outcome. Future studies should use appropriate instruments that assess outcomes in a standard manner[68,69] and take cognizance of guidelines relevant to all chronic conditions (see www.who.int/classifications/icf/en). These studies would preferably be prospective in nature and designed to avoid selection bias. A number of countries already have registers of DSD cases, but there could be added benefit from pooling such resources to enable prospective, multicenter studies to be undertaken on a larger number of cases that are clearly defined. Allied to this should be an educational program to ensure that multiprofessionals tasked with providing care to families with a child with DSD are suitably trained to discharge their responsibilities.

APPENDIX 1: ROLE OF SUPPORT GROUPS

The value of peer and parent support for many chronic medical conditions is widely accepted, and DSD, being lifelong conditions that affect developmental tasks at many stages of life, are no exception.

Those affected by DSD and parent members value the following:

- Peer support ends isolation and stigma, providing a context in which conditions are put into perspective and intimate issues of concern can be discussed safely with someone who has "been there."
- Children who form relationships with peers and affected adults early in their lives benefit from a feeling of normalcy early on, with support in place well before adolescence. Adolescents often resist attempts to introduce them to peer support.
- Support groups can help families and consumers find the best quality care.

Although clinical practice may focus on gender and genital appearance as key outcomes, stigma and experiences associated with having a DSD (both within and outside the medical environment) are more salient issues for many affected people.

Support groups complement the work of the health care team and, together, can help improve services. Initiatives by support groups have led to improvements in

management of DSD and research directed toward clinically relevant issues. Dialogue between health care professionals and support groups and collaboration as partners is to be encouraged.

APPENDIX 2: LEGAL ISSUES

Basic principles of medical law will remain even as research and clinical experience evolve in etiology, diagnosis, and treatment. This Appendix draws on practice in 3 countries on standards of medical negligence and patient informed consent. In the United States, the medical profession sets standards of care on the basis of prevailing medical custom.[89] However, a treatment may also be that used by a respected minority of practitioners.

Informed consent in the United States was founded on the principle of battery, whereby it is an offense to violate another person's bodily integrity without consent. Nowadays, most states are concerned with negligent nondisclosure to the patient. The standard of adequate disclosure may be physician based, requiring conduct of a reasonable practitioner, or it may be patient based, asking what a reasonable patient would find material. Physician-based disclosure must include information about risks, alternatives, outcomes, and prognosis, with or without treatment.

US courts assume that parents know what is best for their child when parental authority applies to consent for the child (substituted judgment). Parental decisions are deferred to except in situations in which potentially life-saving treatment is withheld. Consent to treatment by a child depends on an understanding of its nature and consequences.

Medical negligence in the United Kingdom defines treatment that falls below the standard expected of a reasonably competent practitioner. The standard of proof in court is whether negligence is demonstrated on the balance of probabilities. It is incumbent on the practitioner to demonstrate that treatment was consistent with a rationally defensible body of medical opinion. A shift in parental prerogative to consent to treatment was reflected in the Children Act 1989 in which parental rights were replaced by parental responsibilities. United Kingdom courts can intervene with orders made requiring or preventing a specific action related to the child. Age is not a barrier to informed consent, providing that a minor demonstrates an understanding of the issues sufficient to have the capacity to consent.

Colombian law is noted for a reasoned set of guidelines advanced by the highest court in cases of DSD.[90] A protocol was formulated for parental and physician intervention. The process of consent requires "qualified and persistent informed consent" over an extended period of time. Authorization is given in stages to allow time for the parents to come to terms with their child's condition. The court aimed to strike a balance between parental autonomy for those who did and those who did not want early surgery for their child until there was clear evidence of harm in deferring surgery until the child was competent to decide. Parents cannot consent for children over 5 years of age, because by then, children are deemed to have identified with a gender and, thus, are considered to be autonomous.

ACKNOWLEDGMENTS

The Lawson Wilkins Pediatric Endocrine Society and the European Society for Paediatric Endocrinology gratefully acknowledge unrestricted educational grant support for the consensus meeting from Pfizer Endocrine Care, Novo Nordisk, Ferring, and Organon.

Participants in the International Consensus Conference on Intersex were: John Achermann (London, United Kingdom), Faisal Ahmed (Glasgow, UK), Laurence Baskin (San Francisco, CA), Sheri Berenbaum (University Park, PA), Sylvano Bertelloni (Pisa, Italy), John Brock (Nashville, TN), Polly Carmichael (London, UK), Cheryl Chase (Rohnert Park, CA), Peggy Cohen-Kettenis (Amsterdam, Netherlands), Felix Conte (San Francisco, CA), Kenneth Copeland (Oklahoma City, OK), Patricia Donohoue (Iowa City, IA), Chris Driver (Aberdeen, UK), Stenvert Drop (Rotterdam, Netherlands), Erica Eugster (Indianapolis, IN), Kenji Fujieda (Asahikawa, Japan), Jay Giedd (Bethesda, MD), Richard Green (London, UK), Melvin Grumbach (San Francisco, CA), Vincent Harley (Victoria, Australia), Melissa Hines (London, UK), Olaf Hiort (Lübeck, Germany), Christopher Houk (Hershey, PA), Ieuan Hughes (Cambridge, UK), Peter Lee (Hershey, PA), Leendert Looijenga (Rotterdam, Netherlands), Bernadice Mendoca (Sao Paulo, Brazil), Heino Meyer-Bahlburg (New York, NY), Claude Migeon (Baltimore, MD), Yves Morel (Lyon, France), Pierre Mouriquand (Lyon, France), Anna Nordenström (Stockholm, Sweden), Phillip Ransley (London, UK), Robert Rapaport (New York, NY), William Reiner (Oklahoma City, OK), Hertha Richter-Appelt (Hamburg, Germany), Richard Rink (Indianapolis, IN), Emilie Rissman (Charlottesville, VA), Paul Saenger (New York, NY), David Sandberg (Buffalo, NY), Justine Schober (Erie, PA), Norman Spack (Boston, MA), Barbara Thomas (Rottenburg am Necker, Germany), Ute Thyen (Lübeck, Germany), Eric Vilain (Los Angeles, CA), Garry Warne (Melbourne, Australia), Jean Wilson (Dallas, TX), Amy Wisniewski (Des Moines, IA), Christopher Woodhouse (London, UK), and Kenneth Zucker (Toronto, Ontario, Canada).

The work of Alan Rogol, Joanne Rogol, Pauline Bertrand, and Pam Stockham in organizing the meeting is gratefully appreciated.

abstract

FREE

Parental consent generally is required for the medical evaluation and treatment of minor children. However, children and adolescents might require evaluation of and treatment for emergency medical conditions in situations in which a parent or legal guardian is not available to provide consent or conditions under which an adolescent patient might possess the legal authority to provide consent. In general, a medical screening examination and any medical care necessary and likely to prevent imminent and significant harm to the pediatric patient with an emergency medical condition should not be withheld or delayed because of problems obtaining consent. The purpose of this policy statement is to provide guidance in those situations in which parental consent is not readily available, in which parental consent is not necessary, or in which parental refusal of consent places a child at risk of significant harm. *Pediatrics* 2011;128:427–433

INTRODUCTION

Minors (persons under the age of legal consent as defined by state law) often require care in the prehospital environment and present to emergency departments (EDs) with medical concerns. Parental consent generally is required for the medical evaluation and treatment of minor children. In most cases, children will present to the ED with a parent or legally authorized decision-maker who can provide informed consent for evaluation and treatment. However, a number of well-recognized exceptions to this "general rule" have been outlined in common and statutory law to allow for the treatment of minors without parental consent in situations that frequently occur in EDs.[1–14] The purpose of this document is to provide guidance for those situations in which parental consent is not readily available, in which parental consent is not necessary, or in which parental refusal of consent places a child at risk of harm.

The American Academy of Pediatrics (AAP) supports the principle that all pediatric patients who present to any emergency medical services (EMS) provider or ED for evaluation and treatment should receive an initial evaluation or medical screening examination (MSE) regardless of ability to pay or presence of a legally authorized decision-maker who can provide consent. The AAP has written 2 previous versions of this document. The original document, "Consent for Medical Services for Children and Adolescents," was published in 1993 and subsequently revised in 2003.[15] The recommendations made in the 2003 revision remain important and pertinent to current practice. In addition to reaffirming the 2003 recommendations, this policy statement attempts

to explore additional situations in which obtaining consent presents special challenges.

EVALUATION AND TREATMENT OF THE UNACCOMPANIED MINOR

If a parent or legal guardian is present or available, the health care professional treating the child should make every reasonable effort to obtain and document informed consent. Children occasionally present to the ED unaccompanied by a parent or legal guardian. In some cases (discussed later in this statement), adolescents may have the legal authority to consent for treatment without a parent present. In most situations, however, the child or adolescent will either not have the authority to consent or will be unable to do so. Common and statutory law generally has supported the health care professional in evaluating these children and providing emergently needed care while attempts are made to locate a parent or legally authorized decision-maker. In addition, current federal law under the Emergency Medical Treatment and Active Labor Act (EMTALA) mandates an MSE for every patient seeking treatment in an ED of any hospital that participates in programs that receive federal funding, regardless of consent or reimbursement issues.[16–19] The purpose of the MSE is to determine if an emergency medical condition (EMC) exists, including life- or limb-threatening conditions, severe pain, or conditions with the potential for serious impairment or dysfunction if left untreated. The MSE might require the use of extensive ED resources, including laboratory testing, radiographic imaging, and subspecialty consultation, as needed for diagnosis. Although the ED should attempt to contact the unaccompanied patient's parent or legal guardian to seek consent for evaluation and treatment, the performance of the MSE and the stabilization of the patient with an identified EMC must not be delayed. If an EMC is not identified, EMTALA regulations no longer apply, and the physician or health care professional generally should seek proper consent before further (nonemergent) care is provided. In cases of suspected abuse or neglect, child protective services or local law enforcement officers may have the authority to consent for evaluation and treatment, although the extent of this authority might differ from one jurisdiction to the next.

In situations in which a minor has a condition that represents a threat to life or health and a parent or legally authorized decision-maker is not readily available to provide consent, health care professionals may provide necessary medical treatment or transport the child for more definitive evaluation and stabilizing treatment. The ethical basis for this approach is based in the professional's duty to seek the best interest of the child. The legal basis for taking action in an emergency when consent is not available is known as the "emergency exception rule."

The emergency exception rule is also known as the doctrine of "implied consent." This emergency exception rule is based on the assumption that reasonable persons would consent to emergency care if able to do so and that if the legal guardian knew the severity of the emergency, he or she would consent to medical treatment for the child. Under the emergency exception rule, a medical professional may presume consent and proceed with appropriate treatment and transport if the following 4 conditions are met:

1. The child is suffering from an emergent condition that places his or her life or health in danger.
2. The child's legal guardian is unavailable or unable to provide consent for treatment or transport.
3. Treatment or transport cannot be safely delayed until consent can be obtained.
4. The professional administers only treatment for emergent conditions that pose an immediate threat to the child.

Any time a minor is treated without consent, the burden of proof falls on the professional who is evaluating, treating, or transporting the child to justify and document that the emergency actions were necessary to prevent imminent and significant harm to the child. In addition to actions necessary to save a person's life and prevent permanent disability or harm, the treatment of fractures, infections, pain, and other conditions may broadly be considered as emergent conditions that require treatment. As a general rule, health care professionals should always do what they believe to be in the best interest of the minor. The emergency exception exists to protect the health care professional from liability with the assumption that if the parents were present, they would consent to treatment.[20] The professional must clearly document in the child's record the nature of the medical emergency and the reason the minor required immediate treatment and/or transport and the efforts made to obtain consent from the patient's legal guardian, if unavailable.[15]

EMANCIPATION AND THE MATURE MINOR DOCTRINE

There are 3 situations in which a minor, rather than his or her parents, has the legal authority to make decisions regarding his or her health care: emancipation; the mature minor exception; and exceptions based on specific medical conditions. In fact, every state has enacted minor consent statutes that address some or all of these exceptions to the "general rule."[21,22]

In general, an emancipated minor can function as an adult, independent from

his or her parents, with regard to consent for medical evaluation and treatment.[23] Children who are legally emancipated may give consent for medical treatment and transport. They may also refuse medical care and/or transport. Although emancipated minor laws vary from state to state, most states recognize minors to be emancipated if they are married, economically self-supporting and not living at home, or on active-duty status in the military. In some states, a minor who is a parent or who is pregnant might also be considered emancipated. Other states might require a court to declare the emancipation of a minor.

Most states also recognize a mature minor exception, in which a minor, usually 14 years old or older, displays sufficient maturity and intelligence to understand and appreciate the benefits, risks, and alternatives of the proposed treatment and to make a voluntary and reasonable choice on the basis of that information. States vary in terms of whether a physician can make this determination or whether a judicial determination is required.[23]

Finally, most states allow a minor to consent to evaluation and treatment of specific medical conditions without the consent of a parent, generally including mental health services, treatment for drug and alcohol addiction, pregnancy-related care, contraceptive services, and testing for and treatment of sexually transmitted diseases. The specific nature of these exceptions and the age at which they apply vary from state to state. Because state laws vary, it is important to be familiar with the specifics of emancipated and mature minor laws in the state in which care is being provided.

If none of the 3 scenarios described previously (emancipation, mature minor, or condition-specific exceptions) are applicable, then the minor has no legal authority to either provide consent or refuse medical care. Regardless of whether a child has the legal authority to provide or withhold consent, it is always prudent to attempt to get the child's agreement or assent to treatment and transport. This approach respects the personal dignity and self-determination of the child/patient and minimizes confrontation. A willingness to provide the child with some control and some choice might allow for a compromise that allows transport personnel to achieve a safe transfer. Using force or restraint to evaluate, treat, or transport a child should be reserved only for those situations in which all efforts to negotiate respectfully with the child have failed and the child is at risk of serious harm if he or she is not restrained. In these unusual circumstances, appropriate measures should be taken to ensure the safety of the patient.

CONSENT FOR NONURGENT PEDIATRIC CARE OF CHILDREN ACCOMPANIED BY SOMEONE WHO IS NOT AUTHORIZED TO PROVIDE LEGAL CONSENT

Health care professionals should refrain from providing nonurgent testing and treatment to children who present to medical facilities unaccompanied by a custodial parent or legal guardian. An MSE should be performed to ensure that the child does not have a condition that requires emergent attention, and any treatment necessary to prevent immediate and serious harm to the child should be provided while an attempt is made to obtain consent from a legally authorized decision-maker. The AAP clinical report "Consent for Nonurgent Pediatric Care"[24] describes the issue of "consent by proxy" and provides practical steps that will help to balance a patient's ready access to medical care, family integrity, and the health care professional's need to limit his or her exposure to liability. Unless a minor's right to consent has been legally established, health care professionals should attempt to notify parents or legal guardians of their intentions to test and/or treat the minor and consider delaying all nonurgent diagnostic and treatment decisions until the parent or legal guardian can be reached for informed permission or consent.[24]

REFUSALS OF CONSENT FOR EMERGENT EVALUATION AND TREATMENT

A particularly challenging situation occurs when the health care professional is faced with a legal guardian who refuses to give permission for treatment of a child in situations in which such treatment is considered essential to the child's well-being. Competent adult patients have the right to refuse evaluation and treatment, even for EMCs, unless they are determined to lack decision-making capacity. Under US law, minors are generally considered incompetent to provide legally binding consent regarding their health care; parents or legal guardians are empowered to make those decisions on their behalf, and those decisions are considered legally binding. Except for the exceptions cited previously, parental permission is required before the evaluation and treatment of a child. Parental authority is not absolute, however, and when a parental decision places a child at significant risk or serious harm compared with an alternative decision, the state may intervene to require intervention over the objections of the legal decision-maker.

As long as a child's legal guardian possesses medical decision-making capacity, he or she has the right to refuse medical care for the child. However, the guardian is required to act in the best interest of the child. When a legal guardian refuses to consent to medical care or transport that is necessary

and likely to prevent death, disability, or serious harm to the child, law enforcement officers may intervene under local and state child abuse and neglect laws. It is always preferable to negotiate with the legal decision-maker and attempt to achieve an agreeable plan for safely managing the child's medical condition.

When faced with a guardian who refuses to allow the provision of necessary medical care or transport of a child when it is necessary to save a child's life or prevent serious harm, it might be necessary to notify the police and enlist their assistance in placing the child in temporary protective custody. In a life-threatening emergency, it might be necessary to involve hospital security so that emergent evaluation and treatment can begin while child protective services and the police are notified. Likewise, when a legal guardian appears to be intoxicated or otherwise impaired, involvement of law enforcement officers might be necessary to place a minor in temporary protective custody. Once the professional has received authorization to treat from a state child protective agency or police, the emergency medical professional does not have the right to treat a minor for medical conditions that are not serious or life-threatening. Under these circumstances, a medical professional should provide medical treatment without consent only when the child has a medical condition that poses a risk of death or serious harm, when immediate treatment is necessary to prevent that harm, and when only those treatments necessary to prevent the harm are provided.[25]

INFORMED CONSENT AND THE LANGUAGE BARRIER

If a language barrier exists, informed consent for medical treatment should, when clinical circumstances permit, be obtained through a trained medical interpreter. Using an interpreter not only increases the likelihood of truly informed consent but also enhances the possibility of optimal medical treatment by allowing the professional to obtain accurate information about a child's underlying medical conditions, allergies, current medications, or other relevant and important information. Such interpretation may be performed in person, via videoconferencing, or by telephone, but a certified medical interpreter should be used. Using a family member as interpreter should be avoided unless absolutely necessary, and the medical professional should be aware that translation might not be accurate when a trained interpreter is not used.

CONSENT AND CONFIDENTIALITY

State statutes that allow the consent of a minor do not all guarantee an adolescent protection from parental disclosure. However, some states explicitly require either confidentiality or parental notification. Other states require the health care professional to at least make a good-faith effort to involve the family of the minor in his or her treatment. The only federal law that requires confidentiality for minors is the Family Planning Act.[26] It is crucial that every health care professional be knowledgeable of his or her respective state and all federal laws relating to confidentiality and minors.[27]

The issue of adolescent confidentiality was addressed in the recently published AAP technical report "Patient- and Family-Centered Care and the Role of the Emergency Physician Providing Care to a Child in the Emergency Department."[28] This report suggested that ED health care professionals be familiar with the limitations to and obligations for providing care to the unaccompanied older pediatric patient seeking care without the knowledge of his or her family[15,24,29] and make those limits and obligations clear to the patient. For example, both the patient and the health care provider should identify a secure and confidential means of receiving follow-up information regarding pending laboratory results, return visits, and billing notification. In particular, confidentiality can only be reliably realized when attached to financial accountability. The child must be willing and able to pay the bill for the ED visit or risk a breach of confidentiality as a result of billing notification. Some professional organizations have formalized their opinions on the issue of confidentiality. The American Medical Association recommends a conservative approach to confidentiality and encourages parental involvement whenever possible.[30] The Society for Adolescent Medicine believes that health care professionals have an obligation to protect patient confidentiality when appropriate.[31]

As discussed previously, the lack of legal clarity provides health care professionals with some discretionary control over whether to provide testing and treatment to a minor without parental notification. That responsibility should not be taken lightly, and consideration for issues such as family dynamics (eg, will the child be punished if the parents are consulted?), developmental maturity (eg, is the child a runaway risk?), and the actual scope of testing and treatment must be taken into consideration before excluding or including parents in the discussion. In addition, health care professionals should be honest and consistent with their patients and families. A clinician should never promise a patient confidentiality if he or she might not be able to honor that promise.

PREHOSPITAL CONSENT

EMS providers and EMS medical directors caring for minors might find it difficult or impossible to make real-time

contact with parents or legal guardians of patients, despite the increased availability of communication tools in the prehospital environment (eg, cell phones). Although most EMS systems promote a good-faith effort on the part of the prehospital provider to make contact with the parents and legal guardians of minors, many systems do not have formal policies addressing the lack of informed minor or parental consent. If at all possible, an assessment should be performed to determine if there is a medical emergency, and medical consultation should be sought if the emergency medical technicians are unclear about whether a threat to life or limb exists. If parents are present or accessible and refuse care for their injured or ill child, they must be informed of the risk of not transporting a sick or injured pediatric patient, which might include death or permanent disability. Regardless of religious beliefs or parental desires, every attempt should be made to treat and/or transport a child with a life-threatening emergency or if providers suspect child abuse. EMS providers should involve medical control early in these situations and use law enforcement resources as necessary to ensure that the patient receives the necessary emergency stabilization and transport.

CONSENT DURING A DISASTER

Health care professionals evaluating and treating a minor during a disaster should always attempt to obtain consent from the parents or legally authorized decision-maker. The mere existence of a disaster event does not automatically authorize emergency medical professionals to evaluate and treat minors without parental consent unless the minor's life or health would be jeopardized by delay.[32] However, in an overwhelming disaster scenario, time pressures on medical providers, a chaotic environment, interruption of normal communication methods, the inability to identify patients, and multiple casualties might make it impossible to seek timely informed consent for the evaluation and treatment of minors. In such a situation, medical professionals should act in the best interest of the patient and provide stabilizing care until consent can be obtained.

CONSENT FOR RESEARCH IN THE EMERGENCY SETTING

For research protocols that enroll ED patients, informed consent will require a process separate from that of informed consent for evaluation and treatment. Whether to enroll a child in a research project can never be decided solely by a health care professional but must occur in accord with the requirements of an institutional review board (IRB). The IRB will determine the requirements for informed consent, including the content of the informed consent, who can obtain consent, and whether consent requires the agreement of 1 or both parents.

In some cases, research in the emergency environment is designed to investigate emergency procedures that offer the prospect of direct benefit to potential participants, and in these situations, enrollment must take place immediately, and parents might not yet be available to provide permission.[33] Such special situations are governed by special rules. Under these circumstances, the research can proceed without permission of the parents only under restricted guidelines outlined by federal regulation. These guidelines require that the subject be facing a life-threatening or permanently disabling situation for which the only known therapy is investigational, unproven, or unsatisfactory; that the child is incapable or unable to provide valid consent, and the parents cannot be reached for permission before the time the investigational treatment must be started; and that there is no accepted therapy that is clearly superior to the experimental therapy. In addition, the research protocol must have received IRB approval that the experimental treatment has a realistic probability of benefit that equals or exceeds that of standard care, that the risks of the experimental therapy are reasonable in comparison to the patient's condition and standard therapy, that there is minimal added risk from participation in the research protocol, that there is no possibility of getting prospective consent from those who are likely to need the experimental therapy, that participants and/or parents will be provided with all pertinent information regarding the study as soon as possible, and that alteration or waiver of consent will not adversely affect the rights and welfare of the subjects. Once the legal decision-maker has been informed of the research, he or she might choose to discontinue participation at any time after being fully informed of the consequences of doing so. Finally, federal regulations require that input from community representatives be sought regarding the protocol before IRB approval to gain a form of "community consent" to proceed with the research and that public disclosure of the research and its risks and benefits be made to the community from which potential participants will be enrolled before initiation of the research. Public disclosure of study results is also required by law in this situation.

CONCLUSIONS

A health care professional's decision to treat combined with parental consent and patient assent (when appropriate) is the preferred scenario encountered by the pediatrician working in the emergency medical environment. When any one of those factors is absent or unclear, the health care pro-

vider must be (1) knowledgeable of state and federal laws related to a minor's right (or lack thereof) to consent for testing and treatment and (2) prepared to confront the ethical challenges surrounding those same issues.

RECOMMENDATIONS

1. An MSE and any medical care necessary and likely to prevent imminent and significant harm to the pediatric patient with an EMC should never be withheld or delayed because of problems with obtaining consent.
2. The physician or health care professional should document in the patient's medical record all informed-consent discussions, including the identity of the person providing consent (if the patient) or permission for treatment (if a parent or another adult with legal decision-making authority) and the efforts made to obtain consent from the patient's legal guardian, if unavailable.
3. The physician or health care professional should be familiar with Emergency Medical Treatment and Active Labor Act federal regulations, state laws concerning consent for the treatment of minors, and state laws enumerating the conditions under which minors can provide consent for their own care.
4. Unless a minor is allowed to consent under the law, health care professionals should consider delaying all nonurgent diagnostic and treatment decisions until the parent or legal guardian can be reached for informed permission or consent.
5. The physician or health care professional should seek patient assent for medical testing and treatment from the pediatric patient as appropriate for the patient's age, stage of development, and level of understanding.
6. If a language barrier exists, informed consent for medical treatment from health care professionals should be obtained through a trained medical interpreter.
7. Every EMS agency and ED should develop written policies and guidelines that conform to federal and state laws regarding consent for the treatment of minors, including specific guidelines on financial billing, parental notification, and patient confidentiality for the unaccompanied minor.
8. For research protocols, the decision to enroll a child in a research project must occur in accord with the requirements of an IRB.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Clinical Report—Consent by Proxy for Nonurgent Pediatric Care

abstract

FREE

Minor-aged patients are often brought to the pediatrician for nonurgent acute medical care, physical examinations, or health supervision visits by someone other than their legally authorized representative, which, in most situations, is a parent. These surrogates or proxies can be members of the child's extended family, such as a grandparent, adult sibling, or aunt/uncle; a noncustodial parent or stepparent in cases of divorce and remarriage; an adult who lives in the home but is not biologically or legally related to the child; or even a child care professional (eg, au pair, nanny). This report identifies common situations in which pediatricians may encounter "consent by proxy" for nonurgent medical care for minors, including physical examinations, and explains the potential for liability exposure associated with these circumstances. The report suggests practical steps that balance the need to minimize the physician's liability exposure with the patient's access to health care. Key issues to be considered when creating or updating office policies for obtaining and documenting consent by proxy are offered. *Pediatrics* 2010;126:1022–1031

BACKGROUND INFORMATION

Before providing nonurgent medical care to a minor patient not accompanied by a legally authorized representative (LAR), important questions regarding informed consent and the delegation of parental responsibilities need to be asked and answered. These questions include:

1. Who has a legal right to delegate consent to health care decisions for a child?
2. To whom can the power to consent to health care for a child be delegated?
3. In what circumstances can the power to consent to health care for a child be delegated?
4. What are the limitations on the right to delegate the power to consent to health care for a child?
5. How is authorization of proxy consent verified and documented?
6. When or how often does information on proxy consent need to be updated?

Many aspects of informed consent in pediatrics have been set forth in previous policy statements from the American Academy of Pediatrics (AAP). Some of these statements addressed informed consent in broad terms, and others addressed narrowly focused situations. The AAP statement on informed consent[1] noted that, unlike

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

in other specialties, "the doctrine of 'informed consent' has limited *direct* application in pediatrics," because parents or other surrogates provide informed permission, rather than informed consent, for diagnosis and treatment of children. Other AAP policy statements have provided guidance to pediatricians on consent for treatment of minor patients in specific circumstances such as emergency care,[2] adolescent health issues,[3] genetic testing and newborn screening,[4] procedures that involve sedation,[5] and parental denial of medical care for religious reasons.[6]

This report does not replace the aforementioned policy statements; they stand on their own merit. Instead, this report addresses the potential liability risks that physicians may incur when providing nonurgent medical care to pediatric patients without obtaining permission or consent directly from the patient's LAR. This report is a revision of the 2003 clinical report on consent by proxy.[7] The authors acknowledge that not permitting consent by proxy may pose a challenge to the efficient operation of a busy pediatric practice. However, suggestions are offered to help pediatricians minimize their exposure to legal risk in situations in which an LAR has delegated the authority to consent to nonurgent medical care to another adult. Pediatricians should use their good judgment in balancing the patient's health care needs with their own need for legal protection. Because pediatricians are primarily concerned with their patients' welfare, discretion must be used to differentiate situations in which care can be delayed pending appropriate LAR consent from situations in which the pediatrician should provide care and accept the risk of legal repercussions. Careful planning and good office policies can minimize those instances.

LEGAL BACKGROUND

Except for situations in which a minor's right to consent to care without involvement of an LAR has been legally established, persons who have not yet reached the age of majority do not usually have the right to consent to their own medical care. In most states, the age of majority is 18 years. Thus, a physician is required to obtain consent from an LAR before performing a medical or surgical test, procedure, or treatment on a minor.[8] Under some scenarios, the consent can be obtained from the LAR via telephone, even if a proxy accompanies the minor. Also, judicial decisions and legislative action have resulted in several exceptions to the LAR-consent requirement, which depends on the specific state rule (eg, emergency treatment; treatment of an emancipated or "mature" minor; treatment of an adolescent for, eg, sexual assault, sexually transmitted infections, mental health disorders, drug abuse, and alcohol dependency).

A physician who provides nonurgent care, including the physical examination, to a minor without the consent of someone who is legally authorized to speak for the minor may be vulnerable to legal action. Lawsuits that allege a lack of informed consent usually are based on the concept of negligence but may involve battery as well.[9–11] In general, battery is the unsolicited physical touching of a person. Medical battery may be alleged if treatment is provided without appropriate informed consent, when a procedure is performed that is substantially different from the one for which consent was given, when the treatment exceeds the scope of the consent, or when a physician different than the one to whom consent was granted performs the procedure.[12] A physician may face a battery claim although the treatment or procedure may have been performed without any negligence.[13] When a plaintiff is not satisfied with the results of the medical treatment or procedure but is unable to prove negligence in litigation against the physician, the plaintiff may resort to the theory of battery to seek a recovery. If the plaintiff who alleges an unauthorized procedure cannot prove actual harm, typically only nominal damages will be recovered. However, in a successful battery case, punitive damages may be assessed, which may not be covered by malpractice insurance or dischargeable by bankruptcy. Some states have replaced the theory of battery with the theory of medical negligence. Besides civil liability, physicians may face penalties from licensing boards for performing services without appropriate consent.[14] The impact of state privacy laws and the federal Health Insurance Portability and Accountability Act (HIPAA) on physician liability for disclosure of health information of minors to unauthorized individuals has not yet been tested.

To date, physician liability for treating without consent by an LAR seems to be uncommon. However, past frequency may not reflect future likelihood, because the concepts of informed consent and consent by proxy have evolved both ethically and legally. In fact, inadequate informed consent, which had not previously been a major source of liability for physicians, has become increasingly problematic, especially in the context of issues such as limited English proficiency (LEP) and limited health literacy (discussed later). Consent by proxy could become a source of future concern, and physicians should not ignore the risks associated with it.

Many of the published cases are of older judicial decisions.[15] The ramifications of these cases are unclear to a contemporary jury and judge. In addition, these older cases did not address

issues such as LEP and limited health literacy, which may impact informed consent situations, including consent by proxy. In many of these cases, treatment without consent by an LAR was deemed appropriate by the court either on the basis of the emergency-treatment doctrine or because the court deemed the minor patient to be a "mature" or emancipated minor.[15] However, there is also judicial precedent in which liability was imposed on the physician.[10,16–18]

Although not specifically addressing consent by proxy, more recent court cases have assessed the validity of informed consent when a parent was not present.[19,20] These cases have involved consent by adolescents for treatments and diagnoses other than those already permitted in most jurisdictions, such as treatment of sexually transmitted infections and mental health disorders. In viewing the informed consent as valid, these courts have determined that the adolescents were mature minors, although the minors had not previously sought mature-minor status through adjudication. The courts relied on the adolescents' age, ability, education, training, degree of maturity and judgment, conduct and demeanor, and the nature and risks of the treatments in assessing whether the minor adolescents were capable of consenting on their own. Nevertheless, despite this legal precedent, practitioners should be wary of treating adolescents without parental consent unless the adolescent is seeking treatment for a legally permitted condition.

A claim of "inadequate" informed consent is usually predicated on the notion that a "reasonable" person would have refused the treatment or procedure offered to the plaintiff had proper informed consent been conducted.[12] A claim of inadequate informed consent may be added to a claim of medical malpractice because proof of inadequate informed consent might imply to a jury that the physician was careless about the care delivered.[21] The importance of appropriate informed consent is underscored by recent appellate court decisions that held that neither proof of medical malpractice nor battery is required for a claim of inadequate informed consent to be valid.[22,23]

DEFINITION OF TERMS

Nonurgent Pediatric Care

For the purposes of this clinical report, nonurgent pediatric care is defined as preventive medicine (ie, services encompassed in pediatric health supervision visits, including immunizations and screening tests) and outpatient medical encounters for minor illnesses or injuries. Differences in operations and procedures may depend on whether the nonurgent medical encounter is the initial or a follow-up visit.

Informed Consent

Informed consent is a general principle of law that imposes on physicians a duty to disclose to their patients the benefits and risks associated with each of the following: (1) the proposed course of treatment; (2) alternate treatments; and (3) no treatment at all. In general, informed consent is meant to allow patients to voluntarily consent to medical interventions by reasonably balancing the probable risks against the probable benefits.[24] State standards in assessing the adequacy of disclosure under informed consent can be physician/professional based (ie, benefits and risks that a reasonable physician would disclose), patient based (ie, benefits and risks that a reasonable patient would want to know), or a hybrid of both. Legal requirements for informed consent may also be specific to medical procedures or tests.[25]

Consent by Proxy

The process by which people delegate to another person the legal right to consent to medical treatment for themselves, for a minor, or for a ward is called consent by proxy. There are 3 fundamental constraints on this right to delegate consent for children: (1) the guardian of a minor must have the right to consent to medical treatment for that minor; (2) the guardian must be legally and medically competent to delegate the right to consent to medical treatment for that child; and (3) the right to consent to medical treatment for the child must be delegated to a legally and medically competent adult.[8,15,26] Physicians must realize that persons who have been delegated consent-by-proxy status may have different opinions than the LAR about both recommended and alternate treatment.

Physicians need to be aware that state laws may mandate a hierarchy of persons who may give consent by proxy to nonurgent treatment if an LAR cannot be contacted.[27–29] An example of such a hierarchy is (1) stepparent, (2) grandparent of minor, (3) adult brother/sister, and (4) adult aunt/uncle of minor.[30] When a hierarchy is the rule, a person lower on the list generally cannot give consent if one higher on the list is available. A written power of attorney or affidavit may be needed. Such a document may need to be notarized or witnessed,[26,31,32] may have a time limit to it,[26,31–33] and may be needed to supersede this hierarchy.[30]

State law or custodial agreement may not permit a noncustodial parent to consent to treatment of a child. State law may permit foster care licensees and court-appointed guardians to consent depending on the scope of authority granted by the court and the treat-

ment proposed. Typically, consent to "routine" care is permitted, although the definition of routine may vary among states. Some states have permitted proxies to consent to routine or "ordinary" medical and dental care, which can include radiography, surgery, and anesthesia.[34] Other states have excluded surgery, anesthesia, and even psychotropic drugs from the definition of ordinary care.[26,27,35,36] Immunizations may be excluded from consent by proxy.[26] Some state laws on consent by proxy that are drafted lack specific guidelines for implementation. Also, some states provide immunity for physicians from civil and criminal liability if the physician obtains the consent in good faith.[26]

Minor

A person who is younger than the age of legal competence is a minor by definition. In most states, a person is no longer a minor after reaching 18 years of age.

Current Pediatric Practice

Because there is no legal requirement to provide nonurgent pediatric care to a minor without the consent of an LAR, pediatricians who choose to treat such patients may unwittingly be assuming additional risk of exposure to liability. According to a 2004 periodic survey of AAP fellows, "Pediatricians' Experiences With Child Care Health and Safety,"[37] many pediatricians have not adopted policies to minimize these risks. The survey revealed that fewer pediatricians in 2004, compared with those in 1999, said that it was their policy to see all children brought in by child care providers (16% vs 21%), whereas more pediatricians said that they see children brought in by child care providers only if they have authority from the parents (50% vs 40% [$P < .001$]). One-third of pediatricians responded that they had no set policy regarding treating patients brought in for nonurgent acute care or preventive visits by child care providers. Fewer pediatricians in 2004 than in 1999 said that it was their policy to take all telephone calls from child care providers (16% vs 25%). More said that they take the telephone call only if given authority by the parent (32% vs 21% [$P < .001$]). Fewer pediatricians in 2004 than in 1999 offered telephone consultations to child care providers (36% vs 48% [$P < .001$]). The results of 1 national study showed that only 64% of pediatricians and family practitioners often or always saw adolescent patients for routine health maintenance examinations without parents present.[38] Practices that maintained a specific clinic policy were less likely to see an adolescent for routine care without a parent present, compared with those without such a policy.[38]

FAMILY LIVING ARRANGEMENTS

Changes in family living arrangements and use of child care are leading reasons why someone other than an LAR may bring a minor patient in for nonurgent ambulatory pediatric care. The US Census Bureau has described many aspects of family living arrangements.[39] In 2004, of the more than 73 million children younger than 18 years in the United States, 70% spent most of their childhood living in 2-parent families. However, a significant proportion of children resided in homes with other family configurations. Approximately 1 child in 4 (19.3 million) lived with a single parent, most often a single mother. Also, many children lived with single parents who had cohabiting partners. Furthermore, 4% of children lived with neither parent and lived instead with another adult, usually a grandparent, which means that approximately one-third of all children in the United States do not have 2 parents in the home with legal authority to consent to medical treatment.

CHILD CARE

Census reports confirm that an increasing proportion of children spend substantial amounts of time in the care of a person other than their parents.[40] In 2005, 30% of 11.3 million children younger than 5 years whose mothers were employed were cared for on a regular basis by a grandparent during the mother's working hours.[40] A slightly greater percentage spent time in an organized child care, nursery, or preschool.

DOCUMENTING CONSENT BY PROXY

Whenever someone other than the LAR accompanies the child for medical care, it affords an opportunity to assess the relationship between the child and the caregiver, but it precludes face-to-face contact between the pediatrician and the LAR. If it has been anticipated that a caregiver other than an LAR may bring the child to pediatric visits, arrangements should be made for the LAR to provide a written consent for consent by proxy. In general, these documents specify the name of the LAR, the name of the person to whom the LAR's legal authority to consent to the child's medical care has been delegated, and the relationship of that person to the child. Such documentation may need to delineate the extent of the surrogate's authorization (ie, the circumstances, the kinds of medical services, or the specified time period for which the surrogate may provide consent for medical care). State law related to consent by proxy should always be reviewed. Signatures may be required, and state law may require that the signatures be notarized.[26,41] State law may also dictate the specific time period for which a written consent by proxy is valid.[26,33]

The proxy relationship should be verified and documented periodically. The proxy accompanying the patient

should be the same person to whom proxy has been delegated on the aforementioned form. Requesting a dated signature and photograph identification from the proxy is one way to document that verification. Dissimilar signatures may indicate a problem. It should also be verified that the person is authorized to consent to the specific care that will be provided. The patient's medical record should be flagged to alert the pediatrician and nursing staff of situations in which the caregiver cannot provide consent. If the pediatrician has any doubts about the caregiver's capability to provide permission for medical care (eg, lack of maturity; presence of intoxication[42]; unclear legal standing; or the inability to understand risk communication, perhaps because of language barriers or limited health literacy), then the pediatrician may need to consider deferring elective care until permission from the LAR can be obtained.

If the pediatrician is uncomfortable with consent-by-proxy arrangements, it needs to be communicated with parents as soon as possible. The topic could be broached during early discussions of child care arrangements at prenatal or newborn visits or addressed during medical encounters before the parent returns to employment outside the home. If parents are the caregivers, the pediatrician can explain the importance of the "therapeutic alliance"[43] between the pediatrician, parents, and patient and emphasize why it is preferable for at least 1 parent to be present during nonurgent visits. Offering extended office hours (evenings or weekends) is another way pediatricians have made it possible for working parents to attend their children's medical appointments.

INITIAL VISIT

Pediatricians should be cautious about proxy situations if they are providing initial care for the child. Medical decisions may be made on the basis of information obtained from the proxy that may not be entirely accurate. Similarly, medical decisions may be made on the basis of follow-up visits that are contingent on the accuracy of the information from the documentation during the initial visit. Pediatricians who decide to treat children under these circumstances may want to consider "flagging" such charts so that baseline information obtained from the initial visit can be later verified by the LAR. This would be especially important for details such as medication allergy.

UNACCOMPANIED TRAVEL

Consent-by-proxy forms can be useful in other situations as well. Children who travel without their LAR sometimes require medical treatment for a minor injury or illness, which often occurs when children are visiting friends or relatives without their LAR. Although most LARs will sign a proxy consent form when their children go to school or summer camp, few LARs think about sending a signed proxy consent form along when their children leave home for an extended period (eg, a week visiting grandparents). Depending on state law, a child may not be able to obtain routine medical care (which may or may not be defined under state law) without consent to such care by an authorized adult. Pediatricians may encourage LARs to anticipate these problems and take the steps necessary to ensure that their children traveling without an LAR can receive needed nonurgent medical care. When in doubt, pediatricians should consider the best interests of the child in making their decision about rendering care.

CUSTODY AND CONSENT

It is prudent for the physician to inquire about marital status and custody issues when relevant. In most states, parents who are married to each other have an equal right to consent to medical care for the children of that marriage, and the consent of only 1 parent is required for nonurgent pediatric care in such cases. The physician should not assume which parent has the right to consent for the child when the parents are divorced or legally separated. The right to consent in these situations may be contingent on state law or court order. Some states limit the rights of noncustodial parents and fathers of children born out of wedlock, in which case proof of paternity may not be available, to provide consent to medical care for children.

One of the most difficult situations for securing parental consent for a child's health care occurs when children are used as pawns in marital conflict. "Physical custody" refers to where the child lives. A "residential custodial parent" has sole physical custody, and this parent's home is the child's primary residence. A "noncustodial parent" is usually granted visitation or access rights to the child. "Legal custody," which can be sole (if only 1 parent) or joint (if both parents equally), refers to parental rights and responsibilities, which include medical decisions and other issues that pertain to the child's general welfare. "Joint custody," when used generically, can either be joint legal custody (parents share nearly equal responsibilities for parenting decisions, such as medical care) or joint physical custody (providing the child with a home). It should be noted that each divorce or legal separation agreement is unique, and specific rights may be granted or denied to a parent, even when the court document describes them as having legal custody of the child. It is important, therefore, to inquire about who has "medi-

cal decision-making rights," because it is more directly pertinent to the issue of providing consent for the child's medical care.

Disputing parents can use situations for deciding whether the child should receive nonurgent medical care as an opportunity to spar over parental rights. Generally, if both parents have equal right to consent to care for their child, the physician need only obtain consent from 1 parent to provide that care. However, there may be situations in which it is not clear whether the pediatrician may seek consent from 1 parent if consent has been refused by the other.[8]

The pediatrician should clarify who has the right to medical information and should specifically ask about any joint physical or legal custody agreements.[44] Joint legal custody may be relevant to coordinating medical care, because some joint custody agreements require that both parents need to give consent and be informed about their child's medical needs.

Less commonly recognized is the problem of children visiting a noncustodial parent in another state, especially if that state's law does not permit a noncustodial parent to give permission for the child to receive medical care. These situations are usually unexpected but not unmanageable. For instance, a pediatrician may be puzzled when a family associated with the practice seeks medical care for a child never mentioned or seen previously. It may be a child or stepchild from a previous marriage or relationship who lives in another state and who, while visiting the family, develops a minor illness and needs medical attention. In such situations, pediatricians need to make sure that the adult with the child has the authority to consent to the medical care before treating. Unless a stepparent has legally adopted the child or has been designated as a legally authorized caregiver, he or she may have no legal authority to give consent for treatment.[8] It is suggested that office staff document the name and relationship of the person providing permission and how his or her authority to do so was ascertained.

OTHER CIRCUMSTANCES

Four percent of all US children do not live with either of their biological parents.[39] They may be in foster care, under the care of a relative, with a potential adoptive parent, or in other situations in which their caregiver is not a biological parent. The pediatrician should ascertain the exact nature of the relationship, verify the authority of the proxy, and document the legal basis of the proxy-child relationship and the exercise of the informed consent process within that context.

For some children, there has not yet been a request to the court for a guardian to be appointed. For this reason, authority to consent to these children's nonurgent care may be unclear, but a physician should probably not deny them necessary care because of their legal status. The pediatrician should use his or her best judgment in deciding whether to postpone care until a guardian can be appointed or to render the care. If care is provided, careful documentation of the circumstances is recommended. Pediatricians should notify child protective services when a child needs a legal guardian. As noted above, for children in state custody under a foster care arrangement, there may be restrictions on consent by proxy. Consent for surgery may require a court order.[27,33]

IMMUNIZATIONS

Although some would debate the logic of requiring informed consent for state-mandated services such as immunizations, it is clear that open dialogue about risk is at the crux of the national Vaccine Injury Compensation Program (VICP).[45] Vaccine information statements (VISs) were created to meet the informational requirements of the VICP; however, VISs alone are not considered informed consent. Under the VICP, providers must distribute a VIS to the patient's legal representative every time a covered immunization is administered. Federal law does not require parental consent for immunizations but instead uses the term "legal representative" as one who may consent. Federal law defines legal representative as a parent or other individual who is qualified under state law to consent to the immunization of a minor. Thus, regarding immunizations, state law controls. Non-LAR consent to immunizations may have restrictions under some state laws.[46,47] These state laws may cover procedural requirements (eg, whether consent may be verbal or must be written) or substantive requirements (eg, types of information required). Most states require separate consent for each injection when more than 1 is required to complete immunization. Most states require consent for immunization services provided to adolescents.[48] Some states allow adolescents to self-consent for immunization. Unless the law provides otherwise, immunizations should not be given without appropriate consent.

VISs explain the benefits and risks associated with each childhood immunization. However, VISs are intended to facilitate, not replace, effective risk communication and proper informed consent between the health care professional and the patient's legal representative. Guidelines on the distribution of VISs and documentation of vaccine administration are available in a booklet published by the Department of Health and Human Services[49] (www.cdc.gov/vaccines/pubs/vis/default.htm)

and are summarized in the 2009 AAP *Red Book*.[50] In addition, the AAP produces vaccine administration record forms to help pediatricians comply with the VICP documentation requirements. For non–English-speaking patients, VISs have been translated into 49 languages. These VISs can be accessed and downloaded from the Immunization Action Coalition Web site (www.immunize.org/vis).[51]

LANGUAGE BARRIERS TO INFORMED CONSENT BY PROXY

People with LEP pose a burgeoning challenge in the delivery of health care. A similar approach may be needed for patients or LARs with hearing impairment.[52] LEP has the potential to become a major future medical malpractice issue relating to informed consent,[53] which will be compounded in scenarios that involve consent by proxy. Various federal and state laws and regulations apply to individuals with LEP, including the American With Disabilities Act, the Rehabilitation Act of 1973, Title VI of the Civil Rights Act, and the Health Insurance Portability and Accountability Act (HIPAA). The 2000 US Census noted that 37 million adults and 10 million children older than 5 years primarily spoke a language other than English at home.[54] Furthermore, even among English-speaking patients, a large proportion have poor reading skills.[55] If the proxy does not speak the same language as the pediatrician, it may be difficult to obtain appropriate informed consent. Although patient education materials and consent forms can be developed in various languages for common procedures that require informed consent, it would be unwise to rely exclusively on written informed-consent methods. Translations that are accurate according to the textbook language may not be appropriate to the comprehension level of the reader.

Most pediatricians report using untrained interpreters to communicate with patients and families with LEP,[56] especially in smaller and rural practices but also in states with higher proportions of people with LEP.[56] If the pediatrician suspects that language barriers may compromise the communication between him or her and the proxy necessary for informed consent, other steps may need to be taken. Health care professionals who participate in federal health programs (eg, Medicaid, State Children's Health Insurance Program, TriCare, Medicare) must meet requirements for accommodating patients with LEP, which may involve qualified translators other than family members.[57] Some patients with LEP may be eligible for language assistance if their provider participates in a federal government program.[58] Practitioners may be placing themselves at risk of liability if the proxy has problems understanding the practitioner because of a language barrier. Malpractice lawsuits related to the issue of LEP have been based on both negligence and inadequate informed consent.[59,60] It is preferable to have someone who is medically knowledgeable explain the illness, treatment options, and known risks and benefits in the proxy's own language. The practice should record and retain on file the name, address, and background of the translator. Translators should be instructed that they are to communicate the caregiver's answer directly, which is vital for conveying to the pediatrician whether the respondent's answer indicates an understanding of the elements needed for informed consent and whether an agreement has been reached as to the medical treatment. It is not advisable to use children (eg, the patient or an older sibling or relative) as translators for informed consent. The use of adult family members as translators may result in incorrect history because of concerns about their desire to not disclose personal information. Certain scenarios could violate Title VI of the Civil Rights Act of 1964.[57]

PROBLEMS WITH PROXIES WITH LIMITED HEALTH LITERACY

Besides potential problems with a proxy having a language barrier, some proxies may have limited health literacy. Health literacy is the ability to obtain, process, read, and understand health information so that an appropriate and informed health care decision can be made.[55] Results of the 2003 National Assessment of Adult Literacy indicated that only 12% of the American adult population has proficient health literacy skills,[61] and the Institute of Medicine has estimated that 90 million American adults lack the literacy skills to effectively use the health care system in this country.[55] Thus, physicians must be sure that proxies understand the health information that is being conveyed to them.

SUMMARY

The liability risk of a pediatrician providing nonurgent care without the appropriate informed consent is likely to be low, especially if the care is provided in the best interest of the child. This risk is likely to be higher in certain situations such as those that involve immunizations, language barriers, limited health literacy, and the initial visit. State laws are applicable. Pediatric practices need to anticipate that situations that involve consent by proxy can occur for a variety of reasons. Policies should be developed that promote good, informed decision-making and risk management. Care should be taken to make sure that such policies meet applicable laws without blocking access to necessary but nonurgent health care. Pediatricians have sought ways to accommodate

the diverse living and working arrangements of their patients' families. Many pediatricians are working parents themselves and know well the challenges of family life. Developing a legally sound office policy on consent by proxy is essential for maintaining efficient office operations and strong physician-patient relationships.

IMPLEMENTATION SUGGESTIONS

1. Determine if the practice will see minor patients without an LAR present. It is usually best if all physicians within the practice adopt the same policy; otherwise, problems can occur during coverage situations.
2. If the practice's decision is not to provide nonurgent care to patients without an LAR present, then the policy for the office and an information sheet explaining it should be provided to patients. The policy should also be made clear during contacts with new or prospective patients.
3. If the practice decides to provide nonurgent care to patients accompanied by someone other than their LAR, then it should establish a policy and procedural guide for the office as well as a patient information sheet that explains the policy. This statement may spell out the LAR's responsibilities in providing and documenting his or her consent-by-proxy arrangement. The pediatrician should ensure that office staff members, particularly those involved in telephone triage and scheduling appointments, understand the policy and their responsibilities.
4. It is advisable to create a template form to be used in cases in which individuals other than LARs may be expected to accompany a child to the office. Suggested items to address include:
   a. Who has the legal right to delegate consent to health care decisions for the child?
   b. To whom can the power to consent to health care for a child be delegated?
   c. In what circumstances can the power to consent to health care for a child be delegated (eg, while child is vacationing out of state with grandparents or while parents are traveling overseas and child remains home with the nanny)?
   d. For which services (eg, preventive care, immunizations, laboratory tests) can the power to consent to health care for a child be delegated?
   e. With what limitations can the power to consent to health care for a child be delegated? (For example, the proxy may consent to treatment for a child's sprained ankle but may not be authorized to take child to the visit with the orthopedic surgeon).
   f. How is authorization of proxy consent verified and documented?
   g. When or how often should information on proxy consent be updated?
5. The proxy relationship should be verified and documented periodically.
6. Establish an office procedure for providing and documenting informed consent for proxies with LEP, hearing impairment, and limited health literacy.
7. It is advisable to have legal counsel review office policy and supporting documents to ensure compliance with applicable laws.
8. It is recommended that informed consent, including consent by proxy, be included in residency training and continuing medical education. Such educational efforts have been effective in improving knowledge and attitudes about informed consent.[62]
9. When in doubt about informed consent in a proxy situation, practitioners should use discretion in deciding whether to treat and should base the decision on the best interests of the child.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Contraception and Adolescents

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Adolescence

ABSTRACT

Although adolescent pregnancy rates in the United States have decreased significantly over the past decade, births to adolescents remain both an individual and public health issue. As advocates for the health and well-being of all young people, the American Academy of Pediatrics strongly supports the recommendation that adolescents postpone consensual sexual activity until they are fully ready for the emotional, physical, and financial consequences of sex. The academy recognizes, however, that some young people will choose not to postpone sexual activity, and as health care providers, the responsibility of pediatricians includes helping teens reduce risks and negative health consequences associated with adolescent sexual behaviors, including unintended pregnancies and sexually transmitted infections. This policy statement provides the pediatrician with updated information on contraception methods and guidelines for counseling adolescents.

INTRODUCTION

Pediatricians have an important role in adolescent reproductive health care. Their long-term relationships with patients and families allow them to help promote healthy decision-making around sexuality and include abstinence as a way to avoid the negative consequences associated with risky sexual behaviors. As advocates for the health and well-being of young people, pediatricians communicate their recommendation to adolescent patients to postpone sexual activity until they are ready, because any sexual activity for which the adolescent is ill prepared may have emotional, physical, and financial consequences. However, clinicians recognize that some of their adolescent patients are sexually active or will choose to become so. Recent studies indicate that, for some adolescents, even participating in formal programs that advocate abstinence and signing abstinence pledges do not result in abstinent behavior.[1,2] Pediatricians can have an active role in encouraging their adolescent patients to use contraception to reduce the risk of unintended pregnancies and to prevent sexually transmitted infections (STIs). In previous publications, the American Academy of Pediatrics (AAP) has addressed issues of adolescent sexuality, unwanted pregnancy, STIs, and contraception.[3] This policy statement provides the pediatrician with updated information on adolescent sexual behavior, which may lead to pregnancy, including guidelines for counseling adolescents about available methods of contraception. Current methods available are discussed, as are methods in development.

ADOLESCENT SEXUAL BEHAVIOR AND USE OF CONTRACEPTION

Reported contraceptive use by adolescents has increased in recent years. From 1991 to 2005, the percentage of sexually active high school students who reported using a condom the last time they had sexual intercourse increased from 46.2% to

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

62.8% in 2005.[4] Despite this increase, consistent use of any contraceptive method remains a challenge for most adolescents.

Levels of reported sexual intercourse by adolescents in the United States decreased during the 1990s for both sexes after increasing for the previous 2 decades.[4–6] The Centers for Disease Control and Prevention's 2005 Youth Risk Behavior Surveillance Summary indicated that less than half (46.8%, down from 49.9% in 1999) of all high school students reported having had sexual intercourse in their lifetimes, and approximately one third (34.3%, down from 37.5% in 1991 and 36.3% in 1999) of all students reported having sexual intercourse during the 3 months preceding the survey and are considered currently sexually active.[4–6]

Each year, almost 850 000 adolescent girls become pregnant. The adolescent pregnancy rate has dropped steadily over the past decade. As of 2004, it was estimated that approximately 41.2% of all pregnancies are to adolescents 15 to 19 years of age.[7] Since 1991, the adolescent birth rate has declined by 33%, the lowest rate ever reported for the nation. The pregnancy rate for 15- to 17-year-olds has dropped by 43% to 22.1% of all pregnancies.[7] Approximately 20% of abortions are in adolescents, although these rates continue to decrease.[8,9] Decreases in pregnancy rates are thought to reflect a decrease in reported rates of sexual intercourse and an increase in reported use of longer-acting, more effective contraceptive agents.[10–12] Over the last decade, evaluations of curricula suggest that those with a comprehensive approach to sexuality education have been effective in improving sexual behaviors and, thus, may also contribute to this trend.[13–15] Despite these declining rates of pregnancies and births, adolescent childbearing (22% of women report giving birth before age 20) is still more common in the United States than in other developed countries such as Great Britain (15%), Canada (11%), and France (6%).[16]

Providing information to adolescents about contraception does not result in increased rates of sexual activity, earlier age of first intercourse, or a greater number of partners.[15] In fact, if adolescents perceive obstacles to obtaining contraception and condoms, they are more likely to experience negative outcomes related to sexual activity.[17] Two school-based studies that demonstrated a delay of onset of sexual intercourse used a comprehensive approach to sexuality education that included a discussion of contraception.[18,19]

Race, ethnicity, age, marital status, education, income, requirements for confidential care, and fertility intentions have all been demonstrated to affect contraceptive choice. Trends in methods of contraception used by adolescents over the past 2 decades show an increase in oral contraceptive pill (OCP) use and an increase in male condom use.[20] In recent years, the number of adolescents reporting OCP use has remained stable at approximately 18% to 20%.[21] Use of injectable contraception by adolescents 15 to 19 years of age has increased from 0% to 13% between 1988 and 1995. A 9% decrease in contraceptive-failure–related pregnancies is attributed to the shift to longer-acting birth control methods.[16]

Factors that contribute to lack of contraceptive use or inconsistent use include issues related to adolescent development, such as reluctance to acknowledge one's sexual activity, belief that one is immune from the problems or consequences surrounding sexual intercourse or pregnancy, and denial of the possibility of pregnancy. Other important factors are lack of education and misconceptions regarding use or appropriateness of contraception. However, an adolescent's level of knowledge about how to use contraception effectively does not necessarily correlate with consistent use. Adolescents may not use or may delay use of contraception for several reasons including lack of parental monitoring, fear that their parents will find out, ambivalence, and the perception that birth control is dangerous or causes unwanted adverse effects such as weight gain.[22–25]

THE ROLE OF THE PEDIATRICIAN

Pediatricians should encourage abstinence and provide appropriate risk-reduction counseling regarding sexual behaviors. Ideally, counseling should include discussion about the prevention of STIs, education on contraceptive methods, and family planning services for the sexually active patient. Such discussion necessarily takes place within the context of an individual patient's physical and emotional development as well as his or her social situation. Although pediatricians are optimally suited for such inquiry, we recognize that not every visit will allow the time required. The demands of comprehensive patient evaluation, counseling, and treatment are daunting, indeed, but are part of the ongoing education of teens and often other family members. This report is intended as a guide and, we hope, is helpful to busy clinicians.

When contraceptive services are provided in the pediatrician's office, policies and procedures that address the provision of such services, including confidentiality, should be developed and then explained to families before the provision of such services is ever needed.[26,27]

Counseling Adolescents About Contraception

Comprehensive health care of adolescents should include a confidential sexual history that should be obtained in a safe, nonthreatening environment through open, honest, and nonjudgmental communication with assurances of confidentiality. During the preadolescent years, the pediatrician can provide anticipatory guidance by discussing puberty and offering health education materials to both the youth and his or her family. At the onset of puberty, the patient's history should include

information on both the family's and the patient's attitudes and knowledge about sexual behaviors and the degree of involvement in sexual activity. General information may be offered or accessible to both the family and patient about methods of contraception and their uses. In addition, around this time, health maintenance visits should begin to include private, confidential time with the adolescent to establish rapport as well as assess degree of involvement in sexual activity. For sexually active adolescents who use contraception, the role of the health care professional is to educate and support compliance, to assist in managing adverse effects or, alternatively, to counsel the patient regarding a new contraceptive method as circumstances require, and to provide referrals and follow-up with periodic screening for STIs. Throughout adolescence, comprehensive sexuality education that includes discussion of abstinence, appropriate contraceptive use, and protection from STIs should be provided as part of healthy sexual development. When initiating any hormonal contraceptive method, the need for consistent protection against STIs (either male or female condoms) should be reinforced.

Confidentiality and Consent

The primary reason that adolescents may hesitate or delay obtaining family planning or contraceptive services is concern about lack of confidentiality.[25,28] It is important for pediatricians to develop office policies that ensure patient confidentiality. State requirements and standards of practice should be reviewed, and the development of clear, concise, and standardized office protocols for confidentiality should be developed for staff, patients, and parents.[29] These policies should include information and education regarding when confidentiality must be waived, guidelines for reimbursement of services, medical chart access, appointment scheduling, and information disclosure.

For those patients whose parents are unaware of their contraceptive use, it may be helpful to discuss with the adolescent patient how the contraceptive method will be consistently used in all circumstances. Consistent adolescent contraceptive use is often derailed during weekends away, family vacations, adolescents' trips to stay with other relatives, and/or visits to noncustodial parents.

Sexual Responsibility

Pediatricians can help adolescents identify their own goals for safe and responsible sexual behavior, including reinforcing and supporting abstinence. The promotion of healthy and responsible sexual decision-making is one of the goals of counseling adolescents about contraception. Successful counseling requires a supportive and nonjudgmental pediatrician who engages in effective dialogue, which includes skillful history taking, careful listening, and repetition of simple educational messages that contain essential information.[26,30]

Sexual Decision-Making

Adolescents should be strongly encouraged to postpone or delay the initiation of sexual activity. For patients who are already engaged in sexual intercourse or who are contemplating having sexual intercourse, a discussion of contraceptive methods and prevention of STIs (including HIV and AIDS) is essential. Condom use should always be reinforced, and teens must be reminded that, for some STIs, condoms are not totally protective. Adolescents should be made aware, in a nonthreatening and nonjudgmental manner, that although condom use is essential and may be life-saving, any individual who engages in sexual contact is at risk of contracting STIs that are transmitted through sexual contact, such as herpes simplex and human papillomaviruses, rather than body-fluid exchange, such as gonorrhea and trichomoniasis. Discussions should address and explore the adolescent's reasons for becoming sexually active and the effect that sexual intercourse may have on relationships with peers, parents, and significant others. Clinicians may also find it useful to explore with the adolescent how he or she believes the sexual experiences will change his or her own self-image. Adolescent sexual decision-making has emerged in recent studies as a complex interplay between an adolescent's perception of peer-group expectations, personal self-image, values, and desires and media influences.[30–33] However, a caring, nonjudgmental yet informative, nonparental adult can wield substantial influence in teens' sexual decision-making; teens cite lack of such a person as a missing key feature of sexuality education.[34] Pediatricians, therefore, may have some influence in adolescent sexual decision-making and are especially well positioned to assess risk-taking behaviors in the area of sexuality.[35]

ADOLESCENTS WITH DISABILITIES

The issue of contraception for adolescents with chronic illness or disability is often forgotten. An estimated 10% to 20% of children and adolescents experience a disability or chronic illness by the age of 20 years.[36] Recent data from the National Longitudinal Study of Adolescent Health has shown that physically disabled adolescents are as sexually experienced as adolescents without disabilities. Attitudes about contraceptives as well as sexuality education and counseling needs within this population should not be overlooked.[37] A list of additional resources for clinicians who desire more information about contraception for adolescents with chronic illness and/or disability is included at the end of this statement.

METHODS OF CONTRACEPTION

Numerous reviews and protocols for prescribing and managing contraception are available. The following section focuses on the appropriateness of various contraceptive methods available for adolescents. The pediatrician should emphasize the need for STI prevention as well as contraception with each patient at each visit.[17,38]

Abstinence

Abstinence is the most effective means of birth control and prevention of STIs and is a viable strategy in the clinician's toolkit for reducing unintended pregnancy and achieve reduction in STI rates. Abstinence education generally focuses on delaying the initiation of adolescent sexual activity until marriage or adulthood. Many schools have adopted abstinence-dominant or abstinence-only education programs for school sexuality curricula. To date, the evidence regarding the efficacy of such interventions in the reduction of risky sexual behaviors, including risk for STIs, has not been proven.[14,39] No data have directly examined how well abstinence counseling works to reduce an individual's pregnancy and STI risk. In practice, many adolescents who intend to be abstinent often fail and have sex. A longitudinal analysis of teens and virginity pledges compared pledgers to nonpledgers and found at a 6-year follow-up that 88% of pledgers reported experiencing premarital sex and had STI rates that, statistically, were no different from those of nonpledgers.[2] A recent article provides some practical tips for abstinence counseling within an office-based setting using a comprehensive perspective including motivational interviewing.[40]

Several published studies and evaluations have suggested that comprehensive sexuality education is an effective strategy for helping young people delay initiation of sexual intercourse. In addition, research has shown that these programs do not hasten the onset or frequency of sexual intercourse and do not increase the number of partners that sexually active teens have.[15]

There is some consensus that sexuality education and interventions with some abstinence-based or "abstinence-plus" curriculum components are most effective when targeted at younger adolescents before they become sexually active.[1,41] Some recent studies demonstrated the importance of youth, parent, physician, and education partnerships for the prevention of health risk behaviors such as early initiation of sexual intercourse.[13,42] One study illustrated that an abstinence-only curriculum had no significant impact on the initiation of sex, the frequency of sex among those students who had ever had sex, or the number of sexual partners among those who had ever had sex. Two other studies produced similar results.[1] The AAP supports a comprehensive approach to sexuality education for adolescents. Abstinence should play a part in any comprehensive discussion of sexuality, and resources should be made available for adolescents who feel pressured, but prefer not, to engage in sexual activity.

For some adolescents, abstinence may be a difficult choice. Adolescents who choose to abstain from sexual intercourse should be encouraged and supported by their parents, peers, and society (including the media) and especially by their pediatricians. Adolescents need to know about other contraceptive options before (or if) they decide to have intercourse.

Male and Female Condoms

The male condom is a mechanical barrier method of contraception. The failure rate at the end of first-year use for the male latex condom is 3% with perfect use and as much as 14% with typical use.[43] Latex condoms significantly reduce the transmission of some STIs and, therefore, should be used by all sexually active adolescents regardless of whether an additional method of contraception is used. Male condoms have several other advantages for adolescents, including involving males in the responsibility of contraception, easy accessibility and availability to minors, use without a prescription, and low cost.[44] Polyurethane condoms can be used by adolescents with a documented latex allergy; however, latex condoms are preferred, because they have a higher efficacy rate with typical use than polyurethane condoms.[43] Some adolescents may have local reactions to condoms that have been pretreated with spermicide and should be counseled that condoms without these agents are also available. Nonoxynol-9 is the only chemical agent in spermicidal products available in the United States; there are nonspermicidal hypoallergenic lubricants available over the counter. Only water-based lubricants may be used with latex condoms, and both water- and oil-based products may be used with polyurethane condoms.[44] Currently, there is a general movement away from products with nonoxynol-9 because of concerns that use increases risk of genital ulceration and irritation, which may facilitate the acquisition of STIs.[44] Condom use reported at most recent intercourse by females was 54% and by males was 71%, which is an increase in the last decade.[20] Surveys of high school students over the last decade indicate that condom use has increased, with condom use at last intercourse increasing from 46.2% in 1991 to 62.8% in 2005.[4]

The female condom, another barrier method of contraception, provides contraceptive efficacy in the same range as other barrier methods, such as the diaphragm and cervical cap (with typical use).[45] One trial of the most widely available female condom on the market yielded a failure rate of 0.8% with perfect use and between 12% and 15% with typical use.[46] The female condom also helps protect against STIs. Adolescents' concerns about using a female condom include difficulty of insertion, higher cost than male condoms, and appearance and noisiness of the device. Female adolescents

have reported that the female condom could be useful if their male partners did not want to use a condom. Further education on using the female condom is needed for both genders. For adolescents who already use male condoms, it is important to market the female condom as an alternative contraceptive choice, because male and female condoms should not be used simultaneously.[47] Male condoms are preferred over female condoms because of higher efficacy rates of preventing pregnancy and STIs and lower cost.

Vaginal Spermicides

Vaginal spermicides are a chemical barrier method of contraception applied intravaginally through a variety of forms: gel, foam, suppository, or film. Spermicides consist of 2 components: a formulation (the gel, foam, suppository, or film) and the chemical ingredient that kills the sperm (eg, nonoxynol-9). As with any barrier method, the effectiveness of spermicides depends on consistent and correct use. The combination of vaginal spermicide and condoms is a very effective means of contraception for adolescents, because it provides effective prevention of pregnancy, reduces the risk of contracting an STI, is available without a prescription, and is inexpensive.[48]

There has been a question as to whether use of nonoxynol-9 alone provides adequate protection against STIs and HIV. In high doses, nonoxynol-9 can irritate the vaginal lining, which makes young women more susceptible to HIV transmission. The Centers for Disease Control and Prevention have concluded that women should be discouraged from using nonoxynol-9 alone for STI and HIV protection, because 1 study found that a product containing nonoxynol-9 did not protect against HIV infection and may have caused an even greater likelihood of transmission as compared with a vaginal lubricant.[49,50] Use of spermicide alone is not advocated as a contraceptive method; condoms must be used in conjunction with vaginal spermicides for protection against STIs

Oral Contraceptives

OCPs are a reliable, effective method for the prevention of pregnancy, are available only by prescription in the United States, and are the most popular method of prescribed contraceptive among adolescents.[21] Of the 2.7 million adolescent women who use contraceptives, 44% rely on the pill.[51] The Youth Risk Behavior Surveillance Summary reported that in both males and females who had sexual intercourse during the 3 months before the survey, the percentage who used birth control pills to prevent pregnancy during last sexual intercourse was 17.6% in 2005, down from 20.8% in 1991.[4]

Three forms of OCPs are currently available: the fixed-dose, monophasic combination (each tablet contains the same dose of estrogen and progestin); the phasic dose (the triphasic and biphasic packs that contain varying doses of estrogen and progestin); and the minipill (which contains progestin only). Many of the newer forms of birth control pills have a low dose of estrogen (20–35 μg) and contain new forms of progestin. These low-dose pills are typically the "first-line" therapy for OCP initiation. There is theoretic potential for lowered efficacy of low-dose OCPs in patients who are taking some medications. Some common medications that increase the metabolism of synthetic steroids by increasing conjugation in the gut and enzyme induction in the liver are listed in Table 1.[52–54] In this clinical situation, prescription of OCPs that contain 50 μg of ethinyl estradiol or switching to a hormonal method that avoids first-pass metabolism, such as injectable progestin, may be indicated; efficacy of transdermal or intravaginal contraceptives with these medications are not known. Generally, the standard 28-day pack of pills (21 days of hormone and 7 days of placebo) is prescribed for teens, and daily compliance is encouraged, particularly over the 21 days of hormone-containing pills to maximize efficacy and minimize bleeding irregularities.[55] The 21-day packs, if available, are better for adolescents who are taking OCPs in continuous or extended cycles.

The US Food and Drug Administration (FDA) recently approved a monophasic 30-μg ethinyl estradiol/0.15-mg levonorgestrel pill for extended cycling called Seasonale (Barr Pharmaceuticals, Woodcliff Lake, NJ). This formulation provides 84 days of continuous hormonally active pills followed by 7 days of placebo. This formulation may be particularly appropriate for adolescents with medical conditions such as anemia, severe dysmenorrhea, endometriosis, dysfunctional uterine bleeding, or Von Willebrand and other bleeding diatheses and adolescents who prefer amenorrhea.[56] In addition, adolescents who frequently miss OCPs may have lower failure rates when using continuous or extended regimens of OCPs with shorter or no placebo intervals.

TABLE 1 Medications That Decrease OCP Efficacy

Antibiotics
Rifampin (Rifadin, Rimactane)
Anticonvulsants
Felbamate (Felbatol)
Ethosuximide (Zarontin)
Primidone (Myidone, Mysoline)
Phenobarbital (Solfoton, Barbita, Luminal)
Phenytoin (Dilantin, Phenytek)
Carbamazepine (Tegretol)
Oxcarbazepine (Trileptal)
Topiramate (Topamax)
Antidepressants
St John's wort
Antifungal agents
Griseofulvin (Fulvicin, Grifulvin, Grisactin, Gris-PEG)
Anti-HIV drugs
Protease inhibitors
Nonnucleoside reverse transcriptase inhibitors

The noncontraceptive benefits of OCP use include improvement in acne and decreased menstrual cramping, pain, blood loss, and ovarian cysts. OCP use that exceeds 3 years provides significant protection against endometrial and ovarian cancers. Overall, observational data indicate that OCP use does not increase risk of breast cancer. Adverse effects include nausea, breast tenderness, headaches, and breakthrough bleeding. OCPs are one of the best-studied medications ever prescribed and are a safe option throughout a woman's reproductive years, because the method is completely reversible and has no negative effect on long-term fertility.[57]

OCPs have a failure rate of 0.1% when used perfectly. However, failure rates range between 5% and 8% with typical use and for adolescents may reach 15% to 26% because of noncompliance.[58] Adolescents may have difficulty complying with OCPs because of forgetfulness, attempts to hide contraception from parents, and inconsistency of sexual relations, among other reasons. The National Survey on Family Growth reported that as many as 42% of adolescents 15 to 19 years of age missed 2 or more pills in a 3-month period.[57] Adolescent compliance with OCP use may be enhanced by appropriate patient education and problem-solving techniques, which includes careful instruction regarding the use of OCPs; anticipatory guidance about adverse effects and their management; a discussion of correct pill usage (including when the first pill should be taken during the menstrual cycle or what to do if a pill or pills are late or missed); use of emergency contraception; and frequent follow-up and monitoring. Patients should also be encouraged to use condoms in conjunction with OCPs to provide protection against STIs and additional pregnancy prevention. In addition, when possible, involving the patient's mother can greatly enhance compliance with pill taking.[59]

OCPs have few contraindications in healthy female adolescents. Estrogen-containing OCPs are contraindicated for those with a history of thromboembolism or thrombophilia (ie, factor V Leiden mutation or protein C, protein S, or antithrombin III deficiencies); cyanotic heart disease or pulmonary artery hypertension; systemic lupus erythematosus associated with antiphospholipid antibody syndrome or renal disease, particularly associated with hypertension; or hepatic dysfunction. Patients who are taking anticonvulsant medications and HIV medications need to be counseled carefully and may be encouraged to use injectable progestins (Table 1).

Adolescents need not receive a complete gynecologic examination by the pediatrician before initiating OCPs or any other hormonal contraceptive method.[60] In most circumstances, the pelvic examination may be deferred and OCPs may be prescribed if the patient is healthy, is not pregnant, and has no contraindications to taking the pills. An inspection of the external genitalia and either a urine screen or vaginal swab for STIs may be substituted for a pelvic examination as a screening for initiation of contraceptive use. A pelvic examination is indicated for most situations in which abdominal pain is part of the presenting complaint in a sexually experienced adolescent. Sexually active female adolescents should be screened for STIs, especially chlamydia, at least annually and preferably with each new sexual partner.[61] Guidelines from the American Cancer Society and the American College of Obstetricians and Gynecologists recommend initiation of Papanicolaou (Pap) test screening within 3 years of first intercourse (whether consensual or nonconsensual) or by 21 years of age.[62]

Injectable Hormonal Contraception

Depot medroxyprogesterone acetate (DMPA) injection is a long-acting progestin that is given every 12 weeks (11–13 weeks) as a single 150-mg intramuscular dose. This method of contraception, also known by the brand name Depo-Provera (Pfizer, New York, NY), is highly effective in preventing pregnancy. In the first year of use, the probability of becoming pregnant is approximately 0.3%.[63] Available since 1992 in the United States, some experts believe that the use of this method since 1992 among adolescents who are at high risk of becoming pregnant is one factor responsible for the declining rates of adolescent pregnancy in the United States.[17] This method is convenient for women who do not want to have to remember to take their pill each day, cannot use the patch, or cannot use a contraceptive at the actual time of intercourse.[16] Other advantages include lack of estrogen-related adverse effects and, similar to OCPs, protection against endometrial cancer and iron-deficiency anemia.[64]

The major disadvantage of this contraceptive method for adolescents are menstrual cycle irregularities (present for nearly all patients initially), the need for intramuscular administration every 11 to 13 weeks, and potential adverse effects including acne, weight gain, headaches, and bloating. A new formulation, which is administered subcutaneously, contains 104 mg of medroxyprogesterone acetate (Depo-Subq Provera 104 [Pfizer]), and is given on the same dosing schedule as the intramuscular formulation, is now available. The subcutaneous route makes home administration of Depot-Provera possible, although there have been no studies of home use in the adolescent population. The lower dose could decrease suppression of pituitary function and ovarian estradiol production, although no conclusive data are yet available to indicate such an effect.[65] Two large open-label phase-3 studies have found subcutaneous DMPA to be equally effective as intramuscular DMPA; however, the irregular uterine bleeding that many patients complain of after initiating the drug also accompanies subcutaneous use. As with the intramuscular route, this adverse effect largely resolves over the

first year of use: amenorrhea increased from 26% of patients in month 3 of use to 55% during month 12.[66]

In addition to uterine bleeding irregularities, DMPA use over a prolonged period is associated with a delayed return to fertility, typically 9 to 18 months, while the endometrial lining returns to its pre-DMPA state and ovulatory function returns. Both subcutaneous and intramuscular DMPA show similar delays to fertility after injection.[67] However, for adolescent patients, such a delay does not usually pose a major deterrent to using this method. Both intramuscular and subcutaneous DMPA may be safely recommended for adolescents who have chronic illnesses (eg, seizures, sickle cell disease), are lactating, or are at risk of estrogen-related complications.[64]

Pediatricians should discuss potential adverse effects. Studies have shown that patients are more likely to continue DMPA use if they are counseled about potential irregular bleeding before their first injection, but these studies did not target adolescents specifically.[68] Clinicians must also ensure that the patient is not pregnant at the time of the initial injection and at each injection that occurs at an interval greater than 12 weeks.

Because DMPA suppresses circulating estradiol concentrations, it causes reductions in bone mineral density (BMD), which has generated some concern regarding the long-term effects. A prospective cohort study of adolescents aged 12 to 18 years found that BMD decreased 3.1% after 2 years of DMPA use, whereas BMD increased 9.5% in the controls who were using no hormonal method of contraception.[69] Some other studies have indicated an adverse impact on biochemical markers of bone formation and resorption as well as the decreased BMD.[70–72] In response to these concerns, the FDA issued a "black-box" warning regarding the risk of decreased BMD among DMPA users in November 2004.[73] Currently, the warning recommends limiting the use of DMPA to 2 years and using DMPA as long-term contraception only if other methods are inadequate. The warning also emphasized the lack of certainty regarding peak BMD attained later in life among users of DMPA, but experts think such a restriction may be unwarranted, especially for patients with no other alternatives for contraception. A recently published study of teens and young adult women documented complete recovery of BMD after DMPA use, thus offering some degree of reassurance about use not affecting long-term skeletal health of adolescent patients.[74] In addition, an increased incidence of fractures has not been reported in adolescents using DMPA.

It is important to consider other risk factors for osteoporosis and to tailor counseling and recommendations to each patient. Factors such as small body habitus, chronic alcohol or tobacco use, eating disorders, or illness that necessitates chronic use of corticosteroids may lead a clinician to recommend against DMPA use more strongly. All patients should be encouraged to include foods and/or supplements to ensure intake of at least 1300 mg of calcium each day along with 400 IU of vitamin D, to participate in weight-bearing exercise regularly, and to stop smoking as important measures to promote skeletal health. Using supplemental estrogen has been observed to prevent loss of BMD in 1 study of teens, whereas the use by teens of antiresorptive medications prescribed for postmenopausal women is definitely not recommended.[75] As with all hormonal methods of contraception, condoms should be used in conjunction with DMPA for protection from STIs.

Another injectable hormonal contraceptive (known by the product name Lunelle [previously manufactured by Pharmacia & Upjohn, Kalamazoo, MI]) combined estrogen and medroxyprogesterone acetate. Lunelle was made available in the United States after confirmation of safety in clinical trials in the United States and internationally. However, Lunelle was voluntarily withdrawn from the market by its manufacturer in September 2002 because some doses may not have contained enough hormone to prevent pregnancy. Women who used Lunelle required monthly clinic visits for the injection of medications. Adverse effects were similar to those of Depo-Provera and included weight gain, menstrual irregularity, headaches, and breast tenderness, although adverse effects were fewer than in trials with DMPA alone.[76,77] A general acceptance of and overall satisfaction with Lunelle by women in clinical trials suggested that this method was widely accepted, but its return into the market is not expected in the future.

Progestin Implants

Levonorgestrel implants, also known by the brand name Norplant (previously manufactured by Wyeth-Ayerst Laboratories, St Davids, PA), were highly effective long-acting progestin-only contraceptives that provided pregnancy prevention for up to 5 years. These implants required insertion of subcutaneous polymeric silicone capsules into the upper arm by a trained health care professional. The 6-rod Norplant system was the first progestin implant available in the United States but has been permanently removed from the US market.[78] Implanon (Organon USA, Roseland, NJ), a single-rod implant that contains etonogestrel, the active metabolite of desogestrel, has been used in Europe since 1998 and is now available in some areas of the United States. Highly effective (in clinical trials, no unintended pregnancies were reported in ~73 000 cycles), Implanon may remain in place for 3 years, but it is associated with irregular bleeding in many users, especially during the first year of use.[63]

Levonorgestrel implants are ideal for adolescents who desire an extended length of protection, feel unable to remember to take OCPs, or have already had 1 preg-

nancy. It is also an excellent contraceptive option for females who may have difficulty remembering to use a contraceptive on a daily basis or at the time of intercourse. The major disadvantages for use in the adolescent population include high initial cost and potential adverse effects such as breakthrough bleeding and headaches. The drugs listed in Table 1 also impair the efficacy of levonorgestrel implants. The difficulty of removal of the implant, in combination with these other disadvantages, made Norplant an unpopular form of contraception for adolescents, and although Implanon is easier to remove, it shares many of Norplant's adverse effects. In addition, condoms must be used in conjunction with progestin implants for protection against STIs.[63]

Other Combined Hormonal Contraceptive Methods (NuvaRing and Ortho Evra)

The vaginal ring (NuvaRing [Organon USA]; 15 μg ethinyl estradiol/120 μg etonogestrel) is a round, flexible device that measures 54 mm in outer diameter and 4 mm cross-sectionally; it is inserted in the vagina and stays in place for 3 weeks, with removal for 1 week to induce menstruation followed by insertion of a new ring. This soft silicone vaginal ring releases both estrogen and progestin hormones that protect against pregnancy for 1 month. The ring has been shown to have greater than 99% efficacy when used correctly by adult women. However, trials with adolescent populations have not been conducted. Compliance with the ring is high, and few adverse effects are experienced. Adverse effects would be the same as other combined hormonal methods, which include breast tenderness, headaches, nausea, and some breakthrough bleeding/spotting and an increased risk of the more serious condition of thrombotic events; local adverse effects may include vaginal symptoms of discharge, discomfort, and device problems.[55]

The combination hormonal transdermal adhesive skin patch (Ortho Evra [Ortho-McNeil Pharmaceutical, Raritan, NJ]) can be applied to the abdomen, upper torso, upper outer arm, or buttocks weekly by using 1 patch for each of 3 weeks in a row, followed by 1 week off the patch, during which a withdrawal bleed usually occurs. While in place, the 4.5-cm^3 contraceptive patch delivers 150 μg of norelgestromin and 20 μg of ethinyl estradiol daily. Efficacy rates from 1 study suggested that the overall annual probability of pregnancy was 0.8%, whereas the method failure probability was 0.6%, similar across age and racial groups.[55]

One study reported that women who use the patch are no more likely to become pregnant than women who use a combination OCP. At least 1 study indicated a higher rate of local adverse effects with adolescents who use the patch than with older patients; these effects include patches dislodging as well as irritation and hyperpigmentation.[79–81] Very concrete counseling regarding patch placement with adolescent patients, and perhaps even demonstration of initial placement, is helpful.[81]

Although compliance with using the patch is improved compared with OCPs, the risk of pregnancy with correct use of the patch was higher for women who weigh more than 198 pounds (0.9% in first 12 months of use) compared with women who weigh less (0.3%).[82,83] Obviously, the risks of pregnancy must be discussed as methods are considered; a pregnancy rate of 1% at the end of 1 year in a patient who weighs more than 200 pounds, refuses other methods, and chooses to remain sexually active is a more acceptable alternative than a pregnancy risk of 85% with no protection. For issues related to compliance, the added value of the patch should be considered. It has demonstrated increased compliance, which results in fewer contraceptive failures. Other possible adverse effects of combined hormone methods include temporary irregular bleeding, temporary breast discomfort, weight gain or loss, and nausea.

The most concerning possible adverse effect of transdermal contraception or any combined hormone method is risk of thrombotic events. In the large clinical trials of the transdermal contraceptive patch, 1 case of nonfatal pulmonary embolism occurred during use of the patch, and 1 case of postoperative nonfatal pulmonary embolism was reported. Recently, the higher bioavailability of estrogens delivered transdermally has prompted Ortho McNeil Pharmaceutical to issue a warning specifically related to risk of thrombotic events in Ortho Evra users.[84] An increased risk of venous thromboembolic disorders has been associated with the use of combination hormonal oral contraceptives compared with nonusers; generally, increases in rates by a factor of 3 to 6 have been reported in studies that evaluated healthy young women who had no other risk factors. A review of studies compared the risk of nonfatal venous thromboembolism (VTE) among different OCPs. The authors found that users of OCPs containing desogestrel, a third-generation progestin, had an increased risk compared with users of OCPs containing levonorgestrel.[85] Thus, a baseline risk for VTE of 1 per 10 000 person-years is increased to 3 to 4 per 10 000 person-years during the time when oral contraceptives are being used.[85] The risk is much greater in those over age 35 and those who smoke, especially if cigarette use equals or exceeds 15 cigarettes daily. Although smoking should be discouraged for teens and young adults, smoking and use of combined hormone methods of contraception are not contraindicated in this age group.[86] Whether the patch places teens and women at increased risk of VTEs compared with combined hormone OCPs is not known, because 2 different studies with different methodologies had different outcomes.[87] No studies to date have directly examined whether the patch increases the risk of

thrombotic events compared with other types of estrogen-containing methods. The risk of VTE is slightly elevated but still quite low for anyone on an estrogen-containing method compared with not being on a method. The risk of VTE associated with pregnancy should be weighed against the risks of the patch or any combined hormone method. Compared with the risk of VTE during pregnancy, risk of VTE associated with combined hormone methods is considered lower in healthy young women.[55]

As with oral or transvaginal combined contraceptives, condoms must be used in conjunction with each method for protection against STIs.

Intrauterine Devices

Intrauterine devices (IUDs) are inserted into the uterus and release hormones, ions, or enzymes that prevent sperm from fertilizing the ova or prevent implantation. The effectiveness of IUDs is influenced by several factors, including size of the IUD surface area and the type of IUD used. When used appropriately, IUDs are generally safe, effective methods of contraception with a failure rate of less than 1%. Condoms must be used in conjunction with IUDs for protection against STIs. IUDs have previously not been recommended for adolescents; risk of infection in teens (who often have multiple partners or are serially monogamous) and liability concerns (a patient who has not conceived before using an IUD may attribute future infertility to IUD use) have contributed to clinicians' reluctance to prescribe this method for adolescent patients. IUDs have not been shown to affect fertility in the absence of infection; however, STI rates in adolescent populations are certainly cautionary. In some cases, however, an IUD may be appropriate for an adolescent who already has children and is taking precautions to protect against STIs. Mirena (Berlex, Montville, NJ), a newly developed IUD that contains the progestin levonorgestrel, gradually releases the progestin over an effective period of 5 years and has a failure rate of 0.3%. This IUD may be particularly useful for adolescents with severe menorrhagia and dysmenorrhea, as has been shown in adult women. Also available is the copper IUD called ParaGard, which releases a small amount of copper that kills or immobilizes sperm before they can fertilize an egg. The ParaGard can be removed at any time but should be replaced after 10 years.[88]

Diaphragm and Cervical Cap

The diaphragm and cervical cap are barrier methods of contraception that also require use of a spermicide. Diaphragms are flexible latex cups that are inserted into the vagina before intercourse and must remain in place for 6 hours after intercourse. Cervical caps are latex or silicone cups with a firm rim that adhere to the cervix and provide continuous contraceptive protection for up to 48 hours. Because of risk of toxic shock syndrome, caps should not remain for more than 48 hours.[89] Consistent, correct use of these methods is critical for achieving a high rate of effectiveness. The failure rate of the diaphragm with perfect use is 6% and with typical use is 20%; for the cervical cap, the failure rate is 26% with perfect use and 40% with typical use.[89] These contraceptive methods may not be feasible for some adolescents, because they require a prescription and visit with a health care professional for a fitting, because 1 size does not fit all. The adolescent must also be comfortable and skilled with insertion. Incidence of urinary tract infection increases over baseline with both diaphragms and cervical caps; in addition, condoms must be used in conjunction with these devices for protection against STIs.[89]

Withdrawal

The withdrawal method, which involves the male partner's attempt to withdraw the penis before ejaculation, is still widely used by adolescents in sexual relationships. Adolescents should receive counseling that emphasizes the high failure rate of withdrawal for pregnancy prevention. On average, of every 100 women whose partners use withdrawal, 19 will become pregnant during the first year of typical use. It is important to stress that preejaculatory fluid can contain enough sperm to cause pregnancy. Pregnancy is also possible if semen or preejaculate leaks out onto the vulva. In addition, providers should stress that this contraceptive method does not provide protection against STIs.[90]

Fertility Awareness and Other Periodic Abstinence Methods

Using fertility-awareness methods as a contraceptive option depends on several factors and requires a strong knowledge of the menstrual cycle and reproductive fertility. This method involves the identification of fertile days within each menstrual cycle when intercourse is most likely to result in pregnancy. Couples can abstain during the fertile times of a woman's cycle or use a combination of either barrier or withdrawal methods. As many as 25% of users of these methods will experience an unintended pregnancy within the first year of use, with some estimates of the pregnancy rate even higher.[91] To optimize method efficacy, users of this method should track their menses on a calendar for 3 months while also checking and recording their basal body temperature daily and should check their cervical mucus consistency to track when they ovulate. Pediatricians should be prepared to teach adolescents about the menstrual cycle but should emphasize that ovulation may not be predictable in the first few year(s) after menarche. Thus, abstinence or more reliable methods should be recommended for adolescents. In addition, health care professionals should stress that this contraceptive method provides no protection against STIs if no barrier methods are used during periods of sexual activity.

Emergency Contraception

Emergency contraception can be administered in 2 ways: by orally administering hormones or by inserting a copper-releasing IUD. An IUD can be inserted to prevent pregnancy up to 5 days after unprotected intercourse but is usually not recommended for adolescents (see IUD section).

The most commonly prescribed and best-studied methods of emergency contraception are the combined estrogen-progestin (also called the Yuzpe regimen) and progestin-only regimens. There is now only 1 dedicated product for emergency contraception: Plan B (DuraMed Pharmaceuticals, Pomona, NY). Plan B, a progestin-only regimen that contains levonorgestrel, is widely available as 2 hormone pills that are taken within 72 hours of unprotected intercourse. The most recent data support extending the time limit of use to 120 hours after unprotected intercourse; however, emergency contraception's efficacy diminishes as hormonal administration becomes more remote from the unprotected intercourse event.[92–94] Adolescent patients especially should be counseled that Plan B is 90% effective if used within 24 hours, 75% effective if used within 72 hours, and approximately 60% effective if used within 120 hours. The Plan B regimen can now be simplified to give both tablets at one time without sacrificing efficacy or resulting in more adverse effects.[94] Combination OCPs may be used for emergency contraception when Plan B is not readily available; the dose depends on the specific product chosen.[95] A recent study found that combination OCPs with progestin norethindrone can also be used effectively for emergency contraception. This study found that even a single dose of the oral contraceptives or combined hormone method was effective for emergency contraception.[96] Adverse effects may include nausea, vomiting, and changes in the menstrual cycle during the month of use. The progestin-only regimen is generally preferred, because it is more effective and causes fewer adverse effects.[97,98] Overall, emergency contraceptives reduce the risk of pregnancy after unprotected sex by at least 74%.[99,100]

Most women who need emergency contraception can use it safely. If the patient or practitioner suspects pregnancy, a pregnancy test can be administered; however, pregnancy testing before emergency contraceptive use is not necessary. It is important to note that emergency contraception does not cause abortion and it is not teratogenic if taken in early pregnancy. Women who are already pregnant should not use emergency contraceptives because they are ineffective at terminating established pregnancies; however, using them inadvertently will not have an adverse effect on the fetus.[99] Six studies have found that providing emergency contraception in advance increases the likelihood of women using it when it is needed and does not increase sexual or contraceptive risk-taking behavior.[101–106]

As the AAP states in its policy statement on emergency contraception, reduction of unintended pregnancy is best achieved by strategies that include developing and implementing programs to help delay and reduce sexual activity and increasing the use of effective contraceptives.[95] However, the AAP continues to support improved availability of emergency contraception to adolescents and advocates clinicians' consideration of advance emergency contraception prescription to sexually active adolescents, recognizing that in some cases, emergency contraception may be quite valuable in preventing unintended pregnancy and that emergency contraception is most effective when used soon after unprotected intercourse.[95] Recently, the FDA approved over-the-counter access for Plan B for women 18 years and older, but Plan B still requires a prescription for those younger than 18 years.[107] In view of the potential value of emergency contraception, pediatricians should inform adolescents about the availability of emergency contraception; however, it should not be advocated as a routine method of contraception.

Newer Forms/Formulations of Contraception

The FDA recently approved the first chewable OCP, Ovcon 35 (Bristol Myers Squibb Company, Princeton, NJ), a spearmint-flavored, 28-day regimen pill that contains the same hormones used in standard OCPs. Women who chew the pills instead of swallowing them should drink 8 oz of liquid afterward to ensure that the full dose reaches the stomach.[108] Another method recently approved by the FDA is the FemCap, a soft silicone dome that covers the cervix. FemCap will be available by prescription in 3 sizes and is designed to last 48 hours per use.[89,109] New forms of contraception for males are also being studied, including an implantation system similar to Norplant, weekly and monthly hormone injections, and a contraceptive patch.[110] A progestin-only vaginal ring is being developed, and Norplant II (a 2-rod system as opposed to the 6-rod system in Norplant) is awaiting FDA approval. Condoms must be used in conjunction with these new forms of contraception for protection against STIs.

COMPLIANCE AND FOLLOW-UP

Frequent follow-up is important to maximize compliance for all methods of contraception, to promote and reinforce healthy decision-making, and to screen periodically for risk-taking behaviors and STIs. Follow-up visits should include periodic examinations, reassessment for contraception method, STI surveillance, and cervical cytologic screening (Papanicolaou test) when appropriate. The timing and frequency of reassessment will vary depending on the contraceptive method. In general, sexually active adolescents should have annual STI screening with consideration for repeat screening for chlamydia 3 to 6 months after a positive test result and

treatment and/or with each new partner.[111] Regularly scheduled visits need to occur to assess contraceptive issues such as use, compliance, adverse effects, and complications. Adolescents should receive ongoing support, personal guidance, and reinforcement to enhance effective and consistent contraceptive use, parental support (when possible), and couples counseling or the opportunity for couples interaction with the health care professional. In addition, condom use at each sexual intercourse must be advised and reinforced at every visit.

RECOMMENDATIONS

1. Pediatricians should encourage sexual abstinence as part of comprehensive sexuality education and services offered to their adolescent patients.
2. Pediatricians should be prepared to offer confidential, nonjudgmental education and risk-reduction counseling around issues of sexuality for adolescent patients, including teens with chronic illnesses and/or disabilities.
3. Pediatricians should be aware that extensive information regarding contraceptive choices and decisions for adolescents with chronic illness or disability are available in references and texts on adolescent medicine (see "Additional Resources").
4. Pediatricians should update each patient's sexual history regularly to counsel about and determine risk of STIs as well as needs for contraceptive initiation and management.
5. Time to counsel, educate, and solve problems regarding contraceptive needs and/or management needs to be a part of any given visit, or arrangements need to be made for a separate visit for contraceptive follow-up.
6. Pediatricians should encourage the consistent and correct use of latex condoms with every event of sexual intercourse.
7. Pediatricians should know that it is appropriate to prescribe contraceptives without a "first pelvic examination," but screenings for STIs, especially chlamydial infections, should not be delayed.
8. Pediatricians should ensure access to basic contraceptive services for their teen patients either within their office setting or by referral to appropriate services and/or sites.
9. Pediatricians who offer contraceptive services to adolescents should provide appropriate follow-up to ensure compliance and monitor for adverse effects and complications.

Controversies Concerning Vitamin K and the Newborn

ABSTRACT. Prevention of early vitamin K deficiency bleeding (VKDB) of the newborn, with onset at birth to 2 weeks of age (formerly known as classic hemorrhagic disease of the newborn), by oral or parenteral administration of vitamin K is accepted practice. In contrast, late VKDB, with onset from 2 to 12 weeks of age, is most effectively prevented by parenteral administration of vitamin K. Earlier concern regarding a possible causal association between parenteral vitamin K and childhood cancer has not been substantiated. This revised statement presents updated recommendations for the use of vitamin K in the prevention of early and late VKDB.

ABBREVIATION. VKDB, vitamin K deficiency bleeding.

BACKGROUND

Vitamin K deficiency may cause unexpected bleeding (0.25%–1.7% incidence) during the first week of life in previously healthy-appearing neonates (early vitamin K deficiency bleeding [VKDB] of the newborn [formerly known as classic hemorrhagic disease of the newborn]). The efficacy of neonatal vitamin K prophylaxis (oral or parenteral) in the prevention of early VKDB is firmly established. It has been the standard of care since the American Academy of Pediatrics recommended it in 1961.[1]

Late VKDB, a syndrome defined as unexpected bleeding attributable to severe vitamin K deficiency in infants 2 to 12 weeks of age, occurs primarily in exclusively breastfed infants who have received no or inadequate neonatal vitamin K prophylaxis. In addition, infants who have intestinal malabsorption defects (cholestatic jaundice, cystic fibrosis, etc) may also have late VKDB. The rate of late VKDB (often manifesting as sudden central nervous system hemorrhage) ranges from 4.4 to 7.2 per 100 000 births, according to reports from Europe and Asia.[2,3] When a single dose of oral vitamin K has been used for neonatal prophylaxis, the rate has decreased to 1.4 to 6.4 per 100 000 births. Parenteral neonatal vitamin K prophylaxis prevents the development of late VKDB in infants, with the rare exception of those with severe malabsorption syndromes.[2]

Oral administration of vitamin K has been shown to have efficacy similar to that of parenteral administration in the prevention of early VKDB.[4–6] However, several countries have reported a resurgence of late VKDB coincident with policies promoting the use of orally administered prophylaxis, even with multiple-dose regimens. In a 1997 review of these experiences by Cornelissen et al,[7] surveillance data from 4 countries revealed oral prophylaxis failures of 1.2 to 1.8 per 100 000 live births, compared with no reported cases after intramuscular administration. Newborns receiving incomplete oral prophylaxis tended to have a higher risk of developing VKDB, with rates of approximately 2 to 4 per 100 000. Small daily oral doses, as practiced in the Netherlands, may decrease the risk of late VKDB[8] and approach the efficacy of the parenteral route; however, this needs to be better studied.

Draper and Stiller,[9] using other data from Great Britain, have questioned the results of earlier studies of Golding et al[10,11] that attempted to show an association between intramuscular vitamin K administration in newborns and an increased incidence of childhood cancer. Using data from the National Registry of Childhood Tumors, they estimated the cumulative incidence of childhood leukemia. Three sources of data, including the estimates from Golding et al, provided rates of intramuscular vitamin K use over the same time frame. Their analyses failed to show a correlation between increased use of intramuscular vitamin K and the incidence of childhood leukemia.

The Vitamin K Ad Hoc Task Force of the American Academy of Pediatrics[12] reviewed the reports of Golding et al and other information regarding the US experience[13] and concluded that there was no association between the intramuscular administration of vitamin K and childhood leukemia or other cancers.

Additional studies that have since been conducted by other investigators have not supported a clinical relationship between newborn parenteral administration of vitamin K and childhood cancer. Ross and Davies[14] published a review of the evidence in 2000. They found no randomized or quasi-randomized evidence of an association between parenteral vitamin K prophylaxis and cancer in childhood. Ten case-control studies were identified, of which 7 found no relationship and 3 found only a weak relationship of neonatal administration of intramuscular or intravenous vitamin K with the risk of solid childhood tumors or leukemia.

PEDIATRICS (ISSN 0031 4005).

Recent research on the pathogenesis of childhood leukemia additionally weakens the plausibility of a causal relationship between parenteral administration of vitamin K and cancer. Investigations by Wiemels et al[15] suggest a prenatal origin of childhood leukemia. They found an acute lymphocytic leukemia-associated gene in 12 children with newly diagnosed acute lymphocytic leukemia and postulated that an in utero chromosomal translocation event combined with a postnatal promotional event results in clinical leukemia. Although intramuscular administration of vitamin K could conceivably be a postnatal promotional event, a genetic etiologic explanation further lessens the likelihood of a clinically significant relationship between intramuscular administration of vitamin K and leukemia.

There is concern that adequate vitamin K prophylaxis be provided to the increasing numbers of newborns who are breastfed exclusively to avoid an increased risk of late VKDB with its associated intracranial hemorrhage.[7]

RECOMMENDATIONS

Because parenteral vitamin K has been shown to prevent VKDB of the newborn and young infant and the risks of cancer have been unproven, the American Academy of Pediatrics recommends the following:

1. Vitamin K_1 should be given to all newborns as a single, intramuscular dose of 0.5 to 1 mg.[16]
2. Additional research should be conducted on the efficacy, safety, and bioavailability of oral formulations and optimal dosing regimens of vitamin K to prevent late VKDB.
3. Health care professionals should promote awareness among families of the risks of late VKDB associated with inadequate vitamin K prophylaxis from current oral dosage regimens, particularly for newborns who are breastfed exclusively.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Psychosocial Aspects of Child and Family Health

Coparent or Second-Parent Adoption by Same-Sex Parents

ABSTRACT. Children who are born to or adopted by 1 member of a same-sex couple deserve the security of 2 legally recognized parents. Therefore, the American Academy of Pediatrics supports legislative and legal efforts to provide the possibility of adoption of the child by the second parent or coparent in these families.

Children deserve to know that their relationships with both of their parents are stable and legally recognized. This applies to all children, whether their parents are of the same or opposite sex. The American Academy of Pediatrics recognizes that a considerable body of professional literature provides evidence that children with parents who are homosexual can have the same advantages and the same expectations for health, adjustment, and development as can children whose parents are heterosexual.[1–9] When 2 adults participate in parenting a child, they and the child deserve the serenity that comes with legal recognition.

Children born or adopted into families headed by partners who are of the same sex usually have only 1 biologic or adoptive legal parent. The other partner in a parental role is called the "coparent" or "second parent." Because these families and children need the permanence and security that are provided by having 2 fully sanctioned and legally defined parents, the Academy supports the legal adoption of children by coparents or second parents. Denying legal parent status through adoption to coparents or second parents prevents these children from enjoying the psychologic and legal security that comes from having 2 willing, capable, and loving parents.

Several states have considered or enacted legislation sanctioning second-parent adoption by partners of the same sex. In addition, legislative initiatives assuring legal status equivalent to marriage for gay and lesbian partners, such as the law approving civil unions in Vermont, can also attend to providing security and permanence for the children of those partnerships.

Many states have not yet considered legislative actions to ensure the security of children whose parents are gay or lesbian. Rather, adoption has been decided by probate or family courts on a case-by-case basis. Case precedent is limited. It is important that a broad ethical mandate exist nationally that will guide the courts in providing necessary protection for children through coparent adoption.

Coparent or second-parent adoption protects the child's right to maintain continuing relationships with both parents. The legal sanction provided by coparent adoption accomplishes the following:

1. Guarantees that the second parent's custody rights and responsibilities will be protected if the first parent were to die or become incapacitated. Moreover, second-parent adoption protects the child's legal right of relationships with both parents. In the absence of coparent adoption, members of the family of the legal parent, should he or she become incapacitated, might successfully challenge the surviving coparent's rights to continue to parent the child, thus causing the child to lose both parents.
2. Protects the second parent's rights to custody and visitation if the couple separates. Likewise, the child's right to maintain relationships with both parents after separation, viewed as important to a positive outcome in separation or divorce of heterosexual parents, would be protected for families with gay or lesbian parents.
3. Establishes the requirement for child support from both parents in the event of the parents' separation.
4. Ensures the child's eligibility for health benefits from both parents.
5. Provides legal grounds for either parent to provide consent for medical care and to make education, health care, and other important decisions on behalf of the child.
6. Creates the basis for financial security for children in the event of the death of either parent by ensuring eligibility to all appropriate entitlements, such as Social Security survivors benefits.

On the basis of the acknowledged desirability that children have and maintain a continuing relationship with 2 loving and supportive parents, the Academy recommends that pediatricians do the following:

- Be familiar with professional literature regarding gay and lesbian parents and their children.
- Support the right of every child and family to the financial, psychologic, and legal security that results from having legally recognized parents who are committed to each other and to the welfare of their children.
- Advocate for initiatives that establish permanency through coparent or second-parent adoption for

Technical Report: Coparent or Second-Parent Adoption by Same-Sex Parents

ABSTRACT. A growing body of scientific literature demonstrates that children who grow up with 1 or 2 gay and/or lesbian parents fare as well in emotional, cognitive, social, and sexual functioning as do children whose parents are heterosexual. Children's optimal development seems to be influenced more by the nature of the relationships and interactions within the family unit than by the particular structural form it takes.

CURRENT SITUATION

Accurate statistics regarding the number of parents who are gay or lesbian are impossible to obtain. The secrecy resulting from the stigma still associated with homosexuality has hampered even basic epidemiologic research. A broad estimate is that between 1 and 9 million children in the United States have at least 1 parent who is lesbian or gay.[1]

Most individuals who have a lesbian and/or gay parent were conceived in the context of a heterosexual relationship. When a parent (or both parents) in a heterosexual couple "comes out" as lesbian or gay, some parents divorce and others continue to live as a couple. If they do decide to live separately, either parent may be the residential parent or children may live part-time in each home. Gay or lesbian parents may remain single or they may have same-sex partners who may or may not develop stepparenting relationships with the children. These families closely resemble stepfamilies formed after heterosexual couples divorce, and many of their parenting concerns and adjustments are similar. An additional concern for these parents is that pervasively heterosexist legal precedents have resulted in denial of custody and restriction of visitation rights to many gay and lesbian parents.

Increasing social acceptance of diversity in sexual orientation has allowed more gay men and lesbians to come out before forming intimate relationships or becoming parents. Lesbian and gay adults choose to become parents for many of the same reasons heterosexual adults do. The desire for children is a basic human instinct and satisfies many people's wish to leave a mark on history or perpetuate their family's story. In addition, children may satisfy people's desire to provide and accept love and nurturing from others and may provide some assurance of care and support during their older years.

Many of the same concerns that exist for heterosexual couples when they consider having children also face lesbians and gay men. All parents have concerns about time, finances, and the responsibilities of parenthood. They worry about how children will affect their relationship as a couple, their own and their children's health, and their ability to manage their new parenting role in addition to their other adult roles. Lesbians and gay men undertaking parenthood face additional challenges, including deciding whether to conceive or adopt a child, obtaining donor sperm or arranging for a surrogate mother (if conceiving), finding an accepting adoption agency (if adopting), making legally binding arrangements regarding parental relationships, creating a substantive role for the nonbiologic or nonadoptive parent, and confronting emotional pain and restrictions imposed by heterosexism and discriminatory regulations.

Despite these challenges, lesbians and gay men increasingly are becoming parents on their own or in the context of an established same-sex relationship. Most lesbians who conceive a child do so using alternative insemination techniques with a donor's sperm. The woman or women may choose to become pregnant using sperm from a completely anonymous donor, from a donor who has agreed to be identifiable when the child becomes an adult, or from a fully known donor (eg, a friend or a relative of the nonconceiving partner). Lesbians also can become parents by fostering or adopting children, as can gay men. These opportunities are increasingly available in most states and in many other countries, although they are still limited by legal statutes in some places.

A growing number of gay men have chosen to become fathers through the assistance of a surrogate mother who bears their child. Others have made agreements to be coparents with a single woman (lesbian or heterosexual) or a lesbian couple.[2–4] Still other men make arrangements to participate as sperm donors in the conception of a child (commonly with a lesbian couple), agreeing to have variable levels of involvement with the child but without taking on the responsibilities of parenting.

When a lesbian or a gay man becomes a parent through alternative insemination, surrogacy, or adoption, the biologic or adoptive parent is recognized within the legal system as having full and more or less absolute parental rights. Although the biologic or adoptive parent's partner may function as

PEDIATRICS (ISSN 0031 4005).

a coparent, he or she has no formal legal rights with respect to the child. Most state laws do not allow for adoption or guardianship by an unmarried partner unless the parental rights of the first parent are terminated. An attorney can prepare medical consent forms and nomination-of-guardian forms for the care of the child in the event of the legal parent's death or incapacity. These documents, however, do not have the force of an adoption or legal guardianship, and there is no guarantee that a court will uphold them. Some states recently have passed legislation that allows coparents to adopt their partner's children. Other states have allowed their judicial systems to determine eligibility for formal adoption by the coparent on a case-by-case basis. Coparent (or second-parent) adoption has important psychologic and legal benefits.

Historically, gay men and lesbians have been prevented from becoming foster parents or adopting children and have been denied custody and rights of visitation of their children in the event of divorce on the grounds that they would not be effective parents. Legal justifications and social beliefs have presumed that their children would experience stigmatization, poor peer relationships, subsequent behavioral and emotional problems, and abnormal psychosexual development. During the past 20 years, many investigators have tried to determine whether there is any empiric support for these assumptions.

RESEARCH EVIDENCE

The focus of research has been on 4 main topic areas. Investigators have concentrated on describing the attitudes and behaviors of gay and lesbian parents and the psychosexual development, social experience, and emotional status of their children.

Parenting Attitudes and Behavior, Personality, and Adjustment of Parents

Stereotypes and laws that maintain discriminatory practices are based on the assumption that lesbian mothers and gay fathers are different from heterosexual parents in ways that are important to their children's well-being. Empirical evidence reveals in contrast that gay fathers have substantial evidence of nurturance and investment in their paternal role and no differences from heterosexual fathers in providing appropriate recreation, encouraging autonomy,[5] or dealing with general problems of parenting.[6] Compared with heterosexual fathers, gay fathers have been described to adhere to stricter disciplinary guidelines, to place greater emphasis on guidance and the development of cognitive skills, and to be more involved in their children's activities.[7] Overall, there are more similarities than differences in the parenting styles and attitudes of gay and nongay fathers.

Similarly, few differences have been found in the research from the last 2 decades comparing lesbian and heterosexual mothers' self-esteem, psychologic adjustment, and attitudes toward child rearing.[8,9] Lesbian mothers fall within the range of normal psychologic functioning on interviews and psychologic assessments and report scores on standardized measures of self-esteem, anxiety, depression, and parenting stress indistinguishable from those reported by heterosexual mothers.[10]

Lesbian mothers strongly endorse child-centered attitudes and commitment to their maternal roles[11–13] and have been shown to be more concerned with providing male role models for their children than are divorced heterosexual mothers.[6,14] Lesbian and heterosexual mothers describe themselves similarly in marital and maternal interests, current lifestyles, and child-rearing practices.[14] They report similar role conflicts, social support networks, and coping strategies.[15,16]

Children's Gender Identity and Sexual Orientation

The gender identity of preadolescent children raised by lesbian mothers has been found consistently to be in line with their biologic sex. None of the more than 300 children studied to date have shown evidence of gender identity confusion, wished to be the other sex, or consistently engaged in cross-gender behavior. No differences have been found in the toy, game, activity, dress, or friendship preferences of boys or girls who had lesbian mothers, compared with those who had heterosexual mothers.

No differences have been found in the gender identity, social roles, or sexual orientation of adults who had a divorced homosexual parent (or parents), compared with those who had divorced heterosexual parents.[17–19] Similar proportions of young adults who had homosexual parents and those who had heterosexual parents have reported feelings of attraction toward someone of the same sex.[20] Compared with young adults who had heterosexual mothers, men and women who had lesbian mothers were slightly more likely to consider the possibility of having a same-sex partner, and more of them had been involved in at least a brief relationship with someone of the same sex,[10] but in each group similar proportions of adult men and women identified themselves as homosexual.

Children's Emotional and Social Development

Because most children whose parents are gay or lesbian have experienced the divorce of their biologic parents, their subsequent psychologic development has to be understood in that context. Whether they are subsequently raised by 1 or 2 separated parents and whether a stepparent has joined either of the biologic parents are important factors for children but are rarely addressed in research assessing outcomes for children who have a lesbian or gay parent.

The considerable research literature that has accumulated addressing this issue has generally revealed that children of divorced lesbian mothers grow up in ways that are very similar to children of divorced heterosexual mothers. Several studies comparing children who have a lesbian mother with children who have a heterosexual mother have failed to document any differences between such groups on personality measures, measures of peer group relationships, self-esteem, behavioral difficulties, academic success, or warmth and quality of family relationships.[9,11,15,16,20,21] Children's self-esteem has been

shown to be higher among adolescents whose mothers (of any sexual orientation) were in a new partnered relationship after divorce, compared with those whose mothers remained single, and among those who found out at a younger age that their parent was homosexual, compared with those who found out when they were older.[22]

Prevalent heterosexism and stigmatization might lead to teasing and embarrassment for children about their parent's sexual orientation or their family constellation and restrict their ability to form and maintain friendships. Adult children of divorced lesbian mothers have recalled more teasing by peers during childhood than have adult children of divorced heterosexual parents.[23] Nevertheless, children seem to cope rather well with the challenge of understanding and describing their families to peers and teachers.

Children born to and raised by lesbian couples also seem to develop normally in every way. Ratings by their mothers and teachers have demonstrated children's social competence and the prevalence of behavioral difficulties to be comparable with population norms.[8,24] In fact, growing up with parents who are lesbian or gay may confer some advantages to children. They have been described as more tolerant of diversity and more nurturing toward younger children than children whose parents are heterosexual.[25,26]

In 1 study, children of heterosexual parents saw themselves as being somewhat more aggressive than did children of lesbians, and they were seen by parents and teachers as more bossy, negative, and domineering. Children of lesbian parents saw themselves as more lovable and were seen by parents and teachers as more affectionate, responsive, and protective of younger children, compared with children of heterosexual parents.[25,27] In a more recent investigation, children of lesbian parents reported their self-esteem to be similar to that of children of heterosexual parents and saw themselves as similar in aggressiveness and sociability.[15]

Recent investigations have attempted to discern factors that promote optimal well-being of children who have lesbian parents. The adjustment of children who have 2 mothers seems to be related to their parents' satisfaction with their relationship and specifically with the division of responsibility they have worked out with regard to child care and household chores.[28] Children with lesbian parents who reported greater relationship satisfaction, more egalitarian division of household and paid labor,[29] and more regular contact with grandparents and other relatives[30] were rated by parents and teachers to be better adjusted and to have fewer behavioral problems.

Children in all family constellations have been described by parents and teachers to have more behavioral problems when parents report more personal distress and more dysfunctional parent-child interactions. In contrast, children are rated as better adjusted when their parents report greater relationship satisfaction, higher levels of love, and lower interparental conflict regardless of their parents' sexual orientation. Children apparently are more powerfully influenced by family processes and relationships than by family structure.

SUMMARY

The small and nonrepresentative samples studied and the relatively young age of most of the children suggest some reserve. However, the weight of evidence gathered during several decades using diverse samples and methodologies is persuasive in demonstrating that there is no systematic difference between gay and nongay parents in emotional health, parenting skills, and attitudes toward parenting. No data have pointed to any risk to children as a result of growing up in a family with 1 or more gay parents. Some among the vast variety of family forms, histories, and relationships may prove more conducive to healthy psychosexual and emotional development than others.

Research exploring the diversity of parental relationships among gay and lesbian parents is just beginning. Children whose parents divorce (regardless of sexual orientation) are better adjusted when their parents have high self-esteem, maintain a responsible and amicable relationship, and are currently living with a partner.[22,31] Children living with divorced lesbian mothers have better outcomes when they learn about their mother's homosexuality at a younger age, when their fathers and other important adults accept their mother's lesbian identity, and perhaps when they have contact with other children of lesbians and gay men.[22,24] Parents and children have better outcomes when the daunting tasks of parenting are shared, and children seem to benefit from arrangements in which lesbian parents divide child care and other household tasks in an egalitarian manner[28] as well as when conflict between partners is low. Although gay and lesbian parents may not, despite their best efforts, be able to protect their children fully from the effects of stigmatization and discrimination, parents' sexual orientation is not a variable that, in itself, predicts their ability to provide a home environment that supports children's development.

AMERICAN ACADEMY OF PEDIATRICS

Committee on School Health

Corporal Punishment in Schools

ABSTRACT. The American Academy of Pediatrics recommends that corporal punishment in schools be abolished in all states by law and that alternative forms of student behavior management be used.

It is estimated that corporal punishment is administered between 1 and 2 million times a year in schools in the United States.[1] Increasingly, states are abolishing corporal punishment as a means of discipline, but statutes in some states still allow school officials to use this form of discipline.[2–4]

The American Academy of Pediatrics believes that corporal punishment may affect adversely a student's self-image and school achievement and that it may contribute to disruptive and violent student behavior.[1,5–7] Alternative methods of behavioral management have proved more effective than corporal punishment and are specifically described in the reference articles.[5–7] Physical force or constraint by a school official may be required in a limited number of carefully selected circumstances to protect students and staff from physical injury, to disarm a student, or to prevent property damage.

The American Academy of Pediatrics urges parents, educators, school administrators, school board members, legislators, and others to seek the legal prohibition by all states of corporal punishment in schools and to encourage the use of alternative methods of managing student behavior.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Adolescence

Counseling the Adolescent About Pregnancy Options

ABSTRACT. When consulted by a pregnant adolescent, pediatricians should be able to make a timely diagnosis and to help the adolescent understand her options and act on her decision to continue or terminate her pregnancy. Pediatricians may not impose their values on the decision-making process and should be prepared to support the adolescent in her decision or refer her to a physician who can.

ABBREVIATIONS. β-hCG, β-subunit human chorionic gonadotropin; hCG, human chorionic gonadotropin.

Pediatricians are likely to encounter adolescent patients who become pregnant and need counseling on the options available to them. The American Academy of Pediatrics continues to endorse the principles published in its statement on this topic in 1989,[1] namely:

1. The statement represents an objective guide for pediatricians assisting patients and their families in making decisions about adolescent pregnancy.
2. None of the options offered is necessarily ideal or universally preferred by physicians or their patients.
3. The pediatrician, the adolescent patient, and other concerned persons must be given complete information on all available options to help the adolescent make an informed decision.

More than 1 million individuals <20 years old become pregnant annually.[2–4] Slightly >50% of adolescent pregnancies result in a birth.[2,4] The basic approach to effective ethical counseling has not changed since the 1989 statement; however, medical, sociological, and technological advances warrant an update of earlier information.

Premarital sex, pregnancy, and abortion engender strong personal and individual feelings. Pediatricians and other health professionals should not allow their personal beliefs and values to interfere with optimal patient health care. The physician needs to respect the adolescent's personal decision and her legal right to continue or to terminate her pregnancy and not impose barriers to health services from another provider. Should a pediatrician choose not to counsel the adolescent patient about sexual matters such as pregnancy and abortion, the patient should be referred to other experienced professionals.

IDENTIFICATION

All pregnancy options benefit from an early diagnosis. Some adolescents will seek medical care with characteristic signs and symptoms of pregnancy or as the result of a positive home pregnancy test. However, pregnancy symptoms may also be vague and nonspecific, particularly in the younger adolescent. The pediatrician cannot always rely on the menstrual and sexual history of the patient to diagnose pregnancy. Psychological denial may exist to such an extent that the adolescent may not consider pregnancy to be the cause of her symptoms, even when it is evident to others.

Laboratory test results for pregnancy are likely to become positive before the appearance of clinical symptoms or signs on physical examination. A serum β-subunit human chorionic gonadotropin (β-hCG) assay may show positive results as early as 1 week after conception. Most pregnancies are diagnosed by monoclonal human chorionic gonadotropin (hCG) urine pregnancy tests, which are rapid, cost-effective, specific to hCG, and almost as sensitive as the serum hCG assays. These urine tests will also demonstrate positive results within 7 to 10 days after conception, before the first missed menstrual period. Office personnel can be educated to perform these tests. When there is clinical suspicion of pregnancy, a negative test result suggests the need to repeat the test in 1 to 2 weeks. The pediatrician should use the negative result of the pregnancy test as an opportunity for further counseling.

The physical diagnosis of a normal intrauterine pregnancy can usually be made by 6 weeks from the last menstrual period with the finding of an enlarged softened uterus during a pelvic examination. The fetal heart tones may be detected as early as 10 weeks' gestation by Doppler fetoscopy. The observation or notice of fetal movement occurs at about 20 weeks in women experiencing their first pregnancy. If questions remain about uterine size or the confirmation of pregnancy, obstetric consultation or ultrasonography should be arranged. Ultrasonography can confirm an intrauterine pregnancy, with cardiac activity demonstrable at approximately 6 weeks from the last menstrual period. Concurrent with pregnancy evaluation, appropriate testing for sexually transmitted diseases should be performed.[4,5] Early first trimester complications include ectopic pregnancy and spontaneous abortion, and these problems should be considered if abdominal pain or

This statement has been approved by the Council on Child and Adolescent Health.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

vaginal bleeding develops. An ectopic pregnancy should also be considered in a patient with a positive pregnancy test in the absence of expected uterine enlargement.

COMMUNICATION

While waiting for the results of a urine pregnancy test, the pediatrician has the opportunity to discuss the adolescent's expectations and feelings about her possible pregnancy. The pediatrician should convey the results of the pregnancy test to the adolescent alone in a private setting.

Minors have legal rights protecting their privacy about the diagnosis and treatment of pregnancy. Pediatricians should be familiar with local confidentiality laws being aware that they vary from state to state. In considering confidentiality, the pediatrician should assess the adolescent's ability to understand the diagnosis of pregnancy and appreciate the implications of that diagnosis. The diagnosis should not be conveyed to others, including parents, until the patient's consent is obtained, except when there are concerns about suicide, homicide, or abuse. The pediatrician should be sensitive to the possibility of sexual abuse or incest in the young or developmentally delayed pregnant adolescent. In those cases, the pediatrician should inform child protective services as required by the law in most jurisdictions.

Reactions to the diagnosis of pregnancy vary. Some adolescents may be pleased, while others may be upset or confused. Some may have already discussed potential options with their family or sexual partner. The pediatrician needs to be sensitive to family, social, and cultural issues that may influence the adolescent and her decisions about pregnancy.[5,6] Adolescents should be encouraged to include their parents in a full discussion of their options. The pediatrician should explain how parental involvement can be helpful and that parents generally are supportive. If parental support is not possible, minors should be urged to seek the advice and counsel of adults in whom they have confidence, including other relatives, counselors, teachers, or clergy. This is especially true for younger adolescents, age 12 to 15 years.

MANAGEMENT

The duration of the pregnancy should be assessed and documented because options depend on this assessment. Usually, the adolescent has the following options available:

1. Carrying her pregnancy to delivery and raising the baby.
2. Carrying her pregnancy to delivery and placing the baby for adoption.
3. Terminating her pregnancy.

The pediatrician should discuss with or counsel the adolescent about all three options or refer the adolescent to a health care professional who will discuss all three options.

Financial status should not deprive a person of her options for management of the pregnancy. The pediatrician should be knowledgeable about local funding resources for continuing or terminating her pregnancy. The patient should be counseled to consider all options, encouraged to return for as many visits as needed, and helped to understand the need to make a timely decision. She should be encouraged to include her parents and the father of the baby in these counseling sessions. If the adolescent is reluctant to reveal the identity of the father, the pediatrician should consider the possibility of sexual abuse, sexual assault, or incest. Pediatricians should be aware of state laws about reporting suspected abuse or statutory rape and take appropriate action.

The pediatrician should address any coexisting medical conditions—chronic medical illness, physical disability, or psychiatric illness—that could affect the decision to continue or terminate the pregnancy. If there is a question of the adolescent's mental competence to make an informed decision about the pregnancy, the pediatrician should be aware of state law and procedures necessary to make this determination.

If the adolescent decides to continue the pregnancy, the pediatrician should refer her for timely and appropriate prenatal care. Adolescents receiving prenatal care in comprehensive adolescent pregnancy programs generally have had better outcomes than adolescents not in such programs, and pediatricians may choose to refer preferentially to such programs, when available.[7] Family and social support systems are essential for optimal outcomes for young adolescent parents and their infants.[8]

Adoption is an important option for the pediatrician to discuss with the adolescent. To make appropriate referrals, the pediatrician should be familiar with the available medical, legal, counseling, and social service resources that facilitate adoption. Throughout the pregnancy, the adolescent should have the opportunity to discuss the possibility of adoption with the pediatrician or other health care professionals.

If the adolescent decides to terminate her pregnancy, the pediatrician should be knowledgeable about community resources, considering the stage of pregnancy and any coexisting medical conditions. The pediatrician should also consider the adolescent's financial resources and should be aware of local or federal law affecting the availability of services, parental notification, or consent.[9] With the anticipated US Food and Drug Administration approval of pharmacologic agents, such as mifepristone, and the availability of prostaglandin analogues and methotrexate to induce abortion nonsurgically, pediatricians need to become aware of the nature and availability of these methods and have a clear understanding of their role in the counseling, provision of care, or referral for these methods.

Whatever the adolescent's decision, the pediatrician should follow up with the patient to ensure that there has been a successful referral and that appropriate social support is in place and to discuss the prevention of future unintended pregnancies. If the adolescent chooses to continue her pregnancy, the pediatrician should remain available for further dis-

cussion during the pregnancy should later events require reconsideration of decisions made at the time of the initial confirmation of pregnancy. If the adolescent chooses to place the child for adoption or to terminate her pregnancy, the pediatrician should be available to provide for her subsequent health care and emotional support. In either case, the pediatrician should encourage the adolescent to continue her education and be available to help her identify appropriate community scholastic programs.

The diagnosis of pregnancy is a sensitive and emotional time for the adolescent, her family, and her sexual partner. A warm and accepting environment in which the adolescent feels sufficiently secure to explore her own feelings about pregnancy is essential. Becoming a parent, placing a child for adoption, or having an abortion may have significant personal and long-term consequences for adolescents. It is important to ensure continuing help and support, regardless of the adolescent's decisions about her pregnancy. Ideally, the pediatrician has the counseling expertise, an understanding of adolescent developmental and medical issues, and, often, a long-standing relationship with the patient, and, therefore, is the appropriate person to review these issues with her.

Committee on Children With Disabilities

Counseling Families Who Choose Complementary and Alternative Medicine for Their Child With Chronic Illness or Disability

ABSTRACT. The use of complementary and alternative medicine (CAM) to treat chronic illness or disability is increasing in the United States. This is especially evident among children with autism and related disorders. It may be challenging to the practicing pediatrician to distinguish among accepted biomedical treatments, unproven therapies, and alternative therapies. Moreover, there are no published guidelines regarding the use of CAM in the care of children with chronic illness or disability. To best serve the interests of children, it is important to maintain a scientific perspective, to provide balanced advice about therapeutic options, to guard against bias, and to establish and maintain a trusting relationship with families. This statement provides information and guidance for pediatricians when counseling families about CAM.

ABBREVIATION. CAM, complementary and alternative medicine.

STATEMENT OF THE PROBLEM

The use of complementary and alternative medicine (CAM) is increasing in Western countries. Indeed, more than one third of the adults in the United States have used CAM in recent years.[1,2] Pediatric use of CAM is especially likely among children with chronic illness or disability. Up to 50% of children with autism in the United States probably are using some form of CAM.[3] In many instances, the physician providing medical care is unaware of the concurrent use of CAM. Increasingly, pediatricians providing care for children with chronic illness or disability are discussing CAM with families or are asked to prescribe such treatments. Pediatricians' expertise in biomedicine may not adequately prepare them for discussion of CAM.

BACKGROUND INFORMATION AND DEFINITIONAL ISSUES

CAM has been defined as "a broad domain of healing resources that encompasses all health systems, modalities, and practices and their accompanying theories and beliefs, other than those intrinsic to the politically dominant health system of a particular society or culture in a given historic period."[4] An enormous array of unconventional therapies may be used as alternative therapies (instead of conventional treatments) or as complementary therapies (in addition to conventional treatments) (see Fig 1).

Currently, courses on CAM approaches are offered in the majority of US medical schools.[5] The US government established the Office of Alternative Medicine (now the National Center for Complementary and Alternative Medicine) in the National Institutes of Health to carry out scientific study of CAM.[6]

Biomedicine is based on laws of science and the rigorous applications of the scientific method. It may aptly be called scientific medicine or evidence-based medicine. Disease is explained by pathophysiologic processes, and treatments are designed to affect these processes. The term *biopsychosocial medicine* has long been used to describe a biomedical model that recognizes the importance of psychosocial factors.[7] Biomedical treatments are based on accumulated evidence of effectiveness from peer-reviewed scientific research. There is a hierarchy of research evidence, at the top of which is the controlled clinical trial. Many accepted biomedical treatments lack evidence of effectiveness from controlled clinical trials (eg, the use of physical therapy in the care of the premature infant). Unproven therapies also may be based on pathophysiology and limited research, but they lack accepted standards of proven effectiveness (eg, the use of immunoglobulins in the treatment of autism).[8] Alternative therapies are based on a variety of nonbiomedical beliefs and usually have not been subjected to clinical research. Most are supported by anecdotal evidence, but some alternative therapies have proven effectiveness. For example, preliminary studies of acupuncture in addiction treatment show positive results.[9] In time, such proven therapies may come into wider use and lose their "alternative" status.

Biopsychosocial medicine and CAM have at least one thing in common: both recognize that the relationship between physician-healer and patient is integral to the success of treatments offered. This is part of the age-old "art" of medicine and is a basis of the placebo response.[10] The emphasis of biomedicine on pathophysiology and on technical outcomes has reinforced the perception among some families that physicians undervalue their relationships with their patients. The failure of biomedicine to recognize and respond adequately to individual differences among patients is one reason families turn elsewhere and has contributed to the increasing use of CAM.

The distinctions among unproven therapies, CAM, and biomedicine may become especially blurred in the care of children with chronic illness or disability.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

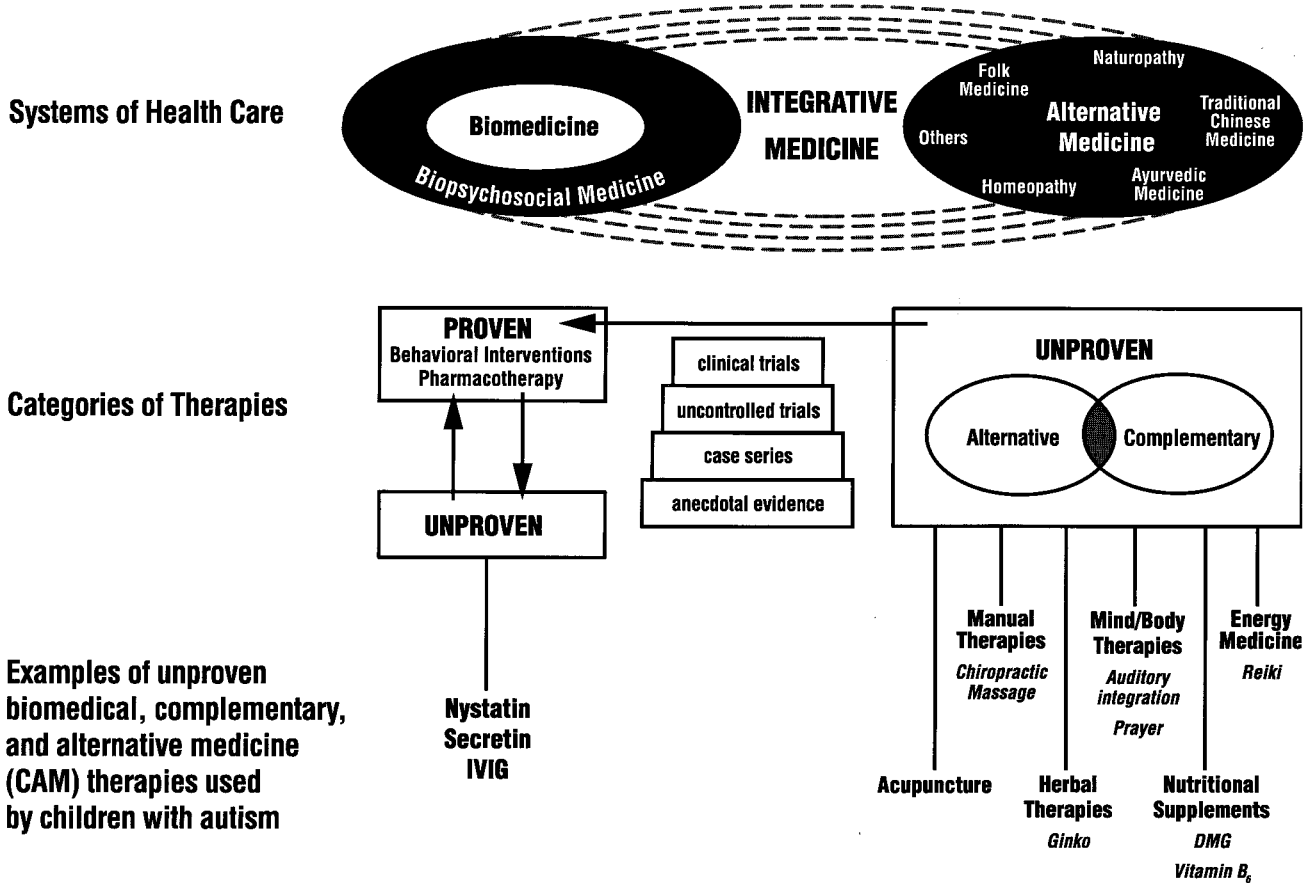

Fig 1. Biopsychosocial medicine and alternative medicine are broad systems of health care that encompass theories, practices, and therapies. Integrative medicine is a term loosely used to describe these systems used in combination. Therapies (whether biomedical, complementary, or alternative) are considered proven or unproven based on a hierarchy of evidence.

Some conventional biomedical therapies lack proof of effectiveness, and some unproven and alternative therapies may in time prove effective. Also, some alternative therapies conceivably may have placebo effects, which confer additional therapeutic gain and enhanced quality of life. These factors may present significant challenges to the health care professional. Moreover, there are no published clinical guidelines regarding the use of CAM in the care of children with chronic illness or disability.[11]

WHY PARENTS OF CHILDREN WITH CHRONIC ILLNESS OR DISABILITY CHOOSE CAM

Parental questioning of a child's diagnosis, treatment, and prognosis reflects a normal process of adjustment to the permanence or chronicity of the condition and the desire to ensure the best possible outcome for their child. Many parents become frustrated with biomedical therapies because of complexity, discomfort, bewildering technology, or uncertainty of cure. Indeed, for some conditions, biomedicine has little or nothing to offer. Also, families may be frustrated because they have not been sufficiently involved in the development of a care plan. The media, condition-specific publications, and parent-to-parent contacts provide essential opportunities for families to learn about resources, including CAM. Furthermore, the Internet has dramatically increased exposure of families to sophisticated marketing, testimonials, and unproven claims. Some parents are attracted to simple explanations of causality, some by an approach perceived to be more "natural." Many try a succession of alternative therapies, believing that any approach that does no harm is worth a trial. For almost all, CAM approaches represent an attempt to gain a sense of control over their child's chronic illness or disability and to improve quality of life.

BALANCING FAMILY-CENTERED CARE WITH THE ETHICAL RESPONSIBILITY OF THE PEDIATRICIAN

The "medical home" concept emphasizes that care should be compassionate and family-centered. Mutual participation in decision making and informed consent are essential elements of respectful care.[12] Decisions and plans should be made through a process of collaborative decision making in which the family receives complete and unbiased information needed to understand and make informed decisions. The quality of the relationship between the health care professional and patient with chronic illness has been shown clearly to affect outcomes.[13] Honest and supportive relationships with health care professionals can help parents cope[14] and promote the child's independence.[15] Such relationships are strengthened when health care professionals understand the perspectives of the family, provide care with flexibility, and attempt to meet the family's needs and expecta-

tions. Clearly, it is optimal for children with chronic illness or disability to receive health care in a setting that is family-centered. At the same time, pediatricians have an ethical responsibility to guard the welfare of children by ensuring that any treatment they endorse is "in accordance with science and proven experience."[16,17] Dilemmas may arise when families ask their pediatrician to endorse or to provide a therapy that is considered by the pediatrician not to be in the best interests of the child. There may be evidence of the possibility of direct harm, unknown risks, or concerns about indirect harm to the child. The pediatrician is in a position to balance a commitment to family-centered care with the ethical responsibility to guard the welfare of children.[18,19]

SUMMARY/CONCLUSION

The use of CAM approaches in the United States is increasing, especially among children with chronic illness or disability. Distinctions among unproven therapies, CAM, and biomedicine may become blurred, presenting special challenges to the pediatrician. To best serve the interests of children, it is important to provide balanced advice about therapeutic options, to guard against bias, and to establish and maintain a trusting relationship with families. Although the focus of this statement is chronic illness or disability, the recommendations that follow also may apply to the use of alternative medicine in other pediatric domains.

RECOMMENDATIONS FOR PEDIATRICIANS WHO DISCUSS ALTERNATIVE, COMPLEMENTARY, AND UNPROVEN THERAPIES WITH FAMILIES

1. Seek information for yourself and be prepared to share it with families.

   Families are likely to be appreciative of information you have obtained through literature searches. Reviews of CAM discuss currently popular alternative approaches and their attendant risks.[3,20–22] Also, Appendix I shows several Web sites that may be useful resources.
2. Evaluate the scientific merits of specific therapeutic approaches.

   Critical evaluation of claims of effectiveness requires training in the scientific method and an understanding of processes of disease. This training is equally important for evaluating conventional biomedical treatments and alternative therapies. Many CAM approaches are based on inconsistent or implausible biomedical explanations, and claims of effectiveness rest on anecdotal information and testimonials. The pediatrician can be uniquely helpful to parents seeking an assessment of the merits of specific therapies by evaluating such therapies and providing guidance.
3. Identify risks or potential harmful effects.

   Alternative therapies may be directly harmful by causing direct toxic effects, compromising adequate nutrition, interrupting beneficial medications or therapies, or postponing biomedical therapies of proven effectiveness. Indirect harm may be caused by the financial burden of the alternative therapy, other unanticipated costs (eg, the time investment required to administer the therapy), and feelings of guilt associated with inability to adhere to rigorous treatment demands. If a child receiving alternative therapy is at direct or indirect risk of harm, the pediatrician should advise against the therapy. In some circumstances, it may be necessary for the pediatrician to seek an ethics consultation or to refer to child welfare agencies. If there is no risk of direct or indirect harm, a pediatrician should be neutral.
4. Provide families with information on a range of treatment options (avoid therapeutic nihilism).

   Although effective treatments to cure the underlying condition or restore function may be lacking, there may be adjunctive treatments to improve quality of life, address specific concerns of the child or family, or modify environmental conditions that may be causing additional problems. Consultation with pediatric specialists may suggest therapeutic options. Discussion of a range of treatment options may avert feelings of frustration and powerlessness that drive families to alternative sources of care.
5. Educate families to evaluate information about all treatment approaches.

   Families should be informed about placebo effects and the need for controlled studies. The pediatrician should explain that anecdotal and testimonial evidence is very weak. Families also should be advised to be vigilant for exaggerated claims of cure, especially if such claims are for treatments requiring intense commitment of time, energy, and money on the part of the family.
6. Avoid dismissal of CAM in ways that communicate a lack of sensitivity or concern for the family's perspective.

   Some alternative therapies considered by families may warrant independent review and evaluation of scientific merit by the pediatrician. Respectful family-centered care rests on the pediatrician's willingness to listen carefully and to acknowledge the family's concerns, priorities, and fears, including social and cultural factors that may affect their choice of therapies. If CAM is chosen against the advice of the pediatrician, he or she should continue to offer care to the child.
7. Recognize feeling threatened and guard against becoming defensive.

   Families may express their opinions in ways that challenge the professional expertise of the pediatrician. They may bring to the discussion of CAM a number of biased assumptions that contribute to an atmosphere of distrust and an adversarial relationship. It may be helpful for the pediatrician to make empathic statements that acknowledge the families' deep concerns, thereby avoiding angry or defensive reactions.
8. If the CAM approach is endorsed, offer to assist in monitoring and evaluating the response.

   The pediatrician can help to establish clinical outcomes and target behaviors or symptoms that can be observed and measured. Sometimes, the

pediatrician and family can agree on a time-limited trial of the proposed approach.

9. Actively listen to the family and the child with chronic illness.

   The pediatrician should be aware of their concerns, their understanding of the condition, and their needs for support. Support groups and community networks can greatly enhance family comfort with the management of the chronic illness or disability.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Creating Healthy Camp Experiences

abstract

FREE

The American Academy of Pediatrics has created recommendations for health appraisal and preparation of young people before participation in day or resident camps and to guide health and safety practices for children at camp. These recommendations are intended for parents, primary health care providers, and camp administration and health center staff. Although camps have diverse environments, there are general guidelines that apply to all situations and specific recommendations that are appropriate under special conditions. This policy statement has been reviewed and is supported by the American Camp Association. *Pediatrics* 2011;127:794–799

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

BACKGROUND

For 150 years, children have been attending camp.[1] Today, approximately 11 million children attend day or resident camp, supported by 1.2 million staff members.[2] Currently, camp programs exist in myriad forms and cater to any interest or population imaginable. The camp experience has been proven to have a lasting effect on psychosocial development, including significant effects on self-esteem, peer relationships, independence, leadership, values, and willingness to try new things.[3] Camps also offer an opportunity to overcome a lack of connection with the natural environment, which has been associated with depression, attention disorders, and obesity.[4] Safety research has revealed that camps have a safety profile equivalent to, or better than, many other activities that parents choose for their children.[5]

Camp health care providers can expect to care for campers with any of the medical and psychological issues seen daily by primary pediatric providers. As a result, the precamp health evaluation takes on increased importance. Parents, the primary health care provider, camp administrators, and camp health care providers should openly share information to ensure that a camper is appropriate for his or her new environment. In addition, parents should medically and psychosocially prepare their child for camp. Camp administration must create appropriate policies and procedures and work in cooperation with local health care providers and facilities to ensure that off-site support is in place.

PREPARING CAMPERS

1. Before choosing a camp, parents or guardians should be encouraged to assess their child's interests, skills, and overall physical, mental, and emotional well-being and evaluate his or her ability

to effectively participate in a particular camp setting. Camp mission statements and promotional handouts can help guide parents when choosing an appropriate camping environment for their child. Before enrolling their child, parents should be aware of preadmission medical requirements for campers and the scope of health services available at camp.

Some day and overnight camps offer programs that require an increased level of physical fitness because of strenuous activities and/or geographic factors such as altitude or remote location. These camps may require a more extensive health evaluation relevant to the nature, conditions, and activities of the camp. Exact health requirements for participation will depend on the program.

2. All campers should provide the camp with a complete annual review of their health by a licensed health care provider, preferably before the first day of camp. This recommendation is consistent with the *Bright Futures* initiative.[6] The appropriateness of the camp's program for the individual camper should be addressed during that review, which, in turn, means that the health care provider must be provided pertinent information about the camp. An evaluation within the 6 months before camp arrival should be considered for children with ongoing health care needs.

   The annual review should include a comprehensive health history. The history should include the child's significant previous illnesses, surgeries, injuries, and allergies and present state of physical and psychological health. Campers with clinically significant medical histories or those with conditions that require long-term management (eg, asthma, seizures, diabetes, anaphylactic allergies, immunocompromise, congenital anomalies, mood or anxiety disorders, attention-deficit/hyperactivity disorder) should have specific medical clearance before participation. A management plan appropriate to the camp program that addresses any ongoing medical or psychological issues should be created. This plan should also address medications, both prescription and over-the-counter, to be used by the child while at camp.[7] Written orders from a licensed health care provider should be obtained for prescription medications, diets, physical activity limitations, or special medical devices. Additional information about coding and documentation related to providing these services is included in the Appendix.

3. Parents or guardians are responsible for providing to the appropriate camp representatives information about any changes in health status, recent travel, new medications, or any changes in maintenance medications. Elective interruption of medications (drug holiday) should be avoided by campers on long-term psychotropic therapy or those on maintenance therapy required for a chronic medical condition.[8–10]

4. Before starting camp, all campers should be in compliance with the recommended childhood immunization schedule published annually by the American Academy of Pediatrics (AAP), the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention, and the American Academy of Family Physicians.[11] Camp administrators should be aware that individual states might require other immunizations in addition to those recommended by the AAP. Polices must also be in place regarding participation in the camp program by campers who are incompletely immunized or unimmunized. People who travel internationally as part of a camp program should consult the Centers for Disease Control and Prevention traveler's health Web site or visit a traveler's clinic for information regarding particular immunization requirements or health concerns that may be associated with their destination.[12]

5. Some inexperienced campers experience acute psychological distress associated with separation from home and loved ones, which is commonly known as homesickness. The following interventions may be helpful for prospective campers and their parents, because they have been found to significantly reduce the incidence and severity of homesickness[9]:

   - Involve the child in the process of choosing and preparing for camp.
   - Discuss homesickness openly. Be positive about the upcoming camp experience and avoid expressing personal doubts or concerns.
   - Arrange practice time away from home with friends or relatives before camp.
   - Frame the time to be spent at camp in comparison with previous enjoyable experiences of similar duration that the child may have had.

Parents should avoid making "pick-up" arrangements in the event of homesickness, because these arrangements may undermine the child's confidence in his or her own independence. Health care providers should

discuss these interventions as part of the anticipatory guidance associated with the health evaluation before camp.

PREPARING THE CAMP

1. Camp administrative officials should have a clear understanding of the essential functions of a camper insofar as their specific camp program is concerned.[13] It is the responsibility of the camp to provide to parents, children, and precamp examiners expectations for successful participation in the camp program. Certain camp activities may increase the risk of complications from specific medical conditions (eg, scuba diving may trigger an asthma exacerbation). It should be a combined effort of parents, health care providers, and camp personnel to identify children who might be at risk and specify the extent of accommodations necessary for safe participation for that child.
2. All camps should have written health policies and protocols that have been reviewed and approved by a physician with specialized training in children's health, preferably a pediatrician or family physician. These policies and protocols should be tailored to the training and scope of practice of the on-site camp health care providers and should be developed with the input of those providers.[14,15] Camp administrators should inquire about the previous training and camp experience of the camp health care provider and provide additional training or support if necessary.[16]

   Camp health policies and protocols should address both major and minor illnesses and injuries and include information on the camp's relationship and coordination with local emergency services. Local emergency medical services providers should be contacted before camp begins to ensure prompt and coordinated response in the event of an emergency.[16,17] Camps should also establish relationships with local dentists and/or orthodontists who are willing to treat dental emergencies if the need arises and with local mental health professionals. The AAP encourages its members to cooperate with local camps in reviewing such policies and protocols and by providing medical support, if practical.

   Illnesses and conditions that commonly affect camp life should be considered for inclusion in protocols for treatment by camp health care providers, including:

   - fever;
   - conjunctivitis;
   - upper respiratory tract infections;
   - otitis externa and media;
   - streptococcal pharyngitis and sore throat;
   - vomiting and diarrhea (including large outbreaks);
   - asthma, anaphylaxis, and allergy management, including food allergies;
   - skin infections: impetigo, fungal, abscess;
   - lice and scabies;
   - dermatitis, including poison ivy and poison oak;
   - insect bites, stings, and tick exposure;
   - common injuries, head injury and concussion;
   - heat- or cold-related illness;
   - homesickness; and
   - behavioral or psychiatric episodes.

   The 2009–2010 H1N1 influenza pandemic and the emergence of methicillin-resistant *Staphylococcus aureus* (MRSA) have highlighted the need for increased screening and surveillance at camps and the ongoing importance of teaching good hygiene practices, the most important of which are good hand-washing and cough/sneeze behaviors. Camps should have in place management plans for infectious outbreaks.[18] These plans should include guidance for caring for ill campers or staff and for isolating ill people from the healthy population. Camp health care providers should also be aware of health hazards that are particular to their area (eg, Lyme disease, Rocky Mountain spotted fever).[19] A camp disaster plan should also be in place.

   On initial arrival at camp, all campers and staff should undergo a screening supervised by the camp health staff to assess the potential for communicable diseases, establish a health status baseline, and identify health problems such as impetigo or lice. Updated medication orders and health history should be made available to camp health staff at this time.
3. Camp health care providers with appropriate knowledge and training should be responsible for the safe storage and administration of medications. This responsibility varies with the type of camp (eg, a camp for children with diabetes or a camp for children with cancer). A protocol should be established for safe transport of medications during out-of-camp trips, and a determination should be made by the on-site health care provider as to the skill of camp personnel to administer medications and the safety of sending a particular child on the trip.[7]

   Camps that maintain oxygen or other emergency medication or equipment should periodically check supplies and ensure that necessary training has been completed. Recent guidelines support

the use of automated external defibrillators (AEDs) in children 1 year or older.[20] All camps should critically review the populations they serve and the need for an AED on site. Camps with an AED should comply with local regulations regarding required protocols and training for their use. With regard to personal emergency medications or medical devices such as inhalers or epinephrine autoinjectors, campers should be instructed in their use before arrival at camp. Parents should also make clear to the camp staff primarily responsible for the camper the situations that may require use of these medications and whether the child is competent in their administration. Specific protocols for administration of these medications or use of specialized equipment by the camper, counselors, or other nonlicensed providers should be created. These devices should be kept in locations that are easily accessible to the people who may need them.[7]

4. A health record system should be maintained that documents all camper and staff illnesses and injuries and that allows for surveillance of the camp illness and injury profile. In addition, camps should consider use of an electronic health record that is compliant with federal guidelines.[21] Camp records should include emergency contacts for all children. The parent or guardian with legal custody should be clearly indicated. Protocols for parental notification should be established. In addition, if a chronic condition exists, the child's primary care physician and any subspecialty physicians should be identified by name, telephone number, and e-mail address, and the date of the last health care visit should be noted.[22] Written authorization to obtain treatment, to transport children in camp vehicles for nonemergent care, and to share medical information should be provided by the parent or guardian.[23] Camps should make clear their requirements for health insurance coverage, and parents or guardians should ensure that their policy is in force at the camp's location. Confidentiality of health information should be maintained.[24] Camp health history and physical examination forms that meet the aforementioned recommendations and that have been reviewed by the AAP are available to camps and health care providers from the American Camp Association.[25]
5. It is important for all camps to have personnel who can administer onsite first aid and cardiopulmonary resuscitation (CPR), irrespective of their distance from definitive medical care. This statement does not address specific camp staff issues; however, those who are involved in waterfront activities should be certified in cardiopulmonary resuscitation.
6. Obesity and related cardiovascular risk factors are important public health priorities, and camp communities should adhere to principles of healthy living.[26] Food that is served and sold in camps should, at least, follow federal guidelines for school nutrition. Camp staff should model healthful food choices for their campers. Food should not be used as a reward, nor should withholding food be used as a punishment. At least 30 minutes of daily physical activity should be included as a component of any camp program. Plain water should be available throughout the day, and sweetened beverages, including sport drinks, should be strictly limited or simply not used.[27]
7. The principles promoted in this statement apply to all camps; it should be noted, however, that inclusion of children with disabilities and other special health care needs may require the establishment of additional assessments and services and that camps designed to serve that population of children and adolescents specifically will be equipped differently. Camp authorities should work with local pediatricians and other health care providers to conduct health appraisals for children before their participation in camp and determine appropriate services and programs for children with special needs.[22] In addition, camp personnel should be familiar with the health and safety guidelines for child care centers developed by the AAP, American Public Health Association, and Maternal and Child Health Bureau and should adhere to those that are appropriate to their programs and facilities.[28]

Parents should feel confident that their children are ready for camp and that their chosen camp is well prepared to care for their children. To this end, the AAP offers the aforementioned recommendations for creating a healthy camp experience.

APPENDIX: CODING AND DOCUMENTATION FOR CAMP/SCHOOL/SPORTS EXAMINATIONS

Pediatric providers should become skilled at and comfortable with establishing coding practices of (and expecting appropriate reimbursement for) their services in performing and documenting camp, school, and sports examinations.

CPT (*Current Procedural Terminology*) Coding

1. When possible, use the preventive medicine services codes (99381–99397). These codes most accurately describe both the comprehensive examination and counseling services rendered. Many camp, school, and sports forms require additional examinations (eg, measuring heart rate and blood pressure after exercise) or counseling (eg, asthma management related to exercise or high altitude) above and beyond the "standard" parameters included in annual evaluations.
2. If the need for examination arises after a patient has already received an annual preventive medicine services examination, health plans typically do not cover the cost of a second examination. Providers may elect to complete camp forms on the basis of a recent preventive medicine services visit or schedule an additional visit. If allowed by the child's insurance, parents may be billed for the additional noncovered services.
3. Office or other outpatient services codes (99201–99215) may be used if a problem is identified during the visit.
4. Office or other outpatient consultation codes (99241–99245) provide a possible alternative method if the "rule of 3 'Rs" is met:
   a. The service is requested by the camp or school (the office record should verify the request).
   b. The services (examination and documentation) are rendered by the provider.
   c. A written report (the completed camp or school form) is provided to the requesting camp or school.
5. In addition, the special report code (99080) may be reported if a provider is required to complete a specific camp or school form.

ICD-9-CM (International Classification of Diseases, Ninth Revision, Clinical Modification) Coding

1. Use code V20.2 if the camp or school service is incorporated into the annual "well-child care" visit.
2. Use code V70.3 if the camp or school service is a separate preventive medicine services, consultation, or office or other outpatient services visit.
3. Use specific problem-based code(s) if specific problems are found and addressed.

Documentation

1. Specific forms are usually provided by the camp or school. Once completed by the provider, these forms should contain documentation consistent with the provider's chart records.
2. Care should be exercised to avoid breaches of issues of confidentiality, especially with preteen and teenaged patients.
3. The American Camp Association has excellent resources to serve as guidelines for proper documentation of camp-related examinations (www.acacamps.org/knowledge/health/forms).

For coding questions, please contact the AAP coding hotline at aapcodinghotline@aap.org.

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

John J. Fraser, Jr, MD, JD; Gary N. McAbee, DO, JD; and the Committee on Medical Liability

Dealing With the Parent Whose Judgment Is Impaired by Alcohol or Drugs: Legal and Ethical Considerations

ABSTRACT. An estimated 11 to 17.5 million children are being raised by a substance-abusing parent or guardian. The importance of this statistic is undeniable, particularly when a patient is brought to a pediatric office by a parent or guardian exhibiting symptoms of judgment impairment. Although the physician-patient relationship exists between the pediatrician and the minor patient, other obligations (some perceived and some real) should be considered as well. In managing encounters with impaired parents who may become disruptive or dangerous, pediatricians should be aware of their responsibilities before acting. In addition to fulfilling the duty involved with an established physician-patient relationship, the pediatrician should take reasonable care to safeguard patient confidentiality; protect the safety of the patient and other patients, visitors, and employees; and comply with reporting mandates. This clinical report identifies and discusses the legal and ethical concepts related to these circumstances. The report offers implementation suggestions when establishing anticipatory office procedures and training programs for staff on what to do (and not do) in such situations to maximize the patient's well-being and safety and minimize the liability of the pediatrician. ***Pediatrics*** **2004;114:869–873;** ***judgment impaired, alcohol, substance abuse, disruptive parent, informed permission, informed consent.***

ABBREVIATIONS. AAP, American Academy of Pediatrics; HHS, US Department of Health and Human Services; OSHA, Occupational Safety and Health Administration.

INTRODUCTION

In the course of providing health care services to children, pediatricians may encounter situations in which a patient arrives at the office accompanied by a parent, guardian, or caregiver who displays signs of judgment impairment. In these circumstances, pediatricians are challenged by an array of professional, ethical, and legal obligations, some of which may conflict. Pediatricians have sought guidance from the American Academy of Pediatrics (AAP) on how to respond to these potentially volatile and risk-laden scenarios. The purpose of this clinical report is to analyze the physician's potentially conflicting duties and suggest ways that he or she can help both the child and the judgment-impaired adult in a situation fraught with legal complexity. This clinical report primarily addresses the situation in which the judgment of the parent, guardian, or caregiver is impaired by use of alcohol or drugs. However, the principles should be applicable to judgment impairment attributable to any cause (eg, prescription medication use, unstable medical condition such as diabetes, suspected dementia).

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

SCOPE OF THE PROBLEM

The Children of Alcoholics Foundation estimates that there are between 11 and 17.5 million children in the United States younger than 18 years currently living with a parent with alcoholism.[1] The number of children living in homes with an adult who abuses drugs is unknown. Clearly, this represents a substantial public health problem that most pediatricians will encounter at some point in their careers. Encounters with children accompanied by an impaired parent may take place wherever pediatric services are delivered. This report focuses on the legal and ethical issues pediatricians and their staff should consider when a patient's parent or guardian arrives at a pediatric office in a judgment-impaired state.

The profound effects of parental substance abuse on children have been described throughout the pediatric literature and summarized comprehensively in various AAP policy statements[2–4] and the manual on substance abuse.[5] A multidisciplinary working group developed a consensus paper titled "Core Competencies for Involvement of Health Care Providers in the Care of Children and Adolescents in Families Affected by Substance Abuse"[6] to identify the pivotal role of the primary health care professional in addressing the health needs of children in substance-abusing environments. It also suggests levels of responsibility and competencies for health care professionals in protecting the health and safety of these children. By virtue of their training and experience, pediatricians are well aware of the long-term risks to the child's physical, mental, and developmental health and safety associated with parental substance abuse. Therefore, it is not necessary for this clinical report to address the effects of parental substance abuse on the child. Instead, the report outlines the immediate risks and legal considerations associated with managing a parent or guardian

whose judgment is impaired from alcohol or drugs during a pediatric office visit.

LEGAL CONSIDERATIONS

Pediatricians should consider the following legal principles when dealing with the parent whose judgment is temporarily impaired by alcohol or drugs:

- the physician-patient relationship;
- the duty to act in the best interest and for the safety of the patient;
- the need to obtain informed consent;
- the importance of safeguarding patient confidentiality;
- the mandated reporting of suspected child abuse and neglect; and
- the duty as an employer and business owner to protect the safety of employees and visitors in the office.

At times, there may be apparent conflict in these obligations. Every case is unique. The general considerations in this report are provided to enable pediatricians to develop office policies responsive to these situations. In translating this guidance into office policy, pediatricians should seek advice from competent legal counsel to ensure that the office policy is appropriate for a specific health care facility in a given state. The report's implementation suggestions serve as general guidance and, as such, should not be considered a specific course of action for a specific situation.

PHYSICIAN-PATIENT RELATIONSHIP

The parents, guardians, or caregivers who accompany infants, children, adolescents, and young adults play an important role in pediatric encounters. Depending on the age and circumstances of the patient, the adult often provides consent to treatment, furnishes pertinent historical information on the family and the child, and is financially responsible for medical care. Nevertheless, the pediatrician needs to remember that the physician-patient relationship exists between the pediatrician and the child. Thus, the pediatrician's first duty is to the patient.

The physician-patient relationship conveys many duties; one is to prevent harm. If there is reason to believe that the parent's impaired judgment substantially risks harming the patient or others, the pediatrician should attempt to decrease that risk by the least restrictive means. For instance, an impaired parent should not be allowed to drive. Not only would the patient be in considerable danger if allowed to ride in a motor vehicle being driven by someone under the influence of chemical substances, but the parent and the public also would be endangered. Depending on the circumstances, taking appropriate action could involve securing alternate transportation (eg, calling a taxi, contacting another family member to intervene). It may necessitate reporting the situation to the appropriate authorities including police or child protective services if discussion with the parent fails to result in a safe and satisfactory resolution. Local laws regarding public drunkenness or impairment may specify the appropriate course of action. Failing to fulfill the duty owed to a patient may constitute medical negligence and may even subject the pediatrician to liability from third parties.

BEST INTEREST OF THE PATIENT

Parents are presumed to have the best interests of their children at heart. Parents exhibiting signs of alcohol or drug impairment may be incapable of caring for a child properly. Therefore, the pediatrician's actions should be guided by the child's best interest, especially when the parent's condition compromises his or her ability to share that interest.

CONSENT TO CARE

Consent to care is a complicated concept in pediatrics. The ethical and legal considerations have been articulated in a number of AAP policy statements.[7–9] Pediatricians should be aware that it is likely that judgment-impaired parents are incapable of giving informed consent for their children's medical treatment. Pediatricians may have to use their judgment in determining whether a parent is incapable of consenting for a child. In some situations, it may be apparent that the parent has recently used alcohol or drugs but may not necessarily be impaired. In these circumstances, the pediatrician should be very careful about providing nonemergent care because of liability concerns brought forth later about insufficient informed consent. Therefore, if the child, by virtue of age or legal status, cannot consent to his or her own medical treatment and the parent's competency to do so is uncertain because of the chemical impairment, it would be advisable to postpone routine nonurgent medical care until consent can be obtained. To provide nonurgent care without consent would risk allegations of unauthorized treatment and even battery.[10,11]

However, in hospital emergency departments, the Emergency Medical Treatment and Active Labor Act[12] (EMTALA) plays a role. Under this act, a physician in certain situations may be mandated to screen for an emergency medical condition regardless of consent. Additional care may need to be given in the absence of consent if a delay would result in a threat of harm to the child's life or health. The EMTALA requirement for a medical screening examination does not apply to physician offices.

CONFIDENTIALITY AND PRIVACY

Parents have a reasonable expectation that information provided to the child's physician during a medical encounter will be considered confidential and protected by applicable laws. Thus, physicians should take reasonable care to safeguard health information obtained from the parent or guardian concerning the family (health and social history). Additional safeguards may be needed for sensitive topics such as substance abuse. These efforts should be reflected in the medical office's security policies for protecting patient records and other forms of identifiable health data according to any state and federal

(Health Insurance Portability and Accountability Act of 1996 [HIPAA]) laws.[13,14]

Due care should be taken to ensure that discussions with parents, patients, and appropriate government agencies concerning the substance-abuse problem and the family are conducted in a manner that protects confidentiality. For example, if the receptionist notices that an adult appears to be intoxicated when checking in for an appointment, it might be prudent to isolate the impaired person from others so that he or she can be spoken to privately. That would be preferable to confronting the impaired parent in the reception area in the presence of his or her child and others. The office could have a policy in place to summon the impaired parent as though it were time for the child's appointment and usher him or her into a more private location (eg, an office, conference room, or examining room) and take the child ostensibly to be weighed or measured in another room. This not only would minimize the risk of the conversation being overheard by others but also could afford an opportunity to discuss the problem without the child being present. However, if the impaired parent is disruptive in the office reception area, quick action may be needed to contain the situation, and in such instances, keeping the impaired person from harming others would take precedence over preserving the confidentiality of his or her chemical impairment.

MANDATED REPORTING

Every state has enacted laws to mandate reporting of child abuse and neglect. This is a legal obligation that is extended to children outside the physician-patient relationship. The physician must put the child's best interest before the parent's expectation of privacy and comply with mandated reporting to child protective services.[15–17]

An issue paper from the US Department of Health and Human Services (HHS) titled "Current Trends in Child Maltreatment Reporting Laws" summarizes how the standards used to determine when a mandatory reporter is required to notify authorities of abuse or neglect vary slightly from state to state.[18] These variances include who is a mandated reporter, the level of knowledge or suspicion of abuse necessary to report, and what constitutes abuse. The HHS issue paper provides a summary of common themes and general information on this complex topic. State Web sites may offer additional guidance to health care providers on mandated reporting of child abuse. However, specific legal advice interpreting the applicable laws and regulations is necessary when developing office policies for these situations.

It is important that mandated reporters understand these nuances in their state law. The patient should be carefully assessed for other signs of neglect or abuse. To do otherwise puts the pediatrician at risk of prosecution for failure to report suspected abuse or neglect of the patient. Should the patient subsequently be harmed as a consequence of the physician failing to act, the physician could be sued for medical negligence or face possible sanctions from a state licensing board. Anyone who is mandated to report suspected child abuse or maltreatment and fails to do so could be subject to criminal charges and could be sued in a civil court for monetary damages for any harm caused by their failure to report.

Two states impose penalties on mandatory reporters who intentionally, negligently, or purposefully fail to report suspected abuse. A few states impose penalties without imposing a standard. Failure to report is classified as a misdemeanor in approximately 35 states. Typically, sanctions are in the form of a fine and/or imprisonment.

Of greater impact on mandatory reporters themselves are the provisions exposing them to civil lawsuits for failure to report. The potential financial liability for additional injury of a child whose maltreatment should have been detected and prevented by a timely report can be considerable.

If a mandated reporter makes a report in earnest concern for the welfare of the child, that reporter is immune from any criminal or civil liability that may result. However, this good-faith immunity may not be available when the liability results from willful misconduct or gross negligence by the mandated reporter. Approximately 30 states impose penalties for false reporting of abuse. The most common standards used are knowingly and/or willfully filing an unproven report of abuse or neglect. A few jurisdictions impose penalties for intentionally making an unproven notification of abuse or neglect.[18]

GENERAL DUTY

In recent years, health care facilities have become targets of violence. Thus, the Occupational Safety and Health Administration (OSHA) has imposed regulations requiring health care employers to establish policies and procedures to safeguard employees from violent actions. Specific recommendations are enumerated in the OSHA regulations under the general duty heading.[19] Several documents are available on the OSHA Web site (www.osha.gov) that can be helpful in establishing practical step-by-step safety policies to protect employees in health care settings from potentially violent visitors.

IMPLEMENTATION SUGGESTIONS

The following suggestions are intended to help pediatricians implement office policies and procedures that may minimize legal risks should a patient arrive at the medical office in the care of an adult whose judgment is impaired.

Safety

Conduct a safety audit of your facility, including procedures for management of judgment-impaired visitors. Establish an office policy and train staff to respond appropriately. Incorporate this policy into your OSHA compliance program. Review and update the policy periodically. If the procedure is implemented, document the incident, how it was handled, and any injuries that occurred and evaluate whether the safety policy needs to be revised as a result of this occurrence. Maintain these records in a secure area of the office. Contact your professional

liability insurance company to determine whether consulting services for developing such a loss-prevention program are available.

Confidentiality

Verify the confidentiality laws applicable in these situations and align your office confidentiality policies with these laws. Unless state laws indicate otherwise, the physician's duty to the patient should take precedence over the parent's expectation of confidentiality. Discuss with the parent your concerns regarding the risk to the child caused by his or her impairment in a compassionate, nonjudgmental fashion. Use the benefit of your previous rapport and professional relationship to show that the concern is for both the child's and the parent's welfare. Both the child and the parent should know what is happening and why it is necessary. Provide a referral for counseling to address the parent's substance abuse and its effect on the child. The Substance Abuse and Mental Health Services Administration of the HHS maintains a searchable directory of 12 000 facilities with treatment programs for drug and alcohol abuse throughout the United States (http://findtreatment.samhsa.gov).

Consent

Remember that an impaired parent cannot consent to medical treatment for the child. Therefore, it would be prudent to postpone nonurgent pediatric care until a time at which consent can be obtained. If no care is delivered, it is suggested that the physician document in the medical record that "valid and sufficient consent was not given by the parent for treatment today."

Mandated Reporting

It would be difficult to imagine how children under the care of an adult whose judgment is sporadically or habitually impaired by alcohol or drugs would not be at risk of harm. Use your best clinical judgment to determine the specific risks that the parent's condition poses to the child, and take action accordingly. Be knowledgeable of your state's laws governing reporting child abuse, standards of abuse, and consequences of failing to report for mandated reporters. Contacting child protective service agencies may be the only way to get treatment for the parent and protection for the child. If you believe that the judgment-impaired person may harm himself or herself or others, take action in accordance with applicable laws. Summoning for police escort or emergency personnel to transport the impaired adult to the emergency department for evaluation and treatment may be necessary. Should the child's custodial parent or guardian agree to it, it may be preferable to release the child to the care of a relative rather than have the child accompany the parent to the emergency department or police station. However, child protective services may be in the best situation to make such determinations.

The greatest risk is to do nothing.

TECHNICAL REPORT

Jane Knapp, MD, and Deborah Mulligan-Smith, MD; and the
Committee on Pediatric Emergency Medicine

Death of a Child in the Emergency Department

ABSTRACT. Of the estimated 40 000 American children ≤14 years old who die each year, approximately 20% die or are pronounced dead in outpatient sites, primarily the emergency department (ED). The ED is distinguishable from other sites at which children die, because the death is often sudden, unexpected, and without a previously established physician-patient care relationship. Despite these difficult circumstances and potentially limited professional experience with the death of a child, the emergency physician must be prepared to respond to the emotional, cultural, procedural, and legal issues that are an inevitable part of caring for ill and injured children who die. All of this must be accomplished while supporting a grieving family. There is also a responsibility to inform the child's pediatrician of the death, who in turn also must be prepared to counsel and support bereaved families. The American Academy of Pediatrics and American College of Emergency Physicians collaborated on the joint policy statement, "Death of a Child in the Emergency Department," agreeing on recommendations on the principles of care after the death of a child in the ED. This technical report provides the background information, consensus opinion, and evidence, where available, used to support the recommendations found in the policy statement. Important among these are the pediatrician's role as an advocate to advise in the formulation of ED policy and procedure that facilitate identification and management of medical examiners' cases, identification and reporting of child maltreatment, requests for postmortem examinations, and procurement of organ donations. *Pediatrics* **2005;115:1432–1437;** ***death, child, postmortem examination, family-centered care.***

INTRODUCTION

Background Information

The death of a child under any circumstances is tragic and devastating. It changes the lives of all those involved who grieve for a life that has ended prematurely. In the immediate aftermath of death there is a great deal of confusion and disbelief. Parents are left struggling with overwhelming emotions and searching for explanations for such a tragedy. Because it is so charged with emotion, this is a time when the skill of caring professionals in the emergency department (ED) can make a difference. This technical report provides support for professionals when they are faced with the difficult task of performing professionally and with compassion at the time of the death of a child.

Children who die and their families are a diverse group. No single policy, plan, or approach can address all the situations and circumstances of death. However, based on the fact that injury is the leading cause of death in children, it is inevitable that many deaths will involve emergency medical services (EMS) systems. An analysis of 1997 national mortality data showed that 16% of deaths in children <19 years old occurred in outpatient hospital sites, primarily the ED, and another 5% were declared dead on arrival at a hospital.[1] The frequently sudden, unexpected nature of a child's death in the ED is an important confounding factor, because even the relatively brief nature of the family's interaction with health care providers can have a profound and enduring impact.

A child's death involves family members, including siblings, and health care providers. Members of the involved health care team potentially include out-of-hospital providers, day care or school personnel, nurses, social workers, child-life workers, mental health professionals, chaplains, and physicians. When a child's death occurs in the ED, it involves both the emergency physician (EP) who cared for the child at the end of his or her life, the pediatrician who has cared for the child before death, and possibly other subspecialty physicians.

Establishing policy in areas of common interest and shared care is one focus of collaborative efforts between the Committees on Pediatric Emergency Medicine of the American Academy of Pediatrics (AAP) and American College of Emergency Physicians (ACEP). Our committees believe that this collaboration between professional organizations to establish consensus policy promotes the highest-quality emergency care for children. This collaboration lead to the jointly published "Death of a Child in the Emergency Department" policy.[2,3] This is the technical report to support those policy recommendations.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

Statement of the Problem

Forty thousand American children ≤14 years old died during the year 2000.[4] Providing and organizing child- and family-centered care at the time of death is the subject of the Institute of Medicine (IOM) report *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families*.[5] In this report, the IOM's Committee on Palliative and End-of-Life Care for Children and Their Families describes current practice and the numerous challenges to providing palliative and end-of-life care for children and families. Perhaps the foremost challenge is the inadequate amount of research on which to base policy. Faced with this recognized scarcity of data, this technical report relies on the available research, expert consensus opinion, and published experience to formulate recommendations.

Overall, the occurrence of a death of a child in the ED is an uncommon event. Thus, few physicians in emergency medicine or pediatrics have a great depth of experience on which to base their practice. Additionally, physicians lack training in palliative, end-of-life, and bereavement care.[6] Only 26% of primary care residency-training programs report education in end-of-life care.[7] Sixty-two percent of pediatric residency program directors who responded to a survey reported that their residents were involved in end-of-life situations, but only 42% indicated that their residents received direct education in palliative care.[8] In a survey of EPs, only 14% recalled having training in notifying parents of a child's death.[9]

Although the IOM has noted that, in general, research on palliative and end-of-life care for all children who die and their surviving families is very limited, there are even less data specific to the death of a child who has received EMS care. With only a modest amount of published EMS for children (EMS-C) research to direct practice, EDs must rely on principles of palliative care and other information such as consensus reports and clinical guidelines in the areas of mental health needs and bereavement practices for guidance.[10–13]

Clearly there are similarities between the needs of children and families in palliative care and those who die in the ED. Most applicable among these similarities are appropriate attention to pain relief; facility design; timely provision of information that is accurate, consistent, and expressed in language that families can understand; provision of immediate and long-term bereavement support; identification of community-based resources; and family involvement in decision-making. Other epidemiologic and medical considerations create unique needs specific to EMS-C for end-of-life care, which are described in "End-of-Life Care in Emergency Medical Services for Children," Appendix F of *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families*[14] and include the number and diversity of personnel involved, unique parental needs when a child dies suddenly and unexpectedly, and medical care issues in the context of sudden death. The areas of EMS-C end-of-life care in need of research investigation and evaluation are summarized in Table 1.

NEW INFORMATION

Education and Training

Education of health care professionals to provide palliative, end-of-life, and bereavement care to children and families is one of the major recommendations from *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families*. This education should include scientific and clinical knowledge and skills, interpersonal skills and attitudes, ethical professional principles, and organizational knowledge skills. A physician who is a skilled communicator with parents and able to convey empathy and compassion can minimize any misunderstandings that might arise during these difficult situations. Education should also consider the bereavement care of siblings and other child acquaintances.[15] These learning objectives are summarized in Table 2.

The understanding that the death of a child is an important, underaddressed issue in EMS-C has initiated efforts to fill gaps in education and training for emergency health care providers through established courses. The AAP Pediatric Education for Prehospital Professionals course contains a child and family

TABLE 1. Research Directions for End-of-Life Care in EMS-C

Issue	Research Questions
Bereavement	What is the association of acute, sudden, or unexpected loss with the development of posttraumatic stress disorder?
	What is the impact on the bereavement process of parental presence during the attempted resuscitation of a dying child?
Critical incident stress management	How does critical incident stress management affect emergency care providers in the short and long term?
	What are the important outcomes to evaluate?
Clinical research on resuscitation	What are the predictors of mortality during resuscitation in the prehospital and ED arenas?
	Is it beneficial to exercise extraordinary intervention in the resuscitation of children who have experienced prolonged hypoxic-ischemic injury?

TABLE 2. Educational Needs of Health Professionals to Provide Palliative, End-of-Life, and Bereavement Care to Children and Families

Learning Domain	Learning Objective
Cognitive knowledge and skills	Learning biological mechanisms of end-stage conditions
	Understanding the pathophysiology of pain and other physical and emotional symptoms
	Developing appropriate expertise and skill in the pharmacology of symptom management
	Acquiring appropriate knowledge and skill in nonpharmacological symptom management
	Understanding the tools for assessing patient symptoms, quality, and prognosis
	Recognizing when consultation with palliative care specialists is appropriate
	Understanding the epidemiology of death in childhood
	Learning clinical indications for and limits of life-sustaining treatments
Interpersonal skills and attitudes	Listening to child patient and families
	Conveying difficult news to children and their families
	Understanding and managing child and family responses to life-threatening illness
	Sharing goal setting and decision-making with the care team
	Developing skills in avoiding and resolving conflicts
	Cultivating empathy, compassion, humility, and altruism
	Developing sensitivity to religious and cultural differences
	Recognizing and understanding one's own feelings and anxieties about the death of a child
Ethical and professional principles	Acting as a role model of clinical proficiency, integrity, and compassion
	Determining and respecting child and family preferences
	Learning principles of end-of-life care
	Understanding societal and population interests and resources
	Balancing competing objectives or principles
	Being alert to personal and organizational conflicts of interests
Organization knowledge and skills	Developing and sustaining effective teamwork
	Identifying and mobilizing supportive resources
	Understanding and managing relevant rules and procedures
	Protecting children and their families from harmful rules and procedures
	Assessing and managing care options, settings, and transitions
	Making effective use of existing financial resources

In: Field MJ, Behrman RE, eds. *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families.* Washington, DC: National Academy Press; 2003:332–333.

interaction module that addresses sudden infant death syndrome, family responses to the death of a child, and community resources for support.[16] The current AAP/American Heart Association Pediatric Advanced Life Support course contains an optional module on coping with death and dying that discusses the priorities for family support.[17] *APLS: The Pediatric Emergency Medicine Resource*[18] has sections on family presence during procedures and resuscitation attempts including CPR, termination of CPR, and the approach to the deceased child and family.

Family-Centered Care

Family-centered care is an approach to health care that shapes health care policies, programs, facility design, and day-to-day interactions among patients, families, physicians, and other health care professionals. The AAP outlined the core principles of family-centered care in the policy statement "Family-Centered Care and the Pediatrician's Role."[19] This statement recommends that parents and guardians should be offered the option to be present with their child during medical procedures and offered support before, during, and after the procedure. The statement does not make recommendations regarding family presence during situations of resuscitation or CPR. Both the Emergency Nurses Association and the American Heart Association recommend that health care providers should offer family members the opportunity to be present during CPR whenever possible.[20,21] The *APLS: The Pediatric Emergency Medicine Resource*,[18] developed jointly by the AAP and ACEP, notes that the family's presence during CPR can help in the acceptance of the child's death.

Additional evidence shows that most family members favor having the choice to be present during resuscitation attempts and that they tend to feel that being present was helpful.[22–27] Results from psychological examinations suggest that family members present during resuscitation attempts have more positive grieving behavior than family members not present during resuscitation attempts.[28] Despite these facts, parents and family members often do not ask if they can be present.

The presence of family members during resuscitation attempts prompts consideration of many additional issues including medicolegal issues. For this reason the Emergency Nurses Association has recommended that multidisciplinary consensus guidelines be developed to help organizations and institutions formulate policy regarding family presence during procedures and CPR. If multidisciplinary consensus can be achieved, these guidelines will be helpful in defining when and how to offer the option of family presence and thus in establishing ED policy.

There is a need for additional research regarding the effects of family presence. The IOM Committee on Palliative and End-of-Life Care for Children and Their Families cautions that most studies on family presence during resuscitation attempts are small, often retrospective, and limited in scope. Because this is such a critical experience for parents and care providers, they recommend that additional system-

atic research on the bereavement outcomes and other consequences of family-presence policies be conducted.

Team-Oriented Approach

The care team can include out-of-hospital providers such as emergency medical technicians and paramedics, social workers, child-life workers, mental health professionals, chaplains (including the families religious or spiritual leader), nurses, and physicians; each team member must understand his or her role. It is essential that team members work together to ensure that the occurrence of a death of a child is managed smoothly and with sensitivity.

Sensitive care includes awareness and respect for varied beliefs and cultural backgrounds. In a country as diverse as the United States, there can be profound differences between families and health care providers in beliefs and practices concerning the end of life. Additionally, open communication may be hampered by language barriers. Because cultural issues are most acute if language barriers are present, it is important that EDs and hospitals have rapid, efficient access to translators. In all cases, the health care team must remain sensitive to issues such as family methods for decision-making, the care of the body after death, and culturally appropriate expressions of grief. This is a daunting task. Appendix D of *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families*, titled "Cultural Dimensions of Care at Life's End for Children and Their Families,"[29] is a complete discussion of the relevance of cultural difference at the end of life.

Effective counseling, especially at the time of death, has a dramatic, positive impact on the family's grieving process, ultimate recovery, and ability to cope.[30–32] When possible, it is helpful to let the family know that the child was not in pain or did not suffer. One team member should be assigned to be with the family continuously during the resuscitation attempt. The purpose of this individual is to answer questions, explain procedures, and/or prepare the family and bring them to the resuscitation area.[33]

The EP has the responsibility of notifying the family of the child's death. The EP also has the responsibility of speaking with the family regarding the circumstances of death and notifying the family if there are concerns of child maltreatment that must be reported and investigated.

Care for the child does not stop with death. Family members should be encouraged to be with their child after death. Many authors have emphasized that being with the child after death is an integral part of bereavement.[34,35] Some families may wish to bathe the child themselves. Many will want to hold and rock their child. Providing the space to do this can be a challenge for creative administrators. However, the benefits to the families in these devastating situations are tremendously positive and enduring. The exact nature of aftercare will be determined and sometimes limited by the circumstances of the child's death, cultural practices, religious beliefs, and practical issues of facilities within the ED. Legal and medical examiner requirements may limit what is done in terms of removing resuscitation tubes and lines. The ED team can be sensitive and supportive by cleaning the resuscitation area and the body, covering disfiguring injuries and wounds as much as possible with clean sheets, and carefully explaining the purpose of remaining tubes or lines.

Kits with plastic molds for an imprint or three dimensional mold of the child's hands and/or feet and Ziploc bags to store a lock of the child's hair can be stored in the ED. Parents surveyed after their child's death have found these small mementos helpful in easing the bereavement after the tragic event.[36]

In addition, a chaplain, social worker, child-life therapist, and/or psychologist should be made available to the family. Families will have immediate and long-term mental health needs. Attention must be paid to the siblings (who are often overlooked in such overwhelming situations), grandparents, and classmates. The pediatrician has a role in monitoring the siblings for signs of emotional and somatic complaints that could be secondary to the death. Also, primary care physicians should take the lead in directly asking families how they are doing. At the very least, a condolence card should be signed by the direct care providers and sent to the family home, along with a list of community resources for grief and loss.

NOTIFYING THE PEDIATRICIAN AND SUBSPECIALISTS OF THE CHILD'S DEATH

The process of bereavement begins in the ED and continues over time. Many children who die have had an established medical home, and others have had complex medical problems for which they may have received care and established relationships with several providers. These pediatricians and/or subspecialists should be notified at the time of such a child's death. They can be a vital source of counsel and support for the bereaved family.

ASSISTING ED STAFF, OUT-OF-HOSPITAL PROVIDERS, AND OTHERS WHO ARE EXPERIENCING CRITICAL INCIDENT STRESS

The professionals who care for children who die after receiving care in the EMS system are also at risk for emotional distress including posttraumatic stress disorder. Access to appropriate mental health services should be available to provide immediate counseling for members of the ED health care team.

POSTMORTEM EXAMINATIONS AND TISSUE AND ORGAN DONATION

In most jurisdictions, the sudden and unexpected death of a child occurring in the field or ED is considered a medical examiners case requiring an autopsy. These legal requirements must be explained to the family.

It is important to explain to families that the extent of an autopsy is often limited to the relevant injury and that there will be no additional disfiguration that would interfere with an open-casket ceremony. Additionally, if it is desired, the medical examiner will often honor requests to restore all organs to the original location.

The AAP Committee on Child Abuse and Neglect has published several policy statements to aid professionals by providing information and guidelines that are helpful in situations in which sudden infant death syndrome and other unexpected infant and child deaths must be distinguished from child abuse. These policies and statements include "Investigation and Review of Unexpected Infant and Children Deaths,"[37] "Distinguishing Sudden Infant Death Syndrome From Child Abuse Fatalities,"[38] and "Addendum: Distinguishing Sudden Infant Death Syndrome from Child Abuse Fatalities."[39] These difficult situations require the collaboration of health professionals to ensure the appropriate utilization of available medical specialists and the preservation of evidence and the performance of additional studies such as an appropriately performed skeletal survey or toxicologic screens. Many child-fatality–review teams have established guidelines for evidence preservation and suggestions for documentation for cases of sudden pediatric death.

Cases that are not referred to the medical examiner should also be considered for autopsy. A forthcoming report from the American College of Medical Genetics on newborn screening notes that we may gain a better understanding of the incidence and spectrum of diseases associated with perinatal and early childhood mortality by implementing uniform child autopsy policies and procedures which ensure availability of appropriate studies (including metabolic and genetic studies for all perinatal deaths, including stillbirths) and early unexpected childhood deaths. Currently, autopsy can provide additional information in more than one third of pediatric deaths,[40] including previously undiagnosed findings, complications, and unsuspected contributors to death.[41–43] This information may be of importance to parents and other relatives in future family planning and to physicians in helping to educate and improve the quality of care in medicine. Providing this information can help parents to make an informed decision when they are asked about permission for postmortem examination. This must be implemented with sensitivity and respect for the family beliefs and values.

Hospitals are required by federal and state laws to have a mechanism for requesting organ donation from the appropriate family members or surrogates.

SUMMARY/CONCLUSIONS

Of the estimated 40 000 American children who die each year, approximately 20% die or are pronounced dead in outpatient sites, primarily the ED. The processes and protocols surrounding the death of a child in the ED are underaddressed and understudied issues related to end-of-life care. Because death in the ED is usually sudden and unexpected, the traditional patient-physician relationship has not been established, the family has not been counseled and advised, and the EP is expected to provide an environment for grieving parents that addresses their emotional, spiritual, and cultural needs while also providing support in responding to legal and procedural demands.

It is unfortunate that, currently, there are few evidence-based data to guide policy in responding to the unique needs of parents and families when a child's death occurs. The recommendations set forth by the AAP, ACEP, and the IOM are vital in solving this problem. Improving the education of physicians in end-of-life care is extremely important. Meeting objectives such as improving and developing clinical knowledge and skills, interpersonal skills and attitudes, ethical principles, and organizational skills can and will help EPs and other team members provide exemplary palliative, end-of-life, and bereavement care to children and families. In addition, creating a family-centered environment in the ED that involves them in the care process can have a positive bereavement effect.

For many families, the process of bereavement after the loss of a child begins in the ED. When a sensitive and understanding environment is provided, the family will truly be in the presence of a system of "care."

Death of a Child in the Emergency Department: Joint Statement by the American Academy of Pediatrics and the American College of Emergency Physicians

Note: Please be advised that the American Academy of Pediatrics and the American College of Emergency Physicians are in the process of independently developing technical reports on this issue that will provide more in-depth educational and clinical information for their respective members on the death of a child in the emergency department. When completed, these reports will be published separately by each organization to supplement this joint policy statement.

ABBREVIATION. ED, emergency department.

The death of a child in the emergency department (ED) is an event with emotional, cultural, procedural, and legal challenges that often distinguish it from other deaths.

The American Academy of Pediatrics and the American College of Emergency Physicians support the following principles:

- Emergency physicians should use a family-centered and team-oriented approach when a child dies in the ED.
- Emergency physicians should provide personal, compassionate, and individualized support to families while respecting social, religious, and cultural diversity.
- Emergency physicians should notify the child's primary care physician of the death and, as appropriate, work with the primary care physician in follow-up of postmortem examination results.
- EDs should incorporate procedures to organize resources and staff to provide a coordinated response to a child's death. These include the following:
  - Working with the primary care physician to ensure notification of subspecialty physicians of the death of their patient.
  - Educating staff as to the resources available to assist families.
  - Facilitating identification and management of a medical examiner's case and identification and reporting of cases of child maltreatment.
  - Promulgating liaisons with other individuals and organizations that may assist families, communities, and staff.
  - Assisting ED staff, out-of-hospital providers, and others who are experiencing critical incident stress.
  - Facilitating organ procurement and obtaining consent for postmortem examinations when appropriate.

TECHNICAL REPORT

Diagnosis of HIV-1 Infection in Children Younger Than 18 Months in the United States

Jennifer S. Read, MD, MS, MPH, DTM&H, and the Committee on Pediatric AIDS

ABSTRACT

The objectives of this technical report are to describe methods of diagnosis of HIV-1 infection in children younger than 18 months in the United States and to review important issues that must be considered by clinicians who care for infants and young children born to HIV-1–infected women. Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be detectable in the child's bloodstream until 18 months of age. Therefore, routine serologic testing of these infants and young children is generally only informative before the age of 18 months if the test result is negative. Virologic assays, including HIV-1 DNA or RNA assays, represent the gold standard for diagnostic testing of infants and children younger than 18 months. With such testing, the diagnosis of HIV-1 infection (as well as the presumptive exclusion of HIV-1 infection) can be established within the first several weeks of life among nonbreastfed infants. Important factors that must be considered when selecting HIV-1 diagnostic assays for pediatric patients and when choosing the timing of such assays include the age of the child, potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and of the child, and characteristics of the virus. If the mother's HIV-1 serostatus is unknown, rapid HIV-1 antibody testing of the newborn infant to identify HIV-1 exposure is essential so that antiretroviral prophylaxis can be initiated within the first 12 hours of life if test results are positive. For HIV-1–exposed infants (identified by positive maternal test results or positive antibody results for the infant shortly after birth), it has been recommended that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. If any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection can be made on the basis of 2 positive HIV-1 DNA or RNA assay results. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 antibody test result obtained at ≥6 months of age. Alternatively, presumptive exclusion of HIV-1 infection can be based on 1 positive HIV-1 virologic test with at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age) or negative HIV-1 antibody test results (at least 1 of which is performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative

virologic test results, 1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age, or 2 negative HIV-1 antibody test results from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection. Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age. For breastfeeding infants, a similar testing algorithm can be followed, with timing of testing starting from the date of complete cessation of breastfeeding instead of the date of birth.

INTRODUCTION

Most children acquire infection with HIV-1 through mother-to-child transmission (MTCT) of the virus.[1] MTCT of HIV-1 can occur in utero, at the time of labor and delivery, and postnatally through breastfeeding.[2] Before treatment or interventions to prevent transmission were available, the rate of MTCT of HIV-1 in the United States was approximately 25%.[3] Major successes have been achieved in prevention of MTCT of HIV-1 in the United States; the MTCT rate has decreased to less than 2%[4] with antiretroviral treatment of HIV-1–infected pregnant women and, for women who do not yet require treatment of their HIV-1 infection, with the use of the following efficacious interventions to prevent transmission: antiretroviral prophylaxis,[3,5–11] cesarean section before labor and before rupture of membranes,[12] and complete avoidance of breastfeeding.[13] The estimated annual number of perinatal HIV-1 infections in the United States has decreased from a peak of 1650 infections in 1991[14] to an estimated 111 infections in 2005.[15] Similarly, the estimated number of perinatally acquired cases of AIDS in the United States peaked in 1992 (945 cases) but subsequently decreased by 95% by 2004 (90 cases).[16]

Despite the dramatic decrease in rate of MTCT of HIV-1 and in the number of pediatric HIV infections and AIDS cases in the United States, MTCT of HIV-1 has not been eradicated in the United States. The timely and accurate determination of the HIV-1 infection status for all children born to HIV-1–infected women is essential. Concomitant with improvements in prevention of MTCT of HIV-1 in the United States, significant advances have been made in the treatment options for HIV-1–infected infants and children. Thus, in contrast to the early years of the epidemic, when therapy for HIV-1 infection was nonexistent or very limited, the outlook today for pediatric patients with HIV-1 infection is much improved. HIV-1 infection now represents, with appropriate therapy, a chronic disease; early antiretroviral treatment allows prolonged symptom-free survival with preservation of immune system function. Exclusion of HIV-1 infection is also important for HIV-1–exposed but uninfected children so that opportunistic infection prophylaxis does not have to be instituted or can be discontinued and so that age-appropriate immunizations for HIV-1–uninfected children can be administered.

Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be present in the child's bloodstream until 18 months of age. As work progresses on eradication of pediatric HIV-1 infection, knowledge and understanding of the available diagnostic modalities for infants and young children, as well as factors that affect the choice and timing of implementation of such diagnostic methods, is essential for the timely provision of appropriate care for both HIV-1–infected and –uninfected infants and young children. The objectives of this technical report are to describe methods of diagnosis of HIV-1 infection in children younger than 18 months in the United States and to review important issues that must be considered by clinicians who care for infants and young children born to HIV-1–infected women. Obviously, the protection of the privacy of health information as required by state and federal laws, as well as the laws and regulations regarding consent for HIV-1 testing, are important issues, but they are outside the scope of this technical report.

METHODS OF DIAGNOSIS OF HIV-1 INFECTION

Both clinical and laboratory-based methods for the diagnosis of HIV-1 infection in children have been developed. Laboratory-based methods include both immunologic and virologic assays.

Clinical Diagnosis

Beginning in the late 1980s, the World Health Organization (WHO) developed clinical case definitions and clinical staging systems for HIV-1 infection.[17–21] In addition, the WHO and the United Nations Children's Fund developed the "integrated management of childhood illness" strategy to provide guidelines for the diagnosis and management of sick children at the primary care level.[22] However, evaluations of clinical staging systems for the diagnosis of HIV-1 infection in children in sub-Saharan Africa, especially in young infants, have suggested limited sensitivity.[23–25] The WHO has released revised case definitions of HIV-1 infection for surveillance purposes and a revised clinical staging classification of HIV-1–related disease in adults and children.[26] Included in these guidelines are clinical criteria for the presumptive diagnosis of severe HIV-1 disease (among HIV-1–seropositive, HIV-1–exposed children younger than 18 months in situations in which virologic testing is not available) to allow for the early initiation of antiretroviral therapy.

Similarly, in the United States, guidelines for the clinical staging of HIV-1 disease were developed in the early years of the epidemic.[27–29] Subsequently, new definitions

of HIV-1 infection in children were published,[30] including clinical diagnosis of HIV-1 infection (a child younger than 18 months who is born to an HIV-1–infected mother and who meets criteria for diagnosis of AIDS on the basis of the 1987 surveillance case definition[27] is defined as being HIV-1 infected). A clinical classification system for children, originally intended for the classification of severity of HIV infection for surveillance purposes, comprises 4 clinical stages that range from asymptomatic infection to AIDS.[30] However, dependence on clinical signs and symptoms for the diagnosis of HIV-1 infection has been largely superseded in the United States and similar settings because of the availability of laboratory-based methods for diagnosis of HIV-1 infection. With virologic assays, the determination of HIV-1 infection status can be accomplished within the first few weeks of life.

Laboratory-Based Methods of Diagnosis

Laboratory-based methods for the diagnosis of HIV-1 infection can be divided into 2 groups: immunologic and virologic. Immunologic assays detect the antibody response to HIV-1 or the extent to which the immune system has deteriorated as a consequence of HIV-1 infection. Virologic assays detect HIV-1 genetic material or components of the virus. All laboratory tests used for the diagnosis of HIV-1 infection must be confirmed (ie, the diagnosis of HIV-1 infection is never based on only a single test result).

Immunologic Assays

Immunologic assays, which detect the antibody response to HIV-1 and are used as screening tests, include enzyme immunoassays or enzyme-linked immunosorbent assays (ELISAs) as well as rapid serologic tests. A Western blot assay or an indirect immunofluorescence assay (IFA) is used to confirm reactive screening test results. These assays are currently available.

Assays that provide an assessment of immune system abnormalities include $CD4^+$ and $CD8^+$ T-lymphocyte absolute counts and percentages, the $CD4^+/CD8^+$ T-lymphocyte ratio, and other assays. Such assays are not currently used routinely to diagnose HIV-1 infection but have been and are being evaluated for such use.

Detection of HIV-1 Antibodies

Antibodies against HIV-1 are found in essentially all HIV-1–infected individuals. An important exception is HIV-1–uninfected children who are born to HIV-1–infected women; even in the absence of infection with HIV-1, these children may have detectable HIV-1 antibodies until 18 months of age. Situations in which HIV-1–infected individuals fail to produce a detectable antibody response against this virus are unusual but have been observed during the acute ("preantibody" or "window") phase of infection (ie, during the first several weeks after infection) and during the very late stages of HIV-1 infection, when immune suppression is severe.[31]

Enzyme-Linked Immunosorbent Assays In general, an HIV-1 ELISA involves adding a patient's fluid sample to inert substrates that contain HIV-1 antigen.[32] Usually, diluted serum or plasma is used, but assays that use urine and oral fluid are also available. For assays that have been approved by the US Food and Drug Administration (FDA), see www.fda.gov/cber/products/testkits.htm. Positive and negative controls for each ELISA are tested in parallel with patient specimens. If anti–HIV-1 antibody is present in the test sample (primary antibody), it will bind to the HIV-1 antigen on the plate. The plate is then washed, and an enzyme-labeled secondary antibody ("conjugate") is added and will bind to human antibody. A chromogenic chemical substrate is applied, which is modified by the enzyme, resulting in a color change in an inert substrate (eg, microtiter well or physical strip/spot). In the case of a microtiter well-based assay, a spectrophotometer measures the resultant optical density. In this situation, a positive, or reactive, ELISA result occurs if the optical density of a patient sample microtiter well significantly exceeds the value calculated as the "cutoff" value. The microtiter optical density cutoff value is determined by using specific algorithms particular to each test kit method, but all kits use, to some degree, the optical density of the parallel negative controls as part of their calculations. As noted above, any ELISA with a reactive (positive) result should be repeated on the same blood sample, and if the result of the ELISA is repeatedly reactive, then the result is confirmed with a Western blot or IFA (see "Indirect Immunofluorescence Assays"). In general, a negative result with the ELISA requires no further confirmatory testing, although for persons suspected of being in the preantibody or window period of early HIV-1 infection, virologic assays (see "Virologic Assays") could be performed or follow-up testing with ELISAs could be performed at a later date.

False-negative results can occur among individuals who are HIV-1–infected but have not yet begun to produce antibodies against HIV-1 (ie, within the first 6 weeks of infection, including those with clinical signs and symptoms of the acute retroviral syndrome)[33] or among individuals in the late stages of HIV-1 infection with concomitant hypogammaglobulinemia. It is important to note that false-positive ELISA results can occur among individuals with immune stimulation (eg, among those with acute [non–HIV-1] viral infections or autoimmune disorders, among pregnant women, and among recipients of multiple transfusions).[32] Finally, because of transplacental transfer of maternal immunoglobulin G (IgG) antibody, children born to HIV-1–infected women are seropositive (even if the child is not HIV-1–infected). Therefore, a positive ELISA result in a child younger than 18 months must be confirmed virologically (see "Virologic Assays") before the child can be considered

HIV-1–infected. (However, a positive ELISA result confirms that the child was exposed to HIV-1.) There are no reliable HIV-1–specific antibody assays to differentiate between maternal and autologous antibody in the child.

ELISAs are less expensive than virologic assays, and they can be readily used for testing large batches of samples. However, their use in batch testing means that, generally, there is a delay of up to 1 week in obtaining test results, depending on the laboratory system used, and such delays often preclude their use in settings such as labor-and-delivery units. This factor was one impetus for the development of the rapid antibody tests described in the next section.

Rapid Tests A number of rapid serologic tests for detection of IgG antibodies against HIV-1 are now available (for assays that have been approved by the FDA, see www.fda.gov/cber/products/testkits.htm). Such assays are based on 1 of 4 principles: particle agglutination, immunodot (dipstick), immunofiltration, or immune chromatography.[32] For example, test kits that include HIV-1 antigens attached to a test strip allow detection of HIV-1 antibodies, if present in the test fluid sample (oral fluid, whole blood, serum, or plasma), through a rapid, visually interpreted color change. Rapid HIV-1 antibody tests are comparable to ELISAs in both sensitivity (99.3%–100%) and specificity (98.6%–100%).[34] They require no special instrumentation outside of the test kit, and results can be available in as little as 20 to 30 minutes. Some of these kits are licensed for point-of-care testing so that clinics without extensive laboratory facilities (but that meet state and federal standards and have appropriately trained personnel) can perform the tests on-site and report the result to the patient immediately. As with routine ELISAs, confirmation of positive results is necessary, but confirmation of a negative result is not. Note that ELISAs cannot be used to "confirm" a rapid-test result, and all reactive rapid HIV-1 test results should be confirmed with either a Western blot or an IFA.[35]

Semiquantitative Antibody Assays Traditional HIV-1 antibody assays have been modified to produce a semiquantitative value. Semiquantitative HIV-1 antibody assays evaluate the quantity of antibody and not simply its presence or absence. Thus, HIV-1–uninfected infants and young children would have decreasing quantities of maternal antibody as more time elapses after birth. Conversely, HIV-1–infected children would lack evidence of such a decrease in the quantity of antibody (because although maternal antibodies against HIV-1 will decay over time, the child will begin to produce antibodies against HIV-1). Although such assays have been advocated for the diagnosis of HIV-1 infection in pediatric patients in resource-limited settings,[36] they have not been incorporated into routine HIV-1 diagnostic algorithms for infants and young children in the United States (because the optimal performance characteristics of such assays generally do not become apparent until late infancy).

Western Blot Assays An immunoblot assay, such as a Western blot assay, typically is used to confirm a reactive ELISA or rapid serologic test result as being truly positive. The Western blot assay detects and visualizes the presence of antibodies against specific HIV-1 proteins (structural and enzymatic).[32] HIV-1 proteins are separated according to their molecular weight by electrophoresis and transferred electrophoretically to a membrane. The subsequent steps are similar to those of the ELISAs. A patient's fluid sample (usually diluted serum or plasma, but assays that use urine and oral fluid are also available; for assays approved by the FDA, see www.fda.gov/cber/products/testkits.htm) is added to the membrane and incubated. If the patient's sample contains antibodies against any of the blotted HIV-1 proteins, these antibodies will bind to them in the areas where the respective proteins are located on the membrane. If antigen-antibody binding takes place, it can be visualized by an enzyme-labeled reaction that involves an anti-Ig (causing visible "bands" to appear on the membrane where the antibody bound the protein).

Different organizations have developed criteria for interpretation of HIV-1 Western blot assay results on the basis of the pattern of bands observed. HIV-1 proteins and their corresponding bands on the Western blot are designated as "p" (protein) or "gp" (glycoprotein), along with molecular weight in kilodaltons. There are 3 groups: envelope (env) glycoproteins (gp41, gp120, gp160), nuclear (gag) proteins (p18, p24/25, p55), and endonuclease-polymerase (pol) proteins (p31/p34, p40, p51/p52, p65/p68). According to the criteria of the Association of State and Territorial Public Health Laboratory Directors,[37] a positive assay result is one that indicates the presence of antibodies to any 2 of the following proteins: p24, gp41, or gp120/gp160. An assay result that indicates no reactivity against any HIV-1 proteins is interpreted as being negative. An assay result that shows reactivity against 1 or more of the HIV-1 proteins but not those required for a positive assay result is interpreted as being indeterminate.

Western blot assays are only performed as confirmation of a repeatedly reactive screening result (ELISA or rapid antibody test). A negative Western blot assay result indicates that the positive ELISA or rapid-test result represents a false-positive result and that the patient does not have HIV-1 antibodies. A positive Western blot assay result confirms the presence of HIV-1 antibodies; thus, in individuals older than 18 months, it is diagnostic of HIV-1 infection. A positive HIV-1 antibody assay result followed by an indeterminate Western blot assay is compatible with (1) an HIV-1–infected child with early HIV-1 infection (before the full range of HIV-1 antibodies have developed), and follow-up HIV-1 diagnostic tests (virologic assays and/or Western blot assay results)

4 weeks later would be positive; (2) an HIV-1–uninfected child, with false-positive ELISA or rapid-test results originally and repeat ELISA/Western blot assays performed 4 weeks later that give the same results as originally obtained and with negative virologic assay results; or (3) an HIV-1–uninfected child with gradual loss of passively acquired maternal HIV-1 antibodies.

Indirect Immunofluorescence Assays The IFA can be used as a confirmatory test for HIV-1 infection. This assay is simple to perform and is less time consuming and less expensive than many Western blot assays. However, it does require an expensive fluorescence microscope and experienced laboratory personnel to read and interpret the results. The IFA is similar to the ELISA. A microscope slide that contains cells (usually human T lymphocytes) that have been infected with HIV-1 is used. There is a control that consists of uninfected cells. The infected and control cells are attached (fixed) onto the slide in specific areas (wells). Test serum is added to each well. The slides are incubated, usually for 30 minutes, which allows specific antibody (if present) to attach to viral antigens in the infected cells. The slides are then washed and dried. Anti-human Ig labeled with a fluorochrome (a substance that fluoresces when exposed to ultraviolet light) is added and will bind to HIV-1 antibodies if present in the sample. If the slide exhibits cytoplasmic fluorescence, it is considered to be a positive (reactive) result, which indicates that HIV-1 antibodies are present.[33]

Immune System Deterioration as a Consequence of HIV-1 Infection

Flow cytometry for immunophenotyping of lymphocytes is widely available in the United States. This method permits the enumeration of T-cell lymphocytes into $CD4^+CD3^+$ T-helper cells and $CD8^+CD3^+$ T-suppressor cells. The hallmark of progression of HIV-1 infection is depletion of $CD4^+$ T lymphocytes, the major cellular target of HIV-1 in humans. Differences in $CD4^+$ T-lymphocyte counts between HIV-1–infected and –uninfected infants may be detectable soon after birth.[38] However, HIV-1–infected infants may maintain normal $CD4^+$ T-lymphocyte absolute counts and percentages throughout infancy. The $CD4^+$ T-lymphocyte percentage was evaluated as a surrogate marker of HIV-1 infection in west Africa, but the sensitivity of this marker was only 87% to 88% at 3 to 6 months of age.[39]

As $CD4^+$ T-lymphocyte depletion progresses, the ratio of $CD4^+$ to $CD8^+$ T lymphocytes decreases. A study explored the possibility of using $CD4^+$ T-lymphocyte counts, $CD8^+$ T-lymphocyte counts, and the $CD4^+/CD8^+$ T-lymphocyte ratio to distinguish between HIV-1–infected and –uninfected infants.[40] In this study, infants who had positive results of HIV-1 DNA polymerase chain reaction (PCR) testing had lower $CD4^+$ T-lymphocyte counts, higher $CD8^+$ T-lymphocyte counts, and lower $CD4^+/CD8^+$ T-lymphocyte ratios compared with infants who had negative results of HIV-1 DNA PCR testing. Additional evaluations of the $CD4^+/CD8^+$ T-lymphocyte ratio as a diagnostic modality have been conducted.[41,42,43] Thus, this method of diagnosis of HIV-1 infection remains investigational.

Other immunologic differences between HIV-1–infected and –uninfected children, which may serve as the basis for diagnostic testing in the future, have been investigated. HIV-1 infection in infants is associated with certain phenotypic markers of lymphocyte activation and differentiation. For example, HIV-1–uninfected infants have higher $CD3^+$, $CD4^+$, and naive $CD4^+$ T-lymphocyte counts, whereas HIV-1–infected infants have higher total $CD8^+$, $CD8DR^+$, $CD45RA\text{-}DR^+$, and $CD28\text{-}DR^+$ T-lymphocyte counts.[44] Also, total IgG, IgA, and IgM concentrations are significantly higher among HIV-1–infected children than among HIV-1–uninfected children, although individual HIV-1–infected children may have normal concentrations.[38]

Virologic Assays

The life cycle of HIV-1[45] begins with attachment of viral particles to cells via $CD4^+$ T-lymphocyte receptors and various coreceptors. After entry into the cell, the virus uncoats. A DNA copy of the RNA genome is produced by the viral-encoded reverse transcriptase. The DNA provirus can either integrate into the host cell genome or it can remain unintegrated in the cytoplasm. Replication of HIV-1 does not occur until the provirus is integrated into the host cell genome and the cell becomes activated either in vivo or in vitro. In vitro activation can occur through the use of various agents, including interleukin 2. Mature viral particles are produced from RNA copies of integrated proviral sequences. Ultimately, budding of mature virions occurs at the cell surface. Virologic tests for the diagnosis of HIV-1 infection encompass culturing of the virus, using nucleic acid amplification tests (NAATs [ie, tests that detect HIV-1 nucleic acids such as HIV-1 DNA or HIV-1 RNA]), and testing for components of the virus (eg, assays for a viral capsid protein [p24 antigen]). Advantages and disadvantages of each of these diagnostic modalities are shown in Table 1.

HIV-1 Culture

HIV-1 culture involves incubating peripheral blood mononuclear cells (PBMCs) from a patient with in vitro–activated PBMCs from an HIV-1–uninfected volunteer and culturing for up to 6 weeks.[46] The culture medium contains interleukin 2, which maintains the target PMBCs in an activated state susceptible to viral infection and replication. Therefore, high levels of viral replication occur within the target PBMCs if infectious HIV-1 is present. Measurement of p24 antigen in the culture supernatant using ELISA allows assessment of the growth of HIV-1 in the PBMCs. The culture is classified as positive for HIV-1 if a significant amount of p24

TABLE 1 **Advantages and Disadvantages of Virological Diagnostic Assays for HIV-1 Infection**

Diagnostic Assay	Advantages	Disadvantages
Culture	Previously considered the gold standard for diagnosis of HIV-1 infection in infants	Labor intensive Requires special laboratory and equipment 2–3 wk required for determination of a positive assay result Expensive Potential biohazard
DNA assays	Most experience to date for diagnosis of HIV-1 infection in infants and young children	Costly Require special equipment, experienced laboratories, trained personnel False-positive results if laboratory contamination occurs Not currently licensed for use in diagnosing HIV-1 infection
RNA assays	Widely available Short turnaround time	Costly Require special equipment, experienced laboratories, trained personnel Low copy numbers (eg, <10 000 copies per mL) may represent false-positive results Not currently licensed for use in diagnosing HIV-1 infection
p24 Antigen assays	More affordable and easier to perform than the other assays	Requires specific equipment, trained personnel

antigen is detected (usually defined as ≥30 pg/mL) and demonstrates significantly increasing concentrations of p24 antigen over subsequent culture supernatant fluid collection time points. The use of viral culture for the diagnosis of HIV-1 infection in infants and young children has been studied extensively.[47–52] Although previously considered the gold standard of HIV-1 diagnostic assays for infants and young children, the disadvantages of viral culture (ie, that it is labor intensive, time consuming, costly, and poses a biohazard risk) are now generally considered to outweigh its advantages. HIV-1 culture has limited availability, and its routine use in the clinical care of HIV-1–exposed infants and young children has been supplanted by HIV-1 NAATs.

HIV-1 NAATs

HIV-1 NAATs that detect viral RNA or proviral DNA are the most widely used assays for diagnosis of children younger than 18 months. Because viral nucleic acid may be present in very small quantities in test samples, NAATs are used to increase the amount of HIV-1 proviral DNA or HIV-1 RNA, or the amount of positive signal, in a test sample.

HIV-1 DNA Assays Amplification of proviral DNA allows detection of cells that harbor quiescent provirus as well as cells with actively replicating virus. HIV-1 DNA PCR assays involve separating double-stranded DNA located in PBMCs from the test sample into 2 single strands by heating.[53,54] On cooling, the HIV-1 DNA strands reanneal with complementary nucleotide sequences of HIV-1–specific primers in the reagent mixture, which allows synthesis of new complementary DNA strands. After 1 heating and cooling cycle, the number of DNA strands that contain the HIV-1 proviral sequence that originated in the test sample has doubled, and through repetition of these steps numerous times, amplification of the HIV-1 proviral DNA from the test sample proceeds in a logarithmic manner. After a set number of amplification steps, HIV-1 proviral sequences are detected by hybridizing amplified DNA to a synthetic, enzyme-labeled HIV-1 DNA probe. A positive result is indicated by a color change in a chromogenic substrate. The sensitivity of HIV-1 DNA assays for the diagnosis of HIV-1 infection in infants and young children has been evaluated (Table 2) in several studies[51,52,55–62] and meta-analyses,[63,64] with estimates as high as 90% to 100% by 1 month of age.[51,56,59] Similarly high specificity has been observed by 1 month of age in nonbreastfed infants.[51,55,56,59]

HIV-1 RNA Assays HIV-1 RNA assays detect plasma (cell-free) viral RNA by using different techniques. Methods of amplification of HIV-1 RNA include target (nucleic acid sequence-based amplification and reverse-transcriptase PCR) and signal (branched-chain DNA) amplification techniques. For HIV-1 RNA assays approved by the FDA, see www.fda.gov/cber/products/testkits.htm. In the nucleic acid sequence-based amplification assay, quantitation of HIV-1 RNA is achieved with internal calibrators, which are amplified along with the patient's sample. As part of the branched-chain DNA assay, a light-emitting chemical reaction occurs, with the amount of light produced being proportional to the amount of RNA in the sample. In reverse-transcriptase PCR, reverse transcriptase is used to convert RNA into DNA; subsequently, amplification is performed by PCR.

— indicates that data were not available.

These assays are available as "standard" or "ultrasensitive" assays, and the lower limit of detection possible when using the ultrasensitive assays is in the range of 50 to 75 HIV-1 copies per mL of plasma.

Numerous studies of the use of HIV-1 RNA assays for the diagnosis of HIV-1 infection in pediatric populations have been conducted,[52,59,65–75] with the reported sensitivity of testing (Table 3) for such assays ranging from 25% to 50% within the first few days of life to 100% by 6 to 12 weeks of age.[65,67] HIV-1 RNA assays have been assessed to be at least as sensitive as, or more sensitive than, HIV-1 DNA assays among young infants.[52,59,66–68,71] Similarly high specificity by 6 to 12 weeks of age (as compared with HIV-1 DNA assays or HIV-1 culture) has been observed among nonbreastfed infants.[52,59,65,68,72]

HIV-1 RNA assays are now commonly used to diagnose HIV-1 infection in infants. HIV-1 RNA assays are often more readily available than HIV-1 DNA assays because of the common use of RNA assays in follow-up testing of patients during treatment for HIV-1 infection. When HIV-1 RNA quantitative assays are used for diagnosis of infants and young children, a plasma viral load of ≥10 000 copies per mL is generally required before

the assay result is interpreted as being positive. Infants with untreated HIV-1 infection typically have extremely high viral loads (eg, >100 000 copies per mL), and many experts agree that HIV-1 RNA assay results of <10 000 copies per mL should not be interpreted as being definitively positive when used for diagnosis of HIV-1 in infancy, and the assay should be repeated on a plasma sample obtained through a separate venipuncture or fingerstick procedure to confirm that such a low-level positive result is a true-positive result.

p24 Antigen Assays

The viral protein p24 exists either bound to anti-p24 antibody or unbound (free) in the bloodstream of HIV-1–infected individuals. Many studies of p24 antigen for diagnosis of HIV-1 infection have been conducted over the past several years,[49,76–93] with the sensitivity of the assay increasing with increasingly effective techniques used to dissociate p24 antigen from anti-p24 antibody (immune complex–dissociated p24 antigen detection).[94] In general, p24 antigen assays have been used much less frequently than HIV-1 DNA- or RNA-amplification techniques for diagnosis of HIV-1 infection because of the relatively poor sensitivity of p24 antigen assays and the absence of readily available commercial, FDA-approved reagents. It should be noted that the ultrasensitive p24 antigen assay performed on plasma samples for diagnostic purposes has a sensitivity of 97% to 100% within the first 6 months of life.[81,85,89,92] However, this assay has not yet been widely recommended for identification or exclusion of HIV-1 infection in infants in the United States, but it may have a role in infant diagnosis in resource-limited settings.

FACTORS THAT AFFECT CHOICE AND TIMING OF USE OF DIAGNOSTIC MODALITIES

Several important factors must be considered when choosing HIV-1 diagnostic assays for pediatric patients and when to use them. Such factors include the age of the child, the potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and of the child, and characteristics of the virus.

Age of the Child

As alluded to previously, serologic testing for HIV-1 in infants and young children born to HIV-1–infected women must be interpreted with caution because of transplacental transfer of maternal HIV-1 antibody.[95] Studies of the decay of maternally derived antibodies to HIV-1 indicate that most children serorevert (ie, lose maternal antibodies) by 12 months of age.[96–99] However, the median time to loss of maternal antibody has varied in different studies, with numbers of subjects ranging from 40 to 520 (eg, 7 months,[100] 11.6 months,[101] and 13.3 months[102]), and a small proportion of uninfected children remained HIV-1 antibody-positive at 15 months[98] or 18 months.[96] Therefore, loss of maternal antibody (seroreversion) as an HIV-1–exposed child

grows older is informative (because it indicates the absence of HIV-1 infection), but HIV-1 seropositivity in a child younger than 18 months is not diagnostic (because a positive antibody test result during the first 18 months of life could represent either persistent maternal antibody in an HIV-1–uninfected child or antibody newly produced by an HIV-1–infected child). Thus, serologic testing of a child younger than 18 months generally cannot be used to diagnose HIV-1 infection; therefore, virologic assays are required. (However, a positive antibody test result in the infant generally indicates maternal HIV-1 infection.)

Potential Timing of Infection of the Child

Infants who are presumed to have been infected with HIV-1 in utero may have detectable virus at birth, whereas infants presumed to have been infected around the time of delivery may not have detectable virus until days or weeks after birth.[103] Thus, in nonbreastfeeding populations, an accurate diagnosis of HIV-1 infection among children of HIV-1–infected women can be made during the first few weeks of life with virologic assays. The sensitivity of testing depends on the timing of the test; sensitivity increases with increasing age of the infant. It has been recommended[104] that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. Furthermore, if any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection can be made on the basis of 2 separate positive HIV-1 DNA or RNA assay results.[105] The Centers for Disease Control and Prevention recently revised its surveillance definition for defining lack of HIV-1 infection in an HIV-1–exposed infant. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 antibody test result obtained at ≥6 months of age. Alternatively, among children with 1 positive HIV-1 virologic test result, presumptive exclusion of HIV-1 infection can be based on at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age). Finally, children can be considered presumptively uninfected with negative HIV-1 antibody test results (at least 1 of which is performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative virologic tests (1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age) or 2 negative HIV-1 antibody tests from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection.[106] Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age.

The diagnosis of HIV-1 infection among infants and young children with a history of breastfeeding is more difficult because of continuing exposure to the virus postnatally. The exclusion of HIV-1 infection among breastfeeding infants and young children cannot be definitively accomplished until after cessation of breastfeeding. There is no consensus on the best approach to testing for HIV-1 infection after breastfeeding has stopped. Some clinicians use an HIV-1 diagnostic testing algorithm similar to that suggested for nonbreastfed infants, with timing of testing based on the date of complete cessation of breastfeeding instead of the date of birth (ie, testing at the time breastfeeding has stopped, again 1–2 months after cessation, and again 3–6 months after cessation), with confirmation of the absence of HIV-1 infection by negative HIV-1 antibody assay results at 12 to 18 months of age; serologic testing should be performed at least 6 months after complete cessation.

Maternal HIV-1 Infection Status

The diagnostic approach to an infant or young child differs according to whether the mother's HIV-1 infection status is known. Children of HIV-1–infected women have maternal antibodies to HIV-1 during the first months of life, and these children may remain HIV-1–seropositive until 18 months of age. Therefore, serologic testing (except if the test result is negative) is not informative in children younger than 18 months, but does reflect the serostatus of the mother. Virologic testing generally is required to determine the HIV-1 infection status of the child.

Women of unknown HIV-1 serostatus and their newborn infants can undergo rapid HIV-1 testing in the peripartum period to ascertain the HIV-1 infection status of the woman and the HIV-1–exposure status of the infant.[107] It is recommended that rapid testing be available at all hospitals that serve pregnant women and that prompt testing using the rapid HIV-1 antibody assays be performed for pregnant women or infants of unknown HIV-1 serostatus.[108]

Rapid HIV-1 antibody testing should be completed and results should be available quickly, because the effectiveness of postexposure prophylaxis administered to the infant (if the mother did not receive prophylaxis) is greatest if initiated within the first 12 hours of life.[109] If the rapid-test result is positive during the intrapartum or immediate postpartum period, antiretroviral prophylaxis can be administered to the mother and/or infant. Subsequent to initiation of antiretroviral prophylaxis, confirmatory testing for HIV-1 infection can be performed. If the confirmatory test result is ultimately negative (suggesting that the initial rapid HIV-1 antibody test result was a false-positive), prophylaxis can then be discontinued. If the confirmatory test result is positive, HIV-1

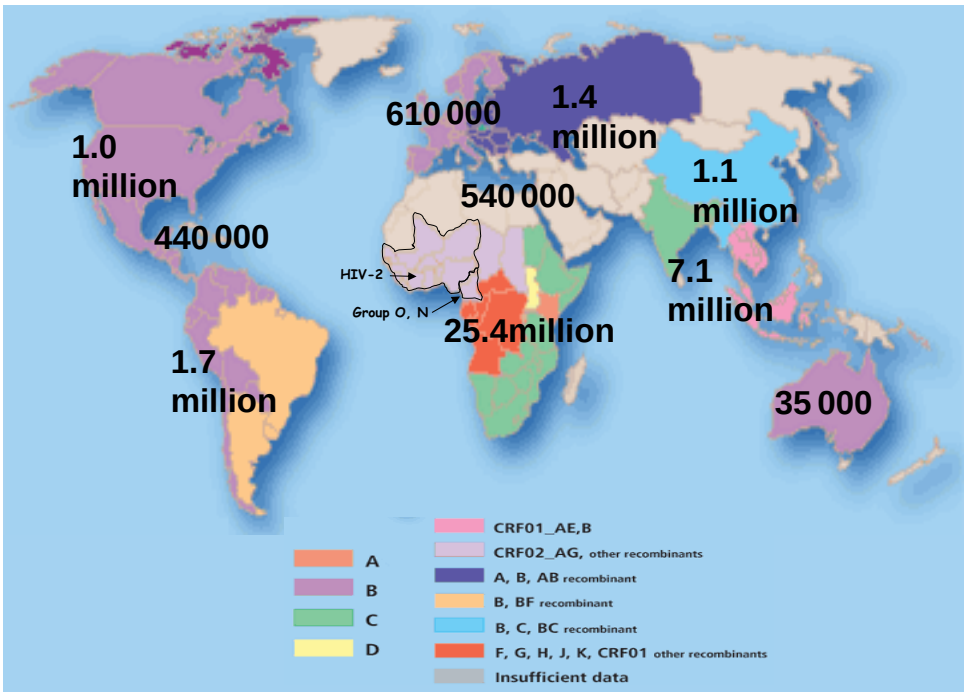

FIGURE 1

Global HIV prevalence and distribution. The estimated numbers of HIV-1–infected individuals in North America, western Europe, central Asia, east Asia, southeast Asia, north Africa and the Middle East, sub-Saharan Africa, and Australia are indicated. The colors depict regional patterns of HIV variation as follows: subtype A in east Africa; subtype B in the Americas, Europe, and Australia; subtype C in southern and eastern Africa and in India; subtype D in east Africa; CRF01_AE and subtype B in southeast Asia; CRF02-AG and other recombinants in west Africa; A, B, and AB recombinants in central Asia; subtype B and BF recombinants in South America; subtypes B and C and BC recombinants in east Asia; rare subtypes, CR01_AE, and other recombinants in central Africa and areas in which there are insufficient data. The principal concentrations of HIV-1 groups O and N in Cameroon, and of HIV-2 in west Africa, are indicated by arrows. (Reproduced with permission from McCutchan FE. Global epidemiology of HIV. *J Med Virol.* 2006;78(suppl1):S8)

infection in the mother and HIV-1 exposure in the child are confirmed. In this situation, antiretroviral prophylaxis is continued, and additional testing is indicated (as described previously).

Antiretroviral Exposure History of the Mother and Child

There are limited published data regarding what effect, if any, maternal and/or infant antiretroviral exposure has on the results of HIV-1 diagnostic testing with NAATs. HIV-1 DNA has remained detectable in PBMCs and lymphoid tissues of HIV-1–infected children despite years of exposure to antiretroviral agents and even when HIV-1 RNA assay results have been negative.[110] In some studies, detection of virus with DNA PCR assays has been reported not to vary according to receipt of maternal or infant antiretroviral prophylaxis.[111] However, a study by Prasitwattanaseree et al[112] suggested that the age at which HIV-1 infection was detectable (by using a DNA PCR assay) among 98 HIV-1–infected infants depended on the duration of exposure to zidovudine by the mother and the infant. Detectable infection at birth was less frequent among children with a longer maternal duration of zidovudine receipt. Among mothers with a short duration of zidovudine receipt, infants who received a long duration of zidovudine were diagnosed later than those who received a short duration. To date, studies have suggested that maternal and infant receipt of perinatal transmission prophylaxis with zidovudine or nevirapine does not decrease the sensitivity of HIV-1 RNA PCR assays performed during the first 6 months of age.[68,72] More research is needed to answer the question of whether the antiretroviral exposure history of the mother or the child affects the results of HIV-1 diagnostic testing with NAATs.

Characteristics of the Virus

HIV-1 viruses are classified into 3 groups; the main group (group M) accounts for at least 90% of HIV-1 infections around the world[113] (Fig 1). The other groups are the outlier group (group O) and the non-M/non-O group (group N).[114] Within group M, clusters of related viral strains are classified into subtypes (clades): subtypes A, B, C, D, E, F, G, K, and O. More than 50% of HIV-1 infections globally are caused by subtype C viruses, which predominates in sub-Saharan Africa and India. Subtypes A and B also account for large proportions of infections worldwide. Subtype B viruses predominate in North America and Europe. In addition to these subtypes, recombinant viruses (for example, BC recombinant viruses) exist. Group O infections seem to be localized to western and central Africa. Infections with group N virus are extremely rare.

An estimated 16.7% of infants in whom HIV-1 was diagnosed in New York State between 2001 and 2002

had infections with non–subtype B strains.[115] False-negative results on HIV-1 DNA assays in infants and young children infected with non–subtype B viruses have been reported.[116–119] Therefore, it has been recommended that, for young children undergoing HIV-1 diagnostic testing who were born to HIV-1–infected mothers whose HIV-1 infection may have originated outside of Europe or the United States, a sample from the mother be tested with a virologic assay at the same time as a sample from the child.[116] The child's assay results can be interpreted only if the maternal test result is positive for HIV-1. Because maternal virus could exist as multiple, perhaps recombinant "quasi species," only 1 of which is transmitted to the child, this approach may not identify all HIV-1–infected children with subtypes other than B. Assays for amplification of HIV-1 proviral DNA or RNA that are sensitive to group O viruses and/or to group M/non-B subtypes have been developed.[68,117,120–122] Although HIV-1 DNA PCR assays optimized for non-B subtype HIV-1 have had limited availability in the United States, the availability has improved recently. Because HIV-1 RNA assays are, in general, more widely availability in formats optimized to identify non-B subtype HIV-1 infection, one of the commercially available RNA assays may be preferable to HIV-1 DNA PCR for identification of the child with non-B subtype HIV-1 infection.

In addition to HIV-1, another human retrovirus associated with AIDS is HIV type 2 (HIV-2). In terms of the more conserved *gag* and *pol* genes, the 2 viruses share approximately 60% overall nucleic acid sequence homology. Otherwise, the 2 viruses share 30% to 40% homology.[123] Similar to HIV-1, there are different subtypes of HIV-2 (subtypes A, B, C, D, E, F, and G), although only HIV-2 subtypes A and B seem to be established significantly in human populations.[124] Although HIV-1 is the major cause of AIDS in the United States and elsewhere in the world, HIV-2 is most prevalent in west Africa. Therefore, most HIV infections in the United States are HIV-1 infections, but HIV-2 infections can be encountered in pediatric practice in the United States (although MTCT of HIV-2 occurs less frequently than MTCT of HIV-1, largely because of the lower maternal viral loads with HIV-2 infection).[125] Whether a specific HIV-1 diagnostic assay is also able to detect HIV-2 infection becomes important in the evaluation of infants and young children who are born to women who may have acquired HIV infection in west Africa. Both virologic[126,127] and serologic assays for the diagnosis of HIV-2 infection have been developed. For HIV-2 diagnostic assays (as well as combined HIV-1 and HIV-2 assays) approved by the FDA, see www.fda.gov/cber/products/testkits.htm.

CONCLUSIONS

Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be detectable in the child's bloodstream until 18 months of age. Therefore, routine serologic testing of these infants and young children is generally only informative before 18 months of age if the test result is negative. Virologic assays, especially HIV-1 NAATs, such as HIV-1 DNA PCR assays, represent the gold standard for diagnostic testing of infants and children younger than 18 months. With such testing, the diagnosis of HIV-1 infection (as well as the presumptive exclusion of HIV-1 infection) can be established within the first several weeks of life among nonbreastfed infants. Important factors that must be considered when selecting HIV-1 diagnostic assays for pediatric patients and when choosing the timing of such assays include the age of the child, the potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and the child, and characteristics of the virus.

In infants and young children of HIV-1–infected women, HIV-1 antibody testing of the child is not helpful around the time of birth (because the result will be reactive because of passively acquired maternal antibody). However, if the mother's HIV-1 serostatus is unknown, rapid HIV-1 antibody testing of the mother or the newborn infant to identify HIV-1 exposure of the infant is essential so that antiretroviral prophylaxis can be initiated within the first 12 hours of life. For HIV-1–exposed infants (identified by positive maternal testing or by positive antibody testing of the infant shortly after birth), it has been recommended that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. If any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection is made on the basis of 2 positive HIV-1 DNA or RNA assays. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 antibody test result obtained at ≥6 months of age. Alternatively, among children with at least 1 positive HIV-1 virologic test result, presumptive exclusion of HIV-1 infection can be based on at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age). Finally, children can be considered presumptively uninfected with negative HIV-1 antibody test results (with at least 1 of the tests performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative virologic test results (1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age) or 2 negative HIV-1

antibody test results from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection. Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age. For breastfeeding infants, a similar testing algorithm can be followed, with timing of testing based on the date of complete cessation of breastfeeding instead of the date of birth.

Clinical Report—Diagnosis and Prevention of Iron Deficiency and Iron-Deficiency Anemia in Infants and Young Children (0–3 Years of Age)

abstract

FREE

This clinical report covers diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants (both breastfed and formula fed) and toddlers from birth through 3 years of age. Results of recent basic research support the concerns that iron-deficiency anemia and iron deficiency without anemia during infancy and childhood can have long-lasting detrimental effects on neurodevelopment. Therefore, pediatricians and other health care providers should strive to eliminate iron deficiency and iron-deficiency anemia. Appropriate iron intakes for infants and toddlers as well as methods for screening for iron deficiency and iron-deficiency anemia are presented. *Pediatrics* 2010;126: 1040–1050

INTRODUCTION

Iron deficiency (ID) and iron-deficiency anemia (IDA) continue to be of worldwide concern. Among children in the developing world, iron is the most common single-nutrient deficiency.[1] In industrialized nations, despite a demonstrable decline in prevalence,[2] IDA remains a common cause of anemia in young children. However, even more important than anemia itself is the indication that the more common ID without anemia may also adversely affect long-term neurodevelopment and behavior and that some of these effects may be irreversible.[3,4] Because of the implications for pediatric health care providers and their patients, this report reviews and summarizes this information.

This clinical report is a revision and extension of a previous policy statement published in 1999,[5] which addressed iron fortification of formulas. This report covers diagnosis and prevention of ID and IDA in infants (both breastfed and formula fed) and toddlers aged 1 through 3 years.

DEFINITIONS

Anemia: A hemoglobin (Hb) concentration 2 SDs below the mean Hb concentration for a normal population of the same gender and age range, as defined by the World Health Organization, the United Nations Children's Fund, and United Nations University.[6] On the basis of the 1999–2002 US National Health and Nutrition Examination Survey, anemia is defined as a Hb concentration of less than 11.0 g/dL for both male and female children aged 12 through 35 months.[7,8] For certain populations (ie, people living at high altitudes), adjustment of these values may be necessary.

Robert D. Baker, MD, PhD, Frank R. Greer, MD, and THE COMMITTEE ON NUTRITION

KEY WORDS

iron deficiency, iron-deficiency anemia, iron intake, infants, toddlers, breastfeeding, formula

ABBREVIATIONS

ID—iron deficiency
IDA—iron-deficiency anemia
Hb—hemoglobin
SF—serum ferritin
IOM—Institute of Medicine
WIC—Special Supplemental Program for Women, Infants, and Children
CHr—reticulocyte hemoglobin
TfR1—transferrin receptor 1
CRP—C-reactive protein
AAP—American Academy of Pediatrics

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed,revised, or retired at or before that time.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Iron sufficiency: A state in which there is sufficient iron to maintain normal physiologic functions.

Iron deficiency: A state in which there is insufficient iron to maintain normal physiologic functions. ID results from inadequate iron absorption to accommodate an increase in requirements attributable to growth or resulting from a long-term negative iron balance. Either of these situations leads to a decrease in iron stores as measured by serum ferritin (SF) concentrations or bone marrow iron content. ID may or may not be accompanied by IDA.

Iron-deficiency anemia: An anemia (as defined above) that results from ID.

Iron overload: The accumulation of excess iron in body tissues. Iron overload usually occurs as a result of a genetic predisposition to absorb and store iron in excess amounts, the most common form of which is hereditary hemochromatosis. Iron overload can also occur as a complication of other hematologic disorders that result in chronic transfusion therapy, repeated injections of parenteral iron, or excessive iron ingestion.

Recommended dietary allowance for iron: The average daily dietary intake that is sufficient to meet the nutrient requirements of nearly all individuals (97%–98%) of a given age and gender.

Adequate intake for iron: This term is used when there is not enough information to establish a recommended dietary allowance for a population (eg, term infants, 0–6 months of age). The adequate intake is based on the estimated average nutrient intake by a group (or groups) of healthy individuals.

IRON REQUIREMENTS FOR INFANTS (UP TO 12 COMPLETED MONTHS OF AGE)

Eighty percent of the iron present in a newborn term infant is accreted during the third trimester of pregnancy. Infants born prematurely miss this rapid accretion and are deficient in total body iron. A number of maternal conditions, such as anemia, maternal hypertension with intrauterine growth restriction, or diabetes during pregnancy, can also result in low fetal iron stores in both term and preterm infants.

Preterm Infants

The deficit of total body iron in preterm infants increases with decreasing gestational age. It is worsened by the rapid postnatal growth that many infants experience and by frequent phlebotomies without adequate blood replacement. On the other hand, sick preterm infants who receive multiple transfusions are at risk of iron overload. The use of recombinant human erythropoietin to prevent transfusion therapy in preterm infants will further deplete iron stores if additional supplemental iron is not provided. The highly variable iron status of preterm infants, along with their risks for ID as well as toxicity, precludes determining the exact requirement, but it can be estimated to be between 2 and 4 mg/kg per day when given orally.[9]

Term Infants (Birth Through 12 Completed Months of Age)

The Institute of Medicine (IOM)[10] used the average iron content of human milk to determine the adequate intake of 0.27 mg/day for term infants from birth through 6 months' completed age. The average iron content of human milk was determined to be 0.35 mg/L, and the average milk intake of an exclusively breastfed infant was determined to be 0.78 L/day. Multiplying these 2 numbers determined the adequate intake of 0.27 mg/day for term infants from birth through 6 months of age in the IOM report. The IOM further reasoned that there should be a direct correlation between infant size and human milk ingestion; therefore, no correction need be made for infant weight. It should be pointed out, however, that although bigger infants may ingest more milk, there is a large variation in iron concentration of human milk, and there is no guarantee that the iron content of the maternal milk matches the needs of the infant for iron.

For infants from 7 to 12 months' completed age, the recommended dietary allowance for iron, according to the IOM, is 11 mg/day, which was determined by using a factorial approach. The amount of iron lost, primarily from sloughed epithelial cells from skin and the intestinal and urinary tracts, was added to the amounts of iron required for increased blood volume, increased tissue mass, and storage iron during this period of life. It was noted that the iron needs of infants do not suddenly jump from 0.27 to 11 mg/day at 6 months of age; this disjuncture is the result of the use of very different methods of determining these values. However, it is clear that healthy, term newborn infants require very little iron early in life compared with the significant amounts of iron required after 6 months of age.

IRON REQUIREMENTS FOR TODDLERS (1–3 YEARS OF AGE)

Using a similar factorial approach as described for infants 7 to 12 months' completed age, the IOM determined that the recommended dietary allowance for iron for children from 1 through 3 years of age is 7 mg/day.[9]

PREVALENCE OF ID AND IDA

There are currently no national statistics for the prevalence of ID and IDA in infants before 12 months' completed age. Hay et al[11] reported on a cohort of 284 term Norwegian infants. Using the definitions provided by Dallman[12] in an IOM report, the prevalence of ID at 6

months of age was 4% and increased to 12% at 12 months of age.

The prevalence of ID and IDA among toddlers (1–3 years of age) in the United States is listed in Table 1 and was derived from National Health and Nutrition Examination Survey data collected between 1999 and 2002.[7,8] The overall prevalence of anemia and possibly ID and IDA in infants and toddlers has declined since the 1970s.[2] Although there is no direct proof, this decline has been attributed to use of iron-fortified formulas and iron-fortified infant foods provided by the Special Supplemental Program for Women, Infants, and Children (WIC) in the early 1970s and the decrease in use of whole cow milk for infants.[8] Still, ID remains relatively common and occurs in 6.6% to 15.2% of toddlers, depending on ethnicity and socioeconomic status. The prevalence of IDA is 0.9% to 4.4%, again depending on race/ethnicity and socioeconomic status,[7,8] but only accounts for approximately 40% of the anemia in toddlers (Table 1). These numbers are comparable to data collected in other industrialized countries.[13,14]

Related to the problem of ID/IDA is the interaction of iron and lead. Results of both animal and human studies have confirmed that IDA increases intestinal lead absorption.[15–17] A reasonably well-established epidemiologic association has been made between IDA and increased lead concentrations.[18] Thus, primary prevention of IDA could also serve as primary prevention of lead poisoning. This possibility is all the more attractive, because lead has been reported to induce neurotoxicity at even very low blood concentrations.[19,20] In addition, preexisting IDA decreases the efficiency of lead chelation therapy, and iron supplementation corrects this effect. In contrast, iron supplementation in a child with IDA who also has lead poisoning without chelation therapy seems to increase blood lead concentrations and decrease basal lead excretion.[21,22] The effect of iron supplementation on blood lead concentrations in iron-replete children with or without lead poisoning is not known. Thus, in theory, selective rather than universal iron supplementation would be more likely to reduce lead poisoning and its potential harmful effects on these children.

TABLE 1 ID, IDA, and Anemia in the 1999–2002 National Health and Nutrition Examination Survey,[7] Children 12 to 35 Months of Age

Population Sampled (No.)	Proportion of US Toddler Population, % (SE)[a]	ID, % (SE)	IDA, % (SE)	All Anemia, % (SE)
General US population (672)		9.2 (1.3)	2.1 (0.6)	5.1 (0.8)
Above poverty line (355)[b]	66.4 (2.9)	8.9 (1.7)	2.2 (0.8)[c]	4.6 (1.1)
Below poverty line (268)[b]	33.6 (2.9)	8.6 (1.6)	2.3 (1.2)[c]	6.2 (1.3)
Enrolled in WIC (360)[d]	44.4 (3.2)	10.7 (2.1)	3.1 (1.2)[c]	6.6 (1.4)
Non-Hispanic white (196)	58.0 (3.8)	7.3 (1.9)	2.0 (0.8)[c]	4.6 (1.2)
Non-Hispanic black (173)	14.1 (2.1)	6.6 (1.8)	1.6 (0.9)[c]	8.3 (1.9)
Mexican American (231)	15.0 (2.2)	13.9 (3.1)	0.9 (0.7)[c]	3.2 (1.2)[c]
Other ethnicity (72)	13.0 (2.7)	15.2 (4.7)[c]	4.4 (2.7)[c]	5.5 (2.7)[c]

Shown are the unweighted number and weighted percentage and SEs for all children with complete data for Hb, SF, transferrin saturation, and zinc protoporphyrin. Anemia was defined as a Hb concentration of <11.0 g/dL; ID[7] was defined as an abnormal value for at least 2 of 3 indicators: SF (abnormal cutoff: <10 μg/dL), zinc protoporphyrin (>1.42 μmol/L red blood cells), and transferrin saturation (<10%); and IDA was defined as anemia plus ID.

[a] Proportion of row descriptor of all children in analytic sample ($N = 672$).

[b] Children with income data ($N = 623$).

[c] Estimate is statistically unreliable. Relative SE (SE of estimate/estimate × 100) ≥ 30%.

[d] Any member of household who received benefits from WIC in the previous 12 months: children with food-security data ($N = 668$).

ID AND NEURODEVELOPMENT

The possible relationship between ID/IDA and later neurobehavioral development in children is the subject of many reports.[3,23–31] Results of a preponderance of studies have demonstrated an association between IDA in infancy and later cognitive deficits. Lozoff et al[3,25] have reported detecting cognitive deficits 1 to 2 decades after the iron-deficient insult during infancy. However, it has been difficult to establish a causal relationship because of the many confounding variables and the difficulty in designing and executing the large, randomized controlled trials necessary to distinguish small potential differences. The authors of a Cochrane Database systematic review, in which the question of whether treatment of IDA improved psychomotor development was examined, stated that there was inconclusive but plausible evidence (only 2 randomized controlled trials) demonstrating improvement if the treatment extended for more than 30 days.[27] McCann and Ames[28] recently reviewed the evidence of a causal relationship between ID/IDA and deficits in cognitive and behavioral function. They concluded that for IDA, there is at least some support for causality, but because specificity for both cause and effect have not been established unequivocally, it is premature to conclude the existence of a causal relationship between IDA and cognitive and behavioral performance. For ID, some evidence of causality exists, but it is less than that for IDA.[28]

It is known that iron is essential for normal neurodevelopment in a number of animal models. ID affects neuronal energy metabolism, the metabolism of neurotransmitters, myelination, and memory function. These observations would explain the behavioral findings in human infants that have been associated with ID.[29–31] Therefore, taking into account that iron is the world's most common

single-nutrient deficiency, it is important to minimize IDA and ID among infants and toddlers, even if an unequivocal relationship between IDA and ID and neurodevelopmental outcomes has yet to be established.

DIAGNOSIS

Iron status is a continuum. At one end of the spectrum is IDA, and at the other end is iron overload. ID and IDA are attributable to an imbalance between iron needs and available iron that results in a deficiency of mobilizable iron stores and is accompanied by changes in laboratory measurements that include Hb concentration, mean corpuscular Hb concentration, mean corpuscular volume, reticulocyte Hb concentration (abbreviated in the literature as CHr) content, total iron-binding capacity, transferrin saturation, zinc protoporphyrin, SF concentration, and serum transferrin receptor 1 (TfR1) concentration. Measurements that are used to describe iron status are listed in Table 2.

In a child with ID, as the Hb concentration falls 2 SDs below the mean for age and gender, IDA is present, by definition; for infants at 12 months of age, this is 11.0 mg/dL.[7,8] When IDA accounted for most cases of anemia in children, "anemia" and "IDA" were roughly synonymous, and a simple measurement of Hb concentration was sufficient to make a presumptive diagnosis of anemia attributable to ID. Particularly in industrialized nations, the prevalence of ID and IDA has decreased, and other causes of anemia, such as hemolytic anemias, anemia of chronic disease, and anemia attributable to other nutrient deficiencies, have become proportionately more common.[32]

TABLE 2 Spectrum of Iron Status

Parameter	ID Without Anemia	IDA	Iron Overload
SF[a]	↓	↓ ↓	↑
Transferrin saturation	↓	↓	↑ ↑
TfR1	↑ ↑	↑ ↑ ↑	↓
CHr	↓	↓	Normal
Hb	Normal	↓	Normal
Mean corpuscular volume	Normal	↓	Normal

[a] Confounded by the presence of inflammation. If SF is normal or increased and the CRP level is normal, then there is no ID. If SF is decreased, then ID is present regardless of the measure of CRP. If SF is normal or increased and the CRP level is increased, then the presence of ID cannot be determined.

Modified from American Academy of Pediatrics, Committee on Nutrition. Iron deficiency. In: Kleinman RE, ed. *Pediatric Nutrition Handbook*. 5th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2004:304.

No single measurement is currently available that will characterize the iron status of a child. The limitations of using Hb concentration as a measure of iron status are its lack of specificity and sensitivity. Factors that limit erythropoiesis or result in chronic hemolysis, such as genetic disorders and chronic infections, may result in low Hb concentrations. Vitamin B_{12} or folate deficiency, although uncommon in the pediatric population, also can result in a low Hb concentration. The lack of sensitivity is largely attributable to the marked overlap in Hb concentrations between populations with iron sufficiency and those with ID.[33] Thus, to identify ID or IDA, Hb concentration must be combined with other measurements of iron status. Once the diagnosis of IDA has been established, however, following Hb concentration is a good measure of response to treatment.

In establishing the definitive iron status of an individual, it is desirable to use the fewest tests that will accurately reflect iron status. Any battery of tests must include Hb concentration, because it determines the adequacy of the circulating red cell mass and whether anemia is present. One or more tests must be added to the determination of Hb concentration if ID or IDA is to be diagnosed. The 3 parameters that provide discriminatory information about iron status are SF, CHr, and TfR1 concentrations.

SF is a sensitive parameter for the assessment of iron stores in healthy subjects[34–36]; 1 μg/L of SF corresponds to 8 to 10 mg of available storage iron.[34,37,38] Measurement of SF concentration is widely used in clinical practice and readily available. Cook et al[36] selected an SF concentration below 12 μg/L as diagnostic for ID after a comprehensive population survey in the United States. Thus, a cutoff value of 12 μg/L has been widely used for adults and denotes depletion of iron stores. In children, a cutoff value of 10 μg/L has been suggested.[39] Because SF is an acute-phase reactant, concentrations of SF may be elevated in the presence of chronic inflammation, infection, malignancy, or liver disease, and a simultaneous measurement of C-reactive protein (CRP) is required to rule out inflammation. Although Brugnara et al[40] found SF concentration to be less accurate than either the CHr or TfR1 concentration in establishing iron status of children, combining SF concentration with a determination of CRP is currently more readily available to assess iron stores and is a reliable screening test as long as the CRP level is not elevated[41] (Table 2).

CHr and TfR1 concentrations are not affected by inflammation (infection), malignancy, or anemia of chronic disease and, thus, would be preferable as biomarkers for iron status. Only the CHr assay is currently available for use in children. The CHr content assay has been validated in children, and standard values have been determined.[40,42] The CHr assay provides a measure of iron available to cells recently released from the bone marrow. CHr content can be measured by flow cytometry, and 2 of the 4 automated hematology analyzers commonly used in the United States have the capability to measure CHr.[43] A low CHr concentra-

tion has been shown to be the strongest predictor of ID in children[40,42,43] and shows much promise for the diagnosis of ID when the assay becomes more widely available.

TfR1 is a measure of iron status, detecting ID at the cellular level. TfR1 is found on cell membranes and facilitates transfer of iron into the cell. When the iron supply is inadequate, there is an upregulation of TfR1 to enable the cell to compete more effectively for iron, and subsequently, more circulating TfR1 is found in serum. An increase in serum TfR1 concentrations is seen in patients with ID or IDA, although it does not increase in serum until iron stores are completely exhausted in adults.[44–46] However, the TfR1 assay is not widely available, and standard values for infants and children have yet to be established.

Thus, to establish a diagnosis of IDA, the following sets of tests can be used at the present time (when coupled with determination of a Hb concentration of <11 g/dL): (1) SF and CRP measurements or (2) CHr measurement. For diagnosing ID without anemia, measure either (1) SF and CRP or (2) CHr.

Another approach to making the diagnosis of IDA in a clinically stable child with mild anemia (Hb concentration between 10 and 11 g/dL) is to monitor the response to iron supplementation, especially if a dietary history indicates that the diet is likely to be iron deficient. An increase in Hb concentration of 1 g/dL after 1 month of therapeutic supplementation has been used to signify the presence of IDA. This approach requires that iron supplementation be adequate, iron be adequately absorbed, and patient compliance with adequate follow-up can be ensured. However, because only 40% of the cases of anemia identified at 12 months of age will be secondary to IDA (Table 1), strong consideration should be given to establishing a diagnosis of IDA by using the screening tests described previously.

PREVENTION OF ID AND IDA

Preterm Infants

The preterm infant (<37 weeks' gestation) who is fed human milk should receive a supplement of elemental iron at 2 mg/kg per day starting by 1 month of age and extending through 12 months of age.[47] This can be provided as medicinal iron or in iron-fortified complementary foods. Preterm infants fed a standard preterm infant formula (14.6 mg of iron per L) or a standard term infant formula (12.0 mg of iron per L) will receive approximately 1.8 to 2.2 mg/kg per day of iron, assuming a formula intake of 150 mL/kg per day. Despite the use of iron-containing formulas, 14% of preterm infants develop ID between 4 and 8 months of age.[48] Thus, some formula-fed preterm infants may need an additional iron supplement,[47] although there is not enough evidence to make this a general recommendation at this time. Exceptions to this iron-supplementation practice in preterm infants would be infants who received multiple transfusions during hospitalization, who might not need any iron supplementation.

Term, Breastfed Infants

Infants who are born at term usually have sufficient iron stores until 4 to 6 months of age.[49] Infants born at term have high Hb concentration and high blood volume in proportion to body weight. They experience a physiologic decline in both blood volume and Hb concentration during the first several months of life. These facts have led to the supposition that breastfed infants need very little iron. It is assumed that the small amount of iron in human milk is sufficient for the exclusively breastfed infant. The World Health Organization recommends exclusive breastfeeding for 6 months, and the American Academy of Pediatrics (AAP) has recommended exclusive breastfeeding for a minimum of 4 months but preferably for 6 months. Exclusive breastfeeding for more than 6 months has been associated with increased risk of IDA at 9 months of age.[49,50] Recommendations for exclusive breastfeeding for 6 months do not take into account infants who are born with lower-than-usual iron stores (low birth weight infants, infants of diabetic mothers), a condition that also has been linked to lower SF concentrations at 9 months of age.[51] In a double-blind study, Friel et al[52] demonstrated that exclusively breastfed infants supplemented with iron between 1 and 6 months of age had higher Hb concentration and higher mean corpuscular volume at 6 months of age than did their unsupplemented peers. Supplementation also resulted in better visual acuity and higher Bayley Psychomotor Developmental Indices at 13 months. Thus, it is recommended that exclusively breastfed term infants receive an iron supplementation of 1 mg/kg per day, starting at 4 months of age and continued until appropriate iron-containing complementary foods have been introduced (Tables 3 and 4). For partially breastfed infants, the proportion of human milk versus formula is uncertain; therefore, beginning at 4 months of age, infants who receive more than one-half of their daily feedings as human milk and who are not receiving iron-containing complementary foods should also receive 1 mg/kg per day of supplemental iron.

Term, Formula-Fed Infants

For the term, formula-fed infant, the level of iron fortification of formula to prevent ID remains controversial.[53,54] For more than 25 years, 12 mg of iron per L has been the level of fortification in standard term infant formulas in the United States, consistent with

guidelines of WIC for iron-fortified formula (at least 10 mg/L), thus creating a natural experiment. The level of 12 mg/L was determined by calculating the total iron needs of the child from 0 to 12 months of age, assuming average birth weight and average weight gain during the first year. The calculation also assumed that formula was the only source of iron during this period. Others have recommended lower amounts of iron in infant formula,[55] and there have been studies to examine iron-fortification levels of less than 12 mg/L.[56–61] However, it is the conclusion of the AAP that infant formula that contains 12 mg of elemental iron per L is safe for its intended use. Although there has been some concern about linear growth in iron-replete infants given medicinal iron,[62] no published studies have convincingly documented decreased linear growth in iron-replete infants receiving formulas containing high amounts of iron. Evidence is also insufficient to associate formulas that contain 12 mg of iron per L with gastrointestinal symptoms. At least 4 studies have shown no adverse effects.[63–66] Reports have conflicted on whether iron fortification is associated with increased risk of infection. Decreased incidence, increased incidence, and no change in number of infections have all been reported.[67,68] The authors of a recent systematic review concluded that "iron supplementation has no apparent harmful effect on the overall incidence of infectious illnesses in children, though it slightly increases the risk of developing diarrhoea."[69] Finally, when examining specifically infants given formula with 12 mg of iron per L, Singhal et al[70] were "unable to identify adverse health effects in older infants and toddlers consuming a high iron-containing formula." They found no difference between controls and the treatment group in incidence of infection, gastrointestinal problems, or general morbidity.

TABLE 3 Foods to Increase Iron Intake and Iron Absorption

	Elemental Iron, mg
Commercial baby food,[a] heme iron	
Meat	
Baby food, lamb, junior, 1 jar (2.5 oz)	1.2
Baby food, chicken, strained, 1 jar (2.5 oz)	1.0
Baby food, lamb, strained, 1 jar (2.5 oz)	0.8
Baby food, beef, junior, 1 jar (2.5 oz)	0.7
Baby food, beef, strained, 1 jar (2.5 oz)	0.7
Baby food, chicken, junior, 1 jar (2.5 oz)	0.7
Baby food, pork, strained, 1 jar (2.5 oz)	0.7
Baby food, ham, strained, 1 jar (2.5 oz)	0.7
Baby food, ham, junior, 1 jar (2.5 oz)	0.7
Baby food, turkey, strained, 1 jar (2.5 oz)	0.5
Baby food, veal, strained, 1 jar (2.5 oz)	0.5
Commercial baby food,[a] nonheme iron	
Vegetables	
Baby food, green beans, junior, 1 jar (6 oz)	1.8
Baby food, peas, strained, 1 jar (3.4 oz)	0.9
Baby food, green beans, strained, 1 jar (4 oz)	0.8
Baby food, spinach, creamed, strained, 1 jar (4 oz)	0.7
Baby food, sweet potatoes, junior (6 oz)	0.7
Cereals	
Baby food, brown rice cereal, dry, instant, 1 tbsp	1.8
Baby food, oatmeal cereal, dry, 1 tbsp	1.6
Baby food, rice cereal, dry, 1 tbsp	1.2
Baby food, barley cereal, dry, 1 tbsp	1.1
Table food, heme iron	
Clams, canned, drained solids, 3 oz	23.8
Chicken liver, cooked, simmered, 3 oz	9.9
Oysters, Eastern canned, 3 oz	5.7
Beef liver, cooked, braised, 3 oz	5.6
Shrimp, cooked moist heat, 3 oz	2.6
Beef, composite of trimmed cuts, lean only, all grades, cooked, 3 oz	2.5
Sardines, Atlantic, canned in oil, drained solids with bone, 3 oz	2.5
Turkey, all classes, dark meat, roasted, 3 oz	2.0
Lamb, domestic, composite of trimmed retail cuts, separable lean only, choice, cooked, 3 oz	1.7
Fish, tuna, light, canned in water, drained solids, 3 oz	1.3
Chicken, broiler or fryer, dark meat, roasted, 3 oz	1.1
Turkey, all classes, light meat, roasted, 3 oz	1.1
Veal, composite of trimmed cuts, lean only, cooked, 3 oz	1.0
Chicken, broiler or fryer, breast, roasted, 3 oz	0.9
Pork, composite of trimmed cuts (leg, loin, shoulder), lean only, cooked, 3 oz	0.9
Fish, salmon, pink, cooked, 3 oz	0.8
Table food, nonheme iron	
Oatmeal, instant, fortified, cooked, 1 cup	14.0
Blackstrap molasses,[b] 2 tbsp	7.4
Tofu, raw, regular, ½ cup	6.7
Wheat germ, toasted, ½ cup	5.1
Ready-to-eat cereal, fortified at different levels, 1 cup	~4.5 to 18
Soybeans, mature seeds, cooked, boiled, ½ cup	4.4
Apricots, dehydrated (low-moisture), uncooked, ½ cup	3.8
Sunflower seeds, dried, ½ cup	3.7
Lentils, mature seeds, cooked, ½ cup	3.3
Spinach, cooked, boiled, drained, ½ cup	3.2
Chickpeas, mature seeds, cooked, ½ cup	2.4
Prunes, dehydrated (low-moisture), uncooked, ½ cup	2.3
Lima beans, large, mature seeds, cooked, ½ cup	2.2
Navy beans, mature seeds, cooked, ½ cup	2.2
Kidney beans, all types, mature seeds, cooked, ½ cup	2.0
Molasses, 2 tbsp	1.9
Pinto beans, mature seeds, cooked, ½ cup	1.8
Raisins, seedless, packed, ½ cup	1.6

TABLE 3 Continued

	Elemental Iron, mg
Prunes, dehydrated (low moisture), stewed, ½ cup	1.6
Prune juice, canned, 4 fl oz	1.5
Green peas, cooked, boiled, drain, ½ cup	1.2
Enriched white rice, long-grain, regular, cooked, ½ cup	1.0
Whole egg, cooked (fried or poached), 1 large egg	0.9
Enriched spaghetti, cooked, ½ cup	0.9
White bread, commercially prepared, 1 slice	0.9
Whole-wheat bread, commercially prepared, 1 slice	0.7
Spaghetti or macaroni, whole wheat, cooked, ½ cup	0.7
Peanut butter, smooth style, 2 tbsp	0.6
Brown rice, medium-grain, cooked, ½ cup	0.5

Note that all figures are rounded.

[a] Baby food values are generally based on generic jar, not branded jar; 3 oz of table-food meat = 85 g; a 2.5-oz jar of baby food = 71 g (an infant would not be expected to eat 3 oz [approximately the size of a deck of cards] of pureed table meat at a meal).

[b] Source of iron value was obtained from a manufacturer of this type of molasses.

Source of iron values in foods: US Department of Agriculture, Agricultural Research Service. USDA National Nutrient Database for Standard Reference, Release 20: Nutrient Data Laboratory home page. Available at: www.ars.usda.gov/ba/bhnrc/ndl.

TABLE 4 Selected Good Vitamin C Sources to Increase Iron Absorption

Fruits	Vegetables
Citrus fruits (eg, orange, tangerine, grapefruit)	Green, red, and yellow peppers
Pineapples	Broccoli
Fruit juices enriched with vitamin C	Tomatoes
Strawberries	Cabbages
Cantaloupe	Potatoes
Kiwifruit	Leafy green vegetables
Raspberries	Cauliflower

Toddlers (1–3 Years of Age)

The iron requirement for toddlers is 7 mg/day. Ideally, the iron requirements of toddlers would be met and ID/IDA would be prevented with naturally iron-rich foods rather than iron supplementation. These foods include those with heme sources of iron (ie, red meat) and nonheme sources of iron (ie, legumes, iron-fortified cereals) (Table 3). Foods that contain vitamin C (ascorbic acid), such as orange juice, aid in iron absorption and are listed in Table 4. Foods that contain phytates (found in soy) reduce iron absorption. Through public education and altering feeding practices, the amount of iron available to older infants and toddlers via a normal diet could be maximized (Table 3).

In developing countries, iron requirements of older infants and toddlers have been met by iron fortification of various foods, including corn flour,[71] soy sauce,[72] fish sauce,[73] and rice.[74] However, there are many technical and practical barriers to a successful fortification program for toddlers. Not the least of these barriers is the determination of which foods to fortify with iron. In the United States, fortification of infant formula and infant cereal has been credited with the decline in IDA. However, toddlers in the United States typically do not eat enough of any other food to serve as a vehicle for iron fortification. Universal food fortification for all ages is problematic, given the possible adverse effects of iron in certain subsets of older children and adults.

As an alternative for toddlers who do not eat adequate amounts of iron-containing food (Table 3), iron supplements are available in the form of iron sulfate drops and chewable iron tablets or as a component of either liquid or chewable multivitamins. Iron sprinkles with or without additional zinc are available in Canada. Barriers to adequate iron supplementation are (1) lack of education for care providers and patients, (2) poor compliance made worse by the perception of adverse effects, including nausea, vomiting, constipation, stomach upset, and teeth staining, (3) cost, (4) current federal supplemental nutrition programs not providing iron supplements, and (5) risk of iron overload.

Screening for ID and IDA

The AAP has concluded that universal screening for anemia should be performed with determination of Hb concentration at approximately 1 year of age. Universal screening would also include an assessment of risk factors associated with ID/IDA: history of prematurity or low birth weight; exposure to lead; exclusive breastfeeding beyond 4 months of age without supplemental iron; and weaning to whole milk or complementary foods that do not include iron-fortified cereals or foods naturally rich in iron (Table 3). Additional risk factors include the feeding problems, poor growth, and inadequate nutrition typically seen in infants with special health care needs as well as low socioeconomic status, especially children of Mexican American descent, as identified in the recent National Health and Nutrition Examination Survey[8,75] (Table 1). Selective screening can be performed at any age when these risk factors for ID and IDA have been identified, including risk of inadequate iron intake according to dietary history.

It has been acknowledged that screening for anemia with a Hb determination neither identifies children with ID nor specifically identifies those with IDA.[76] In the United States, 60% of anemia is not attributable to ID, and most tod-

dlers with ID do not have anemia (Table 2). It is also known that there is poor follow-up testing and poor documentation of improved Hb concentrations. In 1 study, 14% of the children had a positive screening result for anemia. However, only 18.3% of these children with a positive screening result had follow-up testing performed, and of that group, only 11.6% had documented correction of low Hb levels.[77] Therefore, for infants identified with a Hb concentration of less than 11.0 mg/dL or identified with significant risk of ID or IDA as described previously, SF and CRP or CHr levels in addition to Hb concentration should be measured to increase the sensitivity and specificity of the diagnosis. In addition, the AAP, the World Health Organization, and the European Society for Pediatric Gastroenterology, Hepatology and Nutrition also support the use of the measurement of TfR1 as a screening test once the method has been validated and normal values for infants and toddlers have been established.

Another step to improve the current screening system is to use technology-based reminders for screening and follow-up of infants and toddlers with a diagnosis of ID/IDA. Reminders could be incorporated into electronic health records, and there should be documentation that Hb concentrations have returned to the normal range. The efficacy of any program for minimizing ID and IDA should be tracked scientifically and evaluated through well-planned surveillance programs.

SUMMARY

Given that iron is the world's most common single-nutrient deficiency and there is some evidence of adverse effects of both ID and IDA on cognitive and behavioral development, it is important to minimize ID and IDA in infants and toddlers without waiting for unequivocal evidence. Controversies remain regarding the timing and methods used for screening for ID/IDA as well as regarding the use of iron supplements to prevent ID/IDA. Although further study is required to generate higher levels of evidence to settle these controversies, the currently available evidence supports the following recommendations.

1. Term, healthy infants have sufficient iron for at least the first 4 months of life. Human milk contains very little iron. Exclusively breastfed infants are at increasing risk of ID after 4 completed months of age. Therefore, at 4 months of age, breastfed infants should be supplemented with 1 mg/kg per day of oral iron beginning at 4 months of age until appropriate iron-containing complementary foods (including iron-fortified cereals) are introduced in the diet (see Table 3). For partially breastfed infants, the proportion of human milk versus formula is uncertain; therefore, beginning at 4 months of age, partially breastfed infants (more than half of their daily feedings as human milk) who are not receiving iron-containing complementary foods should also receive 1 mg/kg per day of supplemental iron.
2. For formula-fed infants, the iron needs for the first 12 months of life can be met by a standard infant formula (iron content: 10–12 mg/L) and the introduction of iron-containing complementary foods after 4 to 6 months of age, including iron-fortified cereals (Table 3). Whole milk should not be used before 12 completed months of age.
3. The iron intake between 6 and 12 months of age should be 11 mg/day. When infants are given complementary foods, red meat and vegetables with higher iron content should be introduced early (Table 3). To augment the iron supply, liquid iron supplements are appropriate if iron needs are not being met by the intake of formula and complementary foods.
4. Toddlers 1 through 3 years of age should have an iron intake of 7 mg/day. This would be best delivered by eating red meats, cereals fortified with iron, vegetables that contain iron, and fruits with vitamin C, which augments the absorption of iron (Tables 3 and 4). For toddlers not receiving this iron intake, liquid supplements are suitable for children 12 through 36 months of age, and chewable multivitamins can be used for children 3 years and older.
5. All preterm infants should have an iron intake of at least 2 mg/kg per day through 12 months of age, which is the amount of iron supplied by iron-fortified formulas. Preterm infants fed human milk should receive an iron supplement of 2 mg/kg per day by 1 month of age, and this should be continued until the infant is weaned to iron-fortified formula or begins eating complementary foods that supply the 2 mg/kg of iron. An exception to this practice would include infants who have received an iron load from multiple transfusions of packed red blood cells.
6. Universal screening for anemia should be performed at approximately 12 months of age with determination of Hb concentration and an assessment of risk factors associated with ID/IDA. These risk factors would include low socioeconomic status (especially children of Mexican American descent [Table 1]), a history of prematurity or low birth weight, exposure to lead, exclusive breastfeeding beyond 4 months of age without supplemental iron, and weaning to whole milk or complementary foods that do not include iron-fortified cereals or

foods naturally rich in iron (Table 3). Additional risk factors are the feeding problems, poor growth, and inadequate nutrition typically seen in infants with special health care needs. For infants and toddlers (1–3 years of age), additional screening can be performed at any time if there is a risk of ID/IDA, including inadequate dietary iron intake.

7. If the Hb level is less than 11.0 mg/dL at 12 months of age, then further evaluation for IDA is required to establish it as a cause of anemia. If there is a high risk of dietary ID as described in point 6 above, then further testing for ID should be performed, given the potential adverse effects on neurodevelopmental outcomes. Additional screening tests for ID or IDA should include measurement of:
   - SF and CRP levels; or
   - CHr concentration.
8. If a child has mild anemia (Hb level of 10–11 mg/d) and can be closely monitored, an alternative method of diagnosis would be to document a 1 g/dL increase in plasma Hb concentration after 1 month of appropriate iron-replacement therapy, especially if the history indicates that the diet is likely to be iron deficient.
9. Use of the TfR1 assay as screening for ID is promising, and the AAP supports the development of TfR1 standards for use of this assay in infants and children.
10. If IDA (or any anemia) or ID has been confirmed by history and laboratory evidence, a means of carefully tracking and following infants and toddlers with a diagnosis of ID/IDA should be implemented. Electronic health records could be used not only to generate reminder messages to screen for IDA and ID at 12 months of age but also to document that IDA and ID have been adequately treated once diagnosed.

ADDENDUM

Development of This Report

This report was written by the primary authors after extensive review of the literature using PubMed, previous AAP reports, Cochrane reviews, and reports from other groups.[1,6,7,48,77]

The report was also submitted to the following sections and committees of the AAP that were asked to comment on the manuscript: Committee on Fetus and Newborn (COFN); Committee on Psychosocial Aspects of Child and Family Health (COPACFH); Section on Administration and Practice Management (SOAPM); Section on Developmental and Behavioral Pediatrics (SODBP); Section on Gastroenterology, Hepatology, and Nutrition (SOGHN); Section on Hematology and Oncology (SOHO); and Section on Breast Feeding (SOBr).

Additional comments were sought from the Centers for Disease Control and Prevention (CDC), the Department of Agriculture (WIC), the National Institutes of Health (NIH), and the Food and Drug Administration (FDA), because these governmental agencies were involved in the development of the statement and will necessarily deal with its impact. As it was developed it was extensively reviewed and revised by members of the AAP Committee on Nutrition, who unanimously approved this clinical report. It is openly acknowledged that where the highest levels of evidence are absent, the opinions and suggestions of members of the Committee on Nutrition as well as other groups consulted for this statement were taken into consideration in developing this clinical report.

Practice Parameter: Diagnostic assessment of the child with cerebral palsy

Report of the Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

S. Ashwal, MD; B.S. Russman, MD; P.A. Blasco, MD; G. Miller, MD; A. Sandler, MD; M. Shevell, MD, CM, FRCP; and R. Stevenson, MD

Abstract—*Objective:* The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management based on analysis of evidence. For this parameter the authors reviewed available evidence on the assessment of a child suspected of having cerebral palsy (CP), a nonprogressive disorder of posture or movement due to a lesion of the developing brain. *Methods:* Relevant literature was reviewed, abstracted, and classified. Recommendations were based on a four-tiered scheme of evidence classification. *Results:* CP is a common problem, occurring in about 2 to 2.5 per 1,000 live births. In order to establish that a brain abnormality exists in children with CP that may, in turn, suggest an etiology and prognosis, neuroimaging is recommended with MRI preferred to CT (Level A). Metabolic and genetic studies should not be routinely obtained in the evaluation of the child with CP (Level B). If the clinical history or findings on neuroimaging do not determine a specific structural abnormality or if there are additional and atypical features in the history or clinical examination, metabolic and genetic testing should be considered (Level C). Detection of a brain malformation in a child with CP warrants consideration of an underlying genetic or metabolic etiology. Because the incidence of cerebral infarction is high in children with hemiplegic CP, diagnostic testing for coagulation disorders should be considered (Level B). However, there is insufficient evidence at present to be precise as to what studies should be ordered. An EEG is not recommended unless there are features suggestive of epilepsy or a specific epileptic syndrome (Level A). Because children with CP may have associated deficits of mental retardation, ophthalmologic and hearing impairments, speech and language disorders, and oral-motor dysfunction, screening for these conditions should be part of the initial assessment (Level A). *Conclusions:* Neuroimaging results in children with CP are commonly abnormal and may help determine the etiology. Screening for associated conditions is warranted as part of the initial evaluation.

NEUROLOGY 2004;62:851–863

Cerebral palsy (CP) can be defined as a disorder of aberrant control of movement and posture, appearing early in life secondary to a CNS lesion or dysfunction that is not the result of a recognized progressive or degenerative brain disease.[1] The brain abnormality may occur pre-, peri-, or postnatally. The diagnosis of CP always involves a motor deficit and the usual presenting complaint for which medical evaluation is sought is that the child is not reaching motor milestones at the appropriate chronological age. In most

Approved by the Quality Standards Subcommittee in March 2003. Approved by the AAN Practice Committee on August 9, 2003. Approved by the AAN Board of Directors on October 18, 2003.

From the Division of Child Neurology (Dr. Ashwal), Department of Pediatrics, Loma Linda University School of Medicine, CA; Departments of Pediatrics and Neurology (Dr. Russman) and Division of Neurodevelopmental Disabilities, Department of Pediatrics (Dr. Blasco), Oregon Health and Science University and Shriners Hospital for Children, Portland; Pediatrics and Neurology (Dr. Miller), Baylor College of Medicine, Houston, TX; University of North Carolina, Chapel Hill, and Olson Huff Center for Child Development (Dr. Sandler), Mission Children's Health Services, Asheville, NC; Departments of Neurology/Neurosurgery and Pediatrics (Dr. Shevell), Department of Human Genetics, McGill University, and Division of Pediatric Neurology, Montreal Children's Hospital, Montreal, Quebec, Canada; and Pediatrics (Dr. Stevenson), University of Virginia School of Medicine, Charlottesville.

Received May 27, 2003. Accepted in final form December 24, 2003.

instances, a medical history establishes that the child is not losing function, assuring that the patient does not have a progressive disease. This history, combined with a neurologic examination establishing that the patient's motor deficit is due to a cerebral abnormality, leads to the diagnosis of CP. Serial examinations may be necessary to assure the diagnosis of CP, especially when the history is not reliable.

There is agreement that CP is due to a defect or lesion in the developing brain, which may have had its onset in the prenatal, perinatal, or postnatal period.[1] While often a cutoff age for the appearance of symptoms early in life is generally not given, the great majority of children with CP present with symptoms as infants or toddlers, and the diagnosis of CP is made before age 2 years. In some children, symptom onset may be delayed (e.g., dystonic cerebral palsy), whereas in other children the appearance of pseudoprogression of symptoms may occur. The term CP is descriptive and includes a number of etiologies and clinical presentations. Although there is no consensus about a precise age cut-off either for the timing of the insult or the onset of symptoms, of importance is that affected individuals have similar needs for rehabilitation, education, and medical and social services.

CP is a common problem. The worldwide incidence of CP is approximately 2 to 2.5 per 1,000 live births.[2] Each year about 10,000 babies born in the United States develop CP.[3] CP occurs more commonly in children who are born very prematurely or at term. Data from Sweden on 241 children with CP indicate that 36% were born at a gestational age (GA) of less than 28 weeks; 25% at 28 to 32 weeks GA; 2.5% at 32 to 38 weeks GA; and 37% at term.[2]

The types and severity of CP are clinically well established. A Scandinavian study reported that 33% of the CP population was hemiplegic, 44% diplegic, and 6% quadriplegic.[2]

Half of the individuals with CP use assistive devices such as braces, walkers, or wheelchairs to help develop or maintain mobility and almost 70% have other disabilities, primarily mental retardation.[3] Individuals with CP may need specialized medical care, educational and social services, and other help throughout their lives from their families and communities. A study 10 years ago in California of the extra economic costs associated with CP and 17 other congenital disorders (e.g., Down syndrome, spina bifida) showed that CP had the highest lifetime costs per new case, averaging $503,000 in 1992 dollars.[4]

Laboratory tests are not necessary to confirm the diagnosis of CP as it is based on the history and examination. It is a syndrome with many etiologies. Genetic diseases, brain malformations, infections, and anoxic injury to the developing brain are a few of the many causes of CP. Accurate determination of the etiology of CP has specific implications regarding treatment, prognosis, and ongoing medical management of associated conditions. The importance of determining whether there is a malformation, genetic etiology, or injury and whether the injury is due to an acquired pre-, peri-, or postnatal process has obvious significance from the point of view of assessment of recurrence risk, counseling of families, and implementation of prevention programs, and when medicolegal issues arise. Determining causality also helps limit further unnecessary testing. Finally, understanding the etiology of CP has implications for prevention and intervention strategies. This knowledge will direct further research efforts.

Determining the types of evaluations appropriate for children with CP has posed tremendous challenges for parents and health care providers. The purpose of this practice parameter is to review data regarding the value and role of diagnostic tests used to evaluate children diagnosed with CP. Data regarding the role of neuroimaging, metabolic and genetic testing, and evaluation for coagulopathy are discussed. There was insufficient evidence to make any recommendations regarding the role of SPECT scans or evoked potentials in children with CP. This parameter also reviews evidence regarding the prevalence of associated problems such as epilepsy, mental retardation, speech and language disorders, and ophthalmologic and hearing impairments, and the need for their systematic evaluation.

Description of process. Literature searches were conducted with the assistance of the University of Minnesota Biomedical Information Services for relevant articles published from 1980 to March 2002. Medline, CINAHL, and Healthstar databases were searched for relevant articles published from 1966 to 2002, in the English language, using the following key words: CP, magnetic resonance imaging, MRI, computed axial tomography, CT scan, single photon emission tomography, SPECT, metabolic disease, thrombophilia, brain stem evoked potentials, sensory evoked potentials, visual evoked potentials, electroencephalography (EEG), seizures, epilepsy, vision loss, hearing loss, developmental delay, and speech and language delay. Approximately 350 titles and abstracts were reviewed for content regarding the establishment of the etiology of CP. Articles were excluded if the tests were ordered for reasons other than to establish the etiology. We included only studies that contained more than 20 patients; smaller case series were excluded. The ages of infants and children included in these studies were similar to the ages of children typically seen for diagnostic evaluation so it was believed that the evidence-based recommendations included in this parameter were appropriate. It was also believed that as CP is usually due to a static process, it was unlikely for neuroimaging studies to change over time so that data from studies done in older children with CP were valid regarding etiologic yield. Each article was reviewed, abstracted, and classified by a committee member. Data extracted include first author, year, study population, study design, number of patients, types of CP, results of testing,

Table 1 *American Academy of Neurology evidence classification scheme for determining the yield of established diagnostic and screening tests*

Class I: A statistical,[1] population-based[2] sample of patients studied at a uniform point in time (usually early) during the course of the condition. All patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation that is masked to the patients' clinical presentations.

Class II: A statistical, non-referral-clinic-based[3] sample of patients studied at a uniform point in time (usually early) during the course of the condition. Most (>80%) patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation that is masked to the patients' clinical presentations.

Class III: A selected, referral-clinic-based[4] sample of patients studied during the course of the condition. Some patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation by someone other than the treating physician.

Class IV: Expert opinion, case reports, or any study not meeting criteria for class I to III.

This is a new classification scheme developed by the Quality Standards Subcommittee (QSS) for studies related to determining the yield of established diagnostic and screening tests or interventions and is appropriate only when the diagnostic accuracy of the test or intervention is known to be good. Additionally, the abnormality potentially identified by the screening intervention should be treatable or should have important prognostic implications. This classification is different from others currently recommended by the QSS that have been published in recent parameters that relate to diagnostic, prognostic, or therapeutic studies.

[1] Statistical sample: A complete (consecutive), random, or systematic (e.g., every third patient) sample of the available population with the disease;
[2] Population-based: The available population for the study consists of all patients within a defined geographic region;
[3] Non-referral-clinic-based: The available population for the study consists of all patients presenting to a primary care setting with the condition;
[4] Referral-clinic-based: The available population for the study consists of all patients referred to a tertiary care or specialty setting. These patients may have been selected for more severe or unusual forms of the condition and thus may be less representative;
[5] Objective: An outcome measure that is very unlikely to be affected by an observer's expectations (e.g., determination of death, the presence of a mass on head CT, serum B12 assays).

Table 2 *American Academy of Neurology system for translation of evidence to recommendations*

Rating of recommendations	Translation of evidence to recommendations
A = Established as useful/predictive or not useful/predictive for the given condition in the specified population	Level A rating requires at least one convincing class I study or at least two consistent, convincing class II studies
B = Probably useful/predictive or not useful/predictive for the given condition in the specified population	Level B rating requires at least one convincing class II study or overwhelming class III evidence
C = Possibly useful/predictive or not useful/predictive for the given condition in the specified population	Level C rating requires at least two convincing class III studies
U = Data inadequate or conflicting. Given current knowledge, test, predictor is unproven.	

and outcomes measured. A new four-tiered classification scheme for determining the yield of established diagnostic and screening tests developed by the Quality Standards Subcommittee was utilized as part of this assessment (table 1). This classification scheme is different from the one currently used in recently published practice parameters that evaluate diagnostic, prognostic, or therapeutic articles. Depending on the strength of this evidence, it was decided whether specific recommendations could be made, and if so, the level of strength of these recommendations (table 2).

Neuroimaging. Should neuroimaging be routinely obtained in the child with CP?

Evidence. In neonates, neuroimaging is frequently obtained when there is a history of complications during pregnancy, labor, and delivery; when the infant is born very prematurely (<32 weeks); or when neurologic symptoms or findings are present on neonatal examination. A practice parameter regarding the value of and indications for obtaining neuroimaging in preterm and term infants has recently been published.[5] The current parameter addresses the role of neuroimaging in the infant or child who has been diagnosed with or is suspected of having CP based upon a motor deficit or delay that is not worsening and a history and neurologic examination that places the lesion in the CNS. In some situations, the risks of obtaining a neuroimaging study in an infant with CP may potentially outweigh the benefits of further defining the etiology.

Recent data encompassing a total of 1,426 children who underwent either CT[6-14] or MRI[15-24] scans indicated an abnormality in 62% to 100% of individuals (mean for CT, 77%; for MRI, 89%) (tables 3a and 4a). For the combined CT and MRI class I studies (n = 238), 88% of children had abnormal scans whereas 77% of patients in a class II study (n = 22) had abnormal scans as did 83% of children in the class III studies (n = 1166). The timing of the brain insult causing CP may be categorized into prenatal, perinatal, and postnatal subgroups and the neuropathologic changes seen in CP have been linked to the gestational age of the infant at the time of insult. Historical features (e.g., neonatal intracranial hemorrhage, neonatal encephalopathy, stroke, CNS infection, trauma) or prior neuroimaging studies that document such disorders or the presence of a brain malformation may provide sufficient information to establish the etiology when a child is seen later in life as the symptoms of CP evolve. Likewise, findings

on physical examination (e.g., cataracts, chorioretinitis, dysmorphic features, myoclonus, dystonia) may suggest a specific etiology or an alternative diagnosis. An abnormality on MRI does not necessarily mean that the etiology of the motor deficit has been established. For example, the findings of diffuse cortical atrophy, delayed myelination, or polymicrogyria are nonspecific and only suggest that a CNS disturbance was present and may not allow one to know the underlying cause without a more specific workup.

CT. Data from 782 children with CP who had CT scans found abnormalities in 77% (range 62% to 93%) (see table 3a). For the class I studies (n = 140), 86% of children had abnormal scans whereas 78% of patients in class III studies (n = 642) had abnormal scans (there were no class II studies). The yield from CT scans varied depending on the type of CP (hemiplegic > ataxic > mixed > diplegic > quadriplegic > hypotonic > dyskinetic) with the percent abnormal in those with dyskinetic CP being much lower than in other forms of CP (table 3b).

* Etiologies could not be determined in all patients in the studies listed in section a and in some patients more than one category of etiology was given. In some studies there were no data provided as to a specific etiology.

SQ = spastic quadriplegic; M = mixed; SD = spastic diplegic; NA = not available; D = dyskinetic.

When abnormal, CT scans are helpful in delineating the timing of the etiology of CP in most children (table 3c). For the class I studies (n = 111), onset was prenatal in 44%, perinatal in 43%, and postnatal in 0%. For the class III studies (n = 515), onset was prenatal in 29%, perinatal in 52%, and postnatal in 15%. In the remaining patients, the timing of the insult was not determined. Some of the more common etiologies of prenatal onset include intrauterine infection, stroke, toxemia, and placental abruption; of perinatal onset, etiologies include hypoxic ischemic encephalopathy, kernicterus, and trauma; and of postnatal onset, etiologies include infection, trauma, and progressive hydrocephalus. There was insufficient information from the CT studies to calculate an accurate breakdown by specific etiology for any of the three groups although in many of the individual cases a specific etiology was assigned. Etiologies tend to be different in term and preterm babies and are discussed further in the section on MRI.

A CT scan in a child with CP may on occasion detect conditions that are surgically treatable that

Data from the following studies: Yin et al., 2000[16]; Okumara et al., 1997, pt 2[18]; Cioni et al., 1999[19]; Sugimoto et al., 1995[21]; Hayakawa et al., 1996[22]; Krageloh-Mann et al., 1995[15]; Yokochi et al., 1991[24]; Candy et al., 1993[17]; Jaw et al., 1998[20]; Truwit et al., 1992.[23] Abnormalities considered insults on neuroimaging were designated as preterm (insult occurred before 38 weeks gestation whether infant born prematurely or at term), term (insult occurred after full term gestation in the perinatal period up to 1 month of age), or postnatal (insult occurred after 1 month of age in infants born prematurely or at term). Malformations were categorized as preterm if detected in infants born before 38 weeks gestation or term if detected in infants born after a full term pregnancy.

* The data in the malformations section of this table are separated into preterm, term, and post-term as that is how they were reported in the original reports. It is believed, however, that these malformations occur prenatally.

PVL = periventricular leukomalacia.

might not be detected by neurologic examination. The chance of finding a surgically treatable lesion based on data from 702 children with various types of CP is 5% (range 0% to 22.5%) (table 3d). This may vary as one class III study reported that 22.5% of 120 patients had potentially treatable lesions identified (hydrocephalus, porencephaly, arteriovenous malformation, subdural hematomas and hygromas, and a vermian tumor).[10] The majority of other studies reported either no patients with potentially treatable lesions[6,13,14] or lower incidences of 5%,[9] 14%,[11] and 17%.[8] On occasion, CT (as well as MRI) may detect abnormalities that suggest a potentially treatable inborn error of metabolism.

When the CT scan is abnormal, the presence of coexisting conditions should be anticipated. In studies of 240 children with CP, the presence of mental retardation was greater if scans were abnormal than if they were normal or had minor abnormalities (78% versus 39%).[8,11-13] Three of these studies had additional data regarding the relation between CT findings and epilepsy.[8,11,12] Ninety-one percent of children with CP who had an abnormal CT scan had epilepsy or an abnormal EEG in contrast to only 38% of children whose scans were normal or minimally abnormal. One of these studies found normal EEG in 37%, paroxysmal EEG in 44%, and other abnormalities such as hemispheric asymmetry or suppression of activity in 19% of children.[13] Although an abnormal CT suggested greater risk of coexistent conditions, the specific nature of these conditions (e.g., type of epilepsy) did not correlate with scan abnormalities.[13]

Conclusions. Data from three class I (75%) and six class III (77%) studies indicate that the yield of finding an abnormal CT scan in a child with CP is high (average of 77%) and related to the type of CP. Scan abnormalities may determine an etiology in many children but there were insufficient data to assess this further. Scan abnormalities may occasionally (i.e., 5 to 22%) identify treatable conditions and may suggest an increased risk for associated conditions such as mental retardation and epilepsy.

MRI. Data from studies involving 644 children with CP who had MRI scans found abnormalities in

89% (range 68% to 100%) (see table 4a). For the two class I studies (n = 98), 92% of children had abnormal scans whereas 77% of patients in one class II study (n = 22) had abnormal scans as did 89% of children in the class III studies (n = 524). The yield on MRI (table 4b) depended on the type of CP that was present (mixed > quadriplegic > hemiplegic > diplegic > ataxic > dyskinetic > hypotonic) and was somewhat different from that reported using CT.

MRI was helpful in determining whether the injury was prenatal, perinatal, or postnatal in onset (table 4c). Based on studies involving 345 children (class I n = 98; class III n = 247) with different types of CP, onset was prenatal in 37% (29% in class I and 45% in class III studies), perinatal in 35% (45% in class I and 31% in class III), and postnatal in 4% (1% in class I and 5% in class III studies). The yield from MRI also depended on whether the child with CP was born prematurely, at term, or whether CP was due to an insult later in life. Data from studies on 620 patients found that MRI scans were abnormal in 332/335 (99%) preterm infants, 251/272 (92%) term infants, and 23/29 (79%) infants older than 1 month (table 5). In most series, this was due to the fact that MRI was more sensitive in detecting periventricular leukomalacia, other perinatally acquired lesions, as well as subtle congenital anomalies of brain development. MRI can help define abnormalities based on the timing of insult in most patients as summarized in table 5. The etiology of CP in these children was suggested or established based on neuroimaging findings in combination with the clinical history.

Conclusions. Data from two class I (92%), one class II (77%), and seven class III studies (89%) indicate that the yield of finding an abnormal MRI scan in a child with CP is very high (average of 89%) and greater than that reported using CT (77%). The yield on MRI (as with CT) depends on the type of CP that is present. MRI is more likely to be abnormal in cases of CP associated with prematurity, showing abnormalities such as periventricular leukomalacia, compared to infants born at term. An etiology of CP can be determined in many patients based on the results of neuroimaging in combination with the clinical history.

Recommendations. 1. Neuroimaging is recommended in the evaluation of a child with CP if the etiology has not been established; for example, by perinatal imaging (Level A, class I and II evidence).

2. MRI, when available, is preferred to CT scanning because of the higher yield of suggesting an etiology and timing of insult leading to CP (Level A, class I–III evidence).

Metabolic and genetic testing. Should metabolic or genetic testing be routinely ordered in children with CP?

Evidence. Data from 2 class I, 13 class II, and 4 class III studies on 1,384 children with CP who underwent neuroimaging (CT or MRI) and who also had metabolic and genetic testing indicate that it is rare to identify an underlying metabolic or genetic disorder. The mean incidence of metabolic (4%) and genetic disorders (2%) in those children who had CT scans was slightly higher than with MRI (metabolic, 0%; genetic, 1.4%) and did not vary substantially between the different classes of studies (see tables 3d and 4d). The low and variable incidence of metabolic and genetic disorders in these studies was, in part, due to patient selection factors, as in some studies children with metabolic disorders were excluded from analysis.[17] Also, in these retrospective studies, the extent and type of metabolic or genetic testing was variable so that the exact prevalence of such disorders in children with CP remains uncertain.

Since the advent of neuroimaging, it has become more apparent that children with CP may have congenital brain malformations. Data from this same group of 1,426 children found that 7% of patients who had a CT scan and 12% of those who underwent MRI had major brain malformations such as lissencephaly, schizencephaly, or pachygyria (see tables 3d and 4d). Because these malformations are ever increasingly associated with specific genetic disorders (e.g., lissencephaly/Miller-Dieker syndrome/chromosome 17p13.3), their presence in affected children indicates the need for further genetic testing. Certain neurometabolic disorders (e.g., peroxisomal disorders such as Zellweger syndrome) may be associated with cerebral malformations and can present within the first years of life with a motor deficit that might appear to be nonprogressive. At present, no studies have prospectively evaluated children with CP with or without brain malformations to determine the incidence of metabolic or genetic abnormalities.

Metabolic disorders may on rare occasions masquerade as CP. Six small case series (i.e., class IV studies) describe 30 children who ultimately developed what appeared to be dyskinetic CP due to glutaric aciduria (type 1).[25-30] These children typically develop normally until 5 to 10 months of age when they suffer an acute encephalopathy manifested by coma that is followed by dystonia, motor impairment, and macrocephaly (in about 60%).[25] Distinctive MRI and CT findings occur in half the patients and are manifested by frontal and temporal atrophy. Early diagnosis is important as glutaric aciduria is treatable; early intervention may prevent significant motor and cognitive impairment.[28] Other metabolic disorders presenting with symptoms suggestive of CP also have been reported in small case series and include Lesch-Nyhan syndrome,[31] 3-methylglutaconic aciduria,[32] pyruvate dehydrogenase deficiency,[33] argininemia,[34] cytochrome oxidase deficiency,[35] succinic semialdehyde dehydrogenase deficiency,[36] and female carriers of ornithine transcarbamylase deficiency.[37]

Other childhood neurologic disorders (e.g., dopa-responsive dystonia, hereditary spastic paraplegia, ataxia telangiectasia) may initially be misdiagnosed as CP because of the slow rate of progression of symptoms. Other clinical or laboratory features of

NA = not available.

such conditions and observations over time that neurologic symptoms are progressive should suggest that the child does not have CP and mandates the need for further evaluation.

Conclusions. Metabolic or genetic causes for CP occur infrequently (i.e., 0 to 4%). However, the true incidence is unknown as there have been no prospective studies that have examined this issue. In almost all such cases, there are atypical complaints, features in the history of a progressive rather than a static encephalopathy, findings on neuroimaging that are representative of certain genetic or metabolic disorders, or a family history of childhood neurologic disorder with associated CP. Neuroimaging studies have shown that 7 to 11% of children with CP will have a brain malformation suggesting additional risk for genetic and possibly a metabolic etiology.

Recommendations. 1. Metabolic and genetic studies should not be routinely obtained in the evaluation of the child with CP (Level B, class II and III evidence).

2. If the clinical history or findings on neuroimaging do not determine a specific structural abnormality or if there are additional and atypical features in the history or clinical examination, metabolic and genetic testing should be considered (Level C, class III and IV).

3. Detection of a brain malformation in a child with CP warrants consideration of an underlying genetic or metabolic etiology (Level C, class III and IV evidence).

Coagulopathies. Should coagulation studies be performed in children with CP?

Evidence. Patients with hemiplegic CP frequently have suffered a prenatal or perinatal cerebral infarction. Data from three CT studies listed in table 3a (n = 196) found cerebrovascular occlusion, usually in the middle cerebral artery distribution, in 13%,[6] 32%,[11] and 37%[14] of individuals. There are insufficient data concerning the incidence of cerebral infarction or other causes of cerebrovascular compromise in children with other forms of CP.

Children, in contrast to adults, often have a coagulopathy, congenital heart disease, or an infectious process as the etiology of stroke.[38] However, none of the MRI series listed in table 4a focused on children with hemiplegic CP. None of the reported series (see tables 3 and 4) included information indicating that a systematic examination for the etiology of infarction was performed. One class I study[39] and several class II studies have reported coagulation abnormalities as the etiology of neonatal cerebral infarction.[39-42] These have included Factor V Leiden deficiency, the presence of anticardiolipin or antiphospholipid antibodies, and Protein C or S deficiency. One class III study[42] and several class IV case reports[43-46] have also described the relation between neonatal cerebral infarction, coagulopathies, and a later diagnosis of hemiplegic CP.

Conclusions. Class I–III evidence indicates that cerebral infarction due to pre- or perinatal cerebrovascular occlusion occurs in 13 to 37% of children with hemiplegic CP. Class II and III evidence suggests that an etiology of cerebral infarction in this population may be due to a coagulation disorder and that the yield of testing will be higher if done in the neonatal period rather than if the child is evaluated later at the time of diagnosis of CP. There is insufficient evidence regarding the relation between coagulation disorders and other forms of CP.

Recommendations. Because the incidence of unexplained cerebral infarction seen with neuroimaging is high in children with hemiplegic CP, diagnostic testing for a coagulation disorder should be considered (Level B, class II–III evidence). There is insufficient evidence to be precise as to what studies should be ordered.

Associated conditions. What evaluations for associated conditions should be performed in children with CP?

Evidence. Children with CP often have associated conditions such as mental retardation or epilepsy that are equal in severity to their motor impairment. Because of the motor difficulties associated with CP, these conditions may not be readily recognized. These conditions may also seriously hamper the ability of a child to realize his or her intrinsic developmental potential.

Data from three class I and one class II studies involving 886 children with CP summarize the frequency of some of the major associated conditions that occur in children with CP (table 6).[47-49] The incidence of mental retardation (52%), epilepsy (45%), ophthalmo-

logic defects (28%), speech and language disorders (38%), and hearing impairment (12%) are quite significant. Data from some of these studies also suggest that those children who have abnormal neuroimaging are more likely to have one or more of these deficits and in some of the studies severity of scan findings was associated with the severity of deficit.

Epilepsy. Should EEG be routinely performed in the assessment of children with CP?

Evidence. Given the higher frequency of epilepsy in children with CP, EEG is often considered during the initial evaluation.[47] The utility of EEG from a diagnostic perspective in this population has not been prospectively investigated. The vast majority of articles on EEG and CP are class III and IV studies that describe the frequency and types of seizures in children with different forms of CP but do not address the role of EEG in determining the etiology of CP nor in predicting the development of seizures in a child with CP.

Data from studies involving 1,918 children have found on average that 43% (range 35 to 62%) of children with CP develop epilepsy (table 7). In the three class I studies (n = 302), 48% had epilepsy in contrast to 42% of the children in the eight class II studies (n = 1,407) and 43% in the class III studies (n = 209). In none of these studies was there evidence that the EEG was useful in determining the etiology of the child's CP.

Data from one class II study compared patients with CP and epilepsy to those with epilepsy alone.[55] Children with CP had a higher incidence of epilepsy with onset within the first year of age (47% versus 10%), history of neonatal seizures (19% versus 3%), status epilepticus (16% versus 1.7%), need for polytherapy (25% versus 3%), and treatment with second-line antiepileptic drugs (31% versus 6.7%). They also had a lower incidence of generalized seizures (28% versus 59%) and of remaining seizure free (37% versus 90%).[55] Factors associated with a seizure-free period of 1 year or more in epileptic children with CP include normal intelligence, single seizure type, monotherapy, and spastic diplegia. Similar findings have been observed by other investigators in the studies listed in table 7 and are summarized in the review by Wallace.[47] Children with CP who have abnormal neuroimaging studies are more likely to have epilepsy. One class I and two class II CT studies have examined the association between CT findings and epilepsy.[8,11,13] Fifty-four percent of children with CP and an abnormal CT had epilepsy in contrast to only 27% of those who had a normal scan. In one study, EEG abnormalities (described as paroxysmal or asymmetric) were also much more commonly found in those children with an abnormal CT scan.[13]

The prevalence of epilepsy also varies depending on the type of CP that is present. Data from the studies listed in table 7 indicate that children with spastic quadriplegia (50 to 94%) or hemiplegia (30%) have a higher incidence of epilepsy than patients with diplegia or ataxic CP (16 to 27%). In patients with dyskinetic CP, it may occasionally be difficult to differentiate partial complex seizures from dyskinetic movements.

Conclusions. Although approximately 45% of children with CP develop epilepsy, in none of the retrospective studies involving 2,014 children was there evidence that the EEG was useful in determining the etiology of the child's CP. There is no evidence to make any recommendation regarding the child with CP who does not have a history of seizures as to whether an EEG should be ordered to screen for epileptiform abnormalities.

Recommendations. 1. An EEG should not be obtained for the purpose of determining the etiology of CP (Level A; class I and II evidence).

2. An EEG should be obtained when a child with CP has a history or examination features suggesting the presence of epilepsy or an epileptic syndrome (Level A; class I and II evidence).

Mental retardation. Cognitive and neuropsychological function in children with CP are commonly impaired.[58] In general, there is some but no absolute relation between the type of CP and severity of cognitive impairment. Children with spastic quadriplegia have greater degrees of mental impairment than children with spastic hemiplegia. Motor deficits of children with spastic CP appear to correlate with the severity of cognitive deficits in contrast to those children with dyskinetic CP where this relation is lacking.[58]

Children with different forms of CP may be difficult to assess because of the motor deficits and in some forms of CP (e.g., spastic diplegia) the differences between performance and verbal intelligence test scores actually increase with age.[59] Laterality of hemiplegia may also be a contributing factor—those children with right hemiplegia may be more likely to have impaired language function due to left hemisphere injury,[59] although this remains controversial.[60] There is also a strong association between greater intellectual impairment in children with CP and the presence of epilepsy, an abnormal EEG, or an abnormal neuroimaging study.[47]

Ophthalmologic impairments. Visual impairments and disorders of ocular motility are common (28%) in children with CP (see table 6). There is an increased presence of strabismus, amblyopia, nystagmus, optic atrophy, and refractive errors.[61] Children whose CP is due to periventricular leukomalacia are also more likely to have visual perceptual problems. Many of these difficulties should be detected if currently accepted guidelines for vision screening in children with CP are employed.[62,63]

Speech and language disorders. Because of bilateral corticobulbar dysfunction in many CP syndromes, anarthric or dysarthric speech and other impairments related to oral-motor dysfunction are common. For example, articulation disorders and impaired speech intelligibility are present in 38% of children with CP (see table 6).[64,65] Because their impaired mobility can cause limited interaction with individuals in the environment, children with CP might not be able to develop the linguistic skills necessary to develop more complex speech patterns.[66] Language (as opposed to speech) deficits in CP go hand in hand with verbal intellectual limitations associated with mental retardation.[67] Oral-motor problems including feeding difficulties,[68-70] swallowing dysfunction,[65,70] and drooling[71] may lead to potential serious impacts on nutrition and growth,[72] oral health,[73,74] respiration,[75] and self-esteem.

Hearing impairment. Hearing impairment occurs in approximately 12% of children with CP (see table 6). This occurs more commonly if the etiology of CP is related to very low birth weight, kernicterus, neonatal meningitis, or severe hypoxic-ischemic insults. Children with CP who have mental retardation or abnormal neuroimaging studies are at greater risk for hearing impairment. Of concern are recent studies from the Centers for Disease Control that almost half the children found to have severe congenital hearing loss (with or without CP) in the greater Atlanta area were not recognized until almost age 3 years.[76] Established guidelines for neonatal audiometric screening have recently been published.[77]

Conclusions. Children with CP are more likely to have associated conditions including mental retardation (52%), ophthalmologic defects (28%), hearing impairment (12%), and speech and language disorders (38%) and additional oral-motor deficits. Children with CP are also at greater risk for epilepsy (mean 43%; range 34 to 94%). However, there is no evidence that an EEG is helpful in determining the etiology of CP.

Recommendations. Because of the high incidence of associated conditions, children with CP should be screened for mental retardation, ophthalmologic and hearing impairments, and speech and language disorders (Level A, class I and II evidence). Nutrition, growth, and other aspects of swallowing dysfunction should be monitored. Further specific evaluations are warranted if screening suggests areas of impairment.

Recommendations for the evaluation of children with CP. Although there is insufficient evidence to recommend the optimal sequence of tests to determine the etiology of CP, taking into account diagnostic yield and potential treatability, we propose the following consensus-based evaluation as outlined in the algorithm (figure). All children should undergo a detailed history and physical examination. It is important to determine that the child's condition is due to a static and not a progressive or degenerative neurologic disorder. It is also important to classify the type of CP as this has diagnostic implications as well as implications regarding associated problems. Because children with CP commonly have associated mental retardation, ophthalmologic abnormalities, hearing impairments, speech and language disorders, and disorders of oral-motor function, screening for these conditions should be part of the initial assessment. An EEG is recommended when there are features suggestive of epilepsy or a specific epileptic syndrome. In order to establish an etiology and prognosis in children with CP, neuroimaging is recommended, with MRI preferred to CT. However, if neuroimaging performed in the perinatal period provided an etiology of the child's CP, it may obviate the need for later study. Metabolic and genetic studies should not be routinely obtained in the evaluation of the child with CP. If the clinical history or findings on neuroimaging do not determine a specific structural abnormality or if there are additional and atypical features in

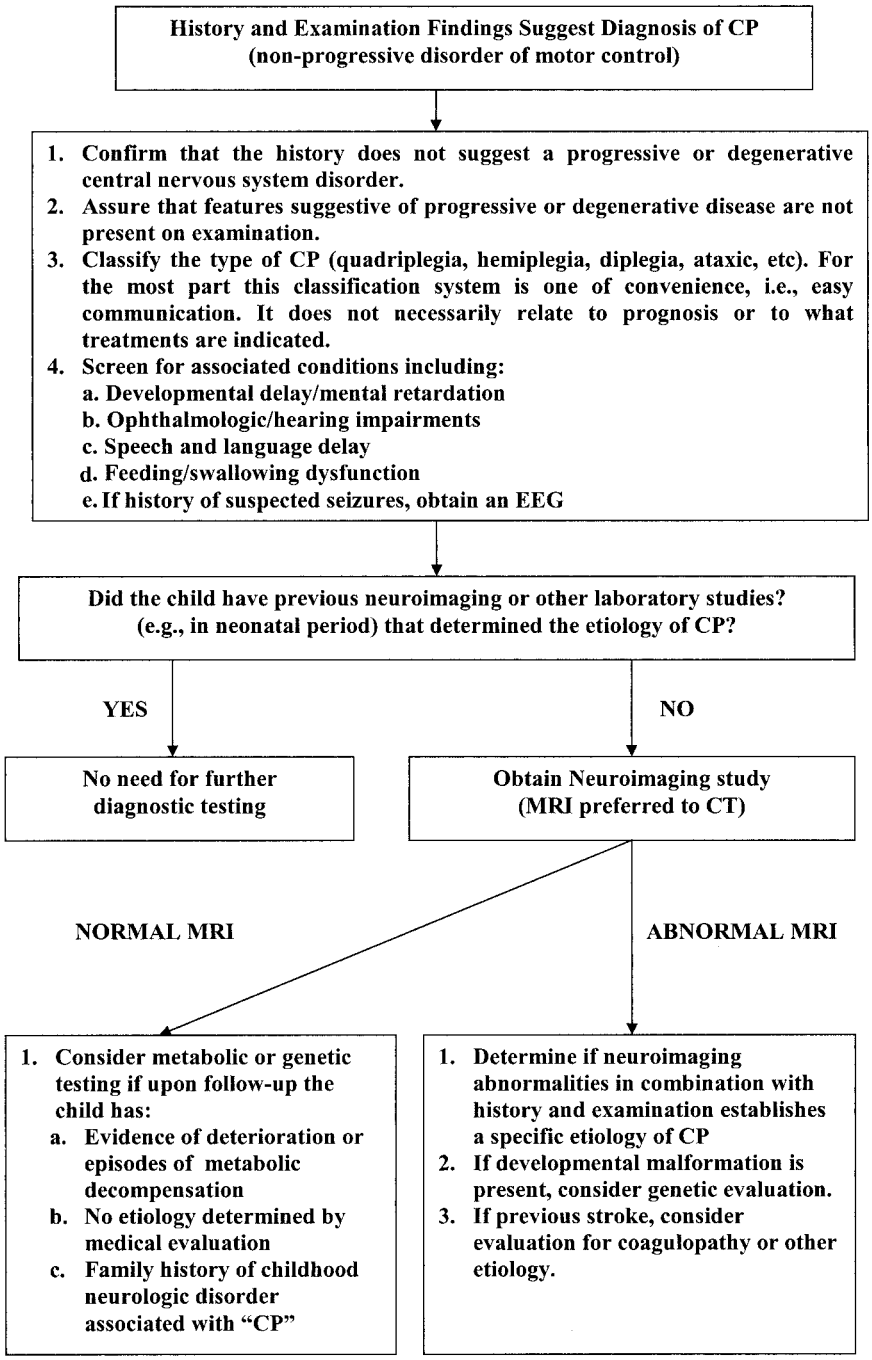

Figure. Algorithm for the evaluation of the child with cerebral palsy (CP). Screening for associated conditions (mental retardation, vision/hearing impairments, speech and language delays, oral motor dysfunction, and epilepsy) is recommended. Neuroimaging (MRI preferred to CT) is recommended for further evaluation if the etiology of the child's CP has not been previously determined. In some children, additional metabolic or genetic testing may be indicated.

the history or clinical examination, metabolic and genetic testing should be considered. Because the incidence of cerebral infarction is high in children with hemiplegic CP, diagnostic testing for a coagulation disorder should be considered.

Future research. 1. Prospective studies on the etiologic yields of genetic, metabolic, and neuroimaging diagnostic tests should be undertaken in large numbers of young children with CP compared with control subjects. This would permit the development of specific diagnostic algorithms.

2. Large prospective cohorts of children with CP should be studied to identify features based on CP subtypes that can improve specific evaluation strategies and enhance etiologic yield.

3. It should be determined at what age and on what basis we can be certain that a child has CP sufficient to justify testing and at what age the yield will be optimal. Strategies of conducting testing simultaneously or sequentially need to be assessed. This should reduce unnecessary testing and provide cost-effective evaluations (i.e., a favorable balance between the cost of testing versus savings from early intervention, prevention of the birth of affected children).

4. Studies are needed to better characterize speech and language, ophthalmologic, auditory, oral-motor, nutrition, and growth deficits in children with

CP. Investigation of the sensorimotor impairments of children with CP is also needed so that studies of early intervention therapies might be done to improve the overall function of children who are likely to have multiple needs.

5. Issues related to quality of life and social support for families need further study. Included should be the benefits that medical testing confers by reducing parental concerns related to determining an etiology and by providing important information regarding prognosis, genetic counseling, and planning future educational and treatment needs.

6. Future research should also be directed to determine the underlying mechanisms causing CP that are associated with perinatal stroke, coagulopathies, genetic disorders, pre- and perinatal inflammatory diseases, and environmental factors.

Mission statement. The Quality Standards Subcommittee (QSS) of the AAN seeks to develop scientifically sound, clinically relevant practice parameters for the practice of neurology. Practice parameters are strategies for patient management that assist physicians in clinical decision making. A practice parameter is one or more specific recommendations based on analysis of evidence of a specific clinical problem. These might include diagnosis, symptoms, treatment, or procedure evaluation.

Disclaimer. This statement is provided as an educational service of the American Academy of Neurology and the Child Neurology Society. It is based on an assessment of current scientific and clinical information. It is not intended to include all possible proper methods of care for a particular neurologic problem or all legitimate criteria for choosing to use a specific procedure. Neither is it intended to exclude any reasonable alternative methodologies. The AAN and the CNS recognize that specific patient care decisions are the prerogative of the patient and the physician caring for the patient, based on all of the circumstances involved.

Practice Parameter: Diagnostic assessment of the child with status epilepticus (an evidence-based review)

Report of the Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

J.J. Riviello, Jr., MD; S. Ashwal, MD; D. Hirtz, MD; T. Glauser, MD; K. Ballaban-Gil, MD; K. Kelley, MD; L.D. Morton, MD; S. Phillips, MD; E. Sloan, MD; and S. Shinnar, MD, PhD

Abstract—*Objective:* To review evidence on the assessment of the child with status epilepticus (SE). *Methods:* Relevant literature were reviewed, abstracted, and classified. When data were missing, a minimum diagnostic yield was calculated. Recommendations were based on a four-tiered scheme of evidence classification. *Results:* Laboratory studies (Na^{++} or other electrolytes, Ca^{++}, glucose) were abnormal in approximately 6% and are generally ordered as routine practice. When blood or spinal fluid cultures were done on these children, blood cultures were abnormal in at least 2.5% and a CNS infection was found in at least 12.8%. When antiepileptic drug (AED) levels were ordered in known epileptic children already taking AEDs, the levels were low in 32%. A total of 3.6% of children had evidence of ingestion. When studies for inborn errors of metabolism were done, an abnormality was found in 4.2%. Epileptiform abnormalities occurred in 43% of EEGs of children with SE and helped determine the nature and location of precipitating electroconvulsive events (8% generalized, 16% focal, and 19% both). Abnormalities on neuroimaging studies that may explain the etiology of SE were found in at least 8% of children. *Recommendations:* Although common clinical practice is that blood cultures and lumbar puncture are obtained if there is a clinical suspicion of a systemic or CNS infection, there are insufficient data to support or refute recommendations as to whether blood cultures or lumbar puncture should be done on a routine basis in children in whom there is no clinical suspicion of a systemic or CNS infection (Level U). AED levels should be considered when a child with treated epilepsy develops SE (Level B). Toxicology studies and metabolic studies for inborn errors of metabolism may be considered in children with SE when there are clinical indicators for concern or when the initial evaluation reveals no etiology (Level C). An EEG may be considered in a child with SE as it may be helpful in determining whether there are focal or generalized epileptiform abnormalities that may guide further testing for the etiology of SE, when there is a suspicion of pseudostatus epilepticus (nonepileptic SE), or nonconvulsive SE, and may guide treatment (Level C). Neuroimaging may be considered after the child with SE has been stabilized if there are clinical indications or if the etiology is unknown (Level C). There is insufficient evidence to support or refute routine neuroimaging in a child presenting with SE (Level U).

NEUROLOGY 2006;67:1542–1550

Endorsed by the American College of Emergency Physicians on August 31, 2006; by the American Academy of Pediatrics on October 3, 2006; and by the American Epilepsy Society on October 3, 2006.

From the Division of Epilepsy and Clinical Neurophysiology and the Critical Care Neurology Service (J.J.R.), Department of Neurology, Children's Hospital, Boston, and Harvard Medical School, MA; Division of Child Neurology (S.A.), Department of Pediatrics, Loma Linda University School of Medicine, CA, CNS representative to the Quality Standards Committee; National Institute of Neurological Disorders and Stroke (D.H.), NIH, Bethesda, MD, CNS representative to the Quality Standards Committee; Comprehensive Epilepsy Center (T.G.), Children's Medical Center, Cincinnati, OH, representative of the Epilepsy Foundation of America; Albert Einstein College of Medicine (K.B.-G.), Bronx, NY, representative of the American Epilepsy Society; Children's Memorial Hospital and Northwestern Medical School (K.K.), Chicago, IL, representative of the American Epilepsy Society; Division of Child Neurology (L.D.M.), Virginia Commonwealth University, Richmond, representative of the Child Neurology Society; Children's Hospital of Orange County (S.P.), CA, representative of the American Academy of Pediatrics; Department of Emergency Medicine (E.S.), University of Illinois at Chicago School of Medicine, representative of the American College of Emergency Physicians; Departments of Neurology and Pediatrics (S.S.), Comprehensive Epilepsy Management Center, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.

Received March 28, 2006. Accepted in final form August 4, 2006.

Approved by the Quality Standards Subcommittee on January 28, 2006; by the Practice Committee on August 5, 2006; and by the AAN Board of Directors on August 17, 2006.

Table 1 *Classification of status epilepticus (SE)*

Type	Definition	Examples
Acute symptomatic (26%)*	SE occurring during an acute illness (an acute CNS insult) (an acute encephalopathy)	Meningitis, encephalitis, electrolyte disturbance, sepsis, hypoxia, trauma, intoxication
Remote symptomatic (33%)	SE occurring without an acute provocation in a patient with a prior history of a CNS insult (a chronic encephalopathy)	CNS malformation, previous traumatic brain injury or insult, chromosomal disorder
Remote symptomatic with an acute precipitant (1%)	SE occurring with a chronic encephalopathy, but with an acute provocation	CNS malformation or previous CNS insult with concurrent infection, hypoglycemia, hypocalcemia, or intoxication
Progressive encephalopathy (3%)	SE occurring with an underlying, progressive CNS disorder	Mitochondrial disorders, CNS lipid storage diseases, amino- or organic acidopathies
Febrile (22%)	SE occurring when the only provocation is a febrile illness, after excluding a direct CNS infection, such as meningitis or encephalitis	Upper respiratory infection, sinusitis, sepsis
Cryptogenic† (15%)	SE occurring in the absence of an acute precipitating CNS insult, systemic metabolic disturbance, or both	No definable cause

* Data for percentages for each group are presented in more detail in appendix 4.
† The category cryptogenic is now used instead of idiopathic, which had been used in the original classification.

Status epilepticus (SE) in children, as in adults, is a life-threatening emergency that requires prompt recognition and immediate treatment. Although various definitions of SE have been used since 1983, the most commonly accepted is a 30-minute duration of seizures based on previous studies that found evidence of brain injury in adult monkeys after 45 to 60 minutes of continuous seizures.[1-3] This 30-minute definition was adopted in subsequent studies of SE and by the working group on SE of the Epilepsy Foundation of America.[4,5] This definition also includes two or more sequential seizures without full recovery of consciousness between seizures.[5]

SE is classified by seizure type and etiology.[6,7] The seizure type is determined by the origin of the epileptic discharge (i.e., focal or generalized) or if insufficient information is available, indeterminate or unclassifiable.[8-10] As defined in table 1, the etiologic classification of SE includes 1) acute symptomatic, 2) remote symptomatic, 3) remote symptomatic with an acute precipitant, 4) progressive encephalopathy, 5) febrile, and 6) cryptogenic (idiopathic).[4,5,11,12] When some of these studies were done the term idiopathic was used for episodes now called cryptogenic. The category idiopathic is now reserved for the genetically determined epilepsies.[13] Remote symptomatic with an acute precipitant refers to SE in a child with a prior known diagnosis of epilepsy.

The incidence of SE in children ranges from 10 to 58 per 100,000 per year for children ages 1 to 19 years (mean 38.8 and median 43.8/100,000/year; 95% CI 18.2 to 59.5/100,000/year) or would be 31,600 (range 7,300 to 41,600) children under age 18 years in the United States per year.[14-17] A higher incidence has been reported in infants younger than 1 year of age in two studies (135.2/100,000/year and 156/100,000/year).[14,16] SE is a common occurrence in children with epilepsy, ranging from 9.1% to 27% over time.[18-20] SE may also be the presenting manifestation of epilepsy. Symptomatic SE is common in infants and younger children. In one study of 394 children aged 1 month to 16 years, more than 80% of children less than 2 years of age had acute symptomatic SE, febrile SE, or a progressive encephalopathy whereas cryptogenic and remote symptomatic SE was more common in children older than 4 years.[21] SE has been reported to recur in 17% of children.[22]

Guidelines for AED treatment have been developed for pediatric SE,[23-25] but specific pediatric guidelines have not been developed for its diagnostic evaluation. The 1993 recommendations of the Epilepsy Foundation of America (EFA) Working Group on Treatment of Convulsive SE included adults and children.[5] These recommendations, including a treatment sequence with antiepileptic drugs (AEDs), were consensus, rather than evidence-based, and are currently under revision including redefining the duration considered necessary to diagnose SE.

These guidelines recommended a Dextrostix level in all patients with SE, noting that hypoglycemia rarely caused SE, but is obtained to avoid a glucose infusion, and recommended consideration on an individual basis of other diagnostic studies including a complete blood count (CBC), serum chemistries (glucose, sodium, calcium, magnesium, and BUN), AED

levels, and urine and blood toxicology studies. A lumbar puncture (LP) was recommended when fever occurred with SE, especially in young children, unless a contraindication to LP was present.

This Practice Parameter reviews available evidence concerning the value of diagnostic testing in children and adolescents with SE and provides recommendations based upon this evidence. Treatment guidelines are not included but are under development.

Description of process. We performed a literature search through the library of the University of Minnesota, and MEDLINE, for English-language articles from 1970 to 2005 and yielded 1,609 articles. The search terms were as follows: status epilepticus and, children and, MRI, cranial CT scan, lumbar puncture, spinal tap, electrolytes, metabolic studies, inborn errors of metabolism, EEG, hyponatremia, hypokalemia, hypocalcemia, hypoglycemia, acidosis, alkalosis, azotemia, hypophosphatemia, hypomagnesemia, pleocytosis, toxicology, intoxication. Seizures occurring in neonates less than 1 month of age were excluded, as these are defined as neonatal seizures and are different in cause and prognosis. The upper age limit was 19 years. Only articles reporting studies with more than 20 patients were included in this review. Articles consisting of single patient case reports or small samples of unusual pathologic findings, that would have biased the analysis, or articles that referred specifically to febrile or refractory SE, were excluded. Febrile SE and refractory SE were excluded because each is a selected population. Twenty-five articles were identified and reviewed for preparation of this Parameter. Relevant position papers from professional organizations were also reviewed.

Individual committee members reviewed titles and abstracts for content and relevance. Those papers dealing with diagnostic assessments of SE were selected for further detailed review. Bibliographies of the articles cited were checked for additional pertinent references. Each of the selected articles was reviewed, abstracted, and classified by at least two committee members. Abstracted data included the number of patients, total episodes of SE (if given), ages, nature of subject selection, case-finding methods (prospective, retrospective, or referral), inclusion and exclusion criteria, classification, etiology, and the results of laboratory, EEG, or neuroimaging tests. A four-tiered classification scheme for determining the validity of studies on yield of established diagnostic and screening tests developed by the Quality Standards Subcommittee was utilized as part of this assessment (appendix 2). Depending on the strength of this evidence, it was decided whether specific recommendations could be made, and if so, the level of strength of these recommendations (appendix 3). Evidence pertinent to each diagnostic test together with the committee's evidence-based recommendations is presented.

Recommendations included in this Parameter were based on review of data regarding the following tests for children presenting in SE: 1) blood culture and LP studies; 2) AED levels; 3) toxicology screening; 4) metabolic and genetic studies; 5) EEG; and 6) neuroimaging including CT and MRI.

Most available literature did not specify whether the diagnostic tests analyzed were uniformly applied during each SE episode. Therefore, where reported data were missing, we calculated a minimum diagnostic yield for each test by dividing the total number of positive diagnostic tests reported by the total number of reported SE episodes from each study (therefore assuming that each diagnostic test was performed for each episode of SE, likely leading to an underestimate of the true diagnostic yield of these tests).

It is now common practice to obtain a CBC and chemistry profiles routinely in children presenting with SE. Thus, we did not develop evidence-based recommendations for these tests but did include in appendix 4 a summary of previous studies regarding their diagnostic yield. Electrolyte (e.g., Na^{++} or other electrolytes, Ca^{++}, glucose) abnormalities or basic metabolic disorders were reported in an average of 6% (range 1 to 16%) of children with SE. In most studies these abnormalities were listed as the etiology. However, it was unclear whether these abnormalities were responsible for the episode of SE and if correction resulted in cessation of SE.

Analysis of the evidence. In 2,093 children from 20 class III studies, SE was attributed to an acute symptomatic cause in 26%, a remote symptomatic cause in 33%, a remote symptomatic with an acute precipitant in 1%, a progressive encephalopathy in 3%, febrile SE in 22%, and cryptogenic in 15% (table 1).

Laboratory studies. Should blood cultures and LP be routinely done in children with SE? Infectious or inflammatory disorders may cause seizures by direct involvement of the CNS, such as with meningitis or encephalitis, or by systemic involvement affecting the brain (i.e., acute symptomatic SE). Systemic illness may aggravate pre-existing epilepsy by lowering the seizure threshold. An infectious disorder may be included in the differential diagnosis if fever is present or if there has been a history of fever or preceding illness. Common clinical practice is that blood cultures are obtained if there is a clinical suspicion of an infection and likewise LP is done when there are clinical features suggestive of CNS infection, especially if fever is present.

Blood cultures (evidence). In six class III studies that reported the category sepsis, with a total of 357 children, blood cultures were reported as positive in 2.5 ± 0.9% (range 0.01 to 3.8%; median 2.6%; 95% CI 1.7% to 3.3%).[33-35,37,38,40] This is a minimum yield based on the assumption that blood cultures were done in all patients with SE whether or not sepsis was suspected. Data were not available to determine

the rate of positive blood cultures in patients in whom sepsis was suspected. Likewise, data were not available to ascertain the incidence of positive blood cultures in those patients clinically considered not to be at risk for infection.

LP (evidence). A documented CNS infection was reported on average in 12.8 ± 6.2% (range 3.4 to 26.1%; median 11.5%; 95% CI 9.9% to 15.6%) of the 1,859 children in the class III studies listed in appendix 4, but the criteria for obtaining a LP, and the actual number done, is not known. Again, this may represent a lower rate of positive studies than if we knew the actual number of LPs done. In addition, if some patients who did not undergo LP had CNS infection, this also would have raised the diagnostic yield. The variability in range may be related to age, with a higher incidence of CNS infections occurring in the younger children, or to selection criteria.[29,30,33,39,41]

A class III study of 49 children with convulsive SE identified 24 children with SE and fever and in this group bacterial meningitis was detected in 4 of 9 children who had a LP done (8% of entire group and 17% of febrile group).[44] None of the 25 children without febrile SE were diagnosed with meningitis. The etiology of CNS infection in these studies was based on author assignment of diagnosis rather than on the reported confirmatory laboratory test results and included bacterial meningitis in 4.8% and encephalitis in 3.0% of children. In three Class III studies (n = 185),[29,31,40] the following diagnoses were documented with LP results: meningitis (14%),[29,31] encephalitis (11%),[29] leukemic meningitis (1%),[29] vasculitis (0.5%),[31] and shunted hydrocephalus (0.5%).[29,31] In 3% of these children, pleocytosis of undetermined etiology was found and suggested that the episode of SE itself was the presumed cause of the pleocytosis.[31]

Conclusions. Data from six class III studies revealed a minimum diagnostic yield of a positive blood culture in 2.5% of children with SE. Data based on the 1,859 children from the studies listed in appendix 4 revealed that the frequency of diagnosed CNS infection rate was 12.8%. In all of these studies there was no indication that tests were done routinely on all children with SE; it was either stated or presumed that the tests were done selectively.

Recommendations. 1. There are insufficient data to support or refute whether blood cultures should be done on a routine basis in children in whom there is no clinical suspicion of infection (Level U).

2. There are insufficient data to support or refute whether LP should be done on a routine basis in children in whom there is no clinical suspicion of a CNS infection (Level U).

Should AED levels be routinely obtained in children taking AEDs who develop SE? If a child with epilepsy treated with AEDs develops SE, it is possible that AED levels are low, because either there had been a therapeutic response at that level or because of inadequate dosing, noncompliance, or withdrawal of the AED.

Table 2 *Results of studies in which AED levels were obtained**

Reference no.	Class	N	Low AED levels	AED withdrawn or D/C	AED noncompliance

* Numbers in columns indicate the number of patients in each study who had an abnormal laboratory value for that test. All studies were class III. Fields marked with — indicates that there was no diagnostic category in that individual study for the column entry.
† Total number of abnormalities for each test given with percentage of total abnormalities discontinued (D/C).
‡ Four acutely withdrawn in <1 week.

AED = antiepileptic drugs.

Evidence. We assumed that AED levels were obtained in those children who were supposed to be on AEDs rather than on all children presenting in SE. One article addressing this question was considered class II.[45] Data on AED levels were available for review in 528 children in SE from nine studies (table 2). AED levels were low in 32% ± 25% (range 2.7 to 63%; median 21%; 95% CI 8.8% to 51%) of those children already on AEDs; they had been withdrawn on average in 9% ± 10% (range 1% to 28%; median 4.2%; 95% CI −0.5% to 18.6%) and patients were noncompliant in 0.2% overall (2.7% when specifically mentioned as a category). Noncompliance was determined by clinical history. In one study it was reported that 4 of the 9 children with low levels had the AED acutely withdrawn or discontinued within 1 week. However, the low AED levels reported in these studies were not necessarily the cause of SE.[7,27,45]

Conclusions. Class II data showed low AED levels in 32% of children on AEDs, although this was not necessarily the cause of the SE.

Recommendation. AED levels should be considered when a child with epilepsy on AED prophylaxis develops SE (Level B, class II and III evidence).

Should toxicology testing be routinely ordered in children with SE? Ingestion of a toxin or drug abuse are possible etiologies of SE that require very prompt diagnosis and treatment.

Evidence. A toxic ingestion was documented in 3.6% (range 1.5 to 5.3%; median 3.8%; 95% CI 2.3% to 6.8%) of 1,221 children enrolled in 11 class III studies.[4,26,27,29-32,36,37,41,43] The specific toxins were theophylline, lindane, carbamazepine, or chemotherapy. This represents a minimum rate as we used as the denominator all patients in the studies. There is no information on whether toxicology testing was performed based on suggestive history or physical examination findings or because initial screening laboratory studies were negative. A routine urine toxicology screen identifies only drugs of abuse and specific serum toxicology levels are needed to identify specific toxins.

Conclusions. Data from 11 class III studies of children with SE revealed a diagnosis of ingestion in 3.6%. It is not known what proportion of these ingestions was suspected. We deemed this yield high enough to consider testing with specific serum toxicology levels, if indicated, since establishing the diagnosis is critical to treatment.

Recommendation. 1. Toxicology testing may be considered in children with SE, when no apparent etiology is immediately identified, as the frequency of ingestion as a diagnosis was at least 3.6% (Level C, class III evidence). To detect a specific ingestion, suspected because of the clinical history, it should be noted that a specific serum toxicology level is required, rather than simply urine toxicology screening.

Metabolic and genetic testing. Should testing for inborn errors of metabolism or genetic (chromosomal or molecular) studies be routinely ordered in children with SE? Inborn errors of metabolism (IEM) and specific chromosomal or genetic disorders may cause neurologic dysfunction and epilepsy. In some patients, seizures may worsen during an intercurrent illness or because of metabolic stress. Historic features suggestive of a metabolic disorder are unexplained neonatal encephalopathy; unexplained developmental delay, especially when there is a neurologic deterioration during an acute illness; unusual odors to the urine; unexplained acidosis or coma, especially with recurrent episodes of intolerance to certain foods; the need to eat frequently to prevent lethargy; or episodes of dehydration disproportionate to fluid loss during an illness. The major conditions that are considered to be IEMs include disorders of amino acid, ammonia, and organic acid metabolism, and disorders affecting mitochondrial and peroxisomal functions.

Evidence. Of 735 children in nine class III studies,[4,29,30,32,34,35,39,41,42] an IEM was diagnosed or present in 4.2% of children (range 1.2 to 8.3%; median 4.0%; 95% CI 2.9% to 5.8%) based on a denominator of all children in these studies, although it is likely that testing was done selectively. When specified, pyridoxine dependency, Leigh's disease, neuronal ceroid lipofuscinosis, and a mitochondrial disorder were each found in 0.3%, and Alper's disease, methylmalonic acidemia, and carnitine deficency in 0.2% each. Data on chromosomal or genetic disorders are not separately available.

Conclusions. Data from nine class III studies revealed that an IEM was diagnosed in approximately 4% of children in these studies with SE.

Recommendations. 1. Studies for inborn errors of metabolism may be considered when the initial evaluation reveals no etiology, especially if there is a preceding history suggestive of a metabolic disorder (Level C, class III evidence). The specific studies obtained are dependent on the history and the clinical examination. There is insufficient evidence to support or refute whether such studies should be done routinely (Level U).

2. There are insufficient data to support or refute whether genetic testing (chromosomal or molecular studies) should be done routinely in children with SE (Level U).

Electroencephalography. Should an EEG be routinely performed in the evaluation of a child with SE? SE is classified as generalized or focal convulsive SE or nonconvulsive SE (NCSE), and the clinical manifestations are associated with electrographic SE. EEG may be needed to demonstrate focality and because the distinction of generalized vs focal epilepsy is important in the choice of chronic AED therapy. Convulsive SE occurs with overt clinical signs, such as tonic, tonic-clonic, or clonic motor movements. Nonconvulsive status epilepticus (NCSE) occurs when either electrographic SE is associated with altered awareness without overt clinical signs, or altered awareness with subtle motor signs, such as minimal eyelid blinking. An EEG done at the time of SE (ictal EEG) can determine if the electrographic discharge is focal or generalized, demonstrate NCSE, or may also distinguish an epileptic event from a nonepileptic event (pseudoseizures).[47,48] EEG has been recommended as routine in a Practice Parameter on the evaluation of the first nonfebrile seizure in children; SE was specifically excluded from the evidence examined.[46]

Evidence. Six class III studies[29,31,34,40,49,50] report 413 EEG findings in 358 children who presented in SE and had an EEG. EEGs were obtained hours to days after the acute episode and 89.3 ± 13.6% (range 66% to 100%; median 92.9%; 95% CI 78.3% to 100%) were abnormal. Findings were described as generalized epileptiform features in 8%, focal epileptiform features in 16%, combined generalized and focal epileptiform features in 19%, generalized slowing in 41%, focal slowing in 6.3%, electrocerebral inactivity in 1.9%, and normal in 7.7%. An epileptiform EEG was noted in 43.1% of these 358 children (table 3). One class III study (n = 407) that focused on the prognosis of children with a first unprovoked seizure also had EEG data on 46 children with SE.[49,50] This study found an abnormal EEG in 62% of children with SE, compared to 41% of children whose seizures were less than 30 minutes in duration.

Nonconvulsive status epilepticus: In adults, NCSE is present in 14% of patients in whom convul-

Table 3 *EEG findings in 358 children with status epilepticus*

EEG findings	No. of patients	Percentage	Range, %

Epileptiform features, generalized and focal	79	19.1	0–42
Electrocerebral inactivity	8	1.9	0–3.9
Total*	413		

* Refers to 413 EEG abnormalities reported in 358 patients from six class III studies (references 29, 31, 34, 40, 49, and 50).

sive SE is controlled but in whom consciousness remains impaired.[51] Data are not available regarding the prevalence of NCSE after the control of convulsive SE in children or with other neurologic conditions (e.g., coma). A single study reported an 8% incidence of NCSE in a mixed population of children and adults with unexplained coma; data on children were not reported separately.[52]

Pseudostatus epilepticus: Pseudostatus epilepticus, defined as a nonepileptic event that mimics SE, may occur in children.[53-55] In the only series of SE in children that reported on pseudostatus epilepticus, 6 of 29 (21%) children admitted with convulsive SE had pseudoseizures (class III).[53]

Conclusions. Data from six class III studies revealed generalized or focal epileptiform activity in 43.1% of the EEGs done for SE. Abnormalities on EEG occur in 62% of children with SE compared to 41% of children with a first unprovoked seizure less than 30 minutes duration. Sufficient data on the prevalence of NCSE in children who presented with SE are not available. One small class III study reported that 21% of children initially thought to be in SE had pseudostatus.

Recommendations. 1. An EEG may be considered in a child presenting with new onset SE as it may determine whether there are focal or generalized abnormalities that may influence diagnostic and treatment decisions (Level C, class III evidence).

2. Although NCSE occurs in children who present with SE, there are insufficient data to support or refute recommendations regarding whether an EEG should be obtained to establish this diagnosis (Level U).

3. An EEG may be considered in a child presenting with SE if the diagnosis of pseudostatus epilepticus is suspected (Level C, class III evidence).

Neuroimaging. Should CT or MRI be performed in children with SE? Neuroimaging studies were recommended based on specific clinical circumstances by the Practice Parameter for the evaluation of a first afebrile seizure in children.[46] Emergent neuroimaging was recommended if there was a focal deficit that did not quickly resolve or if there was no return to baseline mental status after several hours, and nonurgent MRI should be seriously considered in any child with a seizure of partial (focal) onset with or without secondary generalization.

A previously published Practice Parameter on neuroimaging in the patient presenting with a seizure to the emergency department (1996) made no recommendations concerning neuroimaging in SE, but suggested emergent neuroimaging when a serious structural lesion was suspected, especially when there were new onset focal deficits, persistent altered awareness, fever, recent trauma, history of cancer, history of anticoagulation, or a suspicion of AIDS.[56] There have been no Parameters published on the use of neuroimaging in adult or pediatric cases of SE.

Neuroimaging should be done only after the child is stabilized and the SE has been controlled. Neuroimaging options include CT or MRI. MRI is more sensitive and specific than CT scanning, but CT is readily available on an emergency basis. CT and MRI may detect focal changes that may be transient,[57] or secondary to a focal seizure (suggesting the origin of the focus), with MRI being more sensitive. Diffusion-weighted imaging (DWI) and apparent diffusion coefficient (ADC) changes have also been reported after SE in children and suggest cytotoxic and vasogenic edema.[58-61] Progressive changes such as hippocampal atrophy/sclerosis or global atrophy have also been documented.[62] Most childhood SE studies do not report neuroimaging findings specifically or were done before the advent of modern neuroimaging, but the diagnosis made in these studies supports the potential usefulness of neuroimaging.

Evidence. In 20 class III studies involving 1,951 children with SE (323 before the advent of neuroimaging), structural lesions were found in 7.8% (table E-1, on the *Neurology* Web site at www.neurology.org). Specific abnormalities included CNS malformation (1.7%), trauma (1.6%), stroke/hemorrhage (0.9%), neurocutaneous disorder (0.9%), tumor (0.8%), infarct/vascular (0.6%), hemorrhage (0.4%), abscess/cerebritis (0.4%), and arteriovenous malformation (AVM), hydrocephalus, or other (0.2% each). These lesions are potentially diagnosable by neuroimaging.

Five class III studies (n = 174) reported actual CT data.[29,31,40,49,50] Of the CT scans done in children with SE, a mean of 49% (range 29% to 70%; median 53.4%; 95% CI 32.2% to 66.7%) were abnormal. Abnormalities included cerebral edema in 14.4%, atrophy in 12.1%, infection (meningitis/abscess/cerebritis/granuloma) in 4.6%, CNS dysplasia in 3.5% (tuberous sclerosis and Sturge Weber syndrome, 1 each), infarction in 2.9%, tumor and hematoma in 2.3% each, 1.2% each in trauma and AVM, and calcifications in 0.6%; an old deficit/no change was specified in 4.6%.[31] In 38 new-onset cases, CT

was abnormal in 29% (n = 11), with dysplasia in 4, atrophy, infarction, and infection in 2 each, and calcifications in 1.[49,50] The timing after onset of SE when CT was done was not reported. This could affect interpretation of the presence of atrophy, which could be secondary to the episode of SE rather than to a preexisting abnormality. Under-representation of a cortical dysplasia as an etiology is likely due to the lower sensitivity of CT scanning in detecting such malformations.

In one small class III study MRI was done in 9 of 24 children with SE.[42] Imaging findings were reported as normal in two and abnormal in seven of the nine children (78%).[42] Two each had atrophy, hydrocephalus, or cerebritis, and infarction occurred in one.

Conclusions. We assumed that neuroimaging was performed for clinical indications or the absence of a known etiology. The yield of lesions important for diagnosis and treatment was relatively high. Data from 20 class III studies found lesions likely detectable with neuroimaging in 7.8% of children, based on a denominator of all available subjects in the studies, thus these data represent an estimate of the minimal yield of these studies. Neuroimaging can identify structural causes for SE, especially to exclude the need for neurosurgical intervention in children with new onset SE without a prior history of epilepsy, or in those with persistent SE despite appropriate treatment.

Recommendations. 1. Neuroimaging may be considered for the evaluation of the child with SE if there are clinical indications or if the etiology is unknown (Level C, class III evidence). If neuroimaging is done, it should only be done after the child is appropriately stabilized and the seizure activity controlled.

2. There is insufficient evidence to support or refute recommending routine neuroimaging (Level U).

Future research. 1. Prospective studies are needed to define what factors, or combination of factors, may precipitate SE in children.

2. Controlled prospective studies should be conducted to define the role for routine or selective laboratory investigations in the evaluation of children with SE. This should include studies of IEM, and specific serum toxicology levels, as a cause of SE in children with the diagnostic tests now available.

3. Controlled prospective blinded studies should be conducted to define the setting and timing for EEG done in the evaluation of children with SE, and to determine if postictal and unexpected ictal EEG findings have prognostic and treatment significance.

4. Controlled prospective studies with blinded assessments should examine the yield of neuroimaging, either routine or selective, in children with SE.

5. Prospective studies are needed to determine the frequency of NCSE after the control of convulsive SE in children, its etiology, and prognostic significance.

Mission statement. The Quality Standards Subcommittee (QSS) of the AAN seeks to develop scientifically sound, clinically relevant Practice Parameters for the practice of neurology. Practice Parameters are strategies for patient management that assist physicians in clinical decision making. A Practice Parameter is one or more specific recommendations based on analysis of evidence of a specific clinical problem. These might include diagnosis, symptoms, treatment, or procedure evaluation.

Disclaimer. This statement is provided as an educational service of the American Academy of Neurology. It is based on an assessment of current scientific and clinical information. It is not intended to include all possible proper methods of care for a particular neurologic problem or all legitimate criteria for choosing to use a specific procedure. Neither is it intended to exclude any reasonable alternative methodologies. The AAN recognizes that specific patient care decisions are the prerogative of the patient and the physician caring for the patient, based on all of the circumstances involved.

Conflict of interest statement. The American Academy of Neurology is committed to producing independent, critical and truthful clinical practice guidelines (CPGs). Significant efforts are made to minimize the potential for conflicts of interest to influence the recommendations of this CPG. To the extent possible, the AAN keeps separate those who have a financial stake in the success or failure of the products appraised in the CPGs and the developers of the guidelines. Conflict of interest forms were obtained from all authors and reviewed by an oversight committee prior to project initiation. AAN limits the participation of authors with substantial conflicts of interest. The AAN forbids commercial participation in, or funding of, guideline projects. Drafts of the guideline have been reviewed by at least three AAN committees, a network of neurologists, *Neurology* peer reviewers, and representatives from related fields. The AAN Guideline Author Conflict of Interest Policy can be viewed at www.aan.com.

Appendix 2

AAN evidence classification scheme for determining the yield of established diagnostic and screening tests.

Class I. A statistical,[1] population-based[2] sample of patients studied at a uniform point in time (usually early) during the course of the condition. All patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation that is masked to the patients' clinical presentations.

Class II. A statistical, non-referral-clinic-based[3] sample of patients studied at a uniform point in time (usually early) during the course of the condition. Most (>80%) patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation that is masked to the patients' clinical presentations.

Class III. A selected, referral-clinic-based[4] sample of patients studied during the course of the condition. Some patients undergo the intervention of interest. The outcome, if not objective,[5] is determined in an evaluation by someone other than the treating physician.

Class IV. Expert opinion, case reports or any study not meeting criteria for class I to III.

This is a classification scheme developed by the QSS for studies related to determining the yield of established diagnostic and screening tests or interventions and is appropriate only when the diagnostic accuracy of the test or intervention is known to be good. Additionally, the abnormality potentially identified by the screening intervention should be treatable or, should have important prognostic implications. This classification is different than others currently recommended by the QSS that have been published in recent parameters that relate to diagnostic, prognostic or therapeutic studies.

(1) Statistical sample: a complete (consecutive), random or systematic (e.g., every third patient) sample of the available population with the disease; (2) Population-based: The available population for the study consists of all patients within a defined geographic region; (3) Non-referral-clinic-based: The available population for the study consists of all patients presenting to a primary care setting with the condition; (4) Referral-clinic-based: The available population for the study consists of all patients referred to a tertiary care or specialty setting. These patients may have been selected for more severe or unusual forms of the condition and thus may be less representative; (5) Objective: An outcome measure that is very unlikely to be affected by an observers' expectations (e.g., determination of death, the presence of a mass on head CT, serum B12 assays).

Appendix 3

Classification of recommendations

A = Established as effective, ineffective, or harmful for the given condition in the specified population. (Level A rating requires at least two consistent Class I studies.)

B = Probably effective, ineffective, or harmful for the given condition in the specified population. (Level B rating requires at least one Class I study or at least two consistent Class II studies.)

C = Possibly effective, ineffective, or harmful for the given condition in the specified population. (Level C rating requires at least one Class II study or two consistent Class III studies.)

U = Data inadequate or conflicting; given current knowledge, test is unproven.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Diagnostic Imaging of Child Abuse

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Section on Radiology

ABSTRACT

The role of imaging in cases of child abuse is to identify the extent of physical injury when abuse is present and to elucidate all imaging findings that point to alternative diagnoses. Effective diagnostic imaging of child abuse rests on high-quality technology as well as a full appreciation of the clinical and pathologic alterations occurring in abused children. This statement is a revision of the previous policy published in 2000. *Pediatrics* 2009;123:1430–1435

INTRODUCTION

The concept of child abuse as a medical entity has an origin in the studies of pediatric radiologist John Caffey, MD,[1] as well as many other specialists in the field of diagnostic imaging.[2–4] Kempe et al[5] relied heavily on the work of Caffey and his protégé, Frederick Silverman, MD,[6] when developing the now-familiar concept of the "battered-child syndrome."

When all cases of child abuse and neglect are studied, the incidence of physical evidence documented by diagnostic imaging studies is relatively small. However, imaging studies are often critical, particularly in the assessment of the infant and young child with evidence of physical injury. Imaging alterations may also be the first indication of abuse in a child who is seen with an apparent natural illness. When viewed in conjunction with clinical and laboratory studies, imaging findings commonly provide additional objective evidence in the evaluation of possible inflicted injury or abuse.[7] For severely abused infants, the imaging findings alone may form the basis for a diagnosis of the inflicted injury. The role of imaging in cases of suspected abuse is not only to identify the extent of physical injury when abuse has occurred but also to elucidate all imaging findings that point to alternative diagnoses.[8,9] All imaging studies involving use of ionizing radiation should be performed in accordance with the ALARA ([using an exposure] as low as reasonably achievable) principle.[10] Because the detection of inflicted skeletal injury depends on the technical quality of the radiographs and the imaging protocol, recommendations regarding imaging should focus on examinations that provide the highest diagnostic yield at acceptable patient risk and cost.[11] Certain diagnostic imaging studies entail additional risks associated with sedation, and these risks should be weighed against the benefit of the study.[12]

SKELETAL TRAUMA

Although skeletal injuries rarely pose a threat to the life of the abused child, they are often the strongest radiologic indicators of abuse. In fact, in an otherwise normal infant, certain patterns of injury are sufficiently characteristic to permit a firm diagnosis of inflicted injury in the absence of clinical information.[13] Furthermore, dating of skeletal injuries may provide investigators with critical temporal data, which may help in identifying potential assailants. These facts mandate that imaging surveys performed to identify skeletal injury be acquired with at least the same level of technical excellence routinely used to evaluate accidental injuries. The "baby gram" (a study that encompasses the entire infant or young child on 1 or 2 radiographic exposures) or abbreviated skeletal surveys have no role in the imaging of these subtle but highly specific bony abnormalities.[14]

THE RADIOGRAPHIC SKELETAL SURVEY

Equipment

In general, the radiographic skeletal survey is the method of choice for global skeletal imaging in cases of suspected abuse.[14] General-purpose (medium-speed) pediatric imaging systems provide insufficient anatomic detail to image the skeleton of the abused infant or young child. The American College of Radiology has published standards for skeletal survey imaging in cases of suspected abuse. Modern pediatric imaging systems commonly use special film

cassettes and intensifying screens to minimize exposure. Although these low-dose systems are adequate for chest and abdominal imaging, they fail to provide the necessary detail (contrast and spatial resolution) to image subtle metaphyseal, rib, and other high-specificity injuries that are characteristic of abuse. According to the American College of Radiology, high-detail imaging systems should be used for suspected abuse in infancy.[14] These systems should be used without an antiscatter grid. Beyond infancy, faster general-purpose systems are required for thicker body regions (eg, skull, lateral lumbar spine).

Digital or filmless radiography has replaced screen/film imaging in most pediatric health care facilities in the United States.[15] A wide array of digital systems are available, including direct and indirect technologies. Data suggest that despite its lower spatial resolution, digital radiography, with its wide dynamic range and high contrast capabilities, can provide diagnostic performance comparable to high-detail screen/film systems in the evaluation of skeletal injury.[16,17] High-detail digital systems are being used successfully in the rigorous field of mammography, and efforts are currently underway to apply similar techniques to demanding skeletal applications.[18] Unfortunately, most digital systems currently used for skeletal surveys in the United States operate at relatively low spatial resolutions, and they are not routinely optimized for the demanding practice of imaging for suspected child abuse.[15] Imaging departments should use digital systems with sufficient spatial resolution and signal-to-noise characteristics to detect subtle skeletal injuries. Image detail and diagnostic performance can be improved by optimizing exposure to diminish system noise. Acceptable diagnostic accuracy with traditional screen/film imaging has required higher radiation exposures than for routine pediatric radiography, and similarly, an increase in exposure over standard digital radiography can be expected if maximal diagnostic accuracy is to be preserved with the digital medium. However, recent data have suggested that a performance comparable to the high-detail screen/film gold standard may be achievable with high-detail digital imaging at a substantially lower patient dose.[17] Digital facilities should optimize their acquisition and display parameters for high diagnostic performance,[19] and if the resultant images provide insufficient bony detail, an acceptable alternative should be sought. A radiologist should monitor the skeletal survey to ensure that appropriate high-quality images are obtained and to determine if additional views are required to fully define the pathologic alterations.

Imaging Protocol

Once the appropriate imaging system is chosen, a precise protocol for skeletal imaging must be developed to ensure consistent quality. In routine skeletal imaging, an accepted principle is that film must be coned or restricted to the specific anatomic area of interest. It is common practice to encompass larger anatomic regions when skeletal surveys are performed, which results in areas of underexposure and overexposure as well as loss of resolution resulting from geometric distortion and other technical factors. The standard skeletal survey imaging protocol that has been developed by the American College of Radiology[14] is provided in Table 1. Of special note is the inclusion of lateral views of the spine to assess for vertebral fractures and dislocations and separate views of the hands and feet to identify subtle digital injuries. Anteroposterior and lateral views of the skull are mandatory even when cranial computed tomography (CT) has been performed, because skull fractures coursing in the axial plane may be missed with axial CT.[11] A full 4-view examination of the skull (right and left lateral, Townes, and anteroposterior) should be obtained when head injury is present. Skeletal injuries, especially those requiring orthopedic management, necessitate at least 2 radiographic projections. Oblique views of the thorax increase the yield for the detection of rib fractures.[20] At a minimum, right and left oblique views of the thorax should be obtained when rib fractures are evident, and consideration should be given to including obliques in the standard survey protocol. A follow-up skeletal survey approximately 2 weeks after the initial study increases the diagnostic yield[21,22] and should be performed when abnormal or equivocal findings are found on the initial study and when abuse is suspected on clinical grounds. A repeat study may permit more precise determination of the age of individual injuries. Lack of interval change may indicate that the initial radiographic finding is a normal anatomic variant or is related to a bone dysplasia. Views of the skull can be omitted from the follow-up study.

TABLE 1 Complete Skeletal Survey Table[14]

Appendicular skeleton
Arms (AP)
Forearms (AP)
Hands (PA)
Thighs (AP)
Legs (AP)
Feet (PA or AP)
Axial skeleton
Thorax (AP and lateral), to include thoracic spine and ribs
AP abdomen, lumbosacral spine, and bony pelvis
Lumbar spine (lateral)
Cervical spine (AP and lateral)
Skull (frontal and lateral)

AP indicates anteroposterior; PA, posteroanterior.

Radionuclide Bone Scans

When performed by staff experienced with pediatric nuclear imaging, skeletal scintigraphy may offer an alternative or adjunct to the radiographic skeletal survey in selected cases, particularly for children older than 1 year. Scintigraphy can provide increased sensitivity for detecting rib fractures, subtle shaft fractures, and areas of early periosteal elevation. However, scintigraphy is less sensitive than radiography for detection of classic metaphyseal lesions, which are fractures that carry a high specificity for abuse in infants.[23–25] Skeletal scintigraphy usually requires sedation and is generally more expensive than radiographic surveys. Bone scans are used to

supplement radiographic skeletal surveys in the acute-care setting,[24] but for the child who is placed in a "safe" environment, a follow-up skeletal survey is an attractive alternative to initial scintigraphy. If radionuclide bone scans are performed as the initial study, all positive areas must be evaluated further with radiography. Because scintigraphy is insensitive for detecting cranial injuries, skull radiography in at least 2 projections must supplement the bone scan.

Imaging Guidelines

The skeletal survey is mandatory in all cases of suspected physical abuse in children younger than 2 years; its utility diminishes thereafter.[8,26] The screening skeletal survey or bone scan has little value in children older than 5 years. Decisions about which types of imaging to perform for patients in the 2- to 5-year-old age group must be made individually on the basis of the specific clinical indicators of abuse. At any age, when clinical findings point to a specific site of injury, the customary radiographic protocol for imaging that anatomic region should be used. MRI and ultrasonography may be indicated when epiphyseal separations are suspected on the basis of plain-film radiography.[2,27] Evidence suggests that if 1 infant twin is injured, the other is at risk and should also undergo a skeletal survey.[28] Although there seems to be an association between physical and sexual abuse, the prevalence of fractures in sexually assaulted children is low; thus, skeletal surveys should be performed only in selected cases on the basis of specific clinical indications.[29,30] Although the high-quality skeletal survey is essential in the evaluation of suspected physical abuse in infants and toddlers, it may not be available in the emergency department setting during evening hours.[15] The American Academy of Pediatrics has stated that hospitalization of the abused child may be medically necessary for diagnosis,[31] and in some instances it may be advisable to place a child in a safe haven until a proper skeletal survey can be performed.[31] A skeletal survey may be difficult to obtain in a critically injured child on life support. Efforts should be directed at performing an adequate examination in a timely manner, because the results may have an effect on the early investigation of the case.

HEAD TRAUMA

High-energy forces associated with impact or violent shaking result in a variety of central nervous system injuries that can be detected by modern neuroimaging techniques. The evolution of these injuries, as well as processes that develop secondary to the original insult, are often effectively displayed on serial imaging studies.[2,32–35]

All infants and children with suspected intracranial injury must undergo cranial CT, MRI, or both. Strategies should be directed toward the detection of all intracranial sequelae of abuse and neglect with a thorough characterization of the extent and age of the abnormalities.[36] In the acute-care setting, efforts are directed toward rapid detection of treatable conditions. Subsequent studies are designed to more fully delineate all abnormalities, determine the timing of the injuries, and monitor their evolution.

Computed Tomography

CT without intravenous contrast should be performed as part of the initial evaluation for suspected acute inflicted head injury. CT has high sensitivity and specificity for diagnosing acute intraparenchymal, subarachnoid, subdural, and epidural hemorrhage. Abnormalities that require emergency surgical intervention generally are well demonstrated. CT is readily available and rapidly performed for critically ill patients and is generally better than MRI for evaluation of acute hemorrhage. Skull fractures, associated soft tissue swelling, and facial fractures also can be diagnosed on CT images with appropriate bone window and level settings. With modern multidetector CT scanners, the brain can be imaged in a few seconds, usually obviating the need for sedation.

Ultrasonography

Ultrasonography via the anterior fontanelle in young infants has gained an important role in clarifying the nature of extra-axial fluid collections in infancy. Because ultrasonography reliably differentiates convexity subdural from subarachnoid collections, it is particularly useful for the infant with macrocephaly or any infant with large hypodense cerebral convexity collections demonstrated by CT.[37] Subcortical white matter tears in the frontal and anterior parietal parasagittal regions can be demonstrated with ultrasonography.[38] These lesions are less well defined by axial CT, and ultrasonography provides the advantage of a bedside technique. Because ultrasonography is insensitive for detecting small acute subdural hematomas, particularly within the interhemispheric fissure, and many other acute intracranial injuries, it must be performed in conjunction with CT or MRI when traumatic injury is suspected.[29,39]

Magnetic Resonance Imaging

Although cranial MRI has some limitations in the acute-care setting, it remains the best modality for fully assessing intracranial injury, including extra-axial collections, intraparenchymal hemorrhages, contusions, shear injuries, and brain swelling or edema. A strong argument can be made for MRI in all cases with positive cranial CT findings and in selected cases with normal CT results but strong clinical concerns. MRI should be performed with T_1 and T_2 weighting with proton-density or inversion-recovery sequences to differentiate cerebrospinal fluid collections from other water-containing lesions. Gradient echo sequences should be included to detect hemorrhage or mineralization not demonstrable by other MRI techniques. Although the specific type and order of pulse sequences may vary, imaging must be performed at least in the axial and coronal planes. Acute subarachnoid and subdural hemorrhage may be inconspicuous on MRI, and consideration should be given to delaying the examination for 5 to 7 days, permitting subacute

blood to become hyperintense on T1-weighted sequences.

Diffusion-weighted imaging (DWI) is a relatively new and valuable technique for the evaluation of stroke and is gaining a role in the assessment of inflicted cerebral injury. When performed early in the critically injured infant, DWI may provide information regarding cerebral injury before parenchymal abnormalities are visible on CT or conventional MRI sequences.[40,41] The value of the potential findings revealed with DWI must be weighed against the lower sensitivity of MRI in the detection of acute extra-axial blood collections and the practical problems encountered when performing MRI in severely ill infants.

Abused infants may not demonstrate neurologic signs and symptoms despite significant central nervous system injury.[2,42,43] MRI offers the highest sensitivity and specificity for diagnosing subacute and chronic injury and should be considered whenever typical skeletal injuries associated with shaking or impact are identified.[39,44]

SPINAL TRAUMA

Plain radiographs are often sufficient to evaluate vertebral compression and spinous process fractures. Complex fractures may require helical CT with multiplanar reformatted images. If a fracture or subluxation may compromise the spinal contents or if clinical findings indicate spinal cord or nerve root injury, MRI should be performed. Increasing attention has been directed toward a possible association of cervical spinal cord injury and extra-axial hemorrhage with inflicted head injury, and some centers include the cervical region in their cranial MRI trauma protocols.[45,46]

THORACOABDOMINAL TRAUMA

Blunt thoracoabdominal injury may occur in victims of child abuse. The evaluation and management of acute thoracoabdominal injury is the same as for children with accidental injuries.[47] However, when an infant or child sustains serious injury to the chest or abdomen without a known or observed mechanism or when the imaging findings are inconsistent with the purported history, investigation of potential child abuse is warranted. Failure to recognize inflicted blunt abdominal trauma contributes to higher morbidity and mortality rates than those seen with accidental abdominal injury.[48] Pancreatitis, duodenal hematomas, bowel perforation, and thoracoabdominal injury associated with rib fracture heighten the suspicion of child abuse. Chest, abdominal, and cervical spine radiographs often are obtained in the initial assessment of injured children. If internal chest or abdominal injury is suspected and the patient's condition is stable, a CT scan should be performed. A CT scan will best demonstrate many of the injuries associated with child abuse. The chest should be included if serious chest trauma is suspected.

The use of oral contrast is debatable. Oral contrast in the stomach and small bowel is useful to better define the lesser sac of the peritoneum, pancreas, duodenum, and jejunum. However, oral contrast may place the patient at greater risk of aspirating, especially if the patient is obtunded, sedated, or immobilized. If surgery or general anesthesia is likely, it is better to have an empty stomach.

TABLE 2 Imaging Recommendations for Thoracoabdominal Trauma

1.	Helical CT[a] of abdomen and/or thorax with intravenous contrast; nonionic is preferable; gastrointestinal contrast optional
2.	Ultrasonography of abdomen, usually as a follow-up examination
3.	Upper-gastrointestinal series

[a] Relative contraindication: strong history of allergy to iodine, severe shock, and renal failure.

Intravenous contrast is used routinely. Vascular injuries and injuries to the liver, spleen, pancreas, and kidneys are best demonstrated after administration of intravenous contrast material. Helical scanning with proper timing of the intravenous contrast bolus is important for accurate diagnosis. Given the heightened awareness of cancer risks associated with CT scanning in childhood, care should be taken to adjust technical factors to achieve diagnostic quality images at an exposure as low as reasonably achievable.[49,50] The only relative contraindications for intravenous contrast are a strong history of allergy to iodine, severe shock, and renal failure.

Abused children suffer some of the same injuries as children with accidental blunt trauma. In the chest, pulmonary contusion, pneumothorax, pleural effusion, rib fractures, and vascular or tracheobronchial injuries may occur. Abused children have an increased occurrence of pancreatic injuries and duodenal hematomas. Bowel injury should be suspected when there is peritoneal fluid without evidence of solid organ injury and assumed when free intraperitoneal air or extraluminal contrast is observed.[51] Bone windows should be monitored not only for rib fractures but also for signs of pelvic or spine fractures.

Peritoneal lavage rarely is used in pediatric practice. If performed before CT, it may decrease the diagnostic usefulness. Peritoneal lavage sometimes is used when emergency surgery is required to treat a patient whose condition is not stable enough for a CT scan.[49]

The use of ultrasonography in pediatric trauma is controversial. Some institutions have used ultrasonography successfully for a more detailed, comprehensive evaluation of organ injury. However, for seriously injured children and those with suspected child abuse, CT scanning is the preferred initial diagnostic modality in most institutions. Peritoneal fluid alone, which can be detected well with both ultrasonography and CT scanning, is a poor predictor of major trauma in children. An upper-gastrointestinal series sometimes is used to evaluate and follow-up duodenal hematomas.

Nonoperative management of injury to the liver, spleen, kidney, or pancreas is common in most pediatric centers. Follow-up imaging usually is limited but may be useful to help determine recommendations for the level of physical activity (Table 2).

CONCLUSIONS

The diagnostic imaging of suspected inflicted injury in infancy and childhood should be performed with at least the same rigor used in the imaging evaluation of accidental trauma and naturally occurring disease. To be confident that the imaging studies are acquired and interpreted in a thorough and informed manner, clinicians charged with reporting and providing evidence in cases of suspected abuse should work in close collaboration with radiologists experienced in pediatric imaging. This approach will help ensure that child abuse is accurately identified and reliably differentiated from conditions that may simulate abuse.[14]

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Disaster Planning for Schools

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on School Health

ABSTRACT

Community awareness of the school district's disaster plan will optimize a community's capacity to maintain the safety of its school-aged population in the event of a school-based or greater community crisis. This statement is intended to stimulate awareness of the disaster-preparedness process in schools as a part of a global, community-wide preparedness plan. Pediatricians, other health care professionals, first responders, public health officials, the media, school nurses, school staff, and parents all need to be unified in their efforts to support schools in the prevention of, preparedness for, response to, and recovery from a disaster. *Pediatrics* 2008;122:895–901

Background and Information

Schools are generally considered to be safe havens for millions of children and the greatest socializing institutions after the family. However, the recent experiences with natural disasters, in-school violence, acts of terrorism, and the threat of pandemic flu demonstrate the need for schools to be prepared for all-hazard crisis possibilities. For the purposes of this discussion, "crisis" and "disaster" are used interchangeably and refer to events of global and/or community significance rather than to the health emergencies of individual children.

It is important to note that there is a fundamental link between day-to-day emergency readiness and disaster preparedness. Schools that are well prepared for an individual emergency involving a student or staff member are more likely to be prepared for complex events such as community disasters. Individual emergencies are covered in a separate policy statement from the American Academy of Pediatrics (AAP), "Medical Emergencies Occurring at School."[1] It is helpful to view these 2 policy statements together to appreciate the full spectrum of school emergency planning.

There are 55 million US children enrolled in kindergarten through 12th grade, attending 17 000 public school districts and 29 000 private schools.[2,3] Children spend a large part of their time in school, so whether a large-scale crisis occurs during school hours, before or after school, or off the school campus, the school district plays an important role in the unfolding of events.

Although there are no federal laws requiring all school districts to have emergency-management plans, 32 states have reported having laws or other policies that do require plans. An estimated 95% of school districts reported that they have a plan, although there is great variability in these plans.[3]

To help guide the process, the US Department of Education, Office of Safe and Drug-Free Schools, has prepared emergency-management planning guidelines for school systems.[4] The guidelines are intended to give schools, school districts, and communities the critical concepts and components of good crisis planning, stimulate thinking about the crisis-preparedness process, and provide examples of promising practices. These guidelines focus on 4 stages of planning: mitigation and prevention; preparedness; response; and recovery. These school-focused guidelines are also designed to complement and integrate with the complex system of emergency preparedness in the greater community locally, regionally, and nationally.[5]

Funding for these activities comes from a mix of national, state, and local grants. The US Department of Education provides funding to some school districts specifically for emergency-management planning through its Readiness and Emergency Management for Schools grant program. School districts receiving grant funds through this program may use them to improve planning for all 4 phases of crisis planning. The US Department of Homeland Security also provides funding to states and local jurisdictions for emergency-management planning, and some of this funding can be provided to school districts or schools for emergency-management planning.

Despite the availability of grants, many school systems simply do not have the capacity to access these monies and/or efficiently use the funding streams. According to results of a Governmental Accountability Office survey of school districts, many school districts struggle to balance priorities relating to educating students and other admin-

istrative responsibilities with activities for emergency management. Challenges include a lack of emergency equipment, staff training, and expertise in the area of emergency planning.[3]

Studies focusing on recent national disasters have concurred that there are several important deficiencies in school preparedness for emergencies.[6–8] In a 2004 survey of more than 2100 superintendents, most (86.3%) reported having a disaster-response plan, but fewer (57.2%) had a plan for prevention. Most (95.6%) had an evacuation plan, but almost one third (30%) had never conducted an evacuation drill. Almost one quarter (22.1%) had no disaster plan provisions for children with special health care needs, and one quarter reported having no plans for postdisaster counseling. Almost half (42.8%) had never met with local emergency medical services (EMS) officials to discuss emergency planning. Urban school districts were better prepared than rural districts on almost all measures in the survey.[9] Regional differences were also evident. Districts within tornado belts and earthquake/hurricane-prone areas may have more of an impetus to create and practice plans compared with districts located in regions where natural disasters are rare.

Schools may also have to function as the de facto mental health system for children and adolescents not only in the recovery phase but also in the prevention and preparedness stages. Currently, on average, only one fourth of children in need of mental health care get the help they need.[10] Of those receiving care, 70% to 80% already receive some care in a school setting.[11] Mental health and substance abuse issues are the most common reasons for visits to school-based health centers.[12] The capacity to meet the needs of posttraumatic event counseling would add further stress to an already underresourced system and requires additional financial and resource preparedness.[13]

School disaster planning is a facet of larger community planning and, therefore, requires coordinated planning and allocation of community resources. Plans should be developed in partnership with other community groups, including law enforcement, fire safety, public health, EMS, and pediatric and mental health professionals. How these various groups interface varies by region and whether the incident is of local, state, or national significance.[5] Although EMS traditionally involved emergency medical technicians and ambulances, today it encompasses all out-of-hospital care events through emergency department management. In the event of an emergency in a school or in the community while a child is under school jurisdiction, EMS also includes school nurses, teachers, and other school staff. In addition, schools play a role in medical surge capacity (the ability of health care systems to adequately care for large numbers of patients). Schools lend space (eg, shelter, temporary clinics, morgues) and sometimes supplies (eg, school meal diversion) to the community during times of crisis.

Yet, even if there is coordination of planning, community members at large may not be aware of a school district's and/or an individual school's emergency plans. Without community understanding of the school plan, parents separated from their children may amplify the crisis by their well-meaning efforts to reach their children. Without participation in planning, primary care clinicians cannot be expected to assist with a coordinated and integrated response and/or recovery. When community agencies are involved in the prevention stage of planning, they can reinforce prevention messages that may help decrease the extent of the crisis, such as infection-control measures for preventing the spread of pandemic influenza and messages about bullying, parent education/guidance, and media education for violence prevention.

Because each district and each school has a unique set of parameters that affect disaster planning, there is no one ideal school crisis plan.[4] However, the same stages in school disaster planning occur for each type of crisis. These stages, as viewed through the school lens, are outlined below.

Mitigation and Prevention

The goal of mitigation is to minimize the effect of the hazardous event and decrease the need for response, as opposed to simply increasing response capability. From school violence to floods to pandemic influenza, there are measures that schools can take to decrease the risks of these events to children. An important first step is for the school or community to identify situations they could be facing on the basis of geography, community trends, school incident data, and other factors.

To address school violence concerns, schools can review their incident data and assess their violence- and injury-prevention strategies and initiatives to improve the school environment. If gang activity is common in the neighborhood, partnerships with law enforcement may be essential to ensure safe arrival and departure from school. The Office of Juvenile Justice and Delinquency Prevention supports Blueprints for Violence Prevention, a national violence prevention initiative to identify violence prevention programs that are effective and evidence based.[14] From overall improvement of school climate to classroom curricula on antibullying to individual and group counseling programs, there is much that schools can do to maintain safety. Community mental health linkages, if they are available, are important prevention and mitigation resources.

Communicable-disease mitigation can involve surveillance and health education. School absenteeism logs may be helpful as part of syndromic surveillance systems that monitor key community data to detect unusual symptom or illness patterns. Awareness of infection-control measures (ie, use of cough and sneeze etiquette, good hand hygiene, and appropriate sanitation techniques) can decrease disease transmission and can be incorporated easily into classroom culture. These efforts are important in the regular cold and influenza season but assume a more critical function if a pandemic begins to unfold.

To address environmental disasters such as toxic spills, hurricanes, tornadoes, floods, and earthquakes, schools should be having discussions with the local community-planning infrastructure, such as local emergency

planning committees (LEPCs). These groups identify and catalog potential hazards and resources to mitigate disasters, when feasible, and write emergency plans. The local emergency-planning infrastructure can work with schools to address local environmental hazards or vulnerabilities and provide resources for examining the school risk potential. The schools can then translate this information into school protocol so that appropriate essential responses of schools and students can occur.

Preparedness

During the preparedness stage, the school district, as well as the individual schools in the district, identify school crisis teams and clearly delineate the roles that staff would play during emergencies. The crisis teams work with community stakeholders involved in crisis planning (such as LEPCs) and link internal crisis planning to the other community crisis plans. The school crisis teams should assess the medical equipment as well as mental health and other resources available in the school environment. Children with special health care needs must be identified and have valid emergency care plans in place, including plans for managing both individual emergencies related to the child's illness and plans to manage the complex medical needs of the student in the event of a larger community emergency. The emergency information form, developed by AAP and the American College of Emergency Physicians, is useful in developing both an individual health plan and an emergency care plan.[15] Also, children with special health care needs require additional disaster-preparedness planning. Students in wheelchairs may need evacuation chairs that can glide down stairwells when the elevator is inoperable. Multiple evacuation routes need to be preplanned, and assistance staff members need to be assigned for these children. Medication availability during a prolonged lockdown or shelter-in-place situation poses a challenge for students with diabetes and other chronic diseases.[15] The Emergency Medical Services for Children National Resource Center, in association with the National Association of School Nurses, has compiled a list of minimal essential emergency equipment and resources that should be available in all schools.[16] In the event of a large-scale emergency, day-to-day supplies for managing individual student emergencies may not be sufficient.

Police, public health officials, firefighters, and other members of the local disaster-response infrastructure are versed in the Incident Command System, a federally supported system designed to effectively and efficiently manage incidents by integrating agencies, personnel, procedures, equipment, and communications under a common organizational structure. School administrators should collaborate with LEPCs or equivalent agencies so that the school plan is integrated with the Incident Command System. This is the stage at which the challenges of integrating the internal school response with the external school response system are addressed. These challenges include the schools' ability to effectively communicate with the rest of the community, including use of a shared incident command vocabulary and alignment of communication devices such that fire, police, school, and other LEPC members are on the same radio frequency. Practice of the plans through drills and community-wide exercises ensures that gaps will be identified and weaknesses will be addressed.[17] Online self-paced courses in the Incident Command System are available through the Federal Emergency Management Agency (FEMA) Emergency Management Institute as part of the National Incident Management System. These courses were designed for people who have emergency-management responsibilities as well as the general public.[18]

A key challenge that school districts face during preparation relates to lockdowns, evacuations, and relocations. Issues to be addressed include responding to various scenarios, developing plans to transport children when there are not enough buses, having a mechanism to track which children are where, and putting a system in place that ensures children are kept safe during evacuation, are relocated to a place that is appropriate for children, and are released to the most appropriate family member. Additional information (including an algorithm to assist in decision-making) can be found online within the US Department of Education's resource, "Practical Information on Crisis Planning: A Guide for Schools and Communities" (www.ed.gov/admins/lead/safety/emergencyplan/crisisplanning.pdf).

One of the most important aspects of preparedness is addressing parental understanding of the emergency plan and the reunification process. Classrooms should be equipped with "jump-and-go" folders that contain emergency contact information, individual health plans, name tags, and other critical information for all students, particularly the youngest ones. These packets go with the teacher if there is an evacuation. Parents should be informed annually and reminded in advance of high-risk seasons about the district's and individual school's emergency plans, including the differences between lockdown, shelter-in-place, evacuation, and relocation. Parents should clearly understand that well-meaning attempts to approach a school in crisis could direct resources away from children, undermine emergency efforts, and increase risk to students. Schools need to have multiple media outlets to accurately inform parents, including those with limited English proficiency. A detailed plan to reunite children and parents once the crisis has been resolved should be communicated to parents before any crisis occurs. Emergency consent protocols should be reviewed for appropriateness and relevance to large-scale emergencies.

Communication venues (eg, television and radio broadcasts) should consider school issues when planning disaster-preparedness strategies. Local media outlets should be prepared to place emergency public information ahead of other news to increase media attention given to disaster-preparedness efforts. Existing Web sites can be reviewed for their capacity to provide real-time updates.[19]

If a disaster occurs and cell phone use is increased, cell phone towers are typically overwhelmed, yet text messaging, e-mailing, etc, still may work. Ham radios and 2-way radios ("walkie talkies") work between people

who are near each other. Hand-held satellite phones or a satellite phone unit (which requires a contract) are best in worst-case scenarios. In severe situations, word of mouth and hand-painted signs may have to be used. Last, once telephone systems are up and running, voice messages can be a good way to communicate. Many school districts are using technology (eg, automated call-outs, simple voice mail, or automatic call forwarding to another location) to address parent notification and maximize communication.

Response

The response phase is when the planning and preparation efforts are put to the test. The school crisis team is activated, and the routines, which ideally have been practiced and fine-tuned, are rolled out depending on the nature of the crisis. The ideal response involves practiced collaboration with the LEPC and the community response team and use of the Incident Command System.[4,20] In this response, school nurses, teachers, and other school staff become a seamless part of EMS. During the response, and not just during recovery, it is important to identify children who are having trouble coping and address any developing mental health concerns.

School facilities are often designated as disaster evacuation shelter sites. These venues provide shelter for many who have lost their homes as a result of disaster and also provide an opportunity for school officials to assess family and child needs. Likewise, disaster recovery centers operated by FEMA are set up in heavily affected communities to support the reestablishment of infrastructure and the provision of food, supplies, health care, and human services. It is recommended that school district officials, including mental health professionals, be present in all disaster recovery centers to disseminate information and provide guidance for parents seeking support for their children.[20]

The media play an important role during this stage in keeping the public, particularly parents, informed. The parent-reunification plan is activated. From television and radio broadcasts to Web sites to newspapers, the redundant delivery of information via several sources would help to fill in the gaps in the event of power outages or other interruptions in services. During the response, the community needs to be prepared for a surge of external media organizations that would be providing coverage of the event.

Recovery

The goal of recovery, from the school perspective, is to restore the school's infrastructure and return to learning as soon as possible. Although returning to the classroom does not ensure that children are ready to address learning tasks, evidence points to the restorative power of the educational routine in guiding children through emotional crises.[20] The responsibilities of the community are to support schools with the necessary mental health resources and to determine which therapies are appropriate for school incorporation and which are based more appropriately in the community. The AAP has a disaster-preparedness Web site that offers resources for health care professionals and laypersons on various aspects of pediatric emergency and disaster readiness (www.aap.org/disasters).

During this time, the effects on the students and staff should be monitored, and the school system should debrief with the LEPC or equivalent group concerning the lessons learned during the event. Anniversary planning is also an important part of the prolonged recovery.[4,21]

CONCLUSIONS

The ongoing risk of natural disasters, such as hurricanes, and a seemingly growing occurrence of man-made disasters, such as school shootings, have underscored the need for schools to have disaster plans that are uniquely designed for the school culture and interface with the larger community. Clear guidelines are only part of the process. Schools must also have the resources and expertise to implement disaster plans. Pediatricians can play important roles in the development and execution of these plans as both medical home providers and school physicians.

RECOMMENDATIONS

The following recommendations support the 4 stages of school-based crisis planning and are compatible with non–school-based recommendations for disaster preparedness. These recommendations describe how the school's role highlighted in this statement relates to both the pediatrician within the medical home and the school health and safety team (school nurse, social worker, school resource officer), including the school physician. They are intended to assist both pediatricians and school physicians in providing support to schools in their efforts to prepare for disasters.

Recommendations for Pediatricians and Other Community Clinicians

Pediatricians have a role in all aspects of emergency and disaster planning for children.

- Pediatricians or their practices should know the names and means of contacting the school physician(s) (where available) and the school health and safety team (school nurse, social worker, school resource officer).
- Pediatricians should be familiar with AAP resources on emergency and disaster preparedness (www.aap.org/healthtopics/disasters.cfm and www.aap.org/disasters).
- Pediatricians and/or their practices should, at a minimum, familiarize themselves with their local community and school districts' disaster plans. Ideally, these plans should have primary care clinician input in all 4 areas of crisis planning. Pediatricians should also be aware of local EMS capabilities and key contacts.
- Pediatricians can be advocates for improved communication between school officials and local medical and emergency officials in the preparation and prac-

tice of an emergency plan, ensuring that prevention, preparedness, response, and recovery components are addressed and integrated into the larger community plan. This improved communication includes linking disaster planning at the hospitals where they have privileges with school crisis and disaster planning.

- Pediatricians can share information about the school district's response plan with their emergency department clinician colleagues and determine ways to ensure that the school district's response plan is integrated with the overall community disaster plan, emergency medical system, and LEPC or other equivalent groups.
- Pediatricians may opt to reinforce, through waiting-room literature, the health-promotion and injury-prevention messages of the school district(s). Examples are violence-prevention messages, cough/sneeze etiquette and hand-hygiene behaviors, attendance polices that do not encourage children who are ill to attend school (to have perfect attendance), resources for stressed families, and support for individual family crisis planning.
- Reinforcing family awareness of the school district's crisis plan could be part of anticipatory guidance in the medical home, particularly calling attention to the school's plan for parental notification in the event of lockdown, shelter-in-place, or evacuation to an alternative site.
- Pediatricians and/or their practices should be aware of the capacity for each school in the district to provide on-site first aid and should assist the school in developing that capacity.
- Pediatricians may help develop school protocols on absenteeism, psychosocial support, and disease surveillance.
- Students with special health care needs will require individual crisis plans to be developed and implemented at the individual school level. Pediatric primary and specialty care providers should help families and schools plan for prolonged sheltering or evacuation of the medically fragile student and to use the emergency information form.[15]
- Each community has idiosyncratic elements that predispose it to possible crises such as tornadoes, earthquakes, hurricanes, toxic chemical hazards, radiation, and community violence. Pediatricians should have an office-based disaster plan that reflects these hazards and not only be prepared to treat the medical outcomes of these crises but also be aware of the school district's attempts to prepare for these unique disaster issues.
- As a crisis is unfolding, pediatricians should activate their office-based plan (see www.aap.org/disasters/pdf/DisasterPrepPlanforPeds.pdf for guidance on developing an office-based plan), follow the predetermined community and school-based disaster plans, and stay informed through the appropriate communication systems established in the planning process.
- Pediatricians should support efforts of schools to return to the learning mode as soon as possible.
- Assisting others in the school and community in recognizing symptoms of posttraumatic stress is an important role of the clinician. The medical community's collective sense of the emotional effects of a disaster can help guide schools and staff in their continuing interventions. Pediatricians also may participate in those interventions, which can include trauma and grief counseling.

Recommendations for School Physicians

Some school districts use physicians as medical consultants, with some states mandating a school consultant per district. The school physician is a critical member of the school health and safety team (school nurse, social worker, school resource officer). School physicians assist in developing health-related policies and are a ready source of information. They work closely with school nurses and are often the bridge between the educational community and primary care clinicians, emergency department clinicians, other health care professionals, first responders, public health officials, and parents and, as such, have a more in-depth involvement with the school system. School physicians are, thereby, uniquely positioned to assist in developing school crisis-management policies. The presence or absence of a school physician does not preclude pediatricians from becoming involved in the following activities:

- School physicians should support schools in developing a risk-potential profile at both the district and individual school levels, including hazard identification and effects on the physical facility and on people. The risk can be environmental, as with hurricanes, or man-made, as with terrorism and gang violence.
- School physicians should become trained in the FEMA Incident Command System and the National Incident Management Systems instruction.
- School physicians, depending on the school district communication plan, should be prepared to serve as spokespersons for medical queries.
- The school physician can assist in the review of incident data and assess the capacity for the violence-, injury-, and communicable-disease–prevention strategies to address the needs of the district and individual schools.
- The school physician may assist with emergency education and training for staff at individual schools so that staff members are aware of their individual roles in a crisis.
- The school physician should review plans for children with special health care needs, addressing the school's capacity to meet the needs of these children in circumstances when the students will be evacuated or contained for prolonged periods (ie, lockdown, shelter-in-place). School physicians can help advocate for adequate emergency supplies to address evacuation, shelter-in-place, and lockdown needs, including classroom ca-

pacity to have medical information readily available for each student.

- The school physician, along with the school health and safety team, should advocate for practice/drills of the protocols and procedures.
- The role the school physician consultant plays will vary depending on availability and should be predetermined by the consultant and school district.
- The school physician has a key role in reviewing the details of the school's plans for disaster response, adherence to the emergency protocol, and the assessment of the adequacy of services available and should assist with refinement of the school's crisis plan.
- The school physician should actively educate staff and parents regarding common mental health reactions to crisis (including symptoms that indicate a need for treatment), strategies to promote resilience, and interventions to facilitate recovery. The plan should include possible interventions to facilitate the recovery of students who develop mental health problems.
- The school physician can provide communication to the health and mental health community about the crisis/recovery needs of the school and can assist in soliciting community linkages.

Recommendations for Public Policy

All levels of government have a clear, vested interest in protecting the health and safety of children during a disaster. Government can play a critical role in providing clear guidelines and resources to schools to ensure that every school does not need to "reinvent the wheel" and can benefit from the work already completed by other institutions similarly situated to develop optimal preparedness plans and strategies.

Pediatricians, as experts in the physical, mental, social, and emotional health and well-being of children, play a vital role in advocating on behalf of children and their interests. To ensure that children's unique needs are appropriately addressed in planning for emergencies and disasters, pediatrician representation should be integrated throughout all federal, state, and local emergency and disaster planning activities. Working in concert with the AAP on federal efforts, AAP chapters and districts on regional and state efforts, and school administrators, emergency and disaster-preparedness experts, child advocates, and others on local efforts, pediatrician advocacy can ensure that children's physical, mental, social, and emotional needs are incorporated into all emergency- and disaster-preparedness plans. The unique needs of children, including those specific to age and health status, should be addressed in such plans, and pediatricians and pediatric medical/surgical subspecialists are encouraged to participate in emergency- and disaster-preparedness planning to ensure that children's needs are appropriately represented.

- The needs of children of all ages should be integrated into federal, state, and local emergency and disaster plans. Pediatricians and pediatric medical/surgical subspecialists should participate at all levels of emergency and disaster planning.
- Federal, state, and local disaster plans should recognize that children are likely to be at school when a disaster occurs. Disaster-readiness efforts must include specific components to ensure appropriate care for children of all ages and all stages of development, including those with special health care needs, in various school settings.
- Federal agencies should take a leadership role in providing schools with models for preparation, shelter-in-place, evacuation, reunification of children with caregivers, and other aspects of disaster preparedness. The US Department of Education Web site (http://rems.ed.gov) is a useful start but should be greatly expanded.
- Federal and state government agencies should increase the resources provided to school districts to ensure that schools can prepare appropriately for disasters that are likely to occur in their areas.
- State and local disaster drills and exercises should include schools as potential direct or indirect sites of disasters. Special attention should be given to evacuation and reunification plans in these drills.
- Federal, state, and local disaster-response plans should recognize possible problems that will occur if these plans involve using schools as mass care sites. Such plans would interfere with the need to restore educational services for children. State and local planning groups should include representatives from the schools in developing preparedness plans, especially, but not only, if those plans include the use of school buildings or other school resources for the purpose of responding to a community disaster.
- Federal, state, and local disaster-response plans should acknowledge that schools are a critical part of society's infrastructure that should be restored as soon as feasible after a disaster to provide needed continuity of care and education for children as well as a safe place for them to be while their caregivers return to work.

Committee on Pediatric AIDS

Disclosure of Illness Status to Children and Adolescents With HIV Infection

ABSTRACT. Many children with human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome are surviving to middle childhood and adolescence. Studies suggest that children who know their HIV status have higher self-esteem than children who are unaware of their status. Parents who have disclosed the status to their children experience less depression than those who do not. This statement addresses our current knowledge and recommendations for disclosure of HIV infection status to children and adolescents.

ABBREVIATIONS. HIV, human immunodeficiency virus; AIDS, acquired immunodeficiency virus.

Disclosure of HIV infection status to children and adolescents should take into consideration their age, psychosocial maturity, the complexity of family dynamics, and the clinical context.

Many children with perinatally acquired human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS) are surviving to middle childhood and some to adolescence. By the end of 1997, there were over 8000 reported cases of AIDS in children younger than 13 years and over 3000 adolescents with AIDS.[1] The median survival for children with perinatal HIV infection has been reported to be between 8.6 to 13 years and between 36% to 61% of infants with perinatally acquired HIV are expected to survive to age 13 years[2]; the median survival of children after a diagnosis of AIDS is made is longer than 5 years.[3] Consequently, the disclosure of a diagnosis of HIV infection/AIDS to a child is becoming an increasingly common clinical issue. As some family members have been reluctant to discuss the nature of the illness with their infected child or adolescent, this statement gives recommendations for disclosure of illness to HIV-infected children and adolescents.

Considerable guidelines exist about the disclosure of a chronic illness to a child. In general, disclosure is geared to a child's level of cognitive development[4] and psychosocial maturity. For most illnesses, young children receive simple explanations about the nature of their illness and what their responsibilities are in caring for themselves. The exact diagnosis and prognosis of the disease are less important in early discussions with young children. As children mature, they should be fully informed of the nature and consequences of their illness and encouraged to actively participate in their own medical care. Children with a variety of chronic diseases, including those with cancer, have exhibited better coping skills and fewer psychosocial problems when appropriately informed about the nature and consequences of their illness.[5,6]

Nevertheless, some parents and health care professionals are reluctant to inform children about their HIV infection status. Data from several centers indicate that between 25% and 90% of school-age children with HIV infection/AIDS have not been told they are infected.[7–9] Some of the reasons given by family members for not disclosing HIV infection/AIDS status are similar to reasons expressed by parents of children with other serious diseases, which include concerns about the impact that disclosure may have on a child's emotional health and fear by the parents that the knowledge will negatively affect a child's will to live. Additional reasons often given by parents of HIV-infected children include a sense of guilt about having transmitted infection to the child, anger from the child related to knowledge of perinatal transmission, and fear of inadvertent disclosure by the child. Disclosure of status by the child may lead to stigmatization, discrimination, or ostracism toward the child and other family members. Health care professionals and families are also concerned about the difficulty children have keeping a "secret" and limiting the disclosure to selected persons.

Parents may choose not to disclose the health status to their child because of difficulty in coping with their own illness. Denial is common, and parents may not be able to deal with their own infection with HIV or that of a family member. Accepting the full consequences of illness within a family and learning to cope can be a lengthy process for individuals with any chronic disease. Failure to cope with illness appropriately may signify psychosocial dysfunction that merits specific counseling and therapy for parents. Furthermore, while parents may be making requests for nondisclosure based on what they believe is best for their child, physicians also have a responsibility to make an independent assessment of a child's readiness for disclosure.

Families desiring to protect their children from certain problems by concealing information risk having encounters with other issues. Children may de-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

velop inappropriate and hurtful fantasies about their illness. A conspiracy of silence surrounding children infected with HIV may isolate them from potential sources of support. In the unfortunate event of the death of a parent, the opportunity is lost for children to discuss their illness with that parent. Children also may inadvertently learn of the nature of their illness in a manner that is not supportive. If children find out their infection status from someone other than a parent, they may feel unable to confide in their parent or feel a need to conceal that they are aware of their diagnosis.

Studies on the impact of HIV infection/AIDS disclosure to children are limited.[7,8,10,11] Preliminary work suggests, however, that children who know their HIV status have higher self-esteem than infected children who are unaware of their status. Parents who have disclosed the status to their children experience less depression than those who do not.[7] Disclosure should not only take into consideration the child's age, maturity, and the complexity of family dynamics, but the clinical context as well.[8,10,11] In critically ill children, issues of dying rather than disclosure may be more appropriate to address.

Pediatricians may serve as advocates for children in their care to their parents. For adolescents, the American Academy of Pediatrics has established that health care professionals have an ethical obligation to provide counseling to respond to the needs of adolescent patients and to insure that adolescents have an opportunity for examinations and counseling apart from their parents.[12] Consequently, physicians should provide full disclosure of HIV status to their adolescent patients. Physicians are also obligated to encourage adolescents to involve their parents in their care. Adolescents need to be informed about their illness to assist in their own care and to reduce the risk of transmitting the infection to others through unprotected sex or behaviors associated with illicit drug use.[12,13]

Pediatricians should anticipate the need for eventual disclosure when caring for HIV-infected children. Although physicians can listen to and discuss with parents potential reluctance to disclose, pediatricians should not accept parental or guardian requests to withhold the diagnosis under all circumstances. Pediatricians need to inform parents that if older children question them about their HIV infection status they will answer direct questions truthfully. Although disclosure should occur in a supportive environment that optimally includes knowledgeable professionals and parents, some parents may decide to have professionals assume this responsibility. Ongoing counseling is required throughout the child's infection to obtain parental understanding of the importance of disclosure.[13]

The American Academy of Pediatrics recommends the following for disclosure of HIV infection/AIDS status to children and adolescents:

1. Parents and other guardians of an HIV-infected child should be counseled by a knowledgeable health care professional about disclosure to the child of their infection status. This counseling may need to be repeated throughout the course of the child's illness.
2. Disclosure of the diagnosis to an HIV-infected child should be individualized to include the child's cognitive ability, developmental stage, clinical status, and social circumstances.
3. In general, younger children, if symptomatic with illness, are most interested in learning what will happen to them in the more immediate future. They do not need to be informed of their diagnosis, but the illness should be discussed with them. If children are informed of their diagnosis, considerable effort should be directed toward eliciting and addressing their fears and misperceptions.
4. The American Academy of Pediatrics strongly encourages disclosure of HIV infection status to school-age children. The process for disclosure should be discussed and planned with the parents and may require a number of visits to assess the child's knowledge and coping capacity. Older children have a better capacity to understand the nature and consequences of their illness. Considerable effort will need to be directed to facilitate coping with the illness. Symptomatic children, particularly those requiring hospitalization, should be informed of their HIV status. The likelihood of children inadvertently learning about their status in a hospital setting is high. Disclosure should optimally be conducted in a controlled situation with parent(s) and knowledgeable professionals.
5. Adolescents should know their HIV status. They should be fully informed to appreciate consequences for many aspects of their health, including sexual behavior.
6. Adolescents also should be informed of their HIV status to make appropriate decisions about treatment and participation in clinical treatment trials. Physicians should also encourage adolescents to involve their parents in their care.

CLINICAL REPORT

Distinguishing Sudden Infant Death Syndrome From Child Abuse Fatalities

Guidance for the Clinician in Rendering Pediatric Care

AMERICAN ACADEMY OF PEDIATRICS
Kent P. Hymel, MD, and the Committee on Child Abuse and Neglect
NATIONAL ASSOCIATION OF MEDICAL EXAMINERS

ABSTRACT

Fatal child abuse has been mistaken for sudden infant death syndrome. When a healthy infant younger than 1 year dies suddenly and unexpectedly, the cause of death may be certified as sudden infant death syndrome. Sudden infant death syndrome is more common than infanticide. Parents of sudden infant death syndrome victims typically are anxious to provide unlimited information to professionals involved in death investigation or research. They also want and deserve to be approached in a nonaccusatory manner. This clinical report provides professionals with information and suggestions for procedures to help avoid stigmatizing families of sudden infant death syndrome victims while allowing accumulation of appropriate evidence in potential cases of infanticide. This clinical report addresses deficiencies and updates recommendations in the 2001 American Academy of Pediatrics policy statement of the same name.

INTRODUCTION

Approximately 50 years ago, the medical community began a search to understand and prevent sudden infant death syndrome (SIDS).[1,2] Almost simultaneously, medical professionals were awakened to the realities of child abuse.[3–6] Since then, public and professional awareness of SIDS and fatal child abuse during infancy has increased steadily. More recently, well-validated reports of child abuse and infanticide—intentional suffocation presenting as apparent life-threatening events (ALTEs) and/or apparent SIDS—have appeared in the medical literature and in the lay press.[7,8] The differentiation between SIDS and fatal child abuse can be a critical diagnostic decision.[9] Additional funding for research into the causes and prevention of SIDS and child abuse is needed.

For more than a decade, SIDS (also called crib or cot death) has been defined as the sudden death of an infant younger than 1 year that remains unexplained after thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history.[10] Very recently, an expert panel of pediatric and forensic pathologists and pediatricians proposed a new definition of SIDS that is stratified to facilitate research, administrative, and vital-statistics purposes.[11] SIDS is the most common cause of death for children between 1 and 6 months of age. The incidence of SIDS peaks between 2 and 4

months of age. Approximately 90% of SIDS cases occur before the age of 6 months.[12]

SIDS is suspected when a previously healthy infant, usually younger than 6 months, apparently dies during sleep, prompting an urgent call for emergency assistance. Often, the infant is fed normally just before being placed in bed to sleep, no outcry is heard, and the infant is found in the position in which he or she had been placed at bedtime or naptime. In some cases, cardiorespiratory resuscitation initiated at the scene is continued without apparent beneficial effect en route to the hospital, where the infant is finally declared dead. Evidence of terminal motor activity, such as clenched fists, may be seen. There may be serosanguineous, watery, blood-tinged, frothy, or mucoid discharge coming from the nose or mouth. Skin mottling and postmortem lividity in dependent portions of the infant's body are commonly found. Review of the medical history, scene investigation, radiographs, and autopsy are unrevealing.

Despite extensive research, our understanding of the causes of SIDS remains incomplete.[13] The discovery of abnormalities in the arcuate nucleus of the brainstems of some SIDS victims suggests that true SIDS cases likely reflect delayed development of arousal, cardiorespiratory control, or cardiovascular control.[14,15] When the physiologic stability of such infants becomes compromised during sleep, they may not arouse sufficiently to avoid the noxious insult or condition.[16]

The SIDS rates are 2 to 3 times higher among black, Alaska native, and some American Indian populations. SIDS has been linked epidemiologically in research studies to prone sleep position, sleeping on a soft surface, bed sharing, maternal smoking during or after pregnancy, overheating, late or no prenatal care, young maternal age, prematurity, low birth weight, and male gender.[13,17–25] To date, no definitive evidence establishes causality between SIDS and recurrent cyanosis, apnea, ALTEs, or immunizations during infancy.

In recent years, national campaigns aimed at reducing prone sleeping during infancy have succeeded in dramatically decreasing the prevalence of prone positioning and may be associated with a decrease in the incidence of SIDS in the United States and in other countries.[16,26–31] Many of these educational campaigns have also emphasized prompt evaluation and treatment of sick infants, appropriate immunizations, breastfeeding, and avoidance of bed sharing, overheating, overdressing or overbundling, gestational or postnatal passive smoke exposure, and soft sleep materials or surfaces.

SIDS: A DIAGNOSIS OF EXCLUSION

The diagnosis of SIDS is exclusionary and requires a complete autopsy, investigation of the circumstances of death,[32] and review of case records that fail to reveal another cause of death. Infant deaths without such a comprehensive death investigation and infants that are autopsied and whose deaths are carefully investigated but reveal substantial and reasonable uncertainty regarding the cause or manner of death should be designated as "undetermined." Examples of undetermined cases include suspected (but unproven) infant death attributable to infection, metabolic disease, asphyxiation, or child abuse.

A diagnosis of SIDS reflects the clear admission by medical professionals that an infant's death remains unexplained. A young infant's death should be ruled as "attributable to SIDS" when all of the following are true:

- a complete autopsy is performed, including examination of the cranium and the cranial contents, and autopsy findings are compatible with SIDS;
- there is no evidence of acute or remote inflicted trauma, significant bone disease, or significant and contributory unintentional trauma, as judged by skeletal radiologic survey,[33] postmortem examination, and reliable clinical history;
- other causes and/or mechanisms of death are sufficiently excluded, including meningitis, sepsis, aspiration, pneumonia, myocarditis, trauma, dehydration, fluid and electrolyte imbalance, significant congenital defects, inborn metabolic disorders, asphyxia, drowning, burns, or poisoning;
- there is no evidence of toxic exposure to alcohol, drugs, or other substances; and
- thorough death- and/or incident-scene investigation and review of the clinical history reveal no other cause of death.

CHILD ABUSE FATALITIES BY SUFFOCATION

In some cases, it may be difficult or impossible to differentiate between a natural unexplained infant death, an unintentional or accidental infant death, and an unnatural (intentional) infant death. Recent literature has suggested that the index of suspicion for unnatural death should be higher, particularly in families in which an unexplained infant death has occurred previously.[34] More recent publications, however, provide some reassurance that a percentage of recurrent, unexplained infant deaths may be, in fact, natural.[35,36]

Estimates of the incidence of infanticide among cases designated as SIDS range from less than 1% to 5%.[7,9,37–39] The parents of some infants with recurrent ALTEs have been observed trying to suffocate and harm their infants.[7,40] In Great Britain, covert video surveillance was used to assess child abuse risk in 39 young children referred for evaluation of recurrent ALTEs.[7] Abuse was revealed in 33 of 39 cases, with documentation of intentional suffocation observed in 30 patients. Among 41 siblings of the 39 infants in the studies, 12 had previously died suddenly and unexpectedly. Although 11 of these deaths had been classified as SIDS, 4 parents later

admitted to suffocating 8 of these siblings. Other cases previously thought to be multiple SIDS cases within a family[40,41] have been revealed to be cases of serial homicide by suffocation.[8,34]

It is difficult, if not impossible, to distinguish at autopsy between SIDS and accidental or deliberate suffocation with a soft object.[42] However, certain circumstances could indicate the possibility of intentional suffocation, including

- recurrent cyanosis, apnea, or ALTEs occurring only while in the care of the same person;
- age at death older than 6 months;
- previous unexpected or unexplained deaths of 1 or more siblings;
- simultaneous or nearly simultaneous death of twins[43];
- previous death of infants under the care of the same unrelated person[44]; or
- evidence of previous pulmonary hemorrhage (such as marked siderophages in the lung).

MANAGEMENT OF SUDDEN UNEXPECTED INFANT DEATH

Most sudden infant deaths occur at home. Parents are shocked, bewildered, and distressed. Parents who are innocent of blame in their child's death often feel responsible nonetheless and imagine ways in which they might have contributed to or prevented the tragedy.[45] The appropriate medical professional response to every child death must be compassionate, empathic, supportive, and nonaccusatory. Inadvertent comments, as well as unnecessary questioning by medical personnel and investigators, are likely to cause additional stress. It is important for those in contact with parents during this time to remain nonaccusatory even while conducting a thorough death- and/or incident-scene investigation.

Personnel on first-response teams should be trained to make observations at the scene, including position of the infant, marks on the body, body temperature and rigor, type of bed or crib and any defects, amount and position of clothing and bedding, room temperature, type of ventilation and heating, and reaction of the caregivers. Guidelines are available for investigation of the circumstances of sudden, unexplained infant deaths.[32,37] Paramedics and emergency department personnel should be trained to distinguish normal findings, such as postmortem anal dilation and lividity, from trauma attributable to abuse.[46,47]

When a previously healthy infant has died unexpectedly in the absence of external evidence of injury or initial history/scene findings suggestive of another cause/manner of death, then a preliminary diagnosis of "possible SIDS" may be given. Assignment of this preliminary diagnosis should not limit or prevent subsequent thorough case investigation. Parents should be informed that other causes and mechanisms of death will be excluded only by thorough investigation of the circumstances of death, postmortem examination, and review of case records. It should be explained to parents that these procedures might enable them and their physician to understand why their infant died and how other children in the family, including children born later, might be affected. Only after completion of a thorough case investigation (including performance of a complete autopsy, examination of the circumstances of death, and review of the clinical history) that does not reveal another cause of death should a diagnosis of SIDS be assigned as the cause of death.

Depending on local protocols and statutes, if permitted by the medical examiner, the family may be given an opportunity to see and hold the infant once death has been pronounced. It is suggested that an unrelated observer remain with the family throughout this period to serve as a witness should issues regarding postmortem artifacts arise later. A protocol[48] may help in planning how and when to address the many issues that require attention, including baptism, grief counseling, funeral arrangements, religious support, termination of breastfeeding, and the reactions of surviving siblings.[45,49] All parents should be provided with information about sudden infant death[50,51] and the telephone number of the local SIDS support group.[48]

Controversy exists in the medical literature regarding the likelihood of a repetition of SIDS within a sibship.[52–55] When an infant's sudden and unexpected death has been thoroughly evaluated and alternate genetic, environmental, accidental, or inflicted causes of death have been carefully excluded, parents should be informed that the risk of SIDS in subsequent children is not likely increased. Although repetitive sudden and unexpected infant deaths occurring within the same family should compel investigators to consider the possibility of serial homicide,[8] it is important to remember that serial infant deaths within a sibship can also be explained by a fatal, inheritable disorder, 2 separate and unrelated natural disease processes, or an unrecognized environmental hazard.

In many states, multidisciplinary teams have been established to review child fatalities.[56,57] Ideally, a multidisciplinary death-review committee should include a child welfare/child protective services social worker, a law enforcement officer, a public health officer, the medical examiner/coroner, a pediatrician with expertise in child maltreatment, a forensic pathologist, a representative of the emergency medical services (EMS) system, a pediatric pathologist, and the local prosecutor. The proceedings of multidisciplinary death-review committees should remain confidential. Sharing data among agencies helps to ensure that deaths attributable to child abuse are not missed and that surviving and subsequent siblings are protected. Some child-fatality teams rou-

tinely review infant deaths attributable to apparent SIDS.

THE IMPORTANCE OF AUTOPSY, SCENE INVESTIGATION, AND CASE REVIEW

The failure to differentiate fatal child abuse or other causes of death from SIDS is costly. In the absence of postmortem examination, investigation of the circumstances of death, and case review, child maltreatment is missed, familial genetic diseases go unrecognized, public health threats are overlooked, inadequate medical care goes undetected, product-safety issues remain unidentified, and progress in understanding the etiology of SIDS and other causes of unexpected infant death is delayed. Inaccurate vital statistics lead to inappropriate allocation of limited health care resources. By thoroughly investigating apparent SIDS cases, the potential hazards of defective infant furniture, water beds, and bean-bag mattresses have been identified and remedied.[58,59]

If appropriate toxicological tests are not performed, infant deaths attributable to accidental or deliberate poisoning will be missed.[46,60] For example, occult cocaine exposure is potentially lethal. One review of autopsies performed on stillborns and newborns in Los Angeles, California, in the early 1990s found that 17 (40%) of 43 infants who died before 2 days of age without an obvious cause of death at autopsy had toxicological evidence of cocaine exposure. Obviously, these exposures represent intrauterine exposures.[61] Although the age and circumstances of death of these infants would exclude them from the SIDS population, it is enlightening to review the percentage of occult exposure in this population. A second review of 600 infant deaths revealed evidence of cocaine exposure in 16 infants (2.7%) younger than 8 months who died suddenly and unexpectedly.[62] "Lethal" concentrations of cocaine and many other drugs in infancy are not yet established.

Neither child abuse nor SIDS is rare. Some young victims of nonlethal child maltreatment will die from SIDS. In such cases, the failure to differentiate objectively between fatal child abuse and SIDS could result in an inappropriate criminal investigation and/or prosecution for homicide.

POSTMORTEM IMAGING

Radiographic skeletal surveys performed before autopsy in cases of possible SIDS may reveal evidence of traumatic skeletal injury or skeletal abnormalities indicative of a naturally occurring illness. Ideally, the skeletal survey should be performed in a manner comparable to that recommended for living infants in whom abuse is suspected[63,64] and reviewed by a physician experienced in identifying the subtle radiologic alterations seen with abuse, as well as findings that may be confused with inflicted injuries. Thorough documentation of all sites of suspected skeletal injury may require additional procedures that may include specimen resection, high-detail specimen radiography, and histologic analysis. The presence of both old and new traumatic injuries identified on skeletal survey before autopsy may suggest inflicted injuries and may lend focus to the postmortem examination, investigation of the circumstances of death, and police investigation.[33,65]

PATHOLOGY

The American Academy of Pediatrics and the National Association of Medical Examiners (NAME) endorse universal performance of autopsies on infants who die suddenly and unexpectedly by forensic pathologists experienced in the diagnosis of SIDS.[66] Postmortem findings in cases of fatal child abuse most often reveal cranial injuries, abdominal trauma (eg, liver laceration, hollow viscous perforation, or intramural hematoma), burns, or drowning as the cause of death.[67–70] Although cytomegalovirus inclusion bodies have been identified in some infants who died suddenly and unexpectedly, a definitive causal link between cytomegalovirus infection and SIDS has not been established.[71] Forensic pathologists establish the diagnosis of SIDS by exclusion when, after a thorough investigation including a complete autopsy, they are unable to identify a specific cause for a child's death.[46]

Inborn errors of metabolism[72–74] have been implicated in a small percentage of sudden unexplained deaths in infants with autopsy findings consistent with SIDS. When repetitive, sudden, and unexpected infant deaths occur within a sibship, thorough evaluation to exclude or confirm an inborn error of metabolism is essential. Analysis of blood and bile may facilitate diagnosis of a fatal inborn error of metabolism. Blood tests for evaluation of many metabolic disorders are now available at low cost. Many medical examiners routinely screen all victims of sudden unexpected infant death for inborn errors of metabolism at autopsy. If an inborn error of metabolism is suspected by autopsy findings (eg, hepatic steatosis) or history (eg, previous unexpected deaths in childhood in the family), then the forensic pathologist may elect to retain additional tissues such as brain, liver, kidney, heart, muscle, adrenal gland, and/or pancreas for further analysis, pending the results of the postmortem metabolic screening.

CONCLUSIONS

The following are important components in the evaluation of sudden, unexplained infant deaths:

- accurate history taking by emergency responders and medical personnel at the time of death and immediate transmission of this historical information to the medical examiner or coroner;
- prompt investigation of the scene[32,37] at which the infant was found lifeless or unresponsive and careful

interviews of household members by knowledgeable individuals with the legal authority and mandate to conduct such investigations;

- appropriate consultations with available medical specialists (eg, pediatrician, pediatric pathologist, pediatric radiologist, and/or pediatric neuropathologist) by medical examiners and coroners;
- complete autopsy performed by a forensic pathologist within 24 hours of death, including examination of the all major body cavities including cranial contents, microscopic examination of major organs, radiographic examination, and toxicological and metabolic screening;
- collection of medical history through interviews of caregivers, interviews of key medical providers, and review of previous medical charts;
- maintenance of an unbiased, nonaccusatory approach to parents during the death-review process;
- consideration of intentional asphyxia in cases of unexpected infant death with a history of recurrent cyanosis, apnea, or ALTEs witnessed only by a single caregiver;
- use of accepted diagnostic categories on death certificates as soon as possible after review;
- prompt imparting of information to parents when results indicate SIDS or accidental or medical causation of death; and
- review of collected data by locally based infant death-review teams[57] with participation of the medical examiner or coroner.

CELLPHONES DON'T BELONG IN SCHOOL

"You're a teacher in the New York City public school system. It's September, and you're lecturing the class on the structure of an essay. Your students need to know this information to pass your class and the Regents exam, and you, of course, hope that one day our talented students will dazzle and amaze English professors all over the country. You turn your back to write the definition of 'thesis' on the chalkboard. It takes about 15 seconds. You turn around to the class expecting to see 25 students scribbling the concept in their notebook. Instead, you see a group of students who have sprung appendages of technology. Jose has grown an earphone. Maria's thumbs have sprouted a two-way. Man Keung, recently arrived from China, is texting away on a cell phone connected to his wrist. And Christina appears to be playing Mine Sweeper on a Pocket PC on her lap. . . . But as a former New York City public school teacher, I can tell you that cellphones don't belong in the classroom. A student with a cellphone is an uninterested student, one with a short attention span who cares more about his social life than education."

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Mary E. Fallat, MD; Jayant K. Deshpande, MD; and the Section on Surgery, Section on Anesthesia and Pain Medicine, and Committee on Bioethics

Do-Not-Resuscitate Orders for Pediatric Patients Who Require Anesthesia and Surgery

ABSTRACT. This clinical report addresses the topic of preexisting do-not-resuscitate (DNR) orders for children undergoing anesthesia and surgery. Pertinent issues addressed include the rights of children, surrogate decision-making, the process of informed consent, and the roles of surgeons and anesthesiologists. The reevaluation process of DNR orders called "required reconsideration" can be incorporated into the process of informed consent for surgery and anesthesia. Care should be taken to distinguish between goal-directed and procedure-directed approaches to DNR orders. By giving parents or other surrogates and clinicians the option of deciding from among full resuscitation, limitations based on procedures, or limitations based on goals, the child's needs are individualized and better served. ***Pediatrics*** **2004;114: 1686–1692;** ***anesthesia, pediatric surgery, pediatrics, children, resuscitation, cardiac arrest, respiratory arrest.***

CONSIDERATIONS FOR CHILDREN WITH DO-NOT-RESUSCITATE ORDERS WHO REQUIRE ANESTHESIA AND SURGERY

In the 1970s, the Critical Care Committee at the Massachusetts General Hospital developed the original do-not-resuscitate (DNR) guidelines in response to nursing requests for clarification of what should be done when cardiopulmonary resuscitation (CPR) was unwanted or believed to be unwarranted by a patient or surrogate.[1] DNR orders are clinically and ethically appropriate when the burdens of resuscitation exceed the expected benefit. Currently, all hospitals seeking accreditation from the Joint Commission on Accreditation of Healthcare Organizations are required to have a DNR policy in place.[2–6] This policy should define a DNR order and describe the guidelines for its inclusion on a patient's medical record. A DNR order is a written order by an attending physician and precludes resuscitative efforts being undertaken in the event of cardiopulmonary arrest. DNR orders should not have implications regarding the use of other therapeutic interventions that may be appropriate for the patient, including surgery and anesthesia.[7,8]

The controversial topic of DNR orders for patients undergoing surgery and anesthesia has received growing attention in the medical literature since the early 1990s. However, the literature does not specifically address the pediatric age group. For children, DNR orders are written when (1) in the judgment of the treating physician, an attempt to resuscitate the child would not benefit the child and (2) the parent or surrogate decision-maker (with the assent of an age-appropriate child) expresses his or her preference that CPR be withheld in the event that the child suffers a cardiopulmonary arrest, as long as this is in accordance with the child's best interests.[7,9] DNR orders are written on the assumption that cardiopulmonary arrest will be a spontaneous event that is the culmination of the dying process of a child who has a terminal illness or a poor quality of life. The dilemma surgeons and anesthesiologists are confronted with regarding children with DNR orders undergoing an operative procedure is twofold: (1) anesthesia promotes some degree of hemodynamic abnormality that may result in cardiopulmonary arrest, and (2) many routine anesthetic manipulations can be classified as resuscitative measures.

A number of hospitals across the nation still do not have a policy that specifically addresses the extent to which DNR orders apply in the operating room[2,5,10,11] or have a policy that mandates suspension of DNR orders.[9] According to 1 study, surgical procedures are performed in ~15% of patients with DNR orders.[12] The American Academy of Pediatrics and the American Society of Anesthesiologists (ASA) have issued guidelines on forgoing life-sustaining medical treatment, issues of informed consent,[13,14] and evaluation and preparation of pediatric patients undergoing anesthesia.[15] None of these policies address in detail the approach to be taken when an operative procedure is considered for a child with an existing DNR order. This encounter includes the dilemmas of who should assume responsibility (ie, the primary care physician, the surgeon, or the anesthesiologist) for discussing with the parent or surrogate decision-maker the potential risks of cardiopulmo-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

nary arrest during surgery and anesthesia, whether the DNR order should be temporarily suspended during the procedure, and how long a temporary suspension should last if this option is chosen.

SURVEY OF SECTIONS ON SURGERY AND ANESTHESIA

The relevance of this topic was assessed by distributing a survey to the 570 members of the Section on Surgery and 293 members of the Section on Anesthesiology of the American Academy of Pediatrics in 1995. The survey was returned by 242 surgeons (42.5%) and 107 anesthesiologists (36.5%). Demographic data on the respondents are shown in Table 1.

For each group, surgeons and anesthesiologists, finite sample confidence intervals for proportions were computed.[16] The finite population correction factor was used for hypotheses testing as needed.[16] Statistical software used included SPSS version 10 (SPSS Inc, Chicago, IL [2000]) and StatXact version 4 (Cytel Software Inc, Cambridge, MA [2000]).

The majority of surgeons (88.8%) and anesthesiologists (86%) had been asked to operate on or provide anesthesia to a child with a DNR order in place at the time of surgery, and most indicated that they would not refuse to provide these services. Most surgeons (75.3%) and anesthesiologists (69.2%) would agree to honor a DNR order during a palliative operative procedure, but smaller percentages of surgeons (49.6%) and anesthesiologists (46.7%) were willing to honor a DNR order during an elective operative procedure. More than 95% of surgeons and anesthesiologists discuss resuscitation issues before surgery with parents of children who have standing DNR orders, and a majority of each group felt that there should be a hospital policy for children with DNR orders in the operating room. Only 50.5% of anesthesiologists and 27.5% of surgeons stated that their hospital has such a policy in place.

Surgeons and anesthesiologists then were asked which resuscitation maneuvers should be withheld during intraoperative arrest in a child with a DNR order. Results are summarized in Table 2.

The majority of anesthesiologists (86%) and surgeons (94.7%) were willing to withdraw life support at the request of the family a few days after surgery if a child suffered an arrest in the operating room, was resuscitated, and had an adverse change in quality of life. The majority of anesthesiologists (55.1%) felt that the perioperative period ended when the child left the recovery room, with only 38.2% of surgeons agreeing ($P = .0037$). Many anesthesiologists (22.4%) and surgeons (39.5%) felt that the perioperative period should be extended until 24 hours after surgery.

TABLE 1. Demographics of Respondents to Survey Regarding DNR Orders

Community hospital	53 (22.5)	17 (15.9)
Military hospital	2 (0.8)	0 (0)

* A small number of surgeons and anesthesiologists reported multiple affiliations.

DISCUSSION

The medical literature contains some ambiguities on the scope of a DNR order and the resuscitative interventions it prevents during surgery and anesthesia. Resuscitative interventions may be broadly defined as any maneuvers and techniques used to prevent or reverse cardiopulmonary arrest.[17] However, this definition is inappropriate in an operative setting, because anesthetic agents routinely promote cardiovascular instability.[2,5,11,18] Perioperatively, resuscitative measures should only refer to the measures undertaken to restore life once a cardiopulmonary arrest has occurred.[8,19] Surveys of physicians and patients with DNR orders confirm that clarification is needed on the interpretation of a DNR order, especially its applicability in the operating room.[12,20–22]

Physicians caring for children have a duty to respect the wishes of the child and family, to do good (beneficence), and to avoid harm (nonmaleficence), which may lead to conflicting considerations for a child with a DNR order. Some physicians believe that honoring a DNR request harms a child by allowing a potentially reversible death to occur. On the other hand, the child's welfare is best served by not having a poor quality of life unnecessarily prolonged and not having to endure ineffective therapy.[23] Older children and adolescents should be included in the decision-making process (patient assent) when their neurologic status, development, and level of maturity allow. However, legally they require a surrogate decision-maker to act on their behalf (surrogate or parental permission).[14] A child's surrogate, usually a parent, should be the person presumed to be the most appropriate and capable to determine what actions would be in the best interest of the child. Conflicts arise when the parent or other surrogate and/or child and the physician fail to agree on what would be optimal care under a given set of circumstances.

Informed Consent

To respect the child's and family's wishes, physicians must obtain informed permission from a parent or surrogate before a child can undergo any medical intervention including surgery and resuscitation. Ordinarily, resuscitation efforts do not require informed consent, because they are deemed emergency interventions and consent is implied. However, terminally ill or severely disabled children and their parents are often confronted with the decision of whether resuscitation should be attempted in the

TABLE 2. Responses When Asked Whether Resuscitation Maneuvers Should Be Withheld During Intraoperative Arrest in a Child With a DNR Order

	Pediatric Surgeons*		Pediatric Anesthesiologists		*P* Value

* Some respondents did not answer every question

event the child's underlying disease results in cardiopulmonary arrest.

Customarily, physicians will approach the parent or surrogate about instituting a DNR order when it is felt that resuscitation of the child would not be beneficial and would only prolong the time to death.[22] When a parent or surrogate consents to a DNR order, it is under the assumption that cardiopulmonary arrest will be a direct consequence of the child's underlying disease. Surgery and anesthesia constitute a change in the child's medical status, because they introduce additional risks to the patient. Because surgeons and anesthesiologists are rarely involved in the original DNR decision, they cannot be certain that the implications of the DNR status in the perioperative setting were discussed with the patient's parent (or other surrogate).[3] Therefore, the parent or surrogate, the surgeon, and the anesthesiologist should reevaluate the DNR order for a child who requires an operative procedure. This reevaluation process has been called "required reconsideration"[3] and should be incorporated into the process of informed consent for surgery and anesthesia. Discussions regarding consent under these circumstances should be initiated by attending staff, particularly in hospitals with residency teaching programs in which residents may be routinely involved in the consent process.

The surgeon and anesthesiologist must approach the parents and child with compassion. There is often no previous relationship established between the patient, parents, and surgical team, precluding a brief preoperative assessment. "Active listening" is essential. The parent or surrogate should be asked about specific interventions and their understanding of the relative merits of each of these interventions during resuscitation (Table 3).[15] Airway management should be determined by what is mandated by the child's condition and the surgical procedure. Specific prohibition of tracheal intubation is problematic, and beliefs and concerns must be carefully elicited and discussed. Exceptions to the injunctions against intervention should be specifically noted in the patient's medical record. The parent may agree to a temporary suspension of the DNR order during the perioperative period. If so, the temporal end point to the DNR suspension needs to be recorded as well. If an agreement cannot be obtained after thorough discussion, the wishes of the informed parent or surrogate must prevail. In some cases, the parents may feel that the burden of a therapy is not worth the potential benefits and decline the procedure. When an individual physician feels that the parent's wishes are inconsistent with his or her medical, ethical, or moral views, the physician should withdraw from the case after ensuring continuity of care[13] and could consider consulting the institutional ethics committee.

- Chest compressions
- Defibrillation
- Cardiac pacing
- Arrest medications (epinephrine, atropine, sodium bicarbonate, calcium, other vasoactive drugs)
- Postoperative ventilatory support

Role of the Surgeon

The following are operative interventions that might be considered for a pediatric patient with a DNR order:

1. Provision of a support device that will enable the child to be discharged from the hospital (eg, gastrostomy tube or tracheostomy).
2. Urgent surgery for a condition unrelated to the underlying chronic problem (eg, acute appendicitis in a terminal cancer patient).
3. Urgent surgery for a condition related to the underlying chronic problem but not believed to be a terminal event (eg, a pathologic fracture or bowel obstruction).
4. A procedure to decrease pain.
5. A procedure to provide vascular access.

It is the duty of the operating surgeon to discuss risks of a procedure with the parent or other surrogate of any pediatric patient, including how the patient's condition might influence the risk of anesthesia. The American College of Surgeons (ACS) issued

a statement to guide surgeons in operating on patients with an active DNR order.[24] The ACS statement does not make specific reference to patient surrogates, although it is implied.[24] It is expected that the surgeon will advise parents or other surrogates and the child (if developmentally appropriate) regarding operative risks and benefits and advocate a policy of required reconsideration of previous DNR orders. The results of all discussions should be documented in the patient's medical record. The surgeon should also ultimately convey the patient's wishes to the members of the entire operating room team, help operating team members understand the patient's or surrogate's wishes, and find alternate team members to replace individuals who disagree with the patient's or surrogate's wishes. With children, the difficulty arises when there is no one who is willing to honor a family's wish to continue the DNR status during the anesthesia and surgery. Stalemates such as this should be referred to the ethics committee of the institution.

Role of the Anesthesiologist

In 1994 and 1999, the ASA released recommendations on caring for surgical patients with active DNR orders.[15] These guidelines explicitly reject the practice of automatically rescinding the DNR order before procedures involving the use of anesthesia, because this practice "may not sufficiently address a patient's rights to self-determination in a responsible and ethical manner."[15] The purpose of required reconsideration of DNR orders is to determine what is best for the patient under the circumstances, not to convince the patient and family to have the DNR order suspended. The guidelines proposed by the ASA clearly recommend that all physicians involved in the case (primary physician, surgeon, and anesthesiologist) discuss together with the patient (or other surrogate) the appropriateness of maintaining the DNR order during the operation. The 1999 guidelines distinguish between goal-directed and procedure-directed DNR orders.[15] Model procedure-specific DNR documentation forms are published and may be modified for individual hospital use.[9]

A goal-directed approach focuses on the patient's goals, values, and preferences rather than on individual procedures. The primary goal is to do everything to prevent the need for resuscitation, but if it occurs, this approach recognizes that patients are often less concerned with technical details of the resuscitation than with more subjective and personal issues regarding quality of life before and after resuscitation. This model promulgates an approach that honors the family's treatment goals while reflecting the reality and unique aspects of the perioperative environment. However, some anesthesiologists are uncomfortable with the indeterminate nature of a goal-directed DNR order and have ethical or legal concerns about having such crucial decisions rest solely on their best judgment at the time of arrest.

Goal-directed DNR orders may be less feasible if the anesthesiologist and surgeon caring for the child have not established a relationship with the family before surgery. A procedure-directed approach may be more appropriate in these circumstances, which involves careful consideration of a series of specific interventions that are likely to be used (Table 3). Each must be placed in the context of the child's usual quality of life and likelihood of the ability of the procedure to produce the desired effect, given his or her unique physiology. This approach has limited flexibility when an unexpected situation occurs.[9]

Perioperative suspension of the DNR order is considered by some anesthesiologists to be the ideal compromise, because it enables the physician to act without restraint while providing the patient with a realistic chance of achieving the operative goals.[10,25] Anesthetic agents and techniques may promote some degree of hemodynamic and respiratory abnormality, especially in patients with a deteriorated health condition.[2] The deliberate depression of vital functions by the anesthetic may require resuscitative measures to stabilize the patient.[11] Consequently, controversy about the use of these interventions arises when the patient has a written DNR order. Many of the routine anesthetic interventions performed as part of operative maintenance are considered resuscitative measures under different circumstances. These interventions include the use of paralytic agents, vasoactive drugs, blood products, and positive-pressure ventilation. This overlap in terminology promotes confusion and inconsistencies among physicians on the interpretation of a patient's DNR order and what it implies in an operative setting. Keffer and Keffer[8,19] proposed that resuscitation in the operating room be defined as "those measures undertaken to reestablish cardiac rhythm once a cardiac arrest has occurred."[8(p644)] This definition establishes a simple end point beyond which a patient's wish not to be resuscitated would come into play.

The anesthesiologists' concern for patient comfort during the procedure may support perioperative suspension of DNR orders. An active DNR order restricts the physicians' ability to treat any complications of their own procedure during anesthesia. Faced with this dilemma, anesthesiologists are forced to decrease the risk of cardiopulmonary arrest by increasing hemodynamic stability through the use of less anesthetic.[2,11,26] For the patient, this may potentially result in more discomfort and suffering.

One reason to distinguish DNR in the operating room from DNR in other settings is the difference in the success rate of CPR administered for a spontaneous cardiopulmonary arrest versus one that results from anesthesia. Anesthetic-related arrests are believed to be more easily reversible because of the immediate ability to respond and the controlled nature of the event.[3,19,26,27] One study of surgical patients suggested that when a cardiac arrest was ascribed to anesthesia, 92% of the patients were resuscitated successfully.[3,28] However, it is difficult to determine how these statistics apply to terminally ill patients with a DNR designation, because the survey was very broad and inclusive. A more relevant survey was conducted on 4301 seriously ill adult patients, and a few underwent an operative

procedure and had previously written DNR orders in their medical records. Only 3 of the 57 patients with DNR orders (5%) experienced an intraoperative cardiopulmonary arrest, but all died within 5 days of operation.[29]

Traditionally, CPR has been considered a success if the patient survives the initial resuscitation effort. For patients with DNR orders, the success of CPR may be better gauged on the length of patient survival[7] and expected quality of life after resuscitation. Using this definition, CPR may be inappropriate from the parent's or surrogate's viewpoint if resuscitation has the overwhelming probability of resulting in patient suffering and only prolonging the time to death.[7] Anesthesiologists have the duty to inform the parent or other surrogate of the risks and potential benefits of intraoperative resuscitation. Required reconsideration as part of the process of informed consent for anesthesia eliminates ambiguities and misunderstandings associated with patients who have DNR orders by providing anesthesiologists with the opportunity to educate the parent (or other surrogate) to become familiar with their values and perceptions of the child's quality of life and together clarify how the child's DNR order should be interpreted perioperatively. By giving parents or surrogates and clinicians the option of deciding from among full resuscitation, limitations based on procedures, or limitations based on goals, the child's needs are individualized and better served. Regardless of the decision made by the parent or other surrogate, the individual acting on behalf of the child must be readily available for consultation during the procedure. The ASA, like the ACS, advocates that physicians withdraw from a case when they are unwilling or unable to respect and implement a patient's (or other surrogate's) decision to limit the use of resuscitation.[15,24]

If DNR Orders Are Suspended: Qualification of Perioperative Interval

If the family or medical personnel involved in a child's care choose to suspend DNR orders during anesthesia and surgery, it is necessary to define the duration of suspension.[30] The physiologic effects of anesthesia and surgery rarely terminate at the end of the procedure, but the duration thereafter depends on the anesthetic technique used and the type of surgical procedure performed. The acute effects of most anesthetic medications generally resolve within several hours or 1 day after surgery, and most anesthesiologists visit the patient the day after a surgical procedure and document recovery status in the patient record. Recovery of respiratory function after surgery depends on preoperative pulmonary function, chronicity of illness, and length of the procedure. Some patients will experience cardiopulmonary arrest during or immediately after surgery, which may be the result of an acute and reversible complication. It is appropriate to use mechanical ventilation after surgery as long as the patient continues to show significant and sustained improvement in pulmonary function. Once the patient ceases to recover or deteriorates, withdrawal of ventilatory support should be considered. Generally speaking, the suspension of DNR orders should continue until the postanesthetic visit, until the patient has been weaned from mechanical ventilation, or until the primary physician involved in the patient's care and the family agree to reinstate the DNR order.

The surgeon and anesthesiologist should feel comfortable, and should be allowed, to reinstate a DNR order intraoperatively through consultation with the family under certain conditions. For example, if cardiac arrest occurs during surgery and it is apparent that the arrest is the result of an irreversible underlying disease or complication and that CPR would only allow continued deterioration, the DNR order should be reinstated. If resuscitation measures are withheld and intraoperative arrest occurs, such a death should be classified as "expected" for quality-assurance purposes rather than "unexpected." Expected deaths do not require mandatory quality-assurance review.[18,31]

IMPLEMENTING "REQUIRED RECONSIDERATION"

Hospitals are encouraged to develop and maintain written policies permitting the forgoing of life-sustaining treatment of patients, including children, in appropriate circumstances.[13] Once a DNR order is in place according to accepted standards, it is important that it be reviewed before surgery to determine applicability in the operating room and the postoperative recovery period. Hospitals wishing to develop a "required reconsideration" policy (Table 4) may want to address the following elements:

- Include in the discussion with a child's parent or other surrogate information about the likelihood of requiring resuscitative measures, a description of these measures and their reversibility, the chance of success, and possible outcomes with and without resuscitation. Establish an agreement about what, if any, resuscitative measures will be instituted during the procedure.
- Make the decision to uphold or suspend a DNR order on the basis of the planned procedure, the anticipated benefit for the child, and the likelihood of patient compromise as a result of the procedure.
- Document the salient features of the physician-family discussion in the medical record.
- Communicate plans to honor an intraoperative DNR order among relevant staff.
- Require any physician or other health care professional who is unwilling to honor a family's refusal

TABLE 4. Required Reconsideration Options for Pediatric Patients With DNR Orders Who Require Anesthesia and Surgery

Full resuscitation
Perioperative suspension of DNR orders with qualification of perioperative interval
Goal-directed approach
Focuses on patient goals, values, and preferences
Implies personal relationship between physician and patient/family with understanding of quality-of-life concerns
Most subjective approach
Procedure-directed approach
Specific interventions (see Table 3) placed in context of child's quality of life are each reviewed prior to procedure

of resuscitation to withdraw from the case and allow others to assume care. The withdrawing physician or health care professional should make a conscientious effort to identify another physician who is willing to honor the DNR request.[13]

- Recognize that a patient's or surrogate's decision to refuse intraoperative resuscitation can be compatible with the provision of therapeutic measures to treat conditions other than arrest. This decision does not necessarily imply limits on other forms of care such as intensive care.
- If the family chooses to rescind the DNR order in the operating room and arrest occurs with resuscitation, but the patient's process of dying has only been prolonged, make a provision to discuss withdrawal of life support after a determined amount of time.[3,5,19]

POLICY STATEMENT

Drinking Water From Private Wells and Risks to Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT

Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms and cause illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation. With few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This policy statement provides recommendations for inspection, testing, and remediation for wells providing drinking water for children. *Pediatrics* 2009;123:1599–1605

INTRODUCTION

Approximately 15% to 20% of households in the United States obtain their water from private wells.[1] Private wells are not subject to federal regulations of the US Environmental Protection Agency (EPA) or those of the Navajo Nation (which has its own EPA) and are minimally regulated by states. Coliform contamination of home private wells in Iowa in the 1990s was as high as 27%.[2] According to the Centers for Disease Control and Prevention, there were 31 waterborne disease outbreaks reported in the United States in 2005–2006, the latest years for which data are published.[3] Twenty of the outbreaks were from drinking water, of those, 8 were groundwater sources, usually private wells. Those caused illness in 458 people. The etiology of 5 of the outbreaks is known: 1 was *Campylobacter*, 3 were norovirus, and 1 was Hepatitis A. Waterborne illness is undoubtedly underrecognized and underreported.

GROUNDWATER AND WELLS

Groundwater is water below the topsoil and above impervious bedrock. When groundwater collects in and saturates relatively porous fractured bedrock and soil, it is said to be in an aquifer. The water table is a depth below which the soil and fractured bedrock (ie, the aquifer) is saturated with water. The water table can vary from season to season and year to year. For a well to produce water reliably, it must be deep enough so that water can be pumped from the aquifer under virtually all weather conditions. Aquifers are recharged from above by precipitation and runoff.

WELL TYPES

Dug wells usually are shallow holes, 10 to 30 ft deep, lined with rock, brick, tile, or concrete, with a pump in a nearby pump house or in the dwelling. Dug wells usually are relics on older home sites. They are easy to contaminate and unreliable in most of the United States.

For driven wells, pipe is driven through gravel or sandy soil. These wells also tend to be shallow, usually approximately 50 ft deep; the pump is installed at the top of the well or in the dwelling. Driven wells are still relatively easy to contaminate because of their shallowness but can be installed rapidly and inexpensively if the geologic conditions are right. Dug wells and driven wells are often the water source at camps or vacation homes.

Drilled wells are 100 to 400 ft deep and reach bedrock. Most drilled wells have an electric submersible pump at the bottom. Because the water has been filtered by soil on the way down and is relatively safe from contamination while in the aquifer, water from these deeper wells is less likely to be contaminated.

TABLE 1 Relevant Chemicals in Well Water

Chemical	Source	Effects
Nitrates	Sewage	Methemoglobinemia
	Fertilizer	Possible promoter of carcinogenesis
Volatile organics and pesticides	Dry-cleaning agents, gasoline, etc	Compound-specific effects
	Often a source cannot be identified	
Lead	Leached from the brass in a submersible pump, from solder, or from old lead pipes	Impairs neurocognitive development
Arsenic	Occurs in specific rock formations (eg, the "slate belt" in the southeastern United States, Nevada, Alaska, and other areas in the western United States)	Acutely toxic carcinogenic (bladder, skin, and lung) in humans
Chromium VI	Used in the electroplating and other industries	Toxic and carcinogenic in laboratory animals
Radon	Naturally occurring radioactive gas	Carcinogenic (lung) in humans
Fluoride	Naturally in water in a few parts of the United States	Accepted preventive for dental caries, supplement if low concentrations
		Too much can cause dental fluorosis
Uranium	Naturally occurring in western mountains in the United States and in areas that have granite outcrops in the eastern United States	High dose is acutely toxic
		A source of ionizing radiation, which causes cancer
Methyl tertiary butyl ether	Partially oxidized hydrocarbon fuel additive used to oxygenate gasoline	Carcinogenic in laboratory animals
Perchlorate	Oxidizing agent used in rocket fuels, fireworks, and airbag inflators, among other applications	Inhibits synthesis of thyroid hormone
	Can occur naturally	

COMPOSITION OF WELL WATER

Chemicals

The chemical composition of well water varies with region, underlying geologic formation, and environmental contamination and can be harmful, beneficial, or merely undesirable. For example, some fluoride is desirable in drinking water, whereas iron is undesirable. Many other chemicals, some of them potentially toxic, can contaminate well water, with their presence or absence attributable to naturally occurring geologic factors or dispersion from industry, farms, or business (Table 1). The presence of nitrates is particularly problematic for infants.[4] The most commonly occurring pollutant chemicals are volatile organics and pesticides, which may be identifiable in more than one third of US wells,[5] albeit mostly at concentrations below federal public water standards.

Many commercial sources will measure water hardness and concentrations of iron and manganese. Calcium and magnesium carbonate make water hard. Hard water is not toxic, but it may require treatment to prevent precipitation from clogging pipes and causing other problems, such as coating electric hot water heater elements and causing them to burn out. Manganese and iron can appear as rust-colored to black flecks and can stain clothing, plumbing, and fixtures. So-called iron and manganese bacteria can grow in such water and form visible black slimy colonies of microorganisms, sometime clogging pipes and faucets.

Microorganisms

Microorganisms, including bacteria, viruses, fungi, and parasites, can contaminate the ground water that supplies wells (Table 2). The major source of these organisms is fecal material from animals and humans. Analyzing well water at its point of use for "total coliforms" is the commonest way of detecting fecal contamination of the water. Where available, testing for fecal coliforms and/or *Escherichia coli* may be performed as a combined assay with total coliforms and used for the annual bacterial testing. The absence of coliforms is good but not absolute evidence that significant fecal contamination is not present. Samples that contain any coliforms should be retested to determine if they are fecal coliforms; specimens that test positive should be examined for the presence of *E coli* or other pathogens.

Much of the information describing the pathogens that can be present in well water has been obtained from investigations of waterborne outbreaks. In the United States, most waterborne outbreaks are associated with noncommunity water systems, chiefly private or communal wells.[3]

MITIGATION

Bacterial

If test results confirm bacterial contamination, the water system must be treated. The first approach is to inspect the well to make sure that there are no structural defects that may have fostered the contamination. "Shock chlorination," using concentrations of chlorine that are 100

TABLE 2 Pathogenic Microorganisms Found in Well Water

Bacteria	Viruses	Parasites
Escherichia coli, including O157:H7	Norovirus, sapovirus	*Giardia intestinalis*
Salmonella species	Rotavirus	*Cryptosporidium*
Shigella species	Enteroviruses	*Cyclospora*
Campylobacter jejuni	Hepatitis A and E	Microsporidia
Yersinia enterocolitica		*Isospora*
Mycobacterium avium-intracellulare		*Naegleria fowleri*

to 400 times the amount found in municipal water supplies, should be performed initially. This can be performed by the homeowner using household bleach (many Web sites [eg, www.water-research.net/shockwelldisinfection.htm] have instructions), but consultation with the health department or other experienced individuals is advisable before the first time.

Most other treatment measures require the service of a trained home water-treatment professional. If bacterial contamination persists despite efforts at continuous disinfection, natural or structural factors may be present that may not be under the control of the well owner. This may require that the well be closed and a new well be drilled. A certified well contractor should fill or seal the contaminated well.

Chemical

Chemical contaminants are approached by investigating the possibility that the contamination exists on the homeowner's or on an adjacent homeowner's property, such as from agricultural application of nitrogen-containing fertilizers, pesticide application, or fuel tanks. If the water supply cannot be remediated further and the well is still contaminated or the chemicals in question are naturally occurring, then it is possible to filter out or treat for virtually any chemical or biological contaminant.[6] However, treatment can become complex and/or expensive and can require meticulous or professional maintenance.

Because there are no standards for private wells for many contaminants of concern, those seeking a specific concentration to indicate potability have little choice but to apply the same standards that municipalities do under the Safe Drinking Water Act amendments of 1996 (Pub L No. 104–182 [for the current list of drinking water contaminants, see www.epa.gov/safewater/mcl.html]). Municipalities regard water that is persistently above these federal standards as not potable. Nonetheless, well owners or home occupants are under no obligation to apply this same standard to their well water.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Pediatricians should ask whether a family drinks water from a private well at home, on vacation, when traveling, in child care, or other locations where they might drink water. This is particularly important for families with an infant. Families with children of high school age or younger should follow the algorithm in Appendix 1. A description of the tests and some rationale for their use is provided as follows.

Routine Testing

A. Purchase of a New Home With a Well

The builder should provide the results of coliform, nitrate, inorganic (total dissolved solids, iron, magnesium, calcium, chloride), fluoride, radon, and lead testing. If the well was shock-chlorinated after drilling, it should be retested for coliforms after some period of time as recommended by the local health department or agricultural extension agent. Have the builder or agent provide a site plan with the well, its water lines, and the septic tank and field.

B. Purchase/Rental/Lease of an Existing Home With a Well

Recommend including the well and septic field in any general inspection. If this cannot be performed, families should arrange for well inspection and testing as described in 1A and have the septic tank located and inspected to determine if it needs to be pumped. If there are filters, softeners, or other devices in the water-supply lines, determine from the seller or landlord what they are treating.

C. Vacation Homes, Camps, etc

A vacation home or camp with a shallow well and no other water source should be tested each season, if possible. If not, consider bottled water for infants or anyone with a compromised immune system. For a short stay, it may be safer and more convenient to use bottled water for drinking and cooking for everyone. Boiling water and filtration systems on the tap can reduce the risk of acquiring microorganisms from the untested well water. Boiling water means that the water must be brought to a full boil for 1 to 3 minutes, but recommendations vary and local advice should be sought. Filtration will allow viruses and possibly some *Giardia* cysts through.

Test kits are available for coliforms and nitrate, but it is difficult for the consumer to judge the accuracy and quality control for each product. Thus, for families with an infant, for whom it is crucial to know that the nitrate concentration is below 10 mg/L, home testing is inadvisable.

D. Child Care and School

Child care in rural and suburban areas can be in a setting where the water comes from a private well. Parents should inquire about the child care center's water source if they have any doubt. If the water comes from a well, parents should ask whether the well has been regularly and recently tested for nitrate and coliforms and what the results were. If recent results are not available, infants should be given bottled water until the well is shown not to have excessive nitrate concentrations.

E. Scheduled Testing

Every spring, the well should be examined to make sure that there are no mechanical problems. Well water should be tested annually for coliforms and nitrates. Testing more than once per year may be warranted in the following special situations: (1) someone in the household is pregnant or nursing; (2) there are unexplained illnesses in the household; (3) neighbors find a dangerous contaminant in their well water; (4) there is a change in the odor or taste of the well water; (5) there is a chemical spill in proximity of the well; or (6) there was a significant repair or replacement in the well. Routine testing for *Giardia* and *Cryptosporidium* organisms is not recommended because of the technical difficulty

(filtering very large volumes of water) and expense. However, in the following situations, it may be prudent to test for these parasites: (1) members of family have developed gastrointestinal disease attributable to *Giardia* and/or *Cryptosporidium* species; (2) the well is at the bottom of a hill and/or is shallow (vulnerable to runoff); or (3) the well is in a rural area where animals graze. The risk factors for *E coli* O157:H7 are similar to those for *Giardia* and *Cryptosporidium* species. So when these situations exist, vigilance should be maintained for *E coli* O157:H7 contamination and/or clinical symptoms. Much information about potential for contamination is local lore, so national sources of information about drinking water, such as the EPA Web site, repeatedly advise contact with local experts. Thus, the time of annual testing for nitrates and coliforms is a reminder to check with the health department about any water-quality problems that have emerged.

Occasional Testing

F. New Infant

A new infant or a child younger than 1 year in the home should prompt testing if the yearly test has indicated any fluctuation in nitrate concentrations or has never been performed. Even a breastfed infant may need water at some time, and boiling does not remove and can concentrate nitrate.

G. Damage or Disturbance to the Well

If a new submersible pump is installed or the well integrity is compromised, such as by a falling tree, a vehicle collision, a flood, or a cut to the water line during landscaping, the well should be tested and, if necessary, shock-chlorinated.

H. Sentinel Illnesses

Every episode of gastroenteritis does not require well testing or an investigation of the cause of the illness. However, if multiple individuals become ill with gastroenteritis, if the gastroenteritis is recurrent, or if a pathogen causing the gastroenteritis is a bacteria or parasite that may have been present in the well water as a result of fecal contamination, then well testing for pathogens is indicated. Any occurrence of methemoglobinemia in an infant consuming well water requires testing the well water for nitrate. An elevated blood lead concentration in a child living in a home built after 1978, or a persistently elevated blood lead concentration, requires testing for lead in well water. At some point in the evaluation of unusual or cryptogenic illness, the possibility of contaminated well water should be considered. For a list of symptoms associated with various well contaminants, see the work by Wagenet et al[6]

2. Fluoride is an accepted preventive for dental caries, and if a child's drinking water contains little or none, then supplements (available as drops or chewable tablets) are necessary. The American Academy of Pediatrics recommends no fluoride supplementation before 6 months of age; from 6 months to 3 years of age, children (including those who are breastfed) require fluoride supplementation if the water has a fluoride concentration of less than 0.3 ppm. Supplementation from 3 to 16 years of age is recommended where drinking water fluoride concentrations are less than 0.6 ppm.[7] To avoid dental fluorosis, water with fluoride concentrations greater than 2 ppm should not be consumed by children younger than 9 years.
3. Become familiar with well water considerations in your area. Advocate for water safety practices that will protect the health of children.

RECOMMENDATIONS TO GOVERNMENT

1. Local governments should provide access to information about local groundwater conditions. Recommendations for testing should be easily available with a telephone call or a Web-page visit. If water contamination becomes a public health issue, then multiple means of alerting and informing the public should be considered. In areas where agricultural land is being developed, paved, or put to any new use, local governments should consider mailing or using some other active means of getting their policies and recommendations concerning well testing to homes with permitted wells and the possibility of being affected by the new use.
2. Tests determined to be necessary for the safety and health of the families drinking well water should be convenient and, if possible, free or inexpensive (see Appendix 2 for current costs).
3. Community wells that serve just enough households to be regulated are sometimes exempted from testing that is required of larger systems. Although this may be appropriate, it should not be routine, and adequate local data should justify any exemption.
4. For housing that has drinking water supplied by a private well, states should require testing for coliforms, nitrate, fluoride, and any contaminant of local concern when a dwelling is sold, and the results should be made available to the buyer before closing.

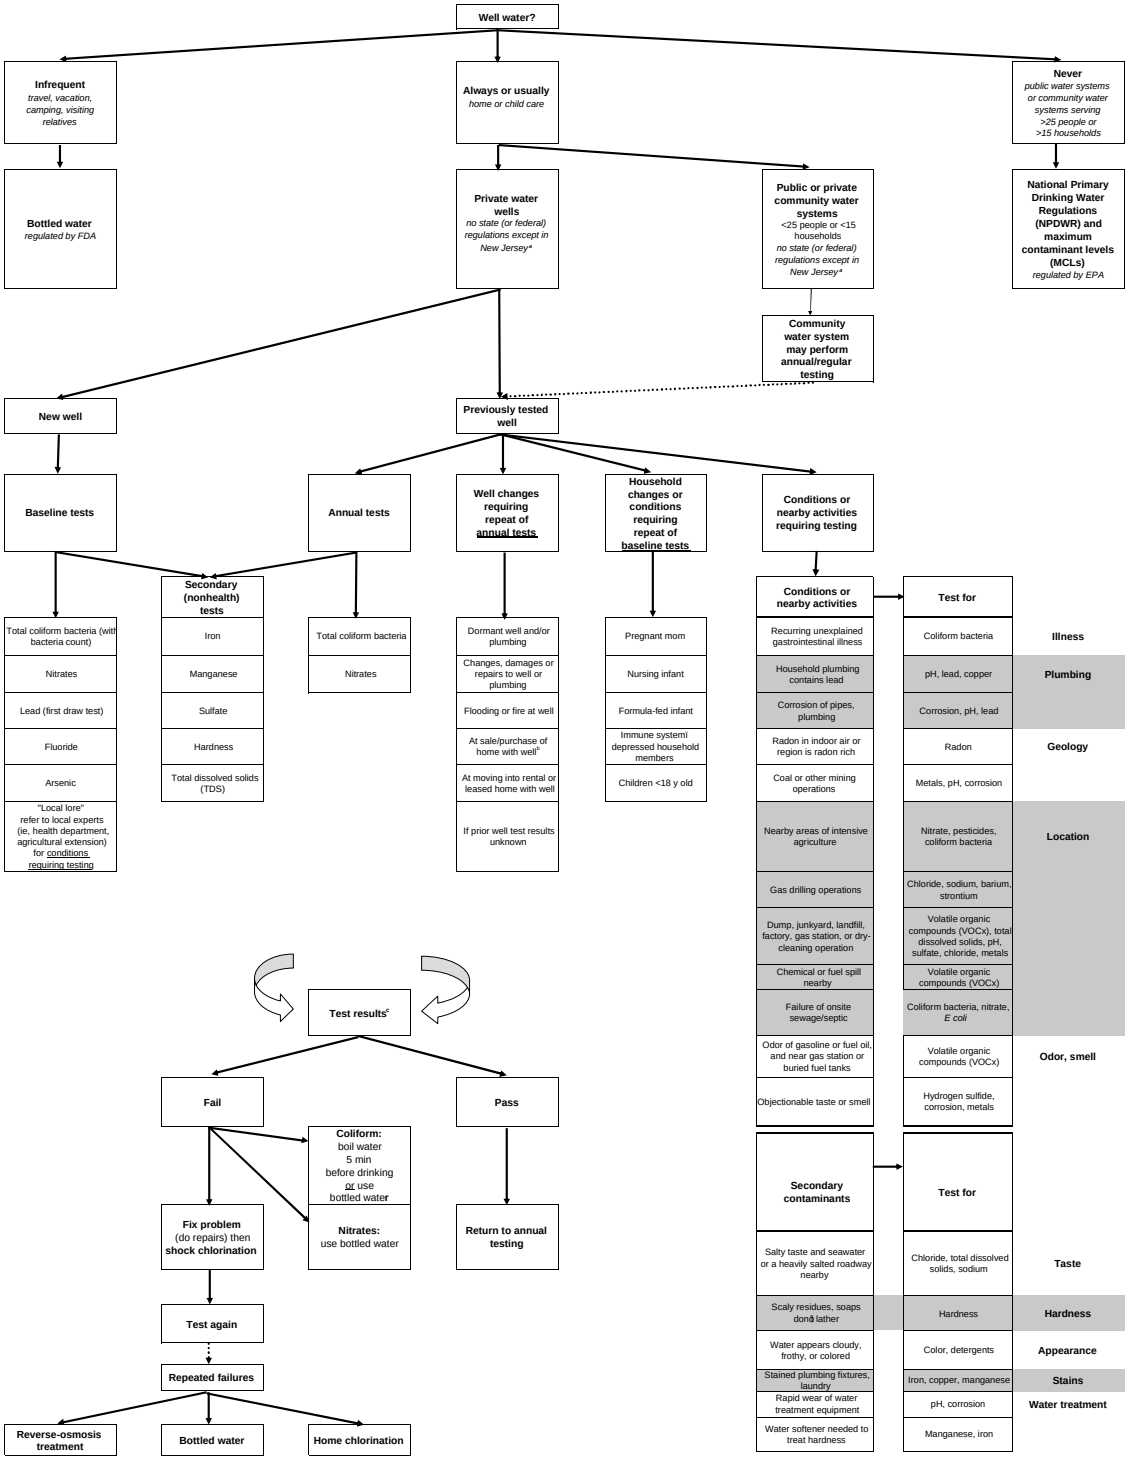
APPENDIX 1 Flowchart for Testing Well Water



[a] Testing at sale/purchase of home is required by law in state of New Jersey.

[b] Testing at sale/purchase of homes is often required by mortgage lender/bank, VA/FHA (Veteran Affairs/Federal Housing Administration), or county health department.

[c] Maximum contaminant levels from the EPA, same as those used by public water systems. FDA indicates Food and Drug Administration.

APPENDIX 2 Well Water Tests, Recommended Frequency, and Approximate Costs

Test	Frequency	Approximate Costs, 2006 $
Annual tests	Annually	30
Total coliform bacteria		
Nitrate		
Common inorganic test battery		25
Fluoride		
Chloride		
Hardness		
Copper	Every 3–5 y	
Iron		
pH		
Manganese		
Uranium		
Arsenic		10
FHA/VA loan for new well; additional 1-time tests		10
Color		
Turbidity		
Odor	Every 3–5 y	
Sodium		
Lead (first draw) (1-time test free for FHA/VA loans)	Every 10 y for homes built before 1985	15, stand-alone lead test
Additional "more thorough" 1-time tests		25
Zinc		
Cadmium		
Detergents		
Miscellaneous individual tests		15 each
Nitrate, chloride, hardness, copper, iron, pH, manganese, color, turbidity		
Fluoride, sodium, detergents, conductivity, total solids, ammonia nitrogen		
Arsenic, barium, cadmium, chromium, lead, silver, selenium, uranium		
Organic compound tests		
Volatile petroleum screen (gasoline, MTBE), in water		60
Volatile petroleum screen (gasoline, MTBE), in soil		80
Diesel organics and fuel oil		140
Volatile organics screen (especially solvents, degreasers)		135
Semivolatiles organic screen (including wood preservatives)		200
Semivolatiles organic screen plus chlordane, PCBs, and toxaphene		275
PCBs		150
Chlorinated acids: herbicides screen		200
Carbamate pesticides		125
Radiologic tests		
Radon in water		25
Radon in air		20
Radon in air (long-term) "α track"		25
Gross α (radioactivity in water; does not test for radon)	Every 5–10 y	55
Gross β		55
Radium (if gross $\alpha > 5$ pCi)		195
Radium 228 (only)		150
Gamma		50

FHA indicates Federal Housing Administration; VA, Veteran Affairs; MTBE, methyl tertiary butyl ether; PCB, polychlorinated biphenyl.

TECHNICAL REPORT

Drinking Water From Private Wells and Risks to Children

Walter J. Rogan, MD, Michael T. Brady, MD, the Committee on Environmental Health, and the Committee on Infectious Diseases

ABSTRACT

Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms, leading to significant illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation, and with few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This report reviews relevant aspects of groundwater and wells; describes the common chemical and microbiologic contaminants; gives an algorithm with recommendations for inspection, testing, and remediation for wells providing drinking water for children; reviews the definitions and uses of various bottled waters; provides current estimates of costs for well testing; and provides federal, national, state, and, where appropriate, tribal contacts for more information. *Pediatrics* 2009;123:e1123–e1137

BACKGROUND

Approximately 15% to 20% of households in the United States obtain their water from private wells.[1] Public drinking water systems are regulated by the US Environmental Protection Agency (EPA), with national drinking water regulations providing the legally enforceable standards. Unlike municipal water supplies and some community wells, private wells are not subject to federal regulations and are minimally regulated by states. States sometimes require that a well be dug or drilled by a certified contractor and that the water from the well be tested at least once for nitrate and coliform bacteria. After that, the owner of the well is not required to inspect the well or test the water; only New Jersey requires testing at the time of resale. The states, the Navajo Nation, and the EPA offer suggested inspection and testing schedules (Appendix).

Well water is not sterile, nor does it need to be, but it should be free of fecal contamination; such contamination is usually detected by coliform bacteria counts. In Iowa wells in the 1990s, 27% had coliforms.[2] Rigorous data are not available to compare the frequency of illness between children drinking well water versus municipal water. In a Canadian study of 235 rural households using well water, the odds of a child younger than 10 years having an episode of gastrointestinal illness, given the presence of at least 5 colony-forming units of *Escherichia coli* in the water, was 4.2 (95% confidence interval: 1.1–16.2) times higher than that for adults older than 50 years.[3] However, the risk as compared with the child drinking uncontaminated water was not studied. In a clinical trial of reverse-osmosis water filters, which should remove all infectious agents, in families drinking municipal water meeting bacteriologic standards, approximately 30% of acute gastrointestinal illnesses were prevented by the filters, with no difference according to age group. This study showed that even bacteriologically "clean" water produces some illnesses and that, because the background rate of illness was higher in the young children, the use of reverse-osmosis water filters prevented more illnesses in that age group.[4] It is likely, then, that contaminated water from a well would add to an already higher rate of such illness in children.

Well water can be a significant source of nitrate,[5] which comes from both sewage and fertilizer. In Iowa[2] and New York State,[6] approximately 2% of wells had nitrate concentrations greater than 10 mg/L, which should not be

consumed by infants. Other chemicals, such as solvents, fuel additives, and pesticides, also may contaminate private wells.

According to the Centers for Disease Control and Prevention, 28 waterborne disease outbreaks were reported in the United States in 2005–2006, the latest years for which data are published.[7] Twenty-three of the outbreaks were from drinking water, of those 8 were groundwater sources, usually private wells. Those caused illness in 458 people. The ages of the individuals were not reported. The etiology of 5 of the outbreaks is known: 1 was *Campylobacter*, 3 were norovirus, and 1 was Hepatitis A. Waterborne illness is undoubtedly underrecognized and underreported.

Although recommendations regarding wells note that infants are most susceptible to nitrate-induced methemoglobinemia,[8] recommendations regarding well water specific to families with children are not available; similarly, recommendations that address events that might expose a child to untested water, such as the birth or adoption of a child, are not available. As a general principle, children are likely to be more susceptible to waterborne illness than adults, because they drink relatively more water, develop gastroenteritis more often, and become dehydrated more quickly when they develop gastrointestinal illness. Thus, the fact that adults can consume the water without incident is not a guarantee that the child can do so. What follows is a selective compilation of information and recommendations concerning wells and well water.

GROUNDWATER AND WELLS

Groundwater is water below the topsoil and above impervious bedrock. When groundwater collects in and saturates relatively porous fractured bedrock and soil, it is said to be in an aquifer. The water table is a depth below which the soil and fractured bedrock (ie, the aquifer) is saturated with water. The water table can vary from season to season and year to year. For a well to produce water reliably, it must be deep enough so that water can be pumped from the aquifer from which it draws under virtually all weather conditions. Aquifers are recharged from above by precipitation and runoff. Wells drilled into water under sufficient pressure to come out of the ground spontaneously are called artesian wells because of their existence in the French region of Artois ("artesian," in old French, means "of Artois") (Fig 1).

Groundwater is naturally filtered on its way from the surface to the water table, so it is relatively free of particulate organic material and bacteria. It will only remain so if it is protected on its way from the aquifer to the tap.

WELL TYPES

Dug wells usually are shallow holes, 10 to 30 ft deep, lined with rock, brick, tile, or concrete, with a pump in a nearby pump house or in the dwelling. Dug wells usually are relics on older home sites. They are easy to contaminate and unreliable in most of the United States.

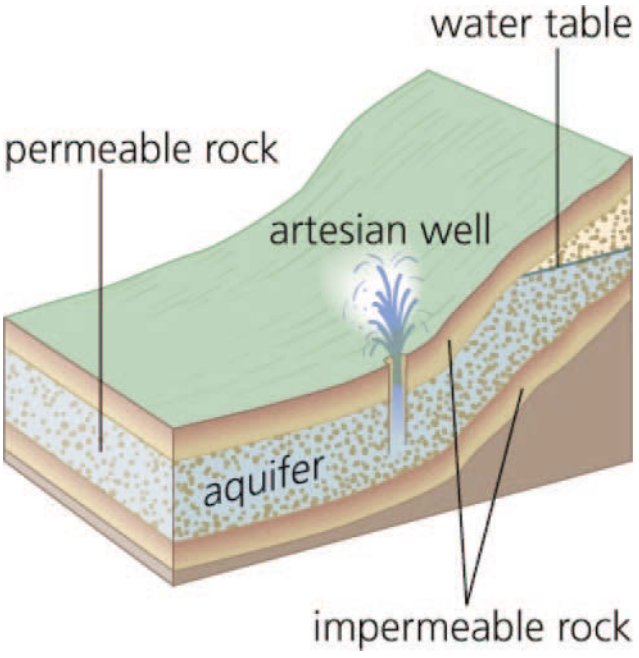

FIGURE 1
An artesian well. (Copyright © 2006 by Houghton Mifflin Harcourt Publishing Company; reproduced with permission from *The American Heritage Dictionary of the English Language*. 4th ed. Boston, MA: Houghton Mifflin Harcourt; 2006.)

For driven wells, a pipe is driven through gravel or sandy soil. These wells also tend to be shallow, usually approximately 50 ft deep; the pump is installed at the top of the well or in the dwelling. Driven wells are still relatively easy to contaminate because of their shallowness but can be rapidly and inexpensively installed if the geologic conditions are right. Dug wells and driven wells are often the water source at camps or vacation homes.

Drilled wells are 100 to 400 ft deep and reach bedrock. Most drilled wells have an electric submersible pump at the bottom.

Although the recommended minimum distances vary on the basis of the contaminant, private wells should be as far as feasible and no less than 50 ft from septic fields; they should be even further from underground fuel tanks, sheds in which fertilizers or other chemicals are stored, livestock, and cultivated fields. Thus, when siting a new well or when there is concern about contamination of an existing well, consultation with the local health department should be sought. In addition, the well should be on relatively high ground (ie, uphill from septic tanks) and covered by a well housing unit of impermeable material such as concrete. Although it is occasionally necessary to access the wellhead, security of the well housing should take precedence over convenience of access. If a homeowner is in doubt about the safety or integrity of the well, inspection by the state or county health department or a licensed well contractor should be arranged. In addition, if there is a flood or if the well housing is damaged by a vehicle, tree, etc, professional inspection is warranted.

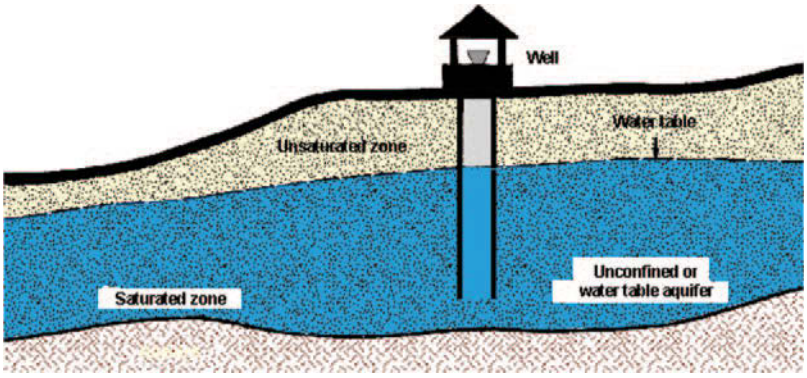

FIGURE 2
An unconfined aquifer and well (http://ecommons.library.cornell.edu/bitstream/1813/3408/2/What%20is%20Groundwater.pdf.) (Adapted from Raymond L Jr. *What Is Groundwater?* Ithaca, NY: Cornell Cooperative Extension, Cornell University; 1988:6.)

COMPOSITION OF WELL WATER

Chemicals

Nitrates

Nitrate is the most familiar and one of the most common contaminants of wells. Nitrate comes from either sewage or fertilizer. Agricultural scale application of fertilizer and permeable soil can lead to nitrate contamination of area groundwater. Nitrate is reported from the laboratory as nitrate nitrogen (NO_3-N); a level of 3 mg/L or greater indicates contamination. Water with a nitrate concentration of greater than 10 mg/L should not be used to prepare infant formula or other foods or given to a child younger than 1 year to drink.[8] The presence of nitrate requires testing for coliforms. Nitrate with no coliforms is likely from fertilizer; if possible, neighboring wells should be tested to determine if the aquifer, rather than the well, is contaminated. Nitrate with coliforms is likely from sewage (either livestock or human). Septic fields or tanks, manure fields, or settling ponds also can be sources of contamination. Examination of neighboring wells may be helpful in determining the source. The standard for nitrate is set to protect infants from methemoglobinemia. There is some evidence that long-term effects, such as gastric cancer, might result from exposure to even smaller amounts of nitrate if they help form endogenous *N*-nitroso compounds, which are potent carcinogens in many species. So far, however, the data are largely ecological and inconsistent.[9]

Volatile Organic Compounds and Pesticides

Volatile organic compounds and pesticides are problems throughout the United States. Although individual sources of these compounds are sometimes identified, such as abandoned dry cleaning shops with underground storage tanks, these compounds are very mobile and can appear without specific sources. The US Geological Survey evaluated 1255 domestic wells between 1992 and 1999, and found volatile organic compounds in 44% and pesticides in 38%.[10] Wells were more likely to be contaminated if they were shallow, were in a more urban area, or if they drew water from an aquifer with no impermeable layer between the surface and the water (see Fig 2).

Inorganic Compounds

Most state health departments and many commercial sources offer testing for inorganic compounds including calcium, sodium, fluoride, chloride, iron, manganese, magnesium, pH, hardness, and total dissolved solids. Total dissolved solids usually consist of calcium and magnesium as their bicarbonates. These bicarbonates make water "hard." Hard water is not toxic; however, the calcium and magnesium precipitate when the water is heated, and this precipitation will eventually cause electric hot water heaters, coffee pots, kettles, and any electrical device in which water is heated repeatedly to fail as the precipitate insulates the heating element. Hard water also forms scum with soaps and detergents.

Manganese and iron can appear as rust-colored to black flecks and can stain clothing, plumbing, and fixtures. However, their levels are not usually high enough to be toxic. So-called iron and manganese bacteria can grow in such water and form black slimy colonies of microorganisms, sometimes clogging pipes and faucets.

Sodium Chloride

Sea salt is a problem near the ocean and in areas where there was formerly salt water. Most people cannot or will not drink enough salt water for it to be toxic. Domestic desalinization is neither economic nor practical except under extraordinary circumstances.

Lead

Lead is not often present in groundwater but can be leached from the brass in a submersible pump, from solder, and, in some cases, old lead pipes if the water is naturally acidic or made acidic by treatment. For example, techniques such as anion exchange remove nitrate and sulfate but leave the water acidic.

Arsenic

Arsenic occurs in specific rock formations, for example, the "slate belt" in the southeastern United States. Its presence in well water is sometimes predictable from geologic data. Arsenic has been reported to be a common well contaminant in Maine,[11] parts of North Carolina,[12] Alaska, and parts of the western United States. Arsenic is extremely toxic and is known to cause bladder, skin, and

lung cancers in humans[13]; however, there have been no reports of acute or subacute arsenic poisoning from well water in the United States. A substantial fraction of the population of Bangladesh must drink from arsenic-contaminated wells, with resulting intoxication.[14]

Radon

Radon is a naturally occurring radioactive gas. Radon, similar to uranium, emits α particles containing 2 protons and 2 neutrons. α particles are strongly ionizing but do not penetrate far into tissue or other substances. Miners exposed to radon in underground mines develop excess lung cancer.[13] Some radon exposure from water occurs by ingestion, although showering, bathing, cleaning, and spraying water are likely to produce higher exposures. Radon in well water commonly exceeds the concentrations allowed in municipal water but does not correlate well with indoor air measurements.[15]

Fluoride

Fluoride is the lightest halogen on the periodic table. It occurs naturally in water in a few parts of the United States. Fluoride is an accepted preventive for dental caries; if a child's drinking water contains none, fluoride supplements are recommended. The American Academy of Pediatrics recommends no fluoride supplementation before 6 months of age; from 6 months to 3 years of age, children require fluoride supplementation if the water has <0.3 ppm (3 μg/L) fluoride. Supplementation from 3 to 16 years of age is recommended for children in areas where drinking water fluoride concentrations are <0.6 ppm.[16] Fluorosis, a condition that results from excess fluoride intake, produces tooth discoloration in children. The discoloration can range from mild white specks to brown streaks with pitting. According to the American Academy of Pediatric Dentistry,[17] fluorosis is most commonly caused by giving fluoride supplements to a child who already has adequate fluoride in drinking water or by the child's ingestion of fluoridated toothpaste rather than from excess fluoride in well water. However, because caries prevention is achieved at drinking water concentrations of 1 ppm and the risk of dental fluorosis increases with concentration,[18] children younger than 9 years should not drink water with a fluoride concentration of >2 ppm.[1] Determining fluoride concentration in well water should be performed as part of the initial evaluation of the well.

Uranium

Uranium in groundwater, although mostly found in the Western mountains in the United States, can also be found in areas that have granite outcrops, the result of granite intrusion into existing subterranean strata and subsequent weathering. There have been reports of high uranium concentrations in waters of Connecticut and South Carolina.[19,20] Those who drink uranium-containing water absorb and then excrete it; urinary concentrations as high as 25% of peak can be present 6 months after exposure has ceased.[19] Exposures likely to be encountered in drinking water have not resulted in acute toxicity. Radiation carcinogenesis, however, is currently thought to have no threshold, and the biological effects of ionizing radiation reports[21] estimated that some cancer may be attributable to background uranium exposure, including uranium in water.

TABLE 1 Most Common Pathogenic Microorganisms Found in Well Water

Bacteria	Viruses	Parasites
E coli, including O157:H7	Small round-structured viruses, including norovirus	*Giardia intestinalis*
Salmonella species	Rotavirus	*Cryptosporidium parvum*
Shigella species	Enteroviruses	*Cyclospora*
Campylobacter jejuni	Hepatitis A and E	*Microsporidia*
Yersinia enterocolitica		*Isospora*
M. avium-intracellulare		*Naegleria fowleri*

Methyl Tertiary Butyl Ether

Methyl tertiary butyl ether (MTBE) is a partially oxidized hydrocarbon fuel additive used to oxygenate gasoline. The oxygenation of gasoline during certain seasons was mandated by the Clean Air Act in 1990 (Pub L No. 101–549) to reduce carbon monoxide emissions. Motor vehicle exhausts are the primary source of ambient carbon monoxide levels, and carbon monoxide is highest during the cold-weather months. Oxygenated gasoline is designed to increase the combustion efficiency of gasoline, thereby reducing carbon monoxide emissions. The tertiary butyl group on MTBE hinders breakdown by sterically protecting the molecule; as a result, uncombusted MTBE can persist in the environment. MTBE is now found in water supplies throughout the United States. Because it has no other uses, its presence indicates contamination by gasoline; its concentrations are higher in wells near gasoline stations and particularly high near gasoline stations that sell oxygenated fuel.[22] MTBE is toxic and carcinogenic in experimental animals[23] and is now banned in most states. Ethanol will likely replace MTBE entirely for oxygenating fuel.

Perchlorate

Perchlorate is an oxidizing agent used in rocket fuels, fireworks, and airbag inflators. It also occurs naturally. Perchlorate is a well-studied steric inhibitor of the thyroid symporter, which transports iodine across the gland's membrane before hormone synthesis. It is now recognized as a water pollutant. There is evidence that perchlorate interferes with thyroid function in adult women in the United States, even at background exposures.[24]

Microorganisms

Microorganisms, including bacteria, viruses, fungi, and parasites, may contaminate the groundwater that supplies wells (Table 1). The major source of these organisms is fecal material from animals and humans. Analyzing well water at its point of use for "total coliforms" is the most common way of detecting fecal contamination of the water. Coliform bacteria may be pathogenic or nonpathogenic. Coliforms include many species of

Gram-negative bacteria found in the intestinal tract of animals and humans, in the soil, on vegetation, and in surface water runoff. Although coliforms do not reproduce in water, they can survive there for extended periods of time. Thus, assessing total coliforms in a water sample is a useful screening tool, because it does not require sophisticated technology and is inexpensive. No coliforms of any sort should be detectable in 100 mL of water. The absence of coliforms is good but not absolute evidence that significant fecal contamination is not present. The presence of coliforms does not mean that pathogens are present, but it does make fecal contamination and, thus, contamination by pathogens much more likely. Samples that contain any coliforms should be retested to determine if they are fecal coliforms; specimens that test positive should be examined for the presence of *Escherichia coli* or other pathogens.

Much of the information describing the pathogens that may be present in well water has been obtained from investigations of waterborne outbreaks. In the United States, most waterborne outbreaks are associated with noncommunity water systems, chiefly private or communal wells.[7] The microorganisms listed in Table 1 typically cause a gastrointestinal illness. However, there are notable exceptions; for example, enterovirus exposure may be asymptomatic but may also result in a febrile illness associated with sore throat, rash, myalgia, or, less commonly, aseptic meningitis syndrome. *Naegleria* species may cause a fatal meningoencephalitis. *Mycobacterium avium*-intracellulare and *Cryptosporidium* species may be found in well water, producing systemic or pulmonary disease in specific vulnerable populations. *Legionella* species and *M avium*-intracellulare are present naturally in water and do not represent fecal contamination. However, disease from *Legionella* species typically results from inhalation rather than ingestion of bacteria. Outbreaks caused by *Legionella* species typically occur in large buildings after colonization of the water-distribution system[7] and have not been identified as a result of contamination of well water.

Iron and sulfur bacteria also may be present in well water. Although these bacteria do not pose a health threat, they can cause the water to smell (like "rotten egg") and taste bad; they also increase the likelihood that plumbing equipment will become plugged or corroded.

MITIGATION

If test results confirm bacterial contamination, the well must be inspected to identify any structural defects that may have permitted the contamination. After any such defects are repaired, the well must be treated to eliminate pathogenic bacteria immediately, usually by "shock chlorination," which uses concentrations of chlorine that are 100 to 400 times the amount found in municipal water supplies. This can be done by the homeowner using household bleach, (many Web sites have instructions [www.water-research.net/shockwelldisinfection.htm]), but consultation with the health department or other experienced individuals is advisable the first time. The highly chlorinated water needs to be held within the water system pipes for 12 to 24 hours before it is completely flushed out of the system. The water should be retested in 1 to 2 weeks. If shock chlorination does not eliminate the bacteria, a continuous disinfection system or further repairs to the well are needed. A consultation with the local health department can help the well owner understand which additional treatment measures are required.

If the contamination is ongoing but under the control of the homeowner, such as from a failing septic field, that problem must be fixed before the well can be used for drinking water again. Successful, lasting decontamination of a well may require more persistent efforts. Swistock and Sharpe[25] disinfected and installed sanitary well caps on 16 wells with coliform contamination; coliforms were again present in 7 of the wells within 60 days and in all but 2 within a year. The 2 wells that did not have coliforms after 1 year had low initial coliform counts and no *E coli*. The authors suggested that contamination may occur far from the well head and may commonly be an aquifer problem. Such a problem is beyond the scope of the homeowner. If the well cannot be used, it should not be abandoned, because it would still provide access for contamination of groundwater. A certified well contractor should fill or seal the contaminated well.

Chemical contaminants are approached by investigating the possibility that the contamination from fertilizers, pesticides, or fuel from leaking tanks exists on the homeowner's or on an adjacent homeowner's property. However, remediation may be inconvenient and/or expensive. If the water supply cannot be remediated and the well is still contaminated or the chemicals in question are naturally occurring, it is possible to treat for or filter most chemicals.[26] An illustration of the relative sizes of filterable contaminants versus filter pore size is provided in Fig 3.

Carafe and faucet-mounted filters usually are designed to reduce lead, some organic materials, *Giardia* and *Cryptosporidium* cysts, and sediment. These units are intended for municipal water and would not be suitable for more heavily contaminated well water. Most other treatment measures require the service of a trained home water-treatment professional, at least for initial installation. Chemical disinfection with chlorine, ozone or hydrogen peroxide, distillation, and ultraviolet light can remove or kill many microorganisms. Chlorine is effective at killing bacteria and viruses but is less effective against *Giardia* species and not effective against *Cryptosporidium* species. Reverse-osmosis filters, usually used in conjunction with activated charcoal and mechanical filtration, can remove inorganic materials, microorganisms, and all but a few organic compounds; however, they are expensive. Treatment systems must be properly maintained to ensure safe water. Most filters, membranes, or ultraviolet lights need to be replaced at least once per year and more frequently if damaged or not working properly.

Consumer Reports magazine periodically reviews home water-treatment devices, including the inexpensive carafe and faucet-mounted types. Although the emphasis is on treating municipal water, they also review reverse-osmosis filters. *Consumer Reports* is available in libraries and through a subscription Web site. NSF International (www.nsf.com) is a not-for-profit, nongovernmental, independent agency

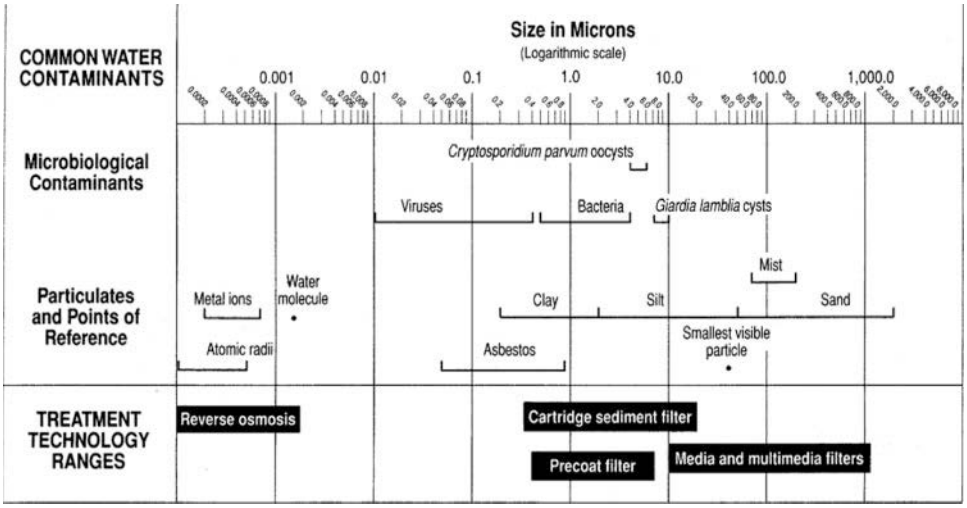

FIGURE 3
Filters and particle sizes for water contaminants.[24]

that tests and certifies consumer products, including water-treatment devices. The NSF Web site allows the consumer to pick the contaminants that are present, and the NSF will provide names of appropriate products and manufacturers. NSF certification is a voluntary program paid for by the manufacturer of the device. Some states and universities, such as Purdue University (www.purdue.edu/dp/envirosoft/groundwater/src/treat.htm#menu), provide descriptions of water-treatment devices. All sites recommend that the water first be tested and then the treatment device or devices selected to deal with the contaminants that are present.

Because there are no standards for private wells for many contaminants of concern, those seeking a specific concentration to indicate potability have little choice but to apply the same standards that municipalities do under the Safe Drinking Water Act amendments of 1996 (Pub L No. 104–182 [for the current list of drinking water contaminants, see www.epa.gov/safewater/mcl.html]). Municipalities regard water that is persistently above these federal standards as not potable. Nonetheless, well owners or home occupants are under no obligation to apply this same standard to their well water.

BOTTLED WATER

Bottled water is often labeled to describe its characteristics, source, or method of treatment. Bottled water is regulated as a packaged food by the US Food and Drug Administration under the Federal Food, Drug and Cosmetic Act (21 USC §301 et seq [1938]) if it is in interstate commerce (ie, crosses a state line). Food and Drug Administration rules for bottled water mirror EPA rules for municipal water. Thus, bottled water in interstate commerce should be free of coliform bacteria and have <1 mg/L of nitrate nitrogen.

Distilled water is boiled (killing microbes), and the steam is condensed to remove salts, metals, minerals, asbestos, particles, and some organic materials, giving it a "flat" taste. Purified water originates from any source but has been treated to be essentially pure H_2O. It must contain <10 ppm of total dissolved solids and may also be free of microbes if treated by distillation or reverse osmosis. Sterilized water originates from any source but has been treated to be free from all microbes. These waters should be sterile until opened. Other bottled waters may or may not be sterile.

Artesian water, groundwater, spring water, and well water are from underground aquifers, the waters of which may or may not be treated. It may or may not be sterile. Bottled drinking water is intended for human consumption and sealed in bottles and may contain disinfectants. Some of these are fluoridated, which should be noted on the label. Mineral water is groundwater that naturally contains ≥ 250 ppm of total dissolved solids. Carbonated water, soda water, seltzer water, sparkling water, and tonic water are considered soft drinks and are not regulated as bottled water.

CONCLUSIONS

Well water can be used safely by families, but regular testing is recommended by all relevant authorities. A recommended approach to testing is given in the accompanying policy statement[25] and outlined as a flowchart in that statement. In much of the United States, well water is hard and must be softened in order not to damage hot water heaters, kettles, and other devices, but softening per se does not remove most other contaminants or microorganisms. Whether and how water is treated should be guided by the results of testing. Testing can be expensive, and the American Academy of Pediatrics encourages states and counties to provide free or low-cost testing to families who need their water tested and cannot afford it. A list of current costs is provided in the accompanying policy statement[27]; these costs are, of course, subject to change. Inexpensive water filters can remove lead, *Cryptosporidium* species, and some volatile hydrocarbons, but these are designed more for tap water from municipal water supplies and may not be suitable for well water. Water contamination is inher-

ently local, and families with wells and pediatricians are encouraged to keep in contact with state and any local programs. A list of contacts, all of which are current as of May 2007, is provided in the Appendix. Within states, private well water programs, resources, guidance, testing groups, and regulations are found in a variety of state Departments of Health, Public Health, Environment, Natural Resources, Licensure or Water, and sometimes within multiple departments within a state. Many states also have university-based Cooperative Extension services with private well water resources. Unfortunately, website addresses change frequently. In addition to web site addresses, the Appendix includes both document titles, and, when available, authorship organization names to aid in internet searches for relevant information. Bottled water should be considered for travel or other circumstances in which an infant might need water and the source of the water is unknown, but bottled water is subject to limited regulation.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health

abstract

FREE

Advances in a wide range of biological, behavioral, and social sciences are expanding our understanding of how early environmental influences (the ecology) and genetic predispositions (the biologic program) affect learning capacities, adaptive behaviors, lifelong physical and mental health, and adult productivity. A supporting technical report from the American Academy of Pediatrics (AAP) presents an integrated ecobiodevelopmental framework to assist in translating these dramatic advances in developmental science into improved health across the life span. Pediatricians are now armed with new information about the adverse effects of toxic stress on brain development, as well as a deeper understanding of the early life origins of many adult diseases. As trusted authorities in child health and development, pediatric providers must now complement the early identification of developmental concerns with a greater focus on those interventions and community investments that reduce external threats to healthy brain growth. To this end, AAP endorses a developing leadership role for the entire pediatric community—one that mobilizes the scientific expertise of both basic and clinical researchers, the family-centered care of the pediatric medical home, and the public influence of AAP and its state chapters—to catalyze fundamental change in early childhood policy and services. AAP is committed to leveraging science to inform the development of innovative strategies to reduce the precipitants of toxic stress in young children and to mitigate their negative effects on the course of development and health across the life span. *Pediatrics* 2012;129:e224–e231

INTRODUCTION

"It is easier to build strong children than to repair broken men."

Frederick Douglass (1817–1895)

From the time of its inception as a recognized specialty of medicine, the field of pediatrics has attached great significance to both the process of child development and the social/environmental context in which it unfolds. When the American Academy of Pediatrics (AAP) was founded in 1930, the acute health care needs of children were largely infectious in nature.[1] Over the ensuing 80 years, as increasingly effective vaccines, hygiene, and other public health initiatives produced dramatic gains, astute observers began to note that many noninfectious disease entities, such as developmental, behavioral, educational, and

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

family difficulties, were playing increasingly prominent roles in affecting child health and well-being.

In 1975, the term "new morbidity" was introduced to describe those noninfectious entities that appeared to be most prevalent.[2] This important conceptualization underscored a growing realization that significant societal changes (eg, increasing numbers of single parents and families with 2 working parents) were challenging pediatric health care providers to address complex concerns that were not strictly medical in nature. Although the impact of these "new" morbidities on pediatrics, public health, and society in general is no longer in question,[3–5] the professional training and practice of pediatricians continues to focus primarily on the acute medical needs of individual children. The pressing question now confronting contemporary pediatrics is how we can have a greater impact on improving the life prospects of children and families who face these increasingly complex and persistent threats to healthy development.

The need for creative, new strategies to confront these morbidities in a more effective way is essential to improve the physical and mental health of children, as well as the social and economic well-being of the nation.[6] Developmental, behavioral, educational, and family problems in childhood can have both lifelong and intergenerational effects.[7–18] Identifying and addressing these concerns early in life are essential for a healthier population and a more productive workforce.[5,6,19–21] Because the early roots or distal precipitants of problems in both learning and health typically lie beyond the walls of the medical office or hospital setting, the boundaries of pediatric concern must move beyond the acute medical care of children and expand into the larger ecology of the community, state, and society. Because this call for a broader, contextual approach to health is not new,[22] and the track record of matching rhetoric with effective action is limited, there is a compelling need for bold, new thinking to translate advances in developmental science into more effective interventions.

THE MERITS OF AN ECOBIODEVELOPMENTAL FRAMEWORK

The accompanying technical report[23] presents an ecobiodevelopmental (EBD) framework for understanding the promotion of health and prevention of disease across the life span that builds on advances in neuroscience, molecular biology, genomics, and the social sciences. Together, these diverse fields provide a remarkably convergent perspective on the inextricable interactions among the personal experiences (eg, family and social relationships), environmental influences (eg, exposures to toxic chemicals and inappropriate electronic media), and genetic predispositions that affect learning, behavior, and health across the life span. Applying this EBD framework to the challenges posed by significant childhood adversity reveals the powerful role that toxic stress can play in disrupting the architecture of the developing brain, thereby influencing behavioral, educational, economic, and health outcomes decades and generations later.[24] In contrast to positive or tolerable stress, toxic stress is defined as the excessive or prolonged activation of the physiologic stress response systems in the absence of the buffering protection afforded by stable, responsive relationships.[25] Within the ongoing interplay among assets for health and risks for illness, toxic stress early in life plays a critical role by disrupting brain circuitry and other important regulatory systems in ways that continue to influence physiology, behavior, and health decades later.[23] In short, an EBD approach to childhood adversity suggests that (1) early experiences with significant stress are critical, because they can undermine the development of those adaptive capacities and coping skills needed to deal with later challenges; (2) the roots of unhealthy lifestyles, maladaptive coping patterns, and fragmented social networks are often found in behavioral and physiologic responses to significant adversity that emerge in early childhood; and (3) the prevention of long-term, adverse consequences is best achieved by the buffering protection afforded by stable, responsive relationships that help children develop a sense of safety, thereby facilitating the restoration of their stress response systems to baseline.[25] An EBD approach recognizes that it is not adversity alone that predicts poor outcomes. It is the absence or insufficiency of protective relationships that reinforce healthy adaptations to stress, which, in the presence of significant adversity, leads to disruptive physiologic responses (ie, toxic stress) that produce "biological memories"[26] that increase the risk of health-threatening behaviors and frank disease later in life. The recent AAP technical report[23] summarizes the growing evidence base that links childhood toxic stress to the subsequent development of unhealthy lifestyles (eg, substance abuse, poor eating and exercise habits), persistent socioeconomic inequalities (eg, school failure and financial hardship), and poor health (eg, diabetes and cardiovascular disease). Given the extent to which costly health disparities in adults are rooted in these same unhealthy lifestyles and persistent inequalities,[5,9] the reduction of toxic stress in young children ought to be

a high priority for medicine as a whole and for pediatrics in particular.

AN IMPORTANT ROLE FOR THE PEDIATRIC MEDICAL HOME

The effective reduction of toxic stress in young children could be advanced considerably by a broad-based, multisector commitment in which the profession of pediatrics plays an important role in designing, implementing, evaluating, refining, and advocating for a new generation of protective interventions. Pediatric providers are uniquely qualified and placed to assist in translating recent advances in developmental science into effective interventions for the home, the clinic, and the community. In addition to regular interactions with young children and an appreciation for the important role that families[27–29] and communities[30] play in determining child well-being, pediatricians bring several time-honored perspectives to this challenging task. These perspectives include a developmental approach to health, an understanding of the advantages of prevention over remediation, and an awareness of the critical importance of effective advocacy to promote changes in well-established systems that influence child health and development, even when those systems lie outside the traditional realm of pediatric practice.[31] In this context, it is essential that innovative and practical strategies continue to be developed that strengthen the capacity of the medical home to reduce sources of toxic stress and to mitigate their impact on the lives of young children. Rather than continuing the current trend of "doing more with less," as pediatricians take on a wide range of additional responsibilities, payment reforms should reflect the value of pediatricians' time and knowledge, as well as the importance of a pediatrician-led medical home serving as a focal point for the reduction of toxic stress and for the support of child and family resiliency. This additional work and the reprioritization of efforts should reflect pediatricians' interest in preventive care that is more developmentally relevant,[32] parents' desire for a greater emphasis on their child's emerging skills and behavior,[33] the commitment to team-based services within the pediatric medical home,[28] and the growing evidence base that early developmental interventions can have significant effects on life-course trajectories.[34]

As the most logical candidate for a universal platform to promote healthy development and optimal life course trajectories, the pediatric medical home has become the focus of both increasing expectations and formidable challenges. High expectations are grounded in the public's deep respect for pediatricians as trusted guardians of child health. Compelling challenges include (1) the need for more extensive training for all health professionals on the adverse effects of excessive stress on the developing brain, as well as on the cardiovascular, immune, and metabolic regulatory systems (the technical report[23] is a start); (2) the significant constraints on existing, office-based approaches to fully address the new morbidities effectively; (3) the relatively limited availability of evidence-based strategies, within the medical home and across the full array of existing early childhood service systems, that have been shown to reduce sources of toxic stress in the lives of young children or mitigate their adverse consequences[35]; and (4) the financial difficulties associated with the incorporation of evidence-based developmental strategies into the pediatric medical home.

A Critical Assessment of Prevention at the Practice Level

From immunizations to seat belts to parenting education, the field of pediatrics has always embraced the centrality of prevention. That said, some degree of childhood adversity is inevitable, and dealing with manageable levels of stress is an important part of healthy development. Because the essence of toxic stress is the absence of buffers needed to return the physiologic stress response to baseline, the primary prevention of its adverse consequences includes those aspects of routine anticipatory guidance that strengthen a family's social supports, encourage a parent's adoption of positive parenting techniques, and facilitate a child's emerging social, emotional, and language skills. Examples include the promotion of the 7Cs of resilience (competence, confidence, connectedness, character, contribution, coping, and control),[36] optimism,[37] Reach Out and Read,[38–40] emotional coaching,[41–44] and numerous positive parenting programs (eg, Triple P,[45–47] Incredible Years,[48] Home visiting,[49,50] and Nurturing Parenting[51,52]). Although AAP resources, such as *Bright Futures*,[53] *Connected Kids*,[54] and the clinical report "The Pediatrician's Role in Child Maltreatment Prevention,"[55] already provide significant recommendations in this area, implementing a comprehensive, yet practical program of effective anticipatory guidance that nurtures the child's emerging social, emotional, and language skills and promotes positive parenting remains an ongoing challenge.

Beyond working to improve the impact of anticipatory guidance provided in the medical home, some motivated pediatric providers also advocate for a variety of community-based interventions that are implemented in homes,[56,57] preschools,[58] and

schools,[59–61] as well as through an extended array of programs organized by faith-based organizations, social groups, and recreational centers. A more thorough description of the full range of practices designed to strengthen parenting skills and enhance child development can be found elsewhere.[35,62–64] Although most primary prevention programs have not been evaluated systematically, those that show promise should be assessed and, if found to be effective, replicated and taken to scale. As the number of evidence-based services increases, the pediatric community needs to continue to advocate for systemic changes in reimbursement strategies that incentivize collaboration among pediatric medical homes and the full range of effective community-based resources.[65]

Screening for Children and Families at Risk

Identifying children at high risk for toxic stress is the first step in providing targeted support for their parents and other caregivers. The challenges of developing secondary prevention strategies within the medical home begin with the implementation of practice-relevant screening and proceed through the complexities of diagnostic evaluations, sharing information, formulating joint action plans with parents, locating needed services beyond the medical home, arranging successful referrals, and conducting an ongoing monitoring and assessment of intervention impacts. That said, after several decades of prescriptive guidelines and outcome evaluations of a broad array of prevention strategies, the cumulative evidence of effectiveness is mixed. Some primary care practices have been successful in regularizing the identification and management of new morbidities within their daily routines. Many continue to struggle with the basics of developmental screening, routine referral, and ongoing collaboration with community-based programs outside the medical system.[32] All confront the limited availability of accessible and affordable preventive supports for children and families experiencing significant adversity.

Within this highly variable and multidimensional context, the AAP and others have encouraged pediatric providers to develop a screening schedule that uses age-appropriate, standardized tools to identify risk factors that are highly prevalent or relevant to their particular practice setting.[29,66,67] In addition to the currently recommended screenings at 9, 18, and 24/36 months to assess children for developmental delays, pediatric practices have been asked to consider implementing standardized measures to identify other family- or community-level factors that put children at risk for toxic stress (eg, maternal depression, parental substance abuse, domestic or community violence, food scarcity, poor social connectedness). Pediatric providers have been encouraged to use *Current Procedural Terminology* code 99420 when they are assessing a child's risk and, if additional visits are needed to address any identified concerns, providers are encouraged to bill for that additional time by using codes 99401-4.[68] Continued advocacy at the national and state levels is needed, however, to ensure proper payment for the time needed for universal screening, problem identification, and ongoing assessments. More specific recommendations (regarding which screening tools should be used, when they should be administered, and how to secure reimbursement for their use) will be presented in a forthcoming AAP policy statement on social-emotional screening.

Collaborating With the Community

Routine screening for increased vulnerability is useful only if collaborative relationships exist with local services to address the identified concerns (as outlined in several previous reports[69–71]); moreover, it is also essential that those services demonstrate evidence of effectiveness. This is particularly important for the identification of young children experiencing toxic stress, given the limited proportion of community-based interventions for which significant, positive impacts have been documented in this domain, and the relatively modest magnitude of impact found for those that have been shown to be effective.

Rethinking Advocacy Beyond the Office Setting

Because so many of the origins and consequences of childhood toxic stress lie beyond the boundaries of the clinical setting, pediatric providers are often called on to work collaboratively with parents, social workers, teachers, coaches, civic leaders, policy makers, and other invested stakeholders to influence services that fall outside the traditional realm of clinical practice.[72] In many cases, these efforts extend even further afield, moving into the realm of ecologically based, public health initiatives that address the precipitants of toxic stress at the community, state, and national levels. Translating advances in developmental science into effective interventions and lifelong health will require a fundamental shift in the way the general public and policy makers view and invest in early childhood. Pediatric providers are integral to this effort, as they have a long history of advocating for systemic changes to advance child health and development.[31]

Examples of preventive interventions that could serve as targets for pediatrician-led advocacy campaigns include (1) education efforts focused

on parents, foster parents, child care providers, and preschool teachers to increase awareness of the adverse consequences of toxic stress in early childhood for lifelong outcomes in learning, behavior, and health; (2) calls for investments in the development of creative, new strategies that can be incorporated into home-, school-, and center-based services to reduce sources of toxic stress and to strengthen the relationships that buffer children from the long-term consequences of significant adversity; (3) investments in community-based mentoring activities (eg, after-school programs, Big Brother/Big Sister, Little League, gymnastics, martial arts programs) that provide supportive relationships for vulnerable children that help them learn to cope with adversity in an adaptive manner; (4) investments in selected early-intervention programs, early-childhood mental health services, specialized family therapies, and medicolegal partnerships that have demonstrated evidence of positive impacts on vulnerable young children and families; (5) professional development programs that educate judges and other key participants in the juvenile court and foster care systems about the biology of adversity and its implications for case management, child custody, and foster care of children who have been abused or neglected; and (6) collaborative efforts with social workers, mental health providers, and other related professionals to address urgent needs as early as possible and to integrate effective services for the most vulnerable children and their families.

Treatment of Toxic Stress

Finally, the pediatric community must provide strong, proactive advocacy for more effective interventions for children with symptomatic evidence of toxic stress. These could include (1) the formation and/or continuous strengthening of local traumatic stress networks to treat children and families experiencing significant adversity; and (2) increasing the number of accessible, affordable, and culturally competent mental health professionals who are qualified to provide evidence-based treatments, such as trauma-based cognitive behavioral therapy and parent-child interaction therapy. In addition to the paucity of appropriately trained professionals in this area of significant unmet need, inadequate or inappropriate reimbursement mechanisms often block access to services for the most vulnerable young children. In such circumstances, pediatricians can be powerful advocates for expanded insurance coverage for childhood mental health services, even when they do not provide those services themselves.[73]

REAFFIRMING A COMMITMENT TO LEAD

This Policy Statement builds on numerous previous statements, including those regarding the new morbidities,[3] community pediatrics,[30] family-centered care,[27] home visitation,[49] and the prevention of child abuse.[55] The proposed EBD framework (1) incorporates growing evidence of the impact of toxic stress on the developing brain, (2) informs a deeper understanding of the early life origins of both educational failure and adult disease, and (3) underscores the need for collaborative efforts to prevent the long-term consequences of early adversity. The AAP is committed to leading an invigorated, science-based effort at transforming the way our society invests in the development of all children, particularly those who face significant adversity.[74]

RECOMMENDATIONS

1. All health care professionals should adopt the proposed EBD framework as a means of understanding the social, behavioral, and economic determinants of lifelong disparities in physical and mental health (see technical report[23]). Psychosocial problems and the new morbidities should no longer be viewed as categorically different from the causes and consequences of other biologically based health impairments.
2. The growing scientific knowledge base that links childhood toxic stress with disruptions of the developing nervous, cardiovascular, immune, and metabolic systems, and the evidence that these disruptions can lead to lifelong impairments in learning, behavior, and both physical and mental health, should be fully incorporated into the training of all current and future physicians (see technical report[23]).
3. Pediatricians should adopt a more proactive leadership role in educating parents, child care providers, teachers, policy makers, civic leaders, and the general public about the long-term consequences of toxic stress and the potential benefits of preventing or reducing sources of significant adversity in early childhood. Protecting young children from adversity is a promising, science-based strategy to address many of the most persistent and costly problems facing contemporary society, including limited educational achievement, diminished economic productivity, criminality, and disparities in health.
4. Pediatricians should be vocal advocates for the development and implementation of new, evidence-based interventions (regardless of the provider or venue) that reduce sources of toxic stress and/or

mitigate their adverse effects on young children, as they are likely to produce better outcomes and potentially be more cost-effective than trying to treat or remediate the numerous consequences of excessive childhood stress that reach far into adulthood. Such advocacy is particularly important when budget constraints force critical reassessments of public spending priorities.

5. Pediatric medical homes should (1) strengthen their provision of anticipatory guidance to support children's emerging social-emotional-linguistic skills and to encourage the adoption of positive parenting techniques; (2) actively screen for precipitants of toxic stress that are common in their particular practices; (3) develop, help secure funding, and participate in innovative service-delivery adaptations that expand the ability of the medical home to support children at risk; and (4) identify (or advocate for the development of) local resources that address those risks for toxic stress that are prevalent in their communities.

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Early Childhood Caries in Indigenous Communities

abstract

FREE

The oral health of Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian, Alaska Native) is a major child health issue: there is a high prevalence of early childhood caries (ECC) and resulting adverse health effects in this community, as well as high rates and costs of restorative and surgical treatments under general anesthesia. ECC is an infectious disease that is influenced by multiple factors, including socioeconomic determinants, and requires a combination of approaches for improvement. This statement includes recommendations for preventive oral health and clinical care for young infants and pregnant women by primary health care providers, community-based health-promotion initiatives, oral health workforce and access issues, and advocacy for community water fluoridation and fluoride-varnish program access. Further community-based research on the epidemiology, prevention, management, and microbiology of ECC in Indigenous communities would be beneficial. *Pediatrics* 2011;127:1190–1198

dental caries, early childhood caries, oral health, Indigenous, First Nations, American Indians

ABBREVIATIONS

ECC—early childhood caries
IHS—Indian Health Services
AI/AN—American Indian/Alaska Native

Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian, Alaska Natives) face many health disparities compared with the general American and Canadian populations. Oral health disparities for Indigenous children exemplify many of the inequities and the major need for health promotion, disease prevention, and early care services in these communities. Various organizations have provided guidelines on health promotion, disease prevention, and early visits for dental care; however, the severity of dental disease and the barriers to care in Indigenous communities require special consideration.

Early childhood caries (ECC) is defined as the presence of tooth decay that involves any primary tooth in a child younger than 6 years.[1] Also referred to as early childhood tooth decay in the vernacular (and formerly called baby-bottle tooth decay), the term ECC better reflects that the disease process is much more complex and involves transmission of infectious bacteria, dietary habits, and oral hygiene. ECC is an infectious disease; *Streptococcus mutans* is the most dominant causative organism. The causative triad for caries includes the presence of cariogenic bacteria, diet (exposure to fermentable carbohydrate), and host susceptibility (integrity of tooth enamel). ECC has been termed the most prevalent pediatric infectious disease and the most common chronic disease of children.[2]

The effects of ECC go beyond the oral cavity and influence overall childhood health and well-being, which are already compromised for many

Indigenous children. ECC has been associated with other infectious diseases, such as respiratory tract infections and acute otitis media, in the first year of life, but the relationships are weak and may indicate common risk factors.[3] When left to progress, ECC can become painful and result in altered chewing, eating, and sleeping patterns in addition to potential growth restriction.[3] Early tooth loss as a result of ECC may result in speech difficulties and associated self-esteem issues because of altered appearance. Children with ECC are known to be at increased risk of decay in both primary and permanent dentition and may also experience malalignment and crowding of permanent teeth that result in poor bite.[4] Dental caries has also been associated with obesity in children from low socioeconomic status, possibly from common risk factors.[5] The other consequence of more severe ECC is that it frequently requires extensive treatment under general anesthesia—a procedure all too common among Indigenous children.[6]

ORAL HEALTH STATUS IN INDIGENOUS CHILDREN

The poor oral health of Indigenous children in Canada and the United States is a major public health issue. In some Canadian Indigenous communities, the prevalence of ECC exceeds 90%.[4] Similarly, in the United States, the disparities in oral health for Indigenous children are significant and may be increasing. A 1999 Indian Health Services (IHS) survey of 2663 American Indian/Alaskan Native (AI/AN) children between 2 and 5 years of age revealed that 68% had untreated decay, which is more than 3 times greater than the rate found in children from the National Health and Nutrition Examination Survey (19%).[7] The same survey revealed that 60% of preschool-aged AI/AN children had severe ECC constituted by decay on a maxillary incisor or 6 or more decayed teeth. When compared with a similar survey in 1991, a statistically significant increase in the number of decayed, missing, and filled teeth was found in AI/AN children.[7]

One of the major consequences of more severe ECC is the need for pediatric dental surgery under general anesthesia with the related economic burdens of health care fees and transportation and accommodation costs for families from remote communities to urban centers.[8] In addition to the potential health risks of general anesthesia, the benefits of rehabilitative treatment under general anesthesia may be short-lived, because relapse and recurrent decay are common if proper oral hygiene behaviors are not maintained postoperatively.[9,10] The reliance on and necessity for operative treatment of ECC is evidenced by the fact that pediatric dental surgery is the most common outpatient surgical procedure in many Canadian pediatric hospitals,[11] and wait times are substantial.[12,13] Results of recent studies also suggest that a significant number of First Nations children with dental caries require repeat dental procedures under general anesthesia.[6]

RISK FACTORS FOR ECC

There are a multitude of risk factors associated with ECC; however, the single greatest risk factor for ECC is being poor.[14] Unfortunately, Indigenous children in the United States and Canada face poverty rates more than double those of the general population; approximately 52% of Canadian First Nations children live in poverty,[15,16] and 36% of US AI/AN children overall and up to 60% of children of single parents who reside on reservations live in poverty.[17]

The infectious disease model of caries indicates the influence of poverty, household crowding, family size, nutrition, health behaviors, parenting practices, and other risk factors. An association is found between parents' oral health status and the oral health status of their infants.[18] Dietary factors influence the availability of fermentable carbohydrates required for caries formation but also influence host susceptibility, because primary tooth enamel development is influenced by prenatal and early infant nutrition.[19] Among American Indigenous populations, ECC has been found to be associated with parenting practices such as prolonged use of the bottle or training cups with sugar-containing drinks and a high frequency of sugary snacks per day.[19–23] Environmental tobacco smoke and maternal smoking status also have been associated with increased risk of caries among children.[24,25]

PREVENTION STRATEGIES

Restorative or surgical treatment of ECC is challenging and costly for children, but especially so for those from remote communities, and is unlikely to solve dental disease in Indigenous communities. Disease prevention is likely to be the most cost-effective alternative and the best long-term solution to oral health problems in these communities.[26] Primary prevention of dental disease not only preserves healthy teeth but also decreases the current tremendous demand for restorative and surgical care. With ECC being a result of the interplay of oral bacteria, substrate, and host as well as family, economic, and social conditions, health-promotion strategies that emphasize community development and address the determinants of health are required along with strategies that focus on disease prevention.[27,28] This will take collaboration among Indigenous communities; dental, primary care, and public health practitioners; and decision-makers, policy-makers, and researchers involved with young children.

Oral Health Promotion

Oral health promotion, like overall health promotion, should be part of a total healthy-living strategy, because many health disparities have similar underlying issues, such as socioeconomic challenges, food availability and costs of nutritious choices in remote communities, exposure to environmental tobacco smoke, and unacceptably low rates of breastfeeding and nutritious food awareness, access, and availability.

Disease Prevention

The first dental experience for many Indigenous children is for dental treatment resulting from caries rather than for preventive care. In fact, regular dental visits are not the norm for many Indigenous children.[29] Perceptions that deciduous teeth are not important and the acceptance that ECC and dental surgery are inevitable parts of childhood can be a barrier to adopting available prevention strategies.[29,30] These barriers may be reduced by increasing awareness of the importance of oral health to the overall well-being of the child; of the consequences of poor oral health, including the risks of general anesthesia; and that ECC is a potentially preventable disease.

ECC prevention should start during the prenatal period, progress through the perinatal period, and continue with the mother and infant within the context of the family and during preschool programs.[31,32] Given the evidence for vertical transmission of cariogenic bacteria, primarily from mother to child, involving pregnant women in oral health screening, dental treatment, and education on oral health hygiene and bolstering their nutrition along with the use of fluoride toothpaste are strategies that can assist in the prevention or delay of ECC.[31] Recent guideline documents support the safety of dental care in pregnancy to reduce or delay ECC in infants.[33–35] Prenatal visits may also provide an opportunity to build awareness of the importance of oral health for mothers and their infants.

Fluoride

Many national and international organizations, agencies, and governments, including the World Health Organization, the US Surgeon General, the Centers for Disease Control and Prevention, Health Canada, the American Dental Association, the American Academy of Pediatric Dentistry, the Canadian Dental Association, the Canadian Academy of Pediatric Dentistry, the American Academy of Pediatrics, and the Canadian Paediatric Society, strongly endorse the use of fluorides for the prevention and control of caries. Fluoride use is recognized by the American Dental Association, American Academy of Pediatric Dentistry, and Canadian Dental Association as a safe and highly effective strategy for preventing and controlling caries.[36–40] Multiple products provide fluoride. Effectiveness may require adherence (eg, toothpastes) or access to dental care or funding (eg, fluoride varnish).

Water fluoridation is seen as effective and inexpensive, does not require daily adherence, and promotes equity, because it benefits everyone regardless of socioeconomic status.[2,41] The World Health Organization has reported that fluoridation has substantial advantages, especially for high-risk groups, when it is culturally acceptable and technically feasible.[42] A recent unpublished study performed in Alaskan communities revealed a reduction in caries of 30% to 50% with community fluoridation, even when other risk factors were accounted for (Michael Bruce, Arctic Investigations Program, Centers for Disease Control and Prevention, verbal communication, June 6, 2009). In North America, there is wide disparity in the access to water fluoridation. It is estimated that 45% of Canadians benefit from access to fluoridated water,[43] whereas in 1998, less than 10% of First Nations people who lived on reservations had access to fluoridated water.[44] In 2006, 69% of US residents were served with community water fluoridation.[45] The role of public controversy in hindering the uptake of water fluoridation in Indigenous communities has not been documented.

Topical fluorides have been found to be effective in preventing caries. A Cochrane Collaboration review revealed that fluoride varnish substantially reduces tooth decay in both primary and permanent teeth.[46] A randomized controlled trial of fluoride varnish offered at least 2 times per year in Indigenous communities in northern Ontario, Canada, revealed an 18% reduction in the 2-year mean caries increment in participating Indigenous children and an adjusted odds ratio for caries incidence of nearly 2 times higher in the control group than in the fluoride-varnish group.[47] Lawrence et al suggested that the costs of fluoride varnish, although small, can be reduced and access could be improved through the expansion of providers of fluoride-varnish applications to include other health workers such as dental hygienists, dental therapists, dental assistants, and primary health care providers such as public health nurses, physician assistants, and other community health workers trained to administer fluoride varnish.[47] In more than 140 Canadian First Nations communities participating in the Children's Oral Health Initiative program, dental professionals and trained aides apply fluoride varnish.[48] Similar initiatives exist in the United States; 37 states provide primary care provider reimbursement for preventive oral health services, including fluoride-

varnish application, to Medicaid-eligible children younger than 3 years during well-child visits (Amos S. Deinard, Department of Pediatrics, University of Minnesota [Minneapolis, MN], verbal communication, November 22, 2009).[49] The application of fluoride varnish at the conclusion of "well-child" visits but before vaccinations at an IHS pediatric clinic was believed to be an effective way of reaching more AI/AN children.[50] IHS considers 4 or more topical applications of fluoride varnish between 9 and 24 months of age as best practice for children involved with Head Start programs.[51]

According to the American Academy of Pediatric Dentistry, the Canadian Dental Association, the American Academy of Pediatrics, and the Canadian Paediatric Society, fluoride supplements are appropriate for children at high risk of dental caries and may be necessary if the patient is not receiving adequate fluoride from other sources such as water and toothpaste.[37–40] Most Indigenous children fit into the high dental-caries-risk category, and few Canadian Indigenous communities have access to fluoridated drinking water. However, adherence can be an issue with supplements, especially by children at greatest risk, and the authors of a recent systematic review of fluoride supplementation concluded that the evidence for the prevention of caries in primary teeth is weak and inconsistent.[52] Health Canada's First Nations and Inuit Health does not recommend fluoride supplementation for First Nations children but instead puts more emphasis on oral hygiene, fluoride varnish, and fluoridated toothpaste (P. Cooney, BDS, Chief Dental Officer, Health Canada [Ottawa, Ontario, Canada], verbal communication, March 23, 2010).[53]

Canadian Dental Association and American Academy of Pediatric Dentistry guidelines support the use of fluoridated toothpaste twice daily; they suggest that children (2–5 years of age in the American Academy of Pediatric Dentistry guideline and 3–6 years of age in the Canadian Dental Association guideline) be assisted during brushing and use a small amount (eg, green pea–sized portion) of fluoridated toothpaste and that infants (younger than 2 years in the American Academy of Pediatric Dentistry guideline and younger than 3 years in the Canadian Dental Association guideline) have their teeth brushed by an adult using a minimal amount or rice grain–sized portion of fluoridated toothpaste, especially for children at high risk of dental caries.[37,38] Because of the high risk of dental caries in Indigenous children, supervised use of fluoridated toothpaste for Indigenous children starting at the first tooth eruption should be encouraged.

Sealants

Sealants have traditionally been used on occlusal tooth surfaces to protect pits and fissures from dental caries. Results of recent reviews have indicated that there is agreement that in populations at high risk of dental caries, such as First Nations and Inuit populations, all children should receive sealants, and some literature supports the placement of sealants on both primary and permanent molars.[54,55] However, the use of sealants for primary teeth may need to be promoted, because some dental professionals consider sealants for permanent teeth only.

ACCESS TO EARLY ORAL HEALTH CARE AND THE ROLE OF PRIMARY HEALTH CARE PROVIDERS

A measure of the geographic and workforce barriers to ECC prevention and care is the 1999 survey of oral health in AI/AN, which revealed that 68% of AI/AN children 2 to 5 years of age had untreated caries, compared with just 19% of US children as a whole.[56] In the face of this ECC epidemic in AI/AN communities, there are severe dental workforce shortages. The ratio of dentists per person is 1:2800 for AI/AN communities compared with the US average of 1:1500.[56] This situation is unlikely to improve in the near future, because the IHS vacancy rate for dentists is higher than it has been for many years and is currently at 24% despite recruitment efforts.[57] Innovative approaches for recruitment and human resource planning is required, including the expanded roles of other members of the dental health team and other primary care providers in oral health with a focus on the delivery of preventive strategies.

A number of professional associations, including the American Academy of Pediatric Dentistry, the Canadian Dental Association, the American Academy of Pediatrics, and the Canadian Paediatric Society, have called for comprehensive dental health care through dentists and an oral health examination for infants within 6 months after the first tooth erupts or by 12 months of age.[58,59] A lack of access to dental care contributes to the oral health disparities experience by AI/AN[60] and Canadian Indigenous children. Unfortunately, many dentists and primary care providers are still unaware of these new recommendations or are hesitant to examine and treat very young patients because of inadequate education or training, which limits its access to early preventive care by high-risk populations.[61] Inadequate numbers of dentists and the challenges of recruiting and retaining dentists in IHS clinics, tribal health facilities, and remote Indigenous communities cause significant issues for access. In some Indigenous communities, other members of the oral health team provide components of a comprehensive oral health program

supported by dentists. Health Canada supports training and utilization of dental therapists for First Nations communities.[48] Dental therapists are commonly used in northern communities in some Canadian provinces and territories, and more recently, a dental health aide program has evolved in Alaska. The effective use of appropriate dental health aides is seen by some in the American Dental Association as key to improving the oral health of Alaska Native people,[26] but there is some disagreement on the extent of the roles and scope of practice of the various types of dental health aides.

Primary care providers (eg, pediatricians, family physicians, nurse practitioners, community health nurses, physician assistants) in various Indigenous communities in North America are in unique positions to complement the work of dental health professionals. These health care providers often are afforded the opportunity to examine young children long before they are seen by dental personnel. In many Indigenous communities, well-infant, infant health, and immunization clinics are provided on a regular basis through community health nurses and physicians. These providers have an opportunity to emphasize the importance of good oral health practices as part of their overall health-promotion activities. In addition, they may be able to provide oral health screening for infants and young children and arrange referrals to dental health professionals. The American Academy of Pediatrics, through its Oral Health Initiative, has developed training programs for children's oral health to integrate these concepts into routine pediatric care.[62] This training helps complement the current American Academy of Pediatrics policy statements on oral health for children.[39,58]

ORAL HEALTH RECOMMENDATIONS FOR INDIGENOUS COMMUNITIES*

Clinical Care

- ECC should be considered an infectious disease that is influenced by a variety of factors including socioeconomic conditions, parenting practices, and maternal and infant nutrition.
- Early childhood oral health should be included as part of overall childhood health and well-being.
- Oral health should be discussed during well-child care visits by using motivational interviewing and anticipatory guidance on oral hygiene and diet for the parents and caregivers of infants and children.
- Supervised twice-daily use of fluoridated toothpaste should be promoted for all Indigenous and other high-risk children after the first tooth has erupted (rice grain–sized portion of toothpaste for infants and pea-sized portion for children).
- Community health nurses, family physicians, or pediatricians should perform oral health screening during early childhood health assessments and provide referrals as needed to dental health providers.
- Women in Indigenous communities should be provided the access to receive preconception and prenatal screening for oral health, anticipatory guidance for oral health and hygiene, and referral for dental care if required.
- Primary care providers should be aware of the access to fluoride in the drinking water for the various Indigenous communities in their service area.

*See Appendices 1–3 for evidence grades for the recommendations.

Community-Based Promotion Initiatives

- Change should be promoted in Indigenous communities to alter practices of frequent consumption of sugar-containing drinks and sugary snacks through education and improving the selection of foods available in the communities.
- Community-based activities should be used to emphasize the importance of oral health for the pregnant woman and her infant(s).

Workforce and Access Issues

- Early access to dental health professionals (to establish a dental home) should be provided by 12 months of age to provide the full range of oral health-promotion and interceptive disease-prevention services.
- All Indigenous children should have access to the evidence-based schedule for fluoride varnish and an assessment to determine the need for sealant placement on deep grooves and fissures on primary teeth. Alternative health or child care professionals and dental auxiliaries (or trained lay child care workers such as early childhood development workers) should be used to ensure access to fluoride-varnish programs. Fluoride varnish can be provided as part of a regular child health clinic program (well or sick visit) by trained health auxiliaries, community health workers, family physicians, or pediatricians. When specific programs are available, participation should be encouraged.
- Oral health services should be provided to pregnant women in Indigenous communities to get their teeth cleaned and examined and to have any needed periodontal and dental work performed before their infant is born.
- Roles that other dental health and primary health care providers can

assume should be considered in areas where it is difficult to recruit and retain an adequate number of dentists to provide oral health services and promote an early dental visit by the first year of life.

- Adequate cultural competency training opportunities should be provided for dentists, dental hygienists, therapists, and assistants to work in Indigenous communities. Advocate for increased representation of Indigenous people in oral health professions.
- Oral health training should be incorporated into pediatric and family medicine residency programs.

Advocacy

- Indigenous communities should be provided with information on water fluoridation, and opportunities for fluoridation (capital and maintenance costs and training for operators) of the community drinking water should be advocated within and for Indigenous communities.
- Appropriate funding for access to fluoride-varnish programs and for other oral health prevention and treatment services to Indigenous populations should be advocated.

Research

- Further community-based participatory research on the epidemiology, prevention, management, and microbiology of ECC in Indigenous communities and ECC-prevention projects should be supported.

ACKNOWLEDGMENTS

This positionpaper was developed collaboratively between the American Academy of Pediatrics and the Canadian Paediatric Society. We thank Rebecca L. Slayton, DDS, PhD, Rocio Quinonez, DMD, MS, MPH, FRCDC Michael J. Young, MD, and Peter Cooney, BDS, LDM, DDPH, MSc, FRCDC for reviewing the statement.

APPENDIX 1 Levels of Evidence and Grade of Recommendations for Individual-Level "Clinical/Prevention" Recommendations

Recommendation	US Preventive Services Task Force[63]		Canadian Task Force on Preventive Health Care[64]	
	Grade	Level of Certainty	Grade	Level of Evidence
Use motivational interviewing and anticipatory guidance on oral hygiene and diet for the parents and caregivers of infants and children	B	Moderate	B	II-3
Promote the supervised use of fluoridated toothpaste for all Indigenous and other high-risk children after the first tooth has erupted ("smear" of toothpaste for infants and pea-sized amount for children)	A	High	A	I
Community health nurses, family physicians, or pediatricians should perform oral health screening during child health assessments and provide referrals as needed to dental health providers	B	Moderate	B	II-3
Provide women with preconception and prenatal screening for oral health, anticipatory guidance for oral health and hygiene, and referral for dental care if required	B	Moderate	B	I
Ensure that all Indigenous children have access to (1) the series of fluoride varnish and (2) an assessment to determine the need for sealant placement on deep grooves and fissures	A A	Moderate High	A A	II-1 I

APPENDIX 2 Grades of Recommendations

Grade	US Preventive Services Task Force[63]	Canadian Task Force on Preventive Health Care[64]
A	High certainty that the net benefit is substantial	Good evidence to recommend
B	High certainty that the net benefit is moderate or there is moderate certainty that the net benefit is moderate to substantial.	Fair evidence to recommend
C	Recommends against routinely providing the service. There may be considerations that support providing the service in an individual patient. At least moderate certainty that the net benefit is small.	Existing evidence is conflicting and does not allow to make a recommendation for or against; however, other factors may influence decision-making.
D	Recommends against the service. Moderate or high certainty that the service has no net benefit or that the harms outweigh the benefits.	Fair evidence to recommend against the action.
I	Current evidence is insufficient to assess the balance of benefits and harms. Balance of benefits and harms cannot be determined.	Insufficient evidence (in quantity or quality) to make a recommendation; however, other factors may influence decision-making.

APPENDIX 3 Levels of Evidence/Certainty Regarding Net Benefit

US Preventive Services Task Force[63]		Canadian Task Force on Preventive Health Care[64]	
Level of Certainty	Description	Level of Evidence	Description
High	Evidence usually includes consistent results from well-designed, well-conducted studies in representative primary care populations. These studies assess the effects on health outcomes. This conclusion is unlikely, therefore, to be strongly affected by the results of future studies.	I	Evidence obtained from at least 1 properly randomized trial
Moderate	The evidence is sufficient to determine the effects of the service on health outcomes, but confidence in the estimate is constrained by factors such as Number, size, or quality of studies Inconsistency of findings across studies Limited generalizability of findings Lack of coherence in the chain of evidence As more information becomes available, the magnitude or direction of the observed effect could change, and this change may be large enough to alter the conclusion	II-1 II-2 II-3	Evidence obtained from well-designed controlled trial without randomization Evidence obtained from well-designed cohort or case-controlled analytic studies, preferably from >1 center or research group Evidence obtained from comparisons between times and places, with or without the intervention; dramatic results in uncontrolled experiments could also be included in this category
Low	The available evidence is insufficient to assess effects on health outcomes. Evidence is insufficient because of Limited number or size of studies Important flaws in study design/methods Inconsistency of findings across studies Gaps in the chain of evidence Findings not being generalizable Lack of information on important health outcomes More information may allow estimation of effects of health outcomes.	III	Opinions of respected authorities based on clinical experience, descriptive studies, or reports of expert committees

Section on Cardiology

Echocardiography in Infants and Children

ABSTRACT. It is the intent of this statement to inform pediatric providers on the appropriate use of echocardiography. Although on-site consultation may be impossible, methods should be established to ensure timely review of echocardiograms by a pediatric cardiologist. With advances in data transmission, echocardiography information can be exchanged, in some cases eliminating the need for a costly patient transfer. By cooperating through training, education, and referral, complete and cost-effective echocardiographic services can be provided to all children.

Advances in echocardiography, including the introduction of Doppler and color flow mapping, have provided prompt, detailed, and noninvasive diagnoses of cardiac disorders. Although performance of echocardiographic studies in adults is fairly straightforward, the nearly infinite variety of cardiovascular abnormalities in the infant and child make similar studies in infants and children much more difficult to perform and interpret.

Although echocardiographic equipment is now available in nearly all communities in the United States, many areas do not have pediatric cardiologists. Additionally, many community hospitals can treat neonates with mild or moderate respiratory disease, but lack facilities and personnel to treat children with cardiac diseases. Transfer to a tertiary care center may be costly and disruptive to the family, but may be life-saving. The challenge is to bring the technology and expertise to the community hospital and to assure prompt transfer of the infant with life-threatening congenital heart disease but to avoid unnecessary transfers.

The American Academy of Pediatrics' 1995 policy statement with regard to access to pediatric subspecialty services states that: "When the services of a physician specialist or other health care professional are needed by children, plans should use providers with appropriate pediatric training and expertise. Pediatric-trained medical and surgical specialists should have completed an appropriate fellowship in their area of expertise and be certified by subspecialty boards in a timely fashion if certification is available."[1] In virtually all parts of the country, pediatric cardiologists are available by telephone to help guide the application of diagnostic studies and to aid in their interpretation. Should congenital heart disease be indicated by echocardiographic findings, a physician specifically trained in pediatric cardiology should be consulted. In emergency situations, data can be exchanged by telephone or fax. Within a few hours' time, videotapes can be delivered by courier. Telephone transmission of diagnostic images such as an echocardiogram can now be accomplished.

Interpretation of echocardiographic studies is highly dependent on appropriate and thorough collection of data by the ultrasound technologist. Although most community hospitals have sonographers skilled in performing echocardiographic studies in adults, these sonographers usually have little training or experience in performing studies in infants and children with serious congenital heart disease. Sonographers based in community hospitals face several logistical problems when placed in the position of needing further pediatric training and experience. These problems consist of time away from their community hospital, funding for training, and educational commitment from their community hospitals and from a training center. These problems can be solved if all involved parties (sonographer, community hospital, community-based pediatricians, and tertiary pediatric cardiology care centers) work together.

The American Academy of Pediatrics encourages all parties involved in providing pediatric cardiology care to establish linkages among themselves to ensure prompt, cost-effective administration of quality echocardiographic services.

Education of Children With Human Immunodeficiency Virus Infection

ABSTRACT. Treatment for human immunodeficiency virus (HIV) infection has enabled more children and youths to attend school and participate in school activities. Children and youths with HIV infection should receive the same education as those with other chronic illnesses. They may require special services, including home instruction, to provide continuity of education. Confidentiality about HIV infection status should be maintained with parental consent required for disclosure. Youths also should assent or consent as is appropriate for disclosure of their diagnosis.

ABBREVIATIONS. HIV, human immunodeficiency virus; AIDS, acquired immunodeficiency syndrome; CNS, central nervous system; IDEA, Individuals With Disabilities Education Act; IFSP, Individual Family Service Plan; IEP, Individualized Education Program; AAP, American Academy of Pediatrics.

Asymptomatic children with human immunodeficiency virus (HIV) infection cannot be distinguished from children without infection, and their educational opportunities should be the same as other children. Children and youths with HIV infection should not be excluded from school or isolated within the school setting.[1] The spread of HIV infection in school has not been documented, and fear of its communicability must be allayed by appropriate education of all school personnel. Participation in school provides a sense of normalcy for children and adolescents with HIV infection and offers opportunities for socialization that are important to their development. School attendance promotes a sense of belonging and reduces feelings of isolation and rejection.[2] Those with HIV infection should participate in all activities in school[3,4] to the extent that their health permits, which includes a spectrum of illness ranging from no symptoms to acquired immunodeficiency syndrome (AIDS). The need to exclude children or youths with HIV infection from school to protect their own health is unusual. Such a decision should be made by the physician in consultation with the child's parent or caregiver.

HIV INFECTION AND DEVELOPMENTAL DELAY

The majority of children with HIV infection reaching school age have normal cognitive function.[5–8] When symptoms develop in a child or adolescent with HIV infection, central nervous system (CNS) dysfunction can occur and cause a decrease in cognitive function followed by a decline in academic performance. Controlled clinical trials of antiretroviral therapy have shown improved neurodevelopmental function in symptomatic children.[9] Clinical trials have also shown that with different antiretroviral therapy, CNS disease occurs at different rates, indicating that optimal therapy can delay or prevent CNS dysfunction.[9] The pediatrician should ensure that initiation of developmental testing, evaluation of CNS function, and appropriate referral of children and youths to early intervention and special education programs are the same as for children and youths with other chronic illness that can require such services. Physical education programs suitable for the needs of the developmentally disabled or chronically ill child, including those with HIV, should be available.

FEDERAL DISABILITIES RIGHTS LAWS

Important protections exist for children and adolescents with disabilities including HIV infection. Several laws have been enacted to improve the availability of services in schools to assist children with special health care needs to benefit optimally from education.[10] The pediatrician should be familiar with federal disabilities rights laws.

The Individuals With Disabilities Education Act (IDEA), as reauthorized in 1997, is an outgrowth of the Education of All Handicapped Children Act of 1975 (PL 94-142) and the Education of the Handicapped Act Amendments of 1986 (PL 99-457). IDEA is a federal program that applies to children and youths, ages 3 to 21 years, with developmental disabilities and health impairments. It includes a provision to encourage states to expand opportunities for children younger than 3 years who would be at risk of having substantial developmental delay if they did not receive early intervention services. IDEA guarantees access to needed educational services and provides for related services that may be required to assist a child with a disability to benefit from special education. Related services include transportation, speech pathology, audiology, counseling, physical therapy, and medical services for diagnosis. For persons to be eligible for services under IDEA, their condition, specified by the law, must have the potential to interfere with the educational process and normal school performance and requires special educational-related services.

For infants and toddlers birth to age 3 years with disabilities, an annual Individual Family Service Plan (IFSP), which is a component of IDEA, is developed

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

to provide early intervention services. For children and youths 3 to 21 years of age who require special assistance, schools must prepare an Individualized Education Program (IEP) and update it annually. The IEP sets out a plan for special education and related services to meet the child's education goals. The plan is designed by a multidisciplinary team that includes the student's parent(s), regular education teacher, special education teacher, a representative of the school administration, and, when appropriate, the student. Ideally, the IEP team may include the pediatrician and school nurse who are knowledgeable about the student's condition.

Section 504 of the Rehabilitation Act of 1973 is available for any children or adolescents with special health care needs and is applicable to those who do not require special education instruction. It provides the legal support for education in regular classes with the use of supplementary services including medical, nursing, psychological, physical, and occupational therapies.

The Americans With Disabilities Act also provides children and youths with disabilities certain protections by ensuring that schools and school programs are available and accessible. For example, this act mandates wheelchair-accessible buildings.

HIV MANAGEMENT IN THE SCHOOL SETTING

School personnel must be educated about HIV disease and the potential long-term needs of the infected student. All schools should have programs for educating school personnel in standard precautions and in recognition and management of medical emergencies.[11,12] Students with chronic illnesses, including HIV, may need medications administered during the school day and established school procedures should be used.[13] Confidentiality must be ensured. Under optimal circumstances and with parental consent (and student assent when appropriate), the person(s) giving medications should be informed of the student's diagnosis and the side effects associated with the drugs being taken. In the event that the HIV diagnosis is not disclosed to school personnel, only the person(s) directly involved with the provision of medication should be informed of the student's need for medication. Some medications have special requirements, such as increased fluid requirements. Appropriate access to fluid and bathroom privileges should occur in response to physician requests.

HOME INSTRUCTION

Children and youths with symptomatic HIV infection or other chronic illnesses may be absent from school and need home instruction sporadically until the illness improves, or may require other special school arrangements including permanent home instruction when the disease progresses. The policy on home instruction published by the American Academy of Pediatrics (AAP) provides guidelines for reference, and schools must meet the requirements and Section 504 of the Rehabilitation Act of 1973, the Americans With Disabilities Act of 1990, and IDEA.[14] Home instruction should be provided promptly under IDEA guidelines through the special education coordinator working with the school medical advisor and the student's physician. The student's physician should help parents to facilitate the transition between school and other special arrangements, including home instruction.

The student's ability to continue his or her education may diminish as disease progresses, and anger, withdrawal, or depression can be present. The school should continue to work with the medical system to assist the family with counseling and emotional support. The school may also assist other students to a better understanding of chronic illness and how to be supportive of their classmates. Although family disruption and community rejection occur for students with HIV infection, they are more common in families who may need assistance from school mental health personnel.

CONFIDENTIALITY

As long as disclosure of HIV infection can stigmatize students and families, confidentiality is important. The need to safeguard the rights of the student must be balanced with information essential to the school to educate the students and faculty. The primary responsibility of the pediatrician is to care for the child or youth and the family. Disclosure of the child's HIV status should be done only with the consent of the parents and age-appropriate assent of the student. Some families may not permit disclosure, which should not prohibit the student from attending school. Also, some HIV-infected children who attend school have not had their conditions diagnosed. An effective HIV/AIDS education program for school personnel provides accurate information about HIV infection and its transmission. This education should provide reassurance to school personnel and a more accepting environment for the HIV-infected student.[11]

EXPOSURE TO ILLNESS

Specific immunization requirements as recommended by the AAP[2] are designed to be applicable to HIV-infected children and youth. General immunization requirements for healthy children are also available in the *1997 Red Book*. These immunization requirements are designed to protect all children and adolescents and should be rigorously enforced to reduce risk of exposure to vaccine-preventable illnesses. Parents should be informed when measles or varicella is occurring in the school setting.[1] Parents of children and youths at increased risk of developing severe illnesses should consult their physician.

CONCLUSION

Transmission of HIV from mother to child has been significantly decreased with treatment, resulting in fewer HIV-infected children entering preschool and kindergarten. The advent of early aggressive antiretroviral therapy has prolonged the number of years that children can attend school,[15] enabling many to continue their education through high school and perhaps higher education. An understanding by school personnel of chronic illness man-

ifestations attributable to HIV infection is essential for providing appropriate educational programs.

RECOMMENDATIONS

1. All children and youths with HIV infection should have the same right as those without infection to attend school and receive high-quality educational services.
2. Children and youths with HIV infection should have access to special education and other related services in accord with their needs as the disease progresses.
3. Mechanisms for administration of medications, including confidential methods for HIV infection, should be in place in all schools. This includes appropriate facilitation of specific needs for fluids or bathroom privileges.
4. Continuity of education must be ensured for children and adolescents with HIV infection and encompasses the spectrum of traditional school, medical day treatment programs, and home schooling.
5. Confidentiality of HIV infection status should be respected and maintained, with disclosure given only with the consent of the parent(s) or legal guardian(s) and age-appropriate assent of the student.
6. The pediatrician/medical home provider should maintain appropriate communication with the school to facilitate the education of children in their care.

CLINICAL REPORT

Effects of Early Nutritional Interventions on the Development of Atopic Disease in Infants and Children: The Role of Maternal Dietary Restriction, Breastfeeding, Timing of Introduction of Complementary Foods, and Hydrolyzed Formulas

Guidance for the Clinician in Rendering Pediatric Care

Frank R. Greer, MD, Scott H. Sicherer, MD, A. Wesley Burks, MD, and the Committee on Nutrition and Section on Allergy and Immunology

ABSTRACT

This clinical report reviews the nutritional options during pregnancy, lactation, and the first year of life that may affect the development of atopic disease (atopic dermatitis, asthma, food allergy) in early life. It replaces an earlier policy statement from the American Academy of Pediatrics that addressed the use of hypoallergenic infant formulas and included provisional recommendations for dietary management for the prevention of atopic disease. The documented benefits of nutritional intervention that may prevent or delay the onset of atopic disease are largely limited to infants at high risk of developing allergy (ie, infants with at least 1 first-degree relative [parent or sibling] with allergic disease). Current evidence does not support a major role for maternal dietary restrictions during pregnancy or lactation. There is evidence that breastfeeding for at least 4 months, compared with feeding formula made with intact cow milk protein, prevents or delays the occurrence of atopic dermatitis, cow milk allergy, and wheezing in early childhood. In studies of infants at high risk of atopy and who are not exclusively breastfed for 4 to 6 months, there is modest evidence that the onset of atopic disease may be delayed or prevented by the use of hydrolyzed formulas compared with formula made with intact cow milk protein, particularly for atopic dermatitis. Comparative studies of the various hydrolyzed formulas also indicate that not all formulas have the same protective benefit. There is also little evidence that delaying the timing of the introduction of complementary foods beyond 4 to 6 months of age prevents the occurrence of atopic disease. At present, there are insufficient data to document a protective effect of any dietary intervention beyond 4 to 6 months of age for the development of atopic disease.

INTRODUCTION

Over the past several decades, the incidence of atopic diseases such as asthma, atopic dermatitis, and food allergies has increased dramatically. Among children up to 4 years of age, the incidence of asthma has increased 160%, and the incidence of atopic dermatitis has increased twofold to threefold.[1] The incidence of peanut allergy has also doubled in the past decade.[2] Thus, atopic diseases increasingly are a problem for clinicians who provide health care to children.

It has been recognized that early childhood events, including diet, are likely to be important in the development of both childhood and adult diseases. This clinical report will review the nutritional options during pregnancy, lactation, and the first year of life that may or may not affect the development of atopic disease. Although

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

atopic diseases have a clear genetic basis, environmental factors, including early infant nutrition, may have an important influence on their development and, thus, present an opportunity to prevent or delay the onset of the disease. This clinical report replaces an earlier policy statement[3] from the American Academy of Pediatrics (AAP) that addressed the use of hypoallergenic infant formulas and included provisional recommendations for dietary management for the prevention of atopic disease. This report is not directed at the treatment of atopic disease once an infant or child has developed specific atopic symptoms.

DEFINITIONS

The following definitions are used throughout this clinical report (adapted from work by Muraro et al[4]):

Allergy: A hypersensitivity reaction initiated by immunologic mechanisms.

Atopy: A personal or familial tendency to produce immunoglobulin E (IgE) antibodies in response to low-dose allergens, confirmed by a positive skin-prick test result.

Atopic disease: Clinical disease characterized by atopy; typically refers to atopic dermatitis, asthma, allergic rhinitis, and food allergy. This report will be limited to the discussion of conditions for which substantial information is available in the medical literature.

Atopic dermatitis (eczema): A pruritic, chronic inflammatory skin disease that commonly presents during early childhood and is often associated with a personal or family history of other atopic diseases.

Asthma: An allergic-mediated response in the bronchial airways that is verified by the variation in lung function (measured by spirometry) either spontaneously or after bronchodilating drugs.

Cow milk allergy: An immunologically mediated hypersensitivity reaction to cow milk, including IgE-mediated and/or non—IgE-mediated allergic reactions.

Food allergy: An immunologically mediated hypersensitivity reaction to any food, including IgE-mediated and/or non—IgE-mediated allergic reactions.

Hypoallergenic: Reduced allergenicity or reduced ability to stimulate an IgE response and induce IgE-mediated reactions.

Infants at high risk of developing allergy: Infants with at least 1 first-degree relative (parent or sibling) with documented allergic disease.

The following definitions are from various industry sources:

Partially hydrolyzed (PH) formula: Contains reduced oligopeptides that have a molecular weight of generally less than 5000 d (Table 1).

Extensively hydrolyzed (EH) formula: Contains only peptides that have a molecular weight of less than 3000 d (Table 1).

Free amino acid—based formula: Peptide-free formula that contains mixtures of essential and nonessential amino acids (Table 1).

TABLE 1 **Examples of Hydrolyzed Protein and Amino Acid–Based Infant Formulas Available in the United States**

Extensively hydrolyzed casein (cow milk protein)
Enfamil Nutramigen Lipil (Mead Johnson Nutritionals, Evansville, IN)
Enfamil Pregestimil (Mead Johnson Nutritionals)
Similac Alimentum Advance (Ross Products, Columbus, OH)
Partially hydrolyzed whey (cow milk protein)[a]
Good Start Supreme (Nestlé USA, Glendale, CA)
Partially hydrolyzed whey/casein (cow milk protein)[a]
Enfamil Gentlease Lipil (Mead Johnson Nutritionals)
Partially Hydrolyzed Soy (Soy Protein)
Good Start Supreme Soy (Nestlé USA)
Free amino acid–based
Neocate (and Neocate 1+ for children >12 mo) (Nutricia North America, Gaithersburg, MD)
EleCare (Ross Pediatrics)

[a] For infants with known cows milk allergy, the residual milk protein peptides in these formulas may cause an allergic reaction.

DIETARY RESTRICTIONS FOR PREGNANT AND LACTATING WOMEN

The earliest possible nutritional influence on atopic disease in an infant is the diet of the pregnant woman. However, studies generally have not supported a protective effect of a maternal exclusion diet (including the exclusion of cow milk and eggs) during pregnancy on the development of atopic disease in infants, as summarized in a 2006 Cochrane review.[5–10] Although previous AAP publications have suggested that pregnant women avoid peanuts,[3,11] a more recent study has reported that there is no association between the maternal consumption of peanuts during pregnancy and childhood peanut allergy.[12] Previous AAP publications have advised lactating mothers with infants at high risk of developing allergy to avoid peanuts and tree nuts and to consider eliminating eggs, cow milk, and fish from their diets while nursing.[3,11] Dietary food allergens can be detected in breast milk, including peanuts, cow milk protein, and egg.[13–15] Two studies found a preventive effect of maternal dietary exclusion of milk, egg, and fish while breastfeeding on the development of atopic dermatitis in the infant.[16,17] Other studies found no association between the development of atopic diseases and a maternal exclusion diet.[8,18,19] A 2003 study found no association between breastfeeding and peanut allergy, and there was no difference in peanut intake during lactation between mothers with and without children with peanut allergy.[12] Dietary food allergens in human milk may interact with the mucosal immune system[20] and induce allergic reactions in infants who are known to be clinically allergic to the antigen. Rare cases of anaphylaxis to cow milk protein present in human milk have been described even in exclusively breastfed infants.[21]

Consideration of a large number of studies on maternal diet, not all of which were randomized or included dietary restriction during lactation, demonstrated no impact on various outcomes among the majority of the studies, particularly when follow-up was beyond 4 years, and led one recent group of reviewers to conclude that there is no convincing evidence for a long-term preventive effect of maternal diet during lactation on

atopic disease in childhood.[22] A 2006 Cochrane review also concluded that there was insufficient evidence that antigen avoidance during lactation was beneficial in preventing atopic disease in the breastfed infant, with the exception of atopic dermatitis.[5] Because the available published trials have had methodologic shortcomings, more data are necessary to conclude that the avoidance of antigens during lactation prevents atopic dermatitis in infants.[5]

ROLE OF HUMAN MILK AND EXCLUSIVE BREASTFEEDING ON THE DEVELOPMENT OF ATOPIC DISEASE

Since the 1930s, many studies have examined the benefits of breastfeeding on the development of atopic disease. In general, these have been nonrandomized, retrospective, or observational in design and, thus, inconclusive.[22,23] Of course, it is not possible to truly randomize breastfeeding, which is always a confounding variable in these studies. Acknowledging this difficulty, Kramer[23] proposed 12 criteria to apply to studies designed to assess the relationship between atopic disease and breastfeeding. These criteria included nonreliance on late maternal recall of breastfeeding, sufficient duration of exclusive breastfeeding, strict diagnostic criteria for atopic outcomes, assessment of effects of children at high risk of atopic outcomes, and adequate statistical power. Unfortunately, no studies to date have completely fulfilled these criteria.

Atopic Dermatitis

A 2001 meta-analysis of 18 prospective studies compared the incidence of atopic dermatitis in infants who were breastfed versus infants who were fed cow milk formula.[24] Overall, there was a protective effect of exclusive breastfeeding for 3 months (odds ratio [OR]: 0.68; 95% confidence interval [CI]: 0.52–0.88), the stronger effect having been shown for infants with a family history of allergy (OR: 0.58; 95% CI: 0.4–0.92). No protective effect of breastfeeding was seen in children who were not at risk of developing allergy (OR: 1.43; 95% CI: 0.72–2.86).[24] A 2005 study published from Sweden[25] found no effect of exclusive breastfeeding for ≤4 months on the incidence of atopic dermatitis in the first year of life with or without a family history of atopic disease. On the other hand, another 2005 study from Sweden[26] found that exclusive breastfeeding for more than 4 months reduced the risk of atopic dermatitis at 4 years of age (OR: 0.78; 95% CI: 0.63–0.96) with or without a family history of allergy. In their review, Kramer and Kakuma[27] also found no benefit of exclusive breastfeeding beyond 3 months of age on the incidence of atopic dermatitis in studies in which parents were not selected for risk of allergy.

A series of recent reports from the German Infant Nutritional Intervention Program[28–30] also found that breastfeeding reduces the incidence of atopic dermatitis, supporting the results of the meta-analysis.[24] In the interventional arm of this study, 1834 newborn infants identified as being at high risk of developing atopic disease were enrolled in a 3-year longitudinal, prospective study. Breastfeeding infants at risk for atopic disease were enrolled in the study before 14 days of life and, at that time, were exclusively breastfed and had no history of formula supplementation. Infants were randomly assigned at the time of entry to receive supplements of 1 of 3 hydrolyzed formulas (2 extensively hydrolyzed formulas and 1 partially hydrolyzed formula) or a cow milk formula, if formula supplementation had begun. Eight hundred eighty-nine mothers exclusively breastfed for 4 months and did not use any of the formula supplements they were randomly assigned to use. Nine hundred forty-five infants were introduced to the randomly assigned formula before 4 months and, thus, were not exclusively breastfed. Of these, 689 infants were randomly assigned to receive one of the hydrolyzed formulas, and 256 were randomly assigned to receive cow milk formula. The incidence of atopic dermatitis in infants who were exclusively breastfed, breastfed with supplemental hydrolyzed formula, and breastfed with supplemental cow milk formula was 9.5%, 9.8%, and 14.8%, respectively, at the 1-year follow-up.[28–30] Thus, exclusive breastfeeding for 4 months showed a positive effect compared with breastfeeding with supplemental cow milk formula in these infants at high risk of developing allergy. Breastfeeding with supplemental hydrolyzed formula (both partially and extensively hydrolyzed) also showed a positive effect compared with breastfeeding with supplemental cow milk formula; however, breastfeeding with supplements of hydrolyzed formulas showed no advantage compared with exclusive breastfeeding. Both groups showed a one-third decrease in the risk of atopic dermatitis compared with the risk of breastfeeding with supplements of cow milk formula. Thus, exclusive breastfeeding or breastfeeding with hydrolyzed formula is not enough to prevent the majority of cases of atopic dermatitis.

The advantages of breastfeeding are less clear for infants who are not selected for high risk of developing atopic disease, as shown in the noninterventional arm of the German Infant Nutritional Intervention Program.[28] In this arm, mothers unselected for a history of atopy who either formula fed or partially breastfed their infants were free to select cow milk–based or hydrolyzed formulas. No differences in the incidence of atopic dermatitis occurred among the 3 groups of infants (exclusively breastfed for 4 months, cow milk formula fed with or without breastfeeding, and hydrolyzed formula fed with or without breastfeeding). This lack of effect has been attributed to reverse causation; thus, mothers who knew that their infants were at risk of developing allergy were more likely not only to breastfeed but also to breastfeed for a longer period of time. Alternatively, mothers who were not going to breastfeed or were going to supplement with formula were more likely to choose hydrolyzed formula if they believed that their children were at risk of developing atopy. This reverse causation effect may explain why some studies have found an increased incidence of atopic dermatitis in breastfed infants.[31–33]

In summary, for infants at high risk of developing atopy, there is evidence that exclusive breastfeeding for at least 4 months or breastfeeding with supplements of

hydrolyzed infant formulas decreases the risk of atopic dermatitis compared with breastfeeding with supplements of standard cow milk–based formulas. On the basis of currently available evidence, this is less likely to apply to infants who are not at risk of developing atopy, and exclusive breastfeeding beyond 3 to 4 months does not seem to lead to any additional benefit in the incidence of atopic eczema.[27]

Asthma

The evidence for the protective effects of human milk on the development of asthma is more controversial. A 2001 meta-analysis of 12 prospective studies that met preestablished criteria found that exclusive breastfeeding for at least 3 months was protective against the development of asthma between 2 and 5 years of age (OR: 0.70; 95% CI: 0.60–0.81).[34] The effect of breastfeeding was even stronger when the analysis was limited to children from families with a history of atopic disease (OR: 0.52; 95% CI: 0.35–0.79). No benefit was seen in children from families without a history of atopic disease (OR: 0.99; 95% CI: 0.48–2.03).[34] Two more studies[35,36] not included in this meta-analysis supported these results. On the other hand, a 2002 Cochrane review found no benefit of exclusive breastfeeding beyond 3 months on the incidence of asthma in families not preselected for a history of atopic disease.[27]

Two additional reports in the literature with a more accurate definition of asthma[37,38] made a distinction between the wheezy bronchitis associated with viral infections in younger children and that of the allergic disease seen in older children associated with respiratory spirometric changes. In the first of these studies, a cohort of 1246 children in Tucson, Arizona, was followed from birth to 13 years of age.[37] The study found that an association between breastfeeding and asthma at 13 years of age depended on the presence of maternal asthma in children with atopic disease. Infants whose mothers had asthma were at greatest risk of developing asthma by 13 years of age if they had been breastfed exclusively for ≥4 months (OR: 8.7; 95% CI: 3.4–22.2). When infants with atopic disease whose mothers had asthma were exclusively breastfed for any length of time (either greater than or less than 4 months), the risk of developing asthma between 6 and 13 years of age was also increased (OR: 5.7; 95% CI: 2.3–14.1). An increased risk of developing asthma was not found in breastfed children of mothers without asthma. However, in this same study during the first 2 years of life, exclusive breastfeeding was associated with significantly lower rates of recurrent wheezing of infancy (OR: 0.45; 95% CI: 0.2–0.9), similar to results from a recent study performed in Perth, Australia.[35]

In the second of these studies, a long-term longitudinal study from New Zealand,[38] 1037 children from a general population (not selected for risk of allergic disease) were followed from 3 to 26 years of age. Five hundred four infants were breastfed for 4 weeks or more, and 533 infants were formula fed from the time of birth or breastfed for less than 4 weeks. Breastfeeding for more than 4 weeks significantly increased the risk of developing asthma at 9 years (OR: 2.40; 95% CI: 1.36–4.6) and at 21 years (OR: 1.83; 95% CI: 1.35–2.47). This increased risk was not related to the presence of maternal atopic disease, unlike in the Tucson study. The study has been criticized for retrospective determination of breastfeeding and unclear definitions of atopic heredity.[22] There was also no evidence of a "dose-response" effect of breastfeeding on the incidence of atopy or asthma.

In summary, at the present time, it is not possible to conclude that exclusive breastfeeding protects young infants who are at risk of atopic disease from developing asthma in the long term (>6 years of age), and it may even have a detrimental effect.[37,38] On the other hand, breastfeeding seems to decrease the wheezing episodes seen in younger children (<4 years of age) that are often associated with respiratory infections.[35,36]

Food Allergy

Food allergy, similar to atopic dermatitis and asthma, is more likely to occur in infants with a family history of atopic disease. In a prospective study of infants born to families with a history of atopic disease, it was determined that 25% will develop food allergy between birth and 7 years of age.[39] Because both atopic dermatitis and asthma are closely associated with the development of food allergy, it is difficult to sort out the effect of breastfeeding on the development of food allergy. As reviewed above, maternal dietary exposure during pregnancy and lactation is unlikely to contribute significantly to the development of food allergy in the infant, although many food antigens can be found in human milk. In theory, human milk should inhibit food antigen absorption; however, prospective studies have failed to show a protective effect of human milk–specific antibodies to cow milk on infant sensitization.[40] Investigations of the role of breastfeeding on the outcomes of allergies to specific foods have been few, and the results may have been influenced by additional dietary variables such as length and degree of breastfeeding exclusivity. In reviewing the available studies, Muraro et al[22] concluded that exclusively breastfeeding for at least 4 months in infants who are at risk of developing atopic diseases is associated with a lower cumulative incidence of cow milk allergy until 18 months of age. A Cochrane review included only 1 study with a blinded challenge (using the double-blind, placebo-controlled food-challenge technique) and concluded that at least 4 months of exclusive breastfeeding did not protect against food allergy at 1 year of age.[27] Overall, firm conclusions about the role of breastfeeding in either preventing or delaying the onset of specific food allergies are not possible at this time.

ROLE OF HYDROLYZED FORMULA ON THE DEVELOPMENT OF ATOPIC DISEASE

The role of partially hydrolyzed and extensively hydrolyzed formulas for the prevention of atopic disease has been the subject of many studies in both formula-fed and breastfed infants in the last 15 years. Most studies with published results have been of infants at high risk of developing allergy.

Approximately 100 studies in the literature have examined the role of hydrolyzed formulas on the development of atopic disease. However, using the criteria of a 2006 Cochrane review,[41] only 14 randomized or quasi-randomized (eg, using alternation) trials in term infants compared the use of partially or extensively hydrolyzed formula with the use of human milk or an adapted cow milk formula.[42–55] All of these trials have followed up with at least 80% of study participants. It is important to note that none of these studies reported any adverse effects, including any adverse effect on infant growth. No long-term studies have compared partially or extensively hydrolyzed formula to exclusive breastfeeding. Thus, there is no evidence that the use of these formulas is any better than human milk in the prevention of atopic disease.

Three studies of 251 infants examined the effect of partially hydrolyzed formula on reduction of the occurrence of any allergy compared with cow milk formula in infants at high risk of developing allergy.[49,51,52] Two of these studies found no significant effect,[51,52] and a third study found an OR of 0.45 (95% CI: 0.22–0.94) for partially hydrolyzed formula versus cow milk formula.[49] Three more studies[53–55] examined prolonged feeding of extensively hydrolyzed formula compared with partially hydrolyzed formula in 411 infants at high risk of developing allergy. None of these studies found a significant difference in the incidence of atopic dermatitis between the 2 feeding groups. Two of these studies[53,55] of 352 infants also examined other manifestations of atopic disease and did not show a significant difference in the occurrence of food allergy, cow milk allergy, or asthma between the groups of infants who were fed extensively or partially hydrolyzed formula.

A very large published study from the German Infant Nutritional Intervention Program[30] raised additional issues. In the interventional arm of this study, 945 newborn infants were identified as being at high risk of developing atopic disease and were enrolled in a longitudinal, prospective study through 12 months of age. Although the majority of infants were breastfed initially, formula was introduced in the first 4 weeks to most infants. The infants were randomly assigned to receive 1 of 3 hydrolyzed formulas ($n = 689$) or cow milk formula ($n = 256$). The 3 hydrolyzed formulas were a partially hydrolyzed whey-based formula, an extensively hydrolyzed whey-based formula, and an extensively hydrolyzed casein-based formula. The incidence of atopic dermatitis was significantly reduced in those using the extensively hydrolyzed casein-based formula (OR: 0.42; 95% CI: 0.22–0.79; $P < .007$) and the partially hydrolyzed whey-based formula (OR: 0.56; 95% CI: 0.32–0.99; $P < .046$) but not the extensively hydrolyzed whey-based formula (OR: 0.81; 95% CI: 0.48–1.4; $P < .44$), compared with the incidence in those in the cow milk formula group. However, the overall results for prevention of allergic disease (atopic dermatitis, urticaria, and food allergy) for the 3 hydrolyzed formulas compared with cow milk formula were less impressive (extensively hydrolyzed whey-based: OR: 0.86; 95% CI: 0.52–1.4; partially hydrolyzed whey-based: OR: 0.65; 95% CI: 0.38–1.1; and extensively hydrolyzed casein-based: OR: 0.51; 95% CI: 0.28–0.92; $P < .025$). Thus, this study indicated that different hydrolysates have different effects on atopic disease, and there may be an advantage for the extensively hydrolyzed casein-based formula. However, as the study demonstrated, it is difficult to show that partially hydrolyzed formulas have a very large effect on the reduction of atopic disease in infants who are fed formula or mixed feedings of human milk and formula, even if they are at high risk of developing allergic disease. If atopic disease associated with cow milk allergy has occurred, partially hydrolyzed formula is not recommended, because it contains potentially allergic cow milk peptides.

More studies are needed to determine if any of the hydrolyzed formulas have any effect on the incidence of atopic disease later in childhood and adolescence and whether the modest effects of the use of extensively or partially hydrolyzed formulas in early childhood can be confirmed and are sustained. Such studies should also include a cost/benefit analysis of the use of the more expensive hydrolyzed formulas. It should be noted that the potential benefit of these formulas has only been documented in infants at risk of developing atopic disease. Additional studies are needed among unselected infants or infants at low risk.

The use of amino acid–based formulas for prevention of atopic disease has not been studied. Soy formulas, on the other hand, have a long history of use for atopic disease in infants. In a recent meta-analysis of 5 randomized or quasi-randomized studies, the authors concluded that feeding with soy formula should not be recommended for the prevention of atopy in infants at high risk of developing allergy.[56]

ROLE OF INTRODUCTION OF COMPLEMENTARY FOODS ON ATOPIC DISEASE

Many studies have examined the duration of breastfeeding and its effect on atopic disease. However, few studies have examined the timing of the introduction of complementary foods as an independent risk factor for atopic disease in breastfed or formula-fed infants. An expert panel from the European Academy of Allergology and Clinical Immunology has recommended delayed introduction of solid foods for 4 to 6 months in breastfed or formula-fed infants.[22] The AAP has also recommended that solid foods be delayed until 4 to 6 months of age and that whole cow milk be delayed until 12 months of age.[11] Before publication of this clinical report, AAP recommendations for infants who are at risk of developing atopic disease were to avoid eggs until 2 years of age and avoid peanuts, tree nuts, and fish until 3 years of age.[3,11] These guidelines for solid food introduction and avoidance of specific allergens were based on the evidence of a few studies with various limitations.[39,57–59] Three newer studies have reported mixed results regarding the timing of the introduction of solid foods and development of childhood atopic disease.[60–62]

In a prospective (nonrandomized) study of infants at risk of developing atopic disease by Kajosaari[57], atopic dermatitis and history of food allergy were reduced at 1

year of age if the introduction of solid foods was delayed until 6 months compared with at 3 months of age. However, in a 5-year follow-up study, no difference was seen in the incidence of atopic dermatitis or symptoms of food allergy.[57] In a second prospective study of a birth cohort of 1210 unselected children between 2 and 4 years of age, there was more atopic dermatitis but not asthma in infants who were fed 4 or more solid foods compared with no solid foods before 4 months of age.[58] This difference was maintained in a 10-year follow-up study in 85% of the original study infants.[59]

In a study of 257 preterm infants (34.4 weeks' gestational age; birth weight: 2.3–2.4 kg), the introduction of 4 or more, compared with fewer than 4, solid foods before 17 weeks after term was associated with a higher risk of atopic dermatitis (unconfirmed by skin-prick testing) at 12 months after term (OR: 3.49; 95% CI: 1.51–8.05).[60] Also in this study, the introduction of solid foods before 10 weeks of age or atopic disease in either parent increased the risk of atopic dermatitis in infants (OR: 2.94; 95% CI: 1.57–5.52). In a more recent prospective, longitudinal cohort study in which atopic dermatitis was confirmed by skin testing, 642 infants were followed until 5.5 years of age.[61] The history of the introduction of solid foods was carefully recorded during the first year of life. Most children had at least 1 parent with a positive skin-prick test result. Rice cereal was introduced at a median age of 3 months, milk was introduced at a median age of 6 months, and egg was introduced at a median age of 8 months. However, the later introduction of solids had no effect on the prevalence of asthma or atopic dermatitis (confirmed by skin-prick testing), although there was an increased risk of atopic dermatitis in relation to the late (6–8 months) rather than the earlier introduction of eggs (OR: 1.6; 95% CI: 1.1–2.4) or milk (OR: 1.7; 95% CI: 1.1–2.5).[61]

Finally, an ongoing prospective, cohort study[62] of 2612 infants (without a risk of developing atopic disease) found no evidence to support delayed introduction of solid foods beyond 6 months of age for prevention of atopic disease. However, in the same study, the effect of delayed introduction of solid foods for the first 4 months of life was less clear. Another study has even suggested that children exposed to cereal grains before 6 months of age (as opposed to after 6 months of age) are protected from the development of wheat-specific IgE.[63]

In summary, the evidence from these conflicting studies, in balance, does not allow one to conclude that there is a strong relationship between the timing of the introduction of complementary foods and development of atopic disease. This raises serious questions about the benefit of delaying the introduction of solid foods that are thought to be highly allergic (cow milk, fish, eggs, and peanut-containing foods) beyond 4 to 6 months of age; additional studies are needed.

SUMMARY

It is evident that inadequate study design and/or a paucity of data currently limit the ability to draw firm conclusions about certain aspects of atopy prevention through dietary interventions. In some circumstances in which there are insufficient studies (pregnancy and lactation avoidance diets, timing of introduction of specific complementary foods), the lack of proven efficacy does not indicate that the approach is disproved. Rather, more studies would be needed to clarify whether there is a positive or negative effect on atopy outcomes. The following statements summarize the current evidence within the context of these limitations.

1. At the present time, there is lack of evidence that maternal dietary restrictions during pregnancy play a significant role in the prevention of atopic disease in infants. Similarly, antigen avoidance during lactation does not prevent atopic disease, with the possible exception of atopic eczema, although more data are needed to substantiate this conclusion.
2. For infants at high risk of developing atopic disease, there is evidence that exclusive breastfeeding for at least 4 months compared with feeding intact cow milk protein formula decreases the cumulative incidence of atopic dermatitis and cow milk allergy in the first 2 years of life.
3. There is evidence that exclusive breastfeeding for at least 3 months protects against wheezing in early life. However, in infants at risk of developing atopic disease, the current evidence that exclusive breastfeeding protects against allergic asthma occurring beyond 6 years of age is not convincing.
4. In studies of infants at high risk of developing atopic disease who are not breastfed exclusively for 4 to 6 months or are formula fed, there is modest evidence that atopic dermatitis may be delayed or prevented by the use of extensively or partially hydrolyzed formulas, compared with cow milk formula, in early childhood. Comparative studies of the various hydrolyzed formulas have also indicated that not all formulas have the same protective benefit. Extensively hydrolyzed formulas may be more effective than partially hydrolyzed in the prevention of atopic disease. In addition, more research is needed to determine whether these benefits extend into late childhood and adolescence. The higher cost of the hydrolyzed formulas must be considered in any decision-making process for their use. To date, the use of amino acid–based formulas for atopy prevention has not been studied.
5. There is no convincing evidence for the use of soy-based infant formula for the purpose of allergy prevention.
6. Although solid foods should not be introduced before 4 to 6 months of age, there is no current convincing evidence that delaying their introduction beyond this period has a significant protective effect on the development of atopic disease regardless of whether infants are fed cow milk protein formula or human milk. This includes delaying the introduction of foods that are considered to be highly allergic, such as fish, eggs, and foods containing peanut protein.

7. For infants after 4 to 6 months of age, there are insufficient data to support a protective effect of any dietary intervention for the development of atopic disease.
8. Additional studies are needed to document the long-term effect of dietary interventions in infancy to prevent atopic disease, especially in children older than 4 years and in adults.
9. This document describes means to prevent or delay atopic diseases through dietary changes. For a child who has developed an atopic disease that may be precipitated or exacerbated by ingested proteins (via human milk, infant formula, or specific complementary foods), treatment may require specific identification and restriction of causal food proteins. This topic was not reviewed in this document.

POLICY STATEMENT

Electronic Prescribing Systems in Pediatrics: The Rationale and Functionality Requirements

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Clinical Information Technology

ABSTRACT

The use of electronic prescribing applications in pediatric practice, as recommended by the federal government and other national health care improvement organizations, should be encouraged. Legislation and policies that foster adoption of electronic prescribing systems by pediatricians should recognize both specific pediatric requirements and general economic incentives required to speed the adoption of these systems. Continued research into improving the effectiveness of these systems, recognizing the unique challenges of providing care to the pediatric population, should be promoted.

BACKGROUND

The American Academy of Pediatrics (AAP) is committed to providing the best and safest health care system possible for children.

Statement of Problem

The AAP recognizes that the "increasing complexity in patient care in addition to the public's increased scrutiny of the health care system underscores the need to make patient safety an issue of high priority."[1] The AAP supports national efforts to improve patient safety and the recommendations of the Institute of Medicine, the Institute for Safe Medical Practices, the Leapfrog Group, and others who encourage the implementation and use of electronic prescribing (e-prescribing) by physicians as a method to improve patient safety.[2,3]

New Information

E-prescribing systems reduce transcription errors by eliminating illegible prescriptions. Computerized decision support can ensure that prescriptions are checked for drug-drug and drug-allergy interactions before the prescription is written. Dosage calculators can ensure that the correct dose of medication is given on the basis of patient age and weight, and dose-range checking can alert prescribers when doses outside the predetermined ranges are prescribed. Many e-prescribing systems can also check formulary information to determine if a selected medication is covered by a patient's insurance, thereby decreasing patient drug cost and increasing both patient and physician compliance with insurers' preferred-drug prescription programs.[5–9] Additional information is available in the accompanying technical report on e-prescribing.[4] Research examining the impact of e-prescribing on reducing malpractice claims might result in a commensurate reduction in malpractice

liability insurance. Ongoing research will be needed to study the types of errors that may continue to occur after implementation of these systems, including potential new types of errors introduced by the use of e-prescribing systems. This research will guide refinements and improvements to the effectiveness of these systems.[8,10,11]

SUMMARY/CONCLUSIONS

The AAP believes there is sufficient evidence supporting the ability of e-prescribing systems to prevent medical errors and enhance patient care.[5–9] However, as with any new technology, the use of these systems may have unintended consequences or novel risks that will need to be monitored and studied over time.

RECOMMENDATIONS

1. Federally sponsored research should be conducted to document, in both inpatient and ambulatory (office) settings, specific characteristics of e-prescribing systems that are most beneficial in preventing errors and enhancing patient care. Office processes and methods of implementation that facilitate the effective and efficient use of e-prescribing systems require study.[10,12–14]

   Accurate data on the incidence and scope of prescribing errors, adverse drug events, and near-miss errors must be available. Regulations should be promoted to facilitate no-fault, anonymous adverse drug event reporting systems as an enabling step toward understanding and intervening to prevent medical errors.[1]

2. Because safety for children is paramount, e-prescribing systems used for the care of children should include, at a minimum, pediatric-specific decision support such as weight-based dose calculations and alerts and pediatric drug information and formulation options.[3,7,15–17]

   When possible, e-prescribing systems should be implemented as part of a robust electronic health record. Such implementations offer advantages well beyond those of freestanding e-prescribing systems. When implementing a stand-alone e-prescribing system, thought should be given to the potential future need to transfer data to, or interface the e-prescribing system with, an electronic health record.

3. Federal legislation that would unify state regulations and allow for e-prescribing and digital transmission of all prescriptions directly to pharmacies, including those for controlled drugs, should be encouraged.[18] The AAP furthermore supports legislation that would require all pharmacies, either directly or through a clearinghouse, to accept digitally transmitted and signed prescriptions. The AAP supports a process for the development of standards for the transmission of digital prescriptions, analogous to the standards-development process under the Health Insurance Portability and Accountability Act for electronic data interchange.

4. Despite significant benefits to medical and liability insurers, patients, and pharmacy benefit managers,[19] e-prescribing applications are an office-practice expense that generates a disproportionately small or no pediatric practice revenue; therefore, the AAP believes adoption of e-prescribing technology would be hastened by the offering of incentives such as pay-for-performance bonuses to practices that routinely use e-prescribing systems that incorporate clinical decision-support alerts.

5. Because practitioners in rural or low-income areas may face financial and system barriers and, in many cases, do not have access to the network infrastructure to support e-prescribing systems, federal grant and loan programs should be available to support system enhancements such as Internet access and start-up costs.

IMPLEMENTATION

Recommendations 1 and 5 (federally funded research and federal grants and loans for e-prescribing systems) may be implemented by providing research grants through the National Library of Medicine, the Agency for Healthcare Research and Quality, the Health Resources and Services Administration, and other federal and local agencies.

Recommendation 2 (minimum standards for e-prescribing systems) may be implemented by educating providers before purchase of such systems on the required elements through published reports such as the accompanying technical report.[4] Such reports should also be shared with standards-development organizations to encourage the inclusion of minimum requirements into the development of these standards.

Recommendation 3 (federal legislation on e-prescribing) requires action by the collaborative action of the Drug Enforcement Administration to develop standards for the secure digital transmission of category II controlled substances and enable federal legislation that takes precedence over the restrictions placed by state regulations.

Recommendation 4 (incentives for purchase) should be part of federal and state initiatives to reduce medical errors. Efforts to encourage larger insurers to underwrite such systems should continue—with demonstration projects to document the cost savings to them by the adoption of e-prescribing systems.

TECHNICAL REPORT

Electronic Prescribing Systems in Pediatrics: The Rationale and Functionality Requirements

Robert S. Gerstle, MD, Christoph U. Lehmann, MD, and the Council on Clinical Information Technology

ABSTRACT

This technical report discusses electronic prescribing systems and their limitations and potential benefits, particularly to the pediatrician in the ambulatory setting. In the report we acknowledge the benefits of integrating these systems with electronic health records and practice-management systems and recommend that the adoption of electronic prescribing systems be done in the context of ultimately moving toward an electronic health record. This technical report supports the accompanying American Academy of Pediatrics policy-statement recommendations on the adoption of electronic prescribing systems by pediatricians.

INTRODUCTION

Electronic prescribing (e-prescribing) systems are computer applications designed for use by clinicians to generate paper or electronic medication prescriptions.[1] They offer the clinician and the patient the promise of safer prescribing and improved office efficiencies, 2 major drivers for the adoption of such systems. Many organizations, notably the Institute of Medicine (IOM), the Institute for Safe Medical Practice (ISMP), and the Leapfrog Group,[2] involved in efforts to improve medical quality and reduce medical errors, have endorsed e-prescribing systems as a major tool in reducing medical errors.[3] The American Academy of Pediatrics has recognized that within the hospital, computerized physician order entry (CPOE) can prevent medication errors.[4]

One significant cause of medication errors has been the misinterpretation of physician handwriting. The National Hospital Ambulatory Medical Care Survey suggests that the prescription illegibility rate may be 1% to 2%.[5] Illegible orders may account for 30% of errors.[6]

In their simplest implementation, e-prescribing systems provide printer-generated, easily readable prescriptions that are less likely to be misinterpreted or misread by a pharmacist. The most completely envisioned e-prescribing systems provide extensive decision support to the clinician and offer additional office efficiencies designed to streamline the prescribing and renewal process, facilitate insurance formulary adherence, and improve prescribing safety.[7] This technical report will review the current state of e-prescribing to provide the clinician with an understanding of the subject and to better guide clinician decision-making in the adoption of this technology in the office setting.

CPOE is the component of the clinical information system that allows prescrib-

ers to enter orders (for medications and/or clinical procedures) directly into a computer for electronic processing and transmission to appropriate departments and/or individuals for completion.[8] The most obvious advantages of CPOE include the immediate transmission of orders without further transcription or delay to (usually) hospital departments, which eliminates transcription errors by nurses and speeds the health care–delivery process. Most research on CPOE has been performed in the inpatient setting. Analysis of research done on inpatient prescribing by the IOM resulted in the conclusion that 44 000 to 98 000 inpatient deaths could be attributed to avoidable medical errors, and many of these deaths could potentially be prevented by CPOE.[9] In an analysis at 1 academic medical center, 64.4% of errors were rated as likely to be prevented with CPOE (including 43% of the potentially harmful errors).[10]

Less is known about the error rates and resulting morbidity and costs to the medical system that result from prescribing errors in the outpatient setting. In 1 study, the use of e-prescribing in the emergency department demonstrated a reduction in prescriptions that contained errors (odds ratio [OR]: 0.31) or required pharmacist clarification (OR: 0.19).[11] The Center for Information Technology Leadership projects that use of e-prescribing would prevent more than 3 million adverse drug events (ADEs) and prevent 190 000 hospitalizations yearly. Potential financial benefits from the universal adoption of e-prescribing include a savings of $27 billion/year, including $2 billion/year from the reduction in ADEs.[12] As noted previously, knowledge of the specific health, safety, and financial impact of drug errors and e-prescribing in the pediatric outpatient setting is considerably less well understood.

Despite these limitations, there is a groundswell for the adoption of e-prescribing by the medical community. Organizations such as the IOM, ISMP, and Leapfrog Group have strongly endorsed e-prescribing; the Centers for Medicare and Medicaid Services will require e-prescribing as part of its Medicare prescription drug program; and insurers are looking to these systems as a way to avoid costly medical errors and to "enforce" compliance with tiered formularies to drive down their pharmacy costs. Thus, a number of commercial insurers are now underwriting the upfront costs for physicians who are willing to adopt this new technology. Currently, 5% to 18% of physicians are using some type of e-prescribing system in their offices, with this number expected to grow rapidly over the next 3 to 5 years.

BENEFITS

E-prescribing has potential benefits for public health, the patient, the insurer/pharmacy benefits manager, and the physician. Specific benefits to each are noted below.

Benefits to public health include:

- reduction in medical errors and associated costs to society;
- reduction in drug diversion (forgeries);
- improved patient care and improved health outcomes; and
- improved efficiency and reduced costs associated with prescribing.

Benefits to patients include:

- reduced chance for medication misadventures; and
- improved patient satisfaction.

Benefits to pharmacists, pharmacy benefit managers, and insurers include:

- workflow efficiencies;
- improved compliance with formulary prescribing, with attendant reduction in drug costs; and
- reduction in costs attributable to preventable ADEs.

Benefits to the physician include:

- improved office efficiencies for medication renewals;
- incentive reimbursement for compliance with formulary programs; and
- improved record keeping and documentation.

CPOE AND E-PRESCRIBING SYSTEMS REDUCE MEDICAL ERRORS AND IMPROVE OUTCOMES

Hospital-Based Studies

Accurately determining the frequency of medication errors is limited by findings that medical errors are significantly underreported in the incident-reporting systems used by many hospitals, especially when errors did not reach the patient (near-miss events).[13] Despite this limitation, however, 2.4% of hospitalized patients develop a clinically significant ADE during their hospitalization.[14] Medication errors are one of the most common medical errors and the most frequent cause of adverse events, accounting for 19% to 20% of all adverse events.[9,15,16] In pediatric patients, the most common type of medication error is a dosing error at the ordering stage.[17–19]

Preventable ADEs (eg, ordering and administering an incorrect medication or dosage) are more common than nonpreventable ADEs (eg, a newly developed drug allergy). In 1995, Leape et al[17] described poor dissemination of drug knowledge (29%) and inadequate availability of patient information (18%), such as the results of laboratory tests, as the most common causes of ADEs. An analysis of significant ADEs concluded that 52% of the cases were preventable; of these events, 50% could have been prevented by a pharmacist.[20]

E-prescribing tools have been used successfully to reduce errors in the prescribing process. Use in the emergency department demonstrated a reduction in prescriptions that contained errors (OR: 0.31) or required pharmacist clarification (OR: 0.19).[11]

Decision support provides knowledge, information, and data to the provider to optimize the selection and specification of medication for ordering. Such knowledge may be provided at the point of care through updated formularies for handheld devices and online guidelines and tools for specific domains such as infectious diseases.[21,22] A computer-assisted antibiotic-management program was able to reduce ADEs and reduce total costs in 1 study[23] and reduce length of stay and antibiotic use in another.[24] E-prescribing tools have been used successfully to prevent the prescription of gender-specific drugs for patients of the opposite gender.[10]

Pediatric Studies

Children are at increased risk of certain specific types of ADEs. Pharmacologic factors, including age-based variability in absorption, metabolism, and excretion of drugs as compared with adults, pose special vulnerabilities to the adverse effects of overdosing (often by an order of magnitude). Physiologic factors, such as the nearly universal need for weight or body surface area considerations in dosing and recognition of the variability of organ development, also make the medication process for pediatric patients more prone to dosage errors than for adults.[4,25]

Error rates for children seem to be inversely related to the weight of the patient, with infants in the NICU being most likely to experience medication errors and potential ADEs.[26,27] A study of errors for preterm neonates before discharge demonstrated a linear increase in medical error rates that was inversely related to birth weight, although the overall rate of errors was lower in comparison with children and adults.[28] Medical errors in pediatric patients are more likely to be caused by calculation or dose errors than in adults. Medications in adults that require weight-based calculation (the norm for pediatric patients) were found to be more error prone.[29,30]

Process factors, including the need for individualized dilution of stock medications and fluids (because of weight and body surface area considerations), place children at increased risk of medication errors in comparison with adults. Location-specific factors, such as the fast pace and high complexity in ICUs, are associated with a sevenfold risk of medication errors.[31]

Medication errors may occur at any step in the process, from ordering (56%) to transcription (6%), dispensing (4%), and administration (34%).[32–34] Orders by prescribers are the most error-prone steps in the medication process, with the wrong dosage being the most common type of error.[35–37] These errors may or may not be caught by subsequent checks, such as during dispensing and administration.[38] In pediatric inpatients, almost three quarters of all medication errors were discovered in the ordering stage.[27] In academic pediatric critical care settings, prescribing error rates of 11% to 30% were observed, compared with 6% of prescription errors in an internal medicine setting.[10,39,40]

The evidence for error reduction in pediatric patients using computerized systems is not yet robust. A recent Cochrane review[41] concluded that limited data from randomized trials exist on which to assess the effects of clinical decision-support systems in neonatal care. However, some evidence that highlights the benefits of CPOE in the neonatal population is emerging. Cordero et al[42] reported that implementation of CPOE resulted in a significant reduction in medication turnaround times and medication errors for selected drugs (gentimycin) and a decrease in ancillary service (radiology) response time. CPOE eliminates illegibility. Vanderbilt University's WizOrder system reduced the rate of errors caused by illegible pediatric intensive care orders from 1 error per 100 orders to zero.[39] CPOE with calculators and point-of-care decision support has also been used successfully to drastically reduce provider errors in the ordering of total parenteral nutrition[43] and continuous infusions.[44] An ambulatory study from Singapore showed that automated calculation reduced pediatric prescribing errors from 28.2% to 12.6%.[45] CPOE has also been shown to reduce errors in the ordering of chemotherapy agents in pediatric patients.[46]

Ambulatory Care Studies

ADEs are common in ambulatory care, and many are preventable or ameliorable.[34] E-prescribing tools in outpatient settings have been used successfully to lower prescription costs through electronic, evidence-based decision support during the prescribing process.[47] Computerized prescription systems have been shown in randomized trials to improve the quality of anticoagulation.[48]

LIMITATIONS OF CPOE AND E-PRESCRIBING IN REDUCING ERRORS

Computerized ordering and prescription tools have been advertised as means to reduce the frequency of ADEs.[49] However, evidence exists that computerized systems cannot prevent all errors or ADEs and may, in some situations, be responsible for new types of errors.[50,51] A recent study of a 110-bed computerized Veterans Administration hospital found 70 ADEs per 100 patient-days (significantly higher than previously reported).[14] The authors suggested that the legible and accessible electronic records may have facilitated the increased identification of ADEs. Of note in the Veterans Administration study is the finding that errors in ordering (74%) accounted for a larger percentage of errors than previously reported (56%).[51] At the same time, errors

during transcription and administration were reduced. The authors speculated that these findings were a direct result of the system design—a computerized system that eliminates need for transcription and ensures legibility but lacks decision support for drug selection and dosing—and will "redistribute" error frequencies. In other words, unless an electronic system is designed to prevent errors at the ordering stage, it will not prevent these errors; on the contrary, it will increase the speed at which these errors can be committed and executed. Another recent study from the University of Pennsylvania that evaluated an older CPOE system with very limited decision support received significant media attention when the authors concluded that a leading CPOE system often facilitated medication-error risks.[50] Although there was no comparison between manual ordering and CPOE, the authors emphasized that electronic systems will do just what they are designed to do. If they are not designed to provide decision support, they will not do so. In contrast, a study of the WizOrder CPOE system at Vanderbilt University demonstrated that a CPOE system that includes sophisticated decision support at the point of order entry may reduce medication-prescribing errors by 99.4% and rule violations (deviations from ordering policy) by 97.9%.[39] A recent study in a PICU showed that implementation of a CPOE system, even in the early months after implementation, was not associated with an increase in mortality.[52]

In addition to incomplete design, computerized prescription-writing tools are limited to the content of the program. For example, they may have a limited drug inventory or lack dose-range information and may, especially when used on handheld devices, pose usability problems.[53] Fernando et al,[54] who used simulated test cases, found that computing systems currently in use in approximately three quarters of general practices in the United Kingdom have clinically important safety deficiencies.

The Rand Electronic Prescribing Expert Advisory Panel has provided 60 capability recommendations for ambulatory prescribing systems.[1] However, a recent study of 10 commercially available e-prescribing systems demonstrated that only 50% (range: 26%–64%) of these recommendations were implemented.[55] It must be recognized that electronic systems are only as good as they are designed and implemented. A system that strives to provide legibility and accessibility only will improve the error rate in transcription and administration processes but not in ordering processes. For CPOE and e-prescribing systems to reduce provider ordering errors, they must be integrated with sophisticated clinical decision-support capabilities.[39]

E-PRESCRIBING SYSTEMS

An e-prescribing system, at its simplest, is a computer application that allows physicians to print out prescriptions (a word processor would fulfill this definition). The advanced vision of an e-prescribing system, however, is that of an application that facilitates the rapid and efficient generation of prescriptions (including electronic renewals); includes a knowledge base with drug information relevant to the prescribing process; performs all necessary calculations automatically and accurately; checks for prescription completeness, drug contraindications, drug interactions, allergies, and medical conditions that affect prescribing; verifies appropriateness of dose on the basis of patient age, weight, gender, and medical conditions (eg, renal insufficiency); checks insurance formulary preferences; and then transmits the prescription electronically to the pharmacy. An ideal closed-loop system would also receive data back from the pharmacy to confirm that the patient has filled the prescription.

Although generating printed prescriptions would be expected to reduce medical errors related to handwriting, it is the integrated clinical decision support, automatic calculations, and electronic transmittal functions that are likely to have the greatest effect on physician prescribing habits and to improve the safety and efficiency of the prescribing process. Merely printing out prescriptions can be done on a word processor; a fully functional e-prescribing application requires significant domain knowledge often contained in database tables and is most effective when integrated (bidirectional data transfer) with office practice–management and/or electronic health record (EHR) systems. Higher levels of systems are associated with higher startup costs and complexity and are generally associated with higher benefits. These levels of e-prescribing have been described.

Electronic Drug Reference Only; No Prescription-Writing Capability

This functionality is supplied by commercially available software programs, many of which are designed for mobile personal digital assistants, that allow access to drug dosages, contraindications, adverse effects, and drug interactions. It is important that reference data be kept current and updated at least monthly.

Stand-Alone Prescription Writer With No Medication History or Supporting Data

In addition to providing electronic drug references, a stand-alone writer provides computerized printing of prescriptions that are then given to the patient or manually faxed to the patient's pharmacy.

Reference Data and Prescription Writer With the Addition of Basic Supporting Data Such as Allergies, Demographics, Past Prescriptions and Formulary Information, Which Can Be Used to Generate Alerts

This functionality allows the application to incorporate clinical decision support (including drug-allergy, drug-

drug, and dose-range checking; renal function adjustments; and possibly preferred insurer formulary information) but requires the input of information (eg, demographics, allergy history, other concurrent medications, renal function/creatinine), often manually, depending on interfaces to practice-management systems, laboratory systems, EHRs, and insurer formulary databases.

Medication Management: Long-term Tracking and Monitoring of Each Patient's Active Medications

This level contains the previous functionality and maintains a database of the patient's previous prescriptions and prescription renewals. These applications typically monitor for drug-drug interactions automatically. These systems should also allow for the manual entry of other medications the patient is taking. Less commonly available, but useful, is the ability to enter alternative and nonprescription medications. Some vendors offer the ability to check for drug interactions with alternative medications.

Unidirectional Connectivity From Practices to Pharmacies, Payers, Pharmacy Benefit Managers, or Clearinghouses

This type of system typically provides the previous functions and allows for the electronic transmittal of prescriptions to pharmacies and often includes subscriptions to electronic versions of insurance formularies to identify preferred and tiered drugs and alert for noncovered medications. This requires that patient insurance information be entered into the e-prescribing system or transferred from practice-management systems.

Integration With a More Complete EHR

Systems integrated with an EHR allow for a wider range of clinical decision support without the need to manually reenter data into the e-prescribing system. They also automatically update the patient's current medication list within the EHR.

Bidirectional Connectivity Between Physicians, Pharmacies, Payers, Pharmacy-Benefit–Management Programs, or Clearinghouses

This functionality is not generally available in systems today but is in the planning stages. It would allow for feedback of prescription information from the pharmacy to the clinician, such as confirming that the prescription has been received, has been given to the patient, or is overdue for refilling, thus enabling compliance monitoring by the physician and improved medical management.

Bidirectional functionality could allow physicians to receive up-to-date information from other physicians' prescribing systems or from the pharmacy on their patient's prescriptions, such as information on prescriptions prescribed by another physician or in another care setting. Up-to-date medication lists are essential for accurate drug-interaction checking.

BARRIERS AND POTENTIAL SOLUTIONS TO E-PRESCRIBING ADOPTION

Despite the opportunities potentially available with the use of e-prescribing systems, a number of potential barriers have slowed their adoption. Among others, these barriers include the following.

Failure to Recognize Current System Deficiencies

Often, physicians do not perceive that they make prescription errors or have illegible handwriting. They do not perceive themselves as part of the drug-error problem and are often reluctant to change their practices.[56]

Technology Barriers (Equipment Setup and Maintenance) in the Office Setting

The lack of access to a broadband Internet connection especially affects smaller and more rural practices. Those practices may also suffer from lack of access to the technological support they need.

Implementation, Training, and Maintenance Cost

Establishing e-prescribing in the office is not a 1-time expense. Licensing and maintenance-agreement costs are ongoing and are generally not offset by a reduction in other office expenses. E-prescribing may not be more time-efficient than handwriting prescriptions and could affect office productivity, particularly in the initial implementation phase. Additional manual data-entry requirements may also reduce efficiency. Potential office cost benefits may result from improvements in the medication-renewal process, reduction in manual chart pulls, and compliance with insurer incentive programs for using generic or preferred drugs. However, even these efficiencies may not always allow for a reduction of office staff, which would equate to decreased office salary expense.

Beneficiary-Payer Discrepancy (Misaligned Incentives)

Although providers must carry the bulk of the investment for e-prescribing systems, benefits from automation are more likely to accrue primarily to others such as insurers, pharmacists, and patients. Patients appreciate the potential of having prescriptions ready to be picked up without a wait. Without incentives to physicians to invest in e-prescribing systems, the adoption of this technology by physicians is likely to be slow.[12]

Interface/Integration Costs

It is likely that physicians in the future will want to implement a complete EHR system in their offices. Transferring data from the e-prescribing system or integrating the e-prescribing system with an EHR system can be difficult and expensive. Physicians expecting to move

to an EHR system in the near-to-medium future will need to build in a transition strategy to avoid duplicate data-entry costs.

Existing Legacy Systems

Although most pharmacies can accept facsimile transmissions, many still do not have the ability to electronically accept transmitted prescriptions into their electronic pharmacy systems and, thus, miss out on potential benefits. Even where pharmacies can accept the electronic transmissions or facsimiles, pharmacy workflow may be such that the drug is not dispensed before the patient arrives to pick up the medication.

Legal and Regulatory Barriers

In regard to e-prescribing, nonuniform state regulations and lack of federal standardization (preempting state regulations) place an additional burden. In particular, regulations on controlled substances that mandate triplicate prescriptions and special forms may significantly limit the use of e-prescribing. Pediatricians commonly prescribe schedule II controlled substances (eg, stimulants for attention-deficit/hyperactivity disorder) and might, therefore, not be able to fully benefit from e-prescribing. The Drug Enforcement Agency currently allows e-prescribing of controlled drugs in category III to VI and is considering issuing digital certificates and using public-key infrastructure encryption to allow for digital prescription for category II drugs.[57] Until state and federal legislatures generate a uniform regulatory approach, e-prescribing systems are required to fulfill all mandates or to be tailored for use in specific states.

Negative Past User Experiences

Poorly designed systems have been available for several years and may have given the market a bad reputation. Current systems are evolving to be more user friendly, intuitive, and customizable. Nonetheless, any potential user of an e-prescribing system should test a system that is in actual use before investing the significant resources required. Testing should include some of the more complex prescriptions used in practice, such as prednisone tapers, drugs that require additional information or diagnosis to be included on the prescription, drugs with as-needed indications, and over-the-counter (OTC) drugs (covered by some insurers with prescription). Physicians must be aware of the fluidity of the vendor market and must appreciate the risk involved in the bankruptcy, sale, or merger of their e-prescribing system vendor and the possible subsequent discontinuation of software maintenance and technical support for their system.

Lack of Standards

Several transmission standards for prescriptions exist; however, a move toward consolidation of standards has been underway, and the recent Centers for Medicare and Medicaid Services move to establish electronic standards under the Medicare Part D prescription drug plan will help to establish a de facto standard.[58] However, these rules, regulations, and standards only apply to prescription drugs. E-prescribing systems may not be set up to handle prescribing or provide decision support for OTC and alternative medications.

OPTIONS AND FUNCTIONAL REQUIREMENTS

There are many ways to implement e-prescribing systems; solutions that work for one practice may not work for another. Careful consideration of the risks and benefits of implementation alternatives is necessary. It is critical that physicians considering the use of e-prescribing be aware of the risks including costs (purchase, training, workload, and maintenance) as well as legal and regulatory requirements in their state.

All systems that are capable of electronically transmitting prescriptions share certain characteristics such as a need for connectivity. Most will require dedicated telephone lines or broadband Internet connectivity, a potential problem in more remote areas. All of them will require a computer, modem to connect to the telephone (usually dedicated digital subscription line) or Internet (via digital subscription line or cable), and likely a router. The need for connectivity may introduce a single point of failure in which a malfunction may render the whole system inoperable, particularly for those applications that run as an application service-provider (ASP) system.

If more than 1 computer or device in the office is to be used for prescribing, a computer network or a way to synchronize information will be necessary. The input equipment can be a computer (desktop, laptop, tablet computer), wireless handheld device, or personal digital assistant. The network can be wired, wireless, or a combination of both. A wireless router and perhaps several wireless antennas will be required for wireless networks. When local printing of prescriptions is planned, printing may be centralized within the office, or multiple printers may be necessary, possibly convenient to each examination room. If integrated electronic facsimile transmission is not part of the e-prescribing system, a fax machine for manual transmission may be required. Technical help is usually required to wire and set up networks.

Systems can be administered from off-site centralized locations through an ASP, where everything is "done for you" to manage the system, or maintained on-site in the office. ASP systems use secure connections to allow office access devices to be logged into the remote system. With the ASP model, patient data are typically stored off-site, but in either case regular data backups need to be ensured.

Computer interfaces to transfer data from other office

systems (eg, practice management or scheduling) can initially be expensive but may save providers time by eliminating the need to enter demographic data and by keeping data current and synchronized across multiple systems with single data entry. There are usually additional costs associated with purchasing and integrating various databases, including insurance company drug formularies, prescribing-information updates, decision-support data, and pharmacy lists with up-to-date fax numbers.

A number of insurers have been paying the implementation costs for selected e-prescribing systems, at least for their high-volume prescribers. Insurance companies expect to realize benefit from providing e-prescribing systems to providers by steering physicians to the selection of specific preferred drugs and the reduction in ADEs to insured clients. Some medical societies have negotiated "discounted" deals with preferred e-prescribing providers. It is estimated that the direct cost of implementing a stand-alone system can be under $2000 per physician and, in some cases, considerably less. However, the cost of implementing an integrated EHR with an e-prescribing component is considerably higher. Providers will need to determine if an integrated EHR solution, although more expensive and difficult to implement, will have other offsetting benefits that would justify the additional work and expense.

Physicians must be aware that the market for these applications is somewhat "fluid" as vendors come, go, and merge with others. Choosing a product from a well-established, financially stable vendor, although no guarantee of sustainability, will help to ensure longer-term product support. Thus, it is important that an "exit strategy" be in place, including provision for recovery of the data contained in the system (in a standard nonproprietary database format). Ongoing costs are for equipment depreciation and replacement, renting telephone or Internet access, licensing and maintenance-agreement costs, and staff training and can vary considerably.

An expert consensus panel recently published recommendations for comparing e-prescribing systems.[1] They categorized the functionality to be assessed into the categories summarized below. They noted that no current system met their recommended criteria fully.

Patient Identification

Patient name, gender, and date of birth or age must be visible throughout the ordering process. These data should be imported from other systems when available, or the system should allow for manual entry when not imported. Duplicate records created under separate identities for one individual should be able to be reconciled and merged. The ability to perform patient searches using combinations of date of birth, gender, and partial name helps to positively locate and identify patients.

Access to Patient Historical Data

The system and clinicians should have access to external sources of data (hospitals, pharmacies, laboratories, EHRs) and be able to review all patient prescriptions, not just those written by the current provider, as well as OTC and alternative medications taken by the patient. The ability to manually enter additional patient medications is required. Current and past medication-prescription details should be viewable by class, with start and stop dates. When a medication is discontinued or changed, a notification should be sent to the original prescriber. When a diagnosis is entered, a list of medications by diagnosis should be viewable.

Medication Selection

When the e-prescribing system is presented with a patient diagnosis, a customizable selection of appropriate medications should be presented to the user. Prepopulated lists or dynamically maintained lists of common medications based on prescribing frequency can speed medication ordering. Medication options should not be influenced by vendor or insurer promotional considerations.

When the system displays a preferred drug, the rationale for that preference should be immediately viewable, and contraindicated medications (based on allergy or drug interactions) should not be viewable as a preferred medication choice. Prescribing by medication name should override restricted-medication menus. The system should provide formulary status and cost to the patient for medication options on the basis of insurance and any benefit or prescribing caps. Clinical summary data useful to the selection process should be easily accessible.

The user should be able to easily select the drug form and available strengths for each medication. Dosing recommendations based on calculations of body size (weight or body surface area) and age, when appropriate, should be available. When appropriate, adjustments calculated and based on renal and liver function should be made. The ability to default to generic drug name on prescriptions should be available (unless specifically overridden) to aid in insurance prescribing compliance programs and reduced costs to patients.

Alerts and Other Messages to Prescribers

Dose-range checks based on dose, dose per weight, daily dose, daily dose per weight, and lifetime dose-checking alerts should be available. Prescribers should be alerted when there is a contraindication or precaution based on allergy, drug interaction, medical condition, or laboratory results. The system should send a reminder when a medication is indicated in a particular instance (immunization due or medication based on diagnosis, laboratory results, and peer-reviewed recommendations). Messages should provide a clear rationale for any rec-

ommendations. Messages not based on patient safety concerns should be suppressible to avoid "alert fatigue." A user should be able to prioritize safety alerts and set a threshold that allows only alerts of a certain level/priority to result in a message to a provider while other alerts are suppressed. Providers should be able to override alerts with reasonable justification, and the system should track all changes and their justification. Prescribers should be able to flag or correct (update) incorrect information.

Patient Education

Patient medication-information sheets, written at an appropriate level for patients and their parents, and patient medication lists should be printable. Information sheets should be editable or customizable (and then saved for reuse) for pediatric indications (eg, β_2 blockers used for migraine control, not heart disease; digoxin for arrhythmia control, not congestive heart failure). Patient education materials should be able to be edited or personalized and be available in other languages in addition to English.

Data Transmission and Storage

Prescriptions should be able to be transmitted to the patient's pharmacy of choice. Transmission should conform to current Health Level 7 (HL7) and National Council for Prescription Drug Programs standards. Physicians should receive transmission and dispensing receipts and should be notified of any transmission failures.

When prescriptions are printed locally and given to the patient, prescription abbreviations should be avoided, and the prescriptions should be consistent with best-practice recommendations (eg, Joint Commission on Accreditation of Healthcare Organizations or ISMP).[59,60]

Monitoring and Renewals

The prescriber should be notified electronically when a prescription or refill is not dispensed within a provider-specified time period. Ideally, the system should alert the clinician to place orders for manufacturer-recommended laboratory monitoring and alert the physician when laboratory results require action. Prescriptions and renewals entered should be clearly attributable to the person who enters the order.

Many e-prescribing systems have a messaging ability integrated into the system so that nurses and clerical staff can access the system and forward renewal requests that come in directly from patients. Office processes and staff training needs require attention.

Transparency and Accountability

The system should clearly display any sponsorships or relationships that could represent conflicts of interest and any sources and methods used to develop clinical decision-support rules and messages.

Prescriber-Level Feedback

Prescribers should be able to review profiles of their own prescribing patterns and history of overriding alerts.

Security and Confidentiality

Systems must be compliant with the Health Insurance Portability and Accountability Act (HIPAA). Access to protected health information should be auditable. Each user should have a unique sign-on and password and role-based access privileges. The system should support data integrity checking of stored and transmitted data. Provisions for the routine backup of data and secure storage must be considered. Firewalls may be needed to protect systems, and antivirus software must be current if the network is not dedicated to the e-prescribing application. Access-management processes must be in place (eg, to revoke access when an employee is terminated).

CONCLUSIONS

Ultimately, the issue for consideration is "not if, but when." A uniform system for providing incentives and removing barriers to the adoption of e-prescribing systems by physicians who wish to use these systems will likely be needed to accelerate the migration to e-prescribing. The expenditure of time and money to implement a well-designed e-prescribing system has the potential, in the long run, to benefit society, the patient, the insurer, and the physician.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Robert S. Gerstle, MD, and the Task Force on Medical Informatics

E-mail Communication Between Pediatricians and Their Patients

ABSTRACT. This report addresses specific e-mail patient communication issues relevant to pediatricians and their appropriate use of e-mail in the office setting. The report briefly reviews: 1) e-mail privacy and security concerns; 2) e-mail in the office environment; 3) the legal status of e-mail; and 4) available e-mail technologic solutions. *Pediatrics* 2004;114:317–321; *electronic communications, health care delivery, medical liability, e-mail, pediatrics.*

ABBREVIATIONS. HIPAA, Health Insurance Portability and Accountability Act; PHI, protected health information.

The American Academy of Pediatrics Periodic Survey of Fellows No. 51 documented that of the 1616 active US members reporting from October 2001 to February 2002, 14% already use e-mail to communicate with patients. Reasons cited for using e-mail included managing requests for prescription refills (54%), communicating test results (41%), and scheduling appointments (37%). Reasons for not using e-mail to communicate with patients included lack of physician time (52%), lack of office staff time (42%), concerns about privacy or confidentiality (45%), lack of interest in communicating via e-mail (38%), and too few patients with e-mail (34%).[1] The volume of e-mail sent daily in the United States was expected to exceed 9 billion messages in 2003.[2] A Harris Interactive survey reported in April 2002 that "about 90% of US adults who use the Internet say they would like to communicate with their physicians online . . . ."[3] The study went on to report, "56% said that ability to communicate with their physician online would help influence their choice of physician."

The popularity of e-mail is attributable to some of its unique characteristics, namely its ability to allow asynchronous communication and rapid message transfer, making it a hybrid of the telephone and the written letter.[4] As it is used, e-mail is a more informal means of communication than the letter, but more rapidly transmitted. Like a letter, it can be sent or read by the recipient at convenient times, avoiding "telephone tag." In addition, it is "self-documenting," providing a lasting copy for future reference. Thus, it is no surprise that pediatric patients and their families share the desire to use e-mail to communicate with their pediatricians.[3–5] E-mail would seem to offer physicians and patients obvious benefits for facilitating communication. Therefore, it may seem somewhat surprising that there has been relatively slow adoption of e-mail as a patient communication tool by pediatricians and other physicians.[4] There are many reasons for this, including but not limited to concerns about maintaining the confidentiality of e-mail, physician concerns about the potential volume of e-mail correspondence, and potential legal issues.[1,5]

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

BACKGROUND: E-MAIL TECHNOLOGY

The transmission of e-mail messages requires: 1) access to a global network of linked computers, called the Internet; 2) the existence of an addressing system that enables messages to be routed through that network of computers to their correct destinations; and 3) programs that split messages into standard-sized "pieces," pack them into electronic "envelopes" or packets that have address information for routing each packet, and reassemble the message at the intended destination.

By design, the Internet is a very robust communication system with an architecture that was structured to maintain communication in case of national disasters that might result in the destruction of significant amounts of the national communications network (such as in the case of nuclear war). Messages transmitted across the Internet are not normally encrypted; nor is there typically authentication of author identity. Lack of encryption allows those with access to the Internet network to intercept, read, or potentially alter messages as they pass to their final destinations. These risks are not unique to e-mail. Telephones can be tapped (legally or illegally); scanners can monitor portable telephone communications; traditional mail can be intercepted, read, or altered, and letters can be forged. Despite potential confidentiality and security risks, it seems on the basis of volume alone that most people are comfortable using e-mail, particularly for relatively trivial or mundane communication needs. The perceived benefits of this fast, asynchronous, and relatively inexpensive form of communication appear to outweigh the risks to most users.

PRIVACY AND SECURITY RISKS

Physicians have special ethical and legal obligations to maintain the privacy and confidentiality of their communications with and regarding patients. Additionally, pediatricians and others who provide medical services to children and adolescents have special burdens and responsibilities by the nature of their patient population.[6,7] E-mail communication with patients adds complexity and responsibilities for the pediatrician, the office staff, and the patient and patient's family.

Pediatricians have the legal responsibility, whenever health information is requested by or communicated to an individual, to ensure that: 1) the individual has a legitimate right to release or gain access to that information before releasing or communicating that information by letter, by phone, in person, or by e-mail; 2) the information is directed only to those having a right to receive it; and 3) the information is accurately transmitted and received. These are the requirements to ensure the authenticity, confidentiality, and integrity of information exchange.[8,9]

Authenticity refers to a recipient's ability to positively know the identity of an individual sending a communication.[10] Anyone can send e-mail with virtually anyone's name attached to it. The inability of e-mail to provide methods of authentication presents a significant risk to patients and physicians. E-mail authentication has been one of the more difficult issues to address when using e-mail for medical communication. Two general solutions to the authentication problem, digital certificates and secure networks, will be discussed briefly later in this report.

Confidentiality refers to the need to protect information from those who have no legitimate right to the information presented.[11] Risks to patient confidentiality occur when multiple individuals (eg, family members) share the same e-mail address, when access passwords are not used or are not kept secured, when computers are left on and unattended without logging out of e-mail, or when e-mail at work or at school is used for personal communication. Using e-mail on systems that belong to employers, other organizations, or schools presents particular problems. Many e-mail users do not know that most organizations and companies, as policy, consider organizational e-mail to be their property and reserve the right to read e-mail on their systems. Another threat to confidentiality results from the ease with which e-mail messages can be misaddressed and erroneously sent to unintended recipients, instantaneously broadcast to multiple recipients, or forwarded by others to unintended recipients.

Integrity of message transmission refers to having absolute knowledge that the message received was unaltered and identical to the one transmitted and that the message was sent and received by the appropriate person.[11] Because e-mail messages can be intercepted, especially by hackers who break into an e-mail server but also by individuals who might gain access to another's personal electronic mailbox, there may be justifiable concern about integrity of messages. Of more concern is that a message sent to one individual might be altered by the recipient. The altered message, its intent perhaps drastically changed, might then be forwarded to another person.

E-MAIL IN THE PHYSICIAN OFFICE ENVIRONMENT

Office e-mail and confidentiality policies, procedures, and processes need to be in place before e-mail with patients can successfully, safely, and effectively be used in the office. Merely distributing or advertising a practice's e-mail address to patients may have unintended consequences. This address will rapidly become quite public, resulting in the office receiving a variety of unsolicited e-mail. A major concern is that individuals who are not current office patients may e-mail the office with medical questions. Office processes may get mired with the volume of e-mail received. The practice needs a way to determine which messages are from "legitimate" or established patients or families and needs to decide whether it will respond to queries from nonpatients. Distinguishing which messages are from current patients from those that are not can be difficult. E-mail address names may be aliases (eg, Superstud2) or common or nonunique names (eg, David Miller or Jose Rivera). Pediatric offices typically identify patients by the child's name but may have problems identifying e-mail from a parent, particularly if the message does not reference the child's name and birth date. Incorporating structured e-mail forms that require specific patient identifying information (eg, first and last name, date of birth, and practice identification or Social Security number) to be completed as part of the message helps simplify patient identification. In addition, the use of passwords as a means of identification and access can diminish the risk of outside or inappropriate access to communications.

Another concern beyond identification is that of e-mail attachments. E-mail attachments can cause a variety of problems, including the transmission of computer viruses (potentially paralyzing the computer system), the use of excessive memory, the need to read and print messages and attached documents for inclusion in patient records (using staff resources), or the need for versions of software that are not available on the office system. To rectify this issue, pediatric offices can consider restricting the use of attachments as part of patient messages. Attachments might be restricted to reports or attachments from professional sources, such as other physician offices, emergency departments, and hospital medical records departments. Having the ability to control which users may append attachments can lend a lot of flexibility to an e-mail system.

Occasionally, situations occur in which an office may want to have the ability to block the receipt of e-mail from certain individuals. E-mail systems that allow the office the ability to inactivate passwords or block e-mail from specific individuals can effectively

restrict e-mail system access for selected patients by the office when necessary.

It is very important for practices to set realistic expectations for e-mail and communicate those expectations to families. Patients must understand what the office considers a reasonable response time for nonurgent messages and must understand that emergency communication is appropriately handled by telephone, not by e-mail. Communications that are usually appropriate for e-mail include routine appointment requests, billing questions, routine prescription refill requests, provision of follow-up information, and chronic disease management questions. By providing patients with office e-mail policies in written form before they receive an e-mail password, posting the policies on the practice Web site, and verbally reinforcing these policies, pediatricians and their staffs can help patients to understand and adhere to the appropriate use of e-mail.

There are other considerations the pediatrician needs to address before providing pediatric patients with e-mail access to the office. Policies can address the age at which pediatric patients can begin to send e-mail to the office themselves. Will children and parents receive the same brochures and sign the same consents (or assents)? Will parental permission be required before a child can receive a password to access office e-mail? Although there are not necessarily any right or wrong strategies, patients and their parents must know and understand office practices and policies.

Patients typically desire to communicate by e-mail with their physician's office to schedule appointments, refill prescriptions, resolve billing questions, request referrals, obtain test results, get forms or immunization records completed, ask nonurgent medical questions, or provide medical follow-up. Most of these tasks can be delegated to an appropriate office staff member. Patients must understand who in the office will read and triage e-mail as well as the limits to privacy that messages will have in the office. Patients must know when, for example, messages addressed to a particular individual in the office, even about personal matters, may be first subjected to clerical or nurse review. E-mail systems that can automatically triage messages to the appropriate office staff member, depending on the type of message, can improve efficiency and patient confidentiality. Patients can be informed that by restricting e-mail messages to one issue per message, message triage efficiency and patient confidentiality might be enhanced. The office also needs to have policies and processes to address messages that arrive when a pediatrician or designated office staff person is unavailable or has elected not to have the messages forwarded to them, and to address e-mail received on weekends, holidays, or whenever the office is closed. Routine policies can be incorporated into a patient e-mail brochure, and the policy can be reinforced using the "auto reply" feature included in most e-mail software, stating when action will be taken on messages and telling the patient to call the office for more urgent matters. Copies of e-mail messages with responses can be incorporated into patient charts. Patients can be advised to retain copies of e-mail sent by the office to avoid their forgetting or misunderstanding the intent of messages.

A well-constructed patient brochure outlining office e-mail policies and the appropriate use of e-mail will help control patient expectations and prevent misuse of e-mail by patients. Although some offices may require patients to sign a consent form allowing e-mail communication, it is more important that patients and parents clearly understand the differences among, and appropriate use of, each available form of communication. It is a good practice to document that each patient has been provided with written information that addresses the appropriate use of e-mail and office policies and procedures that support e-mail. This information can be provided before office e-mail addresses or access passwords are given to patients.

Drawing an analogy to telephone communications, e-mail communication is another way to enhance patient communication and satisfaction and to build goodwill. Just as there are no regulations that preclude charging patients for telephone advice, except as may be contained in insurance contracts, there are no restrictions on charging patients for advice rendered by e-mail. Some insurers have begun to consider e-mail an important part of chronic disease management and have started to selectively reimburse physicians for e-mail communication related to disease management.[12,13] More plans are expected to begin reimbursing clinicians for online consultation for both acute and chronic conditions. Because e-mail self-documents, it can provide the evidence of medical work that telephonic communication does not offer. Thus, insurers have been more willing to consider reimbursement for e-mail interactions. *Current Procedural Terminology*[14] codes for care plan oversight (99374-99380) already exist and are reimbursable under some insurance plans.[15] Case management services telephone calls (99371-99373) presently are restricted to telephone use but might be broadened in the future to include e-mail services.

LEGAL STATUS OF E-MAIL IN HEALTH CARE

The Health Insurance Portability and Accountability Act (HIPAA)[8,9] privacy and security regulations apply to e-mail communications that contain a patient's protected health information (PHI), as defined in HIPAA privacy regulations.[16] HIPAA requires encryption of messages when sending PHI over the Internet. If the pediatrician is using a third party to manage the e-mail system, HIPAA privacy regulations require a written business associate agreement with the service provider. HIPAA privacy regulations require that physician offices provide each of their patients or patient's families with an outline of the office's privacy practices. Final HIPAA security regulations[9] released on February 20, 2003, require physician office networks to have appropriate protection (firewalls and physical security) to prevent unauthorized individuals from gaining access to clinical e-mail or medical records, and to have appropriate safeguards to prevent the loss or unauthorized access to or distribution of PHI. Privacy regu-

lations under HIPAA also require the ability to provide for author and user authentication for e-mail transmissions.

Just as for telemedicine, issues related to medical licensing and jurisdiction can be raised when communicating with patients and providing patient care or advice across state lines by e-mail. Although it is unlikely the pediatrician would be in jeopardy of prosecution for practicing medicine without a license by giving medical advice to an established patient via e-mail, it is important that pediatricians check their state's law on this issue. Some states have begun to address this issue in their state medical practice legislation, with the possibility of requiring a state medical license for such transactions.

There can also be medical liability risks related to providing "medical care" by e-mail or Internet communication. Before medical liability can exist, one must demonstrate that a patient-physician relationship has been formed. The establishment of the patient-physician relationship, or "duty," has not been well clarified when using e-mail or the Internet exclusively to provide advice in the absence of any physical contact. Arguably, an analogy can be drawn to the situation in which a physician provides general information on a local radio or television broadcast. In such cases, in which information is general in nature and not meant to diagnose or treat a specific individual, there is no relationship or duty established. Although case law has not been well established, there have been concerns raised as to whether a patient-provider relationship would be initiated when advice is given in an online forum ("bulletin board" or "chat room"). However, in cases in which there is a previous patient-physician relationship or in which a Web site is created to solicit patient queries, the risk of medical liability is greater.

Failure to meet patients' service expectations or follow one's own office policies and procedures can result in liability. The situation in which a physician fails to respond in an appropriate time frame to a patient e-mail, resulting in an adverse outcome, for example, might present a liability risk, emphasizing the need to educate patients about the appropriate use of e-mail and about appropriate response time expectations. Patients must be instructed and must understand when it is appropriate to escalate queries by telephoning the office directly. Although e-mail is widely used, neither the legal nor medical liability communities have significant precedents for dealing with potential e-mail communication risks. Pediatricians should monitor for the development of such precedents in the future.

E-MAIL TECHNOLOGIC SOLUTIONS

There are two commercially available solutions to the problem of providing authenticated, confidential, secure e-mail: secure servers or digital signatures.[17] Each of these approaches affords remedies for authentication of identities and facilitates secure communication with patients. No system, however, is perfect. Any system depends on patients and providers recognizing their responsibilities to keep passwords private and secure and to log off of systems properly when leaving computers unattended.

The secure server solution is analogous to doing banking online. The pediatrician's office must initially authenticate the identity of the patient, such as at the time of an office visit, and provide a sign-on code and temporary password specific to that individual. When the patient logs on to the system for the first time, he or she then changes the temporary password to a new and confidential one known only to the user. When a message is sent to that patient's system mailbox by the office, a secondary nonsecured notice is sent to the patient's identified home e-mail account alerting the patient to log on to his or her secure mailbox on the system. Logging on is accomplished securely using the patient's confidential password and via the Web browser's secure socket layer. Secure socket layer transmission across the Internet is encrypted between the mail server and the patient. Only the individual with the password to that account has access to it. From the secure mailbox, patients can also securely send messages back to the pediatric office. Such messages reside on the server, and the office logs on to the mail system securely, as does the patient. In this type of system, unencrypted messages containing medical information never travel on the Internet.

Digital signatures rely on the use of "keys" to encode (encrypt) messages sent across the Internet. The sender of a message has a private key that is used for coding the message. The receiver has a complementary public key to decode the message, thus making it readable.[18] These keys are not physical devices but rather strings of random characters that are used in the mathematical encrypting algorithm. Authentication of identity occurs before a key is released to a user, and a certification authority handles management of public and private keys. Authentication can still be an issue depending on the identity control mechanisms used.[17,18] Presently, these systems are complex to administer and cumbersome to use. However, in the future, perhaps by using smart cards or biometric forms of authentication (eg, fingerprint readers), these systems may grow in popularity.

Commercially available e-mail systems can provide added value beyond simply the ability to transmit and receive e-mail. They can provide e-mail encryption, authentication, and password management; can facilitate automatic triaging of messages on the basis of message type; and can provide the ability to "auto-fax" prescriptions to pharmacies. Some systems can assign "rights" to certain users (such as to append attachments) or allow for associated business transactions (charges for communications) to be handled online. Costs of these systems can vary widely, but for a very modest cost, most offices can implement basic secured messaging.

CONCLUSION

Successful communication between patients and pediatricians is an essential element to providing quality care and maintaining patient satisfaction. Although under certain circumstances, only face-to-

face communication is appropriate, there are other times when other forms of communication, including direct telephone contact, facsimile transmission, traditional mail, and now, e-mail would be appropriate—although they should not be considered interchangeable. Pediatricians and their patients must be aware of the risks, benefits, and limitations of any form of communication. E-mail is still an emerging vehicle for communication. Its ability to allow for the rapid asynchronous transmittal of messages and to "self-document" makes it particularly popular despite the potential confidentiality risks. These risks can be acceptably minimized with appropriate forethought and planning.

abstract

Children with chronic medical conditions rely on complex management plans for problems that cause them to be at increased risk for suboptimal outcomes in emergency situations. The emergency information form (EIF) is a medical summary that describes medical condition(s), medications, and special health care needs to inform health care providers of a child's special health conditions and needs so that optimal emergency medical care can be provided. This statement describes updates to EIFs, including computerization of the EIF, expanding the potential benefits of the EIF, quality-improvement programs using the EIF, the EIF as a central repository, and facilitating emergency preparedness in disaster management and drills by using the EIF. *Pediatrics* 2010;125:829–837

INTRODUCTION

Children with chronic medical conditions, including children with special health care needs, rely on multiple medications, medical technologic devices, and complex management plans, which can cause them to be at increased risk of acute deterioration, medical errors, and suboptimal outcomes. Their conditions make them particularly vulnerable and prone to complications; therefore, they frequently rely on emergency care in the ongoing management of their special medical conditions. A detailed understanding of an individual's special health care needs is required to provide optimal emergency care.[1–9]

When children with special health care needs access emergency medical services (EMS) or seek emergency care in a busy emergency or urgent care facility (or in the midst of a disaster), it is difficult for EMS personnel and/or the attending physician to review lengthy medical records (if they are available at all) and coordinate care with multiple specialty care providers.[9] A summary describing their medical condition(s), medications, and special health care needs is necessary to reduce delays in diagnosis and treatment and facilitate greater efficiency in the provision of emergency care to children with special health needs.

The transfer of traditional health-record information is slow and becoming more difficult for the following reasons:

1. Because of greater documentation requirements, health records are more comprehensive, which makes it more difficult to find important items related to the patient's condition.

2. Delays are often caused by information-transfer consent requirements and misunderstandings surrounding the regulations of the Health Information Portability and Accountability Act (HIPAA).
3. Minimum necessary standards for release of information under HIPAA can interfere with gathering a complete set of pertinent information.
4. In a disaster scenario, the transfer of health records can be problematic because of an inability to access them, or paper records may be destroyed in the disaster.

The emergency information form (EIF) was proposed as a means to provide rapid access to a health summary for children with special health care needs in a 1999 joint policy statement (reaffirmed in 2002) by the American Academy of Pediatrics (AAP) and the American College of Emergency Physicians (ACEP).[9] The EIF is a type of personal health record that was introduced as a concise, single-sheet summary designed to provide the essential information needed initially to treat a patient with special health care needs.

Experience since publication of the 1999 statement has identified the following:

- The EIF has been underused, because many health care providers and families of children with special health care needs are unaware of the EIF. Many providers consider EIF completion to be time-consuming and do not recognize the need for the EIF.
- The paper-based EIF is helpful but suboptimal for incorporation into electronic health records (EHRs) and for central repository access.[10]
- Maintaining and/or updating EIFs can be difficult and time-consuming.
- Vaccine schedules and requirements change frequently, so the immunization table on the EIF needs to be able to accommodate these changes.
- Disaster-management plans must include medical care for children with special health care needs. If a disaster compromises the availability of health records, an EIF would be beneficial in providing useful information such as medication doses.[11,12]

ADVANCING THE EIF TO A COMPUTER APPLICATION

- The computerized EIF can be easily updated with new information (eg, newly identified allergies, change in severity, addition of new problems, change in advance directives, change in specialists and their contact information) and provides an automated date stamp as to when it was most recently updated.
- The computerized EIF can be modified to accommodate system changes, such as legal requirements, immunization tables, and consents.
- A paper form physically limits the amount of information provided on the form and is not sufficiently adaptable for patients with a large set of problems. A computerized EIF can expand and adapt to the needs of the patient.
- The use of a computer-based EIF permits a central repository through which the EIF can be accessed remotely via the Internet rapidly. A capability to access a number of EIFs can also be built into such a system to facilitate a coordinated disaster response for children with special health care needs.
- Computerization of EIFs facilitates quality-improvement measures targeted at children with special health care needs and the use of the EIF.
- Computerization of EIFs facilitates the deployment of EIFs as a database that can be integrated into the EHR and can potentially be shared and networked between compatible hospitals and systems.
- A computerized EIF can accept templates or cut-and-paste management routines (clinical pathways) that are frequently recommended, such as the standard initial management of a child with tetralogy of Fallot.
- It should be noted that a computerized EIF might not be retrievable in the event of a power failure or damage to communication infrastructure (includes the Internet). An inkjet-printed paper document will smear. A water-resistant paper document or a "thumb drive" or compact disc containing the file in a plastic bag (together with insurance papers and other key documents) is more likely to be usable under certain disaster conditions.

EXPANDING THE POTENTIAL BENEFIT OF THE EIF

- The process of initiating an EIF by the medical home and the patient's specialists should include a review of likely emergencies and recommended therapies in the event of an acute exacerbation of the child's chronic condition(s). This review enables subspecialists to recognize the difficulties faced by nonspecialists encountering their patients for the first time and facilitates the codification of initial management measures to improve communication with other care providers involved in the patient's care. Examples of this include which laboratory tests should be ordered for a patient with an inborn error of metabolism, what type of intravenous fluid should be started, and whether the patient should be fed or kept off oral intake (NPO).
- Because EIF use is not yet routine, quality-improvement programs should target EIF initiation and

maintenance, and this should be added to the growing list of quality indicators for a primary care medical home that manages children with special health care needs.[9]

- The process of initiating an EIF affords the primary care physician and appropriate specialists an opportunity to further explore and discuss the difficult issues surrounding end-of-life care options for children and the inclusion of advance directives. Updating the EIF permits recurring opportunities to confirm or update these advance directives. Many states have an official form that permits out-of-hospital providers to honor advance directives that must be completed, and in these instances, this form could be electronically attached to the EIF, or the EIF could list the physical or online location of the completed official form.
- The process of initiating and maintaining an EIF should include an action plan for a disaster and a method to monitor disaster preparedness as part of a quality-improvement program.

QUALITY-IMPROVEMENT PROGRAMS USING THE EIF

- "EIF maintenance" includes the initial EIF as well as updating it when appropriate and confirming its validity during each health care visit. Each review or modification of the EIF should be dated.
- The percentage of children with special health care needs with an EIF in a practice can be audited by dividing the number of EIFs in the practice that are known to exist by all children with special health care needs in the medical home primary care practice (EIF-eligible patients). A central repository of computerized EIFs would facilitate the identification of all the EIFs in the practice. Improvements in this percentage demonstrate quality improvement.
- EIF maintenance can be monitored by the mean number of days since the last EIF update or confirmation for all the EIFs in the practice. Reducing this mean value demonstrates quality improvement, because more-current EIFs are more accurate.
- The EIF can be used to track the participation level and frequency of disaster drills. Whether this is an actual drill done at home or a discussion or mental review of what to do in the event of a specific type of disaster can be documented in the EIF. Because electrical power failure is such a common event, the EIF should document that an action plan for this has been reviewed with the family and whether an actual trial or drill has been done at home. The percentages of EIFs with a documented electrical power failure action plan review and/or an actual home drill can be used as a quality parameter. Increasing percentages demonstrate quality improvement. As this number approaches 100%, further quality improvement can be documented by monitoring the mean number of days since the last electrical power failure action plan review and/or actual home drill. Reducing this mean value demonstrates quality improvement, because recent review and practice of a disaster action plan should improve the likelihood of success.

EIF CENTRAL REPOSITORY

A central repository would provide access by primary care providers, patients, parents, pharmacies, other specialists, and emergency care practitioners.

Although central EIF-repository maintenance and access is highly desirable, implementation faces significant challenges. Measures that promote immediate access and revision/update inherently conflict with measures that preserve confidentiality of protected patient information.

Routine access can be secured by user authentication via the standard method (log in plus password). Known authorized users have access to the EIFs of patients with whom they are known to be linked but not to those of other patients, which permits the expected users of the EIF to have easy access to confirm, update, and revise the EIF at each routine visit.

Emergency access to the EIF is a more difficult issue. The Midwest Emergency Medical Services for Children Information System (www.memscis.org) is an EIF central repository program in Minnesota that uses a "break-the-glass" entry for emergency access to EIF information.[10] This terminology clearly distinguishes routine EIF-maintenance activities from emergency information access. Emergency access via the "glass breaker" is obtained by entering the requestor's identifying information. No system with broad access can totally guarantee patient confidentiality.

The Internet is far-reaching and is the obvious means to achieve broad access via a centralized server or a linked set of servers. Sophisticated traces can identify unauthorized access sources; however, tracing access from public terminals, unauthorized use of an open terminal, freestanding Internet stations, unsecured wireless networks, and foreign-country access is substantially more difficult or impossible.

Although high security is desired to protect patient information when developing new information systems, it should be noted that standard paper-record systems in use have relatively low security/protection measures. Parents and patients should be made

aware of the inherent compromises in patient confidentiality that must be made to facilitate emergency access. Although perfect confidentiality is often expected or desired, it is unrealistic, especially when compared with the current security status of all health records (paper and electronic).

The Midwest Emergency Medical Services for Children Information System has demonstrated feasibility on a smaller scale, and its experience suggests the need for the advocacy of local physician champions and referral center entities for enrollment success to be achieved.[10]

THE ROLE OF THE EIF IN PREPARING FOR A DISASTER[11,12]

- The EIF permits many different health care providers, regardless of background, to provide initial care to children with special health care needs.
- The EIF should include a plan in the event of a disaster, the most common of which is the loss of electrical power. Lack of access to medications, water, food, shelter, and transportation should also be considered. At a minimum, medical home practitioners should consider the planned response for likely emergencies and disasters.
- For technology-dependent children, the loss of electrical power (a common occurrence even in the absence of natural disasters) is a significant disaster event. A simple temporizing measure is that all critical life-support devices should include an internal battery back-up, a power-failure alarm, and a secondary means of back-up power (see Technical Appendix 1). A hospital's back-up generator electricity is a fairly reliable source of electricity, and transport to the hospital to use it can be considered, but it should not be relied on entirely, because back-up generators are not always reliable, there might be significant traffic getting to the hospital, and there might be overcrowding at the hospital because of other patients doing the same thing. Identifying alternate sites of back-up power should be part of a disaster plan. Hospitals should anticipate their role as a source of electrical power during a prolonged power failure and should plan back-up generator capacity to meet the needs of the hospital plus the needs of technology-dependent patients who are likely to use the hospital's electrical power.
- The EIF should include a prompt to enter the date of the most recent disaster drill for the most common type of disaster that is anticipated, such as the loss of electrical power.
- The different types, severity, and duration of disasters make it practically impossible to develop a single action plan to specifically and comprehensively manage all disasters. Some geographic regions are more prone to specific types of disasters, and some patients are particularly more vulnerable to specific types of disasters. Determining the most likely disaster (after electrical power failure) is geographic and patient specific.
- Extreme disasters are uncommon, yet survivability during an extreme disaster depends on being prepared in knowing what to do and having the necessary equipment and resources to survive. Extreme and less common disasters are more difficult to drill and are more realistically reviewed with mental exercises that verbally simulate what might happen and what the response would be.
- Because disasters are usually uncommon and difficult to predict, it might be more useful to prepare for generic categories of shortages rather than for a specific type of disaster. For example, several different types of disasters will result in the nonavailability of an important resource that is normally available, such as food, water, shelter, clothing, medication, electrical power, transportation, and medical services. However, mass trauma, bioagent, chemical, or radiation exposure disasters represent challenges that are not necessarily related to resource shortages.

RECOMMENDATIONS

1. Medical home primary care physicians (ideally together with motivated families) are the most qualified persons to globally coordinate completion of the EIF for children with special health care needs[4,8] by obtaining specific recommendations from the pertinent specialists (eg, what type of intravenous fluid to use for a patient with a metabolic condition or what antidysrhythmia measures should be tried first in a patient with recurrent dysrhythmias). Specialty care physicians will need to assist and provide specialty recommendations to ensure that their patients are properly managed.
2. Completion of the EIF should be the responsibility of the medical home primary care physician and specialty care providers for every child with special health care needs. Medical home primary care physicians should be strongly encouraged to include an EIF as part of the patient's health care maintenance and medical home. For the onset of new conditions for which the tertiary pediatric center has initial access to the patient, an EIF should be initiated during hospitalization (eg, a preterm infant is born, hospitalization

for newly diagnosed diabetes mellitus, hospitalization for a traumatic brain injury sustained in an automobile collision).

3. Ideally, EIFs should be reviewed periodically by local emergency care providers to confirm that the recommendations are clear and that the necessary specialized equipment, medications, and services are available at the emergency care center.
4. EIF maintenance should be a routine part of the ongoing care of children with special health care needs and should be performed every 6 months (and at each health encounter as needed) to confirm the validity of the EIF and/or update specific changes in the patient's clinical status on the EIF.
5. End-of-life planning and advance-directive updates and confirmations should be included in the EIF-maintenance process when appropriate. The EIF affords medical home primary care physicians with an opportunity to discuss this most difficult but necessary topic as part of the patient's ongoing care. This can also serve as a reminder for the medical home primary care physician to discuss with the family the need for any forms required by out-of-hospital providers to honor advance directives.
6. A central standardized electronic repository of EIFs needs to be established and maintained to facilitate updates to and retrieval of EIFs. The repository should be set up by a national medical lead agency, such as the AAP and/or the ACEP, a private national health care organization, and/or an agency of the federal government.
7. An electronic EIF that is compliant with existing American Society for Testing and Materials Continuity of Care Record (ASTM CCR) and Health Level 7 Continuity of Care Document (HL 7 CCD) standards and with HIPAA requirements should be endorsed by the AAP and ACEP as a first step toward a national repository of EIFs. When possible, the EIF data elements should use standardized nomenclature such as the Systematized Nomenclature of Medicine (SNOMED). In addition, the EIF should be accessible via the Internet. EIF standardization will facilitate EHR development and help to ensure that the content of the EIF is accessible in a variety of clinical settings.
8. A central repository does not guarantee availability of the information. A water-resistant paper document or a thumb drive or compact disc that contains the file, kept in a plastic bag (together with insurance papers and other key documents), is more likely to be usable under certain disaster conditions.
9. Quality-improvement parameters of EIF use and maintenance should be added to the growing list of quality indicators for a primary care medical home.
10. Disaster planning should be included as part of the EIF-maintenance process. Medical home primary care providers must consider and anticipate the most likely emergencies and other potentially serious disasters and review the planned response with patients and caregivers. At a minimum, medical home practitioners should consider the planned response for likely emergencies and disasters.
11. Although it might be an expectation that the computerized EIF should be included in this policy statement, the specifications of creating a computerized entity with all the functionality described is a difficult task given the evolution of computer systems, EHRs, access methods, confidentiality/security requirements, and the experience of pilot projects that are currently determining the best way to achieve this. The actual computerized EIF and a reasonable implementation plan should be developed into a technical report to follow. Although other computerized EIF entities have been proposed, it would be premature for the AAP to endorse any of these at this time. A sample computerized EIF is provided for reference (see Appendix 2). The paper EIF version (www.aap.org/advocacy/eif.doc) contained in the original policy statement (www.pediatrics.org/cgi/content/full/104/4/e53) can still be manually modified to achieve part of the functionality described above until a computerized EIF standard can be developed and recommended.
12. Fair reimbursement for these services is necessary. Initiating, completing, and maintaining an EIF and other quality-improvement activities associated with the EIF add value but are time-consuming activities that optimize care coordination for children with special health care needs. Optimal care coordination is worthy of and, indeed, contingent on fair reimbursement for these services by medical home primary care and specialty care providers. *Current Procedural Terminology* (CPT) codes for telephone calls, prolonged service, team conferences, and care-plan oversight and management already exist and can be used to bill for these services. Reimbursement for these services should be a standard part of all health benefit packages.

TECHNICAL APPENDIX 1: ELECTRIC POWER ALTERNATIVES

A simple and economical recommendation for powering life-support devices in the event of an electrical power failure is for all technology-dependent patients to have an available 12-V inverter, which is an inexpensive device that plugs into a car's cigarette lighter to deliver 110 to 120 volts of alternating-current (VAC) power. By plugging into a 12-V inverter, the patient's life-support device can be further sustained by using the automobile's battery, which can provide power on its own for a moderate period (depending on the power requirements of the life-support device) and indefinitely as long the automobile's engine is running (until the car runs out of gas). There are different power capacities of 12-V inverters (measured in watts) that must exceed the sum total of the power requirements of the life-support devices required by the patient. For example, if the patient's ventilator is rated at 110 to 120 VAC, 100 W, and the patient's oxygen concentrator is rated at 110 to 120 VAC, 150 W, then the 12-V inverters must be able to match this power capacity. This can be accomplished by having two 12-V inverters (one rated at >100 W and the other rated at >150 W) or a single 12-V inverter rated at more than 250 W. Using two 12-V inverters requires that 2 cigarette-lighter sockets be available. Using a single 12-V inverter requires that this inverter have two 120-VAC outlet sockets on the inverter to accommodate both devices.

The power ratings of the 12-V inverters are limited by the electrical current capacity of the automobile's wiring and fuses. Typically, most cigarette lighters are on 20-ampere (A) (sometimes 10-A) fused lines, which means that if the 12-V inverter draws more than 20 A of current, the fuse will blow (break) and no power will be available until the fuse is replaced. Replacing the fuse with a 30-A fuse (ie, one that is rated higher than what is in the car) is dangerous, because the higher current will exceed the electrical-current capacity of the wiring and could cause a fire. Power in watts is calculated by multiplying voltage and current (amperes). Thus, the 20-A circuit fuse limits the maximum wattage to 240 W (12 V × 20 A). Having 2 cigarette-lighter sockets in the same car does not increase this maximum, because it is likely that both cigarette lighter outlets are on the same circuit. If the sum exceeds 20 A or 240 W, the 20-A fuse will still blow.

The watt rating (power rating) of the life-support device should be stamped on the device itself. If it is not, then the current rating (in amperes or milliamperes) should be stamped. If the device plugs into a standard household outlet, it will be rated at 120 VAC. If the device is rated at 1.5 A, then the power rating will be 180 W (120 V × 1.5 A). The power rating (in watts) of the 12-V inverter must exceed the power rating of the life-support device. These calculations are all theoretical and must be tested in a drill to determine if everything will actually work. During the drill, it should be confirmed that the life-support device is in fact running off of the 12-V inverter and not the device's internal battery. Depleting the internal battery will test the 12-V inverter's ability to charge the battery as well, but a back-up power option must be available in case this does not work. Note that it will take more power and current to run the life-support device and charge the battery at the same time, so the drill should test the 12-V inverter under these more stressful conditions. Some devices have uneven power requirements such that periodic surges of power are required. For example, a feeding pump might have a low power consumption while pumping formula, but its power consumption will increase if pumping in something more viscous, such as formula with cereal. Power surges must also be within the range of power that the inverter can deliver.

There are high-wattage (eg, 500, 1000, and 2000 W) 12-V inverters, but they cannot be plugged into an automobile cigarette lighter. They can run off of an automobile battery directly with high-capacity cables. This requires more technical expertise and is more risky, because there is the possibility of a battery short circuit, which could melt wires, damage the life-support device, or cause a fire. If the life-support device requires such high power, it would be useful to get some technical advice on how to do this. The process is similar to "jumping" a dead car battery with jumper cables. A high-wattage life-support device will deplete the automobile's battery rapidly, so the car's engine should be running to prevent the battery from dying. The process of starting the car (ie, turning the key) will place a large stress on the car's battery briefly, which could cause a brief decrease in power to the life-support device if it is running on the car's battery when the car is started.

Portable generators can also be used to provide electrical power. These generators require gasoline and

motor oil to run. Small generators are rated at approximately 500 W, with larger generators capable of 5000 W and higher. Generators are fairly reliable, but they are often kept in storage and difficult to access when they are suddenly needed. Also, storage does not necessarily guarantee that the generator will work when it is needed. It should be noted that gasoline cannot be stored. Its composition changes with time, and old gasoline will likely damage the generator (similar to putting gum in it) regardless of whether the gasoline is stored in the generator's tank or in a gasoline-storage container. Because gasoline cannot be easily stored, it is often siphoned from automobile gas tanks. This can be hazardous to the siphoner's lungs if done incorrectly. Most generators require special motor oil, so several liters of the correct oil need to be available when the generator is run. All of these factors require that periodic drills be done to be certain that the generator will run when it is needed. Follow the generator's maintenance instructions during periods of nonuse to reduce the likelihood of generator failure when it is truly needed.

The generator or automobile engine must be run in a well-ventilated location to avoid carbon monoxide accumulation. When traveling outside of the United States, it should be noted that different countries use different voltage, current, and outlet-socket configurations.

Sophisticated generators that burn propane, natural gas, liquid petroleum gas, diesel fuel, or fuel oil or use fuel cells are much more expensive and beyond the scope of this report.

Disclaimer: The information contained in Technical Appendix 1 does not represent the opinion, recommendation, or policy of the AAP and is provided for information and consideration only. The AAP recommends that families contact the manufacturer(s) of electrical equipment used in the care of children with special health care needs in developing a plan of action in the event of electrical power failure.

APPENDIX 2: SAMPLE COMPUTERIZED EIF

Disclaimer: The information contained in Appendix 2 does not represent the opinion, recommendation, or policy of the AAP and is provided for information and consideration only as an example of a computerized EIF. It is not intended to serve as a standard of medical care.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Endorsement of Health and Human Services Recommendation for Pulse Oximetry Screening for Critical Congenital Heart Disease

abstract

FREE

Incorporation of pulse oximetry to the assessment of the newborn infant can enhance detection of critical congenital heart disease (CCHD). Recently, the Secretary of Health and Human Services (HHS) recommended that screening for CCHD be added to the uniform screening panel. The American Academy of Pediatrics (AAP) has been a strong advocate of early detection of CCHD and fully supports the decision of the Secretary of HHS.

The AAP has published strategies for the implementation of pulse oximetry screening, which addressed critical issues such as necessary equipment, personnel, and training, and also provided specific recommendations for assessment of saturation by using pulse oximetry as well as appropriate management of a positive screening result. The AAP is committed to the safe and effective implementation of pulse oximetry screening and is working with other advocacy groups and governmental agencies to promote pulse oximetry and to support widespread surveillance for CCHD.

Going forward, AAP chapters will partner with state health departments to implement the new screening strategy for CCHD and will work to ensure that there is an adequate system for referral for echocardiographic/pediatric cardiac evaluation after a positive screening result. It is imperative that AAP members engage their respective policy makers in adopting and funding the recommendations made by the Secretary of HHS. *Pediatrics* 2012;129:190–192

Delayed diagnosis of critical congenital heart disease (CCHD) can result in death or injury to infants. The current approach to detect CCHD in the United States relies on prenatal ultrasound examinations and the physical examination findings in the newborn nursery. Unfortunately, this approach fails to identify a significant number of cases of CCHD, which may lead to late diagnosis with significant morbidity, permanent injury of vital organs, and in some cases, death. A number of studies have revealed that adding pulse oximetry to the assessment of the newborn can enhance detection of CCHD. Pulse oximetry is a readily available, noninvasive, and painless technology that can be incorporated into the routine assessment of the newborn.

On September 21, 2011, the Secretary of Health and Human Services (HHS), Kathleen Sebelius, recommended that screening for CCHD be

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

added to the recommended uniform screening panel (RUSP). This recommendation was based in large part on the Secretary's Advisory Committee on Heritable Disorders in Newborns and Children's recommendations and a 2-day comprehensive evidence review of screening strategies by national and international stakeholders. The American Academy of Pediatrics (AAP) strongly supports the decision of the Secretary of HHS to add screening with pulse oximetry to the RUSP. The AAP has been a vigorous advocate of early detection of CCHD to prevent childhood deaths or injury that might occur as a result of late detection.

There are a number of important issues that relate to the implementation of pulse oximetry into the routine care of the newborn. A detailed description of these issues has been published by the AAP.[1] This publication provides a detailed screening algorithm developed by the Secretary's Advisory Committee on Heritable Disorders in Newborns and Children. It also provides detailed recommendations regarding necessary equipment, personnel and training, and appropriate management of a positive screening result. The highlights of screening implementation are as follows:

- The screening is targeted toward healthy newborn infants in the newborn nursery.
- Screening should be performed with motion-tolerant pulse oximeters. It is appropriate to use either disposable or reusable pulse oximetry probes.
- Screening should not be undertaken until 24 hours of life or as late as possible if early discharge is planned to reduce the number of false-positive results. Separate consideration for home births is necessary.
- Oxygen saturations should be obtained in the right hand and one foot. Threshold for a positive screening result is detailed in the publication and relates to both the absolute reading by the pulse oximeter as well as the difference between the 2 extremities. Screening that has a pulse oximetry reading of $\geq$95% in either extremity with a $\leq$3% absolute difference between the upper and lower extremity would be considered a pass, and the screening would end. It is recommended that repeated measurements be performed in those cases in which the initial screening result was positive, again in an effort to reduce false-positive results. Infants with saturations <90% should receive immediate evaluation. It is important to note that the oxygen saturation thresholds for a positive screening result may vary at high altitude. Appropriate studies need to be performed at high altitude to establish reliable thresholds.
- In the event of a positive screening result, CCHD needs to be excluded with a diagnostic echocardiogram. Infectious and pulmonary causes of hypoxemia should also be excluded.

The AAP can play an important role in assuring the safe and effective implementation of screening for CCHD. This includes preparing members to implement screening; engaging pediatricians to participate in quality-improvement activities to ensure that newborn infants are appropriately screened with follow-up echocardiograms and specialty care, as required; partnering with public health agencies for surveillance of CCHD; and advocating for appropriate payment for all screening-related activities. In addition to promoting the implementation of pulse oximetry based screening programs, the AAP supports widespread surveillance for CCHD. Such surveillance will yield several benefits, including documentation of any improvement in detection as well as identification of areas of weakness for this comprehensive screening strategy.

Although the Secretary of HHS has recommended that screening for CCHD be added to the RUSP, it will be up to states to determine how they wish to incorporate this into their own screening programs. This may be accomplished by legislation, regulation, or adoption as a standard of practice. The majority of disorders identified on the RUSP are adopted by most states, but there is variability among the states. A number of states have already incorporated routine screening for CCHD into the statewide panel. These states can serve as a paradigm for subsequent implementation by other states.* It will be critical that AAP chapters work with state health departments to implement the new screening strategy for CCHD in a manner that is adequately financed, cost-effective, and practical; that ensures screening and for echocardiographic/pediatric cardiac evaluation and therapeutic intervention as indicated with provision for follow-up for all newborn infants within the framework of the medical home; and that ensures that related payment issues for technical and professional services are addressed. It is hoped that through these collaborative efforts, the burden of delayed diagnosis of congenital heart disease will be reduced and the health of children will be enhanced for years to come.

*For more information on your state law, please contact the AAP Division of State Government Affairs at stgov@aap.org.

RECOMMENDATIONS

- Pulse oximetry screening for CCHD should be performed by using evidence-based guidelines such as those reported by the Secretary of HHS Advisory Committee Work Group, as detailed in the algorithm in the special article on screening for congenital heart disease.[1]
- AAP members should encourage incorporating pulse oximetry screening into routine newborn care and the development of effective systems to allow for timely and accurate diagnostic assessment with echocardiography and to ensure a medical home for those found to have CCHD.
- AAP chapters, AAP members, and local advocates should engage their respective policy makers at the federal and state legislative and regulatory levels in considering, adopting, funding, and implementing the recommendations made by the Secretary of HHS to ensure the development of the educational materials; training; equipment, including echocardiography and telemedicine needs; system development; and support with access to funding ensured for all components of medically necessary care.
- The AAP will actively engage other stakeholders and the American Medical Association to develop appropriate *Current Procedural Terminology* codes for pulse oximetry screening with appropriate relative value units and should advocate for appropriate payment for CCHD screening-related activities.

Reviewers

This document has been reviewed in draft form by individuals chosen for their unique perspectives and technical expertise. The purpose of this independent review was to elicit candid and critical comments that would assist in making this publication as sound and effective as possible. We thank the following individuals for their review of this document:

Stephanie Chalupka, EdD, APRN, BC ..... University of Massachusetts Lowell

Ellen Crain, MD, PhD ..... Albert Einstein College of Medicine

Michael Fleming, MD ..... Board Chair, American Academy of Family Physicians

Geralyn Glenn, MHSA ..... America's Health Insurance Plans

Antoinette Gardner, RN, MEd, AE-C ..... Chair, National Asthma Educator Certification Board

Vincent Hutchinson, MD ..... Harlem Children's Zone Asthma Initiative

Ameesha Mehta-Sampath, MPH ..... U.S. Environmental Protection Agency

Karen Rance, MSN, CPNP, AE-C ..... National Association of Pediatric Nurse Practitioners

Susan Rappaport, MS ..... American Lung Association

Elaine Rubin, PhD ..... Association of Academic Health Centers

Jonathan Samet, MD, MS ..... The John Hopkins Bloomberg School of Public Health

Megan Sandel, MD, MPH ..... Boston University Medical Center

Michael Shannon, MD ..... Harvard Medical School

Lauren Sorce, RN, MSN, CPNP-AC/PC ..... National Association of Pediatric Nurse Practitioners

Susan Stone, PhD ..... U.S. Environmental Protection Agency

Darryl Zeldin, MD ..... National Institute of Environmental Health Sciences

We also thank the following individuals, who reviewed the document on behalf of the American Academy of Asthma, Allergy, and Immunology:

Stuart Abramson, MD; Leonard Bacharier, MD; Jane Maroney El-Dahr, MD; Steve Kagen, MD; David Peden, MD; and Stephen A. Tilles, MD.

Although the reviewers listed above provided constructive comments and suggestions, they did not see the final draft of the document before its release. Responsibility for the final content rests with The National Environmental Education & Training Foundation.

Table of Contents

Introduction

These guidelines are the product of a new Pediatric Asthma Initiative aimed at integrating environmental management of asthma into pediatric health care. This document outlines competencies in environmental health relevant to pediatric asthma that should be mastered by primary health care providers, and outlines the environmental interventions that should be communicated to patients.

These environmental management guidelines were developed for pediatricians, family physicians, internists, pediatric nurse practitioners, pediatric nurses, and physician assistants. In addition, these guidelines should be integrated into respiratory therapists' and licensed case/care (LICSW) management professionals' education and training.

The guidelines contain three components:

- **Competencies:** An outline of the knowledge and skills that health care providers and health professional students should master and demonstrate in order to incorporate management of environmental asthma triggers into pediatric practice.
- **Environmental History Form:** A quick, easy, user-friendly document that can be utilized as an intake tool by the health care provider to help determine pediatric patients' environmental asthma triggers.
- **Environmental Intervention Guidelines:** Follow-up questions and intervention solutions to environmental asthma triggers.

Although environmental factors may play a role in the prevalence of asthma in the population, these guidelines are not directed at the primary prevention of pediatric asthma on a general scale. They are aimed instead at educating health care professionals on how to advise families about environmental interventions that can reduce or eliminate triggers for children who are already diagnosed with asthma.

It is important to recognize that environmental management is only one component of a comprehensive asthma management plan. These guidelines are founded upon the National Asthma Education and Prevention Program's (NAEPP) "Guidelines for the Diagnosis and Management of Asthma"[1] and it is recommended that they be used in conjunction with the clinical and pharmacological components of the NAEPP Guidelines. Additional guidance includes the use of pulmonary function testing and referral to an asthma specialist, either a pulmonologist or an allergist. No attempt is being made with these guidelines to supersede those of NAEPP, but rather to complement them. All children should have a written asthma care plan, and every child with mild persistent or more severe asthma should be treated with long-term control medication.

Environmental asthma triggers include indoor and outdoor allergens — such as dust mites, cockroaches, animal allergens, molds, and pollens — and indoor and outdoor pollutants and irritants, including environmental tobacco smoke (or secondhand smoke), chemicals, combustion by-products, and ozone and particulate matter. Although viruses and upper respiratory infections can exacerbate an asthma attack, they are not considered environmental asthma triggers for purposes of these guidelines.

The role of the asthma specialist (allergist or pulmonologist) may be crucial in helping to improve the care of these children. Primary care providers and asthma specialists should work together in evaluating the child, and in developing appropriate therapies and interventions. These guidelines are intended to guide primary care providers to consider environmental factors that may affect their patients' asthma. In some cases triggers may be more readily apparent than others. However, primary care providers should refer patients for allergy testing for confirmation of allergy when complicated or expensive interventions are being considered.

These guidelines are intended to be used with children (0-18 years) already diagnosed with asthma. Referral to a specialist is advised if the diagnosis of asthma is in doubt. Sources of guidelines for making the diagnosis of asthma include the NAEPP Guidelines and resources from Kaiser Permanente, the American Academy of Allergy Asthma & Immunology, and the American Academy of Pediatrics.

Background on the Pediatric Asthma Initiative

The Pediatric Asthma Initiative was launched by The National Environmental Education & Training Foundation, in partnership with the National Institute of Environmental Health Sciences and a steering committee of experts from academic institutions, federal agencies, and medical and nursing organizations. The Pediatric Asthma Initiative replicates the strategic framework of the National Strategies for Health Care Providers: Pesticides Initiative[2] developed by NEETF and the U.S. Environmental Protection Agency in partnership with a wide range of stakeholders. The Pesticides Initiative provides a model for incorporating environmental health information into the education and practice of primary health care providers. The Pesticides Initiative's National Pesticide Competency Guidelines for Medical & Nursing Education and the National Pesticide Practice Skills Guidelines for Medical & Nursing Practice served as models for the asthma guidelines.[3,4] Additional models were identified through a comprehensive literature search, in order to capitalize on current best practices and build upon existing tools and resources.

Environmental Management of Pediatric Asthma

The last several decades have seen a significant rise in the prevalence of asthma in children ages 0-17. Between 1980 and 1996, 12-month asthma prevalence among children increased from 3.5% to 6.2%. As of 2002, nine million U.S. children (12.2%) had ever been diagnosed with asthma[5], 6.1 million children (8.3%) currently had asthma[6], and 4.2 million (5.8%) had experienced an asthma attack within the previous year.[5] Asthma is more prevalent in children living in families below the poverty level. Children in poor families are more likely to have ever been diagnosed with asthma (16%) than children in families that are not poor (11%).[5] Children in fair or poor health are almost 7 times more likely to have had an asthma attack in the past 12 months than children in excellent or very good health (29% versus 4%).[5] In 2002, children age 5-17 missed 14.7 million school days due to asthma.[6] The environmentally attributable annual cost of pediatric asthma is estimated to be $2.0 billion.[7]

The role of environmental triggers of asthma is well recognized and has been included in the NAEPP Guidelines. Studies, such as the inner-city asthma study about individualized, home-based environmental interventions for hundreds of children in major U.S. cities, have demonstrated that environmental interventions decrease exposure to allergens, resulting in reduced asthma-associated morbidity.[8] However, in general, neither medical and nursing education programs nor pediatric practices frequently or fully incorporate environmental management and environmental history-taking into pediatric asthma treatment. A recent study reported that, although over half of practicing pediatricians surveyed had seen a patient with health issues related to environmental exposures, fewer than one-fifth were trained in taking an environmental history.[9]

The need for improvements in health professionals' environmental health knowledge has been expressed by leading health institutions, including the Institute of Medicine, the American Medical Association, and others.[10-14] Recognizing this need, the Ambulatory Pediatric Association issued a list of competencies for specialists in pediatric environmental health.[15] The American Academy of Pediatrics published a book on the identification, prevention, and treatment of childhood environmental health problems, which states that, "Avoiding environmental allergens and irritants is one of the primary goals of good asthma management."[16] The American Academy of Allergy Asthma & Immunology, acknowledging the importance of educating health care providers in this area, created an environmental management of asthma online continuing education program for its health care provider members.

A comprehensive approach to nursing and medical practice requires awareness, recognition, and treatment of critical factors that affect individual and community health, even if these factors are not obvious at first either to patients or their providers. Environmental interventions can occur if pediatric health care providers are knowledgeable about the importance and details of the issue, and able to communicate them effectively and sensitively to their patients' families.

Integration into the Curriculum and Clinical Practice

Although some modest progress has been made in introducing environmental management of pediatric asthma into medical and nursing curriculum and practice, studies conducted by medical and nursing expert workgroups, as well as leading medical and nursing organizations, recommend that environmental health content should be increased. Rather than compete with a crowded curriculum by adding separate course content, environmental management of asthma content can be integrated into existing pediatric instruction. This can be done by using environmental management of pediatric asthma to enhance existing case studies, or as exemplars. Additional opportunities for integration include the full range of continuing education programs, including Internet-based continuing education offerings, policy statements issued by national professional associations, and certification of training in environmental management of pediatric asthma.

For both medical and nursing education, a primary strategy for incorporating environmental management of pediatric asthma into existing curricula is to develop and support faculty champions/leaders who can take a leadership role in integrating children's environmental health into their institution in a sustainable fashion. These faculty members can lend expertise and support in their institutions and surrounding communities, teach courses, integrate competencies into curriculum, and serve as role models for how to integrate environmental health into health professional education. Residency Review Committees can require that such content be included in the residency curriculum. In addition, medical and nursing students can play a role in influencing curricula by educating fellow students through student organizations, such as the American Medical Student Association and National Student Nurse Association, and by encouraging school faculty and deans to introduce such content into the courses they offer.

Below are specific examples of points of insertion for environmental management of pediatric asthma content in medical and nursing curricula. It is recommended that such content be incorporated at all levels of the curricula.

- For medical education, the competencies can be incorporated into various courses throughout the four years of medical school and in residency. In the 1st and 2nd year of medical school, competencies can be taught in physical diagnosis, introduction to clinical medicine, and introduction to patient assessment courses. In the 3rd year, this material can be reinforced during clinical rotations and be included in medical school clerkships in pediatrics and family medicine. In the 4th year, such content can be included in electives for evidence-based medicine, environmental health, preventive health, epidemiology, or similar subject curriculum; in rotations for emergency medicine, public sector medicine, primary care, and pediatric medicine; and in instruction in ethical and legal issues of medical practice. Education should continue throughout residency training so that when a physician sees a child with asthma, environmental exposures and potential interventions are always included in the asthma management plan.
- For nursing education, environmental management of pediatric asthma content can be incorporated into various courses, electives, and units of instruction, depending on the curricula and course offerings of each school. For example, competencies in the knowledge, identification, and management of asthma triggers could be incorporated into patho-physiology, pediatric nursing, or community health nursing courses. Each of the competencies can be taught in classroom settings and reinforced in clinical rotations

for various subjects, such as community health, public health, home health, maternal/child health, and primary care management. Competencies could also be incorporated into additional units of instruction on topics such as health promotion, health education/teaching; protection and prevention of illness and injury; leadership in nursing; and current trends and issues in nursing practice including school nursing. The communication skills and advocacy competencies can be included in instruction on ethical, legal, and public policy issues and the patient advocacy role of the nurse. Additional points of insertion include environmental health nursing electives and fieldwork emphasizing environmental health.

There are numerous opportunities for incorporating environmental management of pediatric asthma content into pediatric health care practice. Practicing clinicians can introduce environmental management of pediatric asthma content into their daily practice by incorporating environmental history-taking and management of environmental triggers into the practices and protocols of the health settings where they deliver health care. Examples include adding environmental history-taking to electronic medical records, understanding the reimbursement available for teaching about environmental triggers and asthma management, or making referrals to asthma specialists or educators. Medical and nursing organizations and institutions can promote inclusion of environmental management of pediatric asthma in continuing education by offering continuing medical and nursing education sessions at conferences, grand rounds, and other educational functions, and by posting online modules on their websites.

In addition to medical and nursing curricula and clinical practice, it is recommended that environmental management of pediatric asthma content be integrated into the education and training of physician assistants, respiratory therapists, and licensed case/care (LICSW) management professionals.

Part 1: Competencies for Environmental Management of Asthma

The set of competencies developed for the environmental management of asthma follow the normal sequence of interaction of health care provider and patient: knowledge, diagnosis, intervention/treatment, counseling, and education/communication. In addition, health care providers can play an important role in achieving wider health gains through advocacy of environmental improvements in the communities where they work. Sensitivity to the special needs of communities and individual families is very important when dealing with environmental interventions related to asthma.

These competencies apply to all settings where children (0-18 years) spend time, including homes, schools, daycares, cars, school buses, and recreational and occupational environments.

Competency I:
Knowledge of Environmental Asthma Triggers

1. **Develop a comprehensive knowledge base of indoor environmental triggers of asthma:**
   a. Recognize the components of indoor air pollution
   b. Recognize the effects of environmental tobacco smoke on asthma
   c. Recognize the sources and effects of dust mites on asthma
   d. Recognize the sources and effects of animal allergens on asthma
   e. Recognize the role of cockroach antigen on asthma
   f. Recognize the sources and effects of combustion by-products on asthma
   g. Recognize the sources and effects of mold on asthma
   h. Recognize the sources and effects of solvents and other chemical irritants
2. **Develop a comprehensive knowledge base of outdoor environmental triggers of asthma:**
   a. Recognize the components of outdoor air pollution
   b. Recognize how to interpret EPA's Air Quality Index (AQI)
   c. Recognize the effects of pollen (weeds, grasses, trees) on asthma
   d. Recognize the effects of molds on asthma
3. **Identify what particular environmental exposures are unique to the community in which one is practicing**
4. **Recognize the climatic factors that can exacerbate asthma**

Discussion:

A thorough knowledge of the environmental triggers of asthma is the basis for environmental interventions. Competency includes knowing both the effects as well as the sources of each trigger. Health care providers should have both a general knowledge of triggers as well as specific knowledge of the most frequent or common environmental triggers in their patients' communities, usually a result of outdoor air pollution (industrial smokestacks, releases of chemicals, roadways heavily used by trucks, etc.) or seasonal climate factors.

The list of triggers included here is not intended to be all-inclusive. Rather, it includes the triggers that appear to be most prevalent and for which there is the most evidence of impact. As further studies are undertaken, other triggers may be added to this list.

For specific information on environmental issues and sources of pollution in your area, speak with the state environmental department or local public health or environmental programs. Consult EPA's Envirofacts program (www.epa.gov/enviro/index_java.html) as a starting point in identifying environmental factors by zip code or map. Additional information on environmental asthma triggers can be obtained from a variety of organizations, such as the ones listed in the Appendix (page 28).

Competency II: Identification of Environmental Triggers of Asthma

1. **Be able to take a thorough environmental history for pediatric asthma patients**
2. **Determine when to refer for subspecialty consultation**
3. **Inquire about exposures that are unique to the pediatric asthma patient**
4. **Inquire about exposures unique to the community of the pediatric asthma patient**

Discussion:

While some families affected by asthma may recognize a connection between environmental factors and asthma, other families may not have considered them as potential triggers. Taking an environmental history can be a first step in creating the awareness that such a connection may exist. Families will not always make these connections, therefore it is important for health care providers to ask about the unique exposures that individuals might face in the home (or other indoor environments such as school and daycare) as well as in the community.

Health care providers should take into account the age of the child, the type of dwelling the child lives in, and the community or regional exposures that are most prevalent. There are some parts of the country, such as the South and Northwest, with relatively warm and humid climates where dust mite exposure and sensitivity are highly prevalent; in other areas, such as the Northeast, cockroach allergen sensitivity is more common. As a general rule, allergy becomes a more important part of asthma with each year of age from preschool up to about age 10-12, at which point roughly 80-90 percent of asthmatic children will have allergic triggers.

Most asthma specialists will perform specific testing to determine which allergen may trigger a patient's asthma symptoms. Skin testing is one efficient way to test for a large number of allergens, although other allergy testing procedures are available. In some cases, a thorough environmental history may point to a few specific triggers. An alternative to skin testing is the CAP-RAST, an in-vitro allergen specific test, which may be considered for a select group of major inhalant indoor environmental allergens e.g. house dust mite, pets, molds and cockroach. Proper interpretation of test results will likely require input from an allergy specialist.

Competency III:
Environmental Intervention and Treatment

1. **Understand the evidence for the various mitigation strategies for environmental triggers of asthma discussed under Competency I.**
2. **Be able to provide accurate information about the benefits and harms of products and services for control of environmental triggers**

Discussion:

A continuing difficulty in environmental management of asthma is that the data vary widely on different environmental triggers. Even triggers that might be commonly encountered in practice are often not well studied. Part 3 of these guidelines contains fact sheets for the most common environmental triggers and recommended interventions.

A number of products are promoted to the general public and people with asthma, claiming that they will remove environmental triggers of asthma. While some products such as allergen–impermeable pillow covers are recommended, others, such as ozone generating air cleaners that may result in harmful levels of ozone indoors are not recommended. Ozone-generators can, under certain conditions, produce levels of the lung irritant ozone significantly above levels thought harmful to human health. Ozone can damage the cells lining nasal passages and lungs making it difficult to breathe, and can exacerbate asthma symptoms. Parents should also be made aware that such air cleaning devices are sometimes placed in schools. Providers should understand the issues involved and provide information to families.

Competency IV: Ability to Counsel Caregivers and Pediatric Asthma Patient on the Reduction of Environmental Asthma Triggers

1. **Be able to counsel about reducing the effects of indoor environmental triggers of asthma, including:**
   a. reducing the child's exposure to tobacco smoke
   b. reducing exposure to indoor air pollution
   c. reducing dust mites in the home
   d. reducing animal allergens
   e. ways to mitigate cockroach antigen in the home
   f. reducing indoor exposure to molds
   g. avoiding exposure to solvents and other chemical irritants
2. **Be able to counsel about reducing the effects of outdoor environmental triggers of asthma, including:**
   a. reducing exposure to pollen
   b. reducing outdoor exposure to molds
   c. reducing or restricting exercise under adverse conditions, such as on AQI alert days
3. **Be able to recognize the stages of behavioral change as they relate to parental desires to stop smoking and other trigger abatements**

Discussion:

The term counseling is used here to give the sense of an interactive effort, in which the family affected by asthma is seen as a partner, an active participant in caring for the child with asthma. Counseling and educational efforts should extend to the variety of people who care for the person with asthma. This could include the child, older siblings, parents, grandparents, a babysitter, or other caregivers in the home. In addition to the child's own home, there may be other places (homes of relatives or neighbors, daycare centers, schools, the adolescent's and parents' workplace, recreational facilities) where the child spends significant amounts of time, and it may be appropriate to provide information to people in those settings as well.

Exercise-induced asthma could be related to stress from the exercise itself, or triggered by environmental exposures to air pollution or climatic factors if the exercise is done outdoors. In the latter case, providers should discuss with families options for indoor exercise.

Competency V: Effective Communication and Patient Follow-Up Skills

1. **Be culturally and linguistically competent**
2. **Be aware of developmental implications and discuss issues at an age- appropriate level**
3. **Identify where in your area pediatric asthma patients can be referred for home visits and home evaluations**
4. **Develop a system to track the pediatric asthma patients in your practice**
5. **Determine when to refer to an asthma educator or other social services**

Discussion:

Primary care providers need good communication skills with patients, families, and people in the community. While some environmental interventions are fairly simple and straightforward, others relate to highly sensitive issues. Some patients' families may be less likely to offer honest answers to sensitive questions (particularly on smoking and cockroaches) and may be unreceptive to entertaining the possibility of an intervention. Knowing different ways of asking about tobacco usage, for example, can help in getting the necessary information without alienating the respondent. While sensitive, the information is needed for accurate diagnosis and intervention.

Adherence to interventions for sensitive topics (e.g., smoking cessation, reducing exposure to pet allergens in the home) may present special challenges for the health care provider. Health care providers will need skills in enlisting the help of patients' families, even when it may involve considerable effort or sacrifice on their parts, for such things as removing pets from the home, or committing to quitting smoking or smoking only outdoors. People sometimes signal a willingness to change behaviors, such as smoking cessation, and providers should be sure not to miss such opportunities.

Because pediatric asthma covers the age range of 0-18 years, practitioners need to develop age-appropriate levels of communication for dealing with children, from infants to young adults.

It is also important to have good lines of communication between the primary care professional and the asthma specialist. Referrals are likely for various reasons, including prudent diagnosis, teaching the patient how to manage the asthma, allergy testing, interpreting pulmonary function testing, etc.

Competency VI: Advocacy

1. **Be able to assess an environmental exposure in the community**
2. **Be aware of smoking cessation programs offered in the community**
3. **Be able to communicate with community members, school board members, political groups, legislative bodies, media, and other stakeholders about environmental risks**
4. **Work with school officials to identify potential environmental exposures and advocate for targeted prevention strategies**
5. **Collaborate with community leaders to promote clean air where children live, learn, work, and play**
6. **Understand the concept of environmental justice and special needs of at-risk populations**

Discussion:

Health care providers have an important proactive role to play in working with the community to prevent certain environmental exposures. Developing networks of community groups and public officials can enhance a provider's effectiveness in accomplishing goals. Providers should also become aware of community resources, such as smoking cessation programs, to which they can refer patients.

The emphasis is on partnerships, which combine the efforts of family, relatives and neighbors, health care provider, school, and community in a collaborative effort.

Part 2: Environmental History Form for Pediatric Asthma

This form is intended for use with children already diagnosed with asthma. Designed for ease of use, the Environmental History Form is obviously not comprehensive and is intended as an initial intake tool. Questions with a "yes" answer should be followed up with additional in-depth questions on particular triggers and recommendations about possible interventions provided in Part 3. It is recommended that a health care provider (physician, nurse, nurse practitioner, or physician's assistant) administer the questions rather than being given to the patient's caregiver to fill out.

The Environmental History Form is also available as a Word document on the Web (http://www.neetf.org/Health/asthmahistoryform.htm); If the practice uses an electronic medical record, clinicians can cut and paste all or parts of it into their existing history-taking templates. In addition to clinical practice, the form can be used as a teaching tool at nursing and medical schools along with the competencies and the intervention guidelines.

The far right hand side of the form has a column labeled "Follow Up", which allows the provider to add notes about what has or has not been done about particular triggers. Practitioners should be able to make a viable recommendation to control the environmental trigger about which they are asking; therefore, questions which do not have a follow-up action that can reasonably be taken are not included on this form.

Practitioners should use a great deal of sensitivity in taking an environmental history. As noted earlier, some families are aware of possible connections between behavior, conditions in the home and school, and pediatric asthma. Others are unaware of these linkages, and the environmental history will be the first opportunity to make these connections. Providers should not hesitate to ask the questions for fear that the answers will be inaccurate. Even if a question is not answered accurately, the question itself suggests to the person that there is a connection between asthma and the activity in question, and therefore may be a useful motivation to change behavior in the future.

It is very important to ask about all environments in which a child with asthma may be spending significant amounts of time, including all residences where the child sleeps or spends time, schools, daycares, camps, work, recreational activities, and college dorms (for 17-18 year olds). This form should also be used to elicit information on triggers commonly overlooked, such as weekly trips to a relative where a hobby or pet is located.

Environmental History Form for Pediatric Asthma Patient

Specify that questions related to the child's home also apply to other indoor environments where the child spends time, including school, daycare, car, school bus, work, and recreational facilities.

				Follow up/ Notes
Is your child's asthma worse at night?	❑ Yes	❑ No	❑ Not sure	
Is your child's asthma worse at specific locations? If so, where? _____	❑ Yes	❑ No	❑ Not sure	
Is your child's asthma worse during a particular season? If so, which one? _____	❑ Yes	❑ No	❑ Not sure	
Is your child's asthma worse with a particular change in climate? If so, which?_____	❑ Yes	❑ No	❑ Not sure	
Can you identify any specific trigger(s) that makes your child's asthma worse? If so, what? _____	❑ Yes	❑ No	❑ Not sure	
Have you noticed whether dust exposure makes your child's asthma worse?	❑ Yes	❑ No	❑ Not sure	
Does your child sleep with stuffed animals?	❑ Yes	❑ No	❑ Not sure	
Is there wall-to-wall carpet in your child's bedroom?	❑ Yes	❑ No	❑ Not sure	
Have you used any means for dust mite control? If so, which ones? _____	❑ Yes	❑ No	❑ Not sure	
Do you have any furry pets?	❑ Yes	❑ No	❑ Not sure	
Do you see evidence of rats or mice in your home weekly?	❑ Yes	❑ No	❑ Not sure	
Do you see cockroaches in your home daily?	❑ Yes	❑ No	❑ Not sure	
Do any family members, caregivers or friends smoke?	❑ Yes	❑ No	❑ Not sure	
Does this person(s) have an interest or desire to quit?	❑ Yes	❑ No	❑ Not sure	
Does your child/teenager smoke?	❑ Yes	❑ No	❑ Not sure	
Do you see or smell mold/mildew in your home?	❑ Yes	❑ No	❑ Not sure	
Is there evidence of water damage in your home?	❑ Yes	❑ No	❑ Not sure	
Do you use a humidifier or swamp cooler?	❑ Yes	❑ No	❑ Not sure	
Have you had new carpets, paint, floor refinishing, or other changes at your house in the past year?	❑ Yes	❑ No	❑ Not sure	
Does your child or another family member have a hobby that uses materials that are toxic or give off fumes?	❑ Yes	❑ No	❑ Not sure	
Has outdoor air pollution ever made your child's asthma worse?	❑ Yes	❑ No	❑ Not sure	
Does your child limit outdoor activities during a Code Orange or Code Red air quality alert for ozone or particle pollution?	❑ Yes	❑ No	❑ Not sure	
Do you use a wood burning fireplace or stove?	❑ Yes	❑ No	❑ Not sure	
Do you use unvented appliances such as a gas stove for heating your home?	❑ Yes	❑ No	❑ Not sure	
Does your child have contact with other irritants (e.g., perfumes, cleaning agents, or sprays)?	❑ Yes	❑ No	❑ Not sure	

What other concerns do you have regarding your child's asthma that have not yet been discussed?

_____

_____

NEETF Pediatric Asthma Initiative

Part 3:
Environmental Intervention Guidelines

These environmental intervention guidelines are to be used for children already diagnosed with asthma. A separate fact sheet is provided for each of the major environmental asthma triggers. The questions on these fact sheets are intended to supplement the questions listed in the environmental history form related to each trigger. Interventions that are thought to be the most crucial for each asthma trigger are listed first and in ***bold*** *type. In addition to educating families on effective interventions, it is also important to explain why certain interventions are not recommended, particularly the use of ozone-generating air cleaners which may be harmful. Furthermore, providers should give families affected by asthma: educational materials (an example of a patient handout is listed under each trigger); relevant website information; and information about allergy supplies, smoking cessation programs, and other community resources. A variety of these materials available from a number of organizations are listed at http://www.neetf.org/Health/asthma_resources.htm.*

The intervention guidelines assume a two-visit concept for the patient. The first visit includes taking an environmental history, possible allergy testing or referral, and a commitment by the parent to work on reducing exposures to known allergens or irritants. The second, follow-up visit involves counseling of the patient or patient's family on controlling the exposures that trigger the child's asthma. In addition to this two-visit concept, providers should work with the family to schedule appropriate follow-up visits to evaluate the patients' self-management skills. It is very important to ask about all environments in which a child with asthma may be spending significant amounts of time, including all residences where the child sleeps or spends time, such as schools, daycares, camps, and college dorms.

Although primary care providers do not perform skin testing as an asthma specialist might, in vitro testing is an option that may be considered. However, any testing should be focused on allergens that are identified by the environmental history, and should not replace timely allergy referral. The health care provider should try to document sensitivity for each suspected allergen through allergy testing before making any major or costly recommendations related to environmental controls. However, some simple and low cost recommendations may be reasonable, particularly in areas where widespread exposure to cockroaches or dust mites is well known. Providers can assist families in implementing environmental interventions by helping them prioritize the changes they make in the home. For example, providers can encourage families to begin by creating a safe sleeping zone for the child.

A separate fact sheet is not provided for outdoor pollens (from trees, grass, or weeds) and molds. To avoid exposures, children should be recommended to stay indoors with windows closed in an air conditioned environment — if possible — during the season in which they have problems with outdoor allergens, especially during the afternoon.

Viral illnesses are not included in this list of environmental triggers, although their importance in triggering and exacerbating asthma is recognized. Primary care providers should remain aware that when a child with known asthma develops an upper respiratory infection, an asthma exacerbation is likely to follow.

As noted earlier, environmental management is only one component of a comprehensive asthma management plan. It is recommended that these materials be used in conjunction with the National Asthma Education and Prevention Program's clinical and pharmacological guidelines.

Dust Mites and Asthma

Dust mites are tiny microscopic relatives of the spider that live on mattresses, bedding, upholstered furniture carpets, and curtains. These tiny creatures feed on the flakes of skin that people and pets shed daily, and they thrive in warm and humid environments.

Additional History Questions to Supplement the History Form

- Did you know that dust mite exposure can trigger asthma symptoms?
- What type of floor covering is in your child's bedroom?
- Do you have a vacuum cleaner with a HEPA filter?
- What have you tried so far to reduce dust/dust mite exposure?
- How often do you wash your child's bed linens?
- Are you currently using a mattress or pillow covering on your child's bed?
- Do you use other ways to decrease dust mite exposure?

Possible Interventions:

No matter how clean a home is, dust mites cannot be totally eliminated. The following suggestions can reduce exposure. Emphasis should be placed on reducing dust mite exposure where the child sleeps.

- **Encase all pillows and mattresses of the beds that the child sleeps on using allergen impermeable encasings.** (There are numerous sources for allergen impermeable encasings, and prices as well as quality may vary.)
- **Wash bedding weekly to remove allergen. Wash in hot water (130˚ F) to kill mites**
- Replace wool or feathered bedding with synthetic materials that will withstand repeated hot water washing
- Either remove from the bedroom or wash and thoroughly dry stuffed toys weekly
- Move stuffed toys away from the pillow the child sleeps on
- Vacuum once or twice weekly preferably using a vacuum cleaner with a HEPA filter or a double-layered microfilter bag (when the child is not around)
- Use a damp mop or rag to remove dust, not a dry cloth that just stirs up dust mite allergens
- Avoid use of humidifiers
- The following interventions are expensive and are only recommended after an allergist has identified your child as allergic to dust mites:
- Consider replacing draperies with blinds or other wipeable window covering
- Consider carpet removal in the child's bedroom
- Consider removing upholstered furniture
- Consider using portable air cleaner with HEPA filter for child's bedroom
- **Avoid use of ozone generators and certain ionic air cleaners which can actually generate harmful ozone**

Follow-Up / Notes:

Possible Information Flyer to Give to Patient Families:

Asthma & Allergy Prevention: Dust Mites
http://www.niehs.nih.gov/airborne/prevent/mites.html

Animal Allergens and Asthma

Additional History Questions to Supplement the History Form

- What type of furry pet(s) do you have (and how many of each)?
- Is it a strictly indoor pet? _____ outdoor? _____ indoor/outdoor? _____
- Does your child sleep with the pet?
- Has your child's asthma become worse since having the pet?
- If you moved your pet outdoors, did your child's asthma improve?
- If there is evidence of rodents in your home, how severe is the problem (mild, moderate, severe, very severe)
- Does your child's classroom (or other places he/she spends time) have a furry pet that he/she plays with?

Possible Interventions:

Interventions with regard to pets should only be recommended if the child is allergic to the animal. Testing should therefore be done before making any recommendations. To reduce your child's exposure to animal allergens, the first two options below have been shown to be the most effective:

- **Consider finding a new home for indoor cats, dogs, and pet rodents**
- **At a minimum, keep pets outside**
- If neither of those are possible, the following may help reduce exposure:
- Keep pets out of the child's bedroom
- Encase mattresses and pillows
- Remove carpets
- Vacuum regularly using a cleaner with a HEPA filter or a double-layered microfilter bag (when the child is not around)
- Use portable air cleaner with HEPA filter for child's bedroom
- Keep pets off furniture and out of cars
- Bathing cats and dogs has been shown to decrease these allergens, however, it must be done at least twice a week to be effective
- **If rats or mice have been observed, use the least toxic extermination method, such as traps and baits**
- **Also use methods listed for cockroach control (See Cockroach Allergen and Asthma fact sheet on page 22)**

Follow-Up / Notes:

Possible Information Flyer to Give to Patient Families:

Allergy & Asthma Prevention: Pets & Animals
http://www.niehs.nih.gov/airborne/prevent/pets.html

Cockroach Allergen and Asthma

Additional History Questions to Supplement the History Form:

- Approximately how many cockroaches do you see in your home on a daily basis?
- Do you see evidence of cockroach droppings?
- How do you get rid of the cockroaches in your home?
- Does your child's school (or other places she/he spends time) have cockroaches?

Possible Interventions:

Eradication can be very difficult, especially in apartment buildings, and it is often temporary. Roaches follow food and water sources in your house. In general, the **least toxic methods of roach control should be employed first.**

- **Clean up all food items/ crumbs/ spills as soon as possible**
- **Store food and trash in closed containers**
- **Limit spread of food around house, especially bedrooms**
- **Fix water leaks under sinks**
- **Mop kitchen floor at least once a week**
- **Clean counter tops daily**
- Take garbage out daily
- Check for and plug up crevices outside your house that cockroaches may enter
- **Use the integrated pest management (IPM) approach for extermination — least toxic methods first**
- Use boric acid powder under stoves and other appliances
- Use bait stations and gels. It is highly recommended to use a professional, licensed exterminator.
- If you choose to apply the pesticides yourself, read the product label and follow all directions carefully
- Avoid using liquid sprays inside the house, especially near places children crawl, play, or sleep
- **Never attempt to use industrial strength pesticide sprays that require dilution**

Follow-Up / Notes:

Asthma & Allergy Prevention: Cockroaches
http://www.niehs.nih.gov/airborne/prevent/roach.html

Mold/Mildew and Asthma

Mold spores are allergens that can be found both indoors and outdoors. Molds are found indoors in dark, warm, and humid environments such as basements, attics, bathrooms, and laundry rooms. They are also found in air conditioners, humidifiers, refrigerator drip trays and garbage pails. Molds grow outdoors in moist shady areas. They are common in soil, decaying vegetation, compost piles, rotting wood, and fallen leaves. Mold growth outdoors is seasonal, first appearing in early spring and thriving until the first frost.

Additional History Questions to Supplement the History Form:

- Do you see mold growth in any part of your home?
- How large an area is the mold growth? (i.e. greater than 3 ft. x 3 ft?)
- Does your child's school (or other places he/she spends time) have mold growth?
- Do you have problems with moisture or leaks in your home?
- Do you frequently have condensation on your windows?
- Have you tried using something to decrease the humidity in your home?

Possible Interventions:

The emphasis should first be on controlling all sources of moisture in the house. Items that are too moldy to clean should be discarded. The size of the mold contamination in the house should determine how the mold gets cleaned up. Generally, an area of 3 feet x 3 feet or larger should be cleaned by a professional.

- Check faucets, pipes, and ductwork for leaks and repair as soon as possible
- Control indoor humidity
  - Use a dehumidifier or air conditioner (non evaporative or water-filled type) to maintain indoor relative humidity below 50%
  - Clean the dehumidifier as instructed by the manufacturer
  - Do not use a humidifier
  - Vent bathrooms and clothes dryers to the outside
  - Install and use exhaust fans in the kitchen, baths and damp areas
  - Avoid carpet and wallpaper in rooms prone to dampness
  - For those who own a home with an evaporative cooler, control the humidity level with a dehumidifier
- When first turning on home or car air conditioners, have your child leave the room or drive with the windows open for several minutes to allow mold spores to disperse
- Remove decaying debris from the yard, roof, and gutters
- Your child should avoid raking leaves, mowing lawns, or working with peat, mulch, hay, or dead wood if he/she is allergic to mold spores
- If you choose to clean mold yourself, use chlorine solution diluted 1:10 with water but do not mix bleach with other cleaning solutions containing ammonia due to toxic fumes
- Quaternary ammonium compounds are effective fungicides when bleach cannot be used
- For extensive mold contamination, (greater than 9 square feet – 3 ft. x 3 ft.) professional removal is recommended.

Follow-Up / Notes:

Asthma & Allergy Prevention: Mold Spores
http://www.niehs.nih.gov/airborne/prevent/mold.html

Environmental Tobacco Smoke and Asthma

Cigarette smoke contains many toxic chemicals and irritants. Children exposed to tobacco smoke have increased asthma exacerbations and other problems, including lower respiratory infections and middle ear infections. Infants have an increased risk of sudden infant death syndrome. Simply "smoking outside" is not enough to limit the harm to children from tobacco smoke. Remember that smoke settles in clothes, hair, car upholstery, and furniture. Once a parent or a caregiver acknowledges that he/she smokes, the provider should consider writing a referral for a smoking cessation or a community support program.

Additional History Questions to Supplement the History Form:

- Who in the family smokes cigarettes?
  How many cigarettes per day?
  Does he/she (they) smoke in the house? _____
  Outside? _____ Both inside and outside? _____ In the car? _____
- Does anyone who spends time at your house smoke (friends, neighbors, relatives)?
- Have you established a smoking ban or no smoking policy in the household?
- Does anyone smoke in childcare settings where the child stays?
- Describe the circumstances when your child may be exposed to smoke?

Possible Interventions:

- **Keep your home and car smoke-free**
- **Seek support to quit smoking, consider aids such as nicotine gum, patch, and medication from your doctor to help you in quitting**
- **Choose smoke-free childcare and social settings**
- Seek smoke-free environments in restaurants, theaters, and hotel rooms
- If you choose to smoke, do not smoke near your child

Follow-Up / Notes:

Possible Information Flyer to Give to Patient Families:

Asthma & Allergy Prevention: Cigarette Smoke
http://www.niehs.nih.gov/airborne/prevent/smoke.html

Air Pollution and Asthma

This category covers a wide range of toxic chemicals and pollutants, whether from industrial or vehicle pollution outdoors, or from the use of wood stoves, volatile organic compounds, or other substances indoors. Combustion by–products (e.g., nitrogen dioxide) and other pollutants can be respiratory irritants. Solvents and other chemicals can be found in building materials and can volatize during the 1-2 year period after new construction. Diesel exhaust from school buses and other forms of air pollution can also worsen asthma. Health care providers may want to sign up for Enviroflash email or pager notification of air quality forecasts in areas where it is offered. (For more information, see: http://cfpub.epa.gov/airnow/index.cfm?action=airnow.enviroflash)

Additional History Questions to Supplement the History Form:

Indoor Air Pollution Questions

- Do you live in a home that was built in the past 1-2 years?
- If you recently made changes to your house – installed new carpets, painted, or other changes – how long ago was that?
- Was there a change in your child's asthma symptoms after moving to a new house or having the work mentioned above done in your home?
- Do you ever notice a chemical smell in your home?
- If you have a wood burning fireplace or stove, how many times per month in the winter do you use it?
- Does anyone in your house use strong-smelling perfumes, scented candles, hairsprays, or other aerosol substances?

Outdoor Air Pollution Questions

- Do you live within 300 yards of a major roadway or highway? _____ An area where trucks or other vehicles idle? _____ A major industry with smokestacks? _____
- Is residential or agricultural burning a problem where you live?
- How do you hear about air quality alerts?

Possible Interventions:

For **indoor** air pollution, the two best approaches to reducing indoor air pollution are source control and ventilation.

- **Eliminate tobacco smoke**
- **Use good housekeeping practices to control particles**
- **Install an exhaust fan close to the source of contaminants, and vent it to the outside**
- Properly ventilate the room where a fuel-burning appliance is being used
- Ensure that wood stove doors are tight-fitting
- Follow manufacturers' instructions when using an unvented kerosene or gas space heater
- Ensure that fireplaces are properly vented so smoke escapes through the chimney
- Never use a gas-cooking appliance as a heating source
- Open windows especially when indoor pollutant sources are in use (this option must be balanced against the concern of mold or other plant allergens and outdoor air pollution)
- Parents should change clothes prior to returning from work if they work around any strong smelling chemicals or paints or other toxic substances
- Avoid strong odors and minimize use of products and materials that emit irritants, such as smoke, strong perfumes, talcum powder, hair sprays, cleaning products, paint fumes, sawdust, chalk dust, air freshener sprays, and insect sprays

Outdoor air pollution, especially ozone and particulate matter can increase asthma symptoms.

- **Monitor air quality index levels and reduce your child's outdoor activities when the AQI is in the unhealthy range**
- **If your child's symptoms are worse or he/she requires more albuterol (rescue medicine) the day after AQI levels are in the unhealthy range, contact your health care provider**
- Use HEPA filters in household vents
- Reduce use of candles, wood-burning stoves and fireplaces
- If particle pollution levels are high outdoors, do not vacuum the floor since this increases particle levels indoors
- Advise your child to stay away from the exhaust pipe of idling school buses and trucks
- Consider moving to a new location if this is possible

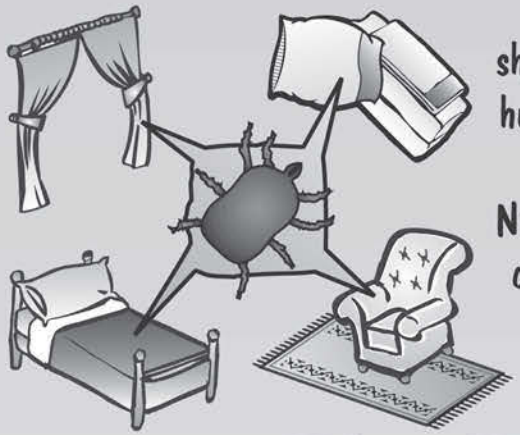
Sample Patient Flyers

DUST MITES

Dust mites are tiny microscopic relatives of the spider and live on mattresses, bedding, upholstered furniture, carpets and curtains.

These tiny creatures feed on the flakes of skin that people and pets shed daily and they thrive in warm and humid environments.



No matter how clean a home is, dust mites cannot be totally eliminated. However, the number of mites can be reduced by following the suggestions below.

Preventive Strategies

- Encase your mattress and pillows in dust-proof or allergen impermeable covers (available from specialty supply mail order companies or some bedding and department stores).
- Wash all bedding and blankets once a week in hot water (at least 130-140° F) to kill dust mites. Non-washable bedding can be frozen overnight to kill dust mites.
- Replace wool or feathered bedding with synthetic materials and traditional stuffed animals with washable ones.
- If possible, replace wall-to-wall carpets in bedrooms with bare floors (linoleum, tile or wood) and remove fabric curtains and upholstered furniture.
- Use a damp mop or rag to remove dust. Never use a dry cloth since this just stirs up mite allergens.
- Use a dehumidifier or air conditioner to maintain relative humidity at about 50% or below.
- Use a vacuum cleaner with either a double-layered microfilter bag or a HEPA filter to trap allergens that pass through a vacuum's exhaust.
- Wear a mask while vacuuming to avoid inhaling allergens, and stay out of the vacuumed area for 20 minutes to allow any dust and allergens to settle after vacuuming.

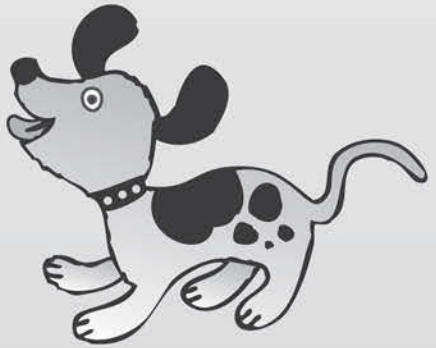
NIEHS
National Institute of Environmental Health Sciences

http://www.niehs.nih.gov/airborne/prevent/mites.html

PETS & ANIMALS

Many people think animal allergies are caused by the fur or feathers of their pet. In fact, allergies are actually aggravated by:

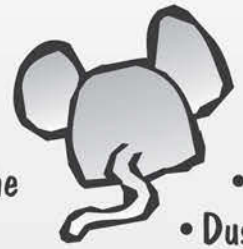
- proteins secreted by oil glands and shed as dander
- proteins in saliva (which stick to fur when animals lick themselves)
- aerosolized urine from rodents and guinea pigs



Keep in mind that you can sneeze with and without your pet being present. Although an animal may be out of sight, their allergens are not. This is because pet allergens are carried on very small particles. As a result, pet allergens can remain circulating in the air and remain on carpets and furniture for weeks and months after a pet is gone. Allergens may also be present in public buildings, schools, etc. where there are no pets.

Preventive Strategies

- Remove pets from your home if possible.
- If pet removal is not possible, keep them out of bedrooms and confined to areas without carpets or upholstered furniture.
- If possible, bathe pets weekly to reduce the amount of allergens.

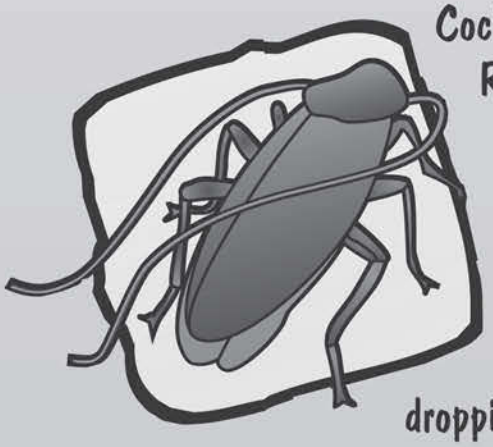


- Wear a dust mask and gloves when near rodents.
- After playing with your pet, wash your hands and clean your clothes to remove pet allergens.
- Avoid contact with soiled litter cages.
- Dust often with a damp cloth.

NIEHS
National Institute of Environmental Health Sciences

http://www.niehs.nih.gov/airborne/prevent/pets.html

COCKROACHES



Cockroaches are one of the most common and allergenic of indoor pests. Recent studies have found a strong association between the presence of cockroaches and increases in the severity of asthma symptoms in individuals who are sensitive to cockroach allergens. These pests are common even in the cleanest of crowded urban areas and older dwellings. They are found in all types of neighborhoods. The proteins found in cockroach saliva are particularly allergenic but the body and droppings of cockroaches also contain allergenic proteins.

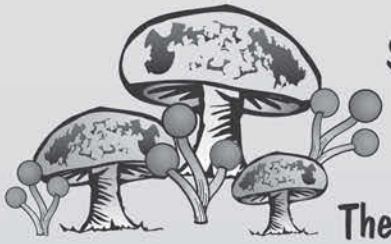
Preventive Strategies

- Limit the spread of food around the house and especially keep food out of bedrooms.
- Keep food and garbage in closed, tight-lidded containers. Never leave food out in the kitchen.
- Do not leave out pet food or dirty food bowls.
- Mop the kitchen floor and wash countertops at least once a week.
- Eliminate water sources that attract these pests, such as leaky faucets and drain pipes.
- Plug up crevices around the house through which cockroaches can enter.
- Use bait stations and other environmentally safe pesticides to reduce cockroach infestation.

NIEHS
National Institute of Environmental Health Sciences

http://www.niehs.nih.gov/airborne/prevent/roach.html

MOLD SPORES



Several molds that grow both indoors and outdoors, produce allergenic substances. These allergens can be found in mold spores and other fungal structures (e.g. hyphae). There is no definite seasonal pattern to molds that grow indoors. However outdoor molds are seasonal, first appearing in early spring and thriving until the first frost.

Indoor molds are found in dark, warm, humid and musty environments such as damp basements, cellars, attics, bathrooms and laundry rooms. They are also found where fresh food is stored, in refrigerator drip trays, garbage pails, air conditioners and humidifiers.

Outdoor molds grow in moist shady areas. They are common in soil, decaying vegetation, compost piles, rotting wood and fallen leaves.

Preventive Strategies

- Use a dehumidifier or air conditioner to maintain relative humidity below 50% and keep temperatures cool.
- Vent bathrooms and clothes dryers to the outside, and run bathroom and kitchen vents while bathing and cooking.
- Regularly check faucets, pipes and ductwork for leaks.
- When first turning on home or car air conditioners, leave the room or drive with the windows open for several minutes to allow mold spores to disperse.
- Remove decaying debris from the yard, roof and gutters.
- Avoid raking leaves, mowing lawns or working with peat, mulch, hay or dead wood. If you must do yard work, wear a mask and avoid working on hot, humid days.

NIEHS
National Institute of Environmental Health Sciences

http://www.niehs.nih.gov/airborne/prevent/mold.html

CIGARETTE SMOKE

Cigarette smoke contains a number of toxic chemicals and irritants. People with allergies may be more sensitive to cigarette smoke than others and research studies indicate that smoking may aggravate allergies.

Smoking does not just harm smokers but also those around them. Research has shown that children and spouses of smokers tend to have more respiratory infections and asthma than those of non-smokers. In addition, exposure to second-hand smoke can increase the risk of allergic complications such as sinusitis and bronchitis.

Common symptoms of smoke irritation are burning or watery eyes, nasal congestion, coughing, hoarseness and shortness of breath presenting as a wheeze.

Preventive Strategies

- Don't smoke and if you do, seek support to quit smoking. Contact Puff-Free Partners, such as:

ASTHMA HOME ENVIRONMENT

☑ CHECKLIST

Home visits provide an opportunity to educate and equip asthma patients with the tools to effectively manage their disease in concert with a physician's care. This checklist—designed for home care visitors—provides a list of questions and action steps to assist in the identification and mitigation of environmental asthma triggers commonly found in and around the home. The checklist is organized into three sections—building information, home interior and room interior. The room interior is further subdivided by categories (such as bedding and sleeping arrangements, flooring, window treatments, and moisture control). This will allow the home care visitor to focus on the specific activities or things in a room—in particular the asthma patient's sleeping area—that might produce or harbor environmental triggers. The activities recommended in this checklist are generally simple and low cost. Information on outdoor air pollution follows the checklist. The last page includes information on U.S. Environmental Protection Agency (EPA) resources and an area for the home care visitor to record a home visit summary.

If the patient's sensitivities to allergens (such as dust mites, pests, warm-blooded pets and mold) and irritants (such as secondhand smoke and nitrogen dioxide) are known, the home care visitor should begin by focusing on relevant areas. This checklist covers the following allergens and irritants, which are commonly found in homes. Information is also provided on chemical irritants—found in some scented and unscented consumer products—which may worsen asthma symptoms.

Dust Mites

Triggers: Body parts and droppings.

Where Found: Highest levels found in mattresses and bedding. Also found in carpeting, curtains and draperies, upholstered furniture, and stuffed toys. Dust mites are too small to be seen with the naked eye and are found in almost every home.

Pests (such as cockroaches and rodents)

Triggers: Cockroaches – Body parts, secretions, and droppings.
Rodents – Hair, skin flakes, urine, and saliva.

Where Found: Often found in areas with food and water such as kitchens, bathrooms, and basements.

Warm-Blooded Pets (such as cats and dogs)

Triggers: Skin flakes, urine, and saliva.

Where Found: Throughout entire house, if allowed inside.

Mold

Triggers: Mold and mold spores which may begin growing indoors when they land on damp or wet surfaces.

Where Found: Often found in areas with excess moisture such as kitchens, bathrooms, and basements. There are many types of mold and they can be found in any climate.

Secondhand Smoke

Trigger: Secondhand smoke – Mixture of smoke from the burning end of a cigarette, pipe or cigar and the smoke exhaled by a smoker.

Where Found: Home or car where smoking is allowed.

Nitrogen Dioxide (combustion by-product)

Trigger: Nitrogen dioxide – An odorless gas that can irritate your eyes, nose, and throat and may cause shortness of breath.

Where Found: Associated with gas cooking appliances, fireplaces, woodstoves, and unvented kerosene and gas space heaters.

BUILDING INFORMATION

(This information may be helpful to determine reasonable mitigations.)

What type of building does the patient live in?

- ☐ House
- ☐ Duplex
- ☐ Apartment
- ☐ Mobile home
- ☐ Other_____

Notes:

Does the patient own or rent?

- ☐ Own
- ☐ Rent

Notes:

Questions	Answers	Action Steps
HOME INTERIOR		▲ **MAY REQUIRE ADDITIONAL TIME AND/OR RESOURCES.**
Secondhand Smoke		
Does anyone smoke in the home or car?	☐ Y ☐ N	■ Keep the home and car smoke-free. ■ Do not allow visitors to smoke in the home. ■ Take the smoke-free home pledge and post a smoke-free home decal or magnet to show that the house is a "smoke-free" zone.
Notes:		
Warm-blooded Pets (such as cats and dogs)		
Is the patient's asthma worse when around warm-blooded pets?	☐ Y ☐ N	■ If possible, remove the pet from the home or keep the pet outside. ■ If this is not possible, keep the pet out of the patient's sleeping area and off of the furniture.
Notes:		
Consumer Products		
Is the patient's asthma worse when around chemicals or products with strong odors (such as cleaners, paints, adhesives, pesticides, air fresheners, or cosmetics)?	☐ Y ☐ N	■ Limit patient's exposure as much as possible by minimizing product use, using products only when patient is not present, or trying alternative products. ■ If products are used, carefully follow manufacturer's instructions on the label and make sure the area is well ventilated.
Notes:		
Heating and Cooling Systems		
Does the heating and cooling system use filters?	☐ Y ☐ N	▲ If so, replace the filters quarterly. ▲ Use filters with higher efficiency than standard furnace filters, such as upgraded pleated filters, if heating or cooling system manufacturer's specifications allow.
Notes:		

Questions	Answers	Action Steps
HOME INTERIOR (continued)		▲ **MAY REQUIRE ADDITIONAL TIME AND/OR RESOURCES.**
Does the heating system use a fuel-burning appliance (such as an oil or gas furnace)? *Notes:*	☐ Y ☐ N	▲ Have the heating system - including furnaces, flues and chimneys - professionally inspected annually. ▲ Promptly repair cracks or damaged parts.
Are supplemental heating sources used? (Check all that apply) *Notes:*	☐ Fireplace ☐ Wood-burning stove ☐ Unvented kerosene or gas space heater ☐ Other_____	■ Properly ventilate the room where a fuel-burning appliance is used. Consider using appliances that vent to the outside whenever possible. ■ Never use a gas-cooking appliance as a heating source. ■ If using a fireplace, make sure it is properly vented to help ensure smoke escapes through the chimney. ■ If using a wood-burning stove, make sure that doors are tight-fitting. Use aged or cured wood only and follow the manufacturer's instructions for starting, stoking, and putting out the fire. ■ If using an unvented kerosene or gas space heater, follow the manufacturer's instructions for proper fuel to use and keep the heater properly adjusted.
Are there air conditioning window units? *Notes:*	☐ Y ☐ N	■ Run window air conditioner with the vent control open to increase the outdoor ventilation rate during the cooling season.
ROOM INTERIOR		
Bedding and Sleeping Arrangements		
What does the patient sleep on? (Check all that apply) *Notes:*	☐ Mattress with box springs ☐ Sofa ☐ Other_____	▲ Cover patient's mattress in a dust-proof (allergen impermeable) zippered cover. Clean cover according to manufacturer's instructions. ■ If it is necessary for the patient to sleep on upholstered furniture such as a sofa, then cover furniture with washable slipcovers or sheets and vacuum furniture regularly (including removing cushions and vacuuming in cracks and crevices).
What types of bedding does the patient use? (Check all that apply) *Notes:*	☐ Bedspread (e.g., comforter, quilt) ☐ Blankets ☐ Pillows ☐ Sheets ☐ Other (e.g., sleeping bag) _____	■ Choose washable bedding. ■ Wash bedding regularly in hot water and dry completely. ▲ Cover patient's pillow in a dust-proof (allergen impermeable) zippered cover. Clean cover according to manufacturer's instructions.

Questions	Answers	Action Steps
ROOM INTERIOR (continued)		▲ **MAY REQUIRE ADDITIONAL TIME AND/OR RESOURCES.**
Flooring		
What type of floor covering is present? (Check all that apply)	☐ Carpeting ☐ Hardwood floor, tile, or vinyl flooring ☐ Throw rugs ☐ Other_____	■ If carpeting is present, vacuum carpets, area rugs, and floors regularly. ■ If possible, use a vacuum cleaner with a high efficiency filter. ■ Mop hard surface floors regularly. ■ Wash throw rugs regularly in hot water. Dry completely. ■ Clean baseboards regularly using a damp cloth with warm, soapy water. ■ Someone besides the patient should vacuum, sweep, empty the dust canister and change the vacuum bag. ■ If possible, the patient should stay out of rooms when they are being vacuumed or swept. ■ If the patient vacuums, sweeps, empties the dust canister, or changes the vacuum bag, he or she should wear a dust mask.
Notes:		
Upholstered Furniture and Stuffed Toys		
Is there upholstered furniture present?	☐ Y ☐ N	■ Cover upholstered furniture with washable slipcovers or sheets. ■ Vacuum upholstered furniture regularly, including removing cushions and vacuuming in cracks and crevices. ▲ If replacing furniture, consider purchasing a non-upholstered furniture - such as vinyl, wood, or leather - that can be easily wiped down.
Notes:		
Are stuffed toys present?	☐ Y ☐ N	■ Choose washable stuffed toys, and wash frequently in hot water. Dry completely. ■ Limit the number of stuffed toys in patient's bed and sleeping area.
Notes:		
Window Treatments		
What window coverings are present? (Check all that apply)	☐ Curtains or drapes ☐ Blinds ☐ Shades ☐ Other_____	■ Vacuum drapes regularly. ■ Wash and dry curtains regularly. ■ Dust window sills, blinds, and shades regularly using a damp cloth with warm, soapy water. Dry completely. ▲ If possible, replace curtains or drapes with plastic, vinyl, wood, or aluminum blinds.
Notes:		
Cooking Appliances		
Are gas cooking appliances used?	☐ Y ☐ N	■ When cooking with a gas appliance, turn on an exhaust fan or open a window. ■ Avoid misuse of the appliance by following the manufacturer's instructions for operation.
Notes:		

Questions	Answers	Action Steps
ROOM INTERIOR (continued)		▲ **MAY REQUIRE ADDITIONAL TIME AND/OR RESOURCES.**
Moisture Control		
Is there evidence of water damage, moisture, or leaks (such as damp carpet or leaky plumbing)? *Notes:*	☐ Y ☐ N	■ Dry damp or wet items within 24-48 hours to avoid mold growth. ▲ Fix water leaks (such as leaky plumbing) as soon as possible. ▲ Replace absorbent materials, such as ceiling tiles and carpet, if mold is present. ▲ Use air conditioner or dehumidifier to maintain low indoor humidity. If possible, keep indoor humidity below 60% (ideally between 30-50%) relative humidity.
Do you see or smell mold or mildew (such as in the bathroom on tub, shower, walls, or windows)? *Notes:*	☐ Y ☐ N	■ Open a window or turn on an exhaust fan when there is excessive moisture in the room, such as when showering or cooking. ■ Scrub mold off hard surfaces with detergent and water. Dry completely. ■ Clean up mold and dry surfaces completely before painting or caulking. ▲ Replace absorbent materials, such as ceiling tiles and carpet, if mold is present.
Is standing water present (such as in refrigerator drip pans, air conditioner drip pans, or house plants)? *Notes:*	☐ Y ☐ N	■ Empty and clean refrigerator and air conditioner drip pans regularly. ■ Avoid standing water in plant containers.
Are humidifiers used in the patient's house? *Notes:*	☐ Y ☐ N	■ Use humidifier only when conditions require it, use the correct setting to maintain indoor relative humidity between 30-50 percent, and clean humidifier reservoirs regularly. ■ Use low mineral content water to prevent the build-up of scale and dispersal of minerals into the air. ■ Follow manufacturer's instructions for use, maintenance, and replacement of any materials supplied with the humidifier.
Are rooms and moisture-producing appliances—such as stoves, clothes dryers, or dishwashers—properly vented (including venting to the outside if specified by the manufacturer)? *Notes:*	☐ Y ☐ N	■ Increase ventilation or air movement by opening doors and/or windows when practical. Use fans as needed. ■ Run the bathroom exhaust fan or open the window when showering. ■ Use exhaust fans or open windows whenever cooking or washing dishes. ■ Vent appliances properly according to manufacturer's specifications.

Questions	Answers	Action Steps
ROOM INTERIOR (continued)		▲ **MAY REQUIRE ADDITIONAL TIME AND/OR RESOURCES.**
Pest Control		
Is there evidence of cockroaches and/or rodents (such as droppings or dead specimens in traps)? *Notes:*	☐ Y ☐ N	■ Clean all surfaces where you have seen pests. ■ Use poison baits, boric acid, or traps to kill pests. Minimize use of sprays. If sprays are used: limit the spray to the infested area, carefully follow the instructions on the label, make sure there is plenty of fresh air where the spray is being used and, if possible, keep patient out of the room.
Are there food crumbs or open or unsealed food? *Notes:*	☐ Y ☐ N	■ Clean all food crumbs or spilled liquids right away. ■ Store food in sealed containers. ■ Remove food, bags, newspapers, and empty boxes, cans, and bottles from the sleeping area. ■ Put all garbage in plastic trash bags. Seal trash bags and put them into garbage cans with fitted lids every day.
Are there holes or gaps between construction materials and pipes that could allow pests to enter the house? *Notes:*	☐ Y ☐ N	■ Seal holes or gaps between construction materials and pipes, or ask the owner to do so.
Is there evidence of standing water or leaks? *Notes:*	☐ Y ☐ N	■ Dry damp or wet items within 24-48 hours to avoid mold growth. ■ Avoid standing water in house plant containers and drip pans. ▲ Fix water leaks (such as leaky plumbing) as soon as possible.

OUTDOOR AIR POLLUTION

Exposure to air pollution (mainly ozone and particle pollution) can trigger asthma attacks. The Air Quality Index (AQI) is a tool to provide the public with clear and timely information on local air quality and whether air pollution levels pose a possible health concern. The AQI is reported and forecasted every day in many areas throughout the U.S. on local weather reports and through national media. Asthma attacks are most likely to occur the day **after** outdoor pollution levels are high.

People can take simple steps to reduce their exposure to outdoor air pollution. When the AQI reports unhealthy levels:

- Limit physical exertion outdoors.
- Consider changing the time of day of strenuous outdoor activity to avoid the period when air pollution levels are high or consider postponing sports activities to another time.
- Reduce the intensity of the activity, or spend less time engaged in strenuous activities. For example, coaches can rotate players more frequently in strenuous sports, like soccer. Resting players reduces their exposure to air pollution.

To learn more about and access the AQI, visit www.epa.gov/airnow.

Educational Resources:

To learn more about EPA's programs on:

- Asthma and steps you can take to remove environmental triggers from the home, visit www.epa.gov/asthma.
- Secondhand smoke and how to make your home and car smoke-free, visit www.epa.gov/smokefree or call the smoke-free home pledge number at 1-866-SMOKE-FREE (1-866-766-5337).
- Household pest management and how to apply integrated pest management at home, visit www.epa.gov/pesticides/controlling/home.htm.

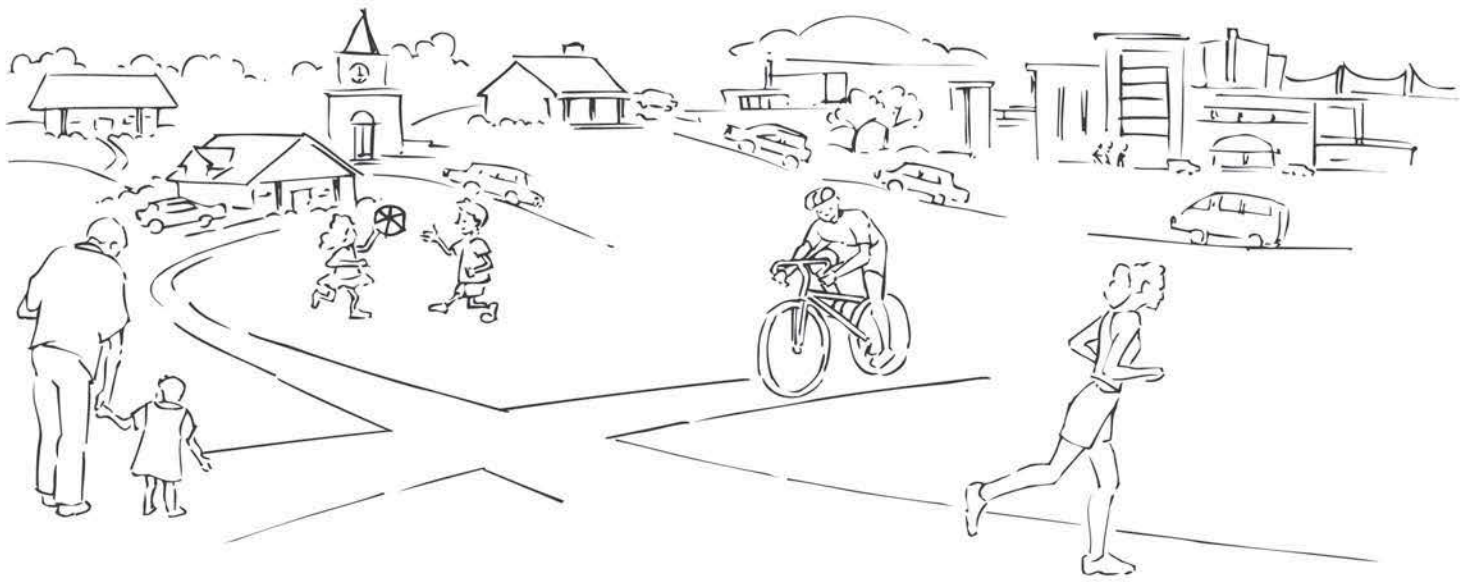
ASTHMA AND OUTDOOR AIR POLLUTION



1 Air pollution can make asthma symptoms worse and trigger attacks.

If you or your child has asthma, have you ever noticed symptoms get worse when the air is polluted? Air pollution can make it harder to breathe. It can also cause other symptoms, like coughing, wheezing, chest discomfort, and a burning feeling in the lungs.

Two key air pollutants can affect asthma. One is *ozone* (found in smog). The other is *particle pollution* (found in haze, smoke, and dust). When ozone and particle pollution are in the air, adults and children with asthma are more likely to have symptoms.

2 You can take steps to help protect your health from air pollution.

► *Get to know how sensitive you are to air pollution.*

- Notice your asthma symptoms when you are physically active. Do they happen more often when the air is more polluted? If so, you may be sensitive to air pollution.
- Also notice any asthma symptoms that begin up to a day *after* you have been outdoors in polluted air. Air pollution can make you more sensitive to asthma triggers, like mold and dust mites. If you are more sensitive than usual to indoor asthma triggers, it could be due to air pollution outdoors.

► *Know when and where air pollution may be bad.*

- *Ozone* is often worst on hot summer days, especially in the afternoons and early evenings.
- *Particle pollution* can be bad any time of year, even in winter. It can be especially bad when the weather is calm, allowing air pollution to build up. Particle levels can also be high:
  - — Near busy roads, during rush hour, and around factories.
  - — When there is smoke in the air from wood stoves, fireplaces, or burning vegetation.

► ***Plan activities when and where pollution levels are lower.*** Regular exercise is important for staying healthy, especially for people with asthma. By adjusting when and where you exercise, you can lead a healthy lifestyle and help reduce your asthma symptoms when the air is polluted. In summer, plan your most vigorous activities for the morning. Try to exercise away from busy roads or industrial areas. On hot, smoggy days when ozone levels are high, think about exercising indoors.

► ***Change your activity level.*** When the air is polluted, try to take it easier if you are active outdoors. This will reduce how much pollution you breathe. Even if you can't change your schedule, you might be able to change your activity so it is less intense. For example, go for a walk instead of a jog. Or, spend less time on the activity. For example, jog for 20 minutes instead of 30.

► ***Listen to your body.*** If you get asthma symptoms when the air is polluted, stop your activity. Find another, less intense activity.

► ***Keep your quick-relief medicine on hand when you're active outdoors.*** That way, if you do have symptoms, you'll be prepared. This is especially important if you're starting a new activity that is more intense than you are used to.

► ***Consult your health care provider.*** If you have asthma symptoms when the air is polluted, talk with your health care provider.

- If you will be exercising more than usual, discuss this with your health care provider. Ask whether you should use medicine before you start outdoor activities.
- If you have symptoms during a certain type of activity, ask your health care provider if you should follow an asthma action plan.

3 Get up-to-date information about your local air quality:

Sometimes you can tell that the air is polluted—for example, on a smoggy or hazy day. But often you can't. In many areas, you can find air quality forecasts and reports on local TV or radio. These reports use the Air Quality Index, or AQI, a simple color scale, to tell you how clean or polluted the air is. You can also find these reports on the Internet at: *www.epa.gov/airnow.* You can use the AQI to plan your activities each day to help reduce your asthma symptoms.

Policy Statement—Equipment for Ambulances

Almost 4 decades ago, the Committee on Trauma of the American College of Surgeons (ACS) developed a list of standardized equipment for ambulances. Beginning in 1988, the American College of Emergency Physicians (ACEP) published a similar list. The 2 organizations collaborated on a joint document published in 2000, and the National Association of EMS Physicians (NAEMSP) participated in the 2005 revision. The 2005 revision included resources needed on ambulances for appropriate homeland security. All 3 organizations adhere to the principle that emergency medical services (EMS) providers at all levels must have the appropriate equipment and supplies to optimize prehospital delivery of care. The document was written to serve as a standard for the equipment needs of emergency ambulance services in both the United States and Canada.

EMS providers care for patients of all ages, who have a wide variety of medical and traumatic conditions. With permission from the ACS Committee on Trauma, ACEP, and NAEMSP, the current revision includes updated pediatric recommendations developed by members of the federal Emergency Medical Services for Children (EMSC) Stakeholder Group. The EMSC Program has developed several performance measures for the program's state partnership grantees. One of the performance measures evaluates the availability of essential pediatric equipment and supplies for basic life support (BLS) and advanced life support (ALS) patient care units. This document will be used as the standard for this performance measure. The American Academy of Pediatrics (AAP) has also officially endorsed this list.

For purposes of this document, the following definitions have been used: a neonate is 0 to 28 days old, an infant is 29 days to 1 year old, and a child is >1 through 11 years old with delineation into the following developmental stages:

- Toddlers (1–3 years old)
- Preschoolers (3–5 years old)
- Middle childhood (6–11 years old)
- Adolescents (12–18 years old)

These standard definitions are age based. Length-based systems have been developed to more accurately estimate the weight of children and predict appropriate equipment sizes, medication doses, and guidelines for fluid volume administration.

PRINCIPLES OF PREHOSPITAL CARE

The goal of prehospital care is to minimize further systemic insult or injury and manage life-threatening conditions through a series of well-defined and appropriate interventions, and to embrace principles that ensure patient safety. High-quality, consistent emergency care demands continuous quality improvement and is directly dependent on

the effective monitoring, integration, and evaluation of all components of the patient's care.

Integral to this process is medical oversight of prehospital care by using preexisting protocols (indirect medical oversight), which are evidence based when possible, or by medical control via voice and/or video communication (direct medical oversight). The protocols that guide patient care should be established collaboratively by medical directors for ambulance services, adult and pediatric emergency medicine physicians, adult and pediatric trauma surgeons, and appropriately trained basic and advanced emergency medical personnel. Current Institute of Medicine (IOM) recommendations encourage each EMS agency to have a pediatric coordinator to specifically coordinate the capability of the service to care for nonadult patients.

EQUIPMENT AND SUPPLIES

The guidelines list the supplies and equipment that should be stocked on ambulances to provide the accepted standards of patient care. Previous documents regarding ambulance equipment referred to essential or minimal equipment necessary to adequately equip an ambulance. Equipment requirements will vary, depending on the certification levels of the providers, population densities, geographic and economic conditions of the region, and other factors.

The following list is divided into equipment for BLS and ALS ambulances. ALS ambulances must have all of the equipment on the required BLS list as well as equipment on the required ALS list. This list represents a consensus of recommendations for equipment and supplies that will facilitate patient care in the out-of-hospital setting.

REQUIRED EQUIPMENT: BLS AMBULANCES

A. Ventilation and Airway Equipment

1. Portable and fixed suction apparatus with a regulator (per federal specifications; see Federal Specification KKK-A-1822F reference)
   - Wide-bore tubing, rigid pharyngeal curved suction tip; tonsillar and flexible suction catheters, 6F–16F, are commercially available (have 1 between 6F and 10F and 1 between 12F and 16F)
2. Portable oxygen apparatus capable of metered flow with adequate tubing
3. Portable and fixed oxygen-supply equipment
   - Variable flow regulator
4. Oxygen-administration equipment
   - Adequate-length tubing; transparent mask (adult and child sizes), both nonrebreathing and valveless; nasal cannulas (adult, child)
5. Bag-valve mask (manual resuscitator)
   - Hand-operated, self-reexpanding bag; adult (>1000 mL) and child (450–750 mL) sizes, with oxygen reservoir/accumulator; valve (clear, disposable, operable in cold weather); and mask (adult, child, infant, and neonate sizes)
6. Airways
   - Nasopharyngeal (16F–34F; adult and child sizes)
   - Oropharyngeal (sizes 0–5; adult, child, and infant sizes)
7. Pulse oximeter with pediatric and adult probes
8. Saline drops and bulb suction for infants

B. Monitoring and Defibrillation

All ambulances should be equipped with an automated external defibrillator (AED) unless staffed by ALS personnel who are carrying a monitor/defibrillator. The AED should have pediatric capabilities, including child-sized pads and cables.

C. Immobilization Devices

1. Cervical collars
   - Rigid for children aged 2 years or older; child and adult sizes (small, medium, large, and other available sizes)
2. Head immobilization device (not sandbags)
   - Firm padding or commercial device
3. Lower extremity (femur) traction devices
   - Lower extremity limb-support slings, padded ankle hitch, padded pelvic support, traction strap (adult and child sizes)
4. Upper and lower extremity immobilization devices
   - Joint-above and joint-below fracture (sizes appropriate for adults and children), rigid support constructed with appropriate material (cardboard, metal, pneumatic, vacuum, wood, or plastic)
5. Impervious backboards (long, short; radiolucent preferred) and extrication device
   - Short (extrication, head-to-pelvis length) and long (transport, head-to-feet length) with at least 3 appropriate restraint straps (chin strap alone should not be used for head immobilization) and with padding for children and handholds for moving patients

D. Bandages

1. Commercially packaged or sterile burn sheets
2. Triangular bandages
   - Minimum of 2 safety pins each
3. Dressings
   - Sterile multitrauma dressings (various large and small sizes)
   - ABDs, 10 × 12 in or larger
   - 4 × 4-in gauze sponges or suitable size
4. Gauze rolls
   - Various sizes
5. Occlusive dressing or equivalent
   - Sterile, 3 × 8 in or larger
6. Adhesive tape
   - Various sizes (including 1 and 2 in), hypoallergenic
   - Various sizes (including 1 and 2 in), adhesive
7. Arterial tourniquet (commercial preferred)

E. Communication

Two-way communication device between EMS provider, dispatcher, and medical control

F. Obstetrical Kit (Commercial Package Is Available)

1. Kit (separate sterile kit)
   - Towels, 4 × 4-in dressing, umbilical tape, sterile scissors or other cutting utensil, bulb suction, clamps for cord, sterile gloves, blanket
2. Thermal absorbent blanket and head cover, aluminum-foil roll, or appropriate heat-reflective material (enough to cover newborn)

G. Miscellaneous

1. Sphygmomanometer (pediatric and adult regular- and large-sized cuffs)
2. Adult stethoscope
3. Length/weight-based tape or appropriate reference material for pediatric equipment sizing and drug dosing based on estimated or known weight
4. Thermometer with low temperature capability
5. Heavy bandage or paramedic scissors for cutting clothing, belts, and boots
6. Cold packs
7. Sterile saline solution for irrigation (1-L bottles or bags)
8. Flashlights (2) with extra batteries and bulbs
9. Blankets
10. Sheets (minimum of 4), linen or paper, and pillows
11. Towels
12. Triage tags
13. Disposable emesis bags or basins
14. Disposable bedpan
15. Disposable urinal
