POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Sports Medicine and Fitness

Promotion of Healthy Weight-Control Practices in Young Athletes

ABSTRACT. Children and adolescents are often involved in sports in which weight loss or weight gain is perceived as an advantage. This policy statement describes unhealthy weight-control practices that may be harmful to the health and/or performance of athletes. Healthy methods of weight loss and weight gain are discussed, and physicians are given resources and recommendations that can be used to counsel athletes, parents, coaches, and school administrators in discouraging inappropriate weight-control behaviors and encouraging healthy methods of weight gain or loss, when needed. ***Pediatrics*** **2005;116:1557–1564;** ***athlete, weight gain, weight loss, wrestling, eating disorders.***

ABBREVIATION. NWCA, National Wrestling Coaches' Association.

INTRODUCTION

With the growth and advancement of youth sports, children and adolescents are becoming more involved in sports in which weight control is perceived to be advantageous for the individual and/or team. Bodybuilding, cheerleading, dancing, distance running, cross-country skiing, diving, figure skating, gymnastics, martial arts, rowing, swimming, weight-class football, and wrestling all emphasize thinness, leanness, and/or competing at the lowest possible weight. Other sports, such as football, rugby, basketball, and power lifting emphasize gaining weight by increasing lean muscle mass. In their attempt to lose weight and body fat or gain weight and muscle mass, some athletes resort to unhealthy weight-control practices,[1–5] which can potentially be harmful to their performance and/or their health. Pediatricians need to be able to recognize the young athlete who is at risk of developing unsafe weight-control practices and provide the athlete, family members, coaches, athletic trainers, and athletic directors with accurate information about healthy weight-control practices.

WEIGHT LOSS

Many athletes attempt to lose weight or body fat, hoping to improve performance, improve appearance, or meet weight expectations. Practices that are used to reduce weight include food restriction, vomiting, overexercising, diet-pill use, inappropriate use of prescribed stimulants or insulin, nicotine use, and voluntary dehydration (Table 1). Voluntary dehydration practices include fluid restriction, spitting, and the use of laxatives and diuretics, rubber suits, steam baths, and saunas. Weight loss becomes a problem when nutritional needs are not met or adequate hydration is not maintained.

Athletes may practice weight-control methods during the sports season only or year-round. These practices can impair athletic performance and increase injury risk. They also may result in medical complications including delayed physical maturation; oligomenorrhea and amenorrhea in female athletes; development of eating disorders; potential permanent growth impairment; an increased incidence of infectious diseases; changes in the cardiovascular, endocrine, gastrointestinal, renal and thermoregulatory systems; and depression.[1,4,6–9]

Dehydration

Hypohydration and dehydration are used by athletes in weight-sensitive sports in an attempt to lose weight or appear more lean and, thus, obtain a perceived advantage. Because the body does not store fluid or electrolytes before exercise, it is predisposed to dehydration.[10] The extent of the dehydration is determined by sweat loss and the inability or refusal to replace those losses with oral fluids.[11] On the basis of studies in adults, weight loss by dehydration results in suboptimal performance because of impaired strength, reaction time, endurance, and electrolyte imbalance and acidosis. It also may result in temporary learning deficits,[4,12–14] inability to concentrate, lethargy, mood swings, and changes in cognitive state.[15–20]

Hypohydration affects prolonged aerobic exercise more than it affects short, high-intensity anaerobic exercise.[10,21] In adults, a decrease in performance is seen when hypohydration is 2% or more (Table 2). Two to 3% hypohydration results in decreased reflex activity, maximal oxygen uptake, physical work capacity, and muscle endurance and impaired temperature regulation.[22] With additional hypohydration,

TABLE 1. Definition of Hydration

Euhydration: a normal state of body-water content
Dehydration: the process of incurring water deficit
Hypohydration: the extent (or level) of this deficit (usually described as percent of initial body weight)
Voluntary dehydration: purposeful restriction of fluids or use of measures to dehydrate oneself, often to produce weight loss

doi:10.1542/peds.2005-2314

TABLE 2. Effects of Various Levels of Hypohydration

Adults
2–3% hypohydration
Decreases reflex activity
Maximal oxygen uptake decreases by 10%[22]
Physical work capacity decreases by 22%[22]
Muscle strength decreases
Muscle endurance decreases
Impairment in temperature regulation
4–6% hypohydration
Maximal oxygen uptake decreases by 27%[22]
Physical work capacity decreases by 48%[22]
Muscle strength decreases more
Endurance time is reduced
Severe impairment in temperature regulation
Headaches, difficulty with concentration, impatience, sleepiness
>8% hypohydration
Heat cramps
Heat exhaustion
Heat stroke
Children
1% hypohydration
Reduces aerobic performance[25]
Increases core temperature[26]
No studies in children for higher levels of hypohydration exist

these parameters decrease even more,[22] and additional symptoms including reduced muscle strength, headache, difficulty concentrating, impatience, and sleepiness occur.[23] Dehydration retards the acclimation process and affects thermoregulation during exercise. The thermoregulatory effect of dehydration intensifies when athletes exercise. For every 1% hypohydration in adults, there is an associated increase of 0.1 to 0.4°C in body temperature.[23,24] When hypohydration exceeds 8%, heat cramps occur, followed by heat exhaustion and heat stroke (body temperature of more than 40.5°C or 105°F). These are serious, life-threatening events.

In children, 1% hypohydration is enough to induce a reduction in aerobic performance.[25] For ethical reasons, studies have not been performed in young children with greater levels of hypohydration. A study with 10- to 12-year-old boys who exercised intermittently in the heat suggested that the increase in their core temperature, at any level of hypohydration, was greater than in adults.[26]

Children have the following characteristics that are similar to adults:

1. Involuntary dehydration can occur with prolonged exercise even if the child is given fluids ad libitum.[11,26,27] This occurs principally when the fluids are unflavored.[28,29]
2. Dehydration causes greater body heat storage (excessive increase in core body temperature),[21,30] decreases blood volume, and results in reduced exercise tolerance,[28] increasing the risk of heat-related illness.[21,30–34]
3. Heat acclimation and training result in an increased sweating rate, which may provide heat dissipation by evaporation but also produces greater fluid loss.[28]
4. The likelihood of heat intolerance increases with conditions that are associated with excessive fluid loss (febrile state, gastrointestinal infection, diabetes insipidus, and diabetes mellitus), suboptimal sweating (spina bifida, sweating-insufficiency syndromes), excessive sweating (selective cyanotic congenital heart disease), abnormal sweating (cystic fibrosis), inadequate drinking (people with mental retardation and young children), abnormal hypothalamic thermoregulatory functions (anorexia nervosa, advanced undernutrition, previous heat-related illness), and obesity.[30,35,36]

Children have certain characteristics that, when compared with adults, predispose them to dehydration and heat illness, including the following:

1. Children produce more heat relative to body mass for the same exercise.[21,30,33]
2. Children have lower cardiac output for any given metabolic level.[30,33]
3. Children have higher thresholds before beginning to sweat.[34,35,37]
4. Sweating capacity is considerably lower in children,[30] reducing their ability to dissipate body heat by evaporation.[30,34,35,37]
5. Children become slightly more dehydrated with lower climatic and metabolic heat stress.
6. Children have a greater ratio of body surface area to body mass, which causes them to absorb heat more quickly when the ambient temperature exceeds skin temperature. Thus, a high level of solar radiation can be more detrimental to children.[28,30]
7. Children's ability to maintain thermohomeostasis during prolonged running in very hot or very cold environments is less efficient.[30,34,38]
8. Children are less efficient in dissipating heat in very hot environments.[11]
9. Children take longer to acclimate to hot, humid environments (2 weeks versus 1 week),[11,30] which increases their risk of heat-related disorders.[38,39]
10. Core body temperature increases more in children for the same level of hypohydration.[11,26]
11. Recent studies indicate that children's thirst is inadequate and that they become dehydrated easier (O. Bar-Or, MD, McMaster University and Chedoke Hospital, Hamilton, Ontario, Canada, verbal communication, October 1, 2003).

Children have a few characteristics that are beneficial in protecting them from dehydration in comparison with adults, including the following:

1. Children have shorter performance times in hot environments, and when exercising at the same intensity as adults. With shorter performance times, children are less likely to dehydrate themselves.[11,30]
2. Sodium and chloride concentrations in the sweat of prepubescent children are lower than those of pubescent children, who in turn have lower sodium losses than adults.[11]
3. Children's sweat rates are reduced, resulting in less sodium and chloride loss.

Dehydration over several days may be cumulative when the athlete who is dehydrated does not suffi-

ciently replace the fluid loss. An athlete may develop 2% to 3% hypohydration one day, not fully rehydrate overnight, and then on subsequent days dehydrate further by repeating the previous day's experience. This process leads to progressive dehydration, to the extent that the athlete becomes 5% to 8% hypohydrated. The greater the body-fluid deficit, the longer it takes to restore this deficit completely.[23] Replacement of intracellular fluids, when dehydration has occurred over 2 or 3 days, requires 48 hours.[40]

When children are given plain water, they will not replace their fluid losses completely. However, when children are given flavored drinks such as grape-, tropical-, or orange-flavored water, voluntary drinking increases by 44.5%,[28,41] a sufficient amount to replace their fluid losses completely.[11,28–30,32] When 6% carbohydrate and 18 mmol/L of sodium are added to flavored water, voluntary drinking is increased by an additional 45.5%.[28–30,41]

Prevention and Treatment of Dehydration

Sweat rates vary among athletes; therefore, one must consider each athlete individually and rely on previous experience with a particular athlete to estimate how much fluid he or she will require.[42]

Fluid ingested before, during, and after exercise reduces dehydration, core temperature, heart rate, and cardiac strain[6]; it maintains skin blood flow and increases exercise performance.[43,44] Thirst is a late indicator of dehydration in adolescents and adults; therefore, efforts must be made to maintain euhydration. The best way to assess hypohydration is to weigh the athlete before and after exercise. The amount of weight lost should be replaced with an equal volume of fluids before the next exercise session. The fluid should contain carbohydrates to replenish glycogen stores as well as sodium chloride.[11,21,45] The concentration of sodium in sports drinks is lower than the sodium concentration in the sweat of both adults and children.[41] Even if children drink enough sports drinks to maintain euhydration, their total body sodium would be decreased and their total sodium loss would not be replaced.[45] If this is repeated over several days and the sodium is not replaced in food or drink, symptomatic hyponatremia may develop.[45]

Food Restrictions/Binge-Purge Behavior

The most common way for athletes to attempt weight loss is by restricting food intake. They may develop other disordered eating behaviors such as purging, with or without bingeing, to decrease total energy (caloric) intake. Compulsive exercise or excessive exercise in addition to the normal training regimen also would be considered a form of purging. The spectrum of these disordered eating behaviors ranges from mild to severe, with the risk of development of an eating disorder and the associated morbidity and mortality increasing as the severity of the behavior increases.[46]

Disordered eating behaviors are prevalent in male and female athletes. Ten to 15% of high school boys who participate in "weight-sensitive sports" practice unhealthy weight-loss behaviors.[1,4,47] Numerous studies have reported these practices in wrestlers, with 1 study revealing that 80% of wrestlers lost weight for the wrestling season.[48] Eleven percent of wrestlers were found to have an eating disorder in 1 study,[49] and as many as 45% of wrestlers were found to be at risk of developing an eating disorder in other studies.[4,19,47]

Many studies have revealed an increased incidence of disordered eating behavior (food restriction, vomiting, laxative and diuretic use) in female athletes involved in weight-sensitive sports such as figure skating, gymnastics, diving, long-distance running, rowing, and swimming.[2,5,46] One study of young swimmers reported that 60% of average-weight girls and 18% of underweight girls were trying to lose weight.[50] Most of these swimmers were restricting food intake to lose weight; however, 15% were vomiting or using laxatives or diuretics. In the female athlete, decreased energy availability (calculated as dietary energy intake minus exercise energy expenditure) can lead to menstrual dysfunction, which can result in potential bone mineral density loss. This has been termed the "female athlete triad" (decreased energy availability or disordered eating, menstrual dysfunction, and bone mineral density loss).[3,51] All female athletes with oligomenorrhea or amenorrhea should be evaluated thoroughly to determine the underlying etiology. If low energy availability is the cause, the athlete should be counseled on increasing energy intake enough to resume normal menses.[3,51] If an eating disorder is suspected, referral to a multidisciplinary team of experts in this field is appropriate.

Healthy Weight Loss

Athletes usually require a greater energy (caloric) intake than do nonathletes.[21] The actual energy intake (number of calories) needed depends on the athlete's body composition, weight, height, age, stage of growth, and level of fitness as well as the intensity, frequency, and duration of exercise activity.[52] Athletes need to eat enough to cover the energy costs of daily living, growth, building and repairing muscle tissue, and participating in sport.[53] Athletes who want to lose weight should be counseled on the harmful effects of unhealthy weight-loss practices and inappropriate weight loss. They need to be informed that weight is not an accurate indicator of body fat or lean muscle mass and that body composition measurements can be much more helpful.[54]

Studies have shown that physique does not markedly influence performance except at the extreme ranges (ie, significant endomorphy or ectomorphy).[55] An excessive amount of body fat interferes with acclimation to heat and can decrease speed, endurance, and work efficiency.[4,56] Therefore, weight loss may be beneficial when it is achieved by healthy means and involves losing excess fat without reducing lean muscle mass or causing dehydration.[4] When weight is lost too rapidly or by significant reduction in energy (caloric) intake, lean muscle mass will be lost, which can affect performance negatively.[57]

Weight loss, when necessary, should be gradual

and should not exceed 1.5% of the total body weight, or 1 to 2 lb, each week.[52,56–59] Weight loss beyond these guidelines results in the breakdown and metabolism of muscle, making an athlete weaker.[52,56–60] To lose 1 lb of fat in 1 week, one must expend 14 700 kJ (3500 kcal) more than one consumes.[60] The ideal way to do this is to consume 7350 kJ (1750 kcal) fewer per week and expend 7350 kJ (1750 kcal) more per week by exercising.[56,60] An appropriate diet for most athletes consists of a minimum of 8400 kJ (2000 kcal) each day. Approximately 55% to 65% of the daily energy (caloric) intake should be from carbohydrates, 15% to 20% should be from protein, and 20% to 30% should be from fat.[52,57] The diet should be well balanced, consisting of foods from all groups of the food pyramid. When possible, the athlete should be counseled by a registered dietitian who has experience working with athletes and their families. Sports and Cardiovascular Nutritionists (SCAN), a practice group of the American Dietetic Association, can provide names of registered dietitians with expertise in nutrition and exercise (see www.eatright-.org, or call 800-877-1600, extension 5000).

Once weight has been lost and the desired weight is obtained, that weight should be maintained. Studies have shown that athletes who maintain their desired weight have higher resting metabolic rates than do athletes who are "cyclic" weight losers (177.2 vs 154.6 kJ/m^2 per hour, respectively).[61] They also have higher resting energy expenditures (7702.8 vs 6631.8 kJ/day, respectively) and oxygen consumption (266.5 vs 230.4 mL/minute, respectively).[61] Therefore, athletes who maintain a constant weight can eat more calories than the "cyclic" weight losers and maintain the same weight.[61]

With the exception of sports that require mandatory weigh-ins, coaches of most sports should not discuss weight or weight loss with an athlete. Many coaches inappropriately focus on weight instead of body composition and performance, and most coaches do not have an adequate nutritional background to counsel an athlete about weight loss. In addition, when a coach mentions weight loss to an athlete, that athlete is much more likely to begin harmful practices of weight control rather than consult with the appropriate professionals. Any weight loss desired by an athlete should be discussed with a health care professional, a registered dietitian, an athletic trainer (when appropriate), and the family. Athletes involved in sports that require mandatory weigh-ins should be discouraged from using harmful weight-loss practices and should be encouraged to compete at a weight that is appropriate for their age, height, physique, and stage of growth and development. Weigh-ins should take place in such a manner as to encourage good hydration and competing at a healthy weight. It has been determined that the safest and fairest procedure for wrestlers, to ensure that they are well hydrated at all times, is to have mat-side weigh-ins immediately before their matches.[62] This procedure ensures that competing wrestlers will be at or near the same weight during the match. A wrestler is prevented from dehydrating and weighing in at one weight, and then rehydrating and wrestling at a significantly higher weight while his or her opponent weighs in at his or her natural weight and wrestles at that weight. Mat-side weigh-ins would prevent wrestlers from competing when they are weak from dehydration and prevent the temptation of dehydrating themselves to the degree that is life threatening.

Weight and Body-Composition Measurement

An athlete's weight should typically fall between the 25th and 75th percentiles of weight for height for age (by National Center for Health Statistics guidelines),[63] although some athletes weigh more because of increased muscle mass. The use of body mass index (BMI) in athletes is not recommended; however, if used, most athletes should be between the 50th and 75th percentile for BMI.[64] BMI is a measure of one's weight relative to height and has been used as a fairly reliable indicator of total body fat (obesity) in adults. In 2000, the Centers for Disease Control and Prevention published guidelines for BMI in children and adolescents 2 years and older to aid in diagnoses of overweight and underweight.[64] BMI is not a perfect indicator of body fatness and may falsely classify some children, particularly adolescents, who are of normal fatness as being overweight.[65] Because weight and height velocities do not coincide exactly during the growth spurt and individual patterns of growth vary during this time, care must be taken to avoid a false diagnosis of overweight during puberty.[65] BMI also can be falsely elevated in an athlete or nonathlete with a muscular build as well as in someone who has a high torso-to-leg ratio.[65] Therefore, body-composition measurements (body fat and lean muscle mass), in addition to height-for-weight for age measurements, may be more useful in determining the physical status of an athlete.[54,57]

Anthropometric measurements can be performed to estimate lean muscle mass. For most well-nourished athletes, lean muscle mass should be greater than the 25th percentile.[57] Many methods are available to determine body fat.[4] The most precise method is underwater weighing; however, the equipment for underwater weighing is expensive and of limited availability. Other commonly used methods include skinfold-thickness measurements, air displacement, bioelectrical impedance measurements, girth measurements, and computerized calipers.[4,58] Skinfold measurements are easily performed by someone with experience using high-quality calipers (approximately $200). When performed in the correct manner, published reports on skinfold calibration show an error margin of ±3%.[66] Skinfold measurements can be taken from 3, 4, or 5 sites (right biceps, right triceps, right subscapular, right suprailiac, and right abdominal sites [regardless of whether the athlete is right-handed or left-handed, measurements are always performed on the right side]). The more sites used, the more accurate the results are. Instructions on how to perform skinfold measurements are available.[58,59]

No optimal values for body composition have been established for any sport. The association be-

tween performance and body composition must be individualized for each athlete. A specific percentage of body fat should never be recommended for an individual athlete, but rather a range that is realistic and appropriate.[67] The body fat of "reference adolescents" ranges from 12.7% to 17.2% for males and 21.5% to 25.4% for females.[68] "Low fat" is considered to be 10% to 13% for males and 17% to 20% for females. "Very low fat" is considered to be 7% to 10% for males and 14% to 17% for females.[69,70] Adolescent females who are meeting their energy (caloric) needs will be eumenorrheic.[51]

WEIGHT GAIN

Sports such as football, rugby, basketball, power lifting, and bodybuilding often motivate athletes to gain weight. If weight is gained improperly, it will lead to excess fat, resulting in decreased speed, endurance, and agility and poor acclimation to heat. Overweight athletes, later in life, are at an increased risk of hypercholesterolemia, gall bladder disease, cardiovascular disease, hypertension, and type 2 diabetes mellitus. Often, athletes use supplements (which may be of unproven value and potentially harmful) or anabolic compounds (which are harmful to athletes' health) to gain weight instead of evaluating their nutritional and training programs.

Before trying to change body composition, athletes must understand potential genetic limitations.[71] Athletes with a solid body build (mesomorphy) can expect to gain more weight than athletes with a slender body build (ectomorphy). Inadequate energy intake is often the limiting factor for athletes trying to increase muscle mass. They may overestimate the protein requirements and underestimate the need for carbohydrates.[71]

Healthy Weight Gain

The rate and amount of weight gained and specific muscles developed are determined by an athlete's genetic predisposition, training program, diet, and motivation.[71] To build 1 lb of muscle in 1 week, one must (1) consume 8400 to 10 500 kJ (2000–2500 kcal) more than one expends, (2) consume 1.5 to 1.75 g of protein per kg of body weight per day, and (3) participate in strength training. Consuming 1.5 to 1.75 g of protein per kg of body weight per day rarely is a problem; the average American diet contains 2 to 3 times that amount of protein.[56] If the athlete has not gained the desired weight despite an appropriate training program, adequate rest, and a nutritionally sound diet, it is appropriate to make a recommendation that he or she increase dietary fat.[71] Studies of elite athletes report dietary fat intakes ranging from 29% to 41% in males and 29% to 34% in females.[71] Increased energy (caloric) intake should always be combined with strength training to induce muscle growth and, therefore, increase muscle mass. Gains in muscle hypertrophy are best achieved by performing multiple sets of weight lifting with a relatively high number of repetitions (8–15 repetitions per set).[72] Young athletes should lift lighter weights with an increased number of repetitions under the supervision of a trained adult.[72] Weight gain needs to be gradual, because a gain in excess of 1.5% of body weight per week may result in unwanted fat.[56,60]

RECOMMENDATIONS

1. Physicians who care for young athletes should have knowledge of healthy weight-gain and weight-loss methods. They should understand minimal recommended weight, normal growth curves, and body composition measurements and be willing to educate athletes, families, coaches, athletic trainers, school administrators, and state and national organizations when appropriate. Physicians should understand that all athletes are unique and each athlete must be evaluated individually.
2. All physical examinations of young athletes should include a weight history and a history of eating patterns, hydration practices, eating disorders, heat illness, and other factors that may influence heat illness or weight control.
3. Physicians should be able to recognize early signs and symptoms of an eating disorder and obtain appropriate medical, psychological, and nutritional consultation for young athletes with these symptoms.
4. Nutritional needs for growth and development must be placed above athletic considerations. Fluid or food deprivation should never be allowed. There is no substitute for a healthy diet consisting of a variety of foods from all food groups with enough energy (calories) to support growth, daily physical activities, and sports activities. Daily caloric intake for most athletes should consist of a minimum of 8400 kJ (2000 kcal). Athletes need to consume enough fluids to maintain euhydration. Physicians should engage the services of a registered dietitian familiar with athletes to help with weight-control issues.
5. In sports for which weigh-ins are required, athletes' weight and body composition should be assessed once or twice per year. The most important assessment is obtained before the beginning of the sport season. This should include a determination of body fat and minimal allowable weight when the athlete is adequately hydrated (the National Wrestling Coaches' Association [NWCA] Internet Weight Classification Program is available at www.nwcaonline.com[58] or by calling 717-653-8009 [see Table 3 and Appendix]). Weigh-ins for competition should be performed immediately before competition.[62] Athletes should be permitted to compete in championship tournaments only at the weight class in which they have competed for most other athletic events that year.[58,59,62]
6. Male high school athletes should not have less than 7% body fat. This minimal allowable body fat may be too low for some athletes and result in suboptimal performance. Female athletes should consume enough energy (calories) and nutrients to meet their energy requirements and experience normal menses. There are no recommendations on body-fat percentages in female athletes.

7. A program for the purpose of gaining or losing weight should (*a*) be started early to permit a gradual weight gain or loss over a realistic time period, (*b*) permit a change of 1.5% or less of one's body weight per week, (*c*) permit the loss of weight to be fat loss and the gain of weight to be muscle mass, (*d*) be coupled with an appropriate training program (both strength and conditioning), and (*e*) incorporate a well-balanced diet with adequate energy (calories), carbohydrates, protein, and fat. After athletes obtain their desired weight, they should be encouraged to maintain a constant weight and avoid fluctuations of weight. A weight-loss plan for athletic purposes should never be instituted before the 9th grade.
8. Any athlete who loses a significant amount of fluid during sports participation should weigh in before and after practices, games, meets, and competitions. Each pound of weight loss should be replaced with 1 pt of fluid containing carbohydrates and electrolytes before the next practice or competition. Fluids should be available, and the drinking of such should be encouraged at all practices and competitions.
9. Weight loss accomplished by overexercising; using rubber suits, steam baths, or saunas; prolonged fasting; fluid reduction; vomiting; or using anorexic drugs, laxatives, diuretics, diet pills, insulin, stimulants, nutritional supplements, or other legal or illegal drugs and/or nicotine should be prohibited at all ages.[73,74]
10. Athletes who need to gain weight should consult their physician for resources on healthy weight gain and referral to a registered dietitian. They should be discouraged from gaining excessive weight, which may impair performance, increase the likelihood of heat illness, and increase the risk of developing complications from obesity.
11. Ergogenic aids and nontherapeutic use of supplements for weight management should be prohibited.[73,74]
12. Young athletes should be involved in a total athletic program that includes acquisition of athletic skills and improvement in speed, flexibility, strength, and physical conditioning while maintaining good nutrition and normal hydration. This should be done under the supervision of a coach who stresses a positive attitude, character building, teamwork, and safety.[75]

APPENDIX: CALCULATING MINIMAL WRESTLING WEIGHT

Calculation of a minimal safe wrestling weight using body-fat measurements was first performed in high school athletes.[18,76–80] In 1998, the National Collegiate Athletic Association[59] and the NWCA[58] incorporated this technique into a mandatory program designed to establish the minimal safe wrestling weight for collegiate wrestlers.[58] This program includes hydration testing, body-composition assessment, calculation of a lowest allowable weight class for each wrestler, development of a weight-loss plan for each wrestler (if appropriate), and a nutrition education program specific to wrestling. The wrestler's minimal wrestling weight is established by determining percent body fat when the wrestler is adequately hydrated (urine specific gravity of 1.020 or less for college wrestlers and 1.025 or less for high school wrestlers). If the wrestler is not well hydrated, the body-fat calculations will result in a low and unsafe minimum weight recommendation.[81] The National Federation of High Schools medical advisory committee has recommended that high school wrestling programs adopt the program of the NWCA by the 2004–2005 academic year.[4]

In establishing minimal weight, skinfold calipers (Lange skinfold calipers; Beta Technology Corp, Cambridge, MD), bioimpedance (Tanita, Arlington Heights, IL), air displacement (Bod Pod; Life Measurement, Inc, Concord, CA), and hydrostatic weighing are the only methods currently approved for body-composition measurements.[58,59] The NWCA formula requires skinfold measurements to be taken at the right triceps, right subscapular, and right abdominal sites (regardless of whether the athlete is right-handed or left-handed, measurements are always performed on the right side).[58]

POSITION PAPER

Protecting Adolescents: Ensuring Access to Care and Reporting Sexual Activity and Abuse

Position Paper of the American Academy of Family Physicians, the American Academy of Pediatrics, the American College of Obstetricians and Gynecologists, and the Society for Adolescent Medicine

Position Statement

As physicians and other health care professionals, we have an ethical obligation to provide the best possible care for our adolescent patients. A key tenet for all health professionals is to ensure that adolescents have access to the health services they need, including sexual and reproductive health services. A medical evaluation that addresses sexual and reproductive health includes a careful assessment for abusive or unwanted sexual encounters and the reporting of such cases to the proper authorities. Protection of children and adolescents from predatory, coercive, or inappropriate sexual contact is an important goal of all physicians and health professionals. In meeting our ethical obligations to our adolescent patients, as well as to all of our patients who are children under the age of majority, we rely on our professional judgment, informed by clinical assessment, training, and experience, to address a patient's health conditions or a sensitive situation.

As the primary providers of health care to adolescents, we also have an obligation to make every reasonable effort to encourage adolescents to involve parents in their decisions, as parental support can, in many circumstances, increase the potential for dealing with the adolescent's needs on a continuing basis. If communication between the adolescent and parent cannot be facilitated, access to confidential health care for the adolescent patient must be ensured.

Laws requiring the reporting of sexual abuse exist in every state. There has been a recent trend in using these laws to require the reporting of adolescents' consensual sexual activity. In keeping with the medical and ethical responsibilities that we uphold, the American Academy of Family Physicians, American Academy of Pediatrics, American College of Obstetricians and Gynecologists, and the Society for Adolescent Medicine support the following guidance and principles for our professional members and for broad consideration in the development of public policy:

- Sexual activity and sexual abuse are not synonymous. It should not be assumed that adolescents who are sexually active are, by definition, being abused. Many adolescents have consensual sexual relationships.
- It is critical that adolescents who are sexually active receive appropriate confidential health care and counseling.
- Open and confidential communication between the health professional and the adolescent patient, together with careful clinical assessment, can identify the majority of sexual abuse cases.
- Physicians and other health professionals must know their state laws and report cases of sexual abuse to the proper authority, in accordance with those laws, after discussion with the adolescent and parent, as appropriate.
- Federal and state laws should support physicians and other health care professionals and their role in providing confidential health care to their adolescent patients.
- Federal and state laws should affirm the authority

1054-139X/04/$–see front matter

of physicians and other health care professionals to exercise appropriate clinical judgment in reporting cases of sexual activity.

Supporting Commentary

State Requirements for Reporting Sexual Abuse and Sexual Activity Vary

Every state has laws that require the reporting of child abuse, including sexual abuse, and every state also has laws that specify when sexual activity with a minor is illegal. Most states use age parameters in defining whether consensual sexual intercourse with a minor is illegal under the state's criminal code; these laws are often referred to as "statutory rape" laws. The state child abuse reporting laws vary widely in terms of whether or not they require reporting consensual sexual activity of a minor—or "statutory rape"—as child abuse.

Most states have laws allowing minors to consent to selected categories of medical care without parental consent. Examples include reproductive health services leading to the diagnosis and treatment of sexually transmitted infections (STI) and the diagnosis of pregnancy. These laws give physicians and other health care professionals the opportunity to practice medicine that responds to the best interest of their patients.

State Requirements Have a Significant Impact on Adolescents, Their Health and Their Families

Physicians and other health care professionals confront difficult choices in meeting their ethical obligations and complying with applicable laws. They are bound by their state reporting requirements. They also have an ethical obligation to ensure that their patients are protected from harm and that they will receive essential health care and support at present and in the future. Often, state reporting requirements do not allow sufficient opportunity for health care professionals to exercise sound medical judgment to meet these ethical obligations.

Well-intentioned but rigid laws can lead to outcomes that are both unintended and potentially damaging to the health of an adolescent. When a state's laws require that sexual intercourse with a minor be reported to law enforcement or child welfare agencies, a sexually active adolescent in a consensual relationship may be placed in the untenable situation of forgoing essential health care (e.g., contraception, screening or treatment for sexually transmitted diseases, etc.) or, if he or she seeks that care, being reported to state authorities. Also, the laws often do not take into consideration varying circumstances such as cases in which parents know about the relationship in which the adolescent is involved. In these situations, the legal implications for the parent may be considerable. A parent who knows about an adolescent's consensual sexual relationship and assists him or her in seeking health care may be reported under state abuse or neglect laws. Laws should not interfere with either an adolescent's access to confidential health care or a parent's ability to provide health supervision to his or her child.

A Significant Number of Adolescents are Sexually Active

According to the 2003 Youth Risk Behavior Surveillance Survey, 32% of 9th graders, 41% of 10th graders, 52% of 11th graders, and 61% of 12th graders have ever had sexual intercourse [1]. Among adolescent girls who are sexually active, more than two-thirds have sexual partners who are the same age or only a few years older [2,3]. Enforcement of "statutory rape" and child abuse reporting laws could potentially affect a very large number of adolescents.

Open Communication between the Health Professional and the Adolescent is Essential

Physicians and other health professionals should ensure that the adolescent has not voiced or otherwise indicated to his or her partner that sexual activity was unwanted or undesirable and that the partner is not placing physical or emotional pressure on the adolescent. Physicians and other health professionals should encourage communication about sexual decision-making between adolescents and their families, and should counsel sexually active adolescents about potential health risks.

The Vast Majority of Reportable Cases of Sexual Abuse and Sexual Coercion are Identifiable through Careful Clinical Assessment

These cases include adolescents in a sexual relationship with a family member, a person of authority (e.g., teacher, leader of a youth organization, etc.), or a member of the clergy. Also included are adolescents who are incapacitated by mental illness, mental retardation, drugs, or alcohol, and are unable to

comprehend, make informed decisions about, or consent to, sexual activity. In addition, any intimate relationships that are violent should be considered abusive. Physicians and other health professionals must know their state laws and report such cases to the proper authority, in accordance with state law, after discussion with the adolescent and parent, as appropriate.

The age of the sexually active adolescent, the degree to which the adolescent understands the consequences and responsibilities of sexual activity, and the discrepancy in years between the age of the adolescent and his or her partner are important considerations that must factor into reporting decisions. Although a wide discrepancy in age between partners is of concern when caring for the adolescent patient, partner age by itself is not indicative of exploitation or abuse. Verbal and physical coercion, as well as alcohol and drugs, are some of the strategies used by sexual predators to victimize adolescents. However, sexual abuse and exploitation of an adolescent may occur in any relationship, including those where the partners are the same age, younger, or older.

It is Essential that Adolescents Have Access to Confidential Health Care

The issue of confidentiality of care is a significant access barrier to health care. A recent study of girls under age 18 attending family planning clinics found that 47% would no longer attend if their parents had to be notified if they were seeking prescription birth control pills or devices, and another 10% would delay or discontinue sexually transmitted infection (STI) testing and treatment [4]. Mandatory reporting of sexual activity will likely raise barriers and prevent adolescents from seeking health care, thereby exposing them to preventable health risks (e.g., pregnancy, sexually transmitted disease, suicide). The long-term consequences of limiting access to health care for sexually active adolescents may include an increase in the prevalence of STIs, a rise in unintended teen pregnancy, and escalation in the number of mental and behavioral health issues, including the potential of partner violence. If these and other conditions are not diagnosed early and treated appropriately, adolescents may suffer adverse health outcomes.

Adolescents can have a range of problems, including some of such severity as to jeopardize their development and health, their future opportunities, and even their lives. These issues may be independent of, or related to, sexual activity. However, until a physician or health professional can meet with and make a professional assessment of the individual adolescent, these issues cannot be identified or addressed.

Legal Requirements and Interpretation of Laws that Impede the Provider/Patient Relationship are Detrimental to Adolescents

The medical community has a long-standing commitment to ensure appropriate protection of confidentiality for their adolescent patients. Physicians and other health care professionals are on the front line in assessing the individual emotional, physical, and behavioral needs of adolescent patients. From this unique vantage point, we are able to provide care and counseling to our young patients and to determine the appropriate course of action required in each circumstance, including whether and when to abrogate an adolescent patient's confidentiality. Federal and state laws should allow physicians and other health care professionals to exercise appropriate clinical judgment in reporting cases of sexual activity, (e.g., life-threatening emergencies, imminent harm, and/or suspected abuse). Ultimately, the health risks to adolescents are so compelling that legal barriers should not stand in the way of needed health care.

abstract

FREE

Sexual abuse or exploitation of children is never acceptable. Such behavior by health care providers is particularly concerning because of the trust that children and their families place on adults in the health care profession. The American Academy of Pediatrics strongly endorses the social and moral prohibition against sexual abuse or exploitation of children by health care providers. The academy opposes any such sexual abuse or exploitation by providers, particularly by the academy's members. Health care providers should be trained to recognize and abide by appropriate provider-patient boundaries. Medical institutions should screen staff members for a history of child abuse issues, train them to respect and maintain appropriate boundaries, and establish policies and procedures to receive and investigate concerns about patient abuse. Each person has a responsibility to ensure the safety of children in health care settings and to scrupulously follow appropriate legal and ethical reporting and investigation procedures. *Pediatrics* 2011;128:407–426

INTRODUCTION

Pediatricians and other health care providers are entrusted with the responsibility to improve the health and well-being of children. However, recent allegations of the sexual abuse of hundreds of children by a pediatrician in the United States have reminded us that some among the pediatric profession may use their position of authority and trust to take advantage of their patients.[1] The prohibition against sexual misuse of one's patients goes back in history to Hippocrates, who said: "I will come for the benefit of the sick, remaining free of all intentional injustice, of all mischief and in particular of sexual relations with both male and female persons. . . ."[2] This ban is echoed by statements of the American Medical Association, the Canadian Medical Society, and the British General Medical Council.[2–4] The American Academy of Pediatrics (AAP) strongly endorses this social and moral prohibition, because it constitutes common justice; it is particularly important for pediatric patients, who have greater developmental vulnerability than adults. This policy statement provides guidance for health care professionals and parents faced with concerns of possible sexual abuse or exploitation and other abuse of children by pediatricians, other physicians, other health care professionals, and related health care personnel.

Preventing child sexual abuse is the primary concern of this statement (Table 1). Child sexual abuse is usually perpetrated by people who do not meet the criteria for a specific psychiatric sexual disorder and is defined by the act itself, which is criminal. Pedophilia and hebephilia

TABLE 1 Definitions

Child sexual abuse is defined as engaging children in sexual activities they cannot understand or consent to, including genital or anal contact; exposing the child to exhibitionism, voyeurism, or sexually explicit material; using the child in pornography; and pandering the child for sex by others.[5]
Pedophilia is defined in the *Diagnostic and Statistical Manual of Mental Disorders, 4th Edition (DSM-IV)* as "over a period of at least 6 months, recurrent, intense sexually arousing fantasies, sexual urges, or behaviors involving sexual activity with a prepubescent child or children" and that having "acted on these sexual urges or the sexual urges or fantasies cause marked distress or interpersonal difficulties."[6]
Hebephilia and ephebophilia are defined similarly to pedophilia, but the sexual focus is on postpubertal minor girls and boys, respectively. Hebephilia is commonly used to include both sexual attractions.
Paraphilias are persistent, deviant patterns of primary sexual attraction. Included are attractions such as exhibitionism, fetishism, frotteurism, pedophilia, masochism, sadism, transvestitism, and voyeurism.

are less common psychiatric disorders of sexual attraction, on which a person may or may not act. The sexual abuse of children is, by no means, limited to adults with these psychiatric disorders. Sexual misconduct with patients is a subset of abuse of patients by health care providers and involves issues of inappropriate provider-patient boundaries and sexual behaviors.[7] The AAP statement on professionalism also provides guidance on appropriate provider behavior.[8] Child sexual contact can vary from a single, situational event to planned, compulsive, repetitive behavior. In the extreme, the provider's sexual orientation is to children and the provider repetitively acts on this drive, exhibiting and acting on the paraphilias, pedophilia, or hebephilia.

EPIDEMIOLOGY

The medical literature on the frequency of sexual abuse of pediatric patients by providers is sparse[9–11] compared with what is known about abuse of adult patients. Likewise, there are few data on the incidence of pedophilia among pediatricians. What is known about sexual misconduct by physicians comes from surveys of physicians, surveys of adult patients, and studies of abusive physicians and of children reported for sexual abuse concerns. Data on sexual abuse of adult patients and the physicians who abuse them are reported to provide context to the epidemiology and offender behavior of patient sexual abuse.

Surveys of physicians and patients have revealed that sexual relations between physicians and adult patients are not rare and involve approximately 10% of all medical specialists who care for adults.[12] Fifty-six percent of these physicians indicated that they had never received training in provider-patient sexual boundaries. Most of them believed that sexual contact with current patients is wrong, but only one-third of them opposed sexual contact with former patients.[12]

Among the general literature about health or counseling care provider sexual misconduct with clients is a study of patients who sought psychiatric or counseling care secondary to previous provider sexual acts.[13] Fifty-one percent of the offending providers were clergy, and 49% were health care professionals. Of the health care providers, 85% were from various counseling professions, 7.3% were physicians in medical specialties, and 3.7% were nurses. Likewise, in Ontario, Canada, in the 1980s, one-quarter of the health care providers who had been legally charged with patient sexual contact were psychiatrists. Surveys of psychiatrists revealed that 7% to 10% reported that they had had previous sexual contact with patients.[14]

Studies that examined reports of sexual misconduct by physicians have provided further epidemiologic data. A Canadian task force on sexual abuse of patients found that patients younger than 14 years accounted for 8.7% of these reports, whereas 80% of patients subjected to sexual contact were adult women.[3] Male providers were responsible for 91% of the sexual contacts. Among 567 physicians disciplined by their state medical disciplinary boards between 1989 and 1996 for sexually related offenses involving patients, pediatricians accounted for 14 disciplinary events (2.9%), although they represented 7.8% of all physicians.[15]

Recent national data suggest that approximately 8% of American children experience sexual victimization in a given year,[16] although significant underreporting occurs. Official reports of sexual abuse provide some information on child sexual abuse by health care providers. In an Indiana study of children in out-of-home settings, including both general medical and psychiatric facilities, 1.56% of hospitalized children experienced any form of maltreatment.[17] Approximately half of these hospitalized children's maltreatment was sexual abuse, which constituted 0.85% of all hospitalized children. Rates of abuse were similar in foster homes (overall abuse rate: 1.69%); 0.52% of the children in foster homes sustained sexual abuse. In comparison, rates of abuse were higher in residential homes, such as group homes, in which the overall abuse rate reached 12.0%, and 5.8% of the group-home children were sexually abused. One-third of the maltreatment in hospitals was at the hands of staff, compared with 25% in residential homes. In foster homes, caregivers were responsible for 78% of the maltreatment.

In a study of 38 complaints of pediatric patient abuse by hospital staff, 52.9% involved sexual issues.[9] Males were accused in 87% of these sexual complaints. Physicians represented only

14.3% of the accused, and other providers—nurses (42.9%), therapists (21.4%), and volunteers (21.4%)—were accused more often. Overall, 24% of the abuse complaints were felt to be substantiated by internal review by the hospital's child abuse program, and 18% remained indeterminate. Child protective services staff and police substantiated fewer cases than did hospital staff.

Some literature further characterized the sexual relations between physicians and adult patients and the attributes of practitioners who engage in sexual acts with patients. In an anonymous physician survey by Gartrell et al,[12] 42% of the physicians who had engaged in patient sexual contact had admitted doing so with more than 1 patient; 11 victims was the upper range. Male-physician-with-female-patient events constituted 89% of the reports, female-physician-with-male-patient events constituted 6%, male-physician-with-male-patient events constituted 4%, and female-physician-with-female-patient events constituted 1%. Many physicians reported ongoing sexual relationships with their adult patients that involved multiple encounters. Kardener et al[18] compared 59 physicians from adult specialties who acknowledged engaging in patient sexual contacts with 401 providers who denied such acts. Those who had engaged in sexual acts with patients were more likely to feel that provider-initiated, nonsexual affectionate physical contact with patients was appropriate. In addition, the physicians who admitted sexual contacts were more likely to perceive that such nonerotic physical contacts benefitted the patient and their relationship, contrary to the physicians who reported no sexual contact. It is unclear how these behaviors and attitudes with adult patients translate to pediatric patients, but rationalization and denial of effects on the patient seem to be a common thread.

Physicians who have sexual contact with patients come from all specialties of medicine. Most reported and recognized is inappropriate sexual contact between physicians and adult patients, which can vary from a single, opportunistic event to a pervasive, calculated pattern. When a single patient is involved, the physician may consider the events to represent consensual attraction while ignoring the inherent power differential in the relationship. Also ignored is the potential damage that may result. With multiple victims, the contacts are more likely predatory.

Child sexual offenders can have a "fixed" attraction to children or have a predominant sexual attraction to adults rather than to children but exhibit "regressed" sexual behavior by also sexually abusing children. Approximately half of the perpetrators of child sexual abuse have fixed (predominant) child attractions.[19] Those with fixed child sexual attractions are more likely to abuse strangers or casual acquaintances rather than family members. Fixed offenders select male victims more often (42%) than do regressed offenders (16%). Both types of offenders predominately use threats or intimidation (49%) or seduction or enticement (30%) to engage their victims. Twenty percent of offenses are violent or brutal. Both types of offenders tend to be consistent in the age and gender of victims they prefer and the type of abuse they perpetrate (eg, fondling versus penetration). Abuse by fixed offenders seems more often to be planned and to involve more victims, whereas that of regressed offenders is often impulsive.

Males are most often involved in sexual contact with patients. However, homosexual adults are no more likely to sexually abuse children than are heterosexual adults.[20] Jenny et al[21] also observed that among sexually abused children, the frequency of homosexual abusers was no different than their population prevalence.

Pedophilic molesters often choose vocations or activities that provide them access to children.[22] They carefully select victims, who are often vulnerable, and groom them for prolonged periods while assessing their response to gradually more intrusive sexual activities and their ability to remain silent. They also groom the child's parents and the community to trust them, or even depend on them, for isolated child supervision.

Childhood adversities, in particular, child sexual abuse, childhood family dysfunction, and childhood emotional abuse, likely play a significant role in the development of adult pedophilia.[23] However, most child sexual abuse victims do not become sex offenders. In a study of 224 sexually abused boys, 12% later committed sexual offenses.[24] Associated child neglect, lack of supervision, abuse by females, and intrafamilial violence were risk factors for their becoming offenders. Sexual abusers, in general, begin early in their lives. Forty percent of all sexual assaults against prepubertal children are perpetrated by older juveniles.[25] Some of these events provide the precedents for the development of adult pedophilia, which usually follows juvenile sexual offenses against younger children.

Several aspects of pediatric practice represent unique vulnerabilities for pediatric patients, including frequent, potentially private, contact with children. Pediatricians have a special responsibility to address these vulnerabilities and provide well-considered and well-implemented protections for the children in their care. However, any other field that provides frequent, potentially private, contact with children also has the same potential to at-

tract adults with a sexual orientation to children.[25] The prevalence of pedophilia in the general population and among pediatricians is unknown.[25,26]

In summary, the available literature suggests that a minority of physicians, including pediatricians in particular, engage in sexual relationships with patients. Most of these encounters are heterosexual and occur between adult providers and their adult patients. However, some children are victimized by health care providers including pediatricians. There are no circumstances in which any sexual relationship between a physician and pediatric patient is appropriate. Concern about the sexual abuse of children by a physician requires careful investigation. The following guidance is offered to parents and pediatricians who have concerns of sexual abuse by a pediatric health care provider.

NORMAL PEDIATRIC EXAMINATION PRACTICE

Physicians are responsible for assessing the physical health and development of children, including genital health and pubertal development. Many diseases involve anogenital structures, and genital diseases and anomalies can have important consequences for children. During the course of pediatric physical examinations, it is often appropriate and necessary to examine a child's anogenital region. Other body regions also are sexually sensitive, such as the female chest; the perception of what is a sensitive area will vary among individual children. In addition to the physical examination, the provider's history-taking and verbal interaction can involve sensitive topics.[27]

Bright Futures, which describes preventive care that is to be covered under the Affordable Care Act of 2010 (HR 2590 §2713), is a common source for guidance on age-appropriate examinations during well-child care.[28] It provides recommendations for genital examinations from the newborn to preadolescent to adolescent periods. The newborn examination should assess for anogenital anomalies and testicular descent. The first year of life is an important time to observe for diaper-area skin problems, dislocated hips, femoral pulses, hernias, and normal testicular descent. It is also appropriate to ensure normal male and female anatomy during infant examinations. Subsequently, it is reasonable to assess for genital normalcy, including lack of inflammation, rash, or premature maturation, during each annual examination. Beginning at approximately the 7- to 8-year visits, *Bright Futures* recommends evaluation for signs of normal maturation and development to assist in health surveillance and anticipatory guidance. From then, into adolescence, the male examination will involve inspection for hernias, hydroceles, varicoceles, and inflammatory conditions. The female examination will include inspection for maturation, hymenal normalcy and patency, hernias, and dermatologic and inflammatory conditions. Routine intravaginal examinations and Papanicolaou tests are currently not recommended until the age of 21 years.[29]

In addition to regular well-child examinations, anogenital examinations are appropriate in relation to specific illness complaints. The rule in deciding whether to perform an anogenital examination during acute care should be the pertinence of the examination to the specific complaint. For example, a health care provider would be remiss not to perform a rectal examination in a child with encopresis, but such a procedure would be inappropriate for a simple sore-throat complaint. It is important for pediatricians to not avoid sensitive but indicated examinations for fear of abuse accusations. Certain conditions, such as vaginal and anal anomalies, may require repeated examinations, treatment, or dilations. Whether to wear gloves for genital examinations is dictated by local standards of care. Examinations of infants often will not involve the use of gloves, whereas gloving should become routine by the time the child is a preschooler. Gloving will also be determined by the specific complaint.

Patients should be provided privacy during disrobing and appropriate draping during examinations. Again, the age of the patient and the individual child's and family's temperament will dictate the level of draping and gowning required. The child's comfort should be paramount.

The AAP recently revised its policy on the use of chaperones for pediatric examinations.[30] In general, examinations of younger children should be chaperoned by the child's parent or caregiver. As children become older, their caregivers and the children themselves should participate in the decision of whether to use a chaperone. A full explanation of the examination and the reason(s) for it is always warranted. Likewise, offers of chaperones are recommended, but the decision of whether to use one should be a joint decision of the patient, family, and provider. In general, it is wise for male providers to have a chaperone during female genital examinations. However, even same-gender examinations can be misunderstood and can benefit from chaperoning. The patient's wishes and comfort should determine the gender of the chaperone. Providers should check to determine whether their state or hospital has specific chaperoning mandates and, if so, should abide by them. Providers also should be alert to riskier situations for which they should direct the decision toward chaperone use.[27] Ex-

amples include the intoxicated adolescent, the child with developmental or behavioral difficulties, or the child who has been a sexual abuse victim. In these cases, normal examination practices may be misinterpreted as assaultive. False allegations of provider sexual abuse of patients do occur.[31] Being attuned to patient and parent cues and appropriately using nonfamily chaperones are the provider's best protections. Documenting the offer and use of chaperones in the medical record is good practice and provides additional practitioner protection.

INDICATORS OF POSSIBLE SEXUAL MISCONDUCT BY, OR PEDOPHILIA IN, PEDIATRICIANS

As in other situations of child sexual abuse, grooming behavior by a physician may occur to gain a child's confidence and acquiescence to subsequent abuse.[22,32] Grooming behavior includes perpetrator actions that increase the child's trust and dependence on the perpetrator while gradually obtaining the child's accommodation to sexual contacts. The intrusiveness of sexual activities may escalate slowly. Grooming may include the use of unusually "child-friendly" settings and unusual social contact beyond or outside the normal clinical interaction. Favors or gifts beyond minimal value may be given to the child. Pedophiles, similar to other sex abusers, may select emotionally vulnerable and needy victims.[22,32]

Practitioners who sexually abuse patients may have unique indications or frequencies for genital examinations. The examination techniques themselves may be idiosyncratic, such as involving inappropriately prolonged or intimate contact, contact intended to sexually stimulate the patient, examinations that lack normal gowning and draping for modesty, unnecessarily invasive examinations, or inappropriately ungloved contact. The examination or clinical interaction may be accompanied by inappropriate sexually suggestive, or sexually complimentary, comments. Parents or chaperones may be excluded from situations in which they would normally be present. For example, caregivers of preadolescent children may be excluded from examinations by the provider. The provider may tell the child not to tell the parents or caregivers about the encounter. Photographs of the child may be taken beyond those normally required for clinical documentation. Providers may share inappropriate details about their own personal, social, or sexual background. During the visit, offers of extracurricular contact and activities may be tendered. Unsolicited phone, e-mail, or text contacts, unrelated to clinical care needs, may be among the initial attempts to establish extracurricular interactions.

PREVENTION AND MANAGEMENT OF SEXUAL MISCONDUCT ISSUES THAT INVOLVE CLINIC AND HOSPITAL STAFF

All medical and health care staff involved in the care of children should be screened for past allegations of abusive behavior with children during the recruitment-and-hiring process, which should include careful checking of past employment situations and criminal and child abuse registry background checks. However, such procedures cannot be relied on to provide protection. Staley et al[33] reported that less than 1% of people who molest children have a criminal record.

Pediatric training programs should include education on appropriate professional boundaries, professional interactions during sexually sensitive or explicit discussions or examinations, and when and how to use examination chaperones. As part of the trainee's expected skills acquisition in the categories of "intrapersonal skills and communication" and "professionalism," programs should assess the success of this training. Assessment for inappropriate behavior will be most successful if it includes a review, which queries peers, parents, and nursing staff as well as physician mentors. Concerns about sexual misconduct or contact between a trainee and a patient should be reported to the appropriate state investigative and licensing authorities and may warrant discharge from the training program.

Institutions should have policies and training in place to educate staff about appropriate provider-patient boundaries[7] (Appendix A). Staff should be explicitly informed that sexual contact with patients and their caregivers is strictly forbidden. Policies about chaperoning of sensitive examinations should be implemented. Such examinations should only be conducted in formal examination or clinical settings.[27] Staff should be trained, particularly in settings in which child behavioral issues are likely, to recognize and defuse eroticized and/or disruptive child behavior. Policies and procedures should be in place for staff to report concerns of sexual impropriety (Appendix B). Staff should be educated about these policies and procedures and their responsibility to report concerns expeditiously. However, DesRoches et al[34] recently reported that physicians who are aware of impaired or incompetent colleagues only report two-thirds of these cases to the appropriate authorities. Staff should be taught that such underreporting will not be condoned. Institutions should have policies and procedures for investigating, managing, and reporting these complaints.[35]

Solo practitioners may present greater potential for both real and false accusations of sexual abuse. Their office staff may be less able to

provide chaperoning. Likewise, the power imbalance between the provider and his or her staff is more focused, staff exposure to different practice styles is more limited, and staff may be dissuaded from or lack an avenue for reporting concerns. As such, extra efforts to include safeguards are appropriate. Included might be patient handouts that describe examination policies about genital examinations and rigorous chaperone usage.

Examples of hospital policies on staff-patient boundaries (Appendix A); chaperones for outpatient care (Appendix C); and reporting, evaluation, and management procedures for staff allegations (Appendix B) are available at the end of this statement. These appendixes represent the policies developed by Seattle Children's; they are used by permission of Seattle Children's. They do not represent AAP policy. Although they are specific to a single large pediatric-only hospital, the intention is to provide guidance to others for policy development. The Centers for Disease Control and Prevention also provides advice about screening and monitoring staff, safe environments, and complaint evaluation and management for programs that involve youth.[35]

RESPONSE TO CONCERNS ABOUT CHILD SEXUAL MISCONDUCT BY A PEDIATRICIAN OR OTHER HEALTH CARE PROVIDER

Parents and medical staff should bring any suspicions of inappropriate sexual contacts or troubling events to the attention of the office manager or pediatric practice's medical director in cases that arise in pediatric offices. With institutional or hospital cases, concerns should be brought to the attention of the managing nurses and physicians of the involved service, the hospital's child protection program, the hospital administration, or the hospital's patient or parent advocate. Provisions for confidential reporting should be available. Because concerns may arise from misinterpreted but medically appropriate actions, it is preferable that designated hospital evaluators conduct an initial evaluation before reporting to mandated state investigative agencies. However, when there are conflicts of interest between the accused and the manager, lack of an appropriate manager, or fear of retribution, it may be necessary to report directly to mandated state investigative agencies.

When managers receive reports of possible abuse, the concerns need to be evaluated expeditiously, and appropriate steps should be taken to protect other patients from abuse during the investigation (see Appendix A for sample procedures). Likewise, steps should be taken to maintain the confidentiality and reputation of accused practitioners during the time at which complaints are investigated. Institutions should offer accused providers confidential, outside supportive services. The risk of provider psychological morbidity and self-harm can be significant.

In cases with more definite concerns for abuse that rise to the equivalent of a "reasonable cause to believe" that abuse has occurred, institutional staff are legally required to report, and parents can report to their state's protective services and/or the police. A contact listing for state agencies designated to receive and investigate reports of suspected child abuse and neglect is available from the US Department of Health and Human Services Child Welfare Information Gateway (www.childwelfare.gov/pubs/reslist/rl_dsp.cfm?rs_id=5&rate_chno=11–11172). For more information about the status of current individual state laws and related resources, contact the AAP Division of State Government Affairs (800-433-9016, ext 7799, or stgov@aap.org). Once it is determined that abuse concerns rise to this level, it is possible that concerns will become public and end the accused staff member's confidentiality. More substantive complaints also warrant reporting to the appropriate state professional licensing board. When within-hospital complaints are considered substantiated, they constitute a hospital "critical incident," which generally requires reporting to the state's hospital licensing commission and conducting a critical incident review directed at how policies and procedures could be improved to prevent such incidents. It is the responsibility of institutions to warn the public of such provider behavior through these formal channels, not simply to pass the provider and issue on to some other setting. Likewise, if concerns have become public but have been evaluated and found baseless, institutions, with the consent of the accused, should make public the exonerating findings.

OUTCOMES OF SEXUAL ABUSE BY PROVIDERS

The physical and psychological health consequences sustained by children and adults who have been victims of sexual abuse are significant, and children victimized by physicians will require assessment, followed by medical care and counseling, as indicated. Although not all children exposed to sexual abuse go on to experience sequelae, there is increased risk of a broad range of problems including emotional, behavioral, cognitive, social, and general health impairments. Included are both internalizing and externalizing psychiatric disorders.[36] Past sexual abuse is associated with a greater frequency of depression, anxiety, substance abuse, conduct/antisocial personality disorder, and suicidal ideation and attempts.[37] Other childhood associations have included poor self-esteem; posttraumatic stress dis-

order (PTSD); regressive, withdrawn, or neurotic behaviors; sexually inappropriate behaviors; eating disorders; delinquency; and general behavioral disorders.[38,39] Similar psychological problems remain more common in adults who were victims of childhood sexual abuse.[39,40] In a meta-analysis, childhood sexual abuse was correlated with adult anxiety disorders, depression, eating disorders, PTSD, sleep disorders, and suicide attempts.[41] Past victims of sexual abuse are at increased risk of further sexual victimization in childhood and adult life.[42] The absolute risk for victims of preadolescent sexual assault for some of these consequences of abuse include a 23% risk of PTSD and a 25% to 33% risk of subsequent major depression in young adulthood.[36] Physical and sexual abuse victims experience a doubling of their suicide risk.[42] A New Zealand study attributed 13% of the country's adult mental health burden to sexual abuse.[37] Specific data about the psychiatric morbidity of child sexual abuse in the medical setting are lacking. However, because such sequelae of sexual abuse generally are more common when the sexual abuse has been more frequent and more physically intrusive, is accompanied by other forms of abuse, or occurs in the setting of other family dysfunction,[36,39] isolated assaults by medical providers might result in less future morbidity. Adults who have been exposed to childhood abuse or have witnessed intimate partner violence use more health and mental health services and have poorer health status, more depression, and more interpersonal violence victimization than controls.[43] Although child abuse victimization is associated with the development of criminality and violent criminality, sexual abuse alone or associated with other forms of abuse is not associated with increased violent criminality.[44]

The effects of medical provider sexual contacts or abuse have been most studied in the context of adult psychiatric patients. Patients abused by male providers tend to have increased distrust of and anger directed toward men and to therapists in general and an increase in the number and severity of their mental health and psychosomatic symptoms.[45] In a study of adults who were seeking clinical mental health care after provider sexual contact, posttraumatic stress disorder, major depression, suicidality, misuse of prescription drugs and alcohol, disturbed interpersonal relationships, and employment disruption were all reported.[13] Eighteen percent of these patients were revictimized in subsequent counseling interactions.

Despite these reports of responses to sexual abuse in general and adult responses to sexual abuse by medical and counseling providers, there is no literature on the specific reactions of pediatric patients to medical provider sexual abuse.

Institutions should anticipate that sexual abuse victims and their parents will require assessment and likely will need follow-up counseling. They should assist in referring and financially supporting such efforts.

SUMMARY

It is the responsibility of pediatricians to protect and foster the health of their patients. As such, sexual encounters with patients are destructive and are strictly forbidden. Pediatricians have a responsibility to recognize and report sexually inappropriate acts by their colleagues and other medical staff. When they have "reasonable cause to suspect or believe" (individual states' reporting thresholds vary; providers should check their specific state's law) that abuse has occurred, they are legally required to report to appropriately mandated governmental investigative agencies and licensing boards. The sexual abuse of a child by a pediatrician is a devastating violation of ethical and legal behavior that can severely impair the child's future physical and mental health. When children are abused by those who are entrusted with their medical care, the profession has the responsibility to take the necessary actions to protect future patients from harm by those providers. These actions include helping families affected by abuse by ensuring proper emotional support. Pediatricians should also work with government agencies and licensing bodies to ensure that in the future children are protected from pediatricians and other health care providers who sexually abuse patients.

RECOMMENDATIONS

To protect and foster the health and to earn and maintain the trust of their patients:

1. It is the responsibility of pediatricians to protect and foster the health of their patients. As such, sexual encounters with patients are destructive and are strictly forbidden.
2. Pediatricians and health care providers should know that most sexual offenses of children occur at the hands of adults who have a primary sexual orientation to other adults. However, adults who have a primary sexual attraction to children constitute more risk for planned and multiple-victim child offenses. Sexual offenses are perpetrated by both heterosexual and homosexual offenders. Any sexual abuse of children by medical providers is a profound betrayal of their responsibility for patient well-being, trust, and medical ethics.
3. Medical trainees should be educated about appropriate provider-patient

boundaries and appropriate use of chaperones for examinations.

4. Employees of medical facilities for children should be screened for previous abuse of a child by them both through formal state registries and through contact with previous employers.
5. Pediatricians should be educated about the indications and techniques of the genital examination, should perform routine genital examinations during annual checkups, and should know the indications for performing genital examinations to evaluate other specific medical concerns.
6. Pediatricians must explain to parents and verbal children why they are performing each element of the examination and respect their need for modesty by providing appropriate draping and allowing privacy while changing. They should offer chaperones and provide them whenever requested or required as part of standard practice and local regulations or when the provider feels that a chaperone is needed.
7. Employees of medical facilities for children should be trained about staff-patient boundaries, chaperone use, and their responsibility to immediately report concerns of patient abuse by other staff members. Institutions should have policies and procedures in place to conduct these trainings.
8. Parents should be informed that they have a right to request chaperoned examinations. They should be aware that if they have concerns about sexually inappropriate examinations or provider actions, they should report to the clinic's or medical facility's administration. If their concerns are sufficient, they themselves have a right to report to their state's protective service for investigation.
9. All health care providers and health care institutions are legally mandated reporters for suspicions of child abuse. If health care providers or institutions have reasonable cause to suspect that another health care provider has sexually abused a child, they are legally mandated to report to protective services and/or the police.
    a. Institutions should have policies and procedures in place to receive and evaluate concerns for patient abuse.
    b. Accused employees should have complaints about them managed confidentially, sensitively, and expeditiously. They should be provided with independent, confidential support and counseling services during the investigation.
    c. Individuals and institutions are responsible for following legal guidelines about reporting concerns for child abuse to the appropriate institutional, local, and state authorities.
    d. Individuals and institutions should cooperate with appropriate protective, legal, and licensing agencies in their investigation of concerns for sexual abuse by medical providers.
    e. Institutions remain responsible for the future protection of patients from abuse. They should not pass problem providers along without appropriate notifications.
10. Institutions should assist victims of sexual abuse by staff to receive appropriate assessment and consideration of the need for counseling.

POLICY: To foster an atmosphere of safety and healing, Children's staff [including employees, medical staff, post-graduate trainees, agency contractors, students, and volunteers] are required to maintain a professional relationship with patients and families.

PURPOSE: To assist hospital employees, medical staff, trainees, and volunteers to establish relationships with patients and families/significant others that are therapeutic, professional, and which have defined personal and professional boundaries.
To create an environment in which the discussion of what constitutes a professional relationship with families is routine and common within departments.

PROCEDURE: The **ADDENDUM below** describes the current standards and procedures.

Revised by:

Approved by Medical Executive Committee:

APPROVED BY:

Senior Vice President
Chief Nursing Officer

Pediatrician-in-Chief
Chief Medical Information Officer

President
Chief Operating Officer

ORIGINATED:
REVIEWED:
REVISED: 09/09/09

Additional Key Words: Professional Boundaries; Therapeutic Relationship

ADDENDUM:

I. Elements of a Professional Relationship
- A. A professional relationship requires clearly defined and consistently applied boundaries and limit setting in the context of caring for the patient and family.
- B. Staff interventions are defined by the scope of practice, clinical privileges, roles, and responsibilities and by the essential functions defined in Job Descriptions, and approved medical staff credentials or privileges.
- C. Establishing a professional relationship requires that staff maintain a clear sense of their own distinct identity, emotions, moral principles, spirituality, and personal life, while caring for the physical and emotional needs of the patient and family.
- D. A professional relationship respects patient and family rights and cultural differences. This includes consistent adherence to privacy and confidentiality guidelines, and all other relevant Children's policies.
- E. A professional relationship allows staff to advocate for the patient and family, empowering them to achieve their maximum level of independence and decision-making autonomy during and after the patient's hospitalization or illness.

II. Children's Responsibility in Supporting Professional Relationships
- A. The hospital strives to provide an environment that promotes well-defined boundaries for staff relationships with patients and families. Some characteristics of this environment include:
  1. Open communication and dialogue with peers, supervisors, and directors that include the discussion of boundary dilemmas and professional ethical behavior.
  2. Staff bereavement support as appropriate.
  3. Ethical consultation as indicated or requested.

APPENDIX A Continued

4. Employee Assistance Program consultation to support staff in helping to resolve personal issues contributing to blurred boundaries.
5. Physician Wellness Program to provide support for members of the medical staff and their families as well as residents and fellows.

III. Working with Patients and Families in a Professional Way

A. Some guiding principles to determine professional boundaries and the continuum of professional behavior include, but are not limited to, the following:
   1. Describe your role to the patient and family.
   2. Assess patient and family needs.
   3. Assist with referrals as needed.
   4. Provide care only within the scope of your practice.
   5. Provide care only within regularly scheduled work hours.
   6. Provide consistency in care and support to patients and families without preferential treatment.
   7. Limit communication and contact to subjects related to the care of the patient and services to meet family needs.

B. Refrain from and do not:
   1. Have social contact with patients or families outside of the scope of work.
   2. Provide child care outside of the scope of practice or work hours.
   3. Provide transportation to patients or families in personal vehicles.
   4. Share personal information or problems with patients or families (including home phone numbers, addresses, e-mails, and fax numbers).
   5. E-mail, phone, text, and access patient and/or family personal websites (Facebook, MySpace, Twitter, or other similar electronic sites) for non-clinical or personal use. Use of e-mail for clinical purposes must follow the guidelines outlined in the medical centerôs Computer User Responsibility.
   6. Directly receive gifts of significant monetary value from patients and families.
   7. Offer gifts or money to families or patients.
   8. Share religious or political beliefs with patients and families.
   9. Enter into a business relationship with a patient or family member outside the scope of oneôs position, e.g. hiring a patientôs parent to landscape a staff personôs home.

IV. Additional Rules and Expectations

A. Staff will not engage in a romantic, sexual, or intimate physical relationship with any patient, any member of a current patient's family, or any former patient under the age of 18.

B. Staff will not provide foster care or initiate adoption proceedings for a patient encountered in his or her role as a Childrenôs employee.

C. Staff will continuously evaluate relationships with patients and families using these guidelines.

D. Questions or concerns regarding the appropriateness of relationships with patients and families will be directed to the immediate supervisor, the Director of Human Resources, Seattle Childrenôs Hospital, or anyone in the supervisory chain of command.

E. Should staff or supervisors feel that a staff memberôs relationship with the patient or family member fails to meet these professional guidelines, counseling or other interventions may be indicated. If need be, the staff personôs relationship with the patient or family may be terminated.

F. Failure to maintain a professional relationship with patients and families may lead to corrective action, up to, and including dismissal.

POLICY: Childrenôs will report, investigate and follow up on any concerns of abuse or neglect of a child arising from the actions of a Childrenôs staff member.

PURPOSE: Childrenôs is committed to maintaining and promoting a safe environment for all patients and families. This policy outlines the process for oversight of investigation of alleged abuse or neglect by a Childrenôs staff member.

PROCEDURE: The **ADDENDUM below** describes the current standards and procedures.

Revised by:

Approved by Medical Executive Committee:

APPROVED BY:

Pediatrician-in-Chief Chief Medical Information Officer	Senior Vice President Chief Nursing Officer

ORIGINATED: _
REVIEWED: 10/09
REVISED:

Additional Key Words: CPS, CPT, SCAN, SCPP, Accused Staff, Allegation of Abuse, Child Protective Services, Childrenôs Protection Team, Complaint, Grievance, Human Resources, Patient Safety, Seattle Childrenôs Protection Program, Staff Allegation

ADDENDUM:

I. Applicability. This policy applies to acts by employees, volunteers, members of the medical staff, students, residents, fellows and trainees, all of whom are ñstaff membersò.

II. Initial Identification and Response:

A. Any person who becomes aware of a concern of abuse or neglect by a staff member will immediately notify:
   1. During normal business hours, the manager or medical staff leader of the relevant clinical area (unit, floor, clinic, etc.);
   2. Outside normal business hours, the nursing shift administrator.

B. If any person questions whether actions occurring during normal medical procedures or patient restraint are abusive, the manager, medical staff leader or nursing shift administrator will review the concerns and observations of all present to determine if the actions are consistent with normal practice.
   1. The following must be reported directly and immediately to the Seattle Childrenôs Protection Program (SCPP):
      a. If the patientôs care management team is not unanimous that the events were within normal procedures;
      b. If more than minor injury resulted; or
      c. If the concern creates **reasonable cause to believe** abuse has occurred.
   2. During regular weekday hours, 8:00 am ï 4:30 p.m., contact SCPP at.
   3. After hours and on weekends or holidays, page the on-call SCAN Medical Consultant urgently.
   4. The SCAN Medical Consultant will contact the SCPP Medical Director, Manager or a designee.

C. The manager, medical staff leader or nursing shift administrator should review allegations dealing with unwitnessed events with SCPP.

D. If there are concerns about physical injury or abuse to a child, the attending physician or Suspected Child Abuse or Neglect (SCAN) Medical Consultant should examine the child, recommend treatment of any injuries and document the exam in the patientôs medical record.

APPENDIX B Continued

E. The manager or medical staff leader of the relevant clinical area will, by the end of the business day on which they are notified of the concern:
   1. File an incident report.
   2. Consult with Human Resources.

III. SCPP Investigation and Management

A. The SCPP Manager will assign an appropriate individual to act as Case Manager. Appendices I and II outline the roles of the SCPP Manager and the assigned Case Manager. The Case Manager will usually be a SCAN Social Worker (SW).

B. Disposition of person involved in allegation of abuse:
   1. The supervisor of the involved staff member will immediately remove the person from any duties involving patient care interactions.
      a. If the involved staff member is a member of the medical staff, the SCPP Manager will notify the Department Chair or Division Chief, and the Pediatrician-in-Chief or Surgeon-in-Chief if appropriate, to remove the medical staff member from patient care duties.
      b. In addition, the SCPP Manager will notify the Medical Director of the incident, who will consider whether summary action under the Medical Staff Bylaws is warranted to protect patients. The SCPP Manager will keep the Medical Director informed of the status of the investigation for the same purpose. Upon receiving such notice from the SCPP Manager, the Medical Director will assure notice to:
         i. The Medical Staff Department Director, Division Chief, and Medical Staff President;
         ii. The Department Chair, Pediatrician-in-Chief or Surgeon-in-Chief, if appropriate;
         iii. The physician leader of any practice group where the medical staff member provides patient care;
         iv. The appropriate licensing authority; and
         v. The affected member of the medical staff.
   2. If possible prior to such removal of a Seattle Children's employee, the supervisor will consult with HR. If the supervisor and HR agree, the person may be assigned to non-patient care duties. This consultation will not delay the removal of the person from patient care interactions.
   3. If the person is not assigned to non-patient care duties, the staff member will be placed on immediate paid administrative leave.
   4. The staff member involved in the allegation shall cooperate in the investigation by participating in an interview on request or otherwise as requested by the Case Manager. Failure to cooperate with the investigation on request may be grounds for disciplinary action, up to immediate termination of employment or medical staff privileges or both.
   5. The supervisor of the staff member, working with HR in the case of a Seattle Children's employee, will designate a support person for the staff member.
   6. As a case involving a Seattle Children's employee progresses or is closed, HR will periodically re-evaluate the staff member's status (leave, terms of leave, reassignment, termination or otherwise) and modify it as appropriate.
   7. Any disciplinary action result for a Seattle Children's employee as a result of the investigation shall be documented under normal HR policies.

C. Evaluation:
   1. The Case Manager will conduct an evaluation of the allegation as soon as possible. Evaluation consists of at least the following:
      a. Interview with the person(s) bringing the concern.
      b. Interview with the staff member against whom the allegation has been made regarding the event. The Case Manager will include the person's supervisor in this interview.
      c. Interview with the patient's caregiver/parent(s)/legal guardians. The Case Manager may delegate this interview to an existing assigned social worker if appropriate in the circumstances.
      d. Interview with the patient when indicated. The Case Manager may delegate this interview to an existing assigned social worker if appropriate in the circumstances.

2. The affected child should have a trusted support person present during any interview.
3. The Case Manager will prepare a written evaluation summary.
4. In conducting the investigation outlined above, the Case Manager shall have the authority to conduct such interviews and engage in such additional investigation as the Case Manager deems reasonably necessary for the purposes of the investigation.

D. Reporting.
1. As soon as possible upon the completion of the evaluation, SCPP Manager will review the evaluation summary to determine whether the incident requires reporting to CPS, law enforcement or the Department of Health (for licensed facilities).
2. The SCPP Manager will also consult with the Associate Medical Director for Patient Safety to determine whether the incident requires reporting to the Department of Health as a sentinel event.
3. The SCPP Manager may consult with others, including the Case Manager, SCPP Medical Director, HR representative, Childrenôs general counsel, and others with expertise in the relevant area.

E. If the SCPP Manager determines that reasonable cause exists to believe that abuse or neglect of a child has occurred, the Case Manager will make the report to CPS or law enforcement.

F. If the Case Manager reports the case to CPS, the staff member will remain or be placed on paid administrative leave by his/her supervisor, in consultation with Human Resources (HR) in the case of a Seattle Childrenôs employee. The employee will remain available for any interviews with CPS or law enforcement.

G. The Case Manager will coordinate any patient interview by CPS, law enforcement and Department of Health (DOH) investigators with the patientôs care team. The affected child should have a trusted support person present during any such interview.

H. If CPS or law enforcement determine that the incident was abusive, the SCPP Manager will:
1. Make a report to the DOH at .

I. Consult with the Associate Medical Director for Patient Safety to determine whether the alleged event constitutes a sentinel event requiring a report to the Department of Health.

J. If no report of the incident is made to CPS or law enforcement
1. The Case Manager will advise the family of their right to consult CPS for outside review.
2. The SCPP Manager will advise the person initially identifying the concern of that personôs right or obligation to file an independent report with CPS.

IV. Documentation:

A. The Case Manager will:
1. Document the incident in the patientôs medical record on CIS in the Child Protection folder without identifying the person alleged to have acted improperly by describing the incident as **allegation of abuse by a third party with access to children**.
   a. The individual bringing the concern will not be identified in the record, but will be referred to as a parent, medical staff member, child, volunteer, etc.
   b. If the case is determined not to require reporting, a statement to this effect will be noted in the medical record.
2. Complete the Patient/Family Risk Assessment Form (PFRA).
3. Document all procedures and communications completed or in progress, including dates and times for each step.

B. The SCPP Manager will:
1. Attach all documentation to the appropriate electronic file in Centerpoint.
2. As appropriate, arrange for the Medical Records Department to secure the medical record or relevant portions of the medical record.
3. Request that CPS, law enforcement or DOH investigators provide Seattle Childrenôs with both verbal and written documentation of their disposition of the case.
4. Coordinate notification of the disposition of the case to all relevant parties.

C. If the allegation will affect the childôs on-going treatment or placement, the attending physician at discharge will provide a brief summary of the nature of the incident in the medical discharge summary, without reference to the name of the employee.

APPENDIX B Continued

V. Consequences ï Childrenôs Employee
- A. The SCPP Manager will report to HR any case where a report is made to CPS or law enforcement, or where CPS or law enforcement determines that the incident was abusive. HR shall take immediate action, which may range from continued administrative leave (with or without pay) up to termination of employment.
- B. In any other case, the SCPP Manager shall consult with the supervisor of the staff member involved in the allegation to communicate the results of the investigation. The supervisor shall consult with HR and determine what if any actions to take based on the circumstances of the event.

VI. Consequences ï Medical Staff Member.
- A. In any case where a report is made to CPS or law enforcement regarding a member of the medical staff, or where CPS or law enforcement determine that the incident was abusive, the SCPP Manager shall notify the Medical Director, who shall initiate a formal professional investigation under the Medical Staff Bylaws.
- B. Upon receiving such notice from the SCPP Manager, the Medical Director will assure notice to:
  1. The Medical Staff Department Director, Division Chief, and Medical Staff President;
  2. The Department Chair, Pediatrician-in-Chief or Surgeon-in-Chief, if appropriate;
  3. The physician leader of any practice group where the medical staff member provides patient care;
  4. The appropriate licensing authority; and
  5. The affected member of the medical staff.

APPENDIX I: Staff Allegation of Child Maltreatment Supervisor/Manager Checklist

The Seattle Childrenôs Protection Program (SCPP) provides leadership for staff allegation interventions. This includes case management, including further assessment and reporting, if indicated. Every effort will be made to maintain confidentiality for the patient, witness(es), reported and staff member of concern. When a report is made, the following are steps to be taken.

I. Supervisor/Manager of staff person of concern will:
- A. Gather initial information:
  1. Reporter Name
  2. Witness(es) Name
  3. Staff Person of Concern Name
  4. Patient Name
  5. Location
  6. Attending
  7. Nature of Incident
- B. Immediately contact Seattle Childrenôs Protection Program (SCPP) Manager or Medical Director by speaking in person to:
  1. During day shift Monday ï Friday, the SCPP manager, at ext. 7-2194
  2. After hours/weekends/holidays, SCAN physician, by calling the switchboard
- C. Complete the following:
  1. Emphasize need for confidentiality with all involved staff; instruct all involved individuals not to discuss the case until SCPP has arranged for the person to be contacted.
  2. Work closely with SCPP Case Manager to support investigation process
  3. Complete an incident report
  4. Obtain signed written statement from reporter and send to SCPP Manager (M/S), not to the medical record
  5. Notify patientôs Attending of the incident
     a. If there is potential physical injury, request that Attending or SCAN physician assess and treat patient, including photo documentation
  6. Place staff member on paid administrative leave, or into a ñno patient contactò role when determined by appropriate supervisor, HR and SCPP Manager pending completion of incident review
  7. Working with HR, become or designate a support person for the staff person of concern

8. Provide support to the reporter and witness(es) of the incident as needed
9. Assist the SCPP Case Manager with interviews of witness(es), reporter, and staff person of concern, and, if appropriate, with parent(s)/caregiver/legal guardians and child
10. Ensure the involved staff member is available as needed for interviews
11. With HR, periodically re-evaluate staff personôs employment status (leave, terms of leave, reassignment, or termination) as investigation proceeds
12. Assess and manage transition of employeeôs return to work if this is outcome of review, reemphasizing the need to maintain confidentiality with all involved

II. Documentation

A. Attending and/or SCAN physician will document any exam results and treatment attributable to the incident in the patientôs medical record

B. If the allegation will affect the childôs on-going treatment or placement, a brief summary of the nature of the incident will be summarized by the Attending physician in the medical discharge summary without reference to the name of the involved staff member

C. Any patient complaint or grievance will be managed and documented according to Admin. P & P, ñPatient Complaint or Grievanceò

III. Reporting Considerations

A. SCPP Manager will determine if case is to be reported to CPS, law enforcement and/or DOH

B. If reportable, the SCPP Case Manager will notify CPS and/or law enforcement, and the SCPP Manager will notify DOH.

APPENDIX II: Seattle Childrenôs Protection Program (SCPP) Manager and SCPP Case Manager Roles and Responsibilities

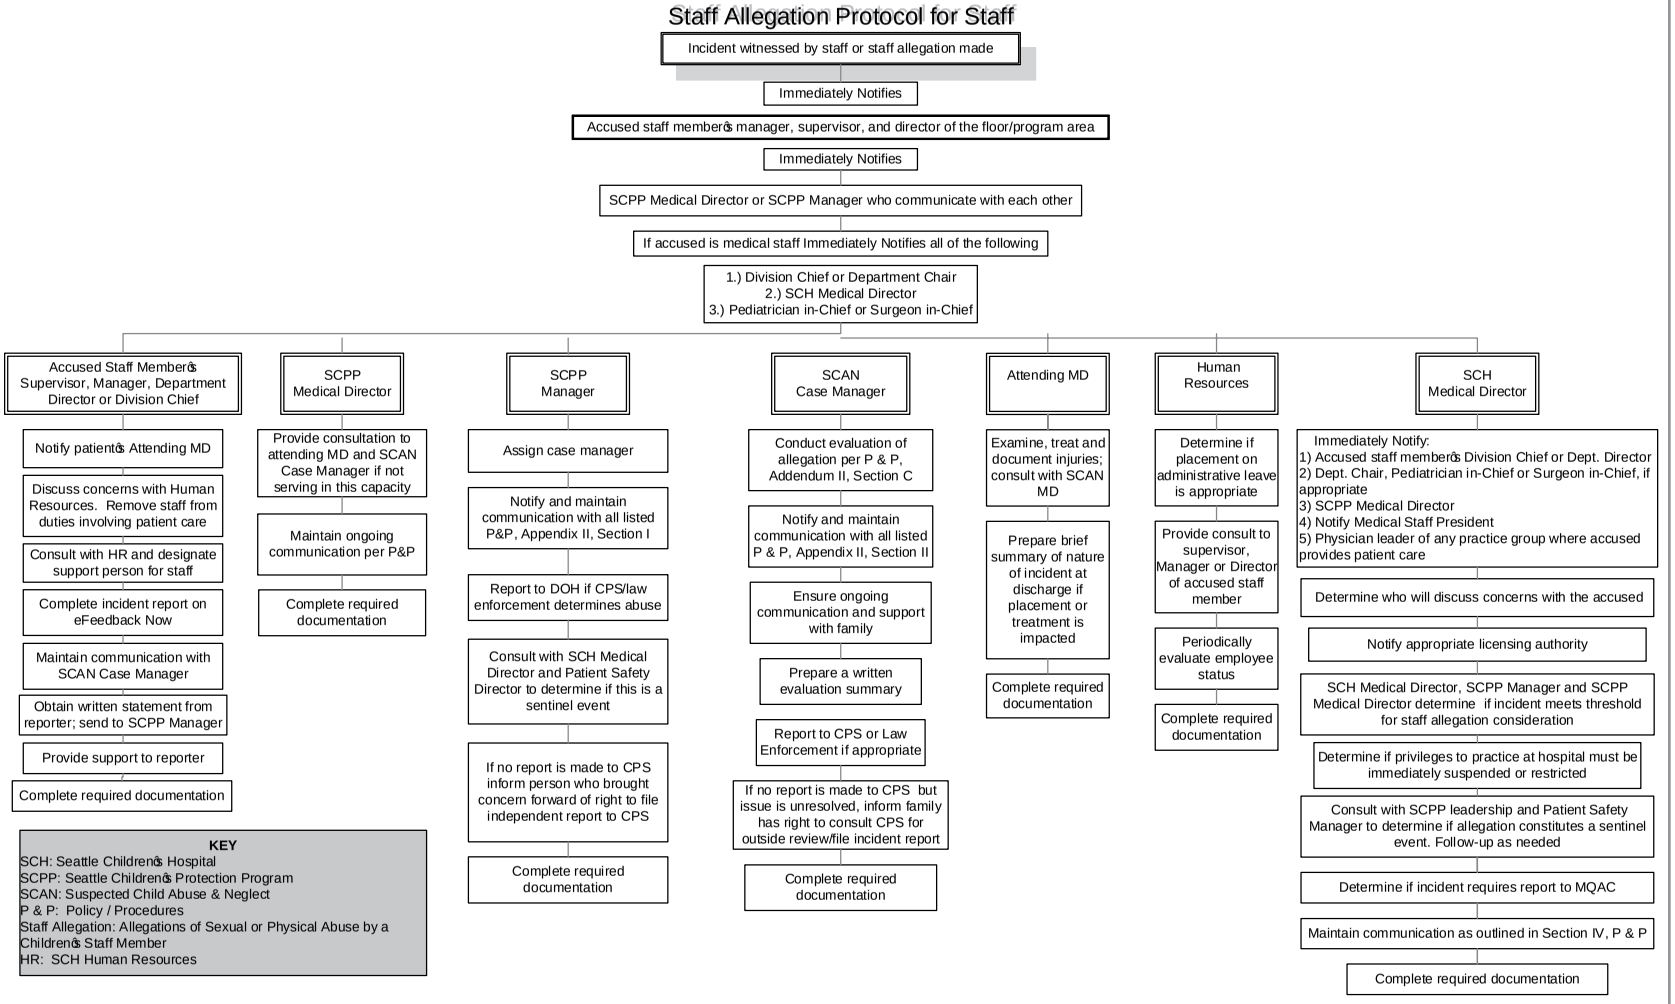
I. The SCPP Manager is responsible for communication (initially and ongoing) with the following:

A. Medical Director
B. Pediatrician-in-Chief or Surgeon-in-Chief, if appropriate
C. SCPP Medical Director
D. Administrator On Call (AOC) (who should notify the appropriate administrative leadership)
E. Clinical on Call (COC) (who should notify the appropriate medical leadership)
F. Chief Nurse
G. Vice President with oversight of SCPP
H. General Counsel
I. Risk Management
J. Human Resources
K. The Department of Health (DOH) (if required)
L. Associate Medical Director for Patient Safety, for consideration of reporting a sentinel event
M. Family and Patient Relations Manager
N. MarComm (if appropriate in the circumstances)
O. Case Manager

II. The Case Manager established under this policy is responsible for communication with the following:

A. Person bringing the concern
B. Any potential witness(es) to the incident
C. Staff memberôs supervisor
D. Staff member
E. Patientôs social worker, if involved
F. Patientôs caregiver/parent(s); and provide for, or arrange support as needed
G. Patient, when indicated
H. Patientôs attending physician
I. Patientôs PMD as appropriate
J. SCAN Medical Consultant, if involved
K. SCPP Manager
L. Child Protective Services (CPS) (if appropriate)
M. Law enforcement (if appropriate)
N. Unit Nursing Director or Clinical Manager

APPENDIX III: Organizational Chart of Staff Allegation Protocol



POLICY: Childrenôs Providers will offer a chaperone to patients or their families for all or any part of a physical exam or sensitive procedure occurring in ambulatory care. This policy assures that patients will be interviewed and examined in a secure and professional manner and serves to protect health care providers from misunderstandings, accusations or inappropriate behaviors regarding physical exams and procedures.

This policy applies to all ambulatory care activities occurring within the Childrenôs Health Care System. Any clinical area may in addition adopt more stringent guidelines.

Childrenôs staff will maintain professional relationships with patients and families.

PURPOSE: Childrenôs is committed to providing an environment where patients and staff feel safe and confident that clinical care is provided in a comfortable, secure, and professional manner.

PROCEDURE: The **ADDENDUM below** describes the current standards and procedures.

BARRIER TECHNIQUES:

CLASS _I_ GLOVES _R_ EYE _A_ MASK _A_ GOWN _A_

Additional Key Words: Confidentiality, Detention, Exam, Examination, Family Centered Care, Genital Exams, Juvenile, Patient Safety, Privacy, Professional Relationship, Staff Safety, Sensitive Exams or Procedures, Touch, Touching

ADDENDUM:

I. Chaperones will be provided in all outpatient activities listed below unless the patient or legally authorized representative requests that a chaperone not be present.
- A. In those circumstances (refusal of chaperone) see **Section IX** below.
- B. Activities requiring chaperones:
  1. Specifically requested by the patient, the parent or legal guardian
  2. Requested by the health care practitioner (i.e. physician, mid-level provider, nurse, or other caregiver) and with the approval of the parent/legal guardian or patient
  3. A potentially sensitive examinations or procedures (i.e. genital, breast, rectal) will be conducted.
  4. See **Sections IV** for considerations applicable in such situations.
  5. Prior to undertaking any such potentially sensitive examination or procedure, the person who will perform it will offer a chaperone to the patient or the legal guardian, as appropriate in the circumstances.

APPENDIX C Continued

II. The following individuals may be considered as appropriate chaperones:
- A. Clinical staff (i.e. attending or consulting physicians, nurses, medical assistants) or other Childrenôs staff who have specifically been trained in patient contact.
- B. Family members for younger-aged children or at the request of an adolescent; **or**,
- C. Other individuals as designated by the patient or legal guardian.
  1. **Note**: Interpreters, office and non-clinical staff are not appropriate for chaperoning sensitive examinations or procedures.
  2. Trainees (e.g. students, interns, residents, fellows) may not act as chaperones for any faculty member.
     a. Trainees may act as chaperones for hospital personnel, such as radiology technologists.
  3. The patient or guardian should have the choice of the chaperoneôs gender.

III. Examinations and patient contacts will be limited to those warranted by the medical issues at hand.
- A. Patients will be draped appropriately for the type of contact and for modesty.
- B. Patients will be provided privacy when they dress or undress, and,
- C. The examiner will wear gloves when conducting genital exams or when there is contact with an older childôs genitals, consistent with community standards.

IV. Sensitive exams or procedures are those involving the breasts, genitals or rectum. Practitioners should in addition be alert to patient-or family-specific concerns about other parts of the body that the patient or family considers sensitive.
- A. The practitioner may determine, on an individual basis, that a chaperone will be required for a breast, rectal, genital or other potentially sensitive exam or procedure, taking into account:
  1. Physician/practitioner patient relationship.
  2. Patient concern or complaint; or,
  3. Patientôs pertinent mental health or developmental history.
- B. See **Section IX** below for cases where the patient or legal guardian declines a chaperone requested by the practitioner.

V. If a chaperone is utilized, sensitive inquiries and history-taking will respect patient confidentiality (per HIPAA regulations) and will be conducted outside the chaperoned physical exam/procedure.
- A. Medical trainees that are a part of the patient care team can be present as part of the normal care/training process.

VI. Chaperones provided by Childrenôs will be HIPAA trained and will respect patient confidentiality and privacy.

VII. Practitioners will be sensitive to historical cues that may heighten patient or family anxiety about provider contacts.
- A. Risk for misunderstanding or misinterpreting examinations is higher when:
  1. Children have experienced past abuse, particularly sex abuse victimization.
  2. Children/adolescents have developmental delays or acutely altered mental states (e.g. intoxications) or chronic altered mental states (e.g. mental illness).
  3. Patients are young or naïve to medical care, or are having their first clinical encounter with a health care provider.
  4. Patients are in juvenile detention settings.
  5. There are patient or family ethnic, cultural or religious considerations specific to the examination or procedure.

VIII. Some adolescents may wish to discuss their personal issues and be examined without their parents or a chaperone present.
- A. When possible, it is appropriate to ask adolescents about their chaperone preferences in private.
- B. When adolescents can consent for their own care, they may also make the decision about utilization of a chaperone.
  1. For those with impaired competence, the legal guardian will be involved in making the decision about having a chaperone present.

IX. A patient (who is authorized to consent to his/her own medical care) or the legal guardian may request that a chaperone not be present for a sensitive exam.
- A. Such, a request will be honored.
- B. However, in such a situation, the practitioner may judge the examination too problematic to complete.
- C. In such cases, the practitioner will make arrangements for subsequent evaluation of non-emergent issues or make an effort to transition patient care to another provider.
- D. In any such case involving emergency medical treatment, practitioners will assure that the patient receives a screening history and examination and any medically necessary stabilizing care.
- E. The practitioner will document the refusal for a chaperone in the medical chart.

X. Staff will not leave the exam room door open in lieu of providing a chaperone.

XI. Documentation:
- A. In the medical chart, practitioners will document:
  1. The name of the chaperone, **or**
  2. In case of refusal of a chaperone by the patient or legal guardian in circumstances described in **Section IX**, the fact that a chaperone was offered and that the patient or legal guardian declined the chaperone.
- B. In addition to the provider documentation, in the medical chart under **Add Hoc** charting, the Registered Nurse and/or Medical Assistance will document if a chaperone has been offered and accepted or declined.
- C. Follow steps below for documentation:
  1. Choose **Ad Hoc** charting under the **Chart** tab.
  2. Under the **Clinical Care** tab, click on **Patient Care Information**.
  3. Choose **Chaperone Form**.
  4. Either check **Accepted** or **Declined**.
  5. If accepted, then type in the **Name** of chaperone.
     a. Click on the binoculars to get a current employee list.
  6. Or, if there was a family member present for the examination, type their name in box.
  7. Type in the name of **Who Accepted** or **Declined** the Chaperone.
  8. Choose the relationship to the patient.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Protective Eyewear for Young Athletes

ABSTRACT. The American Academy of Pediatrics and American Academy of Ophthalmology strongly recommend protective eyewear for all participants in sports in which there is risk of eye injury. Protective eyewear should be mandatory for athletes who are functionally 1-eyed and for athletes whose ophthalmologists recommend eye protection after eye surgery or trauma.

ABBREVIATIONS. ASTM, American Society for Testing and Materials; ANSI, American National Standards Institute; CSA, Canadian Standards Association; HECC, Hockey Equipment Certification Council.

BACKGROUND

More than 42 000 sports and recreation-related eye injuries were reported in 2000.[1] Seventy-two percent of the injuries occurred in individuals younger than 25 years, 43% occurred in individuals younger than 15 years, and 8% occurred in children younger than 5 years.[1] Children and adolescents may be particularly susceptible to injuries because of their aggressive play, athletic maturity,[2–4] and poor supervision in some recreational situations.

The sports highlighted in this statement were chosen on the basis of their popularity and/or the high incidence of eye injuries in that sport. Participation rates and information on the severity of the injuries are unavailable; therefore, the relative risk of significant injuries cannot be determined for various sports. Baseball and basketball are associated with the most eye injuries in athletes 5 to 24 years old.[1]

The eye-injury risk of a sport is proportional to the chance of the eye being impacted with sufficient energy to cause injury. The risk is not correlated with the classification of sports into collision, contact, and noncontact categories. Instead, the risk of eye injury to the unprotected player is roughly categorized as high risk, moderate risk, low risk, and eye safe. The sports included in each of these categories are listed in Table 1.

EVALUATION

All athletes and their parents should be made aware of the risks associated with participation in sports and the availability of a variety of certified sports eye protectors. Although eye protectors cannot eliminate the risk of injury, appropriate eye protectors have been found to reduce the risk of significant eye injury by at least 90% when fitted properly.[4–6] It would be ideal if all children and adolescents wore appropriate eye protection for all eye-risk sports and recreational activities.

Physicians should strongly recommend that athletes who are functionally 1-eyed wear appropriate eye protection during all sports, recreational, and work-related activities. Functionally 1-eyed athletes are those who have a best corrected visual acuity of worse than 20/40 in the poorer-seeing eye.[1,4,7] If the better eye is injured, functionally 1-eyed athletes may be handicapped severely and unable to obtain a driver's license in many states.[8]

Athletes who have had eye surgery or trauma to the eye may have weakened eye tissue that is more susceptible to injury.[9] These athletes may need additional eye protection or may need to be restricted from certain sports; they should be evaluated and counseled by an ophthalmologist before sports participation.

PROTECTIVE EYEWEAR OPTIONS

Eye protection and different brands of sports goggles vary significantly in both the way they fit and their capacity to protect the eye from injury. An experienced ophthalmologist, optometrist, optician, physician, or athletic trainer can help an athlete select appropriate protective gear that fits well and provides the maximum amount of protection. Sports programs should assist indigent athletes in evaluating and obtaining protective eyewear.

There are 4 basic types of eyewear. The 2 types that are satisfactory for eye-injury risk sports include:

1. Safety sports eyewear that conforms to the requirements of the American Society for Testing and Materials (ASTM) standard F803 for selected sports (racket sports, baseball fielders, basketball, women's lacrosse, and field hockey).[10]
2. Sports eyewear that is attached to a helmet or for sports in which ASTM standard F803 eyewear is inadequate. Those for which there are standard

† Javelin and discus have a small but definite potential for injury. However, good field supervision can reduce the extremely low risk of injury to near-negligible.

specifications include youth baseball batters and base runners (ASTM standard F910), paintball (ASTM standard 1776), skiing (ASTM standard 659), and ice hockey (ASTM standard F513).[10] Other protectors with specific standards are available for football and men's lacrosse.

The 2 types of eyewear that are not satisfactory for eye-injury risk sports include:

1. Streetwear (fashion) spectacles that conform to the requirements of American National Standards Institute (ANSI) standard Z80.3.[11]
2. Safety eyewear that conforms to the requirements of ANSI standard Z87.1,[12] which is mandated by the Occupational Safety and Health Administration for industrial and educational safety eyewear.

Prescription or nonprescription (plano) lenses may be fabricated from any of several types of clear material, including polycarbonate. Polycarbonate is the most shatter-resistant clear lens material and should be used for all safety eyewear.[13]

PROTECTIVE EYEWEAR CERTIFICATION

Protectors that have been tested to an appropriate standard by an independent testing laboratory are often certified and should afford reasonable protection. The Protective Eyewear Certification Council has begun certifying protectors that comply with ASTM standard F803 (racket sports, basketball, baseball, women's lacrosse, and field hockey), ASTM standard F1776 (paintball), and ASTM standard F910 (youth baseball batters and base runners) standards.[10] The Canadian Standards Association (CSA) certifies products that comply with the Canadian racket-sport standard, which is similar to the ASTM standard.[10] The Hockey Equipment Certification Council (HECC) certifies ice hockey equipment including helmets and face shields. The National Operating Committee on Standards in Athletic Equipment certifies baseball and football helmets as well as the face protectors for men's lacrosse and football. For those sports with certified protectors, it is recommended that products bearing the Protective Eyewear Certification Council, CSA, HECC, or National Operating Committee on Standards for Athletic Equipment seals be used when available.

RECOMMENDATIONS

1. All youths involved in organized sports should be encouraged to wear appropriate eye protection.
2. The recommended sports-protective eyewear as listed in Table 2 should be prescribed. Proper fit is essential. Because some children have narrow facial features, they may be unable to wear even the smallest sports goggles. These children may be fitted with 3-mm polycarbonate lenses in ANSI standard Z87.1 frames designed for children.[12] The parents should be informed that this protection is not optimal, and the choice of eye-safe sports should be discussed.
3. Because contact lenses offer no protection, it is strongly recommended that athletes who wear contact lenses also wear the appropriate eye protection listed in Table 2.
4. An athlete who requires prescription spectacles has 3 options for eye protection: a) polycarbonate lenses in a sports frame that passes ASTM standard F803 for the specific sport; b) contact lenses plus an appropriate protector listed in Table 2; or c) an over-the-glasses eyeguard that conforms to the specifications of ASTM standard F803 for sports in which an ASTM standard F803 protector is sufficient.[10]
5. All functionally 1-eyed athletes should wear appropriate eye protection for all sports.
6. Functionally 1-eyed athletes and those who have had an eye injury or surgery must not participate in boxing or full-contact martial arts. (Eye protection is not practical in boxing or wrestling and is not allowed in full-contact martial arts.) Wrestling has a low incidence of eye injury. Although no standards exist, eye protectors that are firmly

TABLE 2. Recommended Eye Protectors for Selected Sports

Sport	Minimal Eye Protector	Comment
Baseball/softball (youth batter and base runner)	ASTM standard F910	Face guard attached to helmet
Baseball/softball (fielder)	ASTM standard F803 for baseball	ASTM specifies age ranges
Basketball	ASTM standard F803 for basketball	ASTM specifies age ranges
Bicycling	Helmet plus streetwear/fashion eyewear	
Boxing	None available; not permitted in the sport	Contraindicated for functionally 1-eyed athletes
Fencing	Protector with neck bib	
Field hockey (men and women)	ASTM standard F803 for women's lacrosse (goalie: full face mask)	Protectors that pass for women's lacrosse also pass for field hockey
Football	Polycarbonate eye shield attached to helmet-mounted wire face mask	
Full-contact martial arts	None available; not permitted in the sport	Contraindicated for functionally 1-eyed athletes
Ice hockey	ASTM standard F513 face mask on helmet (goaltenders: ASTM standard F1587)	HECC OR CSA certified Full-face shield
Lacrosse (men)	Face mask attached to lacrosse helmet	
Lacrosse (women)	ASTM standard F803 for women's lacrosse	Should have option to wear helmet
Paintball	ASTM standard F1776 for paintball	
Racquet sports (badminton, tennis, paddle tennis, handball, squash, and racquetball)	ASTM standard F803 for selected sport	
Soccer	ASTM standard F803 for selected sport	
Street hockey	ASTM standard 513 face mask on helmet	Must be HECC or CSA certified
Track and field	Streetwear with polycarbonate lenses/ fashion eyewear*	
Water polo/swimming	Swim goggles with polycarbonate lenses	
Wrestling	No standard available	Custom protective eyewear can be made

* Eyewear that passes ASTM standard F803 is safer than streetwear eyewear for all sports activities with impact potential.

fixed to the head have been custom made. The wrestler who has a custom-made eye protector must be aware that the protector design may be insufficient to prevent injury.

7. For sports in which a face mask or helmet with an eye protector or shield must be worn, it is strongly recommended that functionally 1-eyed athletes also wear sports goggles that conform to the requirements of ASTM standard F803 (for any selected sport).[10] This is to maintain some level of protection if the face guard is elevated or removed, such as for hockey or football players on the bench. The helmet must fit properly and have a chinstrap for optimal protection.
8. Athletes should replace sports eye protectors that are damaged or yellowed with age, because they may have become weakened and are, therefore, no longer protective.

abstract

FREE

All primary care providers will care for children with cerebral palsy in their practice. In addition to well-child and acute illness care, the role of the medical home in the management of these children includes diagnosis, planning for interventions, authorizing treatments, and follow-up. Optimizing health and well-being for children with cerebral palsy and their families entails family-centered care provided in the medical home; comanagement is the most common model. This report reviews the aspects of care specific to cerebral palsy that a medical home should provide beyond the routine health care needed by all children. *Pediatrics* 2011;128:e1321–e1329

INTRODUCTION

Primary care providers (PCPs) will encounter children with cerebral palsy (CP) in their practice. With a prevalence of 3.6 per 1000, more than 100 000 children in the United States are affected.[1] CP, as recently redefined (see sidebar), is not a single condition with a clear etiology. It includes a continuum of disorders of movement, posture, and coordination caused by a wide variety of nonprogressive conditions that affect the developing brain. It affects body functions and structures, activities, participation, and quality of life.[2] CP ranges in severity from isolated, mild spasticity in the legs to 4-limb involvement (quadriplegia) associated with cognitive impairments, seizures, and complete functional dependency.

SCREENING, SURVEILLANCE, AND DIAGNOSIS

The PCP engages in an integrated process designed to promote early identification of children with CP and expedite referrals to appropriate community services. The first step is to establish a diagnosis of CP. The second step is to identify and access interventions that are most likely to optimize the health and well-being of the child and family. CP is suspected in children who have delayed or abnormal motor development, especially in those with a history of prenatal, perinatal, or postnatal brain insults. A definite cause cannot be identified for many children who have CP. Table 1 lists some perinatal factors that are associated with CP. The American Academy of Pediatrics has developed guidelines on developmental surveillance and screening in practice[4]; these procedures can help with the early identification of children who are at increased risk of having CP.

Delayed motor development, abnormalities of muscle tone, and atypical postures suggest a diagnosis of CP.[5] A careful neurologic examina-

REVISED DEFINITION OF CP[46]: CP describes a group of permanent disorders of the development of movement and posture that cause activity limitations that are attributed to nonprogressive disturbances that occurred in the developing fetal or infant brain. The motor disorders of CP are often accompanied by disturbances of sensation, perception, cognition, communication, and behavior and by epilepsy and secondary musculoskeletal problems.

LOCALIZATION:

Diplegia: lower extremities are affected more than upper extremities.

Quadriplegia (tetraplegia): upper and lower extremities are affected to the same degree.

Hemiplegia: 1 side (often upper extremity) is more substantially involved than its opposite counterpart.

Children with CP typically receive care from multiple providers including orthopedists and neurologists, as well as physical, occupational, and speech-language therapists. They may receive services through Early Intervention and school-based programs. For some children with mild CP, the pediatrician is the primary manager; however, most children with CP receive collaborative and shared care (comanagement) among multiple specialists, coordinated through the medical home. For children with severe disabilities, specialists may serve as the primary manager.[3]

Parents, teachers, and therapists often approach pediatricians for medical and habilitative recommendations. Physicians who are knowledgeable about medical and functional issues, including community resources, can empower families by listening and responding to their concerns. Children with CP and their families benefit from family-centered, evidence-based, coordinated, and collaborative care that is based on shared decision-making in the context of the medical home.

tion might reveal alterations or asymmetries in muscle tone, strength, reflexes, posture, and coordination. For example, the occurrence of hand preference before 12 months of age is often suggestive of hemiplegia. An 8-month-old child who demonstrates palmar thumbs (adducted thumbs with clenched fists), scissoring of the legs, and hyperreflexia might have spastic CP. Many infants with CP have persistent infantile reflexes including the Moro reflex and asymmetrical tonic neck responses. Although neurologic findings in CP might change during infancy (eg, a floppy neonate who develops spasticity by 6 months of age), the brain lesion in CP is nonprogressive. Some infants who are born prematurely, especially those who weigh less than 2000 g, might have transient changes in muscle tone but not develop CP. Their findings include increased adductor tone in the lower extremities, truncal arching, and head lag. The symptoms usually resolve between 8 and 12 months of age.[6] Developmental surveillance (eg, serial examinations separated by 1 or 2 months) might be helpful to determine if the child is developing typically or has significant delays or other neurologic findings that suggest CP. Repeated evaluations also help foster the doctor/family relationship. The PCP can diagnose a child with CP in many instances. If questions remain, the child can be referred to a child neurologist or developmental pediatrician.

TABLE 1 Perinatal factors associated with the occurrence of CP

Chorioamnionitis (maternal infection)
Maternal disorders of clotting (eg, factor V Leiden deficiency)
Birth weight < 2000 g
Intracranial hemorrhage
Newborn encephalopathy (recurrent seizures, hypotonia, coma)
Periventricular leukomalacia
Hydrocephalus
Congenital malformations

Neurodegenerative disorders such as leukodystrophies, lysosomal storage diseases, ataxia telangiectasia, and mitochondrial disorders are uncommon conditions that might initially mimic CP; however, unlike CP, the manifestations of these conditions worsen over time. Glutaric aciduria and dopa-responsive dystonia (Segawa syndrome) are 2 rare progressive but treatable conditions that might be confused with CP. It is important to differentiate spastic diplegic CP from familial spastic paraplegia, which is a heritable condition in which lower-extremity spasticity and weakness worsen over time. Occasionally, a child who has transient toe-walking might be suspected of having spastic diplegia. Children who have progressive deterioration of cognitive or motor skills (ie, losing milestones) and those who have significant diurnal variation in symptoms should be referred to a child neurologist or neurodevelopmental specialist for further evaluation.[7]

Pediatric providers who identify abnormalities of development, tone, or posture in infants and toddlers should share their concerns with the child's family to facilitate patient/family self-management and access to resources. This requires spending sufficient time with family members to provide detailed feedback and to answer all questions. Referral to an Early Intervention or preschool program should be initiated even if a definitive diagnosis has not yet been established. These programs can perform formal developmental evaluations with standardized measures (such as the Bayley Scales of Infant Development and the Peabody

TABLE 2 Diagnostic Assessment and Classification of Children With CP

Category	Examples
I. Motor abnormalities	
A. Type of motor disorder	Spasticity; dyskinesia (dystonia and choreoathetosis); ataxia; hypotonia
B. Functional motor abilities	
a. Gross motor	Ambulation
b. Use of hands and arms	Self-help skills
c. Oromotor and speech	Communication; eating and drinking
C. Musculoskeletal changes	Contractures; hip dysplasia; torsional deformities, including scoliosis; joint instability; osteoporosis; pain
II. Associated impairments	
A. Central nervous system	Cognitive deficits; seizures; hearing impairments; vision impairments; attentional problems; behavioral problems; sleep disturbances
B. Gastrointestinal	Constipation; gastroesophageal reflux disease; malnutrition; drooling; incontinence; dysphagia; complications associated with enteral feedings
C. Respiratory	Aspiration, acute and chronic; pneumonitis and pneumonia; restrictive lung disease, secretion management
D. Genitourinary	Incontinence; voiding dysfunction; recurrent urinary tract infections
E. Dental	Poor hygiene; caries; periodontal disease
III. Distribution	
A. Anatomic	Limbs (hemiplegia, diplegia, quadriplegia); trunk; bulbar region
B. Radiologic	Periventricular leukomalacia; damage to basal ganglia or thalamus
IV. Causation and timing	Hyperbilirubinemia; in utero stroke (cortical cerebral infarction)
V. Severity	Degree of involvement (eg, weakness); number of associated impairments; GMFCS

Developmental Motor Scales), provide therapeutic and educational services, and assist families in connecting to parent support groups. Some communities have local volunteer organizations that can help families with peer support and linkage to helpful resources. Family Voices, a national organization, has established family-to-family health information centers in most states.[8]

The American Academy of Neurology has established practice parameters for the diagnostic evaluation of a child with suspected CP.[8] A brain MRI scan should be obtained in all children suspected of having CP if the etiology has not been established (eg, by perinatal imaging).[7] Those with hemiplegia and quadriplegia are most likely to have radiographic abnormalities.[9] When appropriate, formal gait analyses may be performed to inform decisions regarding therapeutic, medical, and surgical interventions to maximize mobility. Similarly, radiographic swallow studies may be used to evaluate dysphagia and determine strategies for optimizing nutrition and minimizing aspiration events. All children suspected of having CP should be promptly referred for formal hearing and vision evaluations. Formal developmental testing and electroencephalography might be helpful in the care of some children.

ASSESSMENT FOR INTERVENTION PLANNING

After a diagnosis of CP is suspected (or established), the PCP should evaluate the child's overall function to determine which interventions would be most beneficial. Family goals, structure, and resources should be considered when developing treatment plans that might include clinical consultations, community-based programs, and educational services. Traditionally, children with CP are classified on the basis of distribution of affected limbs and the predominant type of tone or movement abnormality (eg, "spastic diplegia"). However, a complete assessment, necessary for appropriate prognostication and treatment planning, must also include assessment of associated impairments and overall severity of CP (see Table 2). The PCP can make these determinations through the history and physical examination. In addition, the PCP can categorize children according to the Gross Motor Function Classification System (GMFCS), which provides a measure of the overall severity of the disability.[10]

An ongoing summary form or checklist of the primary and associated conditions should be maintained in each child's medical record to expedite accurate, serial assessments. Nickel and Desch[11] have published extensive guidelines for the care of children and adolescents with CP. In addition to the list of conditions based on a review of systems,[12] information on activities and participation should be included. Table 3 lists some suggested information that could be included on this form. It is important to note that tone or movement abnormalities are often mixed rather than pure. For instance, spasticity and dystonia frequently co-occur. In such instances, a child tends to have a greater severity of functional impairment and disability and is less likely to benefit from common interventions such as selective dorsal rhizotomy or systemic medication. Most children with spasticity also have impairments of strength and coordination. Thus, reducing spasticity might

"unmask" underlying weakness or dystonia and further limit function. Likewise, a pattern of spasticity in the limbs and hypotonia in the trunk and midline (including poor head control) is common in children with quadriplegic CP. Many communities have medical teams for children with CP that include orthopedics, physical therapy, occupational therapy, orthotics, neurosurgery, social work, and developmental pediatrics or physiatry. Referral to those programs might greatly benefit children and adolescents with more complex or severe involvement. Other children might benefit from consultations with specialists in pulmonology, gastroenterology, or endocrinology.

PROGNOSIS

Parents often ask about the severity of their child's CP and prognosis for independent ambulation.[13] Children with good head control at 9 months of age who bear weight through their hands while prone at 18 months, sit by 24 months, and crawl by 30 months have a good prognosis for independent ambulation.[14,15] The GMFCS[10] provides a measure of overall severity of CP. Children who are the most severely affected (GMFCS level V) have the highest rates of mortality and morbidity, including respiratory tract infections. For example, children who cannot lift their head in prone, cannot roll over, or require feeding by gastrostomy tube by 5 years of age have significantly higher mortality rates than other children with CP.[16] Children with intractable seizures or with recurrent aspiration pneumonitis also have worse prognoses. Although the brain lesion associated with CP is nonprogressive, individual function might decline across the life span. Thus, an ambulatory child with CP might opt for wheelchair mobility during adolescence to conserve time and energy; if this decision enhances participation in activities (eg, being able to go to the mall with friends), it should not be viewed as a failure. Ambulation status, IQ, quality of speech, and hand function predicted employment status in 1 group of youth with CP.[17]

ONGOING CARE IN THE MEDICAL HOME

Optimizing Practices

High-quality health care for children with CP depends on collaborations

TABLE 4 Recommended Components of Medical Homes for Children With CP[11,12]

Medical Home Component	Examples
Information systems that provide better quality of care and increased office efficiency	Use specific care plans for children with CP (medical summary, emergency plan, and action plan) Use American Academy of Pediatrics/American College of Emergency Physicians emergency information form for children with special needs[43] Have a registry of patients with CP to help track their progress and initiate contact
Redesigned offices that optimize patient flow and use of space	Have buildings, examination rooms, and equipment (scales, examination tables) that are accessible to children with disabilities[23]
Quality and safety that incorporate patient feedback, outcomes analysis, and evidence-based best practices	Use regular mechanisms (eg, surveys to get feedback from patients and families) Consult with parent advisors through a family advisory committee or other mechanism Keep informed about best practices in CP and resources (including family-to-family information centers) available in the community
Practice management that includes disciplined financial management and advocacy	Try to negotiate care coordination fee from local payers Use billing to reflect time and complexity of condition (eg, using a −25 modifier) Advocate with families to payers for coverage of medically necessary services
Services that include disease prevention, wellness promotion, and chronic disease management processes	Promote optimal nutrition and regular exercise Have specific chronic condition management visits (complex visits that are separate from well-child care) Employ a care coordinator
A process that encourages a collaborative approach to the patient's care, optimized use of the clinical team, prearranged relationships with other specialists, and strong communication within the practice	Have explicit comanagement with specialists
Access to care that offers group visits, e-visits, and same-day visits or a multilingual approach to care, when needed	Provide multilingual care Provide accessible information to patients with visual impairments

among parents; health care providers, including dentists[18]; and community agencies (eg, educational services, recreation programs, parent groups) with ongoing monitoring of the child's health and function. Table 4 offers recommendations for improving practices and their implications for children with CP.[19–21] PCPs are often asked to order or sanction therapies (physical, occupational, or speech) or assistive devices (wheelchairs, bath seats, communication devices, others). The American Academy of Pediatrics provides guidelines for the prescription of therapies[22] and communication devices.[23] The PCP has the right to decline ordering equipment that is of questionable value; referral to a specialist for further review of the request might be helpful. Clinical settings should be physically accessible; the Center for Universal Design offers guidelines for improving accessibility.[24] PCPs should be knowledgeable about community resources for individuals with CP and their families and facilitate linkages to appropriate services. Appendix 1 lists a few Internet sites relating to CP. Office visits for children with CP should be extended to allow for more in-depth evaluations and discussions. Billing should reflect time spent in direct and indirect care (eg, care coordination). Appendix 2 provides some billing codes used when treating children with CP.

Specific Interventions and Treatments

PCPs are often asked to provide specific recommendations to families about specialty care. This requires knowledge of evidence-based care. Many treatments have become common practice, despite a lack of evidence regarding the dose and duration of intervention or expected outcomes. Such interventions include speech and language therapy to improve verbal communication,[24] physical therapy for passive stretching of spastic muscles,[26,27] and sensorimotor integration therapy to promote function.[28]

Strengthening and Tone Management

Although Early Intervention services have generally improved outcomes for children, the specific interventions that most benefit children with CP are uncertain. In addition, therapeutic interventions change over time. For example, increasing emphasis is being placed on muscle strengthening and achieving functional goals. These changes make comparisons among programs difficult. Table 5 lists common interventions categorized according to their current evidence base.

The American Academy of Neurology has published guidelines on the pharmacologic treatment of spasticity in children and adolescents with CP.[29] Treatments recommended include injections of botulinum toxin into spastic muscles, as well as intrathecal baclofen. These interventions are usually not performed directly by PCPs. Systemic medications, including diazepam, baclofen,

TABLE 5 Therapies for Children With CP

Indication	Intervention	Comment
Therapies for which some evidence exists to support their effectiveness		
General	Muscle strengthening	Growing evidence supports its use
	Equine-assisted therapy (hippotherapy)	Increases social participation as well as strength and coordination
Ambulation	AFOs	Choice of specific type of AFO is often a judgment call
	Gait trainers, assistive devices; wheeled mobility	
Drooling	Glycopyrrolate, scopolamine patch, botulinum toxin injections, removal of salivary glands	Short-term improvement has been documented; less is known about long-term effects
Hemiplegia	Constraint-induced movement therapy	Optimal duration and intensity of therapy are uncertain, but several study reports have documented its effectiveness
Joint contractures, dislocations, deformations	Orthoses (like AFOs)	Surgery is more effective if linked with functional abilities (eg, gait)
	Orthopedic surgery	
Malnutrition	Gastrostomy feeding tube	Decision to use is often difficult for families; long-term benefits have not been well studied
Spasticity	Botulinum toxin (type A) injections	Most studies have been of gastrocnemius or biceps muscles
	Dorsal rhizotomy	Generally used for children who are ambulatory; long-term benefits are uncertain
Spasticity/dystonia	Intrathecal baclofen	One of the few interventions that is effective for both dystonia and spasticity
Therapies for which some evidence exists to refute their effectiveness		
General	Hyperbaric oxygen	Because CP is so heterogeneous, it is unlikely that all children would improve with a single therapy; benefits have not been proven
	Patterning	Interventions such as the Doman-Delacato method have been discredited[44]
Promising therapies for which data are insufficient		
General	Stem cell injection	
	Acupuncture	
Dyskinesia	Deep brain stimulation	
Mobility	Treadmill training	
	Neuromuscular electrical stimulation	
	Training in virtual environments	

AFO indicates ankle-foot orthosis.

tizanidine, and dantrolene have been used to diminish spasticity in children with CP, although they might cause weakness or excessive sedation. Moreover, few studies have documented functional gains in children who have been treated with systemic medications. Similarly, trihexyphenidyl (Artane) has been used in children with dystonia, but there is no convincing evidence of its effectiveness.[30] Interventions to reduce spasticity and promote function in children with CP are usually recommended in a sequence from least to most invasive (eg, ankle foot orthoses before intrathecal baclofen).

Nutrition and Growth

A key goal of the medical home for children with CP is to optimize nutritional status and physiologic growth. Children with severe CP often struggle with oral and/or pharyngeal dysphagia, which leads to inadequate intake of calories and nutrients. In addition, gastroesophageal reflux disease (GERD) and gastrointestinal dysmotility are common in children with CP. Aspiration events might occur primarily during feeding or secondarily from gastric refluxate. Appropriate positioning during feeding (head in midline, physiologic chin tuck) might reduce the risk of aspiration, and dietary modifications (thickened feedings, specialized formula, dietary supplements) might promote growth. Management of chronic constipation with regularly implemented bowel programs might reduce symptoms of feeding intolerance, GERD, and generalized discomfort that tend to exacerbate spasticity and disorders of sleep. However, these interventions alone might not be enough. Growth charts for children who have CP are available[31]; however, they only describe how certain samples of children with CP have grown and are not standards for how all children with CP should

grow. When feedings are prolonged, growth is inadequate, or aspiration risk is high, gastrostomy or jejunostomy tubes might be indicated.[32,33] It is important not to overfeed the child enterally. Children with significant GERD might benefit from an antireflux procedure, such as fundoplication at the time of the gastrostomy, although selection criteria are lacking.[34]

Other Comorbid Conditions

In general, the severity of a child's motor impairments and functional limitations correlate with the prevalence of comorbid conditions. Seizures are common among children with CP and are typically managed in consultation with pediatric neurologists. Because children with CP frequently have visual impairments, at least 1 ophthalmology evaluation is recommended. Visual field cuts might be subtle and, when present, can hinder stair negotiation, self-care activities, and academic performance. Cortical visual impairments and refractive errors might further compromise function. Similarly, all children with CP should undergo audiologic testing.

Children with more severe CP often develop osteoporosis over time, especially if they take anticonvulsant medications. Adequate intake of vitamin D and calcium might not completely stave off osteoporosis but can minimize early bone loss. Although it has been suggested that passive weight-bearing in standing frames might increase bone density in children with CP, there is a lack of evidence to support or refute such interventions.[35]

Children with CP, even the milder forms, are more likely than children without CP to have comorbid conditions such as learning disabilities, attention-deficit/hyperactivity disorder, and pervasive developmental disorders.[36] These conditions are managed in the same way that they are in children without CP. Some children with CP have intellectual and developmental disabilities (mental retardation) and might need advocacy from their medical homes for appropriate educational interventions. Impairments of communication might be addressed with augmentative communication devices such as an electronic voice-output communication aid.[23]

FAMILY SUPPORT

Because the child with CP is part of a larger family system, assessment of the family's functioning can help guide interventions and planning. This assessment should include evaluations of family stress, social capital, resources, priorities, and adjustment of parents and siblings to having a child with a disability in the family. By listening carefully to parental concerns, pediatricians can better address family concerns and children's needs. The current US health care system depends on parents to be willing and able to provide long-term care for their children with CP while also balancing competing family needs. However, parents of children with CP generally are in worse physical and emotional health than are parents of typically developing children.[37] For example, in 1 study, more than 70% of mothers of children with physical disabilities reported low back pain.[38] When the health of parents or caregivers is compromised, outcomes for their children with CP might suffer. Pediatricians should provide family-centered care for children with CP and their families, because such care reduces stress and enhances parental well-being.[39] Children with CP and their families might also benefit from referrals to community resources including parent support and advocacy groups, respite programs, and community programs for recreational and adaptive sports. Input from community experts regarding home modifications to reduce architectural barriers (ramps, lifts, roll-in showers) is often indicated but financially challenging. Families might need support in anticipating treatment decisions when their child's CP and secondary conditions are expected to be life-limiting. Such decisions might include writing orders to allow natural death or to provide supportive interventions such as tracheostomy tubes. The principles of palliative care can be helpful in those instances.

TRANSITION AND TRANSFER OF CARE

Adolescents with CP transition from pediatric to adult health care systems, from school to work, and from home to the community. Transitions are affected by physical or cognitive impairments as well as by community and attitudinal barriers such as limited recreational and employment opportunities and lack of peer acceptance.[40] Health-related transition culminates with the transfer of care to adult health care providers. For the person with CP, this transition is influenced by the severity of the disability, family and social supports, community resources, and the availability of interested and capable adult health care providers. To be effective, transition planning should begin when the adolescent is no older than 12 years.[41,42] Likewise, discussions regarding sexuality, including sexual vulnerability, should begin well before the person is an adolescent.[43] Issues of guardianship and informed consent should be addressed when youth with lifelong functional dependencies approach 18 years of age.[44]

abstract

FREE

The pediatric primary care provider in the medical home has a central and unique role in the care of children with spina bifida. The primary care provider addresses not only the typical issues of preventive and acute health care but also the needs specific to these children. Optimal care requires communication and comanagement with pediatric medical and developmental subspecialists, surgical specialists, therapists, and community providers. The medical home provider is essential in supporting the family and advocating for the child from the time of entry into the practice through adolescence, which includes transition and transfer to adult health care. This report reviews aspects of care specific to the infant with spina bifida (particularly myelomeningocele) that will facilitate optimal medical, functional, and developmental outcomes. *Pediatrics* 2011;128:e1645–e1657

INTRODUCTION

Myelomeningocele is a complex chronic condition that affects the child and the family as well as the health care and related service providers. Although the occurrence of spina bifida* is decreasing, every year more than 1500 children are born with spina bifida in the United States. More than 160 000 Americans younger than 18 years are affected by spina bifida, and the 30-year survival rate has improved to nearly 90%.[1] Diagnosis of spina bifida and other neural tube defects (NTDs) is now often made early in pregnancy through α-fetoprotein (AFP) screening and fetal ultrasonography, which provides time for decision-making and planning by families.

A child born with spina bifida faces a long and multifaceted path of medical and surgical care. The complexity and severity of spina bifida depends on the type and location of the defect as well as the occurrence of associated conditions. The average lifetime cost is more than $635 000.[2] Children 1 through 17 years of age with spina bifida have average medical expenditures 13 times greater than children without spina bifida.[3] The primary care management of spina bifida in the medical home provides an opportunity to optimize the child's outcomes with improved quality of care in a cost-effective, family-centered, coordinated system.

*Note: in this report, the term "spina bifida" is used interchangeably with "myelomeningocele."

BACKGROUND

Etiology and Risk

Spina bifida, anencephaly, and other NTDs occur as a result of defective neurulation or closure during the third week after conception of the embryonic neural fold, which becomes the neural tube. Failure of closure in a cephalic direction leads to the development of anencephaly; failure of closure in the caudal direction leads to spina bifida. Myelomeningocele arises as a failure of neurulation by approximately day 28 after conception. The primary defect in the neural tube then leads secondarily to the failure in the formation of portions of the spinal cord and the dorsal elements of the vertebral bodies and overlying tissues, which gives rise to the spina bifida sac. A lesion that involves elements of the spinal cord as well as the meninges within the sac is termed a myelomeningocele (or meningomyelocele). If the meninges but not the neuronal elements are involved, the lesion is classified as a meningocele. These 2 lesions represent open NTDs. Closed NTDs are those in which the overlying skin is intact and include lipomeningocele and lipomyelomeningocele as well as occult spina dysraphisms (Table 1).

The etiology of spina bifida includes genetic and environmental factors.[4] Spina bifida occurs worldwide and in all racial groups, although there are geographic and ethnic variations.[5] Genetic factors are likely to be related to the increased risk in some populations, notably the Irish, Scottish, and other northern Europeans.[6] This risk may be related to altered folate metabolism.[7] In the United States, a slightly higher rate occurs in families of Latin descent.[8] Chromosome disorders including trisomy 13 or 18 and microdeletion of 22q11 are linked to NTDs.[9] Exposure to some prenatal medications increases the risk of spina bifida. These medications include valproic acid, carbamazepine, isotretinoin, methotrexate and other folic acid antagonists, excess vitamin A or its analogs, and retinoic acid.[10] Maternal nutrition (especially folate deficiency), alcohol consumption, obesity, and fever, either attributable to illness or hot tub/sauna use, can increase risk, as does maternal diabetes mellitus.[11,12] Family history of previous NTDs is a significant risk factor, increasing the risk more than 20-fold (eg, from 0.1%–2.5%).[13,14]

Occurrence

In the United States, the birth prevalence of spina bifida has decreased to less than 1 in 1000 live births.[15] This reduction might be related to im-

TABLE 1 Spina Bifida: Types, Description, and Implications

Spina Bifida Type	Description	Clinical Implications
Myelomeningocele	Open NTD posterior vertebral defect and extrusion of spinal cord elements into a meningeal sac; location: cervical, thoracic, lumbar, and/or sacral spine; leads to paraplegia and insensitivity below the lesion and neurogenic bowel and bladder; associated defects include structural brain anomalies (Chiari II malformation, hydrocephalus, brainstem dysfunction abnormalities of the cerebrum and corpus callosum, learning disabilities, dislocated hips and clubbed feet)	Complex multisystem disorder that requires ongoing monitoring by spina bifida team, enhanced primary care in the medical home with bidirectional communication and comanagement with the multispecialty spina bifida care team, early-intervention and special education services, physical therapy and adaptive equipment, and developmental and learning monitoring
Meningocele	Closed NTD posterior vertebral defect without extrusion of spinal cord elements into a meningeal sac; location: cervical, thoracic, lumbar, and/or sacral spine; motor deficits are less likely than with myelomeningocele; structural brain anomalies and Chiari II malformation are less likely	Early closure of spina bifida sac; follow-up by spina bifida team; additional monitoring in the medical home; ongoing monitoring for neurologic function; early-intervention monitoring; periodic monitoring for possible late onset of neurologic signs
Occult spinal dysraphism/lipomeningocele	Closed NTD posterior vertebral defect and with fatty tumor that might contain neuronal elements; location: typically lumbar and/or sacral spine; leads to motor deficits if neuronal elements are involved; associated defects include tethered cord; structural brain anomalies and Chiari II malformation are unlikely	Early neurosurgical intervention; follow-up by spina bifida team; additional monitoring in the medical home; enhanced primary care in the medical home and with follow-up by the multispecialty spina bifida care team; ongoing monitoring for neurologic deficits; early-intervention monitoring
Spina bifida occulta	Benign closed NTD posterior vertebral defect only without a meningeal sac; location: lumbar-sacral spine; usually asymptomatic but can be associated with occult spina dysraphism; usually no associated defects	Monitoring and reassurance within the medical home
Tethered cord	Traction injury to the distal spinal cord caused by anomalous attachment of the spinal cord, which causes subtle and progressive loss in neural function; can occur with any NTD at any time, but often occurs with growth spurts; might be precipitated by ventricular shunt failure	Monitoring of all children and youth with open or closed NTD for signs of tethering; changes in lower extremity strength, function, or sensation; urinary incontinence or enuresis; changes in bowel function; or worsening scoliosis

Spina bifida is a general term for several malformations of the spine and its neural elements, which may be associated with neurologic, neuromotor, developmental, and orthopedic anomalies and are related to structural abnormalities of the brain and cranium.

proved prenatal nutrition, including folic acid supplementation for women of childbearing age and the mandatory enrichment of flour with folate as well as the termination of affected fetuses.[16,17] Despite folic acid fortification, infants continue to be born with NTDs and will need both immediate and long-term medical, surgical, and related interventions.[18]

Clinical Manifestations

The effects of spina bifida relate to the location and size of the defect and the presence of hydrocephalus, brain abnormalities such as the Chiari II malformation, and other neurologic and orthopedic conditions. Thoracic and higher lumbar myelomeningocele lesions are more likely to be associated with significant motor and sensory deficits and structural abnormalities in the lower extremities than are those in the lower lumber or sacral regions.[19] Functional defects of the urogenital and lower intestinal tract are likely at all levels.[20]

Hydrocephalus occurs in ~85% of infants with myelomeningocele and, in most cases, necessitates ventricular shunt placement. Once placed, shunts need to be monitored regularly for potential malfunction. In addition, hydrocephalus is associated with significant problems in learning and cognitive function.[21] After birth, the open spinal lesion needs to be protected from trauma, which could cause additional neurologic damage. In addition, if the lesion is leaking cerebrospinal fluid, measures to protect against infection (meningitis) are required. Surgical closure within 72 hours reduces the risks of infection and additional spinal cord injury.[22,23]

In addition to the primary deficits in motor and sensory function, children and youth with spina bifida experience a range of comorbid conditions including learning disabilities, problems with attention and executive function, dysfunction of upper extremities, strabismus, and seizures. They are also subject to other functional complications such as limitations of movement and ambulation, scoliosis, joint instability, fractures, bowel and bladder dysfunction, altered growth including precocious puberty, and obesity. These children and teenagers will need ongoing prevention because of the increased risk of developing latex allergies.[24] The physical and psychological consequences of impaired mobility and independence, altered appearance, and the long-term needs of the condition also require identification and intervention. The child's physical and developmental disabilities, limited mobility, and chronic health conditions can be barriers to social integration that can have lifelong consequences

TABLE 2 Systemic Effects of Myelomeningocele

System	Effects
Neurologic	
Central	Hydrocephalus, Chiari II malformation, dysgenesis of the corpus callosum
Cranial nerves	Vision, strabismus, hearing, speech, stridor, swallow
Spinal	Tethered cord, progressive loss of motor and sensory function
Motor	Paraplegia, upper extremity hypotonia
Sensory	Loss of sensation and proprioception
Cognitive	Cognitive deficits including learning disabilities, executive function disorders, attention-deficit/hyperactivity disorder
	Lower cranium nerve dysfunction
Vision	
Acuity	Visual acuity problems, rarely severe
Alignment	Strabismus, oculomotor disorders
Oromotor	Oromotor dysfunction, swallowing disorder
Respiratory	
Central	Central ventilatory disorder, apnea, sleep apnea, hypoventilation
Pulmonary	Aspiration, restrictive and obstructive lung disease, pneumonia
	Stridor
Gastrointestinal	
Swallow	Swallowing dysfunction; oral, pharyngeal
Neurogenic bowel	Constipation, soiling, accidents
Urologic	
Neurogenic bladder	Bladder atonia/dystonia, increased bladder pressure, leakage/incontinence, reflux, renal failure
UTI	Bacterial colonization, acute/chronic UTIs
Genital	
Insensitivity	Lack of sexual sensation, erectile dysfunction, and retrograde ejaculation in males
Infertility	Early pubertal onset and increased risk of NTD in infants of women with NTD
Orthopedic	
Spinal	Scoliosis/kyphosis
Extremities	Decreased mobility, hip dislocation, clubbed feet, osteopenia, fracture, linear growth abnormalities
Growth	
Stature	Short stature resulting from limb-length disorders and precocious puberty in females
Weight	Overweight and obesity
Psychology	
Anxiety/depression	Increased anxiety and depression
Behavior	Social isolation, anxiety, depression, immaturity, risk-taking behavior, at increased risk for abuse
Social	
Inclusion	Social isolation, limited friendship, physical and transportation barriers
Employment	Limited work experience, physical/society barriers, loss of health coverage or benefits

Myelomeningocele is the most serious and complex NTD and affects multiple body systems; the severity of these effects is related to the type and location of the NTD and the extent of neuronal injury.

(Table 2).[25] Thus, children with myelomeningocele are like children with spinal cord injuries with the addition of neurocognitive impairments.

The primary care physician plays a central role in long-term comprehensive care through collaborative comanagement with multiple medical and surgical specialists. It has long been recognized that the provider of primary care in the medical home must be knowledgeable about the unique medical issues of spina bifida and its developmental, educational, and social consequences.[26]

Prevention

The mandated supplementation of cereal flours with folic acid in 1998 in the United States and Canada has been linked to a reduction in the prevalence of NTDs.[27] Also, all women of childbearing age should ingest 400 μg (0.4 mg) of folate daily,[28] which may decrease the occurrence of NTDs by up to 70%. Women who have had a previous pregnancy with any NTD and women with spina bifida should take 10 times that dose or 4000 μg (4 mg) daily from the period before conception through the first trimester. On the basis of current American Academy of Pediatrics guidelines, the primary care physician should recommend folic acid to all sexually active females, not just those with a history of an NTD. Folate supplementation has not been the sole factor in reducing the occurrence of NTDs. Better overall nutrition, improved maternal health, and termination of affected pregnancies are additional factors.

DIAGNOSIS AND INITIAL COUNSELING OF THE FAMILY

Prenatal screening by measuring maternal serum AFP concentrations at 15 to 20 weeks of gestation has become the standard of care.[29] The AFP concentration is increased when fetal cerebrospinal fluid is released, as occurs with open myelomeningocele and anencephaly. Thus, a closed NTD might not be detected by measurement of the maternal serum AFP level. Elevated concentrations of AFP can be found in other fetal conditions, including twin pregnancies, ventral wall defects, fetal tumors, congenital nephrosis, and incorrect dating of the pregnancy. Although maternal serum AFP concentration is a useful screen, the results should be interpreted with caution. Maternal serum AFP concentrations more than 2.0 multiples of the median during weeks 15 to 20 after conception are considered abnormal and should be repeated. Abnormal concentrations are followed by high-resolution ultrasonography or other evaluations such as amniocentesis.

Ultrasonographic examination is used to screen for NTDs.[30] Two-dimensional ultrasonographic examination during the first trimester detects more than 90% of cases of anencephaly and more than 80% of encephaloceles but fewer than half of spina bifida cases. Second-trimester ultrasonography can increase the detection of spina bifida to 90% to 95%.[31]

Ultrasonographic examination can also help to monitor the fetus over time. It can be used to characterize the architecture of the spinal defect and the presence of and changes in cerebral ventricles over the course of the pregnancy and to identify other structural abnormalities. Fetal MRI provides additional information to better characterize the NTD, Chiari II defect, and status of ventricles and can detect previously unidentified abnormalities.[32]

Amniocentesis may be warranted if there are concerns that the NTD is related to a genetic or chromosome disorder or to confirm findings from ultrasonography or maternal serum tests. Measuring amniotic fluid AFP and amniotic fluid acetylcholinesterase can be useful for detection of an open NTD.[33] Chromosome analysis (karyotype) and microarray testing can be performed to determine if the NTD is related to chromosome aneuploidy, microdeletion, or another genetic condition.[34]

The process of fetal screening can be confusing and stressful for the expectant mother and her significant other. Counseling and support should be provided to the pregnant woman and her family about the screening procedures and their risks, results, and interpretation. This counseling should be provided by a medical geneticist, genetic counselor, and members of the fetal diagnosis team who are familiar with the procedures and are knowledgeable about the prognosis of NTDs. Counseling should include general information about spina bifida, obstetric care, choices about the pregnancy and delivery, neonatal care, surgery, the likelihood of hydrocephalus and its treatment, and the potential for disabilities and complications. The family should also be made aware of the services, care plan, and types of support that will be provided to them and the child. The option of fetal surgery to potentially reduce the extent of neurologic damage of an NTD and to reduce the need for ventricular shunting should be discussed. Families interested in pursuing fetal surgery should be referred to centers that provide fetal surgery for NTDs.[35]

Families may turn to the pediatric primary care provider for information and guidance when the primary care provider has a previous relationship with the family. In this case, it is essential that the primary care provider have ongoing communication with the prenatal diagnostic team to ensure that reliable and uniform information is provided to fam-

ily members as they look for answers and plan for options and decisions for the pregnancy and subsequent care.

THE ROLE OF THE PRIMARY CARE PROVIDER IN ONGOING CARE IN THE MEDICAL HOME

The optimal care of the infant, child, or youth with spina bifida is best provided by a multispecialty team and a primary care provider who collaborate to provide comprehensive and coordinated care and support to the child and family.[36] The spina bifida team typically includes a clinical nurse specialist or nurse practitioner; pediatric specialists in neurosurgery, orthopedics, urology, developmental pediatrics, and physical medicine; physical therapists; orthotists; psychologists; social workers; and health education professionals. All these specialists might not be available to all teams and for all clinic settings. The care team's goal should be to meet the individual needs of each child and family by providing comprehensive and coordinated care, support, and education to the patients and families and support and assistance to the primary care provider, the child's school or early-intervention program, and other service providers.[37]

The primary care provider's interventions may begin even before birth and continue through transfer to adult health care. Families that have a preexisting relationship with a primary care provider may turn to him or her for guidance and information at the time of prenatal diagnosis. In other cases, the family may select a primary care provider before or at the time of delivery. The primary care provider's confidence in caring for an infant with an NTD might vary depending on knowledge base and previous experience. The spina bifida team can be a valuable resource for the primary care provider to ensure optimal care. An in-depth understanding of the child's needs and those of the parents will develop through contacts during scheduled well-child visits and visits for acute illnesses or other concerns.

The primary care provider usually has *first contact* with the family, whether for routine or acute care. The care of the individual with spina bifida requires the primary care provider to be able to recognize and treat issues unrelated to the spina bifida (such as gastrointestinal or respiratory tract infections) while at the same time identifying and rapidly referring for conditions (eg, headaches or new-onset weakness) that might indicate serious problems (such as ventricular shunt malfunction). This ability requires knowledge about spina bifida and optimal communication. Specialists should routinely communicate with primary care providers by using a combination of technologies such as e-mail, telephone, and fax. Primary care providers should communicate acute symptoms or concerning changes in their patients (eg, headaches or urinary symptoms) to the specialty team.

Newborn Period

For the fetus identified with an NTD, ongoing prenatal planning and care are important, as is the timing, location, and method of delivery (ie, in a tertiary medical center). However, despite the availability of prenatal diagnosis, infants continue to present at delivery with previously unidentified open and closed NTDs. The obstetric and infant care teams should be prepared to address anticipated or unexpected birth of an infant with an open or closed NTD. At birth, a physician, using sterile nonlatex gloves, should assess the open lesion to document its location and size and to determine if it is leaking cerebrospinal fluid.[38] The lesion should be covered and protected using a sterile technique.[22] The dressing should not be removed or disturbed except by the neurosurgical team. The infant should be placed in a prone or lateral position to avoid pressure on the lesion. After stabilization in the delivery room, the infant should be shown to the parent(s) before being transported to the nursery. Admission to the NICU or transportation from an outlying hospital to a NICU should be promptly arranged. Initial neonatal examination of the infant with an open or suspected closed NTD should be performed shortly after birth and should include all the usual elements of a typical newborn physical examination but with particular attention for spinal irregularities, hemangiomata, hair tuft or abnormal pigmentation, dimples, or pits. Assessment of head circumference and tenseness of the anterior fontanel for signs of hydrocephalus, movement of the lower extremities, level of sensation, and deep tendon reflexes and anal wink should be noted. Abnormalities of the lower extremities and flexion or extension contractures of hips, knees, and ankles should be noted. Other physical or neurologic or congenital abnormalities, including structural anomalies of the heart, airway, gastrointestinal tract, ribs, and kidneys, should be assessed. Ventricular size should be evaluated soon after birth by ultrasonography, computed tomography (CT), or MRI; ultrasonography and MRI are better than CT scanning at identifying a Chiari II malformation.

Neurosurgical consultation should be obtained shortly after birth, and arrangements for surgical closure should be made within 72 hours after birth; this step further decreases the risk of central nervous system infection.[23] After repair of the myelomeningocele, head circumference should be measured regularly and carefully to

monitor for increase at a rate greater than the normal curve. On the basis of clinical evidence, the newborn infant should be monitored for the next few weeks to determine if a ventricular shunt is indicated. Serial neuroimaging using ultrasonography can identify the progression of hydrocephalus. The patient is reassessed every 3 to 10 days depending on the level of concern. Progressive hydrocephalus may cause the infant to develop irritability, vomiting, stridor, or poor feeding; 85% or more of infants with myelomeningocele will require a ventricular shunt.[39]

The newborn infant should be evaluated by a urologist before discharge. A baseline sonogram of the kidneys and bladder is typically performed to determine if the infant already has renal involvement or congenital abnormalities. Measurement of serum urea nitrogen (SUN) and creatinine concentrations, a voiding cystourethrogram, and direct measurement of the pressure within the bladder may be indicated as well.

Discharge planning should begin soon after birth and should ensure that all primary and specialty care is arranged before discharge. Communication is open among the specialists, spina bifida team, and support programs, including the early-intervention program, the primary care provider, and the family. A written discharge plan that focuses on the infant's individual and unique needs related to the NTD should be provided to all clinical and support programs and the family. Early follow-up with the primary care provider and the spina bifida team should be arranged.

Primary care of the infant and child with spina bifida within the medical home should ensure that all routine care, services, intervention, and immunizations are provided in line with American Academy of Pediatrics recommendations in *Bright Futures*, with addition of the specific recommendations for patients with spina bifida provided by the Spina Bifida Association of America and others (see "Resources").

Hydrocephalus

Because hydrocephalus develops in most children with open spina bifida (myelomeningocele) and in some children with closed lesions, head growth should be carefully monitored in all infants with spina bifida. Changes in head circumference percentile, the tension of the anterior fontanel, changes in mental status, vomiting, and changes in extraocular movement, such as strabismus or the sunset sign should be discussed with the neurosurgical team. Later, when the cranial sutures and fontanels close, the functional status of the ventriculoperitoneal shunt is determined by signs such as headache, irritability, changes in mental abilities, and vomiting.[40] Shunt failure can occur at any time—days, weeks, or even years after insertion. The primary care provider needs to become familiar with the signs and symptoms of shunt failure and should be in communication with the neurosurgical team.

Development

Most people with myelomeningocele have intelligence within the normal range, but most experience significant learning disabilities. These disabilities include nonverbal learning disorder, poor executive skills, attention deficits, and memory problems.[41,42] These cognitive difficulties might delay the child's maturation and impede his or her ability to acquire the skills needed to live independently, which in turn affects family members.[43] Recognition of these issues and interventions to optimize learning and independence are critical for optimizing learning and social participation.

Cognitive development is affected by several factors, including shunt infection, Chiari II malformation, hydrocephalus with repeat shunt replacements, and neuronal migration disorders (eg, hypoplasia of the corpus callosum). These factors distinguish myelomeningocele from other disorders that are limited to the spinal cord, such as lipomeningocele and traumatic paraplegia. Developmental and learning disorders may become evident at any time from infancy through adolescence; therefore, developmental surveillance should be part of all routine well-child visits. Particular attention should be paid to language and communication, and formal testing should be ordered if concerns develop. Because there is an increased risk of vision and hearing problems in children with spina bifida and hydrocephalus, testing and evaluation should be performed on a regular basis.

The primary care provider should remain in close contact with the child's early-intervention and school program to ensure that information is shared. The child's developmental status, with strengths and weaknesses noted, should be formally evaluated to ensure that appropriate needs are recognized and addressed. The primary care provider might need to provide information to the school program and, at times, advocate for the child and family for specific educational services. An emergency plan for the school should be developed and reviewed annually; it may contain information on medical conditions (eg, if the child develops signs of increased intracranial pressure) as well as a plan for evacuation from the school for the child with limited mobility.

Bowel Function

Almost all people with myelomeningocele have disorders of innervation of the lower intestinal tract and anus

with lower tract dysmotility and poor or absent sphincter control, which lead to fecal incontinence. Fecal incontinence can seriously impair social relations, limit independence, and lower self-esteem.

The management of incontinence is time-consuming; yet, initiating a bowel-management program early in development helps both the family and the child to develop a routine, effective program of management and self-care. The goals of a bowel-management program are to achieve continence and promote regular elimination of stool, which can be achieved with an individualized program that may use timed toileting, changes in diet, and oral laxatives, suppositories, and enemas, singly or in combination. At the initiation of a functional bowel program, constipation and fecal impaction may necessitate a bowel clean-out.

As children become older and capable of self-management, they might benefit from a surgical procedure called antegrade continence enema (ACE).[44] In the Malone antegrade continence enema (MACE) procedure, the appendix and cecum are used to create a catheterizable stoma.[45] In the ACE procedure, the cecum is brought up to the abdominal wall and an ostomy tube is inserted, which saves the appendix for urologic procedures. With either procedure, the patient is able to clean out the colon by irrigating it through the ostomy tube. The irrigation is performed daily or every other day; it may take as long as 2 hours to complete. The ACE/MACE can achieve fecal continence in ~85% of patients.

Urinary Tract Function

Almost all people with myelomeningocele have a neurogenic bladder. They may not be able to store urine in the bladder or may be unable to empty it. Failure to completely empty the bladder and elevated pressure within the bladder increase the risk of urinary tract infection (UTI) and renal tract injury resulting from urinary reflux and can lead to progressive damage to the upper urinary tract and kidneys, with the risk of progressive renal damage, which still occurs in youth and adults with spina bifida. Early evaluation of urinary tract structure and function by ultrasonography, radiographic imaging, and urodynamic testing beginning in infancy can help determine the status of the kidneys and bladder. Urologic treatment is aimed at normalizing pressure within the bladder, providing continence, and minimizing infection and reflux. Close attention to urinary tract function is important, because changes may indicate UTI or tethered cord, including tethering attributable to shunt malfunction. Some children or youth benefit from bladder augmentation or urinary diversion procedures to increase bladder capacity, improve urinary continence, and reduce the risk of progressive renal injury.

Management of the urinary tract typically begins with the early introduction of clean intermittent catheterization (CIC) beginning even in infancy and close monitoring for changes in bladder function. If CIC is unable to optimize pressures within the bladder, a vesicostomy (a hole placed in the abdominal wall into the bladder) may be indicated. Many patients are also maintained on medication to reduce vesicoureteral reflux. These and other interventions improve bladder pressures and urinary continence, which permits the child with myelomeningocele to function better in school and other social settings. The child/teenager is monitored over time for the occurrence of UTIs; some people with repeated infections may benefit from chronic antibiotic prophylaxis to reduce the risk of reinfection, although this is practiced less often now than in the past. Differentiating UTI that requires antibiotic treatment from bacteruria, which is often present but does not need to be treated, may be difficult and require consultation with a urologist.

The primary care provider should be aware of and monitor the child's adherence to the catheterization program while maintaining contact with the urology team regarding medications and interventions. Communication from the primary care provider to the specialist regarding UTIs and other urinary problems is critical. In the case of fever, nonspecific symptoms, or changes in urinary tract function, the primary care provider should maintain a high index of suspicion for UTI. The child should have urinalysis and urine culture obtained if there is a likelihood of bladder or kidney infection. Patterns of bacterial resistance to antibiotics should be carefully monitored. Oral and, occasionally, intravenous antibiotics will be required to treat UTIs in these children. Open and active communication between the primary care provider and the pediatric urology team is essential for maintaining optimal renal function and establishing urinary continence. Blood pressure should be monitored to identify hypertension.

Mobility

Mobility should be addressed from infancy through adulthood. Creeping or crawling gives an infant experiences with control and competence. Mobility aids for toddlers, whether wheeled or upright, continue this process. Being safely mobile in their homes and communities will help children and teenagers become more independent. Walking or using a wheelchair not only promotes confidence and independence but also helps with overall fitness and weight control. In prescrib-

ing wheelchairs or other assistive devices, the focus should be on optimizing age-appropriate functionality and independence for the child or teenager. Many teenagers with spina bifida can safely drive a car but need modifications with hand controls. Driving rehabilitation specialists can be helpful in identifying potential challenges to safe driving, providing appropriate driver training, and suggesting changes needed to the car to make it accessible.

Orthopedic Problems

Orthopedic problems occur in most children with myelomeningocele and tend to be more common and more complex with higher-level lesions; they affect activity more with increasing age and in obese patients.[46] Clubfeet, hip subluxation and dislocation, and knee instability or contractures may be present at birth, especially in patients with lumbar and thoracic lesions. Unbalanced muscle function leads to worsening of existing joint problems or to the onset of new orthopedic disorders. Correcting deformities, maintaining posture, and promoting ambulation to maximize function and independence are generally handled by orthopedists and physical therapists. There is also a need to diagnose and treat fractures, which are more common in children with myelomeningocele, who often have osteopenia. Fractures in insensate limbs may present with redness and swelling without pain and should be suspected by the primary care provider.

Scoliosis occurs in most children with lesions above the second lumbar vertebra (L2). Examination of the back and monitoring of the progression of scoliosis should be performed regularly by the spina bifida team and primary care provider, even in preschool-aged children. Progression of scoliosis should prompt a thorough neurologic evaluation and imaging to identify correctable causes such as tethered spinal cord, hydromyelia, or shunt malfunction and to maintain function. Motor and sensory function and bowel or bladder patterns should be part of the evaluation. The pediatric care provider should continue to monitor lower extremity function and identify any deterioration.

Skin Care

The loss of normal skin sensation and autonomic response to pressure or irritation places people with an NTD or spinal cord injury at risk of breakdown of skin as well as the formation of decubitus ulcerations. Injury to insensate skin can occur at any site of pressure or irritation, including the pelvic area from prolonged sitting, casting, or braces or even tight clothing; abrasion from seating or positioning equipment; or thermal injuries from any of a variety heat sources. Injury to insensate skin can be permanent damage that requires long-term, complicated, and costly treatment and causes additional disabilities.[47] Careful monitoring of skin integrity and for potential sources of injury should begin in infancy and continue along the life span. All sign of injury or breakdown of insensate skin should be treated promptly and vigorously to minimize the risk of complications.[48]

Adolescence

Teenagers face many physical, mental, emotional, and social changes. They must develop their own identities and interests and strive for greater independence. This transition period can be challenging, especially for teenagers with spina bifida. It is important for the parents, teenager, educational system, and health care providers to take an active role in encouraging growth, self-confidence, independence, and competency even before adolescence.

Fitness and well-being should be encouraged from an early age. Physical activity is especially important for those with spina bifida. Physical activity improves general health, reduces obesity, and improves confidence and self-image. Children and teenagers with spina bifida should be encouraged to engage in physical activities with friends and to participate in adapted sports. Attending summer camp or using accessible recreational facilities can also help with well-being and the development of self-care skills such as dressing, bathing, toileting, and mobility. The teenager should be educated to inspect areas of insensate skin while bathing and dressing and to report any signs of irritation or ulceration to prevent decubitus ulceration or other serious injury to the skin. By midadolescence, teenagers should make their own doctor appointments and participate in their individualized education plan (IEP) or 504 plan, if they have one. They should be encouraged to advocate for themselves in school and report problems such as teasing or bullying.[49,50]

The primary care provider should include children and youth in the discussion of their health and related issues from the early school years. Even before adolescence, children should be encouraged to participate actively in health care visits and report their concerns and accomplishments. By early adolescence, some time during each visit should be set aside for private discussions with the child. This time should be increased until the teenager has essentially private office visits with the doctor. Beginning in early adolescence, transition-related issues, such as education about spina bifida, treatments and medications, general health issues, and transition and transfer to adult health care, should be discussed. For some youth with significant cognitive impairment, the goal

of independent decision-making might not be achievable, and planning for personal and financial guardianship might be necessary. These and other topics can be introduced during health maintenance, preventive care, and acute care visits.

The primary care provider should develop an understanding of the mental health risks associated with spina bifida, including social isolation, learned helplessness, and low self-esteem. Youth with spina bifida are at increased risk of both anxiety and depression.[51] The primary care provider should evaluate these conditions and identify the patient's risk of suicide. Interventions such as increasing physical activity and teaching relaxation techniques may be beneficial. Counseling and support should be given to the teenager and family members by the primary care provider. Counseling through school- or community-based mental health professionals may be indicated before anxiety or depression worsens. Whenever these conditions persist or interfere with school or social activities, the adolescent should be referred to a mental health professional who is familiar with the mental health challenges of teenagers with disabilities.

Sexuality

Issues of sexuality in teenagers and young adults with spina bifida are often overlooked or actively avoided. For patients with spina bifida, a number of significant issues related to sexual maturation require attention. Precocious puberty is common in girls with myelomeningocele and hydrocephalus; girls with hydrocephalus have menarche at an average age of 10.9 to 11.4 years rather than the more typical 12.7 years for the average American girl. Precocious puberty affects the physical, physiologic, and emotional outcomes of sexual maturation, including linear growth.[52] The progression of puberty can be delayed by using leuprolide (Lupron), which provides additional time for emotional maturation and improved linear growth; this treatment is usually best managed by a pediatric endocrinologist. Topics of discussion that are important for girls with spina bifida include fertility, pregnancy, and contraceptive choices. Folate supplementation needs to be stressed. Female teenagers who are lonely or naive or have learning disabilities are at increased risk of being taken advantage of sexually or even subject to sexual assault.

For male teenagers, altered sensation, erectile dysfunction, and incontinence affect sexual behaviors, including intercourse.[53] The issues of sexual performance may require referral to a professional who is knowledgeable in male sexual disorders. Treatment with sildenafil (Viagra) or other medications may be beneficial. Sexuality is affected by self-esteem and self-image and might be an issue not addressed by the spina bifida team; the primary care provider might be the only one to address these issues and should initiate treatment or refer to specialty services when indicated.[54]

Transition to Adult Health Care

Transitions for adolescents and young adults with spina bifida should include the orderly transfer to accessible adult medical care as well as transitions in social, educational, vocational, and recreational areas.[55] As part of health care transition, all young people need to develop an understanding of their health care needs and begin to take responsibility for their health care decisions, as their cognitive and learning skills allow. Transition planning should focus on building competencies in self-care, fostering independence and self-advocacy, and assisting with supports and strategies for transfer to adult care providers.[56,57]

The medical home should be part of the transition process, which should include exploring educational and vocational options, obtaining skills for work, finding safe and dependable transportation, deciding on living arrangements, developing healthy social and personal relationships, obtaining medical insurance, and identifying both primary and specialty care providers who are knowledgeable in the care of adults with spina bifida. Transition planning and discussions within the medical home beginning early in adolescence can help to make these changes easier and outcomes more successful. Web sites such as the New York State Institute for Health Transition Training for Youth With Developmental Disabilities Ages 14–25 Years (http://healthytransitionsny.org), the Adolescent Health Transition Project (http://depts.washington.edu/healthtr), the Health Care Transition Initiative (http://hctransitions.ichp.ufl.edu), and the National Health Care Transition Center's Got Transition? page (http://gottransition.org) can provide guidance for families and the primary care provider.

Family Support

Spina bifida has a profound effect on the family, beginning with the prenatal diagnosis; at birth, the families have to face issues such as deformities and complex surgical interventions for closure of the spinal lesion and shunt placement for hydrocephalus. Later, the extent of physical and developmental disabilities becomes clearer. Families must deal with the increased demands for care, including procedures such as catheterization and range-of-motion exercises, more frequent medical appointments, and other interventions, all of which disrupt the family's

TABLE 3 Care of the Child and Youth With Spina Bifida: Potential Roles of the Pediatric Primary Care Provider

Time	Concerns	Actions
Fetuses (prenatal)	Diagnosis	Consult with diagnostic team
	Lesion: type and location	Review obstetric plan
	Other central nervous system findings (hydrocephalus, Chiari II malformation)	Review findings and implications with family
	Other physical findings (orthopedic, other)	Discuss options and plan
	Maternal and family stress and anxiety	Referral to spina bifida team
	Family choices and plan	Update primary care provider and other provider knowledge base
		Family education and support
		Communicate among family and all professionals
Newborns	Stabilization	Consult obstetric and neonatal teams, neurosurgery, others specialists
	Protection of lesion	Family support
	Examination	Monitor head growth
	Surgical closure	Neonatal screening and newborn hearing assessment
	Hydrocephalus	Discharge planning
	Motor function	Primary care and specialty follow-up
	Bowel and bladder function	
	Orthopedic conditions	
	Maternal/family anxiety and depression	
Infants	General health status	Health care per *Bright Futures* recommendations
	Growth	Referral to spina bifida team and support group
	Development	Referral to early-intervention program
	Immunizations	Monitor head growth and shunt function
	Spina bifida-specific concerns: hydrocephalus and shunt function, bowel and bladder function, UTI	Assess for feeding or swallow problems
		Discuss latex precautions
		Supplemental Security Income, Medicaid, and Medicaid Waiver
Preschool-aged children	General health status	Health care per *Bright Futures* recommendations
	Growth and development	Follow-up with spina bifida team and support group
	Spina bifida-specific concerns: vision and strabismus, motor function and mobility, hydrocephalus and shunt function, bowel and bladder function, UTI	Obtain early-intervention assessment, individualized family service plan
		Developmental team evaluation
		Discuss social inclusion and activities
		Bracing and ambulation
		Activity and weight management
		Dental referral
		Toileting
School-aged children	General health status	Health care per *Bright Futures* recommendations
	Growth and development	Follow-up with spina bifida team
	Weight control and healthy diet	School transition, service and support, Section 504/individualized education plan
	Spina bifida-specific concerns: motor function and mobility, hydrocephalus and shunt function, bowel and bladder function, tethered cord	Screen for attention-deficit/hyperactivity disorder, learning disabilities, and executive function disorders
		Bullying and safety
		Self-care and independence
		Physical activities and social group participation
		Neurology and physical therapy follow-up
Teens	General health status	Adolescent health care per American Academy of Pediatrics recommendations
	Weight control and healthy diet	Confidentiality and private visits
	Sexuality	Birth control and folic acid
	Psychosocial stressors	Health care transition
	Spina bifida specific concerns: motor function and mobility, tethered cord	Self-care and independence
	Developing independence	Driving and transportation
		Spina bifida teen support group
		Educational and vocational planning
Adults	General health status	Identify health care resources
	Weight control and healthy diet	Health insurance, Social Security Disability Income
	Spina bifida specific concerns: motor function and mobility, bowel and bladder management, skin care and pressure sores	Education and employment
		Living situation
		Spina bifida adult support group
		Transfer to accessible adult health care

Concerns and actions are not intended to be limited to a single time period but should be addressed and readdressed as part of ongoing health care across the life span.

hopes and plans for both the child and themselves as a family unit.

The ongoing care of the child with spina bifida strains each family member. It alters roles and expectations and decreases opportunities (eg, the parent who cannot go back to work or school). It adds anxiety and stress and even a sense of guilt, which can become the source of depression and friction; it increases the risk of family dysfunction and instability.[57] Adolescence often increases family stress.[58]

Spina bifida affects not only the patient but also his or her siblings, who are subject to stress and feelings of loss, guilt, frustration, and anger. These feelings have consequences for the sibling, for his or her relationship with the child with spina bifida, and for the entire family.[59,60] The psychosocial and emotional consequences of spina bifida on the patient, siblings, and family should be part of the overall care of the child with spina bifida. These factors should be addressed by both the spina bifida team and the primary care provider in the medical home. A family-centered approach to care and anticipation of potential problems will help to identify and address stressors early.

SUMMARY

The standard of care for children and youth with spina bifida remains a program of comprehensive and multidisciplinary support, and the medical home plays a central role. The pediatric primary care provider has frequent contact with the child, including well-child and acute health care visits, and by partnering with the child, parents, and specialty program, builds trust and can help address the medical, developmental, and psychosocial issues of childhood over time. The primary care provider also helps to manage ongoing care of the child's multisystem disorders and the unique nonmedical

TABLE 4 Primary Care Interventions Typically Provided to Children and Teenagers With Spina Bifida

Fetuses (prenatal)
Counsel families in planning and decision-making
Provide information on spina bifida
Options and assistance with family choices
Consult with obstetric, neonatal, and neurosurgical teams
Prenatal (fetal)/postnatal surgery
Discuss postnatal planning and treatment
Family support
Newborns
Postnatal care and stabilization
Surgical repair of spinal lesion
Monitoring and surgery for hydrocephalus
Family support
Referral to multidisciplinary spina bifida term
Primary and specialty follow-up
Infants
Provide early and frequent follow-up
Monitor hydrocephalus
Provide routine and diagnostic-specific primary care
Give family and sibling teaching and support
Discuss recurrence risk and prevention
Refer to early-intervention program
Communicate and coordinate with the spina bifida team
Toddlers
Preventive and well-child care
Developmental monitoring
Mobility
Growth and weight management
Preschool-aged children
Transition from early-intervention program to preschool program
Ambulation and mobility
Bowel and bladder program
Social inclusion
School-aged children
Identify and characterize learning abilities
Ensure appropriate school-based services, Individualized Educational Plan or 504 plan
Monitor secondary conditions including latex allergy
Encourage physical activities, friends, and household responsibilities
Plan for educational transition
Encourage independent self-care and toileting
Preteens
Begin health care transition planning
Advocate for physical activities, recreation and community inclusion,
Monitor progress in school
Address bullying and safety
Monitor growth and puberty
Encourage independence and self-advocacy
Develop and maintain friendships
Teens
Continue transition and transfer process to adult care, activities and social participation
Educate regarding spina bifida and self-care
Provide private health care visits
Provide anticipatory guidance regarding sexuality and reproduction
Encourage independence in health care decision-making
Monitor growth and vital signs (blood pressure)
Encourage physical activities
Manage weight and nutrition
Encourage cardiopulmonary health and fitness
Young adults
Transfer care to a provider of routine adult health care
Provide resources for specialty care: neurosurgery, orthopedics, urology, and others
Monitor weight and physical fitness
Provide information regarding finances such as Social Security Disability Income and health insurance
Monitor education and employment
Help to build and maintain friendships and social support groups
Monitor for deterioration and late-onset complications

issues related to spina bifida and is a first-line resource for patients and families in identifying and addressing strengths, problems, needs, and services.[37] The goals of primary care for children and youth with spina bifida should be to promote optimal health and well-being, to prevent secondary conditions and disabilities, to build on individual strengths and abilities, to help in the development of independence, and to promote social competence and inclusion—in short, to help patients become capable and contributing adults despite the challenges of their chronic health conditions.

The "Guidelines for Spina Bifida Health Care Services Throughout the Lifespan" and "Health Guide for Parents of Children Living With Spina Bifida" and other publications of the Spina Bifida Association (see www.sbaa.org) are useful resources for medical home providers. These and other resources can help in developing a care plan covering from birth through transition and transfer to adult health care, with focus on specific needs at each age and stage. Tables 3 and Table 4 outline some of these activities.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Provision of Educationally Related Services for Children and Adolescents With Chronic Diseases and Disabling Conditions

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Children With Disabilities

ABSTRACT

Children and adolescents with chronic diseases and disabling conditions often need educationally related services. As medical home providers, physicians and other health care professionals can assist children, adolescents, and their families with the complex federal, state, and local laws, regulations, and systems associated with these services. Expanded roles for physicians and other health care professionals in individualized family service plan, individualized education plan, and Section 504 plan development and implementation are recommended. Recent updates to the Individuals With Disabilities Education Act will also affect these services. Funding for these services by private and nonprivate sources also continue to affect the availability of these educationally related services.

The complex range of federal, state, and local laws, regulations, and systems for special education and related services for children and adolescents in public schools is beyond the scope of this statement. Readers are referred to the American Academy of Pediatrics policy statement "The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP)" for additional background materials. The focus of this statement is the role that health care professionals have in determining and managing educationally related services in the school setting.

This policy statement is a revision of a previous statement, "Provision of Educationally Related Services for Children and Adolescents With Chronic Diseases and Disabling Conditions," published in February 2000 by the Committee on Children With Disabilities (http://aappolicy.aappublications.org/cgi/content/full/pediatrics;105/2/448).

Abbreviations
IDEA—Individuals With Disabilities Education Act
IEP—individualized education plan

FEDERAL LAWS

Related services such as speech therapy, occupational therapy, physical therapy, and nursing care are provided to students in school because they are related to the student's education. The term "related services" as currently defined in Part A of the Individuals With Disabilities Education Act (IDEA) includes the following[1]:

> . . . transportation and such developmental, corrective, and other supportive services (including speech-language pathology and audiology services, psychological services, physical and occupational therapy, recreation, including therapeutic recreation, social work services, counseling services, including rehabilitation counseling, orientation and

mobility services, and medical services, except that such medical services shall be for diagnostic and evaluation purposes only) as may be required to assist a child with a disability to benefit from special education, and includes the early identification and assessment of disabling conditions in children.

The legal justification for the provision of related services without qualifying for special education placement can be found in Section 504 of the Rehabilitation Act of 1973.[2] This section prohibits discrimination that is based on disability within federal and federally assisted programs. Regulations promulgated by the US Department of Education have more broadly defined the persons covered by this act, as well as the services that are to be provided. According to Section 504, all children must be provided with an appropriate education that "could consist of education in regular classes, education in regular classes with the use of supplementary services, or special educational and related services." Psychological testing and evaluation, counseling, physical and occupational therapy, medical services, speech pathology, audiology, and orientation mobility instruction are listed among the types of "developmental, corrective, and . . . support services" that may be provided to qualified persons. Thus, Section 504 states that children with chronic diseases and disabling conditions are entitled to appropriate modifications within their educational program to accommodate their special needs regardless of whether their classroom placement is considered regular education or special education. Some school systems have developed flexible, function-oriented "504 modification plans" for students. Unfortunately, some school systems still provide few services.[3] Children with chronic medical conditions, who usually function well in the standard classroom, still need consideration for related services. Examples of such children are those with asthma and allergies, who often find themselves at odds with their schools and school districts because of issues related to classroom modifications (eg, no pets in the classroom, having hand-washing facilities), curriculum modifications (eg, alternatives to standard physical education on an as-needed basis rather than the usual exclusion or full participation), and access to medications.

On December 3, 2004, the IDEA (Pub L No. 108-446)[4] was enacted. Most of the provisions of this law became effective July 31, 2005. The new law is likely to have a major impact on how students with disabilities are educated. Listed below are some of the key changes that occurred with the IDEA 2004.

- The long-established obligations for the individualized education plan (IEP) team to have short-term objectives for each child in his or her IEP will no longer be required as part of the annual goals.
- A child's progress report toward meeting the annual goals must be reported to the IEP team as in the previous IDEA legislation. With the new law, however, there is no longer a reference to "the extent to which the progress is sufficient to attain the goal by the end of the year." The amendments clarify that the transition process for a student with a disability now begins at age 16. In the past, only transition planning, but not the actual transition process, would begin at age 16.
- A new section allows IEP team members to be excused from attendance if their area is not being discussed. When this section is applied with new provisions allowing alternate means of meeting participation (eg, conference calls), consolidation of reevaluation meetings and other IEP meetings, and a pilot program authorizing up to 15 states to use multiyear IEPs, the combined effect is a transformation of the traditional IEP meeting that had been a face-to-face meeting that required all participants to sit around a table at the school.
- The Secretary of Education is authorized to approve proposals from up to 15 states to allow local school districts to offer, with parental consent, a multiyear IEP not to exceed 3 years.
- The Secretary of Education is authorized to grant waivers of statutory and regulatory requirements, for a period not to exceed 4 years, to 15 states that propose to reduce excessive paperwork and noninstructional time burdens. The Secretary is prohibited from waiving requirements related to civil rights or the right of a child to a free appropriate public education.
- Parents of a child who is transitioning from part C (early childhood) to part B (school-age) services can request that an invitation to the initial IEP meeting be sent to representatives of the part C system to assist with a smooth transition of services. This provision does not require a part C representative to attend, but it does encourage collaboration.
- Services comparable to those described in the IEP that are in effect before a child's transfer to a new school must be provided by the new school district. These services must continue until the previous IEP is adopted or a new IEP is developed, adopted, and implemented; regardless of whether the child is transferring in the same state or from another state, the child's previous IEP will be valid. This new provision will help parents of transferring students know what they can expect from their new schools.
- The procedural safeguards notice, which explains the specific rights and responsibilities of the parent in the special education process, will be routinely distributed only once per year. However, a copy will be distributed after the initial referral, when a parent makes a request for an evaluation, when a due process complaint has been filed, or if a parent requests a copy.

- Parents now have 2 years in which to exercise their due process rights after they knew or should have known that an IDEA violation has occurred. Other due process changes can be found at www.pacer.org/idea/2004/summary.htm. The due process hearing is an impartial procedure used to resolve disagreements over issues related to special education services that arise between a parent and a school division. The right of the parents or the school division to request a due process hearing is guaranteed by federal and state laws that govern the education of children with disabilities.
- The right of a student with a disability to stay in his or her current educational placement pending an appeal is eliminated for alleged violations of the school code that may result in a removal from the student's current educational placement for more than 10 days. Before this update of the IDEA, the student with a disability would have been allowed to stay in his or her current educational placement pending an appeal regardless of how many days the violation would have removed him or her from the current placement.
- A child is entitled to receive programming and services necessary to enable him or her to receive a free appropriate public education consistent with section 612(a)(1) during the period in which he or she is in an interim alternative education setting.
- Before the IDEA 2004, the burden was on the school district to show that the behavior resulting in a disciplinary action was not a manifestation of the child's disability before being allowed to apply the same disciplinary procedures as it used for nondisabled children. Other changes in discipline can also be found at www.pacer.org/idea/2004/summary.htm.[4]

Medically Necessary Versus Educationally Needed

Health care professionals frequently view educationally related services as medically necessary or helpful for children and adolescents with chronic diseases and disabling conditions. Although this is appropriate in the health care setting, it is not the standard for services mandated to be provided by public education systems. The additional proviso that the service must be necessary for education or special education is a key component in the laws. Related services are those services indicated as necessary for the child to maximize his or her special education program (ie, IEP). In other words, without the related services, the child might not be able to maximize his or her special education program. This difference in perspective and interpretation by physicians and other health care professionals and parents often leads to misunderstandings, frustrations, conflicts, and problems in the development and implementation of related services within school programs for children with disabilities. To best serve children with disabilities and their families, physicians and other health care professionals need to be familiar with these issues, their legal basis, and the special educational process and system. Maintaining this knowledge is a key function of the medical home provider for children with chronic diseases and disability conditions.[5] Readers are referred to the American Academy of Pediatrics policy statement "The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP)"[6] for additional background materials.

In addition, functional classifications as suggested by the World Health Organization in its International Classification of Impairments, Disabilities, and Handicaps 2[7] offer many advantages to the current diagnostic systems used by the medical home provider for children with disabilities. In 2001, the World Health Organization approved the International Classification of Functioning, Disability, and Health as the international standard for conceptualizing, classifying, and coding function. It evaluates all children within the same structure and metric regardless of diagnosis. It highlights a child's unique strengths and needs for the purpose of directing interventions. This is particularly advantageous in the case of spectrum diagnoses such as autism and cerebral palsy in which a label alone is not sufficient to direct service interventions. A functional assessment of the child provides a more complete picture so that providers can better match resources and needs. Functional classification also looks at individuals within the context of their social and physical environment, taking into account the impact of human and technologic supports on an individual's "activities and participation." In addition, functional classification catalyzes interdisciplinary communication and collaboration by providing a common structure and language for discussion.

Challenges for Schools

Providing related services presents significant opportunities for the children served as well as challenges for the educational system. With greater numbers of children with chronic diseases and disabling conditions entering the school system and the increasing complexity of these conditions, many issues and problems have developed. The availability of services, designation of responsibility for their payment and provision, and conflicting legal imperatives, as well as other obstacles, result in vastly different services in various communities. The current trend of integration and inclusion of many children with a wide range of disabilities in "regular" classrooms and programs is making the provision of related services outside of traditional "special" educational settings a larger and more complex issue. Adequate classroom and school modifications (eg, ramps and accessible sinks and toilets) and support personnel (eg, instructional assistants, school nurses, and special education teachers) are needed in more classrooms and schools.

The difficulties in implementation of related services in schools are as varied and complicated as the disabilities of the children involved. These problems, among others, include:

- lack of clarity about which circumstances should result in a child's exclusion from school for medical reasons;
- uncertainty about the responsibility for, and administration of, complex nursing treatment or therapy in school[8];
- inconsistencies in state and local guidelines and interpretations about which health care professionals should prescribe the type and amount of physical, occupational, and speech therapies;
- uncertainty about medical liability for therapies administered in school;
- conflicting opinions about the appropriateness of some therapies used for children;
- concern about the rising cost of special education services and whether all treatment required in IEPs is warranted; and
- the frequent lack of provision of related services for children who may not qualify for special education but who have chronic diseases and disabling conditions that impair their ability and readiness to attend or participate in school.[9]

School-System Responsibility

In March 1999, the US Supreme Court ruled that complex nursing service (ventilator care) is a related service.[10] The difference between educationally related services and rehabilitation services is unclear. Court rulings have generally mandated that all therapies and equipment (eg, assistive devices) recommended in the IEP be reimbursed by the educational system.[11] However, this has not precluded the application of Medicaid or other public funding for payment of equipment or to support medical service provisions within the IEP for children with disabilities. Although private insurance carriers have generally declined reimbursement for therapies provided in the schools, in specific situations they may be responsible for payment of school-based services and frequently pay for community-based services. One example of private insurance carriers paying for these services would be during the summer when school is not in session. Even if insurance payment is an option, the parents may decide not to make claims against their insurance, because it would create a threat of financial loss, such as lowering the child's available lifetime medical benefits. Generally, school systems are not responsible for acute rehabilitation services.

In communities in which the school systems have borne the responsibility for implementing the IEP and funding most of the therapies, the educational authorities are increasingly concerned about the responsibility for overseeing the provision of complex nursing care and other related services for children with disabilities who attend public school. School systems also are concerned about insurance companies and managed care systems shifting funding responsibilities for rehabilitation and medical diagnostic services from health care to the school system. Each state's mandate to the local school system may vary in the degree that any such services are paid by the school system. The variability of school systems to assume responsibilities has the potential to (1) increase conflicts with local physicians and other agencies responsible for health care provision, (2) contribute to the disjointed nature of health care for children, and (3) result in unnecessary treatment at increased cost,[12] which depletes educational resources for other children.

The special needs of students with complex health conditions that require modifications in the school environment are also commonly documented in an individual student health plan, also known as a student services plan, nursing care plan, or student medications plan. Although these plans are not mandated by law in every state, such plans typically provide information on a student's chronic health condition, instructions on the administration of medication, and emergency contact information. A combination of IEP and individual student health plan is often necessary to help manage a student's health condition in the school and classroom settings.

The Physician's Role

The physician's role mandated by the IDEA as a related service is defined to include only the diagnosis and evaluation of the disability. However, in the context of the medical home, the physician's role also includes the medical management, supervision, and program planning for the child. The IDEA does not mandate that these additional roles be paid for by the public school. Parents often need an advocate for the child who can be objective in assessing the child's special needs and determining realistic expectations. Input from the medical home professionals also assists with placing services in a developmental context in which changes in needs are to be expected over time. The important medical services extend beyond IDEA mandates. Currently, the funding for the physician and other health care professionals' time to complete this role is lacking in most health insurance programs and is not funded by most federal and state funds for education. However, physicians can bill for their consultative services and for other related services with some private insurance plans, Medicaid, and the State Children's Health Insurance Program.

CONCLUSIONS

A multidisciplinary assessment within the school system is required in the initial evaluation of children to deter-

mine their eligibility for services within the educational system. It is also necessary to maintain a comprehensive multidisciplinary approach in the provision of these services, which should be coordinated with the child's medical home professional. The inequalities in the interpretation and provision of services between and within states and school districts need to be corrected. The developmental, educational, functional, and medical needs of the child or adolescent should be determined first, and then the appropriate services to meet these needs should be provided in a timely manner. Issues of who provides the appropriate services and how payment is to be made must be resolved in the context of maintaining the child in the appropriate educational environment.

RECOMMENDATIONS

1. Physicians and other health care professionals should be well informed about the medical and educational needs of children and adolescents with chronic diseases and disabling conditions.
2. Educational opportunities should be developed and made available to physicians and other health care professionals at local, state, and national levels.
3. Physicians and other health care professionals should be aware of the issues and inconsistencies in the IDEA, parts B and C, and Section 504 of the Rehabilitation Act of 1973.
4. Pediatricians, including pediatric subspecialists, and other health care professionals should objectively appraise the special needs of children and adolescents, determine realistic expectations, and advocate for children and adolescents by assisting with establishing an appropriate balance between the recommendations made by the school team and the desires of the family.
5. The initial pediatric focus for services should be on the child or adolescent with a disability and on his or her specific needs, and these needs should not necessarily determine the child's placement. Once these specific needs have been defined, the role of the school system and the role of community providers should be determined. The specific class placement should not determine the provision of related services in school.
6. Care coordination for children and adolescents with chronic and disabling conditions should take place in the medical home, and the medical home must include the primary care physician, pediatric specialists, and other health and human services professionals regardless of the location of, or source of payment for, these services.
7. Physicians and other health care professionals should take a more active role in the development and implementation of individualized family service plans.
8. Physicians and other health care professionals should get involved at the systems level. Physicians, especially pediatricians, should seek representation on local advisory and interagency committees that oversee programs for school placement of children and adolescents with chronic diseases and disabling conditions.

CLINICAL REPORT
Guidance for the Clinician in Rendering Pediatric Care

Joseph F. Hagan, Jr, MD, and the Committee on Psychosocial Aspects of Child and Family Health, and the Task Force on Terrorism

Psychosocial Implications of Disaster or Terrorism on Children: A Guide for the Pediatrician

ABSTRACT. During and after disasters, pediatricians can assist parents and community leaders not only by accommodating the unique needs of children but also by being cognizant of the psychological responses of children to reduce the possibility of long-term psychological morbidity. The effects of disaster on children are mediated by many factors including personal experience, parental reaction, developmental competency, gender, and the stage of disaster response. Pediatricians can be effective advocates for the child and family and at the community level and can affect national policy in support of families. In this report, specific children's responses are delineated, risk factors for adverse reactions are discussed, and advice is given for pediatricians to ameliorate the effects of disaster on children. ***Pediatrics*** **2005; 116:787–795;** ***terrorism, disaster preparedness, posttraumatic stress disorder, anxiety.***

ABBREVIATIONS. AAP, American Academy of Pediatrics; PTSD, posttraumatic stress disorder.

INTRODUCTION

In 1999, the Committee on Psychosocial Aspects of Child and Family Health of the American Academy of Pediatrics (AAP) provided guidelines for the role of the pediatrician in responding to the psychosocial implications of disasters on children.[1] Those guidelines delineated a plan for disaster preparedness and response to disaster and outlined the unique responsibility of the pediatrician at these junctures. Although that statement primarily considered natural disasters, it provided a sufficient theoretic outline for the American pediatrician's response to the terrorist attacks of September 11, 2001 in New York City, New York, and Washington, DC. The events of September 11th underscored the need for a more comprehensive resource for addressing the specific psychosocial effects of disaster on children. What has been learned of the effects on children from a tragedy of this magnitude has done much to augment our understanding of children's reactions to disaster and thus can shape planning for our response to future catastrophes to alleviate the psychosocial burden on children. Pediatricians can assist parents and community leaders not only in accommodating the unique needs of children during disasters but also by being cognizant of the psychological responses of children to reduce the possibility of long-term psychological morbidity and to help our children feel safe in their daily lives.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Disasters Defined

A disaster is a calamitous event that generally involves injury or loss of life and destruction of property; disasters can affect both small and large populations.[2] These events are traumatic and customarily outside the scope of normal human experience; thus, they are likely to involve psychological as well as physical injury.[2,3] For example, studies suggest that ~25% of adults experience symptoms of posttraumatic stress disorder (PTSD) after acute traumatic events (see Figs 1 and 2 for symptomatology in children).[4,5] The inherent resilience of children in conjunction with their specific psychological sensitivities leads to extremely variable rates of PTSD in children after acute trauma. However, the psychological effects of disaster on children are neither uniform nor universal in nature. It is widely accepted that the psychosocial manifestations in children after disaster are influenced greatly by the nature of disaster itself, the level of exposure to the disaster, the extent to which the children and those around them are personally affected by the disaster, and the individual characteristics of children, including their age and stage of development.[2,6–8] In addition, children are uniquely affected by disasters because they are afflicted not only by the trauma of the event but also by their parents' fear and distress.[7] Taken together, these considerations represent challenges to pediatricians and parents alike in recognizing and providing for the unique psychological needs of children.

Nature of Disasters

It is well recognized that the nature and extent of disaster can influence the psychological response of children. Acute events that produce relatively few disruptions in a child's social or living situation are generally less psychologically damaging than chronic traumatic events or events that lead to last-

DISORDER	COMMON DEVELOPMENTAL PRESENTATIONS
309.81 Posttraumatic Stress Disorder (PTSD) PTSD occurs following exposure to an event that involved actual or threatened death or serious injury, or a threat to the physical integrity of self or others. The child or adolescent has symptoms in each of the following three areas for more than 1 month, causing significant distress or impairment of functioning: (1) persistent reexperiencing of the trauma, (2) avoidance of stimuli associated with the trauma and diminished general responsiveness, and (3) increased arousal or hypervigilance. In infancy, a numbing of responsiveness may also occur. (see *DSM-IV* Criteria Appendix, p 339) **308.3 Acute Stress Disorder** (see *DSM-IV* Criteria Appendix, p 311)	**Infancy** Rarely diagnosed but may take the form of extra fears or aggressive behaviors in response to stress. **Early Childhood, Middle Childhood, Adolescence** In children, distressing dreams of the event may, within several weeks, change into generalized nightmares of monsters, of rescuing others, or of threats to self or others. Reliving of the trauma may occur through repetitive play. Children may also exhibit various physical symptoms, such as stomachaches and headaches. **SPECIAL INFORMATION** PTSD follows exposure to acute or chronic stressors that involve actual or threatened death or serious injury to the child or others. The child must have reacted with intense fear, disorganized or agitated behavior, or helplessness. Stressors may be acute or chronic, single or multiple. PTSD may be chronic and associated with significant morbidity. Symptoms of repetitive trauma re-enacting play and a sense of a foreshortened future may persist after distress is no longer present. PTSD must be distinguished from normal bereavement. Bereavement is characterized by sadness and recurrent thoughts, but not by persistent impairment of functioning (see Sadness and Related Symptoms cluster, p 153). Consider sexual abuse/rape (p 45). Because it may be difficult for children to report diminished interest in significant activities and constriction of affect, these symptoms should be carefully evaluated with reports from parents and teachers. In children, the sense of a foreshortened future may be evidenced by the belief that life will be too short to include becoming an adult.

Elk Grove Village, IL: American Academy of Pediatrics; 1996:151.)

ing changes in the social environment.[6,9–12] It is not surprising that children react differently to natural disasters than they do to human-caused disasters.[2,5] Natural disasters such as storms and earthquakes are reported to have a less injurious psychological effect[8] on children than human-caused disasters in which harm is inflicted intentionally, such as war and terrorism, which are associated with higher levels of distress.[2] With inflicted disaster, greater psychopathology may result from children's witnessing intentional acts of violence, which are particularly incomprehensible for adults as well as children. Such disasters that defy the boundaries of human decency and rationale may engender additional horror. War entails chronic exposure to human-made violence, injury, destruction, and death. Children's responses to war are beyond the scope of this review and will not be discussed.

Thousands of children were affected significantly by the events of September 11th. Some were affected directly by losing a parent or family member, being displaced from their home or school, or witnessing the attacks.[13] Still hundreds of thousands more were touched indirectly by viewing the horrific images that consumed the media for weeks after the attacks or observing initial and ongoing responses of public figures and trusted adults. Certainly, a child's personal experience related to September 11th can be predictive of that child's response.[14]

Effects of Parental Reaction

To address the psychological effect of disaster on children adequately, it is necessary to examine the effect of disaster on parents. Among adults in Manhattan subsequent to the September 11th attacks, rates of PTSD and depression were twice that of the normal incidence.[15] Symptoms of PTSD declined in two thirds of the adult population in 3 months' time.

The purpose of this appendix is to provide details on the diagnostic categories for the *DSM-IV* disorders pertinent to children. The disorders are listed in alphabetical order.

Diagnostic criteria for Acute Stress Disorder 308.3

A. The person has been exposed to a traumatic event in which both of the following were present:

   (1) the person experienced, witnessed, or was confronted with an event or events that involved actual or threatened death or serious injury, or a threat to the physical integrity of self or others
   (2) the person's response involved intense fear, helplessness, or horror

B. Either while experiencing or after experiencing the distressing event, the individual has three (or more) of the following dissociative symptoms:

   (1) a subjective sense of numbing, detachment, or absence of emotional responsiveness
   (2) a reduction in awareness of his or her surroundings (eg, "being in a daze")
   (3) derealization
   (4) depersonalization
   (5) dissociative amnesia (ie, inability to recall an important aspect of the trauma)

C. The traumatic event is persistently reexperienced in at least one of the following ways: recurrent images, thoughts, dreams, illusions, flashback episodes, or a sense of reliving the experience, or distress on exposure to reminders of the traumatic event.

D. Marked avoidance of stimuli that arouse recollections of the trauma (eg, thoughts, feelings, conversations, activities, places, people).

E. Marked symptoms of anxiety or increased arousal (eg, difficulty sleeping, irritability, poor concentration, hypervigilance, exaggerated startle response, motor restlessness).

F. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning, or impairs the individual's ability to pursue some necessary task, such as obtaining necessary assistance or mobilizing personal resources by telling family members about the traumatic experience.

G. The disturbance lasts for a minimum of 2 days and a maximum of 4 weeks and occurs within 4 weeks of the traumatic event.

H. The disturbance is not due to the direct physiological effects of a substance (eg, a drug, a medication) or a general medical condition.

Diagnostic criteria for Posttraumatic Stress Disorder 309.81

A. The person has been exposed to a traumatic event in which both of the following were present:

   (1) the person experienced, witnessed, or was confronted with an event or events that involved actual or threatened death or serious injury, or a threat to the physical integrity of self or others
   (2) the person's response involved intense fear, helplessness, or horror. **Note:** In children, this may be expressed instead by disorganized or agitated behavior.

Fig 2. Relevant Criteria of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*. (Reproduced with permission from American Academy of Pediatrics. Appendix C: sections of the relevant criteria of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*. In: Wolraich ML, Felice ME, Drotar D, eds. *The Classification of Child and Adolescent Mental Diagnoses in Primary Care: Diagnostic and Statistical Manual for Primary Care (DSM-PC) Child and Adolescent Version*. Elk Grove Village, IL: American Academy of Pediatrics; 1996:311, 339–304).

However, during this quarter year, children were deeply dependent on the affected parents for their emotional and psychological needs. Any effect of trauma on key or trusted adults can result in magnified psychological effect on the children they care for.[6] An adult's disordered mood or behavior can add to a child's fears. Distressed adults may fail to recognize a child's distress.

Studies since the September 11th attack demonstrate that parents recognize the effects of their reactions on their children. Furthermore, parents are concerned that they are not emotionally available to adequately address their children's fears or their children's concerns of fairness and justice.[7] This realization may be an added stress for parents, and 1 study reports a greater prevalence of mental distress in parents compared with nonparents, particularly in parents with symptoms of PTSD.[13]

B. The traumatic event is persistently reexperienced in one (or more) of the following ways:

(1) recurrent and intrusive distressing recollections of the event, including images, thoughts, or perceptions. **Note:** In young children, repetitive play may occur in themes or aspects of the trauma are expressed.
(2) recurrent distressing dreams of the event. **Note:** In children, there may be frightening dreams without recognizable content.
(3) acting or feeling as if the traumatic event were recurring (includes a sense of reliving the experience, illusions, hallucinations, and dissociative flashback episodes, including those that occur on awakening or when intoxicated. **Note:** In young children, trauma-specific reenactment may occur.
(4) intense psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event

C. Persistent avoidance of stimuli associated with the trauma and numbing of general responsiveness (not present before the trauma) as indicated by three (or more) of the following:

(1) efforts to avoid thoughts, feelings, or conversations associated with the trauma
(2) efforts to avoid activities, places, or people that arouse recollections of the trauma
(3) inability to recall an important aspect of the trauma
(4) markedly diminished interest or participation in significant activities
(5) feeling of detachment or estrangement from others
(6) restricted range of affect (eg, unable to have loving feelings)
(7) sense of a foreshortened future (eg, does not expect to have a career, marriage, children, or a normal life span)

D. Persistent symptoms of increased arousal (not present before the trauma), as indicated by two (or more) of the following:

(1) difficulty falling or staying asleep
(2) irritability or outbursts of anger
(3) difficulty concentrating
(4) hypervigilance
(5) exaggerated startle response

E. Duration of the disturbance (symptoms in criteria B, C, and D) is more than 1 month.

F. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

***Specify* if:**
Acute: if duration of symptoms is less than 3 months
Chronic: if duration of symptoms is 3 months or more

***Specify* if:**
With Delayed Onset: if onset of symptoms is at least 6 months after the stressor

Fig 2. Continued.

Effects on Children

The long-term psychological morbidity among children as a result of the attacks on New York and Washington is still largely unknown. Experts suggest that the current mental health system has been ineffective in identifying and coping with the unique psychosocial burden that the events of September 11th have created.[8,16] Investigators report that a surprisingly large number of children in proximity to the areas of greatest devastation received some form of counseling after the attacks. In the Manhattan area, 22% of children from the community-at-large received some form of counseling after the attacks, which was a much greater rate of counseling than seen with similar tragedies such as the Oklahoma City bombing.[13,17] However, most of this counseling was received in schools. In the Washington area, the total number of children's visits to behavioral health clinics at military treatment facilities did not increase; however, there was a significant increase in the percentage of visits for anxiety disorders and acute stress reactions.[18] The lack of increase in visits to behavioral health clinics coupled with a high incidence of in-school counseling demonstrates that existing or informal therapeutic relationships were the primary source of support for most children after September 11th.[19] However, it is unlikely that these interventions were sufficient to offset psychological injury for children. After September 11th, children and adolescents reported being significantly more worried about how to cope with stressful things in their lives than before the attacks. It is curious that they reported talking to their pediatric primary health care professionals and parents more about

significant concerns in their lives after September 11th, whereas parents reported talking less to their children after September 11th about these same concerns.[20] It is likely that because of the differences in perception of communication between children and adults and the lack of formal psychological evaluations for most of our nation's youth, the psychological burden of many children was not adequately assessed or addressed. In addition, pediatric practitioners in the New York City tristate area reported gaps in their self-perceived knowledge and skills necessary to address the many mental health–related concerns that they encountered in patients after September 11th.[21]

For children who experience a traumatic event, some degree of behavioral symptoms and adjustment reactions are expected and are well within the normal limits of psychological response. The psychological responses of children to disasters can range from transient mild stress reactions to the more severe and prolonged consequences of PTSD.[22] These responses are influenced by the gender, developmental stage, inherent resilience, and social support of the child and the level of exposure of the child to the trauma.[2] Exposure to traumatic and violent events results in expressions of fear, anxiety, and depression.[23] In most cases, these reactions are within the realm of normal responses to a traumatic event, and as children are helped to learn to cope with this stress, their symptoms subside.[2,7]

Stages of Children's Response to Disaster

Parents and caregivers can expect children to respond to disaster in distinct stages.[2,7,24] The first stage, immediately after the disaster, includes reactions of fright, disbelief, denial, grief, and feelings of relief if loved ones have not been harmed.[2] A great deal of altruism is often displayed by children trying to help in the aftermath of such tragedies; this may help them develop resilience and also may be a marker of resilience.

The second stage occurs a few days to several weeks after the disaster and is characterized by developmental regression in many children and manifestations of emotional distress such as anxiety, fear, sadness and depressive symptoms, hostility and aggressive behavior toward others, apathy, withdrawal, sleep disturbances, somatization, pessimistic thoughts of the future, and play demonstrating themes related to the traumatic event.[2,8] Such symptoms are part of the normal recovery process for children after a traumatic disaster and can be expected to last for a few weeks.[2,7,24] Children who experience major loss or traumatic exposures or who are demonstrating marked distress or behavioral disorganization would benefit from counseling urgently, within 1 month of the event.

Children with adverse stress reactions and behavioral symptoms for longer than 1 month's time may be at increased risk of developing PTSD or violent and delinquent behaviors later in life.[7,23] In such cases, it is appropriate and necessary for children to receive counseling from a mental health specialist.[7]

Developmental Effects on Response to Trauma

Children of different developmental stages interpret the world differently and at their own distinctive pace.[7] Their developmental stage uniquely influences their response to traumatic events, and consequently, they display a great deal of variability in adjustment subsequent to traumatic events. Interventions to alleviate the psychological burden should be developmentally appropriate.[25]

The response of younger children to disaster is dominated by mood, anxiety, and behavioral symptoms.[6] They are largely unable to understand the intentions and logic of others and, consequently, have great difficulty distinguishing a deliberate action from an unintentional incident. As a result, in the face of disaster, young children are more concerned with the consequences, and older children are more aware of the underlying principles of a traumatic event.[7] Although older children also experience depression, their anxiety may take on specific and perhaps unrealistic forms and fears, and their behavioral reactions may be complicated by anger or despair as well as their past experiences. Older children are more sophisticated cognitively and, thus, can begin to comprehend the intent and reasoning of others and the implications of the event.

Traumatic and disrupting events can have adverse effects even on children who are too young to verbalize their distress. Although infants and toddlers may have no cognitive comprehension of a disaster, the destruction of routine and loss of loved ones can lead to regression and detachment.[2] In the first year of life, such experiences can manifest as increased crying and irritability, separation anxiety, and an exaggerated startle response.[22] Toddlers and preschool-aged children are likely to experience sleep terrors and nightmares and exhibit behavioral and skill regression manifesting as helplessness, clinging behavior, and increased temper tantrums.[22]

School-aged children often demonstrate the experience of trauma through play, expressing trauma-related themes and aggressive behavior.[2] Similar to their younger counterparts, sleep disturbances and regressive behaviors such as separation anxiety are often seen.[22] School-aged children also may become withdrawn or apathetic or exhibit somatization and behavioral problems. Although fear was the most common primary reaction to the events of September 11th among school-aged children, the developmental diversity of this age group leads to a wide range of responses to such trauma.[7]

Younger school-aged children are yet unable to comprehend another's reasoning or intent and, thus, concentrate on the direct consequences of the disaster. They tend to focus on specific details of the tragedy and on personal safety.[7] They fear injury or death of family members. Conversely, older school-aged children have a greater capacity for social cognition and empathy. They tend to display more empathy for families who were affected by the crisis, have a greater willingness to analyze how or why a tragedy occurred, and focus more on the safety of the society as a whole.[7]

The psychological response to disaster among adolescents most closely resembles that of adults; symptoms of depression and anxiety predominate.[6] However, this does not lessen their risk of developing significant psychological morbidity after the experience of a severe trauma. Adolescents are a particularly vulnerable group, because they are experiencing a period of complex transitions.[26] Children in this developmental stage may differ greatly in their interpretations and reactions to disasters depending on whether they have developed abstract reasoning abilities. Abstract thinking appears, on average, at 16 years of age. Most adolescents are still developing their emotional coping skills, are working to establish their independence and own identity, and are known to be especially susceptible to the development of major psychiatric disorders such as depression.[26] Disasters that result in a loss of lifestyle or loved ones can result in somatization, withdrawal, apathy, and depression.[2] They are likely to engage in risk-taking behaviors such as drug abuse and sexual relationships as mechanisms of coping with traumatic stress.[26] Suicidal thoughts and actions are a concern. In addition, the interference with identity development in adolescence can lead to significant behavioral and emotional problems throughout their lives. Adolescents may try to mask or withhold symptoms of adjustment reactions because they think they are abnormal or inappropriate reactions. Adolescents might attempt to protect other family members who may also be upset.[8] As a result, parents are at risk of underestimating the effects of disaster on their adolescents and may be in a disadvantaged position for getting their children the help that they need.[8]

Gender, Ethnicity, and Other Influences on Response to Trauma

Gender also has a decisive effect on the reaction of children to disaster. Boys display higher rates of behavioral symptoms and require a longer recovery period than girls.[2,6] More specifically, they tend to be more antisocial and display violent and aggressive behaviors and other externalizing symptoms. When faced with disaster, girls display more internalizing symptoms such as anxiety and mood disturbances.[2,6] However, they tend to be more expressive about their emotions than boys and have more frequent thoughts about the disaster.

Cultural differences may affect symptom expression. The experiences of people of Arab American, Persian American, and related ethnicities after the September 11th attacks are noteworthy. Replicating their experience during the Iran hostage crisis 25 years ago, many of these people experienced prejudice and bigotry in general, and some suffered unprovoked physical violence. Their patriotism was questioned, or it was suspected that they condoned the terrorist acts. American travelers were told by authorities to "report suspicious-looking" fellow travelers, with racial profiling as an unintended result. The description of some terrorists as "Islamic fundamentalists" has caused confusion regarding the Islamic religion and places its followers at risk for religious persecution. The teachings of Islam do not condone violent terrorist attacks.

Previous traumatic events such as personal experience of violence, abuse or neglect, foster care, or other stressors increase the risk of an adverse reaction to disaster. Previous experiences also predict more serious symptomatology, as noted in the New York City school experience.[14]

Tens of thousands of immigrant children and adolescents who enter the United States yearly have experienced disasters. Many immigrant families do not discuss their previous experiences with anyone outside their family, including their pediatricians. It is important that pediatricians recognize the possibility of preimmigration trauma as a potential cause of long-term psychological problems. Culturally unique responses to new traumas should be anticipated.

Other Risk Factors for Adverse Reactions

Although all children suffer to some degree from anxiety, fear, and depression when exposed to disaster, it is known that there is a subset of children who are at increased risk of developing long-term psychosocial morbidity and adverse reactions to trauma.[6–8] Children with poor social support, a history of psychopathology, or a shy and fearful nature are at greater risk of trauma-associated psychopathology.[6–8] Children who have experienced previous losses are also at an increased risk of adverse reactions to trauma. A disaster of any nature can awaken unresolved emotions and fears in children related to past crises.[8] Parents and pediatricians should be sensitive to seemingly unrelated concerns put forth by children during times of disaster. In addition, because children are intimately dependent on adults around them for feelings of safety and well-being, children whose family members have difficulty coping with disaster are also at increased risk of adverse reactions to trauma.[2,8]

Children who have had a high level exposure to or have otherwise experienced direct losses from a disaster are more susceptible to severe adverse reactions to trauma.[2,7,8] Direct witnessing of a traumatic event, victimization of the child or those close to the child, and the perception, correct or not, that one's life was in danger are known risk factors for adverse psychosocial symptoms after trauma.[8,27]

Children remote from catastrophic events by both location and experience are not immune to the acute and chronic psychopathologies related to disaster. Several studies have implicated indirect television exposure to disaster as a risk factor for children's reactivity.[8,17,27–29] The amount of information that a child will find valuable in understanding a disaster largely depends on a child's developmental stage.[8] Parents and caregivers should be aware that gruesome and disturbing details are likely unnecessary in facilitating a child's comprehension of a tragedy. Such information has a great potential to engender fear and may be psychologically injurious and thus impede a child's psychosocial recovery. In addition, the subjective response of a child to disaster has been demonstrated to have a high predictive value for

symptoms of PTSD.[27] Therefore, it is critical that a child's peritraumatic reaction and level of direct and indirect media exposure be monitored closely after traumatic events.

Living With Fear

This discussion has considered the responses of children and their communities to specific disaster events. Natural disasters such as earthquakes and floods and human-made disasters such as terrorist attacks and school shootings are single events. The body of literature and review described here address acute and chronic responses to individual events. Less is known about the effect of living in fear.

Is the documented recent and remarkable increase in mental health services for anxiety disorders and related conditions in children a response to the horror of September 11th or a reflection that American children no longer view their world as safe? Has our public policy of a "war on terrorism" protected, scared us, or both?

Do "terror alerts" protect or terrorize? At a minimum, such alerts should identify the seriousness of the concern and, when possible, the specifics of the risk. We should be told what our government is doing to protect us and what we might do to protect ourselves. Who benefits from alerts in which the risk is low or the anticipated events are unknown? Clearly, specific acts of defense or law enforcement may be indicated. Is there a difference between a law-enforcement alert and a public one?

The mandate to pediatricians and parents is clear. The world is perhaps a less safe place since 2001, but we are, for the most part, safe. We must allow our children to have hope. Even children living in unsafe communities or those affected by prejudice, racism, or violence depend on trusted adults to feel safe or protected so that they might anticipate a less stress-laden future. We must communicate to them that they and we are almost always safe from terrorist acts or natural disasters and that we as parents, health care professionals, and community members will take care of them as we take care of one another. Although some may feel the world is a more fearful place now (an opinion that is not universal), we can help our children live with this fear, adjust to it, and plan for the future rather than remain paralyzed in fear.

The Pediatrician and Disaster

The knowledge we have gained from the events of September 11th has revealed many opportunities to improve outcomes for children who are faced with disaster. The pediatrician must be intimately involved in community disaster-preparedness plans to ensure that the unique physical and emotional needs of children are met during times of disaster. Recommendations for disaster preparedness and planning can be found online at www.aap.org/terrorism. In addition, AAP chapters have presented important local initiatives for community preparedness.

When disaster occurs, the pediatrician will be affected. Although the thrust of this statement is to guide pediatric health care professionals in their work with patients and families, it must be acknowledged that we will be affected personally as well. The pediatrician's first response might need to be to ensure personal safety and that of family and colleagues. The experience of personal injury or loss will influence one's ability to respond professionally. The toll taken on us by fear, tension, sadness, and exhaustion must be recognized and demands proactive attention.[21]

During times of crisis, open dialogue with school officials and community leaders is necessary to ensure that psychological care is available to children. In such scenarios, pediatricians are instrumental in creating environments in their offices, homes, schools, and communities where it is safe and acceptable for children to ask questions and attempt to understand the events around them in a supportive atmosphere.[8]

Pediatricians are also significant resources in assisting families in the recovery period after traumatic events. Within their offices, they are often the first to recognize children and adolescents who are experiencing adverse emotional and psychological reactions to disaster.[8] It is helpful for the pediatrician to initiate this discussion; not asking a child what he or she thinks risks suggesting that the disaster is so bad that it cannot be talked about or managed. Often, when parents hear such a discussion, they are surprised at the content and nature of their child's thoughts regarding a disaster. Proper education for parents regarding what type of behaviors to expect from their children after disaster and the effect that their own reactions can have on the psychological stability of children is instrumental to the emotional well-being of our patients.

Immediate identification of the psychologically distressed child and timely referral for appropriate mental health services provides a major opportunity to improve outcomes for children exposed to disaster. The Pediatric Symptom Checklist (PSC)[30] or PSC-17[31] are recommended as appropriate and accessible screening tools.

ADVICE FOR PEDIATRICIANS

1. For additional study, consult the Web sites of the following organizations, which contain up-to-date information regarding children and disasters:
   - The AAP disaster-preparedness Web page (www.aap.org/terrorism) includes up-to-date listings on all aspects of disaster preparedness for children, including their psychological needs. It is well linked to collateral sites, but only approved links are included.
   - The National Center for Children Exposed to Violence of the Yale Child Study Center (www.nccev.org) includes disaster-specific data.
2. For advice dealing with the behavioral needs of children, consult the following sources:
   - The *Diagnostic and Statistical Manual for Primary Care* (*DSM-PC*) *Child and Adolescent Version*[32];
   - *Bright Futures in Practice: Mental Health, Volumes I and II*[30]; and

- *Feelings Need Checkups Too* (CD-ROM available from the AAP at www.aap.org/profed/childrencheckup.htm).

3. For community preparedness:
   - Serve as a resource for families and the community in providing disaster-preparedness plans appropriate for the unique needs of pediatric patients.
   - Collaborate with other professionals whose work affects children and their families, such as nurses, social workers, psychiatrists, and psychologists.
   - Recognize the importance of schools in disaster preparedness. Pediatricians may wish to work with their schools or state education department to be certain that sufficient disaster plans are in place. Help community leaders recognize that there is a high likelihood that a disaster affecting a community could occur while children are in school.
   - Help schools understand their roles in the aftermath of disaster. Practitioners may volunteer to serve as a resource in helping schools identify and manage children's emotional aftermath.
   - Discuss evacuation and relocation planning as an essential part of community disaster preparedness. Recognizing the substantial psychosocial morbidity associated with suddenly leaving home for a strange and unknown place, insist that planners recognize the unique needs of children and families. Reunification plans for children separated from their parents must be in place. First responders should be trained to understand the needs of children who witness violence or disaster.
   - Consider the resources available to families in your community. Part of psychosocial support entails helping families to identify concrete community resources that can meet their physical and emotional needs. Deficiencies in available resources detected after September 2001 can be identified and shared with community leaders.
4. For children and families:
   - Be aware of patients who are at risk of adverse reactions to trauma or the development of symptoms of PTSD.
   - Educate and counsel parents regarding the range of normal emotional and behavioral reactions of children to disaster and at what points they should be concerned; the effect of their own reactions to disaster on the psychological well-being of their children; and children who are at risk of psychological morbidity after disaster.
   - Help parents recognize the potential deleterious effects of indirect disaster exposure from media and the importance of helping children understand information at the developmentally appropriate level so that children are able to correctly process and understand what they see. Help parents understand that their adult need to know for purposes of reassurance typically works as a negative in children.
   - During times of crisis, stress to parents that children's media exposure should be limited and parents must be available to help children understand the relative importance of what they are seeing or hearing. For example, children may have little concept of space and need reassurance that events seen on television may in fact be quite distant from their homes.
   - After disaster, screen for anxiety in all patient encounters. A simple question and expression of concern can be seen as an effective brief intervention. For many children with supportive families, peers, teachers, and others, the reaction to traumatic experience resolves in a few months. A follow-up screening 4 to 6 months after the disaster would be appropriate to identify children with continuing symptoms who may need referral for additional services.
   - Be familiar with the symptoms of PTSD and be prepared to identify and refer children with the condition.
   - Recognizing that some children will have experienced extreme personal loss, be prepared to address bereavement with children and families.[33]

Psychosocial Risks of Chronic Health Conditions in Childhood And Adolescence (RE9338)

AMERICAN ACADEMY OF PEDIATRICS

Committee on Children With Disabilities and Committee on Psychosocial Aspects of Child and Family Health

Chronic health conditions affect many children and adolescents. These conditions are illnesses or impairments that are expected to last for an extended period of time and require medical attention and care that is above and beyond what would normally be expected for a child or adolescent of the same age, extensive hospitalization, or in-home health services. [1] These conditions include, among others, juvenile rheumatoid arthritis, asthma, cystic fibrosis, diabetes, spina bifida, hemophilia, seizure disorders, neuromuscular disease, acquired immunodeficiency syndrome, and congenital heart diseases. Although each specific condition may be relatively or extremely rare, when they are considered together, many children and adolescents are affected.

Health conditions may be characterized by their duration and their severity. Although these terms are often linked, they refer to different aspects of a health condition. A chronic condition is generally one that has lasted or is expected to last more than a defined period of time, usually 3 months or longer. Conditions vary widely in their onset, course, and duration. [2] Severity refers to the impact a condition has on a child's physical, intellectual, psychological, or social functioning. [3] This impact may occur as a result of persistent symptoms, required treatments, limitations of activity or mobility, or interference with school, recreation, work, and family activities.

Current estimates are that between 10 and 20 million American children and adolescents have some type of chronic health condition or impairment. Most of these conditions are relatively mild and interfere little with the children's ability to participate in usual childhood activities. [4] However, at least 10% of children with chronic conditions, ie, approximately 2% of those aged 0 to 21 years (1 to 2 million children and adolescents nationwide), have a chronic condition severe enough to have an impact on their daily lives.

Recent medical and surgical advances have markedly decreased the mortality rates for children and adolescents with chronic conditions. While previously many of these individuals died in childhood or adolescence, current data suggest that at least 90%, even those with severe conditions, survive at least to young adulthood. [5] Given this change in survival, health care for these children and adolescents must be expanded to include more than management of their chronic condition and intercurrent acute illnesses. Pediatric care should also maximize children's functional abilities and sense of well-being, their health-related quality of life, and their development into healthy and productive adults.

PSYCHOLOGICAL RISKS OF CHRONIC CONDITIONS

Over the past two decades, much research has examined the psychological functioning of children and adolescents with various specific health conditions. [6] Large, community-based studies [7,8] and national surveys [9] have assessed the risk of emotional, behavioral, and educational difficulties experienced by children and adolescents with a chronic health condition. Most of these studies have examined parents' ratings of behavioral and emotional status and have not identified specific psychological disturbances. These studies suggest that the majority of children and adolescents with chronic health conditions do not have identifiable mental health, behavioral, or educational difficulties. Children and their families are remarkably resilient in adapting to the additional stresses and challenges presented by a chronic health condition. Children, their siblings, and their parents often learn new coping strategies and show evidence of exceptional strength and mastery as a result. Nevertheless, these same studies show that children and adolescents with chronic conditions do have about twice the prevalence of psychological symptoms as compared to children without a chronic condition. Behavioral or emotional symptoms can be identified in approximately 10% of children overall and in about 20% of children with chronic health conditions.

It is not clear which specific characteristics of the child or adolescent, the family, and the health condition itself contribute most to resilience, to the stresses experienced, and to the risk of developing secondary emotional or behavioral difficulties. One might expect that the more severe the condition is, the greater the likelihood of psychological problems. Most studies show surprisingly little, if any, relationship between severity and problems with psychological adjustment. [6,10,11] The risk of psychological adjustment problems seems to reflect more the presence of a chronic condition than its severity. [12] In general, the increased risk of psychological problems affects children and

adolescents with all kinds of chronic conditions without great variation from one to another. There are characteristics of some conditions that do seem to be associated with higher rates of emotional or behavioral problems. For example, children who have chronic conditions that affect the central nervous system, especially seizure disorders, [7,9] and children and adolescents who have an associated long-term physical disability may be at a higher risk for psychological problems than children with other chronic conditions. [8] Dependence on others for daily activities may also contribute to their risk of psychosocial dysfunction. Specific health conditions may cause specific coping issues for children and adolescents, such as driving with epilepsy, issues involving sexuality for those with cystic fibrosis, or the social stigma of inflammatory bowel disease. However, children and adolescents with any type of chronic condition will have unique psychological stresses in addition to those faced by all children.

If neither the severity nor the type of condition adequately explains the risk of psychological problems, what family and child characteristics might predict this risk? Children's intelligence and temperament appear to contribute to their ability to adapt to the extra stresses of the illness. [13,14] Parents' self-esteem, mental health, social support network, and beliefs about health care all have an impact on the success of children's adaptation, [6,9,13,15] as does the cohesiveness, flexibility, and effectiveness of shared communication within the family. Current research efforts will likely identify additional factors associated with increased risks for psychological problems and factors that foster children's resilience. This information will provide pediatricians with more guidance regarding the prevention and identification of psychological difficulties when working with families whose children have chronic health conditions.

RECOMMENDATIONS FOR PEDIATRIC CARE

Primary care pediatricians have a central role in providing screening, preventive, and supportive services to children and adolescents with chronic health conditions and their families.

The usual pediatric model of assessing children's functioning in their family, in school, and with peers applies to those with a chronic health condition just as it does to all other children and adolescents. Pediatricians who take a comprehensive and family-based view of the broad clinical implications of childhood chronic conditions will recognize their critical role in diminishing the child's risk of psychological adjustment problems. Identifying children and families at risk for coping poorly with the stress of chronic health problems; assisting families to prevent psychological, social, and behavioral complications; and searching for early evidence of such problems should be part of regular pediatric care. Most of the stressful issues for families with children with chronic conditions can be anticipated and dealt with preventively through education and supportive counseling services provided appropriately by the pediatrician. It may be appropriate for some children and adolescents to be referred for mental health services.

Pediatricians should develop links with local schools and other agencies that provide support and services for children and families. Schools play a central role in the education and socialization of all children and often have resources that help with the prevention, identification, and management of psychosocial problems in their students, including those with health impairments. [16] Because increasing numbers of children with chronic conditions are in school from the age of 3 years, schools are a key resource in their long-term management. They frequently provide major assistance to families and to pediatricians in diminishing the psychosocial risks of chronic conditions.

Pediatricians can also help families by ensuring well-coordinated medical care and efficient and effective communication with the many professional providers of care involved with the family. They can help to ensure that families have access to local supportive networks for parents and for children. Also, pediatricians should provide appropriate information about the individual's illness and its management, recreational opportunities, and mechanisms to assist with the financial strain associated with chronic health conditions. [17]

The prevention of psychosocial complications of childhood chronic illness will be met best by a family- and community-centered approach in which the pediatrician assesses the skills and needs of the child and family, participates in planning and implementing comprehensive intervention programs, and supports families in the complex task of raising children and adolescents with chronic conditions. Committee on Early Childhood, Adoption, and Dependent Care

Quality Early Education and Child Care From Birth to Kindergarten

ABSTRACT. High-quality early education and child care for young children improves their health and promotes their development and learning. Early education includes all of a child's experiences at home, in child care, and in other preschool settings. Pediatricians have a role in promoting access to quality early education and child care beginning at birth for all children. The American Academy of Pediatrics affords pediatricians the opportunity to promote the educational and socioemotional needs of young children with other advocacy groups. ***Pediatrics*** **2005;115:187–191;** ***early education, child care, early care and education, preschool, social and emotional development, early brain development, kindergarten readiness, indicators of quality, role of the pediatrician.***

ABBREVIATION. AAP, American Academy of Pediatrics.

QUALITY MATTERS

All of a child's early experiences, whether at home, in child care, or in other preschool settings, are educational. At present, 60% to 70% of children younger than 6 years regularly attend some type of out-of-home child care or early childhood program.[1] The arrangements families make for their children can vary dramatically, including care by relatives; center-based care, including preschool early education programs; family child care provided in the caregiver's home; and care provided in the child's home by nannies or babysitters.[2] How a family chooses this care is influenced by family values, affordability, and availability. For many families, high-quality child care is not affordable, which results in compromises.[3–5]

The indicators of high-quality early education and child care have been studied and are available in many formats (Table 1; see also www.childcareaware.org).[6,7] When care is consistent, developmentally sound, and emotionally supportive, there is a positive effect on the child and the family.[8–21] Children exposed to a poor-quality environment, whether at home or outside the home, are less likely to be prepared for school demands and more likely to have their socioemotional development derailed.[8–21] The inadequate outcomes of children in poor-quality care often cannot be fully remedied in the formal structure of the K-12 educational system because of the need for noneducational services such as mental and behavioral health care. To focus only on the education of children beginning with kindergarten is to ignore the science of early development and deny the importance of early experiences.

Early brain and child development research unequivocally demonstrates that human development is powerfully affected by contextual surroundings and experiences.[21] A child's day-to-day experiences affect the structural and functional development of his or her brain, including intelligence and personality.[21] Experiences influence every child's development and learning, and these experiences can be positive or negative, with long-term consequences for the child, family, and society.[21] Research of high-quality, intensive early childhood education programs for low-income children confirm lasting positive effects such as greater school success, higher graduation rates, lower juvenile crime, decreased need for special education services later, and lower adolescent pregnancy rates.[8–20] Children who attend high-quality early childhood programs demonstrate better math and language skills, better cognition and social skills, better interpersonal relationships, and better behavioral self-regulation than do children in lower-quality care.[8–20] Inferior-quality care, at home or outside the home, can have harmful effects on language, social development, and school performance that are more difficult to ameliorate, especially for children in schools with fewer resources.[8–20] The positive effects from high-quality programs and the negative effects from poor-quality programs are magnified for children from disadvantaged situations or with special needs, and yet these children are least likely to have access to quality early education and child care.[12,13] The out-of-home care arrangements for children of parents who work nontraditional hours such as evenings, weekends, or holidays also compound the access problems. Many families have no quality child care options in their immediate communities.[4,5,22]

BARRIERS TO HIGH-QUALITY EDUCATION AND CHILD CARE

Families struggle to provide quality early experiences for their children. Having a stay-at-home parent does not automatically ensure a child's emotional well-being, social competence, and kindergarten readiness. Stay-at-home parents need access to sound advice and support. Community interven-

doi:10.1542/peds.2004-2213

tions can improve parenting and early experiences for young children, but they are not universally available, even to high-risk families.[23] Families that rely on child care need access to affordable, high-quality programs. However, most child care centers in the United States are rated poor to mediocre in quality, with almost half meeting less than minimal standards.[12–15,22] Efforts to improve the quality of early education and child care through federal, state, and local public policies address licensing and regulation, teacher or caregiver education and compensation, and adequate funding.

State licensing standards are important for health, safety, and teacher qualifications, but they set a minimum standard, typically considerably below the recommendations of health and safety experts.[6] National organizations such as the American Academy of Pediatrics (AAP), American Public Health Association, National Association for the Education of Young Children, Child Welfare League of America, and Zero to Three have developed standards and voluntary systems of accreditation that are often higher than state licensing regulations. These regulations include information about physical space, staffing ratios, and staff training and compensation.

Adequate compensation of early education providers promotes quality, not only to attract quality directors and teachers but also to decrease staff turnover.[4,5] An underpaid and high-turnover workforce impedes stability and quality of programs. The low level of compensation (approximately $16 000 per year for a child care provider) makes attracting and keeping quality teachers extremely difficult for programs.[1] Yet, developmental brain science studies show that young children, especially infants and toddlers, need stable, positive relationships with their caregivers.[21]

Public funding for quality programs is inadequate, yet studies demonstrate that well-focused investments in quality early education and child care provide high public return.[24] Federal, state, and local funding levels do not provide sufficient resources, even when combined with parent fees, to ensure adequate training of the early education workforce and do not provide reasonable compensation and career advancement opportunities.[4,5] In many states, the cost of early education and child care programs is about twice as expensive as paying for 1 year of tuition at a 4-year public college.[3] The federal government and some communities have addressed the funding problems via subsidies, although many families who are eligible are not served.[4,5] Head Start serves only approximately 60% of all eligible 3- to 4-year-old children, Early Head Start serves less than 5% of all eligible infants and families, and less than one fifth of all eligible families are receiving federal child care subsidies.[4,5] Other innovative strategies promoting access to quality care and education include state initiatives to promote formal education and improved compensation for child care providers, linkages with health care professionals, public-private funding partnerships, and extending K-12 down to universal preschool programs. The real barrier to high-quality programs is a lack of infrastructure supporting quality, regardless of setting, and the necessary funding to make this happen. This infrastructure has to address, on a statewide or commu-

TABLE 1. Indicators of High Quality[7]

State licensing and program accreditation	The requirements for licensing generally ensure basic health and safety of a program but not necessarily high quality; state licensing requirements can be found online at http://nrc.uchsc.edu
Staff-to-child ratio and group size	
For centers	
Birth to 12 mo	1:3 with groups ≤6
13–30 mo	1:4 with groups ≤8
31–35 mo	1:5 with groups ≤10
3 y	1:7 with groups ≤14
4 and 5 y	1:8 with groups ≤16
Family child care	If there are no children <2 y: 1 adult/6 children; when there is 1 child <2 y: 1 adult/4 children; and when there are 2 children <2 y (the maximum), no other children are recommended
Director and staff experience and training	College degrees in early childhood education
	Child development associate's credential
	Ongoing inservice training
	Parent's first-hand observations of care
	Low turnover rate
Infection Control	Hand-washing with soap and running water after diapering, before handling food, and when contaminated by body fluids
	Children wash hands after toileting and before eating
	Routinely cleaned facilities, toys, equipment
	Up-to-date immunizations of staff and children
Emergency procedures	Written policies
	All staff and children familiar with procedures
	Up-to-date parent contact lists
Injury prevention	Play equipment safe, including proper shock-absorbing materials under climbing toys
	Universal Back-to-Sleep practices
	Developmentally appropriate toys and equipment
	Toxins out of reach
	Safe administration of medicines

nity level, high-quality standards, compensation and training for teachers, tracking of availability of services for parental referral, and a reliable financing system that makes these programs available (full day/full year, etc) and affordable in a coordinated way.[4,5] This same systematic approach to the education and socioemotional health of children who are cared for by stay-at-home parents is also necessary.

STEPS TOWARD QUALITY EARLY EDUCATION AND CHILD CARE

Pediatricians have an important role in helping their patients have the highest-quality early experiences possible and also in helping their communities raise the level of quality of care for all young children. Families and communities look to pediatricians for counsel and support in all areas affecting children, including providing quality experiences for children in their early years. Pediatricians can influence families, teachers, and policy makers as partners in improving access to and quality of early childhood educational experiences. Better quality and access will be realized only when the public demands that resources are dedicated to early education and child care as they are for K-12 education. An AAP book titled *The Pediatrician's Role in Promoting Health and Safety in Child Care* offers a detailed blueprint for pediatricians to take steps to improve the quality of care available to patients and includes specific strategies, activities, and resources that can be used in everyday practice.

RECOMMENDATIONS

For each patient, pediatricians are encouraged to

1. Ask families what care arrangements they have made for their infants and young children and support their efforts. Also, ask parents whether they care for other people's children in their home.
2. Provide a true medical home[25] for patients and participate in the 3-way partnership with parents and child care providers or early educators. Remember that access to out-of-home arrangements for children with special health care needs is facilitated when the child's pediatrician and pediatric subspecialists are available to help the early education professionals and child care providers understand the needs of these patients. The 1999 AAP policy statement "The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP)" can be a resource.
3. Become familiar with the essential components of quality programs. As trusted family advisors responsible for the well-being of children, know the essential components of quality. The Early Education and Child Care Special Interest Group (www.healthychildcare.org) of the AAP Section on Community Pediatrics, which all AAP members and affiliate members are eligible to join, is available as a resource. The comprehensive book *Caring for Our Children*[6] lists the national standards for care of children in out-of-home settings.
4. Educate families about the benefits of quality programs that aid young children's safety and development. Using local information, direct families to the resources that will help them locate quality care and help develop strategies to make quality care affordable. This can be done using brochures (eg, *Choosing Child Care: What's Best for Your Family* by the AAP), checklists of quality, and referrals to the local child care resource and referral agency (www.childcareaware.org). A conversation with all families of young children will help promote quality through family education. Brochures and office displays can help facilitate this conversation in a busy practice. Remember to be a resource to families educating their young children at home. Zero to Three (www.zerotothree.org) is a tremendous resource for early brain and child development parent guides, and the AAP Literacy Promotion Technical Assistance program (www.aap.org/advocacy/literacypromo.htm) is a resource for pediatricians.

In their communities, pediatricians can

5. Educate policy makers about the science supporting the benefits from quality care and education and, conversely, the lost opportunities and setbacks that occur from poor-quality care. The resources listed at the end of this statement provide the background for conversations with policy makers about the benefits to children, families, and communities of investing in quality early education and child care. A specific place to start is working within the state to close the gaps between state regulations and the quality standards outlined in *Caring For Our Children*. Each AAP chapter has a legislative group that can help target these public policy makers with visits and letters. Nearly every AAP chapter also has a child care contact, a pediatrician who is familiar with the early education and child care needs in that chapter and has knowledge about local resources. Universal prekindergarten has been given recent focus in many states. Although this would be a tremendous beginning that pediatricians can support, we must continue to remind policy makers that prekindergarten is delivered in child care, schools, and other settings and that starting at 4 years of age will not reap the full benefits of quality early education and child care from birth. Also, conversations about quality should always emphasize that quality programs include parental involvement and strong socioemotional and other developmental elements in a safe, healthy environment.

At the national and state levels, pediatricians can

6. Work to improve funding and quality early experiences for children and facilitate more action by the national AAP and chapters. Recent national funding and systems to provide quality have been under attack in Congress, and most states' budget problems have led to decreased support for funding and access to quality care. Programs that have been shown to improve the quality of early experiences for young children, such as early home

visiting by nurses and early literacy family programs, need coordinated funding and universal implementation.

It will be only through collaborating with early childhood colleagues and combining the force of our sciences that we will successfully influence policy makers to foster the kind of holistic health we envision for all children.

abstract

FREE

The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention recommends reducing the number of doses from 5 to 4 of human diploid cell vaccine or purified chick embryo cell vaccine required for postexposure prophylaxis to prevent rabies in humans. The vaccine doses should be given on day 0 (first day of prophylaxis) and days 3, 7, and 14 after the first dose. For persons with immune suppression, the 5-dose regimen should continue to be used. Recommendations for the use of human rabies immunoglobulin remain unchanged. The American Academy of Pediatrics endorses these recommendations. *Pediatrics* 2011;127:785–787

INTRODUCTION

Rabies is a rapidly progressive encephalomyelitis with a very high case fatality rate. Approximately 55 000 people worldwide, nearly half of whom are children, die annually of rabies. Rabies is caused by RNA viruses in the family *Rhabdoviridae*, genus *lyssavirus*. In the Americas, only type 1 lyssavirus (rabies virus) circulates and is common in wild animals, particularly bats, coyotes, foxes, raccoons, and skunks, in the United States. Virus is transmitted in the saliva of rabid mammals after a bite or through contamination of an open wound or mucous membrane. The incubation period (1–3 months) is long enough to render immunization a highly effective strategy for postexposure prophylaxis (PEP). Approximately 20 000 to 30 000 persons receive PEP in the United States each year, and 1 to 3 cases of human rabies occurs annually. Between 2000 and 2007, 20 of 25 cases of human rabies reported in the United States were acquired within the United States. Among the 20 indigenously acquired cases, 17 were associated with bat rabies virus variants.

In the United States, animal rabies is common. Education of children to avoid contact with stray or wild animals is of primary importance. PEP is indicated once an exposure has occurred. PEP has never failed in the United States since the introduction of modern cell-derived vaccines in the 1970s. Keys to effective PEP have included prompt washing of the wound with copious amounts of soap and water, infiltration of human rabies immunoglobulin into and around the wound, and a 5-dose schedule of intramuscular vaccine administered over 28 days.

BACKGROUND AND RATIONALE

In 2007, when human rabies vaccine was in limited supply, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention formed a rabies work group to review rabies vac-

cine options and then accepted its recommendations to adopt a 4-dose vaccination regimen. The recommendation was published in *Morbidity and Mortality Weekly Report: Recommendations and Reports* on March 19, 2010.[1]

EVIDENCE TO SUPPORT THE RECOMMENDATION

A detailed review of the evidence in support of a reduced, 4-dose schedule for human PEP has been published.[2]

- The induction of rabies-neutralizing antibody is a surrogate for an adequate immune response to vaccination and was achieved in all subjects (~1000) by day 14, when the fourth dose of cell-derived rabies vaccine was given.
- From observational studies that included persons likely exposed to confirmed rabid animals and with imperfect adherence to the 5-dose vaccine schedule, the Rabies Working Group estimated that more than 300 persons in the United States received only 3 or 4 doses annually, and there were no resulting cases of human rabies. Although human PEP failures do occur rarely worldwide, no cases have been attributed to the lack of receipt of the fifth rabies vaccine dose on day 28.
- In animal models ranging from rodents to nonhuman primates, timely PEP was important, but the absolute number of vaccine doses did not contribute to significant differences in survival rates.
- Adverse reactions to the modern cell-derived rabies vaccines are uncommon in children and, theoretically, will be the same or less common with 1 less vaccine dose.
- Preliminary economic assessments indicate that there would be a $16 million cost savings to the United States health care system by using the reduced-dose schedule.

POLICY OR RECOMMENDATIONS

1. Unchanged: For unvaccinated persons, the combination of rabies immunoglobulin and rabies vaccine is recommended for both bite and nonbite exposures regardless of the time interval between exposure and initiation of PEP. If PEP has been initiated and results of appropriate laboratory testing (ie, the direct fluorescent antibody test) indicate that the animal that caused the exposure was not rabid, PEP may be discontinued.
2. New: A regimen of four 1-mL vaccine doses of human diploid cell vaccine (HDCV) or purified chick embryo cell vaccine (PCECV) should be administered intramuscularly to previously unvaccinated, immunocompetent persons (Table 1). The first dose of the 4-dose regimen should be administered as soon as possible after exposure. However, the vaccine regimen may be started weeks to months after the exposure if signs and symptoms of rabies are not present. The date of the first dose is considered to be day 0 of the PEP series. Doses should then be administered on days 3, 7, and 14 after the first vaccination.
3. Unchanged: For persons with immunosuppression (see "Immunocompromised Children" in *Red Book*[4]), rabies PEP should be administered by using the 5-dose vaccine regimen (ie, 1 dose of vaccine on

TABLE 1 Rabies Postexposure Prophylaxis (PEP) Schedule—United States, 2010

Vaccination Status	Intervention	Regimen*
Not previously vaccinated	Wound cleansing	All PEP should begin with immediate thorough cleansing of all wounds with soap and water. If available, a virucidal agent (eg, povidine-iodine solution) should be used to irrigate the wounds.
	Human rabies immune globulin (HRIG)	Administer 20 IU/kg body weight. If anatomically feasible, the full dose should be infiltrated around and into the wound(s), and any remaining volume should be administered at an anatomical site (intramuscular [IM]) distant from vaccine administration. Also, HRIG should not be administered in the same syringe as vaccine. Because RIG might partially suppress active production of rabies virus antibody, no more than the recommended dose should be administered.
	Vaccine	Human diploid cell vaccine (HDCV) or purified chick embryo cell vaccine (PCECV) 1.0 mL, IM (deltoid area†), 1 each on days 0,§ 3, 7 and 14.¶
Previously vaccinated**	Wound cleansing	All PEP should begin with immediate thorough cleansing of all wounds with soap and water. If available, a virucidal agent such as povidine-iodine solution should be used to irrigate the wounds.
	HRIG	HRIG should not be administered.
	Vaccine	HDCV or PCECV 1.0 mL, IM (deltoid area†), 1 each on days 0§ and 3.

Reprinted with permission from Rupprecht CE, Briggs D, Brown CM, et al; Centers for Disease Control and Prevention. *MMWR Recomm Rep.* 2010;59(RR-2):6.

* These regimens are applicable for persons in all age groups, including children.

† The deltoid area is the only acceptable site of vaccination for adults and older children. For younger children, the outer aspect of the thigh may be used. Vaccine should never be administered in the gluteal area.

§ Day 0 is the day dose 1 of vaccine is administered.

¶ For persons with immunosuppression, rabies PEP should be administered using all 5 doses of vaccine on days 0, 3, 7, 14, and 28.

** Any person with a history of pre-exposure vaccination with HDCV, PCECV, or rabies vaccine adsorbed (RVA); prior PEP with HDCV, PCECV or RVA; or previous vaccination with any other type of rabies vaccine and a documented history of antibody response to the prior vaccination.

days 0, 3, 7, 14, and 28). The immunosuppressed patient should be tested for rabies virus–neutralizing antibody with the rapid fluorescent focus inhibition test 1 to 2 weeks after the fifth dose of vaccine. If an acceptable antibody response is not detected, the patient should be managed in consultation with an expert in rabies. Commercial rabies virus antibody tests that are not approved by the US Food and Drug Administration are not appropriate for use as a substitute for the rapid fluorescent focus inhibition test.

4. Unchanged: Sites of intramuscular vaccination remain unchanged (deltoid area in adults; anterolateral aspect of thigh or deltoid in children). The gluteal area should not be used.
5. Unchanged: Recommendations for rabies immunoglobulin use and PEP of previously vaccinated persons have not changed.[3]
6. Unchanged: No routine testing to document seroconversion in healthy patients who have completed PEP is necessary.
7. Unchanged: Recommendations for management and reporting of vaccine adverse events have not changed.
8. Unchanged: Pregnancy and breastfeeding are not contraindications to PEP.

Committee on Pediatric Research

Race/Ethnicity, Gender, Socioeconomic Status—Research Exploring Their Effects on Child Health: A Subject Review

ABSTRACT. Data on research participants and populations frequently include race, ethnicity, and gender as categorical variables, with the assumption that these variables exert their effects through innate or genetically determined biologic mechanisms. There is a growing body of research that suggests, however, that these variables have strong social dimensions that influence health. Socioeconomic status, a complicated construct in its own right, interacts with and confounds analyses of race/ethnicity and gender. The Academy recommends that research studies include race/ethnicity, gender, and socioeconomic status as explanatory variables only when data relevant to the underlying social mechanisms have been collected and included in the analyses.

During recent decades, our understanding of the biological and psychosocial bases of diseases affecting individual children has markedly increased.[1,2] The capacity to apply newly derived information from molecular and genetic science toward preventive child health care will continue to grow in the coming years. Although biological research is necessary and valid, studies that do not address the importance of social determinants as fundamental causes or contributors to disease and unfulfilled potential limit the scope and impact of research conclusions.[3]

In the United States, data on research participants and populations frequently include race, ethnicity, and gender as categorical variables, with the assumption that these variables exert their effects through innate or genetically determined biologic mechanisms. There is a growing body of research that suggests, however, that these variables have strong—and in many areas predominantly—sociological and psychological dimensions. Because data are collected and research questions are formulated in ways that generally do not include the social as well as biological dimensions of these variables,[4,5] it is often difficult to disentangle the biological from the social dimensions. The purpose of this subject review is to highlight the interrelationships among factors such as race, ethnicity, and gender, viewed as social constructs, along with socioeconomic status, and to stimulate appropriate definition and analysis of these variables within any study that proposes mechanisms of disease associated with them.

RACE AND ETHNICITY

It is standard practice to describe participants and populations in terms of "race" or "ethnicity." For example, the decennial census has classified respondents according to the 1977 Office of Management and Budget Directive 15, which includes 4 racial categories (American Indian or Alaskan Native, Asian or Pacific Islander, Black, and White) and 2 ethnic categories (Hispanic Origin and not of Hispanic Origin). The recent revision of this Directive[6] has expanded these categories to 5, by separating Asian from Pacific Islander and expanding the latter to "Native Hawaiian or other Pacific Islander," but the existence of this small number of categories limits investigators to use only those categories to frame and analyze questions. The Revised Directive 15 rejected the use of a "multiracial" category, but does recommend that the 2000 Census allow respondents to check more than 1 category.

Although race historically has been viewed as a biological construct, it is now known to be more accurately characterized as a social category that has changed over time and varies across societies and cultures.[7] Racial disparities in health generally do not reflect biologically determined differences in the genome or physiology.[8] Indeed, genetic differences between racial groups are small compared with genetic differences within groups, so racial differences in diseases are, to a significant degree, currently unexplained.[9] It is possible that racial prejudice (both individual and institutional) as a social stress on groups of children and families can influence health behaviors, such as eating habits, activity levels, and substance use and abuse that might place individual children at increased risk for both short-term and long-term health impairment and disease.[10–12] In addition to effects on behavior, racial prejudice may influence access to and the quality of health services.[11–13] Similarly, difficulties in definition and measurement, heterogeneities of populations, and ethnocentric interpretations of research data[8] make "ethnicity" an imprecise construct by which to attribute causal relationships. Given that race and ethnicity are similar in their social origins, that is, determined predominantly by the relationships among groups who define themselves or define others, the term race/ethnicity is becoming more widely used.

GENDER

Sex and gender are often used interchangeably, but the former is a biologic characteristic, defined by genetic and anatomic features, whereas the latter is a

social characteristic, determined by culturally defined roles and behaviors. Analogous to race/ethnicity, the development of gender is a function of relationships. Ironically, the genetic, physiologic, and behavioral differences between men and women have historically been deemphasized, if not ignored, in research that has extrapolated conclusions based on male populations to women. In recent years, recognition of the importance of considering differences between men and women as a salient independent variable in research led the National Institutes of Health to include women as participants for special consideration in clinical research grant applications, but the focus is primarily on the biological variable, that is, sex, rather than the social variable, gender.[14]

Inclusion of both men and women as participants in research studies is certainly a first step in understanding sex and gender differences in health and disease. However, given the health correlates of the differences in the social roles and behaviors of men and women, any differences found are not inevitable expressions of the biological factor. For example, the increased risk of anorexia and bulimia in girls likely reflects perceived social pressures to adhere to culturally prescribed norms for body shape and size. Furthermore, socially defined gender roles, expectations, and behavior can vary across both time and culture, as well as across subgroups of individuals, defined socially by race/ethnicity and socioeconomic status. For example, the social and psychological pressures experienced by an African-American woman might be very different from those experienced by a white woman, with these pressures having differential impact on the long-term trajectory of disease.[15]

SOCIOECONOMIC STATUS

Analysis of the relationship among biological and social variables is complicated, however, by the difficulty in operationalizing socioeconomic status, a complex concept consisting of 2 aspects, both of which may exert influences on health directly or through associated behaviors. One aspect includes resources, such as education, income, and wealth and the other includes status or rank, a function of relative positions in a hierarchy, such as social class.[16] A recent National Institutes of Health conference examined measures of socioeconomic status and proposed ways to incorporate a variety of these measures into health surveillance and research.[17]

Demonstrated racial/ethnic and gender "effects" may be intricately related to socioeconomic factors, because race/ethnicity interacts with and is confounded by social class or socioeconomic status. For example, environmental pollution may be more intense in impoverished areas and may even be sited in those areas because of discrimination based on race/ethnicity or class.[18] Consequently, it is difficult to disentangle the adverse consequences of that pollution from the effects of discrimination. Although most studies of such confounding and/or interaction have focused on adults, the need for inquiries into such factors affecting child health is equally strong. Little is known about the way that the relationships among these social factors influence the health of children or their effects on the trajectory of the development of adult disease.

Two domains of the relationship between socioeconomic status and health are particularly active areas of research, possibly shedding light on the complexity of the mechanisms whereby this multidimensional variable influences health. The first domain deals with the relationship between the extent of discrepancies in socioeconomic status and health. Numerous studies have documented the relationship between socioeconomic status and health.[19] Despite advances in quality and access to health care services, it is noteworthy that the discrepancy in health status between social classes has persisted over time, even though the specific diseases that produce morbidity and mortality have changed.[20] Furthermore, standard measures of health correlate with the extent of income discrepancy between rich and poor, and the extent of income inequality appears to explain more of the variation in health than is explained by other socioeconomic factors, even the absolute level of income.[20–22] Across industrialized countries, the greater the discrepancy in income distributions, the worse the health status of the entire population.[20] Data across individual states within the United States demonstrate a similar relationship.[21,22]

The second domain of the relationship between socioeconomic status and health explores the relationship between childhood socioeconomic conditions and adult health. In Finland, for example, the childhood socioeconomic status of adult men correlated more closely with ischemic heart disease during middle age than did their adult socioeconomic status.[23] Further research is needed to clarify how the socioeconomic status of children affects both their current and future health status.[24]

CONCLUSION

The American Academy of Pediatrics acknowledges that race/ethnicity, gender, and socioeconomic status can influence child health through social mechanisms. The Academy recommends that child health studies include these critical variables to improve their definitions and enhance our understanding of the effects that relationships (confounding and interactive) among these variables may have on research findings. It is no longer sufficient to use these categories as explanatory. If data relevant to the underlying social mechanisms have not been collected and are otherwise unavailable, researchers should discuss this as a limitation of the possible conclusions of the presented research. The Academy concurs with the conclusions of a recent workshop sponsored by the Centers for Disease Control and Prevention/Agency of Toxic Substances and Disease Registry. Considering the use of race and ethnicity in public health surveillance,[25] the workshop participants concluded that absent careful definitions and analysis, investigators and policymakers may draw erroneous conclusions about race/ethnicity as biologic contributors to illness. Similar errors may result from the failure to consider the social dimensions of gender.

The American Academy of Pediatrics believes that race/ethnicity, gender, and socioeconomic status are likely to emerge as important mediators of childhood health, as well as predictors of adult health status. The Academy recommends that pediatric investigators, in collaboration with social scientists, should develop and apply research methodologies in pediatric research that will result in careful definitions of, analysis of interactions among, and, ultimately, documentation of the effects of these variables on child health. Only then can effective preventive intervention strategies be developed and implemented during childhood to improve the health of our children and the adults into which they will grow.

Race/Ethnicity, Gender, Socioeconomic Status—Research Exploring Their Effects on Child Health: A Subject Review

ABSTRACT. Data on research participants and populations frequently include race, ethnicity, and gender as categorical variables, with the assumption that these variables exert their effects through innate or genetically determined biologic mechanisms. There is a growing body of research that suggests, however, that these variables have strong social dimensions that influence health. Socioeconomic status, a complicated construct in its own right, interacts with and confounds analyses of race/ethnicity and gender. The Academy recommends that research studies include race/ethnicity, gender, and socioeconomic status as explanatory variables only when data relevant to the underlying social mechanisms have been collected and included in the analyses.

During recent decades, our understanding of the biological and psychosocial bases of diseases affecting individual children has markedly increased.[1,2] The capacity to apply newly derived information from molecular and genetic science toward preventive child health care will continue to grow in the coming years. Although biological research is necessary and valid, studies that do not address the importance of social determinants as fundamental causes or contributors to disease and unfulfilled potential limit the scope and impact of research conclusions.[3]

In the United States, data on research participants and populations frequently include race, ethnicity, and gender as categorical variables, with the assumption that these variables exert their effects through innate or genetically determined biologic mechanisms. There is a growing body of research that suggests, however, that these variables have strong—and in many areas predominantly—sociological and psychological dimensions. Because data are collected and research questions are formulated in ways that generally do not include the social as well as biological dimensions of these variables,[4,5] it is often difficult to disentangle the biological from the social dimensions. The purpose of this subject review is to highlight the interrelationships among factors such as race, ethnicity, and gender, viewed as social constructs, along with socioeconomic status, and to stimulate appropriate definition and analysis of these variables within any study that proposes mechanisms of disease associated with them.

RACE AND ETHNICITY

It is standard practice to describe participants and populations in terms of "race" or "ethnicity." For example, the decennial census has classified respondents according to the 1977 Office of Management and Budget Directive 15, which includes 4 racial categories (American Indian or Alaskan Native, Asian or Pacific Islander, Black, and White) and 2 ethnic categories (Hispanic Origin and not of Hispanic Origin). The recent revision of this Directive[6] has expanded these categories to 5, by separating Asian from Pacific Islander and expanding the latter to "Native Hawaiian or other Pacific Islander," but the existence of this small number of categories limits investigators to use only those categories to frame and analyze questions. The Revised Directive 15 rejected the use of a "multiracial" category, but does recommend that the 2000 Census allow respondents to check more than 1 category.

Although race historically has been viewed as a biological construct, it is now known to be more accurately characterized as a social category that has changed over time and varies across societies and cultures.[7] Racial disparities in health generally do not reflect biologically determined differences in the genome or physiology.[8] Indeed, genetic differences between racial groups are small compared with genetic differences within groups, so racial differences in diseases are, to a significant degree, currently unexplained.[9] It is possible that racial prejudice (both individual and institutional) as a social stress on groups of children and families can influence health behaviors, such as eating habits, activity levels, and substance use and abuse that might place individual children at increased risk for both short-term and long-term health impairment and disease.[10–12] In addition to effects on behavior, racial prejudice may influence access to and the quality of health services.[11–13] Similarly, difficulties in definition and measurement, heterogeneities of populations, and ethnocentric interpretations of research data[8] make "ethnicity" an imprecise construct by which to attribute causal relationships. Given that race and ethnicity are similar in their social origins, that is, determined predominantly by the relationships among groups who define themselves or define others, the term race/ethnicity is becoming more widely used.

GENDER

Sex and gender are often used interchangeably, but the former is a biologic characteristic, defined by genetic and anatomic features, whereas the latter is a

social characteristic, determined by culturally defined roles and behaviors. Analogous to race/ethnicity, the development of gender is a function of relationships. Ironically, the genetic, physiologic, and behavioral differences between men and women have historically been deemphasized, if not ignored, in research that has extrapolated conclusions based on male populations to women. In recent years, recognition of the importance of considering differences between men and women as a salient independent variable in research led the National Institutes of Health to include women as participants for special consideration in clinical research grant applications, but the focus is primarily on the biological variable, that is, sex, rather than the social variable, gender.[14]

Inclusion of both men and women as participants in research studies is certainly a first step in understanding sex and gender differences in health and disease. However, given the health correlates of the differences in the social roles and behaviors of men and women, any differences found are not inevitable expressions of the biological factor. For example, the increased risk of anorexia and bulimia in girls likely reflects perceived social pressures to adhere to culturally prescribed norms for body shape and size. Furthermore, socially defined gender roles, expectations, and behavior can vary across both time and culture, as well as across subgroups of individuals, defined socially by race/ethnicity and socioeconomic status. For example, the social and psychological pressures experienced by an African-American woman might be very different from those experienced by a white woman, with these pressures having differential impact on the long-term trajectory of disease.[15]

SOCIOECONOMIC STATUS

Analysis of the relationship among biological and social variables is complicated, however, by the difficulty in operationalizing socioeconomic status, a complex concept consisting of 2 aspects, both of which may exert influences on health directly or through associated behaviors. One aspect includes resources, such as education, income, and wealth and the other includes status or rank, a function of relative positions in a hierarchy, such as social class.[16] A recent National Institutes of Health conference examined measures of socioeconomic status and proposed ways to incorporate a variety of these measures into health surveillance and research.[17]

Demonstrated racial/ethnic and gender "effects" may be intricately related to socioeconomic factors, because race/ethnicity interacts with and is confounded by social class or socioeconomic status. For example, environmental pollution may be more intense in impoverished areas and may even be sited in those areas because of discrimination based on race/ethnicity or class.[18] Consequently, it is difficult to disentangle the adverse consequences of that pollution from the effects of discrimination. Although most studies of such confounding and/or interaction have focused on adults, the need for inquiries into such factors affecting child health is equally strong. Little is known about the way that the relationships among these social factors influence the health of children or their effects on the trajectory of the development of adult disease.

Two domains of the relationship between socioeconomic status and health are particularly active areas of research, possibly shedding light on the complexity of the mechanisms whereby this multidimensional variable influences health. The first domain deals with the relationship between the extent of discrepancies in socioeconomic status and health. Numerous studies have documented the relationship between socioeconomic status and health.[19] Despite advances in quality and access to health care services, it is noteworthy that the discrepancy in health status between social classes has persisted over time, even though the specific diseases that produce morbidity and mortality have changed.[20] Furthermore, standard measures of health correlate with the extent of income discrepancy between rich and poor, and the extent of income inequality appears to explain more of the variation in health than is explained by other socioeconomic factors, even the absolute level of income.[20–22] Across industrialized countries, the greater the discrepancy in income distributions, the worse the health status of the entire population.[20] Data across individual states within the United States demonstrate a similar relationship.[21,22]

The second domain of the relationship between socioeconomic status and health explores the relationship between childhood socioeconomic conditions and adult health. In Finland, for example, the childhood socioeconomic status of adult men correlated more closely with ischemic heart disease during middle age than did their adult socioeconomic status.[23] Further research is needed to clarify how the socioeconomic status of children affects both their current and future health status.[24]

CONCLUSION

The American Academy of Pediatrics acknowledges that race/ethnicity, gender, and socioeconomic status can influence child health through social mechanisms. The Academy recommends that child health studies include these critical variables to improve their definitions and enhance our understanding of the effects that relationships (confounding and interactive) among these variables may have on research findings. It is no longer sufficient to use these categories as explanatory. If data relevant to the underlying social mechanisms have not been collected and are otherwise unavailable, researchers should discuss this as a limitation of the possible conclusions of the presented research. The Academy concurs with the conclusions of a recent workshop sponsored by the Centers for Disease Control and Prevention/Agency of Toxic Substances and Disease Registry. Considering the use of race and ethnicity in public health surveillance,[25] the workshop participants concluded that absent careful definitions and analysis, investigators and policymakers may draw erroneous conclusions about race/ethnicity as biologic contributors to illness. Similar errors may result from the failure to consider the social dimensions of gender.

The American Academy of Pediatrics believes that race/ethnicity, gender, and socioeconomic status are likely to emerge as important mediators of childhood health, as well as predictors of adult health status. The Academy recommends that pediatric investigators, in collaboration with social scientists, should develop and apply research methodologies in pediatric research that will result in careful definitions of, analysis of interactions among, and, ultimately, documentation of the effects of these variables on child health. Only then can effective preventive intervention strategies be developed and implemented during childhood to improve the health of our children and the adults into which they will grow.

abstract

OBJECTIVE: This technical report reviews and synthesizes the published literature on racial/ethnic disparities in children's health and health care.

METHODS: A systematic review of the literature was conducted for articles published between 1950 and March 2007. Inclusion criteria were peer-reviewed, original research articles in English on racial/ethnic disparities in the health and health care of US children. Search terms used included "child," "disparities," and the Index Medicus terms for each racial/ethnic minority group.

RESULTS: Of 781 articles initially reviewed, 111 met inclusion criteria and constituted the final database. Review of the literature revealed that racial/ethnic disparities in children's health and health care are quite extensive, pervasive, and persistent. Disparities were noted across the spectrum of health and health care, including in mortality rates, access to care and use of services, prevention and population health, health status, adolescent health, chronic diseases, special health care needs, quality of care, and organ transplantation. Mortality-rate disparities were noted for children in all 4 major US racial/ethnic minority groups, including substantially greater risks than white children of all-cause mortality; death from drowning, from acute lymphoblastic leukemia, and after congenital heart defect surgery; and an earlier median age at death for those with Down syndrome and congenital heart defects. Certain methodologic flaws were commonly observed among excluded studies, including failure to evaluate children separately from adults (22%), combining all nonwhite children into 1 group (9%), and failure to provide a white comparison group (8%). Among studies in the final database, 22% did not perform multivariable or stratified analyses to ensure that disparities persisted after adjustment for potential confounders.

CONCLUSIONS: Racial/ethnic disparities in children's health and health care are extensive, pervasive, and persistent, and occur across the spectrum of health and health care. Methodologic flaws were identified in how such disparities are sometimes documented and analyzed. Optimal health and health care for all children will require recognition of disparities as pervasive problems, methodologically sound disparities studies, and rigorous evaluation of disparities interventions. *Pediatrics* 2010;125:e979–e1020

INTRODUCTION

Racial/ethnic disparities in health and health care recently have received considerable attention. The Agency for Healthcare Research and Quality has issued an annual national health care disparities report since 2003.[1,2] Reduction and elimination of disparities is one of the major goals of *Healthy People 2010*,[3] part of the strategic plan of the Eunice Kennedy Shriver National Institute of Child Health and Human Development,[4] and part of the strategic imperatives of the Centers for Disease Control and Prevention (CDC).[5] A separate National Institutes of Health center devoted to minority health and health disparities (the National Center for Minority Health and Health Disparities) was founded in 2000.[6] The Institute of Medicine released a landmark monograph on disparities,[7] and a federal bipartisan bill targeting health care disparities recently was introduced.[8]

Little attention has been paid, however, to racial/ethnic disparities in the health and health care of children. For example, only 5 of 103 studies in the Institute of Medicine's extensive review of the literature on health care disparities specifically addressed racial/ethnic disparities in children's health care.[7] The purpose of this technical report, therefore, is to review and synthesize the published literature on racial/ethnic disparities in children's health and health care. The report begins with definitions of key terms and an overview of sociodemographic trends in minority children. Specific minority groups, the importance of racial/ethnic subgroups, studies of interventions to reduce racial/ethnic disparities, and methodologic issues are then reviewed.

DEFINITIONS

"Race/ethnicity" is defined as the child's racial or ethnic group (including "multiracial"), as designated by the parent and/or child. "Minority" will be the term used for children of nonwhite race/ethnicity. Although multiple definitions have been proposed for the term "disparities," the Health Resources and Services Administration definition of disparities was used, which defines disparities as "population-specific differences in the presence of disease, health outcomes, or access to care."[9]

METHODS

Only statistically significant disparities are reported herein (ie, those with either a *P* value of less than .05 or 95% confidence intervals [CIs] that are nonoverlapping with non-Latino white children). The only exception to this rule was inclusion of certain crude outcome rates in large population-based samples in which the differences were considered quantitatively or clinically significant (ie, when there was at least a 50% difference in rates between a specific racial/ethnic minority group and the white population). Only studies that examined racial/ethnic disparities in the context of comparisons to white children were included in the literature review. Notation was made of whether disparities included adjustment for relevant covariates. When appropriate data were available, secular trends for specific disparities are described. Unless otherwise noted, the reference group for any racial/ethnic disparity is non-Latino white children.

LITERATURE SEARCH

The scope of published literature on racial/ethnic disparities is broad. In addition, although racial/ethnic disparities in neonatal and infant mortality rates[10] and dental care[11] have been fairly well described, relatively little has been published on racial/ethnic disparities in children and adolescents. The terms that have been used to describe disparities also have been neither standardized nor consistent. As a consequence, the literature search was limited to only those studies that specifically examined racial/ethnic disparities for US children and adolescents, to ensure a focus on disparities and a body of literature in urgent need of a systematic review. Thus, articles on racial/ethnic disparities in neonatal and infant mortality and dental care were excluded, because disparities in these domains have comparatively been more well described, and articles on pediatric workforce diversity, an area that was addressed in a recent American Academy of Pediatrics (AAP) policy statement,[12] also were excluded.

The database used for the literature search was Ovid Medline; the search encompassed the years 1950 through the first week of March 2007. The initial search strategy included the terms "child" and "disparities" (both as medical subject heading terms and key words), which yielded 666 citations. To ensure that no relevant citations were missed, individual searches also were performed by using "disparities," "child," and Index Medicus terms for each racial/ethnic minority group, which yielded the following children's disparities references: "African continental ancestry group," $n = 35$; "Asian continental ancestry group," $n = 5$; "Pacific Islanders," $n = 2$; "Indians, North American," $n = 17$; "multiracial," $n = 1$; and "Hispanic Americans," $n = 55$. The initial total of all citations was, therefore, 781 articles. To ensure the consistency and reproducibility of this literature search, additional secondary references were not included from the citation lists of the primary articles included in the database.

Abstracts for all 781 articles were reviewed. Because the focus of the literature review was original, peer-reviewed articles in English on racial/ethnic disparities in the health and

health care of US children, review articles, editorials, commentaries, perspective pieces, theoretical or conceptual pieces, transcripts of speeches, letters to the editor, dental care articles, articles that addressed adults or the elderly, articles without analysis of racial/ethnic disparities, articles on neonatal or infant mortality issues, articles on workforce diversity, articles that did not examine disparities in the health of US children, and duplicate citations were excluded. Application of these exclusion criteria yielded 227 articles. The full print versions of these remaining 227 articles were reviewed, and reapplication of the exclusion criteria yielded a final database of 111 articles, 2 of which examined interventions aimed at reducing racial/ethnic disparities (and were considered separately).

SOCIODEMOGRAPHICS OF MINORITY CHILDREN IN THE UNITED STATES

The United States is experiencing a demographic surge in minority children (Fig 1). There are 31.4 million children (younger than 18 years old) of nonwhite race/ethnicity in the United States,[13] comprising 43% of children, and representing an 11% increase since 2000[14] and a 58% increase since 1990.[15] Since 2000, minorities have represented more than half of the population of the nation's 100 largest cities, and 42 of the 100 largest US cities are "minority majority" (defined as populations in which racial/ethnic minorities outnumber the white population).[16] In California, the largest state in the nation, minorities have outnumbered whites since 2000, and currently represent 57% of the state's population.[17,18] Conservative estimates indicate that minorities will constitute half of US children by 2040.[19]

Latinos are the largest and fastest-growing minority group of US children (Fig 1), representing 20% of children in America (equivalent to 15 million).[13,20] African Americans (AAs) are the second-largest minority group of US children, representing 15% of children in America (equivalent to 10.9 million)[13]; between 1990 and 2006, their population proportion slightly decreased. Asians/Pacific Islanders (APIs) are the third-largest minority group of US children, representing 4% of children in America (equivalent to 3 million)[13]; between 2000 and 2006, their population proportion grew by 14% (1990 US Census data are not available on API children). American Indians/Alaska Natives (AIs/ANs) represent 1% of children in America (equivalent to ~661 000)[13]; between 1990 and 2006, their population proportion decreased by 18%. The number of multiracial children in the United States (ie, self-designated by the caregiver as belonging to 2 or more races) in 2006 was 2.9 million, representing 4% of the US population of children,[13] a proportion that has not changed since 1990.

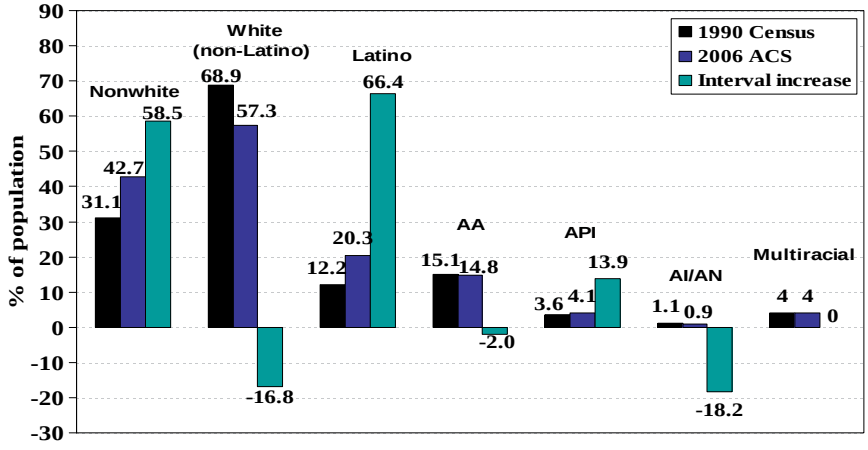

FIGURE 1

Growth of racial/ethnic minority population of US children between 1990 and 2006. ACS indicates American Community Survey. Data were unavailable for APIs for the 1990 US Census, so data depicted are from the 2000 US Census.

HEALTH AND HEALTH CARE DISPARITIES IN SPECIFIC RACIAL/ETHNIC GROUPS OF CHILDREN

African Americans

The vast majority of articles (94 of 109 [86%]) addressed disparities in AA children (Table 1).

Mortality

Eight articles documented AA/white disparities in mortality rates. Overall childhood mortality rates were found to be consistently higher for AA children; national data for a 43-year period revealed marked crude mortality-rate disparities in young children 1 to 4 years of age (twice that of white children) and older children 5 to 14 years of age and increases in the mortality-disparity ratio in the most recent 10-year period. Two other studies that adjusted for relevant covariates documented significantly higher mortality rates for AA children versus white children in the Detroit tri-county area for boys and older girls (10–19 years old) and among children without congenital anomalies in the state of Michigan. AA children also experience higher risks of death from drowning in a swimming pool, especially in public pools, with the drowning rate in hotel/motel pools disproportionately higher. Significant disease-specific mortality-rate disparities were identified for acute lymphoblastic leukemia (ALL), median age at death for Down syn-

TABLE 1 Disparities in the Health and Health Care of AA Children

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Access to care				
Lower accessibility to pediatric primary care providers Neighborhood AA race more strongly associated with access to pediatric primary care providers than neighborhood income	Analysis of spatial accessibility to pediatric primary care providers in Washington, DC	US Census data on all children and American Medical Association/American Osteopathic Association data on concentration of all pediatric primary care providers in Washington, DC	Not adjusted for covariates	27
Double the adjusted odds of having no usual source of care Double the adjusted odds of no health professional/doctor visit in past year	Analysis of household component of 1996 and 2000 MEPS	AA: $n = 2189$; Latino: $n = 4091$; Asian: $n = 325$; white: $n = 6362$	Adjusted for 8 covariates; double the adjusted odds of dissatisfaction with quality of care in 1996 but not 2000	28
Higher adjusted odds of appendicitis rupture	Cross-sectional analysis of full-year samples of hospital discharge records for acute appendicitis from California and New York children 4–18 y of age	California: AA, $n = 297$; Latino, $n = 4304$; API, $n = 459$; white, $n = 4017$; New York: AA, $n = 342$; Latino, $n = 444$; API, $n = 80$; white, $n = 2379$	Adjusted for 7 covariates	29
Higher adjusted proportion in fair or poor health among new SCHIP enrollees in Florida Lower adjusted proportion had usual source of care before SCHIP among new SCHIP enrollees in New York	Analysis of CHIRI data on new SCHIP enrollees in 4 states (<18 y old in Alabama, Kansas, and New York, and 11.5–17.9 y old in Florida)	Total sample: $n = 8975$[b]	Adjusted for 10 covariates	30
Before enrollment in SCHIP Lower adjusted rate of having usual source of care Higher adjusted rate of having unmet needs for health care	Interviews of parents in New York State at the time of SCHIP enrollment of their child (baseline) and 1 y after enrollment	Total sample: $N = 2644$[b] (baseline) and $N = 2290$ (1-y follow-up)	Adjusted for 12 covariates; 1 unadjusted quality-of-care disparity was noted but not adjusted for	31
Greater adjusted odds of not being referred to specialist by health care provider	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	32
Adolescents				
Higher likelihood of fair to poor health among adolescents recently enrolled in SCHIP Less likely to use doctor's offices as their usual source of care among adolescents recently enrolled in SCHIP	Analysis of CHIRI telephone interview data of adolescents newly enrolled in SCHIP in Florida and New York (and their parents)	Total sample: $N = 2036$[b]	No multivariable adjustments performed	33
Significantly lower adjusted odds of use of substance abuse services among adolescents Significantly older age at first use of substance abuse services AA girls at particular risk of underuse of substance abuse services, with only 1 in 25 AA female teenaged substance abusers accessing substance abuse services	Analysis of 5 y of Tennessee Medicaid (TennCare) enrollment, encounter, and claims data for substance abuse services use by adolescents 12–17 y of age	AA: $n = 60\,104$; white: $n = 110\,552$	Adjusted for 4 covariates	34
Female adolescents: higher risk of skipping breakfast, obesity, lacking health insurance, needing but not getting medical care, any sexually transmitted disease, perpetrating violence, and being a victim of violence	Analysis of Add Health (waves 1 and 2), a nationally representative school-based study of youths in grades 7–12, with follow-up into adulthood	AA: $n = 3038$; Latino: $n = 2340$; API: $n = 1021$; AI/AN: $n = 136$; white: $n = 7728$	Prevalence in published tables was not adjusted; authors stated that adjustments for income and parental education had minimal influence on findings; significant disparities were identified by using 95% CIs that did not overlap with measure for white children; no formal statistical evaluation of disparities were provided in article	35

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Male adolescents: higher risk of perpetrating violence and being victim of violence				
Live birth rate for 15- to 17 y-old girls was >3 times higher	1990–1998 natality files from the National Vital Statistics system	Not provided	Expressed as rates per 1000; rates were not adjusted for any covariates	36
Birth rate for 15- to 17 y-old girls was 4–5 times higher AA/white disparity ratio worsened by 23% between 1990 and 1998	Analysis of vital records from the Illinois and Chicago departments of public health	Not provided	Not adjusted for covariates	37
Birth rate for 15- to 19-y-old girls more than twice as high	Birth certificate data reported to CDC National Center for Health Statistics	Not provided	Not adjusted for covariates; no *P* values or 95% CIs	38
Greater adjusted odds of alcohol testing among female adolescents admitted to EDs for traumatic injury	Analysis of data from the National Trauma Data Bank (includes 64 US institutions) on adolescents 12–17 y of age admitted to EDs with traumatic injury	AA: $n = 1760$; Latino: $n = 396$; white: $n = 5584$	Adjusted for 7 covariates	39
Asthma and allergies				
Highest asthma prevalence of any racial/ethnic group (26% higher vs white children) Highest asthma-attack prevalence of any racial/ethnic group (44% higher vs white children) Disparity vs white children has widened progressively over 16-y period, from 15% higher prevalence to 26% higher prevalence vs white children Higher asthma office-visit rate Triple the rate of asthma ED visits Triple the rate of hospital outpatient visits for asthma Ambulatory asthma-visit rate (all outpatient visit types) 1.6 times higher Hospitalization rate 3.6 times higher Hospitalization rate increased at more than double the rate of white children Highest asthma mortality rate of any racial/ethnic group, 4.6 times higher than that of white children Asthma mortality rate increased over 19 y (vs remained the same in white children)	Trends in asthma over time for children 0–17 y of age using data from 5 National Center for Health Statistics sources: National Health Interview Survey, National Ambulatory Medical Care Survey, National Hospital Ambulatory Medical Care Survey, National Hospital Discharge Survey, and mortality component of the National Vital Statistics system	Not provided	No statistical comparisons performed or 95% CIs provided; only unadjusted rates were presented	40
Greater likelihood of current asthma Greater likelihood of ED visit for asthma in past year	National database (NHIS)	AA: $n = 14\,487$; white: $n = 49\,042$	Adjusted for 8 covariates	41
Greater adjusted odds (adjusted odds ratio, 2.5 [95% CI: 1.3–4.8]) of physician-diagnosed asthma, even after adjustment for family income	Rhode Island Health Interview Survey	AA: $n = 142$; Latino: $n = 353$; white: $n = 1274$	Adjusted for 7 covariates	42

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Higher adjusted odds of asthma Lower adjusted odds of ambulatory visits Lower adjusted odds of prescriptions filled	Secondary analysis of 2 y of MEPS data on children 2–18 y of age	Total 1996 MEPS sample size: $N = 3955$; total 1997 MEPS sample size: $N = 5933$	Adjusted for 6–8 covariates; in 1 survey year but not the other, significantly lower adjusted odds of ED visits and internalizing and externalizing behavioral conditions	43
Higher asthma mortality rate, both for underlying cause and any mention	Analysis of 12 y of data from the multiple cause-of-death files from the National Center for Health Statistics	Total sample: $N = 4091$[a,b]	Unadjusted rates, not adjusted for SES or insurance coverage; asthma mortality rate also higher than that of Latino and API children	44
Higher adjusted odds of an asthma ED visit or hospitalization	Analysis of data from parent-response questionnaires administered in 26 randomly selected New York City public elementary schools	Total sample: $N = 5250$[b]	Adjusted for 4 covariates	45
Higher diagnosed asthma prevalence (18%) Higher total potential asthma burden (diagnosed plus possible but undiagnosed asthma)	Cross-sectional analysis of parent-report questionnaire data from 14 low-income, diverse Chicago public elementary schools	AA: $n = 2938$; Latino: $n = 6002$; white: $n = 1560$	Not adjusted for covariates	46
More than double the adjusted odds of having a current asthma diagnosis	Analysis of NHANES III on children 1–16 y of age	Total sample: $N = 11\,181$[b]	Adjusted for 14 covariates; sample size of those with asthma was not provided	47
Worse asthma physical health scores Lower adjusted odds of daily anti-inflammatory use for asthma	Cross-sectional study using parental telephone interviews and electronic records for Medicaid-insured children 2–16 y of age with asthma in 5 managed care organizations in California, Washington, and Massachusetts	AA: $n = 636$; Latino: $n = 313$; white: $n = 512$	Adjusted for SES, health status, age, gender, and other sociodemographic variables	48
Higher adjusted odds of cockroach allergen sensitivity Higher adjusted odds of dust mite allergen sensitivity Higher adjusted odds of mold allergen sensitivity	Cross-sectional analysis of children 6–16 y of age who participated in allergen testing in the NHANES III	AA: $n = 1502$; Mexican American: $n = 1546$; white: $n = 1116$	Adjusted for 8 covariates	49
Higher adjusted odds of asthma Higher adjusted odds of need for urgent medical care for asthma in past 12 mo	Analysis of data from the Los Angeles County Health Survey on children <18 y of age	AA: $n = 566$; Latino: $n = 3675$; API: $n = 361$; white: $n = 1278$	Adjusted for 8 covariates	50
Lower adjusted odds of use of β_2-agonists Lower adjusted odds of use of inhaled steroids	Analysis of data from the Childhood Asthma Severity Study, which used a 12-mo, retrospective, parent-reported questionnaire on asthma in a community sample of children <13 y of age and residing in Connecticut and Massachusetts	AA: $n = 139$; Latino: $n = 255$; white: $n = 549$	Adjusted for 9 covariates	51
Higher adjusted prevalence of asthma overall Among children with family income less than half the federal poverty level, higher prevalence of asthma	Analysis of NHIS data on children 0–17 y of age		Adjusted for 8 covariates; stratified analyses suggested disparities only for poorest children, but sample sizes for other strata may not have been adequate (and not indicated in study)	52

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Breastfeeding				
Lower proportion of children ever breastfed Lower proportion of children who received any human milk at 6 mo of age Lower proportion of children exclusively breastfed at 4 mo of age	Analysis of breastfeeding data on children 12–71 mo of age in the NHANES III (1988–1994)	AA: $n = 1845$; Mexican American: $n = 2118$; white: $n = 1869$	Not adjusted for any covariates	53
Cardiovascular and hypertension				
Higher relative risk of all strokes Higher relative risk of intracerebral hemorrhage Higher relative risk of subarachnoid hemorrhage Higher relative risk of ischemic stroke after exclusion of sickle cell disease	Analyses of databases of the Office of Statewide Health Planning and Development of California for 10 y on all admissions to nonfederal hospitals in California	Not provided	Not adjusted for covariates (except sickle cell disease)	54
Health status				
Lower adjusted odds of being in excellent/very good health	Analysis of cross-sectional data on children 0–19 y of age from the California Health Interview Survey	Total sample: $N = 19\,485$[b]	Adjusted for 4 covariates; higher adjusted odds of making a physician visit in the previous year	55
Higher adjusted likelihood of fair or poor health Higher adjusted likelihood of activity limitations Higher adjusted likelihood of school limitations	Analysis of NHIS data	AA: $n = 5776$; API: $n = 1088$; Latino: $n = 4785$; white: $n = 20\,717$	Not adjusted for family income or health insurance coverage (adjusted only for age, gender, and parental education); lower adjusted likelihood of acute respiratory illness and injuries; interactions noted between race/ethnicity and parental education for selected outcomes in selected groups	56
Greater adjusted scores of global stress in previous month among adolescents	Cohort of adolescents in grades 7–12 in 1 suburban Midwestern public school district	AA: $n = 550$; white: $n = 659$	Adjusted for 7 covariates; interaction noted between race and college education; stress related to racism not examined	57
Higher adjusted odds of poor, fair, or good health status (vs excellent/very good)	Analysis of data from National Survey of Early Childhood Health on children 4–35 mo of age	Total sample: $N = 2068$[b]	Adjusted for 8 covariates	58
Greater adjusted odds of not being in excellent or very good health	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	32
HIV/AIDS				
Represent largest percentages of new HIV/AIDS diagnoses in every age group of children and adolescents and in perinatal transmission Number of new HIV/AIDS diagnoses in every age group of children and adolescents and in perinatal transmission exceed those of all other racial/ethnic groups combined Among females, percentages of new pediatric HIV/AIDS diagnoses are 4–9 times that for white females Among males, percentages of new pediatric HIV/AIDS diagnoses are 2–7 times that for white males	Diagnoses of HIV/AIDS reported to the CDC in 2001–2004 by 33 states that used confidential, name-based reporting of HIV/AIDS cases for at least 4 y	AA: $n = 11\,554$; Latino: $n = 3249$; white: $n = 3707$[a]	No 95% CIs or P values presented; not adjusted for SES or other covariates	59
Longer adjusted length of hospital stay for HIV-infected children	Cohort study of pediatric patients with HIV at 4 sites specializing in the care of pediatric HIV-infected patients	AA: $n = 390$; Latino: $n = 112$; white: $n = 66$	Adjusted for 8 covariates; inpatient length-of-stay data available on only 79 patients	60

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Hospitalizations				
Higher hospitalization rates for ACSCs Higher proportion of all hospital discharges attributable to ACSCs Asthma comprised much higher proportion of all ACSCs	Analysis of 6 y of data on children 1–14 y of age from National Hospital Discharge Surveys, US Census, and the NHIS	AA: $n = 17\,599$; white: $n = 66\,270$	Not adjusted for covariates; only examined 6 ACSCs White race category included all those with missing race	61
Immunization				
For children <48 mo old, lowest rate of being up-to-date on 4:3:1:3:3 immunization series Substantially greater delay and later mean age for all immunization categories and doses	Retrospective cohort study based on Chicago public schools' computerized immunization database on all children completing kindergarten in a 2-y period	Total sample: $N = 66\,556$[b]	Not adjusted for covariates	62
Infectious diseases (other than HIV/AIDS)				
Higher rate ratio of invasive pneumococcal disease among all 3 age groups analyzed (<2, 2–4, and 5–17 y of age)	Analysis of age- and race-specific pneumococcal disease incidence rates from the Active Bacterial Core Surveillance/Emerging Infections Program Network, an active, population-based surveillance system in 7 states, using data from between January 1, 1998, and December 31, 2002	Not stated for children	Not adjusted for covariates	63
Higher incidence rate of tuberculosis	Analysis of 8 y of data on children <15 y of age from the North Carolina Tuberculosis Information Management System database	AA: $n = 114$; Latino: $n = 33$; API: $n = 12$; white: $n = 21$	Not adjusted for any covariates	64
Injuries				
Firearm injury rate >13 times higher	Analysis of data from Minnesota Department of Health's Minnesota Trauma Data Bank on firearm injuries in children 0–19 y of age	Total sample: $N = 175$[b]	Not adjusted for covariates	65
Higher adjusted odds of not putting up stair gate Higher adjusted odds of not installing safety latches or locks on cabinets Higher adjusted odds of not turning down hot-water thermostat setting	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	66
Mental health and behavioral/developmental issues				
Lower adjusted odds of receiving treatment for depression from a mental health specialist	Analysis of National Longitudinal Survey of Youth and the Child/Young Adult supplement, a nationally representative sample of 7- to 14-y-old children	Total sample: $N = 2482$[b]	Adjusted for 28 covariates; no differences for any visit or behavior problem visit	67
Lower adjusted odd of being diagnosed with ADHD without a learning disability Lower adjusted odd of being diagnosed with ADHD with a learning disability Lower adjusted odds among those with ADHD of receiving any prescription medication	Analysis of 5 y of the NHIS	AA: $n = 3562$; Latino: $n = 5552$; white: $n = 11\,287$	Adjusted for birth weight, income, and health insurance coverage	68

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted odds of any mental health service use Lower adjusted odds of outpatient mental health service use Lower adjusted odds of informal mental health service use (self-help groups, peer counseling, clergy counseling, or alternative healers)	Analysis of outcomes for a random sample of 6- to 18-y-old youths receiving services in ≥1 of 5 San Diego County public sectors of care (alcohol and drug abuse, child welfare, juvenile justice, mental health, and public school education services) over a 1.5-y period	AA: $n = 282$; Latino: $n = 332$; API: $n = 88$; white: $n = 554$	Parents and children with limited English proficiency were excluded; adjustment for 12 covariates	69
Among those with autism, receive diagnosis 1.4 y later than white children (after adjustment) Among those with autism, in mental health treatment an average of 13 mo longer than white children before receiving diagnosis of autism (after adjustment)	Analysis of 7 y of Philadelphia County Medicaid claims data for children and adolescents with autism	AA: $n = 242$; Latino: $n = 33$; white: $n = 118$	Adjusted for 3 covariates; Latino children did not significantly differ from AA children for any finding, but no direct Latino-white comparison made	70
Higher proportion of parents with children with ADHD had negative expectations about ADHD treatment (ie, thought treatment could not help) Among those with ADHD or at high risk for ADHD Lower adjusted odds of receiving professional evaluation for ADHD Lower adjusted odds receiving ADHD diagnosis Lower adjusted odds of currently receiving treatment for ADHD	District-wide stratified random sample of 1615 elementary-school children (kindergarten through 5th grade) in north central Florida public school; included telephone contacts, home visits, and teacher symptom-screening questionnaire	AA: $n = 201$; white: $n = 188$	Adjusted for 8 covariates, except parent-reported barriers, which were unadjusted	71
Higher adjusted odds of use of state-funded mental health services	Analysis of New York City data on receipt of services from state-funded mental health care facilities	Total sample: $N = 78\,085$ (including adults)[b]	Adjusted for 7 covariates	72
Higher adjusted odds of developmental delays (based on parental concerns)	Analysis of data from National Survey of Early Childhood Health on children 4–35 mo of age	Total sample: $N = 2068$[b]	Adjusted for 8 covariates	58
Lower adjusted odds of use of specialty mental health services among children for whom an investigation of abuse or neglect had been opened by the child welfare system	Analysis of data from the National Survey of Child and Adolescent Well-being on use of specialty mental health services for 1 y after contact with child welfare among a cohort of children 2–14 y of age	AA: $n = 899$; Latino: $n = 487$; white: $n = 1208$	Adjusted for 11 covariates and 2 interaction terms	73
Lower adjusted odds of receipt of psychotropic medications Lower adjusted odds of receipt of stimulant medications Lower adjusted odds of receipt of antidepressants Lower adjusted odds of receipt of neuroleptics	Cross-sectional analysis of computerized claims for children 2–19 y of age continuously enrolled in a mid-Atlantic state Medicaid program for 1 y	AA: $n = 112\,488$; white: $n = 56\,858$	Adjusted for 3 covariates; disparities persisted across 4 categories of Medicaid eligibility (SCHIP, Temporary Assistance to Needy Families [TANF], foster care, and Supplemental Security Income [SSI])	74
Higher adjusted odds of child's meals not being at the same time daily Higher adjusted odds of family eating lunch or dinner together less often than every day Higher adjusted odds of family never eating lunch or dinner together Watch an adjusted mean of 45 min more of television daily Higher adjusted odds of reading to child less often than every day Lower adjusted mean number of children's books in home	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	66

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Mortality				
Higher adjusted rates of drowning in a swimming pool Higher adjusted rates of drowning in public pools, especially hotel/motel pools	Analysis of 4 y of national data from the Consumer Products Safety Commission on drowning deaths of children 5–24 y of age from death certificates, medical examiner reports, and newspaper clippings	AA: $n = 316$; Latino: $n = 81$; AI/AN: $n = 18$; white: $n = 222$	Adjusted for income; values expressed as rate ratios and 95% CIs, but no P values provided	75
Higher adjusted child mortality rate among boys in the Detroit tri-county area Higher adjusted child mortality rate among 10- to 19-y-old girls in the Detroit tri-county area	Combined death-certificate and census data on childhood mortality in 3 major metropolitan areas: Chicago, Detroit, and New York	AA: $n = 13\,744$; white: $n = 54\,846$	Adjusted for age, gender, and census tract income; no consistent adjusted disparities observed for other 2 cities analyzed (New York and Chicago)	76
Median age at death for those with Down syndrome substantially lower (25 vs 50 y among white individuals) Substantially lower average increase in median age at death for those with Down syndrome between 1968 and 1997 (0.7 vs 1.9 in white individuals)	Analysis of data from multiple-cause mortality files on all deaths with a diagnostic code for Down syndrome	Not indicated	Not adjusted for covariates; included in this analysis because Down syndrome customarily viewed as primarily a pediatric entity	77
Mortality from congenital heart defects 19% higher and declined more slowly over 18-y period Infant mortality rate for ventricular septal defect higher and persistently higher over 18-y period Lower increase of average age at death from congenital heart defects over time Average age at death from congenital heart defects 3–6 times lower About half the average age at death vs white individuals for 5 specific congenital heart defects: transposition of the great arteries, tetralogy of Fallot, ventricular septal defect, pulmonary valve anomalies, and single ventricle	Analysis of data from multiple-cause mortality files compiled by the National Center for Health Statistics from all death certificates filed in the United States with any mention of a congenital heart defect	Not indicated	Not adjusted for covariates; small sample sizes for children 1–4 y	78
Almost twice the mortality rate for children 1–4 y of age between 1950 and 1993 Black/white disparity ratio in mortality rate for children 1–4 y of age increased somewhat during the most recent 10-y period examined Approximately 50% higher mortality rate for children 5–14 y of age between 1950 and 1993 Black/white disparity ratio in mortality rate for children 5–14 y of age increased somewhat during most recent 10-y period examined	Analysis of 43 y of data on children 5–14 y of age from the National Vital Statistics System, the National Longitudinal Mortality Study, and the Area Resource File	Not indicated (except for two 3-y intervals)	Not adjusted for covariates; presented only as population rates; no statistical comparisons or 95% CIs	79
Higher adjusted relative risk of death among children without congenital anomalies	Retrospective cohort study of linked birth and death files for state of Michigan over 6-y period	Total mortality sample: $N = 8362$[b]	Adjusted for 4 covariates; no mortality disparities among children with congenital anomalies	80

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Higher adjusted risk of death among those with ALL	Analysis of 9 population-based registries of the National Cancer Institute's Surveillance, Epidemiology, and End Results program	AA: $n = 356$; Latino: $n = 504$; NA: $n = 61$; API: $n = 410$; white: $n = 3621$	Adjusted for 3 covariates; did not adjust for SES or insurance coverage	81
Higher adjusted odds of in-hospital death after congenital heart surgery	Analysis of data from the KID 2000 of the HCUP, limited to 19 states with adequate race/ethnicity data	AA: $n = 860$; Latino: $n = 1835$; white: $n = 4134$	Adjusted for 8 covariates	82
Nephrology				
Among those with end-stage renal disease, 2.4 times more likely to be on hemodialysis rather than peritoneal dialysis	Analysis of data from Medicare End-Stage Renal Disease registry on all Medicare-eligible children 0–19 y of age undergoing renal replacement therapy in the United States	AA: $n = 368$; white: $n = 870$	Adjusted for 10 covariates	83
Lower adjusted hemodialysis dose Four to 5 times greater adjusted likelihood of inadequate hemodialysis dose	Children and adolescents <18 y old within the North American Pediatric Renal Transplant Cooperative Study registry who began maintenance hemodialysis during a 6.5-y period and who received at least 6 consecutive mo of hemodialysis	AA: $n = 65$; white: $n = 46$	Adjusted for 6 covariates	84
Among children with end-stage renal disease, lower adjusted likelihood to be activated on the kidney transplant waiting list	National longitudinal cohort study using data from US Renal Data System on children 0–18 y of age with end-stage renal disease	AA: $n = 1122$; white: $n = 2162$	Adjusted for 5 covariates; stratified Kaplan-Meier analyses suggested that racial disparities may vary by SES, with significant differences in lowest but not highest SES quartile	85
Obesity, physical activity, and nutrition				
Select larger body size for ideal adult body size and ideal opposite-gender adult body size Less personal and family/peer concern about weight Significantly fewer trying to lose weight	Cross-sectional survey of random sample of all 4th- and 6th-graders in South Carolina public schools	AA: $n = 749$; white: $n = 848$	Adjusted for 2–3 covariates	86
Lower adjusted aerobic fitness level	Progressive treadmill protocol evaluation of aerobic fitness ($\dot{V}0_{2peak}$) of Los Angeles children 7–14 y of age, adjusting for gender, maturational stage, and body composition	AA: $n = 19$; Latino: $n = 36$; white: $n = 18$	Adjusted for 3 covariates but did not include SES	87
Higher adjusted odds of overweight	Analysis of height and weight data collected during 3 mo of physical fitness testing of students in grades 5, 7, and 9 in the Los Angeles County public school system	Total sample: $N = 281\ 630$[b]	Adjusted for 4 covariates	88
Higher adjusted likelihood of insulin resistance (cross-sectional assessment)	Analysis of 3 y of longitudinal data from the Princeton School District Study of 5th- to 12th-graders in 1 suburban Midwestern public school district	AA: $n = 542$; white: $n = 625$	Adjusted for 9 covariates; no significant association with change in insulin resistance over time	89
Higher prevalence of overweight in boys among 8th-graders (35%) and 10th-graders (35%) Higher prevalence of overweight in girls among 8th-graders (32%), 10th-graders (34%), and 12th-graders (28%) (highest prevalence among all racial/ethnic groups studied) Lower likelihood of eating breakfast regularly	Analysis of 10–17 y of data from Monitoring the Future, a nationally representative sample of students in the 8th, 10th, and 12th grades	Total sample: $N =$ 4800–17 074 per study interval, depending on grade and year[a]	Not adjusted for covariates	90

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Less likely to regularly exercise vigorously among girls Higher number of hours of television-viewing on average weekday Higher prevalence of overweight and obesity among girls (highest of any racial/ethnic group) More likely to consume >30% of calories as fat and >10% of calories as saturated fat (highest of any racial/ethnic group) Lower calcium intake	Cross-sectional survey of adolescents 11–18 y of age in 31 public schools in the Minneapolis, St Paul, and Osseo school districts of Minnesota	Total sample: $N = 4746$[b]	Not adjusted for covariates, but the authors stated that stratified analyses adjusting for grade and SES were performed but not reported, because they generally showed patterns similar to those of unadjusted analyses	91
Higher mean BMI Higher BMI percentile Lower mean consumption of fiber per 1000 kcal Lower mean scores on self-administered health knowledge questionnaire	Cross-sectional survey and weight and height measurements of all children in 5th grade in 2 middle schools in Scott County, Mississippi	AA: $n = 121$; Latino: $n = 70$; white: $n = 12$	Not adjusted for covariates; unclear what proportion of potential participants refused to participate	92
Higher prevalence of overweight Higher prevalence of overweight among 6- to 11-y-olds Higher prevalence of overweight among 12- to 19-y-olds Higher prevalence of overweight among girls Higher prevalence of overweight among 6- to 11-y-old girls Higher prevalence of overweight among 12- to 19-y-old girls Higher prevalence of at risk of overweight or overweight Higher prevalence of at risk of overweight or overweight among 12- to 19-y-olds Higher prevalence of at risk of overweight or overweight among girls Higher prevalence of at risk of overweight or overweight among 12- to 19-y-old girls	Analysis of NHANES data on children 2–19 y of age from 1999–2000 and 2001–2002	AA: $n = 1274$; Latino: $n = 1475$; white: $n = 1094$	Not adjusted for covariates	93
Higher adjusted odds of overweight Slower adjusted 1-mile run/walk time	Cross-sectional sample of California public school 5th, 7th, and 9th-graders (10–15 y of age)	AA: $n = 58\,491$; Latino: $n = 330\,758$; Asian: $n = 63\,292$; Pacific Islanders: $n = 7977$; Filipino: $n = 22\,598$; NA: $n = 7977$; white: 275 722	Adjusted for 2 covariates and stratified according to age	94
Ophthalmology				
Lower adjusted odds of being diagnosed with any eye or vision condition Lower adjusted odds of being diagnosed with an eye or vision condition other than conjunctivitis	Analysis of 6 y of data for children 0–17 y of age in the MEPS	Total sample: $N = 2813$[b]	Adjusted for 13 covariates; the authors concluded that disparities indicate possible underdiagnosis, undertreatment, or both	95
Orthopedic issues				
For treatment of supracondylar humerus fractures, more likely to undergo closed reduction with internal fixation (percutaneous pinning)	Retrospective examination of selected pediatric fractures in the KID of the HCUP	AA: $n = 207$; Latino: $n = 659$; white: $n = 1478$	Not adjusted for covariates; no disparities for femur or forearm fractures	96
Quality				
Lower adjusted odds of receiving any counseling during well-child visits	Cross-sectional analysis of 10 y of data on children 0–18 y of age from the National Ambulatory Medical Care Survey	Total sample: $N = 2892$[b]	Adjusted for 7 covariates	97

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted odds of receiving any screening during well-child visits Lower adjusted likelihood of meeting recommended number of well-child visits	Analysis of 3 y of data for children 0–17 y of age in the MEPS	AA: $n = 5137$; API: $n = 890$; Latino: $n = 9392$; white: $n = 14\,041$	Adjusted for 10 covariates	98
Children with cardiovascular disease had bidirectional Glenn surgery at significantly older median age (11 vs 6 mo of age among white infants) Children with cardiovascular disease had Fontan procedure at significantly older median age (60 vs 36 mo of age among white children)	Review of surgical database at Duke University Medical Center of all children who underwent bidirectional Glenn or Fontan stages of single-ventricle palliation over a 4-y period	AA: $n = 20$; white: $n = 47$	Although not adjusted for covariates, no significant differences found between AA and white children in median family income for either measure	99
Lower primary care provider strength-of-affiliation scores (unadjusted and adjusted) Lower primary care provider interpersonal relationship scores (unadjusted and adjusted [if required by managed care organization to stay in network])	Telephone survey of parents of random sample of 413 children attending elementary school in 3 suburban communities in San Bernardino County, California	AA: $n = 100$; API: $n = 91$; Latino: $n = 84$; white: $n = 102$	Adjusted for 11 covariates	100
Lower adjusted scores for timeliness of care Lower adjusted scores for health insurance plan service Lower adjusted scores for getting needed medical care	Analysis of parental survey data on children 0–17 y of age from the national CAHPS Benchmarking Database 1.0 administered by Medicaid sponsors comprising 33 health maintenance organizations from Arkansas, Kansas, Minnesota, Oklahoma, Vermont, and Washington	AA: $n = 1344$; Latino: $n = 842$; API: $n = 291$; AI/AN: $n = 330$; white: $n = 6328$	Adjusted for 4 covariates	101
Lower adjusted scores for comprehensiveness of primary care	Cross-sectional survey of parents of children in 228 classes, from kindergarten through 6th grade, at 18 elementary schools in a large urban school district in California	AA: $n = 458$; API: $n = 1158$; Latino: $n = 1292$; white: $n = 479$	Adjusted for 5 covariates	102
Greater adjusted odds of child being assigned to health care provider Greater adjusted odds of health care provider never/only sometimes understanding how parent prefers to rear child Greater adjusted odds of discussing violence in the community, smoking in the household, use of alcohol or drugs in household, trouble paying for child's needs, and spouse/partner supportive of parenting efforts	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	32
Special health care needs				
Lower adjusted odds of receiving adequate time and information from child's health care provider, among children with special health care needs	Analysis of National Survey of Children With Special Health Care Needs	Total sample: $N = 38\,866$[b]	Adjusted for 6 covariates; no disparities in any unmet need or problem with specialty referral	103
Among children with special health care needs Higher adjusted odds of not identifying a regular clinician Lower adjusted odds of usual source of care being doctor's private office or health maintenance organization Average 2 fewer doctor visits per year	Analysis of data on children 0–17 y of age with special health care needs in the NHIS on disability	AA: $n = 1762$; Latino: $n = 1777$; white: $n = 6365$	Adjusted for 9–10 covariates	104
Among children with special health care needs Higher adjusted odds of child having no physician or nurse Higher adjusted odds of dissatisfaction with care	Analysis of data on children 0–17 y of age from National Survey of Children with Special Health Care Needs	Not indicated	Adjusted for 6 covariates	105

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Among children with special needs	Analysis of data on special needs children 0–17 y of age from the National Survey of Children With Special Health Care Needs	AA: $n = 3820$; Latino: $n = 3210$; white: $n = 28\,916$	Adjusted for 13 covariates	106
Greater adjusted odds of problems with ease of using health care services				
Surgery				
For those hospitalized for appendicitis	Analysis of data on children 1–17 y of age with appendicitis from the Nationwide Inpatient Sample and the KID	Total sample: $N = 428\,463$[b]	Not adjusted for covariates for time to operation, length of stay, or hospital charges; other outcomes include adjustment for 6 covariates	107
Longer time to operation (regardless of disease severity)				
Longer length of stay (regardless of disease severity)				
Higher hospital charges (regardless of disease severity)				
Higher adjusted odds of perforation or other complicating factors				
Lower adjusted odds of a laparoscopic procedure				
Transplantation				
Lower proportion (0%) received preemptive transplants	Retrospective analysis of transplant database at Cincinnati Children's Hospital	AA: $n = 37$; white: $n = 192$	Relatively small sample size of AA children; not adjusted for covariates	108
Fewer living transplants and more cadaveric transplants in most recent time period				
Cause of end-stage renal disease more likely to be acquired and less likely to be congenital or metabolic				
Approximately double the adjusted odds of heart transplantation graft failure	Analysis of 18 y of data from the United Network for Organ Sharing, including annual follow-up of transplant recipients	AA: $n = 717$; white: $n = 3510$	Adjustment for 13 covariates	109
Lower 5-y heart transplant graft survival rate				
Median heart transplant graft survival rate (5.3 y) ∼6 y lower than that for white children (11.0)				
Median age at heart transplant (8 y) 5 y older than that for white children (3 y)				
More likely to have HLA mismatch				
Use of health services				
Reduced physician visits under mandatory enrollment in managed care among those with Medicaid	Difference-in-difference analysis of pre/post impact of mandatory enrollment in managed care for Medicaid beneficiaries in 2 unnamed counties in an unnamed Midwestern state	AA: $n = 4891$; white: $n = 4460$	Adjusted for 3 covariates (all subjects enrolled in Medicaid, so no SES adjustment); no differences observed in hospitalizations or ED use	110
Higher adjusted likelihood of medically unnecessary EMS transports	Analysis of linked EMS and ED billing records for all EMS-to-hospital transports of children 0–17 y old originating in 3 counties in South Carolina over 27 mo	AA: $n = 4331$; Latino: $n = 75$; other: $n = 48$; white: $n = 1239$	Adjusted for 4 covariates	111
Greater adjusted odds of ≥1 y since last physician visit	Analysis of 3 y of NHIS data on children 0–17 y old	AA: $n = 17\,324$; Latino: $n = 12\,765$; API: $n = 2516$; AI/AN: $n = 1067$; white: $n = 62\,572$	Adjusted for 4 covariates	112
Lower adjusted number of physician visits in previous 12 mo				
Double the odds of suboptimal health status				
Among those hospitalized for pneumonia	Analysis of 3 y of data on children 0–17 y of age hospitalized for pneumonia from the National Inpatient Sample of the HCUP	AA: $n = 17\,095$; Latino: $n = 15\,152$; API: $n = 2050$; white: $n = 43\,180$	Adjusted for 6–7 covariates	113
Higher adjusted risk ratio of admission through EDs				
Lower adjusted odds of bronchoscopy				
Lower adjusted odds of mechanical ventilation				
Shorter adjusted length of stay				
Higher adjusted charges				

TABLE 1 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Among Medicaid-covered children	Analysis of data on North Carolina Medicaid-covered children 1–4 y of age from linked Medicaid, WIC service, and birth certificate data	AA: $n = 9288$; white: $n = 11\,351$[c]	Adjusted for 8–9 covariates	114
Lower adjusted odds of well-child care visit in previous year (at 1, 2, and 4 y of age)				
Lower adjusted odds of diagnosis and treatment for otitis media				
Lower adjusted odds of diagnosis and treatment for upper respiratory infections				
Lower adjusted odds of diagnosis and treatment for lower respiratory infections				
Lower adjusted odds of diagnosis and treatment for gastroenteritis				
Higher adjusted odds of diagnosis and treatment for asthma				
Lower adjusted outpatient Medicaid expenditures				
Lower adjusted ED Medicaid expenditures (for 3- and 4-y-olds)				
Lower adjusted prescription drug Medicaid expenditures				
Lower adjusted mean number of calls to doctor's office in past year	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	AA: $n = 477$; Latino: $n = 817$; white: $n = 718$	Adjusted for 9 covariates	32
Greater adjusted odds of at least 1 ED visit in previous year				

MEPS indicates Medical Expenditure Panel Survey; CHIRI, Child Health Insurance Research Initiative; Add Health, National Longitudinal Study of Adolescent Health; NHIS, National Health Interview Survey; NHANES, National Health and Nutrition Examination Survey; ACSC, ambulatory-care–sensitive condition; 4:3:1:3:3, combined series composed of ≥4 doses of diphtheria and tetanus toxoids and pertussis/diphtheria and tetanus toxoids/diphtheria and tetanus toxoids and acellular pertussis vaccine, ≥3 doses of poliovirus vaccine, ≥1 dose of measles-containing vaccine, ≥3 doses of *Haemophilus influenzae* type b vaccine, and ≥3 doses of hepatitis B vaccine; $\dot{V}o_2$, oxygen consumption per unit time; KID, Kid's Inpatient Database; HCUP, Healthcare Cost and Utilization Project; CAHPS, Consumer Assessment of Health Plans Study; EMS, Emergency Medical Services; WIC, Supplemental Nutrition Program for Women, Infants, and Children.

[a] Sample sizes include those 0 to 24 y of age, because those 15 to 24 y of age were grouped together.

[b] Sample sizes were not disaggregated in article according to race/ethnicity.

[c] Sample sizes for initial cohort (1-y-olds)

drome, congenital heart defects (both in terms of the fatality rate and a lower average age at death), and in-hospital death after congenital heart surgery.

Access to Care and Use of Services

Multiple noteworthy disparities were documented in access to health care and use of health services (Table 1). Disparities in access to care include higher rates than those of white children of unmet health care needs, lower rates of access to primary care providers (including race being more strongly associated with this outcome than income), a higher likelihood of having no usual source of care, greater odds of not being referred to a specialist by the health care provider, higher hospitalization rates for ambulatory care–sensitive conditions, and higher odds of appendicitis rupture (considered an access indicator, because it indicates failed access to timely, appropriate care early in the course of appendicitis). Disparities in the use of health services include lower physician-visit rates and higher odds of going 1 year or longer from the last physician visit, a higher rate of emergency department (ED) visits, greater likelihood of medically unnecessary Emergency Medical Services transports, fewer calls to physicians' offices, and, among those with Medicaid coverage, lower odds of well-child care and diagnosis and treatment for various pediatric conditions, and lower expenditures for outpatient and ED care and for prescriptions.

Prevention and Population Health

Disparities were identified in breastfeeding, immunization rates, injuries, obesity, physical activity, and nutrition (Table 1). Breastfeeding is significantly less likely among AA versus white infants, whether measured by ever being breastfed, the proportion exclusively breastfed, or the proportion receiving any human milk. AA children have the

lowest immunization rates for the primary immunization series and have substantially greater delays and a later mean age for multiple immunization categories and doses. They have a substantially higher firearm injury rate and, as young children, have higher odds of living in households without stair gates, cabinet safety latches or locks, or hot-water thermostat settings that have been turned down.

Studies consistently document higher rates of obesity and overweight in AA children (Table 1). One study also revealed selection of larger body size when asked to identify ideal adult body size; less personal, family, and peer concern about weight; and fewer children trying to lose weight. Disparities also have been identified in lower aerobic fitness levels, slower 1-mile run/walk time, lower likelihood of vigorous exercise in females, and higher numbers of television-viewing hours. Nutritional disparities include a higher likelihood of consuming more calories as fat and saturated fat, lower mean consumption of fiber and calcium, and lower likelihood of eating breakfast regularly.

Adolescent Health Issues

AA female adolescents have higher risks versus white female adolescents of skipping breakfast, being obese, lacking health insurance, needing but not getting medical care, having any sexually transmitted disease, perpetrating violence, and being a victim of violence (Table 1). Several studies have also documented live birth rates that are 2 to 5 times higher than for white female adolescents, and the disparity ratio has worsened over time. AA female adolescents also have greater adjusted odds of alcohol testing when seen in the ED for traumatic injury and are particularly at high risk of underusing substance abuse services. Male AA adolescents have a higher risk of perpetrating violence and being a victim of violence. For AA adolescents of both genders, higher risks were identified for underuse of substance abuse services, older age at first use of substance abuse services, and suboptimal health status and lower use of physicians' offices as the usual source of care among those recently enrolled in a State Children's Health Insurance Program (SCHIP).

Health Status

Multiple studies have documented health-status disparities for AA children, whether analyzing global health status or the prevalence of specific conditions (Table 1). Three studies revealed that AA children have higher adjusted odds of fair or poor health and lower odds of excellent or very good health. Higher rates of activity limitations, school limitations, and global stress also were noted. Significantly higher crude rates than in white children have been seen for all stroke categories (both hemorrhagic and ischemic), invasive pneumococcal disease, and tuberculosis. HIV/AIDS disparities are substantial, and include the largest percentages and numbers of new diagnoses in every age group of children and adolescents and via perinatal transmission, as well as longer adjusted lengths of stay for those who are hospitalized.

Asthma, Mental Health Care, and Special Health Care Needs

A particularly extensive body of literature is available on disparities for 3 specific issues: asthma, mental health care (including behavioral and developmental issues), and special health care needs (Table 1).

Several studies have documented that AA children have the highest asthma prevalence of any racial/ethnic group, and this prevalence is substantially higher than that for white children (Table 1). Secular-trend data indicate that this disparity has widened over time. Compared with white children, AA children also experience substantially higher rates of asthma mortality, hospitalizations, ED visits, and office visits, and the disparities in asthma mortality and hospitalizations have widened over time. Additional asthma disparities include higher attack prevalence; lower rates of filled prescriptions; higher potential disease burden (diagnosed plus possible but undiagnosed disease); worse asthma physical health scores; lower odds of use of β_2-agonists, inhaled steroids, and daily anti-inflammatory medication; and higher odds of sensitivities to cockroach, dust mite, and mold allergens.

Several key disparities were noted in mental health care and behavioral/developmental disorders. Most study results have indicated lower use of mental health services, including lower adjusted odds of any mental health service use, outpatient service use, informal service use (such as self-help and peer counseling), receiving treatment for depression from mental health specialists, and receipt of psychotropic, stimulant, antidepressant, or neuroleptic medications (Table 1). One study, however, found higher odds of use of state-funded mental health services in New York City. Higher adjusted odds of developmental delays have been noted, but underdiagnosis, undertreatment, and other disparities for attention-deficit/hyperactivity disorder (ADHD) were found in other studies, including lower adjusted odds of evaluation, receiving a diagnosis, and receiving medication or treatment, and higher proportions of parents with negative expectations about treatment helpfulness. AA children also were found to receive a diagnosis of autism 1.4 years later than white children and to be in mental health treatment an average of 13 months

longer than white children before receiving the autism diagnosis.

National data reveal several disparities for AA children with special health care needs (Table 1), including higher odds of having no regular health care provider, averaging fewer physician visits, being dissatisfied with care, encountering problems with ease of use of services, and not receiving adequate time and information from children's health care providers.

Quality

Numerous disparities were identified in quality of care (Table 1). Lower adjusted odds versus white children were noted for meeting the recommended number of well-child visits and receiving any counseling or screening during well-child visits. Lower adjusted scores were observed for timeliness of care, health insurance plan service, getting needed medical care, primary care comprehensiveness, primary care provider strength of affiliation, and primary care provider interpersonal relationships. Greater adjusted odds were found for the child being assigned to the health care provider; the provider never/only sometimes understanding how the parent prefers to rear the child; and the provider discussing violence in the community, smoking in the household, using alcohol or drugs in household, trouble paying for child's needs, and spouse/partner support of parenting efforts.

Among those with end-stage renal disease, AA children are substantially less likely than white children to be activated on the kidney transplant waiting list but are significantly more likely to receive hemodialysis rather than peritoneal dialysis and to receive an inadequate hemodialysis dose. AA children have lower odds than white children of being diagnosed with any eye or vision condition, are more likely to undergo closed reduction with internal fixation of supracondylar humerus fractures, undergo bidirectional Glenn and Fontan procedures at significantly older ages among those with cardiovascular disease, and have longer time to operation and lengths of stay, higher hospital charges, higher odds of perforation and other complications, and lowers odds of laparoscopic procedures among those with appendicitis. AA patients who have a heart transplant have double the odds of graft failure, lower graft survival rates, a median graft survival time that is 6 years lower, a median age at heart transplant that is 5 years greater, and a higher likelihood of HLA mismatch. AA children are less likely to receive preemptive kidney transplants, and they receive fewer living transplants and more cadaveric transplants.

Asians/Pacific Islanders

There were 24 articles (24 of 109 [22%]) that addressed disparities in API children (Table 2).

Mortality

Only 1 study (Table 2) examined mortality among APIs; it revealed that native Hawaiian children have a higher crude mortality rate than that of white children.

Access to Care and Use of Services

Several studies found disparities for API versus white children in access to health care and use of health services (Table 2). API children have greater adjusted odds of having no usual source of care, having made no visit to a physician or other health care provider in the past year, and going more than 1 year since the last physician visit, as well as a lower adjusted number of physician visits in the past year. Higher adjusted odds of appendicitis rupture also were noted. Among children with cancer, Pacific Islanders had significantly greater odds of death, untimely treatment, not completing treatment as recommended, and loss to follow-up.

Prevention and Population Health

Disparities were identified in injuries, lead intoxication, obesity, and nutrition (Table 2). Data from the state of Minnesota revealed triple the crude firearm injury rate of that in white children. API children were found to have the highest proportion of elevated blood lead concentrations in the state of Rhode Island and are the only racial/ethnic group whose rate increased over time. Higher adjusted odds of overweight occur among Pacific Islander, Filipino, and Asian children, and slower adjusted 1-mile run/walk times were noted for most age groups of API children. API children also have a lower calcium intake—the lowest of any racial/ethnic group.

Adolescent Health Issues

Compared with white adolescents, API adolescents were found to have lower adjusted odds of seatbelt use, sunscreen use, and weekly physical activity and greater adjusted daily hours of television/video-game screen time (Table 2).

Health Status

APIs have a higher adjusted likelihood than that of whites to have fair or poor health status (Table 2). Data from the state of Hawaii revealed that Filipino and Chinese boys have the highest rates of leukemia, and Chinese boys have the highest ALL rate.

Mental Health Care

API children have been found to have lower adjusted odds of any mental health service use, outpatient mental health service use, and 24-hour-care service use (ie, inpatient, residential, group-home, or alcohol/drug abuse treatment) (Table 2). New York City data, however, indicate higher ad-

TABLE 2 Disparities in the Health and Health Care of API Children

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Access to care				
Double to triple adjusted odds of having no usual source of care Double to triple adjusted odds of no health professional/doctor visit in previous year	Analysis of household component of the 1996 and 2000 MEPS	Asian: $n = 325$; AA: $n = 2189$; Latino: $n = 4091$; white: $n = 6362$	Adjusted for 8 covariates; 5 times the adjusted odds of dissatisfaction with quality of care in 2000 but not 1996	28
Higher adjusted odds of appendicitis rupture	Cross-sectional analysis of full-year samples of hospital discharge records for acute appendicitis from California and New York children 4–18 y of age	California: API, $n = 459$; AA, $n = 297$; Latino, $n = 4304$; white, $n = 4017$; New York: API, $n = 80$; AA, $n = 342$; Latino, $n = 444$; white, $n = 2379$	Adjusted for 7 covariates	29
Among children with cancer, compared with Hawaiian residents, Pacific Islanders had significantly greater odds of death, untimely treatment, not completing treatment as recommended, and loss to follow up	Retrospective case-comparison study	Pacific Islander: $n = 100$; Hawaiian residents: $n = 100$	Not adjusted for covariates	115
Adolescents				
Lower adjusted odds of seat belt use Lower adjusted odds of sunscreen use Lower adjusted odds of weekly physical activity Greater adjusted daily hours of television/video-game screen time	Analysis of California Health Interview Survey data on adolescents 12–17 y of age	API: $n = 376$; Latino: $n = 1515$; white: $n = 3263$	Adjusted for 5 covariates; interactions noted with generational status for certain outcomes	116
Cancer				
Among Hawaiian racial/ethnic groups, Filipino and Chinese boys have highest rates of leukemia, and Chinese boys have highest ALL rate	Tumor registry analysis	Total cancer cases: $N = 1237$	Adjusted only for age	117
Health status				
Higher adjusted likelihood of fair or poor health	Analysis of NHIS data	API: $n = 1088$; AA: $n = 5776$; Latino: $n = 4785$; white: $n = 20\,717$	Adjusted for 3 covariates (but not family income or health insurance coverage) Interactions between race/ethnicity and parental education for selected outcomes in selected groups	56
Injuries				
Triple the firearm injury rate	Analysis of data from Minnesota Department of Health's Minnesota Trauma Data Bank on fatal and nonfatal firearm injuries in children 0–19 y of age	Total sample: $N = 175$[a]	Not adjusted for covariates	65
Lead intoxication				
API children have the highest proportion of elevated blood lead levels (23%) in Rhode Island and are only group whose proportion increased over time	Rhode Island Department of Health Surveillance Data	Not stated	Not adjusted for SES or other covariates	118
Mental health and behavioral/developmental issues				
Lower adjusted odds of any mental health service use	Analysis of outcomes for random sample of 6- to 18-y-old youths receiving services in ≥1 of 5 San Diego County public sectors of care (alcohol and drug abuse, child welfare, juvenile justice, mental health, and public school education services) over 1.5-y period	API: $n = 88$; AA: $n = 282$; Latino: $n = 332$; white: $n = 554$	Parents and children with limited English proficiency were excluded	69

TABLE 2 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted odds of outpatient mental health service use Lower adjusted odds of 24-h-care service use (inpatient, residential group home, or alcohol/drug abuse treatment)			Adjusted for 12 covariates	
Higher adjusted odds of use of state-funded mental health services	Analysis of New York City data on receipt of services from state-funded mental health care facilities	Total sample: $N = 78\,085$ (including adults)[a]	Adjusted for 7 covariates	72
Mortality				
Approximately 50% higher mortality rate for children 1–4 y of age Almost 50% higher mortality rate for children 5–14 y of age	Analysis of 43 y of data on children 5–14 y of age from the National Vital Statistics System, the National Longitudinal Mortality Study, and the Area Resource File	Hawaiian residents: $n = 142$; white: 67 200	Not adjusted for covariates; presented only as population rates; no statistical comparisons or 95% CIs; small sample sizes for Hawaiian residents	79
Obesity, physical activity, and nutrition				
Higher adjusted odds of overweight among Pacific Islander children	Analysis of height and weight data collected during 3 mo of physical fitness testing of students in grades 5, 7, and 9 in the Los Angeles County public school system	Total sample: $N = 281\,630$[a]	Adjusted for 4 covariates; Asians (as opposed to Pacific Islanders) had lower adjusted odds (vs white children) of overweight	88
Lower calcium intake (lowest of any racial/ethnic group)	Cross-sectional survey of adolescents 11–18 y of age in 31 public schools in the Minneapolis, St Paul, and Osseo school districts of Minnesota	Total sample: $N = 4746$[a]	Not adjusted for covariates; the authors stated that stratified analyses adjusting for grade and SES were performed but not reported because they generally showed patterns similar to those of unadjusted analyses	91
Higher adjusted odds of overweight in Filipinos, Pacific Islanders, and Asians (but only in males for Asians) Slower adjusted 1-mile run/walk time	Cross-sectional sample of California public school 5th-, 7th-, and 9th-graders (10–15 y of age)	Asian: $n = 63\,292$; Pacific Islander: $n = 7977$; Filipino: $n = 22\,598$; AA: $n = 58\,491$; Latino: $n = 330\,758$; NA: $n = 7977$; white: 275 722	Adjusted for 2 covariates and stratified according to age; API children stratified as Asian, Filipino, and Pacific Islander; run/walk time differences not significant for certain specific age strata for Asian (2), Filipino (4), and Pacific Islander (7)	94
Quality				
Lower quality of primary care (according to parental assessment)	Cross-sectional survey of parents of elementary-school children 5–12 y of age in 1 school district, using Primary Care Assessment Tool	API: $n = 96$; AA: $n = 106$; Latino: $n = 96$; white: $n = 105$	Adjusted for 12 covariates; smaller sample size ($n = 135$) for full multivariable analysis may have had limited power to detect other disparities	119
Lower primary care provider interpersonal relationship scores (unadjusted and adjusted)	Telephone survey of parents of random sample of 413 children attending elementary school in 3 suburban communities in San Bernardino County, California	API: $n = 91$; AA: $n = 100$; Latino: $n = 84$; white: $n = 102$	Adjusted for 11 covariates	100
Among those in which the primary language spoken at home is a language other than English Lower adjusted scores for timeliness of care Lower adjusted scores for provider communication Lower adjusted scores for staff helpfulness	Analysis of parental survey data on children 0–17 y of age from the national CAHPS Benchmarking Database 1.0 administered by Medicaid sponsors comprising 33 health maintenance organizations from Arkansas, Kansas, Minnesota, Oklahoma, Vermont, and Washington	API: $n = 291$; AA: $n = 1344$; Latino: $n = 842$; AI/AN: $n = 330$; white: $n = 6328$	Adjusted for 4 covariates; no disparities for API children in households in which English is primary language; survey was administered only in English and Spanish	101

TABLE 2 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted scores for health insurance plan service				
Lower adjusted scores for getting needed medical care				
Lower adjusted ratings of child's health care				
Lower adjusted overall quality of primary care scores	Cross-sectional survey of parents of children in 228 classes, from kindergarten through 6th grade, at 18 elementary schools in a large urban school district in California	API: $n = 1158$; AA: $n = 458$; Latino: $n = 1292$; white: $n = 479$	Adjusted for 5 covariates	102
For those interviewed in English				
Lower adjusted scores on timely and convenient access to primary care				
Lower adjusted scores on how well primary care physician listens and explains during interactions				
Lower adjusted scores for comprehensiveness of primary care				
Lower adjusted scores on coordination of primary care				
Among those hospitalized for pneumonia	Analysis of 3 y of data on children 0–17 y of age hospitalized for pneumonia from the National Inpatient Sample of the HCUP	API: $n = 2050$; AA: $n = 17\,095$; Latino: $n = 15\,152$; white: $n = 43\,180$	Adjusted for 6–7 covariates	113
Lower adjusted odds of bronchoscopy				
Lower adjusted odds of mechanical ventilation				
Longer adjusted length of stay				
Higher adjusted charges				
Lower adjusted scores for interpersonal relationship with primary care provider	Telephone surveys on primary care experiences of children by using a random, cross-sectional sample of parents of elementary school children 5–12 y of age in a school district in San Bernardino, CA	API: $n = 88$; AA: $n = 94$; Latino: $n = 84$; white: $n = 92$	Adjusted for 9 covariates; findings held true regardless of whether there was patient/provider racial/ethnic concordance	120
Lower adjusted scores for specific primary care services available to child				
Use of health services	Analysis of cross-sectional data on children 0–19 y of age from the California Health Interview Survey	Total sample: $N = 19\,485$	Adjusted for 7 covariates	55
		API: $n = 890$; AA: $n = 5137$; Latino: $n = 9392$; white: $n = 14\,041$	Adjusted for 10 covariates	98
Lower adjusted odds of making a physician visit in the previous year	Analysis of 3 y of data for children 0–17 y of age in the MEPS	API: $n = 2516$; AA: $n = 17\,324$; Latino: $n = 12\,765$; AI/AN: $n = 1067$; white: $n = 62\,572$	Adjusted for 4 covariates	112
Lower adjusted likelihood of meeting recommended number of well-child visits	Analysis of 3 y of NHIS data on children 0–17 y of age			
Greater adjusted odds of ≥1 y since last physician visit				
Lower adjusted number of physician visits in previous 12 mo				
Greater adjusted odds of suboptimal health status				

MEPS indicates Medical Expenditure Panel Survey; NHIS, National Health Interview Survey; HCUP, Healthcare Cost and Utilization Project; CAHPS, Consumer Assessment of Health Plans Study.

[a] Sample sizes were not disaggregated in article according to race/ethnicity.

justed odds of use of state-funded mental health services.

Quality

Several studies have documented API disparities in primary care quality, including lower overall quality of primary care scores, lower primary care provider interpersonal relationship scores, and lower scores for specific primary care services available to the child (Table 2). Lower adjusted primary care quality scores have been found for 4 elements of care among API parents interviewed in English and 6 elements of care among API parents for whom the primary language spoken at home is not English. Among those hospitalized for pneumonia, API children have lower adjusted odds of bronchoscopy and mechanical ventilation, a longer adjusted length of stay, and higher adjusted charges.

Latinos

There were 66 articles (67 of 109 [61%]) that addressed disparities in Latino children (Table 3).

Mortality

Puerto Rican children 1 to 4 years of age were found to have a higher crude mortality rate than their white counterparts (Table 3). A higher drowning rate in neighborhood pools for Latinos also was found, along with higher swimming pool drowning rates in general for Latino male adolescents. Higher adjusted risks of death exist among Latinos (versus whites) with ALL and after congenital heart surgery.

Access to Care and Use of Services

Multiple studies have documented a wide range of disparities in access to care and use of services for Latino children (Table 3). In comparison with white children, Latino children have greater adjusted odds of being uninsured, having no usual source of care or health care provider, having made no physician visit in the past year, having gone 1 year or more since the last physician visit, making fewer physician visits in the past year, making fewer calls to physicians' offices, not being referred to a specialist, having a perforated appendicitis, and never or only sometimes getting medical care without long waits, getting timely routine care or telephone help, and getting brief wait times for medical appointments. Similar findings were noted in studies that focused on Latinos before or at the time of enrollment in SCHIP and among Mexican American children.

Prevention and Population Health

Disparities were identified in breastfeeding, injuries, obesity, physical activity, and nutrition (Table 3). Compared with white infants, a lower crude proportion of Mexican-American infants are ever breastfed. Latino households with children 4 to 35 months of age have lower adjusted odds than do white households of putting up stair gates. Multiple studies have documented significantly higher adjusted odds of overweight and obesity, including 2 studies that showed that Latinos have the highest adjusted rates of overweight and obesity of any racial/ethnic group. Physical-activity disparities included lower adjusted aerobic fitness, slower 1-mile run/walk times, higher average number of television-viewing hours on the average weekday, and lower regular vigorous physical activity among females. Lower calcium intake has been noted, as has as a higher likelihood of consumption of more than 10% of calories as saturated fat.

Adolescent Health Issues

Latina adolescents have a higher risk than do white adolescents of not having health insurance, perpetrating violence, and being a victim of violence. Disparities for male adolescents include a higher risk of no health insurance, going more than 2 years since the last physical examination, and being a victim of violence (Table 3). Latino adolescents recently enrolled in SCHIP have a higher crude likelihood of fair or poor health and are less likely to use physician's offices as their usual source of care. Latina adolescents 15 to 19 years of age have a crude birth rate 3 times higher than their white counterparts and the highest of any racial/ethnic group. Latino adolescents have a lower adjusted odds of being treated in the ED for sexually transmitted diseases, but male Latino adolescents with traumatic injuries have a higher adjusted odds of alcohol testing in the ED. Latino adolescents also have lower adjusted odds of bicycle helmet and sunscreen use.

Health Status

National data reveal a higher adjusted likelihood of fair or poor health in Latinos (Table 3). Compared with whites, Latinos also have twice the percentage of new HIV/AIDS diagnoses among those younger than 13 years old, in perinatal transmission, and among other pediatric cases. They also have a higher crude incidence rate of tuberculosis. In terms of Latino subgroups, both Mexican American and Puerto Rican children have higher adjusted odds of fair or poor health status.

Asthma, Mental Health Care, and Special Health Care Needs

An analysis of national data revealed that Latinos have a higher asthma prevalence than do whites, and there has been a substantial increase in Latino asthma prevalence over time (Table 3). Several studies have documented a particularly high asthma prevalence among Puerto Ricans. Other asthma disparities include higher adjusted odds of asthma ED visits, hospitalizations, activity limitations, and the need for urgent care in

TABLE 3 Disparities in the Health and Health Care of Latino Children

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Access to care				
Triple the adjusted odds of having no usual source of care Double the adjusted odds of no health professional/doctor visit in previous year	Analysis of Household Component of 1996 and 2000 MEPS	Latino: $n = 4091$; AA: $n = 2189$; Asian: $n = 325$; white: $n = 6362$	Adjusted for 8 covariates; double the adjusted odds of dissatisfaction with quality of care in 1996 but not 2000	28
Lower adjusted odds of having a regular source of care Lower adjusted odds of surety of accessing health care among adolescents Lower adjusted odds of being in excellent/very good health	Analysis of cross-sectional data on children 0–19 y of age from the California Health Interview Survey	Total sample: $N = 19\,485$	Adjusted for 7 covariates	55
Among Mexican American children Lower adjusted odds of always/usually obtaining appointment for regular or routine care Lower adjusted odds of always/usually obtaining care for illness or injury Lower adjusted odds of always/usually obtaining advice/help over telephone Higher adjusted odds of always/usually having a long wait in doctor's office	Cross-sectional, population-based, random-digit-dialing survey of parents/guardians of children 3–18 y of age residing in 111 counties in west Texas using 4 items from the CAHPS	Mexican American: $n = 2052$; white: $n = 2655$	Adjusted for 17 covariates; same finding when Mexican American children stratified by language spoken at home	121
Higher adjusted odds of appendicitis rupture in California	Cross-sectional analysis of full-year samples of hospital discharge records for acute appendicitis from California and New York children 4–18 y of age	California: Latino, $n = 4304$; API, $n = 459$; AA, $n = 297$; white, $n = 4017$; New York: API, $n = 80$; AA, $n = 342$; Latino, $n = 444$; white, $n = 2379$	Adjusted for 7 covariates; nonsignificant trend observed in New York	29
Higher adjusted proportion in fair or poor health among new SCHIP enrollees in Florida and New York Lower adjusted proportion had preventive care visits before SCHIP among new SCHIP enrollees in Florida and New York Lower adjusted proportion had usual source of care before SCHIP among new SCHIP enrollees in Florida and New York	Analysis of CHIRI data on new SCHIP enrollees in 4 states (<18 y old in Alabama, Kansas, and New York, and 11.5–17.9 y of age in Florida)	Total sample: $N = 8975$[b]	Adjusted for 10 covariates	30
Before enrollment in SCHIP Lower adjusted rate of having usual source of care Higher adjusted rate of having unmet needs for health care	Interviews of parents in New York State at the time of SCHIP enrollment of their child (baseline) and 1 y after enrollment	Total sample: $N = 2644$ (baseline) and $N = 2290$ (1-y follow-up)[b]	Adjusted for 12 covariates; 1 unadjusted quality-of-care disparity noted	31
Lower adjusted odds of always getting timely medical care without waits Lower adjusted odds of always getting timely telephone help for medical care	Analysis of CAHPS data on cross-sectional cohort from the MEPS	Latino: $n = 1236$; AA: $n = 700$; white: $n = 2184$	Adjusted for 6 covariates	122

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted odds of brief wait times for medical appointments Higher adjusted odds of never/only sometimes getting medical care without long waits Higher adjusted odds of never/only sometimes getting timely routine care Higher adjusted odds of never/only sometimes getting timely telephone help Higher adjusted odds of never/only sometimes getting brief wait times for medical appointments				
Greater adjusted odds of being uninsured Greater adjusted odds of not being referred to specialist by health care provider	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	Latino: $n = 817$; AA: $n = 477$; white: $n = 718$	Adjusted for 9 covariates	32
Adolescents				
Female adolescents: higher risk of no health insurance, perpetrating violence, and being a victim of violence Male adolescents: higher risk of no health insurance, last physical examination >2 y ago, and being a victim of violence	Analysis of Add Health (waves 1 and 2), a nationally representative school-based study of youths in grades 7–12, with follow-up into adulthood	Latino: $n = 2340$; AA: $n = 3038$; API: $n = 1021$; AI/AN: $n = 136$; white: $n = 7728$	Prevalence in published tables was not adjusted; the authors stated that adjustments for income and parental education had minimal influence on findings; significant disparities were identified by using 95% CIs that did not overlap with measure for white adolescents; no formal statistical evaluation of disparities was provided in article	35
Lower adjusted odds of bicycle helmet use Lower adjusted odds of sunscreen use	Analysis of California Health Interview Survey data on adolescents 12–17 y of age	Latino: $n = 1515$; API: $n = 376$; white: $n = 3263$	Adjusted for 5 covariates; interactions noted with generational status for certain outcomes	116
Live birth rate for adolescent girls 15–17 y of age >3 times higher (and highest for any racial/ethnic group)	1990–1998 natality files from the National Vital Statistics System	Not provided	Expressed as rates per 1000; rates not adjusted for any covariates	36
Higher likelihood of fair-to-poor health among adolescents recently enrolled in SCHIP Less likely to use doctor's offices as their usual source of care among adolescents recently enrolled in SCHIP	Analysis of CHIRI telephone interview data of adolescents newly enrolled in SCHIP in Florida and New York (and their parents)	Total sample: $N = 2036$[b]	Not adjusted for covariates	33
Lower adjusted odds of being treated for sexually transmitted infections in the ED	Analysis of 7 y of data from the National Hospital Ambulatory Medical Care Survey on children 12–19 y of age	Latino: $n = 1710$; AA: $n = 8170$; white: $n = 8930$	Adjusted for 4 covariates	123
Birth rate for 15- to 19-y-old girls almost 3 times as high	Birth certificate data reported to CDC National Center for Health Statistics	Not provided	Not adjusted for covariates; no *P* values or 95% CIs	38
Greater adjusted odds of alcohol testing among male adolescents admitted to EDs for traumatic injury	Analysis of data from the National Trauma Data Bank (includes 64 US institutions) on adolescents 12–17 y of age admitted to EDs with traumatic injury	Latino: $n = 396$; AA: $n = 1760$; white: $n = 5584$	Adjusted for 7 covariates	39

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Asthma and allergies				
Puerto Rican children have significantly higher adjusted odds of having current asthma (and are only racial/ethnic minority group with higher odds after adjustment for income and neighborhood factors)	Cross-sectional parental survey of 26 randomly selected New York City public elementary schools	Latino: $n = 2058$; AA: $n = 1171$; white: $n = 798$; Asian: $n = 646$	Adjusted for 4 covariates; Asian children had significantly lower adjusted odds of having current asthma (vs white children)	124
Higher adjusted odds of an asthma ED visit or hospitalization Higher adjusted odds of an asthma ED visit or hospitalization among Puerto Ricans, Dominicans, and "other Latinos" but not Mexicans	Analysis of data from parent-response questionnaires administered in 26 randomly selected New York City public elementary schools	Total sample: $N = 5250$[b]	Adjusted for 4 covariates	45
Higher diagnosed asthma prevalence among Puerto Rican children (22%) Higher total potential asthma burden (diagnosed plus possible but undiagnosed asthma) among Puerto Rican children	Cross-sectional analysis of parent-report questionnaire data from 14 low-income, diverse Chicago public elementary schools	Latino: $n = 6002$ (Puerto Rican: $n = 473$); AA: $n = 2938$; white: $n = 1560$	Not adjusted for covariates	46
Higher asthma prevalence Substantial rise in asthma prevalence over 11-y period (more than doubled)	Trends in asthma over time for children 0–17 y of age using data from 5 National Center for Health Statistics sources: National Health Interview Survey, National Ambulatory Medical Care Survey, National Hospital Ambulatory Medical Care Survey, National Hospital Discharge Survey, and Mortality Component of National Vital Statistics System	Not provided	Only unadjusted rates were presented; no differences or lower rate of asthma attack prevalence vs white children; no statistical comparisons performed or 95% CIs provided	40
Lower adjusted odds of daily anti-inflammatory use for asthma	Cross-sectional study using parental telephone interviews and electronic records for Medicaid-insured children 2–16 y of age with asthma in 5 managed care organizations in California, Washington, and Massachusetts	Latino: $n = 313$; AA: $n = 636$; white: $n = 512$	Adjusted for SES, health status, age, gender, and other sociodemographic variables	48
Higher adjusted odds of cockroach allergen sensitivity among Mexican American children Higher adjusted odds of dust mite allergen sensitivity among Mexican American children	Cross-sectional analysis of children 6–16 y of age who participated in allergen testing in the NHANES III	Mexican American: $n = 1546$; AA: $n = 1502$; white: $n = 1116$	Adjusted for 8 covariates; Mexican American children were the only Latino children examined	49
Higher adjusted odds of asthma-associated activity limitations Higher adjusted odds of need for urgent medical care for asthma in past 12 mo	Analysis of data from the Los Angeles County Health Survey on children <18 y of age	Latino: $n = 3675$; AA: $n = 566$; API: $n = 361$; white: $n = 1278$	Adjusted for 8 covariates	50
Lower adjusted odds of use of inhaled steroids Lower adjusted odds of use of inhaled steroids among those cared for in private practices	Analysis of data from the Childhood Asthma Severity Study, which used a 12-mo, retrospective, parent-reported questionnaire on asthma in a community sample of children <13 y of age residing in Connecticut and Massachusetts	Latino: $n = 255$; AA: $n = 139$; white: $n = 549$	Adjusted for 9 covariates	51

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
For Puerto Rican children, higher adjusted odds of physician-diagnosed asthma	Analysis of NHIS data on 3- to 17-y-olds currently symptomatic with wheezing	Puerto Rican: $n = 40$; Mexican: $n = 122$; AA: $n = 174$; white: $n = 610$	Adjusted for 10 covariates	125
Breastfeeding				
Lower proportion of children ever breastfed among Mexican American children	Analysis of breastfeeding data on children 12–71 mo of age in the NHANES III (1988–1994)	Mexican American: $n = 2118$; AA: $n = 1845$; white: $n = 1869$	Not adjusted for any covariates	53
Health status				
Higher adjusted likelihood of fair or poor health	Analysis of 3 y of NHIS data on children 0–17 y of age	Latino: $n = 12\,765$; API: $n = 2516$; AA: $n = 17\,324$; AI/AN: $n = 1067$; white: $n = 62\,572$	Adjusted for 4 covariates	112
HIV/AIDS				
Approximately twice the percentage of new HIV/AIDS diagnoses vs white children for those <13 y of age, perinatal transmission, and other pediatric cases Number of new HIV/AIDS diagnoses exceeds that for white children for those <13 y of age, perinatal transmission, and other pediatric cases Although Latino children constitute 14% of US children, number of new HIV/AIDS diagnoses among those 0–24 y of age[a] ($n = 3249$) almost equal to that of white individuals of same age ($n = 3707$)	Diagnoses of HIV/AIDS reported to the CDC in 2001–2004 by 33 states that used confidential, name-based reporting of HIV/AIDS cases for at least 4 y	Latino: $n = 3249$; AA: $n = 11\,554$; white: $n = 3707$[a]	No 95% CIs or P values presented for children; not adjusted for covariates	59
Infectious diseases (other than HIV/AIDS)				
Higher incidence rate of tuberculosis	Analysis of 8 y of data on children <15 y of age from North Carolina Tuberculosis Information Management System database	Latino: $n = 33$; AA: $n = 114$; API: $n = 12$; white: $n = 21$	Not adjusted for any covariates	64
Injuries				
Higher adjusted odds of not putting up stair gate	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	Latino: $n = 817$; AA: $n = 477$; white: $n = 718$	Adjusted for 9 covariates	66
Mental health and behavioral/developmental issues				
Significantly lower adjusted odds of externalizing behavioral disorders Significantly lower adjusted odds of ambulatory visits	Secondary analysis of 2 y of MEPS data on children 2–18 y of age	Total 1996 MEPS sample size: $N = 3955$; total 1997 MEPS sample size: $N = 5933$	Adjusted for 7–9 covariates	43
Lower adjusted likelihood of mental health services use among Medicaid-eligible adolescents in substance abuse treatment	Analysis of Oregon's substance abuse treatment database (Client Processing Monitoring System) for adolescents 12–17 y of age admitted to publicly funded treatment for a substance use disorder during a 9-y period	Total sample: $N = 25\,813$[b]	Adjusted for 17 covariates	126
Lower adjusted odds of receiving treatment for any condition from a mental health specialist	Analysis of National Longitudinal Survey of Youth and the Child/Young Adult supplement, a nationally representative sample of 7- to 14-y-old children	Total sample: $N = 2482$[b]	Adjusted for 28 covariates	67

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted odds of receiving treatment for behavior problems from a mental health specialist Lower adjusted odds of receiving treatment for depression from a mental health specialist				
Triple the adjusted odds of unmet need for mental health care	Cross-sectional analyses of data on children 3–17 y of age from the NHIS, the National Survey of American Families, and the Community Tracking Survey	Latino: $n = 695$; AA: $n = 867$; white: $n = 3049$	Adjusted for 8 covariates	127
Within 6 mo of a new episode of depression Lower adjusted odds of filling an antidepressant prescription Lower adjusted odds of any mental health visit Lower adjusted odds of any mental health visit or antidepressant prescription filled (combined)	Analysis of Washington state Medicaid claims for children 5–18 y of age	Latino: $n = 90$; AI/AN: $n = 154$; white: $n = 1048$	Adjusted for 5 covariates	128
Higher rate of unmet need for mental health services (no services among children with identified need)	Analysis of data from National Survey of America's Families for children 6–17 y of age	Latino: $n = 6022$; AA: $n = 6371$; white: $n = 31\,240$	Not adjusted for covariates	129
Higher adjusted odds of use of state-funded mental health services	Analysis of New York City data on receipt of services from state-funded mental health care facilities	Total sample: $N = 78\,085$ (including adults)[b]	Adjusted for 7 covariates	72
Substantially lower adjusted odds of receiving an ADHD diagnosis during outpatient primary care provider visits Substantially lower adjusted odds of receiving a stimulant prescription during outpatient primary care provider visits Substantially lower adjusted odds of receiving an ADHD diagnosis or stimulant prescription during outpatient primary care provider visits	Analysis of 6 y of data on children 3–18 y of age from National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey	Latino: $n = 4117$; AA: $n = 5074$; white: $n = 16\,406$	Adjusted for 3 covariates	130
Higher adjusted odds of developmental delays (based on parental concerns)	Analysis of data from National Survey of Early Childhood Health on children 4–35 mo of age	Total sample: $N = 2068$[b]	Adjusted for 8 covariates	58
Lower adjusted odds of use of specialty mental health services among children for whom an investigation of abuse or neglect had been opened by the child welfare system	Analysis of data from the National Survey of Child and Adolescent Well-being on use of specialty mental health services for 1 y after contact with child welfare among a cohort of children 2–14 y of age	Latino: $n = 487$; AA: $n = 899$; white: $n = 1208$	Adjusted for 11 covariates and 2 interaction terms; no longer significant adjusted odds in 1 of 3 models (when provider supply, linkage variables, and interactions added)	73
Higher adjusted odds of family never eating lunch or dinner together Higher adjusted odds of reading to child less than every day	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	Latino: $n = 817$; AA: $n = 477$; white: $n = 718$	Adjusted for 9 covariates	66

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Lower adjusted mean number of children's books in home				
Mortality				
Higher swimming pool drowning rates for adolescent boys Higher rates of drowning in neighborhood pools, including community shared apartment and housing complex pools	Analysis of 4 y of national data from the Consumer Products Safety Commission on drowning deaths of children 5–24 y of age from death certificates, medical examiner reports, and newspaper clippings	Latino: $n = 81$; AA: $n = 316$; AI/AN: $n = 18$; white: $n = 222$	Adjusted for income; values expressed as rate ratios and 95% CIs, but no P values were provided	75
Higher mortality rate for Puerto Rican children 1–4 y of age	Analysis of 6 y of data on children 5–14 y of age from the National Vital Statistics System, the National Longitudinal Mortality Study, and the Area Resource File	Puerto Rican: $n = 265$; white: $n = 67\,200$	Not adjusted for covariates; presented only as population rates; no statistical comparisons or 95% CIs; small sample sizes in 1979–1981 interval	79
Higher adjusted risk of death among those with ALL	Analysis of 9 population-based registries of the National Cancer Institute's Surveillance, Epidemiology, and End Results program	Latino: $n = 504$; AA: $n = 356$; AI/AN: $n = 61$; API: $n = 410$; white: $n = 3621$	Adjusted for 3 covariates; did not adjust for SES or insurance coverage	81
Higher adjusted odds of in-hospital death after congenital heart surgery	Analysis of data from the 2000 KID of the HCUP, limited to 19 states with adequate race/ethnicity data	Latino: $n = 1835$; AA: $n = 860$; white: $n = 4134$	Adjusted for 8 covariates; in full model, P value for Latino ethnicity was .05	82
Obesity, physical activity, and nutrition				
Significantly lower adjusted aerobic fitness level	Progressive treadmill protocol evaluation of aerobic fitness ($\dot{V}O_{2peak}$) of Los Angeles children 7–14 y of age, adjusting for gender, maturational stage, and body composition	Latino: $n = 36$; AA: $n = 19$; white: $n = 18$	Adjusted for 3 covariates but not SES	87
Double the adjusted odds of overweight Highest overweight prevalence of any racial/ethnic group	Analysis of height and weight data collected in 3 mo of physical fitness testing of students in grades 5, 7, and 9 in the Los Angeles County public school system	Total sample: $N = 281\,630$[b]	Adjusted for 4 covariates	88
Higher prevalence of overweight in boys among 8th-graders (35%), 10th-graders (40%), and 12th-graders (30%) (highest prevalence among all racial/ethnic groups studied) Higher prevalence of overweight in girls among 8th-graders (27%), 10th-graders (32%), and 12th-graders (19%) (highest prevalence among all racial/ethnic groups studied) Lower likelihood of eating breakfast regularly Less likely to regularly exercise vigorously among girls Higher number of hours of television-viewing on average weekday	Analysis of 10–17 y of data from Monitoring the Future, a nationally representative sample of students in the 8th, 10th, and 12th grades	Total sample: $N = 4800$–$17\,074$ per study interval, depending on grade and year[b]	Not adjusted for covariates	90

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Higher prevalence of overweight and obesity Boys more likely to consume >10% of calories as saturated fat Lower calcium intake	Cross-sectional survey of adolescents 11–18 y of age in 31 public schools in the Minneapolis, St Paul, and Osseo school districts of Minnesota	Total sample: $N = 4746$[b]	Not adjusted for covariates, but stratified analyses adjusting for grade and SES were performed but not reported because generally showed patterns similar to those of unadjusted analyses	91
Among Mexican Americans Higher prevalence of overweight Higher prevalence of overweight among 6- to 11-y-olds Higher prevalence of overweight among 12- to 19-y-olds Higher prevalence of overweight among boys (and highest of all racial/ethnic groups analyzed) Higher prevalence of overweight among 6- to 11-y-old boys (and highest of all racial/ethnic groups analyzed) Higher prevalence of overweight among 12- to 19-y-old boys Higher prevalence of overweight among girls Higher prevalence of at risk of overweight or overweight (and highest of all racial/ethnic groups analyzed) Higher prevalence of at risk of overweight or overweight among 6- to 11-y-olds Higher prevalence of at risk of overweight or overweight among 12- to 19-y-olds Higher prevalence of at risk of overweight or overweight among boys (and highest of all racial/ethnic groups analyzed) Higher prevalence of at risk of overweight or overweight among 6- to 11-y-old boys (and highest of all racial/ethnic groups analyzed) Higher prevalence of at risk of overweight or overweight among 12- to 19-y-old boys (and highest of all racial/ethnic groups analyzed) Higher prevalence of at risk of overweight or overweight among girls Higher prevalence of at risk of overweight or overweight among 12- to 19-y-old girls	Analysis of NHANES data on children 2–19 y old from 1999–2000 and 2001–2002	Latino: $n = 1475$; AA: $n = 1274$; white: $n = 1094$	Not adjusted for covariates; Mexican Americans only Latino group analyzed	93
Higher adjusted odds of overweight and highest adjusted odds of any racial/ethnic group Slower adjusted 1-mile run/walk time	Cross-sectional sample of California public school 5th, 7th, and 9th-graders (10–15 y old)	Latino: $n = 330\,758$; AA: $n = 58\,491$; Asian: $n = 63\,292$; Pacific Islander: $n = 7977$; Filipino: $n = 22\,598$; AI/AN: $n = 7977$; white: $n = 275\,722$	Adjusted for 2 covariates and stratified according to age	94

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Orthopedics				
For treatment of supracondylar humerus fractures, more likely to undergo closed reduction with internal fixation (percutaneous pinning)	Retrospective examination of selected pediatric fractures in the KID of the HCUP	Latino: $n = 659$; AA: $n = 207$; white: $n = 1478$	Not adjusted for covariates; no disparities seen for femur or forearm fractures	96
Quality				
Lower adjusted odds of receiving any counseling during well-child visits Shorter well-child visit duration	Cross-sectional analysis of 10 y of data on children 0–18 y of age from the National Ambulatory Medical Care Survey	Total sample: $N = 2892$[b]	No multivariable adjustments performed for visit duration; counseling findings were adjusted for 7 covariates	97
Lower primary care provider strength-of-affiliation scores (unadjusted and adjusted) Lower primary care provider interpersonal relationship scores (unadjusted and adjusted [if required by managed care organization to seek referral and to stay in network])	Telephone survey of parents of random sample of 413 children attending elementary school in 3 suburban communities in San Bernardino County, California	Latino: $n = 84$; AA: $n = 100$; API: $n = 91$; white: $n = 102$	Adjusted for 11 covariates	100
Among those in which the primary language spoken at home is a language other than English Lower adjusted scores for timeliness of care Lower adjusted scores for provider communication Lower adjusted scores for staff helpfulness Lower adjusted scores for health insurance plan service Lower adjusted ratings of child's personal doctor Lower adjusted ratings of specialist Lower adjusted ratings of health plan	Analysis of parental survey data on children 0–17 y of age from the national CAHPS Benchmarking Database 1.0 administered by Medicaid sponsors comprising 33 health maintenance organizations from Arkansas, Kansas, Minnesota, Oklahoma, Vermont, and Washington	Latino: $n = 842$; AA: $n = 1344$; API: $n = 291$; AI/AN: $n = 330$; white: $n = 6328$	Adjusted for 4 covariates; no disparities noted for Latino children in households in which English is primary language	101
Among those seen in the ED for acute gastroenteritis Lower adjusted likelihood to undergo >2 diagnostic tests Lower adjusted likelihood of having undergone radiography	All patients seen in the ED over a 6-mo period with a discharge diagnosis of acute gastroenteritis as identified through a computerized patient log	Latino: $n = 143$; AA: $n = 122$; white: $n = 132$	Adjusted for 7 covariates	131
Lower mean participatory decision-making score for child's physician	Cross-sectional, population-based, random-digit-dialing survey of parents/guardians of children 3–18 y of age residing in 111 counties in west Texas	Latino: $n = 1720$; white: $n = 2156$	Adjusted for 11 covariates	132
Lower adjusted scores for comprehensiveness of primary care	Cross-sectional survey of parents of children in 228 classes, from kindergarten through 6th grade, at 18 elementary schools in a large urban school district in California	Latino: $n = 1292$; API: $n = 1158$; AA: $n = 458$; white: $n = 479$	Adjusted for 5 covariates	102

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Among those hospitalized for pneumonia Higher adjusted risk ratio of admission through EDs Lower adjusted odds of bronchoscopy Lower adjusted odds of mechanical ventilation Longer adjusted length of stay Higher adjusted charges	Analysis of 3 y of data on children 0–17 y of age hospitalized for pneumonia from the National Inpatient Sample of the HCUP	Latino: $n = 15\,152$; API: $n = 2050$; AA: $n = 17\,095$; white: $n = 43\,180$	Adjusted for 6–7 covariates	113
Greater adjusted odds of child being assigned to health care provider Greater adjusted odds of parent being not very likely to recommend child's well-child care provider Greater adjusted odds of health care provider never/only sometimes understanding how parent prefers to rear child Greater adjusted odds of health care provider never/only sometimes understanding child's specific needs Greater adjusted odds of discussing violence in the community, and use of alcohol or drugs in household	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	Latino: $n = 817$; AA: $n = 477$; white: $n = 718$	Adjusted for 9 covariates	32
Special health care needs				
Among children with special health care needs Higher adjusted odds of being uninsured Higher adjusted odds of having no usual source of care Higher adjusted odds of not identifying a regular clinician Higher adjusted odds of not being satisfied with care Higher adjusted odds of being unable to get needed medical care Lower adjusted odds of usual source of care being doctor's private office or health maintenance organization Higher adjusted odds of not having seen doctor in previous 12 mo Average 2 fewer doctor visits per year	Analysis of data on children 0–17 y of age with special health care needs in the NHIS on disability	Latino: $n = 1777$; AA: $n = 1762$; white: $n = 6365$	Adjusted for 9–10 covariates	104
Lower adjusted odds of receiving adequate time and information from child's health care provider	Analysis of National Survey of Children With Special Health Care Needs	Total sample: $N = 38\,866$[b]	Adjusted for 6 covariates; no disparities in any unmet need or problem with specialty referral	103
Among children with special health care needs Higher adjusted odds of having no usual source of care Higher adjusted odds of having difficulty receiving referrals for specialty care	Analysis of data on children 0–17 y of age from the National Survey of Children With Special Health Care Needs	Not indicated	Adjusted for 6 covariates	105

TABLE 3 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Higher adjusted odds of dissatisfaction with care Higher adjusted odds of family members having to reduce or stop employment because of child's condition				
Among children with special health care needs Higher adjusted odds of not receiving family-centered care Higher adjusted odds of parents experiencing employment consequences as a result of child's condition	Analysis of data on children 0–17 y of age from the National Survey of Children With Special Health Care Needs	Latino: $n = 3424$; API: $n = 197$; AA: $n = 3833$; white: $n = 28\,967$	Adjusted for 6 covariates	133
Among children with special needs Greater adjusted odds of problems with ease of using health care services	Analysis of data on special-needs children 0–17 y of age from the National Survey of Children With Special Health Care Needs	Latino: $n = 3210$; AA: $n = 3820$; white: $n = 28\,916$	Adjusted for 13 covariates	106
Surgery				
For those hospitalized for appendicitis Longer time to operation (regardless of disease severity) Longer length of stay (regardless of disease severity) Higher hospital charges (regardless of disease severity) Higher adjusted appendicitis rate Higher adjusted odds of perforation or other complicating factors	Analysis of data on children 1–17 y of age with appendicitis from the Nationwide Inpatient Sample and the KID	Total sample: $N = 428\,463$[b]	Not adjusted for covariates for time to operation, length of stay, or hospital charges; other outcomes include adjustment for 6 covariates	107
Use of health services				
Greater adjusted odds of ≥1 y since last physician visit Lower adjusted number of physician visits in previous 12 mo Greater adjusted odds of suboptimal health status Greater adjusted odds among Puerto Rican children of suboptimal health status Mexican American children had greater adjusted odds of suboptimal health status and ≥1 y since last physician visit and made a lower adjusted number of physician visits in the previous year	Analysis of 3 y of NHIS data on children 0–17 y of age	Latino: $n = 12\,765$; AA: $n = 17\,324$; API: $n = 2516$; AI/AN: $n = 1067$; white: $n = 62\,572$	Adjusted for 4 covariates	112
Lower adjusted mean number of calls to doctor's office in previous year	Analysis of data on children 4–35 mo of age from the National Survey of Early Childhood Health	Latino: $n = 817$; AA: $n = 477$; white: $n = 718$	Adjusted for 9 covariates	32

[a] Sample sizes includes those 0 to 24 years of age, because the CDC grouped those 15 to 24 years of age together.

[b] Sample sizes were not disaggregated in article according to race/ethnicity.

the previous 12 months, as well as a higher potential asthma burden (diagnosed plus possible but undiagnosed asthma). Latinos have lower adjusted odds of use of inhaled steroids and of daily anti-inflammatory medications. Disparities among Latino subgroups (compared with white children) include higher adjusted odds of asthma ED visits and hospitalizations among Puerto Ricans, Dominicans, and "other Latinos" (except Mexican Americans) and higher adjusted odds of cockroach and dust mite allergen sensitivity among Mexican Americans.

Eleven studies documented Latino disparities in mental health care and behavioral/developmental issues (Table 3). Disparities included significantly higher unmet need for mental health care, and lower odds of any mental health visit, outpatient visits, antidepressant prescriptions, and receiving treatment from a mental health specialist for any condition, behavior problems, or depression. Latinos have higher odds of developmental delays but lower odds of being diagnosed with externalizing behavioral disorders. Lower odds were noted for use of mental health services among children being investigated for possible abuse or neglect and among Medicaid-eligible teenagers in substance abuse treatment, although 1 study found higher odds of use of state-funded mental health services in New York City. Latinos have substantially lower adjusted odds of receiving an ADHD diagnosis or receiving stimulant prescriptions during outpatient primary care visits. Young Latino children have higher adjusted odds of being read to less than every day, of having fewer numbers of children's books in the household, and of the family never eating lunch or dinner together.

Many disparities have been documented for Latino children with special health care needs, including higher adjusted odds of being uninsured, having no usual source of care, parental dissatisfaction with care, having unmet medical care needs, not having seen the physician in the past year, not receiving adequate time and information from the health care provider, averaging fewer doctor visits per year, experiencing difficulties receiving specialty referrals, having family members reduce or stop employment because of the child's condition, not receiving family-centered care, and experiencing problems with ease of use of health care services.

Quality

Compared with white children, Latino children have higher adjusted odds of being assigned to a health care provider and lower adjusted scores for comprehensiveness of primary care and primary care provider strength of affiliation, interpersonal relationship, and participatory decision-making (Table 3). Latino children have a shorter average well-child visit duration, lower adjusted odds of receiving any counseling during well-child visits, and greater adjusted odds of the parent not being very likely to recommend the child's health care provider, of the health care provider never or only sometimes understanding the child's specific needs and how the parent prefers to rear the child, and of the provider discussing violence in the community and use of alcohol or drugs in the household. Similar disparities in the quality of primary care were noted for Latino children living in households in which English is not the primary language spoken (in comparison with white children).

Among those seen in the ED with acute gastroenteritis, Latino children had lower adjusted odds than white children of undergoing 2 or more diagnostic tests and of having undergone radiography (Table 3). Among children with supracondylar humerus fractures, Latinos were more likely to undergo closed reduction with internal fixation.

American Indians and Alaska Natives

Sixteen articles (15%) addressed disparities in AI/AN children, which is the fewest articles for any racial/ethnic group (Table 4).

Mortality

AI/AN children have a higher age-specific crude mortality rate compared with that of white children, both in national and urban samples (Table 4). A higher adjusted risk of death also has been documented for AI/AN children with ALL.

Use of Health Services

AI/AN children have higher adjusted odds than white children of going 1 year or longer since their last physician visit (Table 4).

Prevention and Population Health

Data from the state of Minnesota reveal a firearm injury rate for AI/AN children that is more than 7 times higher than that for their white counterparts (Table 4). Several studies have documented higher adjusted odds of overweight and obesity among AI/AN children. Other studies have shown a slower adjusted 1-mile run/walk time and lower calcium intake among AI/AN boys.

Adolescent Health Issues

Female AI/AN adolescents have higher risks than their white counterparts of needing but not getting medical care and of perpetrating violence (Table 4). Male AI/AN adolescents have a higher risk than their white counterparts of skipping breakfast, having poor/fair health status, and perpetrating violence. National data from 2 studies revealed that the birth rate for AI/AN fe-

TABLE 4 Disparities in the Health and Health Care of AI/AN Children

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Adolescents				
Female adolescents: higher risks of needing but not getting medical care and perpetrating violence Male adolescents: higher risk of skipping breakfast, poor/fair health status, and perpetrating violence	Analysis of Add Health (waves 1 and 2), a nationally representative school-based study of youths in grades 7–12, with follow-up into adulthood	AI/AN: $n = 136$; AA: $n = 3038$; API: $n = 1021$; Latino: $n = 2340$; white: $n = 7728$	Prevalence in published tables not adjusted, but authors stated that adjustments for income and parental education had minimal influence on findings; significant disparities were identified by using 95% CIs that did not overlap with measure for white adolescents; no formal statistical evaluation of disparities provided	35
Live birth rate for adolescent girls 15–17 y of age >2 times higher	1990–1998 natality files from the National Vital Statistics System	Not provided	Expressed as rates per 1000; not adjusted for covariates	36
Birth rate for 15–19 y-old girls almost 3 times as high	Birth certificate data reported to the CDC National Center for Health Statistics	Not provided	Not adjusted for covariates; no *P* values or 95% CIs	38
Injuries				
Firearm injury rate >7 times higher	Analysis of data from Minnesota Department of Health's Minnesota Trauma Data Bank on fatal and nonfatal firearm injuries in children 0–19 y of age	Total sample: $N = 175$[a]	Not adjusted for covariates	65
Mental health and behavioral/developmental issues Lower adjusted likelihood of mental health services use among Medicaid-eligible and non–Medicaid-eligible adolescents in substance abuse treatment	Analysis of Oregon's substance abuse treatment database (Client Processing Monitoring System) for adolescents 12–17 y of age admitted to publicly funded treatment for a substance use disorder during a 9-y period	Total sample: $N = 25\,813$[a]	Adjusted for 17 covariates	126
Within 6 mo of a new episode of depression Lower adjusted odds of filling an antidepressant prescription Lower adjusted odds of any mental health visit or antidepressant prescription filled	Analysis of Washington State Medicaid claims for children 5–18 y of age	AI/AN: $n = 154$; Latino: $n = 90$; white: $n = 1048$	Adjusted for 5 covariates	128
Mortality				
Significantly higher age-specific mortality rate among 1- to 14-y-old urban children (vs urban white children)	Vital statistics data for 10 y from King County, Washington	Not stated for this outcome	Not adjusted for covariates	134
Approximately 50% higher mortality rate for children 1–4 y of age Higher mortality rate for children 5–14 y of age	Analysis of 6 y of data on children 5–14 y of age from the National Vital Statistics System, the National Longitudinal Mortality Study, and the Area Resource File	AI/AN: $n = 1336$; white: $n = 67\,200$	Not adjusted for covariates; presented only as population rates; no statistical comparisons or 95% CIs	79
Higher adjusted risk of death among those with ALL	Analysis of 9 population-based registries of the National Cancer Institute's Surveillance, Epidemiology, and End Results program	AI/AN: $n = 61$; AA: $n = 356$; API: $n = 410$; Latino: $n = 504$; white: $n = 3621$	Adjusted for 3 covariates; not adjusted for SES or insurance coverage	81
Obesity physical activity and nutrition				
Higher adjusted odds of overweight	Analysis of height and weight data collected in 3 mo of physical fitness testing of students in grades 5, 7, and 9 in the Los Angeles County public school system	Total sample: $N = 281\,630$[a]	Adjusted for 4 covariates	88

TABLE 4 Continued

Disparity (vs White Children)	Study Design	Sample Size(s)	Notes	Ref No.
Higher prevalence of overweight and obesity (highest prevalence of any racial/ethnic group for boys) Lower calcium intake among boys	Cross-sectional survey of adolescents 11–18 y of age in 31 public schools in the Minneapolis, St Paul, and Osseo school districts of Minnesota	Total sample: $N = 4746$[a]	Not adjusted for covariates, but authors stated that stratified analyses adjusting for grade and SES were performed but not reported because they generally showed patterns similar to those of unadjusted analyses	91
Higher adjusted odds of overweight Slower adjusted 1-mile run/walk time	Cross-sectional sample of California public school 5th-, 7th-, and 9th-graders (10–15 y old)	AI/AN: $n = 7977$; AA: $n = 58\,491$; Asian: $n = 63\,292$; Filipino: $n = 22\,598$; Latino: $n = 330\,758$; Pacific Islander: $n = 7977$; white: 275 722	Adjusted for 2 covariates and stratified according to age; run/walk times not significantly different for 2 older strata for both genders	94
Ophthalmology				
Lower adjusted odds of being diagnosed with any eye or vision condition	Analysis of 6 y of data for children 0–17 y of age in the MEPS	Total sample: $N = 2813$[a]	Adjusted for 13 covariates; the authors concluded that disparities indicated possible underdiagnosis, undertreatment, or both; no disparities in being diagnosed with an eye or vision condition other than conjunctivitis	95
Quality				
Lower adjusted scores for timeliness of care Lower adjusted scores for provider communication Lower adjusted scores for health insurance plan service Lower adjusted ratings of child's personal doctor Lower adjusted ratings of health plan	Analysis of parental survey data on children 0–17 y of age from the CAHPS Benchmarking Database 1.0 administered by Medicaid sponsors comprising 33 health maintenance organizations from Arkansas, Kansas, Minnesota, Oklahoma, Vermont, and Washington	AI/AN: $n = 330$; AA: $n = 1344$; API: $n = 291$; Latino: $n = 842$; white: $n = 6328$	Adjusted for 4 covariates	101
Use of health services				
Greater adjusted odds of ≥1 y since last physician visit More than double the adjusted odds of suboptimal health status and highest prevalence of any racial/ethnic group	Analysis of 3 y of NHIS data on children 0–17 y of age	AI/AN: $n = 1067$; API: $n = 2516$; AA: $n = 17\,324$; Latino: $n = 12\,765$; white: $n = 62\,572$	Adjusted for 4 covariates	112

MEPS indicates Medical Expenditure Panel Survey; Add Health, National Longitudinal Study of Adolescent Health; NHIS, National Health Interview Survey; CAHPS, Consumer Assessment of Health Plans.

[a] Sample sizes were not disaggregated in article according to race/ethnicity.

male adolescents is 2 to 3 times higher than that of white adolescents.

Health Status

AI/AN children have higher adjusted odds than do white children of being in poor or fair health and the highest prevalence of these suboptimal health ratings of any racial/ethnic group (Table 4).

Mental Health Care

Within 6 months of a new episode of depression, AI/AN children have lower adjusted odds than white children of any mental health visit or antidepressant prescription being filled. AI/AN youth in treatment for substance abuse also have a lower adjusted likelihood of mental health services use.

Quality

Compared with the parents of white children, the parents of AI/AN children gave lower adjusted scores for their child's health care timeliness, health care provider communication, and health insurance plan service, and lower adjusted ratings for their child's personal doctor and health plan (Table 4). National data also reveal lower adjusted odds of being diagnosed with any eye or vision condition.

Multiracial Children

The search terms did not yield any articles on disparities among multiracial children.

DISPARITIES AMONG RACIAL/ETHNIC SUBGROUPS

Fifteen studies (14%) included analyses of disparities in 1 or more racial/ethnic subgroup (in comparison with white children). Five studies of APIs (21% of all studies of APIs) and 10 studies of Latinos (15% of all studies of Latinos) examined racial/ethnic subgroup disparities; none of the analyses for AA or AI/AN children included subgroup analyses.

STUDIES EVALUATING INTERVENTIONS TO REDUCE DISPARITIES

The search terms yielded only 2 studies that evaluated interventions to reduce racial/ethnic disparities (Table 5). A quasi-experimental evaluation of a school-based Internet and video intervention that focused on health snacks and gym labs resulted in significant reductions in dietary fat intake among all 3 minority groups as well as among those in the white group, and significant increases in physical activity among low-income children in all 3 minority groups and white children. It was unclear, however, what the control group received, there was no overall difference between intervention and control children in fat-intake reduction, and participants in

TABLE 5 Results of Studies Evaluating Interventions to Reduce Disparities in the Health and Health Care of Minority Children

Disparity Targeted	Findings	Study Design	Sample Size(s)	Notes	Ref No.
Nutrition and exercise in middle-school children	Dietary fat intake significantly reduced in intervention-group girls for AA, Latino, AI/AN, and white children; significantly increased physical activity among those with lowest income among AA, Latino, Asian, and white children	Quasi-experimental evaluation of a 4-session Internet and video intervention with healthy snack and gym labs; intervention occurred in 2 urban, low- to middle-income middle schools (gym lab in 1) in the Midwest	AA: $n = 58$; white: $n = 47$; Asian: $n = 9$; Latino: $n = 4$; AI/AN: $n = 4$	Small sample sizes from only 2 schools; unclear what control group received (if anything); unclear when postintervention evaluation occurred; no overall difference between intervention and control children in fat intake reduction; both groups actually decreased their amount of physical activity	135
Immunization rates among 0- to 2-y-olds	No statistically significant differences (vs white children) in postintervention population immunization rates for 24-mo-olds among AA and Latino children; no statistically significant difference (vs white children) in postintervention population immunization rate for Latino (but not AA) 12-mo-olds	Prepopulation/postpopulation study in Monroe County, New York, of impact of community-wide reminder, recall, and outreach system for childhood immunizations administered by lay outreach workers in 8 practices (expanded to 10 after 4 y). Outcomes were monitored in a 10% random sample selected from suburban practices and a 25% random sample from urban practices.	Total sample: $N = 20\,132$[a]	9%–74% of cohort (depending on study region) did not receive intervention; immunization rates unadjusted (not adjusted for any potential confounders)	136

[a] Sample sizes were not disaggregated in article according to race/ethnicity.

both the intervention and control groups decreased their amount of physical activity.

A preintervention and postintervention study in an upstate New York county of the effects of a community-wide reminder, recall, and outreach system for childhood immunizations resulted in no statistically significant differences from 24-month-old white children in postintervention immunization rates for 24-month-old AA and Latino children, and no statistically significant difference between only Latino and white 12-month-old children in postintervention immunization rates. Up to 74% of the cohort, however, did not receive the intervention in some county regions, and the immunization rates were not adjusted for confounders.

METHODOLOGIC ISSUES

Failure to evaluate children separately from adults was the most common reason for exclusion of studies from the final database, accounting for 27 (22%) of the excluded studies. Another commonly encountered methodologic issue was the combination of all nonwhite children into 1 group, which occurred in 11 (9%) of the excluded studies. An additional 10 studies (8%) failed to provide a white comparison group. Among the 109 studies in the final database, 27 (22%) did not perform multivariable or stratified analyses to ensure that racial/ethnic disparities persisted after adjustment for socioeconomic status (SES) and other potential confounders.

IMPLICATIONS

Extensiveness and Pervasiveness of Disparities

A comprehensive review of the literature revealed that racial/ethnic disparities in children's health and health care are quite extensive, pervasive, and persistent. Disparities were noted across the spectrum of health and health care, including in mortality rates, access to care and use of services, prevention and population health, health status, adolescent health, chronic diseases, special health care needs, quality of care, and organ transplantation. In addition, the data indicate that racial/ethnic disparities are persisting or worsening over time, at least in the few areas for which data from secular-trend studies are available, such as overall mortality rates, elevated blood lead concentrations, and asthma prevalence, mortality, and hospitalizations.

Mortality and Chronic Disease

Although racial/ethnic disparities in adult mortality[21] and chronic disease[22] rates have received much attention, little attention has been paid to these issues in children (other than for infant mortality). Nevertheless, review of the literature identified disparities in mortality rates for all 4 major racial/ethnic groups of US children. The extent and diversity of these mortality-rate disparities are concerning: these disparities include substantially greater risks than for white children of all-cause mortality; death from drowning, from ALL, from congenital heart defects, and after congenital heart defect surgery; and an earlier median age at death for those with Down syndrome and congenital heart defects. Additional research is needed to determine whether other racial/ethnic disparities exist in childhood mortality rates, the causes of these disparities, and interventions that are effective in reducing or eliminating mortality-rate disparities.

Extensive childhood disparities were found for chronic diseases, including asthma, cancer, eye disorders, HIV/AIDS, kidney disease, mental health, special health care needs, and stroke. In particular, multiple studies have been conducted on disparities in asthma, mental health, and special health care needs. Nevertheless, many gaps exist in the literature, and further study is needed to determine the etiology of and effective interventions for disparities in childhood chronic diseases.

Disparities as a Quality Issue

It has been suggested that a useful approach to addressing racial/ethnic disparities in children's health care is to frame disparities as a quality-of-care issue.[23] This review of the literature identified multiple racial/ethnic disparities in the quality of children's health care, including inequalities in the quality of primary care, asthma care, cardiovascular surgery, mental health care, pneumonia hospitalizations, ophthalmologic care, orthopedic conditions, and care of children with end-stage renal disease. Additional study is warranted, not only of the etiology and pervasiveness of disparities in the quality of pediatric care, but also of interventions that would be effective in achieving quality improvement among racial/ethnic minority children.

Research Implications

In the course of reviewing the disparities literature, certain key methodologic and research issues were identified. Attention to these issues has the potential to advance the field and enhance the rigor of studies. A total of 48 studies were excluded from the database because they combined all minority children into a nebulous "nonwhite" category, failed to include a comparison group consisting of white children, or did not perform separate analyses with children disaggregated from adults.

Occasionally, there may be statistically legitimate reasons to not compare study findings for specific minority racial/ethnic groups with those of white children (such as when there truly are

small sample sizes for specific minority groups in the study population). The recurrent findings in the literature, however, of combining minority children into a "nonwhite group" and failure to collect data for specific, populous minority groups of children raise several key issues. It is critical that current and future pediatric research be relevant, meaningful, and generalizable for all children. The explosive growth in racial/ethnic diversity of US children makes it imperative that pediatric research funding not ignore specific questions or populations. In addition, as new interventions, practices, and technologies are evaluated, it is important to consider translational research on the application of these innovations to diverse populations and settings.

Almost one-quarter of the excluded studies did not use multivariable or stratified analyses to adjust for covariates that might confound disparities findings. For several domains, such as mental health, asthma, and vision disorders, there is an unresolved issue that warrants further investigation; it is unclear whether (1) a general quality issue exists for minority children of underdiagnosis and undertreatment of certain conditions, (2) there is a lower prevalence of these conditions in certain groups, (3) racial/ethnic differences occur in access or treatment preferences, or (4) some combination of these phenomena apply.

More disparities research is needed on API and AI/AN children, because a paucity of studies on these groups was identified. The few studies that examined relevant subgroups of racial/ethnic minority children identified noteworthy racial/ethnic disparities. More research is needed on childhood disparities among black subgroups (such as AAs versus Caribbean blacks versus recent African immigrants), Latinos (such as Mexican Americans, Puerto Ricans, and Cuban Americans), AIs/ANs (such as major tribal groups), and APIs (such as Chinese Americans versus Vietnamese versus Hmong). Our call for more studies on racial/ethnic subgroup disparities echoes a recommendation published 15 years ago by the AAP Task Force on Minority Children's Access to Pediatric Care that more attention be paid to the heterogeneity of API populations.[24]

Limitations

Certain limitations of this literature review should be noted. The literature search consisted of studies from 1950 through March 2007, so studies after March could not be included. Because the search strategies only identified published citations with "disparities" as a key word, studies that reported disparities or disparities interventions but did not use this key word would have been missed; in particular, research from earlier years before the "disparities" term enjoyed wider usage would have been overlooked. The focus was on racial/ethnic disparities, so studies that documented a lack of disparities were not reviewed. Only 21 studies, however, were excluded that found no significant differences according to race/ethnicity, equivalent to 9% of the database of full-print studies examined, and 17% of all exclusions.

Interventions to Reduce Disparities

This literature review identified only 2 studies that evaluated interventions to reduce racial/ethnic disparities in children's health and health care and that also compared the minority group to a white group, and none was a randomized, controlled trial. These findings suggest that there is a need for rigorous evaluations of interventions aimed at reducing childhood disparities, especially in light of the substantial number of studies identified that documented a wide variety of racial/ethnic disparities in children's health and health care.

Only articles that examined racial/ethnic disparities in the context of comparisons to white children were included in the literature review. For certain health outcomes for which racial/ethnic disparities are well documented, published studies may only have focused on disparities interventions limited to a single minority group. Because the literature-search inclusion criteria required comparison between a minority group and a white group, successful disparities-intervention studies limited to a single minority group were excluded, by necessity, from this technical report, such as recent randomized trials of interventions to insure uninsured Latino children and prevent HIV in AA girls.[25,26]

CONCLUSIONS

This technical report documents that racial/ethnic disparities in children's health and health care are extensive, pervasive, and persistent. Disparities were noted across the spectrum of health and health care, including in mortality rates, access to care and use of services, prevention and population health, health status, adolescent health, chronic diseases, special health care needs, quality of care, and organ transplantation. Methodologic flaws were identified in how such disparities are documented and analyzed. Without recognition of child health disparities as pervasive problems, sound methodologies to assess the magnitude of disparities, and rigorous evaluation of disparities interventions, the pediatric community will not be able to realize the vision of the AAP to attain optimal physical, men-

tal, and social health and well-being of all infants, children, adolescents, and young adults.

Committee on Environmental Health

Radiation Disasters and Children

ABSTRACT. The special medical needs of children make it essential that pediatricians be prepared for radiation disasters, including 1) the detonation of a nuclear weapon; 2) a nuclear power plant event that unleashes a radioactive cloud; and 3) the dispersal of radionuclides by conventional explosive or the crash of a transport vehicle. Any of these events could occur unintentionally or as an act of terrorism. Nuclear facilities (eg, power plants, fuel processing centers, and food irradiation facilities) are often located in highly populated areas, and as they age, the risk of mechanical failure increases. The short- and long-term consequences of a radiation disaster are significantly greater in children for several reasons. First, children have a disproportionately higher minute ventilation, leading to greater internal exposure to radioactive gases. Children have a significantly greater risk of developing cancer even when they are exposed to radiation in utero. Finally, children and the parents of young children are more likely than are adults to develop enduring psychologic injury after a radiation disaster. The pediatrician has a critical role in planning for radiation disasters. For example, potassium iodide is of proven value for thyroid protection but must be given before or soon after exposure to radioiodines, requiring its placement in homes, schools, and child care centers. Pediatricians should work with public health authorities to ensure that children receive full consideration in local planning for a radiation disaster.

ABBREVIATIONS. TMI, Three Mile Island; KI, potassium iodide; SI, International System of Units; CT, computed tomography (scan); NRC, Nuclear Regulatory Commission; FDA, Food and Drug Administration.

INTRODUCTION

Several large-scale radiation disasters have befallen children in the past, including the detonation of nuclear bombs in Hiroshima and Nagasaki, Japan; the nuclear power plant disaster in Chernobyl; and exposure to a cesium-127 source scavenged from an abandoned hospital in Brazil. In each case, postevent medical surveillance proved that children were disproportionately affected after radiation exposure.

In recent years, accidents at several nuclear power plants have proven such events can lead to the widespread discharge of radioactive materials into the environment. Additionally, acts of domestic terrorism involving chemical and biological weapons have recently occurred, raising fears about the intentional use of a radioactive device against a civilian population that includes children. Because of these threats, there is a need for pediatricians to become more informed about the issues that would occur in the case of a significant radiologic event.

HISTORY

Several historical events have shaped our understanding of the consequences of radiation disasters. The atomic bomb blasts in Hiroshima and Nagasaki in 1945 during World War II remain the most defining moments in the consequences of a nuclear exposure. The Avalon Project at Yale Law School[1] estimated that in Hiroshima, the bomb released power equal to 15 kilotons of trinitrotoluene (TNT), killing an estimated 66 000 and injuring 69 000 of the 255 000 exposed. The Nagasaki release, containing a 22-kiloton force, killed an estimated 39 000 among the 195 000 exposed. In 1954, fallout from nuclear weapons tests on Bikini Island fell on neighboring islands, producing significant health effects in children; of 32 Marshallese exposed to fallout before 20 years of age, 4 developed thyroid cancer and 1 developed leukemia.[2] This event led the American Academy of Pediatrics to establish the Committee on Radiation Hazards and Congenital Malformations, the predecessor to the Committee on Environmental Health.[2]

On March 28, 1979, a nuclear power plant, Three Mile Island (TMI), had a near "meltdown" (overheating of the fuel rods and a release of radiation) that produced negligible doses among people living nearby: a maximum of 0.001 Sv (100 mrem) and an average dose to the community of 0.00001 Sv (1 mrem).[3] The TMI accident brought into question the safety of nuclear power plants and the potential consequences of a power plant mishap.[4,5] Immediate administration of potassium iodide (KI) was recommended for those living near TMI, but it was not available. There were no biological effects of the exposure but significant psychologic sequelae occurred.[4,5]

In April 1986, a power plant in Chernobyl (also known as Chornobyl), Ukraine, had a mishap that produced a meltdown. The area around the reactor was heavily contaminated with plutonium, cesium, and radioactive iodine. An estimated 120 million Ci of radioactive material were released, contaminating

more than 21 000 km^2 of land, with the greatest areas of fallout occurring in Ukraine, Belarus, and the Russian Federation.[6,7] Approximately 135 000 people were permanently evacuated.[8] A total of almost 17 million people, including 2.5 million younger than 5 years of age, were exposed to excess radiation.[7] The first delayed effect, beginning 4 years after exposure, was the occurrence of a great excess of cases of thyroid cancers in children and adolescents, especially among those younger than 4 years of age at the time of the accident.[9] Seventeen years later, the area remains uninhabited because of persistent concerns about environmental contamination.

On September 13, 1987, in Goiania, Brazil, a lead canister containing 1400 Ci of radioactive cesium was left in a building when it was abandoned by radiotherapists. The canister was taken and opened by looters. Children played with the material inside, rubbing it on their bodies so they glowed in the dark.[10] An estimated 250 people were exposed, with some receiving radiation doses as high as 10 Sv (1000 rem); 4 died of acute radiation sickness.[11] Victims developed radiation-associated illnesses that ranged from significant skin injury (radiation burns) to acute radiation sickness to long-term health problems. Thousands of people rushed to emergency departments because of fear of contamination.[10] Mitigation efforts required the removal of 6000 tons of clothing, furniture, dirt, and other materials.[12]

SOURCES OF POTENTIAL RADIATION EXPOSURE

Humans are exposed to an estimated average of 0.0036 Sv (360 mrem) of radiation annually. This radiation exposure comes from a number of natural and manmade sources, including cosmic radiation and radon, cigarette smoke, medical devices, home appliances, and pharmaceutical agents. Air flight is associated with cosmic radiation exposure; a flight from New York to London results in an estimated 0.00005 to 0.0001 Sv (5–10 mrem) of radiation exposure. Radiation exposure from medical radiography can range from 0.00005 to 0.0001 Sv (5–10 mrem) for a chest radiograph to as much as 0.05 Sv (5000 mrem) for computed tomography (CT).[13]

Radiologic threats can be unintentional or intentional. Unintentional threats include power plant disasters such as Chernobyl and TMI. Intentional threats are associated with military conflict or terrorism. Three major types of radiation disaster threats are 1) the detonation of a nuclear weapon; 2) damage of a facility that contains nuclear material (eg, a nuclear waste reprocessing facility, food irradiation plant, or nuclear power plant); and 3) dispersal of nuclear material, either by detonation of a conventional explosive (a radioactive dispersal device or "dirty bomb") or the release of nuclear materials in transit. Any of these occurrences could result from human error or terrorist activity.

Terrorist use of a radioactive dispersal device is considered the most likely present-day threat.[14] Radioactive dispersal devices are designed to use radioactive material obtained from relatively accessible sources, such as university research laboratories or hospital radiation therapy centers.[14,15] Although they would not produce significant damage to nearby structures, these devices could render an area uninhabitable; as little as 1 Ci of radioactive material can be dispersed several blocks, forcing evacuation and closure of that area.

In the United States, there are 103 active nuclear reactors in 66 power plants across 31 states.[16] Nuclear power plants pose several distinct radiation risks. The most important of these risks is the potential for release of radioiodines into the environment. Additionally, spent reactor fuel rods, which are typically retained by the nuclear power plant for many years, present a radiation hazard that is distinct from an incident that releases a radioactive cloud.

Since the 1990s, the possibility of a terrorist group creating a nuclear weapon has become more possible.[17] A low-yield detonation device (<10 kilotons) would require only a small amount of plutonium or highly enriched uranium, both of which are thought to be obtainable in the current era.[10]

RADIATION CHARACTERISTICS AND TERMINOLOGY

Unstable atoms, in an effort to achieve stability, emit energy in the form of ionizing radiation. Ionizing radiation is a type of high-frequency energy that has adverse biologic effects, including damage to DNA, production of free radicals, disruption of chemical bonds, and production of new macromolecules.[17,18] Ionizing radiation can be particulate and electromagnetic. Radionuclides, elements that emit ionizing radiation, exist naturally (eg, uranium) or can be manmade (plutonium).

There are 5 types of ionizing radiation: α-particles, β-particles, γ-rays, x-rays, and neutrons.[14] Each has different characteristics and behaviors. α-Particles consist of 2 protons and 2 neutrons; they are extremely heavy with a limited ability to penetrate clothing or skin. However, when inhaled or ingested, they can penetrate epithelial tissue layers to a 50-μm depth, sufficient to produce cellular injury (explaining the association between the α-emissions of inhaled radon and development of lung cancer). β-Particles, consisting of electrons only, have greater penetrance than do α-particles. They can produce internal injury when inhaled or ingested as well as skin injury. Unlike α-particles, which originate primarily from natural sources, β-particles most commonly come from radionuclides used in medicine (eg, xenon) or created as by-products of nuclear reactors (eg, radioactive iodines).[19] Neutrons are a powerful but uncommon type of radiation, emitted only after a nuclear detonation. Neutrons are highly destructive, producing 10 times more tissue damage than γ-rays produce.[15]

γ-Rays and x-rays are part of the electromagnetic spectrum. Unlike α- and β-particles, these rays have no mass. γ-Rays are emitted from radioactive materials, including cesium and cobalt, or after a nuclear detonation. Having high energy and no mass, γ-rays are highly penetrant. X-rays, which are unlikely to be encountered in a radiation disaster, transfer energy along shorter paths with little scatter, whereas neu-

trons have greater mass and transfer energy along longer paths.

The units of measure of energy absorbed from x-rays and γ-rays are the rad (radiation absorbed dose) and the rem (roentgen equivalent man—a weighting or quality factor). The rem is based on greater relative biologic effectiveness (RBE) of doses from particulate radiation, such as neutrons. Thus, (rem) = (rad) × RBE. The rad and rem have been replaced by Gray (1 Gy = 100 rad) and Sievert (1 Sv = 100 rem), respectively, in accordance with the International System of Units (SI). The unit of activity for radiation emission of a radionuclide is Ci (curie) or, in SI, the Becquerel (Bq). These units and other terminology are summarized in the Appendix. The radionuclides and radioactive emissions associated with a radiation disaster are listed in Table 1.

CONSEQUENCES OF A RADIATION DISASTER

Radiation Biology

Radiation exposure can be divided into external, internal, whole body, or partial body. Internal irradiation can occur after inhalation of a radioactive gas or ingestion of contaminated food (including produce, grains, and milk from goats or cows that have been grazing on contaminated fields). Radiation effects can be direct, interacting with target tissues; or indirect, producing free radicals or other harmful molecules. The cellular effects of radiation are highly variable, correlating directly with the cell's typical rate of division and inversely with the extent of cell differentiation.[14] The sensitivity of tissues to radiation, from most to least, is: lymphoid > gastrointestinal > reproductive > dermal > bone marrow > nervous system. Ionizing radiation produces chromosome breaks in a variety of somatic cells; these breaks can persist for decades after exposure and may account for increased rates of cancer after irradiation. Other significant modulators of cellular injury after radiation exposure include dose, type of radiation, and age of the exposed person.[17]

Health Effects

Health effects after a radiation exposure will depend greatly on the circumstances surrounding the release. For example, after detonation of a nuclear weapon or radioactive dispersal device, there may be thermal or blast injury in addition to radiation exposure. In contrast, a nuclear power plant disaster can produce a radioactive cloud with no associated blast.

Specific health outcomes after radiation exposure are typically divided into short-term and long-term; short-term effects appear within days to weeks after exposure, and long-term effects appear months to years later. Short-term effects are dependent on the degree of radiation exposure and the tissue irradiated. Nausea and vomiting appear after exposures as little as 0.75 to 1.0 Gy (75–100 rad); a hematopoietic syndrome (severe lymphoid and bone marrow suppression) typically appears after 3.0 to 6.0 Gy (300–600 rad) exposures and may cause death in 8 to 50 days. Postirradiation lymphocyte counts correlate strongly with dose received; if the lymphocyte count decreases by more than 50% within 24 to 48 hours, a moderate radiation exposure or worse has occurred. Bone marrow and lymphoid depression lead to anemia and an increased risk of infection; the decrease in platelets can lead to generalized bleeding.[15] The mean lethal dose ($LD_{50/60}$), that is, the radiation dose for which 50% of an exposed population would be expected to die within 60 days, is 4.0 Gy (400 rads). Long-term effects (described below), include psychologic injury and increased cancer risk.

VULNERABILITIES IN CHILDREN

Children have a number of vulnerabilities that place them at greater risk of harm after radiation exposure. Because they have a relatively greater minute ventilation compared with adults, children are likely to have greater exposure to radioactive gases (eg, those emitted from a nuclear power plant disaster). Nuclear fallout quickly settles to the ground, resulting in a higher concentration of radioactive material in the space where children most commonly live and breathe. Studies of airborne pollutants are needed to test the long-held belief that the short stature of children brings them into greater contact than adults with fallout as it settles to earth. Radioactive iodine is transmitted to human breast milk, contaminating this valuable source of nutrition to infants. Cow milk, a staple in the diet of most

TABLE 1. Radionuclides Produced After a Radiation Disaster

Element	Symbol	Source	Radiation	Respiratory Absorption	Gastrointestinal Absorption	Primary Toxicity	Treatment
Americium	^{241}Am	NWD	Alpha	75%	Minimal	Skeletal, liver deposition, bone marrow suppression	DTPA, EDTA
Cesium	^{137}Ce	MF	Beta, gamma	Complete	Complete	Whole body irradiation	Prussian blue
Cobalt	^{60}Co	MF, FI	Beta, gamma	High	<5%	Whole body irradiation	Supportive
Iodine*	^{131}I	NWD, NPP	Beta, gamma	High	High	Thyroid ablation, cancer	Potassium iodide
Phosphorous	^{32}P	MF	Beta	High	High	Rapidly dividing cells	Aluminum hydroxide antacids
Plutonium	$^{238,239}Pu$	NW, NWD	Alpha, gamma	High	Minimal	Lung, bone, liver	DTPA, EDTA
Strontium	^{90}Sr	NWD	Beta, gamma	Limited	Moderate	Bone-follows calcium	Supportive

Adapted from Jarrett DG. *Medical Management of Radiological Casualties*. Bethesda, MD: Armed Forces Radiobiology Research Institute; 1999.

NWD indicates nuclear weapon detonation; DTPA, diethylenetriaminepentaacetic acid; EDTA, edetic acid (ethylene-dinitrillo tetraacetic acid); MF, medical and research facilities; FI, food irradiation facilities; NW, nuclear reactor waste sties; NPP, nuclear power plants.

* There are numerous radioiodines, including ^{132}I. However, ^{131}I is the most prevalent and clinically important radioisotope.

children, can also be quickly contaminated if radioactive material settles onto grazing areas.

In utero exposure to radiation also has important clinical effects, depending on the dose and form of the radiation; transmission of radionuclides across the placenta may occur, depending on the agent. After exposures to external radiation, fetal doses of 0.60 Sv (60 rem) have produced small head size and mental retardation (in Japanese atomic bomb survivors), when exposures occurred between 8 and 25 weeks of gestational age.[2] A dose-response effect was found in the occurrence of small head size without mental retardation, which occurred in fetuses exposed to ≥0.2 Sv (≥20 rem) between weeks 4 and 17 of gestation.

Radiation-induced cancers occur more often in children than in adults exposed to the same dose. Finally, children also have mental health vulnerabilities after any type of disaster, with a greater risk of long-term behavioral disturbances.[20–22]

MANAGEMENT

A radiation disaster would be followed by a massive, integrated federal, state, and local public health response. Relevant consequence management agencies at a federal level would include the US Department of Homeland Security, the Environmental Protection Agency, the Federal Emergency Management Agency, the Nuclear Regulatory Commission (NRC), the Department of Energy, and the Department of Justice. State and local departments of health, working closely with federal agencies, would develop the appropriate local response, for example, initiation of the emergency broadcast system, the implementation of disaster or evacuation plans, recommendations for evacuation versus sheltering, instructions to begin the administration of KI, and the creation of local shelters for displaced families.

Evacuation and Sheltering

Evacuation is the most important action after a radiation release has occurred, particularly after a radioactive cloud release in which there is time to escape exposure. However, in previous power plant mishaps, the radioactive cloud dispersed in minutes, making immediate evacuation impossible. Moreover, given the magnitude of the task of evacuating an entire population, which could include more than 500 000 residents (on the basis of the location of existing plants), evacuation plans may fail. Evacuation can be extremely chaotic, leading to motor vehicle crashes and other injuries, so caution should be exercised. Relocation may be temporary or long-term, depending on the environmental persistence of radioactivity. The decision to recommend rehabitation versus long-term relocation is made by federal, state, and local agencies on the basis of projected radiation dose levels, the environmental persistence of the radionuclide, physical damage to roads and buildings, and other factors that could affect the safety of the population.[23] If evacuation is impossible, a safe place should be sought within the home or another building. For example, the shielding factor (the ratio of dose received inside the structure to the dose which would be received if the structure were not in place[23]) for γ-rays after a radioactive cloud release is 0.9 for a wooden frame structure, 0.6 for a home basement, 0.4 for the basement of a masonry home, and 0.2 for a large office or industrial building.[23] The duration of sheltering required will depend on the extent of environmental contamination. Families should follow the instructions provided through the local emergency broadcasting system.

Treatment

The management of the child who has sustained significant radiation exposure is dependent on the type and degree of exposure as well as the presence of concomitant injuries.[14] Principles of disaster management, including containment, decontamination, prehospital care, and field triage, should be fully employed.[14] The first phase of managing pediatric radiation victims will be to determine if topical decontamination is warranted. Removal of clothing is responsible for more than 90% of the effectiveness of decontamination after a chemical or radiation exposure.[19] With the implementation of disaster protocols, emergency medical services will establish "hot," "warm," and "cold" zones; contaminated victims will be decontaminated in the field and then transported to a health care facility. However, because disaster victims may come to health care facilities by private vehicle, potentially bringing radioactive materials with them, hospitals and urgent care facilities should develop their own plans for management of a contaminated victim. The hospital radiation safety officer is a vital consultant in the management of patients; radiation detection devices should be placed at the site of care. Additionally, a site for the placement of contaminated clothing should be established. The skin should be washed with warm water; measures should be taken to prevent hypothermia. Children with radioactive material embedded in skin should undergo careful débridement that minimizes further tissue injury. Care to skin burns should be minimal; irrigation alone is recommended.[15,23] Irrigation solutions should be collected in containment vessels and disposed of properly.

Children who have no external contamination (eg, those who have inhaled radioactive material) can be treated according to routine protocols. However, biologic fluids, including saliva, blood, urine, and stool, may be contaminated and require special handling precautions.

Initial medical management includes careful assessment of airway, breathing, and circulation, particularly when there is the potential for blast or thermal injury.[14] Surgical intervention, if warranted, should be performed as soon as possible, ideally within 48 hours of irradiation before wound healing and immunity become impaired.[15]

Specific pharmacotherapy for victims of significant radiation exposure is limited; the decision to use these agents should be made after consulting with an authority on clinical management of radiation victims (eg, a consultant from the NRC or a radiation therapist). KI administration is the cornerstone of

preventive treatment after known or suspected exposure to radioactive iodine (radioiodines are common by-products of nuclear power plant activities and, therefore, likely to be emitted after a power plant incident).[14] Other drugs have been suggested[14] but have not been proven effective or without serious adverse effects, especially in children.

KI is the same compound used, in smaller quantities, to iodize table salt. When ingested immediately before, during, or shortly after exposure to radioiodines, KI "floods" the thyroid, blocking uptake of inhaled or ingested radioiodines. When taken promptly after a radioiodine release and at proper dose, KI is effective in preventing radiation-induced thyroid effects.[9] The Food and Drug Administration (FDA) currently recommends that KI be administered only after certain levels of radioiodine exposure, on the basis of risk-benefit analyses derived from the Chernobyl disaster, in which more than 18 million children and adults in Poland (immediately adjacent to Ukraine and Belarus) received at least 1 dose of KI.[9,24] The FDA recommends adhering to the guidance about the threshold for intervention and appropriate dosing but also recognizes that ". . . the exigencies of any particular emergency situation may mandate deviations from those recommendations. With that in mind, it should be understood that as a general rule, the risks of KI are far outweighed by the benefits with regard to prevention of thyroid cancer in susceptible individuals."[25]

Children and pregnant or lactating women should begin taking KI if the predicted thyroid exposure, as projected by government sources, is 0.05 Gy (5 rad) or more (Table 2).[9] Short-term adverse effects associated with KI use in Poland were generally mild, consisting of gastrointestinal tract distress or rash.

KI administration to newborns has been associated with evidence of transient decreases in thyroxine along with increases in thyroid-stimulating hormone. The FDA has therefore recommended that newborns who receive KI have their thyroid function monitored. On the basis of the rate of thyroid hormone synthesis in the newborn, monitoring of thyroid function by measurement of thyroid-stimulating hormone activity 2 to 4 weeks later should be sufficient after a single KI dose; longer periods would be needed for newborns who receive more than 1 dose of KI. The FDA has recommended KI for pregnant women for self-protection and for the protection of the fetus.[9] However, repeated KI dosing by pregnant women could produce neonatal hypothyroidism. The risks versus benefits of continued KI dosing by pregnant women depend on the probability of continued radioiodine exposure.

Radioiodine and KI are secreted into breast milk. For lactating women and their infants, expert consultants have firmly recommended that infants of exposed mothers should not breastfeed because of the risk to exposed infants of additional exposure to radioiodine from breast milk. Exposed women should temporarily cease breastfeeding unless there are no alternatives.[24] (This is contrary to FDA advice suggesting that infants whose mothers receive KI after radioiodine exposure may breastfeed.[9])

The FDA has recommended against repeated dosing of KI in pregnant women and neonates unless other protective measures (ie, evacuation, sheltering, and control of the food supply) are unavailable.[25] Young infants requiring repeat doses of KI should have their thyroid function closely monitored, and therapy with thyroid hormone should be instituted in cases in which hypothyroidism develops.[9] KI should not be given to individuals with known iodine sensitivity or to those with dermatitis herpetiformis or hypocomplementemic vasculitis (both rare conditions associated with an increased risk of iodine hypersensitivity). KI should be used with caution in individuals with thyroid disease (such as multinodular goiter, Graves disease, and autoimmune thyroiditis), especially if dosing extends beyond a few days.[25] Such individuals should have monitoring of thyroid function.

KI is currently made as a 130-mg and a 65-mg tablet. The tablet can be placed in any liquid and administered in an appropriate volume. Super saturated potassium iodide (SSKI) drops are available and can be administered if necessary; however, at their concentration of 1000 mg/mL, accurate dose titration for children would be difficult. The FDA has also released recent guidance for home preparation of KI for infants in children[26,27] (Tables 3 and 4). The FDA statement emphasizes the need to place KI in a tasty solution, because it is very salty; raspberry syrup best disguises the taste of KI. KI mixed with low-fat chocolate milk, orange juice, or flat soda (for example, cola) has an acceptable taste. Low-fat white milk and water do not hide the salty taste of KI.[26,27]

The protective effects of a dose of KI last approximately 24 hours. The need for more than a single dose will depend on several factors, including the ability to quickly evacuate the area of radiation contamination. If evacuation is not possible, KI should be given for the persistent presence of radioiodines (which have half-lives ranging from 5 hours to 7 days). Recommendations for continued dosing should be made by the Environmental Protection

TABLE 2. Guidelines for KI Administration*[9,24]

Patient	Exposure, Gy (rad)	KI Dose (mg)
>40 y of age	>5 (500)	130
18 through 40 y of age	≥0.1 (10)	130
Adolescents 12 through 17 y of age†	≥0.05 (5)	65
Children 4 through 11 y of age	≥0.05 (5)	65
Children 1 mo through 3 y of age‡	≥0.05 (5)	32
Birth through 1 mo of age	≥0.05 (5)	16
Pregnant or lactating women	≥0.05 (5)	130

* KI is useful for exposure to a radioiodine only. KI is given once only to pregnant women and neonates unless other protective measures (evacuation, sheltering and control of the food supply) are unavailable.
Repeat dosing should be on the advice of public health authorities.
† Adolescents weighing more than 70 kg should receive the adult dose (130 mg).
‡ KI from tablets or as a freshly saturated solution may be diluted in water and mixed with milk, formula, juice, soda, or syrup. Raspberry syrup disguises the taste of KI the best. KI mixed with low-fat chocolate milk, orange juice, or flat soda (eg, cola) have an acceptable taste. Low-fat white milk and water did not hide the salty taste of KI.

TABLE 3. Guidelines for Home Preparation of KI Solution Using 130-mg Tablet[26]

- Put 1 130-mg KI tablet in a small bowl and grind into a fine powder with the back of a spoon. The powder should not have any large pieces.
- Add 4 tsp (20 mL) of water to the KI powder. Use a spoon to mix them together until the potassium iodide powder is dissolved in the water.
- Add 4 tsp (20 mL) of milk, juice, soda, or syrup (eg, raspberry) to the KI/water mixture. The resulting mixture is 16.25 mg of KI per teaspoon (5 mL)
- Age-based dosing guidelines:
  - Newborn through 1 mo of age: 1 tsp
  - 1 month through 3 y of age: 2 tsp
  - 4 years through 17 y of age: 4 tsp (if child weighs more than 70 kg, give 1 130-mg tablet)

How already prepared potassium iodide mixture should be stored:

Potassium iodide mixed with any of the recommended drinks will keep for up to 7 days in the refrigerator.

The FDA recommends that the potassium iodide drink mixtures be prepared fresh weekly; unused portions should be discarded.

TABLE 4. Guidelines for Home Preparation of KI Solution Using 65-mg Tablet[27]

- Put 1 65-mg KI tablet in a small bowl and grind into a fine powder with the back of a spoon. The powder should not have any large pieces.
- Add 4 tsp (20 mL) of water to the KI powder. Use a spoon to mix them together until the potassium iodide powder is dissolved in the water.
- Add 4 tsp (20 mL) of milk, juice, soda, or syrup (eg, raspberry) to the KI/water mixture. The resulting mixture is 8.125 mg of KI per teaspoon (5 mL)
- Age-based dosing guidelines:
  - Newborn through 1 mo of age: 2 tsp
  - 1 mo through 3 y of age: 4 tsp
  - 4 y through 17 y of age: 8 tsp or 1 65-mg tablet (if child weighs more than 70 kg, give 2 65-mg tablets)

How already prepared potassium iodide mixture should be stored:

Potassium iodide mixed with any of the recommended drinks will keep for up to 7 days in the refrigerator.

The FDA recommends that the potassium iodide drink mixtures be prepared fresh weekly; unused portions should be discarded.

Agency, the NRC, or other federal or state agencies that will be conducting environmental assessment. Radioactive dispersal devices generally would not contain radioiodines, so administering KI after detonation of a radioactive dispersal device would be inappropriate.

Other aspects of clinical care after radiation exposure are listed in Table 5 and include serial complete blood cell counts with close monitoring of absolute lymphocyte count, administration of antiemetics as needed, rigorous infection control, and aggressive treatment of infectious illnesses. Management of infection is the mainstay of therapy, because victims have significant immunosuppression; neutropenia and lymphopenia may last for several weeks.[15,19] Should a severe radiation exposure occur, other interventions to consider (although sufficient data are currently lacking) include administration of hematopoietic growth factors, (eg, granulocyte colony-stimulating factor) and HLA antigen typing for victims in whom the need for bone marrow transplantation is anticipated.[17] Available data suggest that granulocyte- and granulocyte-macrophage colony-stimulating factors should be administered within 24 to 72 hours of radiation exposure for optimal efficacy.[23]

Management of the psychologic harm to children after a radiation disaster requires that pediatricians provide advice to parents and supportive counseling to children and families.[28–31] Pediatricians should screen children closely for the presence of adjustment reactions and stress responses after a disaster has occurred. They should additionally assist parents in identifying the early signs of adjustment reactions, particularly in toddlers and other children who may have difficulty verbalizing their feelings. Finally, children should be referred for mental health services in a timely manner when behavioral disturbances are found.[32]

Other specific clinical recommendations are available from the Oak Ridge Institute for Science and Education,[18] from the Armed Forces Radiobiology Research Institute,[19] and in recent clinical reviews.[14,17]

LATE EFFECTS

Cancer

Among long-term injuries to children, carcinogenesis is most important. Studies suggest that radiation exposure during childhood is associated with a greater risk of cancer than is exposure at other ages.[4,13] For example, the risk of breast cancer is increased in women who are exposed to high levels of radiation as children, especially if the radiation exposure occurs before the pubertal development of breast tissue.[13,33–35] A peak in childhood leukemia occurred 5 to 6 years after the detonation of the nuclear bomb in Hiroshima and Nagasaki. There were 46 cases among those who were then younger

TABLE 5. Diagnostic Measures to Consider in Victims of Radiation Exposure

Test	Timing
Nasal swab to identify inhalation*	Immediately
Skin swabs to identify external contamination*	Immediately and at frequent intervals
Urine and stool analysis to identify internal contamination*	Immediately and at 24 h
Complete blood cell and platelet counts	Daily for 1 wk
Absolute lymphocyte count	Every 12 h for 3 d
HLA antigen subtyping	Before lymphocyte count decreases
Lymphocyte cytogenetics	Before lymphocyte count decreases

* A radiation safety officer or other authority should be consulted in all aspects of management.
Adapted from Jarrett DG. *Medical Management of Radiological Casualties.* Bethesda, MD: Armed Forces Radiobiology Research Institute; 1999

than 19 years of age (16 acute lymphocytic, 18 acute myelogenous, 10 chronic myelogenous, and 2 other). The excess cases diminished 16 years after exposure.[36]

Radiation-induced thyroid cancer in children has been well characterized. In the Chernobyl disaster, a cloud of radioactive elements including radioiodines was released. In the area of fallout in the Ukraine, 577 children and adolescents developed thyroid cancer between 1991 and 1997 (compared with 59 cases of thyroid cancer in the 5 years preceding the disaster). The number was greatest among those who were exposed at 5 years of age or younger. The latency period was short and the cancer was aggressive. In most cases, the radiation dose was 0.50 Gy or more.[37] In the United States, published data suggest that elevated rates of thyroid cancers and adenomas occurred among a cohort of children exposed to fallout from nuclear weapons tests in Nevada between 1951 and 1958.[38] Benign thyroid neoplasms are more common than thyroid cancer after radiation exposure; these can produce morbidity because of the possible need for surgery and lifelong medical follow-up.

Radiation-induced tumors can be benign or malignant and are histologically indistinguishable from the same cancers in the general population. The latency period for carcinogenesis after radiation exposure is typically 2 to 3 years for leukemia and 10 or more years for thyroid cancer and other solid tumors.[2,14,23] The latency period for thyroid cancer in children exposed to radioiodines after the Chernobyl disaster was shorter; an increase was observed beginning 4 years after the event.[9]

Psychologic Effects

One of the most common and disabling consequences of radiation exposure is the development of chronic fear and anxiety. More than 6 years after Chernobyl, the large populations exposed in the 2 areas of fallout had a high prevalence of distress and behavioral disorders; 35.8% of respondents had a psychiatric diagnosis as defined by the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition*.[39] A significantly higher rate was found among mothers with children younger than 18 years of age.[8,23,40,41] In an 11-year follow-up study of mothers and their young children, there continued to be significant psychosocial morbidity, with significantly higher scores on measures of social isolation and negative life events.[42] Similarly, studies in Pennsylvania after the TMI incident found long-term behavioral disturbances in mothers of young children.[43,44] Local inhabitants performed worse on behavioral tasks, had a greater incidence of psychosomatic symptoms, and had higher concentrations of neuroendocrine stress hormones than did controls.[11] The Kemeny Commission, convened to investigate the consequences of the TMI disaster, concluded that mental stress would be the main effect of a nuclear reactor disaster.[11,45]

Studies of the Goiania disaster also demonstrated that stress and behavioral reactions can follow perceived exposure; those living in the area of radiation exposure and those unexposed had behavioral and cardiovascular-neuroendocrine effects that persisted for more than 3 years.[23] Emotional effects are even greater for those who witness injured or mortally wounded victims after a radiation disaster.[11] These behavioral consequences can disrupt interpersonal relationships, attitude, and social outlook, causing or contributing to chronic medical conditions including hypertension.[23] Psychobehavioral disturbances are further magnified when disasters are accompanied by the loss of a family home or lack of timely information.[8,46] Finally, disaster workers and health care professionals can be incapacitated by the emotional distress of a radiation disaster.[23] This distress has multiple origins, including the inability to enter contaminated areas to rescue victims and the difficulty in wearing personal protective equipment.

PREPARING FOR A RADIATION DISASTER

Clinical Issues

Local planning for a possible radiation disaster focuses on the creation of disaster management protocols, education of first responders and health care professionals, and acquisition of appropriate equipment and supplies. First responders should receive training in radiation consequence management, because they may unknowingly enter a radioactive area. Emergency physicians as well as pediatricians and other primary care physicians are potential medical responders to a radiation event and should also obtain training in this area.[18] Issues including emergency department configuration for the management of radiation-exposed individuals should be addressed.[18] Recent data indicate that most US hospitals remain unprepared for a nuclear event.[47]

In November 2001, the FDA issued updated guidance about KI use after exposure to radioactive iodine; KI is ineffective for other radionuclide exposures. According to these guidelines, the benefits of KI exceed its risks when a certain level of exposure has occurred (Table 2). KI efficacy is greatest when administered immediately before the exposure, at which time it can prevent 100% of radioiodine from reaching the thyroid. However, the efficacy of KI is 80%, 40%, and 7% when administered 2, 8, and 24 hours after exposure, respectively[48]; these rates are markedly lower in children who are iodine-deficient. KI appears to have little clinical value when administered 12 hours or more after exposure.

Currently, the NRC recommends that state and local governments consider providing KI to all citizens living within 10 miles of a nuclear power plant as a supplement to plans for evacuation and sheltering.[49] In December 2001, the NRC wrote to the 31 states that had or were located near 10 miles of a nuclear power plant, offering 2 KI pills for every person living within 10 miles of a plant.[50] If states and local governments adopt the plan to use KI, communities should consider storage of KI in schools and child care centers. Additionally, strategies that permit the rapid administration to large numbers of children (eg, an entire elementary school) should be developed. The appropriateness of KI distribution to all US families remains controversial.

Universal prescription of KI has not been recommended by the NRC or FDA because the risks of radioiodine exposure exist only in certain regions and because of the risk of inappropriate use. However, given its limitless shelf-life, low incidence of adverse effects,[9,24] and need for rapid administration, universal access should be considered. KI is available without a prescription at some pharmacies but is not yet widely available. KI may be purchased through the Internet; however, families should be cautioned against using the medication before consulting with authorities.[9] In April 2002, the FDA listed 2 products, Thyro-Block (MedPointe Inc, Somerset, NJ), and IOSAT (Anbex Inc, Palm Harbor, FL), which are approved for over-the-counter use as a thyroid-blocking agent in radiation emergencies.[25] In November 2002, the *Medical Letter of Drugs and Therapeutics* listed these and additionally listed ThyroSafe (Recip US, Honey Brook, PA) as an FDA-approved product.[51] IOSAT can be obtained at 866-283-3986 and through the Internet at www.nukepills.com; Thyro-Block can be obtained at 800-804-4147 and at www.nitro-pak.com; and Thyro-Safe can be obtained at 610-942-8972 and at www.thyrosafe.com.[51] KI also can be ordered from Anbex Inc at 727-784-3483 and at www.anbex.com.

Communities near a nuclear power plant should have access to KI as an adjunct to evacuation and sheltering. It is prudent for parents living within 10 miles of a nuclear reactor to keep KI in their homes. In addition, schools and child care centers located within a 10 mile radius of a nuclear power plant should have immediate access to KI. It is unclear, however, whether people within a larger radius should stockpile the drug. Although current recommendations call for those within a 10-mile radius to have access to KI, there have been recent concerns that a nuclear power plant mishap could discharge a radioactive cloud with far greater reach. In the Chernobyl disaster, changes in wind direction and rainfall resulted in an unevenly distributed deposition of radionuclides. The 3 most highly contaminated areas were the 20-mile zone surrounding the reactor; the Bryansk, Russia area and Gomel and Mogilev regions of Belarus (120 miles north-northeast of the reactor); and the Kaluga-Tula-Orel area of Russia (300 miles northeast of the reactor).[52]

As a result of these concerns, some have suggested that all people living within a 50-mile radius of a nuclear power plant should stockpile KI.[50] There have also been proposals for the stockpiling of KI by all those living within a 200-mile radius of a nuclear plant.[50] Because rapid and complete evacuation of a region is dependent on population density, a more cogent approach might be to vary the recommended KI distribution radius by population density. In population-dense regions, a 50-mile radius could be used, and areas with a lower population could adhere to the 10-mile radius recommendation.

The establishment of nuclear disaster response teams is also a part of community planning. Such teams should include mental health professionals who are trained to respond to the emotional and behavioral needs of children after a radiation event. Because children with psychologic trauma may be unable to verbalize their feelings, parents and pediatricians should be attentive to subtle signs of stress, anxiety, or depression.

Preparatory training exercises are also recommended. To date, involvement of pediatricians and mental health professionals in mock radiation disasters has been minimal. However, without these participants, mock disasters are likely to make unrealistic assumptions about the behavior of all victims, including children.[20] The inclusion of pediatricians and mental health specialists in planning will provide the opportunity to evaluate, improve, and enhance the response.

Public Health Actions

States and local governments have begun to develop strategies to protect their local population after a radiation release.[53] These include the establishment of threshold radiation concentrations that would require evacuation and educational campaigns for the public. All residents in at-risk areas should receive educational information and detailed emergency response plans.[53] Special plans should be made for children with disabilities.

Local hospitals also have a key role in the preparation for a radiation disaster. Policies of the Joint Commission on Accreditation of Healthcare Organizations require that health care facilities develop disaster management guidelines and that these guidelines be subject to twice-yearly drills. Because radiation events represent a unique catastrophe, hospitals should provide detailed guidance. Pediatricians may have the role of assisting hospitals in the development of plans for treating pediatric victims.

Schools and child care facilities should also be included in response plans, particularly if they are located within 10 miles of a nuclear power plant. School evacuation plans should be created and practiced. Many school districts have already been successful in creating algorithms for evacuation of children and their rapid reunification with parents.[54] School plans should consider the designation of an out-of-state relative or friend as a "family contact," because during a disaster, it is often easier to call long-distance than locally to find a family member. As with planning for all disasters, medical directives (eg, health care proxy) should be considered in the event the parent of an ill or injured child cannot be immediately contacted. Schools should have written plans that define locations within the school building or in nearby structures that would afford the best protection from a radiation cloud. School-based crisis-management teams that manage other events associated with psychologic trauma should be trained to respond to the consequences of a radiation disaster.

PREVENTION

Radioactive materials are used throughout the country, particularly in research and medical treatment. These radioisotopes are subject to theft or sab-

otage. For example, in 1996, a radiographer disappeared for approximately 2 weeks with a cache of radioactive iridium; in the same year, 2 radioactive cobalt sources were stolen from an abandoned industrial facility.[10] Many other confiscations of radioactive material have occurred.[55] These cases illustrate the ease with which radionuclides can be stolen and then used for the creation of a radioactive dispersal device. Stricter regulation and heightened surveillance of all high-dose radioactive materials is necessary to prevent such events from occurring.

The safety and vulnerability of nuclear power plants to terrorism has been questioned,[55,56] particularly since the events of September 11, 2001, when fuel-filled commercial airplanes were used as weapons.[14,57] Several acts of nuclear power plant sabotage have reportedly occurred in the past.[58] In addition to the risks associated with terrorist activity, the aging of US nuclear reactors has led to beliefs that a mishap is inevitable.[59] Concerned scientists and environmental advocates have long argued that nuclear power plants carry a risk of harm too great to justify their continued existence; calls for the shutdown of all US power plants have been building in recent years.[60] Currently, however, more than 20% of US electrical power is provided by nuclear power.[61] All sources of electrical energy have unwanted consequences or are currently unfeasible in terms of economic cost. Fossil fuel combustion releases carbon dioxide and other greenhouse gases as well as mercury, arsenic, and other pollutants; these emissions are associated with asthma, cancer, cardiovascular disease, and other chronic illnesses. Hydroelectric, solar, and wind energy, while clearly preferred, all have significant use limitations.[62] Until safer, sustainable sources of energy are available and with the need to decrease the use of fossil fuels, the immediate closure of existing nuclear plants may not be prudent.[62]

However, many have argued that future nuclear power plants should not be placed near heavily populated areas, and existing plants in densely populated regions should be decommissioned as quickly as possible. Additionally, the amount of nuclear wastes continues to grow; most are being stored in vulnerable, above-ground sites. Plans to create a large underground nuclear waste storage facility are nearly complete.[63] The proposed facility will house more than 77 000 tons of radioactive waste, delivered via an estimated 108 000 train and truck shipments over a 30-year period.[64] These plans, if implemented, will require intense security from terrorism, protection from crashes or other vehicular mishaps, and careful consideration of the potential for and effects of earthquakes in the vicinity.[65]

Through their daily practice, pediatricians can participate in the prevention of adverse effects of ionizing radiation. Radiation damage is incompletely repaired and adds throughout life.[66] Exposures from CT scans are high, compared with those from radiography, as noted in a joint statement of the Society for Pediatric Radiology and the National Cancer Institute.[67] The CT-scan dose to the brain is up to 600 times the dose to the chest from an anterior-posterior (AP) and lateral X-ray.[67] Children not only have greater susceptibility to radiogenic cancer[68] but also have longer life expectancies compared with adults, during which the latent period for cancer can be exceeded. The margin of safety for radiation effects diminishes as radiation exposures accumulate. Pediatricians can preserve the margin of safety by requesting radiologic procedures only when the benefits outweigh the risks and checking to ensure that CT operators are using settings appropriate for children.[69] Conservative use of diagnostic radiation procedures should decrease mortality and morbidity from the acute effects of a radiation disaster.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Pediatricians should increase their knowledge about emergency medical aspects of radiation exposure.
2. Pediatricians should become familiar with local preparedness and evacuation protocols and work with public health agencies on their development.
3. Pediatricians should assist local schools and child care facilities in developing protocols to reunite children with their parents in the event a disaster.
4. All children at risk should receive KI before exposure, if possible, or immediately afterward. This will require that KI be available in homes located within 10 miles of a nuclear power plant. Child care facilities and schools within 10 miles of a nuclear power plant should plan to stockpile the agent. It may be prudent to consider stockpiling KI within a larger radius because of more distant windborne fallout, as occurred after Chernobyl; this will be determined by local and national public health authorities.
5. The risks and benefits of using KI should be discussed with parents. KI is available without a prescription, and families should be cautioned against using the medication before consulting with authorities.
6. Because radioiodines pass into breast milk, pediatricians should caution lactating mothers not to breastfeed their infants after the release of radioiodines, unless no alternative is available. The restriction is temporary, until public health authorities declare it safe to go back to breastfeeding. Public health authorities will also advise about the safe consumption of produce and milk after a radiation disaster.
7. The pediatrician should recognize and respond to the psychosocial consequences of disasters in children.[23,29,70]

RECOMMENDATIONS FOR GOVERNMENT

1. Pediatricians should be included in all aspects of planning for a radiation disaster. Disaster planning exercises should include pediatric casualties and victims with mock psychologic injuries.
2. Future sites for nuclear power facility construction should be selected to minimize the risk to populations. For existing power plants in popu-

lated regions, an accelerated timeline for decommissioning should be considered.
3. Guidelines for the population radius within which to recommend KI stockpiling should be developed; distribution plans should also be created.
4. The FDA should facilitate the development of a pediatric preparation of KI.
5. Plans should be developed for rapid communication with the public about evacuation versus sheltering, the safety of breast milk, and local food consumption.
6. Government planners should make mental health a high priority in the response plan for a radiation incident.

APPENDIX: GLOSSARY OF TERMS

Types of Radiation

Ionizing radiation: a high-frequency, low-amplitude form of radiation that interacts significantly with biological systems.
Alpha particle (α-particle): a particle emitted from the nucleus of an atom. It contains 2 protons and 2 neutrons and is identical to the nucleus of a helium atom. Having a very large mass, α-particles have poor penetration. They pose little hazard after external exposure but can produce tissue injury when inhaled or ingested.
Beta particle (β-particle): a high-speed particle, identical to an electron, emitted from the nucleus of an atom.
Neutrons: a powerful but uncommon type of radiation, emitted only after a nuclear detonation. Neutrons are highly destructive, producing 10 times more tissue damage than γ-rays produce.
Gamma-rays (γ-rays): a form of ionizing radiation having no mass. Like visible light, γ-rays are made of photons. γ-Rays have significant penetrance and are the most important external radiation hazard after a radiation disaster.
X-rays: like γ-rays, x-rays have no mass; their energy is emitted from electrons, and γ-rays are emitted from nuclei.

Radiation Exposure Terms

Becquerel (Bq): the International System of Units (SI) measurement of radioactivity, defined as decay events per second. 1 Bq = 1 disintegration per second.
Curie (Ci): the traditional measure of radioactivity, as measured by radioactive decay. 1 Ci = 3.7×10^{10} disintegrations per second.
Radiation absorbed dose (rad): the energy deposited by any type of radiation to any type of tissue or material. 1 rad = 0.01 Gray
Roentgen equivalent man (rem): the unit of *human* exposure to radiation. 1 rem = 0.01 Sievert
Gray (Gy): the SI unit for the energy deposited by any type of radiation, in joules per kilogram. 1 Gy = 100 rad
Sievert (Sv): the SI unit for measurement of human exposure to radiation, in joules per kilogram. 1 Sv = 100 rem
Weighting or Quality Factor: a term that correlates rem with rad (rem = rad $\times$ quality factor), based on factors including the type of radiation. The quality factor for β-particles, γ-rays, and x-rays is 1; therefore, with exposure to these forms of radiation, rad = rem. The quality factor for α-particles is 20 (1 rad = 20 rem).

ACKNOWLEDGMENTS

We wish to thank Drs David V. Becker, Professor of Radiology and Medicine, Weill-Cornell Medical College, and Jacob Robbins, Scientist Emeritus, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, for their most helpful review of this statement.

CLINICAL REPORT

Radiation Risk to Children From Computed Tomography

Guidance for the Clinician in Rendering Pediatric Care

Alan S. Brody, MD, Donald P. Frush, MD, Walter Huda, PhD, Robert L. Brent, MD, PhD, and the Section on Radiology

ABSTRACT

Imaging studies that use ionizing radiation are an essential tool for the evaluation of many disorders of childhood. Ionizing radiation is used in radiography, fluoroscopy, angiography, and computed tomography scanning. Computed tomography is of particular interest because of its relatively high radiation dose and wide use. Consensus statements on radiation risk suggest that it is reasonable to act on the assumption that low-level radiation may have a small risk of causing cancer. The medical community should seek ways to decrease radiation exposure by using radiation doses as low as reasonably achievable and by performing these studies only when necessary. There is wide agreement that the benefits of an indicated computed tomography scan far outweigh the risks. Pediatric health care professionals' roles in the use of computed tomography on children include deciding when a computed tomography scan is necessary and discussing the risk with patients and families. Radiologists should be a source of consultation when forming imaging strategies and should create specific protocols with scanning techniques optimized for pediatric patients. Families and patients should be encouraged to ask questions about the risks and benefits of computed tomography scanning. The information in this report is provided to aid in decision-making and discussions with the health care team, patients, and families.

INTRODUCTION

Computed tomography (CT) is a valuable and essential addition to the array of imaging modalities for children. CT uses x-rays to provide rapid, consistent, and detailed information about virtually any organ system in infants and children. Because x-rays are an integral component for image formation with CT, there is an obligatory radiation exposure during the CT examination. Ionizing radiation has been demonstrated to increase the risk of cancer in individuals exposed to high doses of radiation. Moreover, recent reports have discussed the potential risk of cancer that results from the lower radiation exposure from CT examinations. These publications have raised concerns on the part of pediatricians, patients, and families. A review of this literature, however, shows widely differing opinions concerning the cancer risk of diagnostic imaging studies. Although many different statements on ionizing-radiation risk exist in the literature, one principle has been supported consistently by the authors of articles to which this report refers: any estimated risk of a CT scan is far less than the likely benefit to the patient for indicated examinations.

This clinical report is intended to serve as a resource for pediatric health care

professionals and to improve understanding of pediatric CT radiation and its potential risk in the development of cancer. The report also includes suggestions for an informed discussion of this issue between those who provide and those who receive care. It is important to understand that the purpose of this commentary is not to perform an exhaustive review of the literature regarding low-level radiation biological effects; rather, the purpose is to summarize current opinions about the risks of cancer from exposure to radiation from imaging studies and to provide pediatricians with information that will be helpful in discussions with patients and families/caregivers regarding the radiation risks of CT examinations and the important clinical advantages of these studies.

IONIZING RADIATION

Ionizing radiation is defined as high-energy radiation that is capable of producing ionization in the tissues through which it passes and can be absorbed. One gray (Gy) is the absorption of 1 joule (J) of radiation energy by 1 kg of matter. One Gy equals 100 radiation absorbed doses (rads). The sievert (Sv) takes into account the biological effects of radiation and is determined by multiplying the gray by a quality factor. It is important to realize that ionizing radiation is continuously present in our environment. This radiation exposure is termed "background radiation" and includes natural and man-made sources. Natural sources of radiation include cosmic rays, radon, radiation from terrestrial rock, and natural radionuclides. These sources account for most of the radiation exposure received by all inhabitants of the United States. The amount of background radiation varies depending on location. Residents of Denver, Colorado, for example, receive approximately twice the annual background radiation received by those who live at sea level. This is because of increased cosmic ray exposure at the higher elevation as well as increased terrestrial radiation from the rock in the surrounding mountains. In the United States, the average background radiation is approximately 3 mSv/year per person.

Man-made radiation includes that of industrial and medical origins, with the latter being the larger source by far. Medical radiation can be measured several different ways. For example, the exposure to radiation from diagnostic radiologic procedures can be described as the dose that strikes the surface of the body, or entrance dose. However, the entrance dose is higher than the average dose to which the entire body is exposed. This entrance dose will not necessarily reflect the risk, because different parts of the body vary in their sensitivity to the effects of ionizing radiation. For example, studies of the Japanese survivors of atomic bomb detonations have demonstrated that the lung is more sensitive to the oncogenic risks of high doses of radiation than the liver, which in turn is more sensitive than skeletal muscle or skin. Radiation energy deposited in an individual organ is the organ dose (measured in grays). When several organs are irradiated, the effective dose (measured in sieverts) is used to quantify the total patient risk and is computed by taking into account the dose to each organ as well as that organ's relative radiosensitivity (eg, lungs are more susceptible than skin).

For a given dose, there is a difference in cancer risk from radiation exposure to children compared with adults. There are several reasons for this difference. First, for the most part, tissues and organs that are growing and developing are more sensitive to radiation effects than those that are fully mature.[1,2] Second, the oncogenic effect of radiation may have a long (for example, decades) latent period. This latent period varies with the type of malignancy. Leukemia has a shorter period (approximately $\leq$10 years) than solid malignancies. An infant or child, therefore, has a longer life expectancy in which to manifest the potential oncogenic effects of radiation compared with older adults. For example, a solid radiation-induced malignancy with a 30-year latent period will more likely occur in a 10-year-old than in a 50-year-old, on the basis of life expectancy. Pierce et al[1] summarized the radiation cancer risk at different ages and stated that those exposed at 50 years of age have approximately one third of the risk of a 30-year-old and that "[p]rojection of lifetime risks for those exposed at age 10 is more uncertain. Under a reasonable set of assumptions, estimates for this group range from about 1.0–1.8 times the estimates for those exposed at age 30." This increased sensitivity varies with age, with the younger ages being more at risk. Because the risk varies with age, the increased pediatric risk compared with adults will also vary depending on exactly which age groups are compared.[1] Third, in the case of CT scanning, the radiation exposure from a fixed set of CT parameters results in a dose that is relatively higher for a child's smaller cross-sectional area compared with an adult.[3]

DIAGNOSTIC IMAGING

X-rays are used in radiography, fluoroscopy, angiography, and CT. The dose depends on patient factors (such as age and size), technical factors (equipment settings and procedure length), and equipment model. Nevertheless, it is helpful to be familiar with some representative doses for common imaging studies (Table 1).

Three factors have made CT scanning the focus of much of the recent interest in ionizing-radiation exposure from diagnostic imaging. First, CT scanning provides a disproportionately higher amount of the radiation exposure from diagnostic imaging. In 2000, Mettler et al[4] reported that CT scanning accounted for 11% of procedures that used ionizing radiation in a large academic radiology department but accounted for 67% of the radiation exposure. Second, indications for CT scanning and the number of CT scans are increasing rapidly. In a more recent study at the same institution, CT scan-

TABLE 1 **Estimated Medical Radiation Doses for a 5-Year-Old Child**

Imaging Area	Effective Dose, mSv	Equivalent No. of CXRs
3-view ankle	0.0015	1/14th
2-view chest	0.02	1
Anteroposterior and lateral abdomen	0.05	2½
Tc-99m[2] radionuclide cystogram	0.18	9
Tc-99m radionuclide bone scan	6.2	310
FDG PET[3] scan	15.3	765
Fluoroscopic cystogram	0.33	16
Head CT	4	200
Chest CT	3	150
Abdomen CT	5	250

CXR indicates chest radiograph; Tc-99m, technetium 99m; FDG PET, fluorodeoxyglucose positron emission tomography.
Data were provided by R. Reiman, MD (Duke Office of Radiation Safety [www.safety.duke.edu/RadSafety], written communication, 2006).

ning accounted for 15% of the procedures and 75% of the dose.[5] Third, CT scanning can be performed by using a wide range of techniques with variable radiation exposures that produce very similar image quality. With conventional ("plain") radiographs, an increase in radiation dose makes the image darker, and most individuals will recognize that the film was overexposed. However, changing the amount of radiation for a CT study affects the amount of mottle (or image noise) with little other effect on the appearance of the image. Above a level of diagnostic quality, this decrease in mottle with increasing radiation will have no effect on diagnostic accuracy of the CT study and may not even be appreciated, but the exposure may have been unnecessarily high, especially in children.[6] Until recently, the same CT-examination parameters were used for children and adults. In fact, a change in these parameters with a resultant reduction in dose, ranging from approximately 50% to 90%, has been shown to be satisfactory for a child's CT study.

RISKS OF IONIZING RADIATION FROM DIAGNOSTIC IMAGING

No published studies have directly attributed cancer to CT scanning, and it is important to recognize how difficult it would be to perform such a study. The lifetime risk of fatal cancer in the general population is approximately 1 in 5. To perform a study to detect an increase from 0.2000 (the 1-in-5 risk in the general population) to 0.2002 (the 1-in-5 risk seen in the general population plus a 1-in-5000 potential risk from a CT scan) would require hundreds of thousands to millions of subjects and extremely careful matching of the subjects in the study to ensure an accurate result. Until such a study is completed and verified by the scientific community, estimates of risk must be based on other forms of ionizing-radiation exposure, and some assumptions must be made to apply these risks to the risks from diagnostic imaging. The most widely used source of risk estimates comes from data on atomic bomb survivors.

CT scanners and other diagnostic imaging equipment use low-dose radiation, which is defined as a dose of less than approximately 100 mSv. There are numerous studies of populations receiving high doses of radiation above 500 mSv that have demonstrated an increased risk of cancer. These studies, reviewed in the 2005 report of the Biological Effects of Ionizing Radiation (BEIR) Committee of the National Academy of Sciences,[7] provided widely accepted evidence that, at higher exposures, the risk of cancer increases linearly with increasing dose until extensive cell killing takes place at very high exposures. The relationship between radiation exposure and cancer risk from low-dose radiation is less clear.

Because of the diversity of opinion and the many different studies that have been performed, a broad range of estimates of the risk of ionizing radiation from diagnostic imaging can be supported by selecting specific publications from the peer-reviewed literature. It is impossible to provide a complete review of this literature here, and without a complete review, any summary could be biased. To our knowledge, there are no reviews that are considered to be authoritative.

Statements that are based on expert panel reviews of available information are additional sources of estimates of the risks of low-level radiation. The BEIR Committee of the National Academy of Sciences recently released their seventh statement in 2005. The committee concluded that "the risk of cancer proceeds in a linear fashion at lower doses without a threshold and that the smallest dose has the potential to cause a small increased risk to humans."[7] The United Nations Subcommittee on Atomic Radiation 2000 report stated that "an increase in the risk of tumor induction proportionate to the radiation dose is consistent with developing knowledge and that it remains, accordingly, the most scientifically defensible approximation of low dose response."[8] The International Commission on Radiation Protection recommendations (2005) stated that "the weight of evidence on fundamental cellular processes supports the view that in the low dose range up to a few tens of mSv, it is scientifically reasonable to assume that in general and for practical purposes cancer risk will rise in direct proportion to absorbed dose in organs and tissues."[9]

In the absence of definitive evidence of the effects of low-level radiation, these consensus statements provide useful guidance. They suggest that it is reasonable to act on the assumption that the low-level radiation used in diagnostic imaging may have a small risk of causing cancer. If one assumes that radiation from a CT examination may cause cancer, it is reasonable that the medical community seek ways to decrease radiation exposure. Two ways to achieve this reduction are to use radiation doses that are as low as reasonably achievable (ALARA), which means that no more radiation should be used than is required to achieve the necessary diagnostic information, and to perform these studies only when they are necessary.

ROLE OF PEDIATRIC HEALTH CARE PROFESSIONALS

Pediatric health care professionals have an important role in the use of CT on children.[10] The health care professional ultimately decides whether a CT examination is necessary. With this important role comes a responsibility to recognize both the value of CT and its risks, which, as described previously, it is reasonable to assume are very small but real. The health care professional should also be able to discuss these risks in a manner that is informative and understandable to patients and families. One must recognize that the decision regarding a CT examination will often depend on the combination of the interaction with consultants, such as radiologists, and the family. There is a vast pool of information available on the Internet, much of which may be confusing with respect to CT, radiation, and cancer. The pediatric health care professional should be in a position to be able to answer questions and address concerns.

The pediatric health care professional is usually the first, and often the only, source of direct communication with the child and the family. This relationship carries with it an opportunity to inform and educate the family. Recent reviews that covered CT technology and its role in the imaging armamentarium[11,12] are salient for pediatric health care professionals. CT has an increasingly recognized role as the first, if not only, imaging examination for a wide variety of disorders that affect infants and children. What is most important to realize is that the use of CT is not infrequent in children and that the frequency of CT examinations is increasing. A recent review summarized investigations indicating that CT use has increased substantially over the last 1 to 2 decades, including estimates of at least 10% growth per year.[13] Currently, approximately 11% of CT examinations are performed on children,[4] which could account for more than 7 million pediatric CT examinations per year in the United States.[13,14] The use of CT for common problems such as trauma (closed head injury, skeletal evaluation including cervical spine assessment, and blunt abdominal trauma), appendicitis, and renal calculi has increased the frequency of CT examinations in adult and pediatric populations. Most clinicians believe that CT studies on children prevent hospitalization for head injuries and that negative findings in patients with acute onset of abdominal pain can obviate surgical explorations. These studies provide information that leads to earlier and more definitive diagnosis.

This increased use, however, must be based on a firm understanding that the CT study is the best study for the clinical situation being evaluated and that the possibility of a very small risk of cancer is considered when making the decision to order the study. The possible cancer risk is not clearly understood by many health care professionals, as concluded by 2 recent investigations. In the first investigation, Lee et al[15] surveyed emergency department patients, physicians, and radiologists. The results indicated that only 7% of patients indicated that there was any discussion outlining the radiation risks and benefits from an abdominal CT examination. In addition, only 9% of emergency department physicians believed that the lifetime risk of cancer was potentially increased by CT scanning. Moreover, 75% of physicians surveyed underestimated the accurate range for the equivalent number of chest radiographs for a CT examination (Table 1). In another recent investigation, Jacob et al[16] surveyed physicians in the United Kingdom and found that only 12.5% were aware of the potential association of CT radiation and cancer. Less than 20% correctly identified the relative radiation dose of CT examinations.[16] These studies support a continued and compelling need for radiation safety education for health care professionals and the public.

The pediatric health care professional should also be able to provide summary information to families on local practice patterns of radiology colleagues. It is reasonable to have information immediately available from the radiology practice in addition to that stated above. This information should include:

- additional expertise of the practice (pediatric radiology fellowship training, American Board of Radiology Certificate of Added Qualification, and current Maintenance of Certification in pediatric radiology);
- appropriate pediatric head and body CT protocols consisting of size- or age-based adjustments in scanner settings; and
- American College of Radiology accreditation of the CT scanners and the radiologists who interpret those studies in the practice.

An important role of the pediatric health care professional is to communicate with the radiologist to decide whether CT is the best study to perform. This consultation will vary from practice to practice, but it should be the goal of both parties to facilitate discussions on imaging strategies. These discussions provide an opportunity to share information, such as the number of studies using ionizing radiation to which the patient has been exposed. In addition to the pediatric health care professionals and radiologists, the integration of other care providers, such as surgical consultants or emergency department physicians, in decisions regarding pediatric CT policy or practice should also be fostered. Other imaging techniques such as ultrasonography or MRI may be suitable alternatives to CT examination, and they do not use ionizing radiation. If the CT examination is indicated and the radiology department uses a low-dose technique, another way to reduce CT dose is to limit the number of times (or phases) the child is scanned for the individual examination. It is very common for adult CT protocols to involve multiple scans through the same body part, which can double or triple the radia-

tion dose to the patient. For most indications for pediatric CT scans, a single pass through the body part of interest is usually sufficient for diagnostic purposes.

ROLE OF THE RADIOLOGIST

The value of having the pediatrician consult with the radiologist in the process of forming imaging strategies, such as with suspected appendicitis, as well as performing individual indicated CT examinations was discussed above. The importance of this consultation role should not be understated. The decision whether CT imaging should be obtained is determined, in large part, by the pediatric health care professional. However, the radiologist also has a responsibility to perform only those examinations that are appropriate. Any question by either party should trigger communication to be mutually certain about optimizing the child's care.

The radiologist also has a responsibility to create protocols and adjust scanning techniques on the basis of special considerations of pediatric patients.[17] These technical considerations have been reviewed recently for chest and abdomen CT.[12] In short, the exposure factors, many of which contribute to the radiation dose, must be adjusted. The amount of radiation necessary for diagnostic CT examinations in infants and young children is less than that in adults. If the same settings are used for both children and adults, children will receive an unnecessary and excessive amount of radiation. Many manufacturers now provide at least some basic pediatric guidelines, but it is still the decision of the radiology practice if these are to be used.

Additional expertise in pediatric imaging may be available in certain practice settings. Although this is not requisite for appropriate CT examinations on children, it would be unusual for a practice with this expertise not to align with the current recommendation of size-adjusted pediatric CT. Radiologists, regardless of whether they are fellowship-trained pediatric radiologists, should be able to provide either health care professionals or families with information on the CT protocols and techniques used and be able to discuss the radiation equivalent of CT, potential risks, and any additional techniques (such as breast shields) used in the practice. In addition, radiologists must keep up to date with rapidly evolving CT technology. For example, the newest multidetector array CT scanners are extremely fast (a complete infant chest examination is possible in approximately 1 second). This fast technology is accompanied by expanded uses in current applications as well as new applications. Furthermore, the radiology practice should also be able to keep pace with potential changes in radiation exposure from this technology as well as new technology to help manage radiation doses.[18]

CONCLUSIONS AND INFORMATION FOR FAMILIES AND PATIENTS

Concerns about radiation exposure are understandable, and questions should be encouraged, particularly when scientific communications are reported in the lay press.[19]

The following information can serve as a foundation for this discussion of CT examination and risks.

- Radiation is an essential component of a CT examination.
- The amount of radiation that a CT examination provides is low-level radiation.
- The cause-and-effect relationship between low-level radiation, such as with CT, and cancer is not certain, but expert panels that have examined this question have suggested that there is a small risk that increases with increasing dose.
- No direct connection between CT examinations and subsequent development of cancer has been demonstrated, so the risks of CT scans must be estimated, and these estimates vary depending on the information used.
- The amount of radiation that CT provides depends on many factors, especially the protocols used and equipment settings for the individual examination.
- In general, properly performed CT examinations of children should expose a child to much lower exposures than those for the same procedure on an adult.
- The potential benefit from an indicated CT examination is clinically recognized and documented and is far greater than the potential cancer risk.
- Radiologists are specialists in CT who are trained to use the least amount of radiation necessary (the ALARA principle, discussed previously).

In summary, there is wide agreement that the benefits of an indicated CT scan far outweigh the risks. It is the responsibility of those health care professionals who use CT scanning to ensure that each CT scan is indicated. It is the responsibility of radiology personnel to ensure that radiation risk is minimized by using the ALARA principle to determine the correct technique. The information provided in this clinical report is offered to aid in decision-making and discussions with the health care team, patients, and families.

Recognizing and Responding to Medical Neglect

Guidance for the Clinician in Rendering Pediatric Care

Carole Jenny, MD, MBA, and the Committee on Child Abuse and Neglect

ABSTRACT

A caregiver may fail to recognize or respond to a child's medical needs for a variety of reasons. An effective response by a health care professional to medical neglect requires a comprehensive assessment of the child's needs, the parents' resources, the parents' efforts to provide for the needs of the child, and options for ensuring optimal health for the child. Such an assessment requires clear, 2-way communication between the family and the health care professional. Physicians should consider the least intrusive options for managing cases of medical neglect that ensure the health and safety of the child.

INTRODUCTION

Pediatricians are sometimes confronted in practice by children whose medical needs are being neglected. In the United States, medical neglect accounts for 2.3% of all substantiated cases of child maltreatment.[1] This represents the "tip of the iceberg," because only the most egregious and intractable cases are likely to be reported to authorities.

Medical neglect usually takes 1 of 2 forms: failure to heed obvious signs of serious illness or failure to follow a physician's instructions once medical advice has been sought. Either of these situations can be fatal in some cases or can lead to chronic disability.[2]

Several factors are considered necessary for the diagnosis of medical neglect[3]:

1. a child is harmed or is at risk of harm because of lack of health care;
2. the recommended health care offers significant net benefit to the child;
3. the anticipated benefit of the treatment is significantly greater than its morbidity, so that reasonable caregivers would choose treatment over nontreatment;
4. it can be demonstrated that access to health care is available and not used; and
5. the caregiver understands the medical advice given.

In many cases, no harm will occur if the caregiver opts not to seek medical care for an ill child. For example, if children have high fevers caused by self-limited viral illnesses, they are unlikely to suffer adverse consequences if they do not receive medical care, even if they appear acutely ill. On the other hand, if a child with a stomachache caused by appendicitis fails to receive medical care, the results can be dangerous. However, when a procedure carries inherent danger or a drug has significant adverse effects, labeling a caregiver's reluctance to cooperate as neglect may be problematic.[2] In some situations, health care professionals may evaluate risks and benefits of drugs or procedures differently than families.

REASONS THAT FAMILIES FAIL TO SEEK APPROPRIATE MEDICAL CARE

Many factors can lead to children not receiving appropriate medical care. It is important to consider these etiologies in planning for the alleviation of the problem. The child can be seen as the center of an ecological framework within which lack of medical care may result from interactions among a variety of interdependent factors.[4]

Patient and Parent Factors

Poverty or Economic Hardship

Many families lack financial resources to care for children with acute or chronic illnesses. For some parents, taking time from work to care for sick children can lead to decreased income or even loss of their jobs.

Lack of Access to Care

The number of children in the United States who do not have health insurance is estimated to be between 8.7 and 11.1 million.[5] Other barriers to access include geographic constraints (such as long distances to care and lack of transportation), lack of baby-sitters for siblings, lack of available health care professionals, and language barriers.

Family Chaos and Disorganization

Some families lack order and routine in their lives. Interactions are inconsistent and fragmented. Parents may be unable to respond to the children's needs in an effective manner. These families may have a difficult time responding appropriately to medical emergencies, and it may be even more difficult to meet the needs of chronically ill children who require ongoing medications and treatments.

Lack of Awareness, Knowledge, or Skills

Caregivers may not be aware of the signs or symptoms in their children that could indicate serious illness. They may not understand why a medication or treatment is prescribed or why it is important to follow through with their physicians' instructions.

Lack of Trust in Health Care Professionals

Some families may refuse advice because they lack trust in physicians or organized medicine because of what they have heard from friends or the media or because of previous negative experiences with the health care system.

Impairment of Caregivers

If a child's caregiver is developmentally delayed or mentally ill, he or she may not have the capacity to respond to the child's health care needs. Substance abuse can also interfere with normal caregiving. In cases in which parents cannot comprehend the child's need for care, the children might need protection from a social service agency if they are in danger, even if the parents are trying to meet the children's needs.

Caregiver's Belief Systems

Some caregivers have belief systems that are inconsistent with Western medicine. A parent of a child who has a serious illness may decide to rely on untested remedies or alternative medicines. Some caregivers will seek healing through religion rather than medical care. The special case of religiously motivated medical neglect is discussed further below.

The Child's Attitudes and Behavior

In some cases, particularly in adolescents, the child will reject medical care and refuse to comply with medications, treatments, or diet. Children might assert their independence by not cooperating or use their illness to gain attention from their parents or deflect family conflict. Children may also be influenced by their peers and may not want to accept the fact they are ill and need treatment. They may feel they are more likely to "fit in" with others if they are not ill.

Physician Factors

Pediatricians' Misunderstanding of Different Cultures

What some pediatricians may consider obvious medical neglect might be acceptable parenting practices in other cultures. It is important for pediatricians to have knowledge of the beliefs and practices of the families they serve.[6] If children are in danger, interventions necessary to protect them are indicated even if the parents think they are doing the right thing. However, pediatricians should work to understand others so they can effectively educate parents while respecting different cultures. Some American Indian/Alaska Native cultures actively encourage adolescent children to make their own decisions about medical care. If the adolescent makes a potentially harmful decision, the parents must be informed about the consequences of that decision and urged to intervene with the child, whether through persuasion or overruling the decision.

Lack of Parent Health Literacy and Lack of Communication in the Medical Setting

Communication between pediatricians and parents can be affected by the parents' level of health literacy. Health literacy is defined by the US Department of Health and Human Services as "the degree to which individuals have capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions."[7] Parents often misunderstand complicated medical instructions and explanations of the justifications for treatment. Likewise, physicians

may not clearly communicate or adequately assess caregivers' comprehension of complicated medical instructions and justifications for treatment.[8] This lack of understanding can lead to poor adherence by families. If parents and physicians do not speak the same language, this also can complicate communication. Pediatricians should be cognizant of the factors that limit effective communication with patients and parents and work to overcome those barriers.[9] The American Academy of Pediatrics policy statement "Ensuring Culturally Effective Pediatric Care"[10] provides excellent resources for pediatricians seeking information on cultural competency.

THE PEDIATRICIAN'S RESPONSE TO MEDICAL NEGLECT

When confronting a family in which a child is being medically neglected, the child's well-being should be the physician's first concern. Several management options are available to pediatricians. Generally, the least restrictive, most collaborative approach to the situation is the best. Whenever possible, the family should be assisted in understanding the need for obtaining necessary medical care. The management of medical neglect involves initially identifying the underlying problem that led to the neglect. Once this is done, the pediatrician has many options for rectifying the situation. The following suggested intervention options are listed from least restrictive to most restrictive.

1. If the parents are not fluent in English, access services in the community to facilitate translation.
2. Be sure the family's concerns are understood. The medical staff must understand the family's view of their child's medical condition and its proposed treatment. Recognizing the family as a partner in the decision-making process assures caregivers that their opinions are respected and opens the door to compromise and improved adherence.
3. Counsel the family about the need for care and educate the parents and patient. The parents should be educated about the dangers of the illness and the importance of seeking medical care and complying with treatment. The family's support should be enlisted in addressing the problem. Make sure the parents understand what medications are indicated, how they work, and when they are to be given. Special programs are available to teach parents and children about the management of some chronic illnesses such as diabetes and asthma.
4. In some cases, it will be helpful to expand the circle of caregivers who will help with the child's medical care. For example, the extended family of the child might be enlisted to assume some of the care responsibilities for the ill child.
5. Involve the family in the development of a medical plan. When physicians collaborate with their patients in the development of treatment plans, physicians and families can reach shared understanding of the etiology, prognosis, and treatment options. Engaging the caregivers throughout the planning process can empower families and enlist them in support of treatment plans.
6. When necessary, work with the family to develop a written contract that outlines exactly what care needs to be provided. Sometimes families have a difficult time keeping track of treatments, medications, and appointments, especially when they have a chronically ill child with complicated medical problems. A written contract that is agreed to by both the physician and the family can serve as a "blueprint" for the family to follow. It also provides the physician with documentation that the family understood and agreed to the care plan. If intervention is required later by social service agencies, this documentation can be helpful to demonstrate that the family was informed of the importance of the child's medical care. When contracting with families, physicians should make sure that the parents or caregivers can read and understand the care plan.
7. Enlist community resources to aid in caring for the child. Resources such as visiting nurses, transportation services, financial relief, and respite care should be used if needed and available. Some organizations that advocate for people with specific chronic illnesses will provide educational opportunities about disease management, support groups, or "peer counselors." Although organizing these interventions is often beyond the scope of pediatric practice, pediatricians should be aware of community resources that are available to support the families of their patients and be prepared to make appropriate referrals. The medical home must recruit and coordinate a multidisciplinary team to make decisions in complex cases of medical neglect. By gathering together the essential health and human services professionals involved in the case, treatment and rehabilitative regimens and services can be coordinated for the involved families. Enlist knowledgeable members from the family's cultural/ethnic/medical belief system to assist in understanding the actions of the family and to help the health and human services professionals meet the needs of the neglected child.
8. Arrange for directly observed therapy for children with chronic serious illnesses. Daily home visits by a nurse or paraprofessional could be considered in cases in which there is lack of compliance with medications. Roberts et al[11] reported on the use of directly observed therapy to ensure that HIV-positive children received their antiretroviral therapy. In

4 of 6 cases, this approach led to sustained decreases in the patients' viral loads and allowed the children to remain in their homes instead of being placed in foster care. Although this is an expensive alternative, it is less expensive than providing foster care for a medically complicated child.

9. A partial hospital or day-hospital program may be helpful in cases in which family dysfunction and lack of patient compliance are issues. In some areas, partial hospital programs offer medical and mental health care for chronically ill children. Such programs offer family, group, behavioral, and individual therapy as well as education for parents and children about coping with illness.[12] These programs, when available, are useful in treating children and families with complex histories in which chronic illness has been managed inadequately because of social and psychological factors.
10. Refer families to child protective services agencies to ensure that necessary medical care is received. When other options are not available or have not been successful, it may be necessary to involve child protective services if the child is being harmed (or potentially harmed) by lack of medical care. The child protective services agency should understand what the nature of the child's medical problem is and why appropriate medical care is critical to the child's health and development. In many areas, the child protective services system has access to resources for family support that might not be available otherwise. In extreme cases in which the family is not able to cooperate, placing the child in foster care may be the only option.

MEDICAL NEGLECT IN CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Children with multiple medical problems can present a challenge to any parents. These children often require multiple regular medical appointments, multiple therapies such as physical, speech, and occupational therapy, medical equipment monitoring, special diets, and multiple medications. When the families of chronically ill children have limited resources, the challenges they present can be overwhelming. The primary care pediatrician can be helpful in providing a medical home that coordinates care and avoids duplication of services. A partnership with these families is critical so that problems can be identified and dealt with early. It is critical to always review the care plan so that the family can concentrate on therapies and interventions that are most likely to be beneficial and so that marginally effective therapies can be eliminated.

SPECIAL RESPONSIBILITIES OF PEDIATRICIANS CARING FOR CHRONICALLY ILL CHILDREN WHO MISS MULTIPLE APPOINTMENTS

Some parents with chronically ill children fail to keep multiple medical appointments. Depending on the seriousness of the child's illness, lack of medical care could adversely affect the child's health. In some cases, physicians inform such parents in writing that they will no longer be able to provide medical care for the child. When families tie up and then do not use scarce appointment slots, clinics are often unable to serve other families effectively. In other cases, clinic staff will contact the parents and simply reschedule the child for another appointment.

In either case, pediatricians should consider whether the child is at risk of harm because of the acts of the parents. If so, other interventions should be considered, including asking a clinic social worker or other staff member to discuss the problem with the parents, requesting a home visit by a nurse, or, in extreme cases, referring the family to the local child protective services agency. The important point is that each case needs to be considered individually to ensure the well-being of each child.

For chronically ill and complex patients, the medical home becomes an important asset in dealing with the competing demands for the caregivers' time and attention. In partnership with the families, primary care pediatricians can assist them in developing reasonable care plans involving many subspecialties and disciplines, such as physical and occupational therapy.

Pediatricians should work with families to facilitate the availability of appointment times that meet the demands parents face, such as jobs, child care, and transportation.

DETERMINING WHETHER A TREATMENT OFFERS SIGNIFICANT BENEFIT

One of the 5 factors that constitute medical neglect is caregivers refusing recommended health care that offers significant "net benefit" to the child. In many cases, the question of net benefit of a therapeutic modality can be debated. For example, if parents refuse medical intervention for a newborn infant at the limit of viability, is it medical neglect? In many cases, we do not have data on the relative benefits of various therapeutic interventions, and in some cases what one person would deem beneficial, another might think is of no value.

When these situations occur, it is important that the caregivers and health care professionals have an opportunity to communicate openly about their values and opinions. It is critical that these discussions be documented in the health record and acknowledged by providers and families. Involving a hospital's ethics committee can be helpful in resolving instances of conflicting opinions.[13]

RELIGIOUSLY MOTIVATED MEDICAL NEGLECT

Medical neglect evaluations should focus on the child's needs rather than the caregiver's motivations or justifications. Religious objections, therefore, should not be granted fundamentally different status from other types of objections.[14]

Although competent adults have the right to refuse life-saving medical care for themselves, the US Supreme Court has stated that parents do not have the right to deny their children necessary medical care.[14] The court made this clear in 1944 in *Prince v Massachusetts*.[15] "The right to practice religion freely does not include the liberty to expose the community or child to communicable disease, or the latter to ill health or death. . . . Parents may be free to become martyrs themselves. But it does not follow they are free, in identical circumstances, to make martyrs of their children. . . ."[15] The American Academy of Pediatrics has taken a firm stance on the rights of seriously ill children to receive life-saving medical care even if their parents subscribe to religious beliefs that are antithetical to medical care.[16]

SUMMARY

Medical neglect of children can cause harm or death. The pediatrician's responsibility is to the child. If parents or caregivers are not meeting the child's medical needs, the pediatrician is encouraged to work to ensure that the family has adequate resources to care for the child. The pediatrician has several important roles in working on behalf of medically neglected children, including engaging the family, understanding the family's circumstances, explaining the need for therapy, and collaborating with professionals and resources within the community to ensure that the child's health is optimized.

abstract

FREE

The purpose of this statement is to recommend implementation of a mandatory influenza immunization policy for all health care personnel. Immunization of health care personnel is a critically important step to substantially reduce health care–associated influenza infections. Despite the efforts of many organizations to improve influenza immunization rates with the use of voluntary campaigns, influenza coverage among health care personnel remains unacceptably low. Mandatory influenza immunization for all health care personnel is ethically justified, necessary, and long overdue to ensure patient safety. *Pediatrics* 2010;126:809–815

INTRODUCTION

Health care–associated influenza outbreaks are a common and serious public health problem that contributes significantly to patient morbidity and mortality and creates a financial burden on health care systems. Annual immunization of health care personnel (HCP) is a matter of patient safety and necessary to significantly reduce health care–associated influenza infections. Immunization rates of 80% or higher are essential for providing the "herd immunity" needed to have a significant impact on transmission of influenza by HCP in medical settings, but overall immunization rates for HCP remain near 40%.[1]

Mandatory immunization is not a novel concept. Many health care facilities currently require specific vaccines and a tuberculin skin test as conditions for working in specific areas of the institution or for employment. Despite the sustained efforts of many organizations to improve influenza immunization rates with the use of voluntary campaigns, influenza coverage among HCP in the United States remains unacceptably low.

Mandatory programs for all HCP should be implemented nationwide. Mandating influenza vaccine for all HCP is ethically justified, necessary, and long overdue. Employees of health care institutions have both ethical and professional obligations to act in the best interests of the health of their patients. Medical and religious exemptions to required influenza immunization can be granted on an individual basis. Individual organizations and practices must decide at a local level the additional objections to vaccination, which may be required by state law (eg, philosophical), that are reasonable and the ones they are willing to accept for an individual to be granted an exception and be allowed to continue to work. Policies should be developed for management of exempted HCP during influenza season, including efforts to ensure patient and staff safety and to identify ill HCP.

BACKGROUND

Influenza Is a Significant Public Health Problem

Each year in the United States there are, on average, more than 36 000 deaths and 200 000 hospitalizations associated with the influenza virus, which makes influenza outbreaks a major public health concern.[2] Serious morbidity and mortality can result from influenza infection in any person of any age. Rates of serious influenza-related illness and death are highest among children younger than 2 years, seniors 65 years and older, and people of any age with medical conditions that place them at increased risk of having complications from influenza, such as pregnant women and those with underlying chronic cardiopulmonary, neuromuscular, and immunodeficient conditions. Transmission from an infected, previously healthy child or adult begins as early as 1 day before the onset of symptoms and persists for up to 5 to 7 days; infants and immunocompromised persons may shed virus even longer. Some infected individuals remain asymptomatic yet contagious.[3]

Immunization is the most effective way to prevent influenza outbreaks, so it is recommended for everyone 6 months of age and older.[2] Among healthy adults, including HCP, annual immunization with a vaccine antigenically well matched to circulating strains reduces laboratory-confirmed influenza cases by 70% to 90%.[1] In contrast, the vaccine has been shown to be less effective for some high-risk groups.[1] Many individuals at high risk of influenza and its associated complications are in frequent, close contact with HCP because of their need to seek inpatient and outpatient medical services.[1] Therefore, immunization of HCP is a critically important step for protecting those at risk from health care–associated influenza.

HCP Immunization Rates Remain Low

The growing understanding of the impact of influenza on all age and risk groups has prompted the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention (CDC) to expand annual influenza immunization recommendations to include all people aged 6 months and older.[4] This universal recommendation includes HCP and persons in training for health care professions, such as physicians, nurses, workers in hospital and outpatient care settings, medical emergency response workers, employees of nursing home and longer-term care facilities, and students in these professions.[1] There also is no contraindication to receiving influenza vaccine for HCP who are pregnant or breastfeeding.

The Advisory Committee on Immunization Practices began recommending influenza immunization for HCP in the early 1980s.[5] Despite this long-standing recommendation, overall immunization rates for HCP remain near 40%.[1] It is surprising that many HCP and the organizations that employ them have been inexcusably silent in addressing this patient safety issue. The low seasonal immunization rate among HCP prompted the US Department of Health and Human Services to make increasing HCP immunization rates to 60% a part of their *Healthy People 2010* objectives. However, even this modest objective has not been achieved in many institutions.[6] The gap is magnified when one considers that The Joint Commission estimates that influenza immunization rates of 80% or higher are essential for providing the herd immunity necessary to substantially reduce health care–associated influenza infections.[7]

During the 2009–2010 influenza season, it was recommended that HCP protect themselves against both the expected seasonal influenza strains and the 2009 pandemic H1N1 influenza A virus. The Advisory Committee on Immunization Practices recommended that HCP be a priority group to receive the 2009 H1N1 monovalent vaccine when it was first released, a time when its availability for the general public was limited.[8] In January 2010, the CDC estimated that the percentage of HCP receiving influenza vaccine[8] was as follows:

- 61.9% for seasonal influenza vaccine;
- 37.1% for 2009 H1N1 monovalent vaccine; and
- 34.7% for both vaccines.

Voluntary Programs Are Not Sufficient to Increase HCP Immunization Rates

Efforts to increase immunization rates among HCP have focused primarily on voluntary programs, which attempt to increase rates by ensuring that the vaccine is conveniently available and free of charge and providing influenza-prevention education and incentives or rewards to improve participation. A more comprehensive approach involves the use of signed declination statements coupled with education about risks and benefits of being immunized. However, use of declination statements in 22 hospitals resulted in only a modest increase in influenza immunization.[9] It is difficult to assess the overall effectiveness of declination statements, because the language and context can vary among programs, and multiple strategies for preventing influenza are often initiated simultaneously.[10]

These efforts may lead to an immediate increase in immunization rates, although a lasting effect has yet to be shown. The CDC has reported that an

employer recommendation was associated with two- and fourfold higher coverage rates for seasonal and 2009 H1N1 influenza vaccination, respectively, when compared with employers who made no recommendation. Coverage rates for both influenza vaccines improved by three- to eightfold when employers required influenza immunization of HCP.[8]

It seems that sustainability of herd immunity in health care settings can be achieved only through a mandated policy. Despite many organizations' efforts to improve influenza immunization rates with the use of voluntary campaigns, influenza coverage among US HCP remains unacceptably low at a rate of 44.4% between 2006 and 2007,[1] and even fewer receiving both seasonal and H1N1 vaccines during the 2009–2010 season. Voluntary programs have proven to be ineffective, in part because HCP have misconceptions regarding the risks and benefits of the vaccines. HCP were more likely to believe that seasonal influenza vaccine was safe when compared with the 2009 H1N1 vaccine (80.9% vs 66.6%), although the 2009 H1N1 vaccine was manufactured by using the same processes as seasonal vaccine and had undergone more extensive human safety testing. HCP also were more likely to report that seasonal influenza vaccine was worth the time and expense when compared with the 2009 H1N1 vaccine (74.2% vs 62.8%). Immunization coverage was higher among HCP in hospitals than in outpatient clinics and among HCP working in intensive care, burn, and obstetric units or around seriously ill patients. A survey conducted at 2 obstetric outpatient facilities revealed that 34% to 39% of the obstetric HCP surveyed did not receive yearly influenza immunizations.[11] HCP with a bachelor's degree or higher were more likely to be immunized against the 2009 H1N1 virus.[8]

The Joint Commission found that reasons HCP decline immunization include fear of getting influenza-like illness from the vaccine, fear of adverse effects, perceived low or no likelihood of developing influenza disease, and concern about exposure to thimerosal, among others.[7] With the use of live-attenuated influenza virus (LAIV) vaccine, some HCP expressed concern that the vaccine virus could be shed to vulnerable patients, infecting them with the influenza virus. Although LAIV recipients shed vaccine virus, much lower amounts are shed than during natural infection, and transmission is unlikely to occur. Serious illness has not been reported among unvaccinated, otherwise healthy persons who have been infected inadvertently with virus from LAIV vaccine.[1] These findings highlight the importance of educating HCP of the risks, benefits, and basic principles of influenza vaccination. Given the ineffectiveness of voluntary programs in increasing rates of HCP influenza immunization and the effectiveness of influenza immunization in decreasing infection among those most vulnerable to severe complications from influenza, mandatory programs must be implemented around the country.

Health Risks to Patient Populations Cared for by Unimmunized HCP

Mandatory influenza immunization of HCP is a matter of patient safety. The risk of transmission is augmented, because many HCP work when they are mildly symptomatic or ill, which puts their co-workers and patients at risk.[12] A serosurvey conducted in 4 acute care hospitals in the United Kingdom revealed that 23% of HCP had serologic evidence of influenza virus infection during a single influenza season; the majority reported mild illness or subclinical infection. One limitation of this study is that comprehensive culture or polymerase chain reaction–based surveillance was not also performed.[1]

It is well known that HCP can transmit influenza virus to patients and coworkers before the onset of symptoms or during symptomatic illness.[2] The results of 2 published studies highlight the negative effect that HCP infected with influenza can have on their patients.

- In a NICU, 19 of 54 (35%) infants were infected with influenza A as a result of health care–associated transmission; 6 became ill, and 1 died. Only 15% of staff survey respondents in this NICU had received influenza vaccine—67% of physicians and 9% of nurses. Fourteen percent of the employees reported taking time off from work because of illness, which suggests that these symptomatic personnel had a role in transmission.[13]
- During an outbreak of influenza in a bone marrow transplant unit, there were 7 cases of health care–associated influenza; 6 patients developed pneumonia, and 2 patients died.[14] Five staff members developed influenza-like illness during the outbreak. Surveys revealed a vaccination rate of 12% among unit staff. The hospital took measures the following influenza season to implement a multifaceted voluntary education program aimed at improving immunization rates. However, even with these aggressive measures, 42% of the staff on the bone marrow transplant unit remained unimmunized the following year.[14]

THE SOLUTION: MANDATORY IMMUNIZATION OF ALL HCP

Annual influenza epidemics account for 610 660 life-years lost, 3.1 million days of hospitalization, and 31.4 million outpatient visits.[15] Influenza in the

United States generates a cost burden estimated to be $87 billion per year.[15] The bulk of this cost is a result of work absenteeism and premature mortality. "Presenteeism," or working while symptomatic, also contributes a significant amount to the cost burden and decline in productivity associated with influenza infection. Influenza B virus infection in healthy adults impairs the ability to perform certain tasks to a level similar to that seen with sleep deprivation or alcohol consumption.[16] Presenteeism is a threat to patient safety. In addition, healthy adults who receive the influenza immunization have 25% fewer upper respiratory infections, 44% fewer physician visits, and 43% fewer sick days off, saving an average of $47 per person annually and highlighting the cost-effectiveness of immunization against influenza.[17] A decision-analytic computational simulation model that determined the cost/benefit of employer-sponsored workplace immunization from the employer's perspective found cost savings across diverse occupational groups in all seasonal influenza scenarios.[18]

Mandatory immunization is not a novel concept. All states have laws that require certain vaccines for school entry or attendance. Many health care facilities currently require specific vaccines and a tuberculin skin test as conditions for working in certain areas of the institution or for employment.[2,12] Despite this reality, implementation of mandatory influenza immunization programs for HCP continues to be controversial to some who argue that a mandatory program violates civil liberties. The US Supreme Court ruled in 1905 in *Jacobson v Massachusetts* that states have the power to require immunization if it is necessary for public health or safety of the people. The power of states to enforce immunization requirements or other public health initiatives is constitutionally permissible when the intervention:

- is a public health necessity;
- has proven to be effective;
- is not "gratuitously onerous or unfair"; and
- does not pose a health risk to the subject.

For example, school immunization laws are judicially sanctioned, which emphasizes the fact that mandatory immunization programs have long existed without infringing on constitutional rights.[19]

Evidence That Mandatory Influenza Vaccine Policy Increases Rates of Immunization

Each of the following examples resulted in a substantial increase in employee immunization rates, which demonstrates success with the implementation of a mandatory program.

- BJC Health care, a large nonprofit health care organization with approximately 26 000 employees, implemented a mandatory influenza immunization program in 2008 after voluntary models failed to increase rates above 80%.[20] BJC made influenza immunization a condition of employment as a patient safety initiative. Employees could be granted medical or religious exemptions on review by an occupational medicine professional. Medical exemptions were granted to 321 employees (1.2%), of which 107 were for an egg allergy, 83 for previous allergic reaction or allergy to an influenza vaccine component, and 15 for a history of Guillain-Barré syndrome. Exemptions were granted to 116 other employees, of whom 14 cited pregnancy,[20] although it is highly recommended that pregnant women receive influenza vaccine because of the documented increase in risk of serious complications, including death.[12] Religious exemptions were granted to 90 employees. The result was an immunization rate of 98.4% for the organization of 25 980 employees. Only 8 employees refused to be vaccinated, and their employment was terminated.[20]
- Seattle's Virginia Mason Medical Center implemented a mandatory influenza immunization program in 2005. The medical center reported a 99% immunization compliance rate among its employees.[7]
- The National Institutes of Health Clinical Center passed a mandatory influenza immunization policy in 2008. The policy required that employees who had patient contact be immunized or complete an online declination statement specifying the reason for refusal. The policy achieved 100% participation in that all 2754 employees who were identified to have direct patient contact were either immunized or formally declined vaccination. Compared with vaccination rates of 40% to 60% from previous years, the organization achieved an immunization rate of 88% (2424) among employees with patient contact. Of employees who formally declined, 36 reported medical contraindications to influenza vaccine, and 294 declined for other reasons such as concerns about adverse effects, belief that they were not at risk of influenza, or perceptions that the vaccine was ineffective or harmful. Philosophical reasons were cited 5 times as frequently as religious reasons for declining vaccination.[21]
- Hospital Corporation of America, which includes 163 hospitals, 112 outpatient centers, and 368 physician practices in 20 states, put a mandatory policy into effect in late 2009. The policy required all employees in contact with patients to either receive the annual influenza

vaccine or wear a surgical mask in patient areas. Before the policy, vaccination rates in Hospital Corporation of America facilities varied from 20% to 70%. This mandatory policy offered influenza vaccine to 140 599 HCP; 96% of these employees complied.[22]

A Mandatory Recommendation as a Public Health Intervention Is Justified

Medical and religious exemptions can be granted on an individual basis,[20,23] so mandating influenza immunization for HCP is ethically justified. The regulations of New York State's mandatory program highlight the details that compel individuals to be vaccinated to protect the public from seasonal and pandemic influenza.[24] Employees of health care institutions have an ethical and professional obligation to act in the best interest of the health of their patients. Three criteria that a public health intervention must meet to justify mandatory status have been proposed.[25]

1. **There should be clear medical value from the intervention to the individual.** The positive effects of the influenza vaccine on the health of the person immunized are well known.
2. **The public health benefit of the mandatory intervention must be clear to justify the infringement on personal liberties.** Populations staying at or frequenting hospitals are especially vulnerable to increased health risks from influenza. HCP were obliged to take preventive measures to protect patients when they joined the profession. The effects on the health of patients and on the loss of days worked by personnel have been sufficiently demonstrated.
3. **A mandate must be considered the only option.** Current rates of influenza immunization are unacceptably low among HCP, despite decades-long recommendations using myriad other strategies. When other approaches have failed, a mandate is a reliable way to achieve improvement. "If it is possible to obtain herd immunity, for example, without a mandate but through education, insurance coverage, public outreach and so on, then a mandate would not be needed and should not be used."[25] To satisfy a mandate, each health care facility should design, implement, and evaluate a program tailored to fit its particular needs.

Key Points to Consider in Implementing a Mandatory Influenza Immunization Policy

To maximize success when implementing a mandatory policy, relevant factors include:

- Having full support of health care leadership.
- Customizing the plan for each institution; the policy must be tailored to the geographic setting, educational resources, financial assets, local culture, and potential language barriers.
- Making vaccine free to all HCP.
- Publicizing the program to HCP at all levels by:
  - communicating program details regularly;
  - making presentations about influenza prevention and the program;
  - holding "question-and-answer" sessions; and
  - creating a volunteer team of staff HCP to offer education (and vaccine, if possible) to fellow HCP with concerns.
- Offering convenient times and locations for education and immunization administration, preferably within the institution; vaccinators should adapt to accommodate HCP schedules, including:
  - expanding available hours to receive vaccine;
  - increasing the number of locations at which vaccine is given; and
  - offering vaccine at various venues and gathering places within the institution.
- Using a universal form with defined acceptable medical and religious exemptions, which will be more effective, concrete, and uniform than requiring a physician's note.
- Creating a clear institutional policy for management of employees who are exempted from immunization.

These recommendations for the prevention and control of influenza in HCP will have a considerable impact on practice. Therefore, the American Academy of Pediatrics has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at www.aapredbook.org/implementation.

CONCLUSIONS

Mandatory influenza immunization programs for HCP will benefit the health of employees, their patients, and members of the community. The influenza vaccine is safe, effective, and cost-effective. Health care organizations must work to assuage common fears and misconceptions about the influenza virus and the vaccine. Immunizing all HCP will serve as an example to patients and highlight the safety and effectiveness of annual immunization. HCP fail to lead by example if they recommend universal immunization, including influenza, to their patients but do not require it of themselves.

Data clearly show that an influenza vaccine mandate is necessary and

long overdue. Health care–associated influenza outbreaks are becoming more common, creating a financial burden on health care systems, and contributing to patient morbidity and mortality. Voluntary programs have failed to increase immunization rates to acceptable levels. Results from a recent CDC survey indicate that HCP who were subject to employer requirements for vaccination were more likely to be vaccinated, compared with those not subject to such requirements.[8] Large health care organizations have implemented highly successful mandatory annual influenza immunization programs without significant problems. The implementation of mandatory annual influenza immunization programs for HCP nationwide is long overdue. For the prevention and control of influenza, now is the time to put the health and safety of the patient first.

The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics (AAP) recommend routine administration of hepatitis A vaccine for household members and close contacts, including baby-sitters, when children are adopted from countries with high or intermediate rates of hepatitis A infection. This policy expands previous AAP recommendations to immunize travelers to countries who are seeking to adopt a child in countries with high or medium hepatitis A endemicity. All previously nonimmune unvaccinated people who anticipate close exposure to international adoptees during the 60 days after their arrival should receive hepatitis A immunization, ideally 2 or more weeks before the arrival of the adopted child. *Pediatrics* 2011;128:803–804

INTRODUCTION

Hepatitis A virus (HAV) causes an acute liver infection that is most commonly acquired from exposure to people shedding virus in feces. Most infected children younger than 6 years are asymptomatic. Fewer than 10% of children younger than 4 years develop any symptoms after infection. Thirty percent to 40% of children 4 through 9 years of age are noted to have jaundice. Transmission is highest during the 1 to 2 weeks before jaundice or elevation of liver enzyme levels occurs and during the week after symptoms develop. Risk of transmission diminishes over time, but HAV can be found in stool for extended periods, particularly in neonates and young children. The incubation period is 15 to 50 days (average of 28 days). Some recent HAV outbreaks have been traced to international adoptees. Hepatitis A vaccine is recommended for all children 12 through 23 months of age, for people who are at increased risk of infection, for people who are at increased risk of severe hepatitis A disease, and for any person who desires immunity.[1]

BACKGROUND AND RATIONALE

During the period 1998–2008, approximately 18 000 children were adopted annually from foreign countries. Of these children, 99.8% were from countries with high or intermediate rates of HAV infection,[2] and 85% were younger than 5 years. The incidence of HAV infection in these countries is highest in children younger than 5 years. Hepatitis A vaccine is not routinely administered in these countries. In 2007, a case of fulminant HAV infection was reported in a grandmother of an asymptomatic 1-year-old adopted from Ethiopia who had a laboratory-

confirmed HAV infection. An investigation of this event identified 20 additional cases of acute hepatitis A in patients who had no international travel but had close personal contact with newly arriving internationally adopted children.[3]

Since 2007, the Centers for Disease Control and Prevention has received reports of 14 more clusters of acute HAV infection after exposure to asymptomatic newly arriving adoptees. In a 1998 outbreak, 12 secondary cases were identified, and there were 2 hospitalizations and tertiary cases in an elementary school. Data from 3 adoption clinics in the United States revealed that 1% to 6% of adoptees were acutely infected with HAV.

The risk of HAV infection in close contacts of international adoptees is estimated to be 106 per 100 000 contacts within the initial 60 days of arrival.[4] This rate is 100 times greater than that estimated for symptomatic HAV infection in the general US population.

NEW VACCINE RECOMMENDATIONS

On February 25, 2009, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention updated its policy for hepatitis A vaccine. Hepatitis A vaccine is now recommended for all previously unvaccinated people who anticipate close personal contact with an international adoptee from a country of high or medium endemicity (see www.cdc.gov/mmwr/preview/mmwrhtml/rr5507a1.htm#Fig4) during the 60-day period after arrival. Close contacts include household members and baby-sitters. The first dose of the 2-dose series should be given as soon as adoption is planned, ideally 2 or more weeks before arrival of the adopted child. The second dose should be given to provide long-term immunity.

abstract

FREE

The Centers for Disease Control and Prevention (CDC) guidelines for the prevention of perinatal group B streptococcal (GBS) disease were initially published in 1996. The American Academy of Pediatrics (AAP) also published a policy statement on this topic in 1997. In 2002, the CDC published revised guidelines that recommended universal antenatal GBS screening; the AAP endorsed these guidelines and published recommendations based on them in the 2003 *Red Book*. Since then, the incidence of early-onset GBS disease in neonates has decreased by an estimated 80%. However, in 2010, GBS disease remained the leading cause of early-onset neonatal sepsis. The CDC issued revised guidelines in 2010 based on evaluation of data generated after 2002. These revised and comprehensive guidelines, which have been endorsed by the AAP, reaffirm the major prevention strategy—universal antenatal GBS screening and intrapartum antibiotic prophylaxis for culture-positive and high-risk women—and include new recommendations for laboratory methods for identification of GBS colonization during pregnancy, algorithms for screening and intrapartum prophylaxis for women with preterm labor and premature rupture of membranes, updated prophylaxis recommendations for women with a penicillin allergy, and a revised algorithm for the care of newborn infants. The purpose of this policy statement is to review and discuss the differences between the 2002 and 2010 CDC guidelines that are most relevant for the practice of pediatrics. *Pediatrics* 2011;128:611–616

INTRODUCTION

Group B streptococcal (GBS) disease has been a leading cause of neonatal morbidity and mortality since the 1970s.[1,2] Maternal colonization with GBS in the genitourinary or gastrointestinal tract and transmission to the infant during the labor-and-delivery process is the principal risk factor for early-onset invasive GBS disease.[3] Women who are identified as being GBS-colonized through culture-based screening are more than 25 times more likely to deliver an infant with early-onset infection than are women with negative prenatal cultures.[4] Identification of maternal colonization through universal, culture-based screening with intrapartum antibiotic prophylaxis (IAP) for women with positive screening results has been recommended since 2002.[5] This strategy, endorsed by the American Academy of Pediatrics, has been widely adopted in the United States and has resulted in an estimated 80% decrease in early-onset GBS infection.[6]

However, even in the era of universal screening, cases of GBS disease continue to occur.[7–11] To evaluate data published after the Cen-

TABLE 1 Evidence-Based Rating System Used to Determine Strength of Recommendations

Category	Definition	Recommendation
Strength of recommendation		
A	Strong evidence for efficacy and substantial clinical benefit	Strongly recommended
B	Strong or moderate evidence for efficacy, but only limited clinical benefit	Generally recommended
C	Insufficient evidence for efficacy, or efficacy does not outweigh possible adverse consequences	Optional
D	Moderate evidence against efficacy or for adverse outcome	Generally not recommended
E	Strong evidence against efficacy or for adverse outcome	Never recommended
Quality of evidence supporting recommendation		
I	Evidence from at least 1 well-executed randomized, controlled trial or 1 rigorously designed laboratory-based experimental study that has been replicated by an independent investigator	
II	Evidence from at least 1 well-designed clinical trial without randomization; cohort or case-controlled analytic studies (preferably from more than 1 center); multiple time-series studies; dramatic results from uncontrolled studies; or some evidence from laboratory experiments	
III	Evidence from opinions of respected authorities based on clinical or laboratory experience, descriptive studies, or reports of expert committees	

Adapted with permission from Centers for Disease Control and Prevention. Guidelines for the prevention and treatment of opportunistic infections among HIV-exposed and HIV-infected children: recommendations from CDC, the National Institutes of Health, the HIV Medicine Association of the Infectious Diseases Society of America, the Pediatric Infectious Diseases Society, and the American Academy of Pediatrics. *MMWR Recomm Rep.* 2009;58(RR-11):1–166.

ters for Disease Control and Prevention (CDC) issued guidelines for the prevention of GBS perinatal disease in 2002, the CDC called a meeting of clinical and public health representatives in June 2009. The goal of the meeting was to identify potentially modifiable reasons for continued GBS disease and to address these issues. The American Academy of Pediatrics was represented by members of its Committee on Infectious Diseases and Committee on Fetus and Newborn. The purpose of this policy statement is to review and discuss the differences between the 2002 and 2010 CDC guidelines that are most relevant for the practice of pediatrics. Table 1 outlines the evidence-based rating system that supports each recommendation; strength (indicated by a letter) and quality (indicated by a roman numeral) of evidence are shown in parentheses. The 2010 CDC guidelines can be accessed online (www.cdc.gov/groupbstrep/guidelines/guidelines.html).

LABORATORY DIAGNOSIS OF GBS COLONIZATION

The 2002 guidelines from the CDC recommended universal culture-based screening for GBS at 35 to 37 weeks of gestation. In the intervening years, new diagnostic technologies have been developed, including pigmented enrichment broths, chromogenic agars, DNA probes, and nucleic acid amplification tests (NAATs). These methods have been validated for antenatal testing for GBS colonization and are used in many clinical laboratories, which enables more rapid identification of GBS. A positive test result for GBS by culture, DNA probe, or NAAT performed during antenatal screening indicates colonization, and the woman should receive IAP. However, infants with early-onset GBS can be born to women with negative antenatal screening results, because all laboratory-screening methods are imperfect. Culture-based screening, especially if processing in the laboratory does not always follow the CDC guidelines, may not identify all colonized women.[7,11] Infants with signs and symptoms of sepsis should be managed according to the neonatal algorithm (Fig 1) and receive an initial antibiotic regimen that includes ampicillin regardless of maternal screening results.

Recommendations

- Options for GBS identification from culture of maternal vaginal/rectal swabs have been expanded to include a positive identification from chromogenic agar media. Identification of GBS directly by nucleic acid amplification tests (NAATs), such as commercially available polymerase chain reaction assays, can also be used after broth enrichment if laboratories have validated their NAAT performance and instituted appropriate quality controls (CII).

INTRAPARTUM ANTIBIOTIC PROPHYLAXIS

Penicillin and ampicillin have each been demonstrated in controlled clinical trials to be effective in preventing early-onset GBS disease when administered during labor.[12,13] Penicillin and ampicillin at the recommended dosages for IAP rapidly achieve therapeutic concentrations in the fetal circulation and then amniotic fluid. Cefazolin has similar pharmacokinetics when compared with penicillin, and IAP dosing achieves high intra-amniotic concentrations.[14–16] Cefazolin has been the preferred alternative for IAP for penicillin-allergic women at low risk of anaphylaxis since 2002, although it has been used uncommonly for this indication. At least 4 hours of IAP with one of these β-lactam antibiotics is effective

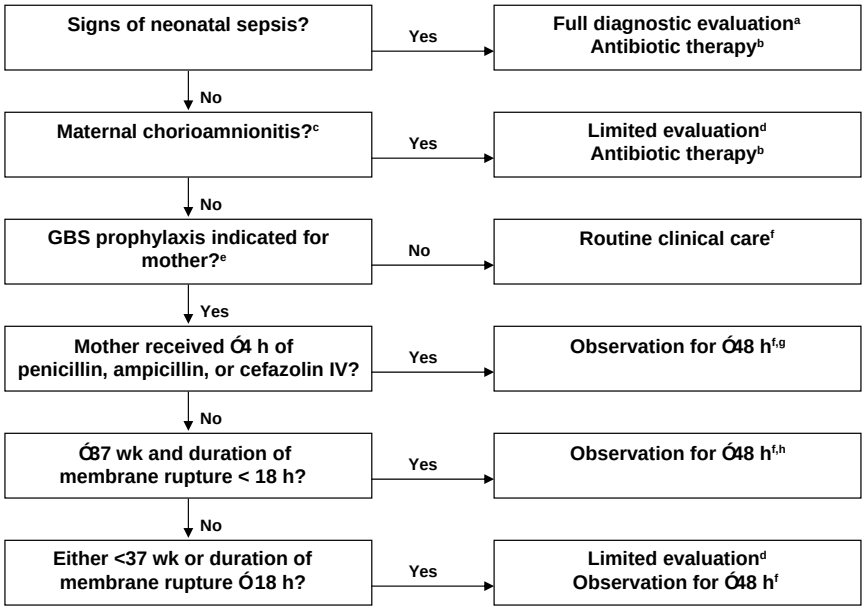

FIGURE 1

Algorithm for the prevention of early-onset GBS infection in the newborn. (Adapted with permission from Centers for Disease Control and Prevention. Prevention of perinatal group B streptococcal disease: prevention of perinatal group B streptococcal disease from CDC, 2010. *MMWR Recomm Rep.* 2010;59[RR-10]:1–32.) [a] Full diagnostic evaluation includes a blood culture; CBC count, including white blood cell differential and platelet counts; chest radiograph (if respiratory abnormalities are present); and lumbar puncture (if the patient is stable enough to tolerate procedure and sepsis is suspected). [b] Antibiotic therapy should be directed toward the most common causes of neonatal sepsis, including intravenous ampicillin for GBS and coverage for other organisms (including *Escherichia coli* and other Gram-negative pathogens) and should take into account local antibiotic-resistance patterns. [c] Consultation with obstetric providers is important in determining the level of clinical suspicion for chorioamnionitis. Chorioamnionitis is diagnosed clinically, and some of the signs are nonspecific. [d] Limited evaluation includes blood culture (at birth) and CBC count with differential and platelets (at birth and/or at 6–12 hours of life). [e] GBS prophylaxis is indicated if 1 or more of the following is true: (1) mother is GBS-positive within the preceding 5 weeks; (2) GBS status is unknown and there are 1 or more intrapartum risk factors, including <37 weeks' gestation, rupture of membranes for ≥18 hours, or temperature of ≥100.4°F (38.0°C); (3) GBS bacteriuria during current pregnancy; or (4) history of a previous infant with GBS disease. [f] If signs of sepsis develop, a full diagnostic evaluation should be performed, and antibiotic therapy should be initiated. [g] If at ≥37 weeks' gestation, observation may occur at home after 24 hours if other discharge criteria have been met, there is ready access to medical care, and a person who is able to comply fully with instructions for home observation will be present. If any of these conditions is not met, the infant should be observed in the hospital for at least 48 hours and until discharge criteria have been achieved. [h] Some experts recommend a CBC count with differential and platelets at 6 to 12 hours of age.[24] IV indicates intravenously.

in preventing early-onset GBS disease in neonates. The definition of adequate IAP has been clarified to include penicillin, ampicillin, or cefazolin for at least 4 hours before delivery. Duration of IAP shorter than 4 hours and all other regimens, including clindamycin and vancomycin, are considered to be inadequate prophylaxis for infants because of lack of data regarding efficacy and limited data regarding favorable pharmacokinetics. No clinical trials have evaluated the efficacy of non–β-lactam regimens for IAP in women with serious penicillin allergy. Although clindamycin is the most commonly chosen IAP regimen in the United States for penicillin-allergic women at low risk of anaphylaxis, current data indicate that approximately 20% of GBS isolates are resistant to clindamycin. Clindamycin should never be used for IAP if susceptibility testing of the mother's GBS isolate has not been performed. Several recent studies have revealed that susceptibility testing is rarely performed on GBS isolates,[5,6,17] and early-onset GBS disease has been reported in infants born to mothers who have received clindamycin IAP.[11,17]

Recommendations

- Penicillin remains the agent of choice for IAP, and ampicillin is an acceptable alternative (AI).
- Penicillin-allergic women who do not have a history of anaphylaxis, angioedema, respiratory distress, or urticaria after administration of penicillin or a cephalosporin should receive cefazolin (BII).
- Penicillin-allergic women at high risk of anaphylaxis should receive clindamycin if their GBS isolate is susceptible or vancomycin if their GBS isolate is intrinsically resistant to clindamycin (CIII).
- The definition of adequate IAP has been clarified to be at least 4 hours of penicillin, ampicillin, or cefazolin. The initial intravenous dose of penicillin is 5 million units; for ampicillin and cefazolin, the initial dose is 2 g (AIII).
- All other antibiotics, doses, or durations are considered inadequate for the purposes of neonatal management (AIII).

PREVENTION OF EARLY-ONSET GBS DISEASE

The revised 2010 GBS American Academy of Pediatrics guidelines for neonatal management were designed to broaden the scope to include all neonates, to increase the clarity of the recommendations, and to decrease unnecessary laboratory evaluations and empirical antibiotics for infants at low risk. Although this strategy will never prevent all infections, the revised guidelines should result in a further decrease in cases of perinatal GBS disease. The management of neonates continues to be based on clinical signs,

the presence of maternal risk factors for GBS neonatal disease, and the likely efficacy of IAP (or maternal antimicrobial treatment in the case of clinical or occult chorioamnionitis) in preventing early-onset disease. The revised infant management algorithm (Fig 1) is derived from recent data summarized in the published CDC document regarding the epidemiology of GBS disease and the usefulness of a "limited evaluation" of well-appearing neonates.

All newborn infants with signs suggestive of sepsis should have a full diagnostic evaluation, including a lumbar puncture if the infant is stable enough to undergo the procedure; 15% to 38% of infants with early-onset meningitis have sterile blood cultures, so evaluating the cerebrospinal fluid is required for optimal diagnostic sensitivity.[18–21] If the care provider believes that a noninfectious condition is responsible for the infant's signs (eg, transient tachypnea of the newborn) and there are no maternal risk factors for sepsis in an otherwise well-appearing infant, the lumbar puncture can be deferred or eliminated. Empirical antimicrobial therapy, typically intravenous ampicillin and gentamicin (unless local antibiotic-resistance patterns suggest the need for another combination), then should be initiated promptly. Chorioamnionitis continues to be a significant risk factor for early-onset GBS sepsis in infants born to GBS-colonized women. All well-appearing newborn infants born to women who have a clinical diagnosis of chorioamnionitis from their obstetric provider should undergo a "limited evaluation," which includes a complete blood cell (CBC) count and differential and a blood culture before initiation of empirical antimicrobial therapy. The sensitivity of the CBC count is improved if delayed for 6 to 12 hours after birth. Empirical therapy should be discontinued as soon as the clinical course and laboratory evaluation exclude sepsis.

The indications for maternal IAP remain unchanged and include 1 of more of the following: (1) GBS culture–positive within preceding 5 weeks; (2) GBS status unknown with 1 or more intrapartum risk factors including less than 37 weeks' gestation, prolonged rupture of membranes for $\geq$18 hours, or temperature of $\geq$100.4°F (38.0°C); (3) GBS bacteriuria during current pregnancy; and (4) history of a previous infant with GBS disease. When a cesarean delivery is performed before onset of labor with intact amniotic membranes, the risk of early-onset GBS disease among infants is extremely low[22,23]; therefore, IAP is not recommended as a routine practice for cesarean deliveries performed under these circumstances, regardless of the GBS colonization status of the woman or the gestational age of the infant.

In well-appearing newborn infants born to women without an indication for IAP, routine clinical care is indicated unless signs of sepsis develop. For well-appearing term newborn infants born to mothers with an indication for IAP to prevent GBS disease and receipt of 4 or more hours of penicillin, ampicillin or cefazolin at the appropriate doses before delivery, routine care, and 48 hours of observation continue to be recommended. However, if these infants meet other discharge criteria, including term birth and ready access to medical care, discharge can occur as early as 24 hours after birth. In this latter circumstance, follow-up care by a care provider within 48 to 72 hours is recommended.

In well-appearing term newborn infants whose mothers had an indication for GBS prophylaxis and rupture of membranes for $<$18 hours but who received inadequate IAP—either by duration before delivery or by inappropriate agent or dose—observation in the hospital for at least 48 hours is recommended. These infants would include infants born to women with a serious penicillin allergy who received either clindamycin or vancomycin. This revised recommendation is based on the poor sensitivity of the "limited-evaluation" assessments in this circumstance and also data indicating that signs of early-onset GBS sepsis appear in more than 98% of neonates within this interval of hospitalization. The authors of several studies have reported the sensitivity of an abnormal CBC count in predicting GBS sepsis to range from 41% to 68%, whereas the presence of clinical signs has a sensitivity of 92%.[24–27] The yield of blood culture can be low among newborn infants exposed to intrapartum antibiotics.[28] Finally, for all preterm neonates ($<$37 weeks of gestation) or for term newborn infants born in the setting of rupture of membranes 18 hours or more before delivery without adequate maternal IAP, a limited evaluation and observation for at least 48 hours is recommended.

Recommendations for Management of Newborn Infants

- All newborn infants with signs of sepsis should undergo a full diagnostic evaluation (including a lumbar puncture) and receive empirical antimicrobial therapy (AII).
- All well-appearing newborn infants born to women given a diagnosis of chorioamnionitis by their obstetrical provider should undergo a limited diagnostic evaluation (no lumbar puncture) and receive empirical antimicrobial therapy (AII).
- For all women who received adequate IAP defined as penicillin (preferred), ampicillin, or cefazolin (penicillin-allergic women at low

risk of anaphylaxis) for 4 or more hours before delivery, their newborn infants require only routine care and observation in the hospital for 48 hours (BIII). If these infants meet other discharge criteria, including term birth and ready access to medical care, discharge can occur as early as 24 hours after birth with follow-up care by a care provider within 48 to 72 hours (CII).

- Well-appearing term newborn infants whose mothers received no or inadequate IAP (including clindamycin or vancomycin) and had rupture of membranes for less than 18 hours require only observation for 48 hours (BIII).
- Well-appearing term infants born to women with no or inadequate IAP and rupture of membranes for 18 or more hours before delivery should undergo a "limited evaluation" (ie, blood culture and CBC count with differential and platelets at birth) and observation for at least 48 hours (BIII).
- All preterm infants born to women with no or inadequate IAP should undergo a limited evaluation and observation for at least 48 hours (BIII).

Policy Statement—Recommendations for the Prevention of *Streptococcus pneumoniae* Infections in Infants and Children: Use of 13-Valent Pneumococcal Conjugate Vaccine (PCV13) and Pneumococcal Polysaccharide Vaccine (PPSV23)

abstract

Routine use of the 7-valent pneumococcal conjugate vaccine (PCV7), available since 2000, has resulted in a dramatic reduction in the incidence of invasive pneumococcal disease (IPD) attributable to serotypes of *Streptococcus pneumoniae* contained in the vaccine. However, IPD caused by nonvaccine pneumococcal serotypes has increased, and nonvaccine serotypes are now responsible for the majority of the remaining cases of IPD occurring in children. A 13-valent pneumococcal conjugate vaccine has been licensed by the US Food and Drug Administration, which, in addition to the 7 serotypes included in the original PCV7, contains the 6 pneumococcal serotypes responsible for 63% of IPD cases now occurring in children younger than 5 years. Because of the expanded coverage provided by PCV13, it will replace PCV7. This statement provides recommendations for (1) the transition from PCV7 to PCV13; (2) the routine use of PCV13 for healthy children and children with an underlying medical condition that increases the risk of IPD; (3) a supplemental dose of PCV13 for (*a*) healthy children 14 through 59 months of age who have completed the PCV7 series and (*b*) children 14 through 71 months of age with an underlying medical condition that increases the risk of IPD who have completed the PCV7 series; (4) "catch-up" immunization for children behind schedule; and (5) PCV13 for certain children at high risk from 6 through 18 years of age. In addition, recommendations for the use of pneumococcal polysaccharide vaccine for children at high risk of IPD are also updated. *Pediatrics* 2010;126:186–190

INTRODUCTION

Invasive disease attributable to *Streptococcus pneumoniae* remains a significant public health problem in children despite widespread use of the 7-valent pneumococcal conjugate vaccine (PCV7) in US infants 2 through 23 months of age. PCV7 was also recommended for certain children 24 through 59 months of age. After the introduction of PCV7, dramatic decreases in invasive pneumococcal disease (IPD) attributable to vaccine serotypes were noted in children. A significant decrease in adult pneumococcal disease attributable to vaccine sero-

types was also seen. However, IPD attributable to serotypes not included in the PCV7 increased in frequency, which prompted the need for development of a pneumococcal conjugate vaccine with expanded coverage.[1]

On February 24, 2010, the US Food and Drug Administration licensed a new 13-valent pneumococcal polysaccharide-protein conjugate vaccine (PCV13) (Prevnar 13 [Wyeth Pharmaceuticals Inc, Madison, NJ]) for use in children 2 through 71 months of age. This new vaccine will replace the previously recommended PCV7. PCV13 contains the same 7 pneumococcal capsular polysaccharides found in PCV7 and 6 additional pneumococcal serotypes, which are now responsible for substantial rates of IPD in US children. The 13 capsular polysaccharides included in the vaccine are 1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F.

The American Academy of Pediatrics (AAP), through its Committee on Infectious Diseases, actively participated in the development of the recommendations for use of the new PCV13 vaccine, which were approved by the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention.[2] PCV13 will replace PCV7 and use the same routine and catch-up immunization schedules recommended for PCV7 for healthy children through 59 months of age and for children at high risk through 71 months of age. In addition, a single supplemental dose of PCV13 is recommended for healthy children 14 through 59 months of age and children at high risk 14 through 71 months of age who were completely immunized with PCV7. No active recall of children is recommended, but the supplemental dose should be given at the next appropriate medical visit of the child who has been completely immunized with PCV7.

A single dose of PCV13 may be administered to children 6 through 18 years of age who are at increased risk of IPD because of sickle cell disease, anatomic or functional asplenia, HIV infection or another immunocompromising condition, or presence of a cochlear implant or cerebrospinal fluid leak. Children at high risk who are 2 years old or older should also receive 23-valent pneumococcal polysaccharide vaccine (PPSV23) at least 8 weeks after their last dose of PCV13. A second dose of PPSV23 is recommended 5 years after the first dose for children with sickle cell disease, anatomic or functional asplenia, HIV infection, or other immunocompromising conditions.

BACKGROUND

IPD is a leading cause of morbidity and mortality throughout the world, and an estimated 14.5 million episodes occurred in children younger than 5 years in the year 2000, resulting in an estimated 826 000 pediatric deaths representing 11% of all deaths in children 1 through 59 months of age.[3] In the United States, before introduction of PCV7, an estimated 16 250 cases of IPD occurred annually in children younger than 5 years, and 80% of cases of IPD in children were attributable to 1 of the 7 serotypes contained in PCV7.[4] After widespread use of PCV7, IPD attributable to all pneumococcal serotypes decreased by 75% in children younger than 5 years and decreased by 45% overall when all age groups were considered, secondary to herd immunity. The reduction in IPD attributable to serotypes contained in PCV7 was even more dramatic (100% in children younger than 5 years and 94% when people of all ages were considered). After accounting for the indirect effects on incidence of IPD, the cost per life-year saved (estimated at $10 400) made PCV7 immunization a cost-effective intervention.[5] In an analysis of 753 cases of IPD in children who had been completely immunized with PCV7, only 4% were true "vaccine failures." The remaining cases were attributable to serotypes not contained in PCV7.[6]

Rates of IPD attributable to serotypes not contained in PCV7 have increased for all age groups since 2000. By 2006–2007, only 2% of IPD cases in children younger than 5 years were caused by PCV7 types, but the 6 additional serotypes included in the new PCV13 vaccine caused 63% of IPD cases in this age group. A report published in the *Morbidity and Mortality Weekly Report* estimated that 4600 cases of IPD occurred in US children younger than 5 years in 2007. Approximately 2900 of these cases (63%) were attributable to serotypes contained in PCV13 and would be potentially preventable with widespread use of PCV13.[7]

DISCUSSION

PCV13 was licensed by the Food and Drug Administration on the basis of safety and immunogenicity. The vaccine is available in single-dose, prefilled syringes that do not contain latex. The vaccine is a sterile solution of 13 capsular polysaccharides of *S pneumoniae*, with each capsular polysaccharide conjugated to a nontoxic variant of diphtheria toxin carrier protein. The vaccine contains no thimerosal or other preservatives but does contain polysorbate 80 and 0.125 mg of aluminum (as aluminum phosphate adjuvant) and succinate buffer.

Vaccine safety was studied in 13 controlled trials involving 4700 healthy infants 6 weeks through 15 months of age who received PCV13 and 2700 infants who received PCV7 as the control population. PCV13 was given simultaneously with other recommended childhood vaccines. Rates of local reactions at the injection site were not different between the 2 groups. Systemic reaction rates (fever, irritability,

sleep disturbances) were also not different between the PCV13 and PCV7 groups.

There were 3 deaths among the infants who received PCV13 (0.063%) and 1 death among the PCV7 recipients (0.036%). All infants died from sudden infant death syndrome (SIDS). The death rate from SIDS was consistent with the published background rates of SIDS in the United States.

Safety was also assessed in 354 patients 7 through 71 months of age who received at least 1 dose of PCV13 but had not previously received PCV7. An additional 284 children 15 through 59 months of age who had received at least 3 doses of PCV7 were given 1 or 2 doses of PCV13 and followed for adverse reactions. Vaccine was well tolerated in these groups, and no significant adverse events were reported.

Immunogenicity was assessed by measuring immunoglobulin G (IgG) antibody concentrations by enzyme-linked immunosorbent assay (ELISA) and by assessing functional antibody responses (opsonophagocytic activity). For 12 of the 13 serotypes, the percentage of children who achieved antibody responses of $\geq$0.35 μg/mL was similar to the percentage of children who achieved antibody responses of $\geq$0.35 μg/mL 1 month after the third dose of PCV7. For serotype 3 (not contained in PCV7), only 63.5% of children achieved an antibody concentration of $\geq$0.35 μg/mL. Functional opsonophagocytic antibody responses were elicited for all 13 serotypes. Responses after the fourth dose of PCV13 showed an increase in antibody concentrations measured by ELISA for all 13 serotypes.

PCV13 is currently being studied in children 72 months old and older with conditions that put them at high risk, but no data are currently available regarding safety or immunogenicity in this population of older children. However, on the basis of the experience with PCV7, it is likely that PCV13 will be as safe and effective in reducing the risk of pneumococcal disease in this high-risk, older population of children.

RECOMMENDATIONS

Children who have not previously received PCV7 or PCV13 or who are incompletely immunized with PCV7 or PCV13:

- PCV13 is recommended for all children 2 through 59 months of age and for children 60 through 71 months of age who have underlying medical conditions that increase their risk of pneumococcal disease or complications (Table 1).
- PCV13 is recommended as a 4-dose series given at 2, 4, 6, and 12 through 15 months of age (Table 2).
- For children within this age range who have received 1 or more doses of PCV7, the series should be completed with PCV13 when it is available in the office. Thus, previously administered PCV7 doses count toward completion of the recommended series (Table 3).
- The immunization schedule for infants and toddlers 2 through 59 months of age who have not received any previous PCV7 or PCV13 or who need "catch-up" immunization are the same as those published previously for PCV7, with PCV13 replacing PCV7 in the schedule (see Table 3.53 in *Red Book*[8] (p532)). The only addition to Table 3.53 is the extension of age in children with underlying medical condi-

TABLE 1 Underlying Medical Conditions That Are Indications for Pneumococcal Immunization Among Children, According to Risk Group: Advisory Committee on Immunization Practices, United States, 2010

Risk Group	Condition
Immunocompetent children	Chronic heart disease[a]
	Chronic lung disease[b]
	Diabetes mellitus
	Cerebrospinal fluid leaks
	Cochlear implant
Children with functional or anatomic asplenia	Sickle cell disease and other hemoglobinopathies
	Congenital or acquired asplenia or splenic dysfunction
Children with immunocompromising conditions	HIV infection
	Chronic renal failure and nephrotic syndrome
	Diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; or solid organ transplantation
	Congenital immunodeficiency[c]

[a] Particularly cyanotic congenital heart disease and cardiac failure.
[b] Including asthma, if treated with prolonged high-dose oral corticosteroids.
[c] Includes B- (humoral) or T-lymphocyte deficiency; complement deficiencies, particularly C1, C2, C3, and C4 deficiency; and phagocytic disorders (excluding chronic granulomatous disease).

TABLE 2 Recommended Routine Immunization Schedule for PCV13 Among Infants and Children Who Have Not Received Previous Doses of PCV7 or PCV13, According to Age at First Dose: Advisory Committee on Immunization Practices, United States, 2010

Age at First Dose, mo	Primary PCV13 Series, No. of Doses[a]	PCV13 Booster Dose at 12–15 mo of Age, No. of Doses[b]
2–6	3	1
7–11	2	1
12–23	2	—
24–59 (healthy children)	1	—
24–71 (children with certain chronic diseases or immunocompromising conditions[c])	2	—

[a] Minimum interval between doses is 8 weeks except for children vaccinated at 12 months of age or younger for whom the minimum interval between doses is 4 weeks. The minimum age for administration of the first dose is 6 weeks.
[b] Given at least 8 weeks after the previous dose.
[c] For a complete list of conditions, see Table 1.

TABLE 3 Recommended Transition Schedule From PCV7 to PCV13 Vaccination Among Infants and Children, According to Number of Previous PCV7 Doses Received: Advisory Committee on Immunization Practices, United States, 2010

PCV7	PCV7	PCV13	PCV13	—
PCV7	PCV7	PCV7	PCV13	—
PCV7	PCV7	PCV7	PCV7	PCV13

[a] No additional PCV13 doses are indicated for children 12 through 23 months of age who have received 2 or 3 doses of PCV before 12 months of age and at least 1 dose of PCV13 at 12 months of age or older.
[b] For children with underlying medical conditions (see Table 1), a single supplemental PCV13 dose is recommended through the age of 71 months.

tions, for whom PCV13 is recommended through 71 months of age.

Supplemental dose recommendation:

- A single supplemental dose of PCV13 is recommended for all healthy children 14 through 59 months of age who are fully immunized with PCV7. The supplemental dose should be given at least 8 weeks after the last dose of PCV7.
- For children fully immunized with PCV7 who have underlying medical conditions that increase their risk of pneumococcal disease or complications, a single supplemental dose of PCV13 is recommended for children 14 through 71 months of age, including children who may have previously received PPSV23.
- No active recall of patients is recommended. The supplemental dose should be given at the next medical visit of the child.

Children 6 through 18 years of age with conditions that place them at high risk:

- A single dose of PCV13 may be administered to children 6 through 18 years of age who are at increased risk of IPD because of sickle cell disease, anatomic or functional asplenia, HIV infection or other immunocompromising condition, or presence of cochlear implant or cerebrospinal fluid leaks, regardless of whether they have previously received PCV7 or PPSV23.

Use of PPSV23 among children 2 through 18 years of age who are at increased risk of IPD:

- Children with an underlying medical condition that increases the risk of IPD should receive PPSV23 at 2 years of age or as soon as possible after a diagnosis of chronic illness is made after the age of 2 years.
- Doses of PCV13 should be completed before PPSV23 is given, with a minimum interval of 8 weeks between the last dose of PCV13 and the dose of PPSV23.
- If a child has previously received PPSV23, he or she should also receive the recommended doses of PCV13.
- A second dose of PPSV23 is recommended 5 years after the first dose in children with sickle cell disease or functional or anatomic asplenia, HIV infection, or other immunocompromising conditions, but no more than 2 total doses of PPSV23 are recommended at this time.

IMPLEMENTATION OF THE NEW RECOMMENDATIONS

The introduction of a new vaccine may have considerable impact on the practice. Therefore, the AAP has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at www.aapredbook.org/implementation.

PCV13 is approved for the Vaccines for Children (VFC) program through 18 years of age, and the vaccine will be covered by the Vaccine Injury Compensation Program. PPSV23 is not covered by the Vaccine Injury Compensation Program.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Recommendations for Preventive Pediatric Health Care

Bright Futures
Prevention and health promotion for infants, children, adolescents, and their families™

Each child and family is unique; therefore, these **Recommendations for Preventive Pediatric Health Care** are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in satisfactory fashion. **Additional visits may become necessary** if circumstances suggest variations from normal.

Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits.

These guidelines represent a consensus by the American Academy of Pediatrics (AAP) and Bright Futures. The AAP continues to emphasize the great importance of **continuity of care** in comprehensive health supervision and the need to avoid **fragmentation of care.**

[a] If a child comes under care for the first time at any point on the schedule, or if any items are not accomplished at the suggested age, the schedule should be brought up to date at the earliest possible time.

[b] A prenatal visit is recommended for parents who are at high risk, for first-time parents, and for those who request a conference. The prenatal visit should include anticipatory guidance, pertinent medical history, and a discussion of benefits of breastfeeding and planned method of feeding per AAP statement "The Prenatal Visit" (2001) [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;107/6/1456].

[c] Every infant should have a newborn evaluation after birth, breastfeeding encouraged, and instruction and support offered.

[d] Every infant should have an evaluation within 3 to 5 days of birth and within 48 to 72 hours after discharge from the hospital, to include evaluation for feeding and jaundice. Breastfeeding infants should receive formal breastfeeding evaluation, encouragement, and instruction as recommended in AAP statement "Breastfeeding and the Use of Human Milk" (2005) [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;115/2/496]. For newborns discharged in less than 48 hours after delivery, the infant must be examined within 48 hours of discharge per AAP statement "Hospital Stay for Healthy Term Newborns" (2004) [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;113/5/1434].

[e] Blood pressure measurement in infants and children with specific risk conditions should be performed at visits before age 3 years.

[f] If the patient is uncooperative, rescreen within 6 months per AAP statement "Eye Examination and Vision Screening in Infants, Children, and Young Adults" (1996) [URL: http://aappolicy.aappublications.org/cgi/reprint/pediatrics;98/1/153.pdf].

[g] All newborns should be screened per AAP statement "Year 2000 Position Statement: Principles and Guidelines for Early Hearing Detection and Intervention Programs " (2000) [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;106/4/798]. Joint Committee on Infant Hearing. Year 2007 position statement: principles and guidelines for early hearing detection and intervention programs. *Pediatrics.* 2007;120:898–921.

[h] AAP Council on Children With Disabilities, AAP Section on Developmental Behavioral Pediatrics, AAP Bright Futures Steering Committee, AAP Medical Home Initiatives for Children With Special Needs Project Advisory Committee. Identifying infants and young children with developmental disorders in the medical home: an algorithm for developmental surveillance and screening. *Pediatrics.* 2006;118:405–420 [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;118/1/405].

[i] Gupta VB, Hyman SL, Johnson CP, et al. Identifying children with autism early? *Pediatrics.* 2007;119:152–153 [URL: http://pediatrics.aappublications.org/cgi/content/full/119/1/152].

[j] At each visit, age-appropriate physical examination is essential, with infant totally unclothed, older child undressed and suitably draped.

[k] These may be modified, depending on entry point into schedule and individual need.

[l] Newborn metabolic and hemoglobinopathy screening should be done according to state law. Results should be reviewed at visits and appropriate retesting or referral done as needed.

[m] Schedules per the Committee on Infectious Diseases, published annually in the January issue of *Pediatrics.* Every visit should be an opportunity to update and complete a child's immunizations.

[n] See AAP *Pediatric Nutrition Handbook,* 5th Edition (2003) for a discussion of universal and selective screening options. See also Recommendations to prevent and control iron deficiency in the United States. *MMWR Recomm Rep.* 1998;47(RR-3):1–36.

[o] For children at risk of lead exposure, consult the AAP statement "Lead Exposure in Children: Prevention, Detection, and Management" (2005) [URL: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;116/4/1036]. Additionally, screening should be done in accordance with state law where applicable.

[p] Perform risk assessments or screens as appropriate, based on universal screening requirements for patients with Medicaid or high prevalence areas.

[q] Tuberculosis testing per recommendations of the Committee on Infectious Diseases, published in the current edition of *Red Book: Report of the Committee on Infectious Diseases.* Testing should be done on recognition of high-risk factors.

[r] "Third Report of the National Cholesterol Education Program (NCEP) Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III) Final Report" (2002) [URL: http://circ.ahajournals.org/cgi/content/full/106/25/3143] and "The Expert Committee Recommendations on the Assessment, Prevention, and Treatment of Child and Adolescent Overweight and Obesity." Supplement to *Pediatrics.* In press.

[s] All sexually active patients should be screened for sexually transmitted infections (STIs).

[t] All sexually active girls should have screening for cervical dysplasia as part of a pelvic examination beginning within 3 years of onset of sexual activity or age 21 (whichever comes first).

[u] Referral to dental home, if available. Otherwise, administer oral health risk assessment. If the primary water source is deficient in fluoride, consider oral fluoride supplementation.

[v] At the visits for 3 years and 6 years of age, it should be determined whether the patient has a dental home. If the patient does not have a dental home, a referral should be made to one. If the primary water source is deficient in fluoride, consider oral fluoride supplementation.

[w] Refer to the specific guidance by age as listed in Bright Futures Guidelines. (Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents.* 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008.)

Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States

Summary

Widespread use of fluoride has been a major factor in the decline in the prevalence and severity of dental caries (i.e., tooth decay) in the United States and other economically developed countries. When used appropriately, fluoride is both safe and effective in preventing and controlling dental caries. All U.S. residents are likely exposed to some degree to fluoride, which is available from multiple sources. Both health-care professionals and the public have sought guidance on selecting the best way to provide and receive fluoride. During the late 1990s, CDC convened a work group to develop recommendations for using fluoride to prevent and control dental caries in the United States. This report includes these recommendations, as well as a) critical analysis of the scientific evidence regarding the efficacy and effectiveness of fluoride modalities in preventing and controlling dental caries, b) ordinal grading of the quality of the evidence, and c) assessment of the strength of each recommendation.

Because frequent exposure to small amounts of fluoride each day will best reduce the risk for dental caries in all age groups, the work group recommends that all persons drink water with an optimal fluoride concentration and brush their teeth twice daily with fluoride toothpaste. For persons at high risk for dental caries, additional fluoride measures might be needed. Measured use of fluoride modalities is particularly appropriate during the time of anterior tooth enamel development (i.e., age <6 years).

The recommendations in this report guide dental and other health-care providers, public health officials, policy makers, and the public in the use of fluoride to achieve maximum protection against dental caries while using resources efficiently and reducing the likelihood of enamel fluorosis. The recommendations address public health and professional practice, self-care, consumer product industries and health agencies, and further research. Adoption of these recommendations could further reduce dental caries in the United States and save public and private resources.

INTRODUCTION

Dental caries (i.e., tooth decay) is an infectious, multifactorial disease afflicting most persons in industrialized countries and some developing countries (*1*). Fluoride reduces the incidence of dental caries and slows or reverses the progression of existing lesions (i.e., prevents cavities). Although pit and fissure sealants, meticulous oral hygiene, and appropriate dietary practices contribute to caries prevention and control, the most effective and widely used approaches have included fluoride use. Today, all U.S. residents are exposed to fluoride to some degree, and widespread use of fluoride has been a major factor in the decline in the prevalence and severity of dental caries in the United States and other economically developed countries (*1*). Although this decline is a major public

health achievement, the burden of disease is still considerable in all age groups. Because many fluoride modalities are effective, inexpensive, readily available, and can be used in both private and public health settings, their use is likely to continue.

Fluoride is the ionic form of the element fluorine, the 13th most abundant element in the earth's crust. Fluoride is negatively charged and combines with positive ions (e.g., calcium or sodium) to form stable compounds (e.g., calcium fluoride or sodium fluoride). Such fluorides are released into the environment naturally in both water and air. Fluoride compounds also are produced by some industrial processes that use the mineral apatite, a mixture of calcium phosphate compounds. In humans, fluoride is mainly associated with calcified tissues (i.e., bones and teeth) because of its high affinity for calcium.

Fluoride's ability to inhibit or even reverse the initiation and progression of dental caries is well documented. The first use of adjusted fluoride in water for caries control began in 1945 and 1946 in the United States and Canada, when the fluoride concentration was adjusted in the drinking water supplying four communities (*2–5*). The U.S. Public Health Service (PHS) developed recommendations in the 1940s and 1950s regarding fluoride concentrations in public water supplies. At that time, public health officials assumed that drinking water would be the major source of fluoride for most U.S. residents. The success of water fluoridation in preventing and controlling dental caries led to the development of fluoride-containing products, including toothpaste (i.e., dentifrice), mouthrinse, dietary supplements, and professionally applied or prescribed gel, foam, or varnish. In addition, processed beverages, which constitute an increasing proportion of the diets of many U.S. residents (*6,7*), and food can contain small amounts of fluoride, especially if they are processed with fluoridated water. Thus, U.S. residents have more sources of fluoride available now than 50 years ago.

Much of the research on the efficacy and effectiveness of individual fluoride modalities in preventing and controlling dental caries was conducted before 1980, when dental caries was more common and more severe. Modalities were usually tested separately and with the assumption that the method would provide the main source of fluoride. Thus, various modes of fluoride use have evolved, each with its own recommended concentration, frequency of use, and dosage schedule. Health-care professionals and the public have sought guidance regarding selection of preventive modalities from among the available options. The United States does not have comprehensive recommendations for caries prevention and control through various combinations of fluoride modalities. Adoption of such recommendations could further reduce dental caries while saving public and private resources and reducing the prevalence of enamel fluorosis, a generally cosmetic developmental condition of tooth enamel.

This report presents comprehensive recommendations on the use of fluoride to prevent and control dental caries in the United States. These recommendations were developed by a work group of 11 specialists in fluoride research or policy convened by CDC during the late 1990s and reviewed by an additional 23 specialists. Although the recommendations were developed specifically for the United States, aspects of this report could be relevant to other countries. The recommendations guide health-care providers and the public on efficient and appropriate use of fluoride modalities, direct attention to fluoride intake among children aged <6 years to decrease the risk for enamel fluorosis, and suggest areas for further research. This report focuses on critical analysis of the scientific evidence regarding the efficacy and effectiveness of each fluoride modality in preventing and controlling dental caries and on the use of multiple sources of fluoride.

The safety of fluoride, which has been documented comprehensively by other scientific and public health organizations (e.g., PHS [*8*], National Research Council [*9*], World Health Organization [*10*], and Institute of Medicine [*11*]) is not addressed.

HOW FLUORIDE PREVENTS AND CONTROLS DENTAL CARIES

Dental caries is an infectious, transmissible disease in which bacterial by-products (i.e., acids) dissolve the hard surfaces of teeth. Unchecked, the bacteria can penetrate the dissolved surface, attack the underlying dentin, and reach the soft pulp tissue. Dental caries can result in loss of tooth structure, pain, and tooth loss and can progress to acute systemic infection.

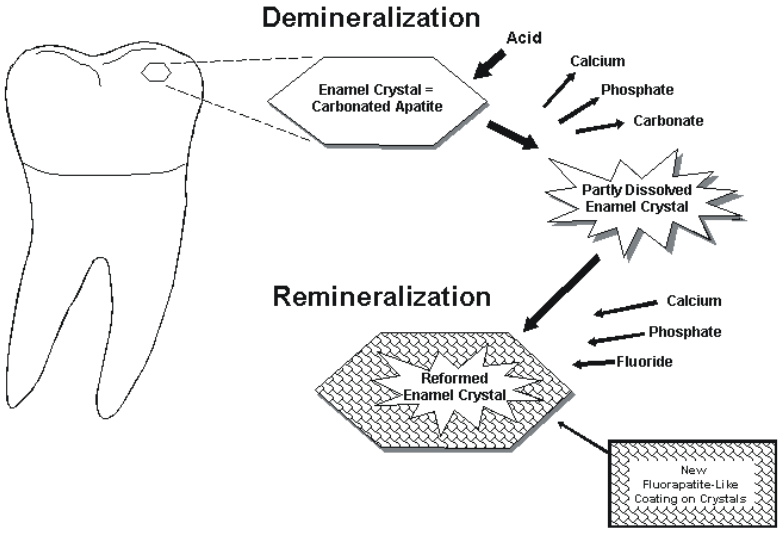
Cariogenic bacteria (i.e., bacteria that cause dental caries) reside in dental plaque, a sticky organic matrix of bacteria, food debris, dead mucosal cells, and salivary components that adheres to tooth enamel. Plaque also contains minerals, primarily calcium and phosphorus, as well as proteins, polysaccharides, carbohydrates, and lipids. Cariogenic bacteria colonize on tooth surfaces and produce polysaccharides that enhance adherence of the plaque to enamel. Left undisturbed, plaque will grow and harbor increasing numbers of cariogenic bacteria. An initial step in the formation of a carious lesion takes place when cariogenic bacteria in dental plaque metabolize a substrate from the diet (e.g., sugars and other fermentable carbohydrates) and the acid produced as a metabolic by-product demineralizes (i.e., begins to dissolve) the adjacent enamel crystal surface (Figure 1). Demineralization involves the loss of calcium, phosphate, and carbonate. These minerals can be captured by surrounding plaque and be available for reuptake by the enamel surface. Fluoride, when present in the mouth, is also retained and concentrated in plaque.

Fluoride works to control early dental caries in several ways. Fluoride concentrated in plaque and saliva inhibits the demineralization of sound enamel and enhances the remineralization (i.e., recovery) of demineralized enamel (*12,13*). As cariogenic bacteria metabolize carbohydrates and produce acid, fluoride is released from dental plaque in response to lowered pH at the tooth-plaque interface (*14*). The released fluoride and the fluoride present in saliva are then taken up, along with calcium and phosphate, by demineralized enamel to establish an improved enamel crystal structure. This improved structure is more acid resistant and contains more fluoride and less carbonate (*12,15–19*) (Figure 1). Fluoride is more readily taken up by demineralized enamel than by sound enamel (*20*). Cycles of demineralization and remineralization continue throughout the lifetime of the tooth.

Fluoride also inhibits dental caries by affecting the activity of cariogenic bacteria. As fluoride concentrates in dental plaque, it inhibits the process by which cariogenic bacteria metabolize carbohydrates to produce acid and affects bacterial production of adhesive polysaccharides (*21*). In laboratory studies, when a low concentration of fluoride is constantly present, one type of cariogenic bacteria, *Streptococcus mutans*, produces less acid (*22–25*). Whether this reduced acid production reduces the cariogenicity of these bacteria in humans is unclear (*26*).

Saliva is a major carrier of topical fluoride. The concentration of fluoride in ductal saliva, as it is secreted from salivary glands, is low — approximately 0.016 parts per million (ppm) in areas where drinking water is fluoridated and 0.006 ppm in nonfluoridated areas (*27*). This concentration of fluoride is not likely to affect cariogenic activity. However, drinking fluoridated water, brushing with fluoride toothpaste, or using other fluoride

FIGURE 1. The demineralization and remineralization processes lead to remineralized enamel crystals with surfaces rich in fluoride and lower in solubility



Source: Adapted from Featherstone JDB. Prevention and reversal of dental caries: role of low level fluoride. Community Dent Oral Epidemiol 1999;27:31–40. Reprinted with permission from Munksgaard International Publishers Ltd., Copenhagen, Denmark.

dental products can raise the concentration of fluoride in saliva present in the mouth 100- to 1,000-fold. The concentration returns to previous levels within 1–2 hours but, during this time, saliva serves as an important source of fluoride for concentration in plaque and for tooth remineralization (*28*).

Applying fluoride gel or other products containing a high concentration of fluoride to the teeth leaves a temporary layer of calcium fluoride-like material on the enamel surface. The fluoride in this material is released when the pH drops in the mouth in response to acid production and is available to remineralize enamel (*29*).

In the earliest days of fluoride research, investigators hypothesized that fluoride affects enamel and inhibits dental caries only when incorporated into developing dental enamel (i.e., preeruptively, before the tooth erupts into the mouth) (*30,31*). Evidence supports this hypothesis (*32–34*), but distinguishing a true preeruptive effect after teeth erupt into a mouth where topical fluoride exposure occurs regularly is difficult. However, a high fluoride concentration in sound enamel cannot alone explain the marked reduction in dental caries that fluoride produces (*35,36*). The prevalence of dental caries in a population is not inversely related to the concentration of fluoride in enamel (*37*), and a higher concentration of enamel fluoride is not necessarily more efficacious in preventing dental caries (*38*).

The laboratory and epidemiologic research that has led to the better understanding of how fluoride prevents dental caries indicates that fluoride's predominant effect is posteruptive and topical and that the effect depends on fluoride being in the right amount in the right place at the right time. Fluoride works primarily after teeth have erupted, especially when small amounts are maintained constantly in the mouth, specifically in dental plaque and saliva (*37*). Thus, adults also benefit from fluoride, rather than only children, as was previously assumed.

RISK FOR DENTAL CARIES

The prevalence and severity of dental caries in the United States have decreased substantially during the preceding 3 decades (*39*). National surveys have reported that the prevalence of any dental caries among children aged 12–17 years declined from 90.4% in 1971–1974 to 67% in 1988–1991; severity (measured as the mean number of decayed, missing, or filled teeth) declined from 6.2 to 2.8 during this period (*40–43*).

These decreases in caries prevalence and severity have been uneven across the general population; the burden of disease now is concentrated among certain groups and persons. For example, 80% of the dental caries in permanent teeth of U.S. children aged 5–17 years occurs among 25% of those children (*43*). To develop and apply appropriate and effective caries prevention and control strategies, identification and assessment of groups and persons at high risk for developing new carious lesions is essential (*44*). Caries risk assessment is difficult because it attempts to account for the complex interaction of multiple factors. Although various methods for assessing risk exist, no single model predominates in this emerging science. Models that take multiple factors into account predict the risk more accurately, especially for groups rather than persons. However, for persons in a clinical setting, models do not improve on a dentist's perception of risk after examining a patient and considering the personal circumstances (*45*).

Populations believed to be at increased risk for dental caries are those with low socioeconomic status (SES) or low levels of parental education, those who do not seek regular dental care, and those without dental insurance or access to dental services (*45–47*). Persons can be at high risk for dental caries even if they do not have these recognized factors. Individual factors that possibly increase risk include active dental caries; a history of high caries in older siblings or caregivers; root surfaces exposed by gingival recession; high levels of infection with cariogenic bacteria; impaired ability to maintain oral hygiene; malformed enamel or dentin; reduced salivary flow because of medications, radiation treatment, or disease; low salivary buffering capacity (i.e., decreased ability of saliva to neutralize acids); and the wearing of space maintainers, orthodontic appliances, or dental prostheses. Risk can increase if any of these factors are combined with dietary practices conducive to dental caries (i.e., frequent consumption of refined carbohydrates). Risk decreases with adequate exposure to fluoride (*44,45*).

Risk for dental caries and caries experience* exists on a continuum, with each person at risk to some extent; 85% of U.S. adults have experienced tooth decay (*48*). Caries risk can vary over time — perhaps numerous times during a person's lifetime — as risk factors change. Because caries prediction is an inexact, developing science, risk is dichotomized as low and high in this report. If these two categories of risk were applied to the U.S. population, most persons would be classified as low risk at any given time.

Children and adults who are at low risk for dental caries can maintain that status through frequent exposure to small amounts of fluoride (e.g., drinking fluoridated water and using fluoride toothpaste). Children and adults at high risk for dental caries might benefit from additional exposure to fluoride (e.g., mouthrinse, dietary supplements, and professionally applied products). All available information on risk factors should be considered before a group or person is identified as being at low or high risk for dental caries. However, when classification is uncertain, treating a person as high risk is prudent until further information or experience allows a more accurate assessment. This assumption

*For this report, the term "caries experience" is used to mean the sum of filled and unfilled cavities, along with any missing teeth resulting from tooth decay.

increases the immediate cost of caries prevention or treatment and might increase the risk for enamel fluorosis for children aged <6 years, but reduces the risk for dental caries for groups or persons misclassified as low risk.

RISK FOR ENAMEL FLUOROSIS

The proper amount of fluoride helps prevent and control dental caries. Fluoride ingested during tooth development can also result in a range of visually detectable changes in enamel opacity (i.e., light refraction at or below the surface) because of hypomineralization. These changes have been broadly termed enamel fluorosis, certain extremes of which are cosmetically objectionable (*49*). (Many other developmental changes that affect the appearance of enamel are not related to fluoride [*50*].) Severe forms of this condition can occur only when young children ingest excess fluoride, from any source, during critical periods of tooth development. The occurrence of enamel fluorosis is reported to be most strongly associated with cumulative fluoride intake during enamel development, but the severity of the condition depends on the dose, duration, and timing of fluoride intake. The transition and early maturation stages of enamel development appear to be most susceptible to the effects of fluoride (*51*); these stages occur at varying times for different tooth types. For central incisors of the upper jaw, for example, the most sensitive period is estimated at age 15–24 months for boys and age 21–30 months for girls (*51,52*).

Concerns regarding the risk for enamel fluorosis are limited to children aged ≤8 years; enamel is no longer susceptible once its preeruptive maturation is complete (*11*). Fluoride sources for children aged ≤8 years are drinking water, processed beverages and food, toothpaste, dietary supplements that include fluoride (tablets or drops), and other dental products. This report discusses the risk for enamel fluorosis among children aged <6 years. Children aged ≥6 years are considered past the age that fluoride ingestion can cause cosmetically objectionable fluorosis because only certain posterior teeth are still at a susceptible stage of enamel development, and these will not be readily visible. In addition, the swallowing reflex has developed sufficiently by age 6 years for most children to be able to control inadvertent swallowing of fluoride toothpaste and mouthrinse.

The very mild and mild forms of enamel fluorosis appear as chalklike, lacy markings across a tooth's enamel surface that are not readily apparent to the affected person or casual observer (*53*). In the moderate form, >50% of the enamel surface is opaque white. The rare, severe form manifests as pitted and brittle enamel. After eruption, teeth with moderate or severe fluorosis might develop areas of brown stain (*54*). In the severe form, the compromised enamel might break away, resulting in excessive wear of the teeth. Even in its severe form, enamel fluorosis is considered a cosmetic effect, not an adverse functional effect (*8,11,55,56*). Some persons choose to modify this condition with elective cosmetic treatment.

The benefits of reduced dental caries and the risk for enamel fluorosis are linked. Early studies that examined the cause of "mottled enamel" (now called moderate to severe enamel fluorosis) led to the unexpected discovery that fluoride in community drinking water inhibits dental caries (*57*). Historically, a low prevalence of the milder forms of enamel fluorosis has been accepted as a reasonable and minor consequence balanced against the substantial protection from dental caries from drinking water con-

taining an optimal concentration of fluoride, either naturally occurring or through adjustment (*11,53*). When enamel fluorosis was first systematically investigated during the 1930s and 1940s, its prevalence was 12%–15% for very mild and mild forms and zero for moderate and severe forms among children who lived in communities with drinking water that naturally contained 0.9–1.2 ppm fluoride (*53*). Although the prevalence of this condition in the United States has since increased (*8,58,59*), most fluorosis today is of the mildest form, which affects neither cosmetic appearance nor dental function. The increased prevalence in areas both with and without fluoridated community drinking water (*8*) indicates that, during the first 8 years of life (i.e., the window of time when this condition can develop), the total intake of fluoride from all sources has increased for some children.

The 1986–1987 National Survey of Dental Caries in U.S. School Children (the most recent national estimates of enamel fluorosis prevalence) indicated that the prevalence of any enamel fluorosis among children was 22%–23% (range: 26% of children aged 9 years to 19% of those aged 17 years) (*60,61*). Almost all cases reported in the survey were of the very mild or mild form, but some cases of the moderate (1.1%) and severe (0.3%) forms were observed. Cases of moderate and severe forms occurred even among children living in areas with low fluoride concentrations in the drinking water (*61*). Although this level of enamel fluorosis is not considered a public health problem (*53*), prudent public health practice should seek to minimize this condition, especially moderate to severe forms. In addition, changes in public perceptions of what is cosmetically acceptable could influence support for effective caries-prevention measures. Research into the causes of enamel fluorosis has focused on identifying risk factors (*62–65*). Adherence to the recommendations in this report regarding appropriate use of fluoride for children aged ≤6 years will reduce the prevalence and severity of enamel fluorosis.

NATIONAL GUIDELINES FOR FLUORIDE USE

PHS recommendations for fluoride use include an optimally adjusted concentration of fluoride in community drinking water to maximize caries prevention and limit enamel fluorosis. This concentration ranges from 0.7 ppm to 1.2 ppm depending on the average maximum daily air temperature of the area (*66–68*). In 1991, PHS also issued policy and research recommendations for fluoride use (*8*). The U.S. Environmental Protection Agency (EPA), which is responsible for the safety and quality of drinking water in the United States, sets a maximum allowable limit for fluoride in community drinking water at 4 ppm and a secondary limit (i.e., nonenforceable guideline) at 2 ppm (*69,70*). The U.S. Food and Drug Administration (FDA) is responsible for approving prescription and over-the-counter fluoride products marketed in the United States and for setting standards for labeling bottled water (*71*) and over-the-counter fluoride products (e.g., toothpaste and mouthrinse) (*72*).

Nonfederal agencies also have published guidelines on fluoride use. The American Dental Association (ADA) reviews fluoride products for caries prevention through its voluntary Seal of Acceptance program; accepted products are listed in the *ADA Guide to Dental Therapeutics* (*73*). A dosage schedule for fluoride supplements for infants and children aged ≤16 years, which is scaled to the fluoride concentration in the community drinking water, has been jointly recommended by ADA, the American Academy of Pediatric Dentistry (AAPD), and the American Academy of Pediatrics (AAP) (Table 1) (*44,74,75*). In 1997, the Institute of Medicine published age-specific recommendations

for total dietary intake of fluoride (Table 2). These recommendations list adequate intake to prevent dental caries and tolerable upper intake, defined as a level unlikely to pose risk for adverse effects in almost all persons.

TABLE 1. Recommended dietary fluoride supplement* schedule

	Fluoride concentration in community drinking water†		
Age	**<0.3 ppm**	**0.3–0.6 ppm**	**>0.6 ppm**
0–6 months	None	None	None
6 months–3 years	0.25 mg/day	None	None
3–6 years	0.50 mg/day	0.25 mg/day	None
6–16 years	1.0 mg/day	0.50 mg/day	None

* Sodium fluoride (2.2 mg sodium fluoride contains 1 mg fluoride ion).

† 1.0 parts per million (ppm) = 1 mg/L.

FLUORIDE SOURCES AND THEIR EFFECTS

Fluoridated community drinking water and fluoride toothpaste are the most common sources of fluoride in the United States and are largely responsible for the low risk for dental caries for most persons in this country. Persons at high risk for dental caries might require more frequent or more concentrated exposure to fluoride and might benefit from use of other fluoride modalities (e.g., mouthrinse, dietary supplements, and topical gel, foam, or varnish). The effects of each of these fluoride sources on dental caries and enamel fluorosis are described.

Fluoridated Drinking Water and Processed Beverages and Food

Fluoridated drinking water contains a fluoride concentration effective for preventing dental caries; this concentration can occur naturally or be reached through water fluoridation, which is the controlled addition of fluoride to a public water supply. When fluoridated water is the main source of drinking water, a low concentration of fluoride is routinely introduced into the mouth. Some of this fluoride is taken up by dental plaque; some is transiently present in saliva, which serves as a reservoir for plaque fluoride; and some is loosely held on the enamel surfaces (*76*). Frequent consumption of fluoridated drinking water and beverages and food processed in fluoridated areas maintains the concentration of fluoride in the mouth.

Estimates of fluoride intake among U.S. and Canadian adults have ranged from ≤1.0 mg fluoride per day in nonfluoridated areas to 1–3 mg fluoride per day in fluoridated areas (*77–80*). The average daily dietary fluoride intake for both children and adults in fluoridated areas has remained relatively constant for several years (*11*). For children who live in optimally fluoridated areas, this average is approximately 0.05 mg/kg/day (range: 0.02–0.10); for children who live in nonfluoridated areas, the average is approximately half (*11*). In a survey of four U.S. cities with different fluoride concentrations in the drinking water (range: 0.37–1.04 ppm), children aged 2 years ingested 0.41–0.61 mg fluoride per day and infants aged 6 months ingested 0.21–0.54 mg fluoride per day (*81,82*).

In the United States, water and processed beverages (e.g., soft drinks and fruit juices) can provide approximately 75% of a person's fluoride intake (*83*). Many processed beverages are prepared in locations where the drinking water is fluoridated. Foods and ingredients used in food processing vary in their fluoride content (*11*). As consumption of processed beverages by children increases, fluoride intake in communities without fluoridated water will increase whenever the water source for the processed beverage is fluoridated (*84*). In fluoridated areas, dietary fluoride intake has been stable because processed beverages have been substituted for tap water and for beverages prepared in the home using tap water (*11*).

A study of Iowa infants estimated that the mean fluoride intake from water during different periods during the first 9 months of life, either consumed directly or added to infant formula or juice, was 0.29–0.38 mg per day, although estimated intake for some infants was as high as 1.73 mg per day (*85*). As foods are added to an infant's diet, replacing some of the formula prepared with fluoridated water, the amount of fluoride the infant receives typically decreases (*86*). The Iowa study also reported that infant formula and processed baby food contained variable amounts of fluoride. Since 1979, U.S. manufacturers of infant formula have voluntarily lowered the fluoride concentration of their products, both ready-to-feed and concentrates, to <0.3 ppm fluoride (*87*).

Drinking Water

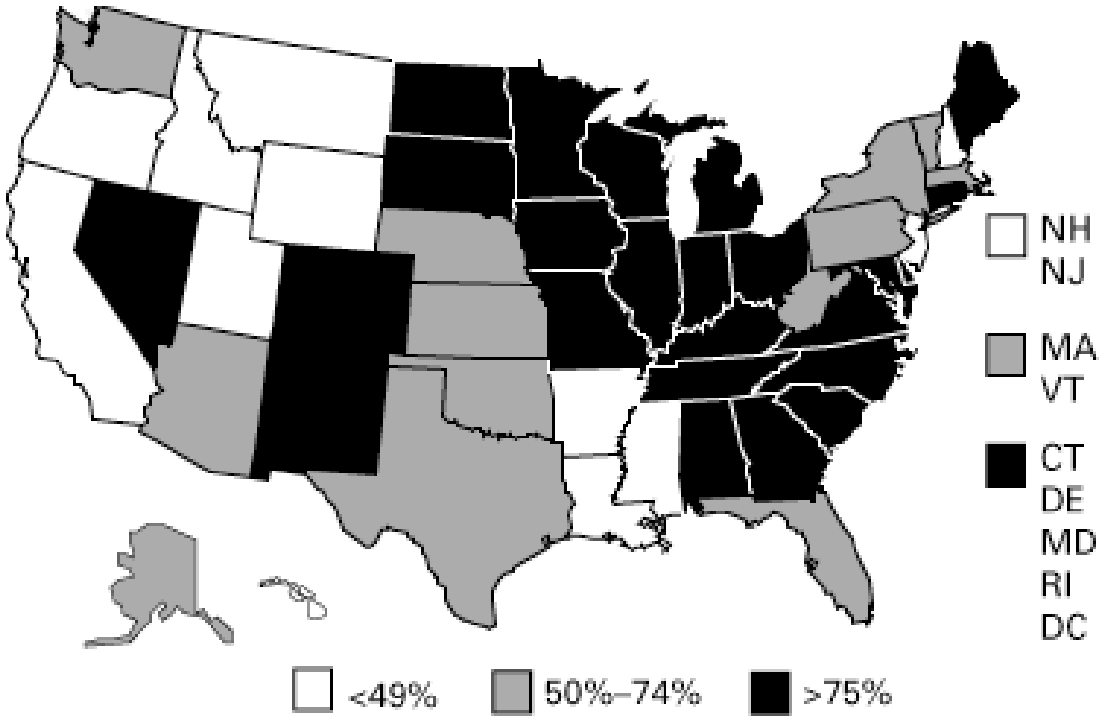
Community Water. During the 1940s, researchers determined that 1 ppm fluoride was the optimal concentration in community drinking water for climates similar to the Chicago area (*88,89*). This concentration would substantially reduce the prevalence of dental caries, while allowing an acceptably low prevalence (i.e., 10%–12%) of very mild and mild enamel fluorosis and no moderate or severe enamel fluorosis. Water fluoridation for caries control began in 1945 and 1946, when the fluoride concentration was

adjusted in the drinking water supplying four communities in the United States and Canada (*2–5*). This public health approach followed a long period of epidemiologic research into the effects of naturally occurring fluoride in drinking water (*53,57,88,89*).

Current federal fluoridation guidelines, maintained by the PHS since 1962, state that community drinking water should contain 0.7–1.2 ppm fluoride, depending on the average maximum daily air temperature of the area. These temperature-related guidelines are based on epidemiologic studies conducted during the 1950s that led to the development of an algebraic formula for determining optimal fluoride concentrations (*67,90–92*). This formula determined that a lower fluoride concentration was appropriate for communities in warmer climates because persons living in warmer climates drank more tap water. However, social and environmental changes since 1962 (e.g., increased use of air conditioning and more sedentary lifestyles) have reduced the likelihood that persons in warmer regions drink more tap water than persons in cooler regions (*7*).

By 1992, fluoridated water was reaching 144 million persons in the United States (56% of the total population and 62% of those receiving municipal water supplies) (*93*). Approximately 10 million of these persons were receiving water containing naturally occurring fluoride at a concentration of ≥0.7 ppm. In 11 states and the District of Columbia, >90% of the population had such access, whereas <5% received this benefit in two states. In 2000, a total of 38 states and the District of Columbia provided access to fluoridated public water supplies to ≥50% of their population (CDC, unpublished data, 2000) (Figure 2).

FIGURE 2. Percentage of state populations with access to fluoridated water through public water systems



Source: CDC, unpublished data, 2000.

Initial studies of community water fluoridation demonstrated that reductions in childhood dental caries attributable to fluoridation were approximately 50%–60% (*94–97*). More recent estimates are lower — 18%–40% (*98,99*). This decrease in attributable benefit is likely caused by the increasing use of fluoride from other sources, with the widespread use of fluoride toothpaste probably the most important. The diffusion or "halo" effect of beverages and food processed in fluoridated areas but consumed in nonfluoridated areas also indirectly spreads some benefit of fluoridated water to nonfluoridated communities. This effect lessens the differences in caries experience among communities (*100*).

Quantifying the benefits of water fluoridation among adults is more complicated because adults are rarely surveyed, their fluoride histories are potentially more varied, and their tooth loss or restorations might be caused by dental problems other than caries (e.g., trauma or periodontal diseases). Nevertheless, adults are reported to receive caries-preventive benefits from community water fluoridation (*99,101–103*). These benefits might be particularly advantageous for adults aged >50 years, many of whom are at increased risk for dental caries. Besides coronal caries, older adults typically experience gingival recession, which results in teeth with exposed root surfaces. Unlike the crowns of teeth, these root surfaces are not covered by enamel and are more susceptible to caries. Because tooth retention among older age groups has increased in recent decades in the United States (*39*), these groups' risk for caries will increase as the country's population ages. Older adults also frequently require multiple medications for chronic conditions, and many of these medications can reduce salivary output (*104*). Drinking water containing an optimal concentration of fluoride can mitigate the risk factors for caries among older adults. Studies have reported that the prevalence of root caries among adults is inversely related to fluoride concentration in the community drinking water (*105–107*).

Water fluoridation also reduces the disparities in caries experience among poor and nonpoor children (*108–111*). Caries experience is considerably higher among persons in low SES strata than among those in high SES strata (*39,46,112*). The reasons for this discrepancy are not well understood; perhaps persons in low SES strata have less knowledge of oral diseases, have less access to dental care, are less likely to follow recommended self-care practices, or are harder to reach through traditional approaches, including public health programs and private dental care (*48*). Thus, these persons might receive more benefit from fluoridated community water than persons from high SES strata. Regardless of SES, water fluoridation is the most effective and efficient strategy to reduce dental caries (*112*).

Enamel fluorosis occurs among some persons in all communities, even in communities with a low natural concentration of fluoride. During 1930–1960, U.S. studies documented that, in areas with a natural or adjusted concentration of fluoride of approximately 1.0 ppm in the community drinking water, the permanent teeth of 7%–16% of children with lifetime residence in those areas exhibited very mild or mild forms of enamel fluorosis (*53,113,114*). Before 1945, when naturally fluoridated drinking water was virtually the only source of fluoride, the moderate and severe forms of this condition were not observed unless the natural fluoride concentration was $\geq$2 ppm (*53*). The likelihood of a child developing the mild forms of enamel fluorosis might be higher in a fluoridated area than in a nonfluoridated area, but prevalence might not change in every community (*115,116*). The most recent national study of this condition indicated that its prevalence had increased in both fluoridated and nonfluoridated areas since the 1940s, with the

relative increase higher in nonfluoridated areas. In communities with drinking water containing 0.7–1.2 ppm fluoride, the prevalence was 1.3% for the moderate form of enamel fluorosis and zero for the severe form; thus, few cases of enamel fluorosis were likely to be of cosmetic consequence (*8,61*). Because combined fluoride intake from drinking water and processed beverages and food by children in fluoridated areas has reportedly remained stable since the 1940s, the increase in fluoride intake resulting in increased enamel fluorosis almost certainly stems from use of fluoride-containing dental products by children aged <6 years (*11*).

Two studies reported that extended consumption of infant formula beyond age 10–12 months was a risk factor for enamel fluorosis, especially when formula concentrate was mixed with fluoridated water (*62,63*). These studies examined children who used pre-1979 formula (with higher fluoride concentrations). Whether fluoride intake from formula that exceeds the recommended amount during only the first 10–12 months of life contributes to the prevalence or severity of enamel fluorosis is unknown.

Fluoride concentrations in drinking water should be maintained at optimal levels, both to achieve effective caries prevention and because changes in fluoride concentration as low as 0.2 ppm can result in a measurable change in the prevalence and severity of enamel fluorosis (*52,117*). Since the late 1970s, CDC has provided guidelines and recommendations for managers of fluoridated water supply systems at state and local levels to help them establish and maintain appropriate fluoride concentrations. CDC periodically updates these guidelines; the most recent revision was published in 1995 (*68*).

School Water Systems. In some areas of the United States where fluoridating a community's drinking water was not feasible (e.g., rural areas), the alternative of fluoridating a school's public water supply system was promoted for many years. This method was used when a school had its own source of water and was not connected to a community water supply system (i.e., stand-alone systems). Because children are at school only part of each weekday, a fluoride concentration of 4.5 times the optimal concentration for a community in the same geographic area was recommended (*118*) to compensate for the more limited consumption of fluoridated water. At the peak of this practice in the early 1980s, a total of 13 states had initiated school water fluoridation in 470 schools serving 170,000 children (*39*). Since then, school water fluoridation has been phased out in several states; the current extent of this practice is not known.

Studies of the effects of school water fluoridation in the United States reported that this practice reduced caries among schoolchildren by approximately 40% (*118–122*). A more recent study indicated that this effect might no longer be as pronounced (*123*).

Several concerns regarding school water fluoridation exist. Operating and maintaining small fluoridation systems (i.e., those serving <500 persons) create practical and logistical difficulties (*68*). These difficulties have occasionally caused higher than recommended fluoride concentrations in the school drinking water, but no lasting effects among children have been observed (*124–126*). In schools that enroll preschoolers in day care programs, children aged <6 years might receive more than adequate fluoride.

Bottled Water. Many persons drink bottled water, replacing tap water partially or completely as a source of drinking water. Water is classified as "bottled water" if it meets all applicable federal and state standards, is sealed in a sanitary container, and is sold for human consumption. Although some bottled waters marketed in the United States contain an optimal concentration of fluoride (approximately 1.0 ppm), most contain <0.3 ppm fluoride (*127–129*). Thus, a person substituting bottled water with a low fluoride concen-

tration for fluoridated community water might not receive the full benefits of community water fluoridation (*130*). For water bottled in the United States, current FDA regulations require that fluoride be listed on the label only if the bottler adds fluoride during processing; the concentration of fluoride is regulated but does not have to be stated on the label (Table 3). Few bottled water brands have labels listing the fluoride concentration.

TABLE 3. U.S. Food and Drug Administration (FDA) fluoride requirements for bottled water packaged in the United States

Annual average of maximum daily air temperature (F) where the bottled water is sold at retail	Maximum fluoride concentration (mg/L) allowed in bottled water	
	No fluoride added to bottled water	Fluoride added to bottled water
≤53.7	2.4	1.7
53.8–58.3	2.2	1.5
58.4–63.8	2	1.3
63.9–70.6	1.8	1.2
70.7–79.2	1.6	1
79.3–90.5	1.4	0.8

Note: FDA regulations require that fluoride be listed on the label only if the bottler adds fluoride during processing; the bottler is not required to list the fluoride concentration, which might or might not be optimal. FDA does not allow imported bottled water with no added fluoride to contain >1.4 mg fluoride/L or imported bottled water with added fluoride to contain >0.8 mg fluoride/L.
Source: US Department of Health and Human Services, Food and Drug Administration. 21 CFR Part 165.110. Bottled water. Federal Register 1995;60:57124–30.

Determining Fluoride Concentration. Uneven geographic coverage of community water fluoridation throughout the United States, wide variations in natural fluoride concentrations found in drinking water, and almost nonexistent labeling of fluoride concentration in bottled water make knowing the concentration of fluoride in drinking water difficult for many persons. Persons in nonfluoridated areas can mistakenly believe their water contains an optimal concentration of fluoride. To obtain the fluoride concentration of community drinking water, a resident can contact the water supplier or a local public health authority, dentist, dental hygienist, physician, or other knowledgeable source. EPA requires that all community water supply systems provide each customer an annual report on the quality of water, including the fluoride concentration (*131*). Testing for private wells is available through local and state public health departments as well as some private laboratories. If the fluoride concentration is not listed on the label of bottled water, the bottler can be contacted directly to obtain this information.

Fluoride Toothpaste

Fluoride is the only nonprescription toothpaste additive proven to prevent dental caries. When introduced into the mouth, fluoride in toothpaste is taken up directly by dental plaque (*132–134*) and demineralized enamel (*135,136*). Brushing with fluoride toothpaste also increases the fluoride concentration in saliva 100- to 1,000-fold; this concentration returns to baseline levels within 1–2 hours (*137*). Some of this salivary fluoride is taken up by dental plaque. The ambient fluoride concentration in saliva and plaque can increase during regular use of fluoride toothpaste *(132,133)*.

By the 1990s, fluoride toothpaste accounted for >90% of the toothpaste market in the United States, Canada, and other developed countries (*138*). Because water fluoridation is not available in many countries, toothpaste might be the most important source of fluoride globally (*1*).

Studies of 2–3 years duration have reported that fluoride toothpaste reduces caries experience among children by a median of 15%–30% (*139–148*). This reduction is modest compared with the effect of water fluoridation, but water fluoridation studies usually measured lifetime — rather than a few years' — exposure. Regular lifetime use of fluoride toothpaste likely provides ongoing benefits that might approach those of fluoridated water. Combined use of fluoride toothpaste and fluoridated water offers protection above either used alone (*99,149,150*).

Few studies evaluating the effectiveness of fluoride toothpaste, gel, rinse, and varnish among adult populations are available. Child populations have typically been used for studies on caries prevention because of perceived increased caries susceptibility and logistical reasons. However, teeth generally remain susceptible to caries throughout life, and topically applied fluorides could be effective in preventing caries in susceptible patients of any age *(151,152)*.

Most persons report brushing their teeth at least once per day (*153,154*), but more frequent use can offer additional protection (*139,141,155–158*). Brushing twice a day is a reasonable social norm that is both effective and convenient for most persons' daily routines, and this practice has become a basic recommendation for caries prevention. Whether increasing the number of daily brushings from two to three times a day results in lower dental caries experience is unclear. Because the amount and vigor of rinsing after toothbrushing affects fluoride concentration in the mouth and reportedly affects caries experience (*157–160*), persons aged ≥6 years can retain more fluoride in the mouth by either rinsing briefly with a small amount of water or not at all.

In the United States, the standard concentration of fluoride in fluoride toothpaste is 1,000–1,100 ppm. Toothpaste containing 1,500 ppm fluoride has been reported to be slightly more efficacious in reducing dental caries in U.S. and European studies (*161–164*). Products with this fluoride concentration have been marketed in the United States, but are not available in all areas. These products might benefit persons aged ≥6 years at high risk for dental caries.

Children who begin using fluoride toothpaste at age <2 years are at higher risk for enamel fluorosis than children who begin later or who do not use fluoride toothpaste at all (*62,63,165–170*). Because studies have not used the same criteria for age of initiation, amount of toothpaste used, or frequency of toothpaste use, the specific contribution of each factor to enamel fluorosis among this age group has not been established.

Fluoride toothpaste contributes to the risk for enamel fluorosis because the swallowing reflex of children aged <6 years is not always well controlled, particularly among children aged <3 years (*171,172*). Children are also known to swallow toothpaste deliberately when they like its taste. A child-sized toothbrush covered with a full strip of toothpaste holds approximately 0.75–1.0 g of toothpaste, and each gram of fluoride toothpaste, as formulated in the United States, contains approximately 1.0 mg of fluoride. Children aged <6 years swallow a mean of 0.3 g of toothpaste per brushing (*11*) and can inadvertently swallow as much as 0.8 g (*138,173–176*). As a result, multiple brushings with fluoride toothpaste each day can result in ingestion of excess fluoride (*177*). For this reason, high-fluoride toothpaste (i.e., containing 1,500 ppm fluoride) is generally contraindicated for children aged <6 years.

Use of a pea-sized amount (approximately 0.25 g) of fluoride toothpaste ≤2 times per day by children aged <6 years is reported to sharply reduce the importance of fluoride toothpaste as a risk factor for enamel fluorosis (*65*). Since 1991, manufacturers of fluoride toothpaste marketed in the United States have, as a requirement for obtaining the ADA Seal of Acceptance, placed instructions on the package label stating that children aged <6 years should use only this amount of toothpaste. Toothpaste labeling requirements mandated by FDA in 1996 (*72*) also direct parents of children aged <2 years to seek advice from a dentist or physician before introducing their child to fluoride toothpaste.

The propensity of young children to swallow toothpaste has led to development of "child-strength" toothpaste with lower fluoride concentrations (*176*). Such a product would be a desirable alternative to currently available products for many young children. Clinical trials outside the United States have reported that toothpaste containing 250 ppm fluoride is less effective than toothpaste containing 1,000 ppm fluoride in preventing dental caries (*178,179*). However, toothpaste containing 500–550 ppm fluoride might be almost as efficacious as that containing 1,000 ppm fluoride (*180*). A British study reported that the prevalence of diffuse enamel opacities (an indicator of mild enamel fluorosis) in the upper anterior incisors was substantially lower among children who used toothpaste containing 550 ppm fluoride than among those who used toothpaste containing 1,050 ppm fluoride (*181*). Toothpaste containing 400 ppm fluoride has been available in Australia and New Zealand for approximately 20 years, but has not been tested in clinical trials, and no data are available to assess whether toothpaste at this concentration has reduced the prevalence of enamel fluorosis in those countries. A U.S. clinical trial of the efficacy of toothpaste with lower fluoride concentrations, required by FDA before approval for marketing and distribution, has not been conducted (*182*).

Fluoride Mouthrinse

Fluoride mouthrinse is a concentrated solution intended for daily or weekly use. The fluoride from mouthrinse, like that from toothpaste, is retained in dental plaque and saliva to help prevent dental caries (*183*). The most common fluoride compound used in mouthrinse is sodium fluoride. Over-the-counter solutions of 0.05% sodium fluoride (230 ppm fluoride) for daily rinsing are available for use by persons aged >6 years. Solutions of 0.20% sodium fluoride (920 ppm fluoride) are used in supervised, school-based weekly rinsing programs. Throughout the 1980s, approximately 3 million children in the United States participated in school-based fluoride mouthrinsing programs (*39*). The current extent of such programs is not known.

Studies indicating that fluoride mouthrinse reduces caries experience among schoolchildren date mostly from the 1970s and early 1980s (*184–191*). In one review, the average caries reduction in nonfluoridated communities attributable to fluoride mouthrinse was 31% (*191*). Two studies reported benefits of fluoride mouthrinse approximately 2.5 and 7 years after completion of school-based mouthrinsing programs (*192,193*), but a more recent study did not find such benefits 4 years after completion of a mouthrinsing program (*194*). The National Preventive Dentistry Demonstration Program (NPDDP), a large project conducted in 10 U.S. cities during 1976–1981 to compare the cost and effectiveness of combinations of caries-prevention procedures, reported that fluoride mouthrinse had little effect among schoolchildren, either among first-grade students with high and low caries experience (*195*) or among all second- and fifth-grade

students (*196*). NPDDP documented only a limited reduction in dental caries attributable to fluoride mouthrinse, especially when children were also exposed to fluoridated water.

Although no studies of enamel fluorosis associated with use of fluoride mouthrinse have been conducted, studies of the amount of fluoride swallowed by children aged 3–5 years using such rinses indicated that some young children might swallow substantial amounts (*191*). Use of fluoride mouthrinse by children aged ≥6 years does not place them at risk for cosmetically objectionable enamel fluorosis because they are generally past the age that fluoride ingestion might affect their teeth.

Dietary Fluoride Supplements

Dietary fluoride supplements in the form of tablets, lozenges, or liquids (including fluoride-vitamin preparations) have been used throughout the world since the 1940s. Most supplements contain sodium fluoride as the active ingredient. Tablets and lozenges are manufactured with 1.0, 0.5, or 0.25 mg fluoride. To maximize the topical effect of fluoride, tablets and lozenges are intended to be chewed or sucked for 1–2 minutes before being swallowed. For infants, supplements are available as a liquid and used with a dropper.

In 1986, an estimated 16% of U.S. children aged <2 years used fluoride supplements (*197*). All fluoride supplements must be prescribed by a dentist or physician. The prescription should be consistent with the 1994 dosage schedule developed by ADA, AAPD, and AAP (Table 1). Because fluoride supplements are intended to compensate for fluoride-deficient drinking water, the dosage schedule requires knowledge of the fluoride content of the child's primary drinking water; consideration should also be given to other sources of water (e.g., home, child care settings, school, or bottled water) and to other sources of fluoride (e.g., toothpaste or mouthrinse), which can complicate the prescribing decision.

The evidence for using fluoride supplements to mitigate dental caries is mixed. Use of fluoride supplements by pregnant women does not benefit their offspring (*198*). Several studies have reported that fluoride supplements taken by infants and children before their teeth erupt reduce the prevalence and severity of caries in teeth (*98,199–207*), but several other studies have not (*19,208–212*). Among children aged 6–16 years, fluoride supplements taken after teeth erupt reduce caries experience (*213–215*). Fluoride supplements might be beneficial among adults who have limitations with toothbrushing, but this use requires further study.

A few studies have reported no association between supplement use by children aged <6 years and enamel fluorosis (*208,216*), but most have reported a clear association (*19,62,64,165,170,199–201,209,210,212,217–222*). In one study, the risk for this condition was high when supplements were used in fluoridated areas (odds ratio = 23.74; 95% confidence interval = 3.43–164.30) (*62*), a use inconsistent with the supplement schedule. Reports of the frequency of supplement use in fluoridated areas have ranged from 7% to 35% (*223–228*). In response to the accumulated data on fluoride intake and the prevalence of enamel fluorosis, the supplement dosage schedule for children aged <6 years was markedly reduced in 1994 when ADA, AAPD, and AAP jointly established the current schedule (Table 1) (*73*). The risk for enamel fluorosis among children this age attributable to fluoride supplements could be lower, but not enough information is available yet to evaluate the effects of this change.

When prescribing any pharmaceutical agent, dentists and physicians should attempt to maximize benefit and minimize harm (*229*). For infants and children aged <6 years, both a benefit of dental caries prevention and a risk for enamel fluorosis are possible. Although the primary (i.e., "baby") teeth of children aged 1–6 years would benefit from fluoride's posteruptive action, and some preeruptive benefit for developing permanent teeth could exist, fluoride supplements also could increase the risk for enamel fluorosis at this age (*138,223*).

Professionally Applied Fluoride Compounds

In the United States, dentists and dental hygienists have been applying high-concentration fluoride compounds directly to patients' teeth for approximately 50 years. Application procedures were developed on the assumption that the fluoride would be incorporated into the crystalline structure of the dental enamel and develop a more acid-resistant enamel. To maximize this reaction, a professional tooth cleaning was considered mandatory before the application. However, subsequent research has demonstrated that high-concentration fluoride compounds (e.g., those in gel or varnish) do not directly enter the enamel's crystalline structure (*230*). The compound forms a calcium fluoride-like material on the enamel's surface that releases fluoride for remineralization when the pH in the mouth drops. Thus, professional tooth cleaning solely to prepare the teeth for application of a fluoride compound is unnecessary; toothbrushing and flossing appear equally effective in improving the efficacy of high-concentration fluoride compounds (*231*).

Fluoride Gel and Foam

Because an early study reported that fluoride uptake by dental enamel increased in an acidic environment (*232*), fluoride gel is often formulated to be highly acidic (pH of approximately 3.0). Products available in the United States include gel of acidulated phosphate fluoride (1.23% [12,300 ppm] fluoride), gel or foam of sodium fluoride (0.9% [9,040 ppm] fluoride), and self-applied (i.e., home use) gel of sodium fluoride (0.5% [5,000 ppm] fluoride) or stannous fluoride (0.15% [1,000 ppm] fluoride) (*73*).

Clinical trials conducted during 1940–1970 demonstrated that professionally applied fluorides effectively reduce caries experience in children (*233*). In more recent studies, semiannual treatments reportedly caused an average decrease of 26% in caries experience in the permanent teeth of children residing in nonfluoridated areas (*191,234–236*). The application time for the treatments was 4 minutes. In clinical practice, applying fluoride gel for 1 minute rather than 4 minutes is common, but the efficacy of this shorter application time has not been tested in human clinical trials. In addition, the optimal schedule for repeated application of fluoride gel has not been adequately studied to support definitive guidelines, and studies that have examined the efficacy of various gel application schedules in preventing and controlling dental caries have reported mixed results. On the basis of the available evidence, the usual recommended frequency is semiannual (*151,237,238*).

Because these applications are relatively infrequent, generally at 3- to 12-month intervals, fluoride gel poses little risk for enamel fluorosis, even among patients aged <6 years. Proper application technique reduces the possibility that a patient will swallow the gel during application.

Fluoride Varnish

High-concentration fluoride varnish is painted directly onto the teeth. Fluoride varnish is not intended to adhere permanently; this method holds a high concentration of fluoride in a small amount of material in close contact with the teeth for many hours. Fluoride varnish has practical advantages (e.g., ease of application, a nonoffensive taste, and use of smaller amounts of fluoride than required for gel applications). Such varnishes are available as sodium fluoride (2.26% [2,600 ppm] fluoride) or difluorsilane (0.1% [1,000 ppm] fluoride) preparations.

Fluoride varnish has been widely used in Canada and Europe since the 1970s to prevent dental caries (*152,239*). FDA's Center for Devices and Radiological Health has cleared fluoride varnish as a medical device to be used as a cavity liner (i.e., to provide fluoride at the junction of filling material and tooth) and root desensitizer (i.e., to reduce sensitivity to temperature and touch that sometimes occurs on root surfaces exposed by receding gingiva) (*240*); FDA has not yet approved this product as an anticaries agent. Caries prevention is regarded as a drug claim, and companies would be required to submit appropriate clinical trial evidence for review before this product could be marketed as an anticaries agent. However, a prescribing practitioner can use fluoride varnish for caries prevention as an "off-label" use, based on professional judgement (*241*).

Studies conducted in Canada (*242*) and Europe (*243–246*) have reported that fluoride varnish is efficacious in preventing dental caries in children. Applied semiannually, this modality is as effective as professionally applied fluoride gel (*247*). Some researchers advocate application of fluoride varnish as many as four times per year to achieve maximum effect, but the evidence of benefits from more than two applications per year remains inconclusive (*240,246,248*). Other studies have reported that three applications in 1 week, once per year, might be more effective than the more conventional semiannual regimen (*249,250*).

European studies have reported that fluoride varnish prevents decalcification (i.e., an early stage of dental caries) beneath orthodontic bands (*251*) and slows the progression of existing enamel lesions (*252*). Studies examining the effectiveness of varnish in controlling early childhood caries are being conducted in the United States. Research on fluoride varnish (e.g., optimal fluoride concentration, the most effective application protocols, and its efficacy relative to other fluoride modalities) is likely to continue in both Europe and North America.

No published evidence indicates that professionally applied fluoride varnish is a risk factor for enamel fluorosis, even among children aged <6 years. Proper application technique reduces the possibility that a patient will swallow varnish during its application and limits the total amount of fluoride swallowed as the varnish wears off the teeth over several hours.

Fluoride Paste

Fluoride-containing paste is routinely used during dental prophylaxis (i.e., cleaning). The abrasive paste, which contains 4,000–20,000 ppm fluoride, might restore the concentration of fluoride in the surface layer of enamel removed by polishing, but it is not an adequate substitute for fluoride gel or varnish in treating persons at high risk for dental caries (*151*). Fluoride paste is not accepted by FDA or ADA as an efficacious way to prevent dental caries.

Combinations of Fluoride Modalities

Studies comparing various combinations of fluoride modalities have generally reported that their effectiveness in preventing dental caries is partially additive. That is, the percent reduction in the prevalence or severity of dental caries from a combination of modalities is higher than the percent reduction from each modality, but less than the sum of the percent reduction of the modalities combined. Attempts to use a formula to apply sequentially the percent reduction of an additional modality to the estimated remaining caries increment have overestimated the effect (*151,253*). For example, if the first modality reduces caries by 40% and the second modality reduces caries by 30%, then the calculation that caries will be reduced by a total of 58% (i.e., 40% plus 18% [30% of the 60% decay remaining after the first modality]) will likely be an overestimate.

QUALITY OF EVIDENCE FOR DENTAL CARIES PREVENTION AND CONTROL

Members of the work group convened by CDC identified the published research in their areas of expertise and evaluated the quality of scientific evidence for each fluoride modality in preventing and controlling dental caries. Evidence was drawn from the most relevant English-language, peer-reviewed scientific publications regarding the current effectiveness of fluoride modalities. Additional references were suggested by reviewers. Members used their own methods for critically analyzing articles. A formal protocol for duplicate review was not followed, but members collectively agreed on the grade reflecting the quality of evidence regarding each fluoride modality. Criteria used to grade the quality of scientific evidence (i.e., ordinal grading) was adapted from the U.S. Preventive Services Task Force (Box 1) (*254*). Grades range from I to III.

BOX 1. Grading system used for determining the quality of evidence for a fluoride modality

Grade	Criteria
I	Evidence obtained from one or more properly conducted randomized clinical trials (i.e., one using concurrent controls, double-blind design, placebos, valid and reliable measurements, and well-controlled study protocols).
II-1	Evidence obtained from one or more controlled clinical trials without randomization (i.e., one using systematic subject selection, some type of concurrent controls, valid and reliable measurements, and well-controlled study protocols).
II-2	Evidence obtained from one or more well-designed cohort or case-control analytic studies, preferably from more than one center or research group.
II-3	Evidence obtained from cross-sectional comparisons between times and places; studies with historical controls; or dramatic results in uncontrolled experiments (e.g., the results of the introduction of penicillin treatment in the 1940s).
III	Opinions of respected authorities on the basis of clinical experience, descriptive studies or case reports, or reports of expert committees.

Community Water Fluoridation

Studies on the effectiveness of adjusting fluoride in community water to the optimal concentration cannot be designed as randomized clinical trials. Random allocation of study subjects is not possible when a community begins to fluoridate the water because all residents in a community have access to and are exposed to this source of fluoride. In addition, clinical studies cannot be conducted double-blind because both study subjects and researchers usually know whether a community's water has been fluoridated. Efforts to blind the examiners by moving study subjects to a neutral third site for clinical examinations, using radiographs of teeth without revealing where the subjects live, or including transient residents as study subjects have not fully resolved these inherent limitations. Early studies that led to the unexpected discovery that dental caries was less prevalent and severe among persons with mottled enamel (subsequently identified as a form of enamel fluorosis) were conducted before the caries-preventive effects of fluoride were known (*255*). In those studies, researchers did not have an a priori reason to suspect they would find either reduced or higher levels of dental caries experience in communities with low levels of mottled enamel. Researchers also had no reason to believe that patients selected where they lived according to their risk for dental caries. In that regard, these studies were randomized, and examiners were blinded.

Despite the strengths of early studies of the efficacy of naturally occurring fluoride in community drinking water, the limitations of these studies make summarizing the quality of evidence on community water fluoridation as Grade I inappropriate (Table 1). The quality of evidence from studies on the effectiveness of adjusting fluoride concentration in community water to optimal levels is Grade II-1. Research limitations are counterbalanced by broadly similar results from numerous well-conducted field studies by other investigators that included thousands of persons throughout the world (*256,257*).

School Water Fluoridation

Field trials on the effect of school water fluoridation were not blindly conducted and had no concurrent controls (*118*). Thus, the quality of evidence for this modality is Grade II-3.

Fluoride Toothpaste

Studies that have demonstrated the efficacy of fluoride toothpaste in preventing and controlling dental caries include all of the essential features of well-conducted clinical trials. These include randomized groups, double-blind designs, placebo controls, and meticulous procedural protocols. Taken together, the trials on fluoride toothpaste provide solid evidence that fluoride is efficacious in controlling caries (*144*). The quality of evidence for toothpaste is Grade I.

Fluoride Mouthrinse

Early studies of the efficacy of fluoride mouthrinse in reducing dental caries experience were randomized clinical trials (*184,185*) or studies that used historical control groups rather than concurrent control groups (*186–189*). The quality of evidence for fluoride mouthrinse is Grade I.

Dietary Fluoride Supplements

The only randomized controlled trial to assess fluoride supplements taken by pregnant women provides Grade I evidence of no benefit for their children. Many studies of the effectiveness of fluoride supplements in preventing dental caries among children aged <6 years have been flawed in design and conduct. Problems included self-selection into test and control groups, absence of concurrent controls, high attrition rates, and nonblinded examiners. Because of these flaws, the quality of evidence to support use of fluoride supplements by children aged <6 years is Grade II-3. The well-conducted randomized clinical trials on the effects of fluoride supplements on dental caries among children aged 6–16 years in programs conducted in schools provide Grade I evidence.

Fluoride Gel

The quality of evidence for using fluoride gel to prevent and control dental caries in children is Grade I. However, data were gathered when dental caries was more prevalent and severe than today. Subjects in earlier studies were probably more representative of persons who now would be characterized as being at high risk for caries.

Fluoride Varnish

The quality of evidence for the efficacy of high-concentration fluoride varnish in preventing and controlling dental caries in children is Grade I. Although the randomized controlled clinical studies that established Grade I evidence were conducted in Europe, U.S. results should be the same.

COST-EFFECTIVENESS OF FLUORIDE MODALITIES

Documented effectiveness is the most basic requirement for providing a health-care service and an important prerequisite for preventive services (e.g., caries-preventive modalities). However, effectiveness alone is not a sufficient reason to initiate a service. Other factors, including cost, must be considered (*254*). A modality is more cost-effective when deemed a less expensive way, from among competing alternatives, of meeting a stated objective (*258*). In public health planning, determination of the most cost-effective alternative for prevention is essential to using scarce resources efficiently. Dental-insurance carriers are also interested in cost-effectiveness so they can help purchasers use funds efficiently. Because half of dental expenditures are out of pocket (*259*), this topic interests patients and their dentists as well. Potential improvement to quality of life is also a consideration. The contribution of a healthy dentition to quality of life at any age has not been quantified, but is probably valued by most persons.

Although solid data on the cost-effectiveness of fluoride modalities alone and in combination are needed, this information is scarce. In 1989, the Cost Effectiveness of Caries Prevention in Dental Public Health workshop, which was attended by health economists, epidemiologists, and dental public health professionals, attempted to assess the cost-effectiveness of caries-preventive approaches available in the United States (*260*).

All other things being equal, fluoride modalities are most cost-effective for persons at high risk for dental caries. Because persons at low risk develop little dental caries, limited benefit is gained by adding caries-preventive modalities to water fluoridation and fluoride toothpaste, even those demonstrated to be effective among populations at high risk.

Members of the CDC work group reached consensus regarding the populations for which each modality would be expected to have the necessary level of cost-effectiveness to warrant its use.

Community Water Fluoridation

Health economists at the 1989 workshop on cost-effectiveness of caries prevention calculated that the average annual cost of water fluoridation in the United States was $0.51 per person (range: $0.12–$5.41) (*260*). In 1999 dollars,* this cost would be $0.72 per person (range: $0.17–$7.62). Factors reported to influence the per capita cost included

- Å size of the community (the larger the population reached, the lower the per capita cost);
- Å number of fluoride injection points in the water supply system;
- Å amount and type of system feeder and monitoring equipment used;
- Å amount and type of fluoride chemical used, its price, and its costs of transportation and storage; and
- Å expertise of personnel at the water plant.

When the effects of caries are repaired, the price of the restoration is based on the number of tooth surfaces affected. A tooth can have caries at >1 location (i.e., surface), so the number of surfaces saved is a more appropriate measure in calculating cost-effectiveness than the number of teeth with caries. The 1989 workshop participants concluded that water fluoridation is one of the few public health measures that results in true cost savings (i.e., the measure saves more money than it costs to operate); in the United States, water fluoridation cost an estimated average of $3.35 per carious surface saved ($4.71 in 1999 dollars*) (*260*). Even under the least favorable assumptions in 1989 (i.e., cities with populations <10,000, higher operating costs, and effectiveness projected at the low end of the range), the cost of a carious surface saved because of community water fluoridation ranged from $8 to $12 ($11–$17 in 1999 dollars*) (*260*), which is still lower than the fee for a one-surface restoration ($54 in 1995 or $65 in 1999 dollars†) (*261*).

A Scottish study conducted in 1980 reported that community water fluoridation resulted in a 49% saving in dental treatment costs for children aged 4–5 years and a 54% saving for children aged 11–12 years (*262*). These savings were maintained even after the secular decline in the prevalence of dental caries was recognized (*263*). The effect of community water fluoridation on the costs of dental care for adults is less clear. This topic cannot be fully explored until the generations who grew up drinking optimally fluoridated water are older.

School Water Fluoridation

Costs for school water fluoridation are similar to those of any public water supply system serving a small population (i.e., <1,000 persons). In 1988, the average annual cost of school water fluoridation was $4.52 per student per year (range: $0.81–$9.72) (*264*). In 1999 dollars,* this cost would be $6.37 per person (range: $1.14–$13.69). Use of this modality must be carefully weighed in the current environment of low caries prevalence, widespread use of fluoride toothpaste, and availability of other fluoride modalities that can be delivered in the school setting.

Fluoride Toothpaste

Fluoride toothpaste is widely available, no more expensive than nonfluoride toothpaste, and periodically improved. Use of a pea-sized amount (0.25 g) twice per day requires approximately two tubes of toothpaste per year, for an estimated annual cost of $6–$12, depending on brand, tube size, and retail source (*265*). Persons who brush and use toothpaste regularly to maintain periodontal health and prevent stained teeth and halitosis (i.e., bad breath) incur no additional cost for the caries-preventive benefit of fluoride in toothpaste. Because of its multiple benefits, most persons consider fluoride toothpaste a highly cost-effective caries-preventive modality.

Fluoride Mouthrinse

Public health programs of fluoride mouthrinsing have long been presumed to be cost-effective, especially when teachers can supervise weekly rinsing in classrooms at no direct cost to the program. In other programs, volunteers or hourly workers provide supervision. Under these circumstances, administrators of fluoride mouthrinsing programs have claimed annual program costs of approximately $1 per child ($1.41 in 1999 dollars*) (*264*). This figure likely is an underestimate because indirect costs are not included (*196,266*). Fluoride mouthrinsing is a reasonable procedure for groups and persons at high risk for dental caries, but its cost-effectiveness as a universal, population-wide strategy in the modern era of widespread fluoride exposure is questionable (*267*).

Dietary Fluoride Supplements

Dietary fluoride supplements prescribed to persons cost an estimated $37 per year. Fluoride supplements in school programs have direct costs of approximately $2.50 per child ($3.52 in 1999 dollars*) for the tablet or lozenge (*264*); program administrative costs and considerations are similar to those in school mouthrinsing programs.

Professionally Applied Fluoride Compounds

High-concentration fluoride gel and varnish are effective in preventing dental caries, but because application requires professional expertise, they are inherently more expensive than self-applied methods (e.g., drinking fluoridated water or brushing with fluoride toothpaste). For groups and persons at low risk for dental caries, professionally applied methods are unlikely to be cost-effective (*268,269*). In the NPDDP study, prophy-

*US$ 1988 converted to US$ 1999 using CPI-Urban (all items). More information is available at the U.S. Department of Labor, Bureau of Labor Statistics website at <http://stats.bls.gov/cpihome.htm>. Accessed June 25, 2001.

lactic cleaning and gel application costs were $23 per year ($66 in 1999 dollars*) for semiannual applications, which prevented 0.03–0.26 decayed surfaces per year (*196*). A Swedish study claimed that fluoride varnish was cost-effective, but few supporting data were presented (*270*). Varnish might be cost-effective in Scandinavian school dental services, in which dental professionals regularly examine and treat each student, but the cost-effectiveness of fluoride varnish in public health programs in the United States remains undocumented. Whether fluoride varnish or gel would be most efficiently used in clinical programs targeting groups at high risk for dental caries or should be reserved for individual patients at high risk is unclear.

Combinations of Fluoride Modalities

Because the caries-preventive effects of a combination of fluoride modalities are only partially additive, estimates of the cost-effectiveness when adding a modality (e.g., fluoride mouthrinse for a group already drinking fluoridated water and using fluoride toothpaste) should take into account these smaller, incremental reductions in caries. This consideration is particularly relevant for groups and persons at low risk for caries (*253*). The scarcity of research on the cost-effectiveness of combinations limits the ability to draw more detailed conclusions.

RECOMMENDATIONS

In developing the recommendations for specific fluoride modalities that address public health and clinical practice and self-care, the CDC work group considered the quality of evidence of each modality's effect on dental caries, its association with enamel fluorosis, and its cost-effectiveness. The strength of the recommendation for each fluoride modality was determined by the work group, which adapted a coding system used by the U.S. Preventive Services Task Force (Box 2). The work group considered these factors when determining the population for which each recommendation applies (Table 4). The work

BOX 2. Coding system used to classify recommendations for use of specific fluoride modalities to control dental caries

Code	Criteria
A	Good evidence to support the use of the modality.
B	Fair evidence to support the use of the modality.
C	Lack of evidence to develop a specific recommendation (i.e., the modality has not been adequately tested) or mixed evidence (i.e., some studies support the use of the modality and some oppose it).
D	Fair evidence to reject the use of the modality.
E	Good evidence to reject the use of the modality.

*US$ 1981 converted to US$ 1999 using CPI-Urban (dental services). More information is available at the U.S. Department of Labor, Bureau of Labor Statistics website at <http://stats.bls.gov/cpihome.htm>. Accessed June 25, 2001.

group recognized that some recommendations can only be addressed by health-care industries or agencies and that additional research is required to resolve some questions regarding fluoride modalities.

Before promoting a fluoride modality or combination of modalities, the dental-care or other health-care provider must consider a person's or group's risk for dental caries, current use of other fluoride sources, and potential for enamel fluorosis. Although these recommendations are based on assessments of caries risk as low or high, the health-care provider might also differentiate among patients at high risk and provide more intensive interventions as needed. Also, a risk category can change over time; the type and frequency of preventive interventions should be adjusted accordingly.

TABLE 4. Quality of evidence, strength of recommendation, and target population of recommendation for each fluoride modality to prevent and control dental caries

Modality*	Quality of evidence (grade)	Strength of recommendation (code)	Target population†
Community water fluoridation	II-1	A	All areas
School water fluoridation	II-3	C	Rural, nonfluoridated areas
Fluoride toothpaste	I	A	All persons
Fluoride mouthrinse	I	A	High risk§
Fluoride supplements			
Pregnant women	I	E	None
Children aged <6 years	II-3	C	High risk
Children aged 6–16 years	I	A	High risk
Persons aged >16 years	¶	C	High risk
Fluoride gel	I	A	High risk
Fluoride varnish	I	A	High risk

* Modalities are assumed to be used as directed in terms of dosage and age of user.

† Quality of evidence for targeting some modalities to persons at high risk is grade III (i.e., representing the opinion of respected authorities) and is based on considerations of cost-effectiveness that were not included in the studies establishing efficacy or effectiveness.

§ Populations believed to be at increased risk for dental caries are those with low socioeconomic status or low levels of parental education, those who do not seek regular dental care, and those without dental insurance or access to dental services. Individual factors that possibly increase risk include active dental caries; a history of high caries experience in older siblings or caregivers; root surfaces exposed by gingival recession; high levels of infection with cariogenic bacteria; impaired ability to maintain oral hygiene; malformed enamel or dentin; reduced salivary flow because of medications, radiation treatment, or disease; low salivary buffering capacity (i.e., decreased ability of saliva to neutralize acids); and the wearing of space maintainers, orthodontic appliances, or dental prostheses. Risk can increase if any of these factors are combined with dietary practices conducive to dental caries (i.e., frequent consumption of refined carbohydrates). Risk decreases with adequate exposure to fluoride.

¶ No published studies confirm the effectiveness of fluoride supplements in controlling dental caries among persons aged >16 years.

Public Health and Clinical Practice

Continue and Extend Fluoridation of Community Drinking Water

Community water fluoridation is a safe, effective, and inexpensive way to prevent dental caries. This modality benefits persons in all age groups and of all SES, including those difficult to reach through other public health programs and private dental care. Community water fluoridation also is the most cost-effective way to prevent tooth decay among populations living in areas with adequate community water supply systems. Continuation of community water fluoridation for these populations and its adoption in additional U.S. communities are the foundation for sound caries-prevention programs.

In contrast, the appropriateness of fluoridating stand-alone water systems that supply individual schools is limited. Widespread use of fluoride toothpaste, availability of other fluoride modalities that can be delivered in the school setting, and the current environment of low caries prevalence limit the appropriateness of fluoridating school drinking water at 4.5 times the optimal concentration for community drinking water. Decisions to initiate or continue school fluoridation programs should be based on an assessment of present caries risk in the target school(s), alternative preventive modalities that might be available, and periodic evaluation of program effectiveness.

Counsel Parents and Caregivers Regarding Use of Fluoride Toothpaste by Young Children, Especially Those Aged <2 Years

Fluoride toothpaste is a cost-effective way to reduce the prevalence of dental caries. However, for children aged <6 years, especially those aged <2 years, an increased risk for enamel fluorosis exists because of inadequately developed control of the swallowing reflex. Parents or caregivers should be counseled regarding self-care recommendations for toothpaste use for young children (i.e., limit the child's toothbrushing to $\leq$2 times a day, apply a pea-sized amount to the toothbrush, supervise toothbrushing, and encourage the child to spit out excess toothpaste).

For children aged <2 years, the dentist or other health-care provider should consider the fluoride level in the community drinking water, other sources of fluoride, and factors likely to affect susceptibility to dental caries when weighing the risk and benefits of using fluoride toothpaste.

Target Mouthrinsing to Persons at High Risk

Because fluoride mouthrinse has resulted in only limited reductions in caries experience among schoolchildren, especially as their exposure to other sources of fluoride has increased, its use should be targeted to groups and persons at high risk for caries (see Risk for Dental Caries). Children aged <6 years should not use fluoride mouthrinse without consultation with a dentist or other health-care provider because enamel fluorosis could occur if such mouthrinses are repeatedly swallowed.

Judiciously Prescribe Fluoride Supplements

Fluoride supplements can be prescribed for children at high risk for dental caries and whose primary drinking water has a low fluoride concentration. For children aged <6 years, the dentist, physician, or other health-care provider should weigh the risk for caries without fluoride supplements, the caries prevention offered by supplements, and the potential for enamel fluorosis. Consideration of the child's other sources of fluoride,

especially drinking water, is essential in determining this balance. Parents and caregivers should be informed of both the benefit of protection against dental caries and the possibility of enamel fluorosis. The prescription dosage of fluoride supplements should be consistent with the schedule established by ADA, AAPD, and AAP. Supplements can be prescribed for persons as appropriate or used in school-based programs. When practical, supplements should be prescribed as chewable tablets or lozenges to maximize the topical effects of fluoride.

Apply High-Concentration Fluoride Products to Persons at High Risk for Dental Caries

High-concentration fluoride products can play an important role in preventing and controlling dental caries among groups and persons at high risk. Dentists and other health-care providers must consider the risk status and age of the patient to determine the appropriate intensity of treatment. Routine use of professionally applied fluoride gel or foam likely provides little benefit to persons not at high risk for dental caries, especially those who drink fluoridated water and brush daily with fluoride toothpaste.

If FDA approves use of fluoride varnish to prevent and control dental caries, its indications for use will be similar to those of fluoride gel. Such varnishes have practical advantages for children aged <6 years at high risk.

Self-Care

Know the Fluoride Concentration in the Primary Source of Drinking Water

All persons should know whether the fluoride concentration in their primary source of drinking water is below optimal, optimal, or above optimal. This knowledge is the basis for all individual and professional decisions regarding use of other fluoride modalities (e.g., mouthrinse or supplements). Parents and caregivers of children, especially children aged <6 years, must know the fluoride concentration in their child's drinking water when considering whether to alter the child's fluoride intake. For example, in nonfluoridated areas where the natural fluoride concentration is below optimal, fluoride supplements might be considered, whereas in areas where the natural fluoride concentration is >2 ppm, children should use alternative sources of drinking water. Knowledge of the water's fluoride concentration is also key in public policy discussions regarding community water fluoridation.

Frequently Use Small Amounts of Fluoride

All persons should receive frequent exposure to small amounts of fluoride, which minimizes dental caries by inhibiting demineralization of tooth enamel and facilitating tooth remineralization. This exposure can be readily accomplished by drinking water with an optimal fluoride concentration and brushing with a fluoride toothpaste twice daily.

Supervise Use of Fluoride Toothpaste Among Children Aged <6 Years

Children's teeth should be cleaned daily from the time the teeth erupt in the mouth. Parents and caregivers should consult a dentist or other health-care provider before introducing a child aged <2 years to fluoride toothpaste. Parents and caregivers of children aged <6 years who use fluoride toothpaste should follow the directions on the label,

place no more than a pea-sized amount (0.25 g) of toothpaste on the toothbrush, brush the child's teeth (recommended particularly for preschool-aged children) or supervise the toothbrushing, and encourage the child to spit excess toothpaste into the sink to minimize the amount swallowed. Indiscriminate use can result in inadvertent swallowing of more fluoride than is recommended.

Consider Additional Measures for Persons at High Risk for Dental Caries

Persons at high risk for dental caries might require additional fluoride or other preventive measures to reduce development of caries. This additional fluoride can come from daily use of another fluoride product at home or from professionally applied, topical fluoride products. Other preventive measures might include dental sealants and targeted antimicrobial therapies. Parents and caregivers should not provide additional fluoride to children aged <6 years without consulting a dentist or other health-care provider regarding the associated benefits and potential for enamel fluorosis. Persons should seek professional advice regarding their risk status or that of their children.

Use an Alternative Source of Water for Children Aged ≤8 Years Whose Primary Drinking Water Contains >2 ppm Fluoride

In some regions in the United States, community water supply systems and home wells contain a natural concentration of fluoride >2 ppm. At this concentration, children aged ≤8 years are at increased risk for developing enamel fluorosis, including the moderate and severe forms, and should have an alternative source of drinking water, preferably one containing fluoride at an optimal concentration.

In areas where community water supply systems contain >2 ppm but <4 ppm fluoride, EPA requires that each household be notified annually of the desirability of using an alternative source of water for children aged ≤8 years. For families receiving water from home wells, testing is necessary to determine the natural fluoride concentration.

Consumer Product Industries and Health Agencies

Label the Fluoride Concentration of Bottled Water

Producers of bottled water should label the fluoride concentration of their products. Such labeling will allow consumers to make informed decisions and dentists, dental hygienists, and other health-care professionals to appropriately advise patients regarding fluoride intake and use of fluoride products.

Promote Use of Small Amounts of Fluoride Toothpaste Among Children Aged <6 Years

Labels and advertisements for fluoride toothpaste should promote use of a pea-sized amount (0.25 g) of toothpaste on a child-sized toothbrush for children aged <6 years. Efforts to educate parents and caregivers and to encourage supervised use of fluoride toothpaste among young children can reduce inadvertent swallowing of excess toothpaste.

Develop a Low-Fluoride Toothpaste for Children Aged <6 Years

Manufacturers are encouraged to develop a dentifrice for children aged <6 years that is effective in preventing dental caries but alleviates the risk for enamel fluorosis. A "child-strength" toothpaste with a fluoride concentration lower than current products could reduce the risk for cosmetic concerns associated with inadvertent swallowing of toothpaste.

Collaborate to Educate Health-Care Professionals and the Public

Professional health-care organizations, public health agencies, and suppliers of oral-care products should collaborate to educate health-care professionals and trainees and the public regarding the recommendations in this report. Broad collaborative efforts to educate health-care professionals and the public and to encourage behavior change can promote improved, coordinated use of fluoride modalities.

Further Research

Continue Metabolic Studies of Fluoride

Metabolic studies with animals and humans to determine the influence of environmental, physiological, and pathological conditions on the pharmacokinetics and effects of fluoride should continue. Research in these areas will enhance the knowledge base concerning fluoride use, thereby resulting in more effective and efficient use of fluoride.

Identify Biomarkers of Fluoride

As an alternative to direct fluoride intake measurement, biomarkers (i.e., distinct biological indicators) should be identified to estimate a person's fluoride intake and the amount of fluoride in the body. Identification of such biomarkers could allow more efficient research.

Reevaluate the Method of Determining Optimal Fluoride Concentration of Community Drinking Water

The current method of determining the optimal concentration of fluoride in community drinking water, which depends on the average maximum annual ambient air temperature, should be reevaluated because of the social and environmental changes that have occurred since it was adopted in 1962. Research into current consumption patterns of water, processed beverages, and processed foods is also needed. Such research will either validate the current method for determining optimal fluoride concentration in community drinking water or indicate improved methods.

Evaluate the Effect of Fluoride Mouthrinse, Fluoride Supplements, and Other Fluoride Modalities on Dental Caries

Additional clinical trials are needed to evaluate the current effect of fluoride mouthrinse, supplements, and other modalities on dental caries both individually and in combination. Cohorts of particular interest are groups and persons at high risk for dental caries, including older adults (i.e., those aged >50 years). Such research, as well as studies to determine the effects of new fluoride modalities and various combinations among groups and persons at high risk, could lead to more effective and efficient use of these interventions.

Study the Current Cost-Effectiveness of Fluoride Modalities

The increasing availability of multiple fluoride modalities and the lower caries prevalence in the United States indicate a need for current cost-effectiveness studies of fluoride modalities, especially logical combinations of regimens in populations with different caries risks. Such research will allow both more efficient use of resources and a better understanding of the additive effects of combined modalities.

Conduct Descriptive and Analytic Epidemiologic Studies

Descriptive and analytic epidemiologic studies should be conducted to determine the association between dental caries and fluoride exposure from several sources, as well as the current role of community water fluoridation in preventing coronal and root caries among adults. Studies should assess the effect of interruption or discontinuation of water fluoridation; the prevalence of fluorosis associated with different patterns of fluoride use and intake among various populations; and the relationship between objectively measured fluorosis and the aesthetic perceptions of persons, parents, and dentists and other health-care professionals. Studies are needed to refine methods of caries risk assessment. As appropriate, studies should use national, state, and local data. Research addressing these questions will improve understanding of the relationships between fluoride modalities and the benefits and unintended effects of their use.

Identify Effective Strategies to Promote Adoption of Recommendations for Using Fluoride

Effective strategies should be identified to promote adherence by parents, caregivers, children, adults, and health-care providers to recommendations regarding fluoride use. Such research could result in more effective behavior change, more efficient use of resources, improved caries prevention, and less enamel fluorosis.

CONCLUSION

When used appropriately, fluoride is a safe and effective agent that can be used to prevent and control dental caries. Fluoride has contributed profoundly to the improved dental health of persons in the United States and other countries. Fluoride is needed regularly throughout life to protect teeth against tooth decay. To ensure additional gains in oral health, water fluoridation should be extended to additional communities, and fluoride toothpaste should be used widely. Adoption of these and other recommendations in this report could lead to considerable savings in public and private resources without compromising fluoride's substantial benefit of improved dental health.

MMWR™
MORBIDITY AND MORTALITY
WEEKLY REPORT

August 17, 2001 / Vol. 50 / No. RR-14

Recommendations and Reports

Continuing Education Activity Sponsored by CDC

Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States

EXPIRATION — August 17, 2002

You must complete and return the response form electronically or by mail by **August 17, 2002**, to receive continuing education credit. If you answer all of the questions, you will receive an award letter for 2.0 hours Continuing Medical Education (CME) credit, 0.2 Continuing Education Units (CEUs), or 2.6 contact hours Continuing Nursing Education (CNE) credit. If you return the form electronically, you will receive educational credit immediately. If you mail the form, you will receive educational credit in approximately 30 days. No fees are charged for participating in this continuing education activity.

INSTRUCTIONS

By Internet

1. Read this *MMWR* (Vol. 50, RR-14), which contains the correct answers to the questions beginning on the next page.
2. Go to the *MMWR* Continuing Education Internet site at <http://www.cdc.gov/mmwr/cme/conted.html>.
3. Select which exam you want to take and select whether you want to register for CME, CEU, or CNE credit.
4. Fill out and submit the registration form.
5. Select exam questions. To receive continuing education credit, you must answer all of the questions. Questions with more than one correct answer will instruct you to "Indicate all that apply."
6. Submit your answers no later than **August 17, 2002**.
7. Immediately print your Certificate of Completion for your records.

By Mail or Fax

1. Read this *MMWR* (Vol. 50, RR-14), which contains the correct answers to the questions beginning on the next page.
2. Complete all registration information on the response form, including your name, mailing address, phone number, and e-mail address, if available.
3. Indicate whether you are registering for CME, CEU, or CNE credit.
4. Select your answers to the questions, and mark the corresponding letters on the response form. To receive continuing education credit, you must answer all of the questions. Questions with more than one correct answer will instruct you to "Indicate all that apply."
5. Sign and date the response form or a photocopy of the form and send no later than **August 17, 2002**, to
   Fax: 404-639-4198
   Mail: MMWR CE Credit
   Office of Scientific and Health Communications
   Epidemiology Program Office, MS C-08
   Centers for Disease Control and Prevention
   1600 Clifton Rd, N.E.
   Atlanta, GA 30333
6. Your Certificate of Completion will be mailed to you within 30 days.

ACCREDITATION

Continuing Medical Education (CME). CDC is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians. CDC designates this educational activity for a maximum of 2.0 hours in category 1 credit toward the AMA Physician's Recognition Award. Each physician should claim only those hours of credit that he/she actually spent in the educational activity.

Continuing Education Unit (CEU). CDC has been approved as an authorized provider of continuing education and training programs by the International Association for Continuing Education and Training and awards 0.2 Continuing Education Units (CEUs).

Continuing Nursing Education (CNE). This activity for 2.6 contact hours is provided by CDC, which is accredited as a provider of continuing education in nursing by the American Nurses Credentialing Center's Commission on Accreditation.

GOAL AND OBJECTIVES

This *MMWR* provides recommendations regarding the use of fluoride to prevent and control dental caries in the United States. These recommendations were prepared by CDC staff members and a work group of specialists in fluoride research or policy. This goal of this report is to increase appropriate use of fluoride modalities in preventing and controlling dental caries through improved professional understanding and practice. Upon completion of this continuing educational activity, the reader should be able to a) list the factors used in the decision to prescribe fluoride supplements; b) describe the recommendations for counseling patients on the use of fluoride products in oral self-care practices, especially for children aged <6 years; c) list the sources for determining the current level of fluoride delivered by a community water system; d) identify the factors used to assess caries risk; e) explain how fluoride prevents dental caries; f) describe the recommendations for choosing the appropriate fluoride modalities for patients; and g) list the risk factors for enamel fluorosis.

To receive continuing education credit, please answer all of the following questions.

1. Which of the following statements are true? (*Indicate all that apply.*)

A. The U.S. Environmental Protection Agency requires all community water systems to provide each customer an annual report that includes the fluoride concentration of their water.

B. Fluoridated community drinking water and toothpaste containing fluoride are the most common sources for fluoride in the United States.

C. A person at high risk for dental caries will not require more frequent exposure to fluoride than persons at low risk.

D. Water and other beverages provide <50% of a person's fluoride intake in the United States.

2. Which of the following persons are believed to be at greater risk for dental caries? (*Indicate all that apply.*)

A. Persons who do not seek dental treatment on a regular basis.

B. Persons with dental insurance.

C. Persons living in families with incomes below the poverty level.

D. Children with an older brother/sister having a history of high levels of dental decay.

3. Which of the following are risk factors for enamel fluorosis for children aged <6 years? (*Indicate all that apply.*)

A. Taking fluoride supplements in an area with fluoridated drinking water.

B. Not being allowed to deliberately swallow toothpaste.

C. Using a pea-sized amount of toothpaste no more than twice a day.

D. Ingesting too much fluoride from any source during critical periods of tooth development.

4. What is the most cost-effective measure to prevent dental caries in the United States?

A. Fluoridation of individual school water systems.

B. Use of a pea-sized amount of fluoride toothpaste twice a day.

C. Adding fluoride to the community water system.

D. Giving fluoride supplements to schoolchildren.

5. Which of the following statements regarding effective fluoride use are true? (*Indicate all that apply.*)

A. Community water fluoridation should be continued as a safe and inexpensive method to prevent dental caries.
B. Parents and caregivers should be provided information on use of fluoride toothpaste for children aged <6 years.
C. Other fluoride modalities (e.g., mouthrinse and professionally applied gels) should be targeted to patients at high risk for dental caries.
D. Fluoride supplements should be provided to children whose primary drinking water has a low fluoride concentration and who are at high risk for dental caries.

6. Enamel fluorosis is . . .

A. hypermineralization of the dentin.
B. hypomineralization of the enamel.
C. demineralization of the enamel.
D. demineralization of the dentin.

7. At what age should a fluoride supplement first be prescribed to a child at high risk for dental caries living in a community where the level of fluoride is below the optimal level?

A. Birth.
B. 3 months.
C. 6 months.
D. 9 months.

8. For which children at high risk should fluoride mouthrinses be used?

A. Those aged ≥2 years.
B. Those attending Head Start programs.
C. Those aged ≥6 years.
D. Those aged ≥2 years living in rural areas.

9. Currently, how many persons in the United States have access to fluoridated water in their communities?

A. 104 million.
B. 114 million.
C. 134 million.
D. 144 million.

10. What is the optimal concentration of fluoride in community water systems in the United States?

A. 0.7 parts per million (ppm).
B. 0.7–0.9 ppm.
C. 0.7–1.0 ppm.
D. 0.7–1.2 ppm.

11. Indicate your work setting.

A. State/local health department.
B. Other public health agency.
C. Hospital clinic/private practice.
D. Managed care organization.
E. Academic institution.
F. Other.

12. Which best describes your professional activities?

A. Family practice.
B. Pediatrics.
C. Nursing.
D. General dentistry.
E. Pediatric dentistry.
F. Dental hygiene.

13. I plan to use these recommendations as the basis for . . . (*Indicate all that apply.*)

A. health education materials.
B. insurance reimbursement policies.
C. local practice guidelines.
D. public policy
E. other.

14. Each month, approximately how many patients do you counsel regarding fluoride use?

A. None.
B. 1–5.
C. 6–15.
D. 16–24.
E. 25.

15. How much time did you spend reading this report and completing the exam?

A. 2–2.5 hours.
B. More than 2.5 hours but fewer than 3 hours.
C. 3–3.5 hours.
D. More than 3.5 hours but fewer than 4 hours.
E. More than 4 hours.

16. After reading this report, I am confident I can list the factors used in the decision to prescribe fluoride supplements.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

17. After reading this report, I am confident I can describe the recommendations for counseling patients on the use of fluoride products in oral self-care practices, especially for children aged <6 years.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

18. After reading this report, I am confident I can list the sources for determining the current level of fluoride delivered by a community water system.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

19. After reading this report, I am confident I can identify the factors used to assess caries risk.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

20. After reading this report, I am confident I can explain how fluoride prevents dental caries.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

21. After reading this report, I am confident I can describe the recommendations for choosing the appropriate fluoride modalities for patients.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

22. After reading this report, I am confident I can list the risk factors for enamel fluorosis.

A. Strongly agree.
B. Agree.
C. Neither agree or disagree.
D. Disagree.
E. Strongly disagree.

23. The objectives are relevant to the goal of this report.

A. Strongly agree.
B. Agree.
C. Neither agree nor disagree.
D. Disagree.
E. Strongly disagree.

24. The figures, tables, and boxes are useful.

A. Strongly agree.
B. Agree.
C. Neither agree nor disagree.
D. Disagree.
E. Strongly disagree.

25. Overall, the presentation of the report enhanced my ability to understand the material.

A. Strongly agree.
B. Agree.
C. Neither agree nor disagree.
D. Disagree.
E. Strongly disagree.

26. These recommendations will affect my practice.

A. Strongly agree.
B. Agree
C. Neither agree nor disagree.
D. Disagree.
E. Strongly disagree.

27. How did you learn about this continuing education activity?

A. Internet.
B. Advertisement (e.g., fact sheet, *MMWR* cover, newsletter, or journal).
C. Coworker/supervisor.
D. Conference presentation.
E. *MMWR* subscription.
F. Other.

Correct answers for questions 1–10

MMWR Response Form for Continuing Education Credit
August 17, 2001/Vol. 50/No. RR-14

Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States

To receive continuing education credit, you must
1. provide your contact information;
2. indicate your choice of CME, CEU, or CNE credit;
3. answer <u>all</u> of the test questions;
4. sign and date this form or a photocopy;
5. submit your answer form by August 17, 2002.
Failure to complete these items can result in a delay or rejection of your application for continuing education credit.

Detach or photocopy.

POLICY STATEMENT

Red Reflex Examination in Neonates, Infants, and Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

AMERICAN ACADEMY OF PEDIATRICS
Section on Ophthalmology
AMERICAN ASSOCIATION FOR PEDIATRIC OPHTHALMOLOGY AND STRABISMUS
AMERICAN ACADEMY OF OPHTHALMOLOGY
AMERICAN ASSOCIATION OF CERTIFIED ORTHOPTISTS

ABSTRACT

Red reflex testing is an essential component of the neonatal, infant, and child physical examination. This statement, which is a revision of the previous policy statement published in 2002, describes the rationale for testing, the technique used to perform this examination, and the indications for referral to an ophthalmologist experienced in the examination of children. *Pediatrics* 2008;122:1401–1404

www.pediatrics.org/cgi/doi/10.1542/peds.2008-2624

doi:10.1542/peds.2008-2624

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

red reflex testing, Bruckner reflex, vision screening

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

Red reflex testing is vital for early detection of vision- and potentially life-threatening abnormalities such as cataracts, glaucoma, retinoblastoma, retinal abnormalities, systemic diseases with ocular manifestations, and high refractive errors. The American Academy of Pediatrics currently recommends red reflex assessment as a component of the eye evaluation in the neonatal period and during all subsequent routine health supervision visits[1] (see also Bright Futures, available at www.brightfutures.org).

The red reflex test uses transmission of light from an ophthalmoscope through all the normally transparent parts of a subject's eye, including the tear film, cornea, aqueous humor, crystalline lens, and vitreous humor. This light reflects off the ocular fundus, is transmitted back through the optical media and through the aperture of the ophthalmoscope, and is imaged in the eye of the examiner. Any factor that impedes or blocks this optical pathway will result in an abnormality of the red reflex. An abnormal red reflex can result from mucus or other foreign bodies in the tear film, corneal opacities, aqueous opacities, iris abnormalities affecting the pupillary aperture (pupil), cataracts, vitreous opacities, and retinal abnormalities including tumors or chorioretinal colobomata. Unequal or high refractive errors (need for glasses) and strabismus (eye misalignment) may also produce abnormalities or asymmetry of the red reflex. There may be significant variation in the red reflex in children from different racial or ethnic groups resulting from their differing levels of pigmentation of the ocular fundus. Nevertheless, the pediatrician who performs these evaluations on a regular basis will quickly become familiar with these variations in normalcy.

PERFORMING THE RED REFLEX TEST

The red reflex test is properly performed by holding a direct ophthalmoscope close to the examiner's eye with the ophthalmoscope lens power set at "0" (see Fig 1). In a darkened room, the ophthalmoscope light should then be projected onto both eyes of the child simultaneously from approximately 18 inches away. To be considered normal, a red reflex should emanate from both eyes and be symmetric in character. Dark spots in the red reflex, a markedly diminished reflex, the presence of a white reflex, or asymmetry of the reflexes (Bruckner reflex) are all indications for referral to an ophthalmologist who is experienced in the examination of children. The exception to this rule is a transient opacity from mucus in the tear film that is mobile and completely disappears with blinking.

All infants and children with a positive family history of retinoblastoma; congenital, infantile, or juvenile cataracts; glaucoma; or retinal abnormalities should be referred to an ophthalmologist who is experienced in the examination of children for a complete eye examination regardless of the status of the red reflex, because these children are at high risk of vision- and potentially life-threatening eye abnormalities. Age of referral to an ophthalmologist depends on specific risk factors (eg, genetic condition, familial eye disease, etc), which can vary

FIGURE 1
Red reflex examination. (Used with permission of Alfred G. Smith, MD, ©1991.)

in age of presentation. However, it is still valuable for the pediatrician to perform red reflex testing on these patients to help determine if it is necessary to expedite this referral. Whenever an opacity or tumor is suspected, an expedited referral is indicated. Because of the urgent nature of diagnosis, it is prudent for the pediatrician to contact the ophthalmologist personally about the possible diagnosis and express (and document) the urgency of the appointment to the parent. It is also essential that the ophthalmologist follow-up with patients, send timely reports to primary care physicians, and make sure that the transfer of care back to the referring physician is clean and understood by all parties.

The purpose of this policy statement, which is a revision of the previous statement published in 2002,[2] is to suggest a policy based on current knowledge and experience for examination of the eyes of neonates, infants, and children to minimize the risk of delay in diagnosis of serious vision-threatening or life-threatening disorders.

Occasionally, some pediatricians find that red reflex

testing can be facilitated by dilating the eyes of the subject. Although in infants, pupils are easily dilated by using various agents, significant complications sporadically have been reported with all commercially available dilating eye drops, including sympathomimetic agents such as phenylephrine and anticholinergic agents such as cyclopentolate hydrochloride and tropicamide. These complications include elevated blood pressure and heart rate,[3] urticaria,[4] cardiac arrhythmias,[5] and contact dermatitis.[6,7] However, pupillary dilation has been performed routinely for many years in almost all new patients seen by pediatric ophthalmologists, with a very low incidence of toxicity. Hence, this procedure seems to be safe when performed in an office setting on infants older than 2 weeks. Nevertheless, to minimize liability exposure, physicians should discuss with the parents the nature and purpose of the proposed diagnostic procedure and any potential risks associated with the procedure or accompanying medications, including but not limited to pain, discomfort, bradycardia, respiratory depression, and hypertension, and document the provision of this information in the medical chart. Such informed-consent precautions are particularly important when testing preterm infants. Preterm infants seem to be particularly sensitive to the adverse effects of mydriatic eye drops; consequently, the concentration of these pharmacologic agents should be reduced.[8]

SUGGESTED EYE DROPS FOR DILATION IN INFANTS

For infants younger than 9 months:

- A combination drop of 0.25% cyclopentolate with 2.5% phenylephrine (Cyclomydril [Alcon Laboratories, Fort Worth, TX]) approximately 15 minutes before examination.
- Note that atropine drops should be avoided in young infants because of the potential for anticholinergic adverse effects.
- For infants older than 9 months:
- Tropicamide 1%, phenylephrine 2.5% ophthalmic drops; give 1 drop of either or both approximately 15 minutes before red reflex testing.
- A combination drop of 0.25% cyclopentolate with 2.5% phenylephrine (Cyclomydril) approximately 15 minutes before examination.

RECOMMENDATIONS

- All neonates, infants, and children should have an examination of the red reflex of the eyes performed by a pediatrician or other primary care clinician trained in this examination technique before discharge from the neonatal nursery and during all subsequent routine health supervision visits.
- The result of the red reflex examination is to be rated as normal when the reflections of the 2 eyes viewed both individually and simultaneously are equivalent in color, intensity, and clarity and there are no opacities or white spots (leukokoria) within the area of either or both red reflexes.
- All infants or children with an abnormal Bruckner reflex or absent red reflex should be referred immediately to an ophthalmologist who is skilled in pediatric examinations.
- It is essential that the referring practitioner communicate the abnormal findings directly to the ophthalmologist and receive confirmation back from the ophthalmologist that proper follow-up consultation was performed.
- Infants or children in high-risk categories, including relatives of patients with retinoblastoma, infantile or juvenile cataracts, retinal dysplasia, glaucoma, or other vision-threatening ocular disorders that can present in infancy, should not only have red reflex testing performed in the nursery but also be referred to an ophthalmologist who is experienced in examining children for a complete eye examination regardless of the findings of the red reflex testing by the pediatrician.
- Infants or children in whom parents or other observers describe a history suspicious for the presence of leukokoria (a white pupil reflex) in 1 or both eyes should be examined by an ophthalmologist who is experienced in the examination of children, because small retinoblastoma tumors or other serious lesions may present in a subtle fashion.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Injury and Poison Prevention

Reducing the Number of Deaths and Injuries From Residential Fires

ABSTRACT. Smoke inhalation, severe burns, and death from residential fires are devastating events, most of which are preventable. In 1998, approximately 381 500 residential structure fires resulted in 3250 nonfirefighter deaths, 17 175 injuries, and approximately $4.4 billion in property loss. This statement reviews important prevention messages and intervention strategies related to residential fires. It also includes recommendations for pediatricians regarding office anticipatory guidance, work in the community, and support of regulation and legislation that could result in a decrease in the number of fire-related injuries and deaths to children.

ABBREVIATION. NFPA, National Fire Protection Association.

For persons of all ages, fires and burns are the fourth most common cause of unintentional injury-related death—after motor vehicles, falls, and poisoning by solids and liquids—causing more than 4000 deaths annually. Approximately 1000 of these deaths occur in children younger than 15 years. Among children younger than 1 year, fire- and burn-related deaths follow nonfirearm homicide and motor vehicle crashes as a leading cause of injury-related death. In children who are between 1 and 9 years of age, deaths from fire and burns are second only to those from motor vehicle injury.[1]

In 1998, an estimated 381 500 residential structure fires resulted in 3250 nonfirefighter deaths, 17 175 injuries, and approximately $4.4 billion in property loss.[2] Residential fires accounted for 74% of all structure fires, 81% of all fire-related deaths, and 74% of injuries resulting from fires. Home fires result in more than 90% of all unintentional fire- and burn-related deaths in children younger than 15 years.[3] Most fire-related deaths in all age groups occur as a result of smoke inhalation, rather than directly from burns.[4]

The rate of deaths from home fires for preschool children is more than double, relative to population, the rate for all age groups combined. In 1997, children playing with fire, usually matches or lighters, accounted for 8% of deaths from home fires and 2 of every 5 deaths from home fires in preschool children.[5,6] Also, young children may have difficulty escaping from burning buildings, even though a smoke alarm may be sounding.

Arson is thought or suspected to be the cause of 13% of 1993–1997 residential structure fires and to account for 19% of associated property loss. Children and adolescents younger than 18 years accounted for 52% of those arrested for arson in 1993–1997; more than one third were younger than 15 years.[7] Preteens may start fires in the course of an otherwise normal phase of development, but usually older juveniles who set fires often have serious psychological problems that may relate to stress, such as child abuse or learning disabilities.[7]

Each year, more than 50 000 acute hospital admissions result from the more than 1.25 million injuries from burns.[8] Although scalds make up a higher percentage of hospital admissions than burns from fires,[9,10] the fatality rate of those hospitalized from fires (12% in the first hospitalization) far exceeds that of other hospitalized patients with burns (3%).[9]

Data from 1996 indicate that cigarettes and other lighted tobacco products were the cause of 33% of residential fires that involved fatalities. Studies have demonstrated the feasibility of manufacturing "fire-safe" cigarettes that do not burn as long when they are not being actively smoked, which makes them less likely to ignite objects and cause a fire.[11]

Examination of trends from 1971 to 1991 shows a decline of approximately 50% in the rates of both fire- and burn-related deaths and acute hospital admissions for injuries from burns, most likely because of an increase in public fire and burn safety education, more widespread use of smoke alarms and automatic residential fire sprinkler systems, stronger building and fire codes and standards, and expansion in the network of burn treatment centers. Changes in lifestyle, such as declines in smoking and alcohol abuse, as well as changes in home cooking practices, have also contributed to this reduced incidence. The decrease in the number of hospitalizations for burn-related injury may, in part, also result from a treatment shift from the inpatient to the outpatient setting.[8]

Depending on the methodology,[12–14] annual economic loss from fire-related fatal and nonfatal unintentional injury is $3.8 to $61.4 billion. The figures keep rising, even though deaths and injuries keep falling, because of our growing awareness of the extent and longevity of harmful effects from fire injury.

PREVENTION MESSAGES AND INTERVENTION STRATEGIES

Deaths and injuries from residential fires may be mitigated by a variety of intervention strategies and

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

prevention messages, some of which are listed below. Others may be found in *Injury Prevention and Control in Children and Youth*, published by the American Academy of Pediatrics.[15]

- Children require close *adult supervision*.
- Functioning *smoke alarms* should be installed and maintained. Smoke alarms should be tested monthly, and batteries should be replaced at least once a year. Alarms with a flashing light in addition to a sound alarm should be installed in households with deaf or hard-of-hearing individuals, including one inside their bedrooms.
- An *escape plan* should be in place with at least 2 exits (when available) from every room of the house and a planned meeting place outside, in front, where everyone can wait for the fire department. The escape plan should be practiced at least every 6 months. (Practice sessions should not include potentially dangerous activities, such as climbing out of windows and using ladders.) If the home has an upper level, a noncombustible fire escape ladder should be available. A special escape plan that meets specific needs should be provided for small children, the aged, and individuals with disabilities. Neighbors of nonverbal, deaf, or hard-of-hearing children should be taught the sign language sign for "fire." Family and guests who are visiting overnight should briefly review a fire exit plan, just as if they were staying at a hotel.
- Preschool-aged children (3 years and older) can begin to *learn what to do in case of a fire*. Parents should teach children that the sound of a smoke alarm means go outside immediately and meet at a designated place and do not hide from firefighters. Because smoke rises, individuals should *crawl low on their hands and knees* under the smoke and toxic gases to exit a room filled with smoke. The cleanest air is 12 to 24 inches above the floor.
- In apartment buildings *elevators should not be used during a fire* because they may stop at a burning floor. Stairs should always be used to exit the building.
- Persons whose clothes catch fire should be taught to *stop, drop, and roll* to smother the flames and use cool running water immediately to begin treatment of the burn.
- Adults should learn from manufacturers' instructions or from their local fire department how to select and use a *fire extinguisher* properly; ie, when the fire is small and self-contained, and when they have a clear escape route available.
- Automatic home fire *sprinkler systems* are affordable and practical for many homes.
- All *caregivers* should be familiar with all possible exits of a house or apartment, instructed in the event of a fire about escape routes, instructed not to smoke, given emergency telephone numbers, and instructed to leave the house immediately with the children and call the fire department from a neighbor's house or an outside telephone.

Educational messages about the prevention of fires and burns are part of the work of the National Fire Protection Association (NFPA), the US Fire Administration, the US Consumer Product Safety Commission, and other organizations. The NFPA *Risk Watch* injury prevention curriculum, designed for children in preschool through grade 8 and their families, contains comprehensive fire and burn prevention messages, as well as other important injury prevention messages.[16] The NFPA also offers the *Learn Not To Burn* program, which focuses exclusively on fire and burn prevention.

RECOMMENDATIONS

1. As part of office anticipatory guidance, parents should be counseled about fire and burn prevention including adequate supervision of children, use of smoke alarms, escape plans, safe behavior in fires, and initial treatment of burns (stop, drop, and roll/cool and call), and other fire and burn prevention messages.[15] Material from the AAP TIPP (American Academy of Pediatrics, The Injury Prevention Program), and the NFPA may assist in this effort. Special planning information should be given to families having children with special needs.
2. School-aged children or adolescents who set fires are often crying out for help. They may have experienced a loss or failure, or may be stressed, abused, confused, angry, or frustrated. Pediatricians and parents should realize that these children and adolescents need psychological help; setting fires is a symptom of an underlying problem.
3. Pediatricians can work with other community members in the following activities:
   - encouraging adolescents and adults not to smoke;
   - working with media to increase public awareness of fire- and burn-related injury and prevention;
   - working with fire departments and local schools to provide comprehensive fire and burn prevention education to students and their families, and advocating for inclusion of this information in the school health education curriculum;
   - working with fire departments and other community agencies to distribute and install smoke alarms in giveaway programs targeted to areas at high risk for fires[17–19];
   - supporting the lowering of insurance premiums for sprinkler-protected buildings;
   - establishing or maintaining an adequate fire-response system; and
   - helping to sustain the network of burn centers that treat children.
4. Pediatricians should promote and support legislation and regulation to accomplish the following:
   - decrease the use of cigarettes and other smoking materials and/or promote the manufacture and substitution of fire-safe cigarettes—those that are less likely to start fires[15];
   - support a strong flame-retardant clothing law; and

- improve and enforce fire building codes and/or laws that require working smoke alarms and sprinkler systems in all new buildings and retrofit multiple-family rental units (building codes related to well-lighted hallways, wiring, appliances, heating devices, and sprinklers may also have an impact on reducing the number of fire-related injuries and deaths).[20]

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Reducing the Risk of HIV Infection Associated With Illicit Drug Use

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric AIDS

ABSTRACT

Substance abuse, specifically the use of illicit drugs that are administered intravenously, continues to play a role in the transmission of human immunodeficiency virus type 1 (HIV-1) among adolescents and young adults (youth). Risks of HIV-1 infection may result from direct exposure to contaminated blood through sharing of injection drug equipment and from unsafe sexual practices (while under the influence of drugs and/or in exchange for drugs). Reducing the risk of HIV-1 infection that is associated with illicit drug use requires prevention education and prompt engagement in treatment. Providing patients with education, instruction on decontamination of used injection drug equipment, improved access to sterile syringes and needles, and postexposure prophylaxis may decrease their risk of acquiring HIV-1 infection. Pediatricians should assess risk behaviors as part of every health care encounter, including queries about tobacco, alcohol, and marijuana use. The risks and benefits of postexposure prophylaxis with antiretroviral drugs should be considered for youth with a single recent (within 72 hours) high-risk exposure to HIV-1 through sharing needles/syringes with an HIV-1–infected individual or having unprotected intercourse with an individual who engages in injection drug use. Such prophylaxis must be accompanied by risk-reduction counseling, appropriate referrals for treatment, and evaluation for pregnancy and associated sexually transmitted infections. There is an urgent need for more substance-abuse prevention and treatment programs, legislation that facilitates unencumbered access to sterile syringes, and expedient availability of reproductive health care services for sexually active youth, including voluntary HIV-1 counseling and testing.

BACKGROUND

Illicit drug use continues to play a major role in the transmission of human immunodeficiency virus type 1 (HIV-1) in the United States. Injection drug users, men who have sex with men and engage in injection drug use, and heterosexuals who have sexual contact with an injection drug user were responsible for 23% of reported acquired immunodeficiency syndrome (AIDS) cases among adults and adolescents in 2003.[1] Among youth 13 to 24 years of age, these transmission categories accounted for 13.4% of AIDS cases in 2003. Of the approximately 40 000 new HIV-1 infections each year in the United States, an estimated 50% occur among individuals younger than 25 years.[2–4] The most common mode of acquisition of HIV-1 infection among youth is sexual contact. Young women 13 to 24 years of age are infected most often by heterosexual exposure to partners with HIV-1 infection. Heterosexual contact was reported by 52% of females as their primary risk factor for HIV-1 infection, and 15% reported "no identified risk"

because they did not know that their partner was infected with HIV-1.[3] Male-to-male sex accounts for 33% of HIV-1 infections in males 13 to 19 years of age and 62% of HIV-1 infections in males 20 to 24 years of age.[3] These young men commonly fail to disclose their sexual behavior for fear of rejection and alienation.[4] Of significant concern to public health officials and health care professionals is that these estimates may significantly underrepresent actual infections. Many youth have not been tested, and those who are aware of their HIV-1 infection status may not seek medical care, which poses a risk of unintended transmission and disease progression. For example, the prevalence of HIV-1 infection in a cohort of approximately 3500 young men who have sex with men in 7 US cities was found to be 7.2%. Approximately three fourths of these HIV-1–infected young men (15–22 years of age) were unaware of their HIV-1 serostatus.[5]

Risk factors for injection drug use may include tobacco, alcohol, and marijuana use[6–8] and depression.[9] Several recent studies have identified an association with illicit drug and alcohol use as well as high-risk sexual activity in youth who engage in body-modification practices, including tattoos, body piercing, and branding.[10–12] Drug dependence among youth also is associated with a history of childhood sexual abuse.[13]

There is a direct risk of HIV-1 transmission associated with sharing needles that are used to inject intravenous drugs or to apply tattoos and reusing tattoo ink(s). Youth may unintentionally put themselves at risk of acquiring HIV-1 by engaging in sexual activity while under the influence of illicit drugs or alcohol. In this scenario, youth may fail to use condoms and perhaps select particularly high-risk sexual partners.[14]

REDUCING THE RISK OF HIV-1 INFECTION ASSOCIATED WITH ILLICIT DRUG USE

Preventing and Treating Illicit Drug Use/Substance Abuse

The development and implementation of reproducible, efficacious strategies to prevent the onset of substance use is critical. These primary prevention efforts should begin early and be directed at children and adolescents who have not yet established a pattern of drug dependence or injection drug use. Initiatives should be coordinated and broadly based, with the involvement of families, schools, and community agencies including correction services/detention centers. At a community level, efforts also should be made to reach out to all youth. Homeless, runaway, and incarcerated youth are subpopulations that may be at higher risk. Pediatricians can and should take a leadership role in these initiatives. In clinical care settings, pediatricians should routinely assess patients for risk of substance use[15] and attendant comorbidities.[16] The HEADSS risk-assessment instrument[17] is one of a number[18] of useful approaches to identify substance abuse and other high-risk activities in adolescents. Even in the absence of current high-risk activities, pediatricians should discuss approaches that families can use to facilitate an interactive and ongoing dialogue regarding the use of illicit drugs, alcohol, and tobacco products[19]; the relationship of illicit drug use and unsafe sexual activity; and attendant health-related risks including the risk of HIV-1 acquisition.[20,21] Discussions of substance abuse[19] fit in appropriately with routine anticipatory guidance for adolescents, including discussions of sexuality,[22] sexual orientation,[23] condom use,[24] and contraception. These topics need to be discussed with a nonjudgmental approach,[20,23] with careful attention to local laws concerning confidentiality.[18,25,26] Pediatricians should also familiarize themselves with state laws that govern the delivery of medical services to minor youth.[18] Assurance of confidentiality is important to youth who may be reticent to share information regarding high-risk behaviors, depression, or sexual-identity concerns for fear of disclosure to parents. A confidentiality policy presented in the presence of youth and their parent(s) may encourage young people to share personal information more openly.[26]

Access to treatment programs is essential for youth with substance-abuse problems. Adolescent-specific programs are effective, but ongoing intervention is needed to avoid relapse.[27] Effective treatment for such youth is hampered by the dearth of available and affordable ambulatory and inpatient programs.[27,28] Of an estimated 1.4 million youth 12 to 17 years of age who required treatment for substance abuse in 2002, only 10% received services.[29] Only 7% of substance-abuse treatment centers provide services for individuals younger than 18 years.[29] The paucity of inpatient treatment facilities for substance abuse poses secondary risks of infection, untreated mental health issues, and academic failure. Such facilities need to be more readily accessible,[28] and treatment needs to be reimbursed adequately to ensure continued availability of services.[30] There also is a need to encourage medical insurance companies to provide adequate reimbursement to pediatricians who are willing to address substance-abuse problems in their practices.

Preventing Acquisition of HIV-1 Infection Among Those With a Substance-Abuse Problem

Education

Educational initiatives to reduce health risks that are associated with substance abuse should address all known drugs including alcohol and tobacco. Community-based programs can provide information to users of injection drugs and other illicit drugs about risky sexual behaviors that are linked to transmission and acquisition of HIV-1, the relationship between the exchange of sex for drugs and HIV-1 infection, and the protection to be gained from the proper use of condoms. Efforts should

be made to encourage cessation or reduction of illicit drug use, promote entry into substance-abuse treatment programs, to discourage the sharing of injection drug paraphernalia, to educate about safe sex practices, and to support access to mental health services. When helping youth with substance-abuse problems move into treatment, a nonconfrontational, empathetic approach is needed. Motivational enhancement therapy offers one such approach to helping youth accept care for substance-abuse problems.[15] The pediatrician can be an invaluable educational resource to youth-serving community-based organizations.

Decontamination of Used Injection Drug Equipment

A significant proportion of drug-dependent individuals are unwilling or unable to stop injection drug use and do not have access to new or sterile needles and syringes. Bleach disinfection of injection equipment is an important strategy to reduce the risk of HIV-1 infection from reusing or sharing needles and syringes when no safer options are available.[31] In a recent study of injection drug users, rinsing syringes with a 1:10 bleach solution (bleach to water) resulted in no recovery of viable HIV-1.[32] The disinfection procedure requires flushing the barrel of the syringe at least 2 times with a minimum of 30 seconds' exposure to the solution, followed by 1 to 2 rinses with clean water before reuse.[32]

Access to Sterile Syringes and Needles

The public health risks associated with shared use of injection drug paraphernalia have led many national and governmental entities not only to advocate for access to sterile syringes and needles but also to remove existing state laws that invoke criminal penalties for possession of injection drug equipment.[33] In many states, these laws have been crafted to provide a potentially legal safety net for physicians and pharmacists who prescribe or dispense needles and syringes. It is currently illegal for physicians to prescribe injection equipment for injection drug users in only 2 states: Delaware and Kansas. It is illegal for pharmacists to fill prescriptions for injection equipment for injection drug users in 4 states: Delaware, Kansas, Georgia, and Hawaii.[34]

In 2000, New Hampshire, New York, and Rhode Island adopted new syringe laws that partially or completely removed the requirement for a prescription to purchase syringes as well as legal penalties for syringe possession.[35] In Rhode Island, the prescription of syringes to patients who are injection drug users is provided in concert with an agreement to document this care in the medical record, to make syringe prescription a part of the patient's ongoing medical care, to include other harm-reduction strategies in the patient's care, to assist patients in disposing of used syringes safely, and to notify the pharmacy at the time of initial prescription.[36] That program seems to be associated with reductions in injection drug use risk behavior.[36] Such programs should be considered in other states.

Initiatives with the singular objective of increasing access to sterile injection drug equipment remain controversial, because they do not directly address the causes and broader consequences of injection drug use. Despite mounting evidence to counter concerns of escalating injection drug use resulting from unencumbered access to sterile equipment, the controversy remains an impediment for some states and cities to enact legislation to provide this service. Syringe-exchange programs reduce the risk of HIV-1 acquisition from use of shared needles,[37,38] and their association with other counseling and HIV-1 risk-reduction services leads to reduction of high-risk sexual behaviors as well, further enhancing the effectiveness of such programs to limit the spread of HIV-1 among those who engage in injection drug use as well as their sexual partners.[39,40] Syringe-exchange programs do not lead to an increase in injection drug use,[41] nor do they lead to formation of social networks that might enhance transmission of HIV-1 and other diseases.[42] Although prospective, randomized, controlled trials have not been feasible and not all programs have been able to demonstrate a protective effect against the spread of HIV-1 infection, the number of studies that have demonstrated benefits from needle-exchange programs, particularly those conducted within the context of comprehensive drug treatment, is now sufficient to support efforts to make such programs more widely available.[43]

Access to sterile equipment is most likely to be successful in reducing the risk of HIV-1 transmission if it operates in the context of a comprehensive program that provides counseling, opportunities to be engaged in prevention education, and opportunities to receive health care services and if it emphasizes treatment. The provision of clean needles and syringes to injection drug users who have access to treatment but are unwilling or unable to enter treatment or remain abstinent while in treatment may reduce the acquisition or transmission of HIV-1 infection. Syringe-exchange programs are currently available in 31 states, the District of Columbia, and Puerto Rico. Referral to substance-abuse programs was provided by 95% of the syringe-exchange programs. Injection drug users who are referred to substance-abuse treatment programs by syringe-exchange programs have short-term outcomes comparable to those referred by other resources.[34]

Postexposure Prophylaxis

In situations in which an HIV-1–uninfected adolescent has a single recent exposure (within 72 hours) to HIV-1 from sharing injection drug equipment with an HIV-1–infected individual, some experts will consider providing postexposure prophylaxis (PEP).[44] The risk of HIV-1 transmission for each episode of needle or syringe exposure is estimated at 0.67%. Pediatricians should be able

to provide their patients who have an at-risk exposure through injection drug use access to a system for prompt evaluation, counseling, and possible PEP.[45] However, for adolescents who continue needle sharing and, thus, potentially expose themselves to HIV-1, PEP is not routinely recommended, and behavioral interventions to reduce repeated exposure are more appropriate. Current US Public Health Service guidelines include consideration of PEP with combination antiretroviral therapy in patients after injection drug use if the likelihood of shared needles between an HIV-1–uninfected and HIV-1–infected person is significant, the event is sporadic rather than frequent, and combination antiretroviral therapy is begun within 72 hours of exposure.[46] PEP might also be considered for sexual exposure to an HIV-1–infected individual who engages in injection drug use. Additional information regarding PEP among pediatric and adolescent patients can be obtained from a recent AAP clinical report.[47] If PEP is provided, it is critical that risk-reduction counseling related to injection drug use and referral to appropriate substance-abuse treatment be provided concomitantly. Youth with possible percutaneous HIV-1 exposure attributable to injection drug use also should be assessed for hepatitis B and hepatitis C virus infection and, if not previously fully immunized, given hepatitis B vaccine.

CONCLUSIONS AND RECOMMENDATIONS

The transmission of HIV-1 is one of many adverse consequences of illicit drug use. Initiatives to reduce the risk of HIV-1 transmission should include the following.

1. Engaging youth in care
   - Engagement of a youth in his or her own health care is critical to achieving a physician-patient relationship in which honest discussions about high-risk behavior are possible. Pediatricians should review their state laws governing health care services available to minors without parental consent. Confidentiality policies should be developed and discussed with both the youth and parent(s) present. Pediatricians should advocate for services (mobile vans, drop-in centers) that can engage hard-to-reach youth populations such as homeless and runaway youth.

2. Preventing and treating substance abuse
   - Primary prevention activities in the community and in care settings should be directed at families of preadolescents and youth and should promote healthy lifestyles. Physicians should support frank discussion between families and their children to avoid the initiation of illicit drug use, including alcohol and tobacco use. Parents also should be given information and strategies on ways to incorporate dialogue about substance use and sexual activity in their homes.
   - Pediatricians should advocate for youth-friendly substance-abuse treatment facilities that are able to accommodate all youth, including those who are uninsured, underinsured, and undocumented. Pediatricians should familiarize themselves with referral sources for substance-abuse prevention and treatment and mental health services.

3. Preventing acquisition of HIV-1 infection
   - Pediatricians should assess HIV-1–related risk behaviors as part of every health care encounter.
   - Pediatricians should advocate for seamless access to reproductive health care services for youth and be aware of the close association of illicit drug use and high-risk sexual activity.
   - Pediatricians should advocate for unencumbered access to sterile syringes and improved knowledge about decontamination of injection equipment. Physicians should be knowledgeable about their states' statutes regarding possession of syringes and needles and available mechanisms for procurement. These programs should be encouraged, expanded, and linked to drug treatment and other HIV-1 risk-reduction education. It is important that these programs be conducted within the context of continuing research to document effectiveness and clarify factors that seem linked to desired outcomes.
   - For youth with a single recent (within 72 hours) high-risk exposure to HIV-1 through either sharing needles/syringes with an HIV-1–infected individual or engaging in unprotected intercourse with an individual who engages in injection drug use, the risks and benefits of PEP with antiretroviral drugs should be considered. Such prophylaxis must be accompanied by risk-reduction counseling and referral to appropriate substance-abuse treatment.

Reimbursement for Foods for Special Dietary Use

ABSTRACT. Foods for special dietary use are recommended by physicians for chronic diseases or conditions of childhood, including inherited metabolic diseases. Although many states have created legislation requiring reimbursement for foods for special dietary use, legislation is now needed to mandate consistent coverage and reimbursement for foods for special dietary use and related support services with accepted medical benefit for children with designated medical conditions.

ABBREVIATION. AAP, American Academy of Pediatrics.

BACKGROUND

Special foods are recommended by physicians to foster normal growth and development in some children and to prevent serious disability and even death in others. Many of these special foods are technically specialized formulas for which there may be a relatively small market, which makes them more expensive than standard formula. Since publication of the American Academy of Pediatrics (AAP) policy statement in 1994,[1] many states have created legislation for mandating reimbursement for foods for children with inborn errors of metabolism. Third-party payment for foods for special dietary use is inconsistent, however, and state statutes regarding reimbursement vary widely. Some states require coverage only for inherited metabolic diseases, such as phenylketonuria, and others include a range of metabolic conditions. Legislation is now needed to mandate consistent coverage and reimbursement for all aspects of foods for special dietary use and related supplies and services for children with designated medical conditions.

There is a great need for pediatricians and the AAP to take a leadership role in this area of child health affecting infants, children, and adolescents by building on the legislative advancements that have been made as a result of the 1994 policy.[1] A model bill (Pediatric Medical Nutrition Support Act) for proposed legislation is available on the AAP Web site (http://www.aap.org/policy/m972.html).

DEFINITION OF FOODS FOR SPECIAL DIETARY USE

The US Food and Drug Administration, in the Code of Federal Regulations,[2] defines special dietary use of foods as the following:

a. Uses for supplying particular dietary needs that exist by reason of a physical, physiologic, pathologic, or other condition, including but not limited to the conditions of diseases, convalescence, pregnancy, lactation, allergic hypersensitivity to food, [and being] underweight and overweight;
b. Uses for supplying particular dietary needs which exist by reason of age, including but not limited to the ages of infancy and childhood;
c. Uses for supplementing or fortifying the ordinary or usual diet with any vitamin, mineral, or other dietary property. Any such particular use of a food is a special dietary use, regardless of whether such food also purports to be or is represented for general use.

MEDICAL CONDITIONS COVERED

Diseases covered would include all chronic diseases or conditions of childhood requiring special dietary intervention, including inherited metabolic diseases (Table 1).

Many childhood chronic diseases (eg, inflammatory bowel disease, cystic fibrosis, celiac disease, cancer, congenital heart disease, renal failure, hepatic diseases) are associated with increased nutritional requirements and metabolic demands or with decreased nutrient intakes, limitations of digestion and absorption, and/or increased nutrient losses. An optimal state of nutrition is especially important in these children, and poor nutrition is associated with increased risk of infections, inadequate growth, and poor response to treatment modalities, including surgery.[3,4] The goals of nutritional support for children with these chronic illnesses include normal growth and development, promotion of catch-up growth, and improved clinical outcome. Specialized nutritional support is often required, including enteral tube feedings or parenteral nutrition.

Special nutritional supplements and feeding approaches often are required for infants and children with devastating neurologic diseases or impairments, such as severe cerebral palsy, and progressive neurodevelopmental diseases.[5]

TABLE 1. Medical Conditions for Which Foods for Special Dietary Use May Be Reimbursed*

Conditions requiring specific dietary components
Chronic pulmonary insufficiency
Congenital or acquired chronic cardiac insufficiency
Movement disorder (neuromuscular)
Catch-up growth in children attributable to undernutrition
Rett syndrome
Inflammatory bowel disease
Conditions requiring the alteration of specific dietary components
Short bowel syndrome (long-segment Hirschsprung disease, small intestinal atresia, necrotizing enterocolitis, volvulus, gastroschisis)
Intestinal pseudo-obstruction syndromes
Nonspecific malabsorption syndromes (eg, postviral gastroenteropathy, small intestinal bacterial overgrowth)
Intestinal lymphangiectasia
Abetalipoproteinemia
Microvillus inclusion disease
Eosinophilic gastroenteropathy
Partial villus atrophy attributable to food protein sensitivity
Intestinal transplantation
Exocrine pancreatic insufficiency (eg, cystic fibrosis, Schwachman syndrome, Johanson-Blizzard syndrome, Pearson syndrome, pancreatic hypoplasia, congenital trypsinogen deficiency)
Chronic liver disease with cholestasis
Impaired bile acid synthesis
Bile duct atresia
Interrupted enterohepatic circulation (eg, ileal resection, congenital malabsorption of bile acids, blind loop syndrome)
Enterokinase deficiency
Immunodeficiency states (eg, villus atrophy associated with immunodeficiency conditions, autoimmune enteropathy, or enterocolitis associated with immune deficiency)
Chylothorax
Conditions impairing adequate oral intake
Cystic fibrosis
Acquired immunodeficiency syndrome
Transplant patients: bone marrow, liver, kidney, heart, lung, or multiple organs
Cerebral palsy
Aspiration syndrome
Oral dysfunction
Pharyngeal dysfunction
Esophageal dysfunction
Neurologic disorders
Oral feeding aversion (resulting from chronic use of enteral tube feedings or parenteral nutrition)
Pancreatitis
Treatment of childhood cancer
Chronic renal failure, hemodialysis, and peritoneal dialysis
Anatomic, congenital, or postsurgical defects precluding oral nutritional intake (eg, craniofacial defects)
Metabolic disorders
Disorders of carbohydrate metabolism
Glycogen storage disease
Glucose transport protein deficiency
Galactosemia
Hereditary fructose intolerance
Pyruvate dehydrogenase complex deficiency
Phospho*enol*pyruvate carboxykinase deficiency
Disorders of lipid metabolism
Fasting chylomicronemia
Mitochondrial fatty acid oxidation defects (eg, α-ketoadipicaciduria, methylmalonicadipicaciduria, long-chain acyl-CoA dehydrogenase deficiency, and medium-chain acyl-CoA dehydrogenase deficiency)
β-ketothiolase deficiency
Succinyl-CoA ketoacid transferase
Other organic acidemias
Disorders of vitamin metabolism
Biotinidase deficiency
Holocarboxylase synthetase deficiency
Methylmalonicacidemia
Methylcrotonyl-CoA carboxylase deficiency
Thiamine-responsive maple syrup urine disease
Pyridoxine responsive seizures
Disorders of mineral metabolism
Hypercalcemia
Williams syndrome
Disorders of amino acid or nitrogen metabolism
Phenylketonuria
Cystinosis
Homocystinuria
Glutaric acidemia (types I and II)
Disorders of branched-chain amino acid metabolism (eg, disorders of leucine metabolism, isovaleric acidemia, maple syrup urine disease, 3-hydroxy-3-methylglutaricaciduria, 3-methylcrotonylglycinemia, 3-methylglutaconicaciduria)
Tyrosinemia (types I and II)
Lysinuric protein intolerance
Urea cycle defects (eg, ornithine transcarbamylase deficiency, hyperornithine-hyperammonemia-homocitrullinuria syndrome, argininemia, argininosuccinicaciduria, carbamyl phosphate synthetase deficiency, citrullinemia)
Methylmalonicacidemia
Propionicacidemia
Gyrate atrophy of the choroid and retina
Adrenoleukodystrophy
Miscellaneous mitochondrial disorders and mitochondrial electron transport defects

* List is not intended to be all inclusive.
CoA indicates coenzyme A.

Metabolic diseases include inborn errors of amino acid metabolism, such as phenylketonuria, maternal phenylketonuria, maple syrup urine disease, homocystinuria, methylmalonicacidemia, propionicacidemia, isovalericacidemia, and other disorders of leucine metabolism; glutaricaciduria type I and tyrosinemia types I and II; and urea cycle disorders. These are all disorders treatable by dietary modifications, which can prevent complications like severe mental retardation and death.[6] Manipulations of precursors and limitation of substrates in the diet form a major portion of available therapies. In the case of phenylketonuria, a special National Institutes of Health consensus panel recently recommended uniform policies to remove individual and family financial barriers to acquiring modified low-protein foods and outlined support services required to maintain appropriate phenylalanine concentrations.[7] Children with other metabolic disorders, including those of carbohydrate metabolism, lipid metabolism, vitamin or cofactor metabolism, or mineral metabolism, may also benefit from dietary interventions.

DEFINITION OF REIMBURSABLE EXPENSES

Any health insurance policy that is delivered, issued for delivery, renewed, extended, or modified in a particular state by any health care insurer and that provides coverage for a child should optimally provide coverage of foods for special dietary use of accepted medical benefit. This is meant to cover nutritional support costs over and above usual foods. In addition to the cost of the foods, all medical equipment and medical supplies necessary for the delivery of foods for special dietary use should be covered.

This includes but is not limited to administration tubing, bags, and pumps. Costs of management by health care professionals as necessary to administer or monitor the safe administration of foods for special dietary use should also be covered.

RECOMMENDATIONS

1. All foods for special dietary use with accepted benefit for treatment of a medical condition should be reimbursed as a medical expense, provided the costs are over and above usual foods. Individual and family financial barriers to obtaining these foods should be removed.
2. All states should enact legislation that would require health insurance policy providers to reimburse all foods for special dietary use with accepted medical benefit recommended by a physician to prevent death and serious disability or to foster normal growth and development.
3. All expenses for medical equipment and medical supplies necessary for the delivery of foods for special dietary use should be reimbursed.
4. Reimbursement for foods for special dietary use should be mandatory for the following:
   a. Any medical condition for which specific dietary components or the restriction of specific dietary components is necessary to treat a physical, physiologic, or pathologic condition resulting in inadequate nutrition.
   b. An inherited metabolic disorder, including but not limited to disorders of carbohydrate metabolism, lipid metabolism, vitamin metabolism, mineral metabolism, or amino acid and nitrogen metabolism.
   c. A condition resulting in impairment of oral intake that affects normal development and growth.

Committee on Bioethics

Religious Objections to Medical Care

ABSTRACT. Parents sometimes deny their children the benefits of medical care because of religious beliefs. In some jurisdictions, exemptions to child abuse and neglect laws restrict government action to protect children or seek legal redress when the alleged abuse or neglect has occurred in the name of religion. The American Academy of Pediatrics (AAP) believes that all children deserve effective medical treatment that is likely to prevent substantial harm or suffering or death. In addition, the AAP advocates that all legal interventions apply equally whenever children are endangered or harmed, without exemptions based on parental religious beliefs. To these ends, the AAP calls for the repeal of religious exemption laws and supports additional efforts to educate the public about the medical needs of children.

ABBREVIATION. AAP, American Academy of Pediatrics.

THE PROBLEM

The American Academy of Pediatrics (AAP) recognizes that religion plays a major role in the lives of many children and adults in the United States and is aware that some in the United States believe prayer and other spiritual practices can substitute for medical treatment of ill or injured children. Through legislative activity at the federal and state levels, some religious groups have sought, and in many cases attained, government recognition in the form of approved payment for this "nonmedical therapy" and exemption from child abuse and neglect laws when children do not receive needed medical care. The AAP opposes such payments and exemptions as harmful to children and advocates that children, regardless of parental religious beliefs, deserve effective medical treatment when such treatment is likely to prevent substantial harm or suffering or death.

The US Constitution requires that government not interfere with religious practices or endorse particular religions. However, these constitutional principles do not stand alone and may, at times, conflict with the independent government interest in protecting children.[1] Government obligation arises from that interest when parental religious practices subject minor children to possible loss of life or to substantial risk of harm.[2,3] Constitutional guarantees of freedom of religion do not permit children to be harmed through religious practices, nor do they allow religion to be a valid legal defense when an individual harms or neglects a child.[4]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Acute Illness or Injury

The AAP asserts that every child should have the opportunity to grow and develop free from preventable illness or injury.[5] Children also have the right to appropriate medical evaluation when it is likely that a serious illness, injury, or other medical condition endangers their lives or threatens substantial harm or suffering. Under such circumstances, parents and other guardians have a responsibility to seek medical treatment, regardless of their religious beliefs and preferences. Unfortunately, certain groups have obtained exemptions from legal sanctions and state child abuse and neglect reporting laws based on the child's "treatment" by spiritual means, such as prayer.[6] The overall effect has been to limit the government's ability to protect children from abuse or neglect.

The AAP is concerned about religious doctrines that urge parents to avoid seeking medical help when their children are seriously ill. Each year, some parents' religious views lead them to eschew appropriate medical care for their children, resulting in substantial harm or suffering or death due to treatable conditions such as meningitis, bowel obstruction, diabetes mellitus, or pneumonia (*Boston Globe.* August 12, 1993:1; *Pittsburgh Post-Gazette.* March 16, 1991:B1).[4,7] The AAP considers failure to seek medical care in such cases to be child neglect, regardless of the motivation. The basic moral principle of justice requires that children be protected uniformly by laws and regulations at the local, state, and federal levels. Parents and others who deny a child necessary medical care on religious grounds should not be exempt from civil or criminal action that otherwise would be appropriate. State legislatures and regulatory agencies should remove religious exemption clauses from statutes and regulations to ensure that all parents understand that they should seek appropriate medical care for their children.

Preventive Care

Some religious tenets hold that members should not seek or receive medical care for any condition, including pregnancy. These beliefs can result in increased perinatal and maternal mortality.[8] Some religious groups deny children the benefits of routine preventive care. For example, some parents, acting in accord with state laws, refuse to have their children immunized because of religious beliefs. The AAP does not support the stringent application of medical neglect laws when children do not receive recommended immunizations. Although the risk to unimmunized individuals is relatively low, serious ad-

verse reactions to vaccination are rare and the AAP strongly endorses universal immunization. Recent outbreaks of vaccine-preventable infectious diseases, with consequent serious complications and deaths, have been linked to groups that refused immunization for religious reasons.[9–12]

The AAP therefore supports the use of appropriate public health measures, such as mandatory mass vaccinations in epidemic situations, when necessary to protect communities and their unimmunized members. In addition, the AAP is concerned that children unimmunized for any reason may expose young children, not yet old enough to be protected, to infections such as pertussis or invasive *Haemophilus influenzae* disease. The risk is especially high in child care facilities. In such situations, all parents of children in the facility should be informed of the hazards.

Mature Minors

The weight given to parental religious beliefs in decisions affecting their children's well-being declines with the child's increasing age and development. That is, as minors mature, their interest in and capacity for participating in health care decisions affecting themselves increases, as does their ability to make decisions regarding their parents' religious views. The law and AAP policy recognize the doctrine of the "mature minor."[13] This concept acknowledges that many children, usually beginning in adolescence, can contribute to or make medical decisions, including those about life-sustaining treatment. Thus, in selected cases, disputes may be avoided when a minor has the capacity to make an independent decision in light of religious values and recommended medical therapy.

Need for Care and Respect

The AAP wishes to underscore its recognition of the important role of religion in the personal, spiritual, and social lives of many individuals and cautions physicians and other health care professionals to avoid unnecessary polarization when conflict over religious practices arises. Pediatricians should seek to make collaborative decisions with families whenever possible and should take great care when considering seeking authority to override parental preferences. Nevertheless, physicians who believe that parental religious convictions interfere with appropriate medical care that is likely to prevent substantial harm or suffering or death should request court authorization to override parental authority or, under circumstances involving an imminent threat to a child's life, intervene over parental objections. When caring for children whose prognoses are grave even with treatment, physicians should use restraint in pursuing a court order to initiate or continue treatment when parents object to it. In such situations, physicians should work with the parents and children to ensure provision of appropriate palliative care. Threatening or seeking state intervention should be the last resort, undertaken only when treatment is likely to prevent substantial harm or suffering or death. Even under these circumstances, physicians should respect parental religious beliefs and the role of parents in rearing their children. Of course, a physician may withdraw from these cases, after securing acceptable alternative medical care, when continuing in the doctor-patient-family relationship would violate the physician's own moral precepts.

The AAP emphasizes that all children who need medical care that is likely to prevent substantial harm or suffering or death should receive that treatment. The AAP opposes religious doctrines that advocate opposition to medical attention for sick children. Adherence to such views precludes appropriate assessment and intervention to protect the children. The AAP believes that laws should not encourage or tolerate parental action that prevents implementing appropriate medical treatment, nor should laws exempt parents from criminal or civil liability in the name of religion.

RECOMMENDATIONS

The AAP calls for all those entrusted with the care of children to:

1. show sensitivity to and flexibility toward the religious beliefs and practices of families;
2. support legislation that ensures that all parents who deny their children medical care likely to prevent death or substantial harm or suffering are held legally accountable;
3. support the repeal of religious exemption laws; and
4. work with other child advocacy organizations and agencies and religious institutions to develop coordinated and concerted public and professional action to educate state officials, health care professionals, and the public about parents' legal obligations to obtain necessary medical care for their children.

The Pediatric Vesicoureteral Reflux Clinical Guidelines Panel consists of board-certified urologists and nephrologists who are experts in vesicoureteral reflux in children. This *Report on the Management of Primary Vesicoureteral Reflux in Children* was extensively reviewed by over 50 urologists throughout the country in the summer of 1996. The Panel finalized its recommendations for the American Urological Association (AUA) Practice Parameters, Guidelines and Standards Committee, chaired by Joseph W. Segura, MD, in November 1996. The AUA Board of Directors approved these practice guidelines in November 1996.

The Summary Report also underwent independent scrutiny by the Editorial Board of the *Journal of Urology*, was accepted for publication in November 1996, and appeared in its May 1997 issue. *A Guide for Parents* and *Evidence Working Papers* have also been developed; both are available from the AUA.

The AUA expresses its gratitude for the dedication and leadership demonstrated by the members of the Pediatric Vesicoureteral Reflux Clinical Guidelines Panel and by the consultants affiliated with Technical Resources International, Inc., in producing this guideline.

ISBN 0-9649702-2-8

Introduction

Vesicoureteral reflux refers to the retrograde flow of urine from the bladder into the ureter and, usually, into the collecting system of the kidney. In most individuals, reflux results from a congenital anomaly of the ureterovesical junction, whereas in others it results from high-pressure voiding secondary to posterior urethral valves, neuropathic bladder or voiding dysfunction. Between 3–5 percent of girls and 1–2 percent of boys experience a urinary tract infection before puberty (Jodal and Winberg, 1987). Approximately 40 percent of children with a urinary tract infection have reflux (Bourchier, Abbott and Maling, 1984; Drachman, Valevici and Vardy, 1984). Urinary tract infection is the most common bacterial disease during the first 3 months of life (Krober, Bass, Powell, et al., 1985) and accounts for approximately 6 percent of febrile illnesses in infants (Hoberman, Chao, Keller, et al., 1993). Reflux is a predisposing factor for pyelonephritis, which can result in renal injury or scarring, also termed reflux nephropathy. The most serious late consequence of reflux nephropathy is renal insufficiency or end-stage renal disease. Between 3.1–25 percent of children and 10–15 percent of adults with end-stage renal disease have reflux nephropathy (Arant, 1991; Avner, Chavers, Sullivan, et al., 1995; Bailey, Maling and Swainson, 1993). In addition, reflux nephropathy may result in renin-mediated hypertension and cause morbidity in pregnancy (Martinell, Jodal and Lidin-Jason, 1990).

The primary goals in the management of vesicoureteral reflux in children are to prevent pyelonephritis, renal injury and other complications of reflux. Children with reflux may be managed either medically or surgically. The rationale for medical management is prevention of urinary tract infection with daily antimicrobial prophylaxis, regular timed voiding and, in some cases, anticholinergic medication. These children also undergo periodic screening of the urine for infection and radiologic reassessment of the urinary tract for reflux and renal injury. Many children show spontaneous reflux resolution while receiving medical management. Surgical management of reflux consists of repair of the ureterovesical junction abnormality.

Although vesicoureteral reflux is common, there is disagreement regarding the optimal management, even among specialists caring for these children (Elder, Snyder, Peters, et al., 1992; International Reflux Study Committee, 1981). Because of the lack of consensus regarding management of this common condition, the American Urological Association (AUA) convened a panel of experts to develop treatment guidelines for children with vesicoureteral reflux. The panel was charged with the task of producing practice recommendations based primarily on outcomes evidence from the scientific literature. This *Report on the Management of Primary Vesicoureteral Reflux in Children* is the result of the panel's efforts. The panel members represent various geographic areas, ages, professional activities (academic medical centers, private practice, health maintenance organizations) and expertise (pediatric urology, pediatric nephrology), allowing a broad perspective on the management of reflux.

The recommendations in this report are to assist physicians specifically in the treatment of vesicoureteral reflux in children diagnosed following a urinary tract infection. The recommendations apply to children aged 10 years and younger with unilateral or bilateral reflux with or without scarring. The report therefore deals only peripherally with the diagnostic methods of identifying vesicoureteral reflux, renal scarring and management of children with reflux identified incidentally or by screening of asymptomatic siblings. In addition, the report does not pertain to reflux associated with neuropathic bladder, posterior urethral valves, bladder exstrophy or fixed anatomic abnormalities, such as ectopic ureterocele and ectopic ureter.

Because treatment recommendations are made jointly with the parents of the child, *A Guide for Parents,* based on this report, is available to assist the physician in discussing treatment options with the parents. A summary of this report has been published in the *Journal of Urology*, May 1997.

Executive Summary:

Management of primary vesicoureteral reflux in children

Methodology

In developing recommendations for the management of primary vesicoureteral reflux in children, the AUA Pediatric Vesicoureteral Reflux Guidelines Panel extensively reviewed the available literature on the treatment of pediatric reflux from January 1965 through December 1994 and extracted all relevant data to estimate as accurately as possible desirable and undesirable outcomes of the alternative treatment modalities. The panel followed an explicit approach to the development of practice policies, supplemented by expert opinion. The panel synthesized the evidence using techniques described by Eddy, Hasselblad and Schachter (1992) and Cooper and Hedges (1994). The methodology for these analyses was described by Hasselblad (in press). For a full description of the methodology, see Chapter 2.

Background

Vesicoureteral reflux refers to the retrograde flow of urine from the bladder into the upper urinary tract. Reflux is a birth defect but also may be acquired. Vesicoureteral reflux predisposes an individual to renal infection (pyelonephritis) by facilitating the transport of bacteria from the bladder to the upper urinary tract. The immunologic and inflammatory reaction caused by a pyelonephritic infection may result in renal injury or scarring. Extensive renal scarring causes reduced renal function and may result in renal insufficiency, end-stage renal disease, renin-mediated hypertension, reduced somatic growth and morbidity during pregnancy.

The primary goals of treatment in children with reflux are to prevent renal injury and symptomatic pyelonephritis. Medical therapy is based on the principle that reflux often resolves with time. The basis for surgical therapy is that, in select situations, ongoing vesicoureteral reflux has caused or has a significant potential for causing renal injury or other reflux-related complications and that elimination of the reflux condition will minimize their likelihood. Chapter 1 documents the various methods of diagnosis, treatment and surveillance and follow-up for children with primary vesicoureteral reflux.

Grading of reflux severity is important because more severe reflux is associated with higher rates of renal injury, and treatment success varies with reflux grade. The International Study Classification is the most common and is the grading system used in this report (International Reflux Study Committee, 1981).

Treatment alternatives and outcomes analysis

The panel considered 7 modalities as treatment alternatives, including:

- No treatment (intermittent antibiotic therapy for UTI);
- Bladder training (including timed voiding and other behavioral techniques);
- Antibiotic prophylaxis (continuous);
- Antibiotic prophylaxis and bladder training;
- Antibiotic prophylaxis, anticholinergics (for bladder instability), and bladder training;
- Open surgical repair; and
- Endoscopic repair.

Outcomes were identified as criteria by which effectiveness of treatment would be analyzed (see evidence matrix on page 21, Chapter 3), and the review of evidence was organized around this framework. The outcomes included intermediate outcomes (those not directly perceived by the patient or family but that are associated with or precede health outcomes), health outcomes (effects directly perceived in some way by patient or family), and harms of various forms of management. The following represents a brief summary of

the statistical analysis that was conducted and that formed the basis of the treatment recommendations.

Intermediate outcomes

Reflux resolution—medical therapy (continuous antibiotic prophylaxis)

The database included 26 reports with data pertaining to reflux resolution after medical therapy, comprising 1,987 patients (1,410 girls and 304 boys273 were not identified) and 2,902 ureters. The individual databases of Skoog, Belman and Majd (1987) and Arant (1992) and the data reported from the International Reflux Study, European Branch (Tamminen-Mobius, Brunier, Ebel, et al., 1992) were used to estimate the probability of reflux resolution with continuous antibiotic prophylaxis (see Figure 3 on page 24, Chapter 3). In general, a lower reflux grade correlated with a better chance of spontaneous resolution. Data for Grades I and II reflux showed no differences in regard to age at presentation or laterality (unilateral vs. bilateral). For Grade III, age and laterality were important prognostic factors, with increasing age at presentation and bilateral reflux decreasing the probability of resolution. Bilateral Grade IV reflux had a particularly low chance of spontaneous resolution. All of these estimates are subject to 2 restrictions: (1) estimates are only valid for up to 5 years after diagnosis; and (2) for Grade IV disease, estimates only apply to the time of diagnosis and are not age specific. No data were available for reflux resolution with intermittent antibiotic therapy.

In children with reflux and voiding dysfunction (frequency, urgency, urge incontinence, incomplete bladder emptying), available results from the series with control groups suggested that the reflux resolution rate increased with anticholinergic therapy and bladder training.

Reflux resolution—surgical therapy

In the articles reviewed by the panel, overall surgical success was reported in 959 of 1,008 patients (95.1 percent) and 7,731 of 8,061 ureters (95.9 percent). Surgical success was achieved in 108 of 109 ureters (99 percent) for Grade I, 874 of 882 (99.1 percent) for Grade II, 993 of 1,010 (98.3 percent) for Grade III, 386 of 392 (98.5 percent) for Grade IV and 155 of 192 (80.7 percent) for Grade V reflux.

For endoscopic therapy, most reports in the literature describe results of the use of polytetrafluoroethylene (Teflon™). Overall reflux was corrected in 77.1 percent of ureters after a single injection. Reflux was resolved after initial treatment in only 6 of 19 ureters (31.6 percent) with Grade V disease. Currently, no injectable substance has been approved for endoscopic antireflux surgery by the U.S. Food and Drug Administration.

Renal scarring

The panel felt that relevant data pertaining to renal scarring should be analyzed primarily from studies with a minimum of 5 years of follow-up. Four prospective trials comparing the outcomes of medical and surgical management included analysis of new renal scarring (Birmingham Reflux Study Group, 1987; Elo et al., 1983; Olbing et al., 1992; Weis et al., 1992). None of these trials showed a statistically significant difference in the rate of new renal scarring. In the European arm of the International Reflux Study, the rate of scarring was similar in patients receiving continuous antibiotic prophylaxis and those treated surgically (Olbing, Claesson, Ebel, et al., 1992). However, 80 percent of the new renal scars in the surgical group appeared by 10 months after randomization, whereas new renal scars appeared throughout the 5 years in the group managed medically (Tamminin-Mobius, Brunier, Ebel, et al., 1992). The Birmingham Reflux Study (1987) identified new scars after 5 years in only 6 percent and 5.2 percent of those treated medically and surgically, respectively, with no additional scars detected after 2 years of follow-up. In the prospective study by the Southwest Pediatric Nephrology Study Group of children younger than 5 years of age with Grades I, II or III reflux, normal kidneys at entry and with continuous antibiotic prophylaxis, 16 percent developed new scars (Arant, 1992). On the other hand, the International Reflux Study found new scars in 15.7 percent (medical) and 17.2 percent (surgical) of refluxing children in Europe and 21.5 percent (medical) and 31.4 percent (surgical) in North America (Olbing, Claesson, Ebel, et al., 1992; Weiss, Duckett and Spitzer, 1992). Few data were available to analyze the relationship between bacteriuria and new renal scarring in children with reflux.

Renal growth and function

On the basis of studies available to date, there is no evidence that renal growth is impaired in unscarred kidneys exposed to sterile reflux of any grade or that surgical correction of reflux facilitates growth of the kidney postoperatively. Surgical

correction of reflux stabilizes the glomerular filtration rate but has not been shown to lead to long-term improvement.

Health outcomes

Urinary tract infection

The panel reviewed 41 articles that described the incidence of urinary tract infection in children with vesicoureteral reflux treated with antibiotic prophylaxis or reimplantation surgery. In children with Grades III to IV reflux, the incidence of pyelonephritis was approximately 2.5 times higher in patients treated with antibiotic prophylaxis than in those treated surgically. The incidence of cystitis in patients with vesicoureteral reflux was not significantly different in patients treated medically or surgically. In children treated medically, recurrent symptomatic urinary tract infections were more common in children with voiding dysfunction than in those with normal bladder function.

Hypertension

In the reports reviewed by the panel, no statistically significant difference was found in the risk of hypertension related to treatment modality. However, these studies indicated that renal scarring increases the relative risk of hypertension to 2.92 (95 percent confidence interval 1.2–7.1), compared to the risk without renal scarring.

Uremia

It was not possible to demonstrate that even optimal treatment of reflux and urinary tract infection can prevent progressive renal failure and ultimately uremia after severe bilateral reflux nephropathy has been diagnosed.

Somatic growth

No evidence substantiated an effect of reflux treatment on somatic growth.

Morbidity during pregnancy

The panel performed a limited search of pertinent literature pertaining to reflux, renal insufficiency and adverse outcomes of pregnancy. Although the available data suggest a greater risk of morbidity from pyelonephritis in women who have persistent reflux during pregnancy, the sample size is small and only limited conclusions can be based on this evidence. The panel reviewed 5 studies that demonstrated that women with renal insufficiency exhibit an increased incidence of toxemia, preterm delivery, fetal growth retardation, fetal loss and deteriorating renal function.

Harms of medical treatment

Adverse drug reactions

Potential adverse reactions to antimicrobial prophylaxis include minor effects, such as skin rash, nausea, vomiting, abdominal pain, a bad taste in the mouth, marrow suppression as well as more serious side effects. Few studies dealing with the medical management of reflux included information on any drug reaction.

Harms of surgery

Obstruction

A total of 33 studies provided rates of obstruction after ureteral reimplantation for reflux. The likelihood of obstruction in the 33 series ranged from 0 to 9.1 percent with a combined rate of 2 percent in studies published after 1986. The reoperation rate ranged from 0.3 to 9.1 percent with an overall prevalence of 2 percent. There was no difference among various surgical techniques.

A total of 15 series provided detailed information about postoperative ureteral obstruction following endoscopic treatment of reflux. The 15 series included refluxing ureters treated using polytetrafluoroethylene or collagen as the injected substance. Seven (0.40 percent) persistent obstructions were reported.

Contralateral reflux

The development of contralateral reflux after unilateral ureteral surgery has been reported in numerous series. Of 1,566 ureters considered at risk there was an overall incidence of 142 reported new cases (9.1 percent) of contralateral reflux. The surgical method of reimplantation did not influence the likelihood of new contralateral reflux. Contralateral reflux generally resolves with time and surgical intervention is not usually recommended for at least 1 year.

Recommendations

The panel generated its practice policy recommendations on the basis of evidence-based outcomes and panel opinion, reflecting its clinical

experience in pediatric urology and pediatric nephrology. In this report, statements based on opinion are explicitly identified, and evidence-based recommendations are accompanied by appropriate references. Only a few recommendations could be derived purely from scientific evidence of a beneficial effect on health outcomes.

As a result, the recommendations were derived from a panel survey of preferred treatment options for 36 clinical categories of children with reflux. The treatment recommendations were classified as guidelines, preferred options and reasonable alternatives. Treatment options selected by 8 or 9 of the 9 panel members are classified as guidelines. Treatment options that received 5 to 7 votes are designated as preferred options, and treatment options that received 3 to 4 votes are designated as reasonable alternatives. Treatments that received no more than 2 votes are designated as having no support.

Assumptions

The recommendations listed on pages 5–7 are intended to assist physicians specifically in the treatment of vesicoureteral reflux in children diagnosed following a urinary tract infection. They apply only to children 10 years and younger with unilateral or bilateral reflux and with or without scarring. The recommendations assume that the patient has uncomplicated reflux (e.g., no voiding dysfunction, neuropathic bladder, posterior urethral valves, bladder exstrophy or fixed anatomical abnormalities).

Rationale for recommendations

Specific treatment recommendations for children with reflux with or without scarring are provided on pages 5–6. The panel's overall recommendations for all children follow. The panel's recommendations to offer continuous antibiotic prophylaxis as initial therapy are based on limited scientific evidence. Controlled studies comparing the efficacy of continuous antibiotic prophylaxis and intermittent therapy on health outcomes in children with reflux have not been performed. However, the opinion of the panel is that maintaining continuous urine sterility is beneficial in reducing the risk of renal scarring and this benefit outweighs the potential adverse effects of antibiotics.

Recommendations to proceed to surgery in children with reflux that has not resolved spontaneously are supported by limited scientific evidence: open antireflux surgery is 95–98 percent effective in correcting reflux, and in children with Grades III–IV reflux the risk of clinical pyelonephritis is 2–2.5 times higher in children treated with continuous prophylaxis than in those treated surgically. Nevertheless, randomized controlled trials of such children have shown that most children treated medically do not develop a urinary tract infection while receiving prophylaxis.

Recommendations for more aggressive treatment of girls than boys (e.g., for persistent Grades III–IV reflux in school-aged children) are based on epidemiological evidence that girls have a higher risk of urinary tract infection than boys. Recommendations for more aggressive treatment of Grade V reflux (e.g., surgical repair as initial therapy) are based on panel opinion that such cases are unlikely to resolve spontaneously over time, surgery is effective in resolving severe reflux and these benefits outweigh the potential harms of surgery. More aggressive recommendations for children who have renal scarring at diagnosis are based on panel opinion that such patients have a higher risk of progressive scarring and decreased renal-functional reserve.

An important variable in the scope of treatment is the presence of voiding dysfunction, a common occurrence among children with reflux. Such children may require more aggressive treatment with anticholinergics and bladder training in addition to antibiotic prophylaxis. Surgical repair of reflux is slightly less successful in children with voiding dysfunction and, thus, a higher threshold is necessary before surgery is recommended in such patients. Consequently, children with reflux should be assessed for voiding dysfunction as part of the initial evaluation.

Literature limitations and research priorities

Limitations of the literature

The panel attempted to rely on published evidence whenever possible. Many studies that addressed a particular issue could not be used quantitatively in the various syntheses because of inconsistent reporting of data, limited follow-up, incomplete description of treatments or poorly defined patient populations. Analyses were also complicated by the existence of at least 5 methods

(continued on page 8)

Treatment recommendations for children without scarring at diagnosis

Age at diagnosis: Infants (<1 year)

Initial treatment. Infants with Grades I–IV reflux should be treated initially with continuous antibiotic prophylaxis. In infants with Grade V reflux, continuous antibiotic prophylaxis is the preferred option for initial treatment.

Follow-up treatment. In infants who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. For patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic therapy, periodic cystography or surgery. Surgical repair is the preferred option, however, for patients with persistent unilateral Grades III–IV reflux. Patients with persistent bilateral Grades III–IV reflux or Grade V reflux should undergo surgical repair.

Age at diagnosis: Preschool children (ages 1–5 years)

Initial treatment. Preschool children with Grades I–II reflux or unilateral Grades III–IV reflux should be treated initially with continuous antibiotic prophylaxis. Continuous antibiotic prophylaxis is the preferred option in preschool children with bilateral Grades III–IV reflux. In patients with unilateral Grade V reflux, continuous antibiotic prophylaxis is the preferred option for initial treatment, although surgical repair is a reasonable alternative. In patients with bilateral Grade V reflux, surgical repair is the preferred option and continuous antibiotic prophylaxis is a reasonable alternative.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. In children with persistent Grades I–II reflux, there is no consensus regarding the role of continued antibiotic therapy, periodic cystography or surgery. Surgery is the preferred option for children with persistent Grades III–IV reflux. Patients with persistent Grade V reflux should undergo surgical repair.

Age at diagnosis: School children (ages 6–10 years)

Initial treatment. School children with Grades I–II reflux should be treated initially with continuous antibiotic prophylaxis. Continuous antibiotic prophylaxis is the preferred option for initial treatment of patients with unilateral Grades III–IV reflux. In patients with bilateral Grades III–IV reflux, surgical repair is the preferred option, although continuous antibiotic prophylaxis is a reasonable alternative. Patients with Grade V reflux should undergo surgical repair.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography or surgery. Surgery is the preferred option for persistent reflux in children with Grades III–IV reflux.

(continued on page 6)

Treatment recommendations for children with scarring at diagnosis

Age at diagnosis: Infants (<1 year)

Initial treatment. Infants with scarring at diagnosis and Grades I–IV reflux should be treated initially with continuous antibiotic prophylaxis. In infants with Grade V reflux and scarring, continuous antibiotic prophylaxis is the preferred option for initial treatment, and surgical repair is a reasonable alternative.

Follow-up treatment. In infants who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography or surgery. In boys with persistent unilateral Grades III–IV reflux, surgical repair is the preferred option. Boys with persistent bilateral Grades III–IV reflux, girls with persistent Grades III–IV reflux, and boys and girls with persistent Grade V reflux should undergo surgical repair.

Age at diagnosis: Preschool children (ages 1–5 years)

Initial treatment. Preschool children with scarring at diagnosis and either Grades I–II reflux or unilateral Grades III–IV reflux should be treated initially with continuous antibiotic prophylaxis. Antibiotic therapy is the preferred option in children with bilateral Grades III–IV reflux and scarring, and surgical repair is a reasonable alternative. Surgery is the preferred option for patients with unilateral Grade V reflux. Patients with bilateral Grade V disease and scarring should undergo surgical repair as initial treatment.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography or surgery. Girls with persistent Grades III–IV reflux and boys with persistent bilateral Grades III–IV reflux should undergo surgical repair. Surgery is the preferred option for boys with persistent unilateral Grades III–IV reflux. For patients with persistent Grade V reflux who have not undergone surgery as initial treatment, surgical repair is the preferred option.

Age at diagnosis: School children (ages 6–10 years)

Initial treatment. School children with scarring at diagnosis and Grades I–II reflux should be treated initially with continuous antibiotic prophylaxis. In children with unilateral Grades III–IV reflux and scarring, antibiotic therapy is the preferred option. Patients with bilateral Grades III–IV reflux or Grade V reflux should undergo surgical repair as initial treatment.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued. In patients who have persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography or surgery. Patients with persistent unilateral Grades III–IV reflux who have not undergone surgery as initial treatment should undergo surgical repair.

(continued on page 7)

Other recommendations for children with reflux

In children with vesicoureteral reflux, urethral dilation and internal urethrotomy are not beneficial. In addition, cystoscopic examination of the ureteral orifices does not appear to aid in predicting whether reflux will resolve. In children with symptoms of voiding dysfunction, urodynamic evaluation may be helpful, but evocative cystometry is unnecessary in children with reflux and a normal voiding pattern.

In children with reflux who are toilet trained, regular, volitional low-pressure voiding with complete bladder emptying should be encouraged. If it is suspected that the child is experiencing uninhibited bladder contractions, anticholinergic therapy may be beneficial.

The clinician should provide parents with information about the known benefits and harms of available options, including continuous antibiotic prophylaxis, surgery and intermittent antibiotic therapy. The clinician should indicate to what extent the estimates of benefits and harms are based on scientific evidence or on opinion and clinical experience. Given the general lack of direct evidence that any one treatment option is superior to another (especially when total benefits, harms, costs and inconvenience are considered), parent and patient preferences regarding treatment options should generally be honored.

In children for whom antireflux surgery is chosen, the panel does not recommend the endoscopic form of therapy because of the lack of proven long-term safety and efficacy of the materials used for injection and the lack of approval of such materials by the U.S. Food and Drug Administration.

Follow-up evaluation should be performed at least annually, at which time the patient's height and weight should be recorded and a urinalysis should be performed. If the child has renal scarring, the blood pressure should be measured. In deciding how often to obtain follow-up cystography in children managed medically, the clinician should take into consideration the likelihood of spontaneous resolution (see Figure 3 on page 24, Chapter 3), the risk of continued antibiotic prophylaxis and the risks of radiologic study. In general, cystography does not need to be performed more than once per year.

used for grading reflux, nonuniformity in characterizing reflux grade and patient population, and lack of a standard method for reporting outcomes. Only 3 prospective randomized controlled trials compared medical to surgical therapy—the Birmingham Reflux Study (1987), the International Reflux Study in Children (Olbing, Claesson, Ebel, et al., 1992; Weiss, Duckett and Spitzer, 1992), and a study from Erasmus University, Rotterdam, The Netherlands (Scholtmeijer, 1991). The literature on certain issues, such as complication rates of surgery and adverse drug reactions, was limited and in some cases so sparse that judgments were made on the basis of expert opinion.

Research priorities

The panel identified many research areas as needing further investigation. Presently, there is little information regarding health outcomes pertaining to reflux, and a significant priority should be to continue to acquire this information.

Basic research into the pathogenesis as well as the genetics of vesicoureteral reflux is needed. Further randomized controlled trials studying the role of medical and surgical therapy using dimercaptosuccinic acid scan for evaluation of renal scarring are indicated. Future studies should stratify results by patient gender, age and reflux grade, reporting reflux resolution both by rate of ureteral and patient resolution. Also worthwhile would be studies to confirm the panel's finding that resolution of Grade III reflux depends on patient age or laterality (unilateral vs. bilateral) and the finding that resolution of Grades I and II reflux does not depend on age or laterality.

The extent to which reflux increases the risk of renal scarring associated with urinary tract infection and the mechanism of this effect deserves investigation. Comparison of the efficacy of intermittent and continuous antibiotic therapy would be beneficial. The role of voiding dysfunction in the pathogenesis of reflux and its risk on reflux complications, such as renal scarring and the complications of surgery, also deserve further investigation. Matched controlled studies of anticholinergic therapy and bladder training on reflux-related outcomes in children with voiding dysfunction are necessary.

Less traumatic methods of determining whether reflux is present should be developed as well as techniques of voiding cystourethrography that result in less radiation exposure. Analysis of the costs of reflux treatment and surveillance is important, particularly comparing those associated with medical and surgical therapy. The impact of screening at-risk populations and early medical or surgical intervention on reflux-related outcomes in such patients should be analyzed.

Development of minimally invasive techniques of antireflux surgery is indicated. Newer materials that can be used for endoscopic subureteral injection and that are safe in children should be studied.

The natural history of vesicoureteral reflux in adult women with persistent reflux deserves investigation, including an analysis of the morbidity of persistent reflux, and need for and efficacy of prophylaxis in pregnant and nonpregnant women.

Chapter 1:
Pediatric vesicoureteral reflux and its management

Background

Vesicoureteral reflux (VUR or "reflux") refers to the retrograde flow of urine from the bladder into the upper urinary tract. Normally, the ureter is attached to the bladder in an oblique direction, perforating the bladder muscle (detrusor) laterally and proceeding between the bladder mucosa and detrusor muscle (the "intramural" or submucosal tunnel) before entering the bladder lumen. As the bladder fills, the ureteral lumen is flattened between the bladder mucosa and detrusor muscle, creating a flap-valve mechanism that prevents VUR. Reflux occurs when the submucosal tunnel between the mucosa and detrusor muscle is short or absent and/or there is weak detrusor backing (Figure 1, page 10). In general, the severity of reflux correlates with the degree of deformity of the ureterovesical junction. Reflux is usually a birth defect. In some cases, reflux will disappear as the child grows. Reflux was described in the writings of Galen (Polk, 1965) and da Vinci (Lines, 1982). It was not until the observations of Hutch in 1952, however, that the relationship between reflux and acute pyelonephritis was appreciated (Hutch, 1952).

VUR predisposes an individual to renal infection (pyelonephritis) by facilitating the transport of bacteria from the bladder to the upper urinary tract. The inflammatory reaction caused by a pyelonephritic infection may result in renal injury or scarring. Extensive renal scarring impairs renal function and may result in renin-mediated hypertension, renal insufficiency, end-stage renal disease (ESRD), reduced somatic growth, and morbidity during pregnancy.

VUR may be primary or secondary. Primary VUR refers to reflux resulting from an anatomic deformity of the ureterovesical junction without a causative urinary tract abnormality that may cause reflux. Secondary VUR can result from increased bladder pressure (e.g., detrusor-sphincter discoordination, neuropathic bladder, posterior urethral valves), which destabilizes the ureterovesical junction; abnormal attachment of the ureter (ectopic ureter); or associated lower urinary tract abnormalities (e.g., ectopic ureterocele, prune belly syndrome, bladder exstrophy) that affect ureteral insertion.

The prevalence of reflux in healthy children is unknown but is estimated to be 1 percent (Arant, 1991). In 1993, in the United States approximately 15,000 individuals under 15 years of age were admitted to the hospital for a total of 62,000 days for treatment of pyelonephritis, and reflux was present in approximately 40–50 percent of these patients (U.S. Department of Health and Human Services, 1993).

Approximately 44,000 children are treated (inpatient and outpatient) for urinary tract infection (UTI) associated with VUR each year in the United States (Woodwell, 1993). Woodwell (1993) observed that of the 9.8 million outpatient visits made to urologists annually, 492,000 (5 percent of urologic practice) involve the health of children under age 15. Of these children seen for a variety of urinary complaints, 369,000 were boys and 123,000 were girls under 15 years. Other data (based on the 9.8 million reported visits) suggested that voiding symptoms, urine abnormalities, painful urination, enuresis, bladder symptoms, and UTI (all symptoms not initially related to a diagnosis of VUR) account for 3 million visits to urologists and represented 25.6 percent of symptoms requiring evaluation. Assuming uniform distribution of these complaints within urologic practice, 125,952 visits ($492{,}000 \times 0.256 = 125{,}952$) to urologists caring for children would encompass the symptoms listed above. Data from Lindberg, et al. (1975) estimate that 20 percent of symptomatic individuals will have reflux; therefore, 25,190 visits a year to urologists would include encounters for care and assessment of reflux ($125{,}952 \times 0.2 = 25{,}190$). Health Care Financing Administration data indicate that VUR is diagnosed in 7,000–14,000 hospitalized patients, and that 2 to 3 times as many children are seen as outpatients for evaluation and treatment of reflux.

The typical patient with VUR is a child younger than 10 years old who develops a UTI, either clinical pyelonephritis with fever, abdominal/flank pain, malaise and/or nausea, vomiting, or cystitis

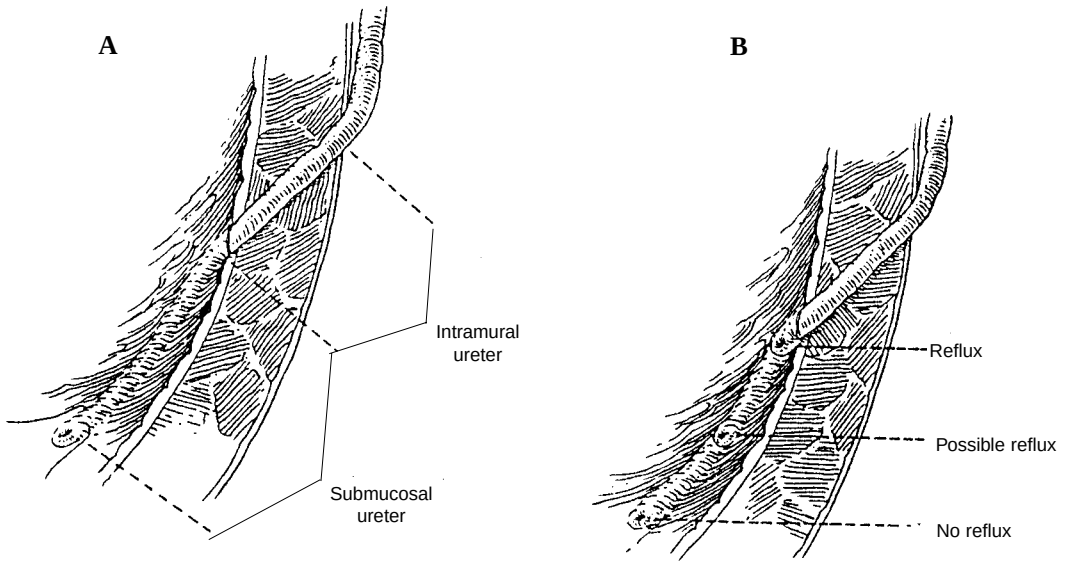

Figure 1. (A) Normal ureterovesical junction. Demonstration of length of intravesical submucosal ureteral segment. (B) Refluxing ureterovesical junction. Same anatomic features as nonrefluxing orifice, except for inadequate length of intravesical submucosal ureter, are shown. Some orifices reflux intermittently with borderline submucosal tunnels (Politano, 1975).

with dysuria, frequency, urgency, and often urge incontinence. Neonates and infants with VUR and pyelonephritis may have nonspecific symptoms.

The average age for diagnosis of reflux in children is 2–3 years. Approximately 75–80 percent of children with primary reflux diagnosed following a UTI are girls, presumably because the incidence of UTI in girls is greater than in boys after 6 months of age. The mean age for the onset of UTI in children is 2–3 years, corresponding to the average age when toilet training occurs. It is thought, by some, that during the process of toilet training, bladder-sphincter dyssynergia occurs, which predisposes to UTI, allowing children who also have VUR to be diagnosed.

A substantial proportion of children with VUR have incomplete maturation of bladder function, with symptoms of bladder instability characterized by urgency, frequency, and diurnal incontinence (van Gool, Hjalmas, Tamminen-Mobius, et al., 1992; Koff, 1992). Because the associated high intravesical pressures can contribute to reflux, assessment of voiding habits is important in evaluating children with VUR.

In recent years, reflux has been discovered prenatally by detection of fetal hydronephrosis, although the diagnosis of VUR is not made until postnatal studies are performed. Approximately 80 percent of these neonates are boys (Elder, 1992), and most have more severe reflux than do females with VUR discovered after UTI. This phenomenon may result from higher voiding pressures in male infants (and presumably fetuses) than in females (Hjalmas, 1976; Sillen, Bachelard, Hermanson, et al., 1996).

Reflux appears to be an inherited trait. For example, in 1 study of 354 siblings of 275 known patients with prior diagnosis of reflux, 34 percent had reflux, and 75 percent of these children were asymptomatic (Noe, 1992). In that study, 13 percent of siblings with reflux already had evidence of renal scarring, and 66 percent of these children had not had a documented UTI. In addition, as many as 67 percent of offspring of women with reflux also have reflux (Noe, Wyatt, Peeden, et al., 1992). Reflux is less common in African-American than in caucasian children (Skoog and Belman, 1991).

Reflux severity can be graded (Figure 2). Reflux grade is important because more severe reflux is associated with higher rates of renal injury, and treatment success varies with reflux grade. In addition, the reflux grade is an indirect indication of the degree of abnormality of the ureterovesical junction. Numerous grading systems have been used.

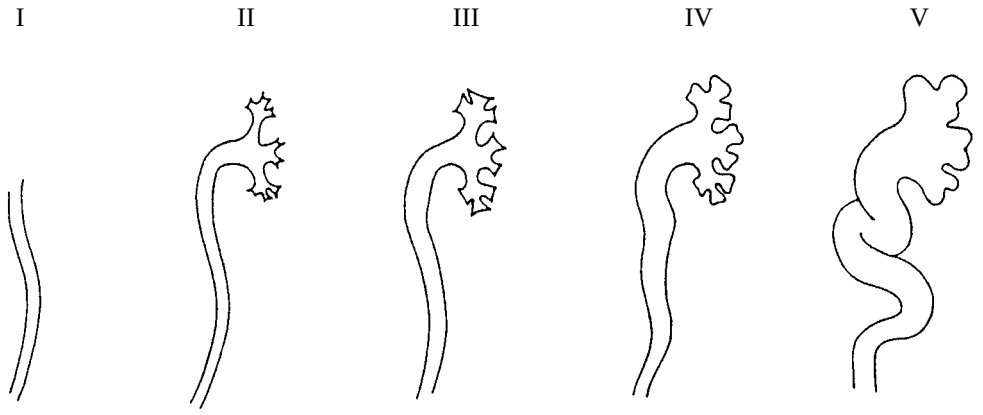

Figure 2. International Study Classification (International Reflux Study Committee, 1981)

The most common classifications are shown in Table 1. These classifications are based on a standard contrast voiding cystourethrogram. The International Study Classification, which was adopted by the International Reflux Study Committee in 1981, is the most common and is the grading system used in this report.

Pathophysiology of renal injury

The likelihood of renal injury after a UTI depends on bacterial virulence factors, the presence or absence of reflux, adherence characteristics of the uroepithelium, anatomic characteristics of the infected kidney, and host inflammatory response. During infection, certain bacteria, particularly those with P-fimbria, may ascend the ureter and enter the renal pelvis and calyces. Bacterial ascent is promoted by the presence of reflux. Intrarenal reflux (reflux from the minor calyx into the collecting duct) of infected urine results in renal parenchymal infection (pyelonephritis). In previously normal kidneys, this initial infection often occurs in the upper or lower poles, because these typically contain compound papillae that favor intrarenal reflux (Ransley and Risdon, 1979). Bacteria often produce an endotoxin, which causes a cellular and humoral immune response as well as an inflammatory response (Roberts, 1992). The sequel of the host reaction is renal parenchymal fibrosis, a renal injury termed reflux nephropathy.

Table 1. Common classifications of vesicoureteral reflux

Description	Grade/classification					
International Study Classification[1]	0	I	II	III	IV	V
Dwoskin-Perlmutter	0	1	2a	2b	3	4
Birmingham	0	1	2	←	3 →	
Australia/NZ		← Mild →		Moderate	← Severe →	
Great Britain		I	II (Voiding)	III (Filling and voiding)		IV (Dilatation)

[1] Classification used in this Report.

Reflux is an important risk factor for developing pyelonephritis. Pyelonephritis occurs in children with and without VUR, as well as in children in whom reflux has resolved spontaneously and in children whose reflux is undetected on a voiding cystourethrogram. In children who develop pyelonephritis, renal scarring results in as many as 40 percent (Rushton and Majd, 1992). Children younger than 5 years old appear to be at greatest risk of renal injury from pyelonephritis, but older children also may develop renal scarring. In 1 report of 34 children older than age 5 who had normal kidneys and who later developed renal scarring, nearly all had both UTI and reflux (Smellie, Ransley, Normand, et al., 1985).

In the neonate with prenatally diagnosed hydronephrosis, medium- or high-grade reflux often is diagnosed. In some of these neonates, typical patterns of renal scarring are found even though no bacteriuria is present. The cause of the renal abnormality is uncertain but may be secondary to abnormal induction of the metanephric blastema by the ureteral bud (Mackie and Stephens, 1975) and/or possibly high voiding pressures during renal development.

Although reflux associated with bacteriuria may cause renal scarring, sterile VUR is not thought to result in renal injury unless abnormally elevated bladder pressures exist (i.e., with posterior urethral valves, neuropathic bladder, bladder outlet obstruction, or detrusor-sphincter dyssynergia) (Ransley and Risdon, 1979).

Diagnosis

In most cases, reflux is diagnosed during evaluation of a UTI. In some cases reflux is diagnosed "incidentally" during screening of patients at risk, for example, those who have a sibling with reflux (Noe, 1992; Wan, Greenfield, Ng, et al., 1996), a mother with reflux (Noe, Wyatt, Peeden, et al., 1992), a multicystic kidney (Selzman and Elder, 1995) or hydronephrosis (Elder, 1992).

The panel did not undertake a formal evaluation of the radiologic literature regarding the accuracy of various methods of diagnosing reflux or detecting upper urinary tract changes secondary to or associated with reflux, because these considerations were deemed outside the scope of treatment guidelines in a child with VUR.

Diagnosis of VUR requires catheterization of the bladder, instillation of a solution containing iodinated contrast or a radiopharmaceutical and radiologic imaging of the lower and upper urinary tract, termed a voiding cystourethrogram (VCUG) or radionuclide cystogram, respectively. The bladder and upper urinary tracts are imaged during bladder filling and voiding. Reflux occurring during bladder filling is termed low-pressure or passive reflux, and reflux occurring during voiding is termed high-pressure or active reflux. Children with passive reflux are less likely to show spontaneous reflux resolution than children who exhibit only active reflux (Mozley, Heyman, Duckett, et al., 1994). Radiation exposure during radionuclide cystography is less than with standard contrast cystography. In the past, many children underwent cystography under general anesthesia. However, this method is flawed because normal micturition does not occur under anesthesia. Other methods for detecting reflux, such as indirect cystography and renal ultrasound, are thought to be less accurate (Blane, DiPietro, Zerin, et al., 1993; de Sadeleer, de Boe, Keuppens, et al., 1994).

Assessment of upper urinary tract

The goal of upper tract imaging is to assess whether renal scarring and associated urinary tract anomalies are present. In a child with VUR, the upper urinary tract can be evaluated by one of several techniques, including renal cortical scintigraphy (renal scan), excretory urography (intravenous pyelography, or IVP), and renal ultrasound. Radiopharmaceuticals used for renal scanning include dimercaptosuccinic acid (DMSA), glucoheptonate, and mercaptoacetyltriglycine (MAG-3). On an IVP, renal scarring is evident from reduction in the thickness of the renal cortex. Several specific patterns of renal scarring have been described (Smellie, Edwards, Hunter, et al., 1975). Renal sonography, a noninvasive method of evaluating the kidney, can show hydronephrosis, renal duplication with an obstructed upper pole and gross renal scars. The surface areas of the kidney on renal sonography roughly correlate with differential renal function (Sargent and Gupta, 1993).

Following an episode of pyelonephritis, renal scarring usually is apparent on scintigraphy within 3 months, but may not be apparent on an IVP or sonography until 1–2 years later.

Assessment of lower urinary tract

The goal of lower urinary tract assessment is to determine whether the bladder empties satisfactorily, whether a bladder abnormality such as a paraureteral diverticulum is present, and in males, to assure that no bladder outlet obstruction such as posterior urethral valves is present. This information is often obtained from the voiding cystourethrogram. At times, bladder trabeculation may be present and suggest that voiding dysfunction is present. Cystoscopic examination of the ureteral orifices has not been helpful in predicting whether spontaneous resolution of a child's reflux is likely (Bellinger and Duckett, 1984; Mulcahy and Kelalis, 1978). Evocative cystometry also does not appear to provide useful information in children with normal voiding function. However, urodynamics may be beneficial in children with voiding dysfunction.

Treatment methods

The primary goals of treatment in children with reflux are to prevent pyelonephritis, renal injury and other complications of reflux. Medical therapy is based on the principle that VUR often resolves over time, and that the morbidity or complications of reflux may be prevented nonsurgically. The basis for surgical therapy is that in selected situations, ongoing VUR has caused or has a significant potential for causing renal injury or other reflux-related complications and that elimination of reflux will minimize the likelihood of these problems. The 7 treatment modalities for VUR considered by the panel follow:

- No treatment (intermittent antibiotic therapy for UTI);
- Bladder training (including timed voiding and other behavioral techniques);
- Antibiotic prophylaxis (continuous);
- Antibiotic prophylaxis and bladder training;
- Antibiotic prophylaxis, anticholinergics (for bladder instability), and bladder training;
- Open surgical repair; and
- Endoscopic repair.

Neither urethral dilation nor urethrotomy have been found to be beneficial in the treatment of children with reflux (Forbes, Drummond, and Nogrady, 1969; Hendrey, Stanton, and Williams, 1973; Kaplan, Sammons, and King, 1973).

No treatment

This management modality involves treating patients with UTI with antibiotics at each occurrence. The philosophy of this therapy is that prompt diagnosis and treatment of UTI will eliminate or minimize the risk of reflux-associated renal infection. Because the continuous antibiotic prophylaxis approach has been used in recent years, few data are available on the intermittent treatment approach.

Bladder training

Bladder training refers to regular, volitional, complete emptying of the bladder through behavioral conditioning to achieve balanced, low-pressure voiding with coordinated relaxation of the external sphincter and pelvic floor during voiding. Measures include a voiding schedule (e.g., every 2–3 hours), complete emptying of the bladder during micturition, re-education in proper voiding dynamics if voiding dysfunction is present, and elimination of constipation. The practice also includes genital and perineal hygiene. The goal of bladder training is to reduce the likelihood of developing UTI and reduce voiding pressure. Infrequent voiding, detrusor-sphincter dyssynergia, and constipation can increase the likelihood of bacteriuria (Smith and Elder, 1994).

Antibiotic prophylaxis

Continuous antibiotic prophylaxis has become the cornerstone in the initial management of patients with reflux. This form of therapy is based on the observations of Lenaghan, Whitaker, Jensen, et al. (1976), who reported that 21 percent of previously normal refluxing kidneys showed scarring on follow-up with intermittent antibiotic therapy, and Smellie, Edwards, Hunter, et al. (1975), who found that children on continuous antibiotic prophylaxis who were kept free of infection did not develop new renal scarring.

Drugs commonly used for prophylaxis include sulfamethoxazole-trimethoprim, trimethoprim alone, and nitrofurantoin, generally administered once daily at a dose calculated to be one-fourth to one-third of the dose necessary to treat an acute infection (Birmingham Reflux Study Group, 1987; Cardiff-Oxford Bacteriuria Study Group, 1978;

Goldraich and Goldraich, 1992; Hannerz, Wikstad, Celsi, et al., 1989; Hanson, Hansson, and Jodal, 1989; Pinter, Jaszai, and Dober, 1988; Smellie, Gruneberg, Bantock, et al., 1988). Prophylaxis usually is continued until reflux resolves or until the risk of reflux to the individual is considered to be low. Many clinicians treating children with reflux obtain urine specimens periodically for urinalysis and/or culture, although the frequency of urine sampling varies widely (Elder, Snyder, Peters, et al., 1992).

Medical management with antibiotic prophylaxis is considered to be successful if the child remains free of infection, develops no new renal scarring, and the reflux resolves spontaneously. On the other hand, breakthrough UTI, the development of new renal scars, or failure of reflux to resolve would be considered failure of medical management. Noncompliance (Smyth and Judd, 1993), allergic reaction, or side effects to the prescribed medication may preclude medical management or lead to its failure.

Antibiotic prophylaxis and bladder training

Many clinicians emphasize the principles of bladder training when placing children with VUR on antimicrobial prophylaxis. Most studies in the literature do not specify whether attention to bladder training was emphasized in the treatment plan, and assessment of the contribution of bladder training to outcome has not been studied in any controlled trials.

Antibiotic prophylaxis, anticholinergics and bladder training

Before toilet training, voiding is an automatic process. During toilet training, however, children may demonstrate a discoordinated pattern, with incomplete relaxation of the external sphincter during voiding, resulting in high intravesical pressure and incomplete bladder emptying. The terms bladder instability, uninhibited bladder contractions, and pediatric unstable bladder refer to reflex detrusor contractions at low bladder volumes. Children with bladder instability typically experience frequency, urgency, and urge incontinence, and girls with this condition may cross their legs or squat down to try to avoid incontinence. Anticholinergic medication, in conjunction with timed voiding, is thought to improve the symptoms of dysfunctional voiding. Typical anticholinergic medications (also often classified as antimuscarinic/antispasmodic agents) include oxybutynin chloride, propantheline bromide, and hyoscyamine.

Open surgical repair

Open surgical management involves modifying the abnormal ureterovesical attachment to create a 4:1 to 5:1 ratio of length of intramural ureter to ureteral diameter. Numerous techniques have been described, and each has undergone minor modifications. The primary techniques evaluated by the panel include intravesical operations, including the Politano-Leadbetter (Politano and Leadbetter, 1958), Glenn-Anderson (Glenn and Anderson, 1967), Cohen transtrigonal (Cohen, 1975) and Paquin and Gil-Vernet procedures, and extravesical operations, including the Lich-Gregoir procedure (Gregoir, 1974) and detrusorrhaphy (Zaontz, Maizels, Sugar, et al., 1987). Surgical techniques for management of children with refluxing megaureter and reflux associated with ureteral duplication were evaluated separately. Studies dealing with laparoscopic correction of reflux, bladder neck plasty/Y-V plasty, and nephrectomy or partial nephrectomy as management for reflux were not reviewed.

Endoscopic repair

The technique of endoscopic injection of polytetrafluoroethylene paste (polytef, Teflon™), for the correction of VUR was reported in 1986 by O'Donnell and Puri (1986). The technique involves injecting 0.1–1 ml of polytef paste into the submucosa deep to the affected ureter. The injected bolus provides a firm buttress against which the ureteric roof may be compressed with rising intravesical pressure. This operative procedure, termed the "STING" (subtrigonal injection) has become very popular, particularly in Europe, because it is less invasive than open surgical techniques and can be performed as an outpatient procedure under general anesthesia. If the initial injection fails to correct reflux, the procedure can be repeated. Polytef is an inert material, yet the long-term safety of this foreign material in the bladder has not been documented (Aaronson, 1995; Puri, 1995). Furthermore, polytef has not been approved by the U.S. Food and Drug Administration for use in the treatment of reflux.

Another substance that has been used for endoscopic therapy is cross-linked bovine collagen (Leonard, Canning, Peters, et al., 1991). Other materials for injection currently under investigation

include autologous collagen, a mixture of cross-linked dextran and hyaluronadan, polyvinyl alcohol foam (Ivalon), polydimethylsiloxane, blood, fat, chondrocytes embedded in biodegradable polymer, bioactive glass, and detachable balloons. The panel did not review studies focusing on the use of these materials. Until an injectable substance is developed with acceptable known risks, open surgical correction of reflux remains the surgical treatment of choice. Nevertheless, the appeal of a safe and effective outpatient procedure for the correction of reflux will undoubtedly continue to stimulate investigation of this technique.

Surveillance and follow-up

In a child with VUR, periodic surveillance is generally recommended to monitor for UTI, because the complications of reflux often occur when infection is present. No guidelines exist for frequency of monitoring (e.g., monthly, every 3 months) or type of surveillance (urine dipstick, dipstick with microscopy, urine culture, or a combination) (Elder, Snyder, Peters, et al., 1992). If the child has symptoms of a UTI, a urine culture should be performed, even if the urinalysis is normal.

Follow-up radiologic testing is performed to monitor the status of reflux, that is, whether it is present (worse, improved, no change) or absent. In addition, studies to determine whether renal injury has occurred may also be performed. In children undergoing medical or surgical therapy, no guidelines exist for frequency or type of follow-up (Elder, Snyder, Peters, et al., 1992).

In a child receiving medical therapy, follow-up cystography is generally performed every 12–18 months. The radionuclide cystogram is preferred by many, because the radiation dose to the gonads is significantly lower than that with a standard contrast cystogram (Conway, King, Belman, et al., 1972). The 2 techniques are sufficiently dissimilar, therefore, the assessment of reflux severity may not be comparable. With digital fluoroscopy equipment and a “tailored” or individualized contrast cystogram performed by a pediatric radiologist, the radiation dose also is significantly lower than that with a standard VCUG (Kleinman, Diamond, Karellas, et al., 1994). In a child with reflux that appears to have resolved spontaneously by cystography, as many as 20 percent might show reflux if the study were repeated in 1 year (Arant, 1992). Most clinicians do not obtain a second cystogram, unless recurrent urinary tract infections have occurred. In addition, periodic upper tract imaging studies (ultrasound, IVP, renal scintigraphy) are often performed, although the ability of these tests to detect renal scarring and growth is variable. In a child treated surgically, follow-up lower and upper tract studies are generally performed at least one time to assess the success of the surgical procedure and to determine whether any complications have occurred.

The panel did not perform an assessment of the accuracy of these tests, nor is there any agreement on the effect these tests have on outcomes. Such studies do, however, document the status of the reflux problem.

Chapter 2: Methodology

The AUA Pediatric Vesicoureteral Reflux Panel developed the recommendations in this *Report on the Management of Primary Vesicoureteral Reflux in Children* following an explicit approach to the development of practice policies (Eddy, 1992) supplemented by expert opinion. The explicit approach provides mechanisms that take into account the relevant factors for making selections from alternative interventions. The use of scientific evidence in estimating the outcomes of intervention is emphasized.

To develop recommendations for this report, the panel undertook an extensive review of the literature on vesicoureteral reflux and extracted data.

The panel reviewed the evidence tabulated in the database and focused attention on randomized, controlled studies wherever possible. The level of availability and quality of the data from which outcomes could be estimated are displayed on the evidence matrix on page 21.

Expert opinion was polled by questionnaire or survey in a blinded fashion when scientific evidence was lacking. The panel generated its practice policy recommendations on the basis of evidence-based outcomes and on expert opinion. In this report, statements based on opinion are explicitly identified, and evidence-based recommendations are accompanied by appropriate references. The recommendations were derived from a survey of preferred treatment options for 36 clinical categories of children with reflux. The treatment recommendations were classified as follows:

- **Guidelines:** Treatment recommendations selected by 8 or 9 of the 9 panel members are classified as guidelines and are strongly worded using "should"; e.g., "Children with Grade V reflux should undergo surgical repair."
- **Preferred options:** Treatment recommendations that received 5 to 7 votes are worded with this classification.
- **Reasonable alternatives:** Treatment recommendations that received 3 to 4 votes are worded with this classification.
- **No consensus:** Treatment recommendations that received no more than 2 votes are worded with this classification and are not to be considered recommendations.

Literature search

The reference database was developed from MEDLINE literature searches encompassing the period January 1965 through December 1994. The search strategy was all-inclusive, using vesico-ureteral-reflux as the major or minor medical subject heading (MeSH keyword). It was important to use this specific form of vesico-ureteral-reflux because similar alternatives (e.g., vesicoureteric reflux) do not capture all reflux articles. All of the citations were imported into a Papyrus Bibliography System (Research Software Design, Portland, OR) and assigned a Papyrus Reference Number. Articles were accepted on the basis of specific criteria (outlined on page 17), as well as the interpretability of the data and inclusion of new data (relative to older published reports updating ongoing studies). A total of 3,207 references were retrieved and reviewed. Of these, 413 (13 percent) were selected for initial panel review. From this group, 168 were accepted for analysis (5.2 percent of initially retrieved articles). Bibliographies of reflux literature from 1960–1965 were reviewed manually to identify any relevant articles that would not have been retrieved electronically; however, no articles from which data could be extracted were identified in this manner. The articles from which outcomes data were extracted are listed in Table A-1 (Appendix A) and are the basis for the panel's analysis of vesicoureteral reflux.

Evidence on some outcomes was reviewed from selected articles that were not analyzed systematically, due to the nature of the material or the lack of a significant number of adequate articles. These areas included the impact of reflux on pregnancy, hospitalization due to antireflux surgery and due to pyelonephritis, adverse drug reactions, adverse effects of surveillance testing, and other surgical harms.

Article selection and data extraction

After identifying articles from the literature search, the panel reviewed the abstracts and selected relevant citations for data extraction. Criteria for admissible evidence included (1) English language and (2) peer-reviewed studies of primary VUR in children younger than 10 years old. The initial exclusions were based on article title, keywords (other than vesicoureteral reflux) or review of the abstract, if present. Specific exclusion criteria included review articles, non–English language studies, non–peer-reviewed studies, older duplicate studies, animal studies, adult studies, case reports with fewer than 5 patients, laboratory studies, studies without treatment outcomes, studies of secondary reflux, letters, editorials, and data from unpublished material.

Each article was accepted for inclusion or rejected on the basis of the treatment outcome data it contained. Inclusion or exclusion of each article was verified by 2 panel members in consultation with the panel chair. Articles were rejected by consensus of the 2 reviewers and the panel chair. Two individual panel members extracted data from each accepted article, and the data were tabulated on the data retrieval form developed by the panel (Appendix B). Each data retrieval sheet was reviewed by the panel chair, providing triple review for each article. Figures A-1–A-4 (Appendix A) list the articles reviewed and accepted by year, the source of the articles, the type of study for the accepted articles, and the reason for article rejection. From this review, reports were accepted for inclusion in the working bibliographic database.

The data were entered into a FoxPro™ (Microsoft Corp.) database. All computer entries were reviewed to ensure accuracy. The tabulated data were categorized according to the pediatric vesicoureteral reflux evidence matrix to facilitate review and to identify areas where limited or no data exist.

Limitations of the literature

The panel attempted to rely on published evidence whenever possible. Many studies that addressed a particular issue could not be used quantitatively in the various syntheses because of inconsistent reporting of data, limited time of follow-up, incomplete description of treatments utilized, or poorly defined patient populations. In addition, many of the datasets that were extracted still contained some deficiencies. Practical problems were encountered in analysis of the scientific literature as follows:

- Only 3 prospective randomized controlled trials (RCTs) compared medical with surgical therapy: the Birmingham Reflux Study, the International Reflux Study in Children, and a study from Erasmus University, Rotterdam, The Netherlands. The strongest evidence for the comparison of efficacy of treatments comes from these RCTs. Because even RCTs can have methodological problems, additional analyses were conducted on cohort studies for selected issues. In general, the results from these analyses were consistent with those of the RCTs.
- At least 5 different methods are used for grading reflux (see Table 1, page 11). The International Study Classification is currently the most common method for reporting data on reflux, and the Dwoskin-Perlmutter System corresponds closely to this grading system. The other systems tend to combine higher reflux grades, frequently making it difficult to extract outcomes data for specific grades of reflux.
- Many studies did not report outcomes by separate reflux grade, and instead combined various grades. Often, the results were not broken down by initial grade of reflux. In some cases, an attempt was made to adjust for this statistically; in other cases, the results were excluded from the analyses. (See Appendix C.)
- Although reflux is diagnosed more frequently in girls than in boys and the sequelae of reflux may be different in girls and boys, most outcomes were not reported separately by patient gender. The literature and data available suggested no difference in resolution by gender.
- No standard method was used for reporting outcomes in children with reflux. Some studies reported selected outcomes on reflux by patient grade, and other studies reported outcomes by ureteral grade. Some studies reported demographic data by patient data and outcome by ureteral data, or vice versa. Consequently, the panel had to assess which information was more important. For example, are patients with unilateral Grade II or III reflux more likely to show

reflux resolution than those with bilateral Grade II or bilateral Grade III reflux? Are patients with bilateral reflux, Grade IV on one side and Grade III on the other, as likely to show reflux resolution as patients with Grade IV reflux on one side and Grade I or II reflux on the other side?

- In series reporting outcomes of surgical correction of reflux, the duration of follow-up tended to be shorter than that in series of medical therapy. Thus, determining the long-term incidence of outcomes such as renal scarring and UTI after surgical therapy was difficult.
- In most series of reflux resolution on medical therapy, the resolution rate by year of follow-up was not provided, and patients were included with varying lengths of follow-up. This factor made combining the data in these series difficult.
- Few studies reported side effects of medical therapy or provided the reasons for changing the prophylactic medication. In addition, most studies of medical therapy did not stratify outcomes by specific antibiotic prophylaxis, making it impossible to analyze whether a particular form of prophylaxis is better than another.

  Issues such as adverse drug reactions or complication rates from surgery are most accurately estimated from large cohort samples taken from the same populations about which inferences are to be made. The literature on issues such as complication rates and adverse reactions was usually based on a convenience sample. In some cases, the information was so sparse that judgments had to be made on the basis of expert opinion.
- Most studies of reflux resolution on medical therapy did not stratify results by patient age, making it difficult to determine whether, for a specific grade of reflux, younger children are more likely than older children to experience reflux resolution. In addition, some studies reported the number of children who had reflux resolution at specific ages, but the initial reflux grade and the age at diagnosis in these patients were not provided.

Combining the evidence

To generate an evidence matrix (see page 21), estimates of the probabilities and/or magnitudes of the outcomes are required for each alternative intervention. Ideally, these come from a synthesis of the evi]dence, either from all available studies or a subset of high-quality data. Some cells in the evidence matrix were derived from a single dataset. If several studies had some degree of relevance to a particular cell or cells of the evidence matrix, the panel used more complicated methods of data synthesis—the Confidence Profile Method (Eddy, Hasselblad, and Shachter, 1992)—as a general framework, and the FAST*PRO software computer package (Eddy and Hasselblad, 1992) for calculations. The more complicated analyses were conducted using logistic models with random effects (Hasselblad, in press), and these calculations were performed using EGRET software (Statistics and Epidemiology Research Corp., 1993). The use of these logistic models for estimating parameters with dichotomous outcomes is described in Appendix C.

Panel members used expert opinion to address outcomes in the evidence matrix for which direct evidence was lacking, recognizing the limitations of opinion as a basis for reaching conclusions about effectiveness. They completed a mailed questionnaire in which they were asked to contrast, on the basis of their opinions and clinical experience, the relative effectiveness of several treatment options (e.g., anticholinergic therapy, bladder training, continuous antibiotic prophylaxis, surgery) in relation to various intermediate and health outcomes. The questionnaire also explored their opinions regarding the natural history and pathogenesis of VUR and the risk of adverse effects from continuous antibiotic prophylaxis and surgical repair. These pooled estimates, which were later presented at a panel meeting to help the group fill in the evidence matrix, are cited in this report along with an explicit statement that they originate from a panel survey and are gross estimates based on expert opinion and not on scientific data.

Dataset analysis

In addition, the panel was able to obtain the datasets of the large studies of Skoog and Belman (1991)[1] and Arant (1992). Analysis of these datasets provided a unique chance to answer some specific questions about resolution of reflux. In particular, the studies were used to determine whether

[1] Provided by Regina O'Donnell of Washington, D.C.

age of presentation affected resolution rates. Standard survival analyses were completed, and parametric analysis was used so that results could be combined across the 2 studies where appropriate. In general, a Weibull hazard model was used, and in many cases the exponential model (a special case of the Weibull model) was appropriate because it involved fewer parameters. Goodness of fit statistics were used to determine the adequacy of each model.

Analytic process

The recommendations in this report were developed on the basis of the scientific evidence and expert opinion, summarized according to the above methodology. A structured approach was used to translate the information into recommendations: confidential voting on standardized questions was conducted to give each panel member an equal voice in the recommendations, and explicit language was used to clarify the rationale for the recommendations and to document whether the assumptions were based on scientific evidence or expert opinion. After systematically reviewing the strengths and limitations of the evidence for each of the principal outcomes in the evidence matrix, panel members completed a confidential survey in which they designated preferred treatments for children presenting initially with reflux and for those with persistent reflux following initial treatment. Separate survey forms (see example in Appendix D) were completed for 36 clinical scenarios that incorporated all possible combinations of patient age (infancy, ages 1–5, ages 6–10), reflux severity (Grades I–II, Grades III–IV, Grade V), laterality (unilateral, bilateral) and the presence or absence of renal scarring at diagnosis. Voting was conducted in September 1995 and again in May 1996 after new data on spontaneous resolution rates became available. Recommended treatments were classified as guidelines, preferred options, reasonable alternatives, or no consensus, as defined on page 16.[2]

The text that resulted from this protocol was presented to the panel for review. Although the panel edited the text to improve consistency and readability, the panel did not deviate from the above protocol, either in determining what to recommend or in the wording of the recommendations. For example, even if some panel members believed that surgical repair is a reasonable alternative for specific clinical situations, the group did not recommend surgery if it received fewer than 3 votes on the survey. Finally, working with a facilitator, the panel listed individually the explicit arguments that formed the rationale for each of its recommendations. These arguments are summarized in Rationale for Recommendations (page 53), which also specifies whether the assumptions are based on scientific evidence or expert opinion. Special caveats about the limited scope of the recommendations (e.g., applying only to patients with uncomplicated reflux) also were made explicit. The final text that resulted from this process appears on pages 49–53.

[2] An exception occurred in evaluating treatments for patients with persistent reflux, because the denominator (the number of panel members voting) was less than 9 if any panel members recommended surgery as initial treatment (i.e., they would not participate in voting for additional treatments). Accordingly, votes for persistent reflux were classified as guidelines if a treatment received 85–100 percent of the total votes or as preferred option if it received 50–84 percent of total votes. No treatments for persistent reflux were classified as reasonable alternatives; if a treatment received no more than 50 percent of the votes, the text stated that there was no consensus. Because of the small sample size in this voting process, a change in the vote of a single panel member could affect the strength of the recommendations (e.g., making a “preferred option” a “guideline”). When differences due to rounding error resulted in illogical discrepancies in the recommendations (e.g., recommending more aggressive treatment for unilateral than for bilateral reflux), the response rate for the overall class of patients was used to calculate the strength of the recommendations.

Chapter 3:
Outcomes analysis for treatment alternatives

Intermediate outcomes and health benefits and harms

Health outcomes are the effects of a medical condition or intervention on patients that are directly perceived in some way by the patient or family. Harms are health outcomes that have a negative impact on the well-being of the patient, ranging from the impact of an acute illness or diagnostic testing (such as a VCUG), to the need for surgery or hospitalization, to death. Health benefits are generally expressed as a reduction in the severity or frequency of a harm.

It is important to distinguish between outcomes directly experienced and appreciated by a patient or parent (health outcomes) and those that patients cannot feel or experience but that are either associated with or precede health outcomes (intermediate outcomes). A patient or parent is only concerned about reflux if it causes symptoms that negatively affect them or if it has the potential to cause such problems. For example, although a direct relationship may be evident between reflux and pyelonephritis, it is the clinical condition of pyelonephritis with fever, pain, and hospitalization that is experienced by the patient. Similarly, renal scarring itself may not affect a patient's well-being, but possible sequelae of hypertension, renal insufficiency, clinical renal failure, symptoms of azotemia, or the need for dialysis, have direct impact. Consequently, reflux and reflux grade are intermediate outcomes, as are renal scarring, serum creatinine, or asymptomatic bacteriuria. In contrast, symptomatic UTI, azotemia, growth failure, as well as the need for x-ray studies, medications, surgery, or dialysis are health outcomes.

Many studies reported in the literature record only intermediate outcomes because the causal connection between intermediate outcomes and health outcomes is assumed or inferred. Analyses of intermediate outcomes are important in developing practice guidelines, but a firm causal connection with health outcomes is essential for validity and relevance.

Analysis of data quality

The evidence matrix on page 21 presents the outcomes of interest, indicating health outcomes, intermediate outcomes and harms for various forms of management, including no treatment, medical therapy and surgical therapies. Areas in which good (defined as 2 or more datasets available), fair (1 well-done dataset), and poor (very little) data are available are indicated. In some areas, a significant amount of interpretable information is available to integrate into a clinical decision, while in others a surprising lack of evidence was found. The areas lacking useful outcomes data highlight the deficiencies in the literature on VUR and emphasize the need for well-developed studies to address areas of uncertainty. The text following the evidence matrix notes areas in which relative benefits and harms may differ by patient population (e.g., different patient ages and grades of reflux).

Analysis of outcomes

The following sections detail the analysis of the variables included on the evidence matrix. The information is organized in relation to outcomes listed on the left side of the evidence matrix, beginning with intermediate outcomes.

Intermediate outcomes

Resolution and diminution of reflux

Over time a considerable proportion of children with reflux will experience resolution or diminution in reflux grade. Because the significance of diminution in reflux grade was difficult to assess, the panel used reflux resolution as an indication of success.

Medical therapy. The database included 26 reports with data pertaining to reflux resolution after medical therapy, encompassing 1,987 patients

(continued on page 22)

Evidence matrix: quality of data–studies of primary vesicoureteral reflux

Key: Good | Fair | Poor | NA Not applicable | No data

Good = 2 or more datasets, Fair = one well-done dataset, Poor = very little data

	No treatment[1]	Bladder training[2]	Antibiotic prophylaxis	Antibiotic prophylaxis & bladder training	Antibiotic prophylaxis, anti-cholinergics & bladder training	Open surgical repair[3]	Endo-scopic repair[4]
Intermediate outcomes (not considered admissible evidence of effectiveness)							
Decrease grade of reflux							
Duration of reflux							
Renal scarring							
Renal growth							
Renal function							
Health outcomes							
UTI							
Pyelonephritis							
Cystitis							
Hypertension							
Uremia							
Growth							
Morbidity during pregnancy[5]							
Death							
Harms (medical treatment)							
Adverse drug reactions						NA	
Hospitalization							
Adverse effects of surveillance testing							
Harms (surgery)							
Obstruction	NA						
Bleeding/transfusion							
Infection							
Contralateral reflux							
Bladder injury							
Pain							
Hospitalization							
Adverse effects of surveillance testing							

Health benefits are positive outcomes that patients can feel or experience directly.
Intermediate outcomes are pathophysiological outcomes that lead to, or are associated with, the development of health outcomes.

1. Includes intermittent antibiotic therapy for episodic UTI.
2. Includes timed voiding and other behavioral techniques.
3. Politano-Leadbetter, Glenn-Anderson, transtrigonal (Cohen), Lich-Gregoir, Paquin, Gil-Vernet, detrusorrhaphy, etc. Also includes repair of duplication anomalies (e.g., common sheath reimplant, ureteroureterostomy, partial nephrectomy).
4. Teflon™, collagen, Ivalon, blood, fat, etc.
5. Women with reflux/reflux nephropathy appear to have a higher risk of UTIs and/or pyelonephritis during pregnancy. UTIs during pregnancy can result in eclampsia, premature delivery, reduced fetal growth and possible fetal loss. Pyelonephritis would require maternal hospitalization. If there is pre-existing renal functional impairment secondary to reflux nephropathy, deterioration of renal function may occur during pregnancy.

(1,410 girls and 304 boys or a ratio of girl to boy, 4.3:1) and 2,902 ureters. In those studies in which the reflux could be classified as unilateral or bilateral, the distribution of ureters was almost equal (767 and 763, respectively). To accommodate a clinically relevant management strategy, children were divided into groups by age at diagnosis as follows: younger than age 1 year; preschool (1–5 years); and school age (6–10 years). The panel excluded from its consideration teenage youths and adults.

The data in these reports were difficult to collate because: (1) the minimum length of follow-up was often 6 months or less; (2) some studies did not report reflux resolution specifically but rather combined resolution and reduction in reflux grade; (3) some studies reported reflux resolution by ureter, and others reported reflux resolution by patient; (4) data showing reflux resolution often combined multiple grades of reflux, particularly in the older literature that did not use either the International or the Dwoskin-Perlmutter System of grading reflux; (5) reflux was not usually assessed annually for all patients, making it difficult to evaluate reflux by year in the majority of studies; and (6) some studies only reported the age at resolution of reflux, making it impossible to determine the actual range of time to reflux resolution.

For these reasons, 3 datasets were used to estimate the probability of reflux resolution as a function of initial grade, age at presentation and initial grade of reflux and laterality (unilateral/bilateral). The individual databases from the studies of Skoog, Belman, and Majd (1987) and Arant (1992) allowed analysis of these specific parameters, whereas the study of Tamminen-Mobius, Brunier, Ebel, et al. (1992) only provided summary resolution curves and sample sizes. The Arant dataset provided information on children with initial grades of I, II and III for ages 0–60 months. The Skoog dataset provided information primarily on Grades II and III for all ages. The Tamminen-Mobius study provided information primarily on Grade IV for all ages, but the results were not available by age. The study of McLorie, McKenna, Jumper, et al. (1990) was also analyzed for Grades III and IV reflux in a manner similar to Tamminen-Mobius, but was not included because the study data were not adequately described for analysis using the Weibull model determined to be the most appropriate for the analysis of the other studies.

The survival curves of these studies were fitted to the data. The results were pooled using an empirical Bayes model (Hedges and Olkin, 1985) when 2 or more studies provided information for a single risk category. The data for Grades I and II did not show any differences by age or laterality. For Grade III reflux, however, age and laterality were important.

Table 2 (page 23) shows the estimated chance of resolution for a child with reflux of a given grade, age and laterality (unilateral/bilateral). For example, assume that a child aged 30 months (2½ years) is diagnosed with unilateral Grade III reflux. Table 2 indicates that the chance of that child's reflux resolving in the next year is 13.4 percent. The chance of that same child experiencing reflux resolution in 3 years is 35.1 percent. The chance of resolution does not depend on how long the child has had reflux before diagnosis or treatment. If reflux does not resolve in the child described previously in the first year, the chance of resolution for the next year is still 13.4 percent. However, the table indicates 25 percent due to patients dropping out once their reflux resolved. For example, 100 patients, age 25–60 months, are diagnosed with Grade III, unilateral reflux. The first year, 13.4 percent will resolve. Therefore, approximately 87 patients remain. During the second year, another 13.4 percent of the 87 patients will resolve, leaving 75 patients with reflux, which means 25 percent of the original 100 patients resolved. A graphic presentation of the data is provided in Figure 3 on page 24.

All of these estimates are subject to 2 restrictions: (1) the estimates are only valid for up to 5 years after diagnosis; and (2) for Grade IV, the estimates only apply to the time of diagnosis, and they are not age specific. Children younger than 1 year with Grade IV reflux may have a higher chance of resolution, and children older than age 5 may have a lower probability.

The mean age at reflux resolution is 4.6–6.8 years (Skoog, Belman, and Majd, 1987; Bellinger and Duckett, 1984). The age beyond which reflux is unlikely to undergo spontaneous resolution is not well documented, however. Goldraich and Goldraich (1992) reported that almost all 10-year-old girls with persistent Grade I or II reflux underwent reflux resolution by age 13. In contrast, only 50 percent of 10-year-old boys with Grade I or II reflux showed resolution by age 13. Few 10-year-old girls or boys with Grade III or IV showed reflux resolution between 10 and 13 years of age. Lenaghan, Whitaker, Jensen, et al. (1976) reported that of 83 refluxing ureters that resolved, reflux resolution occurred after age 14 in 22 (27 percent).

Table 2. Medical therapy–Percent chance of reflux resolution after specified number of years[1]

Risk category (age in months) (number of patients on which estimates are based)	Percent chance (95% confidence interval)				
	1 year	2 years	3 years	4 years	5 years
Grade I[2] (N=15)	39.3 (24.6–51.1)	63.1 (43.2–76.1)	77.6 (57.2–88.3)	86.4 (67.7–94.3)	91.8 (75.7–97.2)
Grade II[2] (N=250)	28 (24.1–31.7)	48.1 (42.3–53.4)	62.7 (56.2–68.1)	73.1 (66.8–78.2)	80.6 (74.8–85.1)
Grade III, unilateral, age 0–24 (N=27)	21.4 (10.8–30.8)	38.2 (20.4–52.1)	51.5 (29–66.8)	61.9 (36.6–77.1)	70 (43.5–84.1)
Grade III, unilateral, age 25–60 (N=27)	13.4 (4.6–21.4)	25 (8.9–38.3)	35.1 (13.1–51.5)	43.8 (17.1–61.9)	51.3 (20.9–70.1)
Grade III, unilateral, age 61–120 (N=15)	10.8 (3.5–17.5)	20.5 (6.9–32)	29.1 (10.2–43.9)	36.7 (13.4–53.8)	43.6 (16.5–61.9)
Grade III, bilateral, age 0–24 (N=62)	12.7 (7–18.1)	23.8 (13.5–32.9)	33.5 (19.5–45)	41.9 (25.1–55)	49.3 (30.3–63.1)
Grade III, bilateral, age 25–60 (N=53)	7 (3.1–10.8)	13.5 (6.1–20.4)	19.6 (9–28.9)	25.2 (11.8–36.6)	30.5 (14.6–43.4)
Grade III, bilateral, age 61–120 (N=14)	2.6 (0.7–4.5)	5.2 (1.4–8.8)	7.7 (2.1–13)	10.1 (2.8–16.9)	12.5 (3.5–20.7)
Grade IV, unilateral[3] (N=28)	16.1 (8.5–23.1)	29.7 (16.4–40.8)	41 (23.5–54.5)	50.5 (30–65)	58.5 (36–73.1)
Grade IV, bilateral[3] (N=96)	4.5 (1–7.9)	6.4 (2–15.1)	7.8 (3–21.8)	8.9 (4–28)	9.9 (4.9–33.7)

[1] The yearly rate of reflux resolution remains constant for each group.
[2] No difference shown by age or laterality (unilateral/bilateral); therefore, these categories were combined.
[3] Estimates only apply to the time of diagnosis and are not age specific.

Medical resolution of reflux in patients with voiding dysfunction. Many children have voiding disorders exhibited by bladder and external sphincter discoordination along with bladder instability that contribute to VUR (Hinman and Baumann, 1973; Hinman, 1986; Allen, 1977, 1978). Clinically, these children in addition to having reflux and UTIs also have a combination of day and night-time enuresis, holding maneuvers, constipation, encopresis, and abdominal pain. The voiding disturbances are primarily a learned phenomenon that significantly increase voiding pressures resulting in decompensation of the ureterovesical junction and reflux. Inappropriate contraction of the voluntary external sphincter during detrusor contraction causes a functional obstruction to urinary flow with the development of elevated intravesical pressure. Many children perform this maneuver to delay bladder emptying while playing games, watching television, or being involved in other activities.

The cornerstone of treatment of patients with voiding dysfunction includes bladder retraining (timed voiding, relaxed voiding, biofeedback) with or without pharmacologic intervention directed at decreasing bladder or sphincter hyperactivity. Children with concomitant constipation or encopresis are often placed on a bowel program. Three prospective studies have found that neither urethral dilatation nor urethrotomy benefited children with VUR (Forbes, Drummond, and Nogrady, 1969; Kaplan, Sammons, and King, 1973; Hendry, Stanton, and Williams, 1973).

The panel selected 2 series that specifically examined the impact of voiding dysfunction on the course of reflux resolution without any intervention

(continued on page 26)

Table 3. Medical resolution of reflux in patients with voiding dysfunction (untreated)

	Inclusion criteria	# Patients and/or # ureters	Resolution (patients)	Resolution (ureters)	Resolution by grade					Treatment regimen	Follow-up period
					I	II	III	IV	V		
Van Gool, Hjalmas, Tamminen-Mobius, et al., 1992	Patients in IRSC with questionnaire suggestive of voiding dysfunction	37/-	4/37 (11%)*		Patients predominantly with Grade III and IV reflux					Daily antibiotic prophylaxis	5 years
Van Gool, Hjalmas, Tamminen-Mobius, et al., 1992	Patients in IRSC with questionnaire not suggestive of voiding dysfunction (control group for above)	147/-	36/147 (25%)*		Patients predominantly with Grade III and IV reflux					Daily antibiotic prophylaxis	5 years
Koff and Murtagh, 1983	Patients with voiding dysfunction with uninhibited contractions on urodynamic evaluation (noncompliant with treatment of voiding dysfunction)	8/12		4/12 (33%)	0/3	1/4	2/3	1/2	0/0	Daily antibiotic prophylaxis Patients were noncompliant with • Anticholinegic medication • Bowel/bladder retraining program	Range 1.5–7 years (mean, 3.9 years)

* $p < 0.05$

directed at abnormal bladder function (van Gool, Hjalmas, Tamminen-Mobius, et al., 1992; Koff and Murtagh, 1983) (Table 3, page 25). In the International Reflux Study in Children, the rate of spontaneous reflux resolution in 37 patients with mild voiding dysfunction was 11 percent (4/37) compared with 25 percent (36/147) in a similar group without voiding dysfunction ($p < 0.05$) at 5 years of follow-up (van Gool, Hjalmas, Tamminen-Mobius, et al., 1992). In addition, recurrent symptomatic UTIs were more common in the group with voiding dysfunction (44 percent) compared with those with normal bladder function (25 percent) during 5 years of follow-up. Despite the increased propensity for symptomatic infections, the International Reflux Study in Children could not demonstrate a correlation between new renal scarring and the presence or absence of voiding dysfunction. Koff and Murtagh (1983) demonstrated a low reflux resolution rate in a small group of 8 children with voiding dysfunction who were noncompliant with treatment of their bladder dysfunction. The reflux resolution rate was 33 percent (4/12 ureters: Grade I, 0/3; Grade II, 1/4; Grade III, 2/3; Grade IV, 1/2) at a mean follow-up of 3.9 years. The rate of symptomatic and asymptomatic infections was 63 percent in this group over the same follow-up. These studies suggest that non-treatment of voiding dysfunction is associated with a lower spontaneous reflux resolution rate and an increased risk of UTI.

Resolution in patients receiving antibiotic prophylaxis, anticholinergics and bladder retraining. Improving voiding dynamics with bladder retraining and pharmacologic intervention can bring about diminution of both voiding and storage pressures. Five clinical series (not randomized controlled trials) specifically examined the role of bladder training and/or pharmacologic intervention in addition to antibiotic prophylaxis in the treatment of children with VUR (Table 4 on pages 27-28). In each study, different inclusion criteria were used to define each treatment group. In addition, each used a variety of techniques to improve bladder training (timed voiding, relaxed voiding, or biofeedback) with single or multiple pharmacologic agents (oxybutynin, imipramine, baclofen, flavoxate, dicyclomine, and diazepam) directed at decreasing bladder or sphincteric hyperactivity. The rate of UTIs for each group over the same period was 16, 63 and 71 percent, respectively. This study concluded that treatment of voiding dysfunction, as demonstrated by uninhibited contractions on urodynamic evaluation, increased the reflux resolution rate and decreased the rate of UTI. Seruca (1989) compared a group of patients prospectively studied and treated for voiding dysfunction with a retrospective control group of patients who were not treated. The overall reflux resolution rate (by ureter) was 92 percent for the former group and 54 percent for the latter. The follow-up period was not specified. Reflux resolution rates in the other 3 studies, which did not include any controls, are also summarized in Table 4. The wide variation in results (37–83 percent) is likely due to differences in inclusion criteria, treatment regimens, and follow-up period.

Available results from the series with control groups suggest that the reflux resolution rate increases with active treatment of those patients with a clinical history suggestive of voiding dysfunction. Given the variability of treatment regimens and the disparity of results, there is a need for controlled, matched studies in this area.

Medical resolution of reflux in patients with duplicated systems. Among the 168 articles reviewed by the panel, 14 included data on patients with duplicated collecting systems. Five studies included data on spontaneous resolution of reflux in patients receiving medical prophylaxis. The 14 studies reporting data on ureteral duplication included 498 patients or at least 546 affected renal units. Three studies, representing a total of 45 patients, did not report data on renal units. Assuming that each of the 45 patients had at least 1 affected renal unit, the total units would approximate 591 renal units or more. Duplication was identified predominantly in girls, with a ratio of 1 male (57) to 5.6 female (322) individuals.

Although 2 reports presented controlled studies comparing single ureteral reflux to duplicated systems (Husmann and Allen, 1991; Ben-Ami, Gayer, Hertz, et al., 1989), limited data are available on medical treatment of reflux in the patients with duplicated systems. The data show that within the population of patients with duplicated systems, Grades I–II may be treated medically whereas Grades III, IV, and V have been treated surgically in most cases. Data on resolution by grade in patients receiving medical treatment are minimal compared with those in patients with duplicated systems treated surgically. Table 5 on page 29 provides data from the 5 studies, including data on resolution in patients with duplicated systems receiving medical therapy.

(continued on page 29)

Table 4. Medical resolution of reflux in patients with voiding dysfunction (treated)

	Inclusion criteria	# Patients and/or # ureters	Resolution (patients)	Resolution (ureters)	Resolution by grade					Treatment regimen	Follow-up period
					I	II	III	IV	V		
Koff and Murtagh, 1983	Patients with voiding dysfunction with uninhibited contractions on urodynamic evaluation (compliant with treatment of voiding dysfunction)	26/43		19/43 (44%)	5/9	3/10	7/11	2/10	2/3	Daily antibiotic prophylaxis treatment for voiding dysfunction: • anticholinergic medication (oxybutynin) • Bowel and bladder retraining program.	Range 1.5-7 years (mean, 3.9 years)
Koff and Murtagh, 1983	Normal urodynamic evaluation (control group for above 2 groups)	28/47		8/47 (17%)	1/3	3/11	4/17	0/9	0/7	Antibiotic prophylaxis	Range 1.5 - 7 years (mean, 3.9 years)
Seruca, 1989	Elevated bladder pressures during bladder filling and/or voiding, with or without abnormal perineal muscle activity	53/74	46/53	68/74 (92%)	8/8	33/33	26/27	1/4	0/2	Daily antibiotic prophylaxis for 6 months, then stopped. Baclofen, flavoxate, dicyclomine, or diazepam given individually or in combination for each type of bladder dysfunction seen on urodynamic evaluation for 12-30 months. 2 patients treated for constipation.	Unknown
Seruca, 1989	Retrospective “control” group from 1980-85 (for the above group)	48/67		36/67 (54%)	12/12	22/35	2/18	0/2	—	Daily antibiotic prophylaxis	Unknown

Table 4. Medical resolution of reflux in patients with voiding dysfunction (treated) (continued)

	Inclusion criteria	# Patients and/or # ureters	Resolution (patients)	Resolution (ureters)	Resolution by grade					Treatment regimen	Follow-up period
					I	II	III	IV	V		
Homsy, Nsouli, Hamburger, et al., 1985	Urodynamic demonstration of detrusor hyperreflexia (15) or detrusor hyperreflexia or dyssynergia (25)	40/53		27/53 (51%)	4/5	18/32	5/8	0/8	—	Daily antibiotic prophylaxis. Oxybutinin for 3-18 months Constipation treated with diet and softeners.	Unknown
Nasrallah and Simon, 1984	History consistent with voiding dysfunction	15/18		15/18 (83%)	4/4	6/7	3/4	2/3	—	Daily antibiotic prophylaxis. Detrusor hyperreflexia: oxybutynin Sphincter spasm: counseling and bladder retraining Nocturnal enuresis: imipramine Small bladder syndrome: imipramine & bladder retraining Detrusor areflexia: Bethanecol and timed voiding.	2 years minimum
Scholtmeijer and Griffiths, 1990	Detrusor instability on video-urodynamic	20/27		10/27 (37%)	1/1	6/13	3/8	0/5	—	Daily antibiotic prophylaxis. Anticholinergic medication	1 year

Table 5. Reflux resolution in patients with duplicated systems treated medically

Study	Grade	Patients in whom reflux resolved	Patients treated medically	Follow-up
Husmann and Allen, 1991	II	7 (10%)	71	0.5–5 years
Peppas, Skoog, Canning, et al., 1991	I–V	10 (14%)	70	Not stated
Kaplan, Nasrallah, and King, 1978	Not stated	5 (22%)	23	Not stated
Lee, Diamond, Duffy, et al., 1991	I–V	19 (50%)	38	1–11 years
Ben–Ami, Gayer, Hertz, et al., 1989	I–IV	14 (44%)	32	Min. 1 year
Total		**55 (24%)**	**234**	

The 5 studies, representing 234 patients, included data on follow-up of patients considered medically stable for variable periods from 1–5 years. Reflux resolution occurred in 24 percent of patients (55/234). The range of time to resolution varied from 24 months (Husmann and Allen, 1991) to 39–68 months (Lee, Diamond, Duffy, et al., 1991). The studies including matched control populations showed that the chance of resolution in patients with duplicated systems is lower or equal to that in patients with single systems (Husmann and Allen, 1991; Ben-Ami, Gayer, Hertz, et al., 1989).

Resolution—Open surgery. The panel reviewed 86 reports outlining open surgical success, encompassing 6,472 patients and 8,563 ureters (see Table E-1, Appendix E). Because results were reported in 1 of these 2 categories, the data represent different populations. Surgical success is defined as an open operation performed through an abdominal incision that corrected VUR without postoperative ureteral obstruction and that was confirmed by postoperative cystography. Surgical success was obtained both with "standard" techniques such as the Politano-Leadbetter procedure (16 reports), Cohen transtrigonal procedure (12 reports), Lich-Gregoir with modifications (13 reports) and Gil-Vernet (4 reports), and with mixtures of the above procedures (that could not be separated) or unique operations that could not be classified within the above procedures (44 reports).

Overall, surgical success was reported by patients in 959 of 1,008 patients (95.1 percent), or reported by ureter in 7,731 of 8,061 ureters (95.9 percent). When surgical success was reported by reflux grade, a smaller database was available for analysis. Surgical success was achieved in 108 of 109 ureters (99 percent) for Grade I reflux, 874 of 882 ureters (99.1 percent) for Grade II, 993 of 1,010 (98.3 percent) for Grade III, 386 of 392 (98.5 percent) for Grade IV, and 155 of 192 (80.7 percent) for Grade V. Surgical success in Grade V reflux, which was treated using a wide variety of procedures, is shown in Table E-2, Appendix E. Surgical success was also analyzed by surgical technique when that information was available (Table E-3, Appendix E).

Overall, the data on surgical success by any technique suggest a narrow range of success rates centering around 95 percent. Surgical success is most likely in Grades I–III, with at least median success in Grade IV reflux. For Grade V, the success rate ranges from 34 to 100 percent.

Resolution—Endoscopic therapy. Endoscopic therapy is a newer form of surgical treatment for reflux and refers to the subureteric injection of some material under the refluxing ureteral orifice. The technique and its limitations are described in Chapter 1. Most reports in the literature describe results of the use of polytetrafluoroethylene (Teflon™) (Table 6 on page 30). If the procedure is unsuccessful, as assessed by postoperative VCUG, it may be repeated. The results of this type of therapy are difficult to interpret because success is often described as resolution or reduced grade of reflux after 1, 2, 3, or even 4 injection procedures. Most reports focus on reflux resolution by ureter

Table 6. Results of endoscopic correction (Teflon™) for vesicoureteral reflux

Study	Grade	Procedures[1]				Patient cure (1 injection)
		1st	2nd	3rd	Obstruction

[2] Eight other ureters reported to be obstructed, but did not need surgical correction.

rather than by patient. Overall, reflux was corrected in 77.1 percent of ureters after a single injection. However, reflux was resolved after the initial treatment in only 6 of 19 ureters (32 percent) with Grade V reflux. In patients with a completely duplicated system, reflux was corrected in 58.1 percent of ureters after 1 injection (Table 7 on page 31).

Success with collagen injections is even more difficult to interpret because reflux correction may not be durable. For example, in 1 report of 60

Table 7. Reflux resolution following endoscopic correction (Teflon™) for vesicoureteral reflux, duplicated systems

ureters with primary reflux, 47 (78 percent) showed resolution 1 month after treatment, but only 29 of 47 (61 percent) still showed resolution at 1 year (Leonard, Canning, Peters, et al., 1991). In another series, all 97 treated ureters showed resolution immediately after injection, but reflux recurred in 40 ureters (41.2 percent) at 1 month and in 5 more ureters (5.2 percent) at 1 year following therapy (Frey, Berger, Jenny, et al., 1992). Whether more systems would begin to reflux with time because of implant degradation or migration is uncertain.

At present, endoscopic treatment remains an investigational procedure in the United States, awaiting testing of a material that has proven benefit and safety.

Renal scarring

Renal scarring is an important outcome in the long-term assessment of results of medical or surgical therapy. Renal scarring may predispose to hypertension requiring medical therapy. Extensive renal scarring may cause renal insufficiency and end-stage renal disease, with its attendant morbidity and mortality.

The presence of renal scarring is documented on imaging studies, including renal scan (DMSA, MAG-3), excretory urography (IVP) and renal sonography. These techniques have certain limitations. For example, there is variable sensitivity among these studies in their ability to detect renal scars. Furthermore, timing of the imaging study is important; a renal scar may be evident on DMSA scan within 6 months of an episode of pyelonephritis, whereas it may not be apparent on IVP or sonography for 1–2 years. Early identification of renal inflammation by DMSA during an episode of pyelonephritis does not necessarily indicate that these areas will later develop scarring, however. Interpretation of the studies is variable among radiologists (Patel, Charron, Hoberman, et al., 1993). In an individual with renal scarring, it may be difficult to distinguish between a new scar adjacent to the existing one and progression of an old scar. Finally, in an individual who is found to have a renal scar on the first imaging study of the kidney, it is impossible to determine whether the scar resulted from infection or was congenital, since 20–40 percent of neonates with prenatally diagnosed hydronephrosis secondary to VUR have renal parenchymal abnormalities at birth (Elder, 1992).

Renal scarring may be new or progressive. The finding of new renal scarring suggests that a new renal injury has occurred since the previous imaging study. Progressive renal scarring, on the other hand, may represent either extension of the original renal injury or may result from a newer renal insult.

Prevention of new renal scarring is one of the primary goals of treatment of VUR. Most studies of reflux have not assessed this specific outcome. When interpreting the results of various studies pertaining to reflux, it is important to understand the limitations of each type of imaging study used in the evaluation of renal scarring (see page 12). Unless otherwise indicated, studies that combined patients with both new and progressive renal scarring have not been included in the panel's analysis.

Table 8. Scarring after treatment in prospective trials of surgery compared with antibiotic treatment for vesicoureteral reflux

Study	Population	Method of evaluation	Treatment	Follow-up	New scarring
Elo, Tallgren, Alfthan, et al., 1983	Matched uncontrolled follow-up study with 40 girls in each arm. Mean age of 5.2 years	IVP	Medical—antibiotic, primarily sulfisoxazole	4.3 years (average)	7.5% (3/40)
			Surgery—Politano-Leadbetter procedure	4.3 years (average)	17.5% (7/40)
Birmingham Reflux Study Group, 1987	161 children younger than age 15 years, allocated randomly to either surgery or antibiotic treatment	IVP	Medical treatment	5 years	6% (5/84)
			Surgical treatment	5 years	5.2% (4/77)
Olbing, Claesson, Ebel, et al., 1992	306 children younger than age 11 years, with nonobstructive Grades III or IV VUR and with previous UTI	IVP	Medical treatment	5 years	15.7% (19/121)
			Surgical treatment	5 years	17.2% (20/116)
Weiss, Duckett, and Spitzer, 1992	Infants and children with Grades III and IV primary VUR	IVP	Medical treatment	4½ years	21.5% (14/65)
			Surgical treatment	4½ years	31.4% (16/51)

Four prospective trials comparing the outcomes of medical and surgical management included analysis of new renal scarring (Table 8 on page 32). None of these trials showed a statistically significant difference in the rate of new renal scarring. The combined relative risk slightly favored medical management but was not statistically significant (see Figure 4 on page 33). In the European arm of the International Reflux Study (Olbing, Claesson, Ebel, et al., 1992), the rate of scarring was similar among those managed medically and those treated surgically; however, 80 percent of the new renal scars in the surgical group appeared by 10 months after randomization, whereas new renal scars appeared throughout the 5 years in the group managed medically.

Several single-arm studies also reported rates of new scarring after medical or surgical treatment. The combined risk for new scarring for 14 such medical reports was 4.1 percent (range, 0–24.7 percent) (Aggarwal, Verrier-Jones, Asscher, et al., 1991; Arant, 1992; Bellinger and Duckett, 1984; Ben-Ami, Sinai, Hertz, et al., 1989; Birmingham Reflux Study Group, 1987; Burge, Griffiths, Malone, et al., 1992; Cardiff-Oxford Bacteriuria Study Group, 1978; Edwards, Normand, Prescod, et al., 1977; Homsy, Nsouli, Hamburger, et al., 1985; Husmann and Allen, 1991; Jakobsen, Genster, Olesen, et al., 1977; Koff and Murtagh, 1983; Scholtmeijer and Griffiths, 1988; Shah, Robins, and White 1978), and for 7 such surgical reports was 4.6 percent (range, 0–16.7 percent) (Beetz, Schulte-Wisserman, Tröger, et al., 1989; Birmingham Reflux Study Group, 1987; Burge, Griffiths, Malone, et al., 1992; Carpentier, Bettink, Hop, et al., 1982; Hjalmas, Lohr, Tamminen-Mobius, et al., 1992; Scholtmeijer and Griffiths, 1988; Scott, Blackford, Joyce, et al., 1986). These reports are difficult to compare directly, however, because the length of follow-up and distribution of reflux grades varied among the studies. In the majority of these studies, the minimum follow-up

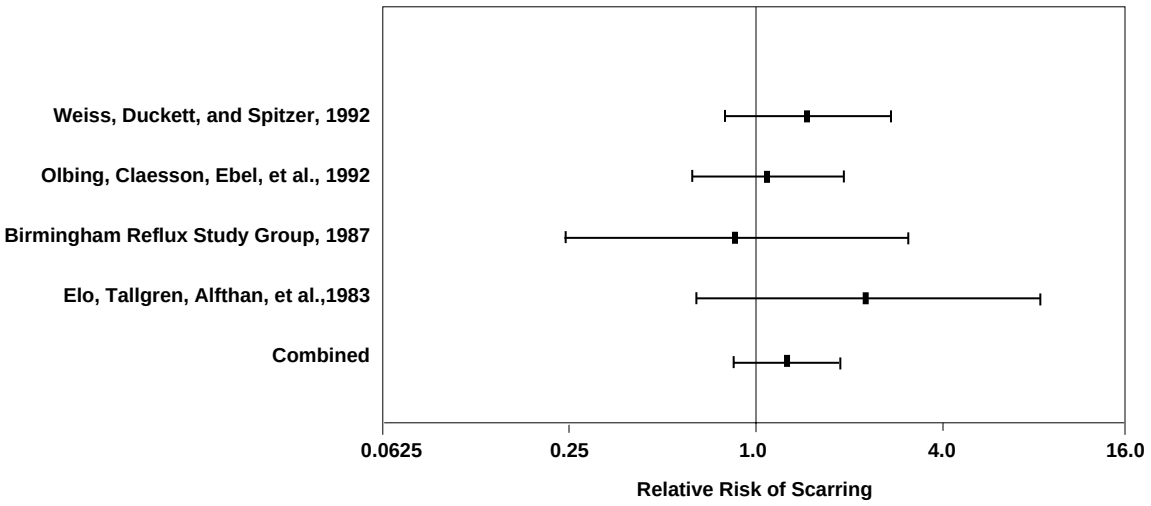

Figure 4. Relative risk of new scarring for surgery compared with antibiotic treatment

Analysis from 4 prospective trials of the risk of new scarring after surgery compared to that after medical treatment showed that the combined relative risk slightly favored medical management but was not statistically significant.

was 3 months. Furthermore, identification of renal scarring in most studies has depended on intravenous urography, but the quality of films and expertise of radiologists were probably inconsistent. The Birmingham Reflux Study (1987) identified new scars after 5 years in only 6 percent and 5.2 percent of children treated medically and surgically, respectively, with no additional scars detected after 2 years of follow-up. On the other hand, the International Reflux Study found new scars in 15.7 percent (medical) and 17.2 percent (surgical) of refluxing children in Europe and 21.5 percent (medical) and 31.4 percent (surgical) in North America (Table 8). When patients with VUR discovered before 5 years of age whose kidneys were of normal size by planimetry and had no evidence of renal scarring on initial intravenous urography were treated medically and followed for 5 years, renal scarring was detected in 10 percent of patients with Grades I or II reflux and 28 percent of those with Grade III VUR. Of the scars, 42 percent were detected after 1 year of follow-up, 25 percent after 3 years and 33 percent after 5 years (Arant, 1992). More recently, renal scarring has been confirmed on DMSA scan within 6 months after acute pyelonephritis in children (Rushton and Majd, 1992).

Renal scarring: Relationship to bacteriuria. Because VUR is most frequently diagnosed after an infant or child presents with UTI and animal models of ascending pyelonephritis (via surgically created VUR) reliably produce renal scarring, the 2 events, when they occur clinically, are often thought to be causally related. Renal scarring is often detectable on the initial renal imaging study obtained following the diagnosis of UTI, and is proportional to the severity of VUR and the sensitivity of the technique. This observation suggests that previous undiagnosed UTIs may have occurred, which resulted in pyelonephritic injury. However, new or progressive renal scarring during follow-up is less common, despite additional episodes of bacteriuria.

The panel attempted to analyze the relationship between bacteriuria and new renal scarring in children with reflux. However, few data are available that would permit such an analysis. Only 14 reports described the frequency of UTI in children with and without new or progressive renal scarring (Aggarwal, Verrier-Jones, Asscher, et al., 1991; Anderson and Rickwood, 1991; Arant, 1992; Beetz, Schulte-Wissermann, Tröger, et al., 1989; Birmingham Reflux Study Group, 1983; Birmingham Reflux Study Group, 1987; Cardiff-Oxford Bacteriuria Study Group, 1978; Edwards, Normand, Prescod, et al., 1977; Goldraich and Goldraich, 1992; McLorie, McKenna, Jumper, et al., 1990; Shah, Robins, and White, 1978; Skoog, Belman,

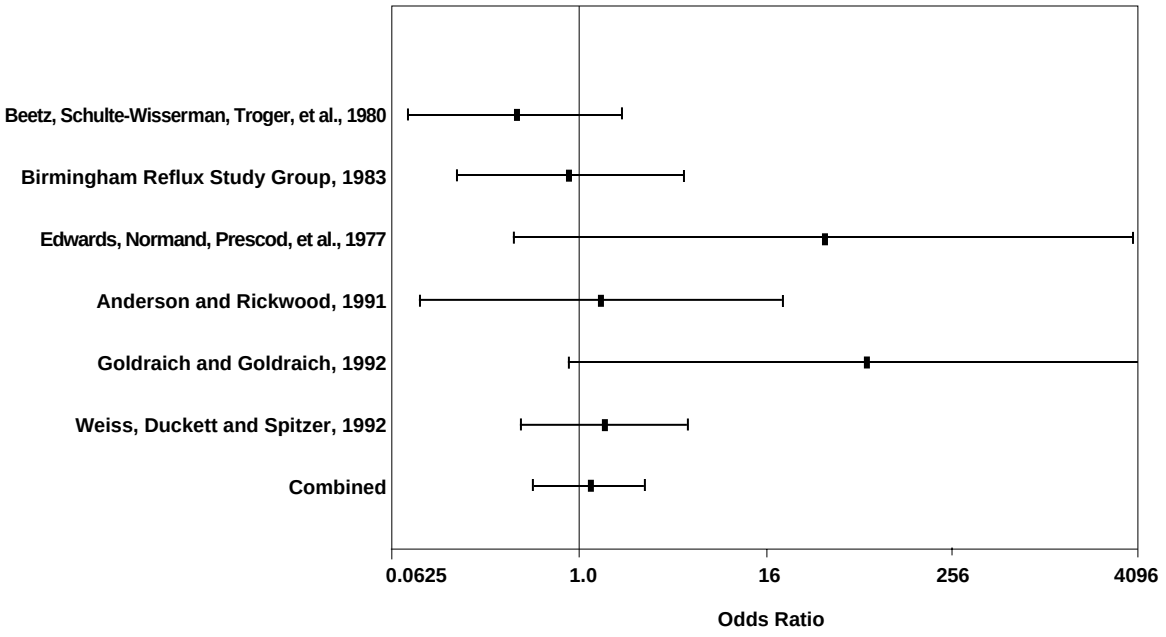

Figure 5. New or progressive scarring and bacteriuria

Analysis of the relationship of bacteriuria and renal scarring in children with reflux showed that the risk of developing new or progressive scarring was 1.18 times as great for an individual with UTI as that for an individual without infection (i.e., the risk is only slightly increased).

and Majd, 1987; Smellie, Gruneberg, Leakey, et al., 1976; Weiss, Duckett, and Spitzer, 1992). Most of these studies provided information only for the presence or absence of bacteriuria in those with new or progressive scarring, and not for those who did not develop such scarring. Using the empirical Bayes method of Hedges and Olkin (1985), an estimated odds ratio of 1.18 (95% CI 0.52–2.68) is derived (see Figure 5 on page 34). In other words, the risk of developing new or progressive scarring for an individual with UTI is 1.18 times as great as that for an individual without infection, that is, the risk of developing new or progressive scarring is only slightly increased.

Several factors may contribute to this surprising lack of association between scarring and infection in children with reflux. First, few of the reports characterized the types of infections (febrile, nonfebrile, asymptomatic) in these children. Febrile UTIs are more likely to represent renal parenchymal inflammation, and thus place the patient at greater risk for scarring than does nonfebrile UTI. In the study by Goldraich and Goldraich (1992), all 7 of the children with new renal scars by DMSA scan had a febrile UTI in the previous year. The remainder of the reports were not as precise. In addition, the progressive scarring recorded may have been the result of a UTI that occurred before treatment (medical or surgical) was initiated. The radiologic technique used to detect new or progressive scarring may not have been sufficiently sensitive to evaluate this parameter properly. Furthermore, once the initial diagnosis of UTI and VUR has been made, most parents/patients are more likely to be attuned to the symptoms of UTI (particularly fever), and patients are more likely to receive prompt diagnosis and treatment. In addition, it is possible that UTIs were under-reported to the investigator by referring physicians, or that suspected UTIs (or episodes of unexplained fever) may have been treated with an antibiotic without urine culture. For example, in a study of 50 febrile infants, all of whom underwent protocol urine culture, 15 ultimately found to have bacteriuria initially had received diagnoses other than UTI (Hoberman, Chao, Keller, et al., 1993).

Renal growth

A clinical impression, supported by many reports, is that renal growth is impaired when VUR

is present (Scott and Stansfield, 1968; Lyon, 1973; Redman, Scriber, and Bissada, 1974), especially with Grades IV and V reflux (Pinter, Jaszai, and Dober, 1988; McRae, Shannon, and Utley, 1974), or recurrent infection (Peratoner, Messi, and Fonda, 1984; Scott and Stansfield, 1968; Kelalis, 1971). Moreover, accelerated renal growth has been recorded after reflux was corrected (Carson, Kelalis, and Hoffman, 1982; Atwell and Vijay, 1978; Willscher, Bauer, Zammuto, et al., 1976; Scott and Stansfield, 1968) or during adolescence (Claesson, Jacobsson, Jodal, et al., 1981). Most studies with useful data on renal growth have been conducted retrospectively without an appropriate control group and for durations of follow-up in which some patients may have been followed no more than 1 year (Atwell and Cox, 1981; Atwell and Vijay, 1978; Willscher, Bauer, Zammuto, et al., 1976). Standardized methods for assessing renal growth have seldom been used, making comparisons among studies difficult. Furthermore, many patients have renal scarring when reflux is recognized or develop new or progressive scarring during follow-up (Birmingham Reflux Study Group, 1987; Bellinger and Duckett, 1984; Weiss, Duckett, and Spitzer, 1992; Olbing, Claesson, Ebel, et al., 1992; Smellie, Edwards, Normand, et al., 1981).

Renal growth is most often assessed as renal length measured from intravenous urography or, more commonly in recent years, by renal ultrasonography. Before interpreting data obtained using these techniques, it must be recognized that the distance between the table top and tray alters the renal image projected onto the film (Riggs, 1977). Renal dimensions are distorted when the distance between the x-ray source and film is altered and magnified when urographic films are taken when the patient is in the prone position. Poor technique or inadequate bowel preparation may obscure the exact margins of the renal outline. With renal ultrasonography, the angle of the transducer to the longitudinal aspect of the kidney may distort renal dimensions.

Of the various estimates of renal size from renal length, standards exist only for normal—not scarred—kidneys (Hodson, Drewe, Karn, et al., 1962; Hodson, Davies, and Prescod, 1975; Eklof and Ringertz, 1976; Rosenbaum, Korngold, and Teele, 1984). Moreover, some kidneys are “short and fat” while others are “long and thin.” Renal scarring is noted most often in upper or lower poles (Hannerz, Wikstad, Johansson, et al., 1987). Renal size can be assessed more reproducibly by estimating planimetric surface area (Claesson, Jacobsson, Olsson, et al., 1981). This two-dimensional measurement of renal parenchyma surface area from a standardized urographic film is not compromised by differences in renal width or hydronephrosis. In addition, identification of parenchymal thinning may be a more sensitive indicator of renal scarring in the small but growing kidney (Olbing, Claesson, Ebel, et al., 1992). Even when a parenchymal scar is not obvious, discrepancies in renal size between kidneys suggest unilateral disease in the smaller kidney, especially when compensatory hypertrophy in the contralateral kidney results in its being larger than expected for age, body length, or vertebral height (Claesson, Jacobsson, and Jodal, 1981). Renal size cannot be estimated from any radionuclear study currently in use. Even when a kidney contributes more than 50 percent of total renal function on a radionuclide scan, normal renal size cannot be presumed.

Two reported studies provide data on renal growth in patients with reflux treated either medically or surgically; each was conducted prospectively and had a minimum of 5 years of follow-up in every patient. The Birmingham Reflux Study (1987) used renal length whereas the International Reflux Study (Weiss, Duckett, and Spitzer, 1992) employed planimetric surface area—both taken from intravenous urography. At the outset of both studies, each treatment group included many patients with previous renal scarring. No differences in renal growth were detected between groups in either study. Another study that was not conducted prospectively reported similar findings—no difference in renal growth during medical management or after surgical correction of reflux (Peratoner, Messi, and Fonda, 1984). However, patients in both treatment groups had kidneys that were smaller than normal or that grew suboptimally during the follow-up period. The number of kidneys that were small because of renal scarring or parenchymal thinning was not reported. On the basis of clinical studies available to date, there is no evidence to support the notion that in the absence of voiding dysfunction, renal growth is impaired in unscarred kidneys exposed to sterile reflux of any grade (Arant, 1992; Smellie, Edwards, Normand, et al., 1981) or that surgical correction of reflux facilitates growth of the kidney postoperatively (Birmingham Reflux Study Group, 1987; Peratoner, Messi, and Fonda, 1984; Beetz, Hohenfellner, Schofer, et al., 1991; Weiss, Duckett, and Spitzer, 1992).

Renal function

The rationale for identifying reflux early is to introduce treatment that best prevents scarring and preserves renal function. Scott, Blackford, Joyce, et al. (1986) reported marked improvement in glomerular filtration rate (GFR) for most patients in whom reflux was corrected surgically. Using the same technique for measuring GFR, however, Poulsen, Johannesen, Nielsen, et al. (1989) found that GFR was preserved during nonsurgical management of children with reflux. During long-term observations, others have found no adverse effect of continued sterile reflux on kidney function (Birmingham Reflux Study Group, 1987; Weiss, Duckett, and Spitzer, 1992). In prospective, controlled treatment trials, surgical correction of even severe reflux has had no benefit on GFR 5 years later (Birmingham Reflux Study Group, 1987; Weiss, Duckett, and Spitzer, 1992).

When renal scarring is severe but unilateral, renal function would be expected to be normal. Even when both kidneys are scarred, overall renal function may be preserved by compensatory changes in structure and function of remaining nephrons (Berg, 1992). In fact, the degree of renal functional impairment in patients with reflux nephropathy has been related directly to parenchymal size of both kidneys (Claesson, Jacobsson, Jodal, et al., 1981). Serum creatinine concentration will remain within the range of normal values for age until scarring reduces functional nephron mass sufficiently to lower GFR. When renal function is decreased below normal for age, one must conclude that maximal functional compensation has taken place already in kidneys that are small or scarred.

A radionuclide study that reports an allocation of the percent of isotope excreted by right and left kidneys cannot be used to interpret overall renal function. Total GFR should be corrected to 1.73 m^2 body surface area and calculated by timed urine collection and clearance methodology, from serum creatinine and height (Schwartz formula) or from another radionuclide study that measures and reports actual GFR as well as split functions. No decision to remove a kidney or surgically correct VUR can be made on the basis of split functions alone. When a patient has bilateral renal scarring, every functioning nephron should be conserved because each contributes to overall renal function.

Health outcomes

Urinary tract infection

Most infants and children with VUR present with UTI, usually acute pyelonephritis with the attendant risk of renal parenchymal injury (Weiss, Tamminen-Mobius, Koskimies, et al., 1992). The relationship between renal injury (presumably pyelonephritic scarring) and UTI complicated by acute pyelonephritis has been examined (Martinell, Claesson, Lidin-Janson, et al., 1995). UTIs were characterized retrospectively by conventional criteria (e.g., fever) as either acute pyelonephritis, cystitis or unspecified. Of the 45 patients with renal scarring, 33 (73 percent) had acute pyelonephritis as their first UTI, compared with 18/42 (43 percent) who did not have renal scarring ($p < .001$).

Pyelonephritis can result in destruction of one or more lobes of the kidney with replacement of normal kidney by fibrotic tissue (renal scarring). In addition to short-term morbidity, the long-term consequences of renal scarring include hypertension and functional impairment, both most frequently seen after loss of critical mass of kidney tissue. Thus, prevention of UTI, and particularly acute pyelonephritis, is an important goal in the management of infants and children with VUR.

UTI may occur following diagnosis of reflux and initiation of therapy. If it occurs in a child receiving antibiotic prophylaxis, the infection may occur because of antibiotic resistance to the prophylactic antibiotic (in which case the organism is resistant to the antimicrobial) or because of non-compliance with therapy (in which case the organism is usually sensitive to the antimicrobial). Children who have undergone successful surgical therapy often do not continue to receive antibiotic prophylaxis after the imaging studies demonstrating reflux resolution have been performed. In these children, development of UTI is independent of the previous structural abnormality and secondary to host uroepithelial adherence characteristics and bacterial virulence factors.

The panel reviewed 41 articles that reported the incidence of UTI (as defined by bacteriuria, regardless of clinical symptoms) in children with VUR treated either with antibiotic prophylaxis or reimplantation surgery. The International Reflux Study in Children randomized infants and children with Grades III and IV VUR to either medical or surgical management. In the European branch of the study (Jodal, Koskimies, Hanson, et al., 1992), 59

of 151 surgical patients (39.1 percent) had at least 1 UTI during the 5-year follow-up (0.65 per 100 patient-months), compared with 59 of 155 medical patients (38.1 percent) (0.63 per 100 patient-months). In the U.S. branch (Weiss, Duckett, and Spitzer, 1992), 21 of 64 surgical patients (32.8 percent) (1.8 per 100 patient-months) compared with 20 of 68 medical patients (29.4 percent) (2.3 per 100 patient-months) had at least 1 UTI during the 5-year follow-up. There was no significant difference in UTI rate between medical and surgical treatment either in the European or the U.S. data. The incidence of UTI in a third uncontrolled, but matched (n = 40 each) study was 2.81 per 100 patient-months following surgery and 3.34 per 100 patient-months with medical management with a comparable duration of follow-up (Elo, Tallgren, Alfthan, et al., 1983). Combining data from all 3 studies yields a relative risk of 0.97 (95% CI 0.79–1.19), indicating almost no difference between the 2 treatments with respect to the risk of bacteriuria. In support of this observation, another study (Beetz, Schulte-Wissermann, Tröger, et al., 1989) reported an incidence of UTI after surgery alone that was comparable to the surgical arms of the 2 randomized controlled trials, and a study of UTI with antibiotic prophylaxis alone (Hanson, Hansson, and Jodal, 1989) reported rates comparable to those in the medical arms of the 2 randomized controlled trials.

Because the risk of renal injury is related to acute pyelonephritis rather than to UTI in general, incidence rates of acute pyelonephritis were compared in both the European and U.S. branches of the International Reflux Study in Children. In the European branch (Jodal, Koskimies, Hanson, et al., 1992), acute pyelonephritis was observed in 15 of 151 surgical patients (9.3 percent) (0.17 per 100 patient-months) compared with 33 of 155 medical patients (21.3 percent) (0.35 per 100 patient-months) (p = 0.03). In the U.S. branch (Weiss, Duckett, and Spitzer, 1992), 5 of 64 surgical patients (7.8 percent) (0.3 per 100 patient-months) compared with 15 of 68 medical patients (22.1 percent) (0.7 per 100 patient-months) had at least 1 episode of acute pyelonephritis (p = 0.085). In the nonrandomized and uncontrolled, but matched study (Elo, Tallgren, Alfthan, et al., 1983), 72.5 percent medical patients compared with 22.5 percent surgical patients (1.41 per 100 patient-months medical and 0.44 per 100 patient-months surgical) had acute pyelonephritis. Combining the data from the 3 studies, the relative risk of acute pyelonephritis with surgical treatment is 0.39 (95% CI 0.26–0.58) compared with medical treatment (Figure 6). An additional uncontrolled and unmatched study examined the incidence of acute pyelonephritis with either surgery or medical therapy (Amar, Singer, and Chabra, 1976). Follow-up varied from 1–14 years. Acute pyelonephritis was reported in

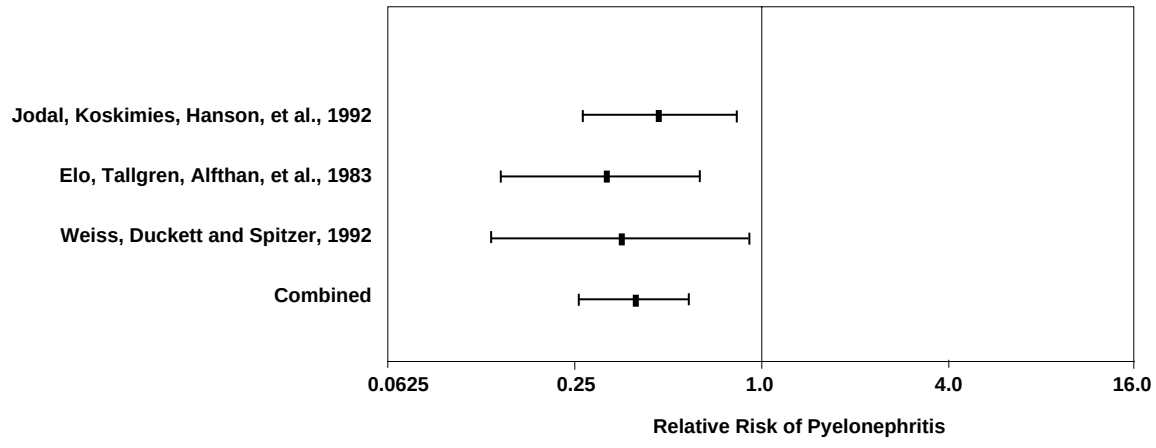

Figure 6. Relative risk of pyelonephritis for surgery compared with antibiotic treatment

Analysis of the risk of acute pyelonephritis after surgery compared to that after medical treatment showed the combined relative risk significantly favored surgical treatment. The combined relative risk of acute pyelonephritis with surgical treatment is 0.39 (95% CI 0.26–0.58) compared with medical treatment.

none of 111 surgical patients compared with 5 of 99 medical patients. In a study of surgical patients only (Willscher, Bauer, Zammuto, et al., 1976), 223 children were followed postoperatively for 0.5–7 years. Three of 175 girls (1.7 percent) had acute pyelonephritis. In a study of medical patients only (Hanson, Hansson, and Jodal, 1989), 12 of 44 (27.3 percent) girls who were treated for 860 months developed acute pyelonephritis (1.44 per 100 patient-months).

In summary, of the few studies that were adequate for analysis, the overall incidence of UTI in patients with VUR was not significantly different in patients treated with antibiotic prophylaxis (medical management) or ureteral reimplantation (surgical management). The incidence of acute pyelonephritis was significantly greater with medical management. Despite the risk of renal parenchymal injury from acute pyelonephritis and its potential for healing with scarring, the incidence of scarring was no greater in medical than in surgical patients (Jodal, Koskimies, Hanson, et al., 1992; Weiss, Duckett, and Spitzer, 1992). The factors that may account for the surprising lack of an association between new or progressive renal scarring and pyelonephritis in the literature are discussed on pages 33–34.

Hypertension

Reflux nephropathy is considered one of the most common causes of severe hypertension in children, when it is examined in a retrospective fashion (i.e., of those who present with severe hypertension, reflux nephropathy is a frequent diagnosis). The panel reviewed 10 studies that reported blood pressure (BP) measurements after reimplantation surgery. Only 2 characterized the patient population sufficiently to provide meaningful analysis. Wallace, Rothwell, and Williams (1978) reported longer than 10-year follow-up of 166 children with VUR treated surgically. Of 158 preoperative BP measurements that were compared with the American Academy of Pediatrics 1977 BP norms, 24 (15.2 percent) had BP higher than the 95th percentile for age and sex (either systolic, diastolic, or both.) Hypertension was defined as a BP of ‡140/90 in their follow-up, because all 141 subjects were older than 14 years of age. Eighteen (12.8 percent) were hypertensive. Of these, 7 had preoperative bilateral renal scarring (of 38 with this finding on IVU) and 7 had preoperative unilateral renal scarring (of 62 with this finding on IVU). In Beetz' series (Beetz, Schulte-Wissermann, Tröger, et al., 1989), 189 children were evaluated at least 5 years after successful VUR surgery. Ten patients (5.3 percent), all of whom were older than age 14, were found to be hypertensive (BP > 140/90). Of 61 patients with renal scarring (all preoperative), 7 (11.5 percent) were hypertensive at the time of follow-up compared with 3 of 128 patients (2 percent) of those without scarring. Preoperative BP levels were not reported.

Lenaghan, Whitaker, Jensen, et al. (1976) reported hypertension (defined as >140/90) in 10 of 102 children (9.8 percent) treated nonsurgically, who were followed-up for 5–18 years. Patients with scarred kidneys were not distinguished from those without scarring.

Thus, no statistically significant difference was found in the risk of hypertension related to treatment modality (medical or surgical). These studies indicated that renal scarring increases the relative risk of hypertension to 2.92 (95% CI 1.2–7.1), compared with the risk in patients without renal scarring.

Numerous medications are used to treat hypertension in children and adults with renal scarring. Angiotensin-converting enzyme inhibitors, which may be used for treatment of those with renin-mediated hypertension, may be associated with some side effects (Kim and Swartz, 1993). In addition, use of these drugs during pregnancy may cause oligohydramnios and irreversible neonatal renal failure (Rosa, Bosco, Graham, et al., 1989).

Uremia

Since 1987, the North American Pediatric Renal Transplant Cooperative Study has registered virtually all children with end-stage renal disease (ESRD), defined as a GFR so low that only kidney dialysis or transplantation will sustain life. Although overlap of diagnostic categories (e.g., hypoplasia, dysplasia, obstructive uropathy) is likely, VUR was the primary diagnosis in 3.1 percent of this population (Avner, Chavers, Sullivan, et al., 1995). Those with VUR who develop ESRD typically have been those who present with reduced GFR and bilaterally small, scarred kidneys. It is thought that independent of further pyelonephritic injury, these patients have sustained the loss of a critical mass of renal tissue, such that progressive loss of function due to glomerulosclerosis is mediated by maladaptive hemodynamic events (Neuringer and Brenner, 1993).

Although UTI is the most frequent presentation of VUR, it is less commonly the presentation of those patients with impaired GFR, virtually all of

whom have bilateral extensive renal scarring on the initial kidney imaging study. Also, antenatal detection of bilateral hydronephrosis has identified a population of neonates with severe bilateral VUR and impaired GFR before any UTI has occurred. How many patients develop uremia from congenital reflux nephropathy (or dysplasia associated with VUR), rather than after acquired reflux nephropathy from 1 or more pyelonephritic events, remains unknown. Thus, it would not be possible to demonstrate that even optimal treatment of VUR and UTI can prevent progressive renal failure and, ultimately, uremia, once bilateral reflux nephropathy has been diagnosed.

Somatic growth

Two studies mentioned somatic growth associated with nonsurgical VUR treatment and follow-up (Pinter, Jaszai, and Dober, 1988; Smellie, Preece, and Paton, 1983). Neither study substantiated an effect of VUR treatment on somatic growth.

Morbidity during pregnancy

Because of the known association between bacteriuria and adverse outcomes in pregnancy, there is a common perception that the increased risks of pyelonephritis and renal scarring in patients with vesicoureteral reflux may potentially result in increased morbidity during pregnancy in women who have persistent reflux. The panel did not undertake an extensive literature search of references pertaining to the association between reflux and adverse outcomes of pregnancy. However, based on a more selective review, what follows is the panel's current understanding of this association.

One of the potential late complications of VUR and/or pyelonephritic scarring in females is maternal and fetal morbidity. Maternal problems include pyelonephritis, septicemia, renal scarring, hypertension, toxemia, and reduction in renal function, which in some women progresses to ESRD. Fetal complications include preterm delivery, low birth weight, and fetal loss.

On the basis of a retrospective review of 26 studies that included a total of 82,364 pregnancies, approximately 4–7 percent of pregnant women have asymptomatic bacteriuria (Sweet, 1977). If asymptomatic bacteriuria is not treated, pyelonephritis is common. From a combination of 18 studies of pregnant bacteriuric women who were not treated with antibiotics, 28 percent of 1,699 women developed pyelonephritis (Sweet, 1977). Kass (1960) observed a 42-percent incidence of pyelonephritis in 48 patients when asymptomatic bacteriuria in pregnancy was not treated. When bacteriuria was eliminated, pyelonephritis did not occur (Kass, 1960). Women with a history of UTI in childhood appear to have a higher risk of asymptomatic bacteriuria. Martinell, Jodal, and Lidin-Janson (1990) and Sacks, Roberts, Verrier Jones, et al. (1987) found an incidence of 37 percent (24/65 pregnancies) and 50 percent (24/48 pregnancies), respectively. If renal scarring was present, the risk increased to 47 percent (9/19) (Martinell, Jodal, and Lidin-Janson, 1990) and 60 percent (9/15) (Sacks, Roberts, Verrier-Jones, et al., 1987).

Pregnant women with pyelonephritic renal scarring appear to be at higher risk for pyelonephritis than those without renal scarring. In a study of 41 pregnant women with a history of childhood UTI, Martinell, Jodal, and Lidin-Janson (1990) reported an incidence of 21 percent (4/19) in those with scarring compared with 5 percent (1/22) in those without renal scarring. Jacobson (1991) reported that 3 of 30 pregnant women with renal scarring developed pyelonephritis.

The relationship between asymptomatic bacteriuria and maternal/fetal complications is controversial. A meta-analysis of 17 cohort studies including 23,298 patients showed that in women with asymptomatic bacteriuria, the risk of preterm delivery was 2 times higher and the risk of having a low-birthweight baby was 1.5 times higher compared with women without bacteriuria (Romero, Oyarzun, Mazor, et al., 1989). Kincaid-Smith and Bullen (1965) demonstrated that women with bacteriuria at their first prenatal visit had a 2.9 times higher risk of fetal loss during the second and third trimesters, the risk of preterm delivery was 2.7 times higher and the risk of pre-eclampsia was 1.8 times higher than that in women without bacteriuria. Many of these women also had underlying renal scarring. Schieve, Handler, Hershow, et al. (1994) reported on the effects of pyelonephritis during pregnancy on maternal and fetal outcome. Of the 25,476 mother/infant pairs studied, 7.7 percent had a documented UTI. In those with pyelonephritis, the risk of perinatal death was 2.6 times higher and the risk of preterm delivery or low birth weight was 2.5 times higher than in those without UTI.

In women with reflux nephropathy and reduced renal function, the risk of complications is considerable. In addition to pyelonephritis, potential problems include further reduction in GFR, toxemia, preterm delivery, and fetal loss (see Table 9 on page 40). Women with renal scarring and chronic

Table 9. Maternal and fetal complications in patients with moderate or severe renal insufficiency

[1] Rapid deterioration in renal function in all 6 women; 4 progressed to ESRD within 2 years post delivery.
[2] Four with uncontrolled hypertension had rapid deterioration in renal function with progression to ESRD; 10 had slow deterioration in renal function over 7 years but not to ESRD.
[3] Renal deterioration defined by an increase in SCr of 50% during pregnancy.
[4] Of 7 patients without deterioration of renal function during pregnancy, 6 later had deterioration of renal function and 4 required dialysis within a mean interval of 39 months.
[5] Five of 14 patients had accelerated deterioration of renal function with progression to ESRD in 6 months to 4 years.
[6] During pregnancy and up to 6 weeks postpartum; 31% after 6 months postpartum.

hypertension who are receiving angio-tensin-converting enzyme inhibitor therapy (captopril, enalapril) are at particular risk for oligohydramnios and neonatal renal failure, which may be irreversible (Rosa, Bosco, Graham, et al., 1989). This class of drugs, which often is extremely effective, should not be used during pregnancy (Cunningham and Lindheimer, 1992).

The morbidity of persistent reflux during pregnancy has not been studied extensively. Williams, Davies, Evans, et al. (1968) found that 21 percent of women with asymptomatic bacteriuria during pregnancy had reflux on VCUG performed 6 months postpartum, compared with 1.7 percent in a randomly selected group of women examined immediately postpartum (Heidrick, Mattingly, and Amberg, 1967). Martinell, Jodal, and Lidin-Janson (1990) reported that pyelonephritis occurred during pregnancy in 3 of 8 women with reflux, but only 2 of 33 in those without reflux. In the 8 patients with reflux, pyelonephritis occurred in 3 of 9 of pregnancies managed with continuous antibiotic prophylaxis and 2 of 4 managed without prophylaxis.

In this series, reflux generally was Grade I or II. Heidrick, Mattingly, and Amberg (1967) reported that 3 of 9 women with reflux developed pyelonephritis during pregnancy compared with 15 of 312 women without reflux. Although the data suggest a greater risk of morbidity from pyelonephritis in women who have persistent reflux during pregnancy, the sample size is small and only limited conclusions can be made on the basis of this evidence.

Few studies have focused on the outcomes of pregnancies of women with surgically treated reflux. Fryczkowski, Maruszewska, Paradysz, et al. (1991) reported that in 59 pregnancies in 34 women who had undergone antireflux surgery in childhood, 65 percent (22/34) had a UTI during pregnancy, but the incidence of pyelonephritis was not reported. Mansfield, Snow, Cartwright, et al. (1995) studied 62 women who underwent antireflux surgery as children and compared them with 21 women with uncorrected childhood reflux who had not had radiologic follow-up and whose reflux status was unknown. In the surgically treated group, 40 percent (57/141) of pregnancies were complicated by a UTI (18 percent pyelonephritis; 22 percent cystitis). In the uncorrected group, 1.3 percent (1/75) had pyelonephritis and 13.3 percent (10/75) had cystitis. The 2.5 times higher incidence of UTIs demonstrated in the surgically treated group has not yet been explained adequately but may be related to host factors that subject them to a higher inherent risk of UTI. In this retrospective study, no data were presented concerning the initial presentations, voiding dysfunction, indications for patient selection for surgery, or extent of renal scarring. Antibiotic prophylaxis during pregnancy was inconsistently prescribed. There was no significant difference in the rate of fetal loss in the 2 groups. Although these studies indicate that UTIs are common during pregnancy in patients who have undergone antireflux surgery, data are not presented on the effect of antireflux surgery on subsequent pyelonephritis.

Death

Death can be attributed to VUR only indirectly. Unrecognized or inadequately treated UTI may result in urosepsis and death, which occurred frequently in the pre-antibiotic era. Moreover, death could occur as a complication of anesthesia or surgery performed to correct VUR. In a patient with renal scarring who develops hypertension which, after a period of being asymptomatic, may result in heart failure or encephalopathy, death could result if treatment were unsuccessful. Women with bilateral renal scarring, even those with no previous symptoms, may exhibit acute deterioration of renal function during pregnancy and require aggressive treatment to prevent death; some of these women regain renal function after delivery, while others do not (Jacobson, Eklof, Eriksson, et al., 1989). Progressive deterioration of renal function over many years in patients with severe bilateral renal scarring is a major cause of ESRD in patients younger than 30 years of age (Arant, 1991; Pistor, Scharer, Olbing, et al., 1985; Salvatierra, Kountz, and Belzer, 1973; Mathew, 1987). The average mortality rate for patients on chronic dialysis in the United States is about 25 percent each year (Bloembergen, Port, Mauger, et al., 1994). Others die as a complication of renal transplantation. While none of these causes of death is the immediate consequence of untreated VUR, the possibility of an association cannot be ignored.

Harms of medical treatment

Adverse drug reactions

Antibiotic prophylaxis. One of the mainstays of the medical management of VUR is antimicrobial prophylaxis. The usual medications administered are trimethoprim/sulfamethoxazole, trimethoprim alone, and nitrofurantoin. The dose prescribed for prophylaxis typically is one-fourth to one-third of the dose recommended for full therapy. The incidence of drug-related adverse effects is lower with reduced dosages. Most reports describing adverse drug reactions pertain to adult patients taking the full dosage of the medication (Lawson and Paice, 1982).

Potential adverse reactions to antimicrobial prophylaxis include minor effects such as nausea, vomiting, abdominal pain, and bad taste in the mouth, as well as more serious side effects (Table 10 on page 42). Very few studies dealing with the medical management of reflux have reported minor effects. Determining whether abdominal complaints are related to medication or some other factor is often difficult. Underreported side effects may contribute to the lack of compliance with medication in some cases, and the need to change antibiotic prophylaxis because of side effects is also probably underreported. Bacterial resistance to antibiotic prophylaxis may also occur and is discussed in the section on UTI (page 36).

Reported side effects of trimethoprim/sufamethoxazole prophylaxis are uncommon. Uhari, Nuutinen,

Table 10. Adverse effects of antimicrobials commonly prescribed for antibiotic prophylaxis in children

Antibiotic	Adverse reactions
Cotrimoxazole	Skin rash/urticaria, nausea, vomiting, anorexia, dental caries (1–4%)
	Rare (<0.1%): serious dermatologic, hematologic, cardiovascular, central nervous system, endocrine, renal, hepatic effects
Trimethoprim	Skin rash/urticaria, nausea, vomiting, anorexia (2.5–7%)
	Rare (<0.1%): serious dermatologic, hematologic, cardiovascular, central nervous system, endocrine, renal, hepatic effects
Nitrofurantoin	Nausea, vomiting, abdominal pain 34% (less with macrocrystals) Headache, dizziness (less with macrocrystals); skin rash/urticaria
	Rare (<0.1%): hematologic, cardiovascular, central nervous system, gastrointestinal, hepatic, respiratory, dermatologic effects

Source: Computerized Clinical Information System, March 1996 (Micromedex, Inc., Denver CO); American Hospital Formulary Service Drug Information, 1995.

and Turtinen (1996) reported that medication was changed because of adverse effects in 15 percent of children receiving sulfonamides and 8 percent receiving trimethoprim. The most common adverse effect is allergic skin reaction, usually from the sulfa, and accounts for 90 percent of nonfatal drug reactions (Lawson and Paice, 1982). Uhari, et al. (1996) reported that 4.5 percent of children receiving prophylaxis developed urticaria, with an incidence of 7.4 events per 100 years at risk. Allergic skin reaction may occur after several weeks or months of therapy, but anaphylaxis is rare. Although neutropenia, thrombocytopenia and/or eosinophilia occur in 12–34 percent of children taking full-dose trimethoprim/sulfamethoxazole for only 10 days (Asmar, Maqbool, and Dajani, 1981), the incidence of these side effects in children receiving prophylactic dosages for periods as long as 1 year ranged from 0 percent (Smellie, Gruneberg, Normand, et al., 1982; Uhari, Nuutinen, and Turtinen, 1996) to 41 percent (Holland, Kazee, Duff, et al., 1982). In the latter study, in children with a white blood count (WBC) less than 5000/mm3, the WBC level normalized by the following visit in all cases. Another potential problem is dental caries related to the fructose in the liquid preparation, but this can be prevented by having the children brush their teeth after taking the drug. Other side effects include nausea, vomiting, abdominal pain, hepatotoxicity, and significant hypersensitivity reaction, but these effects have been reported only anecdotally in children. Although sulfamethoxazole and trimethoprim compete for sequential sites in the metabolic pathway of bacterial folic acid synthesis, children receiving prophylaxis have not developed folic acid deficiency. Trimethoprim/sulfamethoxazole is the most common drug associated with reactions requiring hospital admission, although the drug accounted for only 0.07 percent of hospital admissions (Mitchell, Lacouture, Sheehan, et al., 1988).

Trimethoprim alone has been reported to cause side effects in as many as 27 percent of patients (Brendstrup, Hjelt, Petersen, et al., 1990). Reported side effects included nausea, vomiting, or abdominal pain in 14 percent of patients, bad taste in the mouth in 6 percent, and headache, dizziness, dermatitis and pruritus in 8 percent. Of children receiving trimethoprim prophylaxis, 8 percent changed the drug because of side effects (Uhari, Nuutinen, and Turtinen, 1996). Hematologic and allergic reactions are uncommon (Smellie, Gruneberg, Normand, et al., 1982).

The incidence of side effects associated with nitrofurantoin depends on the drug preparation. Nitrofurantoin suspension is tolerated poorly, and as many as 55 percent of children taking this medication experience a side effect, including nausea, vomiting, or abdominal pain in 34 percent, bad taste in the mouth in 27 percent, and headache, dizziness, dermatitis, pruritus or fever in 12 percent; 30 percent changed the medication because of side effects (Brendstrup, Hjelt, Petersen, et al., 1990). Many of these effects may be eliminated by administering nitrofurantoin macrocrystals. The capsule may be opened and placed in the children's

food if they are unable to swallow the capsules. One group of children using the macrocrystals experienced no adverse effects (Lohr, Nunley, Howards, et al., 1977). Hematologic side effects are infrequent (Holland, Kazee, Duff, et al, 1982). More serious adverse reactions are extremely rare, with 1 study documenting only 40 reports out of 8.6 million uses (Coraggio, Gross, and Roscelli, 1989). Approximately 32 percent of children younger than age 2 years and 10 percent older than 2 years of age taking nitrofurantoin prophylaxis changed therapy because of adverse reactions (Uhari, Nuutinen, and Turtinen, 1996). In that study, it was not indicated whether children were receiving the suspension or macrocrystal preparation.

Anticholinergics. In children with bladder instability and VUR, anticholinergic therapy and timed voiding are often recommended in addition to antibiotic prophylaxis. Although several reports describe the frequency of reflux resolution in these patients, few descriptions of the adverse effects of anticholinergic medications are available. One reason for this lack of information may be that the dosage of anticholinergic medication is usually titrated to the lowest effective dose in each child, providing the maximum therapeutic effect in reducing bladder instability while minimizing the side effects. Facial flushing can be brought on more easily in warm or hot temperatures; thus, a lower dose may be necessary in summer or warm climates. A dry mouth is common. This side effect may be particularly bothersome to some children, yet have minimal effect on others. Table 11 lists possible adverse effects of the most commonly prescribed anticholinergic medications.

Hospitalization of patients receiving medical treatment

Many studies reported occurrences of UTI in children with reflux who received medical therapy, and some distinguished between episodes of clinical pyelonephritis and cystitis (Cardiff-Oxford Bacteriuria Study Group, 1978; Hanson, Hansson, and Jodal, 1989; Weiss, Duckett, and Spitzer, 1992). However, none of the studies reported on the proportion of children experiencing clinical pyelo-nephritis who required hospitalization.

Children with clinical pyelonephritis often have fever, and flank or abdominal pain, and may experience nausea, vomiting, and diarrhea. Decisions about whether to admit a child to the hospital for intravenous antibiotic therapy and rehydration vary, and may depend on duration and severity of symptoms, hydration status, sensitivity pattern of the bacterial strain and the child's age. If a child is hospitalized for pyelonephritis, in 1992 the mean length of stay was 4.1 days (U.S. Department of Health and Human Services, 1993).

Harms of surgery

Ureteral obstruction is a recognized complication following ureteral reimplantation. The other harms of surgical treatment of VUR occur less frequently. Many reports do not describe harms explicitly. Others indicate isolated events within the series, and these reports were used to review the types and approximate frequencies of surgical complications of antireflux surgery. The panel recognizes, however, that due to underreporting, the absence of reported complications in many studies may be misleading and that the actual complication rates may exceed reported values.

Table 11. Adverse effects of anticholinergic medications most commonly prescribed for bladder instability in children

Antibiotic	Adverse reactions
Oxybutynin chloride	Xerostomia (usually dose related) 40–45% vasodilation, facial flushing, mydriasis, decreased sweating, tachycardia, blurred vision, drowsiness, constipation (5–30%)
	Rare (< 0.1%): urinary retention, urticaria, hallucinations
Hyoscyamine	Xerostomia, decreased sweating, mydriasis, drowsiness, restlessness, blurred vision, tachycardia (5–30%)
	Rare (< 0.1%): Central nervous system effects, urinary retention, urticaria, speech disturbances
Propantheline	Xerostomia, constipation, cycloplegia (5–30%)
	Rare (<0.1%): Central nervous system, cardiovascular, endocrine, renal effects

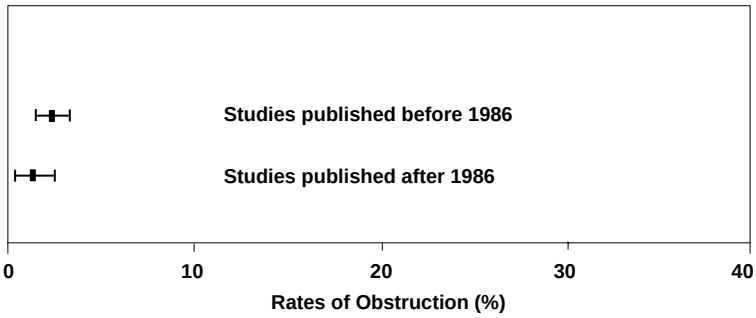

Figure 7. Combined rates of obstruction after surgery

Analysis of 33 studies showed that the rate of obstruction after ureteral reimplantation for VUR was 2 percent in studies after 1986 compared to a rate of approximately 4 percent in studies before 1986.

Obstruction

Thirty-three studies provided rates of obstruction after ureteral reimplantation for VUR (Table E–4, Appendix E). Figure 7 (page 44) shows the rate of obstruction in studies before and after 1986. All studies used either renal ultrasonography or intravenous pyelography to detect hydronephrosis indicative of obstruction. The likelihood of obstruction in the 33 series ranged from 0–9.1 percent, with a combined rate of 2 percent after 1986 (95% CI 1–4). The rate of obstruction was similar for different types of repair. Fourteen studies provided data regarding reoperation for obstruction (Table E-5, Appendix E). The reoperation rate ranged from 0.3–9.1 percent, with an overall incidence of 2 percent. On the basis of these studies, nearly every case of obstruction leads to reoperation so that the best estimate of obstruction is probably the proportion of patients requiring reoperation (2 percent).

Obstruction following endoscopic treatment of reflux. Fifteen series provided detailed information about postoperative ureteral obstruction following the subureteric injection technique as described by O'Donnell and Puri (1984) (Farkas, Moriel, and Lupa, 1990; Sauvage, Saussine, Laustriat, Becmeur, et al., 1990; Dodat and Takvorian, 1990; Puri, 1990; King and Gollow, 1988; Schulman, Pamart, Hall, et al., 1990; Sweeney and Thomas, 1987; Dewan and O'Donnell, 1991; Kaminetsky and Hanna, 1991; Davies and Atwell, 1991; Leonard, Canning, Peters, et al., 1991; Bhatti, Khattak, and Boston, 1993; Frey, Berger, Jenny, et al., 1992; Dewan and Guiney, 1992; Lipsky and Wurnschimmel, 1993). Using renal ultrasound or excretory urography, the incidence of transient dilation was reported in 2 series at 17 and 23 percent (Sweeney and Thomas, 1987; Bhatti, Khattak, and Boston, 1993). The 15 series included a total of 1,741 refluxing ureters treated using either Teflon™ (1,437 ureters) or collagen (304 ureters) as the injected substance. Seven (0.40 percent) persistent obstructions were reported, requiring ureteral reimplantation in 5, ureteral catheter drainage (5 days) in 1, and an unknown treatment in 1 (Dodat and Takvorian, 1990; Puri, 1990; Schulman, Pamart, Hall, et al., 1990; Sweeney and Thomas, 1987; Dewan and O'Donnell, 1991). All persistent obstructions reported occurred in patients with reflux who were treated with Teflon™. The amount of experience with the technique that the centers had gained when the obstructions occurred was not reported. In 10 of the 15 centers, persistent obstructions were not reported.

Bleeding

Although hematoma was reported in only 2 of 771 patients (0.26 percent) undergoing Politano-Leadbetter or Cohen transtrigonal ureteral reimplantation (Brandell and Brock, 1993; Ehrlich, 1985; Ehrlich, 1985; Broaddus, Zickerman, Morrisseau, et al., 1978; Price, Johnson, and Marshall, 1970; Garrett and Switzer, 1966; So, Brock, and Kaplan, 1981; Jonas, Many, Boichis, et al., 1974; Pypno, 1987; Ahmed and Tan, 1982), it occurred in 15 of 1,257 patients (1.2 percent) who received surgery using the Lich-Gregoir method (Arap, Abrao, and Menezes-de-Goes, 1981; Zaontz, Maizels, Sugar, et al., 1987; Funke, Chiari, and Planz, 1980; Marberger, Altwein, Straub, et al., 1978; McDuffie, Litin, and Blundon, 1977; Hampel, Richter-Levin, and Gersh, 1977; Hohenfellner, 1971; Houle, McLorie, Heritz, et al., 1992;

Wacksman, Gilbert, and Sheldon, 1992). In 1 study of the Lich-Gregoir technique, hematoma was reported in 13 of 371 patients (3.5 percent) (Marberger, Altwein, Straub, et al., 1978). Although bleeding from the bladder is thought to be less common after the Lich-Gregoir method than after the intravesical methods (Politano-Leadbetter, transtrigonal Cohen, or Glenn-Anderson advancement), specific data relating to this factor are not available.

Infection

Surgical wound infection following antireflux surgery was reported explicitly in only 2 cases (Garrett and Switzer, 1966). Other series did not report the occurrence or specific absence of this complication.

Bladder injury/voiding dysfunction

Several reports of temporary voiding dysfunction after extravesical ureteral surgery for reflux have been published. The incidence was as high as 15 percent in several series (Houle, McLorie, Heritz, et al., 1992; Wacksman, Gilbert, and Sheldon, 1992; Zaontz, Maizels, Sugar, et al., 1987). In most cases, the voiding dysfunction was associated with bilateral ureteral surgery and was self-limiting. However, intermittent catheterization, which may be problematic for families, was required during the period of voiding dysfunction. Late follow-up suggests that essentially all patients are likely to fully regain voiding efficiency (Fung, McLorie, Jain, et al., 1995). The overall incidence associated with the Lich-Gregoir method was 10 of 125 (8%), in contrast to no reported cases after intravesical techniques.

Contralateral reflux

The occurrence of contralateral reflux (CLR) after unilateral ureteral surgery has been reported in numerous series. It is important to determine not only the initial incidence (usually found at first postoperative cystography) but also the persistence of CLR over time. The presence of resolved VUR in the non-operated ureter has been thought to be a major risk factor for recurrence with contralateral operation, but evidence for this clinical impression is lacking. A recent report demonstrated this relationship in a small group of patients with unilateral antireflux surgery (Ross, 1995).

The incidence and persistence of contralateral reflux were estimated from reports that specifically indicated the occurrence of CLR, including some in which the incidence was zero. By definition this included only unilateral reimplantation or unilateral subureteric injection of Teflon™ in which a contralateral ureter was present. A total of 1,566 ureters were considered at risk, with an overall incidence of 142 reported new CLR (9.07 percent). Not all of these reports included adequate follow-up information, which was used to estimate persistence of the reflux. When specified, the type of surgical procedure was examined in terms of its effect on new CLR.

The rate of new CLR in studies reported before 1986 (13.4 percent) was higher than that reported after 1986 (4.7 percent). Although the reasons for this difference are unclear, an increase in the practice of contralateral reimplantation in case of any suspicion of prior reflux after 1986 and recognition of the influence of voiding dysfunction in reflux management in recent years may also have contributed to the difference. Reflux grade did not significantly affect the rate of contralateral reflux, although the rate was highest for Grade IV reflux at 3.7 percent compared with 1.5 percent for Grades I and II (Table 12). The surgical method of reimplantation did not influence the likelihood of new CLR. The rate of CLR after endoscopic treatment using Teflon™ was 2.9 percent and was not significantly different from that for other open surgical methods of correction.

Table 12. Estimated percentage chance of contralateral reflux for studies reported in 1987 or later (by grade and surgical method)

Factor	Estimate (95% confidence interval)
Grade	
Grade I/II	1.52% (0–5.49%)
Grade III	2.80% (0–12.73%)
Grade IV	3.66% (0–12.67%)
Grade V	2.53% (0–9.77%)
Surgical method	
Politano-Leadbetter	5.21% (1.29–10.31%)
Transtrigonal	1.90% (0.25–4.24%)
Lich-Gregoir	2.33% (0.26–5.39%)
Open surgery - other	5.07% (1.47–9.63%)
Teflon™	2.95% (0–10.58%)

Recent studies have offered some new insight. Ross, Kay, and Nasrallah (1995) reported a high incidence of CLR in ureters with previously demonstrated VUR. Diamond, Rabinowitz, Hoenig, et al. (1996) indicate that CLR is related to the grade of VUR rather than to the surgical technique.

Although uniform duration of follow-up is not available, the overall resolution rate of new CLR was 52.1 percent with 28.7 percent persisting at time of follow-up.

Follow-up was usually 1–2 years after surgical reimplantation; 13.8 percent of patients with new CLR underwent surgical correction at varying points of follow-up. Little follow-up data are available for patients reported after 1986. Clearly, an early decision to operate would mask possible spontaneous resolution.

Postoperative pain

No specific data are available regarding pain after surgical repair of VUR. Recent advances in pediatric pain management have altered the approach to pain management in children after major surgery. The increasingly widespread use of epidural analgesia and patient-controlled analgesia have markedly improved pain control after many surgical procedures (Cain, Husmann, McLaren, et al., 1995). Continuous epidural analgesia is particularly well suited to antireflux surgery because it reduces incisional pain as well as the intensity and frequency of bladder spasms, a common occurrence after reimplantation surgery. Urethral catheterization is necessary while the epidural catheter is in place. Although no objective data are available, these complications appear to be less severe after extravesical reimplantation, in part because of the usually shorter period of catheterization. Several studies have reported the use of intravesical repairs without postoperative catheter drainage (Brandell and Brock, 1993).

Hospitalization after antireflux surgery

The length of hospitalization in children undergoing open antireflux surgery was reported in 10 studies, with a total of 637 patients and 826 ureters (Table 13). The mean stay varied from 2.4 days (Zaontz, Maizels, Sugar, et al., 1987) to 13.9 days (Rezmi, Ozen, Erkan, et al., 1984). The length of stay appeared to vary with the surgical technique and whether postoperative ureteral stents were used.

Following extravesical forms of ureteroneocystostomy (e.g., detrusorrhaphy), Zaontz, Maizels, Sugar, et al. (1987) reported a mean length of stay of 2.4 days. Wacksman, Gilbert, and Sheldon (1992), reporting a similar surgical technique, had a longer hospital stay of 4.2–5.2 days. Patients undergoing intravesical techniques of antireflux surgery (Cohen, Leadbetter-Politano, Glenn-Anderson) had hospital stays averaging 2.7–10.6 days (Brock, 1983; Burbige, 1991; Fort, Selman, and Kropp, 1983).

Temporary ureteral stents generally are used after ureteroneocystostomy with tapering, a technique utilized in children with Grade V and some with Grade IV reflux. Some clinicians also use postoperative stents in lower grades of reflux to maintain the patency of the newly-created

Table 13. Mean and range of hospital stay for surgical therapy of vesicoureteral reflux

Study	Patients	Ureters	Reimplantation type1	Mean hospital stay (days)	Hospital stay range with/ without catheterization
Hampel, Richter-Levin, and Gersh, 1977	51	83	LG	4	Not stated
So, Brock, and Kaplan, 1981	52	87	GA, LP	5	3 to 9 days
Fort, Selman, and Kropp, 1983	63		GA, LP, Cohen, Hutch	10.6/9.3	6–12/3–16 days
Remzi, Ozen, Evkan, et al., 1984	89	143	LP	13.94	11.6/15.3 days[2]
Ehrlich, 1985	63	74	Kalicinski	6	Unstated
Pypno, 1987	43	80	Cohen	8.6	5–14 days

Burbige, 1991	120	180	LP, Cohen	4.2/5.6	5–7/3–5 days
Wacksman, Gilbert, and Sheldon, 1992	132	211	Detruss.	4.2–5.2	Not stated
Brock, 1993	34	57	GA, LP, Cohen	5.4/2.7	4–8/2–4 days
Totals	637	826			

[1] GA=Glenn-Anderson; LP=Leadbetter-Politano.
[2] Remzi reports the average stay with a urethral catheter/suprapubic tube. His patients had no ureteral catheters.

ureterovesical junction. In general, patients with ureteral stents have had a longer length of stay (5.4–5.6 days) than nonstented patients (2.7–4.2 days) (Brock, 1993; Burbige, 1991).

Concerns regarding length of stay were not raised in the United States until relatively recently and now are emphasized because of the increasing cost of medical care in this country. In a review of 186 children undergoing ureteroneocystostomy from 1986 to 1994, McCool and Joseph (1995) found that the mean length of stay had decreased from 3.6–2.3 days. It is likely that average lengths of stay for children undergoing open antireflux surgery will continue to decrease.

Most endoscopic interventions for reflux are treated as outpatient procedures or require less than 24-hour in-hospital stays.

Adverse effects of surveillance testing

Risk of urinalysis

Routine urinalysis and urine cultures carry very little risk except skin sensitivity to cleansing agents. There is potential for misinterpretation of urinalysis and/or urine culture due to inappropriate collection and/or contamination that may result in erroneous diagnosis of UTI and therefore inappropriate therapeutic decisions.

Risk of radiologic evaluation

Surveillance evaluation using radiologic techniques represents a major component of follow-up in patients with reflux. Risks of surveillance for the various methods can be divided into risks related to physical manipulation in the performance of the test and risk from contrast or radiation.

Renal imaging

Harms from physical manipulation. All imaging techniques using contrast or radioactive tracer require administration via venipuncture, which may be stressful to infants and children and their parents to a variable degree. In addition, extravasation of the imaging agent into the soft tissues may cause inflammation, particularly with iodinated contrast, but this complication is uncommon. Ultrasonographic studies appear to have little significant impact on children, either from the direct manipulation or from the transmitted sound waves.

Risk of contrast. Adverse reactions to intravenous contrast media are uncommon in the pediatric population. Minor reactions with IVP (ionic contrast media) occur in 6 percent and include nausea, vomiting, urticaria, flushing, pruritus, and headache (Gooding, Berdon, Brodeur, et al., 1975). Major reactions, including cardiac arrest, pulmonary edema, apnea, seizures, bronchospasm,

[3] Assuming digital fluoroscopic time over the bladder of 3 to 5 seconds; Kleinman et al., 1994.

laryngeal edema, and shock, are rare. In a large group of pediatric patients, the incidence of serious reactions to ionic contrast media was 0.5 percent, but there were no deaths (Gooding et al., 1975). The risk of adverse reaction with nonionic contrast media is significantly less (Bisset, Strife, and Kirks, 1991). There is no risk of allergy to agents used for scintigraphy.

Radiation exposure. The average radiation exposure in children undergoing upper urinary tract evaluation is shown in Table 14, page 47. The average annual radiation exposure in the environment is 0.250 rad (Mettler and Upton, 1995).

Cystography

Harms from physical manipulation and contrast. McAlister, Cacciarelli, and Shackelford (1974) describe atypical cases involving complications of cystography, and suggest ways of avoiding complications in clinical experience. Zerin and Shulkin (1992) studied 228 children who had voiding cystourethrograms or radionuclide cystograms and noted irritative voiding symptoms in 70 (35.1 percent). Three patients developed fever, and urine cultures were negative in all. Sixty-three of 228 patients received no postprocedural prophylaxis, and postcatheterization symptoms were only slightly higher (37 percent) compared with 34.5 percent in the nonantibiotic group. No significant difference in symptoms was reported between children having nuclear cystograms and those having contrast cystograms. There is a risk of inducing a UTI if the procedure is not performed using sterile technique. Individuals allergic to iodinated contrast do not develop an allergic reaction during VCUG.

The psychological consequences of cystographic studies have not been formally addressed, but anecdotal experience suggests that many children sustain varying degrees of psychological trauma from catheterization.

Radiation exposure. The average radiation exposure in children undergoing lower urinary tract studies is shown in Table 15.

Chapter 4: Treatment recommendations

Only a few recommendations can be derived purely from scientific evidence of a beneficial effect on health outcomes (as opposed to intermediate outcomes; see page 20). Evidence of the efficacy of medical management on health outcomes is available only for Grades I–IV reflux. Control data are lacking to compare outcomes for intermittent with those for continuous antibiotic therapy. Open surgical repair, although proven to cure reflux in 90–98 percent of patients, has not been demonstrated to improve health outcomes other than pyelo-nephritis; for this outcome, the evidence suggests that children with Grade III or IV reflux receiving continuous antibiotic prophylaxis are 2.5 times more likely to develop pyelonephritis than children who have undergone successful antireflux surgery. Accordingly, based on health outcomes data alone, health outcomes for medical and surgical treatment can be compared only for children with Grade III or IV reflux. Even for these patients, available outcomes data provide little information on whether the benefits of treatment exceed its potential risks, nor do they aid the clinician in selecting the most appropriate treatment options for initial therapy or for persistent reflux. Thus, evidence-based recommendations provide limited practical guidance for the clinician. The need for further outcomes research is addressed in Chapter 5.

The following more detailed recommendations, which generally lack empirical scientific support, reflect the clinical experience and opinion of the panel. The panel recognizes the limitations of relying on opinion as a basis for generating practice guidelines. This description of practice patterns is instead offered as an aid to clinicians interested in more detailed recommendations and in the perspective of pediatric urologists and nephrologists who specialize in reflux care. Full documentation of the panel's underlying rationale for the recommendations is provided: statements based on opinion are explicitly identified, and evidence-based recommendations are accompanied by appropriate references to outcomes analyses in Chapter 3 (see Rationale for recommendations, page 52).

As outlined in Chapter 2, the recommendations were derived from a survey of preferred treatment options for 36 clinical categories of children with reflux. The recommendations are based on the outcomes analysis presented in detail in Chapter 3 and on the clinical experience and opinion of the panel. Treatment options selected by 8 or 9 of the 9 panel members are classified as guidelines and given the strongest recommendation language. (The word "should" is used to indicate treatment options in this category; e.g., "Children with Grade V reflux should undergo surgical repair.") Treatment options that received 5 to 7 votes are designated as preferred options, and treatment options that received 3 to 4 votes are designated as reasonable alternatives. Treatments that received no more than 2 votes are designated as having no consensus and are not recommended.

Assumptions

The treatment modalities considered included (1) no treatment (including intermittent antibiotic therapy); (2) bladder training; (3) continuous antibiotic prophylaxis; (4) antibiotic prophylaxis and bladder training; (5) antibiotic therapy, bladder training and anticholinergics; (6) open surgical repair; and (7) endoscopic repair. These modalities are described in Chapter 1. The recommendations assume that the patient has uncomplicated reflux (e.g., no breakthrough UTI, voiding dysfunction, duplex systems, or other comorbid conditions); see Special considerations below regarding the care of patients with additional complications. The recommendations apply only to the scope of the topic of this report (see Chapter 2) and therefore do not address diagnosis of reflux, treatment of patients over age 10, management of reflux complicated by other factors (see Special considerations below) or surveillance testing.

Special considerations

The treatment recommendations apply only to patients with uncomplicated reflux. More aggressive treatment interventions may be indicated for children with breakthrough UTI or other medical

complications, such as renal insufficiency, new or progressive scarring, obstructive congenital anomalies of the upper urinary tract (e.g., ureteropelvic junction), solitary kidney, intrarenal reflux, secondary reflux (e.g., neuropathic or iatrogenic reflux, reflux associated with structural urologic anomalies such as ureterocele, ectopic ureter, posterior urethral valves, prune-belly syndrome, or exstrophy), or other medical comorbid conditions. There is limited direct evidence that duplication anomalies increase the risk of developing persistent reflux; surgical cure rates appear to be comparable with duplex and single systems (see Chapter 3, page 26). Treatment options may be countermanded by such factors as antibiotic allergies, intolerance or noncompliance, limitations in surgical skills and inadequate hospital facilities. Finally, the intensity of treatment may need to be modified depending on the nature of the doctor-parent-patient relationship and to accommodate such factors as limited access to care and personal preference.

An important variable in the scope of treatment is the presence of concurrent voiding dysfunction, a common occurrence among children with reflux. Because resolution of voiding dysfunction may be accompanied by resolution or diminution of reflux, such children may require more aggressive treatment with antibiotics, anticholinergics, and bladder training (e.g., timed voiding, biofeedback, parental monitoring of voided volumes). Surgical repair of reflux is less successful in children with voiding dysfunction, and thus a higher threshold is necessary before surgery is recommended in such patients. Children with reflux should therefore be assessed for voiding dysfunction as part of their initial evaluation.

Recommendations

The recommendations that follow emphasize the importance of shared decision-making in the management of reflux. The treatment recommendations are tabulated in Table 16 on pages 52–53.

Recommendations for children without scarring at diagnosis

Age at diagnosis: Infants (<1year)

Initial treatment. Infants with Grades I–IV reflux should be treated initially with continuous antibiotic prophylaxis. In infants with Grade V reflux, continuous antibiotic prophylaxis is the preferred option for initial treatment.

Follow-up treatment. In infants who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (see Duration of medical management, page 51). For patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic therapy, periodic cystography, or surgery. Surgical repair is the preferred option, however, for patients with persistent unilateral Grades III–IV reflux. Patients with persistent bilateral Grades III–IV reflux or Grade V reflux should undergo surgical repair.

Age at diagnosis: Preschool children (ages 1–5 years)

Initial treatment. Preschool children with Grades I–II reflux or unilateral Grades III–IV reflux should be treated initially with continuous antibiotic prophylaxis. Continuous antibiotic prophylaxis is the preferred option in preschool children with bilateral Grades III–IV reflux. In patients with unilateral Grade V reflux, continuous antibiotic prophylaxis is the preferred option for initial treatment, although surgical repair is a reasonable alternative. In patients with bilateral Grade V reflux, surgical repair is the preferred option and continuous antibiotic prophylaxis is a reasonable alternative.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (*see* Duration of medical management, page 51). In children with persistent Grades I–II reflux, there is no consensus regarding the role of continued antibiotic therapy, periodic cystography or surgery. Surgery is the preferred option for children with persistent Grades III–IV reflux. Patients with persistent Grade V reflux should undergo surgical repair.

Age at diagnosis: School children (ages 6–10 years)

Initial treatment. School children with Grades I–II reflux should be treated initially with continuous antibiotic prophylaxis. Continuous antibiotic prophylaxis is the preferred option for initial treatment of patients with unilateral Grades III–IV reflux. In patients with bilateral Grades III–IV reflux, surgical repair is the preferred option, although continuous antibiotic prophylaxis is a reasonable alternative. Patients with Grade V reflux should undergo surgical repair.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (see Duration of medical management, page 51). In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography, or surgery. Surgery is the preferred option for persistent reflux in children with Grades III–IV reflux.

Recommendations for children with scarring at diagnosis

Age at diagnosis: Infants (<1 year)

Initial treatment. Infants with scarring at diagnosis and Grades I–IV reflux should be treated initially with continuous antibiotic prophylaxis. In infants with Grade V reflux and scarring, continuous antibiotic prophylaxis is the preferred option for initial treatment, and surgical repair is a reasonable alternative.

Follow-up treatment. In infants who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (see Duration of medical management). In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography, or surgery. In boys with persistent unilateral Grades III–IV reflux, surgical repair is the preferred option. Boys with persistent bilateral Grades III–IV reflux, girls with persistent Grades III–IV reflux, and boys and girls with persistent Grade V reflux should undergo surgical repair.

Age at diagnosis: Preschool children (ages 1–5 years)

Initial treatment. Preschool children with scarring at diagnosis and either Grades I–II reflux or unilateral Grades III–IV reflux should be treated initially with continuous antibiotic prophylaxis. Antibiotic therapy is the preferred option in children with bilateral Grades III–IV reflux and scarring, and surgical repair is a reasonable alternative. Surgery is the preferred option for patients with unilateral Grade V reflux. Patients with bilateral Grade V disease and scarring should undergo surgical repair as initial treatment.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (see Duration of medical management). In patients with persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography, or surgery. Girls with persistent Grades III–IV reflux and boys with persistent bilateral Grades III–IV reflux should undergo surgical repair. Surgery is the preferred option for boys with persistent unilateral Grades III–IV reflux and girls with bilateral Grades III–IV reflux. For patients with persistent Grade V reflux who have not undergone surgery as initial treatment, surgical repair is the preferred option.

Age at diagnosis: School children (ages 6–10 years)

Initial treatment. School children with scarring at diagnosis and Grades I–II reflux should be treated initially with continuous antibiotic prophylaxis. In children with unilateral Grades III–IV reflux and scarring, antibiotic therapy is the preferred option. Patients with bilateral Grades III–IV reflux or Grade V reflux should undergo surgical repair as initial treatment.

Follow-up treatment. In children who continue to demonstrate uncomplicated reflux, antibiotic prophylaxis should be continued (see Duration of medical management). In patients who have persistent Grades I–II reflux after this period of prophylaxis, there is no consensus regarding the role of continued antibiotic prophylaxis, periodic cystography, or surgery. Patients with persistent unilateral Grades III–IV reflux who have not undergone surgery as initial treatment should undergo surgical repair.

Duration of medical management

The recommendations refer to "persistent reflux" but do not specify the amount of time that must elapse before VUR is considered persistent. Little scientific evidence exists for determining how long to continue antibiotic prophylaxis before recommending surgical repair, and this decision is therefore left to clinical discretion in consultation with parents. The duration of reflux is an important consideration. As indicated in Table 2 (page 23), which is based on the model described in Chapter 2 and Appendix C, the probability that reflux will resolve spontaneously depends on the duration and grade of reflux. Other factors to consider include the patient's surgical candidacy, comorbidities, tolerance of antibiotics, socioeconomic factors, compliance to medications and follow-up, and parental preferences and concerns.

(continued on page 54)

Table 16. Treatment recommendations

Recommendations were derived from a survey of preferred treatment options for 36 clinical categories of children with reflux. The recommendations are classified as follows:

Guidelines = Treatments selected by 8 or 9 of 9 panel members, given the strongest recommendation language.
Preferred Options = Treatments selected by 5–7 of 9 panel members.
Reasonable Alternatives = Treatments selected by 3–4 of 9 panel members.
No Consensus = Treatments selected by no more than 2 of 9 panel members.

The treatment recommendations apply to both boys and girls with primary vesicoureteral reflux.

Treatment recommendations for children without scarring at diagnosis

Clinical presentation (age at presentation)		**Treatment**					
		Initial (antibiotic prophylaxis or open surgical repair)			**Follow-up[1]** (continued antibiotic prophylaxis, cystography or open surgical repair)		
VUR grade laterality	Age (years)	Guideline	Preferred option	Reasonable alternative	Guideline	Preferred option	No consensus[2]
I-II Unilateral or bilateral	<1	Antibiotic prophylaxis					Boys and girls
	1-5	Antibiotic prophylaxis					Boys and girls
	6-10	Antibiotic prophylaxis					Boys and girls
III-IV Unilateral or bilateral	<1	Antibiotic prophylaxis			Bilateral: Surgery if persistent[3]	Unilateral: Surgery if persistent[3]	
	1-5	Unilateral: Antibiotic prophylaxis	Bilateral: Antibiotic prophylaxis			Surgery if persistent[3]	
	6-10		Unilateral: Antibiotic prophylaxis Bilateral: Surgery	Bilateral: Antibiotic prophylaxis		Surgery if persistent[3]	
V Unilateral or bilateral	<1		Antibiotic prophylaxis		Surgery if persistent[3]		
	1-5		Bilateral: Surgery Unilateral: Antibiotic prophylaxis	Bilateral: Antibiotic prophylaxis Unilateral: Surgery	Surgery if persistent[3]		
	6-10	Surgery					

[1]For patients with persistent uncomplicated reflux after extended treatment with continuous antibiotic therapy.
[2]No consensus was reached regarding the role of continued antibiotic prophylaxis, cystography, or surgery.
[3]See Duration of Reflux in the text regarding the length of time that clinicians should wait before recommending surgery.

Table 16. Treatment recommendations (continued)

Recommendations were derived from a survey of preferred treatment options for 36 clinical categories of children with reflux. The recommendations are classified as follows:

Guidelines = Treatments selected by 8 or 9 of 9 panel members, given the strongest recommendation language.
Preferred Options = Treatments selected by 5–7 of 9 panel members.
Reasonable Alternatives = Treatments selected by 3–4 of 9 panel members.
No Consensus = Treatments selected by no more than 2 of 9 panel members.

The treatment recommendations apply to both boys and girls with primary vesicoureteral reflux.

Treatment recommendations for children with scarring at diagnosis

Clinical presentation (age at presentation)		**Treatment**					
		Initial (antibiotic prophylaxis or open surgical repair)			**Follow-up[1]** (continued antibiotic prophylaxis, cystography or open surgical repair)		
VUR grade laterality	Age (years)	Guideline	Preferred option	Reasonable alternative	Guideline	Preferred option	No consensus[2]
I-II Unilateral or bilateral	<1	Antibiotic prophylaxis					Boys and girls
	1-5	Antibiotic prophylaxis					Boys and girls
	6-10	Antibiotic prophylaxis					Boys and girls
III-IV Unilateral	<1	Antibiotic prophylaxis			Girls: Surgery if persistent[3]	Boys: Surgery if persistent[3]	
	1-5	Antibiotic prophylaxis			Girls: Surgery if persistent[3]	Boys: Surgery if persistent[3]	
	6-10		Antibiotic prophylaxis		Surgery if persistent[3]		
III-IV Bilateral	<1	Antibiotic prophylaxis			Surgery if persistent[3]		
	1-5		Antibiotic prophylaxis	Surgery	Surgery if persistent[3]		
	6-10	Surgery					
V Unilateral or bilateral	<1		Antibiotic prophylaxis	Surgery	Surgery if persistent[3]		
	1-5	Bilateral: Surgery	Unilateral: Surgery			Surgery if persistent[3]	
	6-10	Surgery					

[1]For patients with persistent uncomplicated reflux after extended treatment with continuous antibiotic therapy.
[2]No consensus was reached regarding the role of continued antibiotic prophylaxis, cystography, or surgery.
[3]See Duration of Reflux in the text regarding the length of time that clinicians should wait before recommending surgery.

Other management recommendations

In children with VUR, at initial evaluation the urine should be assessed for infection and proteinuria, and the child's height, weight, and blood pressure should be measured. If the child shows evidence of renal scarring, hydronephrosis, or has a solitary kidney, or known underlying renal disease, a serum creatinine should also be obtained.

In children with VUR, urethral dilation and internal urethrotomy are not beneficial. In addition, cystoscopic examination of the ureteral orifices does not appear to aid in predicting whether reflux will resolve (see Chapter 1, page 12). Furthermore, evocative cystometry is unnecessary in children with reflux and normal voiding function. However, in children with symptoms of voiding dysfunction, urodynamic evaluation may be beneficial.

The personal preferences of parents (and, at older ages, patients) must be considered in weighing the benefits and harms of treatment options. The clinician should provide parents with information about the known benefits and harms of available options, including continuous antibiotic prophylaxis, surgery, and intermittent antibiotic therapy. The clinician should indicate to what extent the estimates of benefits and harms are based on scientific evidence or on opinion and clinical experience. Given the general lack of direct evidence that any 1 treatment option is superior to another (especially when total benefits, harms, costs, and inconvenience are taken into consideration), parents' and patients' preferences regarding treatment options should generally be honored. To the extent that parents seek physicians' advice on how to proceed, the specific treatment guidelines are offered (Table 16 on pages 52–53).

In children with reflux, a urine culture should be obtained if there are symptoms and/or signs of a UTI. In a child with a suspected UTI, proper specimen collection is important. In girls and uncircumcised boys who are not toilet trained, a urinalysis or urine culture obtained from a contaminated bag specimen may yield an erroneous diagnosis of infection and therefore result in inappropriate management decisions. In such children, a urine specimen obtained by catheterization or suprapubic aspiration is encouraged to minimize the likelihood of a false-positive diagnosis of UTI.

Follow-up evaluation should be performed at least annually, at which time the patient's height and weight should be recorded. In addition, a urinalysis should be performed. If renal scarring has been demonstrated, the blood pressure should also be measured, irrespective of whether the child has reflux that is persistent, resolved spontaneously, or has been corrected surgically.

In deciding how often to obtain follow-up cystography, the clinician should take into consideration the likelihood of spontaneous resolution (see Table 2 on page 23), the risks of continued antibiotic prophylaxis, and the risks of radiologic study. In general, cystography does not need to be performed more than once per year.

In children with reflux who are toilet trained, regular, volitional low-pressure voiding with complete bladder emptying should be encouraged. If it is suspected that the child is experiencing uninhibited bladder contractions, anticholinergic therapy may be beneficial.

In children in whom antireflux surgery is chosen, the panel does not recommend the endoscopic form of therapy because of the lack of proven long-term safety and efficacy of most materials used for injection and the lack of approval of such materials by the U.S. Food and Drug Administration.

Rationale for recommendations

The following recommendations to offer continuous antibiotic prophylaxis as initial therapy are based on limited scientific evidence. No controlled studies have demonstrated that continuous antibiotic prophylaxis achieves better health outcomes in children with reflux than intermittent treatment of UTI. The opinion of the panel, however, is that maintaining continuous urine sterility is beneficial in reducing the risk of renal scarring and that this benefit outweighs the potential adverse effects of antibiotics.[3] Observational data from patients with

[3] The argument for continuous antibiotic prophylaxis is especially compelling during infancy, when diagnosing UTI is difficult. Recommendations to initiate antibiotic therapy when reflux is diagnosed in school children, even when the reflux is mild (Grades I–II), are based on the panel's belief that such children continue to face a risk of scarring and that this risk is independent of grade.

Grades I–III reflux suggest that at least 50 percent of reflux cases resolve within 3–5 years of continuous antibiotic prophylaxis (see Chapter 3). For Grades I–IV reflux, the panel generally favors continuous antibiotic prophylaxis over immediate surgical repair because it is less invasive and is associated with fewer risks over the short term.

Recommendations to proceed to surgery in cases that have not resolved spontaneously while the patient was receiving continuous antibiotic prophylaxis are supported by limited scientific evidence: open antireflux surgery is 95–98 percent effective in correcting reflux, and the risk of pyelonephritis is 2–2.5 times greater in children with Grades III–IV reflux managed medically compared with surgically treated patients. The expert opinion of most panel members is that surgery also reduces the risk of pyelonephritis in girls with Grades I–II reflux and in boys and girls with Grade V reflux. Panel members believe that breakthrough UTI increases the risk of renal scarring. Although the International Reflux Study showed no difference between medical and surgical treatment in the incidence of new renal scarring at 5 years, 80 percent of new renal scars in the surgical group appeared by 10 months after randomization, and thus the rate of new renal scarring between 1 and 5 years following randomization was higher in the medical group. Some panel members believe that with longer follow-up, the incidence of new renal scars in the surgical group will be less than in the medical group. Some panel members also believe that females with unresolved reflux are more likely to experience pyelonephritis during pregnancy than women without reflux, although women who have had antireflux surgery also develop pyelonephritis. The panel believes that the benefits of immediate correction of reflux in patients for whom surgery was recommended, even when coupled with its risks, outweigh the potential harms of continuous antibiotic prophylaxis (e.g., inconvenience of long-term therapy, adverse drug reactions, periodic surveillance testing).

More aggressive recommendations for the treatment of girls than of boys (e.g., for persistent Grades III–IV reflux in school children) are based on epidemiologic evidence that girls face a higher risk of acquiring UTI than do boys (see Chapter 3, page 36). More aggressive recommendations for the treatment of Grade V reflux (e.g., surgical repair as initial therapy) are based on the panel's opinion that such cases are unlikely to resolve spontaneously on antibiotic therapy, that surgery is effective in resolving severe reflux and that these benefits outweigh the potential harms of surgery. More aggressive recommendations for children who have renal scarring at diagnosis are based on the panel's opinion that such patients face a higher risk of progressive scarring and decreased renal functional reserve.

The panel's treatment recommendations are based on its opinion that the benefits of treatment outweigh the potential harms. There is little scientific evidence to confirm these assumptions, however, and therefore clinicians and parents may choose other options if they assign different weights to potential outcomes. For example, some clinicians and parents may not share the panel's opinion that the benefits of one-time surgical correction of persistent reflux, even when coupled with its potential harms, outweigh the inconvenience, cost, and risk of side effects from long-term antibiotic prophylaxis. Choosing continuous or intermittent antibiotic therapy under such circumstances is appropriate given the lack of scientific evidence to suggest otherwise.

Chapter 5: Research priorities

Many aspects of primary VUR remain incompletely understood. The panel identified the following areas as needing further investigation.

Development of VUR: The cause of the maldevelopment of the ureterovesical junction is unknown. Because VUR is often related to voiding dysfunction, research into the development of the autonomic nervous system of the bladder and its effect on morphological bladder development may allow an understanding of the pathoembryology of VUR.

VUR is greater in severity in newborn boys than girls. This phenomenon may be secondary to elevated voiding pressures in the newborn male (Gierup, 1970; Hjalmas, 1976; Sillen, Bachelard, Harmanson et al., 1996). Whether these differences result from dissimilar forms of urethral development and/or autonomic nervous system development is unknown. Investigation of the bud theory of Mackie and Stephens (1975) as applied to VUR is suggested to better understand the relationship between reflux and renal scarring that may be present at birth. Determination of whether fetal reflux has a "water hammer" effect deserves study.

Further investigation of the neurologic changes of the pediatric bladder with maturation that could influence bladder function and physiology, particularly voiding pressures, is needed. Studies should evaluate whether anatomic changes at the bladder neck or a functional disorder of the striated sphincter or bladder neck could account for elevated intravesical pressures.

Reflux resolution: The panel found evidence, based on a few large studies, that resolution of Grades I and II reflux may not depend on patient age or laterality (i.e., unilateral or bilateral). In Grade III reflux, on the other hand, it was suggested that patient age and laterality were important prognostic considerations. In Grade IV reflux, only laterality could be evaluated. Confirmation of these concepts by other large centers would be worthwhile. Furthermore, refinement of predictive criteria for reflux resolution by patient age, reflux grade, and laterality would be useful. In addition, further study of the likelihood of resolution of low-grade reflux during adolescence, as described by Lenaghan, Whitaker, Jensen, et al. (1976) and by Goldraich and Goldraich (1992), is necessary.

Renal scarring: The development of renal scarring in children with reflux is incompletely understood. Further investigation of the roles of bacterial virulence factors and host immune and inflammatory responses in the evolution of renal scarring is necessary. Studies should evaluate methods of affecting the host immune or inflammatory response that could reduce renal scarring during pyelonephritis (Roberts, 1992). Investigation of why younger children, particularly those under 1–2 years of age, appear to be more likely than older children to develop renal scarring from pyelonephritis would be useful.

It is well recognized that pyelonephritis and renal scarring can occur in children without reflux. The extent to which reflux increases the risk of renal scarring and the mechanism of this effect deserve investigation.

The panel attempted to analyze the association between new and progressive scarring in children undergoing medical or surgical treatment for reflux and bacteriuria. Because of extremely limited data, this relationship could not be evaluated. Further investigation into the factors leading to new renal scarring in children with reflux is important. In addition, assessment of whether there are long-term differences in the incidence of new scars in children managed medically and surgically is necessary.

Further analysis of the risk factors for end-stage renal disease, particularly the relative contributions of "congenital" scarring, intervening infection, voiding dysfunction, and hypertension management, would be useful.

More randomized prospective trials comparing the incidence and timing of new scarring, as assessed by DMSA scan, in children with Grades III and IV reflux are important, because previous studies, which used IVP for scar detection, have been difficult to interpret. Whether the risk of new scarring in a child with Grade III or IV reflux decreases as reflux grade decreases or reflux resolves should also be analyzed.

Voiding dysfunction: The role of voiding dysfunction in the pathogenesis of VUR and its risk in reflux complications, such as renal scarring, deserves further investigation. The role of urodynamic studies in infants and children with reflux,

with or without voiding dysfunction, should be evaluated (Sillen, Bachelard, Harmanson, et al., 1996). Matched, controlled studies of anticholinergic therapy and bladder retraining on reflux-related outcomes in children with voiding dysfunction are also necessary.

Medical therapy: A comparative analysis of the efficacy of various forms of antibiotic prophylaxis in preventing infection and renal scarring would be important. Furthermore, studies to assess the duration and dosage of prophylaxis are indicated. An evaluation of the adverse effects of various forms of continuous antibiotic prophylaxis in children and examination of the proportion who do not tolerate prophylaxis or who develop resistance would be important. In addition, compliance with prophylaxis regimens should be evaluated, in particular comparing those who have received prophylaxis for less than 6 months with those who have received therapy for more than 2 years. In addition, a trial comparing reflux-related outcomes in children receiving continuous prophylaxis with those in children receiving intermittent therapy, particularly comparing children younger than age 5 years with older children, would be prudent. Whether anticholinergic therapy is beneficial in children with reflux but no sign of voiding dysfunction should be studied. The short- and long-term risk of stopping prophylaxis in individuals with reflux who have been infection-free deserves evaluation. The efficacy of periodic surveillance, urinalysis, and urine culture in asymptomatic children with reflux should be studied.

Surgical therapy: Development of new techniques of antireflux surgery, particularly minimally invasive techniques, is indicated. Newer materials that can be used for endoscopic subureteral injection and that are safe in children should be studied. Whether current techniques of antireflux surgery cause transient increases in upper tract pressures, potentially resulting in renal injury, should be studied. In addition, the mechanism for new-onset contralateral reflux in children undergoing unilateral antireflux surgery should be studied further, and methods of preventing contralateral reflux should be developed. More effective techniques should be developed for surgical therapy in children with Grade V reflux. In addition, whether early correction of reflux in children with Grade V reflux alters reflux-related outcomes should be analyzed further.

Bladder function/training: Whether bladder training alters reflux-related outcomes deserves study. In addition, whether reflux resolution is enhanced after successful toilet training and maturation of bladder function should be evaluated. Whether pharmacologic manipulation, beyond simple anticholinergic therapy, could be useful in normalizing bladder dynamics should also be studied.

Imaging: The effect of voiding cystourethrography on children should be analyzed, and less traumatic methods of determining whether reflux is present should be developed. Techniques of voiding cystourethrography that result in less radiation exposure, such as the tailored low-dose fluoroscopic method (Diamond, Kleinman, Spevak, et al., 1996), should be developed. Clinicians should refine the ideal duration of time between cystograms in children being treated for reflux. In addition, the role of newer forms of renal imaging, such as SPECT, helical CT and power Doppler ultrasound, in the diagnosis of acute pyelonephritis and renal scarring, should be studied. Furthermore, the indications for obtaining a voiding cystourethrogram in a child with a UTI should be refined. Efforts should be made to determine prognostic criteria for likelihood of reflux resolution based on bladder volume and pressure at which reflux occurs and volume of refluxing urine.

Genetics of reflux: Further evaluation of the genetics of reflux deserves study. The current literature has not separately analyzed the incidence of pure primary sibling reflux and reflux associated with voiding dysfunction. The gene for VUR should be identified.

Screening for reflux: Many groups of children undergo screening for primary reflux, including siblings of offspring of index patients with reflux and children with a multicystic kidney or a solitary kidney. The impact of screening and early intervention (medical or surgical) on reflux-related outcomes should be analyzed.

Circumcision and UTI: Whether circumcision of neonates with prenatally detected VUR diminishes the incidence of UTI and other reflux-related outcomes deserves study.

Reflux and pregnancy: The natural history of VUR in adult women with persistent reflux deserves study, including a comparison of the morbidity of reflux and need for and efficacy of prophylaxis in pregnant and non-pregnant women. Such an analysis should compare various grades of reflux with and without renal scarring. Comparison of the reflux-related outcomes and morbidity of pregnancy in women who had spontaneous reflux

resolution or antireflux surgery during childhood and those with uncorrected reflux is of utmost importance.

Social and economic factors: An analysis of the costs of reflux treatment and surveillance is important, in particular a comparison of the costs associated with medical and surgical therapy of children with various grades of reflux. In addition, studies of how reflux and its treatment and the need for surveillance affect patient/family dynamics and quality of life deserves study.

Randomized controlled trials: Although the International Reflux Study in children was successful in analyzing many reflux-related outcomes, data related to scarring were based on assessment by IVP rather than DMSA renal scan. Further randomized controlled trials studying the role of medical and surgical therapy using DMSA scan for evaluation are indicated. The long-term outcomes (>10 years) of previously randomized children with unresolved reflux at 5 years should be compared with children undergoing successful surgical or medical therapy.

Future clinical studies of children with reflux should analyze specific reflux-related health outcomes and stratify the results by patient gender, age, and reflux grade. Studies should report reflux resolution both by rate of ureteral resolution and patient resolution. Ideally, reports of UTI and renal scarring will analyze these outcomes for 5–10 years after reflux resolution.

Appendix C: Methodology for combining parameters

Combining relative risks from several different studies is problematic. Several meta-analytic techniques can be used. A fixed effects analysis assumes that the studies all estimate the same parameter (relative risk). The opposite of a fixed effects model is a random effects model. In a random effects model, the parameter does not remain constant from study to study, but rather varies randomly, and the center of the distribution of the parameter of interest must be estimated. This methodology is especially appropriate for combining relative risks from pediatric reflux studies, because the populations used by each study have different mixes of grades, laterality and gender.

One standard method of combining parameters using random effects models is the empirical Bayes (EB) method (Hedges and Olkin, 1985). For this method, we assume that each θ_j estimates a different parameter, θ_j, with known variance, σ_j^2. The θ_j's are assumed to be a sample from a normal distribution with mean μ and variance τ^2. That is, mother nature chooses parameters for each study at random from a normal distribution with mean μ and variance τ^2. The likelihood is proportional to

$$L \propto \exp\left[-\sum_{j=1}^{m} [(\theta_j - \mu)^2 / (\tau^2 + \sigma_j^2) + \ln(\tau^2 + \sigma_j^2)] / 2 \right].$$

Maximum likelihood estimates can be calculated directly using a modified Gauss-Newton algorithm (Hasselblad, 1994) or the EM Algorithm (Dempster, Laird, and Rubin, 1977).

For dichotomous outcomes, such as rates of renal scarring, the same model can be used for the parameters, but the underlying distribution of the parameters is assumed to be binomial instead of normal. This can be accomplished by fitting a multiple logistic regression model with random effects. The EGRET software package (Statistics and Epidemiology Research Corporation, 1993) can be used to estimate such models. This model can be generalized to include multiple variables of interest.

The following example illustrates the use of the method to estimate the effect of both treatment and grade on renal scarring. A dataset was created for each subgroup of each renal scarring study when the study gave results by grade (see Table C-1). Dummy variables were created for each grade to indicate the effect of grade. Grades IV and V were combined because there were so few subjects. Some studies gave their results for a group of grades, and these presented special analysis problems. For those studies, the fraction of subjects in each grade was used in place of the dummy variables. To understand this, assume that one study had 40 percent in grade II and 60 percent in grade III. Then each individual in grade II should be assigned a one for the dummy for grade II and a zero for the other dummies. If this was actually done for all subjects in both grades and the dummy variables were then averaged, the result would be the fraction for each dummy as proposed. A small number of studies did not give a grade distribution, and for these studies an average grade distribution was assigned.

The data in Table C-1 were analyzed using multiple logistic regression analysis. The model assumes that the effects of each content factor are additive (in the log-odds space). Thus, the analysis results must be converted back to probabilities and relative risks. The results for this example are shown in Table C-2.

TABLE C-2. Results of the Multiple Logistic Regression Analysis With Random Effects Using the Data in Table C-1

Variable	Coefficient	Std.Err.Beta	p-value	Odds/Odds ratio
Grade I	-6.125	(1.57)	<.001	.002187
Grade II	-3.739	(.397)	<.001	.02377
Grade III	-3.332	(.770)	<.001	.03573
Grade IV or V	-2.841	(.538)	<.001	.05836
Surgery	-.02613	(.452)	.954	.9742
Random effect term	1.368	(.316)		

The combination of rates, such as complication rates, is a special case of the analysis just described. The general use of a linear model with random effects can be applied to either continuous or dichotomous data. Most standard meta-analytic methods, such as inverse variance weighting and the Mantel-Haenszel method, are special cases of the methods just described.

This report on the Management of Primary Vesicoureteral Reflux was developed by the Pediatric Vesicoureteral Reflux Clinical Guidelines Panel of the American Urological Association, Inc.

This report is intended to furnish to the skilled practitioner a consensus of clear principles and strategies for quality patient care, based on current professional literature, clinical experience and expert opinion. It does not establish a fixed set of rules or define the legal standard of care, pre-empting physician judgment in individual cases.

An attempt has been made to recommend a range of generally acceptable modalities of treatment, taking into account variations in resources and in patient needs and preferences. It is recommended that the practitioner articulate and document the basis for any significant deviation from these parameters.

Finally, it is recognized that conformance with these guidelines cannot ensure a successful result. The parameters should not stifle innovation, but will, themselves, be updated and will change with both scientific knowledge and technological advances.

Report of the National Consensus Conference on Family Presence during Pediatric Cardiopulmonary Resuscitation and Procedures

Deborah Parkman Henderson RN PhD

Jane F. Knapp MD

Introduction

The National Consensus Conference on Family Presence during Pediatric Cardiopulmonary Resuscitation and Procedures was held in Washington, DC, on September 7-8, 2003. The concept, funding, planning and organization for the conference were the Ambulatory Pediatric Association (APA) Presidential Project of James Seidel, M.D., Ph.D. Dr. Seidel was in the final stages of preparation for chairing the conference when he died on July 25, 2003. In Dr. Seidel's absence, the conference was chaired by Deborah Parkman Henderson R.N., PhD, his co-investigator, and Jane F. Knapp, M.D, a colleague.

The National Consensus Conference on Family Presence during Pediatric Procedures and Cardiopulmonary Resuscitation was funded by a grant to the APA from the Maternal Child Health Bureau (MCHB) Partnership for Children. This meeting brought together a panel of over 20 appointed representatives from a multidisciplinary, diverse group of national organizations interested in the emergency care of children. The conference was part of a multiphase process designed with the goal of publishing consensus guidelines useful for defining policy regarding family presence (FP) during pediatric procedures and CPR in the Emergency Department (ED). It is also possible that the consensus panel recommendations could be applied to other settings.

Panel members completed a review of the literature prior to attending the conference. This review, along with results of a pre-conference questionnaire, formed the basis of the discussion during the conference. During the two day conference the participants completed the outline of the guidelines presented here. We believe these recommendations are a powerful testimony to Dr. Seidel's vision for promoting FP through multidisciplinary consensus building. Beyond that vision, however, we hope that the guidelines will make a difference in improving the quality of children's health care.

Historical Perspective

Many health care providers trained during a time when FP during pediatric invasive procedures (IP) and CPR was discouraged and restricted. The rationale was that allowing parents to be present during IP and CPR would be distracting to the health care provider and potentially even harmful for the parents and/or child.[1-3] This practice appears to have been more supported by tradition rather than actual evidence. Yet, this traditional approach has created strong, enduring attitudes and beliefs.

In 1982, the Director of Pastoral Care for Foote Hospital in Jackson, Michigan had an experience where a policeman's wife pleaded to be with her husband while he was undergoing CPR for a heart attack. Uncertain what to do, he hurriedly asked the doctor for permission to bring the woman to her husband's side. This event initiated the development of a program that allowed for the presence of family members during resuscitation. The published accounts of the Foote Hospital experience prompted many hospitals and EDs to re-examine their approach to FP.[4,5] This process sparked an often polarizing debate among health care providers who expressed strong opinions on both sides of the issue. It also provided the impetus for research to critically study family, patient, and provider attitudes and the numerous other concerns that had been raised regarding FP.

The Emergency Nurses Association (ENA) took a proactive stand regarding FP in 1993 when they adopted a resolution to support the option of FP during invasive procedures (IP) and resuscitation.[6] The current ENA position statement continues to support the option for FP and additionally calls for further research related to the impact of FP, the development and dissemination of educational resources, the collaboration of specialty organizations to develop multidisciplinary guidelines and the

establishment of policies and procedures allowing the option of FP during IP and CPR.(www.ena.org)

The American Heart Association reviewed the ethical aspects of CPR and emergency cardiovascular care for the 2000 guidelines.[7] This included a literature review regarding FP during resuscitation attempts. The AHA now recommends that healthcare providers should offer the opportunity to be present during CPR to family members whenever possible.[7]

Statement of the Problem

A decade after the adoption of the ENA resolution on FP, few EDs have written policies regarding FP during IP and CPR. [8] Although many family members and health care providers support the option of FP, parents frequently are not given the option to remain with their child during IP and CPR. Moreover, there remains a lack of collaborative, multidisciplinary guidelines among professional and specialty organizations with an interest in children's healthcare. Barriers to the formulation of consensus guidelines are as basic as the definition of a family member and under what circumstances a family member should be excluded. Controversies such as who makes the decision regarding FP and whether FP increases the risk of litigation remain.

The intention of this conference was to use the UCLA-Rand Appropriateness Method (RAM) methodology to arrive at multidisciplinary consensus recommendations that could be used by health care providers to formulate guidelines for FP during pediatric procedures and resuscitation in the ED.

Literature Review

Excellent reviews and summaries of the research on FP, including studies focused on pediatric patients, have been published. [7,9-14] Although much of the literature concerns acute care settings, a small number of articles relate to intensive care settings.[9,10] Assumptions may be made that parental experience and expectations are the same in these settings, but this has not been studied. Many findings are consistent among a number of published reports and studies. Most parents prefer to stay with their children during procedures and resuscitation.[13,15-19] Children feel less stress when parents are allowed to remain during procedures.[20-25] Among physicians, the likelihood of being in favor of allowing parental presence increases with experience, confidence and competence at dealing with procedures, resuscitation and distressed relatives.[3,12,26] As the invasiveness of procedures increases to CPR (perceived as the most invasive) physicians vary more in their attitudes and are less comfortable with parental presence.[13,28-29] Physicians and nurses differ in their attitudes toward FP. Nurses, generally, are more supportive of FP.[18,29-30] Parents want to be given the option to be present with their child and along with nurses and physicians have expressed the desire to be part of the decision making process.[19,28,31] Although parents want to be present, they seldom ask unless they have been encouraged to do so. Healthcare providers should offer the opportunity to family member whenever possible.[9,32-34] A trained support person is of prime importance to the success of FP during procedures.[5] This support person should be assigned to the family to answer questions, describe and clarify the proceedings and offer comfort.[35] Education appears to be effective in changing nursing and other staff attitudes regarding FP.[37-38]

Health care providers have raised a number of concerns to explain their hesitancy and reluctance regarding FP.[3,26] These are summarized in Table 1. Many studies have attempted to examine these attitudes critically. One study found that children were more cooperative and less fearful when parents were present during dental procedures.[38] Others have found that both families and providers have found parental presence to be beneficial without deleterious effect on interactions or provider performance.[15,25,26,39] Rather than criticizing the quality of care, the majority of family members who were allowed to witness resuscitation felt that everything possible was done for the patient.[5,27,41-43,48] Most reports on FP document no disruptions in patient care and describe family members as quiet observers.[18,43-46]

Table 2 is a summary of the perceived benefits of FP. Many of the studies supporting the benefits of FP during IP and CPR have already been mentioned. It appears that once institutions have

incorporated FP into their practice, staffs have remained supportive.[12,26,43] Family members who were present for procedures or during resuscitation reported that they were glad that they had done so and would choose to do it again.[26,43] Results from psychological examinations suggest that family members present during resuscitation have more positive grieving behavior than family members not present during resuscitation.[46] Although there are no data regarding the risk of litigation and FP, reduced risk behavior was reported by healthcare providers whose attention to patient needs for privacy and pain management were prompted by the presence of family members.[26,46] Those who have reported their experience with FP have not reported increased litigation.[47]

Critical appraisal of the FP literature notes that it is in the initial stages of development with many limitations that frequently include methodological flaws that limit interpretation and prevent comparison of results.[14] Most of the studies are survey or observational in nature and few randomized controlled trials exist. The Institute of Medicine Committee on Palliative and End-of-Life Care for Children and Their Families recommends that additional systematic research on bereavement outcomes and other consequences of parental presence policies be conducted.[48] They note that prospective studies could follow families through the entire process from the discussion of presence during resuscitation to the aftermath including follow-up during bereavement. Additional research would serve to increase the depth of understanding regarding the effect of FP on patients, family members and health care providers, in both acute care and intensive care settings, and provide direction on the best practices for education, implementation of programs and provision of care.

Method

The UCLA-RAM was used to develop recommendations for FP in the ED. This method is a modification of the Delphi method, a structured process for collecting and condensing knowledge from a group of experts through a series of questionnaires. The RAM was originally used to assist in determining the relative weight of benefits and harms of medical procedures, [49-53] but has also been used to develop other medical guidelines and recommendations.54-61 RAM methodology in this case included 1) recruitment of a panel of experts 2) a literature search and compilation of journal articles, 3) development of a list of issues and definitions, 4) design and distribution of first round questionnaire (pre-survey) to the expert panel, 5) expert panel completion of first round questionnaire and subsequent review of the literature, 6) meeting of the expert panel, with presentation of first round results and discussion of definitions and significant issues (Day 1 of meeting); 7) development of second round questionnaire with addition of issues identified during Day 1 of the meeting; 8) presentation of results of second round questionnaire to the expert panel, with discussion and development of agreement on recommendations (Day 2 of the meeting); 9) circulation of the final document for approval by the expert panel.

The expert panel included appointed representatives and guests from the organizations in Table 3. The panel represented a variety of disciplines, pediatric subspecialties (emergency medicine, critical care, and surgery) and educational backgrounds, several having more than one degree (BS-2, EMT-P-1, MS-1, MD-6, MSW/LCSW-2, RN-2, PhD-2). All but two panel members were under 50 years of age, all panel members had experience with FP over 20 times (11/13), and 14 panel members were parents.

Round 1 Survey:

In preparation for the meeting, a Medline search was initiated using key words (individually and combined): family presence, parental presence, presence of relatives, family members, family-witnessed resuscitation, emergency department procedures, pediatric resuscitation, pediatric emergency, and invasive procedures. Forty-one relevant articles dating from 1981 to 2003 were found and collated for review by the expert panel. The articles consisted of personal accounts or position statements (19); review articles (8), and research articles, mostly surveys of bereaved families (14). The Round 1 questionnaire was developed for the meeting after reviewing the articles and identifying areas of interest. The questionnaire included 9 attitudinal questions about parental presence during invasive procedures and resuscitation, using a 4-point Likert scale. Other questions included what type of training should be required for professionals assisting with parental presence, what types of professionals are appropriate for accompanying the family, under what circumstances

participants felt it was appropriate to exclude the family, and what barriers existed to including the family during invasive procedures and resuscitation. The panel was also asked about benefits and drawbacks to allowing parental presence, and what family members or others should be included, if any. Demographic information asked of the panel included the amount of personal experience they had with parental presence, whether the individual was a parent, the individual's age and professional degrees.

Results

All panel members returned the initial survey except one whose appointment came too late to allow return of the survey prior to the meeting. There was only one change in panel membership during the duration of the project. The results of both the first and second round surveys are shown in Table 4.

Conference Day 1

Journal articles concerning FP had been reviewed prior to the conference; additional articles were distributed at the outset at the recommendation of panel members. During the first day of the meeting, the results of the first round survey were presented, with issues identified for further discussion. Results of the first survey showed that 1)all panel members agreed that parental presence should be an option for minor procedures, and 2)most panel members agreed that FP should be an option during all procedures. (Table 4) Panel members' comments about drawbacks in providing the option of FP included 1) possible family interference with procedures, 2) lack of sufficient staff to assist the family, resulting increased costs with implementation, and 3) concerns about the psychological effects on staff. Possible benefits noted included 1) a calming effect for both parent and child, 2) giving the family a sense of control and involvement in the child's care, 3) family awareness of how much was done for the child. Specific terms for use in developing guidelines related to FP were discussed and definitions agreed upon. (Table 5) Because of the broad scope of FP issues, panel members were divided by self-selection into three groups for discussion: Legal-Ethical; Education; and Policy and Procedure. Each of these groups met separately to discuss the topics, and presented the results of the discussion to the entire panel. Areas and issues that had not been identified in the first questionnaire were added to the second round questionnaire. Participants were then asked to complete the second round questionnaire, and the results were tallied prior to the second day meeting. Several issues remained unresolved on the first day, including some key definitions, and possible reasons for not presenting the option of FP. These were left to be discussed on the second day.

Conference Day Two

The second day of the conference began with a presentation of the results of the second round of the survey. There were some notable shifts in the thinking of the panel members from Round 1 to Round 2: 1)there was a trend to allowing parental presence in more invasive procedures such as resuscitation, lumbar puncture, closed reduction of fractures and tapping of a shunt; 2)there was an increase in the feeling that additional training was needed for those who accompany the family during procedures; 3)there were fewer reasons given for exclusion of the families; 4)the panel became more flexible in allowing individuals with a significant relationship to the patient to be present during procedures and CPR. (Table 4) The discussion then turned to an important unresolved issue from the first day of the conference. This was whether the consensus guidelines should use the focused terminology of "parental presence" or the more generalized "family presence". An additional issue of discussion considered the definition of a family member. For the purposes of these guidelines, panel members agreed to the broader term "family presence" and defined family member as a person over 18 years with an established relationship (relative or significant other, including single parents, grandparent as parent, and others) with the patient. Although the panel agreed to the age of 18 years as a general guideline, they also recognized the need for case-specific assessment and decision making. This means, for example, that a teen parent of a child should not be excluded from being present during a procedure or CPR on the basis of age alone.

The panel saw the primary purpose of FP as a supportive presence for the child. This supportive presence would occur during all of the activities from preparation of the family until the end of treatment. They felt that FP should be considered for all families and offered as an option with certain restrictions. Family presence should be offered as an option when the care of the child will not be interrupted and after an assessment for: 1) combative and threatening behavior; 2) extreme

emotional volatility; 3) behaviors consistent with intoxication or altered mental status 4) disagreement among family members and 5) threat to the safety of the health care team. When a family is not offered the option of FP the reason(s) for exclusion should be consistent with one or more of the above restrictions and should be well documented.

The assessment of the family for the conditions noted above should be made by a facilitator who is a member of the patient care team and has the responsibility of presenting the option for FP. Although the panel favored a team decision regarding FP they acknowledged that in cases of disagreement one team member must be ultimately responsible for decision making. That responsibility must rest with the team leader, usually a physician in the hospital setting. The panel recognized that preparation for instances of disagreement must be made well in advance through written policy and procedures. The patient's bedside was not seen as an appropriate forum for spur-of-the-moment debates.

The panel felt that a qualified facilitator should be identified and pre-assigned for some procedures and all instances of CPR. A person is qualified to be a facilitator when they are: 1) a member of the health care team; 2) have been appropriately trained on the knowledge, attitudes and skills necessary for providing the option for FP and 3) are familiar with hospital policy. The panel felt that any of the professionals listed in Table 6 could be trained as qualified facilitators.

The panel also discussed the definition of "invasive procedure". It was decided that it was unnecessary to arrive at an inclusive definition for invasive procedures. The term "procedure" could be used. For procedures the need for a facilitator can be determined on a case-by-case basis. For example, if the family member is prepared and has been present for procedures previously with no adverse effects, there is no need for a separate facilitator. In the case of procedures, the facilitator can have direct patient care responsibilities. In situations of resuscitation, the facilitator should also be familiar with hospital policy and a member of the health care team but it is recommended that they not be involved in the direct care of the patient during the resuscitation.

Process

The process for FP begins with assessment of the family and presentation of the option to be present by a qualified facilitator. The family is prepared and supported through the procedure or resuscitation by the facilitator. This preparation and support may include: an explanation of the procedure of CPR, advance description of the environment and the patient's appearance, provision of sensory and other information, discussion of the family member's role, instructions on where to stand in the treatment room, obtaining/assuring use of protective clothing/equipment, escorting of the family member into and out of the treatment room, providing comfort to the family member, reassessment of the appropriateness of the family member's presence and giving permission to leave. The facilitator can also have an important role in the orderly transition of care and in follow-up after the procedure or in the circumstance of the child's death.

Ethical and Legal Considerations

The panel carefully considered ethical and legal ramifications of FP. This could occur in institutions with and without written FP policies. For example, what are the legal ramifications of denying FP during CPR and procedures? These are currently unknown. The panel did feel that if there is a hospital policy, the staff must be educated as part of implementation and that the policy should be followed to minimize risk. Each hospital must develop its own policies, with review by their own legal counsel. In considering the legal and ethical issues regarding FP, the panel identified a number of exclusionary criteria that they felt could be appropriately outlined as part of policy and when included in written policy should minimize risk. These have been included in the initial assessment. Other potential exclusionary criteria discussed were: possible criminal cases, and potential child abuse cases. In these instances no consensus was reached. The panel believed that hospitals should consider legal review of their policies. Important principles were that the person who is the most appropriate first choice to be present during CPR and procedures is the patient's legal guardian. A policy whose motivation is to represent the best interest of the child should also minimize legal risk.

Patient and Family Rights

The issues of patient and family rights are related to the topics of legal and ethical ramifications of establishing or not establishing policy regarding FP. The panel believed that families have the right to

be with their child and provide support. In most cases this will be the parents. However, the panel recognized that in certain circumstances the parents may not be part of the child's life and other caregivers have adopted the parenting role. They believed that the definition of family must be sufficiently broad to include the important people in a child's life. In the absence of the legal guardian/s other family members who are available can be considered for FP. The issue of who is included and considered appropriate for FP was viewed as a child advocacy issue where decisions are made in the best interest of patient care and are not in conflict with the Health Information Portability and Accountability Act (HIPAA) or other confidentiality policy. Furthermore, they believed that children have the right to have supportive care and to the choice of support. They felt that the patient may, in many circumstances, be able to assist with decision-making about who should be present during a procedure and that ethically this could be done at any age. The panel urged that the needs of chronically ill children be addressed in the same way as others. The panel did not endeavor to arrive at consensus regarding the presence of other children in the room during procedures or CPR.

The panel noted that a critical key step in implementing policy regarding the option for FP is education of healthcare providers. It has been demonstrated that education is effective in changing attitudes and that comfort with FP comes with experience and confidence. Training in FP should be a part of medical and nursing school curricula and a core competency for residency training. In the hospital setting, all of those with potential patient contact must be educated on the option for FP and relevant hospital policy; this can be role specific. Those who have been identified as qualified facilitators must be trained regarding the knowledge, attitudes and skills needed for providing the option of FP.

There is a need for educational programs that present the option of FP, including current evidence of benefits, barriers and solutions, and cultural and diversity issues. Education should also include coping with family groups in discord, and methods for diffusing volatile situations. Safety is always a primary concern, so education should address staff safety, and exit strategies for family members who become overwhelmed. These programs should promote a multidisciplinary approach, train competent facilitators and establish model procedures. Educational methods can vary but advanced role-playing has been recommended by providers experienced in offering the option of FP.[5]

During the discussion it became evident that the consideration of FP is not limited to the ED/hospital setting. Out-of-hospital providers frequently perform procedures or initiate resuscitation in the presence of family members, often in the family's home. The panel emphasized the importance of FP education and training for all levels of healthcare providers. The panel also recommended several directions for future research regarding FP to assist in identifying best practices and long term effects of FP. (Table 7)

Summary

From the beginning of the conference, there was remarkable unanimity among the panel members about the importance of providing the option of FP during procedures and cardiopulmonary resuscitation. The panel agreed on some important recommendations, shown in Table 7. The barriers to implementation of FP were generally agreed to be greatest when healthcare providers 1)had little experience with the process, 2)had not been given adequate education about the positive effects of FP for the child and family; 3)felt anxious about being observed while the family was present, and 4)were concerned about legal issues. There were also concerns about increased costs of providing the option of FP although these were lessened after panel discussion.

MacLean's survey showed that only 5% of nurses worked in critical care and emergency units or departments that had written policies allowing FP during CPR and procedures, even when over 45% of these settings allowed it, and many respondents had personally taken family members to the bedside during resuscitation or procedures.[8] Given the substantial agreement in our multidisciplinary panel about the importance of providing this option, why do so few health care settings support FP with written policies and procedures, and what would be necessary to increase implementation of FP? Traditional practices, attitudes, and healthcare behaviors are learned throughout professional training, and traditional beliefs are that families are emotional, lack understanding of procedures, and may be critical of procedures they do not understand. These beliefs will have to change in order to increase acceptance of FP. In healthcare, change is usually a process that involves education and

research. Today, healthcare providers may also need administrative and legal support to overcome resistance.

Education
To increase implementation of FP, education would have to include not just the teaching of knowledge and skills, but changes in attitude. After two days of deliberation, the panel agreed that education would be of considerable importance in increasing the number of healthcare facilities and settings that provide the option of FP, and support it with written policies and procedures. This education should be provided in core curricula, in-service education, and in orientation classes. All of the panel members also indicated that this additional training was needed by all types of healthcare professionals, including, physicians, nurses, prehospital care providers, social workers, mental health professionals, those involved in pastoral care, and any others that could be involved in the process of providing support for FP during procedures and cardiopulmonary resuscitation. This education should also be provided for safety officers, who are often called upon in these situations, with little training in how to manage stressed families.

Research
The panel felt strongly that more information is needed to determine short and long-term outcomes of FP on healthcare providers, families, and patients. Preferably, multicenter research should be conducted to determine not only the effects of FP, but to identify best practices, legal issues, and to assess what additional costs FP might incur. The panel discussed the relationship of FP with pain management, noting that as pain management improves, healthcare providers may be more willing to include the family in the treatment setting. More research is needed to examine this relationship and how children's pain affects the willingness of healthcare providers to offer the option of FP.

Legal Issues
The panel emphasized the importance of developing appropriate exclusionary criteria to assure the safety of patients, families, and staff. The panel felt that written policies showing reasons for excluding the family would be the best protection for healthcare personnel if the family were not allowed to be present. Documentation in medical records should include reasons for exclusion when appropriate. In addition, the panel suggested that legal review of all written policies would be essential.

We believe that the number of organizations, disciplines and pediatric subspecialties represented at the conference demonstrates an important commitment to improving the care of children and families through communication, collaboration and consensus building. It is our hope that the work of the multidisciplinary panel will provide the additional impetus needed to make offering the option of FP a routine part of the emergency care of children during procedures and CPR.

Table 1. Reasons Given by Health Care Providers for Concern Regarding FP [1-3]
The event may be too traumatic for the family
Clinical care will be impeded
Family members might become too emotional or out of control
Escalating negative behavior of children
Time required to orient parentsStaff may experience increased stress with the family present
ED rooms are too crowded
Staff are focused on the patient and may not be available to assist family members
The shortage of nurses
Risk of increased liability
Witnessing resuscitation may exacerbate the grieving process
The procedure may be interpreted as chaotic
Resuscitation will be prolonged
Health care providers will be intimidated by the family's presence
Family will witness insensitive comments by health care providers

Table 2. Perceived Benefits of Family Presence During Procedures [9,16, 18,26,42,47]

Family sees that everything possible was done for their relative
Reduction of anxiety and fear
Feeling of being supportive and helpful to the patient and the staff
Sharing critical information about the patient and the patient's condition
Maintaining the patient-family relationship
Closure on a life shared together
Facilitating the grieving process in the ED and later at home
Reduced risk behavior among health care providers regarding the patients privacy and pain

TABLE 4
PARENTAL PRESENCE QUESTIONNAIRE
RESULTS

Round 1Survey results are shown in parentheses ( ), and Round 2 survey results are shown in bold numbers. 4 = Strongly Agree, 3 = Agree, 2 = Disagree, 1 = Strongly disagree

Statement				
1. Parental presence should be allowed during suturing of minor lacerations **Avg.** (3.86) **3.87**	Strongly Agree	Agree	Disagree	Strongly Disagree
	(12)**13**	(2)**2**	**0**	**0**
2. Parental presence should be allowed when phlebotomy is being performed. **Avg.** (3.14) **3.87**	Strongly Agree	Agree	Disagree	Strongly Disagree
	(12)**13**	(2)**2**	**0**	**0**
3. Parental presence should be allowed during all procedures. **Avg.** (3.14) **3.43**	Strongly Agree	Agree	Disagree	Strongly Disagree
	(6)**8**	(5)**5**	(2)**0**	(1)**1**

4. Parental presence should be allowed during closed reduction of limb fractures. **Avg.** (3.39) **3.79**	Strongly Agree (6)**10**	Agree (6)**4**	Disagree **1**	Strongly Disagree **0**
5. Parental presence should be allowed during lumbar puncture. **Avg.** (3.72) **3.79**	Strongly Agree (10)**11**	Agree (4)**3**	Disagree **0**	Strongly Disagree **0**
6. Parental presence should not be allowed during any procedures. **Avg.** (1.22) **1.2**	Strongly Agree (0)**1**	Agree (1)**0**	Disagree (1)**1**	Strongly Disagree (12)**13**
7. Parental presence should be allowed during bone marrow aspiration **Avg.** (1.41) **1.40**	Strongly Agree (8)**11**	Agree (3)**3**	Disagree (1)**0**	Strongly Disagree (0)**1**
8. Parental presence should be allowed during tapping of a shunt **Avg.** (3.59) **3.67**	Strongly Agree (7)**12**	Agree (6)**2**	Disagree (1)**0**	Strongly Disagree (0)**1**
9. Parental presence should be allowed during attempted resuscitation (CPR) **Avg.** (3.22) **3.87**	Strongly Agree (6)**13**	Agree (6)**2**	Disagree (1)**0**	Strongly Disagree (1)**0**

****Note: the use of the term "procedures" is used from this point on to include all types of procedures including resuscitation**

10. What type of training (if any) would be necessary for healthcare professionals (physicians/nurses) who accompany the family during procedures? (*Numbers represent the number of panel member responses)*

(0) **0** No additional training needed
(12) **15** Inservice education about specific issues involved in parental presence
(12) **13** Inservice education about procedures for accompanying parents
(10) **9** Crisis intervention training

11. What type of training (if any) would be necessary for mental health professionals (social workers, other mental health professionals) who accompany the family during procedures?

(0) **0** No additional training needed
(12) **15** Inservice education about specific issues involved in parental presence
(14) **13** Inservice education about procedures for accompanying parents
(9) **9** Crisis intervention training

12. What type of training (if any) would be necessary for clergy/pastoral care professionals who accompany the family during procedures?

(0) **0** No additional training needed
(12) **14** Inservice education about specific issues involved in parental presence
(13) **13** Inservice education about procedures for accompanying parents
(9) **9** Crisis intervention training

When parents are allowed to be present during procedures they are often accompanied by a healthcare or other professional for support. Please circle the number corresponding to your feelings about whether you agree or disagree as to the appropriateness of the following professionals performing this service.

Round 1Survey results are shown in parentheses ( ), and Round 2 survey results are shown in bold numbers. 4 = Strongly Agree, 3 = Agree, 2 = Disagree, 1 = Strongly

disagree

Type of Professional	Responses	Average
13. Nurses	Strongly Agree Agree Disagree Strongly Disagree (10)**12** (4)**2** (0)**0** (0)**0**	(3.78)**3.86**
14. Clergy/Pastoral Care	Strongly Agree Agree Disagree Strongly Disagree (4)**7** (9)**8** (1)**0** (0)**0**	(3.22)**3.47**
15. Child life specialists	Strongly Agree Agree Disagree Strongly Disagree (5)**12** (7)**3** (2)**0** (0)**0**	(3.22)**3.78**
16. Social workers	Strongly Agree Agree Disagree Strongly Disagree (8)**13** (5)**2** (1)**0** (0)**0**	(3.50)**3.87**

19.Other **Techs/Aides** **Psychologists** **Translation Svcs.**	Strongly Agree Agree Disagree Strongly Disagree (1)**1** (1)**0** (0)**0**	

20. Which of the following do you think are appropriate reasons for excluding parents/caretakers from being present during procedures? *(Check any you feel may apply)*

(0) 0 Parents may observe errors being made.
(6) 2 Parents may be emotionally overwhelmed by the experience.
(2) 2 Parents may faint.
(2) 3 Parents may become hysterical.
(5) 6 Parents may interfere with professionals.
(3) 0 Parents may not understand why certain procedures are being performed.
(1) 0 Parents may obtain false impressions about their child's care.
(11) 8 There are insufficient staff members to cope with the parents.
(0) 0 Observing procedures may encourage parents to initiate lawsuits.
(4) 0 Staff members may be uncomfortable with parental presence.
(1) 1 The child may be less cooperative if parents are present.
(2) 1 There are no appropriate reasons.
_____ Other:

21. How often do you feel the following are barriers to allowing parental presence?

Round 1Survey results are shown in parentheses ( ), and Round 2 survey results are

shown in bold numbers. 4 = Strongly Agree, 3 = Agree, 2 = Disagree, 1 = Strongly disagree

Barriers	*Number of Responses*
22. Staff discomfort **Avg.** (3.22) **3.27**	Frequently Sometimes Not Often Rarely (5)**6** (7)**8** (2)**0** (0)**1**
23. Physician discomfort **Avg.** (3.58) **3.36**	Frequently Sometimes Not Often Rarely (8)**7** (6)**6** (0)**0** (0)**1**
24. Financial barrierst **Avg.** (1.79) **1.74**	Frequently Sometimes Not Often Rarely (0)**1** (4)**3** (3)**2** (7)**9**
25. Lack of protocols/procedures for parental presence **Avg.** (2.86) **3.20**	Frequently Sometimes Not Often Rarely (4)**5** (6)**8** (2)**1** (2)**1**
26. Risk management issues **Avg.** (2.28) **2.73**	Frequently Sometimes Not Often Rarely (3)**2** (6)**5** (3)**3** (2)**5**
27. Insufficient staff to assist in family presence **Avg.** (2.72) **2.00**	Frequently Sometimes Not Often Rarely (3)**4** (8)**8** (1)**2** (2)**1**
28. Lack of time **Avg.** (2.64) **3.00**	Frequently Sometimes Not Often Rarely (1)**3** (7)**4** (2)**3** (4)**5**
29. Lack of space for parental presence **Avg.** (2.14) **1.80**	Frequently Sometimes Not Often Rarely (2)**0** (4)**4** (2)**4** (6)**7**
30. Other *(Please specify)*	

31. Who should be allowed to be present during procedures? *(Please check one only.)*
(0) 0 No parents or caretakers
(7) 3 Parents or caretakers only
(1) 0 One parent or caretaker only
(0) 3 Any family members that the parents or caretakers select
(3) 3 Any family members that the parents or caretakers select, except children under 12 years of age.
(3) 6 Any individuals that the parents or caretakers select

32. Do you think there would be added costs for implementing a protocol in parental presence?
Yes (9) **13** No (4) **2**

Table 5. Definitions Used for the Purposes of the Discussion	
Family Member	A person over 18 years old with an established relationship (relative or significant other) with the patient.
Family Presence	Attendance of family members in a location that allows visual or physical contact with the patient during procedures or CPR
Procedure	An intervention involving manipulation of the body or penetration of the body's natural barriers.
Restrictions	Situations that might necessitate a family member's being escorted from or being prevented from entering the treatment room.
Resuscitation	A sequence of events including invasive procedures that are initiated to sustain life or prevent further deterioration of the patient's condition.

Table 6. Professionals Qualified to Be Family Presence Facilitators

Nurses
Clergy/Pastoral Care
Child life specialists

Physicians

Table 7. Panel Recommendations for Family Presence

Consensus Recommendations

1. Consider FP as an option for all families during pediatric procedures and CPR.
2. Offer FP as an option when the care to the child will not be interrupted and after an assessment for:
    - Combative and threatening behavior· Extreme emotional volatility· Behaviors consistent with intoxication or altered mental status
    - Disagreement among family members
    - Threat to the safety of the healthcare team
3. If family is not provided with the option for FP, document the reasons why FP was not offered.
4. Consider the safety of the healthcare team at all times.
5. In-hospital, transport and transfer settings should have written policies and procedures for FP, these should include but not be limited to:
    - Definition of a facilitator
    - Definition of family member, legal guardian, etc.
    - Definition of procedure
    - Preparation of the family, including explanations, descriptions, role of the family
    - Process of escorting the family in and out of the treatment room
    - Handling disagreements (wording)
    - Providing support for the staff
6. Healthcare policies regarding FP should undergo legal review.
7. Educate all healthcare providers
    - Include education in FP in all core curricula for health care providers at all levels.
    - Include this education also in health settings as part of hospital orientation.
8. Promote research to include, but not be limited to investigation of:
    - Best methods for education of providers
    - Long term outcomes of FP on the patient, family, and staff.
    - Best means of approaching and instructing families.
    - Best practices for FP.
    - Reasons why families may decline the opportunity to be present
    - Cost-effectiveness of FP
    - Potential legal ramifications of implementing or not implementing FP· Relation of FP to consent issues regarding tissue donation or autopsy.
    - Relation of FP to pain management?

Note: When possible, research methodology such as randomized, controlled trials should be used, including multicenter trials.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT
Guidance for the Clinician in Rendering Pediatric Care

Douglas S. Diekema, MD, MPH; and the Committee on Bioethics

Responding to Parental Refusals of Immunization of Children

ABSTRACT. The American Academy of Pediatrics strongly endorses universal immunization. However, for childhood immunization programs to be successful, parents must comply with immunization recommendations. The problem of parental refusal of immunization for children is an important one for pediatricians. The goal of this report is to assist pediatricians in understanding the reasons parents may have for refusing to immunize their children, review the limited circumstances under which parental refusals should be referred to child protective services agencies or public health authorities, and provide practical guidance to assist the pediatrician faced with a parent who is reluctant to allow immunization of his or her child. ***Pediatrics*** **2005;115:1428–1431;** ***immunization, parental refusals, medical neglect, vaccine refusal.***

ABBREVIATION. AAP, American Academy of Pediatrics.

OVERVIEW OF THE PROBLEM

The immunization of children against a multitude of infectious agents has been hailed as one of the most important health interventions of the 20th century.[1–3] Immunizations have eliminated smallpox infection worldwide, driven polio from North America, and made formerly common infections like diphtheria, tetanus, measles, and invasive *Haemophilus influenzae* infections rare occurrences. By one account, pediatric immunizations are responsible for preventing 3 million deaths in children each year worldwide.[3] Despite this success, some parents continue to refuse immunizations for their children. The number of pertussis cases has increased steadily in the United States over the past 20 years, and Web sites critical of immunization are prominent on the Internet, a source that many parents rely on for health information.[4] It is ironic that the remarkable success of vaccine programs has resulted in a situation in which most parents have no memory of the devastating effects of illnesses such as poliomyelitis, measles, and other vaccine-preventable diseases, making it more difficult for them to appreciate the benefits of immunization.

According to a periodic survey of fellows of the American Academy of Pediatrics (AAP) on immunization-administration practices, 7 of 10 pediatricians reported that they had had a parent refuse an immunization on behalf of a child in the 12 months preceding the survey.[5] Measles-mumps-rubella vaccine was refused most frequently, followed by varicella vaccine, pneumococcal conjugate vaccine, hepatitis B vaccine, and diphtheria and tetanus toxoids and pertussis vaccines. Four percent of pediatricians had refused permission for an immunization for their own children younger than 11 years. When faced with parents who refuse immunization, almost all pediatricians reported that they attempt to educate parents regarding the importance of immunization and document the refusal in the patient's medical record. A small number of pediatricians reported that they always (4.8%) or sometimes (18.1%) tell parents that they will no longer serve as the child's physician if, after educational efforts, the parents continue to refuse permission for an immunization.[5]

The AAP strongly endorses universal immunization. However, for universal childhood immunization programs to be successful, parents must comply with immunization recommendations. The problem of parental refusal of immunization for children is an important one for pediatricians. Parents may have many reasons for refusing immunization. Some parents may object to immunization on religious or philosophical grounds, some may object to what seems to be a painful assault on their child, and others may believe that the benefits of immunization do not justify the risks to their child. Many commonly held beliefs about the risks of immunization are not supported by available data, and they frequently originate from the unsupported claims of organizations that are critical of immunization. These antivaccine information sources not only propagate unproven claims regarding vaccines but also may undermine the physician-family relationship by challenging the parents' trust of the medical profession.

What should the pediatrician do when faced with a parent who refuses to consent to immunizations for a child? The goal of this clinical report is to provide guidance to the pediatrician faced with this difficult situation. The physician faced with a parent who refuses to immunize a child faces 3 important and distinct issues that will be addressed in this report. First, are there situations in which parents who withhold immunizations from their children risk harming them sufficiently that their decision constitutes actionable medical neglect and should be reported to

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

state child protective services agencies? Second, are there situations in which a parental decision to withhold immunization from a child puts other individuals at risk of harm sufficient to justify public health intervention? Finally, how should the pediatrician respond to a parent who refuses immunizations for his or her child?

PARENTAL REFUSALS AND THE BEST INTERESTS OF CHILDREN

Health care professionals and parents are bound by the duty to seek medical benefit for and minimize harm to children in their care. When faced with the decision to immunize a child, the welfare of the child should be the primary focus. However, parents and physicians may not always agree on what constitutes the best interest of an individual child. In those situations, physicians may need to tolerate decisions they disagree with if those decisions are not likely to be harmful to the child.[6] Although decision-making involving the health care of children should be shared between physicians and parents, parental permission must be sought before children receive medical interventions, including immunizations.[7] Parents are free to make choices regarding medical care unless those choices place their child at substantial risk of serious harm.

Whether parents place their children at substantial risk of serious harm by refusing immunization will depend on several factors, including the probability of contracting the disease if unimmunized and the morbidity and mortality associated with infection. The results of such an analysis will also vary depending on the prevalence of disease in the community in which the child resides or the areas in which the child is likely to travel. The balance between the risks and benefits to a given individual favors immunization most strongly when rates of immunization in the community are low and disease prevalence is high. In most cases, however, as immunization rates increase and disease prevalence decreases, the balance may tip the other way.[8,9] Although the benefits of a measles-vaccine program, for example, clearly outweigh the risks at a population level,[10] an unimmunized child living in a well-immunized community derives significant indirect protection from herd immunity.[11] Even in a community with high immunization rates, the risk assumed by an unimmunized child is likely to be greater than the risks associated with immunization. However, the risk remains low, and in most cases the parent who refuses immunizations on behalf of his or her child living in a well-immunized community does not place the child at substantial risk of serious harm.

The role of the physician in these situations is to provide parents with the risk and benefit information necessary to make an informed decision and to attempt to correct any misinformation or misperceptions that may exist. For example, in a national survey of parents, 25% believed falsely that their child's immune system could become weakened as a result of too many immunizations.[12] Exploring and addressing parental concerns may be an effective strategy with reluctant parents. Only in rare cases in which the decision of a parent places a child at substantial risk of serious harm may the health care professional be obligated to involve state agencies in seeking to provide the necessary immunization over the parents' objections. For example, for the situation in which a child has sustained a deep and contaminated puncture wound, it might be justifiable to challenge the decision of a child's parents to refuse treatment with tetanus vaccine. In these situations, the health care professional would involve the appropriate state child protective services agency because of the concern about medical neglect. It would be up to the state agency to decide whether immunization would be required. Although this role of the state has been recognized as constitutionally valid in the United States, courts have closely examined such actions, showing reluctance to require medical treatment over the objection of parents "except where immediate action is necessary or where the potential for harm is rather serious."[13]

COMMUNITY INTERESTS AND PUBLIC HEALTH

The benefits provided by most vaccines extend beyond benefit to the individual who is immunized. There is also a significant public health benefit. Parents who choose not to immunize their own children increase the potential for harm to other persons in 4 important ways.[14] First, should an unimmunized child contract disease, that child poses a potential threat to other unimmunized children. Second, even in a fully immunized population, a small percentage of immunized individuals will either remain or become susceptible to disease. These individuals have done everything they can to protect themselves through immunization, yet they remain at risk. Third, some children cannot be immunized because of underlying medical conditions. These individuals derive important benefit from herd immunity and may be harmed by contracting disease from those who remain unimmunized. Finally, immunized individuals are harmed by the cost of medical care for those who choose not to immunize their children and whose children then contract vaccine-preventable disease.

A parent's refusal to immunize his or her child also raises an important question of justice that has been described as the problem of "free riders."[14–16] Parents who refuse immunization on behalf of their children are, in a sense, free riders who take advantage of the benefit created by the participation and assumption of immunization risk or burden by others while refusing to participate in the program themselves. The decision to refuse to immunize a child is made less risky because others have created an environment in which herd immunity will likely keep the unimmunized child safe. These individuals place family interest ahead of civic responsibility. Although such parents do reject what many would consider to be a moral duty, coercive measures to require immunization of a child over parental objections are justified only in cases in which others are placed at substantial risk of serious harm by the parental decision.

Compulsory immunization laws in the United

States have been upheld repeatedly as a reasonable exercise of the state's police power in the absence of an epidemic or even a single case.[17,18] They also have been found to be constitutional even for cases in which the laws conflict with the religious beliefs of individuals.[19]

When others are placed at substantial risk of serious harm, the range of choices of the individual may be restricted. With regard to immunization, the key question becomes whether the harms associated with unimmunized individuals are great enough to make restrictions permissible. In times of epidemic disease, when an effective vaccine can end the epidemic and protect those individuals who have not yet contracted the disease, the answer clearly is yes.

In a highly immunized population in which disease prevalence is low, the risk of disease from the small number of children who remain unimmunized does not usually pose a significant-enough health risk to others to justify state action.[20] Diseases with very high morbidity and mortality (such as smallpox), however, might create a situation in which even a single case of infection would justify mandatory immunization of the population. For most routine vaccines, less forcible alternatives can be used justifiably to encourage parents to immunize children because of the public health benefit. In the case of vaccines routinely recommended for children, the AAP supports the use of appropriate public health measures, education, and incentives for immunization.[7] Because unimmunized children do pose a risk to other children who lack immunity to vaccine-preventable infections, the AAP also supports immunization requirements for school entry.

RESPONDING TO PARENTS WHO REFUSE IMMUNIZATION FOR THEIR CHILDREN

What is the pediatrician to do when faced with a parent who refuses immunization for his or her child? First and most important, the pediatrician should listen carefully and respectfully to the parent's concerns, recognizing that some parents may not use the same decision criteria as the physician and may weigh evidence very differently than the physician does.[21] Vaccines are very safe, but they are not risk free; nor are they 100% effective.[22] This poses a dilemma for many parents and should not be minimized. The pediatrician should share honestly what is and is not known about the risks and benefits of the vaccine in question, attempt to understand the parent's concerns about immunization, and attempt to correct any misperceptions and misinformation.[23–25] Pediatricians should also assist parents in understanding that the risks of any vaccine should not be considered in isolation but in comparison to the risks of remaining unimmunized. For example, although the risk of encephalopathy related to the measles vaccine is 1 in 1 million, the risk of encephalopathy from measles illness is 1000 times greater.[22] Parents can also be referred to one of several reputable and data-based Web sites for additional information on specific immunizations and the diseases they prevent (see pages 52 and 53 of the *Red Book*[25] for a list of Internet resources related to immunization).

Many parents have concerns related to 1 or 2 specific vaccines. A useful strategy in working with families who refuse immunization is to discuss each vaccine separately. The benefits and risks of vaccines differ, and a parent who is reluctant to accept the administration of 1 vaccine may be willing to allow others.

Parents also may have concerns about administering multiple vaccines to a child in a single visit. In some cases, taking steps to reduce the pain of injection, such as those suggested in the *Red Book*,[26] may be sufficient. In other cases, a parent may be willing to permit a schedule of immunization that does not require multiple injections at a single visit.

Physicians should also explore the possibility that cost is a reason for refusing immunization. For a parent whose child does not have adequate preventive care insurance coverage, even the administrative costs and copayments associated with immunization can pose substantial barriers. In such cases, the physician should work with the family to help them obtain appropriate immunizations for the child.

For all cases in which parents refuse vaccine administration, pediatricians should take advantage of their ongoing relationship with the family and revisit the immunization discussion on each subsequent visit. As respect, communication, and information build over time in a professional relationship, parents may be willing to reconsider previous vaccine refusals.

Continued refusal after adequate discussion should be respected unless the child is put at significant risk of serious harm (as, for example, might be the case during an epidemic). Only then should state agencies be involved to override parental discretion on the basis of medical neglect. Physician concerns about liability should be addressed by good documentation of the discussion of the benefits of immunization and the risks associated with remaining unimmunized. Physicians also may wish to consider having the parents sign a refusal waiver (a sample refusal-to-immunize waiver can be found at www.cispimmunize.org/pro/pdf/RefusaltoVaccinate_2pageform.pdf). In general, pediatricians should avoid discharging patients from their practices solely because a parent refuses to immunize his or her child. However, when a substantial level of distrust develops, significant differences in the philosophy of care emerge, or poor quality of communication persists, the pediatrician may encourage the family to find another physician or practice. Although pediatricians have the option of terminating the physician-patient relationship, they cannot do so without giving sufficient advance notice to the patient or custodial parent or legal guardian to permit another health care professional to be secured.[27] Such decisions should be unusual and generally made only after attempts have been made to work with the family. Families with doubts about immunization should still have access to good medical care, and maintaining the relationship in the face of disagreement conveys respect and at the same time allows the child access to medical care. Further-

more, a continuing relationship allows additional opportunity to discuss the issue of immunization over time.

Committee on Injury and Poison Prevention

Restraint Use on Aircraft

ABSTRACT. Occupant protection policies for children younger than 2 years on aircraft are inconsistent with all other national policies on safe transportation. Children younger than 2 years are not required to be restrained or secured on aircraft during takeoff, landing, and conditions of turbulence. They are permitted to be held on the lap of an adult. Preventable injuries and deaths have occurred in children younger than 2 years who were unrestrained in aircraft during survivable crashes and conditions of turbulence. The American Academy of Pediatrics recommends a mandatory federal requirement for restraint use for children on aircraft. The Academy further recommends that parents ensure that a seat is available for all children during aircraft transport and follow current recommendations for restraint use for all children. Physicians play a significant role in counseling families, advocating for public policy mandates, and encouraging technologic research that will improve protection of children in aircraft.

ABBREVIATIONS. AAP, American Academy of Pediatrics; CSSs, child safety seats; FAA, Federal Aviation Administration; NTSB, National Transportation Safety Board; CFR, Code of Federal Regulations; CAMI, Civil Aeromedical Institute; SAE, Society of Automotive Engineers.

INTRODUCTION

Children younger than 2 years are the only occupants who, under current federal regulation, are not required to be restrained or secured on aircraft during takeoff, landing, and conditions of turbulence; even items such as coffee pots must be secured. This practice relating to nonrestraint of children on airplanes is inconsistent with all occupant protection recommendations of the American Academy of Pediatrics (AAP) in which priority has been placed on safe transportation of children. Many child safety seats (CSSs) used in motor vehicles are also approved for use on aircraft. The Federal Aviation Administration (FAA) has stated that proper use of an approved CSS for aircraft enhances child safety in the event of turbulence or a crash, and the FAA informs parents that a "safety seat can be the most important carry-on item of all."[1] The FAA strongly recommends but has not yet mandated that all children who fly, regardless of age, should be restrained in the appropriate CSS for their weight and size used in conjunction with the aircraft seat belt.

In a 1996 report to the President of the United States, the White House Commission on Aviation Safety and Security stated that it is inappropriate for infants to be afforded a lesser degree of protection than that for older passengers.[2] The Commission recommended that the FAA revise its regulations to require that all occupants be restrained in aircraft during takeoff, landing, and conditions of turbulence and that all infants and small children whose weight is less than 40 lb and whose height is less than 40 in be restrained in an aircraft-approved CSS. The Association of Flight Attendants and the National Transportation Safety Board (NTSB) have called for federal regulation requiring appropriate restraint use.[3–5] The NTSB has also called for the FAA to develop standards for CSS use in aircraft. The FAA has argued that a mandatory requirement for CSS use on aircraft will result in more injuries and deaths to infants and toddlers because parents would not be willing to buy a ticket to reserve a seat for the infant and would opt to travel by car instead[6]; however, no data support this argument.

CURRENT POLICY FOR CHILDREN

Children younger than 2 years are currently allowed to be held in an adult's lap throughout a commercial aircraft flight, as stipulated by the US Code of Federal Regulations (CFR).[7] Alternatively, parents may choose to use a CSS certified under the Federal Motor Vehicle Safety Standards and Regulations for travel in aircraft and motor vehicles.[8] Airlines are required to accommodate the use of approved CSSs for young children with tickets; however, the child must occupy a window seat in a nonexit row. Although many airlines offer discounted rates for children younger than 2 years, these rates are often not advertised, and parents must ask to receive a reduced-rate ticket. If parents want to ensure that the child has a passenger seat in which the CSS can be used, they must purchase a ticket. If the child is held on the lap of an adult, no fare is charged for the child. Children 2 years and older are required to sit in their own passenger seat under the same regulations that apply to all other passengers.

In 1995, in the aftermath of serious and sometimes unexpected events of turbulence, the FAA issued a public advisory to airlines urging the use of seat belts at all times when passengers are seated.[6] Some airlines now comply, but the requirement does not apply to children younger than 2 years because they are not required to be restrained at any time during the flight.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

BACKGROUND

Approximately 25 000 commercial flights depart from and arrive at US airports daily.[9] Although it is estimated that 4.6 million children younger than 2 years fly on US domestic airlines annually, inaccuracies in the passenger manifest, which contains the names of all passengers as required by the US CFR, make it difficult to obtain precise numbers. The NTSB has issued safety recommendations that require standardized reporting of all passengers.[10]

The risk of death or serious injury in an aircraft is exceedingly small. Using data from 1990 forward not controlled for age, the risk of death was calculated at 1 in 8 million.[11] During 1996, there were 319 passenger fatalities and 77 serious injuries on US air carriers operating under the CFR. These data are not provided by year of age of passenger but include all scheduled and nonscheduled services on commercial and cargo carriers.[12] Analysis of aircraft crashes from 1976 through 1979 in which there were fatalities and survivors revealed that unrestrained infant passengers had a relative mortality risk of 5.9 (United States) and 9.6 (worldwide), compared with restrained adult passengers. It could not be determined whether the higher risk of mortality for infants was attributable to lack of restraint use, fragility of infants, or both.[13]

In a study comparing persons fatally injured in aircraft in 1980 and 1990, blunt injury (in particular, head injury) from deceleration forces was the most important threat to survival. Head injuries were listed as the immediate cause of death in 33% of those younger than 15 years.[14] As with other forms of transportation, effective restraint systems decrease the probability of head injury.

Turbulence is the leading cause of nonfatal injuries to aircraft passengers and flight attendants. From 1981 through 1997, there were 342 reports of turbulence affecting major airlines. Three passengers died, 80 had serious injuries, and 769 had minor injuries.[15]

A child on the lap of an adult cannot be effectively restrained in a motor vehicle or aircraft crash. A child who travels on the lap of another occupant or unrestrained in a motor vehicle has a substantially greater risk of injury and death, compared with a restrained child.[16–18] Hazards associated with the on-lap position are also well documented in aircraft crash investigations. Three children on the laps of adults were fatally injured and others nonfatally injured in the 1987 crash in Denver, CO, the 1989 crash in Sioux City, IA, and the 1994 crash in Charlotte, NC—which were all caused by turbulence.[19–21] The NTSB has reported 2 crashes in which CSSs were used and provided protection to children.[3]

CERTIFICATION OF CSSs FOR USE ON AIRCRAFT

The FAA's Civil Aeromedical Institute (CAMI) has conducted studies on CSSs for use with aircraft seats. Crash testing of CSSs using child dummies in 1993 revealed that rear-facing CSSs performed well and could be installed with contemporary aircraft seat belts. However, 6 of the 8 tests with forward-facing CSSs resulted in Head Impact Criteria values of more than 1000, which is the threshold for serious head impact in adults. Difficulty was encountered in securing some of the forward-facing CSSs to the aircraft seats. Moving the anchor points rearward resulted in improved performance of many CSSs; however, most aircraft have seats with poor belt anchor geometry.[22]

Certain restraints that are approved for use in motor vehicles are prohibited for use in aircraft (14 CFR 121.311).[7] When tested, vest and harness type systems allowed excessive forward body excursion, causing the test dummy to slide off of the front of the seat, potentially impacting the seat in front and resulting in injuries.[22,23] Shield type booster seats are incompatible with aircraft seats because of the seatback breakover feature common on airplanes.

POTENTIAL NEW TECHNOLOGY

Testing has shown that aircraft seat belts alone do not adequately protect a child younger than 3 years.[22,23] The CAMI has developed and fully tested a prototype aircraft seat insertion platform, which can be inserted under the CSS and secured to the aircraft seat with the seat belt. Seat belts attached to the platform are used to secure the CSS. The platform improves ease of installation and decreases the forward excursion of the CSS. A CSS designed for use in aircraft that could be used forward or rear facing is a second alternative. One such device is already approved and is being sold. A third alternative is modifying a certain number of passenger seats on each aircraft to accommodate and ensure adequate performance of CSSs. A relatively simple and low-cost modification has been successfully demonstrated at CAMI. The Society of Automotive Engineers (SAE) has recently adopted a performance standard for CSSs installed on airplane passenger seats.[24] The objective of this standard is to establish performance criteria for CSSs when installed in airplane seats. The methods of meeting the SAE standard and the pass/fail criteria are similar to those already imposed on CSSs by automotive regulations (49 CFR 571.213). Inclusion of the SAE standard in automotive regulations for CSSs should be considered.

A national symposium was held by the NTSB in 1999 to explore operation, design, regulations, and experience with CSSs nationally and internationally.[25] At this meeting, FAA Administrator Jane Garvey announced ". . . We [FAA] are committed to 2 things—mandating the use of child restraint systems in aircraft and assuring that children are accorded the same level of safety as are adults." This statement clearly implies the FAA plans to move forward with regulatory actions mandating the use of effective CSSs in airplanes.

ENFORCEMENT OF EXISTING RESTRAINT REQUIREMENTS FOR CHILDREN

The NTSB has documented events in which children 2 years and older have been transported on the lap of an adult. The NTSB has been concerned about the inadequacy and lack of enforcement of passenger protection regulations and has recommended that

the FAA implement measures for enforcing restraint regulation for children 2 years and older.[26]

RECOMMENDATIONS

Consistent with national policies requiring restraint use in all vehicles, the AAP recommends that regulations be promulgated to ensure that all passengers, including those younger than 2 years, are afforded optimal protection during all phases of commercial and general aircraft flights. The AAP believes that children should be afforded the same protection as other passengers and that restraint use in aircraft for children younger than 2 years should be mandatory during takeoff, landing, and conditions of turbulence and should be recommended as much as feasible during flight as it is for all other passengers.

Pediatricians, federal agencies, and airlines are encouraged to work together to accomplish the following:

1. Implement mandatory restraint use requirements using aircraft-approved restraint systems and discontinue the policy of allowing children younger than 2 years to be held on the lap of an adult on aircraft.
2. Enforce current requirements for children older than 2 years, some of whom travel unrestrained and without tickets.
3. Establish standards for appropriate restraint use in aircraft for all children. Amend the CFR[7] by adding a section on child restraint requirements on aircraft providing intrastate, interstate, or overseas transportation. Establish age and weight recommendations for use of CSSs similar to those for motor vehicles.
4. Provide information on current recommendations for the restraint of children younger than 4 years similar to AAP recommendations for restraint use in motor vehicles as follows[27]:
   - Children should be placed in a rear-facing CSS that is properly secured and installed until they are at least 1 year old *and* at least 20 lb in body weight.
   - A forward-facing seat labeled for use on aircraft should be used for children at least 1 year old and 20 to 40 lb in body weight. The AAP is aware of the problems found by the CAMI study with forward-facing seats but believes that these seats afford more protection to children than do seat belts alone, no restraint use, or being held on a lap. The CSS manufacturers label seats that fit and can be satisfactorily restrained to an aircraft seat.
   - According to the FAA, CSSs should not exceed 16 in wide for best fit in aircraft seats; this is especially important in small commuter aircraft.
   - Children who weigh more than 40 lb can be secured in the aircraft seat belt.[28]
5. Establish international standards through the International Civil Aviation Organization requiring that passengers on civil aircraft be restrained during takeoff and landing and when directed by the captain of the aircraft.
6. On all types of passenger aircraft, pursue technologic solutions for improving restraint systems for children who are inadequately protected by existing child restraints or seat belt systems.
7. Educate all airline personnel who have contact with families regarding the importance of, and the requirements for, age-appropriate restraint use on aircraft. This includes travel agents, reservation/gate agents, and cabin crew.
8. The airlines should make available to families CSSs that are compatible and effective in aircraft.
9. Encourage airlines to offer a discounted fare (or a rebate) for restrained children.

Pediatricians should convey the following information to parents:

1. All children should travel properly restrained on aircraft.
2. Similar to travel in motor vehicles, a child is best protected when properly restrained in a CSS appropriate for the age, weight, and height of the child, meeting standards for aircraft until the child weighs more than 40 lb and can use the aircraft seat belt. Child safety seat systems manufactured to US standards for aircraft use after February 26, 1985, bear the label: "This restraint is certified for use in motor vehicles and aircraft" in red letters.[28]
3. Families should explore options for ensuring that each child has an aircraft seat. Currently, to ensure that a child has a seat for the CSS, families must purchase a ticket and should specify a window seat next to the parent in a nonexit row for the CSS. However, it is suggested that parents ask the airline whether the purchase of a seat is required to use a CSS and consider asking for the information in writing. Parents should also ask and be advised about discounted fares and compare the benefits of various airlines. If no discounted or free fare is offered by any airline and it is not feasible to purchase a ticket, parents should select flights that are likely to have empty seats. Parents should inquire about the carrier's policy regarding use of empty seats. Parents who are traveling with CSSs should be reminded that they can request assistance from the airlines between connecting flights.
4. Parents can obtain additional information on safe air travel for children from the FAA (1-800-FAA-SURE and http://www.faa.gov/).

There is a need for accurate exposure data. Accurate passenger manifests should be generated to include all passengers on all flights. Standard reporting for all passenger injuries should be established and made available by age of passenger and restraint use. Epidemiologic studies and the evaluation of preventive measures may thus be conducted.

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

The American Academy of Pediatrics (AAP) reaffirms its strong opposition to female genital cutting (FGC) and counsels its members not to perform such procedures. As typically practiced, FGC can be life-threatening. Little girls who escape death are still vulnerable to sterility, infection, and psychological trauma.

The AAP does not endorse the practice of offering a "clitoral nick." This minimal pinprick is forbidden under federal law and the AAP does not recommend it to its members.

The AAP is steadfast in its goal of protecting all young girls from the harms of FGC.

The Role of Home-Visitation Programs in Improving Health Outcomes for Children and Families

ABSTRACT. Traditional pediatric care is often based on the assumption that parents have the basic knowledge and resources to provide a nurturing, safe environment and to provide for the emotional, physical, developmental, and health care needs of their infants and young children. Unfortunately, many families have insufficient knowledge of parenting skills and an inadequate support system of friends, extended family, or professionals to help with these vital tasks. Home-visitation programs offer an effective mechanism to ensure ongoing parental education, social support, and linkage with public and private community services. This statement reviews the history and current research on home-visitation programs and provides recommendations about the pediatrician's role in supporting and using home visitation.

HISTORY OF HOME-VISITATION PROGRAMS

Home visitation for parents is a widespread early-intervention strategy in most industrialized nations other than the United States. In most countries, home health visiting is free, voluntary, not income-related, and embedded in comprehensive maternal and child health systems. Although a causative link has not been demonstrated conclusively, countries with extensive home visitor programs generally have lower infant mortality than does the United States. This is despite per capita health spending in the United States that far exceeds expenditures in other industrialized countries.[1] Denmark established home visiting by law in 1937 after a pilot program was successful in lowering infant mortality. France provides free prenatal care and home visits by midwives or nurses to provide education about smoking, nutrition, alcohol and other drug use, housing, and other health-related issues. In England, every prospective mother is visited at home at least once before birth, with six more visits typically occurring before the child is 5 years of age.[2] In the United States, home-visitation services have been perceived by many as too costly and unnecessary for all new families.

Home-visitation programs began in the United States in the late 19th century. Public health nurses and social workers provided in-home education and health care to women and children, primarily in poor urban environments.[3,4] At the beginning of the 20th century, the New York City Health Department implemented a home visitor program, using student nurses to instruct mothers about breastfeeding and hygiene. This program reduced the high mortality rate of inner-city infants from summer diarrhea when previous efforts of private agencies had failed.[5] In the late 20th century, as funding for public health nurses has declined relative to the need, home-visitation programs have focused on families with special problems such as premature or low-birth-weight infants, children with developmental delay, teenage parents, and families at risk for child abuse or neglect.[6]

Almost 20 years ago, Dr C Henry Kempe suggested that to ensure the right of every child to comprehensive care, every pregnant woman be assigned a home health visitor who would work with the family until the child began school.[7] Insurance companies declined to pay for this service because of a lack of empirical evidence to support its effectiveness. Kempe continued to advocate home visiting vigorously, suggesting that it could play a major role in the prevention of child abuse. He reiterated these ideas in the 1978 Abraham Jacobi Award Address.[8] In 1980, the American Academy of Pediatrics held a conference on home visitation. The conferees were unable to find sufficient research on home visitation to recommend it as national policy.[4]

In the 1992 Jacobi Award Address, Sia[9] renewed Kempe's arguments, citing additional information about the effectiveness of health-related home-visitation programs in Hawaii in improving health and social outcomes for children. The publication in 1988 of Schorr's book, *Within Our Reach: Breaking the Cycle of Disadvantage*,[10] encouraged Sia and other advocates in Hawaii to move ahead with the first statewide home-visitation program. Begun in 1993, this program currently is the subject of two rigorously designed outcome studies and has stimulated research and development of similar programs in other states.[11]

POTENTIAL BENEFITS OF HOME-VISITATION PROGRAMS

A small but growing body of research has supported the effectiveness of home-visitation programs. The following benefits have been found as an outcome of some, but not all, home visitor programs:[12]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Prenatal Effects

- Increased use of prenatal care[6,13]
- Increased birth weight[6,13]
- Decreased preterm labor and increased length of gestation[6,13]
- Increased use of health and other community resources (eg, prenatal visits, well-child visits, family planning, programs for women, infants, and children [WIC], and immunizations)[6,13]
- Improved nutrition during pregnancy[13]
- Fewer urinary tract infections during pregnancy[13]
- Increased attendance at childbirth classes[13]
- Decrease in maternal smoking[6,13]
- Greater interest by fathers in the pregnancy[6,13]
- Increase in the number of mothers having a labor room companion[6,13]

Postnatal Effects

- Fewer subsequent pregnancies[14,15]
- Increased spacing between pregnancies[6,14]
- Increased length of maternal employment[6,14]
- Increased rate of return to, or retention in, school by mothers[6]
- Fewer emergency department visits[16]
- Fewer accidental injuries and poisonings resulting in a visit to the physician[16]
- Decrease in the number of verified incidents of child abuse and neglect[6,15,16]
- Decrease in physical punishment and restriction of infants, with an increase in use of appropriate discipline for older children[14,17]
- Improved maternal–child interaction and maternal satisfaction with parenting[6,12]
- Increased use of appropriate play materials at home[16]
- Improved growth in low-birth-weight infants[12]
- Higher developmental quotients in infants visited[18]

Long-term Effects

A 15-year follow-up study of families who received a mean of nine home visits by nurses during pregnancy and 23 home visits up to their child's second birthday has demonstrated the following long-term benefits:

- Fewer subsequent pregnancies[15]
- Reduced maternal criminal behavior[15]
- Decrease in use of welfare[15]
- Decrease in verified incidents of child abuse and neglect[15]
- Less maternal behavioral impairment attributable to alcohol and drug abuse[15]

The observed effect of home-visitation programs seems to be greatest in high-risk populations, such as mothers who are teenagers, unmarried, poor, or have been abused themselves, and in children who are preterm or low birth weight. [15]

PERTINENT VARIABLES IN HOME-VISITATION PROGRAMS

Home visitors may be professionals or paraprofessionals, volunteers or paid workers. The services they provide may be social, health-related, or educational and may be targeted to an individual child or to an entire family.[6] They are not intended to replace office-based pediatric care, but rather to supplement and reinforce it. Caution is advised in comparing the outcomes of different home-visitation programs, because they may vary in important ways, including the following:

- Use of trained paraprofessionals versus professional nurses
- Volunteers versus paid visitors
- Onset of services (first trimester vs later; before birth vs after)
- Duration of services (eg, until the second birthday or beyond)
- Frequency of visits
- Universal availability to families versus selective application to families at risk
- Training of providers
- Aim and scope of program
- Intervention strategies used (simple social support vs active intervention, education, and advocacy)
- Adequacy of supervision of visitors
- Ratio of families to visitors
- Client variables and demographics
- Level of risk in families served
- Clients' perception of need for services

ELEMENTS OF SUCCESSFUL HOME-VISITATION PROGRAMS

Olds has made a plea that health and human services groups not make recommendations about, design, or implement home-visitation programs without considering the empirical evidence about the types of programs that are more successful.[14] Current research indicates that more successful programs contain the following elements:[8,14]

1. A focus on families in greater need of services (as opposed to universal programs that may avoid stigmatizing families but might dilute scarce resources), including families with low-birth-weight and preterm infants; children with chronic illness and disabilities; low-income, unmarried teenage mothers; parents with low IQs; and families with a history of substance abuse;
2. Intervention beginning in pregnancy and continuing through the second to fifth year of life;
3. Flexibility and family specificity, so that the duration and frequency of visits and the kinds of services provided can be adjusted to a family's need and risk level;
4. Active promotion of positive health-related behaviors and specific qualities of infant care-giving instead of focusing solely on social support;
5. A broad multiproblem focus to address the full complement of family needs (as opposed to a focus on a single domain such as increasing birth weights or reducing child abuse);
6. Measures to reduce family stress by improving its social and physical environments; and
7. Use of nurses or well-trained paraprofessionals.

COST-EFFECTIVENESS OF HOME VISITATION

Are home-visitation programs cost-effective? Olds writes that "a major portion of the cost for home visitation can be offset by avoided foster care placements, hospitalizations, emergency room visits, and child protective service worker time incurred during the same period that the home visitor program is provided. The long-range financial savings to the community are in all likelihood substantially greater, as is the reduction of human suffering."[6] Olds reports that current home-visitation programs cost between $300 and $1750 per family per year depending on the level and frequency of services provided. Even the most expensive programs pay for themselves by the time the children are 4 years old. Approximately 80% of the cost savings comes from reduction in welfare payments and food stamps, with one third of the savings coming from reduction in unintended subsequent pregnancies.[8,14]

NEED FOR EVALUATION AND SAFETY

Many small home-visitation programs are being developed and implemented around the country. In the absence of careful design, attention to empirical findings from previous research on home-visitation programs, and high standards for field experimentation, it will be difficult to determine whether public and private monies are well spent. Public funding measures for home-visitation programs should require both continuous examination of outcome measures and the ability to make midcourse corrections.[8,14] Accrediting may be a key component to providing some degree of uniformity, accountability, and quality in home-visitation programs. Home-visitation programs also must ensure the safety of their visitors and protect them from the violence often found in the environment of families with the highest needs.[19]

LIAISON WITH PRIMARY PROVIDERS

Home visitors can be health care advocates to improve access to providers of health care. Home visitors can be partners with pediatricians and other clinicians, working in the home setting to provide essential education and supportive services to at-risk children and families and to improve adherence to medical prevention and treatment regimens. Home-visitation programs include a "degree of social support that is difficult to provide in most clinical settings; outreach and liaison between the pediatrician, the family, and the community; involvement with socioeconomic issues that directly affect the well-being of the child and family; reinforcement and follow-up of preventive care, peer helper support, as well as encouragement, by the home health visitor who has the advantage of being with the family in its own home—a more accepting, less threatening setting for the family."[6]

Home-visitation programs should be integrated into a community's existing health care system, expanding the effectiveness of private providers, health maintenance organizations, and public health nurses. Visitation programs can provide or supplement services that are constrained by managed care or budgetary reductions. Aspects of home-visitation services for pregnant women, infants, and preschool children already are provided in many communities through public and home health agencies, parent–child services, hospitals, and private agencies. In some areas, home-visitation programs have linked with Head Start and other community-based family support programs to provide continuous services from conception to the start of school.[20]

CONCLUSION

Home-visitation programs can be an effective early-intervention strategy to improve the health and well-being of children, particularly if they are embedded in comprehensive community services to families at risk.[4] Home-visitation programs are not a panacea, sufficient unto themselves to reverse or prevent the damaging effects on children of poverty and inadequate or inexperienced parenting. Successful home-visitation programs require physician support and participation.

RECOMMENDATIONS

The American Academy of Pediatrics encourages pediatricians to:

1. Recognize that home-visitation programs are complimentary to office-based practice and part of a continuum of care;
2. Become familiar with the outcomes of home-visitation programs and the variables that enhance favorable outcomes;
3. Become aware of and coordinate with the types of home-visitation programs that exist in their area;
4. Advocate for home health visitors as members of the health care family and partners in obtaining information about factors that affect patients' health and assist in the implementation of health care recommendations. In this process, pediatricians should become familiar with the concept of "The Medical Home" as described by Brewer et al[21] and developed by Sia[9];
5. Support referral of high-risk parents to home-visitation programs as early as possible, ideally before or at the time of the prenatal visit to the pediatrician;
6. Be willing to participate in the planning, implementation, and evaluation of home-visitation programs in their communities;
7. Be available to participate in the education and evaluation of home visitors or ensure that home-visitation activities have adequate support;
8. Advocate that home-visitation programs be incorporated into managed health care plans, on a cost-added basis to avoid being compromised by capitation; and
9. Advocate at the local, state, and national levels for the funding, development, and careful evaluation of quality home-visitation programs.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Role of the Medical Home in Family-Centered Early Intervention Services

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Children With Disabilities

ABSTRACT

There is growing evidence that early intervention services have a positive influence on the developmental outcome of children with established disabilities as well as those who are considered to be "at risk" of disabilities. Various federal and state laws now mandate the establishment of community-based, coordinated, multidisciplinary, family-centered programs that are accessible to children and families. The medical home, in close collaboration with the family and the early intervention team, can play a critical role in ensuring that at-risk children receive appropriate clinical and developmental early intervention services. The purpose of this statement is to assist the pediatric health care professional in assuming a proactive role with the interdisciplinary team that provides early intervention services.

EARLY INTERVENTION LEGISLATION

Various federal and state laws now mandate the establishment of community-based, coordinated, multidisciplinary, family-centered programs that are accessible to children with established disabilities or those who are "at risk" of disabilities and their families. Early intervention services are designed to meet the needs of children from birth to 36 months of age who have delays in 1 or more areas of physical, cognitive, communication, social, emotional, or adaptive development. Services are also available to children who have a diagnosed condition that has a high probability of resulting in delayed development. States must offer early intervention services to children with delayed development or those with an established disability. States also have the option of serving those who are at risk for poor developmental outcomes. The type and extent of services are determined through the development of an individualized family service plan (IFSP). In designing the IFSP, the family plays a lead role in the assessment of resources, priorities, and concerns in conjunction with a care coordinator.[1,2]

By federal statute, available services must include:

- early identification, screening, and assessment services;
- care-coordination services;
- medical services only for diagnostic or evaluation purposes;
- family training, counseling, and home visits;
- special instruction;
- speech and language pathology and audiology services;
- occupational and physical therapy;

- psychological services;
- health services that are necessary to enable the infant or toddler to benefit from other early intervention services;
- social work services;
- vision services;
- assistive technology devices and services; and
- transportation, interpretation services, and other related costs that are necessary to enable a family to receive other services.[3,4]

Access to these services has been mandated because early intervention is important if children with disabilities are to achieve their full potential. During the past 25 years, the US Congress has taken a series of steps to promote improved infant and child developmental outcomes through early intervention services. The first major federal legislation was passed in 1975, when the Education for All Handicapped Children Act (Pub L No. 94-142) established the right of children between 5 and 18 years of age to a free, appropriate public education and related services; providing services to children 3 to 5 years of age was optional. The Education of the Handicapped Amendments of 1986 (Pub L No. 99-457) supported the development of early intervention programs for infants and children from birth to 3 years of age with disabilities or delayed development. The law also mandated that a free and appropriate public education be provided by the states' education departments for 3- to 5-year-olds by the 1990–1991 school year. It established guidelines and regulations for the development of far-reaching, coordinated, multidisciplinary services for these children and their families. In 1990, it was amended again as the Individuals With Disabilities Education Act (IDEA [Pub L No. 101-476]). One component of IDEA, Part H (now known as Part C), the Program for Infants and Toddlers With Disabilities, required states to develop and implement community-based systems of care that are coordinated, family centered, and culturally effective, with greater interagency collaboration. Part H required early identification and provision of services to infants and toddlers with delayed development and those with established conditions with a high probability of delay and, at the state's option, those who would be at risk of experiencing delayed development if early intervention services were not provided. Part H required that identified children be referred for a free comprehensive, multidisciplinary evaluation by a team of professionals who, with the family, decide which services are needed. The services that are determined to be necessary are listed on the IFSP, and the needs are reevaluated at least annually. A care coordinator is appointed to help the family access services. Subsequently, Part C of the IDEA Amendments of 1997 (Pub L No. 105-17) encouraged the states that did not serve the at-risk population to track and monitor these children so that they could be referred when needed.[2,3]

The Individuals With Disabilities Education Improvement Act of 2004 (IDEA 2004 [Pub L No. 108-446]) broadened the eligibility criteria for early intervention services. The 2004 legislation required referral for all children involved in substantiated cases of neglect or abuse, children affected by substance abuse or exposed to family violence, and children who are homeless or wards of the state. IDEA 2004 also permitted, at the states' discretion, families to choose to have their child continue in early intervention services until they are eligible for kindergarten.[5]

RATIONALE FOR EARLY INTERVENTION

Until 3 decades ago, in the absence of laws that mandated access to educational services for all children regardless of the degree of disability, many children with developmental disabilities and their families had few choices except state hospital–sponsored custodial care or an isolated homebound existence. Since then, much has been accomplished in the field of health care and special education for children with disabilities. Recent advances in medical expertise and technology have improved the developmental potential, health, and survival rate of infants and children with special health care needs. These advances have enabled children with special health care needs to participate more fully in public education. Neurocognitive research has demonstrated that there are optimal periods for all children during which the brain is particularly efficient at specific types of learning. Well-designed, timely early intervention can improve the outcome and the quality of life of young children at risk of developing cognitive, social, or emotional impairment.[6–9] The early childhood years present a singular opportunity to influence lifelong development and prevent or minimize developmental problems in children with disabilities or those who are at risk of developing disabilities.

THE BENEFITS OF EARLY INTERVENTION

Pediatric health care professionals have a major role in early identification and referral for children with established delays in development as well as children who are at risk of delays. The National Early Intervention Longitudinal Study[10] found that the age at first concerns was later for children with developmental delays (11.1 months) compared with children with diagnosed conditions (eg, Down syndrome) (2.3 months) and children with at-risk conditions (eg, prematurity) (2.1 months). The time between first concerns and development of an IFSP was also longer for children with developmental delays (8.9 months) compared with children with diagnosed conditions (7.1 months) and children with risk conditions (5.9 months). Children with developmental

delays were older than children with diagnosed conditions and risk conditions at the time of the IFSP. Male children with delays entered services at later ages than did female children with delays. White children with delays entered services slightly later than did children of other ethnicities with delays. No gender or ethnicity differences regarding age at entry within diagnosed conditions or at-risk groups were found. Sixty-four percent of families found doctors or other health professionals to be very helpful. Most parents felt that early intervention services helped their child's development and that their family was better off with these services. These findings were not as strong for low-income families or if the child had poor health.

These data suggest that pediatric health care professionals can improve early identification and referral for children at biological and environmental risks as well as those with delayed development without known risk factors. The American Academy of Pediatrics (AAP) has published an algorithm for developmental surveillance and screening in early childhood that can assist the medical home in this process.[11]

Coordinated, community-based, multidisciplinary programs for early intervention have been established for children and their families. The types and severity of the conditions that affect children with disabilities are varied, and so are the intensity and extent of the services provided. Despite these differences, however, studies that evaluated the efficacy of early intervention programs showed that, from a public-policy standpoint, they have achieved much.[12] Recent literature has revealed that these programs may be effective not only in improving some individual child cognitive outcomes but also in leading to important improvements in family function.[11,13–15] Reviews of the literature suggest that for children from birth to 3 years of age, global interventions that are focused on positive family interactions generally are more effective than those that are focused only on the child, but services must be individualized. Early intervention services generally are more effective for children with milder disabilities than for those with severe disabilities.[16] The greatest effect occurs when early intervention services combine child-focused educational activities with explicit attention to parent-child interaction patterns while strengthening the caregiver-child relationship.[6]

Results of the Early Intervention Collaborative Study showed that, despite the great variability of child and family function and of the types and extent of services offered, most young children in early intervention programs improved in all domains of functioning.[17] The Infant Health and Development Program is a multicentered, randomized, controlled, nationwide study of low birth weight preterm infants (and their families) who received coordinated health and developmental services for the first 3 years of life. Children who had received comprehensive, multidisciplinary early intervention services scored higher at 3 years of age on tests of mental abilities than did children who received health services alone. Within the intervention group, cognitive and academic achievement in children with higher birth weight was maintained at 8 years of age.[18–22] School outcomes for children in the intervention group were consistently better than for children who did not receive intervention. Several aspects of family development were also enhanced by the Infant Health and Development Program.

Another long-term study, the Carolina Abecedarian Project, recently revealed that poor children who received early educational intervention starting in infancy had higher scores on mental, reading, and math tests than did children who did not receive the intervention. The participants were assessed at 21 years of age and were found to have completed more years of education, were more likely to attend a 4-year college, and were older when their first child was born.[23]

There has been considerable growth in the field of research regarding efficacy of various treatment modalities for children with specific disabilities. It is important to consider this research when prescribing or providing advice regarding early intervention services. For example, for those with cerebral palsy, data suggest that a functional/behavioral approach warrants initial consideration. Muscle strength training should also be considered for children with cerebral palsy.[1] Additional guidelines for prescribing therapy services for children with motor disabilities were published by the AAP in 2004.[24]

Lipkin and Schertz's review[1] of the literature on early intervention for children with Down syndrome suggested that early intervention may be beneficial in preventing declines in IQ. Preliminary findings have raised promise for treadmill training and augmentative communication to improve outcomes.

Evidence for the benefits of early intervention for children with autism is stronger. The evidence suggests that early, intensive (at least 20 hours/week) behavioral and/or developmental services are helpful in improving communication and social skills,[1,25] but more research is needed (including ongoing research) regarding the types and intensity of services.

The parents and family, as the primary caregivers, play a vital role in ensuring the health and well-being of children. The focus of health and developmental services has evolved from a child-centered, traditional "medical" model to a family-centered "developmental" model. That is, those who coordinate services take into consideration the important contributions of the family unit, the stressors that affect families (social, financial, and/or psychological), and the ability of families to adapt to new challenges. The pediatric health care professional, as the central figure in the medical home, must be attuned to special family circumstances that influence children with

special health care needs. The pediatric health care professional must involve family members in all areas of planning, delivery, and evaluation of health and developmental services. Communication between parents and pediatric health care professionals should be open, comprehensible, culturally sensitive, and sincere, showing mutual respect.[26]

The pediatric health care professional, because of his or her unique training, interest, and commitment, should be a vital member of the early intervention health team. The pediatric health care professional is the most appropriate health care consultant, coordinator, and source of referral for clinical services for children with special health care needs and their families. Whether in a local pediatric health care professional's office or in a multispecialty referral center, these children and their families should be offered comprehensive care that is family centered, continuous, compassionate, and culturally sensitive. Regardless of the pediatric health care setting, this care can be provided in accordance with the precepts of the medical home.[2,27]

RECOMMENDATIONS

The role of the pediatric health care professional caring for children with disabilities and their families should include:

- Surveillance and screening of all infants to identify established disabilities or risks of delayed development following the AAP algorithm.[11] The algorithm contains recommendations to perform surveillance at all well-child visits and administration of a standardized screening tool at the 9- and 18-month visits and again at either the 24- or 30-month visit.
- Referring children with delayed development or established risk factors promptly to early intervention services. The AAP and the US Department of Education Office of Special Education Programs have collaborated to develop a referral form, which accompanies this statement.
- Arranging for medical etiologic diagnostic evaluation as appropriate. Guidelines for evaluation of children with delayed development have been published by the AAP[28] and the American Academy of Neurology.[29] Guidelines for diagnostic assessment of cerebral palsy also are available.[30,31] In addition, the AAP,[32,33] the American Academy of Neurology,[34] and the American Academy of Child and Adolescent Psychiatry[35] have published guidelines for assessment of children with autistic spectrum disorders.
- Being aware of the services and resources available in the community for the child and family and helping to coordinate the health component of the services.
- Collaborating with the family and care coordinator to provide medical input into development of the IFSP while ensuring that goals are functional in nature. Efforts at collaboration have been hampered by lack of payment for these services.
- Advocating for the child's access to the appropriate medical subspecialty and surgical specialty services.
- Supporting families in choosing evidence-based and best practices that meet the specific needs of their child.
- Ensuring that periodic, objective measures of progress are made and used to guide ongoing intervention design.
- Providing continuity of health care, including prescribing specific rehabilitative therapies as appropriate and periodically reviewing the need to continue such services on the basis of the achievement of common goals.
- Periodic and ongoing counseling for the family regarding the child's progress and treatment and management options.
- Helping to provide ongoing services that are aimed at preventing secondary disabilities.
- Maintaining a central medical database that contains pertinent diagnostic and consultative information.
- Negotiating for proper payment for time and effort spent on care coordination,[36] counseling services, and other direct services.
- Advocating for equal access to early intervention programs for all eligible children in need.
- Advocating for ongoing evaluation of early intervention programs through quality assurance and other performance measures.
- Representing state AAP chapters on local and state interagency coordination councils.
- Monitoring and supporting research that uses optimal methodologies to further clarify appropriate treatment modalities for children with specific disabilities.

CONCLUSIONS

By providing leadership for the medical home and as a member of the early intervention team, pediatric health care professionals can help set the standard of care in their communities for children with disabilities or those who are at risk of developmental delays. Through ongoing consultation with developmental and rehabilitation therapists, services and therapy prescriptions should be provided with specific treatment goals in mind. Treatment plans should be regularly and periodically reviewed and revised, if necessary, or renewed if indications show that they are accomplishing their intended purpose.

It is vital for pediatric health care professionals to be sensitive to their role as the medical care provider on the

early intervention team, promoting appropriate education and therapy for children with disabilities. An environment should be created in which the pediatric health care professional, family, and other service providers work together in a caring, collegial, and compassionate atmosphere that ensures that early intervention services are of high quality, accessible, continuous, comprehensive, and culturally effective.

abstract

Youth violence continues to be a serious threat to the health of children and adolescents in the United States. It is crucial that pediatricians clearly define their role and develop the appropriate skills to address this threat effectively. From a clinical perspective, pediatricians should become familiar with *Connected Kids: Safe, Strong, Secure*, the American Academy of Pediatrics' primary care violence prevention protocol. Using this material, practices can incorporate preventive education, screening for risk, and linkages to community-based counseling and treatment resources. As advocates, pediatricians may bring newly developed information regarding key risk factors such as exposure to firearms, teen dating violence, and bullying to the attention of local and national policy makers. This policy statement refines the developing role of pediatricians in youth violence prevention and emphasizes the importance of this issue in the strategic agenda of the American Academy of Pediatrics. *Pediatrics* 2009;124:393–402

INTRODUCTION

A periodic survey of 1632 American Academy of Pediatrics (AAP) members administered by the AAP Task Force on Violence in the late 1990s indicated that injury as a result of violence is a substantial problem being confronted by pediatricians in practices across the country.[1] More than half of the respondents reported having recently seen a child who had sustained an intentional injury as a result of child maltreatment, and more than one third reported having recently treated a child with an injury resulting from domestic or community violence. Most pediatricians feel that they have an important role to play in the prevention of such injuries, and there is evidence to suggest that parents and community leaders also perceive a central role for pediatricians in the prevention of youth violence.[2–4] However, many pediatricians feel ill prepared to screen for and manage forms of violence other than child maltreatment.

In 1999, the AAP published a comprehensive policy statement outlining and defining the emerging role of pediatricians in the prevention of youth violence.[5] This statement represented the culmination of 3 years of focused, strategic thinking and outlined possible interventions that could be woven into routine health maintenance and preventive care practice. The 1999 statement also identified opportunities for pediatricians to assume leadership roles in violence prevention education and advocacy in community-based and out-of-office settings.

Although awareness of youth violence as a key issue in pediatrics has increased since publication of the 1999 statement, AAP periodic survey results have demonstrated a continued need for training and support for pediatricians.[6,7] In response, violent-injury prevention has assumed a higher priority within the AAP,[8] and several ongoing efforts have been initiated, such as the AAP Violence Prevention Symposium (2003); National Chapter Injury Prevention Conference (2005); appointment of a violence prevention subcommittee to the national Committee on Injury, Violence, and Poison Prevention (2005); and the publication of *Connected Kids: Safe, Strong, Secure* (2006).[8] At both the organizational policy and clinical practice levels, the AAP is striving to prepare and engage pediatricians in specific activities aimed at reducing the burden of intentional injuries borne by children in the United States.

This revised policy statement updates the evolving epidemiology of intentional injury, identifies important emerging issues related to violence prevention in children, and reaffirms the basic tenets that support the recommendations made in the original statement 10 years ago. Key new areas highlighted in this revised policy statement incorporate new information and resources concerning bullying and dating violence, and provide further specific counseling guidance for pediatricians

BACKGROUND

Over the last 2 decades of the 20th century, violence emerged as a major public health problem that disproportionately affects children, adolescents, and young adults. Despite recent declines in rates of violent deaths, nonfatal firearm injuries, and violence-related behaviors, such as fighting and weapon carrying,[9–15] homicide remains the second leading cause of death for all children 1 to 19 years of age.[16,17] Significant ethnic disparities in youth violence exposure persist. For example, homicide is the second leading cause of death in the United States for ages 15 to 19, but it is the leading cause of death among black 15- to 24-year-olds.[18]

Cross-national analyses have demonstrated similar rates of violence-related behaviors among adolescents in this country compared with international peers, yet the United States continues to lead the industrialized world in rates of youth homicide and suicide.[19–21] Approximately 3% of direct medical expenses in this country are related to interpersonal assault injuries, and the total cost to society of gun violence is approximately $100 billion, of which $15 billion is attributable to firearm injuries to children.[22–24]

The potential risks and behavioral consequences associated with early childhood exposure to violence in the home and/or witnessing violence in the community are profound. Over the past decade, there has been a great deal of scholarly attention devoted to elucidating those factors that confer risk or promote resilience.[25–28] It is recognized that there is a great deal of overlap among contextual factors, including family dynamics, community norms, and cultural beliefs and practices, that all play critically important roles in determining individual outcomes.[29] Primary care pediatricians routinely have access to young people involved in violence-related behaviors and are particularly well positioned to advise parents and caregivers.[30] Pediatricians are also likely to be aware of community-based resources such as prenatal and early intervention home visitation programs that have demonstrated promise in reducing the subsequent burden of intentional injury borne by young children.[31,32]

Myriad promising primary care interventions have been developed, but few have been evaluated in a scientifically controlled fashion.[33–35] To that end, several governmental health and organized medicine entities, including the Centers for Disease Control and Prevention, the Office of the Surgeon General, the American Medical Association, and the Agency for Healthcare Research and Quality, have sought to synthesize the burgeoning research literature in this area to help identify effective approaches.[36–39] The AAP has also developed and published a number of policy statements and other reports specifically related to addressing youth violence from an evidence-based, best-practices perspective.[40–43] However, the most comprehensive effort to date undertaken by the AAP is the primary care violence prevention protocol titled *Connected Kids: Safe, Strong, Secure*. Developed as a multiyear project supported in part by the Office of Juvenile Justice and Delinquency Prevention of the Department of Justice, *Connected Kids* is a carefully constructed resource aimed specifically at facilitating the primary health care professional's ability to incorporate intentional injury prevention tools and messages into everyday practice.

Another important recent development in the field of violence prevention has been the recognition of the primary importance of resilience factors that enable children and young adults to adapt successfully to stress, including exposures to violence. Scientific support for the crucial role of resilience stems from a number of sources, including analysis of data stemming from the National Longitudinal Study of Adolescent Health.[26,28] This statement discusses *Connected Kid*s, bullying prevention, and dating violence. The related key issues of firearms and media violence[42,43] are included in other AAP policy statements.

CONNECTED KIDS: SAFE, STRONG, SECURE

Connected Kids: Safe, Strong, Secure is a program launched by the AAP in 2005 that addresses violence prevention in the context of routine child health care. The development of *Connected Kids* involved the input of more than 100 experts as well as extensive input from parents and adolescents during a 3-year process.[8,44,45] The final AAP product consists of a clinical guide, 21 parent/patient information brochures, and supporting training materials (see Tables 1–3).

Because of the recent recognition of the primary importance of individual and family resilience discussed above, the *Connected Kids* program implements a strength-based approach to anticipatory guidance, helping parents and families raise resilient children. This approach results in a much broader approach to anticipatory guidance than previous, risk-based approaches. In addition, each topic area specifically addresses the social ecology of childhood by including information about the child's development, the parent's feelings and reactions in response to the child's development and behavior, and specific practical suggestions to help families connect to existing community resources.[46] Feasibility and qualitative field tests conducted in early 2005 yielded enthusiastic results, and rigorous program evaluation using existing practice-based networks is planned. The first randomized, controlled trial published to date of a primary care intervention designed to affect youth involvement in violent behavior demonstrated efficacy in the reduction of both fighting and fighting-related injuries.[47] The availability of an AAP tool like *Connected Kids* has great promise and potential to similarly affect children across the country as pediatricians become comfortable integrating its use into their practices. *Connected Kids* is coordinated with the third edition of *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*[48] and provides assistance in implementation of the *Bright Futures* psychosocial and safety themes. More detailed information is available from the AAP Web site (www.aap.org).

BULLYING

Bullying is a form of aggression in which 1 or more children repeatedly and intentionally intimidate, harass, or physically harm a victim who is perceived as unable to defend herself or himself.[49,50] An issue of emerging concern has been the association of bullying behavior, particularly among young school-aged children, with the subsequent development of serious

assault behaviors. A comprehensive analysis stimulated by the rare but high-profile, multiple-casualty, school-based events in Pearl, Mississippi; West Paducah, Kentucky; Jonesboro, Arkansas; Springfield, Oregon; and Littleton, Colorado in the late 1990s brought into acute focus just how serious a precursor bullying may be.[51] Several professional medical organizations, including the American Medical Association and the Society for Adolescent Medicine, have directed specific attention by way of formal policy or resolution to the issue of youth bullying, often within the context of the broader problem of youth violence.[52,53] Also, the Health Resources and Services Administration of the US Department of Health and Human Services recently launched phase II of a major multiyear awareness campaign thematically titled "Take a Stand, Lend a Hand: Stop Bullying Now."[54]

Although bullying among school-aged children has been well described in other parts of the world, until recently, epidemiologic characterization of the depth and extent of the problem in the United States has been lacking. Nansel et al[55] at the Eunice Kennedy Shriver National Institute of Child Health and Human Development of the National Institutes of Health have created a bullying epidemiology working group and are comparatively analyzing both domestic and international data sets. They have established a prevalence baseline of 30% for children either bullying and/or being bullied on the basis of a large sample of 6th- to 10th-graders.[56] They have also begun to critically analyze the true associations of bullying with some of the traditional violence-related behavioral markers, including weapon carrying and frequent fighting. Bullying and being bul-

lied are both associated with higher rates of weapon carriage and fighting serious enough to result in injury.[57,58] These associations seem to be stronger for bullies than for targets. Also of great concern are the more subtle psychosocial consequences that can be associated with bullying behavior, including the subsequent development of depression and suicidal ideation.[59,60] These problems are more likely to result from the indirect, relational bullying behaviors that are more typically engaged in by young girls and that can be notoriously elusive to identify.[61]

A growing literature has also begun to explore bullying's relationship with somatic conditions, disease morbidity, and the development of long-term behavioral exposures and outcomes manifesting in adulthood.[62–65] The emergence of portable technologies, such as cellular telephones, digital cameras, and personal digital assistants and ready accessibility to social networking Internet sites has led to the advent of technology-assisted bullying behavior—a phenomenon known as "cyberbullying."[66,67]

European researchers have been active for more than 30 years in developing interventions around bullying prevention. The most successful programs have been implemented in Scandinavia on the basis of the model developed by Norwegian investigator Dan Olweus.[68] The Olweus Bullying Prevention Program is a school-based model that has been replicated, refined, and evaluated many times internationally. Olweus proposes specific programmatic interventions at the school-wide, classroom, and individual levels on the basis of the insight that each bullying episode involves 3 groups of children: bullies and their acolytes, victims, and bystanders. However, there is a paucity of published reports in the peer-reviewed literature describing implementation and controlled evaluation of the Olweus Bullying Prevention Program in the United States.[69] It is clear that in this country, it must first be accepted that bullying behaviors cannot be considered a normative rite of passage and that they can be precursors for more serious downstream consequences. In terms of primary prevention, early parenting behaviors such as cognitive stimulation and emotional support have been shown to confer resilience against the future development of bullying behaviors in elementary-aged schoolchildren.[70] Promotion and reinforcement of such parenting skills plus recognition, screening, and appropriate referral as secondary prevention strategies are essential ways that pediatricians can collectively contribute to this aspect of youth violence prevention.

DATING VIOLENCE

The past decade has also seen more attention focused on relationship violence in adolescence, specifically teen dating violence. Depending on case definition and reporting methodology, estimates of the prevalence of teen dating violence have been reported to range from 9% to 46%.[71–73] With most US teenagers dating by middle adolescence,[74,75] it is important that pediatricians be aware of the precursors, symptoms, and behaviors associated with teen dating violence. Appropriate from a developmental standpoint, nascent prevention efforts in this area have focused primarily on peer-group–targeted interventions. One such school-based program that used a randomized, controlled methodology demonstrated efficacy for reducing self-reported teen dating violence victimization and perpetration rates at intervals up to 4 years after intervention.[76–78]

Because routine care-oriented intervention opportunities are more limited in adolescence and preadolescence, it is important that pediatricians avail and extend themselves as community resources to those entities that most influence the development of teen behavior. These would almost certainly include middle and high schools and, depending on the specific constitution of a given community, might also include faith-based organizations, local Boys and Girls Clubs, and/or other prosocial organizations. Most critical, however, is the role of the pediatrician as an information repository for parents and families. Early anticipatory guidance about adolescent cognitive and social development, relationship dynamics, and the risks of teen dating violence is paramount as part of a primary prevention strategy. The *Connected Kids: Safe, Strong, Secure* set of resource materials for early adolescence includes a "tips for parents" brochure on teen dating violence (see Tables 1–3). These materials and associated prompts are available in structured electronic formats to facilitate incorporation in electronic health records and associated decision-support tools.

THE ROLE OF THE PEDIATRICIAN: RECOMMENDATIONS

There are 4 domains in which pediatricians should be expected to employ their skills and influence in the implementation of youth violence prevention strategies: clinical practice, advocacy, education, and research.

Clinical Practice

Clinical practice for intervention, management, and prevention of youth violence should include:

- a working familiarity with the *Connected Kids: Safe, Strong, Secure* primary care violence prevention protocol;
- use of a comprehensive approach, exemplified by the *Connected Kids*

protocol for anticipatory guidance, screening, and counseling of children and families during the course of routine health maintenance (key elements of the protocol should be built into the practice flow sheets or electronic health record age-based prompts; parent and youth education materials should be readily accessible, either as printed material or printed at the time of visit);

- appropriate and timely treatment and/or referral for violence-related problems identified; and
- maintenance of an accurate database of community-based counseling and treatment resources. Whenever applicable, this database should be available through the practice's electronic health record system or linked to the practice's internal and external Web sites.

Advocacy

Pediatricians should advocate for:

- adequate publicly supported community-based behavioral health services;
- protection of children from exposure to firearms;
- bullying awareness by teachers, educational administrators, parents, and children coupled with adoption of evidence-based prevention programs;
- responsible programming on television, video, cable, the Internet, and video game formats that minimizes youth exposure to violent images, messages, and themes;
- the role of health professionals as appropriate public health messengers through print, electronic, or online media; and
- incorporation of content related to youth violence prevention in electronic health records, including screening prompts and links to parent education materials.

Education

Pediatricians should exercise every available opportunity to learn more about violence prevention through:

- formal continuing medical education or professional development programs;
- learning about community resources for children and adolescents; and
- elective course or rotation work in either medical school or postgraduate training.

Research

Pediatricians can contribute to needed research by:

- participating in practice-based research in the area of youth violence prevention;
- contributing data to existing intentional injury surveillance systems; and
- advocating for municipally supported, legislatively mandated active local injury surveillance systems.

POLICY STATEMENT
Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine

Role of Pediatricians in Advocating Life Support Training Courses for Parents and the Public

ABSTRACT. Available literature suggests a need for both initial cardiopulmonary resuscitation basic life support training and refresher courses for parents and the public as well as health care professionals. The promotion of basic life support training courses that establish a pediatric chain of survival spanning from prevention of cardiac arrest and trauma to rehabilitative and follow-up care for victims of cardiopulmonary arrest is advocated in this policy statement and is the focus of an accompanying technical report. Immediate bystander cardiopulmonary resuscitation for victims of cardiac arrest improves survival for out-of-hospital cardiac arrest. Pediatricians will improve the chance of survival of children and adults who experience cardiac arrest by advocating for cardiopulmonary resuscitation training and participating in basic life support training courses as participants and instructors. ***Pediatrics*** **2004;114:1676;** ***basic life support training courses, cardiopulmonary resuscitation, CPR, cardiac arrest, community education, parents, school children, automated external defibrillator, chain of survival.***

INTRODUCTION

Childhood out-of-hospital cardiac arrest is a traumatic event for the entire community. Outcome is determined by timeliness of implementation of cardiopulmonary resuscitation. The establishment of a pediatric chain of survival for victims of cardiopulmonary arrest is advocated in this policy statement. Pediatricians are asked to advocate for basic life support training whenever possible in their local community.

RECOMMENDATIONS

1. Pediatricians should promote parental education in pediatric basic life support. Families of children with special health care needs, neonatal intensive care unit graduates, children who have ready access to water, or children who are active in water sports should be especially encouraged to undergo training and should be assisted in obtaining access to the training.
2. Pediatricians should encourage and collaborate with parents to promote basic life support training for adolescents, parents, caregivers, school personnel, youth leaders, and coaches to build the "chain of survival" in the community.
3. Basic life support training for the aforementioned groups should be advocated in policy advisory discussions at all governmental levels with a goal of making the training readily available and affordable.
4. Pediatricians and pediatric subspecialty providers should lead by example by taking and teaching basic life support training courses.

INTRODUCTION

Pediatricians advocate for the health of children not only at local, state, and national levels but also with individual families and children. Pediatric basic life support training should include injury and cardiopulmonary arrest prevention information and be advocated the same way injury prevention and other preventive pediatric counseling are promoted. In fact, the "chain-of-survival" concept advocated in the Pediatric Advanced Life Support Course is a model in which each critical link in survival from prevention of trauma and cardiac arrest to rehabilitative and secondary preventative care of the survived arrest victim is optimized.[1] Pediatric out-of-hospital cardiac arrest carries a poor prognosis, which seems to be improved only by on-scene application of basic life support.[2] New information regarding sudden infant death syndrome (SIDS) and sudden cardiac death in children prompts careful attention to the role of the public in the chain of survival for an infant or child who experiences cardiac arrest.[3–6] Ventricular fibrillation has been newly considered as an important cause of cardiac arrest in children and adolescents in several recent studies,[3,7] which underscores the importance of basic life support training for the public, because cardiopulmonary resuscitation (CPR) before attempted defibrillation may improve the chances of successful defibrillation.[8] Use of automated external defibrillators (AEDs) in children experiencing sudden cardiac arrest has been advocated by the American Heart Association. This recommendation includes children older than 1 year.[9]

All 50 states have now passed laws authorizing use of AEDs.[10] Efficacy has been demonstrated by Atkins et al[7] in children older than 8 years. These recent observations, along with the progressive improvement in survival of infants and children who undergo cardiac surgery for repair and palliation of congenital cardiac defects, suggest a need to promote pediatric basic life support training for people who could have an opportunity to save the life of a child who experiences sudden cardiac arrest.[11] The epidemiology of sudden cardiac arrest in childhood suggests that pediatricians should advocate for pediatric basic life support training for parents, baby-sitters, child care providers, school personnel and coaches, and other youth leaders. Pediatricians can act as advocates and opinion leaders by serving as participants and instructors in CPR classes in medical settings and communities.[12] Although survival rates from currently available studies after out-of-hospital pediatric CPR are discouraging, the survival rate for in-hospital CPR and for those who achieve return of spontaneous circulation before arrival in an emergency department should stimulate researchers and pediatricians to advocate strongly for pediatric basic life support training for the public to increase the available pool of at-the-scene responders to pediatric cardiopulmonary arrest. The need for establishment and maintenance of an adequate airway in a child cannot be overemphasized. The establishment of a pediatric chain of survival is advocated in the accompanying policy statement.[13] The available information suggests that outcomes will improve for the newly apneic or fibrillating child who receives prompt CPR.[2]

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Pediatric Cardiac and Respiratory Arrest: Success in Resuscitation

Eisenberg et al[14] investigated 119 pediatric cases of out-of-hospital cardiac arrest in King County, Washington, spanning a period from 1976 to 1982. The most common cause of cardiac arrest was SIDS (32%), followed by submersion (22%). Six percent of patients with basic emergency medical technician (EMT) care and 7% with EMT and paramedic care survived to hospital discharge. Of 103 patients for whom electrocardiogram rhythm strips were available, 9 (9%) showed ventricular fibrillation. The majority of patients (77%) showed asystole. Losek et al[15] also investigated out-of-hospital pediatric cardiopulmonary arrest and found few neurologically intact survivors (9 of 114 [8%]). In contrast, Innes and et al[16] showed a 70% success rate, with initial resuscitation of 41 children with inpatient pediatric cardiopulmonary arrest, 10 of whom (24%) were neonates. At 12-month follow-up, 37% were still alive. Attempts were initially successful in 82% of primary respiratory arrest, compared with 36% of cardiac arrests. These data from the inpatient setting suggest a marked improvement in survival with timely application of adequate CPR.

Sirbaugh et al[17] reported on 300 children in Houston in 1999 who were apneic and pulseless outside the hospital. Eleven percent showed a return of pulse. Six patients survived to hospital discharge, 1 with intact neurologic status. Thirteen patients (4%) showed ventricular fibrillation. Eleven percent of the total arrests were believed to result from cardiac causes, and 37% were ascribed to SIDS. Basic CPR was performed by bystanders in 79 (26%) cases. Twenty-two percent of children who arrested at home received bystander CPR, compared with 36% of those who had a cardiac arrest at another location. Sixty-five patients had serious water submersions and were given bystander CPR. Of the 65, 41 (63%) had return of spontaneous circulation before emergency medical services arrived and were not included in the 300 patients. Studies that analyze the outcomes of children who are pulseless and apneic on arrival of emergency medical services professionals and discard cases of successful bystander CPR may introduce a negative bias into the consideration of outcome of out-of-hospital child CPR by negating the bystander CPR. As an aside, in consideration of possible changes in the incidence of ventricular fibrillation and change in survival statistics, no new studies of etiology of cardiac arrest in children have been published, subsequent to the decrease in frequency of SIDS in association with the American Academy of Pediatrics (AAP) "Back to Sleep" campaign.[18]

Gausche et al[19] investigated 830 pediatric patients requiring airway management; 596 patients experienced cardiac arrest. The patients had been randomly assigned to receive bag-valve-mask ventilation or endotracheal intubation. Seventy-one percent and 72% of the children experienced cardiopulmonary arrest in the 2 groups, respectively. Eight percent of subjects from each group survived the arrest. Etiology of the arrest and the number of children who experienced ventricular fibrillation (4%) were provided in a recently published follow-up study.[20]

Hickey et al[21] investigated out-of-hospital cardiopulmonary arrest and found that 9 of 41 patients (22%) who initially presented to the Columbus Children's Hospital emergency department with a documented cardiac rhythm showed ventricular fibrillation or ventricular tachycardia. Of 21 patients with documented rhythm who were secondarily transferred to the hospital, 5 (24%) presented with ventricular tachycardia or fibrillation. These shockable rhythms are thought to have a higher likelihood of successful resuscitation compared with asystole. Of 23 patients who had cardiac arrest and return of spontaneous circulation in the field, 14 (61%) survived to hospital discharge.

BASIC LIFE SUPPORT TRAINING FOR PARENTS AND CAREGIVERS

CPR training has been advocated for parents and caregivers of premature infants, ventilator- and tracheostomy-dependent infants, infants who have undergone cardiac surgery or arrhythmia treatment, and others.[22] The AAP has recommended CPR training for parents and asked pediatricians to identify families with residential swimming pools beginning in the perinatal period for extra targeted counseling regarding drowning prevention.[23] Efficacy of CPR training for parents has been demonstrated in a variety of ways. Moser et al[24] showed that CPR training promoted a sense of control and reduced anxiety in parents of neonatal intensive care unit graduates. These authors studied 480 parents who were trained in CPR in 3 randomized groups: instructor-taught CPR, instructor-taught CPR plus social support, or a self-training video module.[25] Sixty-three percent of subjects were able to demonstrate successful CPR after training. A larger proportion had received one of the instructor methods rather than the self-training video. Less-educated learners and those with better psychosocial adjustment to their child's illness demonstrated slightly lower successful CPR performance rates.

Concerns about CPR training resulting in increased anxiety for parents are unsupported by scientific data.[26–28] CPR training for parents of infants with congenital heart disease fostered a sense of empowerment in these parents and helped relieve anxiety.

BASIC LIFE SUPPORT TRAINING FOR THE PUBLIC

Basic Life Support Training for School Children

Basic life support training for children in schools has been investigated by several groups.[29–31] Plotnikoff and Moore[31] as well as Van Kerschaver et al[32] showed CPR training to an acceptable level in their studies in children as young as 11 and 12 years of age. Plotnikoff and Moore demonstrated a marked decline in performance as early as 5 months after training. Decay of motor skills was more significant than that of cognitive knowledge. Poor performance at retest 5 months after training was felt to indicate

that a refresher course was needed at a shorter interval in this age group. The importance of retraining and the significance of diminution of skills and knowledge over time cannot be overemphasized.[32] Children may especially benefit from an overtraining effect. CPR training in schools in Hampshire, England, was performed in children 7 to 16 years of age. Training was offered in 26% of schools and was provided by school staff in 50.9% of schools and by statutory ambulance services in 30.9% of schools.[30] Other trainers were members of the Red Cross and the St John Ambulance Brigade. Peer-assisted training for boys from Cardiff, Wales, resulted in a lower percentage who reported willingness to provide CPR in an emergency, compared with boys trained by teachers or with girls trained by either method.[33] Vanderschmidt et al[34] demonstrated the need for skills practice and the importance of emphasis on discrete versus continuous skills (ie, teaching basic life support as a series of steps rather than a continuous action). Performance deterioration was noted at 3 months. Basic life support training in school has been recommended for high school students by the AAP.[35]

Basic Life Support Training for School Personnel and Youth Leaders

Basic life support training for the public has been investigated in a variety of settings and by using a variety of methodologies. The AAP has also advocated basic life support training for lifeguards. These recommendations are based on the assessment that basic life support training can augment other injury-prevention strategies in saving lives.

Basic Life Support Training Skills Retention

Studies of pediatric basic life support skills retention in parents trained in preparation for discharge of high-risk infants show retention of skills 2 months after training in a study by Berden et al[36] and 4 months after training in a study by Dracup et al.[37] Deterioration of skills has been uniformly seen 6 and 12 months after training in these studies, respectively. Berden et al[36] suggested a need for a training interval of at most 3 to 6 months for nurses. Hands-on practice by parents was shown to result in improved skills retention in a study by Komelasky and Bond.[38] In this study, it was noted that a predominance of trainees were the infants' mothers.

Barriers to Basic Life Support Training and Implementation

The study of Platz et al[39] involved interviews of 100 family members of cardiac patients. Barriers to CPR included concern for risk of harm to the victim or lack of knowledge and skill to help. Forty-nine percent reported previous CPR training. Fifty-nine percent of people who underwent CPR training did so for a job requirement. Only 7% had trained within the past year. Only 2% recalled a recommendation from a health care professional that they obtain CPR training. An additional, frequently identified barrier to CPR is risk of contracting human immunodeficiency virus (HIV) infection.[40] The lower rate of willingness to perform CPR in the boys trained in the peer-assisted program in Cardiff, Wales, pointed out the importance of how the potential barriers to CPR are presented and discussed in a training program.[33]

Concern for the risk of HIV infection is considered a barrier to bystander CPR performance in many recent studies. However, in a study from Sweden, the bystander CPR rate was higher in public places (53%) than for cardiac arrest in the home (23%).[41] Overall, bystander CPR was attempted for 36% of cardiac arrests, resulting in a 2.5 times increased likelihood of survival if bystander CPR was provided (95% confidence interval: 1.9–3.1). Concern for risk of spread of disease from mouth-to-mouth resuscitation is a major issue even for prehospital emergency care providers.[42] In their evaluation of willingness to perform mouth-to-mouth resuscitation by New York City emergency medical services professionals, Hew et al[42] found that 57% of 77 EMTs and 100% of 27 paramedics said that they would refuse to perform mouth-to-mouth resuscitation. The study suggested a need for education regarding risks of infection along with CPR training and a need for strategic placement of barrier masks for mouth-to-mouth resuscitation. The risk of infection with HIV is low with contact during CPR: 0.09% for health care workers with mucous-membrane contact with HIV-positive persons.[43–45]

Fear of harming the person who requires CPR rescue has resulted in concern for application of bystander CPR.[39,46] Adverse effects of CPR on people surviving CPR to hospital admission were no different for people rescued by bystanders versus advanced life support providers in a review of chest radiographs.[47]

Good Samaritan laws protect any layperson or professional who renders first aid to victims of injury.[48] These state statutes provide immunity to health care professionals except in the case of gross negligence. Health care professionals are not covered in the normal conduct of their jobs. Laws in Louisiana, Minnesota, and Vermont termed "failure-to-act statutes" compel all citizens to aid a victim in need. None of these state laws compel a layperson or health care professional to render emergency aid that could result in their own personal danger. The American College of Emergency Physicians has endorsed statutory protection for Good Samaritan acts, including actions of emergency physicians who respond to in-hospital emergencies.[49]

Concern for the cost and outcome of resuscitation in children may decrease health care professionals' enthusiasm for CPR training programs. Ronco et al[50] reported a 10% survival to hospital discharge for out-of-hospital arrest victims who received CPR. They noted an average cost of $100000 for each survivor and $10000 for each nonsurvivor. Cost-effectiveness of CPR was not investigated, nor was cost of ongoing care of survivors. They did not consider years of potential life lost of nonsurvivors. An overall cost analysis has not been attempted for pediatric out-of-hospital arrest victims. Health care professionals should be reminded that the Hickey et al study[21] and others[15–17] suggest that the best out-

comes are obtained for children who respond to basic life support interventions.

SUMMARY

Basic life support training should be advocated for anyone who has a chance to provide a link in the chain of survival for a victim of cardiac arrest. Pediatric out-of-hospital arrest victims do less well than similar adult patients and less well than in-hospital pediatric patients. The disparity between the different cardiac arrest survival rates suggests a need to stress application of CPR by any available individual in the pediatric setting.[2,12,15] The poor outcomes for children who achieve return of spontaneous circulation only after application of advanced life support interventions demands increased emphasis on basic life support training for anyone who has more than casual contact with children.[15,17,20,21] Pediatricians can improve overall community health by advocating for basic life support training for resuscitation of child and adult cardiac arrest victims and by participating in basic life support courses as students and teachers. The best outcomes will still be obtained through prevention of cardiac arrest. To this end, additional investigations to identify children who are at imminent risk of respiratory arrest as well as those with heart rhythm and structural abnormalities are needed, along with investigations to prevent injury, if we are to improve the lives of children and families.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

The Role of Preschool Home-Visiting Programs in Improving Children's Developmental and Health Outcomes

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Community Pediatrics

ABSTRACT

Child health and developmental outcomes depend to a large extent on the capabilities of families to provide a nurturing, safe environment for their infants and young children. Unfortunately, many families have insufficient knowledge about parenting skills and an inadequate support system of friends, extended family, or professionals to help with or advise them regarding child rearing. Home-visiting programs offer a mechanism for ensuring that at-risk families have social support, linkage with public and private community services, and ongoing health, developmental, and safety education. When these services are part of a system of high-quality well-child care linked or integrated with the pediatric medical home, they have the potential to mitigate health and developmental outcome disparities. This statement reviews the history of home visiting in the United States and reaffirms the support of the American Academy of Pediatrics for home-based parenting education and support. *Pediatrics* 2009;123:598–603

INTRODUCTION AND HISTORY

Home visiting is not a single clearly defined methodology of providing service to children and families. The term "home visiting" is used differently in varied contexts. In this review, we limit our discussion to the use of preschool home-based parenting support to enhance developmental, health, and safety outcomes. Home visiting for parents is an early-intervention strategy in many industrialized nations outside of the United States. In many other countries, home health visiting is free, voluntary, and embedded in a comprehensive maternal and child health system. Although a causative link has not been demonstrated conclusively, countries with extensive home-visiting programs generally have lower infant mortality rates than does the United States, despite per capita health spending in the United States that far exceeds expenditures in other industrialized countries.[1]

Home visiting is deeply rooted in history, going back at least to Elizabethan times in England and endorsed as a strategy by Florence Nightingale in the 19th century.[2,3] Home visiting existed in the United States in the 1880s when public health nurses and social workers provided in-home education and health care to urban women and children. At the beginning of the 20th century, successful reductions in mortality from summer diarrhea in central New York City were demonstrated after using student nurses in the home to instruct mothers about hygiene and breastfeeding.[4] Denmark established home visiting in 1937 after a pilot program showed lower infant mortality rates associated with home visiting. France provides free prenatal care and home visits by midwives or nurses who educate families about smoking, nutrition, drug use, housing, and other health-related issues.[5] In some European countries, many traditional child health-promotion services of American pediatricians are provided by public health nurses, often within the home.[6]

In the last quarter of the 20th century, home visiting gained renewed attention as a strategy for prevention of child abuse and neglect, promotion of child development and parental effectiveness, and reduction of health disparities.[7] C. Henry Kempe, MD, called for a home visitor for every pregnant mother and preschool-aged child in his 1978 Abraham Jacobi Award address.[8] He suggested that integral to the provision of every child's right to comprehensive care is the assignment of a home health visitor who would work with the family until each child began school.[9] His call to action was reiterated by Cal Sia, MD, in the 1992 Jacobi Award address, in part on the basis of his experience with a pioneering initiative to take home visiting statewide as a tool for preventing child abuse and neglect in the

Hawaii Healthy Start effort.[10] Focusing on highly stressed families, this program has expanded and evolved into Healthy Families America and is one of the most rigorously studied of all the family-support initiatives in the United States.[11] Another pioneer in modern home visiting, David Olds, PhD, initiated the Nurse Home Visitation Program with families at risk in Elmira, New York, in 1978 and continues to study the effect of this intervention today. Within the education community, Parents as Teachers (PAT) has gained prominence as a program for promoting child development and school readiness after achieving promising results in Missouri.[12] In New Zealand, Scotland, and other countries, recent development of home-visiting efforts have replicated American models, thus indicating that the promise seen in this country with home visiting is envisioned beyond our shores.[13,14] Lisbeth Schorr, in her 1988 book *Within Our Reach: Breaking the Cycle of the Disadvantaged*, stated:

> "[Home-visiting] programs that succeed in helping the children and families who live in the shadows are intensive and comprehensive, flexible, and staffed by professionals with the time and skills to establish solid relationships with their clients. Intensive medical care for fragile newborn or aged patients who are barely clinging to life, costly though it may be, encounters no general resistance. Intensive care for fragile families requires similar support."[15]

In 1998, the American Academy of Pediatrics called for pediatricians to advocate for the inclusion of home visitors as part of the health care team and for the funding, development, and continued evaluation of home visiting in the promotion of children's health outcomes.[16] Shortly thereafter, this sense of optimism about the promise of home visiting was dampened by new information indicating limitations in the effectiveness of existing models. As comprehensive studies and new reviews of old programs developed, it became apparent that, as in other forms of support for developing children, home visiting may not, in all cases, be as efficacious as its advocates had hoped.[17]

HOME VISITING IS NOT A PANACEA

Although much energy, effort, and research have gone into the development of home-visiting programs, the extent of potential benefits is still inadequately delineated and understood. An ambitious evaluation in 1999 of a statewide home visiting program in Hawaii failed to demonstrate any substantial improvements in either maternal or child development and health outcomes.[18] Although these findings contradicted previous smaller studies and evaluations of earlier pilot programs, the comprehensiveness of this evaluation led to further examination of the evidence base for home visiting. In considering these apparent inconsistencies, it is best to remember that home-visiting programs are heterogeneous in their makeup, thereby compounding the difficulties associated with their evaluation. Programs vary in their approaches and are designed to achieve a variety of goals. Documentation that a home-visiting program design is effective in a particular setting may not support the use of other home-visiting models in that same setting.[19] This heterogeneity cannot be avoided. It is doubtful that an optimal, cost-effective approach will be successful for all outcomes in a diverse array of situations.[20]

Some of the most studied home-visiting efforts have a primary focus on the prevention of child abuse and neglect. Other programs have a strong focus on child development and school readiness or an interest in parental lives, including encouraging mothers and helping them become self-sufficient through further schooling, employment, and delay of future pregnancies.[17,21] Direct provision of health care, enhancement of child development, and support of parenting and mother-child interaction are additional primary goals of some programs.[21]

Most programs provide families with social support and are built on the development of a trusting relationship between the home visitor and parents. These relationships are designed to promote parent effectiveness and help engender strong bonds between the adults and children within families. Case management, linkages to community-based services, skill building for parents, child development education, and improvement in maternal health are common components of programs.[14]

By focusing on families most at risk, programs seek to diminish disparities in health and developmental outcomes. Controversy exists as to whether to use a universal approach, designed to work with all families in a defined geographic area, versus a program focused on populations most at risk of poor outcomes. Most studies indicate that very high-risk groups are more likely to show benefit from home visiting,[22] yet programs focused just on these groups may suffer from stigmatization and lack of acceptance on the part of families being visited. Some risk factors may interfere with the effectiveness of home visitation. For example, substantial evidence exists that families most plagued by domestic violence are least likely to respond to home-visiting support.[23] Other factors that hamper success of home visiting include limited family resources, family mental illness, and families not motivated to participate in the programs.[24] Thus, the very risk factors that make children vulnerable interfere with the effectiveness of the programs that are designed to help them.

Some programs use professional nurses or masters-prepared personnel as their home visitors; others use trained paraprofessionals who are often members of the target community and culturally linked with the families they visit. Although paraprofessionals usually are associated with lower salary costs,[25] the efficacy of the professional-based model is better established. Families may perceive nurse home visitors as more valuable because of their ability to identify and intervene with medical issues. Nurse-based home-visiting programs tend to have better staff retention compared with those that employ paraprofessionals, perhaps contributing to program effectiveness.[26,27] Likewise, programs in which paraprofessionals remained involved over a 2-year time period were more likely to demonstrate effectiveness than those with shorter durations of involvement.[28]

Additional barriers measuring the effectiveness of home-visiting services include variable effects noted at

different program sites, the need to tailor programs to the community, retention of families receiving services, maintaining program intensity, turnover in home visitors, and a drift over time in program focus. Other differences include the intensity of service, the duration of service, the caseloads of the home visitors, the population targeted for services, and training level of the visitors. To be successful, programs must focus on the risk factors that result in disparities in child outcomes, and misidentification of these factors is likely to result in poor program effectiveness.[29]

Within the context of the great heterogeneity of home-visiting programs, generalizations as to their effectiveness have been elusive and difficult to interpret. Frequently, pilot projects have shown positive effects, but many of the studies involving these small initiatives have methodologic flaws. Evaluations of home-visiting programs taken to scale have been mixed and sometimes disappointing in their findings. By itself, home visiting may be insufficient to result in satisfactory improvements in health and social outcomes.[30] It is clear that home-visiting programs are not a panacea for solving the problems of delayed child development and child abuse prevention but one of many tools to be used in a careful and thoughtful manner. Expectations for home visiting need to be tempered by realistic examinations of the current understanding of program effectiveness. Deanna Gomby, in a comprehensive review published in *The Future of Children*, noted

> "that no home visiting model produces impressive or consistent benefits in child development or child health. Several models produce some benefits in parenting and perhaps in the prevention of child abuse and neglect, but only on some of the measures used to assess these outcomes. . .these research results should not dissuade us from action. Children continue to grow, and their families continue to want and need support and services. It is up to us to strengthen existing services and craft new approaches to meet the needs of families and children."[17]

BENEFITS OF HOME-VISITING PROGRAMS

The wide-ranging nature of home-visiting programs and evaluations makes it difficult to draw definitive conclusions about potential benefits. A number of recent meta-analyses have made the task less arduous. Several large literature reviews, including those conducted by the US Task Force on Community Preventive Services,[20,28] one conducted by a British Task Force,[30] and a 2000 study by the Canadian Task Force on Preventive Care,[31] revealed strong evidence to support the effectiveness of perinatal and early childhood programs in preventing child abuse and neglect but no effect when paraprofessionals were used as visitors. A report from the US Surgeon General concluded that nurse home visiting has shown significant effects on the incidence of violence, delinquency, and other related risk factors.[32] Benefits in child development and child health are less clear, and the evidence for their support is inconsistent. Meta-analyses of home visiting published both in the United States and Europe report sufficient evidence that home visiting, when appropriately provided, can:

- improve parenting skills and the quality of the home environment[21,30,33];
- ameliorate several child behavioral problems, including sleep problems[21];
- improve intellectual development among children, especially among those with a low birth weight or failure to thrive[30,34];
- enhance maternal life course such as employment and education[17,21,30];
- reduce the frequency of unintentional injury and the prevalence of home hazards[30];
- improve detection and management of postpartum depression[34];
- possibly improve the attachment between infants and their parents[34];
- enhance the quality of social supports to mothers[30]; and
- improve rates of breastfeeding.[30]

Existing meta-analyses include the following characteristics of successful home-visiting programs:

- Socially deprived mothers show the greatest benefits from home visiting.[34]
- Professional or nurse-based home visiting is generally advantageous for clients.[35] The role of lay paraprofessional home visitors is less known, but paraprofessionals may be helpful depending on the goals and objectives of the home-visiting program and the length of engagement with the home visitor. An advantage of lay home visitors may be the notable cultural bond between the home visitor and mother. Paraprofessional home visitors require more intensive guidance, training, supervision, and support from professionals. Families with significant or complex difficulties require the support of professional home visiting.[36]
- Home visits may be useful for children born preterm or with low birth weight and may result in positive effects on child development. Without sustained support, these positive effects may fade as children grow older.[30,34]
- Services of longer duration and greater intensity correlate with higher degrees of effectiveness.[30,34]
- Generally, the more risk factors present in a child's life, the more likely that developmental outcomes will be affected. However, those families with the poorest functioning are often unresponsive to engagement and intervention. The relationship between benefit and risk status is also not linear. It seems that those at the greatest risk and those at the least risk of poor outcomes are less likely to benefit from home visiting than others.[37]

COST-EFFECTIVENESS OF HOME VISITING

Successful home-visiting programs involve extensive staff development and supervision, the creation of appropriate protocols, adequate supervision, and quality

assurance. Adequate funding is of paramount importance for home visiting to be successful. Cost-sharing issues among local, state, and national funding sources as well as the political nature of funding are major obstacles to program development. These programs are expensive, and their costs are a significant impediment to implementation.

Limited data exist to support the notion that home visiting is cost-effective. Successful programs are associated with reduced emergency department visits, decreases in foster care assignments, fewer hospitalizations, and savings in child protective services expenditures. Home visiting for the purpose of support and observation of newborns with low birth weight who are sent home early has been shown to be cost-effective by saving significant costs for the health insurer while improving overall health status.[38] Unfortunately, the savings from home-visiting efforts often accrue at some point in the future to entities other than the payer of the initial program. Home-visiting programs focused on social issues, child abuse, domestic violence, or child development, even if cost-effective, are unlikely to save costs in the health care sector. However, in all likelihood, the long-term financial savings to the community are substantial, as is the reduction of human suffering.[7,39] Cost savings in these instances will accrue to a variety of educational and social programs that are usually government funded. For these reasons, mechanisms for funding home visiting may be more appropriate from sources other than traditional third-party health care insurance. Payment sources will have to be tailored to the individual goals of each home-visiting program.

LINKING HOME VISITING TO THE PEDIATRIC MEDICAL HOME

Pediatric primary care continues to evolve in an increasingly complex world with shifting morbidities and mortalities and expanding responsibilities for the child health care professional. Recently, Perrin noted:

> "Primary care clinicians face. . .problems where teamwork in practice can greatly improve the services families receive. Especially in high risk communities, many families need access to a wide range of social and other supportive services. . .services that pediatricians know relatively little about."[40]

A 2006 Commonwealth Fund publication reiterated this suggestion with a call for a team approach as key to high-performing systems of well-child care. Such systems require graduated levels of services to fit the acuity and range of need for individual patients and families.[41]

Home visitors may well be essential members of these teams and augment the services of the traditional medical home.[34] Home visitors can be health care advocates and improve access to providers of health care. They can be partners with pediatricians and other clinicians, working in the home setting to provide essential education and supportive services to at-risk children and families and to improve adherence to medical preventive and treatment regimens. They can enhance developmentally oriented anticipatory guidance with individualized content that meets families' individual needs.[42] Home-visiting programs include a

> "degree of social support that is difficult to provide in most clinical settings; outreach and liaison between the pediatrician, the family, and the community; involvement with socioeconomic issues that directly affect the well-being of the child and family; reinforcement and follow-up of preventive care, peer helper support, as well as encouragement by the home health visitor who has the advantage of being with the family in its own home, a more accepting, less threatening setting for the family.[7]

Thus, home-visiting services should not be seen as replacing the contribution of the pediatric health care team but as a complementary service that enhances children's health and developmental trajectories.

In this context, appeals for home visiting linked to well-child care have been frequent, but the "how" and "why" of these linkages are poorly defined and require additional investigation. Little investigative work has been performed in the area of using home visiting linked to the pediatric medical home. One Colorado study showed that paraprofessional home visiting, when combined with an early-intervention program focused on children with developmental delays, resulted in improved involvement with the program.[25] In North Carolina, the combination of a public health department's home-visiting program with links into private physician's offices was helpful in overcoming personal and structural barriers to care.[43] The Commonwealth Fund's Healthy Steps intervention included home visiting by masters-level healthy development specialists with significant gains in the quality of well-child care, although the multifactorial nature of this intervention made it difficult to evaluate the effectiveness of the home-visiting component.[44–46] A South Carolina study showed that a program that linked school-based home visitors to group well-child visits resulted in greater retention of anticipatory guidance and improved satisfaction with care.[47]

These initiatives provide a glimpse into the potential of linking home visitors with the pediatric medical home. A working partnership between home visitors and pediatricians providing well-child care may provide, for those families most at risk, an intensive level of support resulting in better health outcomes. Home-visiting programs should be integrated into a community's existing health care system, expanding the effectiveness of private health care professionals, health maintenance organizations, and public heath nurses. Such integration should be undertaken cautiously with the knowledge that little is yet known to guide the optimal relationships between pediatric medical homes and home-based parenting support. The development of these relationships requires an ongoing evaluation to determine their effectiveness in the enhancement of optimal health and developmental outcomes for all of our children.

RECOMMENDATIONS

1. Sufficient evidence exists to endorse home-visiting services by nurses to prevent child abuse and neglect for at-risk families. Programs that are comprehensive in scope, are intensive in the visit schedule, involve

positive interactions with parents, target high-risk families, and are performed by professionally trained home visitors are known to be successful. Pediatricians should encourage the further expansion and development of programs for the prevention of child abuse and neglect.

2. Substantial evidence exists to support the use of home visiting as a strategy for addressing inequities in children's health status, school readiness, and development. Pediatricians should advocate for additional research and work to define the critical elements of such programs. Pediatricians should work with policy makers to ensure that elements found to be critical for success are applied to home-visiting practice.
3. Home-visiting programs should be comprehensive in nature but have clear primary goals and objectives supported by evidence-based strategies.
4. Pediatricians and others interested in the welfare of children should recognize the limitations of data supporting home-visiting efforts and the need to balance expenditures against the unsupported possible promise of such programs. Further investigative work needs to be performed to define the elements of cost-effective home visiting.
5. Little research has been performed on the linkage of home visitors to pediatric medical homes, which is an area that deserves attention. There is ample reason to believe that the synergy of home visitors working with pediatric clinicians could have positive effects on child health and development. Home visitors should be considered to be a complementary collaborative partner in the provision of developmental assessment and other components of well-child services, especially for at-risk populations. Communication between home visitors and pediatricians ideally should be free flowing while adhering to privacy regulations.
6. As experts in child development, pediatricians should become aware of and participate in development of home-visiting programs in their communities. They should be willing to participate in the planning, implementation, and evaluation of home-visiting programs and work to ensure that the methodologic contents of programs are evidence based.
7. Home-visiting services may have effects that are wide ranging and important to the health and welfare of young children but beyond the scope of traditional pediatric health care. As such, funding streams should be developed that do not rely solely on health insurance mechanisms. Home-visiting services can be cost-effective. Those sectors of society that are most likely to accrue benefit in future cost savings from the social and educational effects of home visiting should contribute to the funding of programs.

abstract

BACKGROUND: The purpose of this statement is to address the state of evidence on the routine use of pulse oximetry in newborns to detect critical congenital heart disease (CCHD).

METHODS AND RESULTS: A writing group appointed by the American Heart Association and the American Academy of Pediatrics reviewed the available literature addressing current detection methods for CCHD, burden of missed and/or delayed diagnosis of CCHD, rationale of oximetry screening, and clinical studies of oximetry in otherwise asymptomatic newborns. MEDLINE database searches from 1966 to 2008 were done for English-language papers using the following search terms: congenital heart disease, pulse oximetry, physical examination, murmur, echocardiography, fetal echocardiography, and newborn screening. The reference lists of identified papers were also searched. Published abstracts from major pediatric scientific meetings in 2006 to 2008 were also reviewed. The American Heart Association classification of recommendations and levels of evidence for practice guidelines were used. In an analysis of pooled studies of oximetry assessment performed after 24 hours of life, the estimated sensitivity for detecting CCHD was 69.6%, and the positive predictive value was 47.0%; however, sensitivity varied dramatically among studies from 0% to 100%. False-positive screens that required further evaluation occurred in only 0.035% of infants screened after 24 hours.

CONCLUSIONS: Currently, CCHD is not detected in some newborns until after their hospital discharge, which results in significant morbidity and occasional mortality. Furthermore, routine pulse oximetry performed on asymptomatic newborns after 24 hours of life, but before hospital discharge, may detect CCHD. Routine pulse oximetry performed after 24 hours in hospitals that have on-site pediatric cardiovascular services incurs very low cost and risk of harm. Future studies in larger populations and across a broad range of newborn delivery systems are needed to determine whether this practice should become standard of care in the routine assessment of the neonate. *Pediatrics* 2009;124:823–836

Congenital heart disease occurs in 9 of every 1000 livebirths.[1] Approximately one quarter of these children will have critical congenital heart disease (CCHD), which by definition requires surgery or catheter intervention in the first year of life.[2] Congenital malformations are one of the

leading causes of infant death in the United States and other developed nations, and CCHD is responsible for more deaths than any other type of malformation.[3,4] Most newborns with CCHD can be diagnosed by echocardiography, palliated with prostaglandin infusion, and treated with surgery or transcatheter interventions. In the current era, congenital heart surgery allows for repair or palliation of nearly all types of congenital heart malformations. Congenital heart surgery, together with transcatheter interventions, has resulted in a marked improvement in survival for those with CCHD.[5] Intervention is typically performed in the first weeks of life to optimize hemodynamics and prevent end-organ injury associated with delayed diagnosis. Because timely recognition of CCHD could improve outcomes, it is important to identify and evaluate strategies to enhance early detection. Pulse oximetry has been proposed as one such strategy, and legislation has been proposed to support this practice.[6]

The present statement reviewed the existing data to evaluate the potential role of pulse oximetry in examining newborns for CCHD. A writing group was appointed by the American Heart Association (AHA) and the American Academy of Pediatrics to evaluate the available literature addressing current detection methods for CCHD, burden of missed and/or delayed diagnosis of CCHD, rationale of oximetry screening, and clinical studies of oximetry in otherwise asymptomatic newborns. Comprehensive searches of the MEDLINE database from 1966 to 2008 were done for English-language publications in scientific journals using the following search terms: congenital heart disease, pulse oximetry, physical examination, murmur, echocardiography, fetal echocardiography, and newborn screening. The reference lists of identified papers were also searched. Published abstracts from major pediatric scientific meetings in 2006 to 2008 were also reviewed. The AHA classification of recommendations and levels of evidence for practice guidelines were used. The classification of recommendations and levels of evidence are shown in Table 1.

PREVALENCE AND SCOPE OF THE PROBLEM

Currently, children with CCHD are diagnosed by a variety of mechanisms. Neonates with CCHD may be diagnosed in the newborn nursery on the basis of physical examination findings, such as heart murmurs, tachypnea, or overt cyanosis. These findings are not always evident before hospital discharge, which may occur before 48 hours of life. A recent study from the United Kingdom suggested that 25% of infants with CCHD were not diagnosed with heart disease until after discharge from the newborn nursery.[7] The median age of diagnosis in these cases was 6 weeks. A recent publication from the United States suggested that delayed or missed diagnosis occurs in 7 per 100 000 livebirths.[8] However, because these data are derived from a birth defect surveillance program with passive and thus incomplete case ascertainment, this calculation most likely represents a minimum estimate.

Newborns with CCHD are susceptible to profound, sudden worsening in clinical status in the first days and weeks of life. These acute physiological changes correspond to changes in pulmonary vascular resistance and closure of the ductus arteriosus. In neonates with CCHD, the ductus arteriosus is often essential for maintaining either pulmonary or systemic blood flow. These CCHD defects are considered *ductus arteriosus–dependent lesions* (Table 2). The newborn hospitalization provides a critical window for caregivers to identify CCHD lesions in order to avoid hemodynamic embarrassment. The timing of constriction or closure of the ductus arteriosus also explains why children with CCHD may be particularly vulnerable to cardiovascular collapse soon after discharge from the newborn nursery.

Morbidity and Sequelae

With the advent of prostaglandin therapy for ductus arteriosus–dependent lesions, many previously lethal con-

TABLE 1 Classification of Recommendations and Level of Evidence

Classification of recommendations
- Class I: Conditions for which there is evidence and/or general agreement that a given procedure or treatment is beneficial, useful, and effective and should be performed. Benefit>>>risk.
- Class II: Conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment.
  - Class IIa: Weight of evidence/opinion is in favor of usefulness/efficacy. It is reasonable to perform procedure/administer treatment. Benefit>>risk. Additional studies with focused objectives needed.
  - Class IIb: Usefulness/efficacy is less well established by evidence/opinion. Procedure/treatment may be considered. Benefit≥risk. Additional studies with broad objectives needed; additional registry data would be helpful.
- Class III: Conditions for which there is evidence and/or general agreement that a procedure/treatment is not useful/effective and in some cases may be harmful. Risk≥benefit. No additional studies needed. Procedure/treatment should not be performed/administered because it is not helpful and may be harmful.

Level of evidence
- A: Data derived from multiple randomized clinical trials or meta-analyses
- B: Data derived from a single randomized trial or nonrandomized studies
- C: Only consensus opinion of experts, case studies, or standard of care

TABLE 2 CCHD Lesions and Associated Clinical Characteristics

Lesion	Prevalence[a]	Hypoxemia	Ductus Arteriosus Dependent
Outflow tract defects			
Tetralogy of Fallot	6.1	Most	Uncommon
D-transposition of the great arteries	4.0	All	Uncommon
Double-outlet right ventricle	1.7	Some	Some
Truncus arteriosus	1.0	All	None
TAPVC	1.2	All	None
Ebstein anomaly	0.6	Some	Some
Right obstructive defects			
Tricuspid atresia	0.5	All	Some
Pulmonary atresia, intact septum	0.8	All	All
Pulmonic stenosis, atresia	6.3	Some	Some
Left obstructive defects			
Hypoplastic left heart	3.3	All	All
Coarctation of the aorta	4.7	Some	Some
Aortic arch atresia or hypoplasia	1.0	Some	All
Aortic valve stenosis (critical)	1.6	Uncommon	Some
Other major heart defects	12.4	Some	Some

TAPVC indicates total anomalous pulmonary venous connection.

genital heart conditions that present with severe hypoxemia, shock, and acidosis in the newborn period are now survivable. The severity of organ damage is a function of the extent of insult, differential flow to organs as the neonatal circulation responds to the hypoxic/ischemic insult, and the oxygen requirement of each organ.

Among sequelae of neonatal hemodynamic compromise, the most important long-term effects relate to the consequences of brain injury from ischemia and reperfusion, because the brain has the highest oxygen requirement of any organ. Cerebrovascular pressure autoregulation and reactivity to CO_2 are affected by hypoxic/ischemic injury, which renders the brain particularly vulnerable to hypotension and decreased cardiac output.[9] Such hemodynamic instability is prevalent among neonates with CCHD who present with shock. Furthermore, preoperative events may interact with genetic mutations and both intraoperative and postoperative factors in determining later neurodevelopmental outcome.[10]

Using brain magnetic resonance imaging, a number of investigators have demonstrated acute brain injury in the newborn with CCHD before surgical intervention. Periventricular leukomalacia, which occurs secondary to vulnerability of the immature oligodendrocyte to hypoxia/ischemia, free radical attack, and excitotoxicity, and likely circulating cytokines, has been found on magnetic resonance imaging in up to 39% of neonates with CCHD.[11–14]

Children with CCHD are reported to experience more frequent impairments in motor function, speech and language, visual-motor-perceptual function, and executive function, as well as increased use of special services.[10,15–22] The greatest frequency of adverse outcomes is found among those with a single ventricle with obstruction to systemic outflow, such as hypoplastic left heart syndrome.[23] In this lesion, systemic perfusion occurs through the patent ductus arteriosus, and ductus closure results in shock and end-organ damage. Prenatal diagnosis of hypoplastic left heart syndrome has been reported in certain studies to reduce early neurological morbidity, with fewer adverse perioperative neurological events such as coma,[24] although earlier age at surgery has not been shown to result in better long-term neurodevelopmental outcomes.[23] One could infer that because delayed diagnosis is associated with damage to various end organs, it might also lead to hypoxic/ischemic brain injury; however, further studies are needed to demonstrate a true causal relationship.

Death Due to Delayed Diagnosis

A number of children with CCHD are so severely compromised at presentation that they die before surgical intervention. For example, investigators have reported that between 3% and 6% of neonates with dextro-transposition of the great arteries died because of hemodynamic compromise before surgical intervention could be offered.[25,26] In a study from the Baltimore-Washington metropolitan area in the 1980s, Kuehl and colleagues[27] reported that among 4360 children with any form of congenital heart disease, 76 (1.7%) died before the identification of heart disease. Delayed or missed diagnosis of CCHD accounted for 1.4 deaths per 10 000 livebirths in that series. In 1994, Abu-Harb and colleagues[28] reported on death due to unrecognized CCHD in infancy over a 6-year period in a region of northern England. Fifty-six of 185 children died in infancy, and 27 (48%) of these deaths resulted from sequelae of undetected CCHD. The great majority of these subjects had CCHD lesions that might have manifested hypoxemia. In another study from the United Kingdom, Wren and colleagues[29] reported that 25% of CCHD lesions were not diagnosed until after hospital discharge, even in the most recent era. The data from these United Kingdom studies suggested that delayed or missed diagnosis of CCHD accounted for 0.4 to 2.0 deaths per 10 000 livebirths.

With the increased use of prenatal ultrasound and a better understanding

of the presentation of CCHD in the past decade, the risk of death before diagnosis has undoubtedly declined, although it is still likely to be important.[30] Two recent studies have reported that the rate of mortality due to delayed diagnosis of CCHD is an order of magnitude lower than in the older studies discussed in the previous paragraph. First, a presentation from a study from metropolitan Atlanta, Ga, that used a population-based surveillance system reported that death due to delayed diagnosis of CCHD occurred in 1.0 of every 100 000 livebirths and may be decreasing with time[31]; however, this estimate could be understated, because in that study, only deaths that occurred before arrival at a hospital or before the child could be stabilized were attributed to delayed diagnosis. Another preliminary study from California reported 2.0 deaths per 100 000 livebirths related to delayed diagnosis of CCHD.[32] Presumably, earlier recognition of CCHD in these patients could have prevented death in at least some of these cases.

Impairment in cardiovascular function from delayed diagnosis may also adversely impact survival during neonatal cardiovascular surgery and recovery. Certain studies that compared outcomes in prenatal and postnatal diagnosis of CCHD have reported better short-term results for those who were diagnosed prenatally.[25,33] However, numerous other studies have failed to document any survival benefit of prenatal diagnosis among infants undergoing congenital heart surgery.[34,35]

In summary, delayed or missed diagnosis is associated with significant morbidity, the most significant being hypoxic/ischemic brain injury. In addition, delayed diagnosis appears to lead directly and indirectly to higher mortality in this population, although the number of deaths that might be prevented through pulse oximetry screening remains to be determined. Methods to improve early detection of CCHD appear warranted.

Customary Practice

Children with CCHD are identified in a variety of ways. Since the late 1980s, prenatal ultrasound has been used to screen for congenital anomalies. An anatomic ultrasound is typically performed at 18 to 20 weeks' gestation. During this process many, but not all, cases of CCHD can be identified by a methodical scan.[36] When CCHD is identified by this approach, the patient is often referred to a pediatric cardiologist for confirmatory imaging and counseling. With knowledge that the fetus has CCHD, the newborn can be delivered in a hospital capable of providing intensive care, including prostaglandin, as well as mechanical ventilation. The newborn can be stabilized and transferred to a congenital heart center.

Prenatal ultrasound, performed by those with specific training in congenital heart disease, can identify a variety of CCHD lesions; however, numerous studies have reported that even when fetal ultrasound is routinely performed during pregnancy, fewer than 50% of cases of CCHD are identified. Most of the published literature comes from European countries, which tend to have more centralized healthcare systems and uniform practices vis-à-vis prenatal ultrasound.[30,37–41] As such, these systems may represent the best-case scenario for population prenatal ultrasound screening. In the United States, many congenital surgery referral centers have reported prenatal detection rates >50% for functional single-ventricle lesions,[35,42] although the detection rate is generally <30% for CCHD lesions with 2-ventricle circulation.[43,44] These studies from referral centers may be biased toward higher detection rates, and population-based data on prenatal detection of CCHD in the United States are sparse.

There are several factors that might account for the relatively low prenatal CCHD detection rate. The quality of anatomic ultrasounds varies considerably.[45,46] A number of medical professionals, including radiologists, perinatologists, and general obstetricians with varying degrees of training, as well as technicians, perform these ultrasounds.[47] In addition to concerns about the quality, there may be limited access to prenatal ultrasound. In the United States, an anatomic ultrasound is not performed in all women.[48] The availability of anatomic ultrasound is likely to be particularly limited in certain racial/ethnic or low-socioeconomic-status groups.[49] Therefore, although prenatal ultrasound plays an important part in the timely identification of CCHD, population-based data demonstrate that this methodology by itself is insufficient to identify a high proportion of cases.

After birth, screening for congenital heart disease by primary care providers is currently accomplished by physical examination within the first 24 hours of life and on subsequent nursery visits. Supplemental tests, including electrocardiograms, pulse oximetry, and chest radiographs, are often obtained in suspicious cases. Echocardiograms can be done either with or without pediatric cardiology consultation. This strategy blends diagnostic assessment approaches from the 1950s to 1970s with the increasing availability of echocardiography. It results in substantial case identification but is regarded as inefficient and costly and misses a significant number of newborns with CCHD.[55]

Skilled physical examination, a sensitive and specific screening tool in

older children, does not always distinguish between neonates with and without congenital heart disease.[50,56] Hypoxemia is difficult to detect in newborns, and the transitional circulation masks important clinical findings such as absent femoral pulses while the ductus arteriosus remains patent. Reports of the late detection of coarctation of the aorta have been published since the 1960s.[51] Perhaps most importantly, physical examination skills are on the decline in current trainees.[52]

Heart murmurs have a prevalence of between 0.6% and 4.2% in newborns and are mistakenly considered a hallmark of heart disease.[53,54] They often do not accompany critical heart defects, particularly those with valve atresia and transposition. Flow murmurs of the transitional circulation, transient tricuspid regurgitation, and small ventricular septal defects are common and of no clinical importance in newborns. Conversely, murmurs of many important complex heart defects, such as tricuspid atresia with ventricular septal defect, double-outlet right ventricle, and total anomalous pulmonary venous return, emerge only after the decline in pulmonary resistance and after neonatal discharge and are often heard but not considered pathological. Practicing pediatricians currently have limited experience in discriminating innocent from pathological murmurs. In a contemporary series in which echocardiography was performed to evaluate for possible heart disease based on suspicious physical examination, fewer than 15% of subjects were found to have significant congenital heart disease.[55]

Clinical experience and epidemiological observations suggest that although physical examination, electrocardiogram, and chest radiograph are useful in identifying many cases of serious congenital heart disease postnatally, they do not have sufficient sensitivity and specificity to detect all cases. Echocardiography, although an essential diagnostic tool, has serious limitations as a universal screening tool, particularly its cost.[56] When used as a screening tool, echocardiography has a high frequency of either false-positive results (usually related to the transitional circulation) or recognition of clinically benign diagnoses (eg, small muscular ventricular septal defects). In addition, there may be an inadequate supply of trained personnel who could perform this screening with a reasonable degree of accuracy. Therefore, there is considerable interest in improving the detection of CCHD with novel diagnostic techniques.

PULSE OXIMETRY AND DETECTION OF CCHD

A common feature of many forms of congenital heart disease is hypoxemia. Hypoxemia results from the mixing of systemic and venous circulations or parallel circulations as one might see in dextro-transposition of the great arteries. Hypoxemia may result in obvious cyanosis. However, generally, 4 to 5 g of deoxygenated hemoglobin is needed to produce visible central cyanosis, independent of hemoglobin concentration.[57] For the typical newborn with a hemoglobin concentration of 20 g/dL, cyanosis will only be visible when arterial oxygen saturation is <80%; if the infant only has a hemoglobin concentration of 10 g/dL, the saturation must be <60% before cyanosis is apparent.[58] Importantly, those children with mild hypoxemia, with arterial oxygen saturation of 80% to 95%, will not have visible cyanosis. Moreover, the identification of cyanosis is particularly problematic in black and Hispanic neonates because of skin pigmentation.[57]

The majority of CCHD lesions present with some degree of hypoxemia in the newborn period. Table 2 demonstrates the frequency of the most common forms of CCHD based on data from the Metropolitan Atlanta Congenital Birth Defects Surveillance Program[53] and the likelihood of having some degree of hypoxemia in the newborn period. To improve timely detection of CCHD, a number of investigators have proposed that pulse oximetry be considered as a complementary modality to the newborn physical examination.[59,60]

Pulse oximetry was developed in the early 1970s based on the different absorption spectra between oxygenated and deoxygenated hemoglobin.[61] Deoxygenated hemoglobin absorbs light in the red band (600 to 750 nm), whereas oxygenated hemoglobin absorbs light in the infrared band (850 to 1000 nm). The ratio of light absorbance at these 2 wavelengths correlates with the saturation of hemoglobin in the capillaries.[62] Pulse oximetry has the potential to identify hypoxemia that might not otherwise produce visible cyanosis, especially among darkly pigmented newborns.

Pulse oximetry is used routinely in the assessment of young children in neonatal intensive care units and emergency departments and has been proposed as an adjunct to the assessment of the newborn in the delivery room.[63] As such, some have proposed that pulse oximetry be considered as a vital sign equivalent in importance to pulse, respirations, and blood pressure.[64] Contemporary use of pulse oximetry has thus already contributed to heightened recognition of congenital heart disease in neonates.

Clinical Studies of Oximetry Screening

Pulse oximetry has gained wide acceptance as a noninvasive method to determine oxygen saturation ($Sp0_2$). The method does not require calibration and is able to provide instantaneous

data that correlate well with blood gas measurements. O'Brien and colleagues[65] have defined reference data for oxygen saturation in healthy full-term infants during their first 24 hours of life. The median value at 20 to 24 hours of life (97.8%) is similar to the results for healthy full-term infants between 2 and 7 days of age (97.6%).[66] Other investigators have reported similar results.[67,68] Beginning in the 1990s, investigators began to explore the possible role of neonatal oximetry in identifying CCHD that might otherwise go undetected. Initially, investigators demonstrated that in neonates with known CCHD, pulse oximetry measurements were significantly lower than in age-matched control subjects. Using a cutoff of 95% in lower-extremity saturation, Hoke and colleagues[59] suggested that 81% of neonates with CCHD could be identified. Given this association, the question arose as to whether oximetry can successfully identify CCHD in a population of newborns not otherwise suspected of having heart disease. To date, several published studies[55,59,60,69–75] have used newborn oximetry to screen for CCHD (Table 3). Most studies were relatively small, and screening protocols differed with respect to both age at screening and cutoff levels for an abnormal screen. Nonetheless, the cumulative experience of these investigations provides a framework for evaluation of the test characteristics of newborn oximetry screening. The results of these studies and differences in study protocols are described below.

Because newborns with CCHD may have clinical deterioration in the first 48 hours of life, one would ideally use oximetry screening soon after delivery. However, arterial oxygen saturation varies considerably in the first 24 hours, with many healthy newborns having arterial saturations of less than 95%. As such, oximetry screening before 24 hours of life can result in a significant number of false-positive results. A study from the United Kingdom reported that the false-positive rate was as high as 5% when oximetry screening was performed in the first 24 hours compared with 1% at the time of hospital discharge.[76] Therefore, to achieve an acceptable specificity, testing >24 hours after birth would appear to be the most reasonable strategy. This screening strategy assumes that the majority of newborns will not be discharged on the first day of life. With early discharge at less than 24 hours of age, many infants would not be screened.

The establishment of a cutoff threshold for an abnormal $Sp0_2$ is important. Other factors being constant, a higher threshold will increase sensitivity and at the same time decrease specificity. Setting the $Sp0_2$ cutoff value closer to the normal level will decrease the number of false-negative screening results at the cost of increasing the number of false-positive screening results. Conversely, a lower $Sp0_2$ threshold will lower sensitivity and raise specificity. Although a number of $Sp0_2$ thresholds have been proposed, many investigators believe that an $Sp0_2$ of ≤95% is appropriate. In studies of healthy populations, the distribution of $Sp0_2$ measured in a lower extremity at 24 hours was reported to be 97.3±1.3%.[68] One study suggested that $Sp0_2$ <92% be considered a positive sign of hypoxemia; however, others have argued that a low threshold is likely to result in a number of infants with CCHD being misclassified as normal without markedly improving specificity.[77]

Most published studies of oximetry screening for CCHD have been performed at relatively low altitude. It is known, however, that arterial saturation in children and adults is lower at high altitudes, especially above 5000 ft. Several investigators have reported the normal $Sp0_2$ values for neonates at high altitude.[77,78] Bakr and colleagues[78] reported a mean $Sp0_2$ of

TABLE 3 Results of Studies Examining Oximetry Screening for CCHD

FP indicates false-positive; TP, total positive; FN, false-negative; TN, total negative; PPV, positive predictive value; NPV, negative predictive value; H+F, hand and foot; F, foot; and NA, not available.

[a] Excludes study by Meberg et al[74] because false-negative data were not included.

95.4% at 24 hours of life from a population evaluated at 5300 ft. Presumably, one would need to establish a different threshold for high-altitude populations to maintain a reasonable balance between sensitivity and specificity of oximetry screening. Pilot projects are currently under way to examine how high altitude impacts newborn screening with oximetry.

Another variation among published oximetry screening studies has been the position of the pulse oximetry probe with respect to the upper or lower extremity. Previous investigators have demonstrated slightly lower Spo_2 measurements in the lower extremity than in the upper extremity in the newborn at 24 hours of life due to shunting at the level of the ductus arteriosus.[68] In general, the mean difference between the Spo_2 in the upper and lower extremities is <1%; however, some newborns with CCHD may have a more profound difference in saturation between the upper and lower body. For example, neonates with some forms of left obstructive heart lesions, such as critical coarctation of the aorta, in which the ductus arteriosus supplies a portion of the systemic flow, may have lower Spo_2 readings in legs than in the arm.[59]

Some investigators proposed that oximetry screening should include measurements of both upper and lower extremities and that differences in Spo_2 of more than 3% or 4% be used to identify newborns with CCHD who might otherwise be missed by measuring lower-extremity Spo_2 alone.[55,79] One study that examined newborns with known CCHD suggested that the addition of upper and lower measurements would increase sensitivity from 89.4% to 92.4% without a decrease in specificity.[79] However, these data were not obtained in the setting of a screening birth cohort but rather among those with known CCHD. It is possible that the inclusion of both upper and lower Spo_2 measurements would result in a significantly higher false-positive rate. Moreover, screening both upper and lower extremities would increase the time required to screen a single newborn. Therefore, a single lower-extremity reading would appear to be the most appropriate for the purposes of large-scale screening.

The results of published studies using oximetry screening to detect CCHD in a representative birth population are shown in Table 3. Ten studies with a total of 123 846 infants screened reported a mean of 0.87% of infants with false-positive screens but a false-positive rate of 0.035% when screening was done after 24 hours; however, there was remarkable dispersion in reported screening performance. Five studies reported a low false-positive rate (≤0.1%) when measurements were made after 24 hours of life. The low false-positive rate is somewhat surprising given the reported variation of Spo_2 reported in normal newborn populations. It is not known whether there might be a publication bias in that only studies with favorable specificity might be published. A low false-positive rate would reduce the number of unnecessary echocardiograms. Nine of 10 studies listed in Table 3 reported sensitivity of <90%, ranging from 0% to 87%. This is explained in part by the fact that hypoxemia is not present in some forms of CCHD (Table 2).

False-positive results can be a cause for concern in public health newborn screening programs that are based on the laboratory analysis of dried blood spot specimens collected on filter paper cards. These false-positive results typically require families to be notified to bring their child in for further testing, and there can be a delay of several days before the results of such testing become available. False-positive newborn screening results have been reported to sometimes result in lasting parental anxiety and possibly elevated use of healthcare services.[80] In the case of pulse oximetry, this type of psychosocial risk of harm is very unlikely to be a problem in the typical hospital setting for infants not subject to early discharge. A positive test result leads to an immediate referral for an echocardiogram, and the results are reported before discharge. However, when the birth center does not have ready access to cardiac consultation, delay in hospital discharge or transfer to another facility may result in anxiety and added stress.

Oximetry screening may be less effective at identifying some CCHD lesions at greatest risk for acute cardiovascular compromise, namely, obstructive left heart lesions. A published analysis of oximetry has suggested that the difficulty in detecting hypoplastic left heart syndrome, aortic stenosis, and coarctation of the aorta limits the usefulness of this screening tool.[81] However, it should be noted that nearly all forms of CCHD—even those unrelated to left heart obstruction—can result in serious morbidity and even death when diagnosis is delayed.[25,31] Moreover, oximetry can detect a significant number of newborns with obstructive left heart lesions and right-to-left shunting at the ductus arteriosus (Table 4). In published series, hypoplastic left heart syndrome was detected in all cases, and coarctation of the aorta was detected in just over half the cases. Studies that have obtained Spo_2 measurements on newborns with known CCHD have similarly reported that a lower-extremity Spo_2 of ≤95% detected hypoplastic left heart syndrome in all cases and critical coarctation of the aorta in the majority of cases.[59,79]

Several studies of screening oximetry have reported incidental findings of

CI indicates confidence interval; DORV, double-outlet right ventricle; HLHS, hypoplastic left heart syndrome; PA, pulmonary atresia; d-TGA, dextro-transposition of the great arteries; TAPVC, total anomalous pulmonary venous connection; Truncus, truncus arteriosus; TA, tricuspid atresia; AA/AS, aortic atresia/aortic stenosis; TOF, tetralogy of Fallot; AVSD, atrioventricular septal defect; CoA, coarctation of the aorta; and PS, pulmonary stenosis.

persistent fetal circulation, defined as elevated pulmonary vascular resistance and right-to-left shunting at the ductus arteriosus. In some reports, these cases have been reported as false-negative findings. In other studies, the investigators have emphasized the benefits of identifying these patients.[69] The finding of persistent fetal circulation in otherwise healthy newborns may be of benefit to medical care.[83] An understanding of the outcome of newborns who are asymptomatic with a decreased lower-extremity Spo_2 will be needed to understand whether identification of this population is a true benefit of oximetry screening.

LIMITATIONS AND CHALLENGES TO NEWBORN PULSE OXIMETRY IN DETECTION OF CCHD

There are technical limitations to oximetry measurement in the newborn. As noted above, the mean Spo_2 in the newborn at >24 hours of age is 97% to 98%; however, when continuous pulse oximetry is used, multiple investigators have demonstrated periodic and/or sustained desaturation below 95% during sleep, feeding, and crying.[65,68,84,85] Sustained rather than variable hypoxemia is consistent with the diagnosis of cyanotic congenital heart disease. Low oximetry readings in the setting of normal arterial oxygen saturation have been reported by multiple investigators.[76,86,87] In fact, falsely low oximetry readings in the newborn population are known to be associated with low peripheral perfusion and motion artifact,[88,89] probe placement site and partial probe detachment,[90] and hyperbilirubinemia or dyshemoglobinemias. It is known that technical differences between the various types of oximeters in general use include measurement of functional or fractional oxygen saturation, preset signal-averaging times, and methods for the exclusion of motion artifact.[91] There has been some research into the variability among various commercially available pulse oximeters; however, most of the variability occurs in the cyanotic range (<90%) or at the highest saturations (99% to 100%). The peak performance of the commercially available oximeters occurs in the range of 92% to 97%.[92] Therefore, in the critical range for oximetry screening (94% to 97%), the variability of the most commonly used oximeters should be negligible.

There has also been concern that pulse oximeters may not be as accurate in darkly pigmented adults and children. At low Spo_2 levels (<70%), commercially available oximeters appear to overestimate arterial saturation by 3% in darkly pigmented subjects.[93] However, when Spo_2 is >90%, measurement bias related to skin pigmentation appears negligible (<0.2%). Lastly, the quality of oximetry measurements may be lower when performed in a screening setting.[94]

When neonates are identified as having hypoxemia (Spo_2 ≤95%), it is necessary to evaluate them for CCHD. Although physical examination, chest radiography, and electrocardiography can assist in this process, echocardiography is now considered the definitive diagnostic modality. Whenever possible, the echocardiograms should be interpreted by pediatric cardiologists; major errors in the interpretation of a newborn echocardiogram by trained pediatric cardiologists are rare.[95]

Although the majority of metropolitan areas in the United States have access to pediatric subspecialists, such as pediatric cardiologists, availability in rural areas can be limited. Approximately 15% of births in the United States occur in nonmetropolitan areas.[96] In these settings, echocardiograms are often performed by sonographers without formal pediatric training and are interpreted by adult cardiologists. Several investigators have found that the accuracy of pediatric echocardiograms interpreted by adult cardiologists is low.[95,97] One alternative is to use telemedicine, in which echocardiograms are interpreted distantly at a pediatric referral center.[98,99] The accu-

racy may be improved by direct guidance of the sonographers by a pediatric cardiologist via videoconferencing. This approach, which has been shown to be efficient and accurate, may be required to enhance detection of CCHD in rural or underserved areas. Another option is for newborns with suspected CCHD to be transported to a tertiary center. This strategy, however, would be expensive and impractical in many cases.

The cost of routine pulse oximetry performed on asymptomatic newborns after 24 hours of age includes both the direct cost of the pulse oximetry and the follow-up costs of any additional examinations and transfers. The largest direct cost component is staff time. At experienced centers, it may take a technician only 45 seconds on average to perform pulse oximetry on a newborn infant. The cost of diagnostic evaluation of infants who are referred for further examination after pulse oximetry depends on the frequency of referral, the duration of the diagnostic evaluation, and the ability for the evaluation to be performed without transfer to another center. A detailed cost accounting, to be reported elsewhere, indicates an average cost of approximately $1 per asymptomatic newborn infant, which includes the cost of diagnostic evaluations, in hospitals with moderate obstetric volume and ready access to pediatric echocardiography. Further work is needed to assess the cost and yield of routine pulse oximetry examination of newborns in a wider range of settings.

Oximetry to enhance the detection of CCHD has been considered previously in an evidence review sponsored by the United Kingdom's National Health Service Health Technology Assessment program.[100] The investigators observed that pulse oximetry is much more effective than current clinical practice in identifying infants with CCHD and more accurate and much less expensive than screening all newborns with echocardiography. The incremental cost per timely diagnosis of life-threatening congenital heart defects was calculated to be approximately $10 000 for pulse oximetry and $10 million for screening echocardiography. Although pulse oximetry was regarded as more promising than either the current practice or other options, the report called for further research to improve estimates of test performance and to inform timing, diagnostic, and management strategies and to "investigate the psychosocial effects of newborn screening for congenital heart disease" (p 127).[100] Another report has suggested families were quite receptive to newborn screening with pulse oximetry, with 99.8% of a sample of parents in Poland reported to approve of the screening technique.[70]

SUMMARY

The association of delayed diagnosis of CCHD with mortality, morbidity, and disability provides a rationale for strategies such as pulse oximetry assessment to improve early detection. Some studies have reported a reasonable detection rate with pulse oximetry; however, the usefulness of oximetry in clinical practice is not well established (Class IIb, Level of Evidence C; Level of Evidence C corresponds to observational studies [case-control and cohort design]). Additional studies in larger populations and across a broad range of newborn delivery systems are needed to determine whether this practice should become the standard of care in the routine assessment of the neonate.

Currently, pulse oximetry is being performed routinely in some delivery centers in the United States and elsewhere.[101] Because pulse oximetry cannot detect all cases of CCHD, the diagnoses in some infants will be missed until after discharge from the newborn nursery. Such cases will provoke the question of whether the newborn oximetry screen was performed accurately. Therefore, it is reasonable for centers that routinely use pulse oximetry to ensure the fidelity of oximetry measurements through periodic quality assessment. Parents and caretakers should also be informed that pulse oximetry cannot detect all cases of CCHD, and hence, a negative test result does not exclude the possibility of heart disease.

Call for Future Studies

Collaborative studies among hospitals conducting routine pulse oximetry should analyze pooled data and report detection, false-positive rates, and false-negative rates of CCHD. A pilot study of pulse oximetry screening has recently completed enrollment at 6 English hospitals by the National Institute for Health Research.[102] In addition, a comprehensive assessment of the impact of pulse oximetry assessment and early detection of CCHD on morbidity, postoperative survival, and hospital costs will allow a more critical evaluation of the economic impact of efforts to improve timely diagnosis of CCHD.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Role of the School Nurse in Providing School Health Services

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on School Health

ABSTRACT

The school nurse has a crucial role in the seamless provision of comprehensive health services to children and youth. Increasing numbers of students enter schools with chronic health conditions that require management during the school day. This policy statement describes for pediatricians the role of the school nurse in serving as a team member in providing preventive services, early identification of problems, interventions, and referrals to foster health and educational success. To optimally care for children, preparation, ongoing education, and appropriate staffing levels of school nurses are important factors for success. Recommendations are offered to facilitate the working relationship between the school nurse and the child's medical home. This statement has been endorsed by the National Association of School Nurses.

Key Words
school nursing, school nurse, school health services

SCHOOL NURSE DEFINITION

The National Association of School Nurses defines school nursing as:

> A specialized practice of professional nursing that advances the well-being, academic success, and lifelong achievement of students. To that end, school nurses facilitate positive student responses to normal development; promote health and safety; intervene with actual and potential health problems; provide case management services; and actively collaborate with others to build student and family capacity for adaptation, self-management, self-advocacy, and learning.[1]

BACKGROUND

After the child's home, school represents the second most influential environment in a child's life. As more students enter schools with health or mental health problems, pediatricians face the challenge of managing their care throughout the school day. The school nurse is the health care representative on site. An understanding of the school nurse's role is essential to ensure coordinated care. There is a recognized relationship between health and learning, as there is between school nurse availability and student well-being and educational success.[2–4] The role of the school nurse encompasses both health and educational goals.[5–7] Students today may face family crises, homelessness, immigration, poverty, and violence, which increase both their physical and mental health needs. School nurses perform a critical role within the school health program by addressing the major health problems experienced by children. This role includes providing preventive and screening services, health education and assistance with decision-making about health, and immunization against preventable diseases. In addition, school nurses may provide interventions for acute and chronic illness, injuries and emergencies, communicable diseases, obesity, substance use and abuse, adolescent pregnancy, mental health, dental disease, nutrition, and sexually transmitted infections.[8–13] School nurses need to be physically present in schools to address these responsibilities appropriately. Improved student outcomes result where schools have a full-time school nurse.[3] Inadequate staffing threatens the school nurse's role as medical home extender.

School nurses are well positioned to take the lead for the school system in partnering with school physicians, community physicians, and community organizations. They facilitate access to Medicaid and the State Children's Health Insurance Program to help families and students enroll in state health insurance programs and may assist in finding a medical home for each student who needs one.

This policy statement has been endorsed by the National Association of School Nurses.

SCHOOL NURSE ROLE

The National Association of School Nurses identifies 7 core roles that the school nurse fulfills to foster child and adolescent health and educational success.[13] The roles are overarching and are applicable to school nurses at all levels of practice, in all geographic settings, and with all clients.

1. The school nurse provides direct care to students.[13] The school nurse provides care for injuries and acute illness for all students and long-term management of students with special health care needs. Responsibilities include assessment and treatment within the scope of professional nursing practice, communication with parents, referral to physicians, and provision or supervision of prescribed nursing care. An individualized health care plan is developed for students with chronic conditions, and when appropriate, an emergency plan is developed to manage potential emergent events in the school setting (eg, diabetes, asthma). Ideally, this health plan is aligned with the management plan directed by the child's pediatrician and regularly updated through close communication. The school nurse is responsible for management of this plan and communication about the plan to all appropriate school personnel.

   The school nurse has a unique role in provision of school health services for children with special health needs, including children with chronic illnesses and disabilities of various degrees of severity. Children with special health needs are included in the regular school classroom setting as authorized by federal and state laws. As a leader of the school health team, the school nurse must assess the student's health status, identify health problems that may create a barrier to educational progress, and develop a health care plan for management of the problems in the school setting. The school nurse ensures that the student's individualized health care plan is part of the individualized education plan (IEP),[14] when appropriate, and that both plans are developed and implemented with full team participation, which includes the student, family, and pediatrician.

2. The school nurse provides leadership for the provision of health services[13] As the health care expert within the school, the school nurse assesses the overall system of care and develops a plan for ensuring that health needs are met. Responsibilities include development of plans for responding to emergencies and disasters and confidential communication and documentation of student health information.

3. The school nurse provides screening and referral for health conditions.[13] Health screenings can decrease the negative effects of health problems on education by identifying students with potential underlying medical problems early and referring them for treatment as appropriate. Early identification, referral to the medical home, and use of appropriate community resources promote optimal outcomes. Screening includes but is not limited to vision, hearing, and BMI assessments (as determined by local policy).

4. The school nurse promotes a healthy school environment.[13] The school nurse provides for the physical and emotional safety of the school community by monitoring immunizations, ensuring appropriate exclusion for infectious illnesses, and reporting communicable diseases as required by law. In addition, the school nurse provides for the safety of the environment by participating in environmental safety monitoring (playgrounds, indoor air quality, and potential hazards). The school nurse also participates in implementation of a plan for prevention and management of school violence, bullying, disasters, and terrorism events. The school nurse may also coordinate with school counselors in developing suicide prevention plans. In addition, if a school determines that drug testing is a part of its program, school nurses should be included in school district and community planning, implementation, and ongoing evaluation of this testing program.[15]

5. The school nurse promotes health.[13] The school nurse provides health education by providing health information to individual students and groups of students through health education, science, and other classes. The school nurse assists on health education curriculum development teams and may also provide programs for staff, families, and the community. Health education topics may include nutrition, exercise, smoking prevention and cessation, oral health, prevention of sexually transmitted infections and other infectious diseases, substance use and abuse, immunizations, adolescent pregnancy prevention, parenting, and others. School nurses also promote health in local school health councils.

6. The school nurse serves in a leadership role for health policies and programs. As a health care expert within the school system, the school nurse is a leader in the development and evaluation of school health policies. These policies include health promotion and protection, chronic disease management, coordinated school health programs, school wellness policies, crisis/disaster management, emergency medical condition management, mental health protection and intervention, acute illness management, and infectious disease prevention and management.[16]

7. The school nurse is a liaison between school personnel, family, health care professionals, and the community.[14] The school nurse participates as the health expert on the IEP[17] and 504[18] teams. IEP teams identify the special education needs of students; 504 teams plan for reasonable accommodations for students' special needs that impact their educational programs.[18] As the case manager for students with health problems, the school nurse ensures that there is adequate communication and collaboration among the family, physicians, and providers of community resources. This is a crucial interface for the pediatrician and the school nurse to ensure consistent, coordinated care. The school nurse also works with community organizations and primary care physicians to make the community a healthy place for all children and families.

SCHOOL NURSE ACTIVITIES

The range of school health services varies by school district. The following health services are the minimum

that should be offered, according to the American Academy of Pediatrics (AAP) manual *School Health: Policy and Practice*:[19]

- Assessment of health complaints, medication administration, and care for students with special health care needs;
- A system for managing emergencies and urgent situations;
- Mandated health screening programs, verification of immunizations, and infectious disease reporting; and
- Identification and management of students' chronic health care needs that affect educational achievement.

The AAP recognizes the need for appropriate management of student health conditions in its policy statement, "Guidelines for Administration of Medication in School."[20] It also recognizes the need for policies for emergency medical situations that can occur in school and the school nurse's role in developing and implementing these policies.[21,22] The school nurse serves as an extension of traditional community health services, ensuring continuity, compliance, and professional supervision of care within the school setting.

SCHOOL HEALTH SERVICES TEAM

The school nurse functions as a leader and the coordinator of the school health services team. The team may also include a school physician, licensed practical nurses, health aides and clerical staff, school counselors, school psychologists, school social workers, and substance abuse counselors. The health team may also expand to create a coordinated school health team that integrates health services, health education, physical education, nutrition services, counseling/psychological/social services, healthy school environment, health promotion for staff, and family/community involvement.[23] Occupational therapists, physical therapists, and speech-language pathologists may also be part of the school health team. A pediatrician often fills the school physician role, because pediatricians are knowledgeable about general pediatrics, school health, and adolescent health. School physicians review guidelines, policies, and programs related to health care in schools. In some schools, a pediatric or family nurse practitioner functions as the school nurse and may provide additional services. Unlicensed assistive personnel (unlicensed individuals who are trained to perform as an assistant to the licensed nurse) may be part of the school health services team. Although they may possess state certification in medication administration as a nursing assistant or other nursing tasks, they must be trained and supervised by the school nurse in accordance with state nurse practice laws to perform delegated nursing tasks. Under this approach, the school nurse has the responsibility to decide which nursing tasks may be delegated and to whom within the school setting, in accordance with state laws and regulations.

Some schools may have a school-based health center in or adjacent to the school, which may provide primary care and psychosocial services. The school nurse coordinates the activities of the school health services team with the child's primary care physician and/or with the school-based health center to provide continuity of care and prevent duplication of services.

PROFESSIONAL PREPARATION FOR SCHOOL NURSES

The AAP supports the goal of professional preparation for all school nurses and recommends the use of appropriately educated and selected school nurses to provide school health services. The National Association of School Nurses has determined that the minimum qualifications for the professional school nurse should include licensure as a registered nurse and a baccalaureate degree from an accredited college or university. There should be a process by which additional certification or licensure for the school nurse is established by the appropriate state board. The AAP supports national certification of school nurses by the National Board for Certification of School Nurses.[24]

CONCLUSION

The AAP supports having a full-time school nurse in every school as the best means of ensuring a strong connection with each student's medical home. Interim steps toward achieving this ideal can be made by achieving the Healthy People 2010 goal, which states that districts should employ at least 1 nurse per 750 students, with variation, depending on the community and student population.[25] Schools with high percentages of students with special health needs would require more intensive ratios of nurse to students; for example, 1 nurse per 225 students when students require daily professional nursing services or interventions, and 1 nurse per 125 when students have complex health needs.[26] The presence of the school nurse in every school allows the school physician to work most efficiently in providing the coordinated care that each student requires.

The AAP recommends and supports the continued strong partnership among school nurses, school physicians, other school health personnel, and pediatricians. These partners serve the health of children and youth best by facilitating the development of a coordinated school health program, facilitating access to a medical home for each child,[27] and integrating health, education, and social services for children at the community level. School nurses, as part of a coordinated school health program, contribute to meeting the needs of the whole child and supporting their success in school.[28]

RECOMMENDATIONS

1. Pediatricians should establish a working relationship with the school nurses who care for their patients with chronic conditions to ensure that individual patients' health plans are executed effectively within the school. In addition, pediatricians' communications with school nurses concerning their patients should be sufficiently clear and detailed to guide school nurses in overseeing the care of individual children.

2. Pediatricians can offer direct support of school nurses by serving on school wellness policy committees, school health advisory committees, emergency preparedness committees, or other school-related decision-making bodies. In addition, local physicians may be asked to consult on or assist in writing school health-related policies.
3. School-based screening for vision, hearing, or other conditions may require coordination between local physicians and the school nurse to ensure students are referred for additional evaluation and treatment, and for communication with students, families, school administration, and the community.
4. Pediatricians should play an active role in supporting the availability and continuing education of the school nurse. This role may encompass updates on new AAP recommendations and research findings that would keep the school nurse's practice as aligned as possible with current AAP policy.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

The Role of Schools in Combating Illicit Substance Abuse

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on School Health and Committee on Substance Abuse

ABSTRACT

Disturbingly high levels of illicit drug use remain a problem among American teenagers. As the physical, social, and psychological "home away from home" for most youth, schools naturally assume a primary role in substance abuse education, prevention, and early identification. However, the use of random drug testing on students as a component of drug prevention programs requires additional, more rigorous scientific evaluation. Widespread implementation should await the result of ongoing studies to address the effectiveness of testing and evaluate possible inadvertent harm. If drug testing on students is conducted, it should never be implemented in isolation. A comprehensive assessment and therapeutic management program for the student who tests positive should be in place before any testing is performed. Schools have the opportunity to work with parents, health care professionals, and community officials to use programs with proven effectiveness, to identify students who show behavioral risks for drug-related problems, and to make referrals to a student's medical home. When use of an illicit substance is detected, schools can foster relationships with established health care experts to assist them. A student undergoing individualized intervention for using illicit substances merits privacy. This requires that awareness of the student's situation be limited to parents, the student's physician, and only those designated school health officials with a need to know. For the purposes of this statement, alcohol, tobacco, and inhalants are not addressed.

THE EFFECT OF SUBSTANCE ABUSE ON CHILDREN IN SCHOOL

Students spend the major part of their day in school. The school environment provides a standard against which young people test behavior.[1] School personnel often serve as highly influential role models by which preadolescents and adolescents judge themselves. Adolescents who perceive that their teachers care about them are less likely to initiate marijuana use, cigarette smoking, drinking to get drunk, and other health risk behaviors.[2] Relationships with teachers and counselors are among the most important and formative ones for many students, especially middle school students.[2] Students who are poorly bonded to school are also less likely to recognize that substance use may reduce the likelihood of them achieving their future goals.[3]

The use of mind-altering chemicals has deleterious effects on school performance.[4–7] Students under the influence of such substances are not ready to learn and are at risk of long-term impairment of cognitive ability and memory.[7,8] Substance use is frequently associated with a lack of motivation and self-discipline as well as reduced school attendance.[9,10] Safety issues also are of concern. Marijuana, like alcohol, is associated with increased risk of motor vehicle crashes and

death.[11–14] In addition, substance abuse is correlated with antisocial and violent behavior, such as bringing guns and knives to school, as well as other risk-taking behaviors.[15–18]

Schools, working in collaboration with community partners and health care professionals, are well situated to identify students with signs and symptoms of illicit drug abuse.[19–21] Poor school performance, underachievement, and truancy may be manifestations of substance use and indicate the need for evaluation and referral of these students to their medical home, where causes for this behavior can be determined. Medical home providers can use screening tools and resources available from federal, state, and local agencies, many of which are categorized both geographically and topically on the Internet (see Fig 1).[22]

Although recent data have suggested that prevalence of substance abuse has been decreasing in recent years, illicit substance abuse remains a major problem among American youth.[23–26] The degree of illicit substance abuse among students has translated into an ongoing societal search for ways to address this problem, including community- and school-based prevention programs, stricter law enforcement techniques, and, more recently, the use of laboratory testing programs within schools.

CRAFFT screening tool for adolescent substance abuse. (Reproduced with permission from the Center for Adolescent Substance Abuse Research, Children's Hospital Boston; 2001.)

SCHOOL-BASED DRUG-SCREENING PROGRAMS

In June 2002, the US Supreme Court broadened the authority of public schools to test students for illicit drugs by allowing random drug testing for all middle and high school students who participate in competitive extracurricular activities.[27] Some schools and districts are performing drug tests or are considering them for students in competitive sports, other physically active extracurricular activities (eg, school band, cheerleading), and, in some cases, all extracurricular activities (eg, chess club, debate team). Students may be excluded from the activity until they have been cleared through a screening process.[28,29] The type of screening performed varies widely (eg, urine, hair sample), as do the specific drugs included in the screen and the response to a positive drug-test result. Technical issues regarding illicit drug testing are addressed in a separate American Academy of Pediatrics (AAP) policy statement on drug testing[30] and in a forthcoming addendum to that statement concerning drug testing in schools and at home.[31]

Consequences of a positive drug-test result may include punitive measures, further student assessment, counseling, therapy, and/or rehabilitation. Random drug testing of students may affect specific students or groups of students differently. The benefits and risks of drug testing as a component of a comprehensive program to prevent or reduce substance abuse in such groups as nonusers, first-time and/or occasional users, and more frequent or addicted users must be determined by scientific studies. Implementation of random drug testing of students should await these results. The optimal means of assessing the implications of a positive drug-test result is an evaluation of the student by a health care professional who is trained or experienced in this process.

Some societal leaders support broad drug testing as an aid in the prevention of drug use and possible early identification of youth who have used drugs, thereby facilitating appropriate assessment and therapeutic referral. Others, including many parents and pediatricians, are concerned that school-based drug testing could unnecessarily label or stigmatize a child and compromise personal and family privacy. The Health Insurance Portability and Accountability Act applies to medical facilities, but children and adolescents do not have the same safeguards to privacy of medical information in the school. Recording positive drug-test results on students' permanent educational records (under guidelines of the Family Educational Rights and Privacy Act), which are accessible to many school personnel, could have negative and long-term consequences. Strict attention to issues of confidentiality must be ensured.

It has not yet been established that drug testing does not cause harm. The following should be considered:

1. Students involved with illicit drugs may decrease their involvement in extracurricular activities to

avoid drug testing. According to the National Institute on Out-of-School Time (www.niost.org), students who spend time in extracurricular activities are 49% less likely to use drugs. Without engagement in such activities, adolescents have a higher likelihood of dropping out of school, becoming pregnant, joining gangs, pursuing or increasing their use of drugs, and/or engaging in other risky behaviors.[32–34]

2. Positive drug-test results may cause increased family conflict rather than improve the home situation for the student.
3. Drug testing of adolescents is not performed for public safety. Even adults have mixed responses to the idea of widely applied drug testing. Although many support the idea of drug testing as a necessary measure for public safety from intoxicated or impaired pilots, bus drivers, police officers, and others, they often voice concerns when the application becomes more pervasive and random.
4. Dollars spent on drug testing may be more effectively spent on drug prevention programs or well-established counseling programs.
5. Drug testing youth who have not been implicated in using drugs may be perceived as being unfair and, thereby, may reduce trust and connectedness with their school, which are essential for maintaining lines of communication.[2,33–35]

Without evidence available to weigh the effectiveness of drug screening against the potentially harmful consequences, such programs should be limited in schools to those that are carefully controlled and comprehensive in scope.[36,37]

DRUG EDUCATION AT SCHOOL

Schools may adopt a variety of alternatives to drug testing to address the issue of substance abuse, including offering after-school programs, incorporating life-skills training into drug education curricula, helping parents become better informed, providing counseling, identifying problem behaviors for early intervention, and promptly referring students to health care professionals for assessment and intervention. School-based health centers should have the capacity to counsel students who are in need of such treatment plans and connect students to available community resources.

Schools are appropriate settings for drug prevention programs for 3 reasons: (1) prevention must focus on children before their beliefs and expectations about substance abuse are established; (2) schools offer the most systematic way of reaching young people; and (3) schools can promote a broad spectrum of drug-related educational policies.[36] Resources for the preparation of teachers, counselors, and other school personnel may be a valuable adjunct.[19,20]

Educators are challenged to make the facts about drug abuse meaningful to children and adolescents without enticing them to try drugs. There are many curricula designed for school use that have been proven to be effective and are delivered to students in ways that are interesting, interactive, and developmentally appropriate.[36,38,39] Although many program approaches are available, some effective programs focus on enhancing students' problem-solving skills or aiding them to evaluate the influence of the media. Other effective programs help improve students' self-esteem, reduce stress and anxiety, or increase activities. These skills are taught by using a combination of methods including demonstration, practice, feedback, and praise.[40]

Another proven approach is "life-skills training," designed to teach skills to confront a problem-specific focus, emphasizing the application of skills directly to the problem of substance abuse. One of the most studied programs is LifeSkills Training (National Health Promotion Associates, White Plains, NY), a universal school-based prevention approach (most often focused on 7th-graders) that teaches general personal and social skills training combined with drug-refusal skills and normative education. LifeSkills Training produces positive behavioral effects on alcohol, tobacco, and illicit drug use. This approach, with booster sessions that follow the initial program, is most effective.[5] These effects continue years after the intervention.[36,41,42] Many effective curricula and drug prevention programs use interactive materials and maximize group interactions with organized activities.[36,38,39,43,44] Studies have demonstrated convincingly that the effects of school programs can be amplified substantially when community components are added.[20]

PARTNERSHIP BETWEEN SCHOOLS, MEDICAL HOME PROVIDERS, AND DRUG REHABILITATION PROGRAMS

Schools may partner with rehabilitation programs to provide care for a student to help successfully reintegrate him or her. Educational planning is an integral part of after-care contracts that pediatricians, mental health professionals, or rehabilitation programs form with students and their families. The school's roles in such a collaborative relationship include identifying any underlying learning disabilities that may have contributed to the problem, making special accommodations for students when necessary, providing remedial work so that students can catch up with their classmates, helping to reinforce expectations for students to attend school and to comply with follow-up or monitoring as prescribed by the health care professional or rehabilitation facility, and assisting with finding after-school programs. It is also important for students who have used substances to be assigned at least 1 trusted adult who is available in the school building to help them if they feel they need it. Those who are assigned to work with the student's drug problems must know how to respect confidentiality of

treatment. This adult or another school health professional, school administrator, or designated staff member should be assigned to work with the student's pediatrician and rehabilitation personnel to communicate the student's progress or failure to progress.

The roles of pediatricians, mental health professionals, and rehabilitation programs in this collaborative relationship are to identify any mental health diagnoses and notify the schools of their relevance to the student's safety at school, to the student's educational program, and to school personnel or operations in general. Health care professionals also need to provide schools with treatment plans that may affect the school day while maintaining the student's confidentiality to the extent that is possible.

COMMUNITY COLLABORATION WITH SCHOOLS

Communities can send a clear and consistent message by developing and implementing a broad, comprehensive approach to dealing with substance abuse. Schools can serve as a focal point for such a community-wide effort. Community agencies can partner with schools to help monitor illicit drug use patterns in the local region to direct specific educational and preventive programs. Substance abuse problems that are associated with other mental health conditions can best be dealt with through comprehensive mental health programs that are capable of addressing prevention and intervention of both conditions. More information is available in the AAP policy statement on mental health in schools.[45] School personnel should receive ongoing training, preferably by a health care professional who is skilled at the recognition of and risk factors for substance use and related disorders so that each staff member is able to guide faculty, parents, families, and others who are concerned about such use. As part of their community/school program to counter substance abuse, the community should provide regular activities that are supportive alternatives to the abuse of drugs.

RECOMMENDATIONS FOR PEDIATRICIANS

Pediatricians should not support drug testing in schools. If testing is performed at all, it should only be done as part of a funded, comprehensive approach to addressing substance abuse in the school and in the community. Examination of alternative approaches should be carefully evaluated for effectiveness and cost.

Because of ongoing concerns about the implications of school-based drug-screening programs, the AAP membership should support and promote alternative school-based efforts to combat substance abuse. In addition, pediatricians should:

1. Serve as a medical home and resource for patients and their families and offer primary (ie, universal approaches designed to target all patients or potential users before a problem occurs) and secondary (ie, approaches targeted at patients who have screened positive for high-risk behaviors such as tobacco, alcohol, or inhalant use) prevention of illicit drug use.
2. Identify patients with personal, medical, mental health, social, or academic problems who might be at high risk for drug abuse. Consider the use of screening tools and questionnaires, such as the Guidelines for Adolescent Preventive Services surveys (www.ama-assn.org/ama/pub/category/1980.html) and the CRAFFT tool,[22] in the care of adolescent populations to identify patients who might need additional assessment and treatment. Mental health problems such as anxiety, depression, attention-deficit/hyperactivity disorder, and other diagnoses may coexist with substance abuse. The patient's progress should be monitored carefully so that ongoing assistance can be provided.
3. Support communication strategies that maintain patient/student confidentiality while coordinating treatment among the medical home provider, the family, and school-based programs.
4. Promote awareness of changing patterns of illicit drug use through local resources as well as through AAP chapter and district channels.
5. Raise awareness about mental health and rehabilitation services related to drug use that are available within the community to aid the student, family, and school.
6. Support and advise communities on the importance of clear and consistent community-wide messaging on illicit substance use and the promotion of activities that are free of drug and alcohol use.
7. Become familiar with the local school district's substance abuse prevention and health promotion programs.

Safe at School Statement of Principles

Diabetes must be managed 24 hours a day, 7 days a week. Effective diabetes management during the many hours a child with diabetes spends at school and school-related activities is vital to the short- and long-term health of a child living with diabetes.

Effective diabetes management is crucial:

- for the immediate safety of students with diabetes;
- for the long-term health of students with diabetes;
- to ensure that students with diabetes are ready to learn and to participate fully in school activities; and
- to minimize the possibility that diabetes-related emergencies will disrupt classroom activities.

Such management requires a team effort that includes school personnel, the student with diabetes, the student's parents/guardians, and the family's health care providers.

The undersigned organizations endorse the following principles to ensure diabetes is properly managed whenever a child with diabetes is present at school or a school-related activity.

1. All school staff members who have responsibility for a student with diabetes should receive training that provides a basic understanding of the disease and the student’s needs, how to identify medical emergencies, and which school staff members to contact with questions or in case of an emergency.

2. The school nurse holds a primary role of coordinating, monitoring, and supervising the care of a student with diabetes. However, in addition to any full- or part-time school nurse, a small group of school staff members should receive training from a qualified health care professional in routine and emergency diabetes care so that a staff member is always available for younger or less-experienced students who require assistance with their diabetes management (e.g., administering insulin, checking their blood glucose, choosing appropriate food) and for all students with diabetes in case of an emergency (including administration of glucagon). These staff members should be school personnel who have volunteered to do these tasks and do not need to be health care professionals.

3. Children possessing the necessary skills and maturity to do so should be permitted to self-manage their disease in the classroom or wherever they are in conjunction with a school-related activity. Such self-management should include monitoring blood glucose and responding to blood glucose levels with needed food and medication while utilizing appropriate safety protocols.

Safe Transportation of Newborns at Hospital Discharge

ABSTRACT. All hospitals should set policies that require the discharge of every newborn in a car safety seat that is appropriate for the infant's maturity and medical condition. Discharge policies for newborns should include a parent education component, regular review of educational materials, and periodic in-service education for responsible staff. Appropriate child restraint systems should become a benefit of coverage by Medicaid, managed care organizations, and other third-party insurers.

ABBREVIATIONS. FMVSS, Federal Motor Vehicle Safety Standard; AAP, American Academy of Pediatrics; NHTSA, National Highway Traffic Safety Administration.

All newborns discharged from hospitals should be transported home in car safety seats that meet Federal Motor Vehicle Safety Standard (FMVSS) 213 and that are selected to meet the specific transportation needs of healthy newborns, premature infants, or infants with special health care needs.

In 1996, 1780 children (newborns to 14 years of age) were killed, and 305 000 were injured as occupants in motor vehicles.[1] Of the fatalities, 60% were unrestrained. The fatality rate for infants was higher than any other age group, 4.4/100 000.[2] In 1996, 653 children (newborns through 4 years of age) were killed as occupants in motor vehicles. Of these fatalities, 52% were unrestrained.

The American Academy of Pediatrics (AAP) has made major contributions to child passenger safety, including contributions to the passage of legislation in all 50 states that requires the use of car safety seats or child restraint devices for infants and young children. Assuring that newborns are restrained properly when riding for the first time establishes the pattern for continued compliance with a measure that can save their lives or prevent serious injury. Correctly used car safety seats are 71% effective in preventing fatalities attributable to car crashes and 67% effective in preventing injury that requires hospitalization. With 100% correct use, about 53 000 injuries and 500 deaths could be prevented each year in the United States among children from birth to 4 years of age.[3]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

RECOMMENDATIONS

1. In conjunction with their medical staff, all hospitals with services for newborns should develop policies for the discharge of newborns in car safety seats that are crash tested and meet the FMVSS 213. These policies should be developed in consultation with a car seat expert who has successfully completed the National Highway Traffic Safety Administration (NHTSA) 4-day course.[4] Although the resources of hospitals and patients vary greatly, at discharge *every* newborn should be properly restrained in a car safety seat.
2. Pediatricians should work with these hospitals in establishing hospital policies that clearly define staff roles for each required task. Also, pediatricians should reinforce the need for compliance with these policies with both hospital staff and parents/guardians. Hospital policies related to newborns should include the following:
   - Methods by which expectant parents will be informed, before delivery, of the importance of using car safety seats and potential problems with vehicle incompatibility. Parents should be advised through prenatal classes, their obstetrical provider, or pediatric prenatal visits to obtain a car safety seat, properly secure it in their vehicle, and resolve compatibility issues before delivery. This is especially important because physicians frequently discharge infants after only a short hospital stay.
   - Designation of an individual responsible for implementing hospital policies and procedures related to discharge of newborns in car safety seats that are used properly. Hospital policy also should include designation of an individual or team specifically trained to assess the needs of infants with special health care needs with regard to the selection of the most appropriate child safety seat.[5–8] Hospitals should develop a policy to ensure provision of a period of observation in a car safety seat before hospital discharge for each infant born at <37 weeks' gestation to monitor for possible apnea, bradycardia, or oxygen desaturation.[5] Provision for periodic in-service education of staff responsible for parent and guardian education on correct use of car safety seats. Those responsible for training other hospital staff and parents and guardians should have successfully completed the NHTSA 4-day course.[4]

- Provision of regular periodic review by a designated person who has completed the NHTSA 4-day course of all materials distributed to parents and guardians of newborns about proper car safety seat use. Hospitals should ensure that information is current, relevant, and accurate, with date of publication or revision noted.[9]
- Provisions to make available an appropriate car safety seat by sale, short-term loan, or donation to parents before discharge if the parents are unable to provide their own. Hospitals should consider giving a low-cost infant car seat, which can also be used for generic instruction, to parents at discharge as a gift.
- Assessment of the degree of compliance with the policies and procedures on discharge in child safety seats in routine quality assurance surveillance by hospital staff. Hospital staffs should take appropriate actions to correct deficiencies when present.

Admission orders for newborns should include an order written by a physician for parent instruction about use of child safety seats. This should be included as a part of standard admission orders to ensure its completion before discharge.

Discharge policies for newborns should include the following:

- Determination of the most appropriate car safety seat for each newborn according to maturity and medical condition by a designated hospital employee.
- Provision of information and training for parents and guardians should be presented before discharge on the generic issues related to correct use of car safety seats. Hands-on teaching including "return demonstration" should be a part of this instruction. The installation of a specific car seat in a specific car must be the parent's responsibility. Resources to address these issues are available from the AAP.[10,11]
- A period of observation in a car safety seat before hospital discharge should be provided to each infant born at <37 weeks' gestation to monitor for possible apnea, bradycardia, or oxygen desaturation.[5]
- Pediatricians with other child health and safety advocates should work for coverage of appropriate child restraint systems as a benefit of coverage by Medicaid, managed care organizations, and other third-party insurers. Until that time, hospitals are encouraged to have a giveaway or loan program for parents who cannot afford to purchase a car seat.

CLINICAL REPORT

Safe Transportation of Preterm and Low Birth Weight Infants at Hospital Discharge

Guidance for the Clinician in Rendering Pediatric Care

Marilyn J. Bull, MD, William A. Engle, MD, the Committee on Injury, Violence, and Poison Prevention and the Committee on Fetus and Newborn

ABSTRACT

Safe transportation of preterm and low birth weight infants requires special considerations. Both physiologic immaturity and low birth weight must be taken into account to properly position such infants. This clinical report provides guidelines for pediatricians and other caregivers who counsel parents of preterm and low birth weight infants about car safety seats. *Pediatrics* 2009;123:1424–1429

INTRODUCTION

Improved survival rates and earlier discharge of preterm (<37 weeks' gestation at birth) and low birth weight (<2500 g at birth) infants have increased the number of small infants who are being transported in private vehicles. Car safety seats that are used correctly are 71% effective in preventing fatalities attributable to passenger car crashes in infants.[1] To ensure that preterm and low birth weight infants are transported safely, the proper selection and use of car safety seats or car beds are necessary.

Federal Motor Vehicle Safety Standard (FMVSS) 213, which establishes design and dynamic performance requirements for child-restraint systems, applies to children weighing up to 65 lb. However, the standard has no minimum weight limit and does not address the relative hypotonia and risk of airway obstruction in preterm or low birth weight infants. Most rear-facing car safety seats are designated by the manufacturer for use by infants weighing more than 4 or 5 lb, with some designated for use from birth regardless of weight.

Infant dummies as small as 3.3 lb have been shown to be satisfactorily restrained in standard rear-facing car safety seats during crash tests.[2,3] Test dummies, however, cannot replicate the airway and tone variables that occur in preterm infants, and there is no information on restraint of infants who weigh less than 3.3 lb (1.5 kg).

Rear-facing car safety seats provide the best protection in a frontal crash, because the forces are transferred from the back of the restraint to the infant's back, the strongest part of an infant's body. The restraint also supports the infant's head. Severe tensile forces on the neck in flexion are also prevented by use of rear-facing car safety seats.[4]

The long-term experience and documented protective value of car safety seats make them the preferred choice for travel for all infants who can maintain cardiorespiratory stability in the semireclined position.[4] A car bed that meets FMVSS 213 may be indicated for infants who manifest apnea, bradycardia, or low oxygen saturation when positioned semireclined in a car safety seat.[2,5] Of note, some preterm and term infants positioned in car beds and car safety seats seem to have similar rates of apnea, bradycardia, and oxygen desaturation.[6,7]

A car bed is designed to accommodate an infant in a fully reclined position and is oriented in the vehicle seat perpendicular to the direction of travel. An infant is secured in the car bed with an internal harness, and the car bed is secured to the vehicle with the vehicle's seat belt. Car beds, like car safety seats, have specific weight requirements designated by the manufacturer and, like car safety seats, should be used according to manufacturer recommendations.

The size of the infant, especially for those born preterm, is an important consideration when selecting a car safety seat or car bed.[2,8] Weight, length, neurologic maturation, and associated medical conditions (especially bronchopulmonary dysplasia) all influence the potential risk of respiratory compromise for infants in seating devices.[6,9]

Preterm infants are subject to an increased risk of oxygen desaturation, apnea, and/or bradycardia,[10] especially when placed in a semireclined position in car safety seats.[5,11–13] Furthermore, frequent cardiorespiratory events and

intermittent hypoxia may adversely affect later neurodevelopment, psychosocial behavior, and academic achievement.[14,15] In 1 study, mental development in preterm infants with 5 or more cardiorespiratory events during 210 hours or more of cardiorespiratory monitoring was associated with a lower mental development index on the Bayley Scales of Infant Development (95.8 vs 100.4; $P = .04$)[14]; physical developmental indices were not different (94.4 vs 91.7; $P = .37$). It is unclear whether the association of cardiorespiratory events and lower mental development reflects an underlying abnormality or a negative consequence of the events. It is rational, if practical, to attempt to reduce the frequency and severity of cardiorespiratory events experienced by preterm infants seated in car safety seats to minimize potential neurodevelopmental sequelae. Therefore, car safety seat monitoring in the infant's own car safety seat before discharge from the hospital should be considered for all infants less than 37 weeks' gestation at birth to determine if physiologic maturity and stable cardiorespiratory function are present, as recommended in the American Academy of Pediatrics publication *Guidelines for Perinatal Care*.[16] Because information is limited about the severity and frequency of adverse outcomes in preterm infants who experience cardiorespiratory events, including those events that occur while in car safety seats, additional research is needed.[17]

Many infants are discharged from the hospital with cardiac/apnea monitors, supplemental oxygen, and, occasionally, portable ventilators, suction machines, batteries, and other equipment. These objects are heavy and could cause injury if they were to hit the child or another vehicle occupant in the event of a sudden stop or crash. Although there is no commercially available securement system for portable medical equipment, restraint is recommended.[18]

No data are available to establish a specific age or neurodevelopmental status at which an infant with respiratory compromise who was discharged from the hospital in a car bed can safely transition to a semireclined car safety seat. Before discontinuing use of a car bed, the physician can consider arranging for a follow-up study to determine when the infant can travel semireclined without apnea, bradycardia, or oxygen desaturation. The time to perform the test may vary depending on the rate of growth and neurologic maturation of the infant and the infant's respiratory status and should be determined by the treating physician.

Car safety seats are used frequently for positioning infants for purposes other than travel. Potential detrimental effects of excessive use of infant seating devices, including exacerbation of gastroesophageal reflux and potentiation of plagiocephaly, have been documented.[19,20] Use of car safety seats for purposes other than travel also may increase the risk of adverse cardiorespiratory and other adverse medical events.

CLINICAL IMPLICATIONS

Several important considerations for transportation of preterm and low birth weight infants at risk for recurrent oxygen desaturation, apnea, or bradycardia include the following.

1. The increased frequency of oxygen desaturation and episodes of apnea or bradycardia while sitting in car safety seats suggests that preterm infants should have a period of observation in a car safety seat, preferably their own, before hospital discharge. This period of observation should be performed with the infant carefully positioned for optimal restraint and the car safety seat placed at an angle that is approved for use in the vehicle. A period of observation for a minimum of 90 to 120 minutes or the duration of travel, whichever is longer, is suggested.[5,6,11,21]
2. Hospital staff who are trained in positioning infants properly in the car safety seat and in detecting apnea, bradycardia, and oxygen desaturation should conduct the car safety seat observation.
3. Hospitals should develop protocols to include car safety seat observation before discharge for infants born at less than 37 weeks' gestation.[22] Some hospital protocols include car safety seat observations for infants at risk of obstructive apnea, bradycardia, or oxygen desaturation other than those born at less than 37 weeks' gestation. Examples include infants with hypotonia (eg, Down syndrome or congenital neuromuscular disorders), infants with micrognathia (Pierre Robin sequence), and infants who have undergone congenital heart surgery.[9]
4. Families should be taught by trained hospital staff how to position the infant properly in the car safety seat.
5. The duration of time the infant is seated in a car safety seat should be minimized. Parents should be advised that car safety seats should be used only for travel.
6. A conventional car safety seat that allows for proper positioning of the preterm infant should be selected if a semiupright position can be maintained safely by the infant. Better observation of the infant may be possible when the child is in a rear-facing car safety seat adjacent to an adult rather than in a car bed. In addition, the protection provided by a rear-facing car safety seat is better documented than the protection provided by car beds.[4]
7. If events documented on cardiorespiratory monitoring in a car safety seat are deemed significant by the treating physician or the hospital policy, interventions to reduce the frequency of desaturation and episodes of apnea and bradycardia are recommended (eg, use of car bed; supplemental oxygen; continued hospitalization or further medical assessment). If a car bed is considered, a similar period of cardiorespiratory monitoring while the infant is in the car bed should be performed before discharge.
8. Infants with documented oxygen desaturation, apnea, or bradycardia in a semiupright position should travel in a supine or prone position in an FMVSS 213–approved car bed after an observation period

that is free of such events as described in point 1 above. This may need to be revised as new evidence becomes available from future research. Specific information regarding currently available car beds can be obtained from several resources.[23]

9. Before transitioning from a car bed, a period of observation of an infant for apnea, bradycardia, and oxygen desaturation in the infant's own semireclined car safety seat should be considered. The study can be performed as a home oxypneumocardiogram, as an outpatient polysomnogram, or as an observed outpatient clinical evaluation performed similarly to that described in point 1 above.
10. Infants at risk of respiratory compromise in car safety seats may be at similar risk with use of other upright equipment, including infant swings, infant seats, backpacks, slings, and infant carriers. Consideration should also be given to limiting the use of these devices until the child's respiratory status in a semireclined position is stable.[24]
11. Infants for whom home cardiac and apnea monitors are prescribed should use this monitoring equipment during travel and have portable, self-contained power available for at least twice the duration of the expected transport time.
12. Commercially available securement systems for portable medical equipment such as monitors are not available; therefore, this equipment should be wedged on the floor or under the vehicle seat to minimize the risk of it becoming a dangerous projectile in the event of a crash or sudden stop.[2,8]

Proper positioning of preterm and low birth weight infants in car safety seats is important for minimizing the risk of respiratory compromise. Specific national guidance for selecting car safety seats and positioning preterm and low birth weight infants includes the following.

1. Infants should ride facing the rear as long as possible and to the highest weight and length allowed by the manufacturer of the seat for greatest protection.[25-27] By the time infants weigh 20 lb or reach the top length allowed by the manufacturer of the seat, they should ride facing the rear in infant seats or convertible car safety seats approved for rear-facing use at higher weights and lengths. Most convertible car safety seats are approved for rear-facing use up to 30 to 35 lb and 36 in. Parents of infants born preterm may benefit from specific counseling about this concept.
2. Infant-only car safety seats with 3-point or 5-point harness systems or convertible car safety seats with 5-point harness systems provide optimum comfort, fit, and positioning for the preterm or low birth weight infant. A small infant should not be placed in a car safety seat with a shield, abdominal pad, or arm rest because of potential breathing difficulty behind the shield or injury to an infant's face and neck during a sudden stop or crash.[2,21]
3. Car safety seats with the shortest distances from the crotch strap to the seat back should be selected to reduce the potential for the infant to slip forward feet-first under the harness (ie, "submarining"). Some car safety seats have crotch-to-seat back distances as short as 5.5 in, which may accommodate some preterm or low birth weight infants well. A small rolled diaper or blanket between the crotch strap and the infant may be added to reduce the risk of submarining (Fig 1) in smaller infants. A car safety seat with multiple harness-strap slots provides more choice and may be more suitable for small but rapidly growing infants. Ideally, car safety seats with harness straps that can be positioned at or below the shoulders should be selected.[21]

FIGURE 1
Car safety seat with a small cloth between crotch strap and infant, retainer clip positioned at the midpoint of the infant's chest, and blanket rolls on both sides of the infant.

4. The infant should be properly positioned in the car safety seat, with buttocks and back flat against the back of the car safety seat. The harness must be snug, and the car safety seat's retainer clip should be positioned at the midpoint of the infant's chest, not on the abdomen or in front of the neck (Fig 1).
5. Some car safety seats come with head-support systems as standard equipment. Many head-support systems, however, are sold as aftermarket products and may decrease the safety provided by the seat and harness system, because they introduce slack into harness straps. Only products that come with the seat or are sold by the manufacturer for use with their specific seat should be used. Most very small infants require positioning support in addition to the head support that comes with the seat. Blanket rolls may be placed on both sides of the infant to provide lateral support for the head and trunk (Fig 1).
6. The rear-facing car safety seat should be reclined approximately 45° or as directed by the instructions

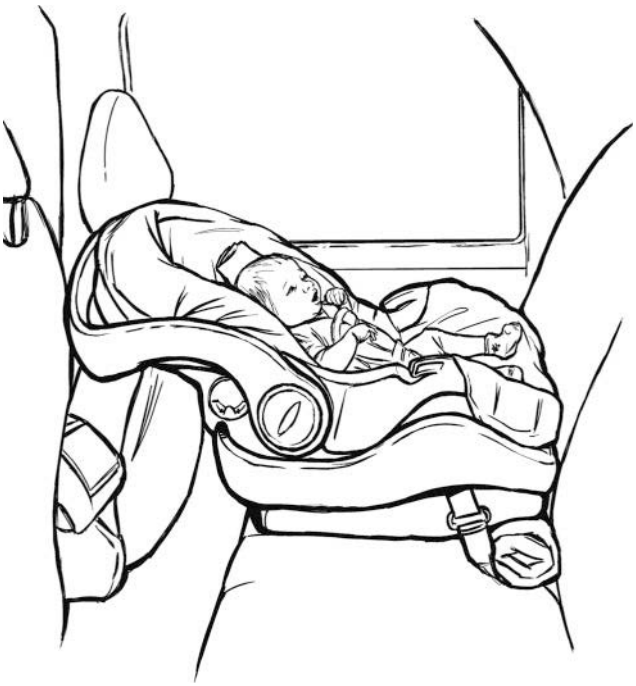

FIGURE 2
Seat with tightly rolled towel to recline seat halfway back at a 45° angle.

provided with the car safety seat. If the vehicle seat slopes and the seat is too upright, the infant's head may fall forward. A lightweight, noncompressible object, such as a tightly rolled blanket or pool "noodle," may be placed under the car safety seat to achieve the appropriate angle. Some car safety seats have built-in angle indicators and angle adjusters to assist with achieving the proper angle (Fig 2).

7. A rear-facing car safety seat should never be placed in the front passenger seat of any vehicle equipped with a passenger-side front air bag because of risk of death or serious injury from the impact of the air bag. In some vehicles without rear seating positions, the air bag can be deactivated when the front seat is used for a child passenger. The back seat is the safest place for all children to travel.[28,29]
8. Infants riding in the rear seat may be more difficult to observe, and whenever possible, parents should arrange for an adult to be seated in the rear seat adjacent to the infant. In the event of a monitor alarm, if a second caregiver is not available, the driver may need to come safely to a stop and assess the infant.
9. An infant should never be left unattended in a car safety seat inside or out of the car.

RESEARCH IMPLICATIONS

1. Studies are needed to gather more information on the severity and frequency of adverse outcomes in preterm infants who experience cardiorespiratory events, including those events that occur while in car safety seats.
2. Studies need to be conducted to determine the risk factors associated with cardiorespiratory events among preterm and low birth weight infants and criteria that indicate neurodevelopmental and physiologic maturity required for an infant to be positioned upright without respiratory compromise.
3. Studies should be designed to assess the correlation of car safety seat monitoring performed in the hospital, while stationary in the car, and while traveling.
4. Methods should be developed to better determine the relative protection provided by rear-facing car safety seats and car beds.
5. Design of car safety seats should be encouraged to specifically meet the positioning and transportation needs of preterm and low birth weight infants.
6. Methods should be developed to better secure heavy medical equipment, such as monitors and oxygen, in vehicles.
7. The efficacy of various protocols for car safety seat monitoring and car safety seats for different patient populations of at-risk infants needs to be determined.

SUMMARY

Proper selection and use of car safety seats or car beds are important for ensuring that preterm and low birth weight infants are transported as safely as possible.

The increased frequency of oxygen desaturation or episodes of apnea or bradycardia experienced by preterm and low birth weight infants positioned semireclined in car safety seats may expose them to increased risk of cardiorespiratory events and adverse neurodevelopmental outcomes.

It is suggested that preterm infants should have a period of observation of 90 to 120 minutes (or longer, if time for travel home will exceed this amount) in a car safety seat before hospital discharge. Educating parents about the proper positioning of preterm and low birth weight infants in car safety seats is important for minimizing the risk of respiratory compromise. Providing observation and avoiding extended periods in car safety seats for vulnerable infants and using car seats only for travel should also minimize risk of adverse events.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Sports Medicine and Fitness

Safety in Youth Ice Hockey: The Effects of Body Checking

ABSTRACT. Ice hockey is a sport enjoyed by many young people. The occurrence of injury can offset what may otherwise be a positive experience. A high proportion of injuries in hockey appear to result from intentional body contact or the practice of checking. The American Academy of Pediatrics recommends limiting checking in hockey players 15 years of age and younger as a means to reduce injuries. Strategies such as the fair play concept can also help decrease injuries that result from penalties or unnecessary contact.

Ice hockey is played by approximately 200 000 children in the United States[1] and a similar number in Canada. It is classified as a collision sport by the American Academy of Pediatrics because of the intentional body contact, called body checking, that occurs. Because collisions in this sport may occur at high speeds, participants are at risk for serious injury. In recent years, an increase in the number of serious head and neck injuries related to body checking has alarmed the hockey community and has led to a reassessment of the role of body checking in the various classifications of youth hockey[2–4]: mite—ages 8 and 9 years; squirt—ages 10 and 11 years; peewee—ages 12 and 13 years; and bantam—ages 14 and 15 years.

In the 1960s, an alarming number of facial injuries in youth hockey players led to the mandatory use of helmets with a face mask.[5] The acceptance and use of the combination helmet–face mask was remarkably successful in virtually eliminating facial trauma. However, shortly after the introduction of the helmet–face mask, an increase in the number of neck and spinal injuries was noted.[4] The improvement in equipment with the helmet–face mask[1,6] was believed to create a false sense of protection from serious injury. A similar situation was observed in football. With additional protection afforded by improved helmets and face masks in the 1950s, there was an increase in cervical spine injuries. The number of spinal injuries did not start decreasing until rule changes in the 1970s prohibited head-first contact. Rule changes instituted in the mid-1970s substantially decreased, but did not eliminate, these tragic injuries. The ice hockey community wanted to learn from the experience in football and avoid a paradoxical increase in injury as a response to wearing protective equipment. This concern led to investigations of the incidence and causes of head, neck, and spine injuries.[7–9]

A Canadian study in 1984[2] revealed 42 spinal injuries in hockey players reported to the Committee on Prevention of Spinal Injuries. The median age of the injured players was 17 years. Of the 42 players, 28 had spinal cord injuries, of which 17 had complete paralysis below the vertebral level of the injury. Being body checked from behind, resulting in a collision with the boards, was the most common mechanism of injury. A 1987 study[7] of high school hockey players revealed that head and neck injuries accounted for 22% of the total number of injuries. The same study showed that body checking was associated with 38% of the total number of injuries. Sixty-six percent of the players surveyed believed that the requirement of a face mask allowed them to be more aggressive in their style of play. The authors of this study recommended rule changes to limit or eliminate body checking to reduce injuries.

A more recent US study reported injuries in youth hockey players 9 to 15 years old.[1] Head and neck injuries accounted for 23% of the total number of injuries. Body checking accounted for 86% of all injuries that occurred during games. Fifty-five percent of the players thought that their helmets and face masks protected them from injuries. Of particular interest is that size differences among players in this series increased with age, with bantam-level players (ages 14 and 15 years) showing the most variation, with reported differences between the smallest and largest players of 53 kg in body weight and 55 cm in height. The bantam-level players sustained the most injuries (54%).

Another Canadian study[10] compared peewee-level players (ages 12 and 13 years) from a league that allowed body checking with another league that did not. Players in the league that allowed body checking had a fracture rate 12 times higher than the rate of the other league. Body checking in combination with substantial differences in size and strength among players was believed to contribute to the high injury rate, with some players being nearly twice as heavy and twice as strong as other players. Players in the same age group could vary significantly in the amount of force they could impart on another player and/or withstand from another player. In 1990, the Canadian Academy of Sports Medicine reported that although the incidence of serious injuries at the mite and squirt level was quite low, serious injuries were noted at the peewee level. Therefore, they recommended banning body checking at the peewee level (ages 12 and 13 years) and below.[11]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

An innovative, unique concept for improved sportsmanship and injury reduction in youth hockey called fair-play has been introduced recently.[12] The fair-play concept of scoring ice hockey games, seasons, or tournaments was developed in response to the perceived increase in violence in youth hockey. The system rewards teams and individual players with few penalties and punishes teams and players with larger numbers of penalties. The authors of this concept believe that the system decreases penalties, intimidation, and violence during hockey and creates a climate that promotes fun and player development.

The potential benefits for the fair-play concept are demonstrated in a recent study[13] involving a youth hockey tournament. The participants were high school students younger than 20 years old, who played the qualifying rounds of the tournament using fair-play guidelines (points are awarded for playing without excessive penalties) and the championship round following regular rules. When the fair-play and regular rules portions of the tournament were compared, the injury rate was 4 times higher during the regular rules portion of the tournament. A doubling of the number of penalties and injury rate during the championship round occurred when fair-play rules were suspended.

CONCLUSION

Studies have shown that a high proportion of youth hockey injuries are attributable to checking and that limiting checking can reduce injuries. Disparities in size and strength can further increase the risk for serious injury from checking and other collisions. Variations in size and strength are present in all age groups but are most pronounced among the bantam-level players (ages 14 to 15 years). Therefore, minimizing checking and other high-impact collisions in this age group could further reduce injuries.

RECOMMENDATIONS

In the interest of enhancing safety in youth ice hockey, the American Academy of Pediatrics recommends the following.

1. Body checking should not be allowed in youth hockey for children age 15 years or younger.
2. Good sportsmanship programs, such as the fair-play concept, have been shown to reduce injury and penalty rates and should be adopted for all levels of youth hockey.
3. Youth hockey programs need to educate players, coaches, and parents about the importance of knowing and following the rules as well as the dangers of body checking another player from behind.

School Bus Transportation of Children With Special Health Care Needs

ABSTRACT. School systems are responsible for ensuring that children with special needs are safely transported on all forms of federally approved transportation provided by the school system, and a plan should be developed to provide the most current and proper support to children with special transportation requirements. This statement provides current guidelines for the protection of child passengers with specific health care needs, including those with a tracheostomy, those requiring use of car seats, or those transported in wheelchairs. Guidelines that apply to general school transportation should be followed, including the training of staff, provision of nurses or aides if needed, establishment of a written emergency evacuation plan, and a comprehensive infection control program.

Research provides the basis for recommendations concerning occupant securement for children in wheelchairs and children with other special needs who are transported on a school bus. Pediatricians can help their patients by being aware of guidelines for restraint systems for children with special needs and by remaining informed of new resources. Pediatricians can also play an important role at the state and local level in the development of school bus specifications.

ABBREVIATIONS. FMVSS, Federal Motor Vehicle Safety Standards; IEP, Individual Education Plan; IFSP, Individual Family Service Plan; OSHA, Occupational Safety and Health Administration.

INTRODUCTION

Many preschool-aged and school-aged children with special needs are transported in school buses. The Individuals With Disabilities Education Act 1997 (Public Law 105-17) has established requirements for preschool children ages 3 to 5 to have access to related services (ie, audiology and occupational therapy). It also requires that infants and toddlers (birth to 3 years of age) have access to these same services; however, it does not specify how these children are to be transported to these services if they are to be conducted outside of the child's natural home or school environment. Although the provider could vary from state to state, it is often the responsibility of the school systems to provide these related services to infants and toddlers.

The Federal Motor Vehicle Safety Standards and Regulations (FMVSS) 222 (School Bus Passenger Seating and Crash Protection) established safety requirements for school bus interiors, but it applied only to able-bodied children. However, a 1994 amendment to FMVSS 222 applied to the securement of wheelchairs and their occupants in school buses.[1] National recommended standards for special education school buses were revised in May 1995 by the Twelfth National Standards Conference on School Transportation.[2]

Wheelchairs are the primary mode of transport on the school bus for many children with special needs. Most wheelchairs have not been developed as certified transit devices and are not currently subjected to any crash-testing requirements. A certified transit wheelchair is one that meets voluntary design and performance requirements for use as a seat by their occupant when traveling in a motor vehicle. Rehabilitation therapists can help identify products that are certified by the manufacturer to meet this standard. Whenever possible a certified transit wheelchair should be used for school bus transportation.[3] Research has provided a basis for recommendations concerning occupant securement for children who must ride in a wheelchair or children with other special needs who are transported on a school bus.[1,4–6]

RECOMMENDATIONS

1. Any child who can assist with transfer or be reasonably moved from a wheelchair, stroller, or special seating device to a seat belt or child restraint system complying with FMVSS 213 (Child Restraint Systems) should be so transferred for transportation. The vehicle seat should be forward facing, equipped with dynamically tested occupant restraints, and provided for the vehicle at the point of manufacture. The unoccupied wheelchair also should be secured adequately in the vehicle to prevent it from becoming a dangerous projectile in the event of a sudden stop or crash.[7]
2. Passenger seats that have a seat belt or child restraint system attached should have a reinforced frame and meet the requirements of FMVSS 208 (Occupant Crash Protection), FMVSS 209 (Seat Belt Assemblies), and FMVSS 210 (Seatbelt Anchorages). The manufacturer of the school bus should be consulted regarding the noted requirements when ordering or retrofitting an existing school bus.[8]
3. All children weighing less than 50 lb should be secured in an appropriate child restraint or safety vest meeting the requirements of FMVSS 213.[8]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

4. Child safety seats or safety vests must be secured to the bus seat in a manner prescribed and approved by the manufacturer of the safety device. The child restraint should not be secured on a school bus seat adjacent to an emergency exit.
5. Child safety seats used to transport children who weigh less than 20 lb or are younger than 1 year should be attached to the school bus seat in a rear-facing position. A child restraint that is approved for rear facing for greater weights should be considered for a child who weighs 20 lb before 1 year of age.
6. Occupied wheelchairs should be secured in a forward-facing position.
7. Three-wheeled, cart-type units and other wheelchair or stroller-type devices should not be permitted for occupied transport in a school bus unless results of impact tests demonstrate that the device can be secured under impact loading conditions. Any wheelchair or stroller-type unit designed and approved by a manufacturer for transportation must be used according to manufacturer's instructions.
8. Wheelchairs should be secured with fastening devices that are attached to the floor. Any occupied wheelchairs should be secured with 4-point tie-down devices. These tie-down systems should be dynamically tested with a dummy the size of a 50th percentile adult male or with a dummy at the appropriate size for the type of wheelchair used. They must have demonstrated capabilities for restraining the wheelchair during a frontal impact with force conditions of 30 mph and 20*g*. The wheelchair securement system must not apply restraint to the occupant and should attach to the frame of the wheelchair rather than to the wheels. The occupant should be restrained to the wheelchair with a separate device.
9. Lap boards and metal or plastic trays attached to the wheelchair or to adaptive equipment should be removed before loading and should be secured separately for transport.
10. An occupant restraint system that has been tested at force conditions of 30 mph and 20*g* for upper torso restraint (ie, shoulder harness) and lower torso restraint (ie, lap belt over pelvis) should be provided for each wheelchair-seated occupant.
11. Any liquid oxygen transported in a school bus should be securely mounted and fastened to prevent damage and exposure to intense heat. An appropriate sign indicating that oxygen is in use should be placed in the school bus.

ADDITIONAL CONSIDERATIONS FOR PASSENGER TRANSPORTATION

The following considerations should be incorporated into the school system plan for the transportation requirements of children with special needs:

1. In accordance with state laws and regulations, a nurse or an aide with appropriate medical training can provide necessary on-board assistance and support to most children with tracheostomies who may require suctioning or emergency care during school bus transport. School systems should consider providing nurses or aides when medically necessary to help reduce the potential for respiratory and other related problems occurring while the children are on the school bus. This assistance should be included where appropriate in the child's Individual Education Plan (IEP) or the family's Individual Family Service Plan (IFSP).
2. School transportation staff should participate in the development of the transportation portion of the IEP or IFSP for children who may need special transportation requirements and medical procedures.
3. School bus transportation staff should have annual access to training programs and resource material in special needs transportation to ensure that they can provide the most current and proper support to children with special transportation requirements. Transportation staff who work with children with special needs can carry out their daily responsibilities when provided with documented training from a team of professionals, including therapists, nurses, and certified child passenger safety technicians that ensures consistent and proper restraint for children with special needs on school buses.[9,10]
4. The caregiver (family, guardian, foster parent) of a child with special needs should be informed of the importance of incorporating appropriate and safe transportation specifications in the child's IEP or IFSP.
5. The caregiver of a child with special needs and the designated bus driver for the child's bus route should share information addressing the specific needs of the child transported before and during the school year. An emergency medical information card should be kept on the bus for each student transported. Transportation personnel should adhere to the school district's policy regarding confidentiality of student information.
6. School systems can help ensure optimum protection for children with special needs during school bus transport by establishing a written plan that outlines procedures for emergency evacuation for each child and by requiring, at the minimum, an evacuation drill for each school year that enables the transportation staff to practice evacuating children under their care. Local emergency response personnel should be invited to participate in evacuation drills.
7. Children who are supported by technology may be at increased risk of acquiring infectious diseases. All caregivers should wash their hands before and after providing direct care for students including toileting, tracheostomy, or gastrostomy care. Standard (universal) precautions should be used when caring for all children when exposed to blood or blood-containing body fluids. Schools should follow the legal requirements of their states or the Occupational Safety and Health Administration (OSHA) with respect to all immunizations, including hepatitis B immunization. Chil-

dren and adults who are in the recommended categories should receive yearly influenza immunization.[11,12] Transportation staff should be provided with training and supplies that prepare them to carry out universal precaution practices and procedures.[10]

The American Academy of Pediatrics encourages states to address and support the transportation requirements of children with special needs. Pediatricians can help their patients by being aware of general guidelines for evaluating restraint systems for children with special needs and remaining informed of new resources as they become available. Periodically updated information on specific restraint systems for children with special needs can be obtained through the Academy.[13] In addition, pediatricians can play important roles at local and state levels to assist in the evaluation and development of school bus specifications responsive to the safe transportation requirements of children with special needs.

AMERICAN ACADEMY OF PEDIATRICS

Committee on School Health

School Health Assessments

ABSTRACT. Comprehensive health assessments often are performed in school-based clinics or public health clinics by health professionals other than pediatricians. Pediatricians or other physicians skilled in child health care should participate in such evaluations. This statement provides guidance on the scope of in-school health assessments and the roles of the pediatrician, school nurse, school, and community.

ABBREVIATION. AAP, American Academy of Pediatrics.

The American Academy of Pediatrics (AAP) has endorsed the importance of comprehensive periodic health assessments. The AAP also has endorsed the concept of the medical home,[1] which refers to the belief that all health care for children and adolescents should be managed by 1 personal health care professional or group of professionals who assume responsibility for the ongoing care of the child. The medical home approach has been shown to improve compliance with health care recommendations and to lower the cost of health care.[2] The AAP also recommends that each comprehensive periodic health assessment visit beginning at 3 years of age should include attention to school health issues. Whenever possible, these assessments should be provided by the child's primary care physician at regular health supervision visits and should be performed as recommended in the *Guidelines for Health Supervision III*[3] from the AAP. Additional visits may be necessary if circumstances suggest variations from normal.

Several different types of routine health assessments are performed in schools. In many schools, part of the core school health services nurses perform, often with the assistance of health aides, include mandated health screening for all students. This may include screening for vision, hearing, blood pressure, and scoliosis. If abnormalities are detected, students are referred to their medical homes for further assessment and treatment if indicated. Actions taken and recommendations for school intervention and/or follow-up must be conveyed to the school nurse so he or she can document the resolution of the situation, which initiated with the screening at school.

The school in communities where students do not have access to medical homes or a school-based health center may provide additional physical examination and assessment services. In these instances, a school nurse, public health nurse, nurse practitioner, physician assistant, or physician performs the school health assessment, often with the assistance of other allied health personnel. A pediatrician or other physician skilled in child health care should participate in the planning and supervising of these assessments. School districts that use school-based health examinations should contract with nearby pediatricians for consultation on the management of problems identified during the assessments.[4] Each child should be examined individually (rather than in groups) to ensure adequate attention to individual problems and concerns and to protect confidentiality and the child's sense of modesty. Parents should consent to the school health evaluation and be present, particularly in the primary grades. Adequate time should be allocated to ensure that all elements of the assessment are addressed. Schools who assume the role of the medical home for their students must partner with a pediatrician, other licensed physicians, or hospital to provide after-hours and holiday emergency or urgent care.

ELEMENTS OF COMPREHENSIVE HEALTH EXAMINATIONS RELATING TO SCHOOL HEALTH

1. An assessment on entry into school should include a review of the medical history with attention to physical, emotional, or family problems that might influence school achievement. Previous participation in preschool experiences should be included in the history. The assessment should include a careful evaluation of language, motor, social, and adaptive development and immunization status.[5] Private physicians or physicians and mid-level health professionals used by the school system should collaborate with designated school officials to design protocols. These protocols should be used to initiate appropriate referrals available in the school or the community and provide placement in the educational system as deemed appropriate by the findings of the medical history, physical examination, and developmental assessment.
2. Subsequent visits should include a history that focuses on new medical problems, medications, changes in the child's developmental and psychosocial status, and an update on school progress and problems. The frequency of subsequent health assessments will vary depending on the child's functional status but should be in compli-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

ance with the AAP-recommended periodicity schedule for child health supervision visits.

3. A complete age-appropriate unclothed physical examination should be performed by a physician or mid-level professional. It should include, but not be limited to, the assessment of height, weight, physical and sexual maturation, and blood pressure. A screening evaluation should be performed to evaluate visual acuity, auditory acuity, emotional maturity, language, dental condition, and motor skills.[6] Any abnormal findings should be monitored by the physician.
4. In the United States, children of various ages participate in sports or physical education sponsored by the school. It is important for the health care professional to be familiar with the physical assessment and requirements to appropriately approve participation in such activities. This assessment should be combined with the health examination and interval history when possible, although it may be performed separately. In any case, the uniqueness of a detailed comprehensive physical examination that includes endurance and muscular assessment must be recognized. Specific descriptions of such an assessment are available.[7,8]
5. The health examination should identify specific health needs and problems that might require cooperation among community resources, and school officials may want to organize the community health professionals and community resources to integrate services available and provide easy access to these services. These services may support administration of medications, physical therapy, problems with access to buildings, anticipated absences, behavioral and emotional needs, special location in class (eg, for visual or auditory problems), or other conditions requiring the assistance of the classroom teacher or school nurse. Easy access to the services will become more important as increasing numbers of chronically ill or disabled students or students with special needs attend classes in their neighborhood schools. The frequency with which these issues are reviewed will depend on the student's specific needs. Direct communication among school personnel, parents, and the physician should occur to determine the requirements of children with special health care needs.
6. Anticipatory guidance for students and parents for physical fitness, nutrition, cardiovascular risk reduction, injury and violence prevention, sexual development and sex education, stress management, alcohol and other drug abuse, and tobacco use should be provided. Anticipatory guidance should be provided for parents about their role in promoting school achievement and learning as priorities in their child's life. Guidance also may be provided to assist parents in helping their child develop responsibility, independence, and self-reliance in the educational process.

THE SCHOOL'S ROLE

A well-organized system within the school that includes a comprehensive health record must be established for accumulating and recording current health information for each student. When a child changes schools, this information must be transferred to the new location. Information from health records should pass freely between the child's medical home and the school nurse and vice versa (with appropriate permission from the parents and/or adolescent). The school nurse and appropriate classroom teacher should review the child's health record, preferably before initiation of school year. For the student with chronic illness or with special health needs or for the child who must take medication during school hours, the school health record may require more frequent review. The school health record should include the following information: name, birth date, and sex of student; parent or guardian contact information; name, address, and telephone number of the child's primary health care physician; dentist and other medical specialists; immunization status and dates of immunizations; pertinent ongoing health problems; medications to be taken by the child; allergies; previous athletic injuries; and restrictions for athletics. Each school district should develop its own system for maintaining the confidentiality of the comprehensive health record. Access to this record should be based on the need to know and should require consent of the student, parent, or both.

A separate emergency information file available to all school personnel should be kept in the administration office and should contain the following information: the names, addresses, and telephone numbers (work and home) of parents or guardians; persons to contact in case of emergency; parental consent forms; and the names, addresses, and telephone numbers of physicians, consultants, dentists, and medical insurance carrier.

CONCLUSION AND RECOMMENDATIONS

In addition to providing a medical home, the pediatrician should be an advocate for students in the school setting and should promote effective communication among school officials, families, and the health care community. Collaboration among pediatricians, school nurses, and the community can ensure that children have access to appropriate and comprehensive screenings and assessments whether offered in the child's medical home or at the school site. The AAP recommends that:

1. All children should receive ongoing care in a medical home in a community practice, clinic, or school-based health center.
2. Core school health services including screening should be planned and implemented under the supervision of the school nurse and school physician when one is present and coordinated with the child's medical home.
3. Any additional health assessments performed in the schools where many students do not have medical homes should follow *Guidelines for Health Supervision III* from the AAP.
4. On completion of the school health assessment, any positive findings requiring medical subspecialist or surgical subspecialist referral, should be

performed in conjunction with the child's primary care provider.

5. Where schools assume medical care for students without medical homes, arrangements must be made to provide coordinated after-hours care for these children when school-based facilities or personnel are not available.
6. Herding of students for school physicals should be denounced because it provides quick superficial evaluation but may not address students complete health care needs.

AMERICAN ACADEMY OF PEDIATRICS

Committee on School Health

School Health Centers and Other Integrated School Health Services

ABSTRACT. This statement offers guidelines on the integration of expanded school health services, including school-based and school-linked health centers, into community-based health care systems. Expanded school health services should be integrated so that they enhance accessibility, provide high-quality health care, link children to a medical home, are financially sustainable, and address both long- and short-term needs of children and adolescents.

BACKGROUND INFORMATION

There are a number of core screening, diagnostic, treatment, and health counseling services that every school should provide[1] and that most schools already do provide.[2] These include management of medical emergencies, medication delivery, services for children with special health care needs, referral of common health problems (such as injury, asthma, behavioral and emotional difficulties), and health screens (such as vision and hearing screens).

Increasingly, schools are used as health access sites for students to receive increased and improved access to care that they are not receiving elsewhere.[3–5] A program with expanded health services may provide, for example, on-site immunizations, full health histories and physical examinations, or on-site therapy for children with special mental health needs. These services provide numerous benefits and potential benefits, including:

1. Students of all ages in some rural areas do not have reasonable access to any other medical services.
2. Less classroom time is lost to travel time.
3. Follow-up compliance may be better.
4. Adolescents, for a variety of reasons (eg, emancipation, independence, desire for confidentiality), often will not seek out or take advantage of services in traditional settings.[6]
5. Families that are not accustomed to using primary or preventive services available to them in traditional settings can be taught to use them through schools.
6. Behavioral risk assessments and ongoing preventive strategies that address major causes of youth mortality (suicide, homicide, accidental injury) often require a degree of access to health and mental health services that schools can provide. Mental health services on a school site can reduce time away from school to travel to regular mental health appointments. When a mental health clinic's presence on a school site is accompanied by close collaboration with school staff, then enhanced behavioral observation and clinical management also occur.

Schools that offer these expanded health services may do so through either school-linked or school-based health centers. "School-based" and "school-linked" are terms used to distinguish between services delivered on school campuses from those coordinated at the school but delivered off campus. In school-linked models, school health professionals collaborate with local community clinics, hospitals, and/or other health professionals and agencies. Some schools have characteristics of both school-linked and school-based models, such as mobile medical service vans that park intermittently outside various school sites.

Health centers' services range from full comprehensive services (preventive and acute care as well as mental health services) to only one component of this care. Many operate from a regular school health office; others are modern, sophisticated, and well-equipped clinics. Some offer services around the clock and every day, while in others a health team from a local practice or clinic visits the school site one half-day per week. Often school staffs do not provide health services; rather community health professionals provide services on a school site through an interagency agreement. The rich diversity of existing models[7] does not allow for simplistic categorization. This diversity exists at every level of education, from preschool to high school.

It is essential that health services provided by the educational sector are integrated with health education, social services, and health services provided elsewhere in the community. It is important that school-based services should not supplant services that could be delivered elsewhere, unless that is part of the agreed-on design. The American Academy of Pediatrics believes that all children and adolescents require a "medical home."[8] All models of health care delivery should aspire to provide health supervision and medical care that is continuous, comprehensive, family centered, culturally sensitive, compassionate, coordinated, and provided by a pediatrician or another physician or health care provider who is well-trained in child and adolescent health.

CHALLENGES

Some challenges for school health centers or for any model of expanded school health services are:

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

1. There is great variability in the degree to which school-based and school-linked services integrate with the medical home and to other community services and the degree to which they complement community services to meet student needs.
2. There is great variability in the degree to which school-based and school-linked services integrate with other components of the school system. School health centers cannot optimally assist students unless they are closely integrated with the school nurse (where one exists), the school's health educational program, and with other traditional or core school programs.[9]
3. Expanded school health services carry inherent and unique issues of patient confidentiality, consent, compliance, and continuity that need different solutions than they would in traditional health care settings and in schools without expanded health services.
4. Fair reimbursement for school-delivered health services is frequently difficult to achieve.[10]

If not addressed, all these issues can remain emotionally, morally, and politically charged, often paralyzing efforts to establish the best and most sustainable intervention and prevention programs. By adhering to a few basic guidelines, schools and their communities may avoid costly redundancies in health care delivery and unnecessary gaps in services.

INTEGRATED SCHOOL HEALTH SERVICES

"Integrated school health services" refers to a community-based approach to identifying the needs of children and youth, then matching them to available resources in the educational, health care, and social services sectors. All stakeholders, usually the school system, community health care providers, families, social service agencies, health plans, managed care organizations, and public health departments, must first decide on common goals and objectives for improving educational performance and child and adolescent health.

This should be based on a comprehensive community needs assessment—the first step in any decision to expand school health services.[1] The district or school and local child health and social services professionals must work closely with parents and community groups to evaluate the current status of child health and determine unmet needs. Services already available to children should not be duplicated unless the school is considered by stakeholders to be the only way to make these services accessible. A needs assessment should be developed that is supported by credible data and conducted by those knowledgeable of existing health care resources and health data in their community. It should be an ongoing process built permanently into the program.

Integrated school health services should have a governing structure that establishes communication among various professional disciplines and agencies, and designs and guides the service delivery program. Membership is at an authority level that ensures appropriate agency participation. Representatives in the administrative structure include students (especially adolescents), parents, pediatricians and other health care providers, school nursing personnel, local health department representatives, school administrators, and educators. It may also include faculty of local institutions of higher education, social service providers, representatives of managed care organizations, public and private mental health care agencies, and representatives of local government and local business, cultural, ethnic, and religious communities. In an integrated school health services plan, school-nursing personnel and, if one exists, the school's own physician or medical consultant, should be involved in the planning and direction of the program.

Once a needs assessment is complete and stakeholders are established, the extent and type of services provided through an integrated school health service program needs to be determined. Services might include any of the following: screening for acute and chronic health problems; preventive health care (disease prevention and health promotion); acute illness care; family planning and reproductive health care; mental health services; social services; substance abuse counseling; dental services; nutritional services; health counseling and education; and transportation to a traditional provider. The decision to choose an enhanced school health office, to link with a nearby community health agency, or to set up a school-based health center is based on what can best complement existing resources.

Last in the process of setting up an integrated school health services plan are formally written agreements and goals. To protect the collaboration from the threats of turf and control conflicts between agencies or to provide a more efficient management structure, some communities may choose to establish a nonprofit corporation to administer the program. More typically the school, school district, or one of the community health or social entities becomes the fiscal and lead agency. In these formal agreements, a formalized communication plan and a plan for collaboration with the medical home (provider or clinic) and health and social service agencies in the community should be included.

School-based health services are often provided by certified nurse practitioners, physician assistants, or licensed or credentialed mental health professionals (social workers, psychologists, etc). Pediatricians or other physicians from a community practice or clinic or from the public health sector frequently serve as medical directors. The medical director, along with the school principal and school-based health professionals, decide on day-to-day activities, protocols, and quality assurance. The activities of the clinical personnel should reflect the decisions of the broader-based governing structure as described above. If primary medical services are delivered on a school site by a nonphysician provider, telephone back-up from a pediatrician or other physician should be available at all times. It is important to establish where students will receive after-hours and weekend telephone and triage services. Onsite consultation, supervision, and quality assurance with periodic chart

review are part of an integrated school health services plan.

Integrated school health service programs require a sound financial base. Sources of funds may include private health insurance plans; traditional school health funds; an Early and Periodic Screening, Diagnostic, and Treatment program; Medicaid; Chapter I; Title X; Title XX; and other government programs.[11]

Among populations with high managed care penetration, there are additional considerations and possibilities.[12] Students enrolled in managed care plans have primary care providers assigned to them. Typically these providers are outside of the school system, they receive monthly capitation funds, and they are expected to provide all primary health care. A number of financial arrangements are possible for this population.[13–17] Health plans may agree to compensate school-based clinical activities on a fee-for-service basis, while still compensating their community-based providers at the same or a reduced amount. School clinics may also be compensated on a capitated basis. In some communities, health plans expect the school's reimbursement to come not from them, but directly from the students' capitated health care providers. In this latter model, there is usually a large portion of the student population that shares one common medical group or community clinic as its primary care provider. These clinicians or their designees come onto the school site to provide services for their patients. The school operates as a satellite location for a traditional primary care agency. In this model, the need to reimburse school providers through a separate agreement with managed care organizations is not necessary. Often, mental health services are contracted out or carved out from managed care health plans, so that mental health providers who work on school sites are compensated no differently than those working in traditional off-school site settings.

Advocacy for new mechanisms of health care financing at both state and national levels may be needed to ensure that dollars flow to all health and human service providers so that there is a seamless web of services for the child and family.

RECOMMENDATIONS

The Academy recommends that the medical service component of an integrated and comprehensive school health program meet the provisions of the current policy statements and manuals of the Academy, ie, "The Medical Home,"[8] *School Health: Policy and Practice*,[18] "Recommendations for Preventive Pediatric Health Care,"[19] "School Health Assessments,"[20] and "Qualifications and Utilization of Nursing Personnel Delivering Health Services in Schools."[21]

1. School-based health care providers must communicate with each student's existing sources of health care, eg, the primary care provider, when there is one. When necessary, and based on the specific design for that school, arrangements may also be made with neighborhood health programs, mental health programs, and health maintenance organizations. This communication needs to established at the onset, and may be via telephone, fax, e-mail, or post. Care should be taken not to disrupt existing services.
2. Part of every integrated health services program charter must be to introduce each student and family to a traditional medical home whenever this is possible in a community. An integrated school health program must include activities that prepare the large portion of students who will inevitably graduate or transfer from school each year. Examples of such activities are those that assist families with health insurance eligibility determinations, applications for insurance, selection of a non–school-based primary care provider, and registration at a community-based clinical practice that will serve as the students' medical home. Even if students receive most services at a school health center, families should be taught when and how to make preventive health appointments, to travel to their medical-home site independently, and to become familiar with a permanent primary care provider of their choice.
3. Parents should be encouraged to be primarily and intimately involved in the health education and health supervision of their children.
4. Issues of medical liability and confidentiality should be identified and addressed during a registration process. Typically a standard parent permission form is prepared as a component of registration for the school-based clinic so that students may receive services. At the very least, this should include permission for the school health center to exchange information with the primary care provider and with the school's traditional health staff (eg, school nurse, school counselor) for matters that pertain to a child's well-being at school. If the school's plan includes provisions for adolescents to receive services without parent notification or health plan billing, this too must be addressed at the time of registration.
5. A comprehensive review of existing resources and funding mechanisms must be done, preferably as part of the initial community assessment. Financial support for providers who supply in-school and after-hours health care should be included. Schools should not rely solely on temporary foundation grants. These funds are appropriate to use for start-up costs and to fund health care costs for students ineligible for any health insurance program. A variety of possible models of funding should be explored. Design and choose a system that is acceptable to all parties at financial risk and that does not fragment continuity of care in an attempt to capture dollars. A long-term funding plan is optimally developed before the integrated school health services program is initiated.
6. An ongoing process of evaluation should be incorporated into all integrated school health programs. Programs should adopt clearly stated goals and then design an ongoing data-based needs assessment. Programs must have the means to collect data and establish mechanisms for anal-

ysis and reporting. Quality assurance and improvement are important parts of the evaluation. Systematic evaluation should provide information about whether the integrated school health services approach is effective and worth the investment.

SUMMARY

Schools can successfully expand access to health care services for all students, particularly underserved populations, when the program includes careful community assessment and endorsement, is integrated with the school's existing health program, has a sound plan for financial sustainability, and pays adequate attention to quality assurance, evaluation, promotion, and integration with a medical home. School health services can be an effective vehicle for integrating psychosocial care and education with medical care.

Pediatricians practicing in public and private sectors should become actively involved in any community effort to develop an integrated school health services initiative. A well-designed integrated health services program, when coupled with comprehensive school health education, could significantly advance the state of health of the nation's children, youth, and families.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

TECHNICAL REPORT

School Readiness

Pamela C. High, MD, and the Committee on Early Childhood, Adoption, and Dependent Care and Council on School Health

ABSTRACT

School readiness includes the readiness of the individual child, the school's readiness for children, and the ability of the family and community to support optimal early child development. It is the responsibility of schools to be ready for all children at all levels of readiness. Children's readiness for kindergarten should become an outcome measure for community-based programs, rather than an exclusion criterion at the beginning of the formal educational experience. Our new knowledge of early brain and child development has revealed that modifiable factors in a child's early experience can greatly affect that child's learning trajectory. Many US children enter kindergarten with limitations in their social, emotional, cognitive, and physical development that might have been significantly diminished or eliminated through early identification of and attention to child and family needs. Pediatricians have a role in promoting school readiness for all children, beginning at birth, through their practices and advocacy. The American Academy of Pediatrics affords pediatricians many opportunities to promote the physical, social-emotional, and educational health of young children, with other advocacy groups. This technical report supports American Academy of Pediatrics policy statements "Quality Early Education and Child Care From Birth to Kindergarten" and "The Inappropriate Use of School 'Readiness' Tests."

EARLY EXPERIENCE MATTERS

All of a child's early experiences, whether at home, in child care, or in other preschool settings, are educational. When early experiences are consistent, developmentally sound, and emotionally supportive, there are positive effects on the child and the family. To focus only on the education of children beginning with kindergarten is to ignore the science of early development and to deny the importance of early experiences. Our current understanding of the importance of early experiences in early brain development and cognitive and social-emotional outcomes for children and the recent US policy agenda aimed at maximizing educational encounters and outcomes for all children converge in our contemporary conceptualization of school readiness. Children who enter school ready to learn are expected to achieve more academically. Academic success has been linked to improved social, economic, and health outcomes.[1–3]

HOW HAS SCHOOL READINESS BEEN DEFINED?

"Ready to Learn" became a national mantra in 1991, when the National Education Goals Panel adopted as its first goal that "by the year 2000, all children will enter school ready to learn."[4] This panel identified readiness in the child as determined by a set of interdependent developmental trajectories. Three components of school readiness were broadly described as:

1. Readiness in the child, defined by:
   - Physical well-being and motor development, including health status, growth, and disability;
   - Social and emotional development, including turn-taking, cooperation, empathy, and the ability to express one's own emotions;
   - Approaches to learning, including enthusiasm, curiosity, temperament, culture, and values;
   - Language development, including listening, speaking, and vocabulary, as well as literacy skills, including print awareness, story sense, and writing and drawing processes; and
   - General knowledge and cognition, including sound-letter association, spatial relations, and number concepts.

2. School's readiness for children, ensured by:
   - Facilitating smooth transition between home and school, including cultural sensitivity;
   - Striving for continuity between early care and education programs and elementary school;
   - Using high-quality instruction, appropriate pacing, and understanding that learning occurs in the context of relationships;
   - Demonstrating commitment to the success of every child through awareness of the needs of individual children, including the effects of poverty and race, and trying to meet special needs within the regular classroom;
   - Demonstrating commitment to the success of every teacher;
   - Introducing approaches that raise achievement, such as parent involvement and early intervention for children falling behind;
   - Altering practices and programs if they do not benefit children;
   - Serving children in their communities;
   - Taking responsibility for results; and
   - Having strong leadership.
3. Family and community supports contributing to child readiness:
   - Mothers should receive excellent prenatal care and children should receive comprehensive health care, optimal nutrition, and daily physical activity, so that children arrive at school with healthy minds and bodies;
   - All children should have access to high-quality preschool; and
   - As their child's first teacher, every parent should devote time daily to helping their child learn and should have access to education and support to be an effective teacher.

WHAT DETERMINES SCHOOL READINESS?

An individual child's school readiness is determined in large measure by the environment in which he or she lives and grows. The Child Welfare League of America described a vision for the United States in which every child is healthy and safe and develops to his or her full capacity.[5] Five universal needs of all children were described. First, children need the very basics of proper nutrition, economic security, adequate clothing and shelter, appropriate education, and primary and preventive physical and mental health services. Second, children need strong nurturing relationships within their families, their communities, and their peer groups. Third, children need opportunities to develop their talents and skills and to contribute to their communities. Children with indications of disability need early assessment and intervention to prevent later, more-serious problems. Fourth, children need protection from injury, abuse, and neglect, as well as from exposure to violence and discrimination. Fifth, children have a basic need for healing. When we have not been able to protect them, children need us to ease the effects of any harm they have suffered by providing emotional support, by addressing physical and mental health care needs, and by sometimes making amends through restorative judicial practices. Meeting these needs requires collaborative comprehensive approaches, so that children become a priority at the levels of the family, the community, and the nation.[5]

Education and child development literature has focused on 4 major conceptualizations of school readiness. The "idealist/nativist" view suggests that children are ready for school when they mature to the level of having self-control, peer relations, and the ability to follow directions and that this process is endogenously determined. In this construct, environment plays only a minor role and little can be done to accelerate this process. In contrast, the "empiricist/environmentalist" view of readiness is determined by what children know (eg, colors, shapes, counting, and address) and how they behave. This is understood as the direct result of what the child has been taught. In both of these constructs, the solution to a child's failure to achieve a universal level of proficiency would be to give the child more time to mature or to learn these more-basic concepts, by placing the child in less-demanding programs.[6] However, research shows that age is a less-important influence on developmental progress than is schooling. In one study, the independent effects of schooling were 4 times greater than those of age on kindergarten performance.[7] In a similar study, any age-associated academic advantage provided at first grade entry dissipated within a few years.[8]

A third perspective on school readiness is a "social constructivist" model, which rejects the idea that readiness is an endogenous process or a defined set of knowledge and sees readiness in social and cultural terms. The focus of this model is on the community and its values and expectations, rather than on the child. A potential problem with this view is the lack of focus on the individual child.

The final construct of readiness that has been proposed is an "interactional relational" model. In this perspective, the focus is on the child and the environment and also on the ongoing interaction between them. This theory focuses on helping all children learn, and it suggests that educational success depends on the reciprocal relationship between the school and the child, particularly on the mentorship of the teacher.[6] This fourth model has gained the greatest recognition by developmentalists, because it is most consistent with the current understanding of the importance of early experiences and early relationships, especially in promoting child development.[9]

INAPPROPRIATE USE OF SCHOOL READINESS TESTING

There are 6 fundamental misconceptions prevalent regarding school readiness, which serve mostly to keep children out of school, rather than ensuring that chil-

dren will be ready and capable when they reach kindergarten. These misconceptions are as follows. (1) Learning happens only at school. (2) Readiness is a specific condition within each child. (3) Readiness can be measured easily. (4) Readiness is mostly a function of time (maturation), and some children need a little more. (5) Children are ready to learn when they can sit quietly at a desk and listen. (6) Children who are not ready do not belong in school.[10]

An emphasis on kindergarten readiness that looks only at the skills of a child places an undue burden of proof of readiness on that child and is particularly unfair because of economic, experiential, and cultural inequities in our society. Typical or normal development in 4- and 5-year-old children is highly variable, and labeling children at such an early age may cause them to be isolated from a more-appropriate learning environment.

In a 1988 national survey, 10% to 50% of children in various states who were eligible to enter kindergarten on the basis of age did not enter because of readiness test scores.[11] A follow-up survey in 1996[12] did show a response to growing concerns about misuse of these kinds of data. Most states had moved away from readiness testing by developing policies against the use of such testing, by issuing publications on appropriate assessment in early childhood, or by providing professional development opportunities in early childhood assessment. However, local districts in many states continue to use standardized testing for young children. Although the definition of kindergarten eligibility in every state is based on child age, many states continue to conduct standard statewide screening or assessment, to allow local districts to choose their own instruments of assessment, and to develop statewide readiness assessments. Few states have no assessment of readiness, and methods for addressing children with special needs are determined locally in most states.[13]

The current disparity between school and child readiness may be because schools are not prepared to offer the necessary and appropriate educational setting for age-eligible children, not because children cannot learn in an appropriate educational setting. If there is a predetermined set of skills necessary for school enrollment, then commitment to promoting universal readiness must address early-life inequities in experience. This may be accomplished by providing access to opportunities that promote educational success, recognize and support individual differences among children, and establish reasonable and appropriate expectations of children's capabilities at school entry for all children.[14] The data gained from testing children at kindergarten entry need to be interpreted carefully. Ideally, data can be used as a tool to help prepare schools for the diverse group of children they will be serving, rather than as a means of excluding children from formal education at their potential entry point. It is the responsibility of the schools to be ready for all children and to work with families to make the school experience more positive for all children, even those who may be at varying stages of readiness. School programs should be flexible and adaptable to each child's level of readiness.

With an increasing national emphasis on school performance and accountability, it is likely that readiness assessment will become more prevalent. Assessing young children is difficult theoretically, psychometrically, and logistically. However, the question is becoming how to assess children, rather than whether they should be assessed. An important remaining issue is how these data will be used. The potential for misuse of these data, with long-lasting effects, is great. Nonetheless, data on the condition of children entering school can be important for interpreting later accountability measures and can help us understand how well early childhood programs perform in raising the developmental level of young children before school entry.

HOW READY ARE US CHILDREN AS THEY ENTER KINDERGARTEN?

A landmark study by the National Center for Education and Statistics surveyed a nationally representative sample of 22 000 first-time kindergarten students and their schools, classroom teachers, and families. The study was designed to gather information about the entry status of the nation's kindergarteners, to inform educational policy and practice. Information was obtained regarding children's cognitive, emotional, social, and physical development, as well as their family interactions and home literacy environment. In the study, children "at risk for school difficulty" were defined as children whose mothers had less than a high school education, children who came from single-mother families, children who had received public assistance, and children who lived in families whose primary language was not English.[15,16]

Fifty-one percent of parents of children who entered kindergarten for the first time in 1998 rated their child's general health as excellent, and 32% rated it as very good. Kindergarteners whose mothers had higher levels of education, who were from 2-parent families, whose families had not used public assistance, and who were of white non-Hispanic descent were rated as having generally better health by their parents. Six percent of the first-time kindergartners were experiencing vision problems, and 3% were identified as having hearing problems. In that study, 12% of boys and 11% of girls were at risk of overweight, defined as BMI at or above age- and gender-specific guidelines. The risk was greater for children whose mothers had not attained a bachelor's degree and for children from homes where the primary language spoken was not English.[15,16]

The study attempted to examine the social and emotional status of first-time kindergartners. Teachers reported that 10% to 11% of children often argued or fought with others or angered easily, and 77% often formed friendships. Single parents were more likely to report behavior problems, such as fighting, arguing, and getting angry. Parents with partners, those with higher education, and those who had not received public assistance were more likely to have kindergartners with prosocial behaviors, such as often forming friendships. Teachers were less likely than parents to report that children were eager to learn (75% vs 92%). Children with lower maternal education, those from single-

mother homes, and those whose families had received public assistance were less likely to be viewed as eager to learn by their teachers.[15,16]

Variability also was seen in home literacy environments and in family interactions for first-time kindergartners. Forty-five percent of parents reported reading with their child every day, but this value decreased to 36% if mothers had less than a high school education, 38% if English was not the primary language spoken at home, 35% for black non-Hispanic children, and 39% for Hispanic children. Almost three fourths of parents reported having more than 25 children's books at home, but this was true for only 38% of kindergartners whose mothers had not graduated from high school and only 35% of those from homes where English was not the primary language spoken. Only approximately one half of kindergartners from black non-Hispanic, Hispanic, or Native American families had more than 25 children's books at home. In contrast, more families that had some of these risks engaged in singing and in exercise and game-playing with their young children. Although 45% of parents overall sang with their children daily, this increased to 51% in single-mother families, 49% in families that had received some public assistance, and 54% in black non-Hispanic families. Twenty-two percent of parents exercised and played games with their children daily. This value increased to 27% for mothers who had not completed high school, 24% for single-mother families, 29% for families that had received some public assistance, 29% for black non-Hispanic families, and 31% for Native American families.[15,16]

Early academic competencies were also surveyed in the study. In 1998 in the United States, as children entered kindergarten for the first time, two thirds recognized their letters, and 29% also recognized beginning sounds; 94% recognized single numerals and shapes and could count to 10, and 58% could count beyond 10, sequence patterns, and use nonstandard units of length to compare objects. Of those children, 37% demonstrated strong print familiarity skills, including knowing that print reads from left to right and knowing where to go when a line of print ends. Kindergartners' performance on math, reading, and general knowledge items increased with the level of their mothers' education and was higher for children from 2-parent families.[15,16]

Overall, children with few risk factors were more likely to have attained these various proficiencies and were in better general health than were children at risk. Follow-up evaluation of the same children in the spring of first grade showed that children who demonstrated early literacy skills and who came from a positive literacy environment, who possessed a positive approach to learning, and who enjoyed very good or excellent general health at kindergarten entry performed better in both reading and mathematics after 2 years of formal schooling than did children who did not have these resources. The relationships between the resources children possessed at kindergarten entry and their reading and mathematics performance in the spring of first grade remained significant after controlling for the influence of children's poverty status and their race/ethnicity.[17]

When these children were evaluated after 4 years of education, in the spring of third grade, children with more family risk factors (eg, living below the poverty level, primary language spoken in the home was not English, mother had not completed high school, and single-parent home) demonstrated lower mean achievement scores in reading, mathematics, and science. Over that time, children with more family risk factors made smaller gains in math and reading, so that the achievement gaps between disadvantaged and more-advantaged children grew wider over the first 4 years of school. The third-graders completed self-descriptive questionnaires evaluating internalizing (eg, shy, withdrawn, or sad) and externalizing (eg, fighting, arguing, or distractibility) behavior problems. Overall problem behavior scores were low; however, children with lower achievement and more family risk factors tended to rate themselves higher on both of the problem behavior scales.[18]

These findings, although they are disturbing, are not surprising to pediatricians, who have long been advocates for underserved pediatric populations. This inequity in school readiness, which is apparent at school entry and is associated with persistent academic underachievement and social-emotional risk, points to a need to address these differences before children enter kindergarten, especially for families and children at risk.

CHILDREN WITH SPECIAL EDUCATIONAL NEEDS

When discussing the issue of school readiness, it is critical to discuss the approximately 20% of children identified as having special educational needs. Foremost in this discussion is the importance of not using screening instruments or testing by nonprofessionals to label children or to place them in special education classes.[19] Farran and Shonkoff[20] argued that children with disabilities are of 2 primary types, namely, normative and nonnormative. Those who are classified as normative constitute only 2% of the population; they may suffer from blindness, deafness, autism, moderate/profound mental retardation, or some type of significant language impairment. It is understood that regular general education may not be appropriate for them. Nonnormative children constitute 18% of the population. Children in this population group may be categorized as having learning disabilities, mild mental retardation, or social and emotional maladjustment. These nonnormative categories may be a reflection more of what society accepts as normal behavior than of a lack of ability or development. The authors warned that "as more and more types of children are excluded because they are deemed not ready, smaller and smaller differences among the remaining children will be accented and new categories will be developed."[20]

It is important to point out that the number of children receiving special education services increases each year. There was a 64% increase in enrollment in special education categories in the public schools between 1976 and 1999, whereas total enrollment of children in elementary and secondary schools increased by less than 12% in that time period. Also, almost 2 million more children were labeled as having learning disabilities in

1999 than in 1977. However, there were 364 000 fewer children labeled as mentally retarded and 234 000 fewer children who were categorized as having speech impairments.[21]

HOW CAN SCHOOLS AND COMMUNITIES PROMOTE SCHOOL READINESS?

Much less has been studied about the readiness of schools and communities to meet the needs of the diverse population of children.[22] One approach to identifying and tracking indicators of school and community preparedness is the School Readiness Indicators: Making Progress for Young Children program, a partnership of 16 states funded by the David and Lucile Packard Foundation, the Ford Foundation, and the Ewing Marion Kauffman Foundation. This initiative has 3 goals, that is, (1) to create a set of measurable indicators related to and defining school readiness that can be tracked at the state and local levels; (2) to have states adopt this indicator-based definition of school readiness, to fill in gaps in data, to track data, and to report findings to their citizens; and (3) to stimulate policies, programs, and other actions to improve the ability of children to read at grade level by third grade. Sample systems indicators tracked by this group include (1) the proportion of children with health coverage; (2) the proportion of 3- and 4-year-old children enrolled in high-quality early education and child care programs; (3) the proportion of schools offering universal access to full-day kindergarten; (4) the proportion of children with hearing, vision, or dental problems not detected at school entry; (5) the number of adults enrolled in adult education programs or programs teaching English as a second language per 100 adults seeking those services; (6) the proportion of births to mothers with less than a 12th-grade education; and (7) the proportion of children younger than 6 years of age in foster care who have had more than 2 placements in 24 months. The complete set of indicators selected by each state is available at the initiative Web site (www.gettingready.org). It is the belief of those investigators that this work will play an important role in shaping the educational agenda for young children and their families across the country.[23,24]

WHAT PEDIATRICIANS CAN DO TO PROMOTE SCHOOL READINESS

Pediatricians can and do promote school readiness in the children they serve, in many ways. In their day-to-day practices in medical homes, pediatric providers promote optimal nutrition, growth, and physical health as part of health maintenance, including provision of immunizations and anticipatory guidance. Their guidance regarding developmental and behavioral issues and concerns can help parents enhance their nurturing relationships with their children. By providing ongoing surveillance and information regarding injury prevention, pediatric providers can help protect children from injury and abuse. Pediatricians can screen for psychosocial risks, such as family violence, maternal depression, substance abuse, and lack of connection to community and family supports. They can counsel families with these kinds of needs and refer them to appropriate resources within the community. Pediatricians can emphasize improved identification of children with delays in their development by integrating regular, systematic, developmental screening and surveillance into their practices.[25] Children identified as having delays and children at risk of delays can then be referred to community-based services, such as early intervention programs, home visitation programs, Head Start, and special education programs available through school departments. After referral, pediatricians can monitor children's participation and progress as a result of the referral.

As part of daily practice, pediatric providers can promote the "5 Rs" of early education, that is, reading together as a daily family activity; rhyming, playing, and cuddling together often; routines and regular times for meals, play, and sleeping, which help children know what they can expect and what is expected from them; praise as reward for everyday successes; and reciprocal and nurturing relationships, which are the foundations of healthy child development. Pediatricians can integrate literacy promotion into their practices toward this end.

Pediatricians should be well informed regarding interventions of known benefit to young children. A review of the effects of low income (the unifying factor associated with developmental risk) on child development identified many evidence-based interventions that have proven efficacy in improving psychosocial outcomes for children at risk.[26] Head Start for healthy preschoolers from low-income families has been shown consistently to improve vocabulary, early writing, and early mathematics scores. Long-term follow-up studies demonstrated remarkable differences for children who participated in these programs, compared with control children, in educational attainment, home ownership, incarceration rates, and employment.[27–30] A study of the economic features of investing in a 1-year, high-quality, universal, preschool education in California estimated a $7000 net present-value benefit per child. This benefit equaled a return of $2.62 for every $1 invested, with an annual return rate of 10% over 60 years. This model did not include other benefits to society, such as the improved health and well-being of participating children and the potential intergenerational transmission of favorable benefits.[31]

Economists at the Federal Reserve Bank of Minneapolis examined the rate of return on investment for early education in Minnesota. When considering the Perry Preschool Program, which provided high-quality preschool to 3- and 4-year-old children in poverty, they found a "real" return on investment, adjusted for inflation, of 16%, with at least 75% of those benefits going to the general public.[32] The benefit/cost ratio (the ratio of the aggregate program benefits over the life of the child to the input of costs) was found to be greater than 8:1.[33]

Other evidence-based interventions with substantial effects on school readiness include early intervention programs for formerly preterm infants, which have been shown to prevent developmental delay, to improve grade retention, and to accelerate placement into special

education.[34–36] Food supplement programs, such as the Special Supplemental Nutrition Program for Women, Infants, and Children, have been shown to reduce rates of low birth weight[37] and iron deficiency.[38–40] Children attending schools with school nutrition programs have improved scores on standardized academic tests.[41] Home visiting by nurses has been shown consistently to reduce rates of childhood injury, to increase fathers' involvement, to reduce family welfare dependency, and to improve school readiness.[42] Housing subsidies have resulted in improved neighborhood safety and reduced exposure to violence.[43] In addition, clinic-based, literacy-promoting programs that include the provision of children's books and anticipatory guidance about the importance of reading aloud with young children have been shown to enhance language development in toddlers[44] and preschoolers.[45]

Programs and policies that are without proven efficacy but are deemed likely to have positive effects on child development include housing policies to decrease frequent moves, smoking cessation programs for parents and pregnant women, improved access to high-quality health care, and identification and treatment of maternal depression and other mental health problems.[26,46]

As respected child advocates and political consultants, pediatricians can promote school readiness by advocating for provision of services that are evidence-based and that demonstrate efficacy in promoting optimal early brain and child development. Some examples include (1) access to health care, including mental health services, for all children; (2) standards for state Medicaid and Early and Periodic Screening, Diagnosis, and Treatment programs that conform, at a minimum, to American Academy of Pediatrics (AAP) recommendations[47]; (3) full funding for Head Start (which now must turn away 4 of 10 eligible children because of lack of resources), for Early Head Start (which now serves <5% of eligible children and families), and for federal child care subsidies (now available to only 1 of 5 eligible families)[48,49]; and (4) improved funding for and infrastructure to support the provision of high-quality, universal, early education and child care from birth to kindergarten for all families, as described in a policy statement from the AAP.[50]

Pediatricians can advocate, individually and through collaboration in their own communities, with their AAP chapters on the state level and in coordination with the AAP Washington office on the national level. AAP chapters can be the centers for advocacy because they have experience, resources, and established relationships with policymakers who will be making decisions at the state level.[51,52] The AAP offers opportunities to affect these policies on a national level through the Federal Advocacy Action Network.. Opportunities also exist for pediatricians to get involved in State Early Childhood Comprehensive Systems activities in their states. The goal of this federally funded initiative is to implement a comprehensive early childhood system that promotes the health and well-being of young children, enabling them to enter school ready and able to learn (for more information, see www.healthychildcare.org).

CONCLUSIONS

School readiness needs to become an outcome measure for community-based programs, rather than an exclusion criterion at the educational starting gate. Indeed, kindergarten should no longer be viewed as the beginning of a child's educational experience. Our new knowledge of early brain and child development has demonstrated that modifiable factors in a child's early experience can greatly affect that child's learning trajectory. Three qualities that are necessary for children to be ready for school are intellectual skills, motivation to learn, and strong social-emotional capacity and support.[9] These qualities are influenced by the health and well-being of the families and neighborhoods in which children are raised. Many US children enter kindergarten with limitations in their social-emotional, physical, and cognitive development that might have been significantly diminished or eliminated through early recognition of and attention to child and family needs. There is much that pediatricians can do to address and to diminish these discrepancies.

POLICY STATEMENT

School Transportation Safety

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Injury, Violence, and Poison Prevention and Council on School Health

ABSTRACT

This policy statement replaces the previous version published in 1996. It provides new information, studies, regulations, and recommendations related to the safe transportation of children to and from school and school-related activities. Pediatricians can play an important role at the patient/family, community, state, and national levels as child advocates and consultants to schools and early education programs about transportation safety.

INTRODUCTION

School transportation plays a consistent and long-term role in the lives of children from preschool through high school. Pediatricians can participate by serving as resources, educators, consultants, and advocates for school transportation safety at the local, state, and federal levels. This revised policy statement provides updated recommendations that can enhance community systems for addressing safe transportation for children to and from school and school-related activities.

Expectations for school transportation and school bus safety should be upheld in an ongoing commitment from communities and states to ensure that children travel to and from school safely. The National Highway Traffic Safety Administration (NHTSA) School Bus Safety Program is committed to reducing school bus crashes, injuries, and fatalities.[1] Congress has indicated that school transportation should be held to the highest level of safety.[2] In addressing school transportation, all modes of travel must be considered, and measures must be taken to promote safety for each mode.

Modes of School Transportation

The Committee on School Transportation Safety of the Transportation Research Board studied the various modes of travel and associated risks for schoolchildren.[3] Estimates of trips per year by mode of transportation during school hours were: passenger vehicle with adult driver, 45%; school buses, 25%, other buses, 2%; passenger vehicle with teen driver, 14%; bicycle, 2%; and walking, 12%. These estimates are limited, because they do not include school bus travel for extracurricular activities during or after normal school hours or during vacations. School bus crashes occur disproportionately on high-speed roads at night during transportation to and from extracurricular activities.[4]

Annually during normal school travel hours, 23.5 million children are transported on 457 000 school buses, totaling 5.8 billion student trips and 3.13 billion miles.[5] Each child who uses school bus transportation travels, on average, 1300 miles per school year. These estimates do not include school or school-related travel during nonschool hours.

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

Key Words
school transportation, school bus, travel on school bus, getting to and from school

Abbreviations
NHTSA—National Highway Traffic Safety Administration
NTSB—National Transportation Safety Board
FMVSSs—federal motor vehicle safety standards
AAP—American Academy of Pediatrics

School Transportation Injury

Annually, there are, on average, 815 student deaths and 152 250 injuries related to school travel during normal school travel hours. (These data are underestimates, because they do not include school-related trips or school bus crashes outside of school hours, and reporting is voluntary.) Two percent of the deaths and 4% of the injuries occurred in school buses. Seventy-five percent of the deaths and 84% of the injuries occurred in passenger vehicles. The fatality rates descend in the following order: (1) passenger vehicles with teen drivers, 55%; (2) passenger vehicles with adult drivers, 20%; (3) walking (pedestrians), 16%; (4) bicyclists, 6%; and (5) school and other buses, 2%. The injury rates descend in the following order: (1) passenger vehicles with teen drivers, 51%; (2) passenger vehicles with adult drivers, 33%; (3) walking (pedestrian), 6%; (4) bicycles, 5%; and (5) school and other buses, 5%.[3]

The Fatality Analysis Reporting System[6] includes fatality data on all school bus–related crashes, not just those during school hours. In the year 2001, 141 persons were killed. Of the fatalities, 16% were pedestrians, 9% were school bus passengers, 4% were school bus drivers, 3% were bicyclists, and the rest (68%) were occupants of other vehicles or other nonmotorists. Of the 22 child pedestrian fatalities, 82% were struck by the school bus. Data from the General Estimates System indicate that 13 000 persons are injured annually in school bus crashes.[7] Of those injured, 46% (5980) were school bus occupants, 8% were school bus drivers, 38% were occupants of other vehicles, and fewer than 0.05% each were pedestrians, pedal cyclists, and nonmotorists.[8] However, the National Transportation Safety Board (NTSB) determined that school bus crash data are incomplete and that injuries cannot be reliably estimated.[9] The first emergency department–based study of nonfatal school bus–related injuries found that the number of injuries (17 000 annually to children 0–19 years of age) greatly exceeded previously published estimates. Motor vehicle crashes were the most frequent injury mechanism.[10]

RECOMMENDATIONS

School Bus Travel

The National Traffic and Motor Vehicle Safety Act of 1966 and the upgrades in the School Bus Safety Amendments of 1974 authorize the Department of Transportation to issue minimum standards for new school buses manufactured for sale in the United States.[11] There are 35 federal motor vehicle safety standards (FMVSSs) that apply to school buses. Large school buses that carry more than 16 passengers are not required to be equipped with seat belts. The long-standing American Academy of Pediatrics (AAP) recommendation that seat belts be installed on all new school buses is further discussed later in this statement. Small school buses (weighing <10 000 pounds) built in accordance with FMVSSs are equipped with lap belts. Vehicles, including multipurpose vehicles that carry 11 or more persons that are sold or leased for transporting students to or from school or school-related events, are required to meet the FMVSS requirements applicable to school buses. States may prescribe additional regulations that apply to the use of any vehicle used to transport preprimary, primary, and secondary school students.[12]

The AAP recommends that all guidelines for safe transportation of all preschool- and school-aged children be applied during all school and school-related trips regardless of the hours of operation.

Preschool-Aged Children

Many school systems provide transportation for preschool-aged children. The NHTSA studies demonstrated that preschool-aged children were safest when properly transported in child safety restraint systems that meet FMVSSs 213 and 225.[13] In January 2001, the Department of Health and Human Services issued transportation safety requirements for Head Start transportation. Within 5 years, transportation was limited to school buses or "allowable alternate vehicles." This provision has since been extended to June 30, 2007. That is, on July 1, 2007, all Head Start children must be transported in a compliant vehicle, unless a waiver has been granted. All vehicles must be equipped with a communication system for emergencies, first aid kit, fire extinguisher, and seat belt cutter. Children weighing 50 pounds or less were required to travel in FMVSS 213–approved child restraints; this has since been updated to apply to children under the weight threshold of FMVSS 213 for approved child restraints (currently 65 pounds). As of January 2004, vehicles must be equipped to use child restraints. Retrofit of lap belts or child-restraint anchorage to properly secure the child safety restraint system to the school bus seat is allowed and must be reinforced according to the applicable FMVSS.[13] The driver must have a commercial driver's license and undergo criminal background checks. As of January 2004, all vehicles must have a bus monitor. Each Head Start agency is required to provide pedestrian-safety education for parents and children. An extension to January 18, 2006, for implementation of the requirement to provide car safety seats and bus monitors was allowed for Head Start programs that filed an application by April 1, 2004. A final rule was published on October 4, 2006, authorizing the Department of Health and Human Services to issue waivers from this requirement to Head Start grantees. The NHTSA has a curriculum for child passenger safety technicians, materials available regarding proper use of child safety restraint systems in school buses, and child passenger training materials for school bus drivers.

The AAP has recommended and advocated that school districts provide height- and weight-appropriate

car safety seats and restraint systems that meet FMVSSs for all preschool-aged children. These systems include booster seats for which a 3-point belt is available for installation. The AAP also supports the Head Start transportation safety requirements.

The AAP further recommends that school-based as well as non–school-based child programs follow guidelines for safe transportation. This includes all early education and child care programs and applies to car-pool transportation as well. The AAP Moving Kids Safely in Child Care program is the first national occupant-protection curriculum for child care providers and administrators; it provides detailed guidelines for safe transportation of all children.[14]

School-Aged Children: Occupant Protection on School Buses

Compartmentalization has been the occupant-protection system for children in large school buses for more than 30 years and was the only available protection before child-restraint systems and seat belts were available for use in the school bus environment. Compartmentalization is provided by seats that are closely spaced with high, energy-absorbing seat backs. Data from real-world crashes comparing seat belt use versus compartmentalization only do not exist. However, recent studies have revealed that compartmentalization does not offer optimal protection and is not consistent with current technology and messages for children and families regarding the use of car safety seats and seat belts in all motor vehicles.[9,15,16]

The NTSB, through a series of crash investigations, determined that compartmentalization as a method of occupant protection on school buses is incomplete. Compartmentalization does not provide protection during lateral (side) impacts with vehicles of large mass or in rollover collisions, because passengers do not always remain completely within the compartment. The NTSB recommended the development and implementation of a seat and restraint system that restrains passengers in the seating compartment. The NTSB also recommended the development of performance standards and requirements for school bus occupant-protection systems on newly manufactured school buses. The NTSB further recommended on-board recording devices to facilitate improved data collection in crashes.[9] For optimal protection of all children, the AAP concurs with these recommendations.

The NHTSA conducted a study of school bus occupant protection in 2000 and determined that lap/shoulder belts on school buses performed best in dummy crash-testing compared with unbelted occupants, compartmentalization, and lap belts. Head-injury measurements were significantly lower with use of lap/shoulder belts than for use of compartmentalization or lap belts. In crash tests, the lap/shoulder belt restraint systems effectively kept the dummies in their seats.[16]

The State of California Vehicle Code requires newly manufactured school buses to have a lap/shoulder belt restraint system, effective 2004 for small school buses and 2005 for large school buses.[17] At the time of this publication, the states of Florida, Louisiana, New Jersey, and New York and many local school districts have passed school bus seat belt laws.[18]

The AAP recommends that all children travel in age-appropriate, properly secured child-restraint systems when transported in all motor vehicles, including school buses, to ensure the safest ride possible. The AAP further recommends that all newly manufactured school buses be equipped with lap/shoulder restraint systems that can also accommodate car safety seats, booster seats, and harness systems. The AAP recognizes the added benefit of improved student behavior and consistent habits of restraint use when traveling in motor vehicles. Policies on seat belt use have been found to improve student behavior and reduce driver distraction.[4,19,20] School districts must ensure the appropriate education of administrators, students, teachers, drivers, and parents in the use of occupant-protection devices.

School Bus Safety Features

The AAP recommends that all school buses, including private, parochial, and contractual, that are used for school and all school-related activity transportation be in compliance with all applicable federal regulations. Buses built before 1977 should be retired from use, because they are deficient in several significant safety standards.[4]

Effective December 2, 1993, the FMVSSs were revised to require mirrors to improve driver visibility in front of and along both sides of school buses.[21] In addition, districts should consider installing strobe lights for use during reduced-visibility conditions, an external loudspeaker system to enable the driver to communicate with children outside the bus, and loading and backing alarms or pulsating backup horns.[22] School bus blind areas created by school bus bodies or mirrors are considerable.[23] Electronic sensor systems are available but have not been evaluated adequately to determine their effectiveness.[4] The AAP recommends that blind spots created by mirror systems and other vehicle-design aspects should be addressed by improved technology designed to decrease both crash and pedestrian injury risks because of limited visibility of a child by the bus driver.

The Children's School Bus Exposure Study, prepared for the California Air Resources Board, found that diesel buses can have significantly higher on-board diesel-related pollutant concentrations than other vehicles because of intrusion of the bus's own exhaust into the cabin.[24] Increased exposure from commuting by school bus was estimated to increase a child's lifetime cancer risk by approximately 4%, increase the incidence of lower respiratory symptoms by approximately 6%, and increase daily hospitalizations for asthma by approxi-

mately 1%. Several states and local governments have adopted airborne toxic control measures that limit school bus idling and idling at schools.[25,26] Bus idling also contributes to poor indoor air quality inside schools from unfiltered air that enters through open doors. The AAP recommends that states adopt measures to protect school-aged children from exposure to toxic air contaminants.[27] Additional measures to reduce children's exposure to vehicle-related pollutants include replacement of older buses, use of alternate-fueled or particulate-trap–equipped buses, retrofitting buses with better emission-control technologies, minimizing bus caravanning, use of cleaner buses on longer routes, having passengers sit at the front of the bus if it is not full, and minimizing idling.[24,28]

School Bus Transportation of Children With Special Medical Needs

Children with special needs and who are older than the preschool-aged child and require special restraint systems should be evaluated individually to determine the most appropriate system that meets their needs for positioning during travel, regardless of their age, weight, and height. Specific recommendations are outlined in the AAP policy statement on school bus transportation of children with special needs.[29]

The use of wheelchairs is common for school bus transportation of children with disabilities. The AAP recommends that states adopt the requirements for use of wheelchairs on school buses outlined in the 1995 National Standards for School Buses[22] and the AAP policy statement on school bus transportation of children with special needs.[29]

School Bus Driver Selection, Training, and Performance

The Transportation Research Board stated that variations in school bus driver recruitment, selection, training practices, and rates of pay are likely to be associated with variations in driver safety performance.[3] In another report, the Transportation Research Board recommended that all states provide formal training for school bus drivers, including training on school bus driver responsibility in ensuring safety of the children inside the bus and in loading zones.[4]

The AAP believes that national standards for the selection, training, and regulation of school bus drivers should be established and implemented to ensure optimal driver performance.

To meet basic requirements, school bus drivers should:

- maintain a valid commercial driver's license;
- be at least 21 years of age;
- show proof of an annual health history, assessment, and physical examination, including vision and hearing assessments, that document the absence of conditions that may compromise driving and child supervision;
- successfully complete a written or oral test covering driver duties, bus-operating procedures, traffic and school bus laws and regulations, record keeping, emergency and crash-related procedures, first aid, basic appreciation of the developmental stages and needs of preschool and school-aged children, child-supervision responsibilities, and transportation of passengers with special needs;
- maintain a satisfactory driving record as determined by the school district;
- successfully pass a review for a criminal record (including convictions of child sexual abuse and incidents or arrests for driving under the influence of alcohol or other drugs) that is reviewed annually; and
- pass a test for illicit drugs and alcohol as required by the district (mandatory testing is recommended if it is not already required).

To demonstrate operational and driving skills, school bus drivers should:

- pass a driving performance test and demonstrate safe loading and unloading procedures;
- demonstrate physical capability to successfully accomplish student evacuation; and
- demonstrate correct use of all occupant-protection systems that may be available on the school bus, including use of car safety seats, seat belt systems, and occupant-protection systems that are used by children with special medical or health needs.

Children with conditions such as anaphylactic allergies, severe asthma, diabetes, attention-deficit/hyperactivity disorder, autism or pervasive developmental disorder, and other chronic conditions may have health and safety issues during transport to and from school and school-related events. For that reason, the following are important:

- Drivers should be included in school plans for children with special medical and transportation needs.
- School bus drivers need to be aware of and prepared to intervene appropriately to ensure the safety of the individual child as well as all children on the trip. Interventions may require training beyond basic first aid.

School Bus Passenger Instruction

Passengers of all ages need to be taught safe riding and pedestrian behavior regardless of the frequency of school bus use. Instruction should include safe pedestrian practices going to and from the bus stop; safe behavior while waiting for the bus; safe practices for boarding and dis-

embarking the bus; safe behavior on the bus, including the use of child-restraint systems and seat belts when present; and procedures for emergency situations. Escort services for children crossing streets and roads should be considered.[30]

School Bus Passenger Supervision

Adult supervision on school buses should focus on ensuring that passengers stay seated and use age-appropriate car safety seats, seat belts, and other occupant-protection systems; ensuring that passengers keep their arms and heads inside the windows; assisting in emergency circumstances; assisting passengers with special needs; and escorting children across roadways. A second adult (other than the driver) serving as a monitor on the school bus can best meet these objectives. The Transportation Research Board states that it is generally agreed that monitors would enhance safety and reduce injuries by 25% to 75%; however, the cost estimate is high ($1.9 billion).[4]

School Bus Routes and Stops

Bus routes should be planned so that the bus does not have to back up, traffic disruptions are minimized, good fields of vision are provided at all stops, and the need for children to cross a street to board or leave the bus is minimized.[4] Escorting children across streets has the greatest potential for injury reduction.[4] Roads, traffic flow, traffic-control devices, and speed-limit enforcement should be maintained to optimize the safety of children.

Bicyclist and Pedestrian Travel to and From School

The motor, cognitive, and behavioral characteristics and abilities and limitations of children of different ages must be considered when assessing supervision needs necessary for students walking to and from school. There is no evidence that generic pedestrian-safety education is effective in reducing pedestrian injury. Bicyclists should be required to wear bicycle helmets properly.[31] Children using nonmotorized vehicles for school and school-related trips should be required to use safety equipment, including helmets.[32] Bicycle helmet use laws and enforcement increase helmet use.[33] Driver education in school zones, including drivers who drop off and pick up students, must be addressed. Most drivers exceed speed limits in school zones.[34] Safe Routes to School, an international movement, promotes infrastructure, environmental measures, enforcement, policy change, and education to enhance and promote safe walking.[35]

School-Zone Improvements

School-zone improvements would enhance the safety of all schoolchildren whether they walk, bike, take the school bus, or are dropped off and picked up with a passenger vehicle. These measures include marked drop-off and pick-up areas that are separate from school buses, school-zone speed-limit enforcement at 25 miles/hour, development of safe routes to school, and well-trained adult crossing guards. Crossing guards have been effective in improving pedestrian safety and have improved speed compliance and traffic control.[36] The NHTSA issued guidelines for a uniform approach for traffic controls for school areas that were designed to enhance the safety of pedestrians. These guidelines further recommend that a school-route travel plan be developed systematically by school, law enforcement, and traffic officials.[37] A multidisciplinary approach, involving school administrators, parent-teacher organizations, city planners, and law enforcement that includes infrastructure design as well as education of both students and drivers, offers potential to decrease death and injury to children in school zones.[38]

The AAP recommends the implementation of measures to improve the environmental infrastructure, including student supervision and crossing guards.

The Pediatrician's Role

The pediatrician should promote school transportation safety at 4 levels: patient and family, community, state, and national. Pediatricians can serve as child advocates and consultants to child care and schools about transportation safety.

For school bus travel, the AAP emphasizes its long-standing position that seat belts be installed on all newly manufactured school buses. Three-point seat belts provide the best protection for school-aged children who have outgrown car safety seats.

Patient and Family Counseling

1. When addressing child passenger safety, inform families that the AAP has guidelines and policy statements for safe transportation of schoolchildren in school buses and other vehicles used for preschool, school, and child care transportation. In particular, inform parents that the AAP recommends that all children who travel in school buses use age- and size-appropriate child-restraint systems and 3-point seat belts when they have outgrown child-restraint systems. Pediatricians should nevertheless counsel parents that large school buses, even when not equipped with seat belts, are the safest mode of school transportation.
2. Inform patients and families about the importance of bicycle helmets and other safety measures for children riding bicycles.
3. Inform parents that teens traveling together, especially with a teen driver, to and from school and to school-related events are at high risk of crash involvement and injury.
4. Promote passage and parent and community enforcement of graduated driver licensing laws, which

reduce fatal crash involvement of 16-year-old drivers by 16% to 21%.[39,40]

Community Role

5. Serve as a consultant to local parent groups, transportation directors, or school boards on the physical, cognitive, and psychosocial development of children as related to school transportation. Provide AAP guidelines and policy statements related to school transportation and teen driving.
6. Provide resources for communities to address safe routes for children who walk or bike to school.
7. Promote mandatory requirements for children to use bicycle helmets.
8. Advocate implementation of the recommendations of applicable policy statements at local school district meetings. Advocate for school districts to enforce graduated driver licensing laws.
9. Work with communities to plan for the transportation of children in planning new school sites and modifying existing sites.
10. Advocate for 3-point seat belt systems in all newly manufactured school buses

State Role

11. Serve as a consultant to state directors of school transportation to ensure that children's needs and AAP guidelines are addressed in school transportation plans.
12. Advocate for mandatory bicycle helmet use laws and enforcement.
13. Share information from AAP policy statements.
14. Serve as a resource and consultant to the state department of education regarding training of bus drivers in areas relating to child passenger safety and child development and behavior.
15. Serve as a resource and consultant to the state department of education on pedestrian and bicycle safety for schoolchildren.

National Role

16. Encourage research to support continued improvement in school bus design and school-zone safety.
17. Advocate for mandated complete collection and reporting of data on fatalities and injuries by school districts and school bus transportation companies for all crash and noncrash events involving the school bus and multipurpose vehicles.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on School Health

School-Based Mental Health Services

ABSTRACT. More than 20% of children and adolescents have mental health problems. Health care professionals for children and adolescents must educate key stakeholders about the extent of these problems and work together with them to increase access to mental health resources. School-based programs offer the promise of improving access to diagnosis of and treatment for the mental health problems of children and adolescents. Pediatric health care professionals, educators, and mental health specialists should work in collaboration to develop and implement effective school-based mental health services. ***Pediatrics*** **2004;113:1839–1845;** ***school, mental health, school-based health center, SBHC, medical home, adolescent, prevention, intervention, confidentiality, assessment, referral, evaluation, school counselor, risk behavior, resilience, individualized education program, IEP, therapy, special education, special needs, curricular, managed care, emotional disorder.***

ABBREVIATIONS. SBHC, school-based health center; AAP, American Academy of Pediatrics; IEP, individualized education program.

"*The burden of suffering experienced by children with mental health needs and their families has created a health crisis in this country.*"[1]

David Satcher, MD, PhD

Pediatric health care professionals increasingly are becoming aware of the high level of mental health needs of children. School violence, high dropout rates, bullying, high suicide and homicide rates, and increased levels of high-risk behaviors are reported commonly across the United States. The human and economic toll of inadequately addressing these mental health problems is significant. Untreated mental health disorders lead to higher rates of juvenile incarcerations, school dropout, family dysfunction, drug abuse, and unemployment.

The proportion of pediatric patients in which psychosocial problems are seen in primary care has increased from 7% to 19% over the past 20 years.[2] According to the 2001 US Surgeon General's report on children's mental health,[1] 20% of children need active mental health interventions, 11% have significant functional impairment, and 5% have extreme functional impairment. These data were derived from the Methodology for Epidemiology of Mental Disorders in Children and Adolescents study, which also found that 13% of children and adolescents have anxiety disorders, 6.2% have mood disorders, 10.3% have disruptive disorders, and 2% have substance abuse disorders, for a total of 20.9% having 1 or more mental health disorders. The Great Smoky Mountain Study of Youth found that 27% of children 9, 11, and 13 years of age have mental health impairment and 20% have a diagnosable mental health condition. This study also found that only 21% of children with mental health problems receive mental health services.[3] Similarly, the Ontario Child Health Study found that only 20% of children with emotional disorders had received mental or social services during the 6 months before the survey despite existence of universal health insurance in Canada.[4] Mental health and substance abuse issues are the most common reasons for visits to school-based health centers (SBHCs).[5]

Another potential indicator of the mental health of our children and adolescents may be the prevalence of risk behaviors. In the 2001 Youth Risk Behavior Survey coordinated by the Centers for Disease Control and Prevention, 30% of youth reported episodic heavy drinking, 14% reported frequent cigarette use, 24% reported using marijuana within the last month, and 9% reported a suicide attempt during the past 12 months.[6] In the United States, suicide is the third leading cause of death in youth 10 to 19 years of age. Homicide is the fourth leading cause of death for children 5 to 14 years of age and the second leading cause of death for youth 15 to 19 years of age.[7]

Acknowledging that mental health needs are significant, physicians must identify and address the barriers to mental health services. A recent American Academy of Pediatrics (AAP) policy statement addressed insurance and managed care barriers.[8] Many families will not address their mental health needs if their health insurance does not offer adequate coverage. Additional barriers include lack of transportation, financial constraints, child mental health professional shortages, and stigmas related to mental health problems. These barriers may help to explain why 40% to 60% of families who begin therapy terminate prematurely[9] and why most people attend only 1 to 2 sessions before terminating services.[10] Another significant barrier is the paucity of training in medical school and primary care residency programs. Pediatricians often are professionally unprepared and usually have inadequate appointment

time to address the mental health needs of children and adolescents. As a result, pediatricians may not uncover significant mental health problems. The medical home model does not require that pediatricians personally provide all services required by the families and children that they treat. This can be accomplished through collaboration and coordination with other agencies, such as mental health agencies, or mental health services provided in schools. Pediatricians can enhance the medical home model by improving communication with schools on mental health concerns of their patients and can improve access to mental health services by encouraging and supporting school-based mental health services.

School-based mental health services are evolving as a strategy to address these concerns by removing barriers to accessing mental health services and improving coordination of those services. School-based mental health services offer the potential for prevention efforts as well as intervention strategies. More than 75% of pediatricians support the provision of psychological and counseling services in schools, which include assessments, interventions, and referrals.[11] Schools are the primary providers of mental health services for many children.[3,12,13] School-based mental health services range from minimal support services provided by a school counselor to a comprehensive, integrated program of prevention, identification, and treatment within a school. In some schools, comprehensive mental health services are provided in an SBHC. There are now more than 1300 SBHCs, with most providing mental health services.[14]

SCHOOL-BASED MENTAL HEALTH SERVICES

One way to categorize components of a school or district's mental health program is to consider a 3-tiered model of services and needs. The first tier is an array of preventive mental health programs and services. Activities in this tier need to be ubiquitous so that they target all children in all school settings. Preventive programs are those that focus on decreasing risk factors and building resilience, including providing a positive, friendly, and open social environment at school and ensuring that each student has access to community and family supports that are associated with healthy emotional development. A sense of student "connectedness" to schools has been found to have positive effects on academic achievement and to decrease risky behaviors.[15] For example, schools should provide students with multiple and varied curricular and extracurricular activities, thereby increasing the chances that each student will feel successful in some aspect of school life. Schools also should provide numerous opportunities for positive individual interactions with adults at school so that each student has positive adult role models and opportunities to develop a healthy adult relationship outside his or her family. Schools can provide families with support services and should implement "prevention" curricula (eg, curricula that decrease risk-taking behaviors). Behavioral expectations, rules, and discipline plans should be well publicized and enforced school-wide. A recent review of effective programs is available for schools and those who advise schools on development of their preventive programs.[16]

The second tier consists of targeted mental health services that are designed to assist students who have 1 or more identified mental health needs but who function well enough to engage successfully in many social, academic, and other daily activities. Services in this tier would include the provision of group or individual therapy to students. For students in special education for learning problems who also have behavioral problems, this tier also may consist of the behavioral components of these students' individualized education programs (IEPs) or individual health service plans that address these students' behavioral issues.

The third tier of health services targets the smallest population of students and addresses needs of children with severe mental health diagnoses and symptoms. These students require the services of a multidisciplinary team of professionals, usually including special education services, individual and family therapy, pharmacotherapy, and school and social agency coordination.[17]

Outcome studies on school-based mental health models are limited, as are outcome studies on typical delivery methods of outpatient mental health services. The Bridges Project is a model that uses the 3-tiered model in schools and has demonstrated positive outcomes with improved school attendance, improved school grades, and improved scores on the Child Behavior Checklist and the Behavior and Emotional Rating Scale.[18]

Preventive Strategies

As they develop the first tier of services (a comprehensive mental health prevention program), each school and district should involve school nurses; pediatricians and other primary care physicians; mental health, social services, and other community agencies; and parents. The program should include: 1) multiple opportunities for students to build developmental assets and resilience to other stresses[19]; 2) behavior and discipline plans; and 3) mental health curricula (eg, violence prevention[20]) that are incorporated into other health education curricula (refer to Fig 1 for a visual description of these tiers of mental health in schools).

Behavior and discipline plans should be schoolwide and provide clear and consistent behavior expectations and consequences. School staff training should teach educators, administrators, and support staff specific fundamentals: 1) building a supportive school environment; 2) the essential components of behavior management techniques; and 3) early recognition of mental health problems. Many schools have prepared teachers, school nurses, and other staff members successfully to volunteer in student assistance programs, whereby these staff members lead after-school support groups designed to help students express themselves to their peers and adults within a safe, comfortable environment.

Schools should have multidisciplinary student-support teams that include school nurses, school

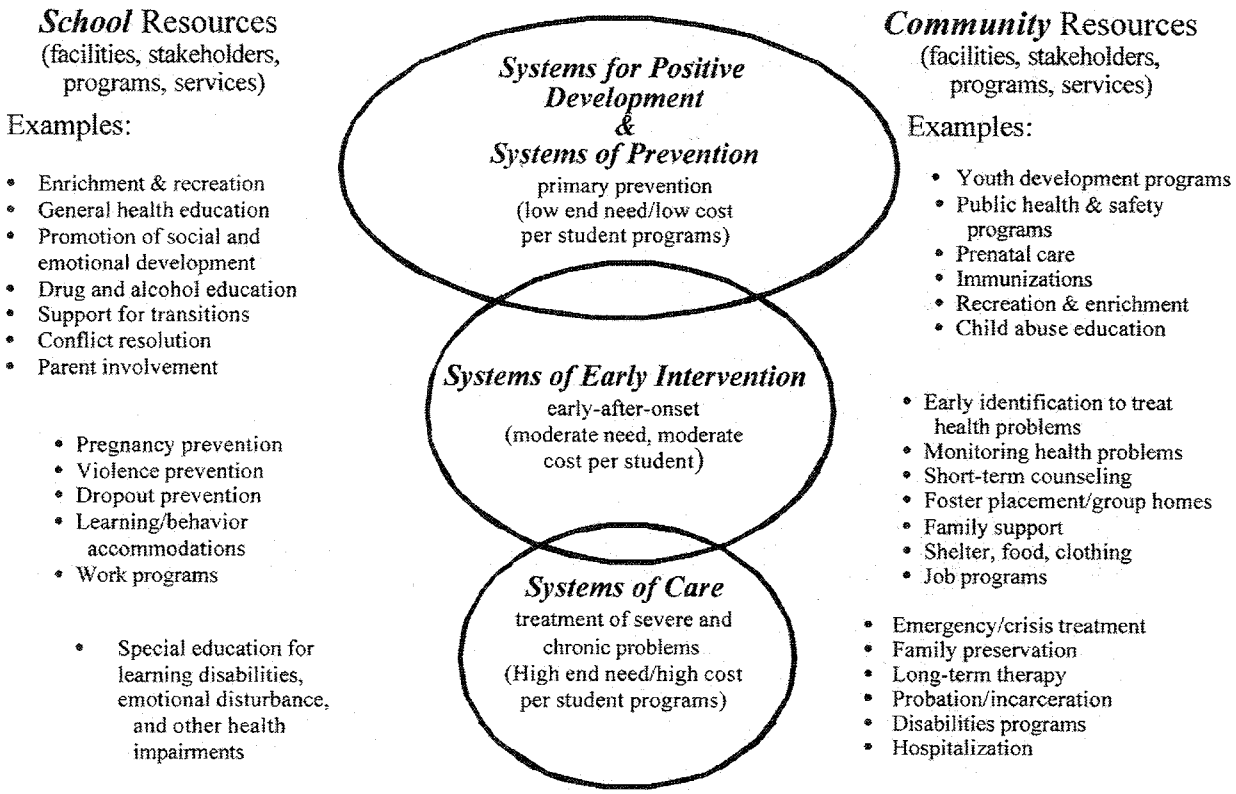

Fig 1. A comprehensive, multifaceted, and integrated approach to addressing barriers to learning and promoting healthy development. Adapted from various public domain documents written by H.S. Adelman and L. Taylor and circulated through the Center for Mental Health in Schools at the University of California (Los Angeles).

personnel, mental health consultants, and school physicians to review and plan evaluations and intervention strategies for students experiencing problems at school or otherwise identified as having potential mental health problems.

Schools can develop relationships with agencies that assist them with external stressors for students, including but not limited to housing, nutrition, clothing, employment, safety in their neighborhood, and after-school care. Support services for families can be established through the development of collaborative relationships with family resource centers. Other social agencies, public health departments, and providers of community-based services are also important partners.

Advantages of Basing Mental Health Services at School

Unlike preventive mental health services and those related to special education, the provision of other mental health services such as individual, group, or family counseling is optional for schools, yet many schools realize the value of helping families meet mental health needs and recognize distinct advantages to providing these services within the school system. One advantage of the familiar setting of school for provision of mental health services is that students and families avoid the stigma and intimidation they may feel when they go to an unfamiliar and perhaps less culturally compatible mental health settings. Of course, receiving services at school may put students at risk of another form of stigmatization, that is, stigmatization by their peers. This issue must be addressed on both a programmatic level (eg, discretion, strategic scheduling of appointments, private waiting areas) and individually with each student receiving services. Providing school-based mental health services eliminates the need for transportation of students to and from off-site appointments and facilitates parent participation in mental health appointments, because many parents live within walking distance of neighborhood schools. These advantages may encourage more parents to seek mental health care for their children and more students to self-refer for treatment. Kaplan et al[21] showed that adolescents with access to SBHCs with mental health services were 10 times more likely than students without such access to initiate a visit for a mental health or substance abuse concern (98% of such visits were at an SBHC). The convenience and comfort of having school-based mental health services also may promote a longer-lasting commitment to following through with all recommended therapy.

In addition to eliminating barriers to access to care, school-based mental health services offer the potential to improve accuracy of diagnosis as well as assessment of progress. One of the major challenges to providing mental health services to students is gaining access to information concerning the functionality of the student in various environments. Schools have a wealth of opportunities to acquire information on how children deal with physical and social stresses and challenges and on how they perform in the academic setting, on community-related roles in

which children engage (eg, in sports, with younger children as a mentor, etc), and on the nature and extent of many sorts of interpersonal relationships (eg, adults, peers).

Mental Health Service Delivery Models

Schools have a convoluted history of involvement in mental health since the late 1890s, when psychology clinics were placed in some schools in Philadelphia, Pennsylvania.[22] Today, some schools have mental health curricula and offer students the services of a wide array of social and mental health professionals, including social workers; guidance counselors; school psychologists; mental health therapists providing group, child, and/or family therapy; and mental health units within SBHCs. These services may be provided by schools or public or private mental health professionals or agencies. The following 3 models are not mutually exclusive. Many schools offer components of more than 1 of these models.

1. School-supported mental health models
   - Social workers, guidance counselors, and school psychologists are employed directly by the school system.
   - Separate mental health units exist within the school system.
   - School nurses serve as a major portal of entry for students with mental health concerns.
2. Community connections models
   - A mental health agency or individual delivers direct services in the school part-time or full-time under contract.
   - Mental health professionals are available within an SBHC or are invited into after-school programs.
   - There is a formal linkage to an off-site mental health professional and/or to a managed care organization.
3. Comprehensive, integrated models
   - A comprehensive and integrated mental health program addresses prevention strategies, school environment, screening, referral, special education, and family and community issues and delivers direct mental health services.
   - SBHCs provide comprehensive and integrated health and mental health services within the school environment.

A recent pilot study[23] on cost of care reported that school-based mental health services were less expensive than private or community-based mental health services. Therefore, cost of providing mental health services at school, versus traditional settings, should not be an inhibiting factor for health insurers (private or Medicaid) and managed care organizations that are already resolved to providing these services somewhere.

Currently, there is great diversity in the scope of mental health services delivered in the school setting. Unfortunately, there is no comprehensive report available on the extent of mental health services offered in schools across the country. Although some schools may not offer any clearly defined mental health programs, most of them offer at least a school guidance counselor. Some schools have specific mental health programs offered on campus through local mental health agencies (multiprofessional groups, outpatient clinics of hospitals, agencies that provide mental health services under Medicaid), local mental health professionals, or arrangements with managed care organizations. Other schools have mental health programs through an SBHC. In a survey of SBHCs performed by Making the Grade,[14] 25% of visits to SBHCs were for mental health reasons. Almost 60% of all SBHCs offer mental health services, averaging 33 hours per week of coverage by a mental health professional.[14]

SPECIAL EDUCATION AND MENTAL HEALTH SERVICES

When providing a mental health service is an integral part of the child's education, the mental health service is mandated by law to be provided by schools. Severe conduct disorders, psychoses, and severe emotional problems are examples of mental health disorders that often impede the student's ability to be educated in a general education program. Rarely, when attention-deficit disorders are not readily treated by medications and the severity precludes students from benefiting from even a modified regular educational program and environment, students with this disorder are placed in a special education program. Services for students with these diagnoses who qualify for special education on the basis of their mental health status may include provision of classrooms with a high teacher-to-student ratio, special education teachers who have been trained to deal with disordered conduct and emotional problems, availability of child psychiatrists and/or psychologists who can help teachers troubleshoot difficult situations, IEPs that include detailed behavior management plans, and ability of the school to deliver multiple medications and monitor the benefits and adverse effects of these medications at school. These services may be provided in either separate or integrated schools. Often, these students attend their neighborhood school but are placed in special classrooms. Other students can be completely integrated with regular education students. Some schools or classrooms operate as day-treatment programs, but they are located on school campuses and have an educational component. As with other services, mental health services provided as part of a student's IEP should allow the student to be in the least restrictive school setting, have clear goals and objectives that are individualized to each student's particular needs, have well-outlined activities that are specifically designed to meet educational program goals, and have designated personnel to carry out the activities. If the school provides transportation to school or school-sponsored extracurricular activities or field trips, accommodations need to be considered so that students do not miss mental health appointments and yet can participate to the fullest extent possible in extracurricular activities. Many of the services that schools provide to these students may be reimbursed through Medicaid pro-

grams for students who are eligible for and enrolled in Medicaid.

CHALLENGES IN SCHOOL-BASED MENTAL HEALTH PROGRAMS

Several challenges exist in school-based mental health care. First, services must be coordinated with the medical home (usually this will be a primary care physician), mental health professionals, and social agencies. Otherwise, services may be duplicated or crucial patient needs may be overlooked. Second, services must be integrated within the school environment so that school personnel view the mental health services as an integral part of the educational system. Integration necessitates gaining the support of the school administration and staff, obtaining confidential space, working with school schedules to minimize missed class time, and avoiding turf issues. Third, because parents are a vital element in mental health treatment for children, creative strategies must be devised to solicit parental involvement in school-based intervention services, not merely parental consent. Finally, because confidentiality of mental health information is mandated by law, a well-defined system must be developed. There must be written, informed consent that is designed to protect confidential information but allow sharing of information that pertains to a student's education and socialization at school or that needs to be shared to ensure the safety of students and staff. School staff members must understand and honor confidentiality, and students and parents should be encouraged to allow sharing of information that would improve the student's success at school. Breaking confidentiality should never be taken lightly but would be necessary when a student is thought to be likely to harm himself or herself or others. Without these confidentiality policies, students and their parents will not trust the mental health care system and may undermine the intent of the services. Specific issues regarding adolescent confidentiality are discussed in the AAP policy statement "Confidentiality in Adolescent Health Care."[24]

School staff members and mental health professionals need to be sensitive to the appropriateness of dealing with certain health issues. It may be determined, for example, that for certain students who are victims of sexual abuse, services are more confidentially provided at a site off the school campus.

Screening for mental health illness differs significantly from early identification of mental illness. A screening program, for example, might evaluate all students in a 6th-grade class for mental illness, whereas an early-identification program would educate staff to recognize early signs and symptoms of illness. Many screening tools have been established for mental health and have been shown to be effective when used in physicians' offices. There is not any scientific evidence yet to support performing school-based screening programs using these tools.

RECOMMENDATIONS FOR SCHOOLS

1. The mental health program (preventive strategies and mental health services) should be coordinated with educational programs and other school-based health services. School social workers, guidance counselors, school psychologists, school nurses, and all mental health therapists should plan preventive and intervention strategies together with school administrators and teachers as well as with families and community members.
2. Preventive mental health programs should be developed that include a healthy social environment, clear rules, and expectations that are well publicized. Staff members should be trained to recognize stresses that may lead to mental health problems as well as early signs of mental illness and refer these students to trained professionals within the school setting.
3. Mental health referrals (within the school system as well as to community-based professionals and agencies) should be coordinated by using written protocols, should be monitored for adherence, and should be evaluated for effectiveness.
4. School-based specific diagnostic screenings, such as for depression, should be implemented at school only if they have been supported by peer-reviewed evidence of their effectiveness in that setting.
5. Roles of all the various mental health professionals who work on campus with students should be defined so that they are understood by students, families, all school staff members, and the mental health professionals themselves.
6. Group, individual, and family therapies should be included as schools arrange for direct services to be provided at school sites. Alternatively, referral systems should be available for each of these modes of therapy so that students and families receive the mode of therapy most appropriate to their needs.
7. It should be documented that mental health professionals providing services on site in school (whether hired, contracted, or invited to school sites to provide services) have training specifically in child and adolescent mental health (appropriate for students' ages) and are competent to provide mental health services in the school setting.
8. Private, confidential, and comfortable physical space should be provided at the school site. Often, this is not difficult for schools if mental health services are provided after school hours. Having school-based services should not preclude the opportunity for mental health services to be provided at nonschool sites for situations in which therapy at school for a student may be ill advised (eg, a student who feels uncomfortable discussing a history of sexual abuse at the school setting). During extended school breaks, schools must provide continued access to mental health services.
9. Staff members should be provided with opportunities to consult with a child psychiatrist or clinical psychologist (on or off the school site) so that they may explore specific difficult situations or student behaviors and review school policies,

programs, and protocols related to mental health.
10. Quality-assurance strategies should be developed for mental health services provided at school, and all aspects of the school health program should be evaluated, including satisfaction of the parent, student, third-party payers, and mental health professionals.
11. Confidentiality of health information should be maintained, as mandated by law.

RECOMMENDATIONS FOR PEDIATRICIANS AND OTHER PROVIDERS OF PRIMARY CARE FOR CHILDREN AND ADOLESCENTS

The following recommendations are targeted to individual pediatricians and/or groups of physicians such as local chapters of the AAP:

1. An ecologic view of mental health should be taken, and support structures should be built not just for individual patients but also for the community. Pediatricians should advocate for schools to develop comprehensive mental health programs with a strong preventive component that focuses on building strengths and resilience, not just on problems, and that involves students' families.
2. Pediatricians should develop a relationship with local schools, serve on school health advisory councils, and promote school-based mental health services (as outlined in "Recommendations for Schools").
3. Management of one's own patients with mental health problems should be coordinated with school-based mental health professionals.
4. Mental health services should be included in IEPs for patients enrolled in a special education program.
5. Pediatricians should advocate for financial and institutional changes that are likely to provide medical homes and families with the option of access to mental health services through school settings, such as coverage of school-based mental health services by health insurers and school billing of Medicaid for school-based mental health services payable under this program.
6. Pediatricians should work with schools to help identify strategies and community resources that will augment school-based mental health programs.
7. Outcomes-based research should be performed on the effectiveness of various school-based mental health models that are designed to improve psychosocial and academic outcomes.
8. Pediatricians, through enhanced collaboration and communication with school mental health service professionals, can strengthen the medical-home model and improve the mental health of their patients.

abstract

FREE

The optimal health of all children is best achieved with access to appropriate and comprehensive health care benefits. This policy statement outlines and defines the recommended set of health insurance benefits for children through age 26. The American Academy of Pediatrics developed a set of recommendations concerning preventive care services for children, adolescents, and young adults. These recommendations are compiled in the publication *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* third edition. The Bright Futures recommendations were referenced as a standard for access and design of age-appropriate health insurance benefits for infants, children, adolescents, and young adults in the Patient Protection and Affordable Care Act of 2010 (Pub L No. 114–148). *Pediatrics* 2012;129:1–5

This policy statement sets forth recommendations for the design of a comprehensive benefit package that covers infants, children, adolescents, and young adults through age 26 and is consistent with the Maternal and Child Health Plan Benefit Model: Evidence-Informed Coverage.[1] These benefit recommendations apply to all public and private health plans. The services outlined in this statement encompass medical care, preventive care, critical care, pediatric surgical care, behavioral health services, and oral health for all children, including those with special health care needs.

That payment schedules must cover the fixed and variable costs of providing the services is implied in the identification of services and products necessary to ensure the health of children. In addition, payments should be adequate so that physicians, pediatric service providers, and manufacturers will have continued incentive to remain in (or enter into) the business of caring for the health and developmental needs of children. Because of the variety and complexity of systems for delivering care and for providing payments, a complete discussion is beyond the scope of this statement; however, without adequate payment there is significant risk that children and families will be unable to access services and products needed to maintain and promote health in children. This risk is compounded by the recognition that health in adulthood is predicted by health in childhood. It is critical to stress that adequate payment for the provision of child health care services is a vital investment in life span health.

This statement replaces the 2006 statement "Scope of Health Care Benefits for Children from Birth Through Age 21."[2]

ESSENTIAL BACKGROUND

All infants, children, adolescents, and young adults through 26 years of age must have access to comprehensive health care benefits to ensure their optimal health and well-being. These benefits must be available through Medicaid, the Children's Health Insurance Program (CHIP), and private health insurance plans, whether the plan sponsor is a commercial insurance company, a self-funded employer, or other arrangement. The Patient Protection and Affordable Care Act of 2010 (Pub L No. 111-148) also mandated the establishment of health insurance exchanges, wherein health plans must provide a minimum set of health benefits. The minimum health benefits for pediatrics include essential services, such as preventive care, hospitalization, ambulatory patient services, emergency medical services, maternity and newborn care, and mental health and substance abuse disorder services. Also included in the set of benefits are behavioral health, rehabilitative, and habilitative services and devices; laboratory services; chronic disease management; and oral, hearing, and vision care. Some of these benefits may be available or provided through the educational and public health systems for children with special needs and children who are uninsured or have inadequate coverage.

Health care benefits should begin with the full array of services recommended by the American Academy of Pediatrics (AAP). Coverage determinations of existing interventions should be based on evidence of usefulness and understanding of risks. Health care benefit coverage should reflect changes in treatment modalities and should adapt to new evidence and changes in standards of care, as well as innovations in care. Recognizing the importance of scientific evidence does not mean that coverage of existing interventions should be denied in the absence of conclusive scientific evidence. If sufficient scientific evidence for an intervention is not available, professional standards of care must be considered. If professional standards of care do not exist or are outdated or contradictory, decisions about existing interventions must be based on consensus pediatric expert opinion (according to the AAP working definition in "Model Contractual Language for Medical Necessity for Children").[3] The benefits should be delivered in an efficient manner by appropriately trained professionals, including primary care pediatricians and other generalists, pediatric medical subspecialists, pediatric surgical specialists, and pediatric dental professionals. These services should be delivered and coordinated in a comprehensive, patient- and family-centered, physician-led medical home—the setting for primary care delivered or directed by well-trained physicians who are known to the child and family, who have developed a partnership of mutual responsibility and trust with them, and who provide accessible, continuous, coordinated, and comprehensive care. These services should include but are not limited to the following broad categories: preventive services; physician/health care provider services; emergency care; hospitalization and other facility-based care; therapeutic services/durable medical equipment/ancillary services; and laboratory, diagnostic, assessment, and testing services.

PREVENTIVE SERVICES

Preventive services primarily assess risk factors for, or prevent the development of, medical conditions or developmental disorders that affect health or development. Preventive services include the following:

A. Health supervision with comprehensive preventive care, according to the AAP "Recommendations for Preventive Pediatric Health Care,"[4] and *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*.[5]
B. Immunizations according to recommendations included in the most current version of the "Recommended Childhood and Adolescent Immunization Schedules."[6]
C. Educational, counseling, and support services for all children, including but not limited to the following:
    1. Anticipatory guidance relating to normal growth and development;
    2. Tobacco-cessation counseling and treatment services for children and/or household contacts; and
    3. Services related to the maintenance of a healthy weight—prevention, management, and treatment of pediatric obesity, malnutrition, eating disorders, or nutritional deficiency, including nutrition counseling and follow-up with physician or credentialed nutritionist and all necessary laboratory services, including evaluation of risk factors.
D. Preventive pediatric oral health services, including the following:
    1. Oral health risk assessment, fluoride varnish, sealants, and similar preventive oral care;
    2. Provision of anticipatory guidance examinations and/or diagnostic investigations; and
    3. Oral surgery, including moderate sedation and general anesthesia services, as indicated, to treat oral health problems.
E. Early intervention services for mental health/substance abuse.
F. Preventive vision services, including screenings and examinations by individuals trained in the care of children for the purpose of

early identification of vision problems.

G. Preventive audiology services, including screening and evaluations by professionals trained in the care of children to provide early detection and diagnosis of hearing problems. These services include newborn and other age-appropriate hearing screenings.

H. Preventive reproductive health services, including coverage for counseling and education to promote healthy choices regarding sexuality, as well as appropriate and effective means of minimizing risks of sexually transmitted diseases and preventing unintended pregnancy. Coverage should also be provided for transition of care to other specialists for treatment of pregnancy in young women or appropriate specialists for children with sexually transmitted diseases for whom treatment is beyond the scope of usual pediatric care.

I. Preventive prenatal care, including prenatal consultation with a pediatrician, as well as counseling and services for all pregnancy and fetal management options, including evaluation of psychological risk factors that may affect the health and safety of the infant or family.

J. Preventive postpartum care, including the following:
   1. Newborn screening for metabolic and genetic disorders, as well as hearing screening and other appropriate tests;
   2. Prompt follow-up visit in the physician's office (as in between 48 and 72 hours following discharge) when indicated by the infant's condition and/or on the recommendation of the infant's physician;
   3. Lactation counseling to increase successful breastfeeding initiation and duration; and
   4. A reasonable length of stay for the newborn infant to permit identification and treatment of early problems and to ensure that the family is able and prepared to care for the infant at home.

PHYSICIAN/HEALTH CARE PROVIDER SERVICES

Physician/health care provider services are delivered (1) in the primary care/medical home setting, (2) by a medical subspecialist or surgical specialist in coordination with the child's primary care physician, or (3) under the direction of the primary care physician in the patient's home or other setting. These services are directed toward diagnosis, appropriate treatment, rehabilitation, or palliative care of diseases and congenital or acquired health conditions. Physician/health care provider services include the following:

A. Diagnosis and treatment of medical conditions.

B. Educational counseling and support services for all children (see also the previous section on preventive services).

C. Transition to adult medical care services for youth.

D. Palliative and hospice care for children with serious or life-threatening conditions.

E. Pediatric medical subspecialty services, including team subspecialty care, family planning, and reproductive services.

F. Pediatric surgical care, including the following:
   1. Pediatric surgical care and surgical specialty services, including comprehensive repair of congenital anatomic malformations; and
   2. Anesthesia and acute and chronic pain management services provided by clinicians with training and expertise in special considerations of pediatric anesthesia care.

G. Behavioral health services, including the following:
   1. Mental health services, including (a) diagnostic evaluation and care planning/coordination services; (b) age-appropriate counseling interventions, including individual, group, or family therapy; family-child interaction training; and behavioral therapy training; (c) psycho-educational testing; (d) crisis management; (e) inpatient and day treatment; and (f) residential care. These services should be covered for behavioral and mental health problems that occur in childhood, impair child or family function, threaten the future health of the child, or impair social relationships and/or academic success.
   2. Services for disorders relating to substance use, abuse, and dependence, including (a) screening, early intervention, and crisis management; (b) appropriate treatment interventions; (c) inpatient and outpatient treatment; and (d) residential care.
   3. Comprehensive medical and psychological evaluation, treatment, and care coordination for suspected or substantiated child physical, emotional, or sexual abuse and/or neglect in both inpatient and outpatient settings.
   4. Individual and family grief and bereavement counseling.

H. Prenatal and neonatal services, including the following:
   1. Genetic counseling and related services, as indicated;

2. Prenatal case management, including consultation with a pediatrician;
3. Care in response to complications resulting from problems during pregnancy, labor, or delivery;
4. Care of all newborn infants, including the following:

a. attendance of a pediatric- or neonatology-trained provider for management of high-risk deliveries or where mandated by hospital regulations;
b. health supervision;
c. treatment of congenital anomalies and other medical and surgical conditions; and
d. newborn intensive care services.

I. Physician-directed, accurate pediatric medical information shared by telephone, telemedicine, e-mail, and/or other Internet services for established and new patients related to pediatric care. This information may include responses to patient or family questions, or may consist of outreach to specific patients relating information deemed important to their health, which may not merit the need for an office visit intervention. These communications should be compliant with regulations of the Health Insurance Portability and Accountability Act of 1996 (HIPAA [Pub L No. 104-191]).

J. Home health care services, where appropriate.

K. Coverage of medical home– or physician-based care coordination and/or case management services (case management may be provided by a case manager or other qualified health care provider working collaboratively with the patient's family and health care team to develop, monitor, and revise a plan to meet the patient's immediate and ongoing health care needs; all children with special health care needs and women with high-risk pregnancies should have access to and coverage for case-management services), including arrangement, coordination, sharing of information among care providers, and monitoring of health care and developmental services to meet the needs of a patient and his or her family.[7]

EMERGENCY CARE, HOSPITALIZATIONS, AND OTHER FACILITY-BASED CARE

These services address acute health care needs, ongoing illness, health or developmental conditions, or injury.

A. Emergency medical and trauma services specifically for children. These services should be covered without regard to preferred provider networks or preferred facility designations, if facility selection is involuntary.

B. Inpatient hospital and critical care services, including labor and delivery/birth center services, acute care, psychiatric care, inpatient rehabilitation, and substance abuse services.

C. Intermediate or skilled nursing facility care in residential and rehabilitative/habilitative settings.

D. Telemedicine services for emergency departments or inpatient facilities that do not have pediatric coverage for critically ill children.

E. Emergent and nonemergent transfer/transport to a hospital or health facility, between health facilities, and between home and health facilities when indicated.

THERAPEUTIC SERVICES/DURABLE EQUIPMENT/ANCILLARY SERVICES

These include specialty services performed in the health care provider's office or delivered in the patient's home or a health care facility, as well as products needed for maintenance of health or treatment of disease.

A. Coverage for medications, biologics, or other compounds included in the US Pharmacopeia with evidence of safety and effectiveness for the treatment of specific conditions.

B. Pediatric oral health services, including the following:
1. Restorative pediatric dental care, including oral surgery with appropriate sedation or anesthesia as needed to correct dental or oral health problems; and
2. Orthodontic services and appliances to correct problems with tooth and jaw alignment that contribute to other medical conditions.

C. Vision services, including corrective lenses, surgery, or other treatments by professionals trained in the care of children, and access to pediatric ophthalmologists for treatment of medical conditions of the eye.

D. Corrective audiology and speech therapy services, delivered by those trained in the care of children. These services include assistive technology (hearing aids, cochlear implants, and so forth) and speech therapy services for children with speech delay.

E. Nutritional evaluation and counseling services by pediatricians, dietitians, nutritionists, and other therapists for eating disorders (including primary obesity, anorexia, and bulimia) and specific nutritional deficiencies.

F. Special diets, infant formulas, nutritional supplements, and delivery (feeding) devices for nutritional

support and disease-specific metabolic needs.

G. Physical, occupational, speech (including speech-generating devices), and respiratory therapy for rehabilitation and habilitation provided in medical centers, private/public-sector offices, schools, residential settings, and the home.

H. Home health care services, including but not limited to physician supervision of care, therapies, private-duty nursing, and home health aides.

I. Rehabilitative and habilitative services and devices.

J. Rental, purchase, maintenance, and service of durable medical equipment, including but not limited to the following:
   1. Equipment necessary to administer aerosolized medications and monitor their effects (nebulizer, spacers for inhalers, peak flow meters);
   2. Glucometers, insulin pumps, and enteral nutrition pumps;
   3. Breast pumps and accessories;
   4. Prostheses/braces, wheelchairs, lifts, and other mobility aids;
   5. Ventilators, positive airway pressure devices, and other pulmonary treatment and monitoring equipment;
   6. Cardiorespiratory monitors, such as pulse oximeters or apnea monitors;
   7. Home dialysis equipment;
   8. Automated home blood pressure monitors; and
   9. Equipment for home-based treatment of newborn jaundice.

K. Disposable medical supplies, including but not limited to the following:
   1. Diapers for developmentally compromised patients;
   2. Urine catheters and ostomy supplies;
   3. Tracheostomy care needs, suction catheters for managing pulmonary secretions, and other tubing and/or mask needs;
   4. Tubing for delivering intravenous or enteral fluids; and
   5. Test strips, lancets, syringes, needles, insulin pump supplies, and other diabetic supplies.

L. Respite services for caregivers of children with special health care needs.

LABORATORY, DIAGNOSTIC, ASSESSMENT, AND TESTING SERVICES

These include services that determine the risk, presence, severity, prognosis, or cause of an illness or testing for diagnosing a specific illness, injury, or disability.

A. Laboratory and pathology services.

B. Diagnostic, assessment, and therapeutic services, such as radiology services, and including age-appropriate sedation as needed.

C. Standardized assessment and monitoring tools for identification, diagnosis, and monitoring of educational, developmental, behavioral, and mental health conditions.

Article abstract—Autism is a common disorder of childhood, affecting 1 in 500 children. Yet, it often remains unrecognized and undiagnosed until or after late preschool age because appropriate tools for routine developmental screening and screening specifically for autism have not been available. Early identification of children with autism and intensive, early intervention during the toddler and preschool years improves outcome for most young children with autism. This practice parameter reviews the available empirical evidence and gives specific recommendations for the identification of children with autism. This approach requires a dual process: 1) routine developmental surveillance and screening specifically for autism to be performed on all children to first identify those at risk for any type of atypical development, and to identify those specifically at risk for autism; and 2) to diagnose and evaluate autism, to differentiate autism from other developmental disorders.

Figure. Practice parameter algorithm.

Autism, autistic spectrum, and pervasive developmental disorders encompass a wide continuum of associated cognitive and neurobehavioral disorders, including the core-defining features of impaired socialization, impaired verbal and nonverbal communication, and restricted and repetitive patterns of behavior (table).[1] Between 60,000 and 115,000 children under 15 years of age in the United States meet diagnostic criteria for autism based on recent prevalence estimates of 10 to 20 cases per 10,000 people. In 1,300 families recently surveyed, the average age at diagnosis of autism was about 6 years, despite the fact that most parents felt something was wrong by 18 months of age and usually sought medical assistance by age 2 years.[2] Fewer than 10% of the children were diagnosed at initial presentation; another 10% were either told to return if their worries persisted, or that their child "would grow out of it." The rest were referred to another professional (at a mean age of 40 months), of which only 40% were given a formal diagnosis, 25% were told "not to worry," and 25% were referred to a third or fourth professional. Almost 20% reported that they either had to exert considerable pressure to obtain the referrals or pay privately. Over 30% of parents referred to subsequent professionals reported that no help was offered (e.g., with education, therapy, or referrals to parent support groups), and only about 10% reported that a professional explained their child's problems. Almost half of the families reported that the school system and other parents were the major source of assistance over time, rather than the medical health care community.

The diagnosis of autism often is not made until 2 to 3 years after symptoms are recognized, primarily because of concerns about labeling or incorrectly diagnosing the child. Identifying children with autism and initiating intensive, early intervention during the preschool years results in improved outcomes for most young children with autism.[3-7] Early diagnosis of autism and early intervention facilitates earlier educational planning, provisions for family supports and education, management of family stress and anguish, and delivery of appropriate medical care and treatment.[3-7]

Clinically identifying children with autism requires two levels of investigation, each addressing a distinct component of patient management (figure).[1] The first level, *Routine Developmental Surveillance and Screening Specifically for Autism*, should be performed on all children and involves first identifying those at risk for any type of atypical development, followed by identifying those specifically at risk for autism. Mental retardation or other medical or neurodevelopmental conditions require separate evaluations and are not within the scope of this document.

The second level, *Diagnosis and Evaluation of Autism*, involves a more in-depth investigation of already identified children and differentiates autism from other developmental disorders. In-depth diagnosis and

Table *Diagnostic Criteria for 299.00 Autistic Disorder*

A. A total of six (or more) items from (1), (2), and (3), with two from (1), and at least one each from (2) and (3):

1. Qualitative impairment in social interaction, manifest by at least two of the following:
   - Marked impairment in the use of multiple nonverbal behaviors, such as eye-to-eye gaze, facial expression, body postures, and gestures, to regulate social interaction
   - Failure to develop peer relationships appropriate to developmental level
   - Lack of spontaneous seeking to share enjoyment, interests, or achievements with other people (e.g., by lack of showing, bringing, or pointing out objects of interest)
   - Lack of social or emotional reciprocity
2. Qualitative impairment in communication, as manifest by at least one of the following:
   - Delay in, or total lack of, the development of spoken language (not accompanied by an attempt to compensate through alternative modes of communication such as gesture or mime)
   - In individuals with adequate speech, marked impairment in the ability to initiate or sustain a conversation with others
   - Stereotyped and repetitive use of language, or idiosyncratic language
   - Lack of varied, spontaneous make-believe, or social imitative play appropriate to developmental level
3. Restrictive repetitive and stereotypic patterns of behavior, interests, and activities, as manifested by at least one of the following:
   - Encompassing preoccupation with one or more stereotyped and restricted patterns of interest that is abnormal either in intensity or focus
   - Apparently inflexible adherence to specific nonfunctional routines or rituals
   - Stereotyped and repetitive motor mannerisms (e.g., hand or finger flapping or twisting, or complex whole-body movements)
   - Persistent preoccupation with parts of objects.

B. Delays or abnormal functioning in at least one of the following areas, with onset prior to age 3 years:

1. Social interaction
2. Language as used in social communication
3. Symbolic or imaginative play

C. The disturbance is not better accounted for by Rett's disorder or childhood disintegrative disorder.

The other pervasive developmental disorders include Asperger's disorder, Rett syndrome, childhood disintegrative disorder, pervasive developmental disorder—not otherwise specified (PDD-NOS), or atypical autism.

Detailed information on other PDD diagnoses can be found in the comprehensive background paper.[1]

evaluation are important in determining optimal interventional strategies based on the child's profile of strengths and weaknesses. For these two areas of investigation, specific clinical questions were defined (see Appendix 2), clinical evidence was summarized, and diagnostic recommendations were developed.

Evidence and recommendations are presented in three sections. The first two sections, *Level One: Routine Developmental Surveillance and Screening Specifically for Autism,* and *Level Two: Diagnosis and Evaluation of Autism,* first present the empiric data for each question and are followed by recommendations linked to the specific evidence. Each is followed by a section on *Recommendations for Research.* The third section, *Consensus-Based General Principles of Management*, presents additional recommendations based on broad consensus. Additional information about autism, including behavioral aspects associated with the core defining deficits, methodology, and clinical evidence are described in the background paper.[1] Specific information about the recommended developmental screening and diagnostic tools can be found at *http://www.aan.com* under *AAN Resources: Practice Statements: Official AAN Practice Statements: Autism, Screening and diagnosis of.*

Description of the process. Experts in the surveillance/screening and diagnosis of autism were selected by 11 professional organizations (see Appendix 1) and convened in June 1998 and January 1999. They reviewed and evaluated the quality of the evidence from the published literature, developed a consensus of evidence-based management recommendations, and published a comprehensive background paper on the surveillance, screening, and diagnosis of autism.[1] Evidence reviewed for this parameter was identified through literature searches using MEDLINE and PsychINFO. Relevant articles were included from all languages using the following search terms: autistic; OR autism; OR pervasive, and NOT treatment. This search produced over 4,000 citations, from which 2,750 studies met the following inclusion criteria: clinical papers published since 1990; review papers and meta-analyses developed for DSM-IV; and the overview of the *National Institutes of Health State of the Science Conference on Autism in 1995.* Relevant book chapters and books were also included, as identified by the expert panel.

The strength of the evidence for each relevant article and book chapter was ranked using the defined criteria shown in Appendix 3. Recommendations were thereby derived based on the strength of the evidence and stratified (**Standard, Guideline,** or **Practice Option**) as defined in Appendix 3.

Level one: routine developmental surveillance and screening specifically for autism. *Analysis of the evidence.* When and how often should developmental surveillance/screening be performed? Approximately 25% of children in any primary care practice show developmental issues. However, fewer than 30% of primary care providers conduct standardized screening tests at well-child appointments.[8-10] The American Academy of Pediatrics (AAP) stresses the

importance of a flexible, continual developmental surveillance process at each well-child visit, and recommends eliciting and valuing parental concerns, probing regarding age-appropriate skills in each developmental domain, and observing each child.[11]

What are the appropriate developmental screening questionnaires that provide sensitive and specific information? Developmental screening tools have been formulated based on screening of large populations of children with standardized test items. Sensitive and specific developmental screening instruments include: the Ages and Stages Questionnaire, the BRIGANCE® Screens, the Child Development Inventories, and the Parents' Evaluations of Developmental Status.[1]

The Denver-II (DDST-II, formerly the Denver Developmental Screening Test-Revised) has been the traditional tool used for developmental screening, but research has found that it is insensitive and lacks specificity. The Revised Denver Pre-Screening Developmental Questionnaire (R-DPDQ) was designed to identify a subset of children who needed further screening. However, studies have shown that it detected only 30% of children with language impairments and 50% of children with mental retardation.[12-15]

How are conventional developmental milestones defined? Conventional developmental language milestones are based on normative data from numerous standardized language instruments for infants.[16-19] Lack of acquisition of the following milestones within known accepted and established ranges is considered abnormal: no babbling by 12 months; no gesturing (e.g., pointing, waving bye-bye) by 12 months; no single words by 16 months; no 2-word spontaneous (not just echolalic) phrases by 24 months; and any loss of any language or social skills at any age. Failure to meet these milestones is associated with a high probability of a developmental disability.

Do parents provide reliable information regarding their child's development? Several studies encompassing 737 children showed that parental concerns about speech and language development, behavior, or other developmental issues were highly sensitive (i.e., 75% to 83%) and specific (79% to 81%) in detecting global developmental deficits.[20-22] However, the absence of such concerns had modest specificity in detecting normal development (47%).[20] An additional study that combined parental concern with a standardized parental report found this to be effective for early behavioral and developmental screening in the primary care setting.[23]

Can autism be reliably diagnosed before 36 months of age? Because there are no biological markers for autism, screening must focus on behavior. Recent studies comparing 109 autistic and 33 typically developing children demonstrated that problems with eye contact, orienting to one's name, joint attention, pretend play, imitation, nonverbal communication, and language development are measurable by 18 months of age.[24-27] These symptoms are stable in children from toddler age through preschool age. Retrospective analysis of home videotapes have also identified behaviors that distinguish infants with autism from other developmental disabilities as early as 8 months of age.[28-30]

Current screening methods may not identify children with milder variants of autism, those without mental retardation or language delay, such as verbal individuals with high-functioning autism and Asperger's disorder, or older children, adolescents, and young adults.

Is there an increased risk of having another child with autism (recurrence)? The incidence of autism in the general population is 0.2%, but the risk of having a second (or additional) autistic child increases almost 50-fold to approximately 10 to 20%.[31-34]

What tools are available with appropriate psychometric properties to specifically screen for autism? Appropriately sensitive and specific autism screening tools for infants and toddlers have only recently been developed, and this continues to be the current focus of many research centers. The Checklist for Autism in Toddlers (CHAT) for 18-month-old infants, and the Autism Screening Questionnaire for children 4 years of age and older, have been validated on large populations of children. However, it should be noted that the CHAT is less sensitive to milder symptoms of autism, as children later diagnosed with PDD-NOS, Asperger's, or atypical autism did not routinely fail the CHAT at 18 months.[27,35]

The Pervasive Developmental Disorders Screening Test–II (PDDST-II) for infants from birth to 3 years of age, the Modified Checklist for Autism in Toddlers (M-CHAT) for infants at 2 years of age, and the Australian Scale for Asperger's Syndrome for older verbal children, are currently under development or validation phases.[1]

What screening laboratory investigations are available for developmental delay, with or without suspicion of autism? *Formal audiologic evaluation.* The Committee on Infant Hearing of the American Speech–Language–Hearing Association developed guidelines for the audiologic assessment of children from birth through 36 months of age.[36] They recommended that all children with developmental delays, particularly those with delays in social and language development, have a formal audiologic hearing evaluation. Three studies have documented that conductive, sensorineural, or mixed hearing loss can co-occur with autism, and that some children with autism may be incorrectly thought to have peripheral hearing loss.[37,38] In addition, transient conductive hearing loss associated with otitis media with effusion can also occur in children with autism.

Audiologic assessment of such children requires modifications of traditional test techniques and environments (e.g., operant test procedures).[39,40] Electrophysiologic procedures are useful for estimating hearing sensitivity and for examining middle ear, cochlear, and VIIIth nerve or auditory brainstem pathway integrity.[41,42] Evoked otoacoustic emissions are useful for examining cochlear (sensory) function,

and is a frequency-specific, as well as a time- and cost-efficient procedure.[43] Frequency-specific auditory brainstem response (ABR) is the single most useful electrophysiologic procedure for use in estimating hearing thresholds, and has been demonstrated to be highly correlated with behavioral hearing thresholds in children who hear normally and in children who have sensorineural hearing loss.[42]

Lead screening. Children with developmental delays who spend an extended period in the oral–motor stage of play (where everything "goes into their mouths") are at increased risk for lead toxicity, especially in certain environments. The prevalence of pica in this group can result in high rates of substantial or recurrent exposure to lead. The National Center for Environmental Health of the Centers for Disease Control and Prevention recommends that children with developmental delays, even without frank pica, should be screened for lead poisoning.[44] Blood lead levels in children with autism are elevated.[1] In one study, the mean blood lead level in 18 autistic children was higher than in 16 nonautistic "psychotic" children or in 10 normal siblings; 44% of the autistic and psychotic children had lead levels significantly above the mean compared with control subjects.[45] In a more recent study, 17 autistic children treated for lead poisoning were compared with 30 children without autism. The autistic children were older at diagnosis, had higher lead levels, and most were reexposed despite close monitoring of their environment.[46]

Level one evidence-based recommendations. *Clinical practice recommendations.*

1. Developmental surveillance should be performed at all well-child visits from infancy through school-age, and at any age thereafter if concerns are raised about social acceptance, learning, or behavior (**Guideline**).
2. Recommended developmental screening tools include the Ages and Stages Questionnaire, the BRIGANCE® Screens, the Child Development Inventories, and the Parents' Evaluations of Developmental Status (**Guideline**).
3. Because of the lack of sensitivity and specificity, the Denver-II (DDST-II) and the Revised Denver Pre-Screening Developmental Questionnaire (R-DPDQ) are not recommended for appropriate primary-care developmental surveillance (**Guideline**).
4. Further developmental evaluation is required whenever a child fails to meet any of the following milestones (**Guideline**): babbling by 12 months; gesturing (e.g., pointing, waving bye-bye) by 12 months; single words by 16 months; two-word spontaneous (not just echolalic) phrases by 24 months; loss of any language or social skills at any age.
5. Siblings of children with autism should be carefully monitored for acquisition of social, communication, and play skills, and the occurrence of maladaptive behaviors. Screening should be performed not only for autism-related symptoms but also for language delays, learning difficulties, social problems, and anxiety or depressive symptoms (**Guideline**).
6. Screening specifically for autism should be performed on all children failing routine developmental surveillance procedures using one of the validated instruments—the CHAT or the Autism Screening Questionnaire (**Guideline**).
7. Laboratory investigations recommended for any child with developmental delay and/or autism include audiologic assessment and lead screening (**Guideline**). Early referral for a formal audiologic assessment should include behavioral audiometric measures, assessment of middle ear function, and electrophysiologic procedures using experienced pediatric audiologists with current audiologic testing methods and technologies (**Guideline**). Lead screening should be performed in any child with developmental delay and pica. Additional periodic screening should be considered if the pica persists (**Guideline**).

Recommendations for research.

1. Develop and validate appropriate autism screening tools with adequate sensitivity and specificity in children younger than 1 year of age that could be used by a wide range of practitioners.
2. Current methods of screening for autism may not identify: 1) children with milder variants of the disorder; 2) children without mental retardation or language delay, such as verbal individuals with high functioning autism and Asperger's disorder; or 3) older children, adolescents, and young adults. Additional tools are needed to help identify and evaluate these groups of patients.
3. Studies are needed to provide insight into the emergence of early auditory behaviors that are considered atypical and may be prevalent in children with autism. Studies are also needed on the audiologic characteristics of individuals with autism to help assess peripheral hearing sensitivity and suprathreshold responses.

Level two: diagnosis and evaluation of autism. *Analysis of the evidence.* Who should diagnose autism? Although educators, parents, and other health care professionals identify signs and symptoms characteristic of autism, a clinician experienced in the diagnosis and treatment of autism is usually necessary for accurate and appropriate diagnosis.[25,47,48] Clinicians must rely on their clinical judgment, aided by guides to diagnosis, such as DSM-IV and the *Tenth Edition of the International Classification of Diseases* (ICD-10), as well as by the results of various assessment instruments, rating scales, and checklists. These instruments and criteria should be used by practitioners not as experienced in the diagnosis of autism.

What are the medical and neurologic concerns in evaluating children with autism? *Familial prevalence.* Family studies have shown that there is a 50-fold to 100-fold increase in the rate of autism in first-degree relatives of autistic children. Within these families, there are also elevated rates of social difficulties; higher incidences of cognitive, communication, learning and executive function deficits; increased stereotyped behaviors; and anxiety, affective, language, and pragmatic disorders.[33,49-55] Monozygotic twin pair studies have also shown a high concordance rate (60%) for DSM-IV Autistic Disorder, 71% for the broader autistic spectrum phenotype, and 92% for an even broader phenotype of social and communication deficits with stereotyped behaviors that nonetheless were clearly differentiated from normal. In contrast, no concordance for autism was noted in dizygotic twin pairs and only 10% were concordant for some form of cognitive, social or language deficit.[56,57]

Large head circumference without frank neuropathology. Children with autism have a larger head circumference; only a small proportion have frank macrocephaly.[33,57-61] Large head size may not necessarily be present at birth, but may appear in early to mid-childhood, perhaps indicating an increased rate of brain growth. Neuroimaging studies in autism also found larger brain volumes without associated neuropathology.[62,63]

Association with tuberous sclerosis complex (TSC) and less often with Fragile X (FraX) syndrome. Seventeen to over 60% of mentally retarded individuals with TSC are also autistic, and these patients commonly have epilepsy.[64-67] In contrast, the number of autistic individuals with TSC has been estimated to be between 0.4% and 3%.[66] This rate increases to 8% to 14% if epilepsy is also present.[66]

Clinical studies report that 3% to 25% of patients with FraX have autism.[68-70] However, no evidence of FraX in autistic individuals was found using cytogenetic (not DNA analysis) techniques;[71] with molecular genetic analyses, only a few autistic individuals were shown to have FraX.[72]

What are the specific deficits of the autistic child's developmental profile? *Speech, language, and verbal and nonverbal communication.* Verbal and nonverbal communication deficits seen in autism are far more complex than simple speech delay, but overlap with developmental language disorders or specific language impairments. Expressive language function ranges from complete mutism (as often seen in children 2 to 3 years of age) to verbal fluency, though verbal abilities are often accompanied by many errors in word meaning (semantics) or language and communicative deficits in social contexts (social-pragmatics).[73-75]

Cognitive deficits. Many autistic individuals demonstrate a particular pattern on intellectual tests that is characteristic of autism, i.e., performance IQ (PIQ) higher than verbal IQ (VIQ), and specific intersubtest scatter, with Block Design typically the highest subtest and Comprehension usually the lowest. However, the PIQ–VIQ split is severity dependent. When Full Scale IQ (FSIQ) and VIQ are both above 70, 80% of autistic individuals will have no significant VIQ–PIQ disparity, and the remainder are evenly divided between those with PIQ $>$ VIQ and those with PIQ $<$ VIQ.[76]

The DSM-IV defines the diagnosis of mental retardation as the combination of subaverage intellectual functioning (IQ $<$ 70) and concurrent deficits in adaptive functioning. Autistic individuals have poorer adaptive function than would be predicted by IQ alone.[77]

Sensorimotor deficits. Impairments of gross and fine motor function are reported as being common in autistic individuals, and are recognized as hypotonia, limb apraxia, or motor stereotypies. Motor deficits are more severe in individuals with lower IQ scores.[78] Hand or finger mannerisms, body rocking, or unusual posturing are reported in 37% to 95% of individuals, and often manifest during the preschool years.[24,58,78] Sensory processing abilities are aberrant in 42% to 88% of autistic individuals and include preoccupation with sensory features of objects, over- or underresponsiveness to environmental stimuli, or paradoxical responses to sensory stimuli.[79]

Neuropsychological, behavioral, and academic impairments. Specific neuropsychological impairments can be identified, even in young children with autism, that correlate with the severity of autistic symptoms.[80] Performance on tasks that rely on rote, mechanical, or perceptual processes are typically spared; deficient performance exists on tasks requiring higher-order conceptual processes, reasoning, interpretation, integration, or abstraction. Dissociations between simple and complex processing are reported in the areas of language, memory, executive function, motor function, reading, mathematics, and perspective-taking.[80-83] There is no reported evidence that confirms or excludes a diagnosis of autism based on these cognitive patterns alone.

When and what laboratory investigations are indicated for the diagnosis of autism? *Genetic testing.* A chromosomal abnormality reported in possibly more than 1% of autistic individuals involves the proximal long arm of chromosome 15 (15q11-q13), which is a greater frequency than other currently identifiable chromosomal disorders.[84-86] Those with the 15q abnormalities typically have moderate to profound mental retardation. The duplication is usually maternally inherited, either pseudodicentric 15 (inverted duplication 15) or other atypical marker chromosomes, with one or two extra copies of the area roughly corresponding to the typical Angelman syndrome (AS)/Prader Willi Syndrome (PWS) deletion region of approximately four million base pairs. Conversely, AS is usually due to a deletion of maternally inherited 15q11-q13 material and has been found in patients with autism and profound mental retardation.[85,87]

Metabolic testing. Inborn errors in amino acid, carbohydrate, purine, peptide, and mitochondrial metabolism, as well as toxicologic studies have been

studied, but the percentage of children with autism who have a metabolic disorder is probably less (and some experts agree that it is considerably less) than 5%.[88,89]

Electrophysiologic testing. The prevalence of epilepsy in autistic children has been estimated at 7[90] to 14%,[91] whereas the cumulative prevalence by adulthood is estimated at 20% to 35%.[90,91] Seizure onset peaks in early childhood and again in adolescence. Mental retardation, with or without motor abnormalities and family history of epilepsy, was a significant risk factor for the development of seizures in autistic individuals.[92-95]

It is unclear whether there is a relationship between autism and an early regressive course (before 36 months), childhood disintegrative disorder ([CDD] after 36 months), Landau–Kleffner syndrome, and electrical status epilepticus during slow wave sleep (ESES). Autism with regression and CDD have both been associated with seizures or epileptiform sleep-deprived EEG (with adequate sampling of slow wave sleep).[96-98] A higher incidence of epileptiform EEG abnormalities in autistic children with a history of regression has been reported when compared to autistic children with clinical epilepsy.[97] Seizures or epileptiform discharges were more prevalent in children with regression who demonstrated cognitive deficits. Regression in cognition and language in adolescence associated with seizure onset has also been observed, but little is known about its cause or prevalence. There may be a causal relationship between a subgroup of children with autistic regression and EEG-defined "benign focal epilepsies."[99] There is insufficient evidence to suggest a role for event-related potentials or magnetoencephalography in the evaluation of autism.

Neuroimaging. CT studies, ordered as standard assessments of children diagnosed with autism during the 1970s and 1980s, reported a wide range of brain imaging abnormalities and suggested that there was an underlying structural disorder in patients with autism. This view changed when Damasio et al.[100] demonstrated that such abnormalities were incidental to coexisting anatomic disorders unrelated to autism. A very low prevalence of focal lesions or other structural abnormalities was found; their inconsistent localization marked them as coincidental. Prevalence of lesions on MRI in children with autism is similar to normal control subjects.[101] CT and MRI studies of autistic subjects screened to exclude those with disorders other than autism confirmed the absence of significant structural brain abnormalities.[63]

Functional imaging modalities such as functional MRI (fMRI), single-photon emission CT (SPECT), or positron-emission tomography (PET) are currently only research tools in the evaluation of autism. There is no evidence to support a role for functional neuroimaging studies in the clinical diagnosis of autism at the present time.[1]

Other tests. There is insufficient evidence to support the use of other tests such as hair analysis for trace elements, celiac antibodies, allergy testing (particularly food allergies for gluten, casein, candida, and other molds), immunologic or neurochemical abnormalities, micronutrients such as vitamin levels, intestinal permeability studies, stool analysis, urinary peptides, mitochondrial disorders (including lactate and pyruvate), thyroid function tests, or erythrocyte glutathione peroxidase studies.[1]

Level two: evidence-based recommendations. *Clinical practice recommendations.*

1. Genetic testing in children with autism, specifically high resolution chromosome studies (karyotype) and DNA analysis for FraX, should be performed in the presence of mental retardation (or if mental retardation cannot be excluded), if there is a family history of FraX or undiagnosed mental retardation, or if dysmorphic features are present (**Standard**). However, there is little likelihood of positive karyotype or FraX testing in the presence of high-functioning autism.
2. Selective metabolic testing (**Standard**) should be initiated by the presence of suggestive clinical and physical findings such as the following: if lethargy, cyclic vomiting, or early seizures are evident; the presence of dysmorphic or coarse features; evidence of mental retardation or if mental retardation cannot be ruled out; or if occurrence or adequacy of newborn screening for a birth is questionable.
3. There is inadequate evidence at the present time to recommend an EEG study in all individuals with autism. Indications for an adequate sleep-deprived EEG with appropriate sampling of slow wave sleep include (**Guideline**) clinical seizures or suspicion of subclinical seizures, and a history of regression (clinically significant loss of social and communicative function) at any age, but especially in toddlers and preschoolers.
4. Recording of event-related potentials and magnetoencephalography are research tools at the present time, without evidence of routine clinical utility (**Guideline**).
5. There is no clinical evidence to support the role of routine clinical neuroimaging in the diagnostic evaluation of autism, even in the presence of megalencephaly (**Guideline**).
6. There is inadequate supporting evidence for hair analysis, celiac antibodies, allergy testing (particularly food allergies for gluten, casein, candida, and other molds), immunologic or neurochemical abnormalities, micronutrients such as vitamin levels, intestinal permeability studies, stool analysis, urinary peptides, mitochondrial disorders (including lactate and pyruvate), thyroid function tests, or erythrocyte glutathione peroxidase studies (**Guideline**).

Recommendations for research.

1. Studies are needed to further identify the usefulness of electrophysiologic techniques to clarify the

role of epilepsy in autism, especially in children with a history of regression.
2. Additional studies to examine potential genetic and/or environmental factors and their relationship to the etiology of autism are needed.
3. Continuing efforts might focus on identifying contributing genes to determine whether the behavioral syndromes (which constitute the basis of DSM-IV and ICD-10) have actual biological validity.
4. Evaluation of environmental factors (e.g., nonspecific infections or other immunologically mediated events) that might contribute to triggering the expression of autistic symptoms or regression requires additional study.

Consensus-based general principles of management. The following recommendations are based on consensus agreement by the participating organizations involved in the development of this parameter.[1]

Surveillance and screening. In the United States, states must follow federal Public Law 105-17: the Individuals with Disabilities Education Act Amendments of 1997–IDEA'97, which mandates immediate referral for a free appropriate public education for eligible children with disabilities from the age of 36 months, and early intervention services for infants and toddlers with disabilities from birth through 35 months of age.

Diagnosis. The diagnosis of autism should include the use of a diagnostic instrument with at least moderate sensitivity and good specificity for autism. Sufficient time should be planned for standardized parent interviews regarding current concerns and behavioral history related to autism, and direct, structured observation of social and communicative behavior and play. Recommended instruments include[1]:

Diagnostic parental interviews

The Gilliam Autism Rating Scale

The Parent Interview for Autism

The Pervasive Developmental Disorders Screening Test–Stage 3

The Autism Diagnostic Interview–Revised

Diagnostic observation instruments

The Childhood Autism Rating Scale

The Screening Tool for Autism in Two-Year-Olds

The Autism Diagnostic Observation Schedule-Generic

Medical and neurologic evaluation. Perinatal and developmental history should include milestones; regression in early childhood or later in life; encephalopathic events; attentional deficits; seizure disorder (absence or generalized); depression or mania; and behaviors such as irritability, self-injury, sleep and eating disturbances, and pica. The physical and neurologic examination should include: longitudinal measurements of head circumference and examination for unusual features (facial, limb, stature, etc.) suggesting the need for genetic evaluation; neurocutaneous abnormalities (requiring an ultraviolet [Wood's] lamp examination); gait; tone; reflexes; cranial nerves; and determination of mental status, including verbal and nonverbal language and play.

Evaluation and monitoring of autism. The immediate and long-term evaluation and monitoring of autistic individuals requires a comprehensive multidisciplinary approach, and can include one or more of the following professionals: psychologists, neurologists, speech–language pathologists and audiologists, pediatricians, child psychiatrists, occupational therapists, and physical therapists, as well as educators and special educators. Individuals with mild autism should also receive adequate assessments and appropriate diagnoses.

Reevaluation within 1 year of initial diagnosis and continued monitoring is an expected aspect of clinical practice because relatively small changes in the developmental level affect the impact of autism in the preschool years. In general, there is no need to repeat extensive diagnostic testing; however, follow-up visits can be helpful to address behavioral, environmental, and other developmental concerns.

Speech, language, and communication evaluation. A comprehensive speech–language–communication evaluation should be performed on all children who fail language developmental screening procedures by a speech–language pathologist with training and expertise in evaluating children with developmental disabilities. Comprehensive assessments of both preverbal and verbal individuals should account for age, cognitive level, and socioemotional abilities, and should include assessment of receptive language and communication, expressive language and communication, voice and speech production, and in verbal individuals, a collection and analysis of spontaneous language samples to supplement scores on formal language tests.
