Ensuring a smooth transition from pediatric to adult-oriented health care services poses additional challenges in the care of childhood cancer survivors as they age out of the pediatric health care system. Pretransition planning is a critical element in the successful transition from pediatric to adult-oriented health care for all adolescents and young adults with special health care needs, including childhood cancer survivors, and the medical home model provides a strong foundation for this planning.[23,24] The pretransition plan should outline the roles of patient, family, subspecialty and community health care providers in the ongoing care of the survivor to ensure a successful transition. Adolescent and young adult survivors should be well versed regarding their own health maintenance needs, their potential health risks, necessary ongoing screening related to their cancer therapy, and health-related behaviors that can reduce their risk of potential adverse sequelae. They need to be aware of the importance of maintaining continuous health insurance coverage to ensure access to screening for their late effects. This can be challenging, because many adolescent and young adult survivors are still defining career goals and, therefore, have not yet attained employer-based health insurance coverage. The adolescent or young adult cancer survivor may be grappling with unique treatment-related health issues, such as infertility, at a time when their sexual maturity and personal relationships are developing. Some may also be at risk of early death because of primary disease recurrence or second malignant neoplasms,[25] which in turn may require frank discussions regarding advanced directives. Therefore, adolescent and young adult survivors should leave the pediatric health care environment equipped with a comprehensive survivorship care plan, along with the knowledge and skills required to keep abreast of new information relating to their potential health risks as that information emerges.

Although late treatment effects can be anticipated in many cases on the basis of therapeutic exposures, the risk to an individual patient is modified by multiple factors. The patient with cancer may present with premorbid health conditions that influence tolerance to therapy and increase the risk of treatment-related toxicity. Cancer-related factors, including histology, tumor site, and tumor genetics, often dictate treatment modality and intensity. Host-related factors such as age at diagnosis, race, and gender may affect the risk of several treatment-related complications. Sociodemographic factors such as household income, educational attainment, and socioeconomic status often influence access to health insurance, remedial services, and appropriate risk-based health care. Organ senescence in aging survivors may accelerate presentation of age-related health conditions in survivors with subclinical organ injury or dysfunction resulting from cancer treatment. Genetic or familial characteristics may also enhance susceptibility to treatment-related complications. Problems experienced during and after treatment may further increase morbidity. Health behaviors, including tobacco and alcohol use, sun exposure, and dietary and exercise habits, may increase the risk of specific therapy-related complications. Although much is known about factors predisposing to cancer-related morbidity and mortality in this growing population, there is still much to learn to inform the development of interventions that will optimize survival rates for pediatric malignancies while limiting or eliminating therapy-related toxicities. This fact underscores the importance of long-term follow-up for childhood cancer survivors to accurately define health outcomes, characterize groups at high risk, and implement risk-reducing interventions.

SUMMARY

Given the high incidence of late effects experienced by childhood cancer survivors, it is essential that individuals who were treated for cancer during childhood receive long-term follow-up care from knowledgeable providers so

that their care is appropriately tailored to their specific treatment-related risk factors. This is an exciting time for providing care to childhood cancer survivors. Discussion regarding the best models for providing survivorship care are emerging concomitantly with the availability of the COG LTFU guidelines. A recent review by Oeffinger and McCabe[26] proposed a "shared-care model" that includes roles for both the primary care provider and the cancer subspecialist in the care of cancer survivors. In this model, the generalist is responsible for routine health maintenance, management of comorbid diseases, and ongoing management of the physical and emotional needs of the survivor. The oncology subspecialist provides the generalist with the survivorship care plan and is available for ongoing consultation with the generalist regarding any areas of uncertainty. Most importantly, the emphasis is on providing ongoing 2-way communication between the generalist and specialist to optimize the follow-up care for childhood cancer survivors.

Ultimately, the goal of this clinical report from the American Academy of Pediatrics is to increase the awareness of general pediatricians to the readily available resource of the COG LTFU guidelines. These guidelines can, in turn, be used to develop a comprehensive yet individualized survivorship care plan for each childhood cancer survivor. The pediatrician works collaboratively with the pediatric oncology subspecialist, who develops the cancer treatment summary and survivorship care plan. The survivorship care plan can be used by general pediatricians as a "road map" for providing risk-based, long-term follow-up care in the community setting. Ultimately, ongoing communication between the pediatric cancer center and the primary care pediatrician is the cornerstone for providing high-quality care to this vulnerable patient population.

CLINICAL REPORT

Male Adolescent Sexual and Reproductive Health Care

abstract

FREE

Male adolescents' sexual and reproductive health needs often go unmet in the primary care setting. This report discusses specific issues related to male adolescents' sexual and reproductive health care in the context of primary care, including pubertal and sexual development, sexual behavior, consequences of sexual behavior, and methods of preventing sexually transmitted infections (including HIV) and pregnancy. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, and delivering appropriate vaccinations. Pediatricians should provide these services to male adolescent patients in a confidential and culturally appropriate manner, promote healthy sexual relationships and responsibility, and involve parents in age-appropriate discussions about sexual health with their sons. *Pediatrics* 2011;128:e1658–e1676

INTRODUCTION

During adolescence, a number of changes occur for boys, including the physical, psychological, and social changes associated with puberty, and the majority of male adolescents report the initiation of sexual behavior.[1] Many of these events, including sexual initiation, are associated with preventable consequences that can lead to significant morbidity and mortality.[2] During this same time period, the number of health visits typically declines, particularly among older male adolescents, and there is a shift from routine to more time-limited acute visits.[3]

For health care providers, including primary care providers and pediatricians, who care for male adolescents, issues of puberty and sexuality are areas that should be commonly addressed with the male patient and his family.[4] Even after the release of the American Medical Association's *Guidelines for Adolescent Preventive Services* (GAPS)[5] and *Bright Futures*,[6] which recommend preventive health services for adolescents, few improvements have been observed in the counseling of male teenagers regarding the prevention of sexually transmitted infections (STIs) or HIV infection.[7,8] Furthermore, data from outpatient ambulatory medical records show that primary care providers are 3 times more likely to take sexual health histories from female than male patients and twice as likely to counsel female patients on the use of condoms.[9,10] Thus, it is important for primary care providers to have an understanding of what sexual/reproductive health care means for the male adolescent.

Addressing male teenagers' sexual/reproductive health includes but is not limited to preventing STIs and HIV. The 1994 Cairo United Nations

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

International Conference on Population and Development and the World Health Organization defined sexual/reproductive health as "a state of physical, mental and social well-being and not merely the absence of disease, dysfunction or infirmity, in all matters relating to the reproductive system, its functions and its processes."[11,12] Sexual health also requires a positive and respectful approach to sexuality and sexual relationships. People should be able to have pleasurable and safe sexual experiences free of coercion, discrimination, or violence. Men, along with women, have the right to be informed and have access to safe, effective, affordable, and acceptable methods of family planning of their choice and the right of access to appropriate health care services.

For health care providers, goals for male adolescents' sexual/reproductive health beyond the prevention of STIs, HIV infection, unwanted pregnancy, and reproductive health-related cancers should include promoting sexual health and adolescent development, healthy intimate relationships and responsible behavior, and responsible fatherhood as well as reducing problems related to sexual dysfunction and infertility.[13] Health care providers require the knowledge, skills, and confidence to screen and examine male adolescents and discuss with them and provide appropriate education about the scope of sexual/reproductive health care for male adolescents.

The goals of this report are to:

1. describe key components of male adolescents' sexual/reproductive health;
2. explain how interactions with male adolescents and their families regarding sexual/reproductive health requires an individualized patient-centered approach; and
3. offer health care providers specific advice on how to deliver sexual/reproductive health care to male adolescents using each encounter with a young man as an opportunity.

I. CORE MALE ADOLESCENT SEXUAL/REPRODUCTIVE HEALTH KNOWLEDGE AREAS

A. Puberty

With pubertal changes and the development of reproductive capacity come questions and concerns. Puberty for male adolescents follows a predictable sequence, but clinicians need to be aware that its timing is variable because of a variety of factors, including heredity and race/ethnicity. For boys, the first visible sign of puberty and the hallmark of the second sexual maturity rating (SMR) stage (SMR2) is testicular enlargement, followed by penile growth (the hallmark of SMR3). During SMR4, a male's testicular volume has reached approximately 9 to 10 cm^3 and his peak height growth typically occurs.

Results from a recent national survey suggest that the median age of boys' pubertal initiation is trending earlier in the United States, especially among non-Hispanic white boys.[14,15] One study used estimates from a sample of non-Hispanic white, non-Hispanic black, and Mexican American males 8 to 19 years of age. Two independent analyses of the same data indicate that the median age of SMR2 for genital development was 10.0 years for non-Hispanic white boys, 9.2 to 9.5 years for non-Hispanic black boys, and 10.3 to 10.4 years for Mexican American boys, whereas the median age of SMR2 for pubic hair development was 12.0, 11.2, and 12.3 years, respectively.[16,17] These data suggest that a significant portion of boys are entering puberty earlier than 9.5 years, which was the previous lowest age of normal entry into puberty for boys. Future studies with comparable measures are needed to confirm these secular trends.

B. Alterations in Growth Associated With Puberty

Health conditions related to male growth and development are not uncommon, can be quite distressing, and might not be identified until adolescence. The frequencies of more common disorders are 1 in 500 to 700 for Klinefelter syndrome; 1 in 1000 to 4000 for fragile X syndrome; 1 in 5000 to 10 000 for Marfan syndrome; and 1 in 8000 to 10 000 for Kallman syndrome.[18–21] Other non–STI-related male genital issues that occur during adolescence include gynecomastia (40%–65% of male teenagers), testicular torsion (8.6 per 100 000 males 10–19 years of age), varicocele (10% of males), and testicular cancer (3.1 in 100 000 males 15–19 years of age).[22–27]

Early and delayed pubertal timing, including short stature, can result in negative consequences for the developing male. Consequences can include higher mean levels of aggression and delinquency. Earlier-maturing boys might have more frequent involvement in risk-taking behaviors, and later-maturing boys might have lower levels of confidence and self-efficacy and increased experiences of teasing, bullying, mental health issues, and substance abuse.[28–30] Even a common issue such as acne, which affects 95% of male adolescents,[31] can be related to self-reported embarrassment, lower self-esteem, depression, and anxiety.[32]

Given the frequency of these growth and developmental concerns, the typical practicing health care provider will certainly see male patients with 1 or more of these disorders.

C. Sexuality

Sexuality, as defined by the World Health Organization in 2002, is a cen-

tral aspect of the human life course and encompasses sex, gender identities and roles, sexual orientation, intimacy, and reproduction.[12] Although sexuality can be experienced and expressed in thoughts, fantasies, desires, beliefs, values, behaviors, roles, and relationships, not all sexuality dimensions are experienced or expressed. One's sexuality is also influenced by a variety of factors including biological, psychological, familial, societal, political, cultural, and religious factors. Before adolescence even begins, boys might be curious and ask questions about sex, body parts, differences between boys and girls, and where babies come from. However, not all parents talk about sex with their children. In the United States, many more mothers than fathers talk about sex with their sons, but mothers are less comfortable talking about sex with their sons than with their daughters.[33,34] Fathers have also been shown to have more difficulty communicating about sexuality-related topics with their adolescents.[35]

A recent study of California teenagers and their parents found that adolescents who reported that their parents had more frequent sexual-related communication also reported feeling closer to their parents, being more comfortable talking with their parents in general, and having more open conversations about sex with their parents.[36] Health care providers are in a position to advise male patients and their parents about the value and importance of repeatedly talking about sex and related topics.[37] Involving parents and sons in sexual health discussions can help reinforce family values and create opportunities for sons to ask clarifying questions instead of relying on misinformation provided by their peers.

Male adolescents should be encouraged to talk with their health care provider about general health and, in particular, sex, relationships, and prevention of STIs/HIV and pregnancy.[38,39] Male adolescents cite their mothers, doctors, and nurses as their principle resources for general health care concerns[39] and cite doctors and other health care providers as 1 of their top 4 sources of sexual health information inclusive of parents, health classes, and television.[38] Schools, media, and the Internet can also play important roles in the provision of sexual health information. For example, male teenagers who received instruction on AIDS prevention and sex education at school were more likely to have fewer sexual partners, engage in fewer sex acts, and use condoms more consistently than those who did not receive such information.[40] However, adolescents should understand the potential negative influence of media and the Internet, because negative sexual health messages from these sources can lead to risky sexual behaviors.[41,42]

D. Sexual Development

During adolescence, teenagers begin the process of developing a sexual self-concept, which involves the combination of physical sexual maturation, age-appropriate sexual behaviors, and formation of a positive sexual identity and sense of well-being. In early adolescence, boys might become preoccupied with body changes, become interested in sexual anatomy and sex, compare changes in their body with others, and explore touching and mutual masturbation. Along with the experience of spontaneous erections, ejaculation related to masturbation, and the onset of nocturnal ejaculatory events during sleep (ie, "wet dreams"), there are many reasons why preadolescent and older boys might have questions and anxieties about their emerging sexuality. Later, male adolescents begin to test their ability to attract others through dating and sexual behavior. It is not uncommon for a male to have anxieties and questions about genital size and function, especially when comparing himself to others and after initiating sexual behavior.[43]

Some male adolescents might be exploring their sexual attraction to others, and others might already recognize that they are heterosexual, homosexual, bisexual, or transgendered. Studies have found that gay male youth who have a supportive environment during the disclosure process can have a more positive psychological adjustment.[44,45] As discussed in the American Academy of Pediatrics (AAP) statement on sexual orientation and adolescents,[46] boys who are questioning and gay and do not have supportive environments are at increased risk of social isolation, school failure, family conflict, substance abuse, depression, suicide, and stigmatization.[47–50] Most sexual-minority youth are quite resilient and work through adolescent development issues. Being gay or bisexual or questioning their orientation is not in itself a problem but is a risk factor for exploring other associated risks.[51] Questioning, bisexual, and gay male youth who fear being "found out" may choose not to openly discuss their concerns with potentially helpful adults such as their health care provider. Because sexual identities might be "fluid" or subject to change during adolescence, providers may find it more beneficial to inquire about sexual attractions and actual behaviors of their adolescent patients rather than asking about sexual identity (ie, how a person identifies his or her own sexuality). The health care provider might ask a series of questions such as, "A question or even a concern that a teen might have is, am I attracted to both guys and girls, just guys, or just girls. . . has that been a question for you? If so, have you been

able to answer that yet?" "Have you ever had sex with women, men, or both?" "Have you ever engaged in vaginal, oral, or anal sex?"

E. Masturbation and Spermarche

On average, the age of first male masturbation occurs between 12 and 14 years of age; most boys learn about masturbation through self-discovery. Masturbation among males is common and ranges from 36% reporting masturbating 3 to 4 times per month to 10% reporting masturbating every other day or daily.[52] There is no evidence that masturbation is harmful in general or to one's sexual development or later adult sexual adjustment.[53,54] However, myths related to negative consequences of masturbation persist and can result in inappropriate anxiety and/or guilt.

Before puberty, boys might masturbate to orgasm; however, no ejaculation will occur until pubertal changes commence.[55] Sperm in the ejaculate, or spermarche, typically appears during SMR3, approximately 12 to 18 months after the testes begin to enlarge. Although mature sperm production begins after the first ejaculate, a young man should be considered fertile from the time of his first ejaculation.

Health care providers can reassure male adolescents that self-masturbation is a normal behavior and can be a positive expression of sexuality and a way to delay having sex and its associated risks. Health care providers can also assist male adolescents with information and resources about normal sexual physiology and function that might not otherwise be available at home or school.

F. Sexual Behavior and Its Consequences

Sexual behavior is a normal part of development. According to the Youth Risk Behavior Surveillance, more than half (59.6%) of school-aged male teenagers report that they have had sex by the 12th grade.[2] Data from the 2002 National Survey of Family Growth (NSFG) indicate that among 15- to 19-year-old male adolescents who reported never having had vaginal sex, nearly one-quarter reported engaging in oral sex or mutual masturbation behaviors.[1,56] More recent data from the NSFG indicate that approximately one-eighth of 15- to 19-year-old males report having oral sex or other sexual contact but not vaginal sex.[57] Oral sex, in particular, is part of the repertoire of sexual behaviors and might predict involvement in other sexual behaviors.[58–60] Thus, at a minimum, three-quarters of US male youth are reporting involvement in varying types of sexual behavior. Male adolescents also report an earlier age of sexual debut[2] and more sexual partners than female adolescents,[1,2,61] which are factors known to be associated with STI-acquisition risk.[62,63] Sexual experience increases as teenagers get older; 59.6% of 12th-grade boys have report having had sexual intercourse, compared with 33.6% of 9th-grade boys.[2]

A substantial number of young men also report engaging in higher-risk sexual behaviors. Data from the 2009 Youth Risk Behavior Surveillance indicate that among male high school students, 25.9% reported using alcohol or drugs before last sex, 16.2% reported 4 or more lifetime partners, and 8.4% reported initiating sex at 13 years or younger.[2] Data from the 2002 NSFG also showed that among 15- to 19-year-old males, 28.6% reported no condom use at last vaginal sex, 11.1% reported engaging in anal sex with a female partner, and 5.6% reported having sex with a prostitute or an HIV-infected person or often/always being high during sex.[7]

Patterns of male adolescent sexual behaviors also vary according to race/ethnicity.[2] Higher proportions of non-Hispanic black high school boys (72.1%) report being sexually experienced compared with Hispanic (52.8%) or non-Hispanic white (39.6%) high school boys. Higher proportions of non-Hispanic black boys (24.9%) initiate sex at 13 years of age or younger compared with Hispanic (9.8%) and non-Hispanic white (4.4%) boys.

National US data on same-sex sexual attraction and behavior is limited. From the 1995 National Longitudinal Survey on Adolescent Health, the mean report of same-sex attraction or relationship among male adolescents was 8.4% (95% confidence interval [CI]: 7.5–9.3).[49] In the 2006–2008 NSFG, 1.8% of 18- to 19-year-olds and 2.3% of 20- to 24-year-olds reported equally to both or mostly/only same-sex attraction.[57] In the 2002 NSFG, 4.5% of male teenagers 15 to 19 years of age and 5.5% of young adult men 20 to 24 years of age reported a same-sex partner.[61] In the 2006–2008 NSFG, 2.5% of male teenagers 15 to 19 years of age and 5.6% of young adult men 20 to 24 years of age reported a same-sex partner.[57] Discordance between sexual attraction/orientation and behavior is also possible, because one's sexual attraction and identity do not always predict sexual behavior.[57,64,65]

G. Unwanted Sex

Although males are more likely than females to agree with the statement, "sex is something that just happens,"[66] the majority (82%) of males 12 to 19 years of age reported feeling pressured by friends to have sex.[67] Among sexually experienced males 15 to 19 years of age, more than half (55%) wished that they had waited longer before having sex for the first time,[68] and more than one-third (38%) of men 18 to 24 years of age reported that they really did not want sex to happen the first time that it did or had mixed feelings about it.[56] Approximately 1 in 12

men (7.6%), particularly those whose first sexual intercourse was at younger than 15 years and non-Hispanic black men, reported that they had actually been coerced to have sex by a female (5.8%) or male (2%).[56] Long-term consequences of sexual abuse of males include HIV risk behaviors, psychiatric disorders, substance abuse, and thoughts of suicide.[69–72]

Many male adolescents and young adults are unaware of state laws on statutory rape and resultant consequences. Although these punitive measures attempt to force people to change their sexual/reproductive health behavior, there are few data to support that such laws are effective deterrents to, for example, adolescent pregnancy.[73] A recently prepared report by the Lewin Group contains a guide to state laws on statutory rape and reporting requirements.[74] It is recommended that health care providers be aware of local statutory rape laws and be able to counsel teenagers about potential legal consequences of early sexuality, especially if a patient's sexual partner(s) is younger than the patient. As discussed in the AAP statement on media education,[75] pediatricians also need to become educated about the public health risks of media such as "sexting." Resources for patients and families that explain more generally the laws about statutory rape, age of consent, sexting, etc (www.sexlaws.org) are also available.

H. Dating Violence

Violence in adolescent relationships can include bullying, threatening, sexual harassment, dating violence, and/or coercion. Within the context of intimate relationships among romantic and sexual partners, such violence can be verbal, emotional, physical, or sexual. Male adolescents can be perpetrators, victims, or both. For example, 9.9% of high school students nationwide reported having been hit, slapped, or physically hurt intentionally by their boyfriend or girlfriend in the past year.[76] Overall, the prevalence of experiencing dating violence was higher among male (11.0%) than female (8.8%) 9th- and 12th-grade students. Despite the high prevalence, many adolescents who are victims or perpetrators of violence do not seek help.[77] Health care providers have an opportunity to promote healthy relationships, improve communication, and improve the detection of unhealthy relationships through screening for intimate partner violence (1 example of a mnemonic screening tool for violent behavior is FISTS [fighting, injuries, sex, threats, and self-defense]) and subsequent referral when appropriate.[78–81]

I. Sexual Function and Dysfunction

Healthy sexual function has an important role in adolescents' and young adults' well-being and development. Few studies, however, have examined sexual health and/or problems with sexual dysfunction among adolescents. Common causes of sexual dysfunction among young adult men include anxiety about performance, premature ejaculation, worries about attractiveness during sex, decreased pleasure associated with condom use, and organic performance-related issues attributable to comorbid medical conditions (eg, diabetes, cardiac disease, neurologic deficits) or adverse effects from medication (eg, selective serotonin-reuptake inhibitors or alcohol).[82,83] Health care providers have an opportunity to screen for problems with sexual performance (eg, "Some men may be worried because they ejaculate too soon or late or have difficulty getting or losing an erection. Have you ever experienced any of these problems?") and offer reassurance or appropriately assess for an underlying medical condition.

J. STIs/HIV, Pregnancy, and Adolescent Fatherhood

Involvement in sexual behaviors places young men and their partners at risk of negative sexual/reproductive health outcomes that are preventable, such as STIs, HIV infection, unintended pregnancy, and reproductive health-related cancers such as anal cancer attributable to human papillomavirus (HPV).

Although adolescents and young adults 15 to 24 years of age represent only one-quarter of the sexually active US population, this population is estimated to account for half of the 18.9 million new STI cases[84] and approximately 30% of all new HIV infections[85] that occur each year. Among STIs, chlamydia, HPV infection, and trichomoniasis account for 88% of all infections.[84] Among all populations, rates of chlamydia and gonorrhea are highest among people 15 to 24 years of age.[86,87] The chlamydia prevalence rate for males 14 to 19 years of age reported from the recent National Health and Nutrition Examination Survey (1999–2002) was found to be 2.3% (95% CI: 1.5–3.5).[88] This rate is not too dissimilar from the chlamydia rate of 3.67% (95% CI: 2.93–4.58) reported among young adult men 18 to 26 years of age in the National Longitudinal Study on Adolescent Health. The Add Health study also reported prevalence rates among 18- to 26-year-olds for gonorrhea (0.44% [95% CI: 0.26–0.77]) and trichomoniasis (1.7% [95% CI: 1.3–2.2%]).[87,89] It is common for males with chlamydia and gonorrhea infections to be asymptomatic. Males who are not circumcised are also more likely to have gonorrhea (adjusted odds ratio: 4.0 [95% CI: 1.9–8.4]) and syphilis (adjusted odds ratio: 1.6 [95% CI: 1.2–2.2]) infections than circumcised males.[90] Racial disparities have been observed for STIs other than HIV. Non-Hispanic black male adolescents have higher

rates of chlamydia, gonorrhea, and trichomoniasis compared with those of other race/ethnicity groups.[85,89,91]

In 2006, an estimated one-quarter of the 1.1 million people living with HIV infection in the United States were not aware of their HIV status. Young people 13 to 24 years of age represent an estimated 10% of undiagnosed cases each year.[92] HIV prevalence among young men who have sex with men is estimated at 7.2% (5.6% for those 15–19 years of age, 8.6% for those 20–22 years of age). Rates are higher for non-Hispanic black, mixed/other race, and Hispanic young men.[93] Young men at higher risk of HIV infection include men who have sex with men; have unprotected sex (especially with multiple partners); are past or present injection-drug users; exchange sex for money or drugs; are past or present sex partners of HIV-infected or bisexual persons or injection-drug users; are being treated for an STI; have a history of blood transfusion between 1978 and 1985; and request an HIV test, because nondisclosure might be indicative of high-risk behavior.[94] Male circumcision among mostly African samples has been associated with a lower risk of HIV acquisition to the male himself and possible benefits to the female by decreasing transmission.[95–98] The Centers for Disease Control and Prevention (CDC) is currently considering guidelines for the role of male circumcision in the prevention of HIV transmission in the United States.[99]

After a reduction in teen births and pregnancies from 1991 to 2005, more recent trends in behavioral risks for pregnancy (eg, declines in contraceptive use) have stalled or are reversing among certain groups, particularly non-Hispanic black and Hispanic teenagers.[100] National data indicate that approximately 750 000 pregnancies occur each year among women younger than 20 years[101]; the majority of teen pregnancies (82%) are unplanned or mistimed.[102] These data translate to approximately 1 in 20 female teenagers becoming pregnant each year.[103] Most of these pregnancies end in a live birth (57%), 27% end in induced abortion, and 16% end in fetal loss.[104] The majority of teen pregnancies are fathered by males who are within 2 years of age or older of their partners.[105–108] Among sexually experienced male adolescents, 1 in 8 (13%) reported that they have impregnated a partner, and 4% are fathers.[109] Because of lacking or inaccurate documentation of paternal age on birth certificates, especially among younger and unmarried mothers,[110] the rates of fatherhood among male adolescents might be even higher.

The consequences of teen pregnancy and STIs, including HIV infection/AIDS, are many and costly. Males diagnosed with an STI can have complications such as epididymitis and infertility[111,112] and, if left untreated, can place female partners at risk for morbidity and mortality, such as acute and recurrent pelvic inflammatory disease and resultant tubal scarring, infertility,[113–115] ectopic pregnancy,[116] and HIV infection/AIDS. Although it can be challenging to disentangle the link between teen pregnancy and poverty, personal costs of teen pregnancy often include truncated schooling, increased unemployment, welfare dependency, lower lifetime earnings, single parenthood, depression, and poor infant outcomes.[117,118] Each year, costs related to adolescent pregnancy and its complications are estimated to be $9 billion,[119,120] and costs related to STIs/HIV infection and their complications are estimated to be $17 billion.[86]

K. Preventing STIs/HIV Infection and Pregnancy

The male adolescent and his partner, family, school, and health care provider all have important roles in preventing the negative consequences of sexual behavior.

Table 1 summarizes the effectiveness of available male contraceptive options.[121] Condoms are the most commonly used contraception method[122] and are highly effective if used consistently and correctly. Over the past 3 decades, the report of condom use by male adolescents at first and most recent sex has increased, particularly among Hispanic and non-Hispanic black males.[1] Seven in 10 male adolescents (71%) report condom use the first and most recent time they had sex.[1] The majority of young men also report using condoms to prevent both pregnancy and STIs/HIV infection.[56] However, during the past 3 decades, there has been little change in male

TABLE 1 Contraceptive Effectiveness: Rates of Unintended Pregnancies per 100 Women

	First-Year Pregnancy Rate, %[a]		Key
	Consistent and Correct Use	As Commonly Used	
Male methods			
Vasectomy	0.10	0.15	0.0%–0.9%: very effective
Male condom	2	15	1%–9%: effective
Withdrawal	4	27	10%–25%: moderately effective
No method	85	85	26%–32%: less effective
Common female hormonal methods			
Progestin-only injectable	0.3	3	—
Combined oral pills, patch, ring	0.3	8	—

[a] Rates are largely from the United States.

Modified from: Trussell J. Contraceptive efficacy. In: Hatcher RA, Trussell J, Nelson AL, et al, eds. *Contraceptive Technology.* 19th Rev ed. New York, NY: Ardent Media; 2007:747–826.

adolescents' consistency of condom use (ie, use with every sexual encounter in the past year); less than half (48%) of sexually active males report consistent use.[1] Barriers to condom use include being embarrassed when buying them, reduced physical sensation, incorrect use and lack of availability, planning, discussion, or negotiation with one's partner.[1,123–128] Reduced likelihood of condom use at most recent sex and inconsistency in condom use have been observed among young men who did not receive formal sex education at school or the community.[129] Low condom use during adolescence, combined with the report of multiple partners, has also been shown to be associated with elevated STI rates when subjects become young adult men.[130]

Approximately 10% of male adolescents report using withdrawal as their contraception method of choice.[1] Although withdrawal does not protect against STIs/HIV infection and, thus, is not an appropriate form of STI/HIV prevention, effectiveness data (Table 1) show that it can substantially reduce the risk of pregnancy for people who report difficulties using contraception (eg, people with latex allergy or during unplanned sex acts).[131] Withdrawal is better than doing nothing, but it must be emphasized that withdrawal is not equivalent to using other barrier methods (eg, condoms), hormonal methods, or dual contraception. Polyurethane condoms are also available for people who are allergic to latex.

Only one-quarter (24%) of male adolescents report the use of dual contraception methods (eg, combined condom use with a hormonal method).[1] This may be explained by a lack of awareness of the partner's contraception methods or familiarity with how female hormonal methods work, including emergency contraception.[132–134] For example, situations in which a male was less likely to use a condom included if the male's partner used a method of contraception, if the male was older at most recent sex, if the male's partner was older at first sexual encounter, and during a casual first sexual encounter.[129] Increased odds of ever or always using any contraceptive method is observed among teenagers who wait longer between the start of a relationship and first sex, discuss contraception before first sex, or use dual contraception methods.[135] Two groups of teenagers, males and non-Hispanic white teenagers, are less likely to regularly talk about contraception and STIs with their partners before first sex than are females and teenagers from other racial groups.[136] Health care providers have an opportunity to talk with males about all types of contraception and provide consistent messages about counseling for risk reduction (Table 2). Some teenagers might choose to take virginity pledges and abstain from sex until marriage. However, such pledges have not been found to have long-term effectiveness in preventing STIs and other adverse outcomes and might actually place pledge-takers at greater risk of STIs and unintended pregnancy. One prospective study found that adolescents who signed abstinence pledges experienced similar STI rates as did adolescents who did not sign pledges.[137] Although pledge-takers delayed initiation of sex for a longer period of time, when pledge-takers initiated sex, they were less likely to use condoms and seek reproductive health care compared with their peers who did not sign pledges.

L. Male Adolescents' Sexual/Reproductive Health Care Use

Male adolescents' use of sexual/reproductive health care services remains low for a variety of reasons. For many, the onset of sexual behavior during adolescence serves as a rite of passage into manhood but does not trigger thinking about preventive behaviors related to the consequences of sexual behavior. Young men might also hold more traditional masculine beliefs that preclude them from seeking care despite having symptoms.[138,139] In addition, the components of young men's sexual/reproductive health care have been poorly defined and have historically received little attention. Unlike females, who have historically received bundled sexual/reproductive health care as part of gynecologic examinations, birth control visits, and prenatal care,[140] this is not typically true for young men. Barriers to care can also play a role in male adolescents' care-seeking in general and sexual/reproductive health care in particular. These barriers include fear; stigma; shame; denial; lack of social support; lack of confidential services; lack of health insurance options especially as they get older; and not knowing where to go for care.[141–146] Given the asymptomatic nature of many STIs, including HIV infection, strategies are needed to raise young men's awareness about sexual/reproductive health services, STI and HIV testing options, and related resources. Promoting sexual/reproductive health for young men can lead to sexual responsibility, healthy intimate relationships, and responsible fatherhood. Health care providers, and pediatricians in particular, are in the best position to deliver high-quality sexual/reproductive health care services to male adolescents and should view even follow-up, acute care, and immunization visits as opportunities to address these health issues. Health care providers can also use "clinical hooks," such as sports physicals or acne follow-up, to keep male adolescents engaged in care and to deliver sexual/reproductive health care services.

TABLE 2 Anticipatory Guidance Topics

Anticipatory Guidance Topics and Questions	Example Message	Resources
Counseling on sexual risk reduction including barriers to condom use		
2 separate sessions, 1 wk apart	Avoiding sex is the safest way to prevent pregnancy and STIs/HIV. If you choose to have sex, take responsibility and use a condom *every* time. If you do not have a condom, choose not to have sex.	www.ahwg.net (see sexual health toolkit—provider, pages C13–C15)
Session 1: assess for personal risk, barriers to risk reduction, and identification of a small risk-reduction step within 1 wk (eg, consistent condom use)	Choosing not to have sex at any point will not diminish one's status or manhood.	www.sexetc.org/topic/guys_health
Session 2: review previous week's behavioral-change successes and barriers, provide support for changes made, identify barriers and facilitators to change, and develop a long-term plan for risk reduction		www.goaskalice.columbia.edu/Cat7.html
Help me understand why condoms are difficult for you to use. Do you vary your condom use depending on who your partner is? How can you reintroduce condom use in a relationship without creating issues about trust?		www.iwannaknow.org
What would you do if your partner does not want you to use a condom?	"I really like you but am not comfortable having sex without using a condom."	
Do you know how to make condom use more pleasurable?	Place a drop of lubrication in the inside tip of the condom. Also, condoms come in various shapes and sizes, and 1 condom type may not fit all.	www.ahwg.net (see sexual health toolkit—provider, pages C36–C37; youth page C50)
What would you do if a condom breaks or slips off?	"Do you know about emergency contraception (eg, Plan B)? This is something we can get and have you take within the next 3 to 5 days to help prevent you from getting pregnant if you are not on birth control."	www.not-2-late.com; 1-888-NOT-2LATE; http://bedsider.org/where_to_get_it
What do you know about the consequences of sexual behavior?	You can have an STI and not even know it. Not all STIs have symptoms, and not all STIs are curable. Getting pregnant as a teenager comes with many legal and economic responsibilities. Having sex can have legal implications depending on who you have sex with and how old you and your partner are.	www.youngmenshealthsite.org/std-general.html www.babycenter.com/babyCostCalculator.htm www.sexlaws.org
Demonstrate or provide resources (eg, videos, handouts) for correct condom use; distribute condoms		
Have you ever been taught, using a condom model, how to correctly put on a condom?	Using a condom can help reduce your risk of getting an STI and/or getting someone pregnant.	www.cdc.gov/condomeffectiveness/brief.html; www.stdcentral.org/SitC/about
How comfortable are you with putting on a condom?	Check that the condom has not expired and has been properly stored. When opening the package, be careful not to rip the condom. Once open, place the correct side of the condom over an erect penis. Hold onto the reservoir tip at the top, remove any excess air and slowly roll the condom all the way down over the erect penis to the penis base. After ejaculation, hold onto the condom rim at the base of the penis, making sure the condom does not slip off or leak. After removing the condom, dispose of it in the trash.	
Communication with partner about sex		
Do you talk with your partner about sex, preventing STIs/HIV, getting tested for STIs/HIV before having sex for the first time, getting tested together, preventing pregnancy, whether she is on birth control?	I encourage you to talk with your partner about contraception and getting tested together before you start engaging in a new sexual relationship.	www.ahwg.net (see sexual health toolkit—provider pages C45–C65)
Do you know about the different types of female birth control methods?		www.youngwomenshealth.org/contra_types.html

Anticipatory Guidance Topics and Questions	Example Message	Resources
Help teenaged fathers understand their role in parenting Help me understand your relationship with your child(ren) (eg, emotional, physical, and financial support and barriers/facilitators to involvement)? Assess for experience of stress Identify local community resources to promote parenting role (parenting classes, educational support, job training, etc)	We know that fathers who are involved in their children's lives can improve the health of their children and the health of the fathers themselves.	www.fatherhood.org

II. ROLE OF THE HEALTH CARE PROVIDER

A. Provide Individualized Sexual/Reproductive Health Care to Male Adolescents

The provision of sexual/reproductive health care to young men in the clinical setting should be individualized on the basis of the patient's developmental and psychosocial needs by using patient-centered approaches.[147] Health care providers need to be comfortable taking a young man's sexual/reproductive history to elicit the type of information needed to determine the appropriate anticipatory guidance, counseling, and treatment. Trust and relationship-building are also critical elements of the male adolescent's visit that help him to feel comfortable regardless of a physician's gender and/or background. Interviewing the young man one-on-one, separate from accompanying parents or guardians, will also improve the quality of information received and ensure confidentiality of the information shared. As with young women, health care providers need to be cognizant of minor consent laws in the states in which they practice and educate patients about specific state laws as appropriate.[148,149]

Myths about adolescent male sexuality still pervade American society. Health care providers should avoid making assumptions or allowing stereotypes about male adolescent sexuality influence interactions with their young male patients. Health care providers need to understand the specific needs of gay, bisexual, or questioning male adolescents and provide support and/or referral resources as appropriate. Sexual initiation during adolescence should be viewed as part of sexual development. Contrary to the image of male promiscuity, the majority of male adolescents have no more than 1 sex partner during a 1-year period. Most male adolescents also believe that they should be responsible for pregnancy prevention and report condom use as a means of preventing both STIs and pregnancy. Rather than holding young men responsible for the negative sexual/reproductive health outcomes seen among young women (pregnancy, STIs/HIV, and relationship violence), health care providers can address the other half of the partner equation that has historically been left out. Health care providers should share clear and consistent messages with all male adolescents, their parents, and schools about sexual health, comprehensive sex education, and regular care-seeking.

B. Deliver High-Quality Sexual/Reproductive Health Care to Male Adolescents

A number of national organizations make recommendations about clinical services that health care providers should deliver, including the AAP's *Bright Futures*,[4] the CDC,[150–152] and the US Preventive Services Task Force (USPSTF).[153] Sexual/reproductive health services that have been shown to be most effective for health care providers to provide include taking sexual health histories, assessing sexual risk, and providing behavioral counseling regarding STIs.[4,150,153] Regarding laboratory screening for HIV infection, the USPSTF recommends HIV testing on the basis of risk factors for the individual and/or clinic setting.[150,154] The CDC and *Bright Futures* recommend HIV testing for all persons 13 years of age and older and subsequent testing for all persons at high risk at least annually.[4,150,154] Regarding laboratory screening for STIs, although the USPSTF has stated that there is insufficient evidence to screen sexually active young men for chlamydia and gonorrhea,[155,156] the CDC recommends chlamydia screening among sexually active young men in high-prevalence settings (eg, STI, Job Corps, or jail clinics) and rescreening of persons infected with chlamydia 3 months later,[151,152] and *Bright Futures* recommends screening sexually active adolescents for chlamydia and gonorrhea.[4] The USPSTF[157] and *Bright Futures*[4] also recommend testing for syphilis on the basis of individual risk factors. *Bright Futures* also recommends an annual genital examination for SMR and observations for signs of STIs (ie, warts, vesicles) and testicles for hydrocele, hernias, varicocele, or masses. Refer to the AAP's recommended childhood and adolescent immunization schedule.[158] The CDC Advi-

sory Committee on Immunization Practices' recent update recommends routine vaccination of male adolescents against HPV starting at age 11 through 12 years, states that the series can be started beginning at age 9 years, and recommends catch-up vaccination among males ages 13 through 21 years who have not been vaccinated previously or have not completed the 3-dose series through age 21 years. Such vaccination is also recommended in AAP immunization schedule (for updates, see: www.aap.org/immunization/izschedule.html).[158,159] Males age 22 through 26 years may be vaccinated (permissive recommendation for this age group). Routine vaccination is recommended among at-risk males including males who have sex with males and immunocompromised males through age 26 years.

The delivery of sexual/reproductive health services is one of the few effective clinical preventive services that can positively affect male adolescents' and young adults' health.[160] However, health care providers miss many opportunities to assess young men's sexual health and deliver STI/HIV services; on average, fewer than one-quarter of male adolescents and young adult men report receiving sexual/reproductive health services compared with more than half of similarly aged female adolescents.[9,10,161,162]

Health care providers can use each encounter in the office setting as an opportunity to address the core recommended components of male adolescents' sexual/reproductive health with all male adolescent patients, including the provision of appropriate resources to patients and parents. Health care providers should consider scheduling an annual sexual/reproductive health visit for the sexually active young man. The health care provider should know how to:

- take a complete sexual history;
- perform a complete sexual/reproductive health examination that includes examination of the skin, breasts, genitals, hair, and, if relevant, the perianal area and documentation of the SMR;
- perform and interpret STI/HIV tests and know how to treat STIs;
- administer vaccinations, as recommended by the AAP,[158] to protect against infections that are transmitted sexually, such hepatitis B and A vaccines and HPV vaccine[159];
- provide anticipatory guidance/counseling on sexual/reproductive health matters (Table 2), including the use of messages about dual methods (eg, "not having sex is the best way to avoid pregnancy and STIs/HIV, but if you choose to have sex, use condoms consistently and use a reliable contraceptive method for the partner"); and
- use resources (Table 3) in varying formats (ie, clinic handouts, books, Web-based resources, community resources) to share and/or refer patients and parents as needed.

C. Take a Sexual History

A comprehensive and confidential sexual assessment is a standard part of the past medical, family, and social history and should begin during early adolescence and be updated at least annually. This can be accomplished face-to-face or through the use of confidential previsit questionnaires (Table 3).[163–165] Components of a comprehensive sexual health assessment should include asking about attractions to females, males, or both; sexual initiation and age of onset; engagement in vaginal, oral, or anal sex; gender of partner(s); number of partners; current STI symptoms or concerns; history and results of STI/HIV testing; use of condoms; partners' use of methods to protect against STIs and/or pregnancy; and experience of sexual abuse. Assess for comfort with changes in one's body, masturbation, knowledge about how to use a condom correctly, hormonal contraception methods, and emergency contraception. Among sexually experienced males, assess pressure to have sex, access to condoms, use of alcohol or other substances when having sex, experience of pregnancy or fatherhood, experience of being a perpetrator or victim of verbal/physical abuse or force to have sex in a relationship, whether sex is pleasurable, and/or problems with sexual performance. Among patients who state a high number of partners or are hesitant to share their number of partners, consider and ask about whether they are exchanging sex for money or drugs. Among non–sexually active young men, assess for dating, pressure or plans to initiate sex, and knowledge about ways of preventing STIs/HIV and pregnancy. During childhood, encourage and provide resources to parents and families to have developmentally appropriate conversations with their sons that continue through adolescence about sexuality, sex, and other sensitive topics.[37]

A number of verbal and written tools are available that can assist health care providers to take a sexual health assessment and other components of the adolescent's psychosocial history,[166] including the HEEADSSS (home, education and employment, eating, activities, drugs, sexuality, suicide and depression, and safety) assessment and *Bright Futures* toolkits (http://brightfutures.aap.org/tool_and_resource_kit.html).[4,167,168]

D. Perform a Physical Examination

Despite the lack of evidence-based guidelines supporting routine testicular screening and teaching of testicular self-examination for detection of testicular cancer, a genital

examination, including examination of the testicles, represents an important part of a male adolescent's complete physical examination during annual preventive health visits and, specifically, as part of a visit related to a genital complaint.[4] The content of the pediatric/adolescent physical examination required to report preventive health care codes (*Current Procedural Terminology* [CPT] codes 99382–99384; 99392–99394) depends on age and developmental level and would be expected to include a male genital examination. There are many reasons to perform a genital examination, including SMR for hair and genital progress in pubertal development; screening for visual signs of STIs such as herpes, warts, and asymptomatic urethral discharge; identification of signs for genetic diseases such as firm testes (Klinefelter syndrome) or ambiguous genitalia (congenital adrenal hyperplasia); evidence of structural anomalies including varicocele, which can affect fertility, or uncorrected hypospadias, which can result in significant embarrassment, problems with sexual function, and/or abnormal urine flow. Other issues might be related to an uncircumcised penis (eg, phimosis and hygiene); hair or skin findings for treatable conditions (eg, folliculitis and tinea cruris); previously unrecognized absent testes attributable to cryptorchidism; evidence of testicular atrophy secondary to central or exog-

enous causes (eg, steroids or marijuana use); and normal findings that might require reassurance (eg, pearly penile papules).[111,168,169]

Ultimately, one of the goals of the genital examination is to help the young man gain a better understanding of his own body and reproductive parts. For example, young men might not be aware of their genital anatomy, the importance of using genital protection as part of sports participation, or general issues related to their hygiene. Guidance can be given by briefly reviewing the main components of the physical examination and, as the examination progresses, by commenting on normal anatomy, what to expect next, and pertinent findings. Examination in gowns will help prevent missing important physical examination findings, such as gynecomastia or truncal acne. Avoiding lengthy discussions while the patient is undressed also allows for greater patient comfort.

Despite the lack of recommendations that support testicular cancer screening, the USPSTF has noted that "clinicians should be aware that patients who present with symptoms of testicular cancer are frequently diagnosed as having epididymitis, testicular trauma, hydrocele or other benign disorders."[170,171] The American Cancer Society has stated that it "does not have a recommendation on regular testicular self-examinations for all men."[172] Risk factors for testicular cancer among men include being white; being between 13 and 39 years of age; having a history of cryptorchidism, testicular atrophy/dysgenesis, testicular trauma, HIV infection, and Klinefelter syndrome; or having a family history of testicular cancer. An external anal inspection, a digital rectal examination, and screening for hernia as part of the male adolescent physical examination should be performed on the basis of specific concerns or complaints such as a bulging mass or pain (hernia examination), hemorrhoid or rectal bleeding (digital rectal examination), or risk factors that would warrant an external anal inspection for HPV lesions in a young man who engages in receptive anal intercourse.

Health care providers might be confronted with male adolescents who refuse a genital examination because of concerns about homophobia, lack of experience with such examinations, fear of getting an erection, or even because of previous abuse. Understanding the specific concern can help the health care provider educate the patient about the importance of this examination, determine the priority of such an examination for a particular patient, and negotiate how and when to complete the required components of the examination. Routinely examining the genitals from childhood through adolescence can help the male patient understand the routine nature of this examination component. The use of a chaperone might also be relevant and should be considered during all genital examinations for patient and/or provider comfort regardless of whether the provider and patient are the same gender.[173]

E. Perform Laboratory Screening

Sexually active male adolescents 13 years of age and older should be offered an HIV test. HIV testing should occur at least once by 16 to 18 years of age or sooner once an adolescent is known to be sexually active or otherwise at risk. Youth at high risk should be tested annually for HIV infection. Adolescents tested for other STIs should be tested for HIV at the same visit. Youth seen in urgent care facilities and emergency departments should be routinely tested for HIV. In addition, routine HIV screening of young persons in high-risk or high-prevalence settings, such as juvenile detention centers and jails, STI clinics, and teen clinics, has been shown to increase the yield for HIV screening. HIV testing options include serologic tests that provide results within 1 to 2 weeks and newer noninvasive oral rapid tests that provide results within 20 minutes.

Sexually active male adolescents are considered to be among the high-risk groups for STIs and, in general, should be screened even if they are asymptomatic for chlamydia using noninvasive urine tests. Other screenings available as urine tests include those for gonorrhea and trichomonas.[89] Routine screening of asymptomatic males should be based on the prevalence rates within the communities. Among sexually active male adolescents with painful urination (dysuria) and/or urethral discharge, urethritis attributable to an STI will be the most common cause of infection, as opposed to urinary tract infection, which affects less than 0.01% of male adolescents with normal urogenital anatomy.[174] Noninvasive tests are the preferred method (eg, urine-based nucleic acid amplification tests [NAATs] to screen for chlamydia and gonorrhea). These tests have high sensitivities and specificities (>90%) as well as high patient acceptability. Refer to the current CDC's sexually transmitted diseases treatment guidelines for best testing strategies if NAATs are unavailable.[152]

For male patients who report sexual behavior with another man, the CDC's sexually transmitted diseases treatment guidelines recommend HIV serologic testing, if HIV-negative or not tested in the previous year; syphilis serologic testing; a test for urethral infection with chlamydia and gonorrhea among men who have had insertive sex during the preceding year; a test for rectal infection with chlamydia and gonorrhea among men who have had receptive anal sex during the preceding year; and a test for pharyngeal in-

fection for gonorrhea among men who have had receptive oral sex during the preceding year.[152] No current guidelines detail screening recommendations for chlamydia of the pharynx or for anal screening of the rectum using anal Papanicolaou tests or HPV typing.[175–177] Anal Papanicolaou tests and/or HPV typing are currently under review as possible screening tools for anal carcinoma. Nucleic acid amplification tests are not currently approved by the Food and Drug Administration for pharyngeal or rectal specimens but might be available for use in some laboratories. Both chlamydia and gonorrhea can infect the rectum, and gonorrhea can also infect the pharynx. However, there is little evidence that chlamydia can cause pharyngeal infection.

Health care providers should be able to diagnose STIs that occur most commonly in male adolescents and young adults, including chlamydia, gonorrhea, HPV, trichomoniasis, herpes, ascending infections (ie, epididymitis), and syphilis. The CDC's sexually transmitted diseases treatment guidelines (www.cdc.gov/std/treatment) and the AAP's *Red Book* (http://aapredbook.aappublications.org) are updated on a regular basis and provide the most up-to-date screening, testing, and treatment recommendations.[152,178] Health care providers should also encourage STI treatment of their partners through provision of expedited partner therapy, if allowed by state law[179] (www.cdc.gov/std/ept); bringing the partner in for testing and treatment; or referral to local public health facilities (www.hivtest.org).

Health care providers are encouraged to communicate to their patients and families that the delivery of sexual/reproductive health services, including STI/HIV testing, is a standard and routine part of adolescent clinical services. State mandates that require an explanation of benefits to be sent to parents of adolescent patients might conflict with patients' rights to confidential care and minor consent. Adolescents who are seeking confidential testing for STIs might require referral to settings that provide confidential STI testing, such as local public health clinics or Planned Parenthood centers. Informed and proactive health care providers can ensure that their patient's confidentiality is maintained.

F. Provide Anticipatory Guidance and Counseling

Health care providers should tailor anticipatory guidance and counseling on the basis of specific risk factors and/or information obtained during an individual male patient's visit and his developmental stage. Health care providers should continue to be up-to-date on coding and local reimbursement practices that allow for the time it takes to counsel on preventive health care matters to be included within a problem-focused visit. Table 2 lists suggested sexual/reproductive health anticipatory guidance topics and messages for male adolescent patients.

The USPSTF recommends moderate- to high-intensity behavioral counseling in the clinic setting to prevent STIs for all sexually active adolescents.[153] One example of such a counseling approach would be 2 separate 20-minute clinical sessions 1 week apart.[180] During the first clinical session, patients are assessed for personal risk, barriers to risk reduction, and identifying a small risk-reduction step within the next week. During the second clinical session, the previous week's behavioral-change successes and barriers are reviewed, support for changes made is provided, barriers and facilitators to change are identified, and a long-term plan for risk reduction is developed. A study of this method found that participants in intervention clinics who were receiving structured behavioral counseling reported significantly higher condom-use rates and fewer new STIs than participants at control sites. Males and females benefited equally from counseling interventions, and brief interventions were more effective among adolescents than older participants.

G. Administer Vaccinations

Reproductive health-related vaccines, including hepatitis A and B and HPV vaccines, should be administered to male adolescents as recommended by the AAP and the CDC's Advisory Committee on Immunization Practices along with other routine immunizations for male adolescents.

III. GUIDANCE FOR HEALTH CARE PROVIDERS

1. Know the core sexual/reproductive health knowledge areas for male adolescents and understand the affect that sexual health has on the male adolescent's quality of life.
2. Encourage parents to talk about pubertal development and have age-appropriate discussions about sexual health with their sons on repeated occasions.
3. Guide male adolescents to build healthy, responsible relationships.
4. Recognize that some male adolescents might be dealing with issues of sexuality that can affect their psychosocial and physical health, provide appropriate support for families,[181] and identify local resources for referral when appropriate.
5. Regardless of reason for the visit and clinical setting, routinely provide quality male sexual/reproductive health services to all male adolescents.
6. Deliver core sexual/reproductive health services to male adoles-

cents: take a sexual history, perform an appropriate examination, screen for STIs/HIV, provide patient-centered and age-appropriate anticipatory guidance, and deliver appropriate vaccinations.

7. Provide sexual/reproductive health services in a confidential and culturally appropriate manner.
8. Use "clinical hooks," such as sports physicals and acne follow-up visits, to keep young men enrolled in general and especially sexual/reproductive health care. Consider promoting an annual sexual/reproductive health visit for male adolescents to address their core sexual/reproductive health issues.
9. Include in clinic settings everything from handouts to posters to make male adolescents feel welcome and comfortable. Educational materials such as handouts, pamphlets, references, and videos should also be made available to reinforce office-based educational efforts.
10. Continue to be up-to-date on coding and local reimbursement practices that allow for preventive health care counseling to be included within problem-focused visits.

CLINICAL REPORT

Maltreatment of Children With Disabilities

Guidance for the Clinician in Rendering Pediatric Care

Roberta A. Hibbard, MD, Larry W. Desch, MD, and the Committee on Child Abuse and Neglect and Council on Children With Disabilities

ABSTRACT

Widespread efforts are being made to increase awareness and provide education to pediatricians regarding risk factors of child abuse and neglect. The purpose of this clinical report is to ensure that children with disabilities are recognized as a population that is also at risk of maltreatment. Some conditions related to a disability can be confused with maltreatment. The need for early recognition and intervention of child abuse and neglect in this population, as well as the ways that a medical home can facilitate the prevention and early detection of child maltreatment, are the subject of this report.

INTRODUCTION

The maltreatment of children, including those with disabilities, is a critical public health issue. For purposes of this report, the terms "disability" and "special health care needs" include the full spectrum of physical, mental, and emotional impairment. Current data on incidence and prevalence of maltreatment in children with disabilities are limited by varying definitions of disability and lack of uniform methods of classifying maltreatment. Nonetheless, children with disabilities and special health care needs are at increased risk of child maltreatment. This report is an update to the previous policy statement, "Assessment of Maltreatment of Children With Disabilities."[1]

The Children's Bureau reported that an estimated 872 000 children were determined to be victims of abuse or neglect in 2004.[2] More than 60% of child victims experienced neglect, almost 20% were physically abused, and 10% were sexually abused. Of the 36 states that reported on disabilities, child victims who were reported with a disability accounted for 7.3% of all victims. Children with the following conditions were considered as having a disability: mental retardation, emotional disturbance, visual impairment, learning disability, physical disability, behavioral problems, or another medical problem. It was believed that these conditions were underrecognized and underreported, because not every child received a clinical diagnostic assessment when child maltreatment was suspected.

Child maltreatment may result in the development of disabilities, which in turn can precipitate further abuse.[3] Studies have been unable to accurately document the extent or rate of abuse among children with disabilities or determine if disabilities were present before the abuse or were the direct result of maltreatment.[4] It should be emphasized also that several case reports and epidemiologic data remind us that the natural history of some medical conditions can include conditions that mimic child maltreatment.[5,6]

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

The numbers of children who survive disabling medical conditions as a result of technologic advances and children who are recognized and identified as having disabilities are increasing.[7] The rates of child maltreatment have been found to be high in the child population in general and in children with blindness, deafness, chronic illness, developmental delays, behavioral or emotional disorders, and multiple disabilities.[8] Minimal research on child abuse has focused specifically on children with disabilities; further study is indicated and has been encouraged.[9,10]

The Child Abuse and Prevention, Adoption, and Family Services Act of 1988 (Pub L No. 100–294) included a mandate to study the incidence of child maltreatment among children with disabilities. This research was funded by the National Center on Child Abuse and Neglect and conducted by the Center for Abused Children With Disabilities at the Boys Town National Research Center.[8] A study by Westat, Inc, determined the incidence of abuse among children with disabilities and the relationship between child abuse and disabilities.[9] Data were collected from 35 child protective services (CPS) agencies across the country, and results indicated that 14.1% of children whose maltreatment was substantiated by CPS workers had 1 or more disabilities. A Nebraska study that used an electronic merger of hospital, central registry, foster care review board, and law enforcement records found disabilities to be twice as prevalent among maltreated children in hospitals as among hospital controls, which is consistent with the hypothesis that disabilities increase the risk of maltreatment. The data are also consistent with the hypothesis that maltreatment contributes to disabilities.[11]

According to research performed by the Boys Town National Research Hospital, children with disabilities were found to be at greater risk of becoming victims of abuse and neglect than were children without disabilities. The study showed that children with disabilities are 1.8 times more likely to be neglected, 1.6 times more likely to be physically abused, and 2.2 times more likely to be sexually abused than are children without disabilities.[8] Another study found the overall incidence of child maltreatment to be 39% in 150 children with multiple disabilities admitted to a psychiatric hospital. Of those children, 60% had been physically abused, 45% had been neglected, and 36% had been sexually abused.[12] In a 2000 study of more than 4500 maltreated children, Sullivan and Knutson[13] observed children with disabilities to be 3.76 times more likely to be neglected, 3.79 times more likely to be physically abused, and 3.14 times more likely to be sexually abused when compared with children without disabilities.[13] Children with behavioral disorders were found to be at the highest risk of all types of maltreatment, and neglect was the most common form of maltreatment across all disability types. A relative-risk matrix for all types of maltreatment among children with specific disabilities was developed. In 1 recent study, caregivers reported that 18.5% of children with autism had been physically abused and 16.6% had been sexually abused.[14] Spencer et al[15] concluded that children with disabling conditions are at increased risk of child abuse and neglect, although the type of maltreatment varies with the specific disabling condition.

LIMITATIONS OF CURRENT RESEARCH

The prevalence of maltreatment of children with disabilities is difficult to calculate, because states do not use comparable definitions of child abuse and neglect. Another major problem with the published literature is the variable definition of "disabilities."[4] The Centers for Disease Control and Prevention describes developmental disabilities as a diverse group of severe chronic conditions that are attributable to mental and/or physical impairments and result in problems with major life activities such as language, mobility, learning, self-help, and independent living. The Americans With Disabilities Act[16] defines "disability" as a physical or mental impairment that substantially limits 1 or more of the major life activities of an individual. This definition includes all types of disabilities, including physical disabilities, cognitive or learning disabilities, motor and sensory dysfunctions, mental illness, or any other kind of physical, mental, or emotional impairment.[17] Perrin[18] reported that most childhood chronic health conditions do not cause disability. The Maternal and Child Health Bureau has defined children with special health care needs as "those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."[19] The term "children with special health care needs" is less limiting than some other terms.[20]

Legal definitions do not always match clinical data. Child development evaluations do not always allow an immediate and precise diagnosis of extent or type of disability, and some studies rely on evaluations by untrained observers. Therefore, evaluation of research efforts is hindered by different definitions of terms (eg, disabilities and maltreatment), noncomparable methods, various study sample sizes, and lack of uniform data collection. Furthermore, changes in reporting laws and societal attitudes can occur during a study period.[21]

Another problem that has been cited in the literature is the lack of recognition and documentation of disabilities by CPS workers and their lack of training on evaluating children with disabilities.[4] In the study by Westat,[9] analyses were based on CPS workers' opinions rather than data empirically derived from physicians or other professionals trained to diagnose disabilities. Bonner et al[4] demonstrated that since 1982, correct and consistent use of a CPS-created system of collecting information regarding disabilities in maltreated children

had decreased, suggesting that disabilities were unlikely to be identified as children enter the CPS system. A survey of 51 state CPS agencies found that in 86% of states, CPS workers used a standardized form to record child-maltreatment cases, but in only 59% of those states did the workers record information regarding preexisting disabilities on the form.[22]

The Westat study was limited to intrafamilial cases.[9] Because it is well known that individuals other than family members can commit harm to children, statistics limited to intrafamilial cases would be likely to underestimate the overall incidence of maltreatment among children with disabilities.

Along with the lack of well-designed research on maltreatment is the lack of research on how to respond to children with disabilities who have been maltreated. A needs assessment of parents, educators, and CPS investigators in 2000 revealed that knowledge and experience in child maltreatment were lacking.[23] Most respondents were interested in training, with recognition of maltreatment in the child with a disability as a top priority. In this same report, a collaborative team-approach response was recommended.

CAUSAL FACTORS

In general, the causes of abuse and neglect of children with disabilities are the same as those for all children; however, several elements may increase the risk of abuse for children with disabilities. Children with chronic illnesses or disabilities often place higher emotional, physical, economic, and social demands on their families.[21] For example, a physical disability that causes difficulty in ambulation can place a child at risk of accidental falls. Therefore, much closer supervision will be needed, which itself can be stressful. Parents with limited social and community support may be at especially high risk of maltreating children with disabilities, because they may feel more overwhelmed and unable to cope with the care and supervision responsibilities that are required.[17] Lack of respite or breaks in child care responsibilities can contribute to an increased risk of abuse and neglect. Finally, the added requirements of special health care and educational needs can result in failure of the child to receive needed medications, adequate medical care, and appropriate educational placements, resulting in child neglect.[17]

Numerous problems have been cited with the provision of care for foster children with disabilities. Foster parents sometimes are not told about a child's medical and emotional problems and are, therefore, not sufficiently educated or prepared to deal with the specific condition. Other problems for foster children with disabilities include lack of permanent placement, lack of a medical home, lack of financial support, and inappropriately prepared foster parents.[3]

Parents or caregivers may feel increased stress because children with disabilities may not respond to traditional means of reinforcement, and sometimes these children's behavioral characteristics (eg, aggressiveness, noncompliance, and communication problems) may become quite frustrating.[8] Behavioral challenges in children who have disabilities may further increase the likelihood of physical abuse.[17]

Parents of children with communication problems may resort to physical discipline because of frustration over what they perceive as intentional failure to respond to verbal guidance. It has been noted paradoxically, however, that families who report higher stress levels may actually have greater insight into problems associated with caring for a disabled child, whereas parents with a history of neglect of a child may not experience the level of stress that a more involved parent may experience.[24]

Although the use of aversive procedures and restraints for children who have disabilities has been fortunately diminishing, in part because of legislative changes (eg, modifications of the Individuals With Disabilities Education Act [Pub L No. 108–446 (2004)]), these practices are still used sometimes in homes, schools, programs, and institutions.[25] Aversive techniques are procedures that use painful or unpleasant stimuli to modify a behavior that has been found to be unacceptable or inappropriate. Restraints are physical measures (such as tie-downs or prolonged seclusion) used to prevent something physical from happening or for "punishment." This includes "therapeutic holding," which has been repudiated as being harmful.[26] During the past 20 years, much research has demonstrated the effectiveness of alternative measures, commonly called "positive behavioral supports," to change behavior.[25] Pediatricians and others who could use additional information about the problems that occur from the use of aversive procedures or restraints can easily get this guidance from the Web sites of organizations such as the Association for the Severely Handicapped (www.tash.org/IRR/resolutions/res02aversive.htm) and the Autism National Committee (www.Autcom.org/restraints.html). Information about positive behavioral support guidelines is available from a US Department of Education–funded program, the Technical Assistance Center on Positive Behavioral Interventions & Supports (www.Pbis.org), and other national and international programs. The American Academy of Child and Adolescent Psychiatry also provides guidance on this subject (www.aacap.org/page.ww?section=Policy+Statements&name=Coercive+Interventions+for+Reactive+Attachment+Disorder).

The presence of multiple caregivers may heighten or reduce the risk of abuse of the child. Infrequent contact of a child with disabilities with other children and adults may make them uniquely vulnerable to molestation because there is decreased opportunity for the child to

develop a trusting relationship with an individual to whom he or she may disclose the abuse[17] and decreased opportunity to learn to resist molestation. On the other hand, children with disabilities who require multiple caregivers or providers may have contact with numerous individuals, thereby increasing the opportunity for abuse, including sexual abuse. However, advantages to having a large number of caregivers are that there are more individuals who may detect the injuries or signs of abuse, and the additional assistance may actually lessen the amount of stress placed on the primary caregivers. Risk may be minimized by careful screening and selection of caregivers, sporadic and unscheduled monitoring of care, and an open mind to recognition that any child may become a victim.

Children with disabilities often have limited access to critical information pertaining to personal safety and sexual abuse prevention. Children who have increased dependency on caregivers for their physical needs may be accustomed to having their bodies touched by adults on a regular basis. Parents may object to their child being provided with education on human sexuality, because they may feel that their children will never be in sexually risky situations because of their special needs. However, children with disabilities may be unintentionally conditioned to comply with authority, which could result in them failing to recognize abusive behaviors as maltreatment.[8] Children with disabilities are often perceived as easy targets, because their intellectual limitations may prevent them from being able to discern the experience as abuse and impaired communication abilities may prevent them from disclosing abuse. Because some forms of therapy may be painful (eg, injections or manipulation as part of physical therapy), the child may not be able to differentiate "appropriate" pain from "inappropriate" pain.

PEDIATRICIAN'S ROLE

Pediatricians should be aware that the presence of disabilities in a child is a risk factor for victimization and that disabilities can also be the result of child maltreatment. The pediatrician should work with families, other health care professionals, and other community resources to ensure the safety of all children, including those with disabilities. The following should be considered.

Identification and Reporting

Pediatricians always need be alert to signs or symptoms that are suggestive of abuse, no less in children with disabilities than in others. However, recognizing the signs and symptoms of maltreatment among children with disabilities may be difficult, because many children may not be able to verbalize that they were abused or they may not understand that what took place was wrong.[17] Because it is common for the physical examination to be normal, especially in sexual abuse and emotional maltreatment, a high index of suspicion in selected cases is warranted.

Familiarity with the natural history of disorders that may mimic child abuse can prevent the misdiagnosis of child maltreatment.[27–29] Children with motor and balance disabilities may experience increased injuries from accidents. Children with neurosensory disabilities may be predisposed to fractures, and in the absence of pain, there may be a delay in seeking medical attention. For example, children with spina bifida have a high risk of fracturing a paralyzed, desensitized limb.[5] Children with severe nutritional deficiency and immobility or chronic steroid use may develop demineralized bones that fracture easily. Children with blood dyscrasias may have bruises of varying ages in unusual places. There are also reports of a variety of disabling conditions that mimic child maltreatment, including methylmalonic aciduria and glutaric aciduria, which can manifest as chronic subdural effusions and mild retinal hemorrhages, with other telltale findings including neurodevelopmental problems.[6,30]

Awareness of injury patterns from inflicted versus noninflicted trauma is important for pediatricians and other professionals who work with children. Signs and symptoms of maltreatment in children with disabilities are commonly ignored, misinterpreted, or misunderstood. Furthermore, many schools, programs, and institutions may have a disincentive to recognize or report child maltreatment because of fear of negative publicity or loss of funding or licensure. Pediatricians may want to act proactively with these entities so that concerns and referrals are more forthcoming if questions or problems arise.

If abuse or neglect is suspected after a careful assessment, a report must be made to the appropriate CPS agency. Every child suspected of being abused or neglected needs a thorough evaluation by an experienced professional.[31] The evaluation process should consist of a structured interview with the child, if possible, and a comprehensive physical examination including appropriate laboratory and radiologic studies as indicated. In many situations, a consultation with a developmental pediatrician, pediatric neurologist, child abuse pediatrician, or other expert in children with disabilities is also indicated.

Treatment

Appropriate medical treatment for injuries, infections, or other conditions should be provided. Each case of abuse or neglect that is clinically confirmed or strongly suspected needs a multidisciplinary treatment plan, which includes a mental health assessment and treatment component that is appropriate for the child's cognitive and developmental level and counseling for the family. This child and family treatment plan should be integrated

with other intervention plans that may already have been developed for the child. Federal legislation requires that each child identified as having a disability should have a written plan of service (an individualized family service plan for children from birth to 3 years of age or an individualized education plan for children 3 through 21 years of age).[32,33] The pediatrician should also make appropriate medical recommendations and provide treatments that are preventive or prescriptive. The pediatrician may help the family explore available child care and respite services. A discussion of injury-prevention guidelines for children with disabilities is also helpful.[34] Although pediatricians can have input into the process, removal of the child from the home or therapeutic foster care placement is at the discretion of the CPS agency only after a thorough investigation.

Education

In-service training for CPS workers, law enforcement professionals, health care professionals, child care providers, early childhood educators, teachers, and judges is crucial, and protocols are necessary for the identification, reporting, and referral of all cases of suspected child maltreatment in all schools, programs, and institutional settings. Experts in child maltreatment and childhood disabilities would be the main group to assist with this educational endeavor. However, general pediatricians can have important roles, for example, with local school districts. In addition, education on risk factors for maltreatment of children with disabilities should be emphasized.

Pediatricians can also be important role models to parents, trainees, and others. In their own offices, clinics, or hospital settings, pediatricians and others who provide care for children with disabilities should not rush to use physical restraints during procedures for these children. Often, taking the time to explain procedures in terms appropriate to developmental level or in other ways to prepare such a child can make restraints unnecessary except in situations when children are dangerous to themselves or others. Even when some types of restraints are needed, such as to prevent a child from scratching at newly repaired lacerations, such restraints should be as comfortable and as minimal as possible and used for the shortest time feasible.

Pediatricians may also have roles to assist in the education about child abuse to their peers, residents, medical students, and other health care students. All health care professionals need adequate training to monitor children with disabilities for signs of abuse and neglect and to screen suspected victims of child maltreatment for disabilities.[35]

Prevention

Support and assistance with parenting skills are often needed by families, especially families who have children with special health care needs. Medical and nonmedical needs of the child and family should be addressed at each health supervision visit. Child and family strengths should be recognized and fostered at each encounter. Family stressors should be identified and addressed, and referrals for appropriate support services should be made. Disability-specific injury-prevention guidelines can be presented to help the family minimize injury.[34] The availability of parent support groups, respite care, and home health services may be explored, and referrals may be made when appropriate. Pediatricians can help educate parents of children with disabilities about the various respite and medical waiver subsidies and programs specific to each state and how to qualify for such funds. Pediatricians can explain the need for getting placed on the inevitable waiting lists for these programs as early as possible. The American Academy of Pediatrics (AAP)–sponsored medical home Web site (www.medicalhomeinfo.org) is an important resource for the pediatrician to find out more information on these programs, including state-by-state resources.

All children with or without disabilities need a medical home that consists of a health care professional who is readily accessible to the family to answer questions, help coordinate care, and discuss concerns.[36] Medical home is an approach to providing comprehensive primary care that is accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. Families should be encouraged and assisted by these health care professionals to work with a variety of agencies and disciplines and pursue resources and services that they need. Child abuse prevention, including indicators of abuse, should be discussed with parents and caregivers.[23,24] Neurodevelopmental and developmental-behavioral pediatricians and child neurologists who are trained and experienced in the diagnosis and evaluation of children with disabilities can also serve as excellent resources to both the general pediatricians and the families.

Advocacy

The pediatrician, in providing the medical home and acting as his or her patient's and family's advocate, may review care that is provided by the various agencies and resources. Much of this advocacy effort can be performed by coordinating efforts and ensuring that recommendations are made and followed.[36] By providing this careful follow-up, if child maltreatment is suspected, the need for appropriate referrals can be identified immediately.

Pediatricians play an important advocacy role in their relationships with various governmental and nongovernmental agencies. State AAP chapters also have an important role in these arenas. State, educational, social, foster care, financial, and health care systems often function in isolation from each other, with very little coordination or communication.[8] Community involvement

can also encourage the development of needed resources, including child care and respite services for families with a child with a special health care need. Foster children with disabilities and their foster parents often suffer from lack of adequate support systems.[4] Communication with schools and other systems with which families interact is another avenue for heightening the awareness of the needs of children who have disabilities and/or special health care needs.

As child advocates, pediatricians are in an ideal position to influence public policy by sharing information and giving educational presentations on child maltreatment and the needs of children with disabilities. They should advocate for state practices or policies that mandate CPS agencies to gather disability information on child-maltreatment cases. Pediatricians should emphasize the devastating costs of child maltreatment to legislators, policy-makers, and the public.[4] Pediatricians should also advocate for screening procedures for potential employees in educational, recreational, and residential settings to help ensure the safety of all children in their care.[37]

One resource that is useful to the pediatrician is the report *A Call to Action: Ending Crimes of Violence Against Children and Adults With Disabilities*.[38] This is a report that includes recommendations on policy, surveillance systems and data collection, violence prevention, intervention, and research needs.[38] The Oregon Institute on Disability & Development has developed prevention resources that may be useful to the pediatrician (www.ohsu.edu/research/oidd/oakspublication.cfm).

GUIDANCE FOR THE PEDIATRICIAN

1. Be capable of recognizing signs and symptoms of child maltreatment in all children and adolescents, including those with disabilities.
2. Be familiar with disabling conditions that can mimic abuse or pose an increased risk of accidental injury that can be confused with abuse.
3. Because children with disabilities are at increased risk of maltreatment, remain vigilant not only in assessment for indications of abuse but also in offerings of emotional support and provision of equipment and resources to meet the needs of children and families.
4. Ensure that any child in whom maltreatment has been identified is evaluated thoroughly for disabilities.
5. Advocate for all children, especially those who have disabilities or special health care needs, to have a medical home.[36] If a child is hospitalized and does not have a medical home, the inpatient attending physician can help the family secure one before discharge, preferably as early as possible in the hospital course.[39]
6. Be actively involved with treatment plans developed for children with disabilities and participate in collaborative team approaches.
7. Use health supervision visits as a time to assess a family's strengths and need for resources to counterbalance family stressors and parenting demands.
8. Advocate for changes in state and local policies in which system failures seem to occur regarding the identification, treatment, and prevention of maltreatment of children with disabilities.
9. Advocate for the implementation of positive behavioral supports and elimination of aversive techniques and unnecessary physical restraints in homes, schools, and other educational and therapeutic programs (both public and private), institutions, and settings for children who have disabilities.
10. Advocate for better health care coverage by both private insurers and governmental funding.

CONCLUSIONS

The AAP supports the belief that pediatricians play a significant role in the prevention, identification, and treatment of child abuse and neglect, especially in children with disabilities, who are at increased risk of maltreatment. Children suspected of being maltreated should be evaluated for developmental, physical, and mental health disabilities. In addition, CPS workers and others involved in the investigation of child maltreatment should work closely with pediatricians to identify disabilities in children.[16] Every effort should be made to ensure the safety of children through collaboration with families, other health care professionals, schools, CPS agencies, and other appropriate resources.

THE RISE OF IN-STORE CLINICS: THREAT OR OPPORTUNITY?

"The recent acquisition by the pharmacy chain CVS of MinuteClinic, a chain of in-store clinics founded in Minnesota, has put this model of primary care delivery back in the spotlight. Although still not widespread, the model is increasing in prevalence . . . and appeals to several stakeholders: payers note that primary care is less expensive when delivered at in-store clinics than when provided in a doctor's office or emergency room, patients value the convenience and low price, entrepreneurs see a profitable business model, and proponents of consumer-driven health care see services that can be paid for out of health savings accounts. Physicians, however, express concern about the quality of care and the potential impact on their businesses. The typical in-store clinic is a kiosk—a small, thin-walled structure located inside a store—staffed by a nurse practitioner. The clinics differ from the old 'doc-in-the-box' model in that they are neither routinely staffed by a physician nor intended to provide all primary care services. Indeed, the range of services—posted as a 'menu' on the company's Web site or on the kiosk—is strikingly small, including common adult vaccinations, screening tests, and treatment for simple conditions. . . . But for these circumscribed services, the clinics provide a compelling value proposition. Care is intended to be quick, inexpensive, and convenient; visits and waiting times are short, the charge is usually less than $50, and extended hours are offered along with ample parking. It's not surprising, then, that patients and investors have taken notice. . . . Some wonder whether this model is a 'disruptive innovation'—that is, a service or technology that enters a market at the low end, initially not performing as well as higher-end incumbents, then improves until it captures the whole market."

Clinical Report—Management of Food Allergy in the School Setting

abstract

FREE

Food allergy is estimated to affect approximately 1 in 25 school-aged children and is the most common trigger of anaphylaxis in this age group. School food-allergy management requires strategies to reduce the risk of ingestion of the allergen as well as procedures to recognize and treat allergic reactions and anaphylaxis. The role of the pediatrician or pediatric health care provider may include diagnosing and documenting a potentially life-threatening food allergy, prescribing self-injectable epinephrine, helping the child learn how to store and use the medication in a responsible manner, educating the parents of their responsibility to implement prevention strategies within and outside the home environment, and working with families, schools, and students in developing written plans to reduce the risk of anaphylaxis and to implement emergency treatment in the event of a reaction. This clinical report highlights the role of the pediatrician and pediatric health care provider in managing students with food allergies. *Pediatrics* 2010;126:1232–1239

INTRODUCTION

Anaphylaxis is a severe, potentially fatal, systemic allergic reaction that occurs suddenly after contact with an allergy-causing substance.[1] Food allergy is a common cause of anaphylaxis.[2] The Centers for Disease Control and Prevention recently reported an 18% increase in food allergy among school-aged children from 1997 to 2007; 1 in 25 children are now affected.[3] Results of studies of children with food allergy indicate that 16% to 18% have experienced a reaction in school.[4,5] Allergic reactions or treatment for anaphylaxis also occur in children whose allergy was previously undiagnosed (~25% of cases of anaphylaxis).[5,6] Fatalities were noted to be overrepresented by children with peanut, tree nut, or milk allergy and among teenagers and those with underlying asthma. Preschool-aged children may experience food-induced anaphylaxis more often than older children, but the majority of food-allergic reactions in preschool- and school-aged children are not anaphylaxis,[7,8] and deaths are rare.[9]

In case series of fatalities from food allergy among preschool- and school-aged children in the United States, 9 of 32 fatalities occurred in school and were associated primarily with significant delays in administering epinephrine.[10–12]

The purpose of this clinical report is to highlight the pediatrician's role in management of food allergy in the school setting and emphasize prevention and treatment of food-induced anaphylaxis.[13] Management of infants, toddlers, and preschool-aged children who are cared for in myriad settings poses additional challenges (eg, infants may suck on

shared toys, grab another infant's bottle, etc) that are beyond the scope of this document.

DOCUMENTING FOOD ALLERGY (DIAGNOSIS) AND ASSESSING RISKS

Before developing a management plan, it is important to ascertain, as best as possible, whether a child has a potentially life-threatening food allergy. It is beyond the scope of this report to present all of the factors that might be considered in rendering a diagnosis, although comprehensive reviews are available,[14] as are national guidelines (www.niaid.nih.gov/topics/foodAllergy/clinical/Pages/default.aspx). The pediatrician may wish to work with a pediatric allergist but should be aware of several key observations:

- Any food may elicit a reaction; however, most significant reactions in children are attributable to peanut, tree nuts (eg, walnut, cashew, etc), milk, fish, shellfish, egg, soy, and wheat. Sesame and other seeds have been reported as potent allergens as well.[15] Fatalities in school-aged children in the United States have primarily been attributed to peanuts, tree nuts, milk, and seafood,[10–12] but as stated previously, anaphylaxis and death are rare in school-aged children.
- Confirmation of a clinical history (eg, urticaria, wheezing shortly after ingestion) by laboratory tests (eg, allergy skin-prick tests or food-specific serum immunoglobulin E [IgE] testing) is a typical modality for securing a diagnosis. However, although increasingly large skin tests and increasing levels of food-specific IgE antibodies correlate with increasing risk of a true allergy, these tests do not, in isolation, diagnose an allergy, nor do they accurately reflect severity of an allergy or the dose of food that might trigger a reaction. A child also may test strongly positive to a food without a previous known ingestion; in this situation, the child may still be at risk of anaphylaxis. Physician-supervised oral food-challenge testing, typically undertaken by an allergist, may be required to confirm or refute a diagnosis when the history and testing is not sufficient to diagnose the food allergy. Caution must be exercised in making a diagnosis of a life-threatening food allergy, because treatment and food-allergen avoidance require significant efforts for everyone involved.
- Although subsequent reactions are not necessarily more severe than initial reactions, they may be. For example, initial mild reactions to peanut may be followed by more severe reactions on subsequent exposures.[16,17]
- Clinical factors such as a history of asthma, previous reactions to trace exposures, and allergies to foods mentioned previously are potential risk factors for fatal anaphylaxis.[10–12,18]

NOTIFICATION OF THE SCHOOL, PRESCRIPTION OF EPINEPHRINE, AND DEVELOPMENT OF A PERSONALIZED EMERGENCY ACTION PLAN

The family must notify the school about the child's potentially life-threatening food allergy. The family may notify the school by providing a written "emergency action plan" or "food-allergy action plan" (see Appendix for a list of resources). It is recognized that multiple forms of plans are in use and that development of a more universal plan would streamline care. The physician/family may also need to provide the school with a list of foods to be avoided and possible substitutions. Physician-recommended substitutions may be required for school food programs.

The following considerations may be helpful in developing emergency plans:

- The written treatment plan could include the child's name, identifying information (child's picture, if provided), specifics about the food allergies, symptoms and treatments, instructions to activate emergency services, and contact information (see Appendix).
- The parent should be given a prescription for self-injectable epinephrine devices to be used at school in addition to ones for use at home. It may be useful to prescribe additional autoinjectors for school: (1) one to be carried by the child in a dedicated pack that is either on his or her person (if it is judged reasonable for the specific child and is in accord with local regulations) or in possession of the supervising adult and (2) other(s) to be kept in the health office, should the self-carried pack be misplaced or an additional dose be needed. The second-dose feature of some types of self-injectors requires handling of a used needle; although access to the second dose is appropriate in some settings by licensed personnel, these types of injectors should be disposed of after the first dose to reduce the risk of needle-stick injury in the school setting (if a second dose is needed, another unit should be used).
- Before creating an action plan, the pediatrician may determine if there is a licensed health care professional who will be assisting the child. When there is not, and only a nonlicensed assistive person is available, the action plan should be as simple as possible. For example, whereas a licensed health professional may be able to administer an antihistamine and observe for progression of symptoms before administering epinephrine, a nonli-

censed professional should not be expected to make a medical or nursing assessment. Instead, the advice may be to give the epinephrine via autoinjector and call for activation of emergency medical services immediately.

- There is no diagnostic test for anaphylaxis, and specific symptoms may vary. A recent report suggested that anaphylaxis is likely to be occurring if any of the following 3 situations are observed[1]:

1. acute onset (minutes to several hours from exposure) of symptoms with involvement of the skin and/or mucosal tissue (eg, generalized hives, pruritus or flushing, swollen lips/tongue/uvula) and signs or symptoms of either respiratory compromise (eg, dyspnea, wheeze/bronchospasm, stridor, reduced peak expiratory flow, hypoxemia) and/or reduced blood pressure or associated symptoms of end-organ dysfunction (eg, hypotonia [collapse], syncope, incontinence); or
2. 2 or more of the following that occur rapidly after exposure to a likely allergen for that patient: involvement of the skin/mucosal tissue; respiratory compromise; reduced blood pressure or associated symptoms; or persistent gastrointestinal tract symptoms (eg, crampy abdominal pain, vomiting); or
3. reduced blood pressure after exposure to a known allergen for that patient (minutes to several hours).

- In the context of a possible allergen ingestion, a simple means to impart instructions regarding when epinephrine should be administered is to suggest that it be injected for significant respiratory (eg, tightness of the throat, hacking cough, hoarseness, shortness of breath, wheezing, etc) or cardiovascular symptoms (eg, paleness, blue skin tone, decreased consciousness/confusion, poor pulses, etc) or if there is progression of symptoms or involvement of more than 1 organ system (eg, more than a few hives). The treatment plans (see Appendix) list key additional symptoms not stated in this report.
- Anaphylaxis may occur without urticaria.[10]
- Dosing of self-injectable epinephrine (either 0.15 or 0.3 mg) has been reviewed in a previous clinical report.[19] Briefly, the manufacturer recommends switching to the 0.3-mg dose at 66 lb, but because that results in underdosing as children approach this weight, consideration should be given to prescribing the 0.3-mg dose at approximately 55 lb.
- Symptoms of anaphylaxis may initially respond to treatment but recur (biphasic response) with possibly more severe manifestations.[10] Therefore, emergency plans should include activation of emergency medical services and transport to a facility at which additional observation and care can be administered in the ensuing hours whenever a significant allergic reaction is believed to have occurred. A second dose of epinephrine is recommended[20–22] in 5 to 20 minutes if significant symptoms progress or are not responding to the first dose.
- Because 25% of anaphylaxis in schools occurs without a previous diagnosis,[6] a prescription for unassigned epinephrine for general use, consistent with district regulations and state laws, should be considered, especially in schools with nurses. A standard anaphylaxis-management protocol should be developed by the school health services staff and the consulting school physician. In districts without a school physician, a standard anaphylaxis-management protocol could be developed in consultation with local public health professionals, community health center staff, or school-of-medicine faculty.

Additional information about administration of medications in schools is addressed in a policy statement from the American Academy of Pediatrics titled "Guidance for the Administration of Medication in School."[23] The diagnosis, treatment plan, and prescriptions should be reviewed periodically and updated at least yearly. Pediatricians should remind parents to be cognizant of expiration dates on epinephrine autoinjectors and to be alerted to proper temperature storage requirements.

- It may be advisable to inject epinephrine at the time of first symptoms if an allergen was ingested that previously caused anaphylaxis.[24]
- It may be advisable to inject epinephrine before symptoms if an allergen was ingested that previously caused anaphylaxis with cardiovascular collapse.[24]
- Emergency action plans can be individualized according to the child's history as well as the abilities of the responsible adult.
- Physicians are encouraged to educate parents/school caregivers that:
  - antihistamines are adjunctive therapies to treat an allergic reaction but cannot be depended on to treat anaphylaxis;
  - inhaled bronchodilators may be given for respiratory reactions but must not be depended on to treat anaphylaxis;
  - medication should not be exposed to extremes in temperature, and expired units should be replaced; and

- epinephrine is generally safe (ie, when in doubt, inject), and parents/school caregivers should be advised about common adverse effects of epinephrine (eg, tremor, tachycardia, flushing/paleness).

- In some adults experiencing anaphylaxis who were raised from the supine to the upright position during transport to a hospital, death occurred suddenly, presumably from "empty-ventricle syndrome" caused by blood pooling in the legs during anaphylactic shock.[25] The implications of this observation for children, who more typically succumb to respiratory insufficiency during anaphylaxis and who may vomit during anaphylaxis, are not known. Nevertheless, caregivers should be advised that individuals with severe anaphylaxis who may benefit from being in a supine position with legs raised should remain in that position and be transported that way by emergency personnel until advanced care can be accessed (eg, additional medications and intravenous fluids).
- Physicians are encouraged to educate families and the student, as appropriate for age (or arrange for education):
  - about how to administer self-injectable epinephrine and educate others, because mistakes are common[26];
  - to consider obtaining medical identification jewelry;
  - about the importance of avoidance strategies (eg, no food-sharing), to notify an adult of any symptoms or if they may have eaten an unsafe food, and when to use self-injectable epinephrine; and
  - to determine if carrying/self-administration of self-injectable epinephrine is appropriate (assuming local and state agencies allow it) (to make these decisions, student, parent/guardian, and school and community factors may be assessed [see: www.nhlbi.nih.gov/health/prof/lung/asthma/emer_med.htm]; however, designated adults [eg, licensed provider or a lay designee] should be additionally responsible for treatment. because the student may not be depended on for or be capable of self-administration).
- Pediatricians can encourage parents to request to meet with key school staff members who have responsibility for the care of their child and to work cooperatively with schools to ensure their child's safety. Key staff members may include the directors of transportation and food service, the building administrator, school nurse, classroom teacher, and director of health services. Pediatricians can provide resources for parents to give to school officials to help them develop food-allergy management protocols at the school board of directors' level. Pediatricians can also serve as a resource to school wellness committees or councils and to boards of education to help them in developing safe policies, regulations, and procedures for children with food allergies.
- Pediatricians (and allergists) are encouraged to counsel parents about the level of exposure that might be dangerous for a specific child, such as ingestion versus inhalation versus touching food residues, so that parents are appropriately vigilant without becoming needlessly hypervigilant about avoidance strategies, particularly because they might affect schools or neighbors.

AVOIDANCE STRATEGIES

Avoidance strategies must be practical and focus on policies to avoid ingestion of the allergen, the primary route that can result in anaphylaxis. There have been no controlled studies to evaluate the effectiveness of potential avoidance strategies. Knowledge about risks primarily come from observational studies and self-report. Avoidance strategies appropriate for a specific child may vary on the basis of the nature of the allergy, circumstances unique to the particular institution, age of the child, and the child's developmental stage and disposition.

BEST-PRACTICE STRATEGIES

The following points may be helpful in instructing families and schools about avoidance strategies.

- Studies of skin contact and inhalation of peanut-butter vapors by children with peanut allergy failed to induce any systemic reactions.[27,28] Lack of a reaction from these casual exposures is not unexpected, because penetration to the systemic circulation by skin contact is unlikely, and peanut-butter vapors do not contain protein. Although these findings suggest that such exposures are of low risk, concern remains for young children transferring skin contact to their mouths.
- Case reports and controlled studies in which foods are vaporized through heating have shown that reactions, primarily respiratory, can be elicited.[29] These observations support limiting exposure to allergens being cooked (eg, in science/craft projects).
- Reports that focused on reactions to peanut in schools from noningestion exposures primarily identified craft projects with peanut butter as a cause of mostly mild reactions.[5] This observation supports not using

food allergens in craft or cooking projects.

- A study showed that peanut can be cleaned from the hands of adults by using running water and soap or commercial wipes but not antibacterial gels alone.[30] In addition, peanut was cleaned easily from surfaces by using soap, wet wipes, and commercial wipes but not dishwashing liquid alone. Results of threshold studies indicated a wide range of doses of peanut that elicit objective symptoms, but the lower range seems to be 10 to 100 mg, on average. More typical eliciting doses are one-half to one whole peanut kernel.[31] These observations indicate that standard cleaning and lack of visible contamination should suffice for most children with peanut allergies.
- On the basis of the aforementioned studies, allergen avoidance might vary depending on the age of the children, and more supervision, cleaning, and containment of the allergen are needed for younger children. Care must be taken not to ostracize or physically separate the child with food allergies. For example, an "allergen-aware" table should include the child's friends who are eating safe meals. Experts have not espoused blanket "bans" on foods,[32] particularly because peanut butter, milk, egg, and other common allergens may be a protein staple of another child's diet. In rare instances, individual schools or classrooms might pursue these options. For example, removal of highly allergenic foods from the vicinity of kindergarten-aged children or children with significant developmental disabilities might be warranted when transfer of the allergen among the children is likely. Schools may wish to ban children from bringing food from home to share with classmates for celebratory functions and offer acceptable alternative options for purchase through school food services.
- Several professional organizations (see Appendix) have advocated procedures to reduce the risk of accidental allergen ingestion that are responsive to previously published observations regarding circumstances leading to allergic reactions.[4,5] These procedures include strict "no food-sharing" policies; use of commercially prepared and labeled, individually wrapped food items; education of those providing foods regarding safe and unsafe foods and label-reading; education of cafeteria/food service staff; a ready supply of safe alternative snacks; and policies of no eating on the school bus and having a means of communication on the bus. Avoidance strategies and emergency management must also be communicated to personnel who may not have primary responsibilities for the student, such as coaches, specialty teachers (art, music, etc), substitute teachers, field trip personnel, etc. These individuals also require training in the use of epinephrine autoinjectors, familiarity with the food-allergy action plan, and indicators for activating the emergency medical response system.
- School food services leadership should be involved in district policy development and assist in the education of cafeteria/food service staff at the individual school level.

SCHOOL TREATMENT GUIDANCE/ DEVELOPMENT OF THE INDIVIDUALIZED HEALTH CARE PLAN

The pediatrician may submit a written emergency action plan, emergency care plan, or food-allergy action plan or emergency medical order so that the school nurse can develop an individualized health care plan (IHCP). The emergency action or care plan is a document created by the pediatrician or school nurse on the basis of medical orders from the pediatrician that is written in simple lay terms for the nonlicensed staff members who may have a supervisory role for a child at any time before, during, or after the school day. The IHCP is a nursing document created by a school nurse with input from the pediatrician's orders that contains a complete school management plan with preventive procedures for day-to-day management in the school. The following information should be considered:

- The student's IHCP is typically developed by the school nurse in collaboration with the family, physician, and other school personnel. General recommendations for materials to be included in the IHCP are included in various state guidelines (see Appendix). The IHCP should be revised according to the child's needs on the basis of age and developmental stages.
- Schools may establish a core team responsible for food-allergy management and actions, to ensure that reasonable and nondiscriminatory avoidance plans are in place, that a food-allergy treatment plan is reviewed and practiced periodically, that people are designated and trained to recognize and treat anaphylaxis, etc (also see Appendix). The pediatrician should be familiar with these responsibilities and may wish to provide education on these procedures, particularly when the plans are part of the student's IHCP. The pediatrician/family may also determine if a full-time registered nurse is present in the student's school during all school hours and advocate for delegation of nursing

services in that school when the school nurse is not present. If there is a before- and/or after-school program, the parent should be aware of the process for ensuring access to epinephrine and allergen reduction during this out-of-school time.

- Results of several studies support the notion that epinephrine may be needed in locations outside of the school cafeteria, that significant delays in administration are associated with fatalities (eg, >20 minutes after symptoms), and prompt administration is advantageous.[6,8,10–12] To ensure access to epinephrine within several minutes, school plans should consider allowing the student to self-carry, if allowed and age appropriate, and/or storing epinephrine in secure and readily accessible locations. Prompt access to a reliable source of autoinjectable epinephrine is critical. To ensure medication security and safety and provide for timely treatment, procedures should be established that specify where the medication will be stored, who is responsible for the medication, who regularly monitors and replaces outdated medication, and who will carry the medication for field trips.
- The adolescent age group seems to be at the highest risk of fatal food-induced anaphylaxis.[10–12] Special attention for this group should include education of the adolescent and his or her peers to reduce risk-taking and to encourage carrying and using medications when needed.[33] Education should be provided to staff, including coaches, trainers, and after-school advisors. Affected students should be permitted to wear/carry clothing/bags/purses that facilitate carrying medications (eg, large pockets, larger purses, book bags, etc).
- Harassment or bullying of students because of their food allergy must be taken seriously. Students should be encouraged to report such behaviors, and the school should address the situation with quick and decisive antibullying policies.
- The legal rights of children with life-threatening food allergies are protected under several laws. If a student qualifies for special education services under the Individuals With Disabilities Education Act and also has food allergies, the food allergy should be addressed in the student's individualized education plan. Section 504 of the Rehabilitation Act of 1973 may also be used to document specific management plans and provides legal recourse for students and their families if they and the school are unable to come to terms on health care plans through normal channels. In some schools, Section 504 plans may not be necessary if the written emergency action plan and/or IHCP provide the necessary procedures for safety. The Americans With Disabilities Act also protects children with life-threatening food allergies who attend schools that do not receive federal funding.
- After a reaction has occurred, it is important to review policies and procedures among the school staff, the child's health care provider, parents, and the child.

SUMMARY

The pediatrician plays an important role in contributing to the management of school-aged children with food allergies. Consultation with a board-certified allergist-immunologist to secure a diagnosis and provide directed treatments and advice is recommended.[34] It is important that there be close communication between the pediatrician and allergist for diagnosis and management. Partnerships with students, families, school nurses, school physicians, and school staff are important for individualizing effective and practical care plans.

Comments on this clinical report were solicited from committees, sections, and councils of the AAP; 5 responded. Additional comments were sought from the Centers for Disease Control and Prevention, National Association of State School Nurse Consultants, National Association of School Nurses, and Food Allergy & Anaphylaxis Network. For recommendations for which high levels of evidence are absent, the expert opinions and suggestions of the members of the Section on Allergy and Immunology and other groups and authorities consulted were taken into consideration in developing this clinical report.

CLINICAL REPORT

Management of Children With Autism Spectrum Disorders

Guidance for the Clinician in Rendering Pediatric Care

Scott M. Myers, MD, Chris Plauché Johnson, MD, MEd, the Council on Children With Disabilities

ABSTRACT

Pediatricians have an important role not only in early recognition and evaluation of autism spectrum disorders but also in chronic management of these disorders. The primary goals of treatment are to maximize the child's ultimate functional independence and quality of life by minimizing the core autism spectrum disorder features, facilitating development and learning, promoting socialization, reducing maladaptive behaviors, and educating and supporting families. To assist pediatricians in educating families and guiding them toward empirically supported interventions for their children, this report reviews the educational strategies and associated therapies that are the primary treatments for children with autism spectrum disorders. Optimization of health care is likely to have a positive effect on habilitative progress, functional outcome, and quality of life; therefore, important issues, such as management of associated medical problems, pharmacologic and nonpharmacologic intervention for challenging behaviors or coexisting mental health conditions, and use of complementary and alternative medical treatments, are also addressed.

doi:10.1542/peds.2007-2362

Key Words
autism, autism spectrum disorders, Asperger syndrome, pervasive developmental disorders, complementary and alternative medicine, early intervention

Abbreviations
ASD—autism spectrum disorder
TEACCH—Treatment and Education of Autistic and Related Communication Handicapped Children
ABA—applied behavior analysis
DTT—discrete trial training
DIR—developmental, individual-difference, relationship-based
RDI—relationship-development intervention
RT—responsive teaching
SI—sensory integration
EEG—electroencephalography
SSRI—selective serotonin-reuptake inhibitor
CAM—complementary and alternative medicine

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

The term autism spectrum disorders (ASDs) has been used to include the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*[1] diagnostic categories autistic disorder, Asperger disorder, and pervasive developmental disorder–not otherwise specified.[2] Recent estimates of the prevalence of ASDs are in the range of 6.5 to 6.6 per 1000, and pediatricians, therefore, are likely to care for children and adolescents with these diagnoses.[3–5] In the companion document to this clinical report,[2] the American Academy of Pediatrics has summarized pertinent background information on ASDs and emphasized the importance of surveillance and screening as well as other potential physician roles in the diagnostic process. However, the role of the primary health care professional extends beyond recognizing signs of ASDs, referring for diagnostic evaluation, conducting an etiologic investigation, providing genetic counseling, and educating caregivers about ASDs and includes ongoing care and management.

ASDs, similar to other neurodevelopmental disabilities, are generally not "curable," and chronic management is required. Although outcomes are variable and specific behavioral characteristics change over time, most children with ASDs remain within the spectrum as adults and, regardless of their intellectual functioning, continue to experience problems with independent living, employment, social relationships, and mental health.[6–8] The primary goals of treatment are to minimize the core features and associated deficits, maximize functional indepen-

dence and quality of life, and alleviate family distress. Facilitating development and learning, promoting socialization, reducing maladaptive behaviors, and educating and supporting families can help accomplish these goals. Ideally, interventions should help mitigate the core features of ASDs, which include impairment in social reciprocity, deficits in communication, and restricted, repetitive behavioral repertoire.

Educational interventions, including behavioral strategies and habilitative therapies, are the cornerstones of management of ASDs. These interventions address communication, social skills, daily-living skills, play and leisure skills, academic achievement, and maladaptive behaviors.

Optimization of medical care is also likely to have a positive impact on habilitative progress and quality of life. In addition to routine preventive care and treatment of acute illnesses, management of sleep dysfunction, coexisting challenging behaviors or psychiatric conditions, and associated medical problems, such as seizures, may be particularly important. Medications have not been proven to correct the core deficits of ASDs and are not the primary treatment. However, associated maladaptive behaviors or psychiatric comorbidities may interfere with educational progress, socialization, health or safety, and quality of life. These behaviors may be amenable to psychopharmacologic intervention or, in some cases, treatment of underlying medical conditions that are causing or exacerbating the behaviors. Effective medical management may allow a child with an ASD to benefit more optimally from educational interventions.

EDUCATIONAL INTERVENTIONS

Education has been defined as the fostering of acquisition of skills and knowledge to assist a child to develop independence and personal responsibility; it encompasses not only academic learning but also socialization, adaptive skills, communication, amelioration of interfering behaviors, and generalization of abilities across multiple environments.[9] Physicians and other clinicians are often in a position to guide families to empirically supported practices and help them evaluate the appropriateness of the educational services that are being offered.

Comprehensive Programs for Young Children

In the last 2 decades, research and program development in the area of educational intervention have focused largely on very young children with ASDs because of earlier identification and evidence that early intensive intervention may result in substantially better outcomes.[9,10] Model early childhood educational programs for children with ASDs have been described in thorough reviews.[9,11,12] These model programs are often categorized as behavior analytic, developmental, or structured teaching on the basis of the primary philosophical orientation. Although the approaches have important differences, they also overlap. For example, contemporary comprehensive behavioral curricula borrow from developmental or cognitive approaches (such as addressing joint attention, reciprocal imitation, symbolic play, and theory of mind and using indirect language stimulation and contingent imitation techniques), and some developmental models (eg, the Denver model) and the structured teaching approach of the Treatment and Education of Autistic and Related Communication Handicapped Children (TEACCH) program use behavioral techniques to fulfill their curriculum goals.[10,13]

Although programs may differ in philosophy and relative emphasis on particular strategies, they share many common goals, and there is a growing consensus that important principles and components of effective early childhood intervention for children with ASDs include the following[9,10,14–16]:

- entry into intervention as soon as an ASD diagnosis is seriously considered rather than deferring until a definitive diagnosis is made;
- provision of intensive intervention, with active engagement of the child at least 25 hours per week, 12 months per year, in systematically planned, developmentally appropriate educational activities designed to address identified objectives;
- low student-to-teacher ratio to allow sufficient amounts of 1-on-1 time and small-group instruction to meet specific individualized goals;
- inclusion of a family component (including parent training as indicated);
- promotion of opportunities for interaction with typically developing peers to the extent that these opportunities are helpful in addressing specified educational goals;
- ongoing measurement and documentation of the individual child's progress toward educational objectives, resulting in adjustments in programming when indicated;
- incorporation of a high degree of structure through elements such as predictable routine, visual activity schedules, and clear physical boundaries to minimize distractions;
- implementation of strategies to apply learned skills to new environments and situations (generalization) and to maintain functional use of these skills; and
- use of assessment-based curricula that address:
  - functional, spontaneous communication;
  - social skills, including joint attention, imitation, reciprocal interaction, initiation, and self-management;

- functional adaptive skills that prepare the child for increased responsibility and independence;
- reduction of disruptive or maladaptive behavior by using empirically supported strategies, including functional assessment;
- cognitive skills, such as symbolic play and perspective taking; and
- traditional readiness skills and academic skills as developmentally indicated.

Specific Strategies

A variety of specific methodologies are used in educational programs for children with ASDs. Detailed reviews of intervention strategies to enhance communication,[9,17–20] teach social skills,[21–24] and reduce interfering maladaptive behaviors[21,25,26] have been published in recent years. Brief descriptions of selected methodologies are provided below.

Applied Behavior Analysis

Applied behavior analysis (ABA) is the process of applying interventions that are based on the principles of learning derived from experimental psychology research to systematically change behavior and to demonstrate that the interventions used are responsible for the observable improvement in behavior. ABA methods are used to increase and maintain desirable adaptive behaviors, reduce interfering maladaptive behaviors or narrow the conditions under which they occur, teach new skills, and generalize behaviors to new environments or situations. ABA focuses on the reliable measurement and objective evaluation of observable behavior within relevant settings including the home, school, and community. The effectiveness of ABA-based intervention in ASDs has been well documented through 5 decades of research by using single-subject methodology[21,25,27,28] and in controlled studies of comprehensive early intensive behavioral intervention programs in university and community settings.[29–40] Children who receive early intensive behavioral treatment have been shown to make substantial, sustained gains in IQ, language, academic performance, and adaptive behavior as well as some measures of social behavior, and their outcomes have been significantly better than those of children in control groups.[31–40]

Highly structured comprehensive early intervention programs for children with ASDs, such as the Young Autism Project developed by Lovaas[35,41] at the University of California Los Angeles, rely heavily on discrete trial training (DTT) methodology, but this is only one of many techniques used within the realm of ABA. DTT methods are useful in establishing learning readiness by teaching foundation skills such as attention, compliance, imitation, and discrimination learning, as well as a variety of other skills. However, DTT has been criticized because of problems with generalization of learned behaviors to spontaneous use in natural environments and because the highly structured teaching environment is not representative of natural adult-child interactions. Traditional ABA techniques have been modified to address these issues. Naturalistic behavioral interventions, such as incidental teaching and natural language paradigm/pivotal response training, may enhance generalization of skills.[13]

Functional behavior analysis, or functional assessment, is an important aspect of behaviorally based treatment of unwanted behaviors. Most problem behaviors serve an adaptive function of some type and are reinforced by their consequences, such as attainment of (1) adult attention, (2) a desired object, activity, or sensation, or (3) escape from an undesired situation or demand. Functional assessment is a rigorous, empirically based method of gathering information that can be used to maximize the effectiveness and efficiency of behavioral support interventions.[42] It includes formulating a clear description of the problem behavior (including frequency and intensity); identifying the antecedents, consequences, and other environmental factors that maintain the behavior; developing hypotheses that specify the motivating function of the behavior; and collecting direct observational data to test the hypothesis. Functional analysis also is useful in identifying antecedents and consequences that are associated with increased frequency of desirable behaviors so that they can be used to evoke new adaptive behaviors.

Structured Teaching

The TEACCH method, developed by Schopler and colleagues,[43] emphasizes structure and has come to be called "structured teaching." Important elements of structured teaching include organization of the physical environment, predictable sequence of activities, visual schedules, routines with flexibility, structured work/activity systems, and visually structured activities.[43] There is an emphasis on both improving skills of individuals with ASDs and modifying the environment to accommodate their deficits. Several reports have documented progress in children who have received TEACCH services as well as parent satisfaction and improvement in parent teaching skills, but these reports were not from controlled studies of treatment outcomes.[44–49] In a controlled trial, Ozonoff and Cathcart[50] found that children treated with a TEACCH-based home program for 4 months in addition to their local day treatment programs improved significantly more than children in the control group who received local day treatment services only.

Developmental Models

Developmental models are based on use of developmental theory to organize hypotheses regarding the fundamental nature of ASDs and design approaches to address

the deficits. The Denver model, for example, is based largely on remediating key deficits in imitation, emotion sharing, theory of mind, and social perception by using play, interpersonal relationships, and activities to foster symbolic thought and teach the power of communication.[12] This program has shifted from a center-based treatment unit to service delivery in homes and inclusive school environments. Several studies have demonstrated improvements in cognitive, motor, play, and social skills beyond what would be expected on the basis of initial developmental rates in children who are treated according to the Denver model, but controlled trials are lacking.[51–54]

Relationship-focused early intervention models include Greenspan and Wieder's developmental, individual-difference, relationship-based (DIR) model,[55] Gutstein and Sheely's relationship-development intervention (RDI),[56] and the responsive-teaching (RT) curriculum developed by Mahoney et al.[57,58] The DIR approach focuses on (1) "floor-time" play sessions and other strategies that are purported to enhance relationships and emotional and social interactions to facilitate emotional and cognitive growth and development and (2) therapies to remediate "biologically based processing capacities," such as auditory processing and language, motor planning and sequencing, sensory modulation, and visual-spatial processing. Published evidence of the efficacy of the DIR model is limited to an unblinded review of case records (with significant methodologic flaws, including inadequate documentation of the intervention, comparison to a suboptimal control group, and lack of documentation of treatment integrity and how outcomes were assessed by informal procedures[55]) and a descriptive follow-up study of a small subset (8%) of the original group of patients.[59] RDI focuses on activities that elicit interactive behaviors with the goal of engaging the child in a social relationship so that he or she discovers the value of positive interpersonal activity and becomes more motivated to learn the skills necessary to sustain these relationships.[56] Some reviewers have praised the face validity of this model, which targets the core impairment in social reciprocity. However, the evidence of efficacy of RDI is anecdotal; published empirical scientific research is lacking at this time. One study reported beneficial effects of RT on young children with ASDs or other developmental disabilities.[58] Parents were taught to use RT strategies to encourage their children to acquire and use pivotal developmental behaviors (attention, persistence, interest, initiation, cooperation, joint attention, and affect). Children in both groups improved significantly on nonstandardized play-based measures of cognition and communication and standardized parent ratings of socioemotional functioning. Although a control group was lacking and the potential role of concurrent educational services was unclear, the improvements were beyond what the authors expected from maturational factors alone.[58]

Speech and Language Therapy

A variety of approaches have been reported to be effective in producing gains in communication skills in children with ASDs.[9,17,20] Didactic and naturalistic behavioral methodologies (eg, DTT, verbal behavior, natural language paradigm, pivotal response training, milieu teaching) have been studied most thoroughly, but there is also some empirical support for developmental-pragmatic approaches (eg, Social Communication Emotional Regulation Transactional Support, Denver model, RDI, Hanen model).

People with ASDs have deficits in social communication, and treatment by a speech-language pathologist usually is appropriate. Most children with ASDs can develop useful speech, and chronologic age, lack of typical prerequisite skills, failure to benefit from previous language intervention, and lack of discrepancy between language and IQ scores should not exclude a child from receiving speech-language services.[60] However, traditional, low-intensity pull-out service delivery models often are ineffective, and speech-language pathologists are likely to be most effective when they train and work in close collaboration with teachers, support personnel, families, and the child's peers to promote functional communication in natural settings throughout the day.[60]

The use of augmentative and alternative communication modalities, including gestures, sign language, and picture communication programs, often is effective in enhancing communication.[17,20,61] The Picture Exchange Communication System (PECS)[62,63] is used widely. The PECS method incorporates ABA and developmental-pragmatic principles, and the child is taught to initiate a picture request and persist with the communication until the partner responds. Some nonverbal people with ASDs may benefit from the use of voice-output communication aids, but published evidence for these aids is scant.[20,64] Introduction of augmentative and alternative communication systems to nonverbal children with ASDs does not keep them from learning to talk, and there is some evidence that they may be more stimulated to learn speech if they already understand something about symbolic communication.[61,62,65]

Social Skills Instruction

There is some objective evidence to support traditional and newer naturalistic behavioral strategies and other approaches to teaching social skills.[22–24,66–68] Joint attention training may be especially beneficial in young, preverbal children with ASDs, because joint attention behaviors precede and predict social language development.[69,70] A recent randomized, controlled trial demonstrated that joint attention and symbolic play skills can be taught and that these skills generalize to different

settings and people.[71] Families can facilitate joint attention and other reciprocal social interaction experiences throughout the day in the child's regular activities. Examples of these techniques are described in the American Academy of Pediatrics parent booklet "*Understanding Autism Spectrum Disorders*."[72]

A social skills curriculum should target responding to the social overtures of other children and adults, initiating social behavior, minimizing stereotyped perseverative behavior while using a flexible and varied repertoire of responses, and self-managing new and established skills.[10] Social skills groups, social stories, visual cueing, social games, video modeling, scripts, peer-mediated techniques, and play and leisure curricula are supported primarily by descriptive and anecdotal literature, but the quantity and quality of research is increasing.[10,15,73] A number of social skills curricula and guidelines are available for use in school programs and at home.[10,66,74,75]

Occupational Therapy and Sensory Integration Therapy

Traditional occupational therapy often is provided to promote development of self-care skills (eg, dressing, manipulating fasteners, using utensils, personal hygiene) and academic skills (eg, cutting with scissors, writing). Occupational therapists also may assist in promoting development of play skills, modifying classroom materials and routines to improve attention and organization, and providing prevocational training. However, research regarding the efficacy of occupational therapy in ASDs is lacking. Sensory integration (SI) therapy often is used alone or as part of a broader program of occupational therapy for children with ASDs. The goal of SI therapy is not to teach specific skills or behaviors but to remediate deficits in neurologic processing and integration of sensory information to allow the child to interact with the environment in a more adaptive fashion. Unusual sensory responses are common in children with ASDs, but there is not good evidence that these symptoms differentiate ASDs from other developmental disorders, and the efficacy of SI therapy has not been demonstrated objectively.[76–78] Available studies are plagued by methodologic limitations, but proponents of SI note that higher-quality SI research is forthcoming.[79] "Sensory" activities may be helpful as part of an overall program that uses desired sensory experiences to calm the child, reinforce a desired behavior, or help with transitions between activities.

Comparative Efficacy of Educational Interventions for Young Children

All treatments, including educational interventions, should be based on sound theoretical constructs, rigorous methodologies, and empirical studies of efficacy.[15] Proponents of behavior analytic approaches have been the most active in using scientific methods to evaluate their work, and most studies of comprehensive treatment programs that meet minimal scientific standards involve treatment of preschoolers using behavioral approaches.[16,38] However, there is still a need for additional research, including large controlled studies with randomization and assessment of treatment fidelity. Empirical scientific support for developmental models and other interventions is more limited, and well-controlled systematic studies of efficacy are needed.

Most educational programs available to young children with ASDs are based in their communities, and often, an "eclectic" treatment approach is used, which draws on a combination of methods including applied behavior analytic methods such as DTT; structured teaching procedures; speech-language therapy, with or without picture communication or related augmentative or alternative communication strategies; SI therapy; and typical preschool activities. Three studies that compared intensive ABA programs (25–40 hours/week) to equally intensive eclectic approaches have suggested that ABA programs were significantly more effective.[31,32,34] Another study that involved children with ASDs and global developmental delay/mental retardation retrospectively compared a less intensive ABA program (mean: 12 hours) to a comparably intensive eclectic approach and found statistically significant but clinically modest outcomes that favored those in the ABA group.[33] Although the groups of children were similar on key dependent measures before treatment began, these studies were limited because of parent-determined rather than random assignment to treatment group. Additional studies to evaluate and compare educational treatment approaches are warranted.

Programs for Older Children and Adolescents

Some model programs provide programming throughout childhood and into adulthood.[11] More commonly, the focus of specialized programs is on early childhood, and published research evaluating comprehensive educational programs for older children and adolescents with ASDs is lacking. However, there is empirical support for the use of certain educational strategies, particularly those that are based on ABA, across all age groups to increase and maintain desirable adaptive behaviors, reduce interfering maladaptive behaviors or narrow the conditions under which they occur, teach new skills, and generalize behaviors to new environments or situations.[13,21,28]

When children with ASDs move beyond preschool and early elementary programs, educational intervention continues to involve assessment of existing skills, formulation of individualized goals and objectives, selection and implementation of appropriate intervention strategies and supports, assessment of progress, and adaptation of teaching strategies as necessary to enable students to acquire target skills. The focus on achieving social communication competence, emotional and be-

havioral regulation, and functional adaptive skills necessary for independence continues. Educational programs should be individualized to address the specific impairments and needed supports while capitalizing on the child's assets rather than being based on a particular diagnostic label.

Specific goals and objectives and the supports that are required to achieve them are listed in a child's individualized education plan and should be the driving force behind decisions regarding the most appropriate, least restrictive classroom placement. Appropriate settings may range from self-contained special education classrooms to full inclusion in regular classrooms. Often, a mix of specialized and inclusive experience is appropriate. Even highly functioning students with ASDs often require accommodations and other supports such as provision of explicit directions, modification of classroom and homework assignments, organizational supports, access to a computer and word-processing software for writing tasks, and social communication skills training. When a paraprofessional aide is assigned, it is important that there be an infrastructure of expertise and support for the child beyond the immediate presence of the aide.[80] The specific duties of the aide should be outlined, the strategies to be used should be defined, and the aide should receive adequate training.

In adolescence, the term "transition" is used to describe the movement from child-centered activities to adult-oriented activities. The major transitions are from the school environment to the workplace and from home to community living. In schools, transition-planning activities may begin at as early as 14 years of age, and by 16 years of age, the individualized education plan should include an individualized transition plan. The emphasis may shift from academic to vocational services and from remediating deficits to fostering abilities. A vocational assessment is often conducted to evaluate the adolescent's interests and strengths and to determine the services and supports needed to promote independence in the workplace and in the community. Comprehensive transition planning involves the student, parents, teachers, the medical home, and representatives from all concerned community agencies. Depending on the individual's cognitive level, social skills, health condition, work habits, and behavioral challenges, preparation for competitive, supported, or sheltered employment is targeted. Regardless of the type of employment, attention to skill development should never stop. Skills necessary for independent living should be taught to the degree possible given the abilities of the person. Sexuality education instruction should be included, and there is a growing body of literature that has addressed the topic.[81–83]

MEDICAL MANAGEMENT

Children with ASDs have the same basic health care needs as children without disabilities and benefit from the same health-promotion and disease-prevention activities, including immunizations. In addition, they may have unique health care needs that relate to underlying etiologic conditions, such as fragile X syndrome or tuberous sclerosis, or to other conditions, such as epilepsy, that often are associated with ASDs. Those with pica or persistent mouthing of fingers or objects should be monitored for elevated blood lead concentrations, particularly if the history suggests potential for environmental exposure.[84] These health care needs are most appropriately met within the context of a medical home.[85,86]

To deliver appropriate and effective medical care, the history, approach to the patient, physical evaluation, and treatment options must be considered in the context of the patient's ASD.[87,88] Familiarizing the patient with the office setting and staff, allowing ample time while talking before touching the patient, allowing the child to manipulate instruments and materials, keeping instructions simple, using visual cues and supports, slowing down the pace, exaggerating social cues, and having family and/or familiar staff available may be helpful in reducing the obstacles to health care provision presented by patients' difficulties with social interaction, communication, and accepting novelty.[88] Often, more time is required for outpatient appointments. In a nationally representative sample, it was found that children with ASDs spent twice as much time with the physician per outpatient visit compared with children in control groups.[89]

Associated Morbidity and Mortality

Health care utilization and costs are substantially higher for children and adolescents with ASDs compared with children without ASDs,[89–91] and available data suggest that mortality is increased as well (standardized mortality ratio: 2.4–2.6).[92,93] The increased mortality in ASDs is thought to be largely, but not completely, accounted for by the increased mortality associated with mental retardation and epilepsy. Cases of suicide in higher-functioning individuals have been reported.[6]

Seizures

The reported prevalence of epilepsy among people with ASDs ranges from 11% to 39%.[94] Comorbid severe global developmental delay/mental retardation and motor deficits are associated with a high prevalence of seizures (42%),[95] whereas the prevalence of seizures is only 6% to 8% in children with ASDs without severe mental retardation, a motor deficit, an associated etiologic medical disorder, or a positive family history of epilepsy.[95,96] The prevalence of epilepsy also was higher in studies that included adolescents and young adults, because the onset of epilepsy in ASDs has 2 peaks: 1 before 5 years of age and another in adolescence.[97] Anticonvulsant treatment in children with ASDs is based on the same criteria that are used for other children with

epilepsy, including accurate diagnosis of the particular seizure type.[98]

Epileptiform abnormalities on electroencephalography (EEG) are common in children with ASDs, with reported frequencies ranging from 10% to 72%.[99] Some studies have suggested that epileptiform abnormalities on EEG[100] and/or epilepsy[101] are more common in the subgroup of children with ASDs who have a history of regression, whereas other studies have not demonstrated this association.[102,103] Autistic regression with epileptiform abnormalities on EEG has been compared by analogy with Landau-Kleffner syndrome and electrical status epilepticus in sleep, but there are important differences between these conditions, and the treatment implications are unclear.[94,104] Whether subclinical seizures have adverse effects on language, cognition, and behavior is debated, and there is no evidence-based recommendation for the treatment of children with ASDs and epileptiform abnormalities on EEG, with or without regression.[104] Universal screening of patients with ASDs by EEG in the absence of a clinical indication is not currently supported.[2,99] However, because of the increased prevalence of seizures in this population, a high index of clinical suspicion should be maintained, and EEG should be considered when there are clinical spells that might represent seizures.

Gastrointestinal Problems

The relationship between gastrointestinal problems and ASDs is unclear, because most studies have not examined representative groups of children with ASDs compared with appropriate controls.[105,106] Surveys published in the gastroenterology literature have stated that gastrointestinal problems, such as chronic constipation or diarrhea, occur in 46% to 85% of children with ASDs.[107–109] Lower rates in the range of 17% to 24% have been reported in other population-based studies,[110–112] and a nested case-control study in the United Kingdom found that only 9% of children with ASDs and the same percentage of controls had a history of gastrointestinal complaints.[113] However, in a recent cross-sectional study that used structured interviews and matched control groups, a lifetime history of gastrointestinal symptoms (including abnormal stool pattern, frequent constipation, frequent vomiting, and frequent abdominal pain) was elicited in 70% of the children with ASDs, compared with 42% of the children with other developmental disabilities ($P = .03$) and 28% of the children without developmental disabilities ($P < .001$).[114]

In children with ASDs undergoing endoscopy, who may or may not be representative of the general population of children with ASDs, high rates of lymphoid nodular hyperplasia and, often, histologically subtle esophagitis, gastritis, duodenitis, and colitis have been described, and preliminary evidence suggests that some immunohistochemical features may be unique to inflammation associated with ASDs.[105,115,116] The existing literature does not support routine specialized gastroenterological testing for asymptomatic children with ASDs.[105] However, if a child with an ASD presents with symptoms such as chronic or recurrent abdominal pain, vomiting, diarrhea, or constipation, it is reasonable to evaluate the gastrointestinal tract. Occult gastrointestinal discomfort also should be considered in a child who presents with a change in behavior, such as outbursts of aggression or self-injury. Radiographic evidence of constipation has been found to be more common in children with ASDs than in controls with abdominal pain (36% vs 10%),[117] and effective management may provide global benefit.

Sleep Disturbance

Sleep problems are common in children and adolescents with ASDs at all levels of cognitive functioning.[118–122] Sleep problems correlate with family distress and may have significant effects on daytime functioning and quality of life of children with ASDs.[123–125] In some cases, there may be an identifiable etiology such as obstructive sleep apnea or gastroesophageal reflux; assessment and treatment are guided by history and physical examination. When there is not an identifiable medical cause, behavioral interventions including sleep-hygiene measures, restriction of daytime sleep, positive bedtime routines, and extinction procedures often are effective.[118,126–129]

Relatively little empirical information is available regarding pharmacologic management of sleep problems in children with ASDs or other developmental disabilities. Recommendations typically are based on case reports and open-label trials, extrapolation from the adult literature, and expert consensus (Table 1).[128] There is some evidence of abnormality of melatonin regulation in children with ASDs,[125,130] and melatonin may be effective for improving sleep onset in children with ASDs as well as children with other developmental disabilities[131–134] and otherwise healthy children with sleep/wake disorders.[135] A recent open-label study suggested that controlled-release melatonin improved sleep in a group of 25 children with ASDs and that treatment gains were maintained at 1- and 2-year follow-up,[136] but randomized, double-blind, placebo-controlled studies are needed. Recently, a child and a young adult with ASDs with significant insomnia were reported to have responded well, with no apparent adverse effects, to open-label treatment with the high-affinity melatonin receptor agonist ramelteon.[137] Antihistamines, α_2-agonists, benzodiazepines, chloral hydrate, trazodone, and newer nonbenzodiazepine hypnotic agents, such as zolpidem and zaleplon, sometimes are used to treat pediatric insomnia.[128] In some cases, other conditions or symptoms, such as epilepsy, depression, anxiety, or aggressive outbursts, warrant pharmacologic treatment, and an agent that also may assist with sleep can be chosen.[118]

TABLE 1 **Selected Potential Medication Options for Common Target Symptoms or Coexisting Diagnoses in Children With ASDs**

Target Symptom Cluster	Potential Coexisting Diagnoses	Selected Medication Considerations	Selected References
Repetitive behavior, behavioral rigidity, obsessive-compulsive symptoms	Obsessive-compulsive disorder, stereotypic movement disorder	SSRIs (fluoxetine,[a] fluvoxamine,[a] citalopram, escitalopram, paroxetine, sertraline)	McDougle et al,[158,b] Buchsbaum et al,[180,b] Sugie et al,[159,b] Hollander et al,[157,b] Moore et al,[160,c] Namerow et al,[181,d] Owley et al[182,d]
		Atypical antipsychotic agents (risperidone,[a] aripiprazole, olanzapine, quetiapine, ziprasidone)	McDougle et al[164,b]
		Valproic acid[a]	Hollander et al[183,b]
Hyperactivity, impulsivity, inattention	Attention-deficit/hyperactivity disorder	Stimulants (methylphenidate,[a] dextroamphetamine, mixed amphetamine salts)	Quintana et al,[168,b] Handen et al,[169,b] RUPP Autism Network[170,b]
		α_2-agonists (clonidine,[a] guanfacine)	Fankhauser et al,[172,b] Jaselskis et al,[173,b] Posey et al,[175,d] Scahill et al (RUPP Autism Network)[174,d]
		Atomoxetine[a]	Arnold et al,[178,b] Jou et al,[176,d] Posey et al[177,d]
		Atypical antipsychotic agents (risperidone,[a] aripiprazole, olanzapine,[a] quetiapine, ziprasidone)	McCracken et al,[162,b] Arnold et al,[163,b] Shea et al,[165,b] RUPP Autism Network,[166,b] Troost et al[167,d]
Aggression, explosive outbursts, self-injury	Intermittent explosive disorder	Atypical antipsychotic agents (risperidone,[a] aripiprazole, olanzapine, quetiapine, ziprasidone)	McCracken et al,[162,b] Arnold et al,[163,b] Shea et al,[165,b] RUPP Autism Network,[166,b] Troost et al[167,d]
		α_2-agonists (clonidine,[a] guanfacine)	Fankhauser et al,[172,b] Jaselskis et al,[173,b] Posey et al[175,d]
		Anticonvulsant mood stabilizers (levetiracetam, topiramate, valproic acid)	Hollander et al[184,d], Rugino and Samsock[185,d], Hardan et al[186,d], Myers[148,c], Myers and Challman[149,c]
		SSRIs (fluoxetine,[a] fluvoxamine,[a] citalopram, escitalopram, paroxetine, sertraline)	McDougle et al,[158,b] Moore et al,[160,c] Namerow et al,[181,d] Owley et al[182,d]
		β-blockers (propranolol, nadolol, metoprolol, pindolol)	Connor et al,[187,d] Ratey et al,[188,d] Myers and Challman[149,c]
Sleep dysfunction	Circadian rhythm sleep disorder, dyssomnia–not otherwise specified	Melatonin	Giannotti et al,[136,d] Jan and Freeman,[131,c] Phillips and Appleton,[133,c] Turk,[134,c] Owens et al[128,c]
		Ramelteon	Stigler et al[137,e]
		Antihistamines (diphenhydramine, hydroxyzine)	Reed and Findling,[189,c] Owens et al[128,c]
		α_2-agonists (clonidine, guanfacine)	Mehta et al,[190,d] Ingrassia and Turk,[191,d] Posey et al,[175,d] Owens et al[128,c]
		Mirtazapine	Posey et al[192,d]
Anxiety	Generalized anxiety disorder, anxiety disorder–not otherwise specified	SSRIs (fluoxetine,[a] fluvoxamine,[a] citalopram, escitalopram, paroxetine, sertraline)	McDougle et al,[158,b] Buchsbaum et al,[180,b] Sugie et al,[159,b] Hollander et al,[157,b] Moore et al,[160,c] Namerow et al,[181,d] Owley et al[182,d]
		Buspirone	Buitelaar et al[193,d]
		Mirtazapine	Posey et al[192,d]
Depressive phenotype (marked change from baseline including symptoms such as social withdrawal, irritability, sadness or crying spells, decreased energy, anorexia, weight loss, sleep dysfunction)	Major depressive disorder, depressive disorder–not otherwise specified	SSRIs (fluoxetine,[a] fluvoxamine,[a] citalopram, escitalopram, paroxetine, sertraline)	McDougle et al,[158,b] Moore et al,[160,c] Namerow et al,[181,d] Owley et al[182,d]
		Mirtazapine	Posey et al[192,d]

Evaluation of Challenging Behaviors

Problematic emotional reactions and behaviors such as aggression and self-injury are common in children and adolescents with ASDs. In some cases, medical factors may cause or exacerbate maladaptive behaviors, and recognition and treatment of medical conditions may eliminate the need for psychopharmacologic agents. For example, in the case of an acute onset or exacerbation of aggressive or self-injurious behavior, a source of pain or discomfort may be identified and treated.[138] Sources of discomfort may include otitis media, otitis externa, pharyngitis, sinusitis, dental abscess, constipation, urinary

TABLE 1 **Continued**

Target Symptom Cluster	Potential Coexisting Diagnoses	Selected Medication Considerations	Selected References
Bipolar phenotype (behavioral cycling with rages and euphoria, decreased need for sleep, manic-like hyperactivity, irritability, aggression, self-injury, sexual behaviors)	Bipolar I disorder, bipolar disorder–not otherwise specified	Anticonvulsant mood stabilizers (carbamazepine, gabapentin, lamotrigine, oxcarbazepine, topiramate, valproic acid)	Kowatch and DelBello,[194,c] Myers and Challman[149,c]
		Atypical antipsychotic agents (risperidone, aripiprazole, olanzapine, quetiapine, ziprasidone)	Cheng-Shannon et al,[195,c] Kowatch and DelBello,[194,c] Myers,[148,c] Myers and Challman[149,c]

tract infection, fracture, headache, esophagitis, gastritis, colitis, allergic rhinitis, and others. When behavioral deterioration is temporally related to menstrual cycles in an adolescent female,[139] use of an analgesic or oral or injectable contraceptive may be helpful. Obstructive sleep apnea may contribute to behavioral deterioration and may be amenable to weight reduction, tonsillectomy and adenoidectomy, or continuous positive airway pressure.[140] Extreme food selectivity has the potential to lead to protein-calorie malnutrition or specific vitamin or mineral deficiencies; however, most studies that evaluated nutritional status in children with ASDs have suggested that despite dietary selectivity, malnutrition is uncommon.[105,141] Although the prevalence in children with ASDs is unknown, pica related to iron or zinc deficiency may respond to supplementation with the appropriate mineral. It should be noted that it is not clear how frequently medical factors cause or exacerbate serious maladaptive behaviors in children with ASDs, and the efficacy of these interventions is based on anecdotes, case reports, and conventional clinical practice rather than empirical support from clinical trials.

It is also important to consider environmental factors that may precipitate challenging behaviors. Parents, teachers, or other caregivers may inadvertently reinforce maladaptive behaviors, and in such cases, the most appropriate and effective interventions are behavioral. In some instances, a mismatch between educational or behavioral expectations and cognitive ability of the child is responsible for disruptive behavior (eg, when the diagnosis of mental retardation has not been recognized), and adjustment of expectations is the most appropriate intervention. In both situations, a functional analysis of behavior, completed by a behavior specialist in the settings in which the problems occur, will identify factors in the environment that exacerbate or maintain the problematic behavior. A strategy for intervention through behavioral techniques and environmental manipulations can then be formulated and tested.

Psychopharmacology

Pharmacologic interventions may be considered for maladaptive behaviors such as aggression, self-injurious behavior, repetitive behaviors (eg, perseveration, obsessions, compulsions, and stereotypic movements), sleep disturbance, mood lability, irritability, anxiety, hyperactivity, inattention, destructive behavior, or other disruptive behaviors. After treatable medical causes and modifiable environmental factors have been ruled out, a therapeutic trial of medication may be considered if the behavioral symptoms cause significant impairment in functioning and are suboptimally responsive to behavioral interventions. In some cases, the diagnosis of a comorbid disorder, such as major depression, bipolar disorder, or an anxiety disorder, can be made reasonably and the patient can be treated with medications that are useful for treating these conditions in otherwise typically developing children and adolescents. Modifications of diagnostic criteria may be necessary to account for clinical presentations of psychiatric conditions in individuals with developmental disabilities,[142,143] and tools such as behavior checklists[144] and structured interviews[145] may be helpful. In other cases, clinicians opt to target specific interfering maladaptive behaviors or symptom clusters in the absence of a clear comorbid psychiatric diagnosis (a target-symptom approach).[146–151]

Recent surveys indicate that approximately 45% of children and adolescents[152–154] and up to 75% of adults[8,155] with ASDs are treated with psychotropic medication. Greater age, lower adaptive skills and social competence, and higher levels of challenging behavior are associated with the likelihood of medication use.[154] The evidence regarding the efficacy of psychopharmacologic interventions in patients with ASDs has been de-

tailed in recent reviews.[148,150,151,156] Although most psychotropic medications have been used in children with ASDs, there is currently insufficient literature to establish consensus regarding an evidence-based approach to pharmacologic management. However, in recent years, there has been an increase in publication of randomized, double-blind, placebo-controlled clinical trials to guide clinical practice.

Surveys performed in the United States suggest that selective serotonin-reuptake inhibitors (SSRIs), atypical antipsychotic agents, stimulants, and α_2-adrenergic agonist antihypertensive agents are the most commonly prescribed classes of psychotropic medications for children with ASDs.[152,153] Double-blind, placebo-controlled trials have demonstrated efficacy of the SSRIs fluoxetine[157] and fluvoxamine[158,159] in the treatment of repetitive and other maladaptive behaviors in patients with ASDs, and open-label trials of these and other SSRIs have shown improvements in target symptoms, including repetitive behaviors, irritability, depressive symptoms, tantrums, anxiety, aggression, difficulty with transitions, and aspects of social interaction and language.[157–161] Potential adverse effects of SSRIs include but are not limited to nausea, drowsiness, sexual dysfunction, constipation, abdominal discomfort, fatigue, headache, dizziness, dry mouth, agitation, behavioral activation, hypomania or mania, apathy, suicidal ideation, and alteration of sleep.

Risperidone has become the first medication with US Food and Drug Administration–approved labeling for the symptomatic treatment of irritability (including aggressive behavior, deliberate self-injury, and temper tantrums) in children and adolescents with ASDs. Two large, multisite, randomized, controlled trials have confirmed the short-term efficacy of risperidone for these severe disruptive behaviors in youth with ASDs,[162–165] and 2 open-label studies, each with a double-blind discontinuation component, have suggested long-term benefits and tolerance.[166,167] Potential adverse effects include but are not limited to excessive appetite and weight gain, insulin resistance, dyslipidemia, hyperprolactinemia, extrapyramidal symptoms, tardive dyskinesia, neuroleptic malignant syndrome, QTc prolongation, dry mouth, urinary retention, constipation, seizures, hematologic abnormalities, and sedation.

Although early studies of the effects of stimulants yielded negative results, recent double-blind, placebo-controlled trials of methylphenidate have demonstrated improvement in hyperactivity, impulsivity, and inattention in children with ASDs.[168–170] Methylphenidate is effective in some children with ASDs, but the response rate is lower than that in children with isolated attention-deficit/hyperactivity disorder, adverse effects are more frequent, and it is unclear whether the results can be generalized to other stimulants.[170,171] Potential adverse effects of stimulant medications include but are not limited to appetite reduction, inhibition of growth, delayed sleep onset, jitteriness, exacerbation of tics, abdominal discomfort, increased blood pressure, increased heart rate, irritability, increased anxiety, and repetitive behaviors.

Two small double-blind, placebo-controlled trials have documented modest benefits of clonidine in reducing hyperarousal symptoms including hyperactivity, irritability and outbursts, impulsivity, and repetitive behaviors in children with ASDs.[172,173] A prospective open-label trial[174] and a retrospective record review[175] have suggested that guanfacine was similarly effective in some patients. Potential adverse effects of these centrally acting α_2-agonists include but are not limited to drowsiness, sedation, dry mouth, decreased blood pressure, dizziness, constipation, and irritability, and these drugs can be dangerous in overdose. Recently, a retrospective study,[176] an open-label trial,[177] and a small double-blind, placebo-controlled crossover trial[178] suggested that atomoxetine may be effective for attention-deficit/hyperactivity disorder–like symptoms in children and adolescents with ASDs, and additional research is warranted. Appetite suppression, nausea, fatigue, mood swings, suicidal ideation, dizziness, and liver injury are among the potential adverse effects of atomoxetine.

A summary of selected target symptoms, potential psychiatric diagnoses, and medication options is provided in Table 1. Pediatricians and other practitioners should only prescribe medications with which they have sufficient expertise, including knowledge of indications and contraindications, dosing, potential adverse effects, drug-drug interactions, and monitoring requirements. It will be important for future research to address the need for more rigorous evaluation of safety and efficacy of psychotropic agents in children with ASDs; the value of combining behavioral and medical interventions; the practice of polypharmacy; delineation of clinical and biological subgroups of patients who may be responsive to particular treatments; the role of drugs in treating deficits in language and nonlanguage cognition, social interaction, and behavioral rigidity; and the potential to alter the neural substrate during early critical periods to affect brain development and future function. Several multisite trials are underway, and others undoubtedly will be forthcoming.[179]

Principles to guide the approach to psychopharmacologic management of ASDs in clinical practice have been proposed by several authors in recent years, and an approach is outlined in Table 2.[148–151] When medications are used, potential benefits and adverse effects should be explained, informed consent should be obtained, baseline data regarding behaviors and somatic complaints should be collected, and potential strategies for dealing with treatment failure or partial response should be reviewed. It is important to have some quantifiable means of assessing the efficacy of the medication and to

TABLE 2 **Clinical Approach to Psychopharmacologic Management**

- Identify and assess target behaviors
  - Parent/caregiver interview
    - Intensity
    - Duration
    - Exacerbating factors/triggers (time, setting/location, demand situations, denials, transitions, etc)
    - Ameliorating factors and response to behavioral interventions
    - Time trends (increasing, decreasing, stable)
    - Degree of interference with functioning
  - Consider baseline behavior-rating scales and/or baseline performance measures/direct observational data
  - Include input from school staff and other caregivers
- Assess existing and available supports
  - Behavioral services and supports
  - Educational program, habilitative therapies
  - Respite care, family psychosocial supports
- Search for medical factors that may be causing or exacerbating target behavior(s)
  - Consider sources of pain or discomfort (infectious, gastrointestinal, dental, allergic, etc)
  - Consider other medical causes or contributors (sleep disorders, seizures, menstrual cycle, etc)
- Complete any medical tests that may have a bearing on treatment choice
- Consider psychotropic medication on the basis of the presence of
  - Evidence that the target symptoms are interfering substantially with learning/academic progress, socialization, health/safety (of the patient and/or others around him or her), or quality of life
  - Suboptimal response to available behavioral interventions and environmental modifications
  - Research evidence that the target behavioral symptoms or coexisting psychiatric diagnoses are amenable to pharmacologic intervention
- Choose a medication on the basis of
  - Likely efficacy for the specific target symptoms
  - Potential adverse effects
  - Practical considerations such as formulations available, dosing schedule, cost, and requirement for laboratory or electrocardiographic monitoring
  - Informed consent (verbal or written) from parent/guardian and, when possible, assent from the patient
- Establish plan for monitoring of effects
  - Identify outcome measures
  - Discuss time course of expected effects
  - Arrange follow-up telephone contact, completion of rating scales, reassessment of behavioral data, and visits accordingly
  - Outline a plan regarding what might be tried next if there is a negative or suboptimal response or to address additional target symptoms
    - Change to a different medication
    - Add another medication to augment a partial or suboptimal therapeutic response to the initial medication (same target symptoms)
    - Add a different medication to address additional target symptoms that remain problematic
  - Obtain baseline laboratory data if necessary for the drug being prescribed and plan appropriate follow-up monitoring
- Explore the reasonable dose range for a single medication for an adequate length of time before changing to or adding a different medication
- Monitor for adverse effects systematically
- Consider careful withdrawal of the medication after 6–12 mo of therapy to determine whether it is still needed

obtain input from a variety of sources, such as parents, teachers, therapists, and aides. Consistent use of validated, treatment-sensitive rating scales and medication adverse-effect scales is desirable. A wide variety of outcome measures have been used in research trials and in clinical practice to measure maladaptive behavior treatment effects.[199] Among the most common are the Clinical Global Impression Scale, Aberrant Behavior Checklist, and Nisonger Child Behavior Rating Form.

Complementary and Alternative Medicine

Complementary and alternative medicine (CAM) is defined by the National Center for Complementary and Alternative Medicine as "a group of diverse medical and health care systems, practices, and products that are not presently considered to be part of conventional medicine."[200] The definition of CAM adopted by the Cochrane Collaboration is "a broad domain of healing resources that encompasses all health systems, modalities, and practices and their accompanying theories and beliefs, other than those intrinsic to the politically dominant health systems of a particular society or culture in a given historical period."[201] Detailed reviews of CAM as related to developmental disabilities and ASD-specific CAM have been published recently.[202–204]

Use of CAM is common in children with ASDs.[152,205–207] Levy et al[206] reported that by the time their clinical population received a formal diagnostic evaluation for a suspected ASD, almost one third of the children already had received a complementary or alternative therapy, and a survey conducted in a predominantly white, middle-to-upper socioeconomic-status private-practice population found that 92% of parents who responded had used CAM therapies for their children with ASDs.[205]

Another recent parent survey found that 52% of the children with an ASD had been treated with at least 1 CAM therapy, compared with 28% of a group of control children without disabilities.[207] Surveys indicate that only 36% to 62% of caregivers who used CAM therapies for their children with ASDs had informed the child's primary care physician,[207,208] although more information on CAM is something that families indicate that they want from their child's primary health care professionals.[209]

It is important that health care professionals understand how to evaluate the evidence used to support all treatments, including CAM, psychopharmacologic, and other interventions. Ideally, the evidence supporting or refuting a treatment should include peer-reviewed studies with appropriately diagnosed, well-defined homogeneous study populations; a randomized, double-blind, placebo-controlled design; an adequate sample size to support the statistical analysis presented; control for confounding factors; and use of appropriate, validated outcome measures. When evaluating the efficacy of studies, it is particularly important to keep in mind confounding factors, such as the placebo effect, and the natural history of the disorder. Participation in a study may alter the way a parent interacts with a child and confound the perceived outcome,[210] and improvements are expected with maturation and educational interventions. Only appropriately controlled studies are helpful in proving that an effect is attributable to the intervention being studied.

The practitioner should encourage families to seek additional information when they encounter the following claims or situations[211]:

- treatments that are based on overly simplified scientific theories;
- therapies that are claimed to be effective for multiple different, unrelated conditions or symptoms;
- claims that children will respond dramatically and some will be cured;
- use of case reports or anecdotal data rather than carefully designed studies to support claims for treatment;
- lack of peer-reviewed references or denial of the need for controlled studies; or
- treatments that are said to have no potential or reported adverse effects.

To help to describe their proposed rationales and mechanisms, CAM therapies used to treat ASDs have been categorized as "nonbiological" or "biological."[204] Examples of nonbiological interventions include treatments such as auditory integration training, behavioral optometry, craniosacral manipulation, dolphin-assisted therapy, music therapy, and facilitated communication. Examples of biological therapies include immunoregulatory interventions (eg, dietary restriction of food allergens or administration of immunoglobulin or antiviral agents), detoxification therapies (eg, chelation), gastrointestinal treatments (eg, digestive enzymes, antifungal agents, probiotics, "yeast-free diet," gluten/casein-free diet, and vancomycin), and dietary supplement regimens that are purported to act by modulating neurotransmission or through immune factors or epigenetic mechanisms (eg, vitamin A, vitamin C, vitamin B_6 and magnesium, folic acid, folinic acid, vitamin B_{12}, dimethylglycine and trimethylglycine, carnosine, omega-3 fatty acids, inositol, various minerals, and others).[203,204]

For most of the aforementioned CAM interventions, there is not enough scientific evidence yet to support or refute their use as treatment for ASDs. However, evaluation of treatments is possible, and a few CAM treatments have been appropriately studied. For example, more than a dozen randomized, double-blind, placebo-controlled trials involving more than 700 patients have demonstrated that secretin (a biological treatment) is not an effective treatment for ASDs.[212,213] Evaluation of nonbiological treatments also is feasible. This has been demonstrated in the case of facilitated communication, a technique that uses a trained facilitator to provide physical support to a nonverbal person's hand or arm while that person uses a computer keyboard or other device to spell. Evidence suggests that the communications produced actually originate from the facilitator[214,215] and that facilitated communication is not a valid treatment for ASDs.[216–218]

Because of methodologic flaws, insufficient numbers of patients, or lack of replication, many CAM therapies have been inadequately evaluated; therefore, evidence-based recommendations for their use are not possible. The most recent and most appropriately designed trials have demonstrated no significant benefit of dimethylglycine,[219,220] vitamin B_6 and magnesium,[221,222] or auditory integration training.[223–225] Both positive[226] and negative[227,228] results have been described for small, methodologically flawed studies of intravenous immunoglobulin. A recent double-blind, placebo-controlled trial revealed no statistically significant differences on Aberrant Behavior Checklist subscale scores between small groups of children with ASDs who were given omega-3 fatty acids and those who were given placebo.[229] However, the investigators noted a trend toward superiority of omega-3 fatty acids over placebo for hyperactivity, which suggests that further investigation may be warranted.[229] The gluten/casein-free diet is based on a hypothesis of abnormal gut permeability and exogenous opiate excess. Although use of the gluten/casein-free diet for children with ASDs is popular, there is little evidence to support or refute this intervention, and reviewers have determined that meaningful conclusions cannot be drawn from the existing literature.[230,231] Subsequent to these reviews, a randomized, double-blind

pilot study demonstrated no significant benefit.[232] Double-blind, placebo-controlled elimination and challenge studies are in progress, and it is anticipated that these studies will provide substantially more useful information regarding the efficacy of the gluten/casein-free diet.[204,230] Measurement of urinary peptides has not been proven to be clinically useful as a marker for ASDs or as a tool to determine if dietary restriction is warranted or would be effective.

Many popular interventions, such as chelation of heavy metals, antifungal agents to decrease presumed yeast overgrowth, and antiviral agents to modulate the immune system, have not yet been studied in people with ASDs; their popularity is based on unproven theories and anecdotes or case reports. None of these interventions can be endorsed as treatment for ASDs outside of well-designed and appropriately monitored clinical trials. Some treatments, such as intravenous chelation, may be particularly dangerous and should be discouraged. One child with autism died as a result of chelation with edetate disodium (Na_2EDTA) despite the facts that a causal association between mercury and ASDs has not been demonstrated, there is no scientific evidence that chelation is an effective treatment for ASDs, and the effectiveness of chelation therapy to improve nervous system symptoms of chronic mercury toxicity has not been established.[233] Unless there is clear evidence of current heavy metal toxicity, chelation by any method is not indicated outside of monitored clinical trials.

In some cases, interesting findings await replication or further investigation. For example, in a double-blind, placebo-controlled trial of vitamin C, improvement was found in total and sensory motor scores on the Ritvo-Freeman Real Life Rating Scale,[234] and several small studies have suggested that music therapy had some short-term benefit on communication skills but not on behavior problems of children with ASDs.[235] Recently, a group of 20 children with ASDs were compared with children without ASDs and found to have an imbalance of methionine and homocysteine metabolism, which was interpreted to represent impaired capacity for methylation and increased oxidative stress.[236] Treatment with trimethylglycine, folinic acid, and methylcobalamin resulted in normalization of laboratory findings. The study did not measure clinical response to the intervention, but anecdotal improvements were noted. Interpretation of these preliminary findings awaits further investigation.

Health care practitioners who diagnose and treat children with ASDs should recognize that many of their patients will use nonstandard therapies. The importance of becoming knowledgeable about CAM therapies, inquiring about current and past CAM use, providing balanced information and advice about treatment options, identifying risks or potential harmful effects, avoiding becoming defensive or dismissing CAM in ways that convey a lack of sensitivity or concern, maintaining open communication, and continuing to work with families even if there is disagreement about treatment choices has been emphasized.[237] It also is essential to critically evaluate the scientific merits of specific therapies and share this information with families, educate families about how to evaluate information and recognize pseudoscience, and insist that studies that examine CAM be held to the same scientific and ethical standards as all clinical research.[202,238]

Parents of children with ASDs will understandably pursue interventions that they believe may present some hope of helping their child, particularly if the therapies are viewed as being unlikely to have any adverse effects. Unfortunately, families are often exposed to unsubstantiated, pseudoscientific theories and related clinical practices that are, at best, ineffective and, at worst, compete with validated treatments or lead to physical, emotional, or financial harm. Time, effort, and financial resources expended on ineffective therapies can create an additional burden on families. Health care professionals can help parents and other caregivers to distinguish empirically validated treatment approaches from treatments that have been proven to be ineffective and those that are unproven and potentially ineffective and/or harmful.

FAMILY SUPPORT

Management should focus not only on the child but also on the family. Although parents once were viewed erroneously as the cause of a child's ASD, it is now recognized that parents play a key role in effective treatment.[9] Having a child with an ASD has a substantial effect on a family. Parents and siblings of children with ASDs experience more stress and depression than those of children who are typically developing or even those who have other disabilities.[239–243] Supporting the family and ensuring its emotional and physical health is an extremely important aspect of overall management of ASDs.

Physicians and other health care professionals can provide support to parents by educating them about ASDs; providing anticipatory guidance; training and involving them as cotherapists; assisting them in obtaining access to resources; providing emotional support through traditional strategies such as empathetic listening and talking through problems; and assisting them in advocating for their child's or sibling's needs.[244] In some cases, referral of parents for counseling or other appropriate mental health services may be required. The need for support is longitudinal, although the specific needs may vary throughout the family life cycle.

One of the chief strategies for helping families raise children with ASDs is helping to provide them with access to needed ongoing supports and additional services during critical periods and/or crises. Natural supports include spouses, extended family members, neigh-

bors, religious institutions, and friends who can help with caregiving and who can provide psychological and emotional support. Informal supports include social networks of other families of children with ASDs and community agencies that provide training, respite, social events, and recreational activities. Formal supports include publicly funded, state-administrated programs such as early intervention, special education, vocational and residential/living services, respite services, Medicaid, in-home and community-based waiver services, Supplemental Security Income benefits, and other financial subsidies. The breadth and depth of services vary, even within the same state or region. Few services exist in many rural areas, and public programs may have long waiting lists.

Sibling support groups offer the opportunity to learn important information and skills while sharing experiences and connecting with other siblings of children with ASDs.[244] Although the research on support groups for siblings of children with disabilities is difficult to interpret because of study-design problems and inconsistent outcome effects on sibling adjustment, these groups generally have been evaluated positively by participating siblings and parents,[244] and there is some evidence of beneficial effects for siblings of children with ASDs.[245]

Because each state has organized its services and access mechanisms differently, physicians and families must learn their own state's unique rules to access supports by contacting the state or county offices of the states' Department of Health and Human Services or Mental Health and Mental Retardation or the state developmental disabilities organization. In addition, local parent advocacy organizations, national autism and related developmental disability organizations, early intervention administrators, and school district special education coordinators often are knowledgeable about various programs and their respective eligibility requirements.

CONCLUSIONS

ASDs are chronic conditions that affect nearly 1 of every 150 children and require ongoing medical and nonmedical intervention. There is a growing body of evidence that supports the efficacy of certain interventions in ameliorating symptoms and enhancing functioning, but much remains to be learned. In addition to their important roles in identifying ASDs through screening and surveillance, establishing the diagnosis, conducting an etiologic evaluation, and providing genetic counseling after a diagnosis is made,[2] pediatricians and other primary health care professionals are in a position to provide important longitudinal medical care and to support and educate families and guide them to empirically supported interventions for their children.

PEDIATRIC ORTHOPAEDIC SOCIETY OF NORTH AMERICA

ABSTRACT

Injury is the number 1 killer of children in the United States. In 2004, injury accounted for 59.5% of all deaths in children younger than 18 years. The financial burden to society of children who survive childhood injury with disability continues to be enormous. The entire process of managing childhood injury is complex and varies by region. Only the comprehensive cooperation of a broadly diverse group of people will have a significant effect on improving the care and outcome of injured children.

This statement has been endorsed by the American Association of Critical-Care Nurses, American College of Emergency Physicians, American College of Surgeons, American Pediatric Surgical Association, National Association of Children's Hospitals and Related Institutions, National Association of State EMS Officials, and Society of Critical Care Medicine.

EMS—emergency medical services
EMSC—Emergency Medical Services for Children (Add words as needed)
PICU—pediatric intensive care unit

INTRODUCTION

Injury results in more deaths in children and adolescents than all other causes combined.[1] Deaths caused by injuries, intentional or unintentional, account for more years of potential life lost under the age of 18 years than do deaths attributable to sudden infant death syndrome, cancer, and infectious diseases combined. It is estimated that 1 in 4 children sustain an unintentional injury that requires medical care each year.[2] The cost of childhood injury in 1996 serves as an illustration for today.[3] In that year, unintentional childhood injuries resulted in an estimated $14 billion in lifetime medical spending, $1 billion in other resource costs, and $66 billion in present and future work losses. Survivors of childhood trauma may suffer lifelong disability and require long-term skilled care. Improving outcomes for the injured child requires an approach that recognizes childhood injury as a significant public health problem. Efforts should be made to improve injury-prevention programs, emergency medical care, and trauma systems for pediatric patients. Additional topics related to the injured child that can complement and enhance our understanding of pediatric trauma management are addressed in other publications from the American Academy of Pediatrics.[4–10] This policy statement provides an overview of the desired components of trauma care systems in meeting the unique needs of injured children.

This statement has been endorsed by the American Association of Critical-Care Nurses, American College of Emergency Physicians, American College of Surgeons, American Pediatric Surgical Association, National Association of Children's Hospitals and Related Institutions, National Association of State EMS Officials, and Society of Critical Care Medicine.

TRAUMA SYSTEMS

The pediatric trauma system functions best as part of the inclusive emergency medical services (EMS), trauma, and disaster response system for the region or state. The inclusive trauma system is defined as 1 in which all hospitals participate in the care of injured patients. The regional adult trauma center or centers and the regional pediatric trauma center or centers are the central components of a trauma system. As was noted in a 2006 Institute of Medicine report, within any given EMS or trauma system, it is likely that not all hospitals will be completely equipped with appropriate pediatric resuscitation equipment or medications.[11,12] The Institute of Medicine report used the word "uneven" to describe the status of pediatric emergency and trauma care in the United States. There may also be significant variability in pediatric training and experience among physicians and nurses who staff hospital emergency

departments.[13] When the trauma system extends over a large geographic area, the outlying hospitals of the system must be able to undertake the stabilization and initial management of injured children who present to the hospital. Optimally, each trauma system will also define for itself the age range of the pediatric patient on the basis of specific hospital and physician resources available.

Even in regions of the country with well-developed trauma systems, most children are treated in facilities with no trauma center designation.[14,15] When a regional pediatric referral center is available within the trauma system, the smallest, most severely injured children often are eventually transported to that facility.[14] Trauma system administrators should recognize that all hospitals with emergency departments may be required to evaluate and resuscitate injured children.[4,6,8] Ideally, physician and nursing coordinators for pediatric emergency medicine should be identified in each facility, with pediatric-specific policies, procedures, and guidelines for care established.[8,11] An example of such guidelines are the Emergency Medical Services for Children (EMSC) performance measures that have been developed to assess a state's operational capacity to provide pediatric emergency care.[16] These guidelines can assist policy makers and care providers in prehospital-based and hospital-based settings in delivering optimal pediatric care.

Protocols for triage, treatment, and transfer of victims of pediatric trauma are an important part of any trauma system. Standard transfer protocols are available from many states and regional systems. The quality of care that is provided within the system should be continuously evaluated by the trauma system administration through performance-improvement processes. Outcomes for pediatric trauma patients should be compared with available benchmarks, and information should be shared with specific providers so that an optimal environment for quality improvement in pediatric trauma care is promoted.

PREHOSPITAL PEDIATRIC TRAUMA CARE

Prehospital emergency care providers are often not as familiar with pediatric emergency management issues as they are with adult care[17] because of infrequent exposure of most EMS personnel to critically ill or injured children. This lack of experience is typically addressed by continuing education efforts for EMS personnel through established courses such as Pediatric Education for Prehospital Professionals,[18] Basic Trauma Life Support,[19] Prehospital Trauma Life Support,[20] or practical experience that is gained in children's hospitals. Pediatric readiness may also be facilitated by the presence of a pediatric emergency coordinator and advocate within each EMS system.[17] No matter how education is accomplished, mechanisms for knowledge and skill retention and continuous evaluation of performance are crucial for prehospital personnel. The method for maintaining skills may include continuous evaluation of performance. Direct feedback to the provider in the field is required in any trauma system to improve outcomes for injured children. There is a relative lack of data supporting the best practices for pediatric resuscitation in the field, including fluid administration, cervical spine stabilization, and airway management of children. Comprehensive support for research in pediatric trauma needs to come from regional, state, and national organizations. Examples of such support include the federally funded EMSC program, the American Pediatric Surgical Association Outcomes and Clinical Trials Center, and the Pediatric Emergency Care Applied Research Network.[21,22]

TRAUMA CENTERS

It has been shown that younger and more seriously injured children have better outcomes at a trauma center within a children's hospital or at a trauma center that integrates pediatric and adult trauma services.[14,23–26] The ability to provide a broad range of pediatric services, including the presence of physicians trained in pediatric emergency medicine, pediatric surgical specialists, pediatric anesthesiologists, and pediatric medical subspecialists, is important. Yet, the nationwide ability to provide around-the-clock trauma care may be in peril because of physician workforce shortages.[27] In particular, trauma care is increasingly unpopular because of lifestyle demands and inadequate reimbursement.[28]

Pediatric protocols for imaging and diagnostic testing[29] and a child-centered and family-centered environment for care[30] should be duplicated in trauma centers that are not part of children's hospitals whenever possible. Hospitals caring for pediatric trauma patients should have specific pain-management and sedation protocols and the ability to provide a full range of pediatric pain strategies for children, including systemic analgesics, regional and local pain control, anxiolysis, and distraction techniques. Pain management is critically important in managing trauma patients and transitioning them to rehabilitation.[9] Continuing education on trauma for hospital providers is important and is best accomplished by current verification in the American College of Surgeons Advanced Trauma Life Support course.[31]

Trauma centers may not have the resources to care for all of the injured children within their referral region at any given time. Thus, the most seriously injured children may need to be stabilized and transported to facilities with these resources. Hospitals that seek regional or state designation or verification through the American College of Surgeons verification process as a Pediatric Trauma Center are examples of facilities that have made an extraordinary effort to provide resources to care for injured children.

A well-equipped and staffed pediatric intensive care unit (PICU) is an essential component of a pediatric trauma center. Data demonstrate that the availability of PICU beds within a region may improve survival in pediatric trauma.[26] Pediatric critical care physicians, surgeons, and anesthesiologists who work together

and are trained in the care of the injured child are needed for optimal care of severely injured and unstable patients in the ICU. In addition to critically injured children, stable patients with the potential for deterioration may also require the specialized services of a PICU. Pediatric trauma care specialists, especially those with critical care training, are in short supply; thus, the nationwide delivery of pediatric trauma care is endangered.[32] PICUs offer a setting with the necessary monitoring devices, equipment, medications, and technology to support physiologic function and are staffed with professionals with the expertise to apply them to the pediatric patient. The presence of experienced PICU nursing and allied health care personnel support the environment necessary for frequent monitoring and assessment of injured children. Trauma care may continue on the inpatient unit once the child is stable and the probability of rapid deterioration is less likely.

Rehabilitation is another vital component of pediatric trauma care. Returning the child to full, age-appropriate function with the ability to reach his or her maximum adult potential is the ultimate goal after critical injury. Early rehabilitation is especially crucial for children who have sustained neurologic injuries. Physical, occupational, cognitive, speech, and play therapy, and psychological support are all essential elements of a comprehensive rehabilitation effort for the injured child and his or her family.

Trauma centers caring for children ideally will have active quality and performance improvement processes as an important component of the trauma service. In many trauma centers, quality improvement activities also include a focus on patient safety. Periodic review of trauma care by the providers of that care is the process that is most likely to improve patient outcomes in any hospital. Trauma care review is facilitated by a comprehensive trauma registry that has ties with national databases so that outcomes can be benchmarked for improved quality of care.

Pediatric trauma center personnel should be aware of reporting requirements for child abuse and neglect within their jurisdiction. Cooperation and collaboration with hospital-based child protection teams are essential for the management of cases of suspected abuse and neglect. The National Association of Children's Hospitals and Related Institutions has recently published guidelines for the establishment and management of hospital-based child protection teams.[33]

INJURY PREVENTION

Injury prevention is the cornerstone of any discussion concerning pediatric trauma. Injury prevention initiatives work.[34,35] However, these initiatives are not promoted equally across the board, often because of limited resources. There are methods to identify and refine the approach to injury prevention initiatives that are specific for the region.[36] Every provider can contribute to injury prevention by documenting not only the nature of the injury but also the circumstances and antecedents as well. EMS systems, emergency departments, hospitals, and trauma centers should support and participate in data collection that promotes an understanding of the causes of injury (such as the use of external cause-of-injury codes or, if selected, participation in the National Electronic Injury Surveillance System [NEISS]) and should incorporate injury-prevention activities into staff and patient education and community-based intervention programs.

RECOMMENDATIONS

- The unique needs of injured children need to be integrated specifically into trauma systems and emergency and disaster planning in every state and region.
- Pediatric surgical specialists and pediatric medical subspecialists should participate at all levels of planning for trauma, emergency, and disaster care.
- Every state should identify appropriate facilities with the resources to care for injured children and establish continuous monitoring processes for care delivered to injured children. Ensuring that the appropriate resources are available is especially important for the youngest and most severely injured children.
- All potential providers of pediatric emergency and trauma care should be familiar with their regional trauma system and be able to evaluate, stabilize, and transfer acutely injured children.
- Although qualified pediatric critical care transport teams should be used when available in the interfacility transport of critically injured children, evaluation and management should begin with the care providers at the first point of entry into the trauma system.
- Every pediatric and emergency care-related health professional credentialing and certification body should define pediatric emergency and trauma care competencies and require practitioners to receive the appropriate level of initial and continuing education to achieve and maintain those competencies.
- Efforts to define and maintain pediatric care competencies should target both out-of-hospital and hospital-based care providers.
- Evidence-based protocols for management of the injured child should be developed for every aspect of care, from prehospital to postdischarge.
- Research, including data collection for best practices in isolated trauma and mass-casualty events, should be supported.
- Pediatric injury management should include an integrated public health approach, from prevention through prehospital care, to emergency and acute hospital care, to rehabilitation and long-term follow-up.
- National organizations with a special interest in pediatric trauma should collaborate to advocate for a

higher and more consistent quality of care within the nation.

- National organizations with a special interest in pediatric trauma should collaborate to advocate for injury-prevention research and application of known prevention strategies into practice.
- State and federal financial support for trauma system development and maintenance must be provided.
- Steps should be taken to increase the number of trainees in specialties that care for injured children to address key subspecialty service shortages in pediatric trauma care. Strategies should include increased funding for graduate medical education and appropriate reimbursement for trauma specialists.

Summary

*Acute gastroenteritis remains a common illness among infants and children throughout the world. Among children in the United States, acute diarrhea accounts for >1.5 million outpatient visits, 200,000 hospitalizations, and approximately 300 deaths/year. In developing countries, diarrhea is a common cause of mortality among children aged <5 years, with an estimated 2 million deaths annually. Oral rehydration therapy (ORT) includes rehydration and maintenance fluids with oral rehydration solutions (ORS), combined with continued age-appropriate nutrition. Although ORT has been instrumental in improving health outcomes among children in developing countries, its use has lagged behind in the United States. This report provides a review of the historical background and physiologic basis for using ORT and provides recommendations for assessing and managing children with acute diarrhea, including those who have become dehydrated. Recent developments in the science of gastroenteritis management have substantially altered case management. Physicians now recognize that zinc supplementation can reduce the incidence and severity of diarrheal disease, and an ORS of reduced osmolarity (i.e., proportionally reduced concentrations of sodium and glucose) has been developed for global use. The combination of oral rehydration and early nutritional support has proven effective throughout the world in treating acute diarrhea. In 1992, CDC prepared the first national guidelines for managing childhood diarrhea (*CDC. The management of acute diarrhea in children: oral rehydration, maintenance, and nutritional therapy. MMWR 1992;41[No. RR-16]*), and this report updates those recommendations. This report reviews the historical background and scientific basis of ORT and provides a framework for assessing and treating infants and children who have acute diarrhea. The discussion focuses on common clinical scenarios and traditional practices, especially regarding continued feeding. Limitations of ORT, ongoing research in the areas of micronutrient supplements, and functional foods are reviewed as well. These updated recommendations were developed by specialists in managing gastroenteritis, in consultation with CDC and external consultants. Relevant literature was identified through an extensive MEDLINE search by using related terms. Articles were then reviewed for their relevance to pediatric practice, with emphasis on U.S. populations. Unpublished references were sought from the external consultants and other researchers. In the United States, adoption of these updated recommendations could substantially reduce medical costs and childhood hospitalizations and deaths caused by diarrhea.*

Introduction

Among children in the United States, acute gastroenteritis remains a major cause of morbidity and hospitalization, accounting for >1.5 million outpatient visits, 200,000 hospitalizations, and approximately 300 deaths/year. Direct medical costs for rotavirus diarrhea, which represents approximately one third of all hospitalizations for diarrhea among U.S. children aged <5 years, have been estimated to be $250 million/year, with an estimated $1 billion/year in total costs to society (*1*). Worldwide, diarrheal diseases are a leading cause of pediatric morbidity and mortality, with 1.5 billion episodes and 1.5–2.5 million deaths estimated to occur annually among children aged <5 years (*2–4*). Although the total number of deaths from diarrhea is still unacceptably high, these numbers have been reduced substantially in the 1980s and 1990s. For example, in 1982, an estimated 5 million deaths/year occurred (*5*), and in 1992, the estimated annual deaths declined to 3 million/year (*6*). A substantial portion of the decrease in mortality is attributable to worldwide campaigns to treat acute diarrhea with oral rehydration therapy (ORT). The

development of ORT represents a successful collaboration between basic and applied biomedical research (*7*). The application of ORT also represents a case of reverse technology transfer (*8*), because protocols originally implemented to benefit patients in developing countries have changed the standard of care in industrialized countries as well.

ORT encompasses two phases of treatment: 1) a rehydration phase, in which water and electrolytes are administered as oral rehydration solution (ORS) to replace existing losses, and 2) a maintenance phase, which includes both replacement of ongoing fluid and electrolyte losses and adequate dietary intake. Although ORT implies rehydration alone, the definition used in this report has been broadened to include maintenance fluid therapy and appropriate nutrition.

The full benefits of ORT for acute gastroenteritis have not been realized, especially in countries with developed market economies that have lagged behind less-developed countries in their use of ORT. One reason for this low usage of ORT might be the ingrained use of intravenous (IV) therapy or the reduced appeal of a technologically simple solution (*9,10*). This is especially true in the United States, where children with all forms of dehydration are treated with IV fluids rather than ORT (*11–16*). Approximately 30% of practicing pediatricians withhold ORT for children with vomiting or moderate dehydration (*17*). In addition, the practice of continued feeding during diarrheal episodes has been difficult to establish as accepted standard of care. Although substantial in vitro and in vivo data support the role of continued nutrition in improving gastrointestinal function and anthropometric, biochemical, and clinical outcomes (*18,19*), early appropriate feeding is often withheld.

In 1992, CDC prepared the first national guidelines for managing childhood diarrhea (*20*). Since the last recommendations were published in *MMWR*, data have emerged regarding diarrhea treatment, including the importance of zinc supplementation and the value of more effective oral solutions of lower osmolarity (i.e., proportionally reduced concentrations of sodium and glucose). These recommendations update the previous report, review the historical background and scientific basis of ORT, and provide a framework for assessing and treating infants and children who have acute diarrhea. The discussion focuses on common clinical scenarios and traditional practices, especially with regard to continued feeding. Limitations of ORT, ongoing research in the areas of micronutrient supplements, and functional foods are reviewed.

These updated recommendations were developed by specialists in managing gastroenteritis, in consultation with CDC and external consultants. Relevant literature was identified through an extensive MEDLINE search by using related terms. Articles were then reviewed for their relevance to pediatric practice, with emphasis on U.S. populations. Unpublished references were sought from the external consultants and other researchers.

Background

Early attempts at treating dehydration resulting from diarrhea were described in the 1830s during epidemics of *Vibrio cholerae* infections (*21,22*). Use of IV fluid did not become widespread until >100 years later. In the 1940s, oral solutions were developed (*23*), and the effect of potassium replacement in reducing mortality was recognized, which led to substantial decreases in case fatality rates. By the 1950s, patients with cholera were being successfully treated with IV fluids (24).

Studies documenting the effectiveness of IV rehydration fluids among economically disadvantaged populations provided an impetus to develop less expensive but equally effective oral solutions. Studies published in 1968 from Dhaka and Calcutta demonstrated the effectiveness of ORS for cholera patients, including those with high stool output (*25,26*). In 1971, oral electrolyte solutions were tested through the large-scale treatment of refugees from Bangladesh (*12,27*). The resulting success of oral solutions hastened development of the first World Health Organization (WHO) guidelines for ORT and the production of standard packets of oral rehydration salts. Now, ORT is accepted as the standard of care for the clinically efficacious and cost-effective management of acute gastroenteritis (*9,20*).

Physiologic Basis for Using Oral Rehydration Solutions

Human survival depends on the secretion and reabsorption of fluid and electrolytes in the intestinal tract. The adult intestinal epithelium must handle 6,500 mL of fluids/day, consisting of a combination of oral intake, salivary, gastric, pancreatic, biliary, and upper intestinal secretions. This volume is typically reduced to 1,500 mL by the distal ileum and is further reduced in the colon to a stool output of <250 mL/day in adults (*28*). During diarrheal disease, the volume of intestinal fluid output is substantially increased, overwhelming the reabsorptive capacity of the gastrointestinal tract.

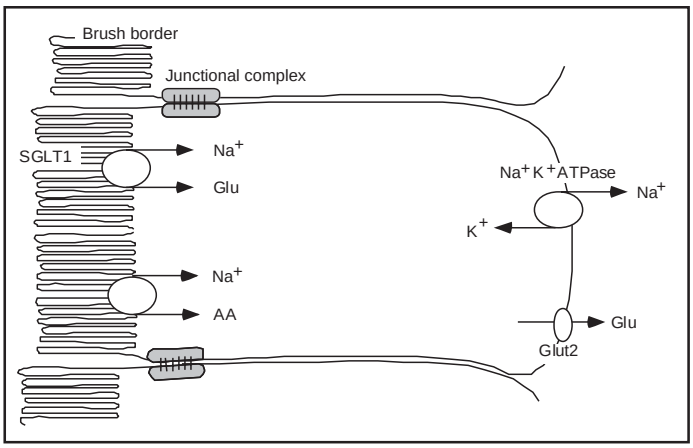
Applied clinical research, first implemented among patients with cholera (*25,29*), demonstrated that although the secretory nature of diarrhea in cholera results in substantial stool losses of water and electrolytes, intact Na-coupled solute co-transport mechanism allows efficient reabsorption of salt and water (*30*). In addition to *V. cholerae* 01 and 139, certain strains of *Escherichia coli*, shigella, salmonella, and other

pathogenic bacteria produce toxins that bind to enterocyte receptors, causing chloride-mediated secretion stimulated by second messengers (e.g., cAMP, cGMP, and calcium) (*31,32*). Even those infectious agents typically classified as causing osmotic diarrhea (i.e., fluid and electrolyte loss caused by malabsorbed intestinal contents) can increase enterocyte secretion. Rotavirus damages the villous brush border, causing osmotic diarrhea, and also produces an enterotoxin that causes a Ca^{++}-mediated secretory diarrhea (*33*).

Studies of intestinal solute transport mechanisms were also crucial in outlining the processes by which solute absorption is maintained. Water passively follows the osmotic gradient generated by the transcellular transport of electrolytes and nutrients. Although three principle mechanisms of sodium absorption have been described (*28*), the mechanism essential to the efficacy of ORS is the coupled transport of sodium and glucose molecules at the intestinal brush border (*34*) (Figure). Co-transport across the luminal membrane is facilitated by the protein sodium glucose co-transporter 1 (SGLT1). Once in the enterocyte, the transport of glucose into the blood is facilitated by GLUT2 (glucose transporter type 2) in the basolateral membrane. The Na^+ K^+ ATPase provides the gradient that drives the process. This mechanism remains intact, even in patients with severe diarrhea (*25*).

ORS in which additional co-transporters of Na (e.g., amino acids or cereals) were added has demonstrated promising results, but larger trials have not confirmed their efficacy (*35,36*). Solutions with a high concentration of co-transporters increase the risk from hypertonic solutions that decrease rather than improve sodium and water transport into the bloodstream. However, solutions of lower osmolarity, but that maintain the 1:1 glucose to sodium ratio, perform optimally as oral solutions for diarrhea management (see Choice of ORS).

FIGURE. Solute-coupled sodium absorption



Home Management of Acute Diarrhea

Treatment with ORS is simple and enables management of uncomplicated cases of diarrhea at home, regardless of etiologic agent. As long as caregivers are instructed properly regarding signs of dehydration or are able to determine when children appear markedly ill or appear not to be responding to treatment, therapy should begin at home. Early intervention can reduce such complications as dehydration and malnutrition. Early administration of ORS leads to fewer office, clinic, and emergency department (ED) visits (*37*) and to potentially fewer hospitalizations and deaths.

Initiation of Therapy

In all cultures, treatment of diarrhea usually begins at home (*38*). All families should be encouraged to have a supply of ORS in the home at all times and to start therapy with a commercially available ORS product as soon as diarrhea begins. Although producing a homemade solution with appropriate concentrations of glucose and sodium is possible, serious errors can occur (*39*); thus, standard commercial oral rehydration preparations should be recommended where they are readily available and attainable. The most crucial aspect underlying home management of diarrhea is the need to replace fluid losses and to maintain adequate nutrient intake. Regardless of the fluid used, an age-appropriate diet should also be given (*18,19*). Infants should be offered more frequent breast or bottle feedings, and older children should be given more fluids.

Severity Assessment

Caregivers should be trained to recognize signs of illness or treatment failure that necessitate medical intervention. Infants with acute diarrhea are more prone to becoming dehydrated than are older children, because they have a higher body surface-to-volume ratio, a higher metabolic rate, relatively smaller fluid reserves, and they are dependent on others for fluid. For this reason, parents of infants with diarrhea should promptly seek medical evaluation as soon as the child appears to be in distress (Box 1). No guidelines have established a specific age under which evaluation is mandated, but usually, the smaller the child, the lower the threshold for health-care provider assessment. When fever is present, infants and children should be evaluated to rule out other serious illnesses (e.g., sepsis and meningitis). Underlying conditions, including premature birth, metabolic and renal disorders, immune compromise, or recent recovery from surgery, might prompt early evaluation, as might concurrent illness, including a

BOX 1. Indications for medical evaluation of children with acute diarrhea

- Young age (e.g., aged <6 months or weight <8 kg)
- History of premature birth, chronic medical conditions, or concurrent illness
- Fever ≥38°C for infants aged <3 months or ≥39°C for children aged 3–36 months
- Visible blood in stool
- High output, including frequent and substantial volumes of diarrhea
- Persistent vomiting
- Caregiver's report of signs consistent with dehydration (e.g., sunken eyes or decreased tears, dry mucous membranes, or decreased urine output)
- Change in mental status (e.g., irritability, apathy, or lethargy)
- Suboptimal response to oral rehydration therapy already administered or inability of the caregiver to administer oral rehydration therapy

concurrent respiratory tract infection. Children with dysentery (blood or mucus in stool) or prolonged diarrhea (lasting >14 days) should be evaluated because stool cultures and antimicrobial therapy might be indicated.

Reports from parents or other caregivers of dehydration can indicate the need for immediate health-care provider evaluation. Reports of changing mental status are of particular concern. When the child's condition is in doubt, immediate evaluation by a health-care professional should be recommended. Clinical examination of the child provides an opportunity for physical assessment, including vital signs, degree of dehydration, and a more detailed history, and for providing better instructions to the caregivers.

Referral for Evaluation

In developed countries, the decision whether to bring a child to an office or ED setting for evaluation is usually made after consultation with a physician or other health-care provider by telephone. Questions should focus on those factors putting a child at risk for dehydration. Whenever possible, quantification is helpful. The clinician should determine how many hours or days the child has been ill, the number of episodes of diarrhea or vomiting, and the apparent volume of fluid output. The child's mental status should be determined. Parents and other caregivers might not mention underlying conditions without prompting; therefore, questions from the health-care provider regarding past medical history are essential.

Clinical Assessment

Diarrhea is characterized by the passage of loose or watery stools; a common case definition of acute diarrhea is ≥3 loose or watery stools/day. The volume of fluid lost through stools can vary from 5 mL/kg body weight/day (approximately normal) to ≥200 mL/kg body weight/day (*40*). Dehydration and electrolyte losses associated with untreated diarrhea cause the primary morbidity of acute gastroenteritis. Diarrhea can be among the initial signs of nongastrointestinal tract illnesses, including meningitis, bacterial sepsis, pneumonia, otitis media, and urinary tract infection. Vomiting alone can be the first symptom of metabolic disorders, congestive heart failure, toxic agent ingestion, or trauma. To rule out other serious illnesses, a detailed history and physical examination should be performed as part of the evaluation of all children with acute gastroenteritis.

History

The clinical history should assess the onset, frequency, quantity, and character (i.e., the presence of bile, blood, or mucus) of vomiting and diarrhea. Recent oral intake, including breast milk and other fluids and food; urine output; weight before illness; and associated symptoms, including fever or changes in mental status, should be noted. The past medical history should identify underlying medical problems, history of other recent infections, medications, and human immunodeficiency virus (HIV) status. A relevant social history can include the number and nature of caregivers, which can affect instructions regarding follow-up care.

Physical Examination

As part of the physical examination, an accurate body weight must be obtained, along with temperature, heart rate, respiratory rate, and blood pressure. When recent premorbid weight is unknown but a previous growth curve is available, an estimate of fluid loss can be obtained by subtracting current weight from expected weight as determined on the basis of the previous weight-for-age percentile. The quality of this estimate will vary, depending on the number and variability of prior data points, differences among scales, and other factors. The general condition of the patient should be assessed, with special concern given to infants and children who appear listless, apathetic, or less reactive. The appearance of the eyes should be noted, including the degree to which they are sunken and the presence or absence of tears. The condition of the lips, mouth, and tongue will yield critical clues regarding the degree of dehydration, even if the patient has taken fluid recently. Deep respirations can be indicative of metabolic acidosis. Faint or

absent bowel sounds can indicate hypokalemia. Examination of the extremities should be included because general perfusion and capillary refill can help in assessment of dehydration. An especially valid sign is the presence of prolonged skin tenting (*41*). Visual examination of stool can confirm abnormal consistency and determine the presence of blood or mucus.

Dehydration Assessment

Certain clinical signs and symptoms can quantify the extent of a patient's dehydration (Table 1). Assessment of the anterior fontanel might be helpful in selected instances, but it can be unreliable or misleading (*41,42*). Among infants and children, a decrease in blood pressure is a late sign of dehydration that heralds shock and can correspond to fluid deficits >10%. Increases in heart rate and reduced peripheral perfusion can be more sensitive indicators of moderate dehydration, although both can be difficult to interpret because they can vary with the degree of fever. Decreased urine output is a sensitive but nonspecific sign. Urine output might be difficult to measure for infants with diarrhea; however, if urinalysis is indicated, a finding of increased urine specific gravity can indicate dehydration.

Prior guidelines, including CDC's 1992 recommendations (*20*) and the American Academy of Pediatrics (AAP) 1996 guidelines (*9*), divide patients into subgroups for mild (3%–5% fluid deficit), moderate (6%–9% fluid deficit), or severe (≥10% fluid deficit, shock, or near shock) dehydration. Other classification schemes, including the 1995 WHO (*40*) and 2001 European Society of Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) guidelines (*43*), divide patients into those indicating no signs of dehydration (<3%–5%), some signs of dehydration (5%–10%), and severe dehydration (>10%). Studies that have evaluated the correlation of clinical signs of dehydration with posttreatment weight gain indicate that the first signs of dehydration might not be evident until 3%–4% dehydration, with more numerous clinical signs evident at 5% dehydration and signs indicating severe dehydration not evident until fluid loss reaches 9%–10% (*40,41*). Because of this threshold effect, distinguishing between mild and moderate dehydration on the basis of clinical signs alone might be difficult. Therefore, these updated recommendations group together patients with mild to moderate dehydration and specify that the signs of dehydration might be apparent over a relatively wide range of fluid loss (i.e., from 3%–9%) (Table 1). The goal of assessment is to provide a starting point for treatment and to conservatively determine which patients can safely be sent home for therapy, which ones should remain for observation during therapy, and which ones should immediately receive more intensive therapy.

Utility of Laboratory Evaluation

Supplementary laboratory studies, including serum electrolytes, to assess patients with acute diarrhea usually are unnecessary (*44,45*). Stool cultures are indicated in cases of dysentery but are not usually indicated in acute, watery diarrhea for the immunocompetent patient. However, certain laboratory studies might be important when the underlying diagnosis is unclear or diagnoses other than acute gastroenteritis are possible. For example, complete blood counts and urine and blood cultures might be indicated when sepsis or urinary tract infection is a concern.

TABLE 1. Symptoms associated with dehydration

Symptom	Minimal or no dehydration (<3% loss of body weight)	Mild to moderate dehydration (3%ï 9% loss of body weight)	Severe dehydration (>9% loss of body weight)
Mental status	Well; alert	Normal, fatigued or restless, irritable	Apathetic, lethargic, unconscious
Thirst	Drinks normally; might refuse liquids	Thirsty; eager to drink	Drinks poorly; unable to drink
Heart rate	Normal	Normal to increased	Tachycardia, with bradycardia in most severe cases
Quality of pulses	Normal	Normal to decreased	Weak, thready, or impalpable
Breathing	Normal	Normal; fast	Deep
Eyes	Normal	Slightly sunken	Deeply sunken
Tears	Present	Decreased	Absent
Mouth and tongue	Moist	Dry	Parched
Skin fold	Instant recoil	Recoil in <2 seconds	Recoil in >2 seconds
Capillary refill	Normal	Prolonged	Prolonged; minimal
Extremities	Warm	Cool	Cold; mottled; cyanotic
Urine output	Normal to decreased	Decreased	Minimal

Geneva, Switzerland: World Health Organization, 1995. Available at http://www.who.int/child-adolescent-health/New_Publications/CHILD_HEALTH/WHO.CDR.95.3.htm.

Acute Gastroenteritis Therapy Based on Degree of Dehydration

Seven basic principles guide optimal treatment of acute gastroenteritis (Box 2) (*43*); more specific recommendations for treating different degrees of dehydration have been recommended by CDC, WHO, and AAP (Table 2) (*9,20,40*). Although the first principle, use of ORS, seems self-evident, one national survey of physicians in emergency care facilities indicated that many would treat mild dehydration with IV therapy, and half would always or routinely use IV therapy for a moderately dehydrated child aged <2 years (*14*).

Treatment should include two phases: rehydration and maintenance. In the rehydration phase, the fluid deficit is replaced quickly (i.e., during 3–4 hours) and clinical hydration is attained. In the maintenance phase, maintenance calories and fluids are administered. Rapid realimentation should follow rapid rehydration, with a goal of quickly returning the patient to an age-appropriate unrestricted diet, including solids. Gut rest is not indicated. Breastfeeding should be continued at all times, even during the initial rehydration phases. The diet should be increased as soon as tolerated to compensate for lost caloric intake during the acute illness. Lactose restriction is usually not necessary (although it might be helpful in cases of diarrhea among malnourished children or among children with a severe enteropathy), and changes in formula usually are unnecessary. Full-strength formula usually is tolerated and allows for a more rapid return to full energy intake. During both phases, fluid losses from vomiting and diarrhea are replaced in an ongoing manner. Antidiarrheal medications are not recommended for infants and children, and laboratory studies should be limited to those needed to guide clinical management.

BOX 2. Seven principles of appropriate treatment for children with diarrhea and dehydration

1. Oral rehydration solutions (ORS) should be used for rehydration.
2. Oral rehydration should be performed rapidly (i.e., within 3–4 hours).
3. For rapid realimentation, an age-appropriate, unrestricted diet is recommended as soon as dehydration is corrected.
4. For breastfed infants, nursing should be continued.
5. If formula-fed, diluted formula is not recommended, and special formula usually is not necessary.
6. Additional ORS should be administered for ongoing losses through diarrhea.
7. No unnecessary laboratory tests or medications should be administered.

Source: Adapted from Sandhu BK. Practical guidelines for the management of gastroenteritis in children. J Pediatr Gastroenterol Nutr 2001;33(Suppl 2):S36–9.

Minimal Dehydration

For patients with minimal or no dehydration, treatment is aimed at providing adequate fluids and continuing an age-appropriate diet. Patients with diarrhea must have increased fluid intake to compensate for losses and cover maintenance

TABLE 2: Summary of treatment based on degree of dehydration

Degree of dehydration	Rehydration therapy	Replacement of losses	Nutrition
Minimal or no dehydration	Not applicable	<10 kg body weight: 60ï 120 mL oral rehydration solution (ORS) for each diarrheal stool or vomiting episode >10 kg body weight: 120ï 240 mL ORS for each diarrheal stool or vomiting episode	Continue breastfeeding, or resume age-appropriate normal diet after initial hydration, including adequate caloric intake for maintenance*
Mild to moderate dehydration	ORS, 50ï 100 mL/kg body weight over 3ï 4 hours	Same	Same
Severe dehydration	Lactated Ringerôs solution or normal saline in 20 mL/kg body weight intravenous amounts until perfusion and mental status improve; then administer 100 mL/kg body weight ORS over 4 hours or 5% dextrose İ normal saline intravenously at twice maintenance fluid rates	Same; if unable to drink, administer through nasogastric tube or administer 5% dextrose ı normal saline with 20 mEq/L potassium chloride intravenously	Same

* Overly restricted diets should be avoided during acute diarrheal episodes. Breastfed infants should continue to nurse ad libitum even during acute rehydration. Infants too weak to eat can be given breast milk or formula through a nasogastric tube. Lactose-containing formulas are usually well-tolerated. If lactose malabsorption appears clinically substantial, lactose-free formulas can be used. Complex carbohydrates, fresh fruits, lean meats, yogurt, and vegetables are all recommended. Carbonated drinks or commercial juices with a high concentration of simple carbohydrates should be avoided.

needs; use of ORS should be encouraged. In principle, 1 mL of fluid should be administered for each gram of output. In hospital settings, soiled diapers can be weighed (without urine), and the estimated dry weight of the diaper can be subtracted. When losses are not easily measured, 10 mL of additional fluid can be administered per kilogram body weight for each watery stool or 2 mL/kg body weight for each episode of emesis. As an alternative, children weighing <10 kg should be administered 60–120 mL (2–4 ounces) ORS for each episode of vomiting or diarrheal stool, and those weighing >10 kg should be administered 120–240 mL (4–8 ounces). Nutrition should not be restricted (see Dietary Therapy).

Mild to Moderate Dehydration

Children with mild to moderate dehydration should have their estimated fluid deficit rapidly replaced. These updated recommendations include administering 50–100 mL of ORS/kg body weight during 2–4 hours to replace the estimated fluid deficit, with additional ORS administered to replace ongoing losses. Using a teaspoon, syringe, or medicine dropper, limited volumes of fluid (e.g., 5 mL or 1 teaspoon) should be offered at first, with the amount gradually increased as tolerated. If a child appears to want more than the estimated amount of ORS, more can be offered. Although administering ORS rapidly is safe, vomiting might be increased with larger amounts. Nasogastric (NG) feeding allows continuous administration of ORS at a slow, steady rate for patients with persistent vomiting or oral ulcers. Clinical trials support using NG feedings, even for vomiting patients (*45*). Rehydration through an NG tube can be particularly useful in ED settings, where rapid correction of hydration might prevent hospitalization. Although rapid IV hydration can also prevent hospital admission, rapid NG rehydration can be well-tolerated, more cost-effective, and associated with fewer complications (*45*). In addition, a randomized trial of ORS versus IV rehydration for dehydrated children demonstrated shorter stays in EDs and improved parental satisfaction with oral rehydration (*46*).

Certain children with mild to moderate dehydration will not improve with ORT; therefore, they should be observed until signs of dehydration subside. Similarly, children who do not demonstrate clinical signs of dehydration but who demonstrate unusually high output should be held for observation. Hydration status should be reassessed on a regular basis, and might be performed in an ED, office, or other outpatient setting. After dehydration is corrected, further management can be implemented at home, provided that the child's caregivers demonstrate comprehension of home rehydration techniques (including continued feeding), understand indications for returning for further evaluation, and have the means to do so. Even among children whose illness appears uncomplicated on initial assessment, a limited percentage might not respond adequately to ORT; therefore, a plan for reassessment should be agreed upon. Caregivers should be encouraged to return for medical attention if they have any concerns, if they are not sure that rehydration is proceeding well, or if new or worsening symptoms develop.

Severe Dehydration

Severe dehydration constitutes a medical emergency requiring immediate IV rehydration. Lactated Ringer's (LR) solution, normal saline, or a similar solution should be administered (20 mL/kg body weight) until pulse, perfusion, and mental status return to normal. This might require two IV lines or even alternative access sites (e.g., intraosseous infusion). The patient should be observed closely during this period, and vital signs should be monitored on a regular basis. Serum electrolytes, bicarbonate, blood urea nitrogen, creatinine, and serum glucose levels should be obtained, although commencing rehydration therapy without these results is safe. Normal saline or LR infusion is the appropriate first step in the treatment of hyponatremic and hypernatremic dehydration. Hypotonic solutions should not be used for acute parenteral rehydration (*47*).

Severely dehydrated patients might require multiple administrations of fluid in short succession. Overly rapid rehydration is unlikely to occur as long as weight-based amounts are administered with close observation. Errors occur most commonly in settings where adult dosing is administered to infants (e.g., "500 mL NS [normal saline] IV bolus x 2" would provide 200 mL/kg body weight for an average infant aged 2–3 months). Edema of the eyelids and extremities can indicate overhydration. Diuretics should not be administered. After the edema has subsided, the patient should be reassessed for continued therapy. With frail or malnourished infants, smaller amounts (10 mL/kg body weight) are recommended because of the reduced ability of these infants to increase cardiac output and because distinguishing dehydration from sepsis might be difficult among these patients. Smaller amounts also will facilitate closer evaluation. Hydration status should be reassessed frequently to determine the adequacy of replacement therapy. A lack of response to fluid administration should raise the suspicion of alternative or concurrent diagnoses, including septic shock and metabolic, cardiac, or neurologic disorders.

As soon as the severely dehydrated patient's level of consciousness returns to normal, therapy usually can be changed to the oral route, with the patient taking by mouth the

remaining estimated deficit. An NG tube can be helpful for patients with normal mental status but who are too weak to drink adequately. Although no studies have specifically documented increased aspiration risk with NG tube use in obtunded patients, IV therapy is typically favored for such patients. Although leaving IV access in place for these patients is reasonable in case it is needed again, early reintroduction of ORS is safer. Using IV catheters is associated with frequent minor complications, including extravasation of IV fluid, and with rare substantial complications, including the inadvertent administration of inappropriate fluid (e.g., solutions containing excessive potassium). In addition, early ORS will probably encourage earlier resumption of feeding, and data indicate that resolution of acidosis might be more rapid with ORS than with IV fluid (*45*).

Clinical Management in the Hospital

Inpatient care is indicated for children if

- caregivers cannot provide adequate care at home;
- substantial difficulties exist in administrating ORT, including intractable vomiting, ORS refusal, or inadequate ORS intake;
- concern exists for other possible illnesses complicating the clinical course;
- ORS treatment fails, including worsening diarrhea or dehydration despite adequate volumes;
- severe dehydration (>9% of body weight) exists;
- social or logistical concerns exist that might prevent return evaluation, if necessary, or
- such factors as young age, unusual irritability or drowsiness, progressive course of symptoms, or uncertainty of diagnosis exist that might indicate a need for close observation.

In addition, studies of mortality caused by acute diarrhea in the United States have identified prematurity, young maternal age, black race, and rural residence as risk factors for suboptimal outcome (*48*); thus, these factors should also be considered when deciding if hospital care is required.

Limitations of ORT

Although ORT is recommended for all age groups and for diarrhea of any etiology, certain restrictions apply to its use. Among children in hemodynamic shock, administration of oral solutions might be contraindicated because airway protective reflexes might be impaired. Likewise, patients with abdominal ileus should not be administered oral fluids until bowel sounds are audible. Intestinal intussusception can be present with diarrhea, including bloody diarrhea. Radiographic and surgical evaluation are warranted when the diagnosis of bowel obstruction is in question.

Stool output in excess of 10 mL/kg body weight/hour has been associated with a lower rate of success of oral rehydration (*49*); however, children should not be denied ORT simply because of a high purging rate, because the majority of children will respond well if administered adequate replacement fluid.

A limited percentage of infants (<1%) with acute diarrhea experience carbohydrate malabsorption. This is characterized by a dramatic increase in stool output after intake of fluids containing simple sugars (e.g., glucose), including ORS. Patients with true glucose malabsorption also will have an immediate reduction in stool output when IV therapy is used instead of ORS. However, the presence of stool-reducing substances alone is not sufficient to make this diagnosis, because this is a common finding among patients with diarrhea and does not in itself predict failure of oral therapy.

Certain patients with acute diarrhea have concomitant vomiting. However, the majority can be rehydrated successfully with oral fluids if limited volumes of ORS (5 mL) are administered every 5 minutes, with a gradual increase in the amount consumed. Administration with a spoon or syringe under close supervision helps guarantee a gradual progression in the amount taken. Often, correction of acidosis and dehydration lessens the frequency of vomiting. Continuous slow NG infusion of ORS through a feeding tube might be helpful. Even if a limited amount of emesis occurs after NG administration of fluid, treatment might not be affected adversely (*45*). The physician might meet resistance in implementing NG rehydration in a vomiting child, but NG rehydration might help the initial rehydration and speed up tolerance to refeeding (*50*), leading to improved patient disposition and quicker discharge.

Hypernatremic Dehydration

Patients with hypernatremic dehydration (i.e., serum sodium concentration >145 mEq/L) respond well to ORT. Those with severe dehydration should first receive IV hydration as previously discussed. Subsequent hydration should be achieved with ORS (*51*). As with isonatremic dehydration, ORS should be administered to replace the calculated deficit and ongoing losses. ORS might be safer than IV therapy because it is less likely to lead to a precipitous increase in intracellular water associated with seizures and elevated intracranial pressure (*43*). For more detailed recommendations regarding therapy of hypernatremic dehydration, other sources should be consulted (*52*).

Dietary Therapy

Recommendations for maintenance dietary therapy depend on the age and diet history of the patient. Breastfed infants should continue nursing on demand. Formula-fed infants should continue their usual formula immediately upon rehydration in amounts sufficient to satisfy energy and nutrient requirements. Lactose-free or lactose-reduced formulas usually are unnecessary. A meta-analysis of clinical trials indicates no advantage of lactose-free formulas over lactose-containing formulas for the majority of infants, although certain infants with malnutrition or severe dehydration recover more quickly when given lactose-free formula (*53*). Patients with true lactose intolerance will have exacerbation of diarrhea when a lactose-containing formula is introduced. The presence of low pH (<6.0) or reducing substances (>0.5%) in the stool is not diagnostic of lactose intolerance in the absence of clinical symptoms. Although medical practice has often favored beginning feedings with diluted (e.g., half- or quarter-strength) formula, controlled clinical trials have demonstrated that this practice is unnecessary and is associated with prolonged symptoms (*54*) and delayed nutritional recovery (*55*).

Formulas containing soy fiber have been marketed to physicians and consumers in the United States, and added soy fiber has been reported to reduce liquid stools without changing overall stool output (*56*). This cosmetic effect might have certain benefits with regard to diminishing diaper rash and encouraging early resumption of normal diet but is probably not sufficient to merit its use as a standard of care. A reduction in the duration of antibiotic-associated diarrhea has been demonstrated among older infants and toddlers fed formula with added soy fiber (*57*).

Children receiving semisolid or solid foods should continue to receive their usual diet during episodes of diarrhea. Foods high in simple sugars should be avoided because the osmotic load might worsen diarrhea; therefore, substantial amounts of carbonated soft drinks, juice, gelatin desserts, and other highly sugared liquids should be avoided. Certain guidelines have recommended avoiding fatty foods, but maintaining adequate calories without fat is difficult, and fat might have a beneficial effect of reducing intestinal motility. The practice of withholding food for ≥24 hours is inappropriate. Early feeding decreases changes in intestinal permeability caused by infection (*58*), reduces illness duration, and improves nutritional outcomes (*18,19*). Highly specific diets (e.g., the BRAT [bananas, rice, applesauce, and toast] diet) have been commonly recommended. Although certain benefits might exist from green bananas and pectin in persistent diarrhea (*59*), the BRAT diet is unnecessarily restrictive and, similar to juice-centered diets, can provide suboptimal nutrition for the patient's nourishment and recovering gut. Severe malnutrition can occur after gastroenteritis if prolonged gut rest or clear fluids are prescribed (*60*).

Children in underdeveloped countries often have multiple episodes of diarrhea in a single season, making diarrhea a contributing factor to suboptimal nutrition, which can increase the frequency and severity of subsequent episodes (*61*). For this reason, increased nutrient intake should be administered after an episode of diarrhea. Recommended foods include age-appropriate unrestricted diets, including complex carbohydrates, meats, yogurt, fruits, and vegetables. Children should as best as possible maintain caloric intake during acute episodes, and subsequently should receive additional nutrition to compensate for any shortfalls arising during the illness.

Pharmacologic Therapy

Antimicrobial Agents

Because viruses (e.g., rotavirus, astrovirus, enteric adenovirus, norovirus, and sapovirus) are the predominant cause of acute diarrhea in developed countries (62), the routine use of antimicrobial agents for treating diarrhea wastes resources and might lead to increased antimicrobial resistance. Even when a bacterial cause is suspected in an outpatient setting, antimicrobial therapy is not usually indicated among children because the majority of cases of acute diarrhea are self-limited and not shortened by antimicrobial agents. Exceptions to these rules involve special needs of individual children (e.g., immune-compromised hosts, premature infants, or children with underlying disorders). Information regarding appropriate antimicrobial therapy of bacterial and parasitic causes of acute infectious diarrhea is available (*63–66*).

Nonantimicrobial Drug Therapies

Nonspecific antidiarrheal agents (e.g., adsorbents such as kaolin-pectin), antimotility agents (e.g., loperamide), antisecretory drugs, and toxin binders (e.g., cholestyramine), are commonly used among older children and adults, but data are limited regarding their efficacy. Side effects of these drugs are well-known, in particular among the antimotility agents, including opiate-induced ileus, drowsiness, and nausea caused by the atropine effects and binding of nutrients and other drugs. In Pakistan, 18 cases of severe abdominal distention associated with using loperamide included 6 deaths (*67*). Bismuth subsalicylate has limited efficacy in treating traveler's diarrhea (*68*) and other causes of acute gastroenteritis among children (*69*). Although the side effects are fewer than those from antimotility agents, certain theoretical concerns regard-

ing the potential toxicity from salicylate absorption remain (*70*), and trials supporting its use have employed frequent doses (e.g., every 4 hours for 5 days) (*71*).

None of these drugs address the underlying causes of diarrhea, specifically increased secretion by intestinal crypt cells. Racecadotril, an enkephalinase inhibitor, preserves the antisecretory activity of enkephalins and does not slow intestinal transit or promote bacterial overgrowth (*72*). Its use has demonstrated promise in two controlled clinical trials among children, among whom it significantly reduced stool output when compared with placebo (*73,74*). Although the majority of cases of acute diarrhea require no adjunctive therapy, racecadotril might prove to be a useful adjunct. More studies are needed.

Antiemetics are usually unnecessary in acute diarrhea management. Using phenothiazines might interfere with oral rehydration by causing sleepiness. Ondansetron, a serotonin antagonist, either by the oral (*75*) or IV (*76*) route, can be effective in decreasing vomiting and limiting hospital admission. However, reliance on pharmacologic agents shifts the therapeutic focus away from appropriate fluid, electrolyte, and nutritional therapy, can result in adverse events, and can add unnecessarily to the economic cost of illness. Because acute diarrhea is a common illness, cost-effective analyses should be undertaken before routine pharmacologic therapy is recommended.

Supplemental Zinc Therapy

Multiple reports have linked diarrhea and abnormal zinc status (*77*), including increased stool zinc loss, negative zinc balance (78), and reduced tissue levels of zinc (*79*). Although severe zinc deficiency (e.g., acrodermatitis enteropathica) is associated with diarrhea, milder deficiencies of zinc might play a role in childhood diarrhea, and zinc supplementation might be of benefit either for improved outcomes in acute or chronic diarrhea or as prophylaxis against diarrheal disease. Reduced duration of acute diarrhea after zinc supplementation among patients with low zinc concentrations in rectal biopsies has been demonstrated (*79*). In Bangladesh, zinc supplements also improved markers of intestinal permeability among children with diarrhea (*80*). In India, zinc supplementation was associated with a decrease in both the mean number of watery stools per day and the number of days with watery diarrhea (*81*). Prophylactic zinc supplementation in India has been associated with a substantially reduced incidence of severe and prolonged diarrhea, two key determinants of malnutrition and diarrhea-related mortality (*82*). In Nepal, this effect was independent of concomitant vitamin A administration, with limited side effects apart from a slight increase in emesis (*83*). In Peru, zinc administration was associated with a reduction in duration of persistent diarrhea (*84*). In two different pooled analyses of randomized controlled trials in developing countries (*85,86*), zinc supplementation was beneficial for treating children with acute and persistent diarrhea and as a prophylactic supplement for decreasing the incidence of diarrheal disease and pneumonia. Among infants and young children who received supplemental zinc for 5 or 7 days/week for 12–54 weeks, the pooled odds ratio (OR) for diarrhea incidence was 0.82 (95% confidence interval [CIs] = 0.72–0.93), and the OR for pneumonia incidence was 0.59 (95% CI = 0.41–0.83). The efficacy and safety of a zinc-fortified (40 mg/L) ORS among 1,219 children with acute diarrhea was evaluated (*87*). Compared with zinc syrup administered at a dose of 15–30 mg/day, zinc-fortified ORS did not increase the plasma zinc concentration. However, clinical outcomes among the zinc-fortified ORS group were modestly improved, compared with those for the control group, who received standard ORS only. In that study, the total number of stools was lower among the zinc-ORS group (relative risk: 0.83; 95% CI = 0.71–0.96), compared with the total number for the control group. No substantial effect on duration of diarrhea or risk for prolonged diarrhea was noted.

Thus, a number of trials have supported zinc supplementation as an effective agent in treating and preventing diarrheal disease. Further research is needed to identify the mechanism of action of zinc and to determine its optimal delivery to the neediest populations. The role of zinc supplements in developed countries needs further evaluation.

Functional Foods

Functional foods can be defined as foods that have an effect on physiologic processes separate from their established nutritional function (*88*). Probiotics have been defined as live microorganisms in fermented foods that promote optimal health by establishing an improved balance in intestinal microflora (*89*). Reviews have evaluated studies of their use in preventing or reducing the severity or duration of diarrheal illnesses among children (*90*), including diarrhea caused by rotavirus (*91*) or associated with antibiotic use (*92*). These products have included various species of lactobacilli or bifidobacteria or the nonpathogenic yeast *Saccharomyces boulardii*. The mechanism of action might include competition with pathogenic bacteria for receptor sites or intraluminal nutrients, production of antibiotic substances, and enhancement of host immune defenses (*93,94*). One meta-analysis concludes that *Lactobacillus* species are both safe and effective as treatment for children with infectious diarrhea (*95*).

A positive recommendation also emerges from a meta-analysis of probiotic use in antibiotic-associated diarrhea (*92*).

Certain trials included in these reviews were of limited sample size, and negative studies might not have been published. Because dietary supplements (e.g., probiotics) are usually not regulated by the federal government, potential exists for great variability among them, providing a challenge to the prescribing physician to make an informed recommendation regarding their use.

Prebiotics differ from probiotics in that they are complex carbohydrates rather than organisms used to preferentially stimulate the growth of health-promoting intestinal flora (*96*). The oligosaccharides contained in human milk have been called the prototypic prebiotic because they foster growth of lactobacilli and bifidobacteria in the colon of breastfed neonates (*97*). Data have linked higher intakes of breast milk oligosaccharides with a lowered incidence of acute diarrhea (*98*). Two randomized trials of prebiotic supplemented infant cereal did not demonstrate a reduced incidence of diarrheal disease among infants and children living in an urban economically depressed area (*99*). Specific recommendations regarding their use should await further well-controlled human trials.

Specific Clinical Scenarios

Oral rehydration therapy is critical in managing specific types of diarrheal diseases.

Acute Bloody Diarrhea (Dysentery)

Dysentery is defined as acute bloody diarrhea caused by invasive microbial infection. This does not include occult blood (detected by guaiac card only) or streaks of blood on the surface of formed stool. The treatment of dehydration in dysentery follows the same principles as treatment of acute watery diarrhea. The child with bloody diarrhea is at higher risk for complications, including sepsis and other systemic diseases; therefore, the threshold for admission of such children to the hospital for close observation is lower. Stool cultures are indicated in the setting of acute bloody diarrhea and are helpful for guiding therapy. Food should not be withheld for children with dysentery any more than in other cases of diarrhea. More frequent, smaller meals might be better tolerated, and higher protein intakes have proven beneficial among children recovering from dysentery (*100,101*).

In the majority of cases, empiric antimicrobial agents should not be administered while awaiting culture results, because antimicrobial therapy might not be indicated even when culture results are positive. Amoebiasis is an unusual cause of bloody diarrhea in young children, even in less-developed countries (*102*). Treatment for amoebiasis should be reserved for those cases in which trophozoites are detected on microscopic examination of the stools (*65*). Recommendations for therapy of specific enteric pathogens associated with bloody diarrhea are available elsewhere (*63–66*).

Persistent Diarrhea and Diarrhea with Severe Malnutrition

These clinical entities are critical, especially among children of developing countries. Therapy should include oral rehydration when indicated, although the specifics of the evaluation, and fluid, electrolyte, and nutritional management differ and are beyond the scope of this review. The reader is referred to other sources for information regarding these conditions (*103,104*).

Choice of ORS

In 1975, WHO and the United Nations Children's Fund (UNICEF) agreed to promote a single ORS (WHO-ORS) containing (in mmol/L) sodium 90, potassium 20, chloride 80, base 30, and glucose 111 (2%) for use among diverse populations. This composition was selected to allow for a single solution to be used for treatment of diarrhea caused by different infectious agents and associated with varying degrees of electrolyte loss. For example, rotavirus diarrhea is associated with stool sodium losses of approximately 30–40 mEq/L; enterotoxigenic *E. coli* infection with losses of 50–60 mEq/L; and cholera infection with losses of ≥90–120 mEq/L (*105*). WHO-ORS has been demonstrated during >25 years of use to be safe and effective at rehydration and maintenance for children and adults with all types of infectious diarrhea.

However, subsequent clinical research, documented in multiple controlled trials and summarized in a meta-analysis (*106*), has supported adoption of a lower osmolarity ORS (i.e., proportionally reduced concentrations of sodium and glucose). A reduced osmolarity ORS has been associated with less vomiting, less stool output, and a reduced need for unscheduled intravenous infusions when compared with standard ORS among infants and children with noncholera diarrhea. In cholera infection, no clinical difference existed between subjects treated with the lower osmolarity solution and those treated with the standard solution, apart from certain increased incidence of asymptomatic hyponatremia (*107*). On the basis of those and other findings, UNICEF and WHO organized a consultation on oral rehydration that recommended a reduced osmolarity solution for global use (*108*). In May 2002, WHO announced a new ORS formulation consistent with these

recommendations, with 75 mEq/L sodium, 75 mmol/L glucose, and total osmolarity of 245 mOsm/L (*109*) (Table 3). The newer hypotonic WHO-ORS is also recommended for use in treating adults and children with cholera, although postmarketing surveillance is under way to confirm the safety of this indication. The composition of commonly available oral rehydration solutions is distinct from other beverages frequently used inappropriately for rehydration (Table 3).

New Solutions

Recipes to improve ORS have included adding substrates for sodium co-transport (e.g., the amino acids glycine, alanine, and glutamine) (*35*) or substituting complex carbohydrates for the glucose (rice and other cereal-based ORS) (*36*). The amino acid preparations have not been demonstrated to be more effective than traditional ORS, and they are more costly. Rice-based ORS can be recommended where training is adequate and home preparation is preferable, and it can be particularly effective in treating dehydration caused by cholera (*36*). Nevertheless, given the simplicity and safety of ORS packets in developing countries and of commercially available ORS in developed countries, these remain the first choice for the majority of clinicians.

Other potential additives to ORS include substances capable of liberating short-chain fatty acids (e.g., amylase-resistant starch derived from corn) (*110*) and partially hydrolyzed guar gum (*111*). The presumed mechanism of action is the enlistment of increased colonic sodium uptake coupled to short-chain fatty acid transport. Other possible future ORS composition changes include addition of probiotics (*91*), prebiotics, zinc (*87*), or protein polymers.

Barriers to ORT

Among patients, barriers to using ORS and continued nutrition during diarrheal disease include cultural practices (*38*), lack of parental knowledge (*11*), lack of training of medical professionals, and cost of commercially available ORS (*112*). Among physicians, preference for IV hydration, even where evidence indicates improved results from oral rehydration (*13,14*), remains a major barrier. Patients, even at times under physician supervision, frequently attempt rehydration with solutions bearing no resemblance to physiologically based ORS. The electrolyte content of different fluids commonly used in treating diarrhea do not contain physiologically sound concentrations of carbohydrates and electrolytes, compared with commonly available ORS (Table 3). An informal survey of hospital Internet sites revealed outdated recommendations

TABLE 3. Composition of commercial oral rehydration solutions (ORS) and commonly consumed beverages

for treating diarrhea that include nonstandard fluids (unpublished data, Caleb K. King, M.D., University of North Carolina, Chapel Hill, North Carolina). A case report of one child whose care was compromised by following advice obtained from a prominent hospital's Internet site highlights the continued gap between knowledge and practice and the ongoing need to disseminate accurate information regarding oral rehydration (*113*).

Conclusion

Treatment of acute diarrhea has relied upon simple and effective therapy of oral rehydration. The critical co-principle in case management of early resumption of feeding of children immediately upon rehydration has also gained wide acceptance. More recent advances in the science of diarrhea treatment include recognition for the role of zinc supplementation in reducing disease severity and occurrence, and development of an oral rehydration solution of lower osmolarity for global use. The combination of oral rehydration and early nutritional support promises to safely and effectively assist a patient through an episode of diarrhea. If the principles of therapy outlined in this report are accepted by all levels of the medical community and if education of parents includes teaching them to begin ORT at home, numerous deaths and unnecessary clinic visits and hospitalizations can be avoided. ORT is suitable for use among children throughout the world (*114*).

AMERICAN ACADEMY OF PEDIATRICS

Committee on Substance Abuse

Marijuana: A Continuing Concern for Pediatricians

ABSTRACT. Marijuana, the common name for products derived from the plant *Cannabis sativa*, is the most common illicit drug used by children and adolescents in the United States.[1] Despite growing concerns by the medical profession about the physical and psychological effects of its active ingredient, Δ-9-tetrahydrocannabinol, survey data continue to show that increasing numbers of young people are using the drug as they become less concerned about its dangers.[1]

ABBREVIATION. THC, tetrahydrocannabinol.

Because the decision of whether to use marijuana is usually made by the time a young person reaches the age of 19 years,[2,3] pediatricians must continue to be cognizant of the implications of marijuana use. Widespread debate exists about marijuana and the possibility of legalizing its use or at least decriminalizing its possession.[4–7] Furthermore, marijuana is being promoted for medical purposes, such as the treatment of glaucoma and the management of nausea and anorexia related to cancer chemotherapy.[4,8,9] Although these topics are beyond the scope of this statement, evidence suggests that pediatricians should continue their vigilant efforts to prevent the use of this drug by young people.

The abuse of marijuana by adolescents is a major health problem with social, academic, developmental, and legal ramifications.[10] Marijuana is an addictive, mind-altering drug capable of inducing dependency.[11] Pediatricians are obligated to develop a reasoned approach to dealing with its use by children and adolescents so they can provide appropriate care and counsel.[12]

EPIDEMIOLOGY

Between 1991 and 1997, the use of marijuana by young people increased dramatically.[1] In 1997, 23% of eighth graders reported having used the drug at some time in their lives, an increase in use from 10% in 1991. Among 10th graders, the number nearly doubled from 23% in 1991 to 42% in 1997. In 1997, 50% of high school seniors reported having used marijuana compared with 37% 6 years earlier. The abuse of marijuana among teenagers has increased as the "perceived harmfulness" of regular use has decreased and the perception of "peer acceptance" has increased.[1,2]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

POTENCY

The potency of marijuana is defined as the percentage of Δ-9-tetrahydrocannabinol (Δ-9-THC) in the dry weight of the sample. Increased sophistication in the selective breeding of marijuana plants has led to a substantial increase in the potency of street samples during the past 2 decades. In 1975, the average potency of THC in confiscated samples was 0.71%; by 1997, the average concentration was 3.71%—a fivefold increase. There is wide variation in the potency of smoked marijuana. Sensimilla (considered by many to be the finest product, produced from the flowering tops of the female hemp plant) had an average potency of 6.6% in 1997. Marijuana sold as loose plant material (leaves, stems, and seeds) had an average potency of 3.2%.[13] In addition, the method of consumption (smoking as a rolled cigarette or in a pipe or packed into a hollowed-out cigar), as well as the presence of adulterating substances, affect the potency.

Because of the documented change in potency, pediatricians must be able to address with their patients what seems to be "casual use" of marijuana. Trends suggest that the low-dose, self-experimentation type of use typical of the 1960s may be giving way to the high-potency–high-reward pattern of compulsive marijuana use prevalent during the late 1990s.[14]

SOMATIC CONSEQUENCES

Marijuana should not be considered an innocuous drug. Regular use has been associated with cardiovascular, pulmonary, reproductive, and immunologic consequences. The physiologic effects of marijuana use include an accelerated heart rate and a minimal rise in blood pressure.[15,16] These effects, which seem to be secondary to Δ-adrenergic vascular mechanisms, are transient and usually not deleterious to the otherwise healthy adolescent. The immediate pulmonary effect of smoking marijuana is bronchodilation, although with long-term use the smoked particles act as an irritant, causing bronchoconstriction and eventual airway obstruction.[17–19] The chronic effects are similar to those of smoking tobacco, and there seems to be a relationship between smoking marijuana and neoplastic changes in the lungs.[20]

Heavy marijuana use may be especially dangerous for adolescents during puberty. Such use has been associated with diminished sperm motility, decreased sperm counts, decreased circulating testosterone levels,[21,22] irregular ovulation, and decreased pituitary gonadotropin levels.[23,24] The metabolites of

marijuana cross the human placenta and are also found in human milk. Although the consequences of the presence of such metabolites in human milk have yet to be identified,[25–27] infants born to mothers who smoke marijuana during pregnancy are shorter, weigh less, and have smaller head circumferences at birth.[27,28] Marijuana and some of its components influence the immune system and affect the body's antitumor activities. Marijuana receptors have been identified on macrophages and T and B lymphocytes, suggesting a molecular basis for immunosuppression by THC.[29–31]

NEUROPHARMACOLOGY

The psychoactive effects of Δ-9-THC are receptor-mediated. The cannabinoid receptor sites in the brain are particularly dense in the outflow nuclei of the basal ganglia, the hippocampus, and the molecular layers of the cerebellum, implicating roles for cannabinoids in the disruption of cognition and coordination. Sparse densities in the lower brainstem areas controlling cardiovascular and respiratory functions may explain why high doses of Δ-9-THC are not lethal.[32]

Anandamide, a derivative of arachidonic acid, is an endogenous chemical in the brain that binds with cannabinoid receptors.[33] Like Δ-9-THC, it has been shown to affect muscle coordination, produce analgesic and tranquilizing effects, and inhibit secretion of follicle-stimulating hormone, prolactin, and growth hormone.[34] The use of anandamide as a marijuana antagonist has substantial effects on rats conditioned to self-treatment with THC[33,34] and has helped elucidate the mechanism by which cannabinoids exert their biological and psychologic effects.

The most pervasive common pathway among drugs of abuse, including cocaine, heroin, opiates, and marijuana, is the stimulation of release of the neurotransmitter, dopamine.[35–38] This endogenous catecholamine stimulates certain dopaminergic projections of the medial forebrain bundle—the brain's so-called reward circuitry.[39] Psychoactive drugs, including marijuana, derive substantial abuse liability from enhancing these circuits; and it is the psychoactive ingredient of marijuana, Δ-9-THC, that stimulates the release of dopamine, mediated through the cannabinoid receptors.[40,41]

In both animal and human experiments, subjects self-administer marijuana. They predictably select high-potency marijuana over low-potency marijuana,[42] supporting the hypothesis that the reinforcing effect and abuse liability of marijuana are positively related to the Δ-9-THC content.

Marijuana is lipophilic and is stored in the brain and other fat-rich areas of the body, forming what has been described as a "depot."[43] The slow release of marijuana and its metabolites from lipid stores may explain the carry-over effects of marijuana on driving and other cognitive and behavioral changes,[44] as well as the absence of acute signs of withdrawal after abrupt discontinuation of use.[45]

BEHAVIORAL AND COGNITIVE CONSEQUENCES

Marijuana affects the brain, resulting in behavioral and cognitive effects. Acutely, marijuana produces euphoria, relaxation, and disinhibition. Persons under the influence of the drug show impaired problem-solving skills and difficulty in organizing thoughts and conversing. Other adverse consequences of marijuana use include interference with coordination; the ability to judge elapsed time, speed, and distance; the ability to track a moving object; and reaction time.[46–49] There is little doubt that marijuana intoxication contributes substantially to accidental deaths and injuries among adolescents, especially those associated with motor vehicle crashes, and is frequently involved in incidents related to driving while intoxicated.[50,51]

Regular use of marijuana also exerts a negative effect on short-term memory, learning, and attention span. Three methodologically strong studies presented compelling evidence that these functions were impaired in frequent users of marijuana (defined as using 20 to 30 days per month), even up to 6 weeks after discontinuation of use,[52] and noticeable impairment in attention and memory was evident even after 24 hours of abstinence.[53,54] Clearly, young people who are frequent users of marijuana experience residual neuropsychologic effects with an impaired ability to learn.[53]

An "amotivational syndrome" has been described in chronic heavy marijuana users. This syndrome is characterized by the inability to sustain attention on environmental stimuli and to maintain goal-directed thinking and behavior.[55] An additional source of concern is the occasional occurrence of dysphoric reactions that may range from mild fear to depersonalization to frank paranoia.[56,57]

Finally, marijuana use often precedes the use of other more dangerous drugs. Although marijuana use does not necessarily predict progression to the use of "harder" drugs, adolescents who use marijuana are 104 times as likely to use cocaine compared with peers who never smoked marijuana.[4,58] Therefore, the use of marijuana as a risk behavior and its role as a "gateway drug" for some teenagers must be considered.

SUMMARY

The seriousness of the behavioral consequences of marijuana use is sufficient to cause great concern and should prompt the pediatrician to counsel young people against any use of the drug. Such counsel should be based on health concerns, including the relationship of marijuana use to trauma associated with intoxication and the effect on memory and learning during this important period of development. Additional reasons for concern and counsel include anxieties and uncertainties about the potential harm that marijuana use may cause to adolescents during a period of rapid change in hormonal secretion, possible teratogenicity, and the known consequences of long-term use.

A discussion of drug use, including the use of marijuana, should be a routine part of primary health

care clinical preventive services for every child and adolescent. An assessment of potential drug use gives the pediatrician the opportunity to offer anticipatory guidance before the onset of drug use, to intervene and minimize consequences if drug use has begun, and to detect and address issues of long-term or heavy use.

Although all users should be counseled about the dangers of the drug and the illicit nature of its use, marijuana is an addictive drug and is capable of producing dependency. Marijuana-dependent teenagers should be offered treatment options, rather than simply punishment, for their illness.

abstract

FREE

The past 2 decades have yielded profound advances in the fields of prenatal diagnosis and fetal intervention. Although fetal interventions are driven by a beneficence-based motivation to improve fetal and neonatal outcomes, advancement in fetal therapies raises ethical issues surrounding maternal autonomy and decision-making, concepts of innovation versus research, and organizational aspects within institutions in the development of fetal care centers. To safeguard the interests of both the pregnant woman and the fetus, the American College of Obstetricians and Gynecologists and the American Academy of Pediatrics make recommendations regarding informed consent, the role of research subject advocates and other independent advocates, the availability of support services, the multidisciplinary nature of fetal intervention teams, the oversight of centers, and the need to accumulate maternal and fetal outcome data. *Pediatrics* 2011;128:e473–e478

The past 2 decades have yielded profound advances in the fields of prenatal diagnosis and fetal intervention. Ultrasonography and magnetic resonance imaging have led to the diagnosis of fetal anomalies that can affect many organ systems. Concomitantly, improvements in minimally invasive techniques and in the understanding of fetal physiology have allowed for more successful and less invasive or risky interventions for fetal diseases in utero. Intervention has been offered for a variety of fetal diseases, including structural abnormalities, cardiac arrhythmias, fetal metabolic diseases, and abnormalities of the placental vessels or membranes. Many of these diseases would be lethal without treatment; some (eg, spina bifida or hypoplastic left heart syndrome) are not necessarily lethal postnatally, but efforts to treat them in utero have been offered with the goal of improving long-term outcomes for the child. Many interventions are offered within the construct of a research protocol. Although fetal interventions are driven by a beneficence-based motivation (ie, a desire to do good, to improve fetal and neonatal outcomes, to ameliorate suffering), advancement in fetal therapies raises ethical issues surrounding maternal autonomy and decision-making, concepts of innovation versus research, and organizational aspects within institutions in the development of fetal care centers.

THE DECISION-MAKING PROCESS

The overarching goal of fetal interventions is clear: to improve the health of children by intervening before birth to correct or treat prenatally diagnosed abnormalities. This stems from a beneficence-based obligation to the fetus. Any fetal intervention, however, has implications for the pregnant woman's health and necessarily her bodily integrity and, therefore, *cannot be performed without her explicit informed consent*.[1] It is impossible to treat the fetus without going through the pregnant woman either physically (in the case of surgical treatments) or pharmacologically (as in the case of medications given to the woman that then cross the placenta to treat the fetus). Because the pregnant woman who chooses to undergo these procedures and treatments must assume some of the risk, respect for her autonomy requires a thorough discussion and evaluation of the maternal risks and harms of any of these therapies as well as her valid consent.[2] A pregnant woman's right to informed refusal must be respected fully.[3]

For many women, as well as the physicians caring for them, decision-making considerations relevant to fetal treatment may seem to parallel the parental decision-making process in determining treatment of childhood ailments. Women weigh the risks and benefits of the intervention for the fetus against the possible outcomes without intervention. For those few treatments that have been shown to be effective and be of low risk or minimal invasiveness, most women will agree to the treatment out of a beneficence-based obligation to their fetuses. Nonetheless, consent still must be based on the pregnant woman's assessment of her *own* interests. And, although a parental decision may, in certain circumstances, be overridden for a child after birth, even the strongest evidence for fetal benefit would not be sufficient ethically to ever override a pregnant woman's decision to forgo fetal treatment.[4,5]

A pregnant woman will often assume quite significant risks for her fetus, and some women might find it difficult to forgo these interventions because of pressures from within themselves, from their families, from their communities, or even from their care providers.[6] A pregnant woman's decision may be affected by factors such as her family's or society's expectations regarding her responsibility as a prospective mother, maternal feelings of guilt and her desire to try and make things "right," or even the psychosocial "therapeutic misconception," that is, the presumption that an intervention with no proven efficacy will actually work merely because it is *offered* by a center, is under a study protocol, or has been covered by the news media.[7,8] The informed consent process should, therefore, contain reasonable safeguards against limits to voluntariness, ranging from undue influence to coercion.

Safeguards should be in place to protect women considering fetal research. One possible safeguard would be to have a research subject advocate who does not have direct ties to the experimental protocol so that this individual can act as an independent advocate for the pregnant woman, especially when the proposed intervention poses significant risks to the pregnant woman.[9] This advocate should be nondirective in his or her support of the woman's decision and focus on meeting the woman's decision-making needs. Involving someone who has an understanding of the culture of research and yet maintains "separateness" from the research team can provide an ethical safeguard to support the pregnant woman.[10] But even outside a research protocol, a pregnant woman receiving treatment that is not experimental may also benefit from an independent advocate who might be her obstetric provider, a perinatal nurse, or a specially trained advocate.

Other family members involved in these decisions also need consideration. Pregnant women have a variety of support persons, including spouses and partners of either sex. The interests of others involved vary depending on their relationship to the woman and fetus. Because families come in differing forms, the woman herself should define these relationships and determine who should assist in any decision-making. In this Committee Opinion, the American College of Obstetricians and Gynecologists (the College) and the American Academy of Pediatrics (the Academy) write about the interests of the father but recognize that the father of the fetus may be absent or uninvolved and that the involved partner may be a man or a woman biologically unrelated to the fetus.

In most cases, the father has a moral interest in the health of the fetus and the pregnant woman, just as he would have interests in the health of the mother and child after delivery. It is appropriate for women to involve fathers in these decisions for good reasons: they will usually be raising this future child together, they will make joint decisions about health issues, and their relationship may be one of mutual support in family decision-making. It may be problematic for a woman to proceed with these interventions without consulting the father. It must be recognized that postnatally, pediatric care commonly involves shared decision-making between a child's mother *and* father, making the recommendation not to grant any authority to the father in the prenatal period uncomfortable for many pediatricians. However, for the reasons stated earlier, the pregnant woman's interests and final decisions regarding fetal interventions assume priority in the

prenatal period. Although it may be appropriate and helpful for the father to be involved in these decisions and have complete access to information (with proper authorization from the pregnant woman), to assign him any authority to assent or dissent would unjustifiably erode the autonomous decision-making capacity of the pregnant woman. The College addressed paternal consent for research in a previous Committee Opinion.[3,11] The College concluded that paternal consent for research on fetuses should not be required but recognizes that federal regulations continue to require this consent in some circumstances.

PREGNANT WOMEN REQUIRE INFORMATION ON RISKS, BENEFITS, OUTCOMES, AND ALTERNATIVES FOR BOTH THE FETUS AND THEMSELVES

One of the challenges surrounding fetal interventions is the difficulty in delivering information to prospective parents that is both thorough and unbiased. Not only do prospective parents need to be informed of the goals of treatment, but they also need to know about the sometimes conflicting data, or more commonly the paucity of data, that support offering or performing interventions. The risks and possible benefits to the fetus undergoing an intervention need to be weighed against the risks and benefits of obstetric and neonatal care without the intervention (which is often the standard of care). Moreover, the range of outcomes of all options must be presented, because prospective parents may erroneously believe that there are only 2 possible results: 1) success (fetal cure) or 2) failure (fetal death).

In addition to information regarding the risks and benefits to the fetus or neonate, women require a frank discussion of the maternal risks of any fetal intervention. The morbidity and mortality associated with some interventions may be quite small (an amniocentesis needle and use of many maternal medications) or quite significant (the performance of a laparotomy and hysterotomy). Maternal hysterotomy may increase the risk of uterine rupture to rates as high as those after a classical cesarean delivery (4%–9%)[12]; these ruptures are associated with significant maternal and neonatal morbidities and mortalities. Moreover, these risks will persist in subsequent pregnancies as well. A thorough disclosure of these risks is always necessary.

INNOVATIVE AND EXPERIMENTAL CARE

One vital, though sometimes difficult, distinction that should be made to prospective parents concerns which fetal interventions are standard or evidence-based therapy and which are innovative or experimental. Certainly any intervention that is being studied as part of a research protocol requires formal institutional review board (IRB) oversight and an approved informed consent process. Federal guidelines indicate that novel interventions that deviate substantially from standard practice do not need to be performed within a research protocol but should eventually be developed into a protocol subject to IRB oversight[13]:

> "When a clinician departs in a significant way from standard or accepted practice, the innovation does not, in and of itself, constitute research. The fact that a procedure is 'experimental,' in the sense of new, untested or different, does not automatically place it in the category of research. Radically new procedures of this description should, however, be made the object of formal research at an early stage to determine whether they are safe and effective. Thus, it is the responsibility of medical practice committees, for example, to insist that a major innovation be incorporated into a formal research project."

An attempt should be made to make clear to patients the distinction between the goals of therapeutic medicine (eg, cure, treatment, or palliation) versus the goals of research (eg, answering a scientific question that contributes to generalizable knowledge). In addition, there is often a blurring of boundaries between research and innovative practice associated with the rapidly developing technologies used in fetal interventions that raises concerns about the protection of pregnant women and their fetuses from the risks of unproven therapies. Although the first few uses of a new intervention may be motivated by a desire to help particular fetuses, once feasibility and potential benefit have been identified, innovations should be subjected to systematic formal research as soon as feasible.[14] This benefits science, because evaluation of new procedures might be hindered if new procedures continue to be considered "innovative therapy" rather than part of careful research. Pregnant women and their fetuses who undergo these interventions must have at least the same protections afforded to other research participants, and studies should be designed to assess the full impact of risks and benefits of these interventions on both the woman and the fetus, for both short- and long-term outcomes.

ALTERNATIVES TO INTERVENTION

The case of prospective parents electing to forgo fetal intervention also needs further exploration. Given the maternal morbidities and experimental nature of many fetal interventions, some women may understandably elect to carry the pregnancy to term but *not* to undergo fetal intervention. It is critical, therefore, for those centers offering fetal interventions to provide care, support, and appropriate referral services for these women and their families. For the fetus with anomalies such as spina bifida, this will involve postnatal neurosurgical treatment, which is currently standard care. For the fetus with lethal abnormalities,

this may take the form of access to palliative care or perinatal hospice programs. In the situation in which the fetal intervention is being offered in an attempt to avoid fetal death, these services could be offered alongside the intervention in case it is unsuccessful.

Finally, the clinical reality of serving women during pregnancy is that some women will elect pregnancy termination when facing the diagnosis of significant fetal anomalies. Centers offering fetal intervention should evaluate pregnant women in a timely fashion, counsel them adequately and nondirectively about all options, and, for women who might opt for pregnancy termination, have in place appropriate mechanisms, including the ability and resources for referral, to support these women through a difficult decision. An integrated palliative care, hospice, or bereavement service can help support women who elect to terminate their pregnancies as well.

Thus, the ethical provision of fetal intervention requires that women are not only well informed but also have, to the greatest extent possible, meaningful access to alternatives to intervention. Practitioners participating in fetal care centers may face significant difficulties in presenting in as nonbiased a fashion as possible these 4 distinct options: 1) fetal intervention, 2) postnatal therapy, 3)palliative care, or 4) pregnancy termination. Certainly each pediatrician, surgeon, and obstetrician involved in these decisions may have his or her own distinct views about the best course of action for any given disease entity, and thus, the counseling of the pregnant woman becomes complicated. Coordination of care and good communication between providers can help to minimize the conflicting information and opinions that may be given to patients.

OTHER NECESSARY SUPPORT SERVICES

The complex emotional stressors that pregnant women and their families may experience when considering fetal intervention may necessitate access to a variety of support services. These may include social services, palliative care and perinatal hospice services, genetic counseling, and ethics consultation, when appropriate.

FETAL CARE CENTERS

Diagnostic and therapeutic efforts are frequently being combined frequently and marketed in the form of fetal care or treatment centers. Fetal care centers can exist in many forms, having developed through a variety of multidisciplinary collaborative relationships among pediatric subspecialists, maternal–fetal medicine specialists, and radiologists. Often, they are freestanding centers, but they also can exist within established pediatric or obstetric departments. Regardless of their origin or site, they typically offer a wide variety of fetal diagnostic services as well as proven therapies and experimental practices of unproven benefit. These centers are driven by a beneficence-based motivation to improve fetal and neonatal outcomes and have frequently been the site of innovation and research that has furthered this end.[15,16] It should be noted that most maternal–fetal medicine divisions already provide such fetal care along with care of pregnant women; these divisions routinely call on pediatric surgeons and other subspecialists to consult with pregnant women without having any direct affiliation with a formal "fetal care" center. The dilemmas that may arise in the context of fetal care are, thus, not unique to fetal care centers; many of these dilemmas are faced by anyone caring for pregnant women. However, in marketing these centers around the fetus and its care, these centers require heightened scrutiny so that the needs and the interests of pregnant women are being adequately addressed.[17]

Conflicts of interest may arise in providing fetal intervention services, because these services may be financially lucrative for the institutions and may benefit the careers of the centers' practitioners. Furthermore, institutional use of resources by a fetal care center for the few women and fetuses who may benefit from an intervention may not be the most just or fair distribution of resources. Even if centers do not perform an intervention in the majority of cases they see, this may simply mean that prenatal counseling is a major component of most "fetal care" and is, in fact, a good justification for the use of resources in this fashion.

Cooperation between fetal care centers should be encouraged to establish collaborative research networks (especially for rare diseases and procedures) and to support multicenter trials to accumulate more robust short- and long-term maternal and fetal outcome data on all categories of fetal intervention. In addition, the establishment of centers of excellence for those procedures that are particularly challenging and rare may help to optimize fetal and maternal outcomes.[18] As with many rare specialty-specific endeavors, the balance of offering geographical access while having the quantity of cases necessary to develop clinical expertise and quality outcomes is difficult to achieve. Limiting interventions to a few centers of excellence for the sake of quality of care will create both geographical and financial barriers to access. Furthermore, those centers not participating in multicenter trials must consider whether to refer patients to centers that are participating to facilitate these research studies and find answers that cannot be discovered by offering interventions "off-study."

OVERSIGHT AND GOVERNANCE

To protect the panoply of interests involved (fetal, maternal, professional, and institutional), centers performing fetal interventions should have organizational structures or groups to provide oversight of both clinical and nonclinical activities. Multidisciplinary teams should be assembled to oversee the care being offered and to ensure that appropriate informed consent is obtained. To protect the interests of the pregnant woman, such teams should include a maternal–fetal medicine specialist. Indeed, because of their particular training, maternal–fetal medicine specialists are best suited to direct the care of the pregnant woman undergoing fetal interventions. Neonatologists also should be involved, because they will typically be the primary physicians managing the care of the neonate and dealing with the medical consequences of the antenatal intervention. Including a variety of other professionals on the team, such as nurses, pediatric and surgical subspecialists, genetic counselors, chaplains, ethicists, and other members of institutional ethics committees, is vital. Ideally, this group would include members, both professionals and nonprofessionals, without direct ties to the center involved. This group can help explore conflicts of interest, distinguish between innovation and research, and ensure that pregnant women are not being unduly influenced, coerced, or taken advantage of in what may be a time of crisis.

There also may be clinical management conflicts that arise between the obstetric and pediatric staff caring for these women, because the focus of care of the 2 groups can differ. Organizational structures within fetal care centers that foster consensus building are crucial to resolving these conflicts. The obstetrician, however, must remain in charge of the pregnant woman's overall care. Moreover, these centers must be able to provide the high-risk and obstetric critical care that these women often need; this may be a challenge when centers are housed in pediatric hospitals but it is necessary to optimize the well-being of the pregnant woman.

Finally, to protect against institutional conflicts of interest, an external advisory group may be necessary to monitor the center's nonclinical activities including marketing, outreach, and community relations. A memorandum of understanding should be developed that delineates the oversight group's authority to veto or halt activities that do not provide adequate benefits or pose inordinate risks.

RECOMMENDATIONS

To safeguard the interests of both the pregnant woman and the fetus, the College and the Academy make the following recommendations:

- Because it is impossible to treat the fetus without going through the pregnant woman either physically or pharmacologically, any fetal intervention has implications for the pregnant woman's health and necessarily her bodily integrity and, therefore, cannot be performed without her explicit informed consent.
- Distinctions should be made to prospective parents between which protocols are standard or evidence-based therapies and which are innovative or experimental interventions. Ordinarily, innovations should be subjected to systematic formal research as soon as feasible. Research must always be offered under proper oversight by an IRB.
- The informed consent process should involve thorough discussion of the risks and benefits for both the fetus and the pregnant woman. The full range of options, including fetal intervention, postnatal therapy, palliative care, or pregnancy termination, should be discussed. The informed consent process should contain reasonable safeguards against limits to voluntariness, ranging from undue influence to coercion.
- Safeguards should be in place to protect women considering fetal research. One possible safeguard would be to have a research subject advocate who does not have direct ties to the experimental protocol so that this individual can act as an independent advocate for the pregnant woman, especially when the proposed intervention poses significant risks to the pregnant woman. Similarly, a woman receiving treatment that is not experimental may also benefit from an independent advocate who might be her obstetric provider, a perinatal nurse, or a specially trained advocate.
- The complex emotional stressors that pregnant women and their families may experience when considering fetal interventions may necessitate access to a variety of support services. These may include social services, palliative care and perinatal hospice services, genetic counseling, and ethics consultation, when appropriate.
- The organization and governance of centers providing fetal interventions should involve a diverse group of professionals. Maternal–fetal medicine specialists and neonatologists should be included in this group. Including a variety of other professionals on the team, such as nurses, pediatric and surgical subspecialists, genetic counselors, chaplains, ethicists, and other members of institutional ethics committees, is vital. Ideally, this group would include members, both professionals and nonprofession-

als, without direct ties to the center involved.

- Cooperation between fetal care centers should be encouraged to establish collaborative research networks (especially for rare diseases and procedures) and to support multicenter trials to accumulate more robust short- and long-term maternal and fetal outcome data on all categories of fetal intervention. In addition, the establishment of centers of excellence for those procedures that are particularly challenging and rare may help to optimize fetal and maternal outcomes.

POLICY STATEMENT

Maternal Phenylketonuria

Organizational Principles to Guide and Define the Child Health System and/or Improve the Health of All Children

Committee on Genetics

ABSTRACT

Elevated maternal phenylalanine concentrations during pregnancy are teratogenic and may result in growth retardation, microcephaly, significant developmental delays, and birth defects in the offspring of women with poorly controlled phenylketonuria during pregnancy. Women of childbearing age with all forms of phenylketonuria, including mild variants such as mild hyperphenylalaninemia, should receive counseling concerning their risks for adverse fetal effects, optimally before conceiving. The best outcomes occur when strict control of maternal phenylalanine concentration is achieved before conception and continued throughout pregnancy. Included are brief descriptions of novel treatments for phenylketonuria. *Pediatrics* 2008;122:445–449

Key Words
phenylketonuria, maternal phenylketonuria, pregnancy, birth defect prevention

Abbreviations
PKU—phenylketonuria
Phe—phenylalanine
PAH—phenylalanine hydroxylase
BH_4—tetrahydrobiopterin
PAL—phenylalanine ammonia lyase

BACKGROUND

Phenylketonuria (PKU) is an autosomal recessive disorder of phenylalanine (Phe) metabolism associated with deficient activity of Phe hydroxylase (PAH) and elevated concentrations of Phe and Phe metabolites. Untreated PKU is characterized by severe to profound intellectual disability, seizures, autistic-like behaviors, microcephaly, rashes, hypopigmentation, and a musty body odor (phenylacetic acid). Hyperphenylalaninemia may be defined as having a blood Phe concentration above the reference range (31–110 μmol/L [0.51–1.8 mg/dL], depending on age). Different schemes exist for classifying subtypes of PKU on the basis of the severity of the clinical or biochemical and/or molecular phenotype.[1–4] Patients have been classified as having mild hyperphenylalaninemia if their blood Phe concentration without dietary therapy is elevated but less than 600 μmol/L (10 mg/dL).[2] Classic PKU is characterized by a Phe concentration higher than 1200 μmol/L (20 mg/dL) while receiving a normal dietary intake of protein.[3] "Variant" or "atypical" forms of PKU (600–1200 μmol/L [10–20 mg/dL] that do not fit the mild or classic descriptions also exist, although there is not yet a universally accepted definition of these variant forms. In rare cases, an elevated blood Phe concentration may be caused by inherited disorders of the biosynthesis or recycling of tetrahydrobiopterin (BH_4), a cofactor in the PAH reaction.

Since the 1960s, newborn screening for PKU has allowed early detection and treatment of the disorder, preventing untoward consequences. Standard current treatment consists of selectively restricting intake of Phe and supplementing tyrosine (the product of normal PAH activity) by using special medical foods that are devoid of or low in Phe while providing enough additional protein, vitamins, and minerals to support normal growth. With good control of Phe concentrations during early childhood, most affected children have normal development measured at 5 years of age. Recommendations for dietary therapy have evolved as experience with different regimens and durations of therapy have accumulated. In earlier therapeutic protocols, treatment was only continued through the first few years of life, theoretically corresponding to the age at which brain myelination is complete. As developmental data accumulated, it became evident that treatment throughout childhood and adolescence was the best course for preserving intelligence. In more recent studies, it has been shown that brain MRI abnormalities and electrophysiologic testing abnormalities referable to the central nervous system are observed in adults who are on unrestricted Phe intake. Accordingly, it is reasonable to continue treatment into adulthood, and most centers recommend lifelong treatment. Strict adherence to the PKU diet is especially important for women during their reproductive years because of the risks to the fetus.

Adults with classic PKU who had good control as children typically have normal intelligence or mild degrees of intellectual deficit. Careful psychometric testing of well-treated individuals has detected instances and degrees of impairment in visual motor skills, abstract reasoning, problem solving, specific aspects of executive control, attention, verbal memory, expressive naming, and verbal fluency,[5] although overall IQ may still be within the reference range. One possible explanation for these neuropsychologic impairments invokes mid-dorsolateral prefrontal cortex dys-

function caused by abnormal catecholamine concentrations.[6] Another theory suggests that abnormal brain myelination and deficiency of brain large neutral amino acids may play a role in impaired cognition.[7–9]

In addition, emotional disorders (depression, anxiety, phobias), as well as hyperactive behaviors, are encountered more frequently in individuals treated for classic PKU than in the general population.[10] However, people with untreated mild hyperphenylalaninemia do not seem to be at risk of developing neuropsychologic impairment.[11]

Poor dietary adherence leads to blood Phe concentrations above the current recommended therapeutic range.[4] High blood Phe concentrations in people who have discontinued their special diets often results in a decrease in IQ, learning disabilities, behavioral problems, and even neurologic complications. White matter abnormalities may develop in people with PKU who have poor dietary control. MRI of the brain may detect dysmyelination, especially T2 enhancement in the periventricular white matter in individuals with PKU who are under poor dietary control. Abnormal areas of white matter may also demonstrate restricted diffusion of water, possibly indicative of increased myelin turnover.[12] These findings are potentially reversible once proper dietary therapy is reinstituted.[13]

During pregnancy, Phe crosses the placenta by active transport, resulting in 70% to 80% increased fetal concentration of Phe compared with maternal concentration.[14] An elevated Phe concentration is toxic and teratogenic to a developing fetus.[15] Abnormalities in the children of women with uncontrolled PKU during pregnancy were first reported by Dent[16] in 1957 and Mabry et al[17] in 1963. The international survey of women with PKU, the results of which were published in 1980, documented an increased risk of spontaneous miscarriage (24%), intrauterine growth retardation (40%), microcephaly (73%), global developmental delays (92%), and congenital heart defects (12%) in their offspring.[18] Postnatal growth retardation, abnormal neurologic findings, and mild craniofacial dysmorphic features also have been reported.[18] The frequency of abnormalities seems to be directly correlated with maternal Phe concentration during pregnancy.[19] Poor fetal growth, microcephaly, and structural heart defects also are more likely to occur if there was "lack of control" of maternal Phe concentrations during critical periods of embryogenesis early in pregnancy.[19]

The Maternal Phenylketonuria Collaborative Study, sponsored by the National Institute of Child Health and Human Development, began in the United States in 1984 to determine fetal outcomes with improved control of maternal Phe concentrations during pregnancy.[19,20] This study became an international effort with participating clinics in Canada and Germany since 1985 and 1991, respectively. The National Institutes of Health consensus conference on PKU in 2000 emphasized the importance of dietary control before conception. This international effort was completed in 2002 and culminated with the International Conference on Maternal Phenylketonuria in April 2002, which provided clear guidelines for the management of pregnancy in women with PKU. The study has provided essential information regarding the effective treatment of women with PKU. This information is now available for clinicians to impart to their patients with PKU to ensure that women with PKU know their risk and how they may be able to have healthy children with timely and appropriate intervention.[18]

The effects of uncontrolled maternal PKU occur regardless of whether the fetus has PKU. The best observed outcomes occur when strict control of maternal blood Phe concentration is instituted before pregnancy or by 8 weeks of gestation at the latest.[19,21,22] Women with PKU who have their blood Phe concentration in good control before conception have an excellent chance for normal pregnancies and neonatal outcome. The achievement of preconceptional and periconceptional dietary control with a Phe-restricted diet significantly decreases the risk of microcephaly, intrauterine growth retardation, congenital heart disease, and developmental delays in the offspring of women with hyperphenylalaninemia.[19] Normal pregnancy and neonatal outcome have been achieved in women with PKU who have blood Phe concentrations between 120 and 360 μmol/L before conception or by 8 weeks of gestation at the latest.[22]

Before conception, counseling and early entrance into a prenatal care program are essential for achieving optimal fetal outcome for women with PKU, variant PKU, and mild hyperphenylalaninemia. It is acknowledged that reinstitution of a Phe-restricted diet and supplements is difficult.[23] Because many pregnancies are unintended, dietary control throughout the childbearing years is essential for preventing an adverse effect on the fetus.[24] The currently recommended Phe concentrations during pregnancy (120–360 μmol/L [2–6 mg/dL] in the United States)[3] are consistent with those currently recommended for PKU treatment during early childhood. Achieving this degree of control requires a major commitment by the woman and support by her treating professionals. The recommendations for maternal control are based on maternal Phe concentration, as opposed to the genotype or severity of the mother's metabolic condition. In 1 study, the IQs of offspring exposed to high concentrations of maternal Phe during pregnancy (>750 μmol/L) were low (mean IQ: 56) and similar whether the mother had PKU or hyperphenylalaninemia and regardless of the genotype, whereas offspring had normal cognitive development (mean IQ: 105) when their average exposure to Phe concentration during pregnancy was less than 360 μmol/L.[25]

Dietary control for adults with PKU is challenging. Although low-Phe flour, pastas, cookies, and nutrition bars have increased dietary options for patients, the PKU diet remains bland, so poor dietary adherence continues to be a major problem. In addition to considerations about the palatability of the PKU diet, economic and health care system issues may contribute to barriers to dietary control. In 1 study that examined impediments to successful dietary control, women with private insurance identified infrequent assistance with the cost of medical food and beverages and low-protein foods as a

barrier, despite the existence of US public law defining the formula as medical foods.[26] Public assistance programs provided more coverage for the cost of the medical foods, clinic visits, and low-protein foods.[26] However, these women were less likely to achieve metabolic control before 10 weeks' gestation. Brown et al[26] believed this may reflect that many women enrolled in public assistance programs were younger and less educated, which are factors associated with late control. Adolescent girls with PKU who become pregnant are at particular risk of not having dietary control until late in their pregnancy, given their young age and the higher risk of unplanned pregnancy.

The National Institutes of Health consensus guidelines recommend that pregnant women with PKU have their Phe concentrations monitored twice weekly.[3] Frequent visits to clinicians who specialize in treating PKU are also recommended for pregnant women with PKU. However, given the limited number of specialist centers, especially centers skilled at caring for adults, there may be a need to travel relatively long distances to obtain appropriate management. Such barriers to access challenge patients to comply with the frequency recommendations for PKU monitoring. In addition, psychosocial, emotional, and social factors contribute to the barriers for successful control of PKU during pregnancy.[26]

All offspring of mothers with PKU will inherit at least 1 abnormal allele at the *PAH* locus from the affected mother. Affected mothers have 2 *PAH* mutations, either in a homozygous (2 identical mutations) or compound heterozygous (2 different mutations) state. Depending on the PKU carrier status of the father, approximately 1 in 120 offspring will also inherit an abnormal *PAH* gene from the father and will have PKU.

A number of novel therapies are being developed for treatment of PKU, including large neutral amino acid supplementation, BH_4 administration, and enzyme therapy using Phe ammonia lyase (PAL). Large neutral amino acids compete with Phe for transport across the blood-brain barrier by the L-type amino acid carrier and consequently decrease the concentration of Phe in the central nervous system.[27] Decreased brain Phe concentration, as measured by proton magnetic resonance spectroscopy, and increased blood concentrations of tyrosine and tryptophan (the respective precursors for dopamine and serotonin) were noted in 1 clinical trial using large neutral amino acid supplements.[28] Oral BH_4, the naturally occurring cofactor to the PAH reaction, has been shown to decrease serum Phe concentrations, especially in patients with mild hyperphenylalaninemia.[29,30] Response to BH_4 has also been documented in patients with classic or variant PKU.[30,31] Another novel therapeutic approach uses the nonmammalian enzyme PAL. PAL converts Phe to transcinnamic acid, a harmless compound, and has been shown to reduce hyperphenylalaninemia in animal models of PKU.[32] PAL therapy has the theoretic potential to increase dietary Phe tolerance, but significant practical hurdles need to be overcome (PAL is destroyed by gastric acidic pH and intestinal proteolysis). Although these are exciting developments, they are not currently approved for use during pregnancy, so the role that such therapies may play in reducing the risk of maternal PKU syndrome is still to be determined.

RECOMMENDATIONS

The recommendations of the American Academy of Pediatrics reflect the guidelines of the Maternal Phenylketonuria Collaborative Study of the National Institutes of Health.[3,19] These recommendations are to be applied to individual patients and their particular care plan with the guidance of their primary care physician in coordination with the patient's metabolic expert physician.

1. All girls and women of childbearing age with elevated Phe concentrations, including those with PKU and milder forms of hyperphenylalaninemia, should be counseled concerning their risks of having an adverse fetal outcome if they have uncontrolled blood Phe concentrations during pregnancy. Education regarding the risks of maternal PKU should begin when an infant is diagnosed with PKU in the newborn period. We recommend that the pediatrician include this information again in anticipatory guidance counseling during preadolescence and adolescence for girls with PKU. All individuals, particularly women and girls of childbearing age, should be referred to an experienced PKU treatment center for genetic and nutritional evaluation and counseling throughout their lifetime.
2. Women with hyperphenylalaninemia who are unable or unwilling to maintain blood Phe concentrations in the range for optimum pregnancy outcome should be counseled before conception regarding the risk of microcephaly, mental retardation, and fetal anomalies in their offspring. Emphasis should also be placed on the education that structural defects, such as congenital heart disease, are associated with poor control early in pregnancy. Dietary therapy should be in place before conception to ensure optimal outcome for the fetus. It is important that these women receive assistance to obtain adequate means for access to reproductive services.
3. Genetic counseling should be offered for all women with PKU before and after conception. Pregnant women with hyperphenylalaninemia should be counseled concerning the risks to the fetus and offered detailed ultrasonographic examinations and fetal echocardiography to detect fetal abnormalities (eg, growth retardation, congenital heart defects). Consideration should be given to maternal Phe concentrations during critical time periods of organogenesis. It is equally important that these women obtain assistance in locating centers with skilled clinicians who are able to provide medical care for pregnant women with PKU.
4. Mothers who give birth to children with features suggestive of maternal PKU, such as congenital heart disease, microcephaly, and suggestive facial dysmorphic features without a known cause, should undergo blood testing for hyperphenylalaninemia. The Phe level of a newborn of a mother with PKU is usually

normal. Consideration should also be given to other teratogenic causes, such as maternal diabetes mellitus, alcohol abuse, or use of isotretinoin. In addition, mothers should be considered for PKU testing if their infants have an initial elevation of Phe concentration on newborn screening that resolves.

5. Pediatricians should work with the families of people with PKU to ensure access to social services, medical foods, and routine reliable visits to a center with expertise in caring for people with metabolic disorders.

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Media Education

abstract

FREE

The American Academy of Pediatrics recognizes that exposure to mass media (eg, television, movies, video and computer games, the Internet, music lyrics and videos, newspapers, magazines, books, advertising) presents health risks for children and adolescents but can provide benefits as well. Media education has the potential to reduce the harmful effects of media and accentuate the positive effects. By understanding and supporting media education, pediatricians can play an important role in reducing harmful effects of media on children and adolescents. *Pediatrics* 2010;126:1012–1017

THE AMOUNT OF TIME SPENT WITH MEDIA

Children and teenagers spend more time engaged in various media than they do in any other activity except for sleeping. A 2010 Kaiser Family Foundation survey of more than 2000 8- to 18-year-olds revealed that children and teenagers in the United States spend an average of more than 7 hours/day with a variety of different media.[1] By the time today's young people reach 70 years of age, they will have spent the equivalent of 7 to 10 years of their lives watching television.[2] There are more homes in America that have a TV than those that have indoor plumbing, and today's child lives in an environment with an average of 4 TVs, nearly 3 DVD players or VCRs, 1 DVR, 2 CD players, 2 radios, 2 video game consoles, and 2 computers.[1] Preadolescents and adolescents can download racy videos, send sexual text messages or explicit photographs to their friends, buy cigarettes and beer on the Internet, and post enticing profiles on Facebook. Yet, across all ages, TV remains the predominant medium. TV-viewing is also beginning at increasingly younger ages. The latest national report revealed that on a typical day, nearly two-thirds of children and infants younger than 2 years are watching TV for an hour and a half.[3] More than 70% of American teenagers have a TV in their own bedrooms, half have a VCR or DVD player, half have a video game console, and one-third have a computer and Internet access.[1] Time spent with media often displaces involvement in creative, active, or social activities.

THE EFFECTS OF MEDIA VIOLENCE ON AGGRESSIVE BEHAVIOR

Results of more than 2000 scientific studies and reviews have shown that significant exposure to media violence increases the risk of aggressive behavior in certain children and adolescents, desensitizes them to violence, and makes them believe that the world is a "meaner and scarier" place than it is.[4–9] Violence appears in various forms of media entertainment such as movies, video games, and TV news. For example, nearly 90% of the top-grossing PG-13–rated films of 1999–2000 contained violence.[10] Research has shown that

news reports of bombings, natural disasters, murders, and other violent crimes have the potential to traumatize young children.[5,11]

SEXUAL CONTENT IN THE MEDIA

American media—both programming and advertising—are highly sexualized in their content. On prime-time TV, more than 75% of shows contain sexual content, yet for only 14% of sexual incidents is any mention made of risks or responsibilities of sexual activity.[12,13] In the first 10 months of 2004, the makers of erectile-dysfunction drugs spent nearly $350 million on advertising, which makes sex seem like a harmless recreational activity.[14] Major networks remain extremely reluctant to advertise birth control pills, condoms, or emergency contraceptives, which could avert thousands of unwanted adolescent pregnancies and elective abortions by adolescents each year.[15–17] Research is beginning to show that all of this sexual content may contribute to early sexual intercourse among teenagers.[18–20]

TOBACCO, ALCOHOL, AND ILLICIT DRUGS

Increasingly, media messages and images normalize and glamorize the use of tobacco, alcohol, and illicit drugs. Tobacco manufacturers spend more than $12 billion per year and alcohol manufacturers spend nearly $6 billion per year to entice youngsters into "just saying yes."[21,22] Smoking and drinking are frequently glamorized and are portrayed as normative behavior on TV and in movies. A new study of top-grossing movies from 1991 to 2009 showed that smoking scenes in movies peaked in 2005 but have decreased significantly since then. However, in 2009, more than half of PG-13 movies still contained smoking scenes.[23] A meta-analysis of 4 studies estimated that 44% of all smoking initiation among children and young teenagers could be attributed to viewing smoking in movies.[24] Alcohol remains the number 1 drug portrayed on American TV, with 1 drinking scene every 22 minutes.[25] More than one-third of drinking scenes are humorous, and negative consequences are shown in only 23% of them.[26] Through popular music, the average teenager is exposed to nearly 85 explicit drug references each day.[27] Again, the behavioral effects are increasingly clear in the research: children and teenagers exposed to more movie images of smoking are at greater risk of smoking,[24,28] and alcohol advertising, in particular, is adept at convincing teenagers to begin drinking.[29–34]

EFFECTS OF MEDIA ON OBESITY AND SCHOOL PERFORMANCE

Increased TV use is documented to be a significant factor leading to obesity[35–39] and may lead to decreased school achievement as well.[40–42] New research is also investigating whether there might be a relationship between overstimulation from high levels of media use and attention-deficit/hyperactivity disorder,[43,44] sleep disorders,[45] and eating disorders.[37]

NEW TECHNOLOGY

The Internet and cellular phones have become important new sources of sexual information, pornography, "sexting" (sending sexual text messages and/or explicit images), and social networking. In a recent study, nearly one-quarter of MySpace profiles referenced sexual behaviors.[46] In another study, 20% of teenagers reported having sent or posted nude pictures or videos of themselves (sexting).[47] Parents, schools, and law enforcement officials are sometimes in a quandary about how to deal with the new social networking sites and with sexting.[48,49] Web sites that promote anorexia nervosa are also putting teenagers at risk of eating disorders.[50]

VALUE OF MEDIA EDUCATION

Media education has the potential to reduce harmful media effects.[51,52] In the past 2 centuries, to be "literate" meant that a person could read and write. In the new millennium, to be "literate" means that a person can successfully understand and decode a variety of different media.[53] Given the volume of information transmitted through mass media as opposed to the written word, it is now as important to teach media literacy as it is to teach print literacy. The prime tenets of media education are as follows[52]:

- All media messages are constructed.
- Media messages shape our understanding of the world.
- Individuals interpret media messages uniquely.
- Mass media have powerful implications.

A media-educated person will be able to limit his or her use of media; make positive media choices; select creative alternatives to media consumption; develop critical thinking and viewing skills; and understand the political, social, economic, and emotional implications of all forms of media.[52] Results of recent research suggest that media education may make young people less vulnerable to negative aspects of media exposure.[52] Media education programs have resulted in less aggressive attitudes[54] and behaviors,[54–58] increased sophistication about advertising,[59] fewer requests for commercial products,[60,61] less alcohol and tobacco use or intentions to use,[62–66] better nutritional habits[67,68] and less obesity,[69,70] better body self-image,[71–73] fewer sexual disclosures on social networking sites,[74] and less overall TV-viewing.[69,70,75] Many countries, including Canada, Great Britain, Australia, and some Latin American countries, mandate media education in their school curricula. However, media edu-

cation should not be used as a substitute for careful scrutiny of the media industry's responsibility for its programming. In addition, simply reducing children's and adolescents' screen media use has been shown conclusively to have beneficial health effects.[69,70,75]

RECOMMENDATIONS

The American Academy of Pediatrics (AAP) recommends the following:

1. Pediatricians need to become educated about the public health risks of media. Given the impact that media have on the health of children and adolescents, AAP chapters and districts, as well as medical schools and residency training programs, should ensure that ongoing education in this area is a high priority.[76]
2. Pediatricians should ask at least 2 media-related questions at each well-child visit:
   - How much entertainment media per day is the child or adolescent watching? The AAP recommends that children have less than 2 hours of screen time per day.
   - Is there a TV set or Internet access in the child's or adolescent's bedroom?[77]

   Children or teenagers who are showing aggressive behavior, have academic difficulties, or are overweight or obese should have additional history taken. A recent study revealed that office-based counseling regarding media is effective and could result in the parents of nearly 1 million additional children learning about the AAP recommendation to limit media time to 2 hours/day.[78] Advice to parents should include the following:
   - Encourage a careful selection of programs to view.
   - Co-view and discuss content with children and adolescents.
   - Teach critical viewing skills.
   - Limit and focus time spent with media. In particular, parents of young children and preteens should avoid exposing them to PG-13– and R-rated movies.[19,23,24,79–81]
   - Be good media role models; children often develop their media habits on the basis of their parents' media behavior.
   - Emphasize alternative activities.
   - Create an "electronic media-free" environment in children's rooms.
   - Avoid use of media as an electronic baby-sitter.
3. Pediatricians should continue to urge parents to avoid TV- and video-viewing for children younger than 2 years. Increasing amounts of research have shown that infants and toddlers have a critical need for direct interactions with parents and other regular caregivers for healthy brain growth.[82–84] In addition, the results of 7 studies have shown that infants younger than 18 months who are exposed to TV may suffer from a delay in language development, and 1 study revealed that infant videos may delay language development.[85–91] No studies have documented a benefit of early viewing.[92]
4. Pediatricians should serve as role models for appropriate media use by limiting TV and video use in waiting rooms and patients' rooms, using educational materials to promote reading, and having visits by volunteer readers in waiting rooms. Pediatricians should also offer in-office reading programs, such as Reach Out and Read, and promote active play.[93]
5. Schools need to begin implementing media education in their curricula. The simplest way to do this would be to incorporate principles of media education into existing programs on drug prevention and sex education.
6. Congress should consider mandating and funding universal media education in American schools.
7. The federal government and private foundations should dramatically increase their funding of media research, particularly in the areas of media education, violence prevention, sex and sexuality, drugs, obesity, and early brain development.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

POLICY STATEMENT

Media Use by Children Younger Than 2 Years

abstract

FREE

In 1999, the American Academy of Pediatrics (AAP) issued a policy statement addressing media use in children. The purpose of that statement was to educate parents about the effects that media—both the amount and the content—may have on children. In one part of that statement, the AAP recommended that "pediatricians should urge parents to avoid television viewing for children under the age of two years." The wording of the policy specifically *discouraged* media use in this age group, although it is frequently misquoted by media outlets as *no* media exposure in this age group. The AAP believed that there were significantly more potential negative effects of media than positive ones for this age group and, thus, advised families to thoughtfully consider media use for infants. This policy statement reaffirms the 1999 statement with respect to media use in infants and children younger than 2 years and provides updated research findings to support it. This statement addresses (1) the lack of evidence supporting educational or developmental benefits for media use by children younger than 2 years, (2) the potential adverse health and developmental effects of media use by children younger than 2 years, and (3) adverse effects of parental media use (background media) on children younger than 2 years. *Pediatrics* 2011;128:1040–1045

INTRODUCTION

From built-in DVD players in minivans to smart cell phone technology, today's children have more access to electronic media than those of any previous generation. As predicted in the 1999 American Academy of Pediatrics (AAP) policy statement,[1] industry has also targeted those in the 0- to 2-year age group (and their parents) as key consumers of electronic media. Educational DVDs/videos, television programs, and even entire cable networks are geared toward this age group.

Currently, 90% of parents report that their children younger than 2 years watch some form of electronic media.[2] By 3 years, almost one-third of children have a television in their bedroom.[3] Parents report that they view television as a peacekeeper and a safe activity for their children while they are preparing dinner, getting ready for work, or doing household chores.[3] Many parents report feeling better knowing that the programming their children watch has been described as educational. Parents who believe that educational television is "very important for healthy development" are twice as likely to have the television on all or most of the time.[4]

Some children are watching television programs or recorded programs (DVDs/videos) intended for their viewing, termed "foreground

media." Others are exposed to programs intended for adults, termed "background media," because the television is on while they are present in the room. Some children are exposed to 4 hours or more of televised programs per day. Other children may be watching a 30-minute DVD while a parent is just taking a shower or preparing dinner. Some children are watching shows with parents or siblings, and some are watching alone. On average, children younger than 2 years watch televised programs 1 to 2 hours/day.[2] Fourteen percent of children aged 6 to 23 months watch 2 or more hours/day of media.[3]

Some media industry executives claim that educational media programs are meant to be watched by both the parent and the child to facilitate social interactions and the learning process.[5] However, it is not clear whether this happens in the real world. In fact, it seems that audible television is associated with decreased parent-child interactions.[6] Although a leading survey of family media use has reported that 40% of parents watch with their child all the time and 28% watch with their child most of the time, parents also report that they avoid co-viewing because their child's media time provides an opportunity for them to do other things.[3]

Although there is equal access to media among children of different socioeconomic groups, the amount of media consumption is unequal. Children who live in homes with lower socioeconomic status and children with single mothers or mothers with less than a high school education are spending more time in front of a screen on a daily basis.[3,7] Another study found no association between family income and early childhood media use but did find a relationship between lower parental education and higher levels of media use in early childhood.[8]

This revised policy statement addresses the past 10 years of research on the effect of media on young children, clarifies the rationale for the position of the AAP on media use by children younger than 2 years, and provides updated recommendations for families, clinicians, and researchers. For the purposes of this policy statement, the term "media" refers to television programs, prerecorded videos, Web-based programming, and DVDs viewed on either traditional or new screen technologies.

LOST IN TRANSLATION: CAN CHILDREN LEARN FROM MEDIA?

Research has found that certain high-quality programs have educational benefits for children older than 2 years. Children who watch these programs have improved social skills, language skills, and even school readiness.[9] However, the educational merit of media for children younger than 2 years remains unproven despite the fact that three-quarters of the top-selling infant videos make explicit or implicit educational claims.[5] To be beneficial, children need to understand the content of programs and pay attention to it. Children older than 2 years and those younger than 2 years are at different levels of cognitive development and process information differently.[10] In fact, 2 studies have found that watching a program such as "Sesame Street" has a negative effect on language for children younger than 2 years,[11,12] and 2 studies have found no evidence of benefit.[13,14] There is a paucity of research on this topic, but the existing literature suggests that media use does not promote language skills in this age group.

Young children have difficulty discriminating between events on a video and the same information presented by a live person, which is referred to as "video deficit."[15–17] Children 12 to 18 months of age are more likely to learn from a live presentation than from a televised one and are also more likely to remember the information from a live presentation afterward.[18] These studies have only been performed on noncommercial videos. Some studies have found that children 1 to 2 years of age can remember an event on video if the screen demonstration repeats several times.[19] Two studies have shown that infants as young as 12 months learn emotional responses after media viewing.[20,21] One longitudinal study performed has thus far found that children younger than 2 years who watch television have no statistical improvement in their cognitive development compared with their nonviewing peers by 3 years of age.[22]

Children aged 12 months and younger do not follow sequential screen shots or a program's dialogue.[23,24] Other research has found that children younger than 18 months do not pay much attention to televised programs.[25] However, there are significant individual differences in attention to and interest in television in this age group that depend on content, setting, and whether a parent is watching with the child.[26] A developmental shift in attention to televised programs occurs between 1.5 and 2.5 years of age.[24,25]

Children progress through developmental milestones on a continuum. Where each individual child is on that continuum determines what that child is capable of learning from a televised program. Some 18- to 24-month-olds might be capable of learning from media, but others might not. Other variables that influence a child's ability to learn are the content of the program, the amount of television watched, and whether a parent is watching with the child.[13,27]

Despite the explicit or implicit marketing claims of educational programs for infants, whether they are actually

learning something from these programs is questionable. More research is needed to determine if early television exposure has any long-term effects on learning.

SECONDHAND TELEVISION: FOREGROUND VERSUS BACKGROUND MEDIA

Many families have reported that they have a television on at least 6 hours/day or that a television is "always on" as background noise.[28] Thirty-nine percent of families with infants and young children have a television on constantly.[29] When a parent has an adult television program on, children are often in the room; 61% are there at least some of the time, including 29% who are there all or most of the time.[3]

Young children may not be paying close attention to a televised program that they cannot understand, but their parents are watching. It might be background media to the child, but it is foreground media to the parent. It distracts the parent and decreases parent-child interaction.[30,31] Infant vocabulary growth is directly related to the amount of "talk time" or the amount of time parents spend speaking to them.[32] Heavy television use in a household can interfere with a child's language development simply because parents likely spend less time talking to the child.[33]

Even if the program is not intended for the child to watch, research has found that children play and interact less with adults when a television is on, perhaps because the adult's attention is focused on the television program. A study that examined 12-, 24-, and 36-month-olds found that background television not only reduced the length of time that a child played but also that it reduced the child's focused attention during play.[34] Children stop to look at a televised program, halt their ongoing play, and move on to a different activity after the interruption.[34] Although most research has been performed on adolescents, study results suggest that background media might interfere with cognitive processing, memory, and reading comprehension.[4,34–36] Only 1 research study, conducted in 1996, resulted in evidence to the contrary. In that study, 10-month-old infants tuned out surrounding noise and concentrated more during play.[37]

Background television has the direct effect of distracting a child and the indirect effect of taking a parent's attention away from the child. In addition, parents' media diet influences the media habits of their children.[3]

A GOOD USE OF TIME?

Children younger than 5 years who watch television spend less time in creative play and less time interacting with parents or siblings.[38] For every hour of television that a child younger than 2 years watches alone, he or she spends an additional 52 minutes less time per day interacting with a parent or sibling. For every hour of television, there is 9% less time on weekdays and 11% less time on weekends spent in creative play for a child younger than 2 years.

Does television displace more developmentally valuable playtime? No research exists at this point to know whether a child would find better things to do with his or her time if all screens were turned off, although evidence suggests that the child would hear more adult speech and talk more.[6] Heavy media use is defined as the television being on always or most of the time. Heavy media use may be a sign of parenting style, so one cannot assume that parents will spend developmentally nurturing time with their child with the television off.[38]

Heavy media use in a household does not seem to affect the amount of time a child of any age plays outside.[4] However, children who live in households with heavy media use spend between 25% (for 3- to 4-year-olds) and 38% (for 5- to 6-year-olds) less time being read to or reading.[3,4] These children have a lower likelihood of being able to read compared with their peers from households with low media use.[4] What is known is that unstructured playtime is critical to learning problem-solving skills and fostering creativity.[39]

HEALTH CONSEQUENCES

Media use has been associated with obesity, sleep issues, aggressive behaviors, and attention issues in preschool- and school-aged children.[1,40] Studies are lacking on the health effects in children younger than 2 years. One area of concern, however, is media's effect on sleep. Television is part of the bedtime routine for many children. In 1 survey, 19% of parents of children younger than 1 year reported that their children have a television in their bedrooms. Twenty-nine percent of children 2 to 3 years of age have a television in their bedroom, and 30% of parents have reported that watching a television program enabled their children to fall asleep.[3] Although parents perceive a televised program to be a calming sleep aid, some programs actually increase bedtime resistance, delay the onset of sleep, cause anxiety about falling asleep, and shorten sleep duration.[41] Specifically, in children younger than 3 years, television viewing is associated with irregular sleep schedules.[42] Poor sleep habits have adverse effects on mood, behavior, and learning. Although the effects of media on infants' cognitive and emotional development are still being explored, there are ample reasons to be concerned.

DEVELOPMENTAL CONSEQUENCES

Since 1999, 3 studies have evaluated the effects of heavy television use on language development in children 8 to

16 months of age. In the short-term, children younger than 2 years who watch more television or videos have expressive language delays,[12,43,44] and children younger than 1 year with heavy television viewing who are watching alone have a significantly higher chance of having a language delay.[44] Although the long-term effects on language skills remain unknown, the evidence of short-term effects is concerning.

Two studies have examined infant media use and subsequent attention problems in school-aged children.[45,46] One of these studies found that the effects of television watching on infants' attention span varied with the content of the programming.

Research findings to date might suggest a correlation between television viewing and developmental problems, but they cannot show causality. Are infants with poor language skills placed in front of the television more? Are infants with shorter attention spans more attracted to screens? Does media exposure contribute to a delay in social or communication skills and diminished attentional capacity? Because these questions remain unanswered, more research is needed.

CONCLUSIONS AND RECOMMENDATIONS

This updated policy statement provides further evidence that media—both foreground and background—have potentially negative effects and no known positive effects for children younger than 2 years. Thus, the AAP reaffirms its recommendation to discourage media use in this age group. This statement also discourages the use of background television intended for adults when a young child is in the room. Although infant/toddler programming might be entertaining, it should not be marketed as or presumed by parents to be educational.

No longitudinal study has determined the long-term effects of media use on infants and children younger than 2 years. The AAP supports research to understand the consequences of early electronic media exposure.

Recommendations for Pediatricians

1. The AAP discourages media use by children younger than 2 years. Pediatricians should discuss these recommendations with parents.
2. The concept of setting "media limits" before 2 years of age should be discussed at health maintenance/well-child visits, because many parents are not aware of the AAP recommendations. It is important to set limits and create balance at an early age. Only 15% of parents report that their pediatrician discusses media use with them.[3] Families should be encouraged to provide supervised independent play for infants and young children during times at which a parent cannot sit down and engage in play with the child. Simply having a young child play with nesting cups on the kitchen floor while a parent prepares dinner is useful playtime.
3. Pediatricians should explain to parents the importance of unstructured, unplugged play in allowing a child's mind to grow, problem-solve, think innovatively, and develop reasoning skills. Unstructured play occurs both independently and cooperatively with a parent or caregiver. The importance of parents sitting down to play with their children cannot be overstated.
4. Families should be strongly encouraged to sit down and read to their child to foster their child's cognitive and language development.

Recommendations for Parents

1. The AAP discourages media use by children younger than 2 years.
2. The AAP realizes that media exposure is a reality for many families in today's society. If parents choose to engage their young children with electronic media, they should have concrete strategies to manage it. Ideally, parents should review the content of what their child is watching and watch the program with their child.
3. Parents are discouraged from placing a television set in their child's bedroom.
4. Parents need to realize that their own media use can have a negative effect on their children. Television that is intended for adults and is on with a young child in the room is distracting for both the parent and the child.
5. Unstructured playtime is more valuable for the developing brain than any electronic media exposure. If a parent is not able to actively play with a child, that child should have solo playtime with an adult nearby. Even for infants as young as 4 months of age, solo play allows a child to think creatively, problem-solve, and accomplish tasks with minimal parent interaction. The parent can also learn something in the process of giving the child an opportunity to entertain himself or herself while remaining nearby.

Recommendations for Industry

1. Independent research should be performed to assess the educational claims made in advertising for infant media products.
2. The Federal Trade Commission should improve its standards for scientifically valid educational claims in product advertising.

Recommendations for Research

1. Researchers should conduct prospective, longitudinal studies to determine the long-term effects of early media exposure on children's future physical, mental, and social health.
2. The AAP supports the National Children's Study by the Eunice Kennedy Shriver National Institute of Child Health and Human Development to examine the effects of environmental influences on children.
3. The mission of the AAP is to attain optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. To this end, the AAP supports continued research to examine the influence of media in children's lives and will offer evidence-based guidance to its members and the public.

abstract

Exposure to violence in media, including television, movies, music, and video games, represents a significant risk to the health of children and adolescents. Extensive research evidence indicates that media violence can contribute to aggressive behavior, desensitization to violence, nightmares, and fear of being harmed. Pediatricians should assess their patients' level of media exposure and intervene on media-related health risks. Pediatricians and other child health care providers can advocate for a safer media environment for children by encouraging media literacy, more thoughtful and proactive use of media by children and their parents, more responsible portrayal of violence by media producers, and more useful and effective media ratings. Office counseling has been shown to be effective. *Pediatrics* 2009;124:1495–1503

INTRODUCTION

Although shootings in schools around the world periodically prompt politicians and the general public to focus their attention on the influence of media violence, the medical community has been concerned with this issue since the 1950s.[1–3] The evidence is now clear and convincing: media violence is 1 of the causal factors of real-life violence and aggression. Therefore, pediatricians and parents need to take action.[4]

In 1972, the US Surgeon General issued a special report on the public health effects of media violence that was based on a growing and nearly unanimous body of evidence.[5] Ten years later, the National Institute of Mental Health issued a comprehensive review of the research on media violence and its effects, which outlined concerns about children's psychological health.[6] At a Congressional public health summit in July 2000, the American Academy of Pediatrics (AAP) was joined by the American Medical Association, the American Academy of Child and Adolescent Psychiatry, and the American Psychological Association in issuing an unprecedented joint statement on the impact of entertainment violence on children.[7] Also in 2000, the Federal Bureau of Investigation released a report on shootings in schools that stated that media violence is a risk factor.[8] In 2003, a panel of media-violence experts convened by the National Institute of Mental Health, at the request of the US Surgeon General, published its comprehensive report on the effects of media violence on youth, which revealed media violence to be a significant causal factor in aggression and violence.[9] Most recently, in 2007, the Federal Communications Commission (FCC) released its report on violent television programming and its effects on children and agreed with the Surgeon General that there is "strong evidence" that exposure to media violence can increase aggressive behavior in

children.[10] The weight of scientific evidence has been convincing to pediatricians, with more than 98% of pediatricians in 1 study expressing the personal belief that media violence affects children's aggression.[11] Yet, the entertainment industry, the American public, politicians, and parents all have been reluctant to accept these findings and to take action.[4] The debate should be over.[9,12]

EXPOSURE

American children between 8 and 18 years of age spend an average of 6 hours and 21 minutes each day using entertainment media (television, commercial or self-recorded video, movies, video games, print, radio, recorded music, computers, and the Internet).[13] Children between 0 and 6 years of age spend an average of almost 2 hours each day using screen media (television, movies, computers).[14,15] Televisions are also commonly present in bedrooms, with 19% of infants, 29% of 2- to 3-year-olds, 43% of 4- to 6-year-olds, and 68% of children 8 years and older having a television in their bedrooms.[13,15,16] The effects of having a television in a child's bedroom are only beginning to be studied, but the early indications are alarming. Children with a television in their bedroom increase their television-viewing time by approximately 1 hour per day.[13,17] Their risk of obesity increases 31%,[17] and their risk of smoking doubles.[18] In addition, if children have a television in their bedroom, parents are less able to monitor what is seen; parents are less able to have consistent rules for children's media use; children participate in fewer alternative activities such as reading, hobbies, and games; and children perform more poorly in school.[19,20]

A large proportion of children's media exposure includes acts of violence that are witnessed or "virtually perpetrated" (in the form of video games) by young people. By 18 years of age, the average young person will have viewed an estimated 200 000 acts of violence on television alone.[21] The National Television Violence study evaluated almost 10 000 hours of broadcast programming from 1995 through 1997 and revealed that 61% of the programming portrayed interpersonal violence, much of it in an entertaining or glamorized manner.[22] The highest proportion of violence was found in children's shows. Of all animated feature films produced in the United States between 1937 and 1999, 100% portrayed violence, and the amount of violence with intent to injure has increased through the years.[23] In a study of the top-rated PG-13 films of 1999–2000, 90% contained violence, half of it of lethal magnitude.[24] An estimated 12% of 22 million 10- to 14-year-olds saw 40 of the most violent movies in 2003.[25] More than 80% of the violence portrayed in contemporary music videos is perpetrated by attractive protagonists against a disproportionate number of women and blacks.[26] Similarly, teenagers' music has become more violent, especially rap music.[3,27,28] And, as teenagers increasingly use the Internet, they are exposed to violence there as well; a survey of more than 1500 10- to 15-year-olds revealed that 38% had been exposed to violent scenes on the Internet.[29] Video games also are filled with violence. A recent analysis of the Entertainment Software Ratings Board (ESRB) ratings of video games revealed that more than half of all games are rated as containing violence, including more than 90% of games rated as appropriate for children 10 years or older (E10+ and T ratings).[30]

Prolonged exposure to such media portrayals results in increased acceptance of violence as an appropriate means of solving problems and achieving one's goals.[2,3,9] American media, in particular, tend to portray heroes using violence as a justified means of resolving conflict and prevailing over others.[24,31] Television, movies, and music videos normalize carrying and using weapons and glamorize them as a source of personal power.[22,32] Children in grades 4 through 8 preferentially choose video games that award points for violence against others, and 7 of 10 children in grades 4 through 12 report playing M-rated (mature) games, with 78% of boys reporting owning M-rated games.[33,34] Of 33 popular games, 21% feature violence against women.[35] Because children have high levels of exposure, media have greater access and time to shape young people's attitudes and actions than do parents or teachers, replacing them as educators, role models, and the primary sources of information about the world and how one behaves in it.[36]

After the tragic shootings at Columbine High School in 1999, the Federal Trade Commission (FTC) investigated whether the motion picture, music, and video-game industries specifically advertised and marketed violent material to children and adolescents. Working with industry-provided documents, the FTC determined that, despite the fact that their own rating systems found the material appropriate only for adults, these industries practiced "pervasive and aggressive marketing of violent movies, music, and electronic games to children," such as promoting R-rated movies to Campfire girls.[37]

Studies have revealed that children and adolescents can and do easily access violent media that are deemed inappropriate for them by the various rating systems and parents.[13,38,39] In a study of PG-, PG-13-, and R-rated films, the rating did not even predict the frequency of violence in the various films.[39] Many parents find the entertainment industry's media-rating sys-

tems difficult to use.[40] The movie ratings are used by approximately three quarters of parents, but only about half of parents say they have ever used the video-game ratings, the television ratings, or the music advisories to guide their choices.[41] Many parents find the ratings unreliably low, with an objective parental evaluation revealing as many as 50% of television shows rated TV-14 to be inappropriate for their teenagers.[42] At the same time, most parents do not even know that their television is equipped with a V-chip ("V" for "viewer" control), and only 20% of parents actually use it.[40] Video games with higher ratings may actually attract more young children (the "forbidden-fruit" hypothesis).[43] The various media ratings are determined by industry-sponsored ratings boards or the artists and producers themselves. They are age based, which assumes that all parents agree with the raters about what is appropriate content for children of specific ages. Furthermore, different rating systems for each medium (television, movies, music, and video games) make the ratings confusing, because they have little similarity or relationship to one another. The AAP offers an informational brochure that pediatricians can offer to parents and children to help them use the various rating systems to guide better media choices.[44]

IMPACT

Research has associated exposure to media violence with a variety of physical and mental health problems for children and adolescents, including aggressive and violent behavior, bullying, desensitization to violence, fear, depression, nightmares, and sleep disturbances. Consistent and significant associations between media exposure and increases in aggression and violence have been found in American and cross-cultural studies; in field experiments, laboratory experiments, cross-sectional studies, and longitudinal studies; and with children, adolescents, and young adults.[9,45–47] The new Center on Media and Child Health at Harvard lists more than 2000 research reports.[48] The strength of the association between media violence and aggressive behavior found in meta-analyses[9,49] is greater than the association between calcium intake and bone mass, lead ingestion and lower IQ, and condom nonuse and sexually acquired HIV infection, and is nearly as strong as the association between cigarette smoking and lung cancer[50]—associations that clinicians accept and on which preventive medicine is based without question.

Children are influenced by media—they learn by observing, imitating, and adopting behaviors.[51] Several different psychological and physiologic processes underlie media-violence effects on aggressive attitudes, beliefs, behaviors, and emotions, and these processes are well understood.[2,3,9] Furthermore, because children younger than 8 years cannot discriminate between fantasy and reality, they may be especially vulnerable to some of these learning processes and may, thereby, be more influenced by media violence.[52,53] However, even older adolescents and young adults are adversely affected by consumption of media violence, demonstrating that the ability to discriminate between fantasy and reality does not inoculate one from the effects of media violence.[54,55]

Some research has indicated that the context in which media violence is portrayed and consumed can make the difference between learning about violence and learning to be violent.[3] Plays such as *Macbeth* and films such as *Saving Private Ryan* treat violence as what it is—a human behavior that causes suffering, loss, and sadness to victims and perpetrators. In this context, with helpful adult guidance on the real costs and consequences of violence, appropriately mature adolescent viewers can learn the danger and harm of violence by vicariously experiencing its outcomes. Unfortunately, most entertainment violence is used for immediate visceral thrills without portraying any human cost and is consumed by adolescents or children without adult guidance or discussion. Furthermore, even if realistic portrayals of harmful consequences of violence reduce the typical immediate short-term aggression-enhancement effect, there still exists the potential long-term harm of emotional desensitization to violent images.[9,47,54] Other studies have shown that the more realistically violence is portrayed, the greater the likelihood that it will be tolerated and learned.[3,56] Titillating violence in sexual contexts and comic violence are particularly dangerous, because they associate positive feelings with hurting others.[57,58] One study of nearly 32 000 teenagers in 8 different countries, for example, revealed that heavy television-viewing was associated with bullying.[59]

In addition to modeling violent behavior, entertainment media inflate the prevalence of violence in the world, cultivating in viewers the "mean-world" syndrome, a perception of the world as a dangerous place.[60–62] Fear of being the victim of violence is a strong motivation for some young people to carry a weapon, to be more aggressive, and to "get them before they get me."[61] For some children, exposure to media violence can lead to anxiety, depression, posttraumatic stress disorder,[56,63] sleep disturbances and nightmares,[56,64] and/or social isolation.[65] Some have defended media violence as an outlet for vicariously releasing hostility in the safety of virtual reality. However, research that has tested this "catharsis hypothesis" revealed that after experiencing media

violence, children and young adults behave more aggressively, not less.[66–68] Numerous studies have shown that an insidious and potent effect of media violence is to desensitize all of us to real-life violence.[69–72]

Interactive media, such as video games and the Internet, are relatively new media forms with even greater potential for positive and negative effects on children's physical and mental health. Exposure online to violent scenes has been associated with increased aggressive behavior.[29] Studies of these rapidly growing and ever-more-sophisticated types of media have indicated that the effects of child-initiated virtual violence may be even more profound than those of passive media such as television. In many games, the child or teenager is "embedded" in the game and uses a "joystick" (handheld controller) that enhances both the experience and the aggressive feelings. Three recent studies directly compared the effects of interactive (video games) and passive (television and movies) media violence on aggression and violence; in all 3 cases, the new interactive-media-violence effect was larger.[54] Correlational and experimental studies have revealed that violent video games lead to increases in aggressive behavior and aggressive thinking and decreases in prosocial behavior.[62,73–76] Recent longitudinal studies designed to isolate long-term violent video-game effects on American and Japanese school-aged children and adolescents have revealed that in as little as 3 months, high exposure to violent video games increased physical aggression.[54,77] Other recent longitudinal studies in Germany and Finland have revealed similar effects across 2 years.[78,79] On the other hand, there is also good evidence that prosocial video games can increase prosocial attitudes and behavior.[80]

Children learn best by observing a behavior and then trying it. The consequences of their behavioral attempts influence whether they repeat the behavior. All violent media can teach specific violent behaviors, the circumstances when such behaviors seem appropriate and useful, and attitudes and beliefs about such behavior. In this way, behavioral scripts are learned and stored in memory.[47] Video games provide an ideal environment in which to learn violence and use many of the strategies that are most effective for learning.[81] They place the player in the role of the aggressor and reward him or her for successful violent behavior. Rather than merely observing only part of a violent interaction (such as occurs in television violence), video games allow the player to rehearse an entire behavioral script, from provocation, to choosing to respond violently, to resolution of the conflict.[54,62,82] Children and adolescents want to play them repeatedly and for long periods of time to improve their scores and advance to higher levels. Repetition increases their effect. In addition, some youth demonstrate pathologic patterns of video-game play, similar to addictions, in which game play disrupts healthy functioning.[81,83] Advances in the measurement of brain function have been applied to the study of media violence. Several studies have linked media-violence exposure to decreases in prefrontal cortex activity associated with executive control over impulsive behavior.[84]

AAP ACTION

Interpersonal violence, for victims and perpetrators, is now a more prevalent health risk than infectious disease, cancer, or congenital disorders for children, adolescents, and young adults. Homicide, suicide, and trauma are leading causes of mortality in the pediatric population. In 2004, unintentional injuries claimed 17 741 lives, homicides claimed 5195 lives, and suicide claimed 4506 lives among 5- to 24-year-olds.[85] Of all deaths by homicide or suicide, fully half were gun related, making gun violence a leading killer of children and adolescents.[86] For young black males, homicide is the leading cause of death, accounting for nearly 45% of all deaths. The homicide rate for black males is 2.7 to 15.8 times higher than for other racial/ethnic groups at the same age.[87] Although violent crime rates have decreased by more than 50% between 1994 and 2004 for young people 12 to 24 years of age, they remain higher at this age than at any other age.[87] Furthermore, the proportion of youth admitting to having committed various violent acts within the previous 12 months has remained steady or even increased somewhat in recent years.[88] In the 2007 National Youth Risk Behavior Survey, 18% of students in the 9th through 12th grades reported carrying a weapon to school in the month preceding the survey, and more than one third had been in a physical fight in the year before the survey.[85] An estimated 30% of 6th- through 10th-graders report either bullying other students or being targets of bullies.[89] A recent large study of New York City students found that nearly 10% of girls and more than 5% of boys reported a lifetime history of being sexually assaulted, and 10% of both boys and girls reported experiencing dating violence in the previous year.[90] Although exposure to media violence is not the sole factor contributing to aggression, antisocial attitudes, and violence among children and adolescents, it is an important health risk factor on which we, as pediatricians and members of a compassionate society, can intervene. Some research has suggested that interventions of the types discussed below can reduce media-violence consumption and its effects on children and adolescents.[2,3,54,91,92]

RECOMMENDATIONS

1. Pediatricians must become cognizant of the pervasive influence that the wide and expanding variety of entertainment media have on the physical and mental health of children and adolescents.[4,93] Residency training conferences, grand rounds, and continuing medical education courses are all important venues that should be used for teaching pediatricians about the effects of media on children and adolescents.
2. Pediatricians should ask at least 2 media-related questions at each well-child visit: (1) How much entertainment media per day is the child or teenager watching? (2) Is there a television set or Internet connection in the child's or teenager's bedroom?[4,93] For all children, healthy alternatives such as sports, interactive play, and reading should be suggested.[94] When heavy media use by a child is identified, pediatricians should evaluate the child for aggressive behaviors, fears, or sleep disturbances and intervene appropriately.[95,96]
3. Pediatricians should encourage parents to adhere to the AAP media recommendations[11,95]:
   - Remove televisions, Internet connections, and video games from children's bedrooms.
   - Make thoughtful media choices and coview them with children. Coviewing should include discussing the inappropriateness of the violent solutions offered in the specific television show, movie, or video game and helping the child to generate nonviolent alternatives. Parents tend to limit sexual content more than violent content,[38] yet research has indicated that the latter is potentially more unhealthy.[2,3]
   - Limit screen time (including television, videos, computer and video games) to 1 to 2 hours per day, using the V-chip, and avoiding violent video games (defined as games that include intentional harm to other game characters, including cartoonish or unrealistic violence as well as realistic or gory violence). Counseling about limiting screen time has been shown to be effective in office settings.[97] For example, just a minute or two of office counseling about media violence and guns could lead to less violence exposure for more than 800 000 children per year.[97] Parents also need to be reminded that they are important role models in terms of their own media use.
   - Avoid screen media for infants or toddlers younger than 2 years.[98] There have been no studies to indicate that screen time contributes positively to infant development,[99,100] and there are now 7 studies that have documented possible language delays among children younger than 2 years who are exposed to television or videos.[100–108]
4. Pediatricians and other child health professionals should ensure that only nonviolent media choices be provided to patients in outpatient waiting rooms and inpatient settings.
5. On a local level, pediatricians should encourage parents, schools, and communities to educate children to be media literate as a means of protecting them against deleterious health effects of media exposure.[93,109,110] Research has demonstrated that media education and thoughtful media use can reduce violent behavior in children.[9,92,111]
6. On state and national levels, pediatricians should work with the AAP and their AAP chapters and districts to collaborate with other health care organizations, educators, government, and research-funding sources to keep media violence on the public health agenda. Media violence is often characterized in the public domain as a values issue rather than what it truly is: a public health issue and an environmental issue. A recent revealed found that two thirds of parents actually favor increased governmental oversight of the media when children and teenagers are concerned.[40]
7. Pediatricians should advocate for more child-positive media. Pediatricians should support and collaborate with media producers, applying our expertise in child health and development toward creating child-friendly and truthful media. The AAP makes the following recommendations to the entertainment industry:
   - Avoid the glamorization of weapon-carrying and the normalization of violence as an acceptable means of resolving conflict.
   - Eliminate the use of violence in a comic or sexual context or in any other situation in which the violence is amusing, titillating, or trivialized.
   - Eliminate gratuitous portrayals of interpersonal violence and hateful, racist, misogynistic, or homophobic language or situations unless explicitly portraying how destructive such words and actions can be. Even so, violence does not belong in media developed for very young children.
   - If violence is used, it should be used thoughtfully as serious drama, always showing the pain and loss suffered by victims and perpetrators.
   - Music lyrics should be made easily available to parents so they can be

read before deciding whether to purchase the recording.

- Video games should not use human or other living targets or award points for killing, because this teaches children to associate pleasure and success with their ability to cause pain and suffering to others.
- Play of violent video games should be restricted to age-limited areas of gaming arcades; the distribution of videos and video games and the exhibition of movies should be limited to appropriate age groups.

8. Pediatricians should advocate for a simplified, universal, content-based media-rating system to help parents guide their children to make healthy media choices. Content should be rated on the basis of research about what types of media depictions are likely to be harmful to children, rather than simply on what adults find offensive. Just as it is important that parents know the ingredients in food they may feed to their children, they should be fully informed about the content of the media their children may use.[4,30,112,113]

Committee on Sports Medicine and Fitness

Medical Concerns in the Female Athlete

ABSTRACT. Female children and adolescents who participate regularly in sports may develop certain medical conditions, including disordered eating, menstrual dysfunction, and decreased bone mineral density. The pediatrician can play an important role in monitoring the health of young female athletes. This revised policy statement provides updated and expanded information for pediatricians on these health concerns as well as recommendations for evaluation, treatment, and ongoing assessments of female athletes.

ABBREVIATIONS. BMD, bone mineral density; LH, luteinizing hormone.

Exercise is good for female children and adolescents. Special medical concerns should be considered, however, when caring for young female athletes. Athletes can develop abnormal eating patterns (termed disordered eating), which can be associated with menstrual dysfunction (amenorrhea or oligomenorrhea) and subsequent decreased bone mineral density (BMD), or osteoporosis. These 3 conditions—disordered eating, amenorrhea, and osteoporosis—often occur together and have been termed the female athlete triad.[1] Although these conditions may also be seen in the nonathlete, this statement will concentrate on the physically active and athletic female.

DISORDERED EATING

Some physically active females, particularly adolescents, may develop an energy deficit when the energy (calories) they expend exceeds their energy (calorie) intake.[2] This deficit may be unintentional, resulting from inadequate replenishment of the caloric (energy) demands of training, or may be intentional—a conscious attempt to lose weight or body fat in the interest of improved appearance or athletic performance. These athletes often restrict food intake but may develop other disordered eating behaviors, such as binge eating and/or purging by vomiting or use of laxatives, diuretics, and diet pills. Compulsive exercise, defined as excessive exercise in addition to a normal training regimen, is another form of "purging," or energy expenditure often overlooked in athletes. The spectrum of disordered eating behaviors ranges from mild—slight restriction of food intake or occasional binge eating and purging—to severe—significant restriction of food intake, as in anorexia nervosa, or regular binge eating and purging, as in bulimia nervosa.[3] Disordered eating may result in adverse health consequences, with the risk of morbidity and mortality increasing as the severity of the behavior increases.

Disordered eating behavior has been reported in young female athletes and dancers.[4–6] One study of young elite swimmers revealed that 60.5% of average-weight girls and 17.9% of underweight girls were trying to lose weight. Most of the girls were trying to lose weight by decreasing their food intake[7]; however, 12.7% were vomiting, 2.5% were using laxatives, and 1.5% were using diuretics.[7] Disordered eating can be seen in athletes participating in all sports. Sports that may place athletes at higher risk for the development of these behaviors include those in which leanness is emphasized (eg, gymnastics, ballet dancing, diving, and figure skating) or perceived to optimize performance (eg, long-distance running and cross-country skiing) and those that use weight classification (eg, martial arts and rowing).[3] A variety of factors may contribute to the development of disordered eating patterns in the young athlete, including pressure to optimize performance or meet inappropriate weight or body fat goals, social factors (eg, idealization of thinness in Western cultures), psychological factors (eg, poor coping skills, unhealthy family dynamics, and low self-esteem), and personality traits (eg, perfectionism, compulsiveness, and high achievement expectations).[3]

Disordered eating behaviors may impair athletic performance and increase risk of injury. Decreased energy (caloric) intake and fluid and electrolyte imbalance can result in decreased endurance, strength, reaction time, speed, and ability to concentrate. Because the body initially adapts to these changes, a decrease in performance may not be seen for some time, and athletes may falsely believe disordered eating practices are harmless. To the contrary, food restriction and purging can result not only in menstrual dysfunction and potentially irreversible bone loss but also in psychological and other medical complications, including depression, fluid and electrolyte imbalance, and changes in the cardiovascular, endocrine, gastrointestinal, and thermoregulatory systems.[8,9] Some of these complications are potentially fatal.

MENSTRUAL DYSFUNCTION

Menstrual dysfunction in athletes may include primary amenorrhea, secondary amenorrhea, oligomenorrhea, and luteal phase deficiency.[10–12]

An adolescent is considered to have delayed pu-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

berty when breast development has not begun by 13.3 years of age.[13] Because sports involvement or poor nutrition may be associated with a delay in development, evaluation might be postponed until 14 years of age, as determined by clinical judgment. Primary amenorrhea is defined as the absence of menses by age 16 years. If menses have not occurred within 4.5 years after the onset of breast development, evaluation should be considered. Secondary amenorrhea is typically defined as the absence of at least 3 to 6 consecutive menstrual cycles in a female who has begun menstruating. Oligomenorrhea refers to menstrual periods that occur at intervals longer than every 35 days.[11,12,14] Although adolescents may have irregular periods or amenorrhea for 3 to 6 months in the first several years after menarche, the cessation of menses for longer than 3 months after regular cycles have begun or persistent oligomenorrhea is considered abnormal.[15]

Menstrual dysfunction is more common in athletes than in the general population. Athletes and dancers who begin training before menarche occurs may experience a later menarche and have an increased incidence of menstrual dysfunction when compared with girls who begin training after menarche occurs.[16–19] The prevalence of secondary amenorrhea in adult athletes ranges from 3.4% to 66% (depending on the sport studied and the criteria used to define amenorrhea),[10–12] compared with 2% to 5% of women in the general population.[12] The prevalence of secondary amenorrhea in the young athlete is unknown.

Luteinizing hormone (LH) pulsatility and, therefore, normal menstrual function are dependent on energy availability (dietary energy intake minus energy expenditure from exercise).[20] Low energy availability causes a hypometabolic state characterized by a variety of substrate and hormonal alterations, including hypoglycemia, hypoinsulinemia, hypothyroidemia, hypercortisolemia, and the suppression of the 24-hour mean and amplitude of the diurnal rhythm of leptin.[2,20–23] Amenorrheic and regularly menstruating athletes display reduced LH pulse frequencies[24] and similarly low 24-hour mean leptin levels.[25] However, amenorrheic athletes are distinctive in having a more extreme suppression and disorganization of LH pulsatility[24] and a complete suppression of the amplitude of the diurnal rhythm of leptin.[25] It is not known whether a particular threshold of energy availability is required to maintain normal reproductive function or whether the macronutrient composition of the diet is important.

Menstrual dysfunction may lead to decreased BMD. Other long-term consequences of a chronically estrogen-depleted state in young women are unknown at this time.

DECREASED BONE MINERAL DENSITY

Hypoestrogenism associated with amenorrhea may predispose to osteoporosis.[26,27] Osteoporosis is defined as premature bone loss and/or inadequate bone formation resulting in low bone mass and microarchitectural deterioration.[1] Adequate levels of estrogen slow bone resorption and improve or maintain bone mass.[28,29] The prevalence of osteoporosis in adult and adolescent women is unknown.[1] Studies of adult female athletes have shown that premature osteoporosis may occur as a result of amenorrhea and oligomenorrhea and may be partially irreversible despite resumption of menses, estrogen replacement, or calcium supplementation.[27,30,31] Amenorrheic adolescents, both athletes and nonathletes, have been found to have lower BMD than eumenorrheic adolescents.[28,32–34] This may be attributable to decreased bone accretion as well as increased bone loss.[35] An overall increase in BMD is demonstrated throughout adolescence. However, the amenorrheic teenager remains osteopenic in comparison with regularly menstruating teenagers.[28,32–35]

High-intensity exercise in some sports for many years may actually increase BMD in specific skeletal sites despite amenorrhea. Elite adolescent ice skaters and gymnasts have been found to have increased BMD in the lower skeleton, compared with controls, despite menstrual dysfunction.[29,36,37]

Girls who begin menarche at a later age and have a lower weight during adolescence have been found to have the lowest BMD when compared with their peers.[34,35] An increased incidence of stress fracture in dancers has been associated with older age at menarche.[38] Weight gain and the resumption of menses result in increased BMD.[33,35] Estrogen replacement therapy may decrease bone loss and potentially increase BMD in the adolescent with secondary amenorrhea.[28,35,39]

CLINICAL EVALUATION

The physical examination that precedes participation in sports is an ideal opportunity to screen for problems of disordered eating, menstrual dysfunction, and decreased BMD.[40] Signs of disordered eating may be recognized by parents, coaches, athletic trainers, teammates, or school nurses and brought to the physician's attention. If an athlete shows signs of disordered eating behavior, further evaluation by the physician, a nutritionist, and a mental health professional may be necessary.[3]

The diagnosis of primary amenorrhea or secondary amenorrhea in an athlete first requires a full evaluation to rule out pregnancy and underlying pathologic conditions. Pathologic conditions that may cause menstrual dysfunction include pituitary tumors (especially prolactinomas), thyroid dysfunction, polycystic ovary disease, premature ovarian failure, and other chronic illnesses.[10]

Evaluation of amenorrhea includes a complete physical examination and pelvic examination when indicated. A pregnancy test is usually indicated. Laboratory studies may include measurement of thyroid-stimulating hormone, prolactin, and follicle-stimulating hormone (FSH). If the athlete shows signs of androgen excess (eg, hirsutism, acne) or if the pelvic examination reveals polycystic ovaries, a determination of levels of LH, testosterone, dehydroepiandrosterone sulfate (DHEA-S), and 17-hydroxyprogesterone may need to be done. A progesterone challenge may help determine if the patient is hy-

poestrogenemic.[10,15] The possible use of anabolic steroids should also be considered.

In the athlete who has been amenorrheic, a study to evaluate BMD may be helpful.[29]

TREATMENT

The female athlete who has restrictive eating patterns because she is unaware of her energy needs may require only nutritional counseling. The female athlete who purposefully engages in disordered eating behaviors is often best treated using a multidisciplinary team approach: with a physician who monitors her medical status and ability to participate safely in sports, a nutritionist who provides appropriate nutritional guidance, and a mental health professional who addresses any psychological issues.[3]

Increased dietary energy intake or decreased energy expenditure (exercise) usually results in the development or resumption of menses and ovulation in adolescent girls and women with exercise-associated amenorrhea.[29,31] Daily requirements for calories, carbohydrates, and protein are greater in athletes than in more sedentary women and girls,[41] and diet should be changed accordingly. The recommended daily dietary allowance of calcium for adolescents is 1200 mg. Amenorrheic athletes should be encouraged to increase their calcium intake to at least 1500 mg daily. If intake of dietary sources of calcium is inadequate, calcium supplements may be recommended. If estrogen levels are deficient, the efficacy of calcium supplementation in improving bone mass may be impaired.[10,29,42]

In adolescents and young women with hypothalamic amenorrhea, estrogen-progesterone supplementation may help maintain bone density, protect the endometrium, and promote regular menses at predictable times.[10,28,35] The criteria for initiating estrogen replacement therapy and the optimal dosing schedule have not been determined. The minimum daily estrogen dose that has been shown to prevent bone loss in postmenopausal women is 0.625 mg of conjugated estrogens[43]; this dose, however, has not been shown to increase BMD in young women with hypothalamic amenorrhea.[28] Supplementation with a low-dose oral contraceptive (<50 μg of estrogen per day) is a readily available source of estrogen and may be associated with an increase in total body BMD.[39]

RECOMMENDATIONS

1. Exercise and sports participation should be promoted in girls and adolescents for health benefits and enjoyment.
2. Dietary practices; exercise intensity, duration, and frequency; and menstrual history need to be reviewed during evaluations that precede participation in sports or other medical encounters in which related problems may present.
3. Amenorrhea should not be considered a normal response to exercise. Exercise-associated amenorrhea or amenorrhea attributable to decreased energy availability should be considered a diagnosis of exclusion. A complete medical evaluation is required for any adolescent with primary or secondary amenorrhea or persistent oligomenorrhea.
4. Disordered eating should be considered in adolescents with amenorrhea. Treatment often requires a team of health care professionals, including a physician, nutritionist, and mental health professional, all experienced in the treatment of eating disorders, in addition to cooperation by coaches, parents, and teammates.
5. Education and counseling should be provided to athletes, parents, and coaches regarding disordered eating, menstrual dysfunction, decreased bone mineralization, and adequate energy (calorie) and nutrient intake to meet energy expenditure and maintain normal growth and development.
6. When athletes and coaches want to know what weight and amount of body fat are best for a given athlete, it is preferable to establish a range of values rather than specific values. It is difficult and potentially dangerous to define an ideal level of weight and/or body fat for each sport or individual participant. Weight is not an accurate estimate of fitness or fatness, and when weight is lost, muscle and fat are lost.
7. An adolescent with menstrual dysfunction attributed to exercise should be encouraged to increase her energy (caloric) intake and modify excessive exercise activity. If an athlete's weight is low, she may be required to gain weight before resuming athletic activity.
8. Estrogen-progesterone supplementation may be considered in the mature amenorrheic athlete.
9. Measurement of BMD may be considered as a tool when making treatment decisions for the amenorrheic athlete.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

CLINICAL REPORT

Medical Conditions Affecting Sports Participation

Guidance for the Clinician in Rendering Pediatric Care

Stephen G. Rice, MD, PhD, MPH, and the Council on Sports Medicine and Fitness

ABSTRACT

Children and adolescents with medical conditions present special issues with respect to participation in athletic activities. The pediatrician can play an important role in determining whether a child with a health condition should participate in certain sports by assessing the child's health status, suggesting appropriate equipment or modifications of sports to decrease the risk of injury, and educating the athlete, parent(s) or guardian, and coach regarding the risks of injury as they relate to the child's condition. This report updates a previous policy statement and provides information for pediatricians on sports participation for children and adolescents with medical conditions.

Key Words
youth, athletes, risk of injury, contact and collision sports, prevention management, strenuousness, safety

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

In 2001, the American Academy of Pediatrics published an analysis of medical conditions affecting sports participation.[1] This updated report replaces the 2001 policy statement and provides additions and changes to increase the accuracy and completeness of the information.

Health care professionals must determine whether a child with a health condition should participate in a particular sport. One way of determining this is by estimating the relative risk of an acute injury to the athlete by categorizing sports as contact, limited-contact, or noncontact sports (Table 1). This categorization may subdivide contact sports into collision and contact sports; although there may be no clear dividing line between the 2, collision implies greater injury risk. In collision sports (eg, boxing, ice hockey, football, lacrosse, and rodeo), athletes purposely hit or collide with each other or with inanimate objects (including the ground) with great force. In contact sports (eg, basketball and soccer), athletes routinely make contact with each other or with inanimate objects but usually with less force than in collision sports. In limited-contact sports (eg, softball and squash), contact with other athletes or with inanimate objects is infrequent or inadvertent. However, some limited-contact sports (eg, skateboarding) can be as dangerous as collision or contact sports. Even in noncontact sports (eg, power lifting), in which contact is rare and unexpected, serious injuries can occur.

Overuse injuries are related not to contact or collision but to repetitive microtrauma; furthermore, overuse injuries generally are not acute. For these reasons, the categorization of sports in Table 1 insufficiently reflects the relative risks of injury. However, the categorization indicates the comparative likelihood that participation in different sports will result in acute traumatic injuries from blows to the body.

For most chronic health conditions, current evidence supports and encourages the participation of children and adolescents in most athletic activities. However, the medical conditions listed in Table 2 have been assessed to determine whether participation would create an increased risk of injury or affect the child's medical condition adversely. These guidelines can be valuable when a physician examines an athlete who has one of the listed problems. Decisions about sports participation are often complex, and the usefulness of Table 2 is limited by the frequency with which it recommends individual assessment when a "qualified yes" or a "qualified no" appears.

The physician's clinical judgment is essential in the application of these recommendations to a specific patient. This judgment is enhanced by consideration of the available published information on the risks of participation, the risk of acquiring a disease as a result of participation in the sport, and the severity of that disease. Other variables to consider include (1) the advice of knowledgeable experts, (2) the current health status of the athlete, (3) the sport in which the athlete participates, (4) the position played, (5) the level of competition, (6) the maturity of the competitor, (7) the relative size of the athlete (for collision/contact sports), (8) the availability of effective protective equipment that is acceptable to the athlete and/or sport governing body, (9) the availability and efficacy of treatment, (10) whether treatment (eg, rehabilitation of an injury) has been completed, (11) whether the sport can be modified to allow safer participation, and (12) the ability of the athlete's parent(s) or guardian and coach to understand and

TABLE 1 **Classification of Sports According to Contact**

Contact	Limited-Contact	Noncontact
Basketball	Adventure racing[a]	Badminton
Boxing[b]	Baseball	Bodybuilding[c]
Cheerleading	Bicycling	Bowling
Diving	Canoeing or kayaking (white water)	Canoeing or kayaking (flat water)
Extreme sports[d]	Fencing	Crew or rowing
Field hockey	Field events	Curling
Football, tackle	High jump	Dance
Gymnastics	Pole vault	Field events
Ice hockey[e]	Floor hockey	Discus
Lacrosse	Football, flag or touch	Javelin
Martial arts[f]	Handball	Shot-put
Rodeo	Horseback riding	Golf
Rugby	Martial arts[f]	Orienteering[g]
Skiing, downhill	Racquetball	Power lifting[c]
Ski jumping	Skating	Race walking
Snowboarding	Ice	Riflery
Soccer	In-line	Rope jumping
Team handball	Roller	Running
Ultimate Frisbee	Skiing	Sailing
Water polo	Cross-country	Scuba diving
Wrestling	Water	Swimming
	Skateboarding	Table tennis
	Softball	Tennis
	Squash	Track
	Volleyball	
	Weight lifting	
	Windsurfing or surfing	

[a] Adventure racing has been added since the previous statement was published and is defined as a combination of 2 or more disciplines, including orienteering and navigation, cross-country running, mountain biking, paddling, and climbing and rope skills.[1]

[b] The American Academy of Pediatrics opposes participation in boxing for children, adolescents, and young adults.[2]

[c] The American Academy of Pediatrics recommends limiting bodybuilding and power lifting until the adolescent achieves sexual maturity rating 5 (Tanner stage V).

[d] Extreme sports has been added since the previous statement was published.

[e] The American Academy of Pediatrics recommends limiting the amount of body checking allowed for hockey players 15 years and younger, to reduce injuries.

[f] Martial arts can be subclassified as judo, jujitsu, karate, kung fu, and tae kwon do; some forms are contact sports and others are limited-contact sports.

[g] Orienteering is a race (contest) in which competitors use a map and a compass to find their way through unfamiliar territory.

to accept the risks involved in participation. Potential dangers of associated training activities that lead to repetitive and/or excessive overload also should be considered.

Unfortunately, adequate data on the risks of a particular sport for athletes with medical problems often are limited or lacking, and an estimate of risk becomes a necessary part of the decision-making process. If primary care physicians are uncertain or uncomfortable with the evaluation and/or the decision-making process, they should seek the counsel of a sports medicine specialist or a specialist in the specific area of medical concern. If the physician thinks that restriction from a sport is necessary for a particular patient, then he or she should counsel the athlete and family about safe alternative activities.

Physicians making decisions about sports participation for athletes with cardiovascular disease (Table 2) are strongly encouraged to consider consulting a cardiologist and to review carefully recommendations from the 36th Bethesda Conference.[12] The complexities and nuances of cardiovascular disease make it difficult to provide important detailed information in a single table.

An athlete's underlying cardiac pathologic condition and the stress that a sport places on that condition are the 2 primary factors determining the risk of participating in that sport. A strenuous sport can place dynamic (volume) and static (pressure) demands on the cardiovascular system. These demands vary not only with activities of the sport but also with factors such as the associated training activities and the environment, as well as the level of emotional arousal and fitness of the competitors. Figure 1 lists sports according to their dynamic and static demands, as classified by cardiopulmonary experts of the 36th Bethesda Conference.[12]

New recommendations on sports participation for athletes with hypertension (Table 2) are available.[10,12] The latest blood pressure tables provide the 50th, 90th, 95th, and 99th percentiles based on age, gender, and height.[10] The blood pressure reading must be at least 5 mm Hg above the 99th percentile before any exclusion from sports is indicated.[10] Periodic monitoring of resting (preexercise) blood pressure levels is preferred for readings above the 90th percentile. A more-complete evaluation is performed for sustained blood pressure readings above the 95th percentile.[10,12]

In earlier legal decisions, athletes have been permitted to participate in sports despite known medical risks and against medical advice, usually in cases involving missing or nonfunctioning paired organs. In recent years, however, courts have been reluctant to permit athletes to participate in competitive athletics contrary to the team physician's medical recommendation. When an athlete's family seeks to disregard such medical advice against participation, the physician should ask all parents or guardians to sign a written informed consent statement indicating that they have been advised of the potential dangers of participation and that they understand these dangers. The physician should document, with the athlete's signature, that the child or adolescent athlete also understands the risks of participation. To ensure that parents or guardians truly understand the risks and dangers of participation against medical advice, it is recommended that these adults write the statement in their own words and handwriting.[59–62]

Additional information on the effects of medical problems on the risk of injury during sports participation is available in *Care of the Young Athlete* by the American Academy of Orthopaedic Surgeons and the American Academy of Pediatrics[63] and *Preparticipation Physical Evaluation, Third Edition,* by the American Academy of Family Physicians, American Academy of Pediatrics, American College of Sports Medicine, American Medical Society for Sports Medicine, American Orthopaedic Society for Sports Medicine, and American Osteopathic Academy of Sports Medicine.[7] In addition, other American Academy of Pediatrics policy statements include relevant material.[64–67]

TABLE 2 **Medical Conditions and Sports Participation**

Condition	May Participate
Atlantoaxial instability (instability of the joint between cervical vertebrae 1 and 2)	Qualified yes
Explanation: Athlete (particularly if he or she has Down syndrome or juvenile rheumatoid arthritis with cervical involvement) needs evaluation to assess the risk of spinal cord injury during sports participation, especially when using a trampoline.[4–7]	
Bleeding disorder	Qualified yes
Explanation: Athlete needs evaluation.[8,9]	
Cardiovascular disease	
Carditis (inflammation of the heart)	No
Explanation: Carditis may result in sudden death with exertion.	
Hypertension (high blood pressure)	Qualified yes
Explanation: Those with hypertension >5 mm Hg above the 99th percentile for age, gender, and height should avoid heavy weightlifting and power lifting, bodybuilding, and high-static component sports (Fig 1). Those with sustained hypertension (>95th percentile for age, gender, and height) need evaluation.[10–12] The National High Blood Pressure Education Program Working Group report defined prehypertension and stage 1 and stage 2 hypertension in children and adolescents younger than 18 years of age.[10]	
Congenital heart disease (structural heart defects present at birth)	Qualified yes
Explanation: Consultation with a cardiologist is recommended. Those who have mild forms may participate fully in most cases; those who have moderate or severe forms or who have undergone surgery need evaluation. The 36th Bethesda Conference[12] defined mild, moderate, and severe disease for common cardiac lesions.	
Dysrhythmia (irregular heart rhythm)	Qualified yes
Long-QT syndrome	
Malignant ventricular arrhythmias	
Symptomatic Wolff-Parkinson-White syndrome	
Advanced heart block	
Family history of sudden death or previous sudden cardiac event	
Implantation of a cardioverter-defibrillator	
Explanation: Consultation with a cardiologist is advised. Those with symptoms (chest pain, syncope, near-syncope, dizziness, shortness of breath, or other symptoms of possible dysrhythmia) or evidence of mitral regurgitation on physical examination need evaluation. All others may participate fully.[13–15]	
Heart murmur	Qualified yes
Explanation: If the murmur is innocent (does not indicate heart disease), full participation is permitted. Otherwise, athlete needs evaluation (see structural heart disease, especially hypertrophic cardiomyopathy and mitral valve prolapse).	
Structural/acquired heart disease	
Hypertrophic cardiomyopathy	Qualified no
Coronary artery anomalies	Qualified no
Arrhythmogenic right ventricular cardiomyopathy	Qualified no
Acute rheumatic fever with carditis	Qualified no
Ehlers-Danlos syndrome, vascular form	Qualified no
Marfan syndrome	Qualified yes
Mitral valve prolapse	Qualified yes
Anthracycline use	Qualified yes
Explanation: Consultation with a cardiologist is recommended. The 36th Bethesda Conference provided detailed recommendations.[12,13,15–18] Most of these conditions carry a significant risk of sudden cardiac death associated with intense physical exercise. Hypertrophic cardiomyopathy requires thorough and repeated evaluations, because disease may change manifestations during later adolescence.[12,13,17] Marfan syndrome with an aortic aneurysm also can cause sudden death during intense physical exercise.[18] Athlete who has ever received chemotherapy with anthracyclines may be at increased risk of cardiac problems because of the cardiotoxic effects of the medications, and resistance training in this population should be approached with caution; strength training that avoids isometric contractions may be permitted.[19,20] Athlete needs evaluation.	
Vasculitis/vascular disease	Qualified yes
Kawasaki disease (coronary artery vasculitis)	
Pulmonary hypertension	
Explanation: Consultation with a cardiologist is recommended. Athlete needs individual evaluation to assess risk on the basis of disease activity, pathologic changes, and medical regimen.[21]	
Cerebral palsy	Qualified yes
Explanation: Athlete needs evaluation to assess functional capacity to perform sports-specific activity.	
Diabetes mellitus	Yes
Explanation: All sports can be played with proper attention and appropriate adjustments to diet (particularly carbohydrate intake), blood glucose concentrations, hydration, and insulin therapy. Blood glucose concentrations should be monitored before exercise, every 30 min during continuous exercise, 15 min after completion of exercise, and at bedtime.	
Diarrhea, infectious	Qualified no
Explanation: Unless symptoms are mild and athlete is fully hydrated, no participation is permitted, because diarrhea may increase risk of dehydration and heat illness (see fever).	
Eating disorders	Qualified yes
Explanation: Athlete with an eating disorder needs medical and psychiatric assessment before participation.	
Eyes	Qualified yes
Functionally 1-eyed athlete	
Loss of an eye	
Detached retina or family history of retinal detachment at young age	
High myopia	
Connective tissue disorder, such as Marfan or Stickler syndrome	
Previous intraocular eye surgery or serious eye injury	

TABLE 2 **Continued**

Condition	May Participate
Explanation: A functionally 1-eyed athlete is defined as having best-corrected visual acuity worse than 20/40 in the poorer-seeing eye. Such an athlete would suffer significant disability if the better eye were seriously injured, as would an athlete with loss of an eye. Specifically, boxing and full-contact martial arts are not recommended for functionally 1-eyed athletes, because eye protection is impractical and/or not permitted. Some athletes who previously underwent intraocular eye surgery or had a serious eye injury may have increased risk of injury because of weakened eye tissue. Availability of eye guards approved by the American Society for Testing and Materials and other protective equipment may allow participation in most sports, but this must be judged on an individual basis.[22,23]	
Conjunctivitis, infectious	Qualified no
Explanation: Athlete with active infectious conjunctivitis should be excluded from swimming.	
Fever	No
Explanation: Elevated core temperature may be indicative of a pathologic medical condition (infection or disease) that is often manifest by increased resting metabolism and heart rate. Accordingly, during athlete's usual exercise regimen, the presence of fever can result in greater heat storage, decreased heat tolerance, increased risk of heat illness, increased cardiopulmonary effort, reduced maximal exercise capacity, and increased risk of hypotension because of altered vascular tone and dehydration. On rare occasions, fever may accompany myocarditis or other conditions that may make usual exercise dangerous.	
Gastrointestinal	Qualified yes
Malabsorption syndromes (celiac disease or cystic fibrosis)	
Explanation: Athlete needs individual assessment for general malnutrition or specific deficits resulting in coagulation or other defects; with appropriate treatment, these deficits can be treated adequately to permit normal activities.	
Short-bowel syndrome or other disorders requiring specialized nutritional support, including parenteral or enteral nutrition	
Explanation: Athlete needs individual assessment for collision, contact, or limited-contact sports. Presence of central or peripheral, indwelling, venous catheter may require special considerations for activities and emergency preparedness for unexpected trauma to the device(s).	
Heat illness, history of	Qualified yes
Explanation: Because of the likelihood of recurrence, athlete needs individual assessment to determine the presence of predisposing conditions and behaviors and to develop a prevention strategy that includes sufficient acclimatization (to the environment and to exercise intensity and duration), conditioning, hydration, and salt intake, as well as other effective measures to improve heat tolerance and to reduce heat injury risk (such as protective equipment and uniform configurations).[24,25]	
Hepatitis, infectious (primarily hepatitis C)	Yes
Explanation: All athletes should receive hepatitis B vaccination before participation. Because of the apparent minimal risk to others, all sports may be played as athlete's state of health allows. For all athletes, skin lesions should be covered properly, and athletic personnel should use universal precautions when handling blood or body fluids with visible blood.[26]	
HIV infection	Yes
Explanation: Because of the apparent minimal risk to others, all sports may be played as athlete's state of health allows (especially if viral load is undetectable or very low). For all athletes, skin lesions should be covered properly, and athletic personnel should use universal precautions when handling blood or body fluids with visible blood.[26] However, certain sports (such as wrestling and boxing) may create a situation that favors viral transmission (likely bleeding plus skin breaks). If viral load is detectable, then athletes should be advised to avoid such high-contact sports.	
Kidney, absence of one	Qualified yes
Explanation: Athlete needs individual assessment for contact, collision, and limited-contact sports. Protective equipment may reduce risk of injury to the remaining kidney sufficiently to allow participation in most sports, providing such equipment remains in place during activity.[22]	
Liver, enlarged	Qualified yes
Explanation: If the liver is acutely enlarged, then participation should be avoided because of risk of rupture. If the liver is chronically enlarged, then individual assessment is needed before collision, contact, or limited-contact sports are played. Patients with chronic liver disease may have changes in liver function that affect stamina, mental status, coagulation, or nutritional status.	
Malignant neoplasm	Qualified yes
Explanation: Athlete needs individual assessment.[27]	
Musculoskeletal disorders	Qualified yes
Explanation: Athlete needs individual assessment.	
Neurologic disorders	
History of serious head or spine trauma or abnormality, including craniotomy, epidural bleeding, subdural hematoma, intracerebral hemorrhage, second-impact syndrome, vascular malformation, and neck fracture.[4,5,28–30]	Qualified yes
Explanation: Athlete needs individual assessment for collision, contact, or limited-contact sports.	
History of simple concussion (mild traumatic brain injury), multiple simple concussions, and/or complex concussion	Qualified yes
Explanation: Athlete needs individual assessment. Research supports a conservative approach to concussion management, including no athletic participation while symptomatic or when deficits in judgment or cognition are detected, followed by graduated return to full activity.[28–32]	
Myopathies	Qualified yes
Explanation: Athlete needs individual assessment.	
Recurrent headaches	Yes
Explanation: Athlete needs individual assessment.[33]	
Recurrent plexopathy (burner or stinger) and cervical cord neuropraxia with persistent defects	Qualified yes
Explanation: Athlete needs individual assessment for collision, contact, or limited-contact sports; regaining normal strength is important benchmark for return to play.[34,35]	
Seizure disorder, well controlled	Yes
Explanation: Risk of seizure during participation is minimal.[36]	
Seizure disorder, poorly controlled	Qualified yes
Explanation: Athlete needs individual assessment for collision, contact, or limited-contact sports. The following noncontact sports should be avoided: archery, riflery, swimming, weightlifting, power lifting, strength training, and sports involving heights. In these sports, occurrence of a seizure during activity may pose a risk to self or others.[36]	

TABLE 2 **Continued**

Condition	May Participate
Obesity	Yes
Explanation: Because of the increased risk of heat illness and cardiovascular strain, obese athlete particularly needs careful acclimatization (to the environment and to exercise intensity and duration), sufficient hydration, and potential activity and recovery modifications during competition and training.[37]	
Organ transplant recipient (and those taking immunosuppressive medications)	Qualified yes
Explanation: Athlete needs individual assessment for contact, collision, and limited-contact sports. In addition to potential risk of infections, some medications (eg, prednisone) may increase tendency for bruising.	
Ovary, absence of one	Yes
Explanation: Risk of severe injury to remaining ovary is minimal.	
Pregnancy/postpartum	Qualified yes
Explanation: Athlete needs individual assessment. As pregnancy progresses, modifications to usual exercise routines will become necessary. Activities with high risk of falling or abdominal trauma should be avoided. Scuba diving and activities posing risk of altitude sickness should also be avoided during pregnancy. After the birth, physiological and morphologic changes of pregnancy take 4 to 6 weeks to return to baseline.[38,39]	
Respiratory conditions	
Pulmonary compromise, including cystic fibrosis	Qualified yes
Explanation: Athlete needs individual assessment but, generally, all sports may be played if oxygenation remains satisfactory during graded exercise test. Athletes with cystic fibrosis need acclimatization and good hydration to reduce risk of heat illness.	
Asthma	Yes
Explanation: With proper medication and education, only athletes with severe asthma need to modify their participation. For those using inhalers, recommend having a written action plan and using a peak flowmeter daily.[40–43] Athletes with asthma may encounter risks when scuba diving.	
Acute upper respiratory infection	Qualified yes
Explanation: Upper respiratory obstruction may affect pulmonary function. Athlete needs individual assessment for all except mild disease (see fever).	
Rheumatologic diseases	Qualified yes
Juvenile rheumatoid arthritis	
Explanation: Athletes with systemic or polyarticular juvenile rheumatoid arthritis and history of cervical spine involvement need radiographs of vertebrae C1 and C2 to assess risk of spinal cord injury. Athletes with systemic or HLA-B27-associated arthritis require cardiovascular assessment for possible cardiac complications during exercise. For those with micrognathia (open bite and exposed teeth), mouth guards are helpful. If uveitis is present, risk of eye damage from trauma is increased; ophthalmologic assessment is recommended. If visually impaired, guidelines for functionally 1-eyed athletes should be followed.[44]	
Juvenile dermatomyositis, idiopathic myositis	
Systemic lupus erythematosis	
Raynaud phenomenon	
Explanation: Athlete with juvenile dermatomyositis or systemic lupus erythematosis with cardiac involvement requires cardiology assessment before participation. Athletes receiving systemic corticosteroid therapy are at higher risk of osteoporotic fractures and avascular necrosis, which should be assessed before clearance; those receiving immunosuppressive medications are at higher risk of serious infection. Sports activities should be avoided when myositis is active. Rhabdomyolysis during intensive exercise may cause renal injury in athletes with idiopathic myositis and other myopathies. Because of photosensitivity with juvenile dermatomyositis and systemic lupus erythematosis, sun protection is necessary during outdoor activities. With Raynaud phenomenon, exposure to the cold presents risk to hands and feet.[45–48]	
Sickle cell disease	Qualified yes
Explanation: Athlete needs individual assessment. In general, if illness status permits, all sports may be played; however, any sport or activity that entails overexertion, overheating, dehydration, or chilling should be avoided. Participation at high altitude, especially when not acclimatized, also poses risk of sickle cell crisis.	
Sickle cell trait	Yes
Explanation: Athletes with sickle cell trait generally do not have increased risk of sudden death or other medical problems during athletic participation under normal environmental conditions. However, when high exertional activity is performed under extreme conditions of heat and humidity or increased altitude, such catastrophic complications have occurred rarely.[8,49–52] Athletes with sickle cell trait, like all athletes, should be progressively acclimatized to the environment and to the intensity and duration of activities and should be sufficiently hydrated to reduce the risk of exertional heat illness and/or rhabdomyolysis.[25] According to National Institutes of Health management guidelines, sickle cell trait is not a contraindication to participation in competitive athletics, and there is no requirement for screening before participation.[53] More research is needed to assess fully potential risks and benefits of screening athletes for sickle cell trait.	
Skin infections, including herpes simplex, molluscum contagiosum, verrucae (warts), staphylococcal and streptococcal infections (furuncles [boils], carbuncles, impetigo, methicillin-resistant *Staphylococcus aureus* [cellulitis and/or abscesses]), scabies, and tinea	Qualified yes
Explanation: During contagious periods, participation in gymnastics or cheerleading with mats, martial arts, wrestling, or other collision, contact, or limited-contact sports is not allowed.[54–57]	
Spleen, enlarged	Qualified yes
Explanation: If the spleen is acutely enlarged, then participation should be avoided because of risk of rupture. If the spleen is chronically enlarged, then individual assessment is needed before collision, contact, or limited-contact sports are played.	
Testicle, undescended or absence of one	Yes
Explanation: Certain sports may require a protective cup.[22]	

This table is designed for use by medical and nonmedical personnel. "Needs evaluation" means that a physician with appropriate knowledge and experience should assess the safety of a given sport for an athlete with the listed medical condition. Unless otherwise noted, this need for special consideration is because of variability in the severity of the disease, the risk of injury for the specific sports listed in Table 1, or both.

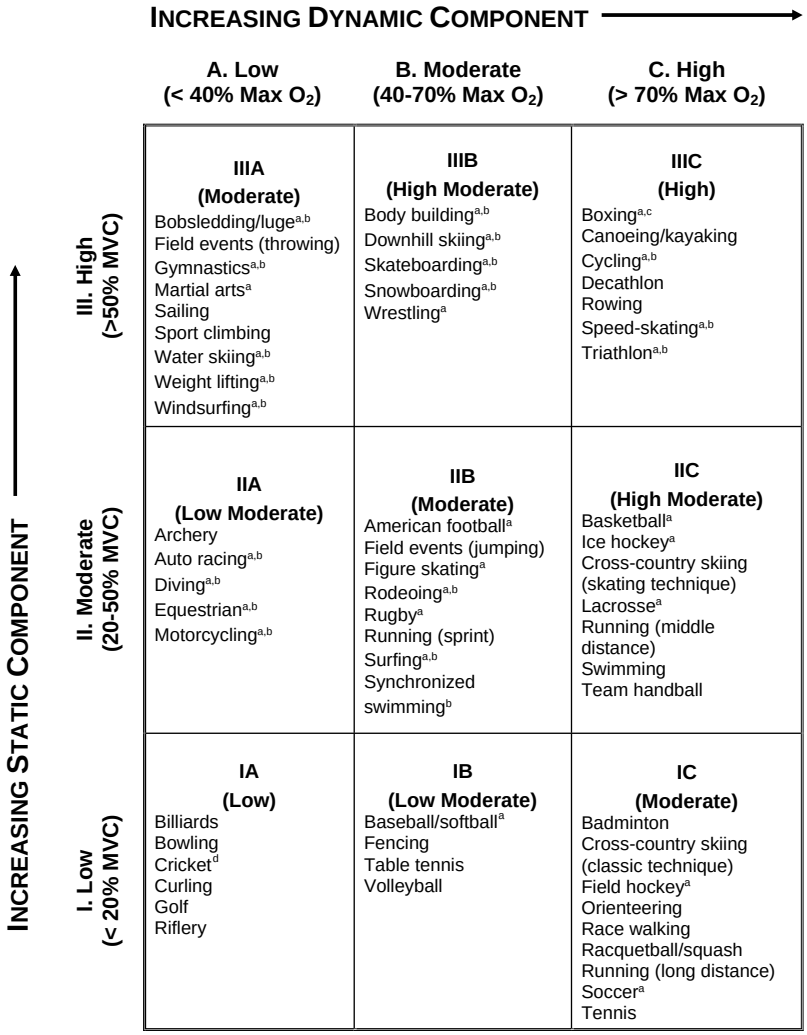

FIGURE 1
Classification of sports according to cardiovascular demands (based on combined static and dynamic components).[1,2] This classification is based on peak static and dynamic components achieved during competition. It should be noted, however, that the higher values may be reached during training. The increasing dynamic component is defined in terms of the estimated percentage of maximal oxygen uptake (Max O_2) achieved and results in increasing cardiac output. The increasing static component is related to the estimated percentage of maximal voluntary contraction (MVC) reached and results in increasing blood pressure load. Activities with the lowest total cardiovascular demands (cardiac output and blood pressure) are shown in box IA, and those with the highest demands are shown in box IIIC. Boxes IIA and IB depict activities with low/moderate total cardiovascular demands, boxes IIIA, IIB, and IC depict activities with moderate total cardiovascular demands, and boxes IIIB and IIC depict high/moderate total cardiovascular demands. These categories progress diagonally across the graph from lower left to upper right. [a] Danger of bodily collision. [b] Increased risk if syncope occurs. [c] Participation is not recommended by the American Academy of Pediatrics.[2] [d] The American Academy of Pediatrics classifies cricket in the IB box (low static component and moderate dynamic component).[58] (Reproduced with permission from Mitchell JH, Haskell W, Snell P, Van Camp SP. 36th Bethesda Conference. American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Medical Emergencies Occurring at School

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on School Health

ABSTRACT

Children and adults might experience medical emergency situations because of injuries, complications of chronic health conditions, or unexpected major illnesses that occur in schools. In February 2001, the American Academy of Pediatrics issued a policy statement titled "Guidelines for Emergency Medical Care in Schools" (available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;107/2/435). Since the release of that statement, the spectrum of potential individual student emergencies has changed significantly. The increase in the number of children with special health care needs and chronic medical conditions attending schools and the challenges associated with ensuring that schools have access to on-site licensed health care professionals on an ongoing basis have added to increasing the risks of medical emergencies in schools. The goal of this statement is to increase pediatricians' awareness of schools' roles in preparing for individual student emergencies and to provide recommendations for primary care and school physicians on how to assist and support school personnel. *Pediatrics* 2008;122:887–894

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

Key Words
school, medical emergency, emergency care plan

Abbreviations
AAP—American Academy of Pediatrics
EMS—emergency medical services
CPR—cardiopulmonary resuscitation
AED—automated external defibrillator
EMT—emergency medical technician
IHP—individualized health plan
IEP—individualized education plan
ECP—emergency care plan

RATIONALE

Many schools lack a licensed health care professional on site to respond to individual student medical emergencies. Injuries are the leading cause of death and disability in the United States, especially among children, with 70% of injury deaths occurring in school-aged youth (5–19 years of age).[1] It is estimated that 10% to 25% of injuries to children occur while they are in school.[2] In addition to injury-related emergencies, status asthmaticus, diabetic crises, status epilepticus, sudden cardiac death, and other medical emergencies can occur in students and staff at school. The prevalence of children with special health care needs attending schools means that there now exists a pool of students with a broad range of medical conditions that may require special equipment, preparation and training of personnel, medications and supplies, and/or transport decisions and arrangements.[3] This statement highlights the role of school personnel, the school health and safety team (school nurse, social worker, school resource officer), school physician, and primary care clinician in each step in the process of managing individual student emergencies occurring at school. It is important to note that there is a fundamental link between emergency readiness and disaster preparedness. Schools that are prepared for an emergency in an individual are more likely to be prepared for complex events such as community disasters. Disaster planning in schools is covered in a separate policy statement from the American Academy of Pediatrics (AAP), "Disaster Planning for Schools."[4] It is helpful to view these 2 policies together to appreciate the full spectrum of school emergency planning.

BACKGROUND

The average school-aged child spends 28% of the day and 14% of his or her total annual hours in school.[2] There are 72.3 million children younger than 18 years living in the United States (according to the 2000 US Census). The Maternal and Child Health Bureau of the US Department of Health and Human Services estimates that of this group, 18 million children and adolescents have special health care needs or a chronic illness. Children with special health care needs or chronic illness account for 25% of the pediatric patients seen in hospital emergency departments each year.[3] Despite its critical importance, school emergency preparedness is frequently inadequate because of barriers such as geographic and physical facility conditions, staffing, staff education and training, and financial resources.

Schools across the nation vary tremendously in their degree of preparedness to deal with emergencies. A survey of schools in rural New Mexico found that schools, particularly in larger communities, were ill prepared to deal with emergencies in students or staff as assessed by evaluating equipment and emergency training (communities with

populations of <200 000 were more likely to have equipment available).[2] Oxygen was available in only 20% of the surveyed schools, epinephrine was available in only 16%, artificial airways were available in only 30%, cervical collars were available in only 22%, and splints were available in only 69%. Annually, 67% of schools activate emergency medical services (EMS) systems for an emergency involving a student, and 37% activate EMS for an emergency involving an adult. EMS response time was less than 10 minutes for 84% of the schools.[2]

A national survey of 573 school nurses conducted by Olympia et al[5] revealed that 68% of the school nurses managed a life-threatening emergency requiring EMS activation in the school year before the survey. Although 86% of the surveyed schools reported having a medical emergency-response plan, 35% of the schools had not tested it during a drill.

Regional statistics demonstrate that injuries are the chief complaint listed for two thirds of EMS dispatches to schools. Medical emergencies, such as breathing difficulties and seizures, account for one quarter of school calls to the EMS system.[3] Compared with non-school–based EMS incidents, school-based EMS incidents are more often attributable to injury, are frequently related to a sporting activity, and are more likely to result in transport to a medical facility.[6] Even in the case of children with special health care needs, approximately half of EMS responses are unrelated to the child's special needs and include traditional causes of EMS calls, such as an acute injury.[1]

Another critical factor in the preparedness of schools for emergencies is medical, nonmedical, and students' training. School medical emergencies can involve students, adults, staff members, or attendees of special events. Because injuries are the most common life-threatening emergencies encountered by children and adolescents inside or outside schools, teachers, school nurses, physicians, athletic trainers, coaches, and students should know general principles of first aid and cardiopulmonary resuscitation (CPR). In a survey of all high schools in Washington State, 80% of teachers thought that CPR training was important, yet 35% of the schools provided no CPR training for students.

The goal of this statement is to increase the pediatric clinician's awareness of the role that schools play in preparing for and responding to the individual student emergency. Recommendations and resources will be provided to assist primary care clinicians and school physicians in supporting schools in this role. The management of individual emergencies is linked to the preparation for large-scale community emergencies.[4] Resources, linkages with EMS, and staff training are all vital to emergency preparedness. It is really the scale and terminology that distinguish the response to an individual emergency from the response to a disaster. The terminology of mitigation and prevention, preparedness, response, and recovery[7] is generally not used for individual emergencies but reserved for large-scale disasters. However, in individual emergencies, the emphasis is less on prevention and more on preparedness and response. The following reflects the role that schools play in these aspects of individual emergency response.

DESCRIPTION OF THE SCHOOL'S ROLE

Readiness for Response

Any child can have a medical emergency in school. Children with special health care needs carry additional risks of emergencies related to their diagnoses. From injury to anaphylaxis to status epilepticus, schools are expected to anticipate and prepare to respond to a wide variety of emergencies.[8,9]

General Preparation

Ideally, schools develop emergency policies with input from the medical community—both EMS and community clinicians. These policies need to be flexible enough to accommodate different students' developmental levels. Integration of EMS into school emergency planning familiarizes them with the location and type of medical resources available at the school. This collaboration leads to the creation of policies and regulations that appropriately delegate authority, assign roles, distribute shared resources, and establish parameters for health care providers. The range of possible policies can vary from general emergency management to use of CPR and automated external defibrillators (AEDs) to life-threatening allergy management; these are discussed briefly below.

- Policies, regulations, and protocols are created to cover all aspects of school jurisdiction, from classroom to playground, school-based health centers (if one is available), before- and after-school programs, field trips, transportation, and athletic events. These are to be clearly stated and communicated to all school staff and parents. Table 1 provides some resources for the creation of such policies.
- Emergency data are to be collected on all children and include parental contact, health care provider contact, medical conditions, medications, allergies, and insurance. Information technology could facilitate the collection, storing, and transfer of these data.
- Protocols should include algorithms for determining levels of emergencies. Minor illnesses or injuries are to be distinguished from emergencies that require EMS activation.
- It is important that the EMS-activation process is clear to all staff. This process ensures accessible and appropriate transportation and care during transport to a hospital or other appropriate medical facility.[10] Although EMS traditionally is thought of as emergency medical technicians (EMTs) and ambulances, it really encompasses prehospital through emergency department management. Therefore, in the event of a medical emergency within school jurisdiction, EMS include school nurses and school staff. Ongoing communication, review, and practice of procedures ensure achievement of this level of integration.

- Participation of physical facilities administrators in the planning ensures that the most efficient access routes to the school, as well as floor plans, are available to EMS.
- Clarity of school staff roles in an emergency is essential for smooth response. Ideally, the school nurse in each building should be the key person to develop and implement the emergency plan, because the nurse is the staff member who is most skilled and familiar with individual students' health issues and community resources. In the absence of a school nurse, members of the school health and safety team (social worker, school resource officer) are designated, trained, and empowered to make decisions concerning health emergencies. Names, telephone numbers, and locations of these designated and trained school personnel are to be provided to all staff members.
- The development of campus-wide communication strategies (2-way radios, pagers, cell phones) is key so that staff members are accurately informed and rumors are minimized, which is especially important in the event of an incident involving violence.
- Schools can determine if using trained students in an emergent situation is feasible within the constraints of confidentiality. These students may maximize limited resources by being used as runners, for mobilizing equipment, helping in evacuation, or providing escorts to response agencies not familiar with school grounds. It is important to define their role ahead of

time, guarantee adequate training, include them in the plan, and practice executing the plan.

- Periodic drills with local EMS and hospital emergency departments are essential components of preparedness. This process allows schools to better understand their barriers to good EMS care, and in turn, EMS professionals get a preemergency look at school operations and physical structure, which allows problem solving to begin before any emergency or crisis.[3]
- The availability of sufficient supplies to address an individual emergency is of utmost importance. A complete emergency medical kit that is secure, carefully organized, and monitored by protocol should be accessible for use by authorized and trained school staff members who have volunteered to serve in an emergency.[10] In 2003, a national consensus group that included the AAP was convened by the Emergency Medical Services for Children National Resource Center and the National Association of School Nurses and published a report titled "Recommended Minimal Emergency Equipment and Resources For Schools: National Consensus Group Report."[11] This report is a valuable reference for putting together an emergency medical kit.[1]
- All equipment should be maintained and inspected at appropriate intervals. If an AED is available on site, an AED maintenance, testing, and repair program is to be incorporated into the AED emergency-response protocol.[1]
- Staff development and training is essential for responding to a medical emergency. Human resources policies and regulations may determine to what extent and capacity staff may respond to an emergency. However, there are certain basics in which all staff members can participate.
- It is important that universal precautions be discussed with the entire staff at the beginning of each year.
- Basic response to emergent situations is to be discussed with the entire staff. This discussion should include responses to large-scale emergencies and minor problems. Because parents have the right to limit medical information given to schools, it is prudent to give general response guidelines for seizures, fainting, bleeding, anaphylaxis, choking, and head trauma so that staff members can become more comfortable with initiating an emergent response even if they are not aware that the child has a medical concern.
- Some staff members may opt for more in-depth training, and it is recommended that at least 1 staff member, in addition to the school nurse, have CPR and first aid training.[1]
- Schools determine if a school staff member accompanies the student to the hospital. If a staff member is to accompany the student, the school must develop policy to clarify when the staff member assumes "in loco parentis" (in-the-absence-of-parents status).
- It is preferable that multiple back-up numbers for emergency contacts be available for each student's family.

Preparation for Children With Special Health Care Needs

- Students and staff members with chronic medical conditions or other special health care needs are more susceptible to medical emergencies and require schools to have a heightened sense of readiness. Students should have an updated individualized health plan (IHP) prepared by the school nurse with input from the family and the primary care clinician. The IHP contains information on medications, activity levels, dietary needs, equipment, transportation, and other accommodations. Using this information, the school can then plan for accommodations for daily classroom activity, field trips, and emergency needs of the student. The IHP can assist school teams in developing individualized education plans (IEPs) or 504 plans.
- Individual emergency care plans (ECPs), developed from information in the IHP, are to be copied and made available for transport with the child if he or she requires hospital treatment and/or management in the event of a community-wide disaster. The emergency information form, developed by the AAP and the American College of Emergency Physicians, is useful in developing both an IHP and an ECP.[12] Unlike IHPs and ECPs, both a 504 plan and an IEP are formal, legal documents, which means that the school is legally bound to implement the elements of the plans. A 504 plan is an agreement between a student's legal guardian and a school district that the student will have full access to all school activities and will have his or her medical needs met.
- Any equipment or medication required for emergency management of a student or staff member (eg, evacuation chair or epinephrine autoinjector) is to be easily accessible.
- Staff who care for students with special needs should have an awareness of the illnesses and be trained to respond to emergencies (eg, seizures, asthma, diabetic ketoacidosis, hypoglycemia, sickle crisis) until a health care professional arrives. This capacity is especially important in the event of a community disaster in which the EMS, prehospital emergency-response system may not be readily available.
- As stated previously, some parents may opt not to disclose a child's disability to teachers out of concern about stigmatization. In these cases, basic awareness training to all staff at the beginning of the year is a prudent approach.

Policies and Procedures for Specific Emergencies

- Life-threatening allergic reactions, particularly related to food triggers, are increasing in schools.[9,13] It is very important that schools have policies, procedures, and protocols for addressing the response to such inci-

dents. School procedures must comply with state and local regulations for administration of epinephrine autoinjectors by nonlicensed personnel.

- Use of CPR and AEDs is a valuable addition to school emergency response.[14,15] An AED program is to be covered by a school policy,[16] and staff members who are trained for such use are to be able to respond effectively to first aid and cardiopulmonary emergencies. Sudden cardiac arrest has an estimated annual incidence of 0.7 to 1.0 per 1000 population[17–20] and is responsible for >50% of all deaths attributable to cardiovascular disease in the United States. If no CPR is provided, each minute that defibrillation is delayed decreases the chances of survival for victims of sudden cardiac arrest attributable to ventricular fibrillation by 8% to 10%.[21,22] High school athlete sudden death is rare. When sudden death of an athlete does occur, it is more likely to affect collegiate than high school athletes. However, sudden cardiac deaths in adult spectators have been reported, and schools need to prepare for them. Professional and collegiate sporting venues typically use emergency medical response teams for spectator care coverage.[23,24] High school event coverage is less organized and typically falls under the responsibility of the athletic director or school administrators.[17–20] Many national agencies that provide certified training programs exist. The American Heart Association's medical emergency-response plan for schools describes the core elements of such a program (Table 2).[1,25,26]
- Communicable-disease emergencies involve exposures for which there needs to be contact tracking and management. Protocols for varicella, pertussis, measles, methicillin-resistant *Staphylococcus aureus*, and meningococcal meningitis exposures are developed in conjunction with local health departments.
- Protocols for responding to specific emergencies (eg, head trauma, choking, lacerations) are helpful to school nurses or designated staff. The Illinois Emergency Medical Services for Children program has an online manual that provides algorithms for managing specific school emergencies.[27]

TABLE 2 **American Heart Association Medical Emergency-Response Plan for Schools[2,23,24]: 5 Core Elements of the American Heart Association Plan**

Effective and efficient communication throughout the school campus
Coordinated and practiced response plan
Risk reduction
Training and equipment for first aid and CPR
Implementation of a lay-rescuer AED program in school with an established need; the program will have 5 elements:
Medical/health care professional oversight
Training of anticipated rescuers in CPR and use of an AED
Coordination with the EMS system
Appropriate device maintenance
Ongoing quality improvement program

Response

Once policies and procedures are in place, the response follows the plan in an organized and efficient manner.

- A staff member, ideally the school nurse, is to assess the situation and activate the appropriate protocol(s) and determine whether EMS needs to be activated.
- When EMS is activated, communication of school entry points to EMTs and a designated greeter to direct them to the emergency are of utmost importance.
- When possible, other students and staff members are removed from the scene.
- All emergency-response interventions should be promptly and accurately recorded and passed on to the EMTs.
- For children with special health care needs, the ECP is activated and information is to be prepared for EMTs.
- Any student who receives emergency epinephrine must be transported to the emergency department as recommended by the American Academy of Asthma Allergy & Immunology.[9,13]
- Parents, legal guardians, or designated emergency contact persons are informed ideally as quickly as possible about the child's injury or sudden illness at school after an emergency response and about actions taken to care for him or her.[10] In addition, notification systems must be in place through a designated spokesperson to inform the school staff, students, the media, and the community at large of the outcome of an individual student's emergency situation in an appropriate manner that respects the student's confidentiality and dispels false rumors.
- The description and disposition of significant illnesses or injuries (including the illnesses or injuries for which a student, staff member, or visitor is released from school to visit a physician or hospital) are to be recorded on an illness and injury form. This information is also used to (1) identify patterns of injury, (2) prevent another such injury or illness, (3) inform parents of the nature and management of the injury, (4) share information with the child's primary care clinician (ie, medical home), local and state child fatality review teams charged with investigating death and near-death events, and/or EMS personnel, and (5) provide information for liability and insurance purposes.[10]

After the Event

- Ideally, the records developed are studied and used to provide feedback to staff, identify areas in need of improvement, and design education programs.
- After an emergency intervention, the ECP is to be reviewed and adjusted as needed.
- Mental health interventions, as appropriate, are preferably planned for all affected students.
- Necessary equipment and medications should be restocked.

CONCLUSIONS

School preparedness for an individual student medical emergency intervention heavily depends on a team effort that involves the school administration and its physician (if applicable), the individual school health and safety team and its nurse, the local community (EMS, local hospital/emergency department), and the student's medical home/primary care clinician. Continued and timely communication between the student's medical home and the school is the key to ensuring that updated IHPs, ECPs, 504 plans, and IEPs are established, when applicable. Some of the documents referenced in this statement can be used as communication tools. The primary care clinician should advise parents and caregivers, particularly for a child with a chronic illness, to be familiar with and support the school emergency-preparedness plan. In addition, medical home clinicians and school physicians can be the best advocates to help a school obtain needed life-saving emergency services for a student with a particular condition. The medical home clinician can play a key role in supporting the school's efforts in ensuring students' safety in school, particularly those with special health care needs.

FACTORS THAT AFFECT SCHOOL EMERGENCY PREPARATION

School administration preparedness for individual student medical emergencies must recognize and address:

1. system factors such as school district size, student/school nurse ratio, students' ages/grade levels, the complexity of student medical needs, prehospital level of training of school personnel, local emergency department capability, local readily available medical treatment facilities, and human and financial resources; and
2. process factors such as protocols and procedures, continuous training and evaluation, and collaboration among the medical and educational homes and community services such as EMS, clinical and mental health support, and follow-up services.

Emergencies that occur in school can be either anticipated risks related to an individual student's medical condition or unanticipated events that occur in an otherwise healthy student or a staff member. The following recommendations are meant to assist primary care clinicians and school physicians in providing support to schools in their efforts to prepare for the individual student medical emergency.

RECOMMENDATIONS FOR PRIMARY CARE CLINICIANS

The medical home plays a key role in helping schools prepare for the individual student emergency. The following are key recommendations for primary care clinicians:

- Communication: Maintain a strong, open, and ongoing line of communication with the school nurse and/or the school physician (when available) regarding the individual student's medical condition and current management in coordination with the parent/caregiver. This linkage informs the school nurse of any changes or updates to the student's IHP, ECP, 504 plan, or IEP when applicable. The emergency information form[13] (developed by the American College of Emergency Physicians and the AAP) is 1 such tool that can be completed by the primary care clinician and may be used to communicate with the school nurse.[13] Table 2 provides selected resources for general and disease-specific emergency care, action, and health plans that can be used by the primary care clinician in communication with the school nurse after obtaining parental permission. The school nurse plays an important role in developing and implementing health plans, activating physicians' orders, and interpreting physicians' instructions for staff, students, and families.
- Familiarity: Be familiar with the individual emergency plan and the disaster plan of the patient's school, the school resources, and staffing and provide advice on issues that might affect the student's disease management and outcome.
- Parent engagement: Advise parents to become familiar with the school's emergency plan and help them evaluate how the plan meets the needs of their children.
- Advocacy: Get involved with the school district's School Health Advisory Council and provide input on health-related policies that will affect individual patient care, including school wellness policies and emergency plans.
- Drafting health plans: Participate in the drafting of IEPs and 504 plans as needed. If a student with a particular special health care need or chronic disease has special education needs, an IEP may be developed by using the IHP as a foundation for details on the student's disease-management routine. To qualify for an IEP, a child must have an impairment that substantially affects his or her academic performance.[24]
- Orders: Provide a clearly written problem list, daily care instructions, accommodations, and orders for the use of emergency medications (eg, epinephrine autoinjector, albuterol) and the necessary current prescriptions to keep these medications and devices available in school for use in a particular student's emergency. This information is used by the school nurse to create the student's IHP and ECP.
- Be available to assess the individual student after an emergency and assist in a prompt and safe return to school and provide support to parents whose child sustained a medical emergency in school.
- Review the documentation and details of the student's school emergency, provide feedback, and provide instructions that amend the individual ECP as necessary.
- Communicate directly with the school physician (where available) as needed.

RECOMMENDATIONS FOR THE SCHOOL PHYSICIAN

The school physician, if one is available, is uniquely positioned to interact with schools in each of the previ-

ously mentioned steps and provide global and system-based recommendations related to individual students' medical emergency readiness as follows:

- Assist administration and collaborate with the school nurse in the planning, development, training, implementation, review, evaluation, update, and approval of the school emergency plan and protocols for individual student emergencies,[9] including medical emergencies and injuries that occur in school, after school, in transport, and on the playground.
- Ensure that the individual emergency preparation seamlessly links with the preparations for disaster planning.
- Be familiar with the spectrum of medical diagnoses of individual students in each of the schools in the district to effectively assist the school nurse in obtaining, interpreting, and implementing the IHP, ECP, IEP, and 504 plans for those students and to anticipate the schools' needs and resources to deal with anticipated emergencies.
- Assist in the development and periodic assessment of programs for emergency education, training, and retraining of school staff and designated volunteers in emergency procedures, including basic life support, first aid, AED use, and emergency medication administration.[1]
- Act as a liaison between the medical home and the school staff to ensure continued communication regarding a student's IHP, ECP, IEP, or 504 plan.
- Provide guidelines and recommendations on the contents of the emergency kit and ensure that the kit medications are safe, accessible, and in adequate supply[9] (see the AAP policy statement "Guidelines for Emergency Medical Care in School"[10] for a guideline for kit contents).
- Oversee school emergency drills in collaboration with the local EMS, hospitals, and community agencies.
- Establish a program for regular AED maintenance, testing, and repair when an AED is available in the school[25] (see Table 2 for highlights of the elements of an AED plan).
- Oversee and manage the medical emergency-response actions on behalf of an affected student (if present in school during an emergency).
- After a student emergency occurs, review the records of the school's management of the medical emergency, its response and adherence to the emergency protocol, the adequacy of services provided, and the accuracy and completeness of data recorded to evaluate access to and quality of emergency services and materials, and make necessary recommendations for changes in the school's protocols, supplies, and individual student ECPs.
- Act as a liaison between the medical home and the local school of the student who sustained the emergency to ensure adequate communication, perform any needed changes/modifications to the student health plan, and assist the primary care clinician in ensuring the student's safe return to class after an emergency.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Medical Home Initiatives for Children With Special Needs Project Advisory Committee

The Medical Home

ABSTRACT. The American Academy of Pediatrics proposed a definition of the medical home in a 1992 policy statement. Efforts to establish medical homes for all children have encountered many challenges, including the existence of multiple interpretations of the "medical home" concept and the lack of adequate reimbursement for services provided by physicians caring for children in a medical home. This new policy statement contains an expanded and more comprehensive interpretation of the concept and an operational definition of the medical home.

ABBREVIATION. AAP, American Academy of Pediatrics.

The American Academy of Pediatrics (AAP) believes that the medical care of infants, children, and adolescents ideally should be accessible, continuous, comprehensive, family centered, coordinated,[1] compassionate, and culturally effective.[2] It should be delivered or directed by well-trained physicians who provide primary care[3] and help to manage and facilitate essentially all aspects of pediatric care. The physician should be known to the child and family and should be able to develop a partnership of mutual responsibility and trust with them. These characteristics define the "medical home." In contrast to care provided in a medical home, care provided through emergency departments, walk-in clinics, and other urgent-care facilities, though sometimes necessary, is more costly and often less effective. Although inadequate reimbursement for services offered in the medical home remains a very significant barrier to full implementation of this concept,[4,5] reimbursement is not the subject of this statement. It deserves coverage in other AAP forums.

Physicians should seek to improve the effectiveness and efficiency of health care for all children and strive to attain a medical home for every child in their community.[6] Although barriers such as geography, personnel constraints, practice patterns, and economic and social forces create challenges, the AAP believes that comprehensive health care for infants, children, and adolescents should encompass the following services:

1. Provision of family-centered care through developing a trusting partnership with families, respecting their diversity, and recognizing that they are the constant in a child's life.
2. Sharing clear and unbiased information with the family about the child's medical care and management and about the specialty and community services and organizations they can access.
3. Provision of primary care, including but not restricted to acute and chronic care and preventive services, including breastfeeding promotion and management,[7] immunizations, growth and developmental assessments, appropriate screenings, health care supervision, and patient and parent counseling about health, nutrition, safety, parenting, and psychosocial issues.
4. Assurance that ambulatory and inpatient care for acute illnesses will be continuously available (24 hours a day, 7 days a week, 52 weeks a year).
5. Provision of care over an extended period of time to ensure continuity. Transitions, including those to other pediatric providers or into the adult health care system, should be planned and organized with the child and family.
6. Identification of the need for consultation and appropriate referral to pediatric medical subspecialists and surgical specialists. (In instances in which the child enters the medical system through a specialty clinic, identification of the need for primary pediatric consultation and referral is appropriate.) Primary, pediatric medical subspecialty, and surgical specialty care providers should collaborate to establish shared management plans in partnership with the child and family and to formulate a clear articulation of each other's role.
7. Interaction with early intervention programs, schools, early childhood education and child care programs, and other public and private community agencies to be certain that the special needs of the child and family are addressed.
8. Provision of care coordination services in which the family, the physician, and other service providers work to implement a specific care plan as an organized team.
9. Maintenance of an accessible, comprehensive, central record that contains all pertinent information about the child, preserving confidentiality.

PEDIATRICS (ISSN 0031 4005).

TABLE 1. Desirable Characteristics of a Medical Home

Accessible
Care is provided in the child's or youth's community.
All insurance, including Medicaid, is accepted.
Changes in insurance are accommodated.
Practice is accessible by public transportation, where available.
Families or youth are able to speak directly to the physician when needed.
The practice is physically accessible and meets Americans With Disabilities Act[10] requirements.
Family centered
The medical home physician is known to the child or youth and family.
Mutual responsibility and trust exists between the patient and family and the medical home physician.
The family is recognized as the principal caregiver and center of strength and support for child.
Clear, unbiased, and complete information and options are shared on an ongoing basis with the family.
Families and youth are supported to play a central role in care coordination.
Families, youth, and physicians share responsibility in decision making.
The family is recognized as the expert in their child's care, and youth are recognized as the experts in their own care.
Continuous
The same primary pediatric health care professionals are available from infancy through adolescence and young adulthood.
Assistance with transitions, in the form of developmentally appropriate health assessments and counseling, is available to the child or youth and family.
The medical home physician participates to the fullest extent allowed in care and discharge planning when the child is hospitalized or care is provided at another facility or by another provider.
Comprehensive
Care is delivered or directed by a well-trained physician who is able to manage and facilitate essentially all aspects of care.
Ambulatory and inpatient care for ongoing and acute illnesses is ensured, 24 hours a day, 7 days a week, 52 weeks a year.
Preventive care is provided that includes immunizations, growth and development assessments, appropriate screenings, health care supervision, and patient and parent counseling about health, safety, nutrition, parenting, and psychosocial issues.
Preventive, primary, and tertiary care needs are addressed.
The physician advocates for the child, youth, and family in obtaining comprehensive care and shares responsibility for the care that is provided.
The child's or youth's and family's medical, educational, developmental, psychosocial, and other service needs are identified and addressed.
Information is made available about private insurance and public resources, including Supplemental Security Income, Medicaid, the State Children's Health Insurance Program, waivers, early intervention programs, and Title V State Programs for Children With Special Health Care Needs.
Extra time for an office visit is scheduled for children with special health care needs, when indicated.
Coordinated
A plan of care is developed by the physician, child or youth, and family and is shared with other providers, agencies, and organizations involved with the care of the patient.
Care among multiple providers is coordinated through the medical home.
A central record or database containing all pertinent medical information, including hospitalizations and specialty care, is maintained at the practice. The record is accessible, but confidentiality is preserved.
The medical home physician shares information among the child or youth, family, and consultant and provides specific reason for referral to appropriate pediatric medical subspecialists, surgical specialists, and mental health/developmental professionals.
Families are linked to family support groups, parent-to-parent groups, and other family resources.
When a child or youth is referred for a consultation or additional care, the medical home physician assists the child, youth, and family in communicating clinical issues.
The medical home physician evaluates and interprets the consultant's recommendations for the child or youth and family and, in consultation with them and subspecialists, implements recommendations that are indicated and appropriate.
The plan of care is coordinated with educational and other community organizations to ensure that special health needs of the individual child are addressed.
Compassionate
Concern for the well-being of the child or youth and family is expressed and demonstrated in verbal and nonverbal interactions.
Efforts are made to understand and empathize with the feelings and perspectives of the family as well as the child or youth.
Culturally effective
The child's or youth's and family's cultural background, including beliefs, rituals, and customs, are recognized, valued, respected, and incorporated into the care plan.
All efforts are made to ensure that the child or youth and family understand the results of the medical encounter and the care plan, including the provision of (para)professional translators or interpreters, as needed.
Written materials are provided in the family's primary language.

Physicians should strive to provide these services and incorporate these values into the way they deliver care to all children. (Note: pediatricians, pediatric medical subspecialists, pediatric surgical specialists, and family practitioners are included in the definition of "physician.")

10. Provision of developmentally appropriate and culturally competent health assessments and counseling to ensure successful transition to adult-oriented health care, work, and independence in a deliberate, coordinated way.

Medical care may be provided in various locations, such as physicians' offices, hospital outpatient clinics, school-based and school-linked clinics, community health centers, and health department clinics. Regardless of the venue in which the medical care is provided, to meet the definition of medical home, a designated physician must ensure that the aforementioned services are provided (see Table 1 for more details).

The need for an ongoing source of health care—ideally a medical home—for all children has been identified as a priority for child health policy reform at the national and local level. The US Department of

Health and Human Services' *Healthy People 2010* goals and objectives state that "all children with special health care needs will receive regular ongoing comprehensive care within a medical home"[8] and multiple federal programs require that all children have access to an ongoing source of health care. In addition, the Future of Pediatric Education II goals and objectives state: "Pediatric medical education at all levels must be based on the health needs of children in the context of the family and community" and "all children should receive primary care services through a consistent 'medical home.'"[9] Over the next decade, with the collaboration of families, insurers, employers, government, medical educators, and other components of the health care system, the quality of life can be improved for all children through the care provided in a medical home.

abstract

FREE

The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics approved updated recommendations for the use of quadravalent (serogroups A, C, W-135, and Y) meningococcal conjugate vaccines (Menactra [Sanofi Pasteur, Swiftwater, PA] and Menveo [Novartis, Basel, Switzerland]) in adolescents and in people at persistent high risk of meningococcal disease. The recommendations supplement previous Advisory Committee on Immunization Practices and American Academy of Pediatrics recommendations for meningococcal vaccinations. Data were reviewed pertaining to immunogenicity in high-risk groups, bactericidal antibody persistence after immunization, current epidemiology of meningococcal disease, meningococcal conjugate vaccine effectiveness, and cost-effectiveness of different strategies for vaccination of adolescents. This review prompted the following recommendations: (1) adolescents should be routinely immunized at 11 through 12 years of age and given a booster dose at 16 years of age; (2) adolescents who received their first dose at age 13 through 15 years should receive a booster at age 16 through 18 years or up to 5 years after their first dose; (3) adolescents who receive their first dose of meningococcal conjugate vaccine at or after 16 years of age do not need a booster dose; (4) a 2-dose primary series should be administered 2 months apart for those who are at increased risk of invasive meningococcal disease because of persistent complement component (eg, C5–C9, properdin, factor H, or factor D) deficiency (9 months through 54 years of age) or functional or anatomic asplenia (2–54 years of age) and for adolescents with HIV infection; and (5) a booster dose should be given 3 years after the primary series if the primary 2-dose series was given from 2 through 6 years of age and every 5 years for persons whose 2-dose primary series or booster dose was given at 7 years of age or older who are at risk of invasive meningococcal disease because of persistent component (eg, C5–C9, properdin, factor H, or factor D) deficiency or functional or anatomic asplenia. *Pediatrics* 2011;128:1213–1218

INTRODUCTION

Neisseria meningitidis is an important cause of invasive bacterial disease in infants, children, adolescents, and young adults. The highest rates occur in children younger than 1 year. Unlike infants in whom serogroup B meningococcus causes the majority of invasive disease, the majority of cases in adolescents and young adults in the United States are caused by serogroups that are included in available vac-

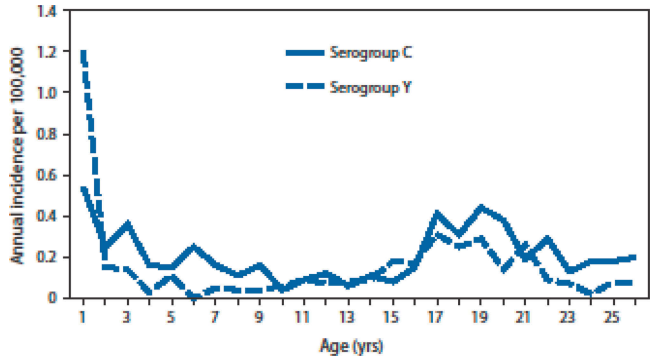

FIGURE 1
Annual incidence of meningococcal disease (serogroup C and serogroup Y), by age—Active Bacterial Core Surveillance (ABCs), United States 1999–2008. (Reproduced with permission from Centers for Disease Control and Prevention. *MMWR Morb Mortal Wkly Rep.* 2011;60[3]:73.)

cines. Adolescents and young adults experience rates of meningococcal disease that exceed those of the general population.[1] Increased risk begins at 14 years of age and persists through the age of 22 years (Fig 1).[1]

BACKGROUND AND RATIONALE

In 2005, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics developed recommendations for the use of the quadrivalent meningococcal conjugate vaccine (MCV4) with the objective of protecting adolescents as well as young adults aged 16 through 21 years, the time at which meningococcal disease rates peak.[2–6] Recent information on persistence of antibodies and the occurrence of breakthrough cases indicates that this recommendation for administration of MCV4 at 11 through 12 years of age may not provide protection for more than 5 years or throughout the full period of highest risk.

Certain immunocompromising conditions predispose to invasive meningococcal infection, including persistent complement component (such as C5–C9, properdin, factor H, or factor D) deficiency, functional or anatomic asplenia, and HIV infection. These immunocompromising conditions may reduce immune response to the meningococcal conjugate vaccine or may require higher titers of antibody to provide protection. Thus, people with these conditions are likely to benefit from a 2-dose primary series.

RATIONALE FOR ADDING A BOOSTER DOSE TO THE ADOLESCENT MENINGOCOCCAL IMMUNIZATION SCHEDULE

In 2005, when the recommendation was made for routine administration of meningococcal vaccine to 11- through 12-year-olds,[2,4] with catch-up immunization through 18 years of age, protective antibody concentrations were expected to persist for 10 years, through the period of increased vulnerability. Recent studies that evaluated antibody persistence after administration of MCV4 demonstrated that approximately 50% of persons vaccinated 5 years earlier will not have protective bactericidal antibody concentrations for serogroups C and Y (Table 1).[7–12] These serologic data demonstrated waning immunity 5 years after MCV4 administration, and serum antibody concentrations returned to levels similar to those detected in vaccine-naive individuals (Sanofi Pasteur [5-year follow-up of 11- to 18-year-olds at first dose], personal communication, sanfi provided slides with the data to the ACIP Meningococcal Working Group. Written communication/unpublished data.).

Additional data suggest that waning antibody concentrations result in increased susceptibility to meningococcal disease in older adolescents and young adults.[13] Comparisons of the numbers of estimated annual cases of serogroup C and Y disease in the period before the vaccine recommendation (2000–2004) with those from post–vaccine-recommendation years

TABLE 1 Summary of Serogroup C Bactericidal Antibody Persistence as Determined by Serum Bactericidal Activity (SBA) 2–5 Years After Vaccination With Menveo and/or Menactra

(2005–2009) revealed a greater reduction in the number of cases among adolescents aged 11 through 14 years (74% reduction) when compared with older adolescents of aged 15 through 18 years (27% reduction).

A case-control study that evaluated vaccine effectiveness of the first licensed MCV4 (Menactra [Sanofi Pasteur, Swiftwater, PA]) noted a decrease in vaccine effectiveness with time since immunization.[14] The overall vaccine effectiveness for adolescents immunized 0 to 5 years previously was 78.0% (95% confidence interval [CI]: 29%–93%). The effectiveness of the vaccine for persons vaccinated less than 1 year earlier, 1 year earlier, and 2 through 5 years earlier was 95% (95% CI: 10%–100%), 91% (95% CI: 10%–101%), and 58% (95% CI: 72%–89%), respectively. Although the 95% CIs around the point estimate were wide, the trend supports waning immunity. Data for vaccine effectiveness beyond 5 years since immunization are not available.

Between July 1, 2006, and October 31, 2010, the Centers for Disease Control and Prevention received 30 reports of serogroup C or Y invasive meningococcal disease in persons aged 15 through 22 years who had previously received a meningococcal conjugate vaccine; 12 of the 30 cases of meningococcal disease occurred in 2010. The mean age of people in these cases from 2010 was 18.2 years (range: 16–22 years). The mean time since they had received their meningococcal conjugate vaccine and the development of meningococcal disease was 3.25 years (range: 1.5–4.6 years). Five of these 12 people with breakthrough meningococcal disease had an underlying condition that might have affected their risk of meningococcal disease (Centers for Disease Control and Prevention, personal communication from Amanda Cohn MD, 2010).[1]

Cases of breakthrough meningococcal disease in MCV4 recipients seem to have clinical manifestations similar to disease occurring in vaccine-naive persons.[14,15] The lack of modification of illness suggests that an anamnestic immune response was not sufficient to modify disease severity. Recent data suggest that the memory response after meningococcal C conjugate vaccine is not rapid enough to protect against disease.[15] The incubation period for invasive meningococcal disease is usually less than 3 days. After initial priming with monovalent meningococcal C (MenC) conjugate vaccine, a memory response after a booster dose is not measurable until 5 to 7 days after the booster.[9]

Herd immunity seems to be important for long-term protection after widespread use of monovalent meningococcal C conjugate vaccine in the United Kingdom. Immunization coverage with MCV4 has been slow in the United States. In the 2009 National Immunization Survey-Teen, 53.6% of adolescents aged 13 through 17 years had received a dose of meningococcal vaccine.[16] To date, there is no evidence that this level of uptake of a single dose of MCV4 provides herd immunity in the United States.

Two studies have assessed the serologic response after a booster dose of MCV4 (Menactra).[7,14] When a booster dose was administered either 3 or 5 years after the first dose, the geometric mean titer elicited after the booster dose was substantially higher than that after the primary dose. This finding is consistent with expectations that the first dose of MCV4 primes the immune system and results in a strong response to the booster dose. Local and systemic reactions to the booster dose were comparable to reactions noted in persons who received a first dose. The duration of protective concentrations of antibody after a booster dose is not known. A booster dose administered at 16 through 18 years of age is expected to result in protective antibody concentrations through the age of 21 years.

The cost of a second dose of MCV4 in adolescents was considered in deliberations that led to the new recommendation. When using the cost-effectiveness measure of quality-adjusted life-years (QALYs), the 2-dose schedule had a lower cost per QALY than did the recommendation for a single dose given at 11 through 12 years of age, because the 2-dose series results in a greater reduction in the number of cases, morbidities, and mortalities attributable to invasive meningococcal disease.[17] Another option was a single dose of MCV4 at 15 years of age. This had the lowest cost per QALY of the 3 options considered (no change in recommendation; single dose at 15 years of age; and 2 doses: at 11–12 years of age and a booster at 16 years of age).[17] However, the cost per QALY for the single dose at 15 years of age and the 2-dose series at 11 and 16 years of age was not significantly different, and the 2-dose series resulted in fewer cases of invasive meningococcal disease and fewer deaths.[17]

RATIONALE FOR A 2-DOSE PRIMARY SERIES FOR PERSONS WITH PERSISTENT COMPLEMENT COMPONENT DEFICIENCY, FUNCTIONAL OR ANATOMIC ASPLENIA, OR HIV

People with persistent complement component deficiency or properdin deficiency respond similarly to healthy children when immunized with the quadrivalent meningococcal polysaccharide vaccine (MPSV4). However, their antibodies wane more quickly than do those of healthy children. Antibody data from this population after administration of MCV4 are lacking. Maintaining high antibody concentrations is important for people with complement component deficiency, because higher antibody con-

centrations are needed for other clearance mechanisms, such as opsonophagocytosis, to kill meningococci.[18,19]

Asplenic people achieve significantly lower geometric mean serum bactericidal activity than do healthy people immunized with monovalent meningococcal C conjugate vaccine. In 1 study, a protective antibody concentration was not achieved in 20% of asplenic people after vaccination.[20] However, the percentage of those in whom protective antibody concentrations did not develop decreased to 7% when a booster dose was given 2 months later, which suggests that a booster dose can increase the proportion of asplenic people who have protective antibody concentrations and might be able to achieve higher circulating antibody concentrations and improve immunologic memory.

Although HIV-infected children may have an increased risk of meningococcal disease, the magnitude of the increased risk has not been established. MCV4 is not routinely recommended for HIV-infected children younger than 11 years. Response rates to MCV4 among HIV-infected adolescents are lower than those in healthy adolescents. In 1 study, seroconversion rates were significantly lower in adolescents with $CD4^+$ T-lymphocyte percentages less than 15% or viral loads greater than 10 000 copies per mL.[21]

A 2-dose primary series has not been studied in older children or adolescents. However, immunogenicity and safety of a 2-dose primary series of MCV4 with either Menactra or Menveo (Novartis, Basel, Switzerland) have been evaluated in infants and young children. Infants who received a 2-dose primary series of Menactra at 9 months and 12 through 15 months of age developed high antibody titers after the second dose. Data provided by Sanofi Pasteur has noted decreases in antibody concentrations for some pneumococcal serotypes when Menactra is administered at the same time as Prevnar 7 (Wyeth Pharmaceuticals, Philadelphia, PA) at 9 months and 12 to 15 months of age. The clinical significance of these decreased antibody concentrations is not clear. Because pneumococcal infections are a more common problem in children with asplenia (functional or anatomic), it would be prudent to provide age-appropriate pneumococcal conjugate vaccines to asplenic children and provide MCV4 after completion of the pneumococcal conjugate vaccine series. Adverse events after 2 doses of Menveo given 2 months apart to children 2 through 5 years of age had similar rates as after a single dose.[22]

UPDATED MENINGOCOCCAL CONJUGATE VACCINE RECOMMENDATIONS

Routine Vaccination of Adolescents 11 Through 18 Years of Age

Routine immunization of adolescents with MCV4 is recommended at age 11 through 12 years along with a 1-time booster dose at 16 years of age (Table 2). For adolescents who receive their first dose of MCV4 at age 13 through 15 years, a 1-time booster should be administered, preferably at age 16 through 18 years, to provide additional protection during the period of increased risk. Adolescents who receive their first dose of MCV4 at or after 16 years of age do not need a booster

TABLE 2 Recommended Vaccination Schedule and Intervals

	Subgroup	Primary Vaccination	Booster Dose
9–23 mo, with high-risk conditions	Children with complement deficiencies	2 doses of MCV4, 3 mo apart	**If the first dose is received at 9 mo to 6 y of age and child remains at increased risk for meningococcal disease**, child should receive an additional dose of MCV4 3 y after primary vaccination; boosters should be repeated every 5 y thereafter
	Children with HIV, if another indication for vaccination exists	2 doses of MCV4, 3 mo apart	
	All others in this age group recommended for vaccination (travelers to the "meningitis belt," etc)	2 doses of MCV4, 3 mo apart (infants receiving the vaccine before travel can receive the doses as early as 2 mo apart)	
2–18 y, with high risk conditions[a]	Children with complement deficiencies or functional or anatomic asplenia	2 doses of MCV4, 2 mo apart	**If the first dose is received at 7 y of age or older and child remains at increased risk for meningococcal disease**, child should receive an additional dose of MCV4 5 y after primary vaccination; boosters should be repeated every 5 y thereafter
	Children with HIV, if another indication for vaccination exists	2 doses of MCV4, 2 mo apart	
	All others in this age group recommended for vaccination (travelers to the Meningitis Belt, etc)	1 dose of MCV4	
All other children aged 11–18 y	—	Routine vaccination with MCV4 at ages 11–12 y	**If vaccinated at age 11–12 y**, should receive a 1-time booster dose at the age of 16 y **If vaccinated at age 13–15 y**, should receive a 1-time booster dose at the age of 16–18 y

Currently, there are currently 2 licensed MCV4 products. One product, Menactra, is manufactured by Sanofi Pasteur and is licensed for use in persons aged 9 months through 55 years of age. The second product, Menveo, is manufactured by Novartis Vaccines and Diagnostics, Inc and is licensed for use in persons aged 2 through 55 years of age. A meningococcal polysaccharide vaccine is also available. This product is licensed for use in persons 2 years of age and older and may be used when meningococcal conjugate vaccine is unavailable or contraindicated.

[a] Includes children who have complement (eg, C5–C9, properdin, factor H, or factor) deficiencies or anatomic or functional asplenia and children with HIV infection; travelers to or residents of countries in which meningococcal disease is hyperendemic or epidemic; and children who are part of a community outbreak of a vaccine-preventable serogroup.

dose. Immunization with the MCV4 vaccine is not recommended after 21 years of age in healthy people because of diminished risk of meningococcal disease after that age.

People at Persistent Increased Risk of Meningococcal Disease

People with persistent complement deficiencies, functional or anatomic asplenia, or HIV infection should receive a 2-dose primary series given 2 months apart. Children aged 9 months or older with persistent complement deficiencies or functional or anatomic asplenia should receive the 2-dose primary series of MCV4. Children aged 2 years or older with functional or anatomic asplenia should receive the 2-dose primary series of MCV4. HIV-infected adolescents (>11 years) should receive a 2-dose primary series of MCV4 if they have not received any doses of MCV4 previously. HIV-infected children aged 2 through 10 years are likely to be at increased risk of meningococcal disease, but the risk is not as great as for invasive *Streptococcus pneumoniae*. MCV4 is not routinely recommended for HIV-infected children younger than 11 years. Providers may elect to give HIV-infected children aged 2 through 10 years a 2-dose primary series of MCV4. People with a history of complement component deficiency, asplenia, or HIV infection who have previously received a single dose of meningococcal conjugate vaccine as their primary dose should receive a second dose at least 2 months later. Booster doses should be given 3 years after the primary series if the primary 2-dose series was given from 2 through 6 years of age and 5 years after the primary series if the primary 2-dose series was given at 7 years of age or older. Boosters should then be given every 5 years. People who are at increased risk of meningococcal disease other than those with immunocompromising conditions (microbiologists who work routinely with *N meningitidis* or travelers to or residents of countries in which meningococcal disease is hyperendemic) should receive a single-dose primary series. If they remain at increased risk, a booster dose should be given 3 years later if the primary dose was given from 2 through 6 years of age and 5 years after the last dose if the previous dose was given at 7 years of age or older. If they continue to remain at risk, additional boosters should be given every 5 years.

IMPLEMENTATION ISSUES

Whenever feasible, the same brand of vaccine should be used for all doses of the vaccination series. Data are limited on the interchangeability of meningococcal vaccine products from different manufacturers. A small study revealed similar antibody responses when either Menactra or Menveo was given after a first dose of Menactra. If vaccination providers do not know or do not have available the brand of vaccine product previously administered, any product should be used to continue or complete the series. People who received quadrivalent meningococcal polysaccharide vaccine 5 or more years previously and remain at risk of meningococcal disease should be revaccinated with MCV4. There are no data to provide guidance as to how to address future needs for MCV4 vaccine in children who may have received vaccine products overseas that differ from products available in the United States. If these children remain at risk of meningococcal disease (healthy adolescent aged 11 years or older, complement deficiency, asplenia, etc), it would be prudent to provide MCV4 according to the recommendations for their risk group.

MCV4 is safe and immunogenic among nonpregnant women aged 11 through 55 years. No data are available on the safety of MCV4 during pregnancy. MCV4 should only be given to a pregnant woman if the benefit of providing vaccine during pregnancy outweighs the potential for risk. There is no contraindication to administering any dose of MCV4 to a woman who is breastfeeding.

Some states, secondary schools, colleges, or universities have policies that require immunization against meningococcal disease as a condition of enrollment. A single dose of MCV4 5 or fewer years before matriculation should be considered acceptable. A booster dose should be administered before matriculation if the adolescent was immunized more than 5 years previously.

Menstruation in Girls and Adolescents: Using the Menstrual Cycle as a Vital Sign

Guidance for the Clinician in Rendering Pediatric Care

AMERICAN ACADEMY OF PEDIATRICS
Committee on Adolescence

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS
Committee on Adolescent Health Care

ABSTRACT

Young patients and their parents often are unsure about what represents normal menstrual patterns, and clinicians also may be unsure about normal ranges for menstrual cycle length and amount and duration of flow through adolescence. It is important to be able to educate young patients and their parents regarding what to expect of a first period and about the range for normal cycle length of subsequent menses. It is equally important for clinicians to have an understanding of bleeding patterns in girls and adolescents, the ability to differentiate between normal and abnormal menstruation, and the skill to know how to evaluate young patients' conditions appropriately. Using the menstrual cycle as an additional vital sign adds a powerful tool to the assessment of normal development and the exclusion of pathological conditions.

INTRODUCTION

Young patients and their parents frequently have difficulty assessing what constitutes normal menstrual cycles or patterns of bleeding. Girls may be unfamiliar with what is normal and may not inform their parents about menstrual irregularities or missed menses. Additionally, girls often are reluctant to discuss this very private topic with a parent, although they may confide in another trusted adult. Some girls will seek medical attention for cycle variations that actually fall within the normal range. Others are unaware that their bleeding patterns are abnormal and may be attributable to significant underlying medical issues with the potential for long-term health consequences.

Clinicians also may be unsure about normal ranges for menstrual cycle length and for amount and duration of flow through adolescence. Clinicians who are confident in their understanding of early menstrual bleeding patterns may convey information to their patients more frequently and with less prompting; girls who have been educated about menarche and early menstrual patterns will experience less anxiety when they occur.[1] By including an evaluation of the menstrual cycle as an additional vital sign, clinicians reinforce its importance in assessing overall health status for both patients and parents. Just as abnormal blood pressure, heart rate, or respiratory rate may be key to the diagnosis of potentially serious health conditions, identification of abnormal menstrual patterns through adolescence may permit early identification of potential health concerns for adulthood.

NORMAL MENSTRUAL CYCLES

Menarche

From the early 1800s to the mid-1950s, menarche occured at increasingly younger ages in the United States, but there has been no further decline in the last 40 to 50 years. This finding also has been seen in international studies of other developed urban populations.[2] The US National Health and Nutrition Examination Surveys have found no significant change in the median age at menarche over the past 30 years except among the non-Hispanic black population, which has a 5.5-month earlier age at menarche than it did 30 years ago.[3] Age at menarche varies internationally and especially in less developed countries; in Haiti, for example, the mean age at menarche is 15.37 years.[4,5] This knowledge may be especially pertinent for practitioners with a large number of immigrant families in their patient population. Although onset of puberty and menarche typically occur at a later age in females from less well-developed nations, 2 large studies have confirmed that a higher gain in body mass index (BMI) during childhood is related to an earlier onset of puberty.[6,7] This earlier onset of puberty may result from attainment of a minimal requisite body mass at a younger age. Other possible explanations for the perceived trend in timing and progression of puberty are environmental factors, including socioeconomic conditions, nutrition, and access to preventive health care.[8]

Despite variations worldwide and within the US population, median age at menarche has remained relatively stable, between 12 and 13 years, across well-nourished populations in developed countries. The median age of females when they have their first period or menarche is 12.43 years (see Table 1).[3] Only 10% of females are menstruating at 11.11 years of age; 90% are menstruating by 13.75 years of age. The median age at which black female adolescents begin to menstruate is earlier (12.06 years of age) than the median age for Hispanic (12.25 years of age) and non-Hispanic white (12.55 years of age) females.[3] Although black girls start to mature earlier than non-Hispanic white and Hispanic girls, US females complete secondary sexual development at approximately the same ages.[9]

Menarche typically occurs within 2 to 3 years after thelarche (breast budding), at Tanner stage IV breast development, and is rare before Tanner stage III development.[10] Menarche correlates with age at onset of puberty and breast development. In girls with early onset of breast development, the interval to menarche is longer (3 years or more) than in girls with later onset.[11–13] By 15 years of age, 98% of females will have had menarche.[3,14]

Traditionally, primary amenorrhea has been defined as no menarche by 16 years of age; however, many diagnosable and treatable disorders can and should be detected earlier, using the statistically derived guideline of 14 to 15 years of age.[3,14] Thus, an evaluation for primary amenorrhea should be considered for any adolescent who has not reached menarche by 15 years of age or has not done so within 3 years of thelarche. Accordingly, lack of breast development by 13 years of age also should be evaluated.[15]

TABLE 1 **Normal Menstrual Cycles in Young Females**

Menarche (median age): 12.43 years
Mean cycle interval: 32.2 days in first gynecologic year
Menstrual cycle interval: typically 21–45 days
Menstrual flow length: ≤7 days
Menstrual product use: 3–6 pads/tampons per day

Cycle Length and Ovulation

Menstrual cycles are often irregular through adolescence, particularly the interval from the first to the second cycle. According to the World Health Organization's international and multicenter study of 3073 girls, the median length of the first cycle after menarche was 34 days, with 38% of cycle lengths exceeding 40 days. Variability was wide: 10% of females had more than 60 days between their first and second menses, and 7% had a first cycle length of 20 days.[16] Most females bleed for 2 to 7 days during their first menses.[17–19]

Early menstrual life is characterized by anovulatory cycles,[20,21] but the frequency of ovulation is related to both time since menarche and age at menarche.[21–23] Early menarche is associated with early onset of ovulatory cycles. When the age at menarche is younger than 12 years, 50% of cycles are ovulatory in the first gynecologic year (year after menarche).

By contrast, it may take 8 to 12 years after menarche until females with later-onset menarche are fully ovulatory.[23] Despite variability, most normal cycles range from 21 to 45 days, even in the first gynecologic year,[16–18] although short cycles of fewer than 20 days and long cycles of more than 45 days may occur. Because long cycles most often occur in the first 3 years postmenarche, the overall trend is toward shorter and more regular cycles with increasing age. By the third year after menarche, 60% to 80% of menstrual cycles are 21 to 34 days long, as is typical of adults.[16,18,24] An individual's normal cycle length is established around the sixth gynecologic year, at a chronologic age of approximately 19 or 20 years.[16,18]

Two large studies, one cataloging 275 947 cycles in 2702 females and another reporting on 31 645 cycles in 656 females, support the observation that menstrual cycles in girls and adolescents typically range from 21 to approximately 45 days, even in the first gynecologic year.[25,26] In the first gynecologic year, the fifth percentile for cycle length is 23 days and the 95th percentile is 90 days. By the fourth gynecologic year, fewer females are having cycles that exceed 45 days, but anovulation is still

significant for some, with the 95th percentile for cycle length at 50 days. By the seventh gynecologic year, cycles are shorter and less variable, with the fifth percentile for cycle length at 27 days and the 95th percentile at only 38 days. Thus, during the early years after menarche, cycles may be somewhat long because of anovulation, but 90% of cycles will be within the range of 21 to 45 days.[16]

ABNORMAL MENSTRUAL CYCLES

Prolonged Interval

A number of medical conditions can cause irregular or missed menses in adolescents. Although secondary amenorrhea has been defined as the absence of menses for 6 months, it is statistically uncommon for girls and adolescents to remain amenorrheic for more than 3 months or 90 days—the 95th percentile for cycle length. Thus, it is valuable to begin evaluation of secondary amenorrhea after the absence of menses for 90 days. Therefore, girls and adolescents with chaotically irregular cycles with more than 3 months between periods should be evaluated, not reassured that it is "normal" to have irregular periods in the first gynecologic years.

Irregular menses may be associated with many conditions, including pregnancy, endocrine disorders, and acquired medical conditions, because all of these conditions are associated with derangement of hypothalamic-pituitary endocrine function (see Table 2). Commonly, polycystic ovary syndrome (PCOS) causes prolonged intervals between menstrual periods, especially in patients with signs of androgen excess. The pathogenesis of PCOS is unclear; many experts believe that PCOS results from primary functional intraovarian overproduction of androgen. Others believe that excessive luteinizing hormone secretion from the pituitary gland, which stimulates a secondary ovarian androgen excess, has a role in causing the disorder. Still others hypothesize that PCOS may be related to hyperinsulinism. Whatever its origins, PCOS accounts for 90% of hyperandrogenism among females and, by definition, is characterized by amenorrhea and oligomenorrhea. Before the diagnosis is confirmed, hyperprolactinemia, adrenal and ovarian tumors, and drug effects (such as those caused by danazol and several psychotropic medications) must be ruled out. Additionally, although uncommon in the general population, congenital adrenal hyperplasia should be ruled out by a negative 17-α-hydroxyprogesterone test result (serum concentrations less than 1000 ng/dL).[27] Treatment of PCOS should target menstrual irregularities, hirsutism if present, obesity, or insulin resistance.

Menstrual irregularities can be caused by disturbance of the central gonadotropin-releasing hormone pulse generator as well as by significant weight loss, strenuous exercise, substantial changes in sleeping or eating habits, and severe stressors. Menstrual disturbances also occur with chronic diseases, such as poorly controlled diabetes mellitus; with genetic and congenital conditions, such as Turner syndrome; and with other forms of gonadal dysgenesis. The diagnosis of pregnancy always should be excluded, even if the history suggests the patient has not been sexually active.

Medications
Exercise-induced amenorrhea
Eating disorders (both anorexia and bulimia)
Tumors
Ovarian tumors
Adrenal tumors
Prolactinomas

Excessive Menstrual Flow

A female's first period usually is reported to be of medium flow, and the need for menstrual hygiene products is not typically excessive. Although experts typically report that the mean blood loss per menstrual period is 30 mL per cycle and that chronic loss of more than 80 mL is associated with anemia, this has limited clinical utility because most females are unable to measure their blood loss. However, a recent study in adult women confirms that the perception of heavy menstrual flow is correlated with a higher objective volume of blood loss.[28]

Attempts to measure menstrual blood loss on the basis of number of pads or tampons used per day or frequency of pad changes are subject to variables such as the individual's fastidiousness, her familiarity or comfort with menstrual hygiene products, and even variation among types and brands of pads or tampons.[29] Most report changing a pad approximately 3 to 6 times a day, although external constraints such as school rules and limited time between classes may make menstrual hygiene more problematic for adolescents than adults. Menstrual flow requiring changes of menstrual products every 1 to 2 hours is considered excessive, particularly when associated with flow that lasts more than 7 days at a time. This type of acute menorrhagia, although most often associated with anovulation, also has been associated with the diagnosis of hematologic problems, including von Willebrand disease and other bleeding disorders, or other serious problems, including hepatic failure and malignancy.[30–33]

The prevalence of von Willebrand disease is 1% in the general population. Von Willebrand disease is the most

common medical disorder associated with menorrhagia at menarche.[34] As many as 1 in 6 girls presenting to an emergency department with acute menorrhagia may have von Willebrand disease.[30] Therefore, hematologic disorders should be considered in patients presenting with menorrhagia—especially those presenting acutely at menarche. Hormonal treatment, in the form of estrogen therapy, may affect hematologic factors and mask the diagnosis. Blood collection to screen for hematologic disorders should be obtained before initiating treatment. Evaluating the patient may include referral to a hematologist or a specialized hemophilia treatment center for appropriate screening.

ANTICIPATORY GUIDANCE

Because development of secondary sex characteristics begins at ages as young as 8 years, primary care clinicians should include pubertal development in their anticipatory guidance to children and parents from this age on. Clinicians should take an ongoing history and perform a complete annual examination, including the inspection of the external genitalia. It is important to educate children and parents about the usual progression of puberty. This includes the likelihood that a child's initial breast growth may initially be unilateral and slightly tender. Breast development will likely then become bilateral, but some asymmetry is normal. Young females and their parents should understand that the progression of puberty also includes the development of pubic hair, which will increase in amount over time and become thicker and curlier. Additionally, clinicians should convey that females will likely begin to menstruate approximately 2 to 2.5 years after breast development begins, keeping in mind that recent studies have suggested that the onset of both breast development and menarche may occur slightly earlier for black girls than for white girls.[35] Young females should understand that menstruation is a normal part of development and should be instructed on use of feminine products and on what is considered normal menstrual flow. Ideally, both parents and clinicians can participate in this educational process.

EVALUATION

Once young females begin menstruating, evaluation of the menstrual cycle should be included with an assessment of other vital signs. By including this information with the other vital signs, clinicians emphasize the important role of menstrual patterns in reflecting overall health status. Clinicians should ask at every visit for the first date of the patient's last menstrual period. Clinicians should convey that the menstrual cycle is from the first day of a period to the first day of the next period and may vary in length.

Both the American Academy of Pediatrics and the American College of Obstetricians and Gynecologists recommend preventive health visits during adolescence to begin a dialogue and establish an environment where a patient can feel good about taking responsibility for her own reproductive health and feel confident that her concerns will be addressed in a confidential setting.[36,37] These visits are also an opportunity to provide guidance to young females and their parents on adolescent physical development based on data that define normal pubertal development, menarche, and menstrual cyclicity.[38] Even during visits with adult patients who interact with adolescents or have children, education about appropriate expectations and normal patterns for the adolescent menstrual cycle may be helpful guidance in the decision to consider evaluation.

Asking the patient to begin to chart her menses may be beneficial, especially if the bleeding history is too vague or considered to be inaccurate. Although uncommon, abnormalities do occur. Confirming normal internal and external genital anatomy with a pelvic examination or ultrasonography can rule out significant abnormalities. Therefore, one might consider the menstrual cycle as a type of vital sign and an indicator of other possible medical problems. Using menarche or the menstrual cycle as a sensitive vital sign adds a powerful tool to the assessment of normal hormonal development and the exclusion of serious abnormalities, such as anorexia nervosa, inflammatory bowel disease, and many other chronic illnesses. Menstrual conditions that suggest the need for further evaluation are listed in Table 3.

Because menarche is such an important milestone in physical development, it is important to be able to educate young females and their parents regarding what to expect of a first period and about the range for normal cycle length of subsequent menses. Girls who have been educated about early menstrual patterns will experience less anxiety as development progresses.[1] It is equally important for clinicians to have an understanding of bleeding patterns of young females, the ability to differentiate between normal and abnormal menstruation,

TABLE 3 Menstrual Conditions That May Require Evaluation

Menstrual periods that:

- Have not started within 3 years of thelarche
- Have not started by 13 years of age with no signs of pubertal development
- Have not started by 14 years of age with signs of hirsutism
- Have not started by 14 years of age with a history or examination suggestive of excessive exercise or eating disorder
- Have not started by 14 years of age with concerns about genital outflow tract obstruction or anomaly
- Have not started by 15 years of age
- Are regular, occurring monthly, and then become markedly irregular
- Occur more frequently than every 21 days or less frequently than every 45 days
- Occur 90 days apart even for one cycle
- Last >7 days
- Require frequent pad/tampon changes (soaking more than 1 every 1–2 hours)

and the skill to know how to evaluate the young female patient appropriately.

POLICY STATEMENT

AACAP/CWLA POLICY STATEMENT ON MENTAL HEALTH AND SUBSTANCE USE SCREENING AND ASSESSMENT OF CHILDREN IN FOSTER CARE

I. INTRODUCTION

Children who are removed from their primary caregivers because of suspected child abuse, neglect, or caregiver impairment have compelling and urgent mental health and are at risk for substance abuse disorders. The American Academy of Child and Adolescent Psychiatry (AACAP) and the Child Welfare League of America (CWLA) urge that these children receive immediate mental health and substance use screening followed by a comprehensive mental health and substance use assessment and periodic reassessments. This screening and assessment is to assure that these children receive prompt and appropriate mental health and substance use care. In order to achieve this, the screening and assessment should be:

II. COMPLETED IN A TIMELY WAY BY TRAINED AND QUALIFIED PROFESSIONALS

An initial mental health and substance use screening should be conducted within 24 hours of a child's placement in the care of the child welfare agency. The mental health and substance use screening is intended to identify children in urgent need of emergency mental health and substance use services, including youth whose behavior may pose a danger to themselves or others. Appropriate training should be provided on the screening protocol, and the individual administering the screening should have on-site or readily accessible mental health and substance use consultation. Ideally, the mental health and substance use screening will take place as part of a child's health examination upon entry into care and be conducted by a health professional with expertise in the developmental and mental health and substance use needs of children in foster care. [3]

Children who are removed from their family may require an intervention to address their separation issues immediately. The screening process should assess the internalized and externalized levels of distress the child is in regarding the separation and identify and support the child's strengths and successful coping strategies. Based on the outcome of the individualized screen the child minimally should be provided a triage intervention to address the child's feelings regarding the separation, the needs of the new placement, and to provide support for the child around the separation. It is recommended that the process be monitored to

ensure all children receive the mental health and substance use screen and appropriate intervention based on their individualized needs.

Children entering foster care and their families should receive a comprehensive mental health and substance use assessment within 60 days of placement, or sooner based on the severity of the child's needs as identified in the screening process. Assessments should be conducted by qualified mental health and substance use providers and include the active involvement of a child and adolescent psychiatrist. The comprehensive assessment should incorporate use of developmentally appropriate techniques and tools, be conducted in a comfortable and accessible setting, and address the child and family's strengths as well as needs. Informed consent should be obtained from the party or parties legally responsible for the child. Where indicated, the child or adolescent ought to be directly involved with procedures such as informed assent and be made partner to all assessments and treatment.

III. CHILD-FOCUSED

This process should include support for the child that acknowledges and addresses that removal from primary caregivers usually constitutes a psychological and social crisis for the child and family. The initial screening should be developmentally sensitive and seek to understand the child's internal experience of the placement and the nature of the child's attachments.

Placement often suddenly separates a child from everything familiar, including places (home, neighborhood, school) and people (primary caregivers, birth family, other family members, friends). This sudden and complete loss may result in unrecognized experiences of trauma and bereavement, which in turn can interfere with making new attachments and with the success of placement. New caregivers may need immediate advice on how to help the child make a positive adjustment. Children may need mental health and substance use services to cope with the trauma of placement, even in the absence of symptoms that constitute a psychiatric diagnosis. Children with internalizing problems, such as depression and anxiety, should receive the same consideration for mental health and substance use care as those with externalizing problems such as disruptive behavior. A child's wishes about placement and visitation should be ascertained and given as much weight as possible.

Children and adolescents should be assessed individually, and adequate time and preparation must be devoted to the assessment so that every child and adolescent has the opportunity to freely express his or her concerns.

IV. FAMILY-CENTERED

Approximately 80% of children placed outside of the home are returned to their family of origin. In order to achieve successful reunification, whenever possible,

we must consider the family of origin including siblings in assessments and services/supports for children placed in out-of-home care. Assessment and services/supports should be both child-focused and family-centered. The definition of family includes biological, foster and adoptive parents, grandparent and their partners, as well as kinship caregivers and others who have primary responsibility for providing love, guidance, food, shelter, clothing, supervision, and protection for children and adolescents (National Peer Technical Assistance Network, 1997). Finally, other persons may be considered members of the family for purposes of assessment and services/supports depending on the family of origin, their culture, ethnicity, language and the culture of their community.

Professionals are expected to work in partnership with the family to:

- assess the individual strengths and needs of the children;
- assess the parents/families strengths and needs to effectively deal with their children's emotional/mental health and substance use needs;
- identify ways to effectively provide the appropriate mental health and substance use services/supports to children and their family; to determine the level of involvement required with the foster family to successfully return the child home; and
- determine the level/type of relationship which is needed between the foster parents and the birth parents to ensure the emotional/mental health and substance use needs of the child are met.

Some specific decisions need to be made early because they have a strong impact on a child's experience while in foster care. These include the following:

- if a child and his birth family can be in immediate and continuing contact (face-to-face visitation and/or by telephone) to decrease the trauma of separation; and
- if the birth parents and foster parents can be expected to communicate with each other to maximize continuity and mutuality in accomplishing therapeutic goals.

Initial assessments and follow up assessments should address these questions as well.

Family members, as defined above, should be considered essential partners for successful treatment unless there is evidence to the contrary. Unless mandated otherwise by the courts, there should always be family involvement in the assessment and reassessment process, the development of the individualized treatment plan and the treatment/support process. All treatment plans should be individualized for the child and family and include family treatment services and supports as part of the plan unless the courts have restricted access/contact due to safety issues or there is evidence to the contrary. The treatment plan should also be in keeping with the permanency plan for the child as well as the family service

plan. When parents are mandated to not have contact and/or are not available to have contact with the child, the initial assessment and reassessments must address the impact of this loss upon the child and recommend effective interventions.

Placing a child in out-of-home care automatically expands the definition of their family, at least temporarily, to include the foster parents. This means including the foster parents' input in the ongoing assessment and treatment/support process. With family-centered practice, when indicated, families are supported and empowered to be an advocate for the needs of their child and for the services which will facilitate the family being successful in dealing with the emotional/mental health and substance use needs of their child. Other key components of family-centered practice include:

- μ# focusing on the whole family as the unit of attention;
- μ# organizing assistance in accord with the family's strengths while acknowledging but not emphasizing deficits;
- μ# except where a child's safety is at risk, service planning and delivery should take family priorities into consideration;
- μ# structuring treatment/support service delivery to ensure accessibility, minimal disruption of family integrity and routine; and
- μ# sharing results of assessments/reassessments with the birth family when a child is returning home (should this not have been done for some reason during out-of-home care) or the adoptive families when a child is being adopted.

V. CULTURALLY SENSITIVE AND ADMINISTERED IN A CULTURALLY COMPETENT MANNER

The assessment and reassessment of children and their families must take into account the influence of each family's heritage. This includes culture, ethnicity and religion and consists of-but is not limited to race, religion, gender, socioeconomic status, language, sexual orientation, geographic origin and location and their immigration status.

Clinicians and/or staff who perform assessments should develop specialized knowledge and understanding about the history, tradition, values, family systems, perceptions, communication styles and artistic expressions of major client groups that they serve (NASW, 2001). Acquiring this knowledge should be accompanied by a regular assessment of their own personal values, beliefs, and biases in an effort to inform their practice and increase the quality of relationships they have with the children and families they serve (NASW, 2001).

This cross-cultural knowledge and personal awareness should be considered and applied to all approaches, skills, and techniques when working with children and

families (NASW, 2001). This kind of approach is necessary to understand the stigma and shame that many cultures associate with mental health and substance use issues. This insight will help clinicians and/or staff to better understand the kind of help people seek, the types of coping and communication styles, social supports needed and the level of resistance to treatment that can be expected from the children and families they serve (DHHS, 2001).

In all circumstances, special consideration should be given to ensure that there are adequate numbers of clinicians and staff who speak the language(s) of the client groups served and when not available that there are procedures in place for obtaining translation and/or interpreter services.

In addition, it is necessary to ensure that all screening tools, protocols, instruments and approaches used in the mental health and substance use screening, assessment, reassessment and treatment process are tailored for the population being served.

This commitment to cultural competence is essential to adequately assess and treat the mental health and substance use needs of children and families in the foster care system. It is recommended that there be a monitoring process to ensure this takes place (DHHS, 2001).

VI. PERIODICALLLY REPEATED WITH STANDARDIZED COLLECTION OF HEALTH INFORMATION

Since all foster children are at serious risk for mental health and/or substance use problems, they need individualized reassessment. The appropriate intervals depend on the severity of the child's disturbance and the family's needs and must be determined on a case-by-case basis that is consistent with requirements for case planning.

Children who are found at initial screening to have mental health and/or substance use problems need to be treated and reassessed at regular intervals as recommended by guidelines from AACAP, the American Academy of Pediatrics and/or CWLA. Reassessments should collect standardized information needed to ensure continuity of care.

Children who need psychotropic medications, including psychostimulants, should be reassessed following the AACAP Policy Statement, "Prescribing Psychoactive Medications for Children and Adolescents." During the initial stabilization period, children should be reassessed frequently and have immediate access to a psychiatrist if they experience any difficulty adjusting to their medication. Once the child is stabilized on a standard dose of medication, he or she should be reassessed in a face-to-face interview no less than every three months. When children are moved to a new placement, all medications should be turned over to the caregiver at the next placement to ensure continuity of care. Once a child has

settled into his or her new placement, all medications should be reassessed to determine if any adjustments are needed. It is crucial that this assessment and reassessment process include clear and regular communication between the clinical service provider and the caregiver(s) where the child is living.

Children and families who are adjusting well to foster care and are in no apparent need of mental health and substance use intervention should also be reassessed in face-to-face interviews at regular intervals-no less than every 12 months or as requested by the child or family. Given the level of vulnerability of children and the potential to be re-victimized/traumatized, professionals must assess and reassess to ensure the ongoing safety and well-being of children in out-of-home care.

Children about to leave the system whether moving to self-sufficiency or returning home should be reassessed. Recognition should be given that children moving into self-sufficiency may still require assistance in dealing with issues related to their family and their individual mental health and substance use needs. Those who need, or desire further mental health and substance use services should have adequate referral and follow-up plans in place to assure proper continuity of care. All parties involved in the child's care should be notified of any follow-up appointments. The clinician should follow the standard procedures (locale specific) that are in place to document summary reports and to assure that the child's health data is conveyed to the next provider or caregiver.

VII. CONCLUSION

These most vulnerable and traumatized of children need and deserve appropriate screening, comprehensive assessment and reassessments, effective mental health and substance use treatment services/supports provided by appropriately trained individuals, including the active involvement, when indicated, of a child and adolescent psychiatrist. We urge local, state and federal authorities to work together with the mental health, substance use and child welfare professions and other relevant child and family serving systems to assure that these children's mental health and substance use needs are met and that the children have the skills, capacities, and support necessary to thrive.

CLINICAL REPORT

Minors as Living Solid-Organ Donors

Guidance for the Clinician in Rendering Pediatric Care

Lainie Friedman Ross, MD, PhD, J. Richard Thistlethwaite, Jr, MD, PhD, and the Committee on Bioethics

ABSTRACT

In the past half-century, solid-organ transplantation has become standard treatment for a variety of diseases in children and adults. The major limitation for all transplantation is the availability of donors, and the gap between demand and supply continues to grow despite the increase in living donors. Although rare, children do serve as living donors, and these donations raise serious ethical issues. This clinical report includes a discussion of the ethical considerations regarding minors serving as living donors, using the traditional benefit/burden calculus from the perspectives of both the donor and the recipient. The report also includes an examination of the circumstances under which a minor may morally participate as a living donor, how to minimize risks, and what the informed-consent process should entail. The American Academy of Pediatrics holds that minors can morally serve as living organ donors but only in exceptional circumstances when specific criteria are fulfilled. *Pediatrics* 2008;122:454–461

INTRODUCTION

In the past half-century, solid-organ transplantation has become standard treatment for a variety of diseases in children and adults. The major limitation for all transplantation is the availability of donors. The gap between demand and supply is attributable to a multitude of factors including failure to procure consent for many potential deceased donors, the growing number of indications for transplantation, and the realization that transplantation can benefit an increasing number of individuals with end-stage organ failure, including those with significant comorbidities. Despite numerous policy attempts to increase the number of deceased donor organs[1] and the acceptance of "expanded-criteria donors,"[2,3] the deceased donor supply is inadequate to meet the growing demand. Instead, living donors constitute an ever-growing proportion of organ donors. Initially restricted to first-degree genetic relatives, living donation then expanded to include more distant genetically related relatives (eg, cousins), emotionally related relatives (eg, spouses), and friends (those with whom the recipient had a strong personal bond) and more recently has expanded to include altruistic strangers.[4] Liberalization of medical criteria and upper age criteria also has permitted more people to qualify as living donors. In 2001, for the first time, more kidney donors were living than deceased, and the trend persists.[5] Living donors have also provided segments of livers and, less frequently, lungs, pancreases, intestines, and skin for transplantation.

Although minors are more likely to be organ recipients than living donors, minors have served as living donors. The American Academy of Pediatrics (AAP) believes that minors may ethically serve as living donors but only in specific, limited circumstances. A minor will most likely be considered to serve as a living organ donor for a minor sibling, although there may be rare cases in which it is morally appropriate for a donation to be considered from a minor donor to an adult family member.

Participation of minors as living organ donors raises serious ethical issues. This report includes a discussion of the ethical considerations regarding minors serving as living donors, using the traditional benefit/burden calculus from the perspectives of both the donor and the recipient. The report also includes an examination of the circumstances under which a minor may morally participate as a living donor, how to minimize risks, and what the informed-consent process should entail.

HISTORY

The first successful kidney transplant between identical twins occurred in 1954.[6] Three years later, judicial rulings permitted renal transplants between 3 sets of identical-twin minors (aged 14, 14, and 19 years, because at that time, the age of majority was 21 years).[7–9] Although live children continue to be a rare source of solid organs in the United States, data from the United Network for Organ Sharing (UNOS) reveal that at least 60 children younger than 18 years served as living kidney donors between 1987 and 2000, during which time approximately 40 000 live kidney

donations occurred.[10] At least 4 minors in the United States have served as living liver donors since 1989.[10] There is a case report from Switzerland of a 13-year-old donating a portion of small bowel to an identical twin.[11] Although children younger than 10 years rarely serve as living organ donors, there is a case report in the literature of a 7-year-old identical twin serving as a kidney donor[12] and a second documented kidney donation by a child younger than 10 years on the Organ Procurement and Transplantation Network data report.[13]

RISK/BENEFIT RATIO

To determine if a living organ donation is ethically permissible, one must examine the risks and benefits to the donor and the recipient. Although ethically the risk/benefit calculation focuses mainly on the risks and benefits to the donor, it also considers the risks and benefits to the recipient and his or her family. The focus on the donor is to ensure that the donation promotes the donor's interests and respects the donor as an end in himself or herself and not merely as a utilitarian organ source. Consider, for example, a donation by someone with cognitive disabilities. There have been several court cases that have prohibited such donations on the grounds that the potential psychological and emotional benefit may be minimal or nonexistent if the individual does not currently understand why he or she is being asked to undergo the donor operation, particularly if that individual is not expected ever to understand the purpose.[14,15]

Risks and Benefits to the Donor

Although serving as an organ donor is not in the donor's medical best interest, it may be in the donor's best interest, all things considered. For example, there are potential psychological and emotional benefits that a minor donor may experience. The child may develop greater self-esteem and be seen as a hero by his or her family, friends, classmates, and larger community. There are also the potential benefits that a child accrues when his or her family is relieved of the burden of caring for a seriously ill family member.[16] For example, the donor may now receive more parental time and energy and more intrafamilial companionship and may benefit from improved financial resources. The psychological benefits may even accrue if the transplant fails, because the donor and his or her family can take solace in the fact that everything possible was done.

However, there are also psychological risks of serving as a living donor, although the data in children are limited.[17] Although some adults experience greater self-esteem after donating, others feel lower self-esteem, a sense of neglect, and lack of appreciation after the donation as the attention refocuses on the recipient.[17] Psychological risks may be greater in younger children, who may not understand the meaning of the lost body part or the reason for any scars.[18]

The donor may experience guilt and blame if the transplant fails and/or the recipient dies.[19] Several cases of adult donor suicides after failed transplants have been reported in the literature.[20] Still, the vast majority of donors understand this risk and do not regret their decision.[21–23]

Another risk is the potential coercive nature of the request: how can children refuse when their parents are asking them to donate?[16,17] And, if a child does refuse, additional guilt may result.[16,23] On the other hand, there are potential psychological and emotional risks from not being allowed to serve as a donor and the possibility of blame, by self or others, for the death of the family member if the child does not donate. These and other psychological risks and benefits need to be studied longitudinally.

There are some significant medical risks to the organ donor. First, there are the risks of surgery and anesthesia themselves. The calculated risk of mortality from kidney donation is approximately 2 in 10 000[24] and is up to 10-fold greater for a left lateral segment living liver donation (with the right-lobe having a greater risk than left-lobe).[25] There are also risks of significant morbidity, including postoperative bleeding and infections. All donors experience acute pain, and some develop chronic pain. The risks of serious or significant morbidity to kidney donors are often quoted at less than 5% regardless of the surgical method of procurement (eg, laparoscopic versus open),[26] although there is minimal experience with laparoscopic kidney procurement in children. The risks of serious or significant morbidity to liver donors cited in the literature are quite variable. One review described the range of serious morbidity for living liver donors between 0% and 69%, acknowledging that the discrepancies were attributable, in part, to individual center definition and recognition of morbidity as well as which liver lobe was being donated and the experience of the center.[27] Other reviews have described the risk of morbidity as ranging from 0% to 100%.[25,28] The true rate of morbidity and mortality for other solid-organ donations is difficult to establish (eg, lung, pancreas, and small bowel) because of the small numbers of reported cases in the literature and the lack of living-donor registries.[29]

Long-term risks for the potential child donor need to be considered as well, especially because there have been no long-term data on the safety of pediatric donation. One study followed 111 minors younger than 16 years who underwent unilateral nephrectomy for unilateral renal disease.[30] The study participants were reevaluated 7.1 to 51.9 years after surgery (average: 26.0 years). The researchers found that renal function was maintained at approximately 75% of the reported normal 2-kidney value.[30] Although adult data suggest that kidney donors are not at increased risk of chronic renal disease,[26,31,32] it was reported recently that 56 previous adult living donors were later placed on waiting lists for deceased kidney transplantation.[33] The contribution of the nephrectomy to the subsequent cause and timing of renal failure in these donors is unknown. Long-term follow-up is necessary to determine the risks to pediatric donors, because children, by the nature of their young age, will have a longer at-risk period of decreased renal reserve than will their adult counterparts. If the need for

the transplant is related to a genetic condition in the recipient, there is a risk that a genetically related donor may develop the same health problem and need a transplant at some time in the future; this may be particularly true of identical twins.

Although the worldwide experience of living pediatric liver donors is too small and too recent to allow statements about the actual long-term risks, these donors theoretically should suffer no long-term risks of liver failure, because the liver is a regenerative organ.

An additional risk to the donor is the restrictions in activities because of the donation. Frequently, organ donors are counseled to refrain from certain activities, especially those perceived as physically hazardous, despite the fact that guidelines have become less restrictive. The AAP now gives a "qualified yes" to participation in contact sports for children with only 1 kidney.[34] The US military will not enlist a person with 1 kidney,[35,36] although they may not necessarily discharge a serviceman who loses a kidney. No recommendations exist for donors of organs other than kidneys, although there should be no long-term restriction of activity for donors of partial organs, such as liver, intestine, and lung.

Benefits and Risks to the Child Recipient and the Family

The main benefit to the recipient is a healthy living graft. For kidney transplantation, if the donor and recipient are siblings, there is a 25% chance that they are HLA identical, which increases mean graft survival on a statistical basis. Ten-year graft survival for HLA-identical siblings is 75% (vs 56% for unrelated HLA-mismatched living donors and 44% for cadaveric donors).[37] If they are identical twins, the graft can survive even without the need for immunosuppression. The recipient's improved medical well-being benefits the recipient as well as the family and the donor. For other transplanted organs, there is no demonstrated benefit of HLA matching except that no organ transplants between identical twins require immunosuppression.

Risks to the child recipient are the medical risks of the transplantation procedure and the psychological and emotional risk of feeling indebted. There is also the potential risk of guilt should the donor sibling develop a significant chronic morbidity or die. Unless the children are identical twins, there are also the risks and adverse effects of immunosuppression, which include increased risk of infection and malignancies.

CONDITIONS UNDER WHICH A MINOR MAY PARTICIPATE AS A LIVING ORGAN DONOR

UNOS data regarding the participation of minors as donors[10] suggest a lack of stringent criteria. In response, the Amsterdam Consensus Panel, an international panel of experts in transplantation, accepted a proposal that minors younger than 18 years should never be allowed to donate.[24] The US Live Organ Donor Consensus Group, a national panel of experts in transplantation, however, argued that minors younger than 18 years could ethically serve but only in rare and exceptional circumstances.[38] The AAP concurs that it may be permissible for a minor to participate as a living organ donor provided that stringent criteria are met. The US consensus group offered 4 conditions, all of which must be satisfied for a minor to ethically serve as an organ donor. The following is a review and modification of these 4 criteria with a fifth criterion added to ensure that minors only serve in very rare and exceptional circumstances.

Condition 1

The first condition requires both the potential donor and recipient to be highly likely to benefit.[38] Condition 1 will most likely occur if donations by minors are restricted to donations within an intimate family setting in cases in which the psychological benefit to the potential donor is likely to be significant.[39] Moreover, minors should never be considered as potential donors for strangers[40] or people they only know through the Internet.

Condition 1 also implies that minors should not be asked to serve as living donors in cases in which the likelihood of success is low. The justification for this restriction is to reduce the psychological burden that the child donor may experience if the donation fails. Although all living donors may experience psychological distress (from either a successful or failed donation), competent adult donors should be allowed to accept lower benefit-to-risk opportunities, because they can give their own informed consent (see "Informed Consent").

Condition 2

The second condition is a requirement that "the surgical risk for the donor [be] extremely low."[38] Although this is not quantified, the risks of certain solid-organ donations such as that of a kidney are known to be smaller than others, such as that of the liver. This would suggest that minors should be restricted to serve as living kidney donors. One could envision the rare situation in which the older adolescent might be permitted to donate a left lateral segment of the liver on the basis of his or her ability to make an informed decision,[41] but the data to support the long-term safety of donation of lung, small bowel, and right liver lobes are currently insufficient to permit individuals younger than 18 years to donate these organs. Again, competent adults should have the right to take greater risks, although the transplant team, as moral agents, can decide that the risks are too great for any living donor.[42]

Condition 3

The third condition mandates that "all other opportunities for transplantation have been exhausted, no potential adult living donor is available, and timely and/or effective transplantation from a cadaver donor is unlikely."[38] To ensure that the child is truly a donor of last resort, children should not undergo donor evaluation until other potential living donors have been evaluated and found to be unable to donate. Children should also not be considered as living donors if deceased donors are likely to become available for their intended recipients.

The current kidney allocation system of the UNOS gives children special priority to receive a deceased donor kidney quickly,[43,44] so unless there are extenuating circumstances (eg, the recipient is highly sensitized), the need to donate to a sibling should be rare. The practice of splitting livers from deceased donors increases availability of deceased donor livers for young children.[45] These practices should eliminate the need for children to donate to their siblings in all but the rarest circumstances.

Condition 3 merits further clarification. For a child to serve as a donor of last resort, the recipient should be likely not to survive the wait to receive a deceased donor organ, despite being an excellent candidate for transplantation. Examples of such situations include cases in which the potential kidney recipient has exhausted sites for dialysis access or is highly sensitized to most potential donors but not the identified child donor.

Some have argued to bypass condition 3 when the donor and recipient are identical twins because of the additional benefit provided to the potential recipient, who will not require immunosuppression.[10,46] Although such a transplant provides great benefit to the recipient and, by extension, to the family, the benefit does not significantly alter the risks to the donor. If it is ethically impermissible for a minor to serve as living donor to a sibling because of the risks or because the child cannot make a voluntary and informed decision, the same standards should hold if the potential child donor is an identical twin.

Condition 4

The fourth condition requires "the minor [to] freely [agree] to donate without coercion (established by the independent donor advocate)."[38] The Advisory Committee on Organ Transplantation of the US Department of Health and Human Services recommends that all living donors have a donor advocate.[47] The donor advocate's primary obligation is to help donors understand the process and procedures and to protect and promote the interests and well-being of the donor. If the donor is a minor, the donor advocate should have (1) training and education in child development and child psychology, (2) skills in communicating with children and understanding children's verbal and nonverbal communication, and (3) working knowledge of transplantation and organ donation. Thus, donor advocacy will usually require partnering of professional colleagues to provide all these skills (an "advocacy team"). Even with an advocacy team, one must realize that the parental request for a child to serve as a donor for a family member may be perceived by the child as a request that cannot be refused. Minors who are evaluated to be donors must be evaluated for maturity and cognitive ability. Before they are allowed to give assent; they must be educated about living donation and counseled at various junctures that it is permissible to say no or to withdraw at any time before the procedure.

No minor should begin the consent process without the support of his or her parents and/or guardians. This decision is too momentous to be left to minors alone but should reflect a shared decision between minor and parent(s). That said, it is important to acknowledge that parents who give permission for their minor to donate have a potential conflict of interest by the nature of their relationship with both the donor and recipient, and because of the recipient's illness, the parents may be prone to focus more heavily on the effect of their decision on the health of the recipient. Parents must have some insight into their own conflicts of interest, and the donor advocacy team should help them analyze their own decision-making processes.

In addition, minors should only be allowed to donate within intimate families and only as a last resort. The child advocacy team should ensure that the degree of emotional intimacy can justify the risks from the perspective of the minor donor, that there are no alternative donors who are adults, and that dialysis is not a realistic possibility for the recipient as a bridge to deceased donor transplantation. Although the US Living Organ Donor Consensus Group did not provide a lower age limit, younger children clearly are less able to make an informed and voluntary decision. Using a Piagetian conception of development,[48] a firm lower age limit of 11 years can be set on the basis of the developmental stage of achieving abstract thought. Institutions that are uncomfortable with donation by preadolescents could alternatively choose a higher age cutoff (eg, 14 years). Nonetheless, recognizing that the cognitive and mental abilities of preadolescents and adolescents can vary greatly, an individual review of each prospective pediatric donor should be undertaken by the advocacy team to establish a child's maturity and understanding irrespective of his or her chronological age.

Condition 5

In addition to the 4 criteria enumerated by the US Live Organ Donor Consensus Group, the AAP would add a fifth criterion. Condition 5 would require the emotional and psychological risks to child donors to be minimized. Data in the bone marrow transplantation literature suggest that the risks can be minimized by preparing future donors through medical role-playing, allowing them to ask questions, and including them in the decision-making process.[49,50] Families need to be educated about the psychological risks that the donor may feel, particularly if most of the family's resources remain focused on the ill recipient. Families must also be educated about the importance of affirming the donor's role and the discomfort that some of the procedures may cause. These 5 criteria are summarized in Table 1.

TABLE 1 When Children May Ethically Serve as Solid-Organ Donors

Children may serve as solid-organ donors if:
Donor and recipient are both highly likely to benefit;
Surgical risk for the donor is extremely low;
All other deceased and living donor options have been exhausted;
The minor freely assents to donate without coercion (established by an independent advocacy team); and
Emotional and psychological risks to the donor are minimized

The first 4 criteria were adopted from the Live Organ Donor Consensus Group's consensus statement on the live organ donor[38] and modified.

DOMINO DONORS

In rare cases, an organ recipient may serve as a living donor in what is known as a "domino" donation.[51] For example, if an individual with cystic fibrosis undergoes a heart-lung transplant because of end-stage pulmonary disease, the removed heart may be "healthy" enough to be used for a solitary heart transplant. In that case, the recipient may simultaneously serve as a donor. This opportunity, although rare, may occur for both pediatric and adult patients, including pediatric patients who cannot understand what is occurring. In such cases, the procurement of the organ poses no additional medical risk to the donor and the use of organs ought to be permissible on the basis of normal standards of parental consent. The potential psychological risks and benefits to minors whose organs are used as domino donations have not been studied, but parents and physicians should consider the potential impact when deciding how much to explain to such minors.

INFORMED CONSENT

Legally, in pediatrics, parental permission is all that is required for consent to clinical treatment (with a few exceptions), whereas parental permission and the child's assent is necessary for research purposes. Ethically, there are guidelines that promote obtaining both parental permission and the child's assent for both clinical and research purposes.[41] The term "assent" is used to signal that the child's decision itself is not sufficient. It is understood to be an active agreement to participate and not a mere failure to object. Because serving as a solid-organ donor is not in a child's medical best interest, although for some children it may be in their overall best interest, the AAP believes that serving as a solid-organ donor should require, at minimum, both parental permission and the child's assent. This would disqualify all younger children and cognitively disabled children who are not able to give meaningful assent.[41]

In seeking parental permission, it is important for the transplant team to acknowledge the tension that parents experience when 1 of their children is ill and the conflict of interest created if they ask 1 of their healthy children to serve as a potential donor. The transplant team must emphasize that minors should only serve as donors of last resort, and the team should help the family consider whether there are other potential healthy adults and/or whether the ill child can wait for a deceased donor organ. When a minor is a potential donor, the transplant team must help the parents weigh the risks and benefits for the healthy child to serve as an organ donor for an ill family member and not just weigh the risks and benefits from the perspective of the family as a unit.

Discussions between the transplant team and the minor must be developmentally appropriate. The psychological and medical aspects of the donation should be explored in language that is understandable to the potential donor. The donor must be informed that the donation may have some acute and long-term health risks.[26] Although there have been few studies that explored the minor's psychological response to serving as an organ donor, the adult literature shows that individuals may have unexpected reactions to donation.[52–54] The minor needs to understand that the donated organ may fail or may be rejected by the recipient or that the original cause of the organ failure may recur and that the outcome is beyond his or her control.[19,21,53] The literature shows that many donors feel neglected after donation as the focus returns to the ill recipient.[52,55] Family members should be reminded that they need to be attentive to the needs of both the donor and the recipient.

Given the potential serious risks of living organ donation without concomitant medical benefit to the donor, minors should not be allowed to serve as solid-organ donors unless they can show some understanding of the risks and benefits of the donation and the procedures to be performed and affirm that their assent is voluntary.

Although what is required for a minor's assent to be adequate is not specified in any clinical or research guidelines,[41,56,57] the ability to understand the risks and benefits of donation and to make an informed decision improves with the developmental maturity of the minor.[41,48] There exist some data to suggest, at least in hypothetical cases, that older adolescents make decisions as well as their adult counterparts,[58–60] but there is not a specific age at which these capacities uniformly exist. Case-by-case review by the transplant team and an independent donor advocacy team is necessary. Additional consultations by a psychiatrist and/or an ethics committee are recommended for younger minors. If there are doubts that the minor can provide voluntary assent or if there is concern about the minor's comprehension of the risks, benefits, or procedures involved, the presumption should be to recommend against the child serving as an organ donor.

Although all children are vulnerable, children with disabilities are even more vulnerable than are healthy children. In the early court cases regarding kidney donation by incompetent individuals, some courts expressed concern about individuals with cognitive disabilities serving as organ donors, because the potential psychological and emotional benefit may be minimal or nonexistent if that individual does not understand why he or she is being asked to undergo the procurement.[14,15] There is also concern that families may be more willing to expose these individuals to risks than they would be with other family members.[61] To alleviate this concern, additional consultations by a psychiatrist and an ethics committee are recommended when a minor with cognitive disabilities is being considered as a potential living donor.

FOLLOW-UP

All children who serve as living solid-organ donors need long-term follow-up. Ideally, national donor registries should be established to collect short-term and long-term medical and psychological data that would allow for more accurate assessment of the risks, benefits, and outcomes of solid-organ donations. All minor donors and their guardians should be asked to authorize the long-term collection and storage of their health data. Parents should be responsible for authorizing the child's registration, but the child should be asked to re-consent

when he or she reaches the age of majority. Costs associated with maintaining living-donor registries should be estimated and included on a prorated basis in the reimbursement for the living-donor procedure. Currently, no such registries exist. Until national registries exist, the burden of collecting long-term follow-up data on pediatric donors must be assumed by transplant programs that perform such transplants.

ROLE OF THE COURTS

In the early years of transplantation (1950s to 1970s), judicial review was often sought when children were considered for organ donation.[39] These cases raised the issue of whether parents can authorize an invasive medical procedure on a healthy child that does not promote the child's medical well-being. The courts affirmed parental authority to authorize such procedures but required that the family demonstrate that the donation was in the donor's best interest, which frequently entailed the family demonstrating that the donor would experience psychological benefit from helping his or her sibling and psychological harm if not allowed to help. Numerous cases affirmed the guardian or parent's authority to authorize a donation from an incompetent adult (defined as a person who has reached the age of majority but lacks decision-making capacity) or child.[7–9,12,62,63] The courts prohibited some donations by minors and other incompetent individuals, particularly when (1) the donor had severe cognitive disabilities and would not benefit from the recipient's survival and (2) the donor was institutionalized and not an intimate member of the family.[14,15] The AAP holds that parental authority is necessary but not sufficient and that the minor's assent also is necessary.

Given that legal precedent for living organ donations by incompetent adults and children is firmly established, the AAP does not believe that every donation by a minor should require court approval. The real value of the judicial review process was historical in that it provided an independent advocate for the potential incompetent donor, a role that should now be fulfilled by donor advocacy teams.[47] A donor advocacy team with special pediatric expertise should be appointed for all individuals younger than 18 years who are being considered as living solid-organ donors. The donor advocacy team should ensure that (1) the minor understands the risks and benefits of the procedure, (2) the minor has the developmental maturity to understand that participation is voluntary, and (3) the minor's decision is voluntary. At least some of the conversations between the potential minor donor and the independent advocacy team should be held in the absence of other family members. If the minor is unwilling to serve or is emotionally or cognitively unable to appreciate, at some level, the risks and benefits or the procedures involved, the donor advocacy team should recommend against the donation. The donor advocacy team should also assess whether the recipient to whom the minor is being asked to donate is an appropriate candidate (eg, a child sibling with a high likelihood of doing well with the graft), that no adult living donors are available, and that waiting for a deceased donor transplant is not clinically appropriate. The donor advocacy team should help ensure that the parents are assessing the risks and benefits of a sibling donation from the independent perspectives of the recipient and of the donor. The donor advocacy team should affirm in writing that it has determined that the minor is operationally capable of understanding the donation procedures and that the minor actively assents to his or her participation. This process, then, should obviate the need for routine court review. Additional consultations (eg, with a psychiatrist and an ethics committee) are recommended for more complex cases such as those involving younger minors (eg, minors between 11 and 14 years old) or minors with cognitive disabilities, with court review as a last resort (eg, if a hospital lacks an ethics committee with sufficient expertise).[16]

CONCLUSIONS

The AAP believes that it is morally permissible for minors to serve as living donors in exceptional circumstances only when the aforementioned 5 criteria are met (see Table 1). A donor advocacy team with training in child development and child psychology, with experience in communication and role-playing with children and with understanding of transplantation and organ donation, should be required for all transplants that involve living minor donors. Hospital ethics committee and psychiatric consultations should be considered for more complex cases, such as when (1) the minor donor has cognitive disabilities or (2) there are procedural questions given the child's age (eg, when younger minors are being considered as kidney donors or when adolescents are being considered for donating a left lateral segment of the liver). Court review of pediatric donations should be rare (eg, if there is a question about whether the 5 criteria in Table 1 are met and the hospital lacks an ethics committee with sufficient expertise).

Parental permission is sufficient for domino donations by children. All other donations by minors should require both parental permission and the child's assent. Although identical twins offer an immunologic benefit as living donors, the best interest of the donor child still requires that they serve as donors of last resort and only if all 5 criteria listed in Table 1 are met.

Finally, long-term follow-up data should be collected to help determine the actual benefits and risks of donation, both medically and psychologically, for children. These data should then be used to modify future recommendations for the permissibility of minors to serve as living solid-organ donors.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Child Health Financing

Model Contractual Language for Medical Necessity for Children

ABSTRACT. The term "medical necessity" is used by Medicare and Medicaid and in insurance contracts to refer to medical services that are generally recognized as appropriate for the diagnosis, prevention, or treatment of disease and injury. There is no consensus on how to define and apply the term and the accompanying rules and regulations, and as a result there has been substantial variation in medical-necessity definitions and interpretations. With this policy statement, the American Academy of Pediatrics hopes to encourage insurers to adopt more consistent medical-necessity definitions that take into account the needs of children. ***Pediatrics*** **2005; 116:261–262;** ***medical necessity, medically necessary, managed care, contract.***

INTRODUCTION

The definition of "medical necessity" in this statement articulates model language that takes into account the unique needs of infants, children, adolescents, and young adults through 21 years of age. To the extent possible, this definition draws on model language developed by Stanford University.[1] For contractual purposes, an intervention will be covered if it is an otherwise covered category of service, not specifically excluded, and medically necessary.

DEFINITION

Health insurers should define medical necessity as health interventions for children that take into account all of the following criteria.

Scope of Health Problems

Medically necessary health interventions are intended to promote normal growth and development and prevent, diagnose, detect, treat, ameliorate, or palliate the effects of a physical, mental, behavioral, genetic, or congenital condition, injury, or disability. They should:

- assist in achieving, maintaining, or restoring health and functional capabilities without discrimination to the nature of a congenital/developmental anomaly;
- be appropriate for the age and developmental status of the child;
- take into account the setting that is appropriate to the specific needs of the child and family; and
- reflect current bioethical standards.

Evidence of Effectiveness

Medically necessary interventions must be reasonably expected to produce the intended results for children and to have expected benefits that outweigh potential harmful effects.

- For new interventions, for which clinical trials have not been conducted, effectiveness should be determined on the basis of clinical judgment after assessing the professional standards of care for children or consensus pediatric expert medical opinion.
- For existing interventions, effectiveness for children should be determined first on the basis of scientific evidence.* If insufficient scientific evidence for children is available, professional standards of care for children must be considered. If professional standards of care for children do not exist or are outdated or contradictory, decisions about existing interventions must be made on the basis of consensus pediatric expert opinion. Giving priority to scientific evidence does not mean that coverage of existing interventions should be denied in the absence of conclusive scientific evidence.

Value

- Medically necessary interventions must consider value for children on the basis of effectiveness. Cost-effective does not necessarily mean lowest price.

Process for Determining Medical Necessity

The American Academy of Pediatrics recommends that health plans describe the processes by which physicians and other health care professionals pro-

* Scientific evidence consists primarily of randomized, controlled clinical trials that either directly or indirectly demonstrate the effect of the intervention on health outcomes. If randomized, controlled clinical trials are not available, observational studies that demonstrate a causal relationship between the intervention and health outcomes can be used. Partially controlled observational studies and uncontrolled clinical series may be suggestive but do not by themselves demonstrate a causal relationship unless the magnitude of the effect observed exceeds anything that could be explained by either natural history of the medical condition or potential experimental biases.

doi:10.1542/peds.2005-0880

vide justification for the medical necessity of health interventions that they prescribe or order. Descriptions of these processes should include:

- how to provide clinical evidence supporting coverage of interventions that meet the needs of the individual child;
- how to incorporate appropriate pediatric medical or surgical subspecialty or expert opinion or testimony supporting coverage of interventions;
- how to assist families or physicians who wish to appeal medical-necessity denials; and
- how and when coverage decisions will be made.

Molecular Genetic Testing in Pediatric Practice: A Subject Review

ABSTRACT. Although many types of diagnostic and carrier testing for genetic disorders have been available for decades, the use of molecular methods is a relatively recent phenomenon. Such testing has expanded the range of disorders that can be diagnosed and has enhanced the ability of clinicians to provide accurate prognostic information and institute appropriate health supervision measures. However, the proper application of these tests may be difficult because of their scientific complexity and the potential for negative, sometimes unexpected, consequences for many patients. The purposes of this subject review are to provide background information on molecular genetic tests, to describe specific testing modalities, and to discuss some of the benefits and risks specific to the pediatric population. It is likely that pediatricians will use these testing methods increasingly for their patients and will need to evaluate critically their diagnostic and prognostic implications.

ABBREVIATION. FISH, fluorescence in situ hybridization.

Recent developments in genetic research have accelerated the discovery of individual genes and enhanced our understanding of how genes work and how gene abnormalities lead to disease. There is a growing list of molecular diagnostic tests, with estimates that 10 to 12 new tests become available each year. Such tests in an individual can provide the following: 1) diagnostic confirmation in a symptomatic patient, including genotype-phenotype correlation in some disorders; 2) carrier testing; and 3) presymptomatic testing for late-onset disorders. They also can be used for population-based screening to predict future genetic disease or assess the risk for complex conditions such as cancer, cardiovascular diseases, and neurodegenerative disorders in otherwise healthy people. Although this subject review focuses on molecular genetic testing that can be used to diagnose many genetic disorders, it should be remembered that this type of technology may not be appropriate for diagnosis of all, or even most, genetic conditions. For example, molecular genetic testing is available for diseases such as cystic fibrosis, sickle cell anemia, and Tay-Sachs disease, but the initial diagnosis of these disorders usually is established by other methods.

The molecular genetic technology underlying genetic testing is complex, as are the issues of pretest counseling about the indications, benefits, and limits of testing. Expert interpretation and explanation of results to individuals and families is essential. Furthermore, predictive genetic testing in children and adolescents leads to complicated medical, psychological, ethical, and legal issues.[1,2] Media publicity combined with entrepreneurial marketing of molecular genetic tests to physicians accentuates the need for the practicing pediatrician to be informed and aware of the technologies and issues related to testing. This subject review will familiarize pediatricians with diagnostic molecular genetic testing and the clinical and ethical issues to be considered in the diagnosis of children and adolescents. A number of other reviews are available regarding the laboratory techniques of this testing and can serve as excellent background resources for understanding the methods by which molecular genetic diagnostic testing is accomplished.[3–5]

BACKGROUND INFORMATION

It is estimated that anywhere from 50 000 to 100 000 genes are contained in the 46 chromosomes present in each human cell. A genetic locus is the place on homologous chromosome pairs where genes are located. Each gene is composed of 2 alternative copies known as alleles, one originating from the maternally derived chromosome and the other originating from the paternally derived chromosome of each chromosome pair. Genes are composed of DNA, and the products of genes are most often proteins that may be used for a variety of purposes, including structural development, regulation of cellular function, enzyme activity, and control of metabolic pathways.

Although most changes in the DNA base-pair composition of genes do not result in disease and are known as *polymorphisms,* some gene changes alter gene function to such a degree that clinical disease is manifested, and these are known as *mutations.* Most genetic disease is caused by single base-pair deletions, additions, or substitutions. However, some disorders are caused by large-scale gene abnormalities, such as deletions of the entire gene, that can be detected by newer methods of diagnosis, such as molecular cytogenetic analysis.

As in all diagnostic testing, it is most important that the clinician have a reasonable index of suspicion based on clinical signs and symptoms that suggest a specific diagnosis. For proper interpretation of molecular genetic test results, it is also important that clinicians understand the probabilistic nature of

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

these tests and the full implication of positive and negative results.

TYPES OF MOLECULAR TESTING

Indirect Analysis

Indirect analysis, often referred to as *linkage analysis,* is used when the location of a gene is known, although the gene itself and its function are not, or when the gene is known but the mutations are too heterogeneous to make direct analysis practical. In addition to its critical importance as a research tool, linkage analysis sometimes may be used to identify heterozygotes (carriers) and in prenatal diagnosis. This diagnostic strategy often requires more than one affected individual in more than one generation. Under such circumstances, it is possible to use markers within or around the gene to track its inheritance within a family.

Markers for DNA sequences in or near genes include restriction fragment length polymorphisms, variable number of tandem repeats, or microsatellite repeats. Any marker known to be linked to a disease gene can be used to track the transmission of the mutant allele within the family studied.

Direct Mutation Analysis

Direct mutation analysis is the approach used when the gene responsible for the condition has been identified and specific mutations within the gene have been characterized. The techniques used to detect these mutations are diverse, including allele-specific oligonucleotide hybridization analysis, heteroduplex analysis, Southern blot analysis, multiplex polymerase chain reaction analysis, and direct sequencing. A detailed description of these techniques is beyond the scope of this subject review but is available elsewhere.[6,7]

Direct mutation analysis is preferred over indirect analysis, as it is mutation-specific and does not require testing of parents or family members. As with all molecular genetic testing, however, it is also subject to limitations that must be recognized when ordering such testing. One of the major limitations of direct mutation analysis is that some diseases are caused by many mutations, not all of which are detected by a particular molecular test. A characteristic example of this complexity is in the molecular diagnosis of cystic fibrosis. In Caucasians of northern European background, about 70% of all cystic fibrosis mutations are accounted for by deletion of 3 base pairs that results in loss of a phenylalanine at position 508 of the cystic fibrosis transmembrane regulator protein. The other 30% of mutations number in the hundreds, making it impractical to screen a single person for all disease-causing alleles.[8] In other populations, such as those of African and Asian descent, there is an even smaller percentage of affected persons who can be detected from a single test or even a panel of the most common mutations, further complicating the use of molecular technology for clinical diagnosis and determination of carrier status. This huge diversity of mutations at a single genetic locus is known as *allelic heterogeneity.* Another limitation of mutation analysis is the result of another type of genetic heterogeneity, known as *locus heterogeneity,* in which mutations at 2 or more genetic loci can produce the same phenotype, as has been demonstrated for congenital sensorineural deafness, for which more than a dozen loci have been identified.[9]

It is important to recognize that mutation analysis, like most other forms of molecular diagnosis, can confirm a diagnosis when the test result is positive. However, a negative test result may not determine conclusively that the patient is unaffected. Table 1 provides a list of some of the genetic disorders for which direct mutation analysis is available. There are many other disorders that may be diagnosed by molecular genetic techniques. Geneticists and other subspecialists usually will have specialized information about testing for disorders within their area of spe-

TABLE 1. Selected Disorders Diagnosable by Direct Mutation Analysis

Disorder	Associated Features	Gene Symbol (Locus)
Achondroplasia	Macrocephaly, short-limbed dwarfism	FGFR3 (4p16)
Apert's disease	Acrocephaly, craniosynostosis, extensive syndactyly of fingers and toes	FGFR2 (10q26)
Charcot-Marie-Tooth disease, type 1A	Progressive sensory and motor neuropathy	PMP22 (17p11)
Crouzon's disease	Bicoronal synostosis, proptosis, hypertelorism	FGFR2 (10q26)
Cystic fibrosis	Recurrent pulmonary infections, exocrine pancreatic insufficiency	CFTR (7q31)
Familial adenomatous polyposis	Adenomatous polyps of the colon, high risk for colorectal cancer in early adulthood	APC (5q21)
Fragile X syndrome	Mental retardation, long-appearing face, large ears, macro-orchidism	FMR1 (Xq27)
Friedreich ataxia	Progressive ataxia, insulin resistance, concentric cardiomyopathy	FRA1 (9q13)
Hemophilia A	Deficient thrombostasis, hemarthrosis	F8C (Xq28)
Huntington's disease	Progressive loss of motor and cognitive function, usually beginning in adulthood	HD (4p16)
Muscular dystrophy (Duchenne's and Becker's)	Progressive muscle weakness	DMD (Xp21)
Myotonic dystrophy	Frontal balding, cataracts, progressive myotonia, infertility, cardiac conduction defects	DMPK (19q13)
Neurofibromatosis, type 1	Café au lait spots, neurofibromas, Lisch nodules, optic gliomas	NF1 (17q11)
Neurofibromatosis, type 2	Vestibular schwannomas and other intracranial and spinal tumors	NF2 (22q12)
Saethre-Chotzen syndrome	Craniosynostosis, ptosis, variable digital anomalies	TWIST (7p22)

cialty practice and are appropriate resources for evaluation, test selection and interpretation, and counseling of patients with suspected genetic disease.

Molecular Cytogenetic Analysis

Standard cytogenetic analysis is used to detect abnormalities in chromosome number or microscopically visible duplications or deletions of chromosomal material. With the advent of molecular cytogenetic techniques, such as fluorescence in situ hybridization (FISH), it is now possible to detect chromosomal rearrangements that are beyond the resolution of light microscopy used for standard cytogenetic analysis.

The use of FISH analysis for genetic diagnosis is made possible when a unique sequence of a gene or group of genes is known and when the disease in question is the result of a deletion of this critical region. This unique sequence, known as a *critical region,* is synthesized in the laboratory and labeled with a fluorescent marker. A sample from a patient is cultured as in standard cytogenetic analysis, and the fluorescent-labeled probe is added to the sample. If the unique sequence is present, the fluorescent probe will hybridize with it and be visible when viewed under a fluorescent microscope. A characteristic example of this type of genetic diagnosis is in a patient suspected to have Williams syndrome, which is known to be associated with a deletion of the elastin gene. When a sample is taken from an affected person and combined with the elastin probe, only 1 fluorescent signal will be visible, whereas 2 signals will be visible in the unaffected person, indicating that both copies of the elastin gene critical region are present. Table 2 provides a partial list of disorders that can be diagnosed by FISH analysis. In addition to detecting large-scale deletions of chromosome material, FISH also can be used to detect abnormalities of chromosome number or large-scale rearrangements that may not be detectable by standard cytogenetic techniques.

BENEFITS AND RISKS OF MOLECULAR DIAGNOSIS

Persons who are at increased risk for a genetic disorder live with uncertainty about their health and that of their children and extended family members. The use of molecular testing may eliminate this uncertainty. When one's health status is known, an appropriate treatment plan can be developed, including timely health supervision, anticipatory guidance, and institution of preventive measures.

Molecular genetic testing seldom poses significant physical risks. However, presymptomatic testing or carrier screening, particularly for diseases with serious health implications, can have profound effects and should not be performed without pretest counseling. The decision to have a test and its results can reverberate throughout the family. As a part of pretest counseling, it should be recognized that genetic testing may reveal information about the extended family, as well as the person being tested, and that a genetic test inadvertently may disclose family secrets involving paternity or adoption. Emotions elicited by test results can shift family dynamics. Family members identified as carrying the gene may feel anger, while one who is identified as a noncarrier may feel guilt for avoiding a disease that affects a close relative. It is also important to recognize that positive test results may be used to discriminate against the patient and family member in the areas of insurability, job hiring and promotion, and adoption of children.[10] Many states have adopted, or are in the process of adopting, laws that protect the privacy of genetic information.

SPECIAL CONCERNS FOR CHILDREN AND ADOLESCENTS

Special considerations must be given to genetic testing of children and adolescents. Because minors may be incapable of giving informed consent, they generally should not be tested except under the following specific circumstances that have been outlined in publications from a number of national organizations, including the American Academy of Pediatrics[2,11–13]: 1) testing should be offered when there are immediate medical benefits, such as institution of measures that can prevent the disease, delay its onset, limit its severity, or prevent secondary disabilities; and 2) testing also may be offered when there is a benefit to another family member and no anticipated harm to the minor. When the results of

TABLE 2. Microdeletion Syndromes Diagnosable by FISH

Syndrome	Site	Comments
Prader-Willi	(del)15q11 (pat)	Hypotonia, obesity, hypogonadism, mental retardation, small fingers

Langer-Giedion	(del)8q24	Characteristic facial features, exostosis, cone-shaped epiphysis, polydactyly, microcephaly, mental retardation
Alagille (arteriohepatic dysplasia)	(del)20p12	Neonatal and infantile cholestasis, peripheral artery stenosis and cardiovascular anomalies, typical facies

genetic testing will be used solely for future reproductive decisions or when parents request it and there are no benefits to the child, in most circumstances it should be deferred until the child can request such testing as an autonomous individual who is able to appreciate the emotional and social consequences, as well as the genetic facts, of the results.

Central to all types of genetic testing is the process of genetic counseling to ensure that the patient has adequate information to give truly informed consent, that he or she is psychologically prepared to cope with the results, and that patients and sometimes other family members receive assistance in understanding the medical, psychological, social, and legal implications of these findings.

SUMMARY

Molecular genetic testing is increasingly available in pediatric practice because of recent developments in genetic research and their rapid translation into clinical practice. The technology behind molecular genetic testing is complex, and such testing has its own limits. Furthermore, testing brings with it complex ethical, legal, and social issues, particularly for children and adolescents. Pediatricians must understand these issues and, through proper consultation with experts and specialists, aim to prepare families adequately before ordering molecular genetic testing.

CME

Practice parameter: Neuroimaging of the neonate

Report of the Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

L.R. Ment, MD; H.S. Bada, MD; P. Barnes, MD; P.E. Grant, MD; D. Hirtz, MD; L.A. Papile, MD; J. Pinto–Martin, PhD; M. Rivkin, MD; and T.L. Slovis, MD

Article abstract—*Objective:* The authors reviewed available evidence on neonatal neuroimaging strategies for evaluating both very low birth weight preterm infants and encephalopathic term neonates. *Imaging for the preterm neonate:* Routine screening cranial ultrasonography (US) should be performed on all infants of <30 weeks' gestation once between 7 and 14 days of age and should be optimally repeated between 36 and 40 weeks' postmenstrual age. This strategy detects lesions such as intraventricular hemorrhage, which influences clinical care, and those such as periventricular leukomalacia and low-pressure ventriculomegaly, which provide information about long-term neurodevelopmental outcome. There is insufficient evidence for routine MRI of all very low birth weight preterm infants with abnormal results of cranial US. *Imaging for the term infant:* Noncontrast CT should be performed to detect hemorrhagic lesions in the encephalopathic term infant with a history of birth trauma, low hematocrit, or coagulopathy. If CT findings are inconclusive, MRI should be performed between days 2 and 8 to assess the location and extent of injury. The pattern of injury identified with conventional MRI may provide diagnostic and prognostic information for term infants with evidence of encephalopathy. In particular, basal ganglia and thalamic lesions detected by conventional MRI are associated with poor neurodevelopmental outcome. Diffusion-weighted imaging may allow earlier detection of these cerebral injuries. *Recommendations*: US plays an established role in the management of preterm neonates of <30 weeks' gestation. US also provides valuable prognostic information when the infant reaches 40 weeks' postmenstrual age. For encephalopathic term infants, early CT should be used to exclude hemorrhage; MRI should be performed later in the first postnatal week to establish the pattern of injury and predict neurologic outcome.

NEUROLOGY 2002;58:1726–1738

Despite the development of sophisticated care techniques, the incidence of neurodevelopmental disability among the survivors of newborn intensive care remains high.[1-4] As newborn special care enters its fifth decade, survival rates for both severely compromised term infants and very low birth weight (VLBW) preterm (PT) infants have increased.[5,6] However, the incidence of cerebral palsy (CP) has not changed during the past 10 years, the number of children with school-based problems is on the rise, and the population of infants at risk for disability is increasing.[7-13] Because the clinical evaluation of these infants may not provide either adequate diagnostic or prognostic information, neuroimaging is frequently used.[14-16]

Neuroimaging plays two important roles: 1) diagnosis of brain injury in the newborn at risk so that appropriate medical management can be provided and 2) detection of those lesions associated with long-term neurodevelopmental disability. Currently, cranial ultrasonography (US), CT, and MRI are the most available means for these tasks.

Goals. The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society seek to develop scientifically sound, clinically relevant practice parameters for physicians for diagnostic procedures, treatment modalities, and clinical disorders. Practice parameters are strategies for patient management that might include diagnosis, symptom, treatment, or procedure evaluation. They make specific recommendations based on the analysis of evidence in the published literature.

This practice parameter provides recommendations in response to questions regarding brain imaging of PT and term infants. For PT infants: which PT infants should undergo routine screening US? When should these studies be performed? Do abnormalities shown by neonatal US require follow-up MRI? What is the ability of US to accurately predict long-term neurodevelopmental outcome for this patient population? For term infants: which imaging strategies are able to provide clinically important information for infants with neonatal encephalopathy? Can MRI provide prognostic information for these infants?

Description of the process. The committee consisted of neonatologists, pediatric neurologists, perinatal epidemiologists, and neonatal radiologists selected by five professional organizations (see the electronic version of this article for appendix 1 at www.neurology.org); we evaluated the quality of the evidence from the published literature. Evidence reviewed for this parameter was identified through literature searches using MEDLINE and EMBASE for the years 1990 to 2000 and CURRENT CONTENTS for 2000. This literature search was updated in June 2001. Relevant articles were chosen from the English-language literature using the following search terms: neonate, infant, brain, cerebral, MRI, MRS, diffusion-weighted imaging (DWI), diffusion tensor imaging, US, echoencephalography, Doppler ultrasonography, cranial axial tomography, near-infrared spectroscopy, SPECT, germinal matrix hemorrhage, intraventricular hemorrhage (IVH), periventricular leukomalacia (PVL), stroke, ischemia, ventriculomegaly, and echodensity. Because neonatal practices and imaging strategies have changed over the past decade,[12,17-21] we reviewed only those references from 1990 onward.

This search produced >1,320 citations, from which 90 met the predefined inclusion criteria: original clinical articles published since 1990, review articles, and reports of meta-analyses.

Each of the selected articles was reviewed, abstracted, and classified (appendix 2) by at least two reviewers. Abstracted data included patient number, mean birth weight (BW), mean gestational age (GA), age at the time of the neuroimaging study, primary neuroimaging measure, primary and secondary outcome measures, and timing of subject selection (prospective, retrospective, case-control, or case series study). We also noted both inclusion and exclusion criteria for patient selection and description of the neuroimaging strategy in addition to the results of the given study.

The strength of the evidence for each relevant article was ranked using the defined criteria shown in appendix 2. Recommendations were derived based on the strength of the evidence and stratified (level A, B, C, or U) as shown in appendix 3.

For the purposes of this practice parameter, a screening neuroimaging study was defined as one that is routinely applied to identify infants at sufficient risk of a specific disorder who would benefit from further investigation or direct action but who have no specific neurologic signs or symptoms requiring medical attention (e.g., infants born before 28 weeks of gestation).

Neuroimaging strategies. Although neuroimaging has proven to be extremely helpful for the assessment of injury to the PT brain and may provide useful information for evaluating the infant with neonatal encephalopathy, there are significant problems associated with imaging of the critically ill infant.[14,22,23] These include the choice of imaging technique, the timing of the imaging study, and regional variations in maturation of the developing brain. Further, transporting acutely ill neonates, many of whom require ventilatory assistance, multiple indwelling catheters, infusions, vasopressor support, and warming lights, represents a major challenge.

Currently, US, CT, and MRI represent the major imaging modalities most widely available for evaluating critically ill infants.

VLBW PT infants. Birth weight (BW) remains one of the most important predictors of infant mortality and morbidity. VLBW infants (BW <1,500 grams) now represent 1.45% of all live births in the United States.[5,6,24] In addition, the survival rates for this population are steadily increasing. In contrast, the handicap rates for surviving infants—particularly those with the lowest BW—are high. At 8 years of age, >50% of children with BW of <1,000 grams are educated in special education classrooms or resource rooms, 20% have repeated a grade in school, and 10% to 15% have spastic motor handicaps.[1,9,13]

Hemorrhage, hypoxia, and ischemia are the major causes of injury to the PT brain, and multiple studies over the past decade have used neuroimaging techniques to assess these injuries.[24-28]

US screening of the VLBW PT infant. Although cranial US of VLBW PT infants is routinely performed

Table 1 *Classification of cranial ultrasound findings for the preterm infant*

Classification		Findings
Intraventricular hemorrhage*	Grade 1	Germinal matrix hemorrhage
	Grade 2	Blood within the ventricular system but not distending it
	Grade 3	Intraventricular hemorrhage with ventricular dilatation
	Grade 4	Parenchymal involvement
Preterm white matter injury†	Cystic lesions	Periventricular
Ventriculomegaly‡	Mild	0.5–1.0 cm§
	Moderate	1.0–1.5 cm§
	Severe	>1.5 cm§

in newborn intensive care units, the target populations, number of examinations, and timing of these studies vary widely. Further, different institutions use different systems of nomenclature to describe IVH, white matter injury, and ventriculomegaly, the three major findings for the PT infant. For this parameter, the grading system for IVH of Papile et al.[29] will be used (table 1). In addition, because there is controversy surrounding the meaning of the periventricular echodensities routinely reported in US studies of PT infants,[28,30-32] injury to the PT white matter will include only periventricular cystic lesions.[114,115] There is a consensus in the field that the degree of ventriculomegaly (see table 1) predicts long-term neurodevelopmental outcome for PT infants studied at or near term.[33,34]

Correlation of US findings with neuropathologic data. Before reviewing data pertinent to the practice parameter questions, the committee reviewed the evidence correlating clinical US findings with neuropathologic data. In four class II studies[35-38] reporting results of a total of 87 autopsies performed on PT infants, US was 76% to 100% accurate in detecting grade 1 lesions of >5 mm and grade 3 and grade 4 hemorrhages (see the electronic version of this article for table 4 at www.neurology.org). Detection of grade 2 hemorrhages was much less accurate.

Correlation of US findings of cystic PVL with neuropathologic data was evaluated in three class II studies.[38-40] Each study found 100% correlation between US findings and neuropathologic data.

Which PT infants should undergo routine screening cranial US? Evidence. Seven class II studies evaluated the need for screening cranial US in low BW PT infants.[25,27,28,41-44] Review of these studies (table 2; see the electronic version of this article for table 5 at www.neurology.org) suggests that although cranial US of 12% to 51% of infants with BW of <1,500 grams or GA of <33 weeks shows some abnormalities in the first 2 weeks of life, major US abnormalities such as grades 3 and 4 IVH or bilateral cystic PVL occur in ≤20% of infants. Furthermore, more severe abnormalities occur in those infants with the lowest BW.

Because infants with grades 3 and 4 IVH are at considerable risk for metabolic abnormalities, posthemorrhagic hydrocephalus, and its sequelae (e.g., apnea and obtundation), such a, US finding would in all likelihood alter the infant's care and thus was considered clinically significant.[16] In addition, cystic PVL and ventriculomegaly are risk factors for CP. These US findings might not only provide critical prognostic information but also influence long-term care strategies. Therefore, it is important to determine which infants are at high risk for grades 3 and 4 IVH, cystic PVL, and/or ventriculomegaly.

In only four studies, the data were presented by specific GA and/or BW groups.[25,28,41,43] In these studies, grades 3 and 4 IVH was noted in 11% of infants with BW of <1,000 grams and in 5% of infants with BW of 1,000 to 1,250 grams; when infants were compared by GA groups, 16% of those with GA of ≤25 weeks and 1% to 2% of infants with GA of >25 weeks had grades 3 and 4 IVH (see the electronic version of this article for table 5 at www.neurology.org). Likewise, cystic PVL was noted in 5% to 26% of infants weighing <1,000 grams, compared with 1% to 5% of infants with BW of >1,000 grams. Ventriculomegaly was described in 5% to 7% of infants weighing <1,000 grams.Conclusions. Twelve percent to 51% of infants with BW of <1,500 grams and/or GA of 33 weeks have cranial US abnormalities (class II evidence). However, major abnormalities such as grades 3 and 4 IVH, cystic PVL, and ventriculomegaly, which might alter treatment or provide prognostic information, are considerably more common (20%–25%) in infants with GA of <30 weeks.

Recommendations (level B). Close to 25% of infants with GA of <30 weeks have significant cranial US abnormalities that trigger important changes in acute and long-term care. Therefore, routine screening cranial US should be performed on all infants with GA of <30 weeks.

When should screening cranial US be performed? Evidence. Multiple class II studies performed before 1990 suggested that >90% of all IVH cases in VLBW PT infants were detected during postnatal days 4 to 5.[45-48]

Data from recent class II studies are shown in table 2 (see the electronic version of this article for table 6 at www.neurology.org). In one study,[28] 248 infants with BW of <1,500 grams underwent regular US at predefined times (1–5 days, 10–14 days, 28 days, and term). Approximately 65% of IVH cases were detected within the first week. The other cases

Table 2 *Incidence and timing of ultrasound abnormalities in preterm infants*

Reference no.	Class	Inclusion criteria	US abnormalities, incidence (%)	Major abnormalities, incidence (%)	No. (%) of major abnormalities	Incidence of major abnormalities by GA or BW	Timing of major abnormalities, incidence (%)
41	II	BW, <1,500 g; GA, <34 wk	IVH, 50/250 (20)	Grades 3 and 4 IVH, 13/250 (5)	13 (5)	GA of <25 wk, 9/57 (16); GA of >25 wk, 4/193 (2)	
42	II	BW, <1,500 g; <33 wk	IVH and/or PVL, 245/338 (43)	Grades 3 and 4 IVH and/or cystic PVL, 75/338 (22)	75 (22)		d 1–3, 27/75 (36); d 4–7, 36/75 (48); d 8–14, 12/75 (16)
43	II	BW, <1500 g	PVL, 14/115 (12)			BW of <1000 g, 12/46 (26)	wk 1, 6/14 (43); wk 3–15, 8/14 (57)
25	II	GA, <32 wk; BW, <1,500 g; or GA, <37 wk with ventilator	IVH, 106/800 (13)	Grades 2–4 IVH, 51/800 (6)	51 (6)	GA of <30 wk, 46/364 (13); GA of >30 wk, 5/436 (1)	
27	II	GA, <33 wk	PVL, 26/172 (15)				wk 1, 19/26 (73); wk 2–7, 7/26 (27)
44	II	GA, <36 wk	PVL, 11/53 (21)				wk 1, 10/11 (91); wk 2, 1/11 (9)
28	II	BW, <1,500 g	IVH, PVL and/or VM, 161/317 (51)	Grades 3 and 4 IVH, PVL and/or VM, 40/317 (13)	40 (12.6)	BW of <1,000 g; 13/114 (11.4); BW of >1,000 g; 4/203 (2)	BW of <1,000 g; wk 1 (52) wk 2 (12); wk 4 (16); term (20)

BW = birth weight; GA = gestational age; wk = week; IVH = intraventricular hemorrhage; PVL = periventricular leukomalacia; VM = ventriculomegaly; d = day.

occurred in the second and third postnatal weeks, and one infant developed severe IVH after postnatal day 28. When BW was <1,000 grams, severe IVH was detected in 10 (77%) of 13 infants on days 1 to 5; 13 (100%) of 13 cases of severe IVH were detected on day 28.

In a study designed to assess changes in US findings across time,[42] 144 infants with BW of <1,500 grams or GA of <33 weeks underwent US between days 1 and 7 and then between days 10 and 14. Fifteen infants (10%) had significant changes in US findings from the first to the second scan. Thirteen infants whose first US showed normal results or grades 1 and 2 IVH were found to have major abnormalities (i.e., grades 3 and 4 IVH and/or PVL) at the time of the second scan. For two infants, US findings changed from a major abnormality during the first US (i.e., PVL) to either normal results or a minor abnormality (i.e., grade 2 IVH) during the second US.

Cystic PVL has been detected in infants without previous US abnormalities as late as postnatal day 104.[27,43,44] In one report,[28] cystic PVL and ventriculomegaly were found in 8 (3%) of 256 neonates after previously normal US findings. For infants weighing <1,000 grams, 3 (50%) of 6 cases of PVL were noted at 36 to 40 weeks' postmenstrual age.

Conclusions. The timing at which US can detect injury in the developing brain may be changing. Grades 3 and 4 IVH, which may alter medical management and prognostic information, may be detected as late as the third postnatal week. Cystic PVL and ventriculomegaly, which may alter prognosis and treatment programs, may be first seen by US at term. Furthermore, these lesions may be detected in many infants after previously normal US findings.

Recommendation (level B). Screening cranial US should be performed on all infants with GA of <30 weeks at 7 to 14 days of age and should be optimally repeated at 36 to 40 weeks' postmenstrual age. This recommendation is designed to detect both clinically unsuspected IVH, which may require additional clinical and/or radiologic monitoring and changes in management plans, and evidence for PVL and/or ventriculomegaly, which are useful for prognosis and best seen when the infants are examined at term.

Do abnormalities of screening cranial US for the PT infant require follow-up MRI either to obtain information for patient management or to provide long-term prognostic data? Evidence. Three recent class II studies (see the electronic version of this article for table 7 at www.neurology.org) compared results of cranial US and MRI performed during the newborn period for PT infants.[26,49,50] Maalouf et al.[26] performed paired MRI and US studies on the same day for 32 infants with GA of <30 weeks. US accurately detected the presence of germinal matrix, IVH, and parenchymal hemorrhage confirmed by MRI (positive predictive values of 0.8, 0.85, and 0.96, respectively). However, in this study and others,[49,50] white matter injury detected by MRI was less well predicted by US (sensitivity of 0.56–0.89). Additional information provided by MRI included depiction of hemorrhagic lesions in 64% of infants and more numerous or extensive cysts in infants with

PVL diagnosed by US.[50] To date, there has not been correlation with neurodevelopmental follow-up.

Conclusions. Compared with US performed on the same day, MRI of PT neonates detects more white matter abnormalities in the first week of life, more hemorrhagic lesions, and more numerous or extensive cysts. There are insufficient data from follow-up studies to indicate whether these additional findings provide more information about the neurodevelopmental prognosis.

Recommendation (level C). Currently, available data from class II studies do not provide sufficient evidence that routine MRI should be performed on all VLBW PT infants for whom results of screening cranial US are abnormal.

What is the ability of neonatal cranial US to predict long-term neurodevelopmental outcome for VLBW PT infants? Evidence. VLBW PT infants are at high risk for neurodevelopmental handicap. Depending on the GA of the cohort and the year of birth, the previously reported incidence of mental retardation and/or CP among PT infants ranged from 7% to almost 50%.[1,4,51,52] Further, the timing of cranial US used to predict outcome in the reported literature varied from the first 2 weeks of life through term. For this reason, the lesions reported and the predictive values for these lesions were difficult to compare. Finally, in several studies, children deemed excessively impaired were omitted from the follow-up assessments, and in many, the outcome measures were reported in broad categories. Therefore, it was difficult to assess the nature of CP or mental retardation across cohorts.

Only reports containing the following data were included: GA and/or BW of the study population, postmenstrual age of the "predictor" US when recorded, neurodevelopmental follow-up rate, age at assessment, and outcome variables.

The six class II studies[34,53-57] (see the electronic version of this article for table 8 at www.neurology.org) compared US findings with the incidence of CP for almost 2,250 VLBW PT children at ages 2 to 9 years. Significant associations between grade 4 IVH, PVL, and/or ventriculomegaly and CP were noted in all six studies. In the largest of these studies,[58] both grade 4 IVH and PVL were associated with CP (odds ratio [OR], 15.4; 95% CI, 7.6–31.1); any grade IVH alone was also associated with CP (OR, 3.14; 95% CI, 1.5–6.5). Similar data were available from one class III study and three class IV studies (see the electronic version of this article for table 8 at www.neurology.org).[59-62]

When the same groups from class II and class III studies[53-55,57-59,63,64] assessed the correlation of neonatal US findings with the developmental quotient, grade 4 IVH and moderate to severe ventriculomegaly were strongly associated with the risk of mental retardation at 2 to 9 years of age (see the electronic version of this article for table 8 at www.neurology.org). In these prospective studies, OR ranged from 9.97 to 19.0. In addition, Whitaker et al.[65] demonstrated that for infants with BW of 500 to 2,000 grams who had grade 4 IVH and/or moderate to severe ventriculomegaly, the OR for the development of any neuropsychiatric disorder at the age 6 years was 4.4.

Conclusions. Grades 3 and 4 IVH, cystic PVL, and moderate to severe ventriculomegaly determined by US have all been shown to be significantly associated with CP at 2 to 9 years of age in VLBW PT infants (class II evidence). In addition, class II evidence, grade 4 IVH, and ventriculomegaly have been significantly associated with mental retardation and neuropsychiatric disorders at the same time points. The OR, which vary depending on the population under study, the lesion, and the outcome measure, all indicate at least a 10-fold elevation in the risk of adverse outcome for VLBW PT infants with US evidence of grades 3 and 4 IVH, cystic PVL, and moderate to severe ventriculomegaly.

Recommendation (level A). For VLBW PT infants, US should be used to predict long-term neurodevelopmental outcome. The findings of grades 3 and 4 IVH, periventricular cystic lesions, and moderate to severe ventriculomegaly are all associated with adverse outcome.

Term infants with neonatal encephalopathy. Clinical examination of the term infant with signs and symptoms of neonatal encephalopathy is often unable to determine the severity or extent of cerebral damage and frequently provides little information regarding the etiology of the insult. Although numerous reports suggest that hypoxic–ischemic encephalopathy (HIE) is a common cause of neonatal encephalopathy, the differential diagnosis of this condition is extensive, including a spectrum of abnormalities ranging from infectious to metabolic abnormalities and congenital malformations.[66,67] Even in those infants with documented HIE, the clinical presentation may vary widely.[68] Of those neonates with moderate to severe HIE, almost one-quarter have mental retardation, seizures, and CP, and promising intervention strategies are now becoming available.[69-71] Therefore, for diagnostic and prognostic reasons, early assessment and diagnosis of infants with neonatal encephalopathy is important.

For the definition of neonatal encephalopathy, the committee used the criteria set forth by the American Academy of Pediatrics and the American College of Obstetricians and Gynecologists in *Guidelines for Prenatal Care*.[72] For results of a study to be rated as class I evidence, infants described therein must meet all of the following conditions:

1. Profound metabolic or mixed acidemia (pH $<$ 7.00 [umbilical cord artery blood sample if obtained]).
2. Apgar score of 0 to 3 for $>$5 minutes.
3. Neonatal neurologic manifestations (e.g., seizures, coma, or hypotonia).
4. Multisystem organ dysfunction (e.g., cardiovascu-

lar, gastrointestinal, hematologic, pulmonary, or renal system).

Although these criteria were originally developed for those infants thought to have HIE, they also describe any infant who requires immediate neonatal evaluation—both to determine the underlying cause of encephalopathy and to provide therapeutic interventions, when available.[67,73,74] Studies in which the entry criteria of the infants evaluated were less rigorously defined received lower classification levels than did those in which infants met these conditions.

Which neonatal neuroimaging strategies can detect cerebral abnormalities that may affect the immediate and long-term management of the infant with neonatal encephalopathy? Evidence. One study discussed gray-scale US of the infant with neonatal encephalopathy.[75] A second study compared findings of gray-scale US and Doppler US with outcome,[76] and a third study compared results of gray-scale US and Doppler US with somatosensory evoked potentials, visual evoked potentials, and results of the cerebral function monitoring.[77] A fourth study compared findings of gray-scale US, Doppler US, and CT.[78] Three other studies compared results of gray-scale US and MRI for infants with neonatal encephalopathy.[79-81] Four studies reported CT findings for these infants.[82-85]

Gray-scale US, Doppler US, and studies comparing US with CT and/or MRI. In one class III study[75] (see the electronic version of this article for table 9 at www.neurology.org), US was performed on 104 encephalopathic term neonates and 70 control term neonates on the first postnatal day. A diffuse increase in echogenicity of the cerebral parenchyma and slit-like ventricles were significantly more common in infants with encephalopathy than in controls (39% versus 1% [$p < 0.001$] and 44% versus 9% [$p <$ 0.00l], respectively), but the investigators found no correlation between US findings on the first postnatal day and neurodevelopmental status at 1 year of age. Similar results were noted in a class II study evaluating term infants with neonatal encephalopathy on the first postnatal day.[76]

In the same class II study,[76] analysis of simultaneous Doppler US demonstrated resistive indices (resistive index = peak systolic velocity minus end diastolic velocity divided by peak systolic velocity) of <0.60 for all children with adverse neurodevelopmental outcome. In another class II study,[78] gray-scale US, Doppler US, and CT were performed on infants with neonatal encephalopathy (see the electronic version of this article for table 9 at www.neurology.org). Gray-scale US was not predictive of outcome, but a resistive index of ≤ 0.5 in the middle cerebral artery was associated with adverse neurodevelopmental outcome at 1 to 2 years (sensitivity, 82%; specificity, 89%). In addition, CT demonstrating generalized decreased density had 91% sensitivity and 100% specificity for adverse outcomes.

Three studies compared early US and MRI studies for infants with neonatal encephalopathy (see the electronic version of this article for table 9 at www.neurology.org).[79-81] An abnormal MRI signal in the basal ganglia in association with an abnormal US result for the basal ganglia was most frequently associated with an adverse neurodevelopmental outcome including CP, seizures, and developmental delay at 1 year of age, while normal findings of US and CT or US and MRI had low negative predictive values.

Conclusions. Seven studies (classes II and III) assessed the role of gray-scale US in the diagnosis of term infants with neonatal encephalopathy. Although gray-scale US can be easily performed at the bedside, there are little data to support the use of this modality in imaging of the encephalopathic term neonate. However, two class II studies of Doppler US suggested that resistive indices of $<0.5–0.6$ are consistent with the diagnosis of HIE.

CT studies. CT can be performed rapidly and without sedation of the neonate. Four studies used CT to evaluate term infants with neonatal encephalopathy. One study[84] reported basal ganglia changes; a second study[82] reported both basal ganglia and thalamic changes. Two studies[83,85] used CT to detect intracranial hemorrhages in infants with signs and symptoms of neonatal encephalopathy who also had low hematocrit or evidence of coagulopathy; in both studies, detection of intracranial hemorrhages altered clinical care.

Conclusions. One class II study and three class IV studies assessed the value of CT for encephalopathic term neonates. Two studies suggested that low attenuation in the basal ganglia and/or thalami indicates severe injury consistent with HIE. The other two studies demonstrated that CT plays a role in the detection of hemorrhagic lesions.

MRI studies. Two studies (see the electronic version of this article for table 9 at www.neurology.org) compared MRI findings with neuropathologic data for infants with neonatal encephalopathy believed attributable to HIE.[86,87] In the larger study,[87] imaging data were compared with results of neuropathologic analyses of the posterior limb of the internal capsule, thalamus, parietal cortex, hippocampus, and medulla. The posterior limb of the internal capsule was the most reliable region analyzed, and agreement of MRI findings was similar to that achieved by two pathologists reviewing the histologic sections ($\kappa = 0.66$). In this study, the MRI abnormality was predictive of the pathologic abnormality with a sensitivity of 0.70 and a positive predictive value of 1.0. The predictive value of a single MRI abnormality was 0.79 (95% CI, 0.61–0.96).

In eight class II studies (see the electronic version of this article for table 9 at www.neurology.org),[2,88-94] conventional T1- and T2-weighted MRI studies were performed for a total of 272 term neonates, most of whom were clinically suspected of having neonatal encephalopathy secondary to hypoxic–ischemic injury. Scans were obtained at ages ranging from 1 to 30 postnatal days, and the mean age range was 2 to

8 days. Three patterns of injury were detected by MRI: 1) injury to the thalami and/or posterior–lateral putamen with involvement of the subcortical white matter in the most severe injuries; 2) injury to the parasagittal gray matter and subcortical white matter, posteriorly typically more than anteriorly; and 3) focal or multifocal injury. Thalamic and basal ganglia damage was the most common abnormality reported. This pattern of injury was detected in almost 40% of infants and represented over one-half of all abnormalities (see the electronic version of this article for table 10 at www.neurology.org). In one class III study,[95] abnormal T1-weighted images showing hyperintensities in a characteristic distribution were demonstrated as early as 3 days after the injury; abnormal T2-weighted images showing hypointensities were demonstrated by 6 to 7 days.

Conclusions. Results of class II studies indicate that characteristic MR patterns of cerebral injury can be detected using conventional T1- and T2-weighted imaging sequences performed at mean ages of 2 to 8 days for encephalopathic term infants.

Diffusion weighted imaging. Studies of adult arterial infarcts have shown that DWI signal changes occur within minutes of symptom onset and hours before changes become apparent on T1- or T2-weighted images.[96] In one class II study[86] and four class III studies[97-100] that investigated the use of DWI in the evaluation of term neonates (see the electronic version of this article for table 11 at www.neurology.org), entrance criteria were not stated in enough detail to determine which infants met strict criteria for acute neonatal encephalopathy, and neonates with focal seizures were also included. MR studies were performed a mean of 2 to 4 days after birth, and DWI findings were compared with those of standard MRI sequences. Abnormal DWI results were reported for two-thirds of infants. For 7% to 58% of infants with abnormal DWI findings, T2- and/or T1-weighted images were also abnormal. Abnormal DWI results and normal T1- and/or T2- weighted images typically occurred when imaging was performed earlier than day 2 of life or when there was diffuse white matter involvement. Robertson et al.[99] described one patient for whom all imaging sequences including DWI and T1- and T2-weighted imaging sequences were normal when performed at 13 hours despite development of DWI and T1- and T2-weighted imaging abnormalities by 5 days. Robertson et al. also described one other patient for whom DWI results were normal at 8 days when T1- and T2-weighted images were abnormal; this decreased sensitivity of DWI in the subacute to chronic phase has also been noted for the adult population, suggesting that the maximum sensitivity of DWI is between 2 and 8 days.

Conclusions. Findings of one class II study and four class III studies suggest that DWI can provide evidence of cerebral injury before conventional MRI techniques for term infants with neonatal encephalopathy. However, DWI results may be negative if it is performed earlier than 24 hours of life or later than 8 days of life.

Proton MRS. A number of investigators have explored the utility of ^{1}H-MRS and 31P-MRS at field strengths of $\geq$1.5 T, but the recommendations for this parameter will be limited to ^{1}H-MRS at 1.5 T because this is the equipment most commonly available for neonatal imaging. All of the studies that evaluated ^{1}H-MRS at 1.5 T used single-voxel point resolved spectroscopy (PRESS) or stimulate echo acquisition mode (STEAM) MRS; although mutivoxel chemical shift imaging (CSI) allows high resolution evaluation of larger regions of tissue, there are no data at this time that assess the role of this modality in perinatal brain injury.

In a number of class II studies (see the electronic version of this article for table 12 at www.neurology.org), echo times of $\approx$136 msec and 272 msec were preferred over the shorter echo times of $\approx$36 msec because of the higher SD of metabolite concentrations measured at these shorter echo times.[20,93] An echo time of 136 msec has the additional advantage of an inverted lactate peak, making distinction from lipids (which can resonate in the same region) more accurate.

One class II study[101] used MRS at 1.5 T within the first 18 hours in 31 cases of suspected HIE and in 7 matched controls. Lactate/creatine ratios ranged from 0 to 0.6 (median, 0.05) for the seven controls. In contrast, the investigators demonstrated lactate/creatine ratios of $>$1.0 for 10 (32%) of the 31 infants with suspected HIE. In three additional class II studies,[93,102,103] proton MRS of the basal ganglia was performed within the first 2 weeks of life on 77 infants with neonatal encephalopathy. Elevated lactate/*N*-acetylaspartate ratios were the most consistent findings, although elevated lactate/creatine and lactate/choline ratios were also reported for infants with suspected neonatal encephalopathy.

Conclusions. Data from class II studies suggest that MRS can play an important role in the assessment of encephalopathic term infants. Lactate/creatine ratios of $>$1 in the first 18 hours are more common in those infants with later neurologic findings consistent with HIE. Elevated lactate/NAA, lactate/creatine, and lactate/choline ratios in the first 2 postnatal weeks are more common in infants with suspected neonatal encephalopathy than in age-matched controls.

Recommendations for diagnostic assessment.

1. For infants with a history of neonatal encephalopathy, significant birth trauma, and evidence for low hematocrit or coagulopathy:

a. Noncontrast CT should be performed to look for hemorrhage (level B).

b. If the CT findings cannot explain the clinical status of the neonate, MRI should be performed (level A).

2. For other neonates with acute encephalopathy:

a. MRI should be performed between days 2 and 8 of life (level A).

b. If single-voxel MRS is available, MRI should include MRS (level B).

c. At the time of MRI, DWI should also be performed if this modality is available (level C).

d. CT should be performed only if MRI is not available or if the neonate is too unstable for MRI (level A).

Can MRI provide prognostic data for term infants with neonatal encephalopathy? Evidence. Eight class II studies (table 3; see the electronic version of this article for table 9 at www.neurology.org) assessed the ability of conventional MRI performed between 2 and 8 days of age to predict neurodevelopmental handicap at postnatal ages of 12 to 24 months.[2,88-94] Although results of several studies suggested that abnormalities of the cerebral white matter are associated with adverse outcome in term infants with neonatal encephalopathy, 50% to 94% of infants with changes in the basal ganglia developed CP, mental retardation, and seizures at 1 to 2 years of age.[2,88,91,94] Barkovich et al.[89] correlated cognitive and motor outcome with timing of conventional MRI. Proton density MRI scans correlated best during the first 3 postnatal days, proton density and T1-weighted images correlated best during the first 7 postnatal days, and T2-weighted images correlated best after 7 to 8 postnatal days. Overall, proton density images during the first 7 postnatal days were the best predictor of outcome in this study.

Similarly, three studies using DWI (table 3; see the electronic version of this article for table 11 at www.neurology.org) performed at a mean age of 2 days in neonatal encephalopathy demonstrated a significantly elevated risk of adverse neurologic outcome, although the small sample sizes make predictions unreliable.[97-99]

Finally, review of the class II studies using proton MRS (table 3; see the electronic version of this article for table 12 at www.neurology.org) within the first 11 days of life demonstrated that lactate/creatine ratios of >1.0 and elevated lactate/NAA or lactate/choline ratios were highly predictive of adverse neurodevelopmental outcome at 1 to 2 years of age.[93,101-103] Infants with lactate/creatine ratios of >1.0 were found to have adverse neurodevelopmental outcome at 1 year of age (OR, 13.2; sensitivity, 66%; specificity, 95%; positive predictive value, 86%; negative predictive value, 88%).[101] Similarly, ele-

vated lactate/NAA and lactate/choline or lactate/creatine ratios in the region of the basal ganglia were significantly associated with CP and mental retardation ($p < 0.001$ for all studies).[102,103] In another report, abnormalities of NAA/creatine, NAA/choline, and choline/creatine ratios in the occipital gray/parietal white matter regions were predictive of adverse outcome at a mean age of 15 months in infants with HIE.[104] Positive predictive values for abnormal neurodevelopmental outcome based on these metabolites were 0.64, 0.68, and 0.75 for values >2 SD from those of controls.

Conclusions. Class II MRI studies demonstrated that the incidence of neurodevelopmental handicap among those infants with abnormalities of the thalami and basal ganglia at mean postnatal ages of 2 to 8 days is significant at 1 to 2 years of age. Limited and predominantly class III DWI evidence demonstrates abnormalities in infants with neonatal encephalopathy at a time when results of conventional MRI are normal. Class II studies of proton MRS performed within the first 8 postnatal days also suggest good to excellent predictive values for this measure for neurodevelopmental outcome at 1 to 2 years of age.

Recommendation. MRI should be performed within the first 2 to 8 days of life to provide predictive data for neurodevelopmental outcome in encephalopathic term infants (level A). DWI (level C) and MRS (level B), when available, should also be performed within the first 2 to 8 days to provide additional prognostic data concerning neurodevelopmental outcome.

Future directions. As the number of infants cared for in neonatal intensive care units grows and survival statistics steadily increase, neuroimaging has become critical technology. Imaging of the developing brain is no longer a research goal; it has become clinically relevant. Neuroimaging can provide diagnostic information but also data used for clinical decision making as well as information on treatment efficacy and prognosis. This becomes particularly important in the anticipation of potential preventive, protective, and rehabilitative strategies for the management of critically ill newborn infants.

Several ongoing clinical trials are assessing the impact of neuroprotective strategies on long-term neurodevelopmental outcome.[105] For these studies, neuroimaging is critical—not only to provide diagnostic entry criteria but also to assess the effect of the intervention and to provide prognostic neurologic information.

Two sets of difficulties must be overcome to more fully incorporate neuroimaging into the newborn intensive care unit. MRI holds great promise; however, this imaging modality and others that may be soon developed must become more infant friendly, and imaging strategies should be developed to provide maximum information in minimum time. This would include the following: improved magnet technology that would allow easy placement of affordable MRI devices in newborn intensive care units, software and hardware advances that would minimize imaging time and allow DWI and/or MRS sequences to be easily performed on critically ill neonates, and MRI-compatible devices that improve our ability to monitor and maintain critically ill neonates. Further, it is important that results of these imaging studies, including processed DWI and MRI data, be available immediately for viewing by all involved specialties.

To provide more accurate information, these MR techniques must be optimized and standardized in terms of types of sequence, parameters for each imaging sequence, regions of brain evaluated, and timing of evaluations. Prospective imaging studies with centralized, blinded readers and well-defined cohorts of infants and matched controls should be performed to determine accurate diagnostic criteria. Similarly, prognostic data can be determined only from blinded standardized follow-up assessments of all infants imaged by the modality under study.

Although there is some recent control data on DWI for neonates,[106,107] the numbers of patients studied are small. There is also a strong need for MRS control data for neonates. For both of these modalities, serial studies are generally lacking, and the impact of timing of the study and regional variation on its result remains unknown. For example, although elevated lactate/NAA, lactate/creatine, and lactate/choline ratios are reported to be more common for infants with suspected HIE, more studies are required to determine the upper limits of these ratios for the normal population at various postnatal ages and to determine the sensitivity, specificity, and predictive values of these ratios. Studies are also needed to determine not only the optimal timing of DWI and MRS evaluation for term infants with neonatal encephalopathy but also the optimal region for investigation for MRS. Long-term follow-up data on the disability rate are of critical importance. Control data, timing studies, neuropathologic correlations, and ultimately outcome assessments are also needed before MRI becomes the standard of care for the VLBW PT neonate. MRS and DWI for this age group have the potential to provide much needed information concerning the timing of white matter injury in the developing brain and may lead to injury-specific interventions.[108]

Preliminary studies suggest that the more aggressive and timely use of advanced structural and functional prenatal imaging techniques to detect and characterize abnormalities may allow intervention to prevent postnatal neurologic morbidity and mortality.[109,110] Prenatal imaging may provide information for consideration of corrective prenatal surgical or medical interventions where appropriate and can assist with the planning of surgical or medical interventions in the intrapartum and postpartum periods. Therefore, studies that correlate prenatal US and MRI findings with results of postnatal neuroimaging and outcome are needed.

Near infrared spectroscopy, nuclear medicine (SPECT and PET), and fMRI are other major imaging technologies not discussed in this parameter because of lack of data; these technologies are under evaluation for use in the assessment of the developing brain.[111-115] The challenge is to develop and implement effective applications of these advanced neuroimaging techniques and to perform studies evaluating their diagnostic and predictive ability. As evidence becomes available,[116] it must be reviewed on a regular basis, and the practice parameter must be modified accordingly.

Appendix 2

Definitions for classification of diagnostic evidence

Class I: Evidence provided by a prospective study in a broad spectrum of persons with the suspected condition, using a "gold standard" for case definition, where test is applied in a blinded evaluation, and enabling the assessment of appropriate tests of diagnostic accuracy.

Class II: Evidence provided by a prospective study of a narrow spectrum of persons with the suspected condition, or a well designed retrospective study of a broad spectrum of persons with an established condition (by "gold standard") compared to a broad spectrum of controls, where test is applied in a blinded evaluation, and enabling the assessment of appropriate tests of diagnostic accuracy.

Class III: Evidence provided by a retrospective study where either persons with the established condition or controls are of a narrow spectrum, and where test is applied in a blinded evaluation.

Class IV: Any design where test is not applied in blinded evaluation OR evidence provided by expert opinion alone or in descriptive case series (without controls).

Definitions for classification of prognostic evidence

Class I: Evidence provided by a prospective study of a broad spectrum of persons who may be at risk for developing the outcome (e.g., target disease, work status). The study measures the predictive ability using an independent gold standard for case definition. The predictor is measured in an evaluation that is masked to clinical presentation and the outcome is measured in an evaluation that is masked to the presence of the predictor.

Class II: Evidence provided by a prospective study of a narrow spectrum of persons who may be at risk for developing the outcome, or by a retrospective study of a broad spectrum of persons with the outcome compared to a broad spectrum of controls. The study measures the predictive ability using an acceptable independent gold standard for case definition. The risk factor is measured in an evaluation that is masked to the outcome.

Class III: Evidence provided by a retrospective study where either the persons with the condition or the controls are of a narrow spectrum. The study measures the predictive ability using an acceptable independent gold standard for case definition. The risk factor is measured in an evaluation that is masked to the outcome.

Class IV: Any design where the predictor is not applied in a masked evaluation OR evidence provided by expert opinion or case series without controls.

Appendix 3

Definitions for strength of recommendations

Level A: Established as useful/predictive or not useful/predictive for the given condition in the specified population (requires at least one convincing class I study or at least two consistent, convincing class II studies).

Level B: Probably useful/predictive or not useful/predictive for the given condition in the specified population (requires at least one convincing class II study or at least three consistent class III studies).

Level C: Possibly useful/predictive or not useful/predictive for the given condition in the specified population (requires at least two convincing and consistent class III studies).

Level U: Data inadequate or conflicting. Given current knowledge, test/predictor is unproven.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Psychosocial Aspects of Child and Family Health

The New Morbidity Revisited: A Renewed Commitment to the Psychosocial Aspects of Pediatric Care

ABSTRACT. In 1993, the American Academy of Pediatrics adopted the policy statement "The Pediatrician and the 'New Morbidity.'" Since then, social difficulties, behavioral problems, and developmental difficulties have become a main part of the scope of pediatric practice, and recognition of the importance of these areas has increased. This statement reaffirms the Academy's commitment to prevention, early detection, and management of behavioral, developmental, and social problems as a focus in pediatric practice.

ABBREVIATIONS. AAP, American Academy of Pediatrics; *DSM-PC, Diagnostic and Statistical Manual for Primary Care.*

ONCE A NEW MORBIDITY

In 1991, the American Academy of Pediatrics (AAP) Task Force on the Future Role of the Pediatrician in the Delivery of Health Care made reference to the 1800s, when pediatrics developed as a medical specialty. "A focus on growth and development was established rapidly, and it was recognized that the child's health was influenced greatly by family attitudes, environment, and socioeconomic class."[1] Thus, the concept of morbidity associated with environmental and psychosocial issues in child health care is not new. Social and behavioral issues were recognized by the early leaders in pediatrics, and the style in which they are addressed constitutes the art of pediatric practice. Carl C. Fischer spoke in 1969 about the role of the AAP in child health care: "The founding fathers, in their wisdom, established the major objective of the Academy, which is to foster and stimulate interest in pediatrics and correlate all aspects of the work for the welfare of children which properly comes within the scope of pediatrics."[2]

Public health initiatives, such as immunizations and improved public hygiene, and specific treatments with new technologies for disease, equip pediatricians at the beginning of this century with the ability to offer prevention, cure, and resolution of ailments and injuries, now a standard expectation of pediatric practice. These advances have led to an emphasis on specialization as an essential component of training for the care of patients. Pediatricians are now challenged to place more attention on activities related to the quality of outcomes, chronic disease management, and the psychosocial consequences of chronic conditions as the behavioral needs of our patients are now recognized as core elements of pediatric care.

THE CURRENT ENVIRONMENT

Although dealing with social, developmental, and behavioral issues may once have been considered an art, advances in the social sciences have established a knowledge base of specific skills and interventions effective in dealing with many psychosocial issues.[3,4] For example, there is a better understanding of long-term consequences of divorce,[5] child sexual abuse,[6] and the ongoing effects of attention-deficit/hyperactivity disorder into adulthood.[7,8] The field of pediatric psychopharmacology has been rapidly evolving over the past decade with the introduction of new medications such as selective serotonin reuptake inhibitors and atypical antipsychotics.[9,10] The practicing pediatrician must have a broader knowledge base to identify these problems and intervene and has a responsibility to become knowledgeable about approaches that work.

When this topic was last reviewed,[11] the new morbidities in pediatric practice demanded competence in the following areas of knowledge:

- physical and environmental factors affecting behavior, including risk factors, and their impact, prevention, and management;
- normal variations of behavior and emotional development and how to help parents deal with them;
- behaviors affecting physical health, including risk factors (eg, medical adherence, smoking), and their impact, prevention, and management;
- mild and moderate behavioral problems, including detection, evaluation, and management; and
- severe behavioral deviations, including recognition, preliminary evaluation, and appropriate referral.

These morbidities remain important foci in the care of children and families. The purpose of this statement is to reaffirm the commitment of the AAP to prevention, early detection, and management of behavioral, developmental, and social problems as a focus in pediatric practice.

NEWER MORBIDITIES

Now an increasingly complex environment brings newer morbidities to the attention of pediatric practitioners, such as:

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

- school problems, including learning disabilities and attention difficulties;
- child and adolescent mood and anxiety disorders;
- the alarming increase in adolescent suicide and homicide;
- firearms in the home;
- school violence;
- drug and alcohol abuse;
- human immunodeficiency virus and acquired immunodeficiency syndrome; and
- the effects of media on violence, obesity, and sexual activity.

These are the morbidities that place our patients at risk. The mortality of meningococcemia is appreciated by all pediatricians, but the morbidity of depression and the mortality of adolescent suicide are more appreciable.[12–14] In other words, after infancy, children in the United States are more likely to die from injuries or violence and suicide than from infectious disease.

In addition, pediatricians are challenged in their practices by aspects that relate to quality of life, social justice, equality in health care access, population and public health, and personal and institutional values, including but not limited to:

- poverty;
- homelessness;
- single-parent families;
- the effects of parental divorce on children;
- the struggles of working parents; and
- issues of child care policy and quality.

Pediatricians' creativity, flexibility, patience, and commitment are being challenged in ways that test the very original motivations for choosing pediatrics as a profession and vocation.

THE BARRIERS

If we embrace the importance of these morbidities, how will we meet these challenges? Why has a good idea not taken hold? Why do disciplines struggle over the conceptualization of these problems and implementation of effective treatments? To practice effectively in this arena, pediatricians must overcome existing educational, economic, and time management obstacles.

THE PATH TOWARD CHANGE

The pediatrician's professional competence and job satisfaction in managing behavioral issues can be enhanced by several changes.

Training and Continuing Medical Education

Pediatric residency training is largely focused on major physical illness in tertiary care hospitals and, to a limited degree, on behavioral issues. Limited training opportunities are provided to integrate psychosocial issues into primary care.

Training in ambulatory settings must expand the emphasis on behavioral, developmental, and psychologic issues. More extensive developmental, behavioral, and adolescent training during residency will better equip pediatricians to address these practice challenges. The experience must be supervised by faculty with training and/or experience in the behavioral/developmental aspects of pediatrics.[15]

Continuing medical education training in the areas of developmental and behavioral pediatrics are now provided by the AAP and other sources.

Improving Diagnostic Skills

The *Diagnostic and Statistical Manual for Primary Care* (*DSM-PC*) *Child and Adolescent Version*[16] describes the full range of psychosocial and behavioral problems encountered by pediatricians, from normal variant behavior through problem behaviors, to syndromic or diagnosable levels. The *DSM-PC* classification of coding of mental conditions in children allows for early identification and enhances the understanding and management of a broader range of psychosocial issues in pediatrics. The *DSM-PC* describes problems intrinsic to the child and situational diagnoses that complicate a child's function. The *DSM-PC* is an essential part of the primary care pediatrician's library, providing accurate and appropriate diagnoses and allowing the documentation of services provided and claims submissions for appropriate reimbursement.

Improving Interviewing Skills

Interviewing skills are essential to all aspects of medicine. There is a need to better learn how to elicit information, including using a narrative interview approach, allowing the child, adolescent, and parents to tell their stories, even when it means giving up control of the interview. There is a need to effectively communicate empathy. Pediatricians also need to recognize their own experience, culture, and values and the impact of their personal issues on the therapeutic relationship. As a skill to be learned, interviewing needs to include supervised practice and feedback as well as mentoring. Formalized and tested screening tools are available to cast a wider net to screening. Many practices develop their own questionnaires to assist in screening and in the interviewing process. Internet-based screening tools are also available to facilitate referral to community mental health services and to improve access.[17]

Improving Pediatric Counseling Skills

Counseling is a skill that is underused in the management of behavioral problems. With a combined knowledge of psychosocial issues, interviewing skills, and diagnostic understanding, pediatricians can effectively counsel patients and families and improve many of the behavioral problems they encounter at early stages of their presentation.

Establishing a Comprehensive Mental Health Model

A collaborative model that integrates physical and mental issues, considers positive and negative aspects of child and family adjustment, and encourages the clinician to make behavioral diagnostic judgments is also important. Strong consideration should be given to an interdisciplinary approach in the ambulatory clinical setting with mental health professionals and physicians working side by side.[18] Col-

laborative approaches can also be created for smaller practices where on-site mental health professionals are not available.

Allocating Time Realistically

Child health supervision visits are effective for detecting abnormalities and preventing illness. When psychosocial issues are detected during such a visit, there may be insufficient time to address the problems adequately. Although developmental issues reflecting normal variations may be managed within the context of health supervision visits, more complex issues, such as divorce, bereavement, school failure, domestic violence, or homosexuality, require additional visits with ample time to discuss the problem. The individual skill level of the pediatrician will determine the complexity of psychosocial issues that he or she can manage effectively.

Ensuring Adequate Reimbursement

Pediatricians must advocate for themselves in their individual practices and for the practice of pediatrics at large by negotiating managed care and fee-for-service contracts with third party payers that ensure reimbursement for excess services provided and by advocating for the mandatory inclusion of benefits for these services in families' insurance contracts, both public and private.

CONCLUSION

The "new morbidity" represents a shift in the understanding of what impacts the health of children and families. Pediatricians witness complex psychosocial family issues and care for the patients impacted by them; understanding and addressing these issues will make the pediatrician more effective in serving children and families. The cooperation of pediatric residency directors, educators, practicing pediatricians, and developmental and behavioral pediatricians will be required for training residents and experienced pediatricians. To effectively address these new morbidities, pediatricians will need a model that encompasses expanded areas of competence in child behavior, development, and family function.

RECOMMENDATIONS

1. Residency training programs should reflect in their curricula psychosocial issues that affect children and their families.
2. Practicing pediatricians are encouraged to increase their knowledge of developmental and behavioral aspects of child health care.
3. Pediatricians should develop an increased understanding of positive and negative factors that influence child psychosocial development.
4. Pediatricians should enhance their interviewing, counseling, and referral skills to better address psychosocial aspects of child and family health care.
5. Pediatricians are strongly encouraged to establish side-by-side practice with mental health professionals to address more complex psychosocial issues encountered in clinical practice.
6. Pediatricians are strongly encouraged to use *DSM-PC* coding to convey to insurance companies and health financing institutions the importance and value of pediatricians spending time addressing psychosocial issues.
7. The pediatrician should become familiar with mental health referral processes and community resources in the mental health field to ensure access and continuity of services.
8. Pediatricians should advocate for children's mental health needs within their professional communities and the education system, as well as among legislators.
9. Pediatricians should enhance their understanding of the newer psychotropic medications and establish collaborative working relationships with child and adolescent psychiatrists.

I certify that all information furnished on this form is true and complete. I understand that anyone who furnishes false or misleading information on this form or who omits material or information requested on the form may be subject to criminal sanctions (including fines and imprisonment) and/or civil sanctions (including civil penalties).

Instructions to Publishers

1. Complete and file copy of this form with your postmaster annually on or before October 1. Keep a copy of the completed form for your records.
2. In cases where the stockholder or security holder is a trustee, include in items 10 and 11 the name of the person or corporation for whom the trustee is action. Also include the names and addresses of individuals who are stockholders who own or hold 1 percent or more of the total amount of bonds, mortgages, or other securities of the publishing corporation. In item 11, if none, check the box. Use blank sheets if more space is required.
3. Be sure to furnish all circulation information called for in item 15. Free circulation must be shown in items 15d, e, f.
4. Item 15h., Copies not Distributed, must include (1) newsstand copies originally stated on Form 3541, and returned to the publisher (2) estimated returns from news agents, and (3), copies for office use, leftovers, spoiled, and all other copies not distributed
5. If the publication had Periodicals authorization as general or requester publication, this Statement of Ownership, Management and Circulation must be published; it must be printed in any issue in October or, if the publication is not published during October the first issue printed after October.
6. In item 16, indicate the date of the issue in which this Statement of Ownership will be published
7. Item 17 must be signed.

Failure to file or publish a statement of Ownership may lead to suspension of Periodicals authorization

CLINICAL REPORT

Newborn Screening Expands: Recommendations for Pediatricians and Medical Homes—Implications for the System

Guidance for the Clinician in Rendering Pediatric Care

Newborn Screening Authoring Committee

ABSTRACT

Advances in newborn screening technology, coupled with recent advances in the diagnosis and treatment of rare but serious congenital conditions that affect newborn infants, provide increased opportunities for positively affecting the lives of children and their families. These advantages also pose new challenges to primary care pediatricians, both educationally and in response to the management of affected infants. Primary care pediatricians require immediate access to clinical and diagnostic information and guidance and have a proactive role to play in supporting the performance of the newborn screening system. Primary care pediatricians must develop office policies and procedures to ensure that newborn screening is conducted and that results are transmitted to them in a timely fashion; they must also develop strategies to use should these systems fail. In addition, collaboration with local, state, and national partners is essential for promoting actions and policies that will optimize the function of the newborn screening systems and ensure that families receive the full benefit of them.

INTRODUCTION

> It's another busy day in pediatric practice, even before you receive the telephone call from the state newborn screening program. One of your newborn patients has an out-of-range result* on the screen for a rare but serious congenital condition. "Now what?" you wonder, as you begin to take down the notes. What additional testing is needed? What is the treatment regimen, and when does it begin? What do you tell the parents? And, what do you do about the rest of your schedule?

In the past decade, new technologies have led to a rapid expansion in the number of congenital conditions that are targeted in state newborn screening programs. As newborn screening programs expand, the likelihood increases that individual pediatricians will one day receive an out-of-range screening result for an unfamiliar congenital condition for one of their patients.

In 2005, the American Academy of Pediatrics (AAP) endorsed a report from the American College of Medical Genetics (ACMG), which recommended that all states screen newborn infants for a core panel of 29 treatable congenital conditions and an additional 25 conditions that may be detected by screening (Appendix 1).[1] The Secretary of Health and Human Services' Advisory Committee on Heritable Disorders and Genetic Diseases in Newborns and Children (ACHDGDNC)† also adopted that report. Some states are now screening for more than 50 congenital conditions, many of which are rare and unfamiliar to pediatricians and other

*A note about language: although physicians often think of screening results as being "normal/abnormal" or "negative/positive," laboratories use the more specific language of "in range" and "out of range" to report results. We felt that it was appropriate to use and promote this language for the sake of clarity and consistency. For ease of reading, we use "parent" as a generic term to connote the adult who is responsible for a child's health care; we recognize that adults other than the biological parent may serve in this role. Where implications of congenital disorders are discussed, these obviously affect only those persons who are related biologically. In some circumstances, a primary care physician may suggest that the biological parent be contacted regarding congenital conditions, even if that parent is not the current primary caregiver for the child.

†A federal advisory committee to the Secretary of Health and Human Services, the ACHDGDNC advises and guides the Secretary regarding the most appropriate application of universal newborn screening tests, technologies, policies, guidelines, and programs for effectively reducing morbidity and mortality in newborns and children having or being at risk for heritable disorders.

primary health care professionals. In the foreseeable future, screening programs will likely adopt screening technologies that will further expand the number of conditions screened and tests offered.

The ACMG, with the support of the Health Resources and Services Administration (HRSA) Maternal and Child Health Bureau (MCHB), has developed and maintains Web-based resources it calls action (ACT) sheets to guide pediatricians through preliminary responses to out-of-range newborn screening results. These brief reference resources provide a focused, single-page summary of differential diagnoses, descriptions of the condition, actions to be taken by the pediatrician, diagnostic evaluation, clinical considerations, reporting requirements, and links to additional resources. ACT sheets are designed to be supplemented by state-specific information regarding referral resources. Many state-program Web sites have additional program-specific educational information; links to these program Web sites are readily accessible through an interactive map maintained by the National Newborn Screening and Genetics Resource Center (http://genes-r-us.uthscsa.edu/resources/consumer/statemap.htm).

Advances in newborn screening technologies and the availability of resources such as ACT sheets are aimed at improving health outcomes for affected children. To optimize this potential, primary care pediatricians (PCPs) must effectively engage the newborn screening program in their state. PCPs who treat patients who routinely cross state borders for care will likely engage multiple newborn screening programs.

The primary goals of this statement are to:

- delineate the responsibilities of PCPs and pediatric medical subspecialists within the newborn screening program;
- introduce 2 algorithms that, together, outline a clear and efficient pathway through the process of fulfilling those responsibilities; and
- outline resources that will support PCPs in addressing these responsibilities.

In addition to these primary goals, this statement addresses the steps that individual PCPs and practices must take to prepare for these responsibilities. We also recognize the significant roles other health care professionals and agencies have on the newborn screening system and identify ways these other entities can support PCPs and improve newborn screening and, therefore, advance improved health outcomes for newborns across the nation.

Limitations of This Statement

State newborn screening systems vary in their specific structure, procedures, and practices; this statement is focused on the core elements that are common to most state newborn screening systems. Newborn screening is increasingly being offered by commercial laboratories that market directly to parents and pediatric health care professionals. These programs introduce another layer of variation, which is beyond the scope of this statement.

Adequate funding of all aspects of newborn screening systems is necessary to ensure optimal performance of the system. This statement includes some general recommendations to promote such funding, and the AAP supports efforts to address financing for the nation's newborn screening systems and their constituent parts. Detailed recommendations for addressing the myriad challenges of system financing lie beyond the purview of this document.‡

Limitations of Newborn Screening

It is important to emphasize that newborn screening panels do not include all possible congenital conditions, and results for conditions on the panel should not be considered diagnostic. Thus, an in-range newborn screening result does not eliminate the possibility that a clinically symptomatic child has a congenital condition. Congenital conditions must be considered whenever an infant has signs or symptoms that are suggestive of (or consistent with) one of the disorders that can be detected by newborn screening.

An important goal of newborn screening is to identify infants with treatable congenital conditions before they become symptomatic. However, clinicians who care for children must be aware that some screened conditions may present with clinical deterioration before notification of newborn screening results. Pediatricians and emergency care physicians are often among the first health care professionals to encounter symptomatic infants, so they should be knowledgeable about the newborn screening program, ACT sheets for suspected conditions, and local or regional pediatric medical subspecialists to whom infants can be referred. The state newborn screening program usually can provide information about suspected conditions and expedite the newborn's follow-up confirmatory testing and care.

THE ALGORITHMS

The PCP plays several significant roles in the newborn screening system. In addition to responding to out-of-range newborn screening results, the PCP serves as a central source of education for parents regarding multiple aspects of the newborn screening system; the PCP also has responsibility for ensuring that newborn screening has been conducted, which can include providing education and encouragement to parents who decline screening. Finally, the PCP must ensure coordinated and comprehensive care for children affected by congenital conditions that are identified through newborn screening. The medical home provides a model for such care; the algorithms presented here address the specific roles of a medical home provider within the newborn screening system (Figs 1 and 2).

3- to 5-Day-Old Visit

The AAP[2] and *Bright Futures*[3] recommend neonatal follow-up visits in a child's medical home shortly after

‡For guidance on the *Current Procedural Terminology* (CPT) codes appropriate for use in the care of children who are identified as having congenital disorders, PCPs should refer to Rappo MA, Rappo PD. A special issue: coding for children with special health care needs. *AAP Pediatric Coding Newsletter*. January 2007. Available at: http://coding.aap.org/newsletterarchive.aspx.

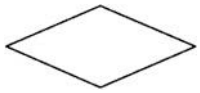
hospital discharge (3 to 5 days of life) and again by 1 month of age to ensure adequate weight gain, resolve neonatal concerns such as hyperbilirubinemia, and address parental questions. At the 3- to 5-day-old visit, the PCP should check for circumstances suggesting that newborn screening might not have been conducted.



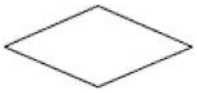
Concern That Newborn Screening Was Not Conducted?

In most cases, newborn screening will occur as a result of standing orders at a hospital or birthing facility. In these cases, the PCP can address other aspects of the visit.

There are circumstances, however, under which the PCP might have cause for concern that the newborn screening was not performed. These circumstances include, but are not limited to, home births, emergency births, hospital transfers, and international adoption. In

addition, although most states mandate newborn screening, most jurisdictions provide parents with the right of refusal (see "Parents Decline Newborn Screening?").

If available discharge papers do not indicate that the newborn screening has been performed, the PCP should make arrangements for specimen acquisition.



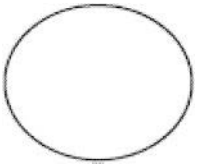
Parents Decline Newborn Screening?

If parental refusal is the reason that newborn screening has not been conducted, or if parents refuse newborn screening suggested by the PCP, the PCP should discuss the possible implications of nontesting and supply the parents with printed materials on newborn screening. Educational materials for parents and PCPs can be accessed through the AAP Web site (www.medicalhomeinfo.org/screening/newborn.html).

Provide Parent Education

Parent concerns and questions should be addressed fully, and a discussion of the general benefits and limited risks of newborn screening is recommended. More familiar conditions, such as congenital hearing loss, phenylketonuria, and sickle cell disease, may be used as examples.

If parental permission is obtained, arrangements for specimen acquisition should be made immediately, and newborn screening should be ordered.

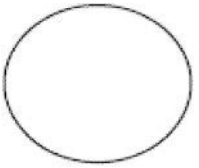


Order Newborn Screening

Newborn screening is conducted through the state newborn screening program, and protocols for ordering the screening vary by state. Contact information for each state's newborn screening program is available (see Appendix 4 and http://genes-r-us.uthscsa.edu/resources/consumer/statemap.htm).

Obtain Waiver

If parental permission is not obtained, parents or guardians should be asked to sign a waiver that documents their decision to decline newborn screening. In many cases, parents already will have signed a waiver at the hospital. PCPs should document the additional conversation and the parents' decision in the patient's chart and may wish to include a waiver signed in the PCP's office. A sample waiver form is included as Appendix 5; appropriate waiver forms should also be available through the state health department.



Flag the Charts of Unscreened Patients

In addition to documenting the discussion of newborn screening and the parents' refusal to consent to the screening, PCPs should flag the chart of any patients who are not screened so that the lack of screening will be taken into account should any subsequent concerns emerge regarding the child's growth or development. Vomiting, poor growth, seizures, developmental delay, lethargy, recurrent pneumonia, or poor feeding should prompt an evaluation that includes consideration of heritable conditions.

The chart note should also prompt the pediatrician to return to the question of newborn screening on subsequent visits to determine if the parents have changed their minds. The usefulness of screening after the neonatal period varies by condition, and use of state newborn screening systems for older infants varies by program.

Special Circumstances

For cases in which newborn screening is delayed because of previous parental refusal, because the infant was receiving total parenteral nutrition, or because of circumstances such as international adoption or an older infant entering care, the PCP should consult with the state newborn screening program regarding the availability and usefulness of the newborn screening protocol.

Newborn screening may not be ordered or may require an additional specimen in the case of preterm births, transfusion before screening, and other circumstances.[4] In these cases, the PCP should consult with a neonatal specialist.

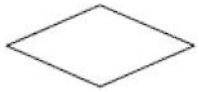
In every circumstance, until and unless newborn screening is conducted, the patient's chart should be flagged to ensure that the lack of newborn screening is considered during ongoing care.

Results Received

In the case of an invalid or out-of-range screening result, the pediatrician identified on the newborn screening card should be called by the state newborn screening program in accordance with the urgency of the need for clinical intervention. In-range results are often transmitted by mail and should arrive before the 2- to 4-week visit.

2- to 4-Week Visit

The PCP cannot assume a "no news is good news" approach with regard to newborn screening. Delays or procedural failures at hospitals, state laboratories, other facilities, or within the newborn screening program may result in late or lost results. An infant's medical follow-up may not occur as planned, or newborn screening results may go directly to the child's birth facility instead of the infant's medical home.



Are Newborn Screening Results Available?

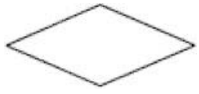
Office staff should check routinely for newborn screening results before the 2- to 4-week visit and pursue missing results before the visit. Using electronic-chart prompts or paper-chart templates for newborn visits will remind office staff to seek out newborn screening results.

Call for Newborn Screening Results

If newborn screening results are not available before the 2- to 4-week visit, the PCP should contact the state newborn screening program or the birthing facility for the results. An increasing number of state newborn screening programs have automated interactive telephone- or Internet-based systems through which pediatric offices can check for newborn screening results at any time.

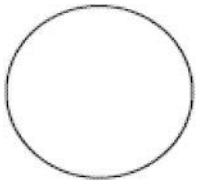
Special Circumstances

Occasionally, newborn screening results may be sent to the nonprimary physician; a physician who provides hospital or perinatal care for the infant may be noted on the newborn screening card even if he or she is not the infant's medical home physician. Clerical or other errors also may result in a physician who is unconnected to the child receiving the newborn screening results. However, the name on the card implies responsibility for the results, and physicians who receive results for patients who are no longer in their care should collaborate with the state newborn screening program and, in some instances, the hospital or birthing facility to locate the infant's family and/or current provider and to proceed with appropriate follow-up until the responsibility for subsequent care is clearly established. Physicians who receive results for patients with whom they or their colleagues have had no interaction should also notify the state newborn screening program immediately.



Screening Results?

The state newborn screening program will report results to the child's physician of record as being in range, invalid, or out of range. Appropriate responses to each of these results are discussed in the next sections.

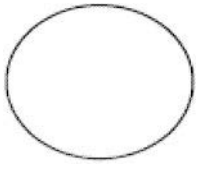


Document In-Range Screening Results and Reassure Family

In-range newborn screening results should be noted in the infant's chart and shared with the parents or guardians. In reassuring the family, the PCP should keep in mind that newborn screening does not rule out congenital conditions that are not included in the panel and does not absolutely guarantee the absence of the conditions that are screened. The PCP might note, however, that false in-range results are quite rare and the family can be reassured that their child is unlikely to be affected by conditions for which screening was performed.

Special Circumstances

Nine states (Arizona, Colorado, Delaware, Nevada, New Mexico, Oregon, Texas, Utah, and Wyoming) mandate an additional screening when the infant is 1 to 2 weeks old on the basis of the belief that a second screening is necessary to identify the maximum number of children with genetic disorders. A second screening is recommended for all infants in several other states, and approximately 25% of all US newborn infants currently receive 2 screenings. The relevance of second screenings for endocrinopathies is the subject of a study currently being designed by the MCHB. PCPs should familiarize themselves with their state's policies and procedures. If a second screening is ordered, it can be introduced and explained to parents within the context of state policies and the current limitations to newborn screening technologies discussed previously.



Reorder Newborn Screening

If the specimen is invalid (eg, collected too early, inadequate specimen, poor drying or application technique, inadequate or illegible patient information), the infant's newborn screening must be reordered and blood redrawn. This screen should be completed promptly to optimize the availability of results. PCPs must be familiar with local protocols for rescreening and should contact parents immediately to direct them to the site at which the second blood specimen will be obtained.

Consult ACT Sheets and State Newborn Screening Program

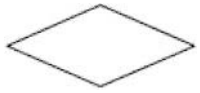
An out-of-range result on the newborn screening panel is not a diagnosis. However, some congenital conditions can be rapidly fatal in infants who appeared entirely healthy a few days earlier; thus, out-of-range screening results should always lead to prompt action by the PCP.

If the state newborn screening program does not provide the ACT sheet specific to the condition for which an out-of-range result was obtained, the PCP should download it (www.acmg.net/resources/policies/ACT/condition-analyte-links.htm).

The ACT sheet should be reviewed and followed in its entirety, but the most important actions are highlighted. These actions include:

- when to contact the family;
- whom to consult and whether an appointment is needed immediately;
- when the patient must be seen by the PCP;
- whether additional confirmatory testing is needed and what tests should be conducted;
- whether treatment is necessary and what treatment to initiate;
- how to educate parents about the condition; and
- when findings need to be reported back to the newborn screening program.

In addition to following ACT sheet recommendations, the PCP should consult with the state newborn screening program regarding out-of-range results. The state program should be familiar with local or regional experts for the conditions on their screening panels. In some states, the programs fund subspecialty clinics to conduct diagnostic evaluations and provide short-term and/or long-term subspecialty care to infants with out-of-range screening results.



Condition Identified?

After an out-of-range screening result is obtained, confirmatory testing and/or definitive consultation with subspecialists are required before a final diagnosis can be made.

To increase the sensitivity of a population screening test for rare conditions (and hopefully minimize the number of false in-range results missed), false out-of-range results are expected to occur, and false out-of-range results are significantly more frequent than true out-of-range results for most newborn screening tests. However, given the seriousness of the congenital conditions included in the newborn screening panel, the PCP must avoid complacency in the face of out-of-range results. Until confirmatory testing and/or definitive consultation with subspecialists can be accomplished, all out-of-range results must be taken very seriously.

Special Circumstances

In addition to true or false out-of-range results, confirmatory tests may identify the child as a carrier of the condition or may lead to an indeterminate result.

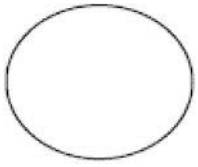
Carriers are individuals who are heterozygous for an autosomal-recessive condition and are usually not at risk of health problems themselves, although this may vary with the condition. Many state programs notify the PCP that the infant has been identified as a carrier, and it may be the responsibility of the PCP to disclose and discuss these results with the parents.

Knowledge of carrier status has 2 implications. First, because most of the conditions tested for on newborn screening are autosomal-recessive in inheritance, it is highly probable that at least 1 of the parents is a carrier also, and both parents might be carriers. If both parents are carriers, they have a 1-in-4 chance with each pregnancy of having an affected child. Alerting parents to the carrier status of their child serves to alert them that they may be at increased risk of having an affected infant with their next pregnancy. (When newborn screening results lead to genetic testing of the parents, pediatricians should be aware that misattributed paternity could be identified. Discussion with a geneticist or genetic counselor about how to manage these sensitive results may be helpful.)

The second implication of identifying a newborn as a carrier is that the infant will be at an increased risk of bearing an affected child when he or she achieves reproductive age if his or her future partner also is a carrier for the same condition. The risk is largely determined by the prevalence of the condition within the population, and additional genetic counseling may be warranted.

Occasionally, confirmatory diagnostic test results will not result in a definitive diagnosis. Uncertain results can be distressing to parents and PCPs, so thorough consultation with a subspecialist is essential. Unfortunately, indeterminate results may not be possible to resolve without more knowledge about some of these conditions and longer-term follow-up of these children.

At this point, it is incumbent on the PCP and the subspecialist to maintain an ongoing collaboration and continue to monitor the infant for signs and symptoms of a suspected condition. Children with uncertain results should have their chart identified for close monitoring. Good communication between the PCP and the consulting subspecialist is essential at this point to ensure that a unified message is conveyed to parents.



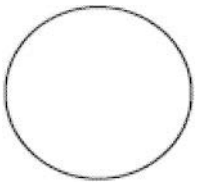
Document False Out-of-Range Results and Reassure Parents

In the event that the initial out-of-range result proves to be a false out-of-range result, the PCP can provide reas-

surance to parents. However, research that evaluated parents of infants with false out-of-range results has suggested that 5% to 20% of these parents will persist in their concerns about the health of their children for months or years after screening.[5–9] Therefore, PCPs should not take the event of a false out-of-range result too lightly and may wish to discuss this issue with parents on subsequent visits to provide additional reassurance and eliminate any misconceptions.

Provide Parent Education

To lay the foundation for comprehensive and collaborative care, it is critical during this time of uncertainty that the parents and family of the neonate be provided with condition-specific information and support as they await final clarification of the child's diagnosis and begin to plan for treatment and management. Parents are usually intensely anxious about the health of their child while the diagnosis is being pursued, and increasingly, parents are adept at tapping into resources on the Internet about specific conditions. Frequent, specific, and supportive communication from the PCP will help to avoid confusion and build trust. Appropriate materials for distribution to parents have been produced by the AAP (www.aap.org), the American College of Obstetricians and Gynecologists (ACOG [www.acog.org]), and MCHB/HRSA (www.mchb.hrsa.gov/screening). State newborn screening programs may also make educational materials available to health care professionals.



Identify the Child as a Child With Special Health Care Needs and Initiate Chronic Care Management

Any child who is given a diagnosis of a significant medical condition should be identified by the medical home physician as a child with special health care needs. Such a child should be entered into the practice's children with special health care needs registry, and chronic condition management should be initiated. Chronic care management provides proactive care for children with special health care needs, including condition-related office visits, written care plans, explicit comanagement with subspecialists, appropriate patient education, and effective information systems for monitoring and tracking the child's condition.[10]

IMPLEMENTING THE ALGORITHM

Role of the Medical Home

Regardless of diagnosis, every child needs a medical home to ensure coordinated and comprehensive care such that all of the medical, psychosocial, and educational needs of the child and family are met successfully within the local community. The PCP is responsible for providing a medical home.

Some conditions identified by newborn screening are relatively mild and or/transitory, and others have a wide spectrum of severity from asymptomatic to life-threatening crises. Plans for continuing care should be made in consultation with the family and appropriate subspecialists in light of the condition affecting the child and the severity of its manifestation. In some cases, the PCP may provide all or most of the ongoing care.

In other cases, the family may view their subspecialist as their primary care physician. Although a subspecialist may provide substantial ongoing care for a child who has been diagnosed with a severe and complex condition, the PCP retains the responsibility for providing a central source of "family centered, accessible, continuous, coordinated, comprehensive, compassionate, and culturally effective" care for the family.[11] The parents and family should be encouraged to maintain their relationship with their PCP. This relationship is critical, especially for cases in which the subspecialist is located at some distance from the family. In a crisis, the PCP may be the only available provider with knowledge of the child; he or she must have up-to-date information regarding the child's treatment.

The complex nature of many conditions identified by newborn screening may require care by a team of medical subspecialists, therapists, nutritionists, and educators.[12] The PCP and other professionals involved in the child's care must collaborate in the provision of acute care for illness or injury; surveillance of growth and development; anticipatory guidance to the family; immunizations; communications with schools, social services, and camps; transitions in care; and communication with other care professionals. In any case, clearly defined roles may help to reduce redundancies of services and prevent fragmentation of care.

The medical home should actively engage public and private resources to aid in the management of chronic conditions. Public health nursing provided through some state public health departments' maternal and child health programs often has a role in assisting PCPs, subspecialists, and families of children with conditions that are diagnosed through newborn screening. The level of public health nursing may vary from simply providing information and referrals to assisting with chronic condition management for a family.

If there is not a local health department or nursing service, PCPs may contact their state maternal and child health department (Title V) and the directors of programs for children with special health care needs through the state department of public health to obtain information on the availability of local family services; the state department of education for contacts with school nurses; and the early intervention agency (Individuals With Disabilities Education Act Part C) for contact information for the local early childhood connections program. Although the state resources for public health vary greatly from state to state, almost all communities have one or all of these resources available for

families. The national organization Family Voices (www.familyvoices.org) can provide information on local organizations and agencies that can offer resources to families with children with special health care needs and can assist families in accessing community services.

For additional information regarding care coordination, see the AAP policy statement "Care Coordination in the Medical Home: Integrating Health and Related Systems of Care for Children With Special Health Care Needs."[13]

Role of the Subspecialist

For most of the conditions that may be detected through newborn screening, the subspecialist will confirm the diagnosis, develop the treatment plan, educate the family about the treatment, monitor treatment, identify complications related to the disease process that may require additional referral, and work with other consultants in coordination of care. When acute illness exacerbates the condition, the PCP should work with the subspecialist to diagnose the acute illness and manage it appropriately to reduce morbidity.

Some children with conditions identified through newborn screening will have long-term sequelae that will require ongoing subspecialty management despite appropriate early intervention. Many of these children will have mild neurodevelopmental disabilities that may present as learning difficulties, attention-deficit/hyperactivity disorder, or other behavioral problems. However, in some instances, more significant cognitive and motor deficits and/or problems that adversely affect the child's feeding skills and respiratory status may be present. It is essential that the PCP provide ongoing screening and surveillance for these developmental disabilities.

Even with appropriate treatment, patients with certain conditions identified through newborn screening can undergo metabolic decompensation during an acute febrile illness. PCPs need to be aware of the initial clinical signs and laboratory abnormalities that may be found when metabolic decompensation occurs and be able to provide immediate intervention to stabilize the child until more specific advice can be obtained from the appropriate treating subspecialist. Effective communication among subspecialists as well as between each subspecialist and the PCP is essential for optimal long-term management of these children.[14] Long-term responsibilities of the subspecialist, in collaboration with the PCP, include:

- Providing genetic counseling and evaluation: Because the majority of conditions diagnosed through newborn screening are hereditary, genetic evaluation and counseling will be necessary for the parents. Older siblings may be affected with the condition but not yet symptomatic; diagnostic studies may be indicated for the siblings, and other relatives may wish to undergo carrier testing. The PCP, the state newborn screening program, and subspecialists are jointly responsible for ensuring that referral for genetic services occurs.
- Providing ongoing parent education and links to available resources: Resources for managing the condition should be made available to the patients and their families. Subspecialists, the PCP, and the state newborn screening program should collaborate in making appropriate referrals to programs for children with special health care needs, childhood early intervention programs, community-based support services, and additional subspecialists who are needed to evaluate and manage associated disabilities. Information from disease-specific advocacy organizations, along with parent brochures and guidance for child health care professionals, may be available through the subspecialist. The Genetic Alliance, a coalition of advocacy groups, serves as another national resource for parents (www.geneticalliance.org). The National Library of Medicine also has material on every condition in the expanded ACMG-recommended panel (http://ghr.nlm.nih.gov).
- Assisting in the transition to adult care: When transition to adult care is appropriate, the subspecialist will work with the PCP to identify a new team of physicians to care for the young adult. As adolescence proceeds, additional genetic counseling and preparation for family planning are appropriate.

RECOMMENDATIONS

Preparing the Practice

Before receiving notice of an out-of-range newborn screening result from their state newborn screening system, PCPs can take several steps to enhance their ability to successfully address their roles and responsibilities within the newborn screening program.

1. PCPs should familiarize themselves with their state newborn screening program via available (online) resources or, if necessary, by contacting the state program. PCPs should develop some familiarity with the conditions being screened and basic operations of their state newborn screening program, including protocols for retesting invalid screening results and conducting second screenings. PCPs should identify the person(s) with whom they should consult in the case of an out-of-range screening result and ensure that contact information is readily available.
2. State-specific contact information for regional pediatric medical subspecialists should be collected and kept on file in the PCP's office.
3. Procedures to address several steps of the algorithm should be developed in advance. These procedures include:
   a. updating contact information for the state newborn screening program and regional pediatric medical subspecialists;
   b. identifying children who are most likely not to have had newborn screening;
   c. confirming receipt of newborn screening results on all patients;

d. obtaining newborn screening results when they are not received from the state program;

e. documenting parental refusal of newborn screening; and

f. obtaining newborn screening specimens in the case of lost, delayed, or invalid results (the CPT code for retesting is 84030, and the diagnosis code is 270.10; PCPs should check with insurers to assess reimbursement).

4. PCPs should establish registries to identify, follow, and provide chronic condition management for children with special health care needs.

5. Educational materials regarding newborn screening should be on hand to distribute to expectant parents, parents who may decline newborn screening, and parents whose child's screening returns an out-of-range or inconclusive result. These materials should be available in languages and at literacy levels appropriate to all patients served. Appropriate materials for distribution to parents have been produced by the AAP (www.medicalhomeinfo.org/screening/newborn.html), ACOG (www.acog.org), and MCHB/HRSA (www.mchb.hrsa.gov/screening). State newborn screening programs may also make educational materials available to health care professionals.

Care coordination plays an essential role in ongoing efforts to integrate health and related systems of care for children and youth with special health care needs.[15] Becoming aware of available resources, being involved in the care coordination process, and developing unique care coordination approaches within one's own practice and community and in relationship with existing tertiary care centers are essential for providing optimal care for children with special health care needs. Families, PCPs, and other professionals can collaborate meaningfully to provide effective coordinated care.[13,15]

PCPs are also encouraged to participate in state, regional, or national registries; quality assurance programs; and/or research projects designed to enhance the care of children with the rare and complex conditions included in the newborn screening panel. They are also encouraged to seek opportunities for additional training and learning about state newborn screening programs and the conditions for which infants are screened and to work with their local AAP chapter and state newborn screening advisory committee (SNSAC) to advance the quality and effectiveness of the newborn screening system at the state and federal levels.

Collaboration With Other Health Care Professionals

The goals of ensuring the successful operation of the newborn screening system and advancing optimal care for infants and their families cannot be accomplished by PCPs alone. Effective collaboration and communication among PCPs and other clinicians and among the systems of care that engage the newborn screening system will ensure the best outcomes for infants and families. In light of this necessary collaboration, recommendations have been developed for prenatal health care professionals, hospitals and other birthing facilities, pediatric medical subspecialists, states and SNSACs, and federal agencies.

Prenatal Health Care Professionals

The prenatal period provides an ideal opportunity to begin to educate a family regarding the importance of newborn screening and the risks and benefits of early identification of the conditions identified through screening. The ACOG Committee on Genetics has asserted that "[o]bstetricians need to be aware of the status of newborn screening in their states and should be prepared to address questions or refer their patients to appropriate sources for additional information."[16] The following specific steps can help bring the awareness and knowledge of the obstetrician to bear in preparing a family for newborn screening and promoting the function of the newborn screening system.

1. Prenatal health care professionals are ideally positioned to educate expectant parents about the newborn screening program in conjunction with the prenatal screening program. The obstetrician is encouraged to begin the education early enough to allow patients the opportunity to ask questions that will assist them in understanding the purpose of newborn screening, its implementation, and the importance of test results and follow-up. Concise, clear, and comprehensive educational materials and/or video presentations already in existence should be made available to expectant parents during the prenatal period. Appropriate materials are available from the AAP (www.medicalhomeinfo.org/screening/newborn.html) and the National Library of Medicine (ghr.nlm.nih.gov/nbs).

2. Prenatal health care professionals should strongly encourage prospective parents to identify a medical home for their infant early in pregnancy. When the mother presents for postpartum care, the prenatal health care professional can further support the medical home by inquiring about the infant's well-being and follow-up care.

3. If an infant is lost to follow-up to the newborn screening program, prenatal health care professionals should assist in locating the family.

Hospitals and Other Birthing Facilities

In most cases, it is the facility at which the infant is delivered that is initially responsible for processing the newborn screening specimen. It is essential that these facilities have policies and procedures in place to ensure high-quality specimen processing and prompt delivery to the designated screening laboratory.

1. Particular attention should be brought to the development of protocols for:

   a. Repeat screening of invalid specimens.

   b. Documenting parental refusal to consent to newborn screening: Parents should be asked to sign a waiver form that documents not only their refusal to consent to newborn screening but also their

understanding of the program and its purpose and the risks associated with their refusal.

c. Adequate training of clinical and laboratory staff and quality assurance programs focused on high-quality specimen processing: Appropriate and complete information regarding the infant, contact information, and medical follow-up must be gathered and submitted with specimens.

d. Assisting public health authorities in locating infants who are lost to follow-up: If the infant's medical home is not clearly identified, the facility at which the child was born should assume responsibility for notifying the family of an out-of-range screening result and referring for additional diagnostic testing and subspecialty care.

2. Identification of the medical home or site of medical follow-up should be established as a condition for discharge.
3. Discharge materials should clearly indicate whether newborn screening was conducted and should identify the PCP and the in-hospital managing physician for later contact, if needed.
4. Hospitals and other birthing facilities should ensure the availability of printed and/or video educational materials, presented in concise and understandable language, to all families, including those whose primary language is not English. These materials should address the purpose of newborn screening, the risks and benefits associated with newborn screening, and the consequences of delaying or refusing newborn screening.
5. Opportunities for further discussion or questions should be made available with either the family's chosen PCP or staff members who are knowledgeable about the screening process and the conditions for which screening is conducted.

Pediatric Medical Subspecialists

Pediatric medical subspecialists play several roles in the care of children who have out-of-range results from newborn screening: they conduct confirmatory testing, care for the primary condition of infants who are affected by congenital diseases, and collaborate in the care of children with disabilities associated with some of the diseases identified through newborn screening. In fulfillment of these roles:

1. Pediatric medical subspecialists should assist the state newborn screening program in the development of educational materials for the public, families, PCPs, the state newborn screening program, and policy makers on specific conditions identified by newborn screening.
2. Pediatric medical subspecialists should serve on their SNSAC.
3. Pediatric medical subspecialists should respond promptly to requests for diagnostic and management services to infants with out-of-range screening results and children with conditions identified by newborn screening. Findings from clinic visits, laboratory studies, imaging studies, and diet and medication changes should be communicated promptly to the PCP, state newborn screening programs, other pediatric medical subspecialists, and the family (as appropriate).
4. Pediatric medical subspecialists should underscore the importance of maintaining a medical home relationship with the PCP for the infant identified with a condition through newborn screening.
5. Pediatric medical subspecialists should assist in the identification of associated disabilities and appropriate referral to other subspecialists for management.
6. Pediatric medical subspecialists should assist in the development of condition-specific protocols for the treatment of acute illness or injury and in the development of the child's care plan for school, activity restrictions, and special feeding/diet programs. Pediatric medical subspecialists should also work with the PCP, the family, and other subspecialists to delineate each person's role in managing acute illnesses, establishing relationships with schools and therapists, providing immunizations, working with social services and camps, and maintaining contact with insurers.
7. Pediatric medical subspecialists should provide ongoing education to the family and PCP about new developments and treatments for the condition and associated disabilities.
8. Pediatric medical subspecialists should work with the PCP and other subspecialists in identifying appropriate adult health care professionals for the transition to adult care.

State Systems

The state's role in newborn screening is to design, coordinate, and manage an effective newborn screening system. It has traditionally been the state's responsibility to oversee key aspects of the newborn screening system, including initial screening, confirmation of diagnosis, and coordination of short-term follow-up for infants with out-of-range screening results as well as longer-term care for children with special health care needs. Ultimately, the state must maintain an adequate public health infrastructure to ensure that every newborn infant receives appropriate care.

The AAP Newborn Screening Task Force set forth a broad agenda for state newborn screening systems in its statement published in 2000.[17] In addition to addressing the recommendations that follow, states are urged to consult that AAP statement for guidance in developing and supporting an effective and comprehensive newborn screening system.

To ensure the appropriate and effective function of newborn screening systems, the following recommendations must be addressed immediately:

1. States must monitor specimen collection and transmission of information between screening hospitals, the testing laboratory, and individual practitioners.

2. Identification of the follow-up medical home must be required on all newborn screening specimens.[16,18]
3. Laboratory collection and handling procedures must be clearly delineated at every site at which newborn screens are obtained or processed. State newborn screening laboratories are expected to maintain up-to-date technology and procedures and be prepared to implement recommended changes in the newborn screening process.[11]
4. Practical mechanisms should be established for retesting infants whose newborn screening results are indeterminate/invalid regardless of the cause.
5. Procedures should be adopted to ensure that the medical home is notified of out-of-range screening results by telephone on a schedule consistent with the urgency of the need for intervention. In the case of urgent out-of-range results, a designated medical subspecialist may be notified in addition to the medical home; the newborn screening program may need to contact the family if efforts to contact physicians are not successful.
6. Procedures should be adopted to ensure that in-range and invalid screening results are available to the medical home within 2 weeks of an infant's birth.
7. When out-of-range screen results are reported, the appropriate updated ACT sheet (or equivalent) and state-specific referral information should be forwarded immediately to the PCP.
8. States must have policies and procedures in place to locate children who have not established a medical home and to ensure that all newborn infants with out-of-range screening results receive appropriate diagnostic follow-up and subspecialty care.
9. States must provide clinicians with contact information for their newborn screening program coordinator and ensure that clinicians are updated promptly should any changes occur.
10. Public health agencies and maternal and child health programs should assist with care coordination for patients with special health care needs and their families.

Because states play a significant educational role in the newborn screening system, the following are recommended:

11. With direction from the SNSAC, states should develop and facilitate distribution of clear and concise educational materials for families at prenatal visits and in the hospital at the time of delivery. Condition-specific materials must be developed for families whose infants have out-of-range screening results; these materials include an explanation of test results, appropriate educational materials on the tested condition, referral for additional diagnostic testing, and referral for subspecialty care. Educational materials developed by the AAP, ACOG, and HRSA/MCHB may be used and/or supplemented with materials developed by the state. These materials can be accessed at www.medicalhomeinfo.org/screening/newborn.html or mchb.hrsa.gov/screening.
12. The state must develop educational information for medical professionals that outlines their responsibilities in the newborn screening process.

Finally, there are a number of steps that can be taken to improve the operation of the newborn screening system, including the following:

13. To prevent delays in processing when screening occurs on the weekend, the newborn screening laboratory responsible for state screening should operate at least 6 days a week, with coverage for holidays. Rapid turnaround time for results is essential for prompt diagnosis and treatment of metabolic conditions.
14. Information systems through which clinicians could directly download newborn screening results should be developed. Policies and regulations must be developed concurrently to protect privacy and confidentiality rights.
15. States should develop and implement information systems that facilitate the tracking of infants across state lines through communication and integration of data across newborn screening systems.
16. States must develop and implement policies that allow for interstate licensure and practice of medicine (including the use of telemedicine) to facilitate consultation and communication to underserved areas and ensure the free flow of information across state lines. There is a shortage of pediatric medical subspecialists across the country and a complete absence from more sparsely populated regions. This challenge must be addressed cooperatively by the states.
17. States should ensure the availability of ongoing care for infants with out-of-range screening results who lack health insurance and for those whose insurance does not provide coverage for necessary services and treatments. Medically required diets and vitamins are among the treatments often excluded from coverage provided by third-party payers.[19]
18. To promote greater understanding of the effects and benefits of the newborn screening system, states should develop information systems that are capable of tracking the multitude of performance measures for the newborn screening system and long-term outcomes of children with special health care needs identified through newborn screening. Performance measures include diagnosis for and treatment of infants with out-of-range screening results, cases missed by newborn screening, false out-of-range result rates, time to diagnosis, parental involvement and satisfaction, the social and psychological effects on families of infants with out-of-range and false out-of-range results, and family access to appropri-

ate and necessary services. Data to support the analysis of cost-effectiveness and cost benefit should also be collected.

19. To provide national data for newborn screening system quality assurance and program comparison, state programs should contribute timely case findings and laboratory data to the national newborn screening data-collection system operated by the National Newborn Screening and Genetics Resource Center (www2.uthscsa.edu/nnsis).
20. SNSACs should be authorized in each state to help implement and ensure the establishment of principles of universal access, clinician and community education, remedial surveillance for accountability, and quality of services for all infants. SNSACs should be chartered with appropriate authority and provided adequate support to effectively fulfill the roles outlined as follows.

State Newborn Screening Advisory Committees

1. SNSACs should comprise a balanced, representative, and diverse membership. Representation by diverse families and societal leaders should be balanced by members of the health care community, including clinicians in practice, representatives of hospitals and professional organizations, and public health experts, including the laboratories and the state. A diverse clinician representation would include pediatricians, obstetricians, family physicians, and nurse and midwife practitioners. In addition, the panel must have access to expert medical subspecialists, health care researchers, and biostatisticians.
2. SNSACs should cooperate with the US Department of Health and Human Services ACHDGDNC and other federal agencies to promote consistency in newborn screening throughout the nation.
3. SNSACs must work to advance state support and development of the newborn screening system, with particular attention to:
   a. efforts to use health information technology to advance clinician and family access to information about newborn screening as well as screening and follow-up services;
   b. optimization and accurate interpretation of privacy laws;
   c. implementation of a systems approach based on the Institute of Medicine principles for patient-centered safety, effectiveness, efficiency, timeliness, and equity[20];
   d. efforts to provide unfettered access, through both print and electronic media, to understandable education materials for families with diverse reading and language abilities; and
   e. development and distribution of resources for PCPs.
4. SNSACs must address identified challenges of fragmented service delivery as well as geographic, cultural, social, and financing barriers across county and state lines.
5. SNSACs should promote a statewide report on newborn health status for identifiable conditions and a national newborn health report that provides data on incidence, outcome, and community participation.
6. SNSACs must develop a mechanism for receiving feedback from parents, medical home practitioners, and subspecialists on the appropriateness of including particular conditions in the newborn screening program. This feedback should then be transmitted to the ACHDGDNC.
7. Each SNSAC is encouraged to develop its own charter and seek statutory establishment and state support.

National Partnerships

Although states remain responsible for newborn screening systems, federal agencies and national organizations play a significant role in the newborn screening system and in supporting families of children with genetic conditions. Strengthening national partnerships between federal agencies and professional, nonprofit, and family organizations provides the opportunity for a coordinated effort to increase the services offered to children with genetic and congenital conditions in all stages of diagnosis, treatment, and follow-up. There are 4 critical points of partnership for these groups: collaboration, funding, oversight, and follow-up.

Collaboration

1. Health care professionals, nonprofit agencies, state and federal public health programs, and families should seek to build relationships with other groups that focus on the newborn screening system. Relationships can be fostered through partnering on national initiatives, inviting other perspectives to serve on project advisory committees, and establishing a systematic method of receiving feedback from families.
2. Research should be performed on all aspects of newborn screening systems, including parent and provider education, results management, laboratory quality, residual specimen storage and use, and, most importantly, efficacy of newborn screening for each proposed condition. A national research agenda for newborn screening should be outlined. Input from federal agencies, professional associations, nonprofit organizations, and family support organizations should be coordinated. Multistate or national collaborations are often necessary to recruit a sufficient number of affected infants to understand the clinical spectrum of the disease and to compare treatment strategies. Collaboration will be key in conducting this research.
3. National partnerships should be developed and coordinated to support state newborn screening sys-

tems and encourage coordination, effective collaboration, and decrease duplication.

Funding

4. Adequate third-party reimbursement, grant applications, nonprofit fundraising efforts, and other sources of funding for newborn screening programs should be pursued by those who seek to improve the newborn screening system. Funding for the components of the newborn screening system and long-term care of children with genetic conditions comes from a variety of sources including screening fees, federal programs, state programs, nonprofit fundraising, insurance companies, and others, and such funding is critical at all levels.
5. Because ongoing research in the areas of education, results management, laboratory quality, and identifying and treating genetic diseases is important as the world of newborn screening continues to expand, funding for the implementation of these research projects should be provided.
6. Because establishing and funding a 24-hour hotline for access to online state-specific newborn screening program contact information can be useful in supporting state newborn screening programs, physicians, and families, a dedicated newborn screening hotline should be considered as part of preparing for national emergencies, natural disasters, or other circumstances.
7. Funding should be provided for demonstration projects directed toward strengthening the communication process between pediatricians and the newborn screening program. These efforts can include the development of telemedicine, effective health information exchanges, and linked information systems to facilitate the communication process.
8. Because the increased level of services required to comanage and coordinate care for patients with special needs identified through newborn screening can pose a significant financial burden for the PCP and the subspecialist, appropriate CPT coding that is aimed at enhanced reimbursement for chronic condition management should be developed.

Oversight

9. ACHDGDNC policies and activities should promote and facilitate uniformity across newborn screening programs, promote coordination between state newborn screening programs, support public health infrastructure for these programs, monitor the quality of these programs, and coordinate and promote research efforts related to newborn screening.
10. The ACHDGDNC should promote federal interagency collaboration and federal agency collaboration with state public health newborn screening programs to encourage coordination and effective collaboration between federal and state agencies.
11. Family involvement in all levels of newborn screening and follow-up care is important and should be encouraged. Families can give feedback on services provided, make suggestions on improving systems of care, advocate for needed services, and support other families that are going through similar situations.

Follow-up

12. Appropriate treatment and chronic condition management for children with congenital conditions should be ensured. Federal agencies, state newborn screening programs, and others can collaborate to create a national definition for follow-up to newborn screening systems.
13. Because enrolling children onto long-term research studies can provide the opportunity to test new treatments and better understand the natural history of chronic conditions, federal agencies and national organizations should promote opportunities for such research and create materials to educate parents about research in general and specific opportunities to participate in research.

National Medical Specialty Organizations, Including the AAP

National medical specialty organizations and their state chapters can play specific roles in the continued development of the collaboration necessary to ensure optimal performance of the newborn screening system throughout the country.

1. They should maintain communication with and participation on the ACHDGDNC to provide information to their constituencies and communicate any concerns to the ACHDGDNC.
2. They should foster education regarding newborn screening and promote pediatric medical subspecialties that focus on metabolic diseases among medical students and residents.
3. They should promote the development and implementation of a Health Plan Employer Data and Information Set (HEDIS) measure on newborn screening.
4. They should comment on the appropriateness of adding new tests to the core screening panel, ensuring that any newborn screening provides clear benefit to all children screened and to their families. These comments should be presented to the ACHDGDNC for consideration and adoption.

CONCLUSIONS

Advances in newborn screening technology, coupled with recent advances in the diagnosis and treatment of rare but serious congenital conditions that affect newborn infants, provide increased opportunities for positively affecting the lives of children and their families. These advantages, however, also pose new challenges to PCPs, both educationally and in response to the management of affected infants.

To respond appropriately, PCPs require immediate

access to clinical and diagnostic information and guidance; ACT sheets from the ACMG are a valuable source of such guidance. PCPs, however, have a proactive role to play in supporting the performance of the newborn screening system and ensuring the successful completion of their responsibilities to the program. PCPs must develop office policies and procedures to ensure that newborn screening is conducted and that results are transmitted to them in a timely fashion. PCPs must also develop strategies to use should these systems fail.

The newborn screening system extends well beyond the PCP's office, and many other stakeholders are essential for ensuring that the system functions well and supporting PCPs in their role within the system. The system is challenged by error, lack of education or information on the part of families and health care professionals, and systemic challenges such as the national shortage of pediatric medical subspecialists and barriers inherent in state licensing requirements. Lack of universal health care coverage and limited funding for newborn screening programs present additional significant challenges.

State and federal entities, hospitals, prehospital health care professionals, pediatricians, and pediatric medical subspecialists should act collaboratively to address these challenges or reduce their effects on the newborn screening system. AAP chapters and individual pediatricians should work together with the AAP and SNSACs to promote actions and policies that will optimize the function of newborn screening systems and ensure that children and families receive the full benefit of them.

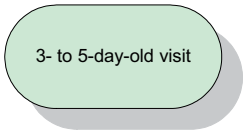
APPENDIX 1 2005 ACMG Recommended Screening Panel

OA	FAO	AA	Hemoglobinopathies	Other
Core panel				
Isovaleric acidemia	Medium-chain acyl-CoA dehydrogenase deficiency	Phenylketonuria	Sickle cell anemia (Hb SS disease) Hb	Congenital hypothyroidism
Glutaric acidemia type I	Very long-chain acyl-CoA dehydrogenase deficiency	Maple syrup disease	Hb S/β-thalassemia	Biotinidase deficiency
3-Hydroxy-3-methylglutaryl-CoA lyase deficiency	Long-chain L-3-hydroxy acyl-CoA dehydrogenase deficiency	Homocystinuria (caused by cystathionine β-synthase)	Hb S/C disease	Congenital adrenal hyperplasia (21-hydroxylase deficiency)
Multiple carboxylase deficiency	Trifunctional protein deficiency	Citrullinemia		Classical galactosemia
Methylmalonic acidemia (mutase deficiency)	Carnitine-uptake defect	Argininosuccinic acidemia		Hearing loss
3-Methylcrotonyl-CoA carboxylase deficiency		Tyrosinemia type I		Cystic fibrosis
Methylmalonic acidemia (Cbl A,B)				
Propionic acidemia				
β-ketothiolase deficiency				
Secondary targets				
Methylmalonic acidemia (Cbl C,D)	Short-chain acyl-CoA dehydrogenase deficiency	Benign hyperphenylalaninemia	Variant hemoglobinopathies (including Hb E)	Galactokinase deficiency
Malonic acidemia	Glutaric acidemia type II	Tyrosinemia type II		Galactose epimerase deficiency
Isobutyryl-CoA dehydrogenase deficiency	Medium/short-chain L-3-hydroxy acyl-CoA dehydrogenase deficiency	Defects of biopterin cofactor biosynthesis		
2-Methyl 3-hydroxy butyric aciduria	Medium-chain ketoacyl-CoA thiolase deficiency	Argininemia		
2-Methylbutyryl-CoA dehydrogenase deficiency	Carnitine palmitoyltransferase II deficiency	Tyrosinemia type III		
3-Methylglutaconic aciduria	Carnitine: acylcarnitine translocase deficiency	Defects of biopterin cofactor regeneration		
	Carnitine palmitoyltransferase I deficiency (liver)	Hypermethioninemia		
	Dienoyl-CoA reductase deficiency	Citrullinemia type II		

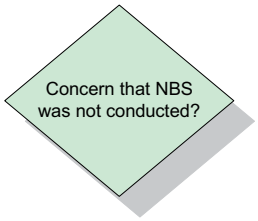
OA indicates disorders of organic acid metabolism; FAO, disorders of fatty acid metabolism; AA, disorders of amino acid metabolism; CoA, coenzyme A.

APPENDIX 2.

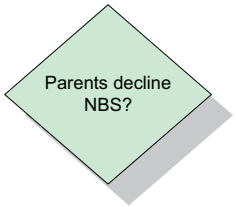
Algorithm 1



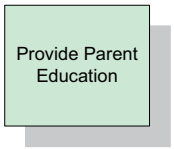
At the 3- to 5-day-old visit, the PCP should check for circumstances suggesting newborn screening might *not* have been conducted. Concerning situations include home or emergency births or international adoption.



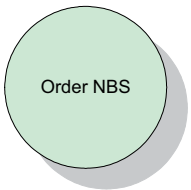
If the PCP has cause for concern that the newborn screening was not ordered and available discharge papers do not indicate the newborn screening has been ordered, the PCP should make arrangements for sample acquisition.



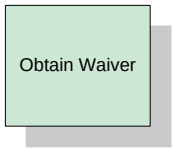
If newborn screening has not been conducted because of parental refusal or if parents refuse newborn screening suggested by the PCP, the PCP should discuss the general benefits and limited risks of newborn screening as well as possible implications of not testing.



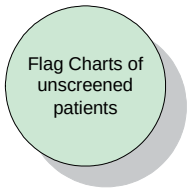
Educational materials for parents and PCPs can be accessed through the AAP Web site (www.medicalhomeinfo.org/screening/newborn.html). Parent concerns and questions should be addressed fully, and a discussion of the general benefits and limited risks of newborn screening is recommended. Very treatable conditions, such as phenylketonuria (PKU) and congenital hypothyroidism (CH), may be used as examples. If parental permission is obtained, arrangements for sample acquisition should be made immediately, and newborn screening should be ordered, as noted previously.



Newborn screening is conducted through the state newborn screening program, and protocols for ordering the screen vary by state. Contact information for each state's newborn screening program is available (http://genes-r-us.uthscsa.edu/resources/consumer/statemap.htm; Appendix 4).



If parental permission is not obtained, parents or guardians should be asked to sign a waiver documenting their choice to decline newborn screening. A sample waiver form is included as Appendix 5; appropriate waiver forms should also be available through the state health department.



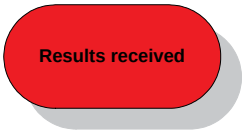
PCPs should flag the charts of any patients who have not been screened so that the lack of screening will be taken into account should any subsequent concerns emerge regarding the child's growth or development. The chart note should also prompt the pediatrician to return to the question of newborn screening with subsequent visits to determine whether parents have changed their minds.

Special Circumstances

- In cases in which newborn screening is delayed, the PCP should consult with the state newborn screening program regarding the availability and usefulness of the newborn screening protocol.
- In the case of preterm births, neonatal transfusion, and other circumstances in which screening is not ordered or a second specimen is required, the PCP should consult with a neonatal specialist.

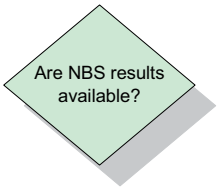
APPENDIX 3.

Algorithm 2

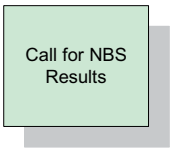


In the case of an out-of-range screening result, the pediatrician identified on the newborn screening card should be called by the state newborn screening program within the first week after birth. Normal results are often transmitted by mail; these may arrive before to the 2- to 4-week visit.

Delays or procedural failures at hospitals, state laboratories, or other facilities or within the newborn screening program may result in late or lost results. The PCP cannot assume a "no news is good news" approach with regard to newborn screening.



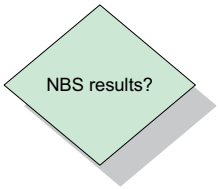
Office staff should check routinely for newborn screening results before the 2- to 4-week visit and pursue missing results in advance of that visit.



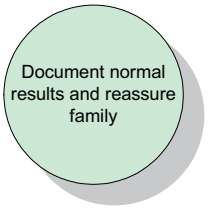
If newborn screening results are not available before the 2- to 4-week visit, the PCP should contact the state newborn screening program for the results at that time.

Special Circumstances

Newborn screening results may occasionally be sent to the wrong pediatrician. Physicians who receive results for patients no longer in their care should immediately contact the state newborn screening program and/or hospital to alert them that the PCP may not have received these results.



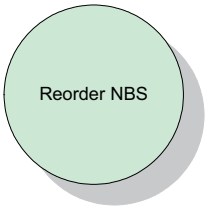
The state newborn screening program will report results as normal, unsatisfactory, or abnormal.



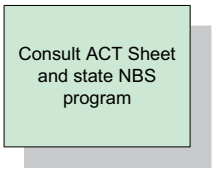
Normal newborn screening results should be noted in the infantôs chart and shared with the parents or guardians. Keep in mind that newborn screening does not rule out congenital disorders that are not included in the panel and does not absolutely guarantee the absence of the disorders that are screened.

Special Circumstances

Currently, 9 states mandate a second screening, and 12 states allow it. If necessary, the PCP should order another newborn screening.



In instances where the specimen is unacceptable for testing, the infantôs newborn screen must be reordered and a specimen must be obtained promptly.



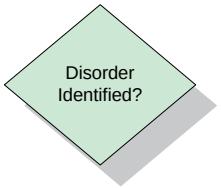
If abnormal results are received, the PCP should access the ACT sheet specific to the disorder. The ACT sheet may be provided by the state newborn screening program or can be accessed at: www.acmg.net/resources/policies/ACT/condition-analyte-links.htm.

The most important actions to take are highlighted on the ACT sheets and include:

- When to contact the family;
- Whom to consult and whether an appointment is needed immediately;
- When the patient must be seen by the PCP;
- Whether further confirmatory testing is needed and what tests should be conducted;
- Whether treatment is necessary and what treatment to initiate;

- How to educate parents about the disorder;
- When findings need to be reported back to the newborn screening program.

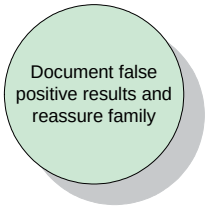
In addition to following ACT sheet recommendations, the PCP should consult with the state newborn screening program.



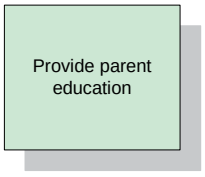
After an abnormal screening result is obtained, confirmatory testing and/or definitive consultation with subspecialists are required before a final diagnosis can be made.

Special Circumstances

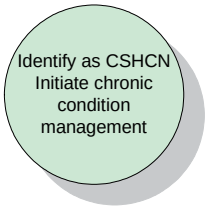
In addition to true or false positive results, confirmatory tests may identify the child as a carrier of the disorder or may be of indeterminate result.



In the event that the initial positive result proves to be a false positive result, the PCP can provide reassurance to parents. Up to 20% of these parents will persist in their concerns about the health of their children for months or years after screening.



To lay the foundation for comprehensive and collaborative care, it is critical during this time of uncertainty that the parents and family of the neonate be provided with disorder-specific information and support as they await final clarification of the childôs diagnosis and begin to plan for treatment and management. Frequent, specific, and supportive communication from the PCP will help to avoid confusion and build trust.



The parents and family of the neonate should be provided with disorder-specific information and support as they await final clarification of the childôs diagnosis and begin to plan for treatment and management.

Any child in whom a significant medical disorder is diagnosed should be entered into the practice's registry for children with special health care needs, and chronic care management should be initiated. Chronic care management provides proactive care for children with special health care needs, including condition-related office visits, written care plans, explicit comanagement with specialists, appropriate patient education, and effective information systems for monitoring and tracking the child's disorder.

A subspecialist may provide substantial ongoing care for a child with a severe and complex disorder. However, the PCP retains the responsibility to provide a medical home, which is the central source of "family-centered, accessible, continuous, coordinated, comprehensive, compassionate, and culturally effective" care for the family, and the family should be encouraged to maintain their relationship with their PCP.

The complex nature of many disorders identified by newborn screening may require care by a team of medical subspecialists, therapists, nutritionists, and educators. Clearly defined roles may help to reduce redundancies of services and prevent fragmentation of care.

THE AMERICAN ACADEMY OF PEDIATRICS STRONGLY RECOMMENDS NEWBORN SCREENING FOR ALL INFANTS

Refusal for Newborn Screening

Child's Name: _____ Child's Date of Birth: _____

Parent's/Legal Guardian's Name: _____

My child's doctor/nurse _____has advised me that my child (named above) should participate in the newborn screening program.

☐ As the parent or legal guardian of my child (named above), I choose to decline participation in my state's newborn screening program.

I have been provided information about newborn screening in my state and the importance of early identification of the diseases. I have had the opportunity to discuss these with my child's doctor or nurse, who has answered my questions regarding the recommended screening. I understand the following:

- The purpose of and the need for newborn screening.
- The risks and benefits of newborn screening.
- **If my child does not participate in newborn screening, the consequences of a late diagnosis of certain conditions can include mental retardation or death.**
- My child's doctor or nurse and the American Academy of Pediatrics strongly recommend that all newborn infants be screened for certain disorders.
- If my child has one of my state's screened conditions, failure to participate in newborn screening may endanger the health or life of my child.

Nevertheless, I have decided at this time to decline participation in the newborn screening program for my child, as indicated by checking the box above.

I acknowledge that I have read this document or it has been read to me in its entirety and I fully understand it.

Parent's/Legal Guardian's Signature _____ Date _____

Witness _____ Date _____

I have had the opportunity to re-discuss my decision not to participate in my state's newborn screening program and still decline the recommended participation.

Parent's initials _____ Date _____ Parent's initials _____ Date _____

Parent's initials _____ Date _____ Parent's initials _____ Date _____

APPENDIX 5: DOCUMENTING REFUSAL TO HAVE INFANTS UNDERGO NEWBORN SCREENING

Despite the best efforts of health care professionals to educate parents and guardians about the need to have their infants undergo newborn screening and the importance of newborn screening in the early identification of certain diseases, some parents and guardians will decline to have their infants undergo newborn screening.

All parents and guardians should be informed about the purpose of and need for newborn screening, the risks and benefits of newborn screening, and the consequences of late diagnosis of certain conditions that would have been identified earlier through newborn screening. The use of this or a similar form that demonstrates the importance you place on newborn screening and focuses attention on the unnecessary risk for which a parent or guardian is accepting responsibility may, in some instances, induce a wavering parent or guardian to accept your recommendation.

Disclaimer. This form may be used as a template for such documentation, but it should not be used without obtaining legal advice from a qualified health care attorney about the use of the form in your practice. Moreover, completion of a form, in and of itself, never substitutes for good risk communication, nor would it provide absolute immunity from liability. For instances in which parents or guardians refuse newborn screening, health care professionals should take advantage of their ongoing relationship with the family and revisit the discussion on subsequent visits. Documentation in the medical chart of such follow-up discussions is strongly recommended, and the template, therefore, makes provision for this documentation.

This form may be duplicated or changed to suit your needs and your patients' needs and should be reviewed with your health care attorney before use. It will be available on the AAP Web[7] site (www.aap.org/bookstore).

TECHNICAL REPORT

Introduction to the Newborn Screening Fact Sheets

Celia I. Kaye, MD, PhD, and the Committee on Genetics

ABSTRACT

Newborn screening fact sheets were last revised in 1996 by the Committee on Genetics of the American Academy of Pediatrics. These fact sheets have been revised again because of advances in the field, including technologic innovations such as tandem mass spectrometry, as well as greater appreciation of ethical issues such as informed consent. The fact sheets provide information to assist pediatricians and other professionals who care for children in performing their essential role within the newborn screening public health system. The newborn screening system consists of 5 parts: (1) newborn testing; (2) follow-up of abnormal screening results to facilitate timely diagnostic testing and management; (3) diagnostic testing; (4) disease management, which requires coordination with the medical home and genetic counseling; and (5) continuous evaluation and improvement of the newborn screening system. The following disorders are reviewed in the newborn screening fact sheets (which are available at www.pediatrics.org/cgi/content/full/118/3/e934): biotinidase deficiency, congenital adrenal hyperplasia, congenital hearing loss, congenital hypothyroidism, cystic fibrosis, galactosemia, homocystinuria, maple syrup urine disease, medium-chain acyl-coenzyme A dehydrogenase deficiency, phenylketonuria, sickle cell disease and other hemoglobinopathies, and tyrosinemia.

NEWBORN screening fact sheets were last revised in 1996 by the Committee on Genetics of the American Academy of Pediatrics (AAP). Publication of these revised newborn screening fact sheets was prompted by advances in the field, including technologic innovations, as well as greater appreciation of ethical issues such as those surrounding informed consent.

NEWBORN SCREENING AS A PUBLIC HEALTH SYSTEM

Every infant born in the United States is screened shortly after birth using heelstick blood spots to detect a variety of congenital conditions. Many infants are also screened for congenital hearing loss. Newborn screening programs have been developed and managed within states, the District of Columbia, Puerto Rico, the US Virgin Islands, and Guam (Table 1). As public health programs, they require a coordinated system of follow-up, diagnosis, and treatment. Periodic program evaluation is also necessary. Thus, newborn screening is not simply a test to identify whether a metabolite is found in unusually high or low concentration in a particular blood spot. Newborn screening is also more than a state-run program that ensures that each abnormal screening result is linked to a particular infant who subsequently receives a diagnostic test and, if indicated, referral for appro-

A dot (●) indicates that screening for the condition is universally required by law or rule; A, universally offered but not yet required; B, offered to select populations or by request; C, testing required but not yet implemented; D, likely to be detected (and reported) as a byproduct of multiple reaction monitoring screening (MS/MS) targeted by law or rule. BIO indicates biotinidase; CAH, congenital adrenal hyperplasia; CF, cystic fibrosis; CH, congenital hypothyroidism; GALT, transferase-deficient galactosemia (classical); HBS/S, sickle cell disease; HB S/C, sickle C disease; HB S/A, S-β-thalassemia; HEAR, hearing screening; 5-OXO, 5-oxoprolinuria (pyroglutamic aciduria); CPS, carbamoylphosphate synthetase; EMA, ethylmalonic encephalopathy; G6PD, glucose 6 phosphate dehydrogenase; HHH, hyperammonemia/ornithinemia/citrullinemia (ornithine transporter defect); NKH, nonketotic hyperglycinemia; PRO, prolinemia; TOXO, toxoplasmosis.

[a] Terminology is consistent with that of the American College of Medical Genetics. *Newborn Screening: Toward a Uniform Screening Panel and System*. Rockville, MD: Health Resources and Services Administration; 2005:63.

[b] Newborn screened for HIV only if mother was not screened during pregnancy.

priate treatment. Newborn screening is a 5-part system[1] in which the pediatrician plays a vital role.

Part 1: Testing of Newborn Infants

Along with the obstetrician, the pediatrician is involved in the education of parents regarding the availability of newborn screening tests, the benefits of early detection of disorders for which screening is performed, the risks that exist for newborn infants who do not receive screening, the process of screening and follow-up, and government requirements that may exist.[2] The pediatrician is also involved in obtaining informed consent in states where this is applicable. Although the timing of specimen collection is straightforward in term, healthy newborn infants, the pediatrician should be aware of factors that may influence the results of a particular screening test, including gestational and postnatal age, early discharge, diet, transfusions, and total parenteral nutrition (Table 2). Results must be documented for all patients in a timely fashion, which may be a challenge in geographic regions with large numbers of neonates, understaffed nurseries and physician offices, and poor technologic support.

Part 2: Follow-up

Proper follow-up of a "not-normal" screening result is crucial if mortality, morbidity, and disabilities are to be avoided. The primary function of the follow-up program is to locate infants with abnormal screening results and facilitate timely diagnostic testing and management. The time frame for follow-up will vary by disorder and by the degree of abnormality of the screening result. Maple syrup urine disease, congenital adrenal hyperplasia, and galactosemia are 3 disorders that can be fatal rapidly unless treatment is instituted very quickly. The pediatrician may be the provider of first contact for screen-positive infants; hence, he or she must be familiar with initial management, including referral management and subsequent diagnostic testing of such infants. The pediatrician also must be prepared to explain to the family the meaning of a positive screening result, the possibility of a false-positive test result, and the steps that must be taken next.

Part 3: Diagnostic Testing

Many of the disorders identified by newborn screening programs are heterogeneous. This variability requires specialized laboratory testing, interpretation, and treatment. The pediatrician works with specialized laboratories and providers in obtaining appropriate specimens, initiating treatment, diagnosis when appropriate, and coordinating care once the diagnosis is confirmed.

Part 4: Disease Management

Infants affected with disorders detected by newborn screening usually require lifelong management. Every

TABLE 2 Effect of Sample Timing, Preterm Birth, Diet, Transfusion, and Total Parenteral Nutrition on Newborn Screening Results

Disorder	Sample Timing	Diet	Preterm Birth	Transfusion	Total Parenteral Nutrition
Biotinidase deficiency	—	—	—	>90 d after transfusion	—
Congenital adrenal hyperplasia	↑ in false-positives first 24 h	—	↑ in false-positives secondary to normal ↑ in 17-hydroxyprogesterone	A few hours (estimated) after transfusion	—
Congenital hearing loss	—	—	—	—	—
Congenital hypothyroidism					
Thyrotropin method	↑ in false-positives before 48 h	—	—	—	—
Thyroxine method	—	—	↑ in false-positives and false-negatives	—	—
Cystic fibrosis	↑ in false-positives in first 24 h	Not known	Not known	Interferes with mutation analysis for 3–6 wk	—
Galactosemia					
Galactose method	—	Galactose-containing formula	—	—	False-negative
GALT method	—	—	—	>90 d after transfusion	—
Homocystinuria	>24 h; second test at 2–4 wk advisable	Adequate protein intake	—	—	False-positive
Maple syrup urine disease	—	—	—	—	False-positive
MCAD deficiency	Before 8 d	—	—	—	—
PKU	—	Adequate protein intake	—	—	False-positive
Sickle cell diseases and other hemoglobinopathies	—	—	↑ in false-negatives with extreme preterm birth	>90 d after transfusion	—
Tyrosinemia	—	Adequate protein intake	Increased likelihood of neonatal tyrosinemia	—	False-positive

— indicates no impact; ↑, increase.

child should have a medical home to coordinate care; that care should be accessible, family centered, continuous, comprehensive, coordinated, compassionate, and culturally competent.[3] The pediatrician plays a central role in the development of the medical home, which includes experts who understand the etiology, pathophysiology, clinical heterogeneity, and psychosocial issues associated with the disorder. Genetic counseling, including discussion of carrier testing of family members and prenatal diagnosis of future pregnancies, may be indicated.

Part 5: Evaluation

The newborn screening system can function optimally only when its components are coordinated, which means that there must be regular and timely communication between nurseries, screening laboratories, state health departments, pediatricians, and subspecialists. To ensure that this is happening, the effectiveness of each component of the system must be assessed continuously through the collection and analysis of data, including outcomes data. Although an adequate evaluation program has not been developed for most newborn screening systems, the pediatrician will be central to the implementation of such a program, particularly through the provision of outcomes data.

NEWBORN SCREENING TASK FORCE REPORT

Several factors have contributed to the need for review of the newborn screening system, including enhanced public interest in newborn screening as a universal genetic screening program; the introduction of new technologies such as tandem mass spectrometry (MS/MS) and DNA-based tests; and changing demographics, which emphasize the importance of human variation and cultural competence. In response to this need, the AAP, with support from the Health Resources and Services Administration and the National Institutes of Health, convened a task force to review the role and operation of newborn screening as a public health system.[4] The Newborn Screening Task Force outlined a national agenda to strengthen state newborn screening systems through the development of model regulations for disease and test selection; minimum standards for sample collection and other activities; model guidelines for follow-up, diagnosis, and treatment; strategies to inform families and the public more effectively; and demonstration projects to evaluate technology, quality assurance, and health outcomes. The task force report emphasized the need for a sixth component of the 5-part newborn screening system: education of professionals and the public.

INFORMED CONSENT

With the introduction of DNA-based testing as a component of newborn screening panels, consumers, health care professionals, and policy makers have become increasingly aware of issues of informed consent for both the performance of the screening tests and retention and use of residual test samples. Although all states require newborn screening, most newborn screening laws or regulations provide exemptions in some situations.[5] Expert panels have not reached consensus, but in general, they have recognized the benefit of informed consent before testing as a tool for educating parents.[6] When the validity and utility of the test have been established, experts have usually concluded that informed consent for newborn screening could be waived.[7] The Newborn Screening Task Force emphasized the need for education and concluded that, "Before newborn screening, parents (on behalf of their children) have a right to be informed about screening, and have the right to refuse screening. They also have a right to confidentiality and privacy protection for information contained in all newborn screening results."[4] The consent process in each state is governed by state law.

Among the benefits, newborn screening may:

- detect a serious, treatable disorder before symptoms are present;
- lead to treatment that can prevent serious problems including mental retardation and death; or
- detect carriers of certain genetic disorders.

Among the risks, newborn screening may:

- fail to identify some children who actually have the condition;require repeat testing;
- cause parental anxiety after false-positive results;
- reveal (through genetic tests) misattributed paternity; or
- detect disorders for which treatment is not effective.

There is agreement that policy guidelines for residual sample retention and use are needed, but to date, there has been no consensus on the content of such guidelines.

MS/MS

Population screening for phenylketonuria (PKU) began in the 1960s using a relatively simple analytic method. New disorders were added as methods to use blood spots were developed and were applicable to large populations at low cost. By the 1990s, scientific advances and technologic innovations led to the possibility of adding numerous new metabolic disorders to the screening panel using MS/MS (Table 3). Consumers throughout the nation acted quickly through their state legislatures to mandate the addition of medium-chain acyl-coenzyme A dehydrogenase (MCAD) deficiency and other disorders of fatty acid oxidation (FAO) to the list of disorders for which newborn screening is mandated. Several states

TABLE 3 **Additional Disorders Detected by MS/MS Screening**

	Description
Amino acid disorders	
Argininosuccinic aciduria	A disorder of the urea cycle. Episodes of hyperammonemia produce acute intoxication. The major symptoms include mental retardation, failure to thrive, liver dysfunction, unusual hair (trichorrhexis nodosa), and seizures.
Citrullinemia	A disorder of the urea cycle. Episodes of hyperammonemia produce coma and seizures. The major symptoms include changes in sensorium (irritability, lethargy), seizures, ataxia, and mental retardation.
Hypermethioninemia	Can be seen in a variety of conditions. It is found in conjunction with homocystinuria and tyrosinemia. Neonatal hypermethioninemia can occur in preterm infants or be attributable to neonatal hepatitis or a combination of factors.
FAO disorders	
Carnitine/acylcarnitine translocase deficiency	Major symptoms are fasting hypoglycemia with seizures and coma, cardiomyopathy, arrhythmias, muscle weakness, and hepatomegaly/abnormal liver function.
3-Hydroxy long-chain acyl-coenzyme A dehydrogenase (LCHAD) deficiency	Results in an inability of the body to break down fatty acids into a usable energy source. LCHAD deficiency can present as hypoglycemia, lethargy, SIDS, hypotonia, and cardiomyopathy.
MCAD deficiency	Can cause recurrent episodes of hypoglycemia, failure to thrive, persistent vomiting, hepatomegaly, and rhabdomyolysis. Acute episodes are usually associated with concurrent illness or fasting and occur in infancy or early childhood.
Multiple acyl-coenzyme A dehydrogenase deficiency (also known as glutaric acidemia-type II)	Often associated with unexplained death in neonates. Other features include respiratory distress, hypotonia, unusual odor (described as "sweaty feet") and liver dysfunction.
Neonatal carnitine palmitoyl transferase deficiency-type II	Symptoms include hypoketotic hypoglycemia with seizures and coma, cardiac arrhythmia, cardiomyopathy, and hepatopathy.
Short-chain acyl-coenzyme A dehydrogenase (SCAD) deficiency	Patients with SCAD deficiency have failure to thrive, developmental delays/hypotonia, metabolic acidosis, recurrent emesis, and a lipid-storage myopathy.
Short-chain hydroxy acyl-coenzyme A dehydrogenase deficiency	The major symptom is hypoketotic hypoglycemia.
Trifunctional protein deficiency	Can present as skeletal myopathy, cardiomyopathy, or SIDS.
Very long-chain acyl-coenzyme A dehydrogenase deficiency	Symptoms are similar to other FAO defects.
Organic acid disorders	
3-Hydroxy-3-methylglutaryl-coenzyme A lyase deficiency	This enzyme catalyzes the final step of leucine catabolism and plays a key role in ketone body formation. The major clinical features are metabolic acidosis and hypoglycemia. Unexplained fevers can occur. Encephalopathy (somnolence, coma, and malaise) and hepatopathy are common. SIDS may occur.
Glutaric acidemia type I	Results from an inherited defect in the degradation of lysine and tryptophan. Macrocephaly with an increase in the size of the extra cerebral fluid spaces occurs before the onset of any neurologic symptoms. Neurologic disease usually presents later in infancy with tonal abnormalities and choreoathetosis secondary to basal ganglia injury.
Isovaleric acidemia	This is a disorder of branched-chain amino acid metabolism that results in recurrent episodes of emesis, dehydration, and severe metabolic acidosis. Other symptoms include anorexia, listlessness, lethargy, neuromuscular irritability, and hypothermia. Acute episodes are associated with concurrent illnesses or high dietary protein intake.
Methylmalonic acidemia	An increase in methylmalonic acid can be seen with a variety of conditions. Transient increases in methylmalonic acid can be detected in otherwise healthy infants. Symptoms can include failure to thrive, episodic dehydration, and hypotonia. A variety of central nervous system changes (dystonia, dysphagia, and dysarthria) can occur. Infants with methylmalonic acidemia have been noted to have distinct facial dysmorphism.
Propionic acidemia	Symptoms are usually episodic emesis, dehydration, and metabolic acidosis. Hematologic abnormalities such as neutropenia, thrombocytopenia, and hypogammaglobulinemia are common. Mental retardation is a consistent feature, and most patients exhibit intolerance to dietary protein.
Multiple-coenzyme A carboxylase deficiency	This is a deficiency of the enzyme that attaches biotin to enzyme proteins that then results in multiple secondary enzyme deficiencies. Symptoms can be linked to deficiencies of the individual enzymes. Recurrent episodes of emesis, metabolic acidosis, and seizures can occur.
Other organic acidemias detected by MS/MS screening	2-Methylbutyryl-coenzyme A dehydrogenase deficiency, 3-methylcrotonyl-coenzyme A carboxylase deficiency, 3-methylglutaconyl-coenzyme A hydratase deficiency, mitochondrial acetoacetyl-coenzyme A thiolase deficiency (3-ketothiolase deficiency)
Other abnormal profiles	Abnormal results may be found on MS/MS screening secondary to hyperalimentation, liver disease, or contamination of the specimen. Also, treatment with medium-chain triglyceride oil, benzoate, valproate, or pyvalic acid can produce abnormal results.

SIDS indicates sudden infant death syndrome.

A dot (●) indicates that screening for the condition is universally required by law or rule; A, universally offered but not yet required; B, offered to select populations or by request; C, testing is required but not yet implemented; D, likely to be detected (and reported) as a byproduct of multiple reaction monitoring screening (MS/MS) targeted by law or rule. 3-MCC indicates 3-methylcrotonyl-coenzyme A carboxylase; ASA, argininosuccinate acidemia; BKT, β ketothiolase (mitochondrial acetoacetyl-coenzyme A thiolase; short-chain ketoacyl thiolase; T2); CBL A,B, methylmalonic acidemia (vitamin B_{12} disorders); CIT I, citrullinemia type I (Argininosuccinate synthetase); CUD, carnitine uptake defect (carnitine transport defect); GA-1, glutaric acidemia type 1; HCY, homocystinuria (cystathionine β synthase); HMG, 3-hydroxy 3-methylglutaric aciduria (3-hydroxy 3-methylglutaryl-coenzyme A lyase); IVA, isovaleric acidemia (isovaleryl-coenzyme A dehydrogenase); LCHAD, long-chain L-3- hydroxyacyl-coenzyme A dehydrogenase; MCD, multiple carboxylase (holocarboxylase synthetase); MSUD, maple syrup urine disease (branched-chain ketoacid dehydrogenase); MUT, methylmalonic acidemia (methylmalonyl-coenzyme A mutase); PROP, propionic acidemia (propionyl-coenzyme A carboxylase); TFP, trifunctional protein deficiency; TYR-1, tyrosinemia type 1; VLCAD, very long-chain acyl-coenzyme A dehydrogenase.

[a] Terminology is consistent with report from the American College of Medical Genetics. *Newborn Screening: Toward a Uniform Screening Panel and System*. Rockville, MD: Health Resources and Services Administration; 2005:63.

Nomenclature source: National Newborn Screening and Genetic Resource Center (http://genes-r-us.uthscsa.edu).

now require screening for MCAD deficiency and other disorders of FAO[8] (Table 4), and a cost/benefit analysis of MS/MS has been published.[9] MS/MS technology can also be used to screen for PKU and some other amino acid disorders and has a rate of false-positive results that is lower than other screening methods. Therefore, states that adopt MS/MS technology to screen for FAO disorders may also revise their panels of amino acid disorders for which they screen (Table 5). In addition, certain screening methods for particular disorders permit the diagnosis of other conditions that were not originally designated on the list of disorders for newborn screening. These have been called "secondary-target conditions" (Table 6). Pediatricians, who are central to the newborn screening system as discussed earlier, will need to be familiar with these new disorders as they are added to screening panels or are diagnosed because the technology for newborn screening identifies them (secondary-target conditions).

ROLE OF DNA ANALYSIS IN NEWBORN SCREENING

Analysis of DNA for mutations is not a primary screening method for any of the disorders for which newborn screening is performed today. However, secondary DNA analysis may be used in conjunction with other tests to decrease the rate of false-positive results. It may also be used as a diagnostic test for certain disorders.

CONCERNS AND CONTROVERSIES

Because the initial test in the newborn screening process is a screening test, there is a significant risk of false-positive (abnormal test, normal infant) and false-negative (normal test, affected infant) results. False-positive results lead to additional testing and parental anxiety, and long-term consequences such as the vulnerable-child syndrome may occur. False-negative results may lead to a delay in diagnosis, because the health care professional may be falsely reassured by a normal newborn screening result. These possibilities raise clinical and ethical issues, which should be discussed with parents before testing.

There is a lack of uniformity between states regarding the diseases screened and the technology used. Such lack of uniformity results in the place of birth determining the likelihood of early diagnosis of these serious but treatable conditions. Newborn screening rules and statutes require that a newborn infant be screened using the panel in the state in which he or she was born, not necessarily the state in which the mother is a resident. There is also controversy regarding whether newborn screening should incorporate conditions for which highly effective interventions that reduce morbidity for the child are unavailable. Numerous state and national organizations have convened groups to discuss these issues and propose policies, but no national consensus has been developed.[10] Finally, it must be emphasized that "normal" results of newborn screenings do not rule out the presence of these disorders, because some variants of these conditions may have onset later in life, and false-negative results may occur. The clinical judgment of the pediatrician remains the most important tool in the diagnosis of all of these conditions.

INDEX OF NEWBORN SCREENING FACT SHEETS

The following newborn screening fact sheets are available at www.pediatrics.org/cgi/content/full/118/3/e934:

- Biotinidase deficiency
- Congenital adrenal hyperplasia
- Congenital hearing loss
- Congenital hypothyroidism
- Cystic fibrosis
- Galactosemia
- Homocystinuria
- Maple syrup urine disease (branched-chain ketoaciduria)
- MCAD deficiency
- PKU
- Sickle cell disease and other hemoglobinopathies
- Tyrosinemia

TABLE 5 **Use of MS/MS for Newborn Screening**

By MS/MS Only	By MS/MS or Other Technique[a]	Not By MS/MS
Argininemia	Congenital adrenal hyperplasia	Biotinidase
Argininosuccinic acidemia	Galactosemia	Cystic fibrosis
Citrullinemia	Hemoglobinopathies	Hearing loss
Hypermethioninemia	Homocystinuria	Hypothyroidism
Hyperornithinemia-hyperammonemia-homocitrullinuria	Maple syrup urine disease	
FAO disorders (such as MCAD deficiency)	PKU	
Organic acidemias	Tyrosinemia	

This is not a comprehensive list of disorders for which newborn screening is possible.

[a] Most states use a method other than MS/MS to screen for these disorders.

Abbreviations: OMIM, Online Mendelian Inheritance in Man; MS/MS, tandem mass spectrometry; CoA, coenzyme A; *BTD*, biotinidase gene; CAH, congenital adrenal hyperplasia; 21-OH, 21-hydroxylase; SW, salt wasting; SV, simple virilizing; AG, ambiguous genitalia; ACTH, adrenocorticotropic hormone; 17-OHP, 17-OH-progesterone; AABR, automated auditory brainstem response; OAE, otoacoustic emission; CH, congenital hypothyroidism; T_4, thyroxine; HPT, hypothalamic-pituitary-thyroid; CF, cystic fibrosis; CFTR, cystic fibrosis transmembrane conductance regulator; IRT, immunoreactive trypsinogen; GALT, galactose 1-phosphate uridyltransferase; GALK, galactokinase; GALE, galactose-4′-epimerase; CBS, cystathionine β-synthase; BIA, bacterial inhibition assay; MSUD, maple syrup urine disease; BCKD, branched-chain α-keto acid dehydrogenase; BCAA, branched-chain amino acid; BCKA, branched-chain α-keto acid; E3, dihydrolipoyl dehydrogenase; E1, thiamine pyrophosphate– dependent decarboxylase; E2, transacylase; MCAD, medium-chain acyl-coenzyme A dehydrogenase; FAO, fatty acid oxidation; SIDS, sudden infant death syndrome; ADHD, attention-deficit/hyperactivity disorder; PKU, phenylketonuria; PAH, phenylalanine hydroxylase; BH4, tetrahydrobiopterin; SCD, sickle cell disease; HPLC, high-performance liquid chromatography; Hb, hemoglobin; HbF, fetal hemoglobin; HbA, normal adult hemoglobin; FA, fetal and adult hemoglobin; MCV, mean corpuscular volume; FAH, fumarylacetoacetate hydrolase; TAT, tyrosine aminotransferase; NTBC, 2-(2-nitro-4-trifluoromethylbenzyl)-1,3-cyclohexanedione

ABSTRACT

Newborn screening fact sheets were last revised in 1996 by the American Academy of Pediatrics Committee on Genetics. This revision was prompted by advances in the field since 1996, including technologic innovations, as well as greater appreciation of ethical issues such as those surrounding informed consent. The following disorders are discussed in this revision of the newborn screening fact sheets: biotinidase deficiency, congenital adrenal hyperplasia, congenital hearing loss, congenital hypothyroidism, cystic fibrosis, galactosemia, homocystinuria, maple syrup urine disease, medium-chain acyl-coenzyme A dehydrogenase deficiency, phenylketonuria, sickle cell disease and other hemoglobinopathies, and tyrosinemia. A series of topics related to newborn screening is discussed in a companion publication to this electronic publication of the fact sheets (available at: www.pediatrics.org/cgi/content/full/118/3/1304). These topics are newborn screening as a public health system; factors contributing to the need for review of the newborn screening system; informed consent; tandem mass spectrometry; DNA analysis in newborn screening; status of newborn screening in the United States; and the effect of sample timing, preterm birth, diet, transfusion, and total parenteral nutrition on newborn screening results.

These topics are newborn screening as a public health system; factors contributing to the need for review of the newborn screening system; informed consent; tandem mass spectrometry (MS/MS); DNA analysis in newborn screening; status of newborn screening in the United States; effect of sample timing, preterm birth, diet, transfusion, and total parenteral nutrition on newborn screening results.

BIOTINIDASE DEFICIENCY

Biotinidase deficiency (Online Mendelian Inheritance in Man [OMIM] database No. 253260)[1] is a disorder of biotin recycling. Biotin is a water-soluble vitamin of the B complex that acts as a coenzyme in each of 4 carboxylases in humans (pyruvate carboxylase, propionyl-coenzyme A [CoA] carboxylase, β-methylcrotonyl CoA carboxylase, and acetyl-CoA carboxylase).[2] Missing a diagnosis of biotinidase deficiency, a condition that is easily treated with vitamin supplementation, can have severe consequences, including seizures, developmental delay, and sensorineural deafness.

Incidence

Neonatal screening for biotinidase deficiency has been instituted in many states (25 at the time of this publication) as well as many countries (approximately 25) since the biochemical basis was elucidated by Wolf et al[3] in 1983. Of slightly more than 8.5 million newborn infants screened worldwide up to 1990, 142 affected infants have been identified, with 76 having profound (<10% activity) deficiency (approximate incidence 1 in 112 000) and 66 having partial (10%–30% activity) deficiency (approximate incidence 1 in 129 000).[4] Most affected individuals who have been identified are of European descent; however, individuals of Turkish, Saudi Arabian, and Japanese descent have been described.[5]

Clinical Manifestations

Biotinidase deficiency can present with clinical symptoms as early as the first week of life up to 10 years of age. Most infants first exhibit clinical symptoms between 3 and 6 months of age.[2] The most commonly affected systems are the central nervous system and skin. Affected children usually have myoclonic seizures, hypotonia, seborrheic or atopic dermatitis, partial or complete alopecia, and conjunctivitis.[2] Other features may include developmental delay, sensorineural hearing loss, lethargy, ataxia, breathing problems, hepatosplenomegaly, and coma.[6,7] Laboratory findings vary and can include ketolactic acidosis, organic aciduria, and mild hyperammonemia.[2]

Individuals with partial biotinidase deficiency can present with skin manifestations and no neurologic symptoms.[8] Several children with profound deficiency have presented later in childhood or during adolescence with hemiparesis and eye findings (scotoma).[9,10] With therapy, the eye problems resolved quickly, but the neurologic findings remained for a longer period of time.[11] There are even reports of adults with profound biotinidase deficiency who have never had symptoms but were diagnosed because their children had positive results of newborn screening.[2]

Pathophysiology

Each of the 4 carboxylases in humans requires biotin as a cofactor. The carboxylases are first synthesized as inactive apoenzymes. After synthesis, biotin is added to the inactive proteins through 2 partial reactions, each of which is catalyzed by the enzyme holocarboxylase synthetase. Ultimately, each of these active, biotin-containing enzymes is degraded. The biotin-containing products of degradation are acted on by biotinidase to liberate biotin, which is recycled and enters the free-biotin pool. Biotinidase deficiency results in inability to recycle endogenous biotin and to release dietary protein-bound biotin. Thus, the brain may be unable to recycle biotin adequately. This may lead to dependence on the biotin that crosses the blood-brain barrier, resulting in decreased pyruvate carboxylase activity in the brain and accumulation of lactate. The neurologic symptoms may be secondary to accumulation of lactic acid in the brain.[2]

Inheritance

Biotinidase deficiency is inherited as an autosomal recessive trait. The biotinidase (*BTD*) gene has been mapped (chromosome 3p25), cloned, and characterized.[12–14] Sixty-two mutations of the *BTD* gene have been described to date.[14] Interestingly, when testing a US population, mutations occur at different frequencies in children with symptoms than in children who were only identified through newborn screening. Two mutations accounted for 52% of the mutations found in symptomatic patients, and 3 other mutations accounted for 52% of mutations in children identified through newborn screening. Partial *BTD* deficiency is predominantly caused by the 1330G→C mutation on one allele in combination with one of the mutations causing profound deficiency on the other allele.[14]

Benefits of Newborn Screening

Biotinidase deficiency has been identified as an appropriate disorder for newborn screening by numerous countries and states because of its prevalence, the potentially tragic outcome if not diagnosed, and availability of effective, low-cost treatment. Unfortunately, once

symptoms have occurred, some of the findings are not reversible with therapy. This is particularly true in the case of the neurologic findings. For example, sensorineural hearing loss is common (detected in approximately 75% of symptomatic children with profound deficiency) and is usually irreversible.[6]

Screening

The best method of screening is a semiquantitative colorimetric assessment of biotinidase activity that can be performed on whole blood spotted on filter paper.[2,15,16] Although the majority (>80%) of patients with biotinidase deficiency demonstrate organic aciduria when symptomatic, a significant percentage (20% in one study) may not; therefore, tandem mass spectrometry (MS/MS) testing should not be used for newborn screening of biotinidase deficiency.[2]

Follow-up and Diagnostic Testing

A positive screening result for biotinidase deficiency should be followed up with definitive testing for diagnosis. Quantitative measurement of enzyme activity should be performed on a fresh serum sample. Residual enzyme activity determines whether the patient has profound (<10% activity) or partial (10%–30% activity) biotinidase deficiency. Most patients with profound deficiency present early in life, whereas those with partial deficiency can present later or with a cutaneous phenotype and no neurologic findings.

Brief Overview of Disease Management

Children with profound biotinidase deficiency have been treated successfully with biotin. Pharmacologic doses of biotin (5–20 mg/day) were determined empirically.[8,17] One patient required a dose of 30 mg/day to resolve dermatitis.[18] For most patients, the currently prescribed dose is probably much more than is needed to overcome the deficiency. It should be stressed that the biotin must be in the free, not bound, form to be effective. There are no known adverse effects of the currently recommended dosage of 5 to 20 mg/day.[19]

Once therapy is instituted, cutaneous symptoms resolve quickly, as do seizures and ataxia. Some of the symptoms (as mentioned previously) are less reversible, including hearing loss and optic atrophy. Children who have developmental delay have been noted in some cases to achieve new milestones and regain lost milestones after beginning therapy.[19] There are individuals reported who have profound biotinidase deficiency, have never been treated, and have never had any associated symptoms.[11]

Partial biotinidase deficiency can probably be treated with lower doses of biotin (1–5 mg/day) and/or only during times of metabolic stress.[19] There are children with partial deficiency who have never had any related illness. In others with partial deficiency, it has been noted that mild intercurrent illnesses such as gastroenteritis can lead to development of typical clinical symptoms that resolve with biotin therapy.[19]

Current Controversies

As noted above, it is difficult to determine if individuals with partial biotinidase deficiency need daily therapy. When such individuals are identified in newborn screening programs, follow-up happens routinely and care is instituted. The negative psychological aspects of learning through newborn screening that an infant potentially has a genetic disorder and the parental anxiety generated should be weighed against the positive aspects, including that the treatment is simple and inexpensive and some individuals with partial deficiency would (at some point) have symptoms. Although this is mildly controversial, it is truly not of enough significance to negate the value of newborn screening for the disorder.

CONGENITAL ADRENAL HYPERPLASIA

Congenital adrenal hyperplasia (CAH) is a family of inherited disorders of the adrenal cortex that impair steroidogenic enzyme activity essential for cortisol biosynthesis.[20,21] Newborn screening focuses exclusively on the most common 21-hydroxylase (21-OH) deficiency CAH (>90% of all CAH cases [OMIM database No. 201910]),[22] which impairs production of cortisol and often aldosterone.[20,21] Prompt diagnosis and treatment of CAH is essential to prevent potential mortality as well as physical and emotional morbidity.[20–23]

Incidence

Health organizations in 13 countries (including 36 US states) screen or will screen for CAH in their newborn screening programs. On the basis of newborn screening data, the incidence of CAH ranges from a low of 1 in 21 270 (New Zealand) to a high of 1 in 5000 (Saudi Arabia) live births.[24] The incidence is 1 in 15 981 live births (Hispanic > American Indian > white > black > Asian) in North America, 1 in 14 970 live births in Europe, and 1 in 19 111 live births in Japan.[25] An exceedingly high CAH incidence (1 in 282 live births) exists among Yupik Eskimos in western Alaska.[26]

Clinical Manifestation and Variability

The spectrum of disease in CAH ranges from the "classic, severe" salt-wasting (SW) form, to "classic, less severe" simple-virilizing (SV), to "mild, nonclassic" forms.[20,21]

Symptomatic Presentation and Morbidity

Neonates with the SW form exhibit adrenal crisis during the first through fourth weeks of life, peaking at approximately 3 weeks of age. This manifests as poor feeding, vomiting, loose stools or diarrhea, weak cry, failure to thrive, dehydration, and lethargy. These symptoms may not be evident until serum sodium concentrations are below 125 mEq/L. If untreated, circulatory collapse, shock, and death are inevitable. Permanent brain injury attributable to shock, lower cognitive scores, and learning disabilities are observed in some with the SW form.[20] Affected females have ambiguous genitalia (AG) (but normal internal reproductive anatomy), prompting a clinical diagnosis in many. Affected males have no obvious physical signs of CAH. Therefore, without newborn screening and in the absence of a positive family history, all male and a minority of female neonates are undiagnosed until adrenal crisis. The SW form affects approximately 70% of patients with CAH that is diagnosed through newborn screening programs.[25,26] If inadequately treated, postnatal virilization (girls), pseudo- or true-precocious puberty (boys), and premature growth acceleration (boys and girls) occur, leading to early growth cessation.[20–23] Patients with the SV form do not manifest adrenal-insufficiency symptoms unless subjected to severe stress but exhibit virilization as in patients with SW.[20,21] Males and some females with the SV form are not diagnosed until much later when symptoms of virilization, precocious pseudopuberty, or growth acceleration occur.[20–23] The markedly advanced skeletal age of patients with the SV form diagnosed late contributes to their short adult stature. Late discovery of incorrect male sex assignment in females with the SW and SV forms causes extreme distress to the family and matured patients. Mild 21-OH deficiency produces no symptoms at birth and manifests as premature sexual hair, acne, and mild growth acceleration in childhood and hirsutism, excessive acne, menstrual disorder, and infertility later in life.[20,21] This milder disorder may be missed by newborn screening programs.

Mortality

The mortality rate for infants with the SW form not detected through newborn screening was 11.9%, which was fivefold higher than that of the general population (2.29%).[23]

Pathophysiology

21-OH deficiency results in cortisol deficiency with or without aldosterone deficiency. Cortisol deficiency from early fetal life leads to increased adrenocorticotropic hormone (ACTH) secretion,[20,21] which then stimulates excess secretion of the precursor steroids including 17-OH-progesterone (17-OHP) and causes hyperplastic changes of the adrenal cortex.[20,21] The precursor steroids can only be metabolized by way of the androgen biosynthetic pathway, resulting in excess androgen production that virilizes the genitalia.[20,21] Aldosterone deficiency contributes to SW. The increased circulating 17-OHP concentration is diagnostic for 21-OH deficiency.

Inheritance and Genotype

21-OH deficiency is an autosomal recessive disorder caused by a mutation of the *CYP21* gene.[20,21] There is an active *CYP21* gene and an inactive pseudo-*CYP21P* gene in normal individuals. Both genes are in the HLA complex on chromosome 6p21.3.[20,21] Most mutations in the *CYP21* gene are the pseudogene sequences, suggesting

that the mutations in *CYP21* were caused by a gene conversion or recombination between *CYP21* and *CYP21P*. The genotypes from 5 different populations of individuals with CAH correlated well with the phenotype in approximately 90% of affected subjects but did not correlate well in the remaining patients.[21]

Rationale for and Benefits of Newborn Screening

The goals of newborn screening are to (1) prevent life-threatening adrenal crisis, thereby averting shock, brain damage, and death, (2) prevent male sex assignment for life in virilized female newborns, and (3) prevent progressive effects of excess adrenal androgens, which cause short stature and psychosexual disturbances in boys and girls. Kovacs et al[23] found the average serum sodium concentration at diagnosis of the SW form of CAH to be 135 mEq/L in individuals detected through newborn screening programs and 125 mEq/L in those detected after development of clinical symptoms. Thus, prevention of severe SW CAH by newborn screening was demonstrated. Worldwide newborn screening data showed that screening prompted early diagnosis of CAH before clinical suspicion in 67% of newborn infants with CAH, including many females with AG.[26] The mortality rate of individuals with CAH identified through newborn screening has not been established yet. Other newborn screening benefits include (1) improved case detection evidenced by twofold higher incidence versus that of case-survey reports (North America and Japan), (2) improved detection of patients with SW CAH (70% with newborn screening vs 43%–60% in patients with clinical symptoms), and (3) improved detection of males, as evidenced by a 1:1 sex ratio in subjects identified through newborn screening versus a male/female ratio of 0.6:1 in patients with clinical symptoms leading to diagnosis.

Screening

Screening for 21-OH deficiency is accomplished by measurement of 17-OHP concentration in the dried blood spot. Newborn screening for CAH requires a rapid process to prompt the diagnosis before the onset of SW symptoms. Sampling at less than 1 day is associated with a high rate of false-positive results, and sampling beyond 5 to 7 days of age reduces the benefit of screening. Normal preterm infants have higher concentrations of 17-OHP than do term infants; therefore, it is important to have 17-OHP reference concentrations in blood spots of preterm and term unaffected infants according to birth weight or gestational age.[27,28] 17-OHP is not influenced if drawn several hours after transfusion.

Dissociation-enhanced lanthanide fluorescence immunoassay, radioimmunoassay, and enzyme-linked immunosorbent assay with a commercial kit are used to measure 17-OHP concentrations in blood spots.[25,26] The screening 17-OHP assays are nonspecific, and the result on a screening study is not equivalent to the diagnostic serum concentrations.[21,26,29] Affected neonates had screening 17-OHP concentrations of 35 to 900 ng/mL of blood, with preterm infants having higher concentrations.[27,29]

MS/MS may have the advantage of rapid 17-OHP detection and may eliminate the variable 17-OHP cutoff concentrations influenced by different reagents/assays. However, comparative studies of immunoassays versus MS/MS are necessary, and because of the complexity of the MS/MS assay for 17-OHP detection, MS/MS may be used as a complementary test. *CYP21* genotyping is not currently used in newborn screening, but it may be helpful in uncertain cases and for genetic counseling.

Almost all neonates with SW CAH have been identified with the first sample test.[26] Newborn screening for CAH is not intended to detect mild cases, although some are detected. In a study performed in Texas, testing again at 1 to 2 weeks increased detection of SV CAH and the mild form.[29] Despite the birth weight- or age-adjusted 17-OHP cutoff concentrations, preterm birth or low birth weight and samples taken at less than 1 day of age are major factors for false-positive results.[24–30] In an international study, 7% of neonates later determined to have CAH (mostly the SV form) were not detected in newborn screening for a variety of reasons (human error, prenatal dexamethasone therapy, or high 17-OHP cutoff concentrations).[25]

Follow-up and Diagnostic Testing

In most newborn screening programs, 2-tiered 17-OHP cutoff concentrations are established to guide evaluation in term and preterm newborn infants. Exceptionally high (urgent) and moderately high (suspected) 17-OHP concentrations are reported. Pediatricians need to be familiar with these concentrations as reported by their local newborn screening program. Most newborn screening programs that screen for CAH report the presumed positive results with instructions. Immediate evaluation (serum electrolytes, 17-OHP) is necessary in newborn infants with AG, in sick or asymptomatic male newborn infants with urgent or suspected 17-OHP concentrations, and in sick female infants with urgent 17-OHP concentrations. The evaluation is necessary in asymptomatic normal female infants with urgent 17-OHP concentrations and in sick female infants with normal genitalia and suspected 17-OHP concentrations, but these newborns are at low risk of having SW CAH. Normal females with suspected 17-OHP concentrations are not at risk of SW CAH but need at least a second screening to be sure that a mild deficiency is not missed.

Diagnosis

Quantitative serum 17-OHP concentration is used for the diagnosis of CAH. Concentrations are generally higher in individuals with the SW form.[29] Care must be

taken to use the appropriate term or preterm normal values for comparison.[26] With age, serum 17-OHP concentrations decrease in unaffected neonates but increase in those with CAH.[30] Concentrations in neonates with SW and SV CAH are higher than the concentrations in infants with the mild form.[21,29] In neonates with mildly elevated 17-OHP concentrations (4–10 ng/mL), the ACTH-stimulation test helps to rule out nonclassic CAH.[20,21] In asymptomatic infants, serial evaluation of electrolytes throughout the neonatal period is necessary if serum electrolyte concentrations remain normal.

Brief Overview of Disease Management

Treatment for CAH involves replacement of cortisol, which suppresses increased ACTH, 17-OHP, and androgen secretion. Replacement of aldosterone with an analog of mineralocorticoid (Florinef) is required for patients with SW CAH. Adequate medical therapy restores normal energy, glucose and electrolyte concentrations, and fluid balance and prevents excess adrenal androgen effects. Special medical care is needed in case of stress. The rate of mortality is 4.3% for treated patients.[23] In virilized female infants, surgical correction is generally performed before 1 year of age and, if necessary, again before menarche. With standard glucocorticoid therapy, adults with classic CAH do not always reach their genetic potential for height, and obesity is common. Inadequate medical therapy causes infertility. Experimental antiandrogenic/antiestrogenic drug therapy to improve height outcome is ongoing in children with CAH. Adrenalectomy is recommended when medical therapy is ineffective.

Carrier testing for CAH is performed most accurately using *CYP21* genotyping.

Pregnant women known to be at risk of having a fetus with CAH can receive prenatal dexamethasone therapy. First-trimester prenatal diagnosis is indicated for these women. An elevated 17-OHP concentration in amniotic fluid by a specific assay (>6–18 ng/mL) is also diagnostic, but normal concentrations do not exclude SV or nonclassic forms of CAH, and concentrations may be normal in mothers who are on dexamethasone therapy. Prenatal treatment is only indicated for female fetuses with classic virilizing CAH. Maternal dexamethasone therapy at 20 μg/kg per day beginning at 5 to 8 weeks' fetal age prevents or reduces AG in most affected females.[31] Controversy regarding prenatal therapy is related to the fact that (1) this treatment must begin before fetal sex can be determined or CAH diagnosis can be made, and 7 of 8 fetuses are thus unnecessarily subjected to this therapy, and (2) long-term safety of early exposure to dexamethasone in utero is unproven to date.[31] Maternal adverse effects include cushingoid features of excessive weight gain, intense striae, edema, discomfort, and emotional instability. In a consensus meeting concerning prenatal CAH therapy, representatives from the US Lawson Wilkins Pediatric Endocrine Society and European Pediatric Endocrine Society recommended that designated teams undertake this specialized therapy using a national protocol approved by institutional review boards. Treatment is preceded by informed consent about the risks and benefits of the therapy, and prospective follow-up and evaluation are needed.[31]

Current Controversy

The major controversy regarding newborn screening for CAH is the cost and impact of evaluating those whose test results are false-positive.[32] A second issue is the use of prenatal dexamethasone therapy for CAH. A large national multicenter study on long-term cognitive and psychological development and other health-related outcomes is required to resolve this issue.

CONGENITAL HEARING LOSS

Congenital hearing loss, for the purposes of this fact sheet, is defined as permanent and is bilateral or unilateral, is sensory or conductive, and averages 30 dB or more in the frequency region important for speech recognition. Congenital hearing loss has many etiologies, with at least half associated with genetic risk factors. Congenital nonsyndromic hearing loss is usually categorized by mode of inheritance—autosomal recessive, autosomal dominant, X-linked, or mitochondrial.[33–35]

Newborn hearing screening programs became possible after the development of hearing screening technologies. Although most states have begun screening for congenital hearing loss, the integration of these programs with ongoing screening and early intervention programs remains a challenge.[36]

Prevalence

Estimates of the prevalence of moderate-to-profound bilateral hearing loss vary, depending on the criteria used to define the different degrees of hearing loss and the characteristics of the studied population.[37] The prevalence of congenital hearing loss also depends on race, birth weight, and other risk factors.[38] Profound and permanent congenital hearing loss is estimated to occur in approximately 1 in 1000 births.[39,40]

Clinical Manifestations

The spectrum of congenital hearing loss ranges from mild to profound hearing loss. In syndromic hearing loss, the auditory pathology may be conductive and/or sensorineural, unilateral or bilateral, symmetrical or asymmetrical, and progressive or stable. The auditory pathology of nonsyndromic hearing impairment is usually sensorineural.[41,42]

Pathophysiology

Approximately half of the cases of congenital hearing loss are thought to be attributable to environmental factors (acoustic trauma, ototoxic drug exposure [aminoglycosides], bacterial or viral infections such as rubella or cytomegalovirus).[39,41,42] The remaining cases are attributable to genetic mutations. Although these cases may seem to be part of a recognizable syndrome, approximately 70% are nonsyndromic (the deafness is not associated with other clinical findings that define a recognized syndrome) and, therefore, clinically undetectable at birth. In the remaining 30%, 1 of more than 400 forms of syndromic deafness can be diagnosed because of associated clinical findings.[39,42]

Inheritance

Approximately 77% of congenital nonsyndromic hearing impairment is autosomal recessive, 22% is autosomal dominant, and 1% is X-linked. As a general rule, individuals with autosomal recessive congenital nonsyndromic hearing impairment have profound prelingual deafness, and dominant mutations lead to a more variable phenotype. More than 90% of children with congenital profound autosomal recessive congenital nonsyndromic hearing impairment are born to parents with normal hearing, and the remaining 10% or less are born to deaf parents.[41]

There has been significant progress in identifying and sequencing autosomal dominant, autosomal recessive, and sex-linked genes for deafness.[41,43] However, it is clear that more genes and mutations await discovery. This knowledge may lead to mutation-specific therapies that can delay or prevent certain forms of genetic deafness, such as the avoidance of aminoglycoside therapy in those with specific mitochondrial mutations.

Benefits of Newborn Screening

The goals of newborn screening are to identify those infants with hearing loss early for prompt intervention to diminish the morbidity associated with congenital hearing loss. Left undetected and untreated, hearing impairment can affect speech and many other cognitive abilities. For children without risk factors, hearing loss frequently escapes detection until the age when hearing children normally begin to talk (9 months or older).[44–48] Current theory views auditory stimulation during the first 6 months of life as critical to development of speech and language skills. Children who are identified early as having hearing loss and receive intensive early intervention perform better on school-related measures (reading, arithmetic, vocabulary, articulation, percent of the child's communication understood by non–family members, social adjustment, and behavior) than children who do not receive such intervention.[49] Early intervention resulted in improvements in receptive language[50] and prevented developmental delays.[51] However, the efficacy of universal newborn hearing screening to improve long-term language outcomes remains uncertain.[52–54]

Screening

Newborn hearing screening is accomplished through the use of a variety of computerized equipment that uses automated auditory brainstem response (AABR), distortion product otoacoustic emissions (OAEs), or transient evoked OAEs. Screening is performed before discharge from the nursery.[55] Screening for congenital hearing loss is a simple process and in some cases may be performed by specially trained volunteers under the supervision of nurses or audiologists. Screening with AABR is accomplished by placement of soft earphones through which a series of soft clicks are introduced, usually at the 30- to 40-dB level. An auditory brainstem response detected through electrodes attached to the infant's forehead and

neck indicates that there is no significant sensorineural hearing loss. If OAE technology is selected as the screening test, a tiny microphone that detects sounds generated by the outer hair cells of the cochlea is introduced into the infant's auditory canal. Presence of those sounds indicates a functioning inner, middle, and outer ear. Each of these tests has advantages and disadvantages that should be considered carefully when selecting equipment. AABR tends to be somewhat more expensive and must be used in a quiet setting. OAE screening may result in higher false-positive rates if the infant's ear canal is blocked by fluid or debris.[56,57] Some hospitals use a combination of screening tests or repeat the OAE screening to reduce the false-positive rate and thereby minimize the need for follow-up after hospital discharge, which may reduce costs overall.[58]

Follow-up and Diagnostic Testing

Infants who do not "pass" the screening are either rescreened before discharge or given an appointment for rescreening as outpatients. Results of the screening are generally transmitted to the primary care physician of record, to the parents, and to the state health department. Failure to pass the screening results in a recommendation for referral to a qualified audiologist for confirmatory testing for congenital hearing loss.

In areas where universal newborn hearing screening is occurring, appropriate and timely diagnosis and intervention continue to be a major challenge. Attrition rates as high as 50% between initial referral and diagnostic confirmation still are not unusual.[36] Linkages between hospital-based screening programs and early intervention programs may not be well established, and data management and tracking of infants through the screening and diagnostic process also may be in the developmental stage.[49] As state programs assume more responsibility for the tracking and follow-up, these linkages will be more firmly established.[36]

Brief Overview of Disease Management

Appropriate management of all persons identified with congenital hearing loss requires a comprehensive pediatric and genetic evaluation.[33] Core personnel include individuals with expertise in the genetics of hearing loss, dysmorphology, audiology, otolaryngology, and genetic counseling. Qualified interpreting services may be needed when the parents are deaf. On the basis of the outcome of the evaluation, other types of professional expertise also may be needed, including professionals with experience with syndromal hearing loss (eg, ophthalmology, cardiology, nephrology, neurology).

After a family history, patient history, and physical examination, it may be possible to ascribe an etiology to the hearing loss. However, in approximately 30% of patients, there will be no obvious etiology.[33] An important goal of the genetic evaluation is to attempt to distinguish isolated or simplex cases, in which the risk of deafness in subsequent offspring may be 25%, from sporadic cases, which have a low risk of recurrence.[33]

After diagnosis of hearing loss, continuity of care for the affected infant is important to reduce morbidity. The pediatrician should ensure referral to the state early intervention program and/or the state program for children with special health care needs as appropriate. Referral to these programs at hospital discharge helps to minimize loss to follow-up.

Current Controversy

The US Preventive Services Task Force did not find evidence for the benefit of (nor evidence against the benefit of) universal newborn hearing screening.[53] They argued that, among low-risk infants, the prevalence of hearing impairment was very low, and substantial numbers of infants would be misclassified. They found that evidence for the efficacy of early intervention for patients diagnosed by screening was incomplete.

Additional controversy centers on the generally inadequate integration of these programs with ongoing newborn screening and early intervention programs.[36] The Newborn Screening Task Force suggested that child health–related programs such as newborn genetic and hearing screening programs would avoid unnecessary duplication of effort if they were more closely aligned with each other.[59]

CONGENITAL HYPOTHYROIDISM

Thyroid hormone deficiency at birth is one of the most common treatable causes of mental retardation. There are multiple etiologies of this disorder, both heritable and sporadic, varying in severity. There is an inverse relationship between age at diagnosis and neurodevelopmental outcome; the later treatment is started, the lower the IQ will be. Most infants seem to be protected for the first few weeks of life by the fraction of maternal thyroid hormone that crosses to the fetus. Because of the urgency in detection and initiating treatment to prevent mental retardation, screening newborns for this disorder was added to existing programs in the mid-1970s.

Incidence

Congenital hypothyroidism (CH) occurs in 1 in 4000 to 1 in 3000 newborns. Programs reporting a higher incidence may include some transient cases. CH seems to occur more commonly in Hispanic and American Indian/Alaska Native people (1 in 2000 to 1 in 700 newborns) and less commonly in black people (1 in 3200 to 1 in 17 000 newborns). Programs report a consistent 2:1 female/male ratio, which is unexplained but speculated to be related to an autoimmune risk factor. Newborn infants with Down syndrome are at increased risk of having CH (approximately 1 in 140 newborns).

Clinical Manifestations

Most affected infants appear normal at birth, without obvious manifestations of CH. This is likely the result of transplacental passage of some maternal thyroid hormone; cord thyroxine (T_4) concentrations are approximately one third of maternal concentrations. In addition, many infants have some functioning thyroid tissue. Gestational age is 42 weeks or greater in approximately one third of these infants. Their birth weight and length fall into the normal range, and their head circumference may be at a slightly higher percentile because of brain myxedema. Approximately 5% of these infants, generally those who are more severely affected, have recognizable features at birth, including large fontanels and wide suturae, macroglossia, distended abdomen with umbilical hernia, and skin mottling. As maternal thyroid hormone is excreted and disappears in the first few weeks, clinical features gradually become apparent. These infants are slow to feed, constipated, lethargic, and sleep more ("sleep through the night" early), often needing to be awakened to feed. They may have a hoarse cry, may feel cool to touch, may be hypotonic with slow reflexes, and may have prolonged jaundice because of immaturity of hepatic glucuronyl transferase. A goiter is seen in 5% to 10% of these infants, most commonly in those with an inborn error of T_4 synthesis. If hypothyroidism goes undiagnosed beyond 2 to 3 months of age, infants will begin to manifest slow linear growth. If this disorder is untreated, studies show a loss of IQ proportionate to the age at which treatment is started: if treatment is started at 0 to 3 months of age, mean IQ is 89 (range: 64–107); if treatment is started at 3 to 6 months of age, mean IQ is 71 (range: 35–96); if treatment is started at older than 6 months, mean IQ is 54 (range: 25–80). Other long-term neurologic sequelae include ataxia, gross and fine motor incoordination, hypotonia and spasticity, speech disorders, problems with attention span, and strabismus. Approximately 10% of these infants will have an associated sensorineural deafness, and approximately 10% will have other congenital anomalies, most commonly cardiac defects.[60] Some newborn screening programs also detect secondary or hypopituitary hypothyroidism in infants. These infants may have

associated midline defects, such as the syndrome of septooptic dysplasia or midline cleft lip and palate. Other pituitary hormones, such as growth hormone, may also be missing.

Pathophysiology

The most common cause is some form of thyroid dysgenesis: aplasia, hypoplasia, or an ectopic gland; thyroid ectopy accounts for two thirds of thyroid dysgenesis. The cause of thyroid dysgenesis is unknown; rare cases result from mutations in the genes that control thyroid gland development, including thyroid transcription factor (TTF-2) and paired box-8 protein (PAX-8). Inborn errors of T_4 synthesis, secretion, or utilization account for two thirds of heritable cases. Errors in iodide trapping, organification of iodide to iodine by thyroid peroxidase (most common inborn error), coupling of monoiodothyronine and diiodothyronine, deiodinase, and an abnormal thyroglobulin molecule all have been described. In mothers with autoimmune thyroiditis, transplacental passage of a thyrotropin-receptor–blocking antibody is associated with transient hypothyroidism. Infants born to mothers with Graves' disease treated with antithyroid drugs also may have transient hypothyroidism. Worldwide, iodine deficiency resulting in endemic cretinism is the most common cause of hypothyroidism at birth. Exposure of the neonate to excess iodine, as with topical antiseptics, can also cause hypothyroidism.

Inheritance

Approximately 85% of cases are sporadic, and 15% are hereditary. Each of the inborn errors of T_4 synthesis is autosomal recessive except thyroid hormone receptor defects, which are autosomal dominant. In the cases associated with transplacental passage of a maternal blocking antibody, future siblings are at risk of having the same problem.

Rationale for and Benefits of Newborn Screening

Most newborn screening programs report no difference in global IQ score compared with sibling or classmate controls, whereas some report a reduction in IQ ranging from 6 to 15 points. Even if there are no differences in global IQ, some show differences in subtest components, such as language or visual-spatial skills. These results are more likely in severely affected infants,[61] those started on too low an initial dose of levothyroxine sodium, or those who are not optimally managed or poorly compliant in the first 2 years of life. However, these differences in IQ nearly disappeared if higher starting doses of levothyroxine, averaging 11.6 μg/kg per day, were used.[62] Recent data suggest that a starting dose of 10 to 15 μg/kg per day normalized serum thyrotropin by 1 month and resulted in a higher IQ as compared with infants started on a lower treatment dose.[63]

Screening

Most screening programs in the United States measure T_4 initially, with a thyrotropin determination on infants whose T_4 level is less than the 10th percentile for that specific assay. Some US newborn screening programs and more in Canada now are screening with an initial thyrotropin measurement. Because there is a thyrotropin surge after birth that decreases over the next 5 days, infants with screening specimens obtained at less than 48 hours of age may have false-positive thyrotropin increases. Each screening program must establish its own T_4 and thyrotropin cutoff levels. Primary T_4 screening programs may identify infants with delayed thyrotropin increase (usually preterm infants) and secondary hypothyroidism. Primary thyrotropin screening programs identify infants with subclinical hypothyroidism (high thyrotropin, normal T_4). The false-positive rate is generally higher for primary T_4 programs compared with primary thyrotropin programs (0.30% vs 0.05%, respectively). Preterm infants have reduced T_4 concentrations and, thus, make up a disproportionate percentage of infants with false-positive results. Neither screening is affected by diet or transfusion, except total exchange transfusion.

Follow-up and Diagnostic Testing

Infants with abnormal screening results must have confirmatory serum T_4 testing and some measure of thyroid-binding proteins (eg, triiodothyronine [T_3] resin uptake), or a free T_4 level, and thyrotropin determination. Once a diagnosis of hypothyroidism is confirmed, studies may be undertaken to determine the underlying etiology. Most useful are imaging studies, either thyroid ultrasound or thyroid uptake and scan, using either technetium 99m pertechnetate or iodine 123. In general, information gained from these studies does not alter management, so they are considered optional; they should never delay onset of treatment. If there is evidence of maternal autoimmune thyroid disease, measurement of thyrotropin-binding inhibitor immunoglobulin in the mother and infant can identify those with likely transient hypothyroidism. If iodine exposure or deficiency is suspected, measurement of urinary iodine can confirm this etiology.

Brief Overview of Disease Management

Levothyroxine is the treatment of choice; only tablets should be used, because liquid preparations are not stable. The recommended starting dose is 10 to 15 μg/kg per day[62,63]; it is important that the initial dose correct hypothyroxinemia as rapidly as possible.[64–66] Treatment can be started after confirmatory studies are obtained, pending results. Treatment goals are to keep the serum T_4 or free T_4 in the upper half of the reference range (10–16 μg/dL [130–204 nmol/L] or 1.2–2.3 ng/dL [18–30 pmol/L], respectively) and the thyrotropin in the

reference range (<6 mU/L). Laboratory evaluation should be conducted (1) at 2 and 4 weeks after initiation of T_4 treatment, (2) every 1 to 2 months during the first year of life, (3) every 3 to 4 months between 1 and 3 years of age, and (4) 2 to 4 weeks after any change in dosage.[67] Prolonged overtreatment can lead to disorders of temperament and craniosynostosis and should be avoided. Close monitoring is essential in the first 2 to 3 years of life, a time at which the brain still has a critical dependence on thyroid hormone. If permanent hypothyroidism has not been established by 3 years of age, levothyroxine treatment can be discontinued for 1 month and endogenous thyroid function can be reevaluated.

Current Controversies

Preterm infants with hypothyroidism can have a delayed thyrotropin increase,[68] most likely because of immaturity of the hypothalamic-pituitary-thyroid (HPT) axis. Such infants may be missed by either the primary T_4 or thyrotropin screening approach. Some programs, therefore, have undertaken or are considering a routine second screening between 2 and 6 weeks of age in preterm infants. Programs that undertake a routine second screening report an additional 10% of cases. In addition, some studies suggest that infants less than 28 weeks' gestational age who lose the maternal contribution of thyroid hormone may benefit from treatment until the HPT axis matures.[69] Additional studies are needed before this can be considered standard of care. Last, some infants seem to have altered feedback of the HPT axis, manifested as persistently high serum thyrotropin concentrations despite apparent adequate treatment.

Special Issues/Concerns

Managing CH presents challenges with stakes that are far greater than management of acquired hypothyroidism. Laboratory evaluation occurs much more frequently, and target T_4 or free T_4 ranges are different for infants. Infants with an altered HPT axis and persistently high thyrotropin concentrations are difficult treatment challenges. With a goal of ensuring optimal treatment and, therefore, optimal neurodevelopmental outcome, these cases should be managed by pediatricians in consultation with pediatric endocrinologists.

CYSTIC FIBROSIS

Cystic fibrosis (CF) (OMIM database No. 219700)[70] is a hereditary disease that has primary effects on the lungs, pancreas, intestine, liver, sweat glands, and male reproductive tract as well as important secondary effects on growth and nutrition.[71] The clinical course is variable, but most patients succumb to lung disease in early adulthood.

Incidence

The incidence of CF is approximately 1 in 3500 in white newborn infants. The incidence in black and Hispanic newborn infants (approximately 1 in 15 000 and approximately 1 in 7000, respectively) is higher than previously suspected. There is a low incidence in Asian infants.

Clinical Manifestations

CF usually presents in infancy. Meconium ileus, a neonatal intestinal obstruction, occurs in approximately 17% of infants with CF. Beyond the perinatal period, CF presents as failure to thrive secondary to exocrine pancreatic insufficiency, chronic respiratory symptoms, or both. Nutritional deficits can be severe at presentation and may lead to edema and hypoproteinemia from protein-calorie malnutrition. Infants may present with hypoelectrolytemia from sweat salt loss. The most common chronic respiratory symptoms are cough and wheeze. If infants are not diagnosed in the newborn period, they often undergo months of illness with concomitant stress

on the parents. Patients are prone to chronic endobronchial infections with *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and other characteristic bacteria throughout childhood. Many of these patients suffer from recurrent intestinal blockages, and a small percentage of patients have severe liver disease. Diabetes is increasingly common during adolescence and young adulthood. Fifteen percent of these patients have mutations that do not lead to exocrine pancreatic insufficiency. They are at risk of recurrent pancreatitis, however. The median predicted age of survival is 33 years.[72]

Pathophysiology

CF results from abnormalities in the CF transmembrane conductance regulator (*CFTR*) protein, a membrane glycoprotein that regulates ion flux at epithelial surfaces. Abnormalities in *CFTR* cause thick secretions that obstruct pancreatic ductules, leading to exocrine pancreatic destruction. In the airway, dehydration of airway surface liquid leads to chronic infection and neutrophil-dominated inflammation. Bronchiectasis and progressive obstructive lung disease then follow.

Inheritance

CF is autosomal recessive. More than 1000 mutations in the *CFTR* gene have been described, but one mutation, ΔF508, accounts for more than 70% of affected chromosomes in individuals of European ancestry. Several-dozen mutations have been characterized as pancreatic sufficient or insufficient on clinical grounds. The American College of Medical Genetics has developed standards and guidelines for population-based CF-carrier screening that include a panel of 25 mutations.[73]

Rationale for and Benefits of Newborn Screening

The principal benefit of newborn screening and early diagnosis is improved height and weight at least through adolescence, demonstrated in a well-controlled clinical trial.[74] Improvement in height and weight likely occurs from early institution of pancreatic enzyme, fat-soluble vitamin and salt supplementation, as well as the general nutritional follow-up that is part of care at a CF center. In addition, it is likely that early diagnosis and attention to nutrition can help patients avoid severe nutritional complications of infancy, although this has not been shown in a controlled trial. Severe nutritional complications of CF in infancy include anemia from vitamin E deficiency, zinc deficiency, linoleic acid deficiency, hypoelectrolytemia, and protein-calorie malnutrition. In addition, vitamin E deficiency at symptomatic diagnosis of CF is associated with cognitive deficits. Thus, early diagnosis through newborn screening is likely to improve developmental outcome. Observational studies support improved pulmonary outcome after newborn screening. In addition, height in CF is correlated with improved pulmonary outcome. Thus, the increase in height in patients identified through screening also may be beneficial. Another benefit of screening is that parents of children identified through screening have been shown to have greater trust in the medical establishment than parents whose children are identified only after symptoms appear.[75]

Screening

Methodology

Determination of immunoreactive trypsinogen (IRT) concentrations from dried blood spots serves as the basis for the first tier in all newborn-screening programs for CF. IRT concentration is high in the blood of infants with CF, presumably from leakage of the protein into the circulation after exocrine pancreatic injury. Two approaches can be taken if the IRT concentration is high. The more common approach is to perform mutation analysis from the dried blood spot for a set of CF mutations. Another approach is based on persistent elevation of IRT concentration, which requires a second dried blood spot taken 2 to 3 weeks after birth.

The value at which the initial IRT concentration is considered abnormal varies from program to program. If mutation analysis is performed from the first dried blood spot, a second specimen is not required. Thus, the IRT cutoff can be set to include a substantial fraction of the newborn population. In some programs, the top 5% of all IRT concentrations are considered abnormal and mutation analysis is performed. In other programs, the cutoff is set at the top 1%.

Programs that are based on persistent elevation of IRT concentration require a second dried blood spot taken at 2 to 3 weeks of age in infants with a high concentration on the first specimen. These programs set the cutoff value for IRT at a higher concentration (0.5% of newborn infants) than programs that perform mutation analysis. Diagnosis through persistent elevation of IRT concentration can identify infants with CF who do not carry mutations included in most mutation-analysis panels.

Timing

Because IRT concentration is frequently high immediately after birth, specificity is improved if the test is performed after the first day of life.

Sensitivity and Specificity

The sensitivity of most CF screening programs, whether based on genotyping or persistent elevation of IRT concentration, is approximately 95%. The specificity of programs that rely on persistent elevation of IRT concentration without genotyping is approximately 99.5% after the first measurement of IRT concentration. The specificity of programs that perform genotyping after the initial elevation of IRT may be as high as 99.9%.

Follow-up and Diagnostic Testing (Short-term)

Timeline

For programs that perform mutation analysis, the diagnosis of CF can be made if 2 mutations are identified from the dried blood spot. If only one mutation is identified from the dried blood spot, then sweat testing, the definitive diagnostic test, should be performed as soon as possible. In programs that do not perform mutation analysis, sweat testing should be performed within a few days of the repeat IRT test. There is some urgency to making the diagnosis. Many patients are pancreatic insufficient in the first weeks of life and are at risk of severe nutritional complications. Pancreatic enzyme-replacement therapy, fat-soluble vitamin supplementation, and salt supplementation should be initiated very soon after diagnosis in pancreatic-insufficient infants.

Test and Procedures

Sweat testing should be performed at more than 1 week of age. Almost all term infants will have adequate sweat amounts by that time.[76] Sweat collection amounts may be inadequate in preterm infants; in such a case, mutation analysis can be performed.[77] Currently, a sweat chloride value of more than 40 mmol/L is required for the diagnosis of CF in the newborn period; infants with values more than 30 mmol/L, however, require follow-up.[78] In programs that perform mutation analysis, confirmatory sweat testing should be obtained even in infants who test positive for 2 mutations.

Brief Overview of Disease Management

Nutrition is an important focus of management beginning in infancy. A recently developed test for fecal elastase may allow convenient determination of need for pancreatic enzyme supplementation. Pancreatic enzyme, fat-soluble vitamin, and salt supplementation will be started in most infants at diagnosis. Outpatient regimens become increasingly complex with age and often include several inhaled medications, nutritional supplements, attention to secretion clearance, and a number of ongoing oral medications to be taken daily. Patients with pulmonary exacerbation require hospitalization to receive intravenous antibiotic therapy and intensive secretion clearance. Every effort should be made to have the infant and family cared for at centers accredited by the Cystic Fibrosis Foundation.

Current Controversies

Three controversies have surrounded newborn screening for CF. One issue has been whether the growth and nutritional benefits of early diagnosis are sufficient to justify screening. Very recently, however, the Centers for Disease Control and Prevention has determined that newborn screening for CF is of benefit.[79] Follow-up studies of pulmonary and cognitive outcomes may further address this issue. A second issue is carrier detection, which occurs in all programs that use mutation analysis as part of the screening. It is not known for sure whether identification of otherwise well infants as carriers of CF may do harm, but studies suggest that this is not the case. A third issue is that approximately 5% of newborn infants identified will have borderline sweat tests (sweat chloride levels of 30–40 mmol/L) and "mild" mutations. It is not clear yet how many of these infants will have important medical problems. Follow-up studies are underway.

Counseling

Parents will require education on all aspects of CF. The care team consists of the primary pediatrician and the CF center staff. Genetic counseling should be arranged for all families.[80]

GALACTOSEMIA

Lactose, or milk sugar, is broken down into its constituent simple sugars, glucose and galactose, before absorption in the intestine. Galactosemia, which is an increased concentration of galactose in the blood, has many causes. The genetic disorders that cause galactosemia vary in severity from a benign condition to a life-threatening disorder of early infancy. Early diagnosis and treatment of the latter condition can be life saving; hence, newborn screening for this disease has been instituted in many states.

Incidence

Three distinct enzyme deficiencies may lead to galactosemia. The most common of these, galactose 1-phosphate uridyltransferase (GALT) deficiency (OMIM database No. 606999),[81] occurs in approximately 1 in 47 000 newborn infants.[82] This disorder is often referred to as "classic galactosemia." Galactokinase (GALK) deficiency (OMIM database No. 230200)[81] seems to be very rare, although there have been no large population studies to assess its incidence. One study found that 1% of North American people were carriers, suggesting a disease frequency of 1 in 40 000.[83] However, a newborn screening study conducted in Massachusetts detected no cases among 177 000 newborn infants.[84] The third disorder, galactose-4′-epimerase (GALE) deficiency (OMIM database No. 230350), occurs in 2 forms; one form is confined to red blood cells and has no symptoms, and the second form, which is exceedingly rare, is generalized, with only a few patients reported nationally.[85,86]

Clinical Manifestations

Infants with classic galactosemia, or GALT deficiency, generally present within the first weeks after birth with a life-threatening illness. Feeding intolerance, vomiting and diarrhea, jaundice, hepatomegaly, lethargy, hypotonia, and excessive bleeding after venipuncture are characteristic findings. Laboratory studies indicate liver and renal tubular disease. Septicemia, particularly with *Escherichia coli*, is not uncommon. Cataracts are generally seen at presentation, but they may be mild in the first few weeks of life and only detectable with slit-lamp examination. Less frequently, patients with classic galactosemia may have a more chronic presentation, with failure to thrive, poor feeding, and developmental delay. Black individuals with classic galactosemia, in particular, frequently have a mild presentation.

Infants with GALK deficiency generally present with bilateral cataracts, which have been observed as early as 4 weeks of age. The cataracts are identical to those seen in classic galactosemia.[87] The great majority of infants with GALE deficiency have an enzyme deficiency that is confined to the red blood cells and causes no symptoms. Five individuals with generalized GALE deficiency had developmental delay, hypotonia, and poor growth; 3 had sensorineural hearing loss.[88]

Pathophysiology

The main metabolic pathway for the conversion of galactose to glucose uses 3 enzymes: GALK, GALT, and GALE. Individuals who lack GALK cannot convert galactose to galactose 1-phosphate. As a result, galactose is converted to galactitol by an alternative pathway. The accumulation of galactitol in the lens results in the development of cataracts. Individuals with classic galactosemia, or GALT deficiency, cannot convert galactose 1-phosphate to uridine diphosphate galactose. Galactose, galactitol, galactose 1-phosphate, and other metabolites accumulate. Although it seems clear that increased galactitol is responsible for the development of cataracts in all forms of galactosemia, it is not known which metabolites are responsible for the other clinical findings in classic galactosemia.[89]

Inheritance

All forms of galactosemia are autosomal recessive in inheritance. More than 150 different mutations have been identified in GALT, the enzyme that is deficient in classic galactosemia. The most common GALT mutation in Europe and North America is Q188R, which is associated with the severe presentation of classic galactosemia. A mutation found in black and some Hispanic individuals is S135L.[90] This mutation is associated with a milder presentation of the disorder.

Benefits of Newborn Screening

Exclusion of galactose from the diet results in marked improvement of the life-threatening complications of classic galactosemia. However, this treatment has only limited efficacy in the prevention of long-term complications. These include impaired cognitive development, with mean IQ in the range of 70 to 90; verbal dyspraxia, a speech disorder attributable to a sensorimotor disturbance of articulation; growth delay, with ultimate height in the normal range; neurologic findings, including tremor and ataxia beginning in midchildhood to middle age; and ovarian failure, manifesting as delayed puberty, primary amenorrhea, secondary amenorrhea, or oligomenorrhea.[91] Prepubertal children with GALT deficiency are also at increased risk of having decreased bone mineral density despite normal calcium intake.[92]

Screening

Newborn screening for galactosemia may test for galactose, galactose 1-phosphate plus galactose, or GALT enzyme deficiency. Some laboratories test for all of these substances. Because GALT is deficient only in classic galactosemia, this newborn screening test alone will not detect the other 2 forms of galactosemia. The GALT enzyme test has the advantage of being independent of

the infant's diet. Therefore, the timing of the newborn screening sample collection will have no effect on the reliability of this test. However, because GALT analysis is performed using red blood cells, there may be a false-negative result for up to 3 months if the infant has received a blood transfusion. Tests for galactose and galactose 1-phosphate depend on the infant's diet; therefore, it is important to be sure that the infant is receiving galactose-containing formula or breast milk before testing. MS/MS can be used as a technology in screening for galactosemia.[93]

Follow-up and Diagnostic Testing

All newborn infants with positive screening results should be evaluated rapidly by an experienced physician for feeding difficulty, signs of sepsis, jaundice, and hepatomegaly. Untreated classic galactosemia may progress very rapidly to hepatic toxicity, with death resulting from sepsis or bleeding. Immediate restriction of dietary galactose is critical and should not await diagnostic testing. Galactose restriction should be instituted immediately even in the asymptomatic child and should be continued until the extent of enzyme deficiency, if any, is known.

Diagnostic studies for classic galactosemia include quantitative analysis of GALT and red blood cell galactose 1-phosphate. In states where the screening test measures GALT activity, these studies will establish or rule out classic galactosemia. When the screening results, including estimates of galactose and galactose 1-phosphate and quantitative GALT activity, are normal, quantitative analysis of GALK and GALE are required to identify these forms of galactosemia. It is likely that another pathway exists that can be responsible for galactose disposal, but this pathway has not been characterized.[94]

Brief Overview of Disease Management

Infants suspected of having galactosemia should be fed with a galactose-free formula until diagnostic testing confirms a specific diagnosis. Children who are seriously ill at the time of diagnosis of classic galactosemia require supportive care, which may include vitamin K supplementation and fresh-frozen plasma transfusions, antibiotics for presumed Gram-negative sepsis, and phototherapy for hyperbilirubinemia. After dietary galactose has been eliminated, most infants improve rapidly. Milk and milk products are excluded from the diet indefinitely, because significant ingestion of galactose at any age can be toxic.[92] Because medications may contain galactose, the pediatrician should instruct parents to ask the pharmacist if a medication is galactose free before administering it to the child. Regular nutritional evaluation is necessary to ensure adequate calcium intake. Regular developmental evaluation and early speech assessment are also required. Girls should be monitored frequently in late childhood and adolescence for pubertal development. Regular measurement of galactose 1-phosphate in red cells is the most common method used to assess dietary compliance.[85]

Lifelong galactose restriction is also indicated for individuals with GALK and generalized GALE deficiencies. No treatment seems to be necessary for red blood cell GALE deficiency.

Current Controversies

In addition to milk products, certain fruits contain significant quantities of galactose.[93] There is no consensus about whether these fruits should be eliminated from the diet, because endogenous synthesis of galactose also occurs.[94] Some authors have suggested that an elemental formula (galactose free) may be preferable to soy formula in the treatment of galactosemia.[95]

Special Issues

Galactose is a reducing substance, and the presence of reducing substances in the urine is sometimes suggested as a test for galactosemia. However, this test is neither sensitive nor specific, and it should not be used as a screening or diagnostic test for galactosemia.

HOMOCYSTINURIA

The term "homocystinuria" designates a biochemical abnormality, not a specific disease entity. There are many causes of homocystinuria. All affect one of the transsulfation pathways that convert the sulfur atom of methionine into the sulfur atom of cysteine. This pathway is the chief route of disposal of methionine. The most common defect, cystathionine β-synthase (CBS) deficiency (OMIM database No. 236200),[96] results in high concentrations of serum methionine. One form of CBS deficiency is responsive to vitamin B_6.[97] Other metabolic variants of homocystinuria include defects of vitamin B_{12} uptake or activation and tetrahydrofolate reductase deficiency (OMIM database No. 236250).

Incidence

Although homocystinuria is a rare disorder, carriers of the condition represent a much larger population. If one assumes a worldwide incidence of 1 in 300 000 individuals, the expected carrier frequency is 1 in 135. Because carriers are more prone to thromboembolic events, ascertainment of these individuals via identification of an affected person needs to be emphasized to primary health care professionals.[98]

Clinical Manifestations

Clinical problems include multiple, recurrent thromboemboli.[99] Arterial or venous thromboses may involve the cerebral, pulmonary, renal, and myocardial circulation.[100] Patients may also exhibit ectopia lentis, glaucoma, cataracts, developmental delays/mental retardation, seizures, psychiatric disturbances, osteoporosis with bone deformities, scoliosis, high palatal arch, muscle weakness with a shuffling gait, and a marfanoid habitus. Death has been reported within the first year of life. Approximately 50% of untreated individuals die by 25 years of age; death is frequently a result of thromboembolic events. Developmental delay is reported in 65% to 80% of untreated individuals.[101]

Pathophysiology

Two mechanisms probably explain most of the clinical symptoms seen: (1) abnormal (hyper) coagulation because of "sticky" platelets; and (2) direct toxicity of homocystine and its metabolites, causing endothelial cell damage.

Inheritance

The specific enzymatic defect should be ascertained. However, all heritable forms of homocystinuria exhibit autosomal recessive inheritance. Prenatal diagnosis is available for CBS deficiency using cultured chorionic villus cells or amniotic fluid cells to measure the activity of this enzyme. The chromosome map location is 21q22. The incidence in Ireland, Australia, Great Britain, and New England is 1 in 50 000, the incidence in Japan is 1 in 1 million, and the worldwide incidence is 1 in 250 000.

More than 90 different disease-associated mutations of the *CBS* gene have been identified. The vast majority of these mutations are "private" mutations that occur in only a single or a very small number of families. The most prevalent mutations are the G307S and I278T mutations.[102] Affected patients vary widely in the extent to which they manifest clinical abnormalities, suggesting considerable genetic heterogeneity. Some of the variability is accounted for by the relative reduction of enzymatic activity. Absent to relatively low residual activity (up to 10%) of CBS has been noted among different families. However, there are reports of individuals with the identical genotype resulting in a different phenotype within the same family.

Rationale for and Benefits of Newborn Screening

The potential for early clinical diagnosis is limited. Ocular abnormalities, because of their distinctive lens displacement, may lead to the diagnosis. The diagnosis should be considered in any child or young adult with thromboembolism affecting both the large and small arteries as well as the veins, particularly in association with developmental disabilities, mental retardation, or skeletal findings. Most patients, however, have nonspecific features so that definitive testing involving the measurement of serum or urine amino acids is not accomplished before the expression of more severe clinical symptoms. Treatment seems to reduce the risk of thromboembolic episodes. Because this is the major cause of mortality and morbidity in these patients, the survival rate may improve with early, effective treatment. The incidence of mental retardation may be prevented or reduced.[103] For patients with classic (homozygous) homocystinuria, early treatment with good biochemical control (lifetime plasma-free homocystine < 11 μmol/L) seems to prevent mental retardation,[104] ectopia lentis seems to be delayed, and the incidence of seizures is reduced.

Screening

The bacterial inhibition assay (BIA) test may be used to detect increased concentrations of blood methionine.[105]

Normal values for serum methionine concentration are noted to be less than 2 mg/dL. Newer methods include direct methionine assay by MS/MS.[106] The false-negative rate seems to correlate with the time that the specimen was obtained and the level of residual CBS activity present (ie, the B_6-responsive form). The false-negative rate increases with earlier newborn discharges. Approximately 1 in 5000 infants is found to have blood methionine concentrations more than 2 mg/dL. The use of a reduced cutoff level (1 mg/dL) increases the false-positive rate from 0.006% to 0.03%.[107] However, use of this cutoff should identify affected infants who have only slightly increased concentrations of methionine and reduce the frequency of false-negative results. It has been suggested that the increased false-positive rate does not represent an undue burden in terms of requests for repeat analysis.

Follow-up and Diagnostic Testing

Quantitative serum or plasma amino acid determination is used for diagnosis of homocystinuria. Plasma amino acids show increased methionine and homocystine concentrations with reduced concentrations of cystine and absent cystathionine. A urine organic acid profile with gas chromatography and MS/MS may be used to determine the presence or absence of methylmalonic acid.

Brief Overview of Disease Management

Treatment depends on the underlying cause of homocystinuria. As a first step, pyridoxine (vitamin B_6) responsiveness should be ascertained, because approximately 50% of patients respond to large doses of this vitamin. Nonresponsive patients with CBS deficiency should be treated with a methionine-restricted, cystine-supplemented diet. Folic acid and betaine therapy may also be helpful with all patients. In the disorders of cobalamin metabolism and transport in which methylmalonic acid and homocystine appear in the urine, hydroxycobalamin treatment (vitamin B_{12}, not cyanocobalamin) may be beneficial. Aspirin and dipyridamole have also been used to decrease the occurrence of thromboembolic phenomena. Clinical variability remains despite therapy. Not all affected individuals have increased methionine concentrations. The relationship between variability and the underlying metabolic processes or compliance has not yet been completely ascertained. One described mutation, G307S, is typically a pyridoxine-nonresponsive mutation, and individuals homozygous for the I278T mutation are usually responsive to pyridoxine therapy. The presence of some activity of the enzyme seems necessary for a clinical response to pyridoxine (vitamin B_6) administration. Individuals who are clinically responsive to pyridoxine generally have milder or more slowly progressive disease.

Current Controversies

Increased concentrations of methionine may be minimal during the first 3 days of life until there is adequate protein intake (milk feedings). This is especially true in patients who are responsive to vitamin B_6, who usually have some residual enzyme activity. This minimal increase probably accounts for the difference in screening frequencies between the United States and United Kingdom, where screening specimens are obtained at 5 to 7 days. It may be preferable to screen for this disorder at 2 to 4 weeks of age. Early discharge at 24 or even 18 hours results in many missed cases and decreases screening effectiveness.

Programs continue to evaluate the efficacy of screening and early treatment. Improvement in screening to decrease the numbers of missed cases is important. Recent evidence has shown that carriers (heterozygotes) for homocystinuria have an increased risk of thromboembolic events. Therefore, genetic counseling and screening should be offered to relatives of persons with homocystinuria.

Special Issues/Concerns

Specialized care is required that includes the ability to monitor amino acids and provide nutritional assessment and planning. Doses of pyridoxine higher than 900 mg have been associated with neuropathy; however, these higher doses are usually not required for adequate treatment. Thromboembolic phenomena are more prone to occur during anesthesia, surgical procedures, and prolonged immobilization.

MAPLE SYRUP URINE DISEASE (BRANCHED-CHAIN KETOACIDURIA)

Maple syrup urine disease (MSUD) (OMIM database No. 248600),[108] also known as branched-chain ketoaciduria, is caused by a deficiency in activity of the branched-chain α-keto acid dehydrogenase (BCKD) complex. Deficiency of the BCKD complex results in accumulation of the branched-chain amino acids (BCAAs) leucine, isoleucine, and valine and the corresponding branched-chain α-keto acids (BCKAs).[109] A pathognomonic finding in individuals with MSUD is the presence of alloisoleucine, a compound that is not present in other individuals. There are 5 phenotypes observed in patients with MSUD: classic, intermediate, intermittent, thiamine-responsive, and dihydrolipoyl dehydrogenase (E3)-deficient. Although enzyme activities overlap to some degree in these phenotypes, in general, lower enzyme activity is associated with a more severe disorder.

Incidence

The worldwide frequency of MSUD (including classic and some variant forms), which is based on routine screening data from 26.8 million newborn infants, is approximately 1 in 185 000.[109,110] Newborn screening of 756 163 newborn infants over an 8-year period in Georgia revealed a much higher frequency of 1 in 84 000.[111] In the population of Mennonites living in Lancaster and Lebanon counties in Pennsylvania, the incidence is 1 in 176 newborn infants, most likely attributable to a founder effect.[112,113]

Clinical Manifestations

Classic MSUD (residual enzyme activity $\leq$2%) is the most severe and most common form. Affected infants are normal at birth, with symptoms usually developing between 4 and 7 days of age; however, lower intake of protein, as in breastfeeding, can delay the onset of symptoms until the second week of life. Initial symptoms are lethargy and poor sucking with little interest in feeding. Weight loss follows with abnormal neurologic signs (alternating hypertonia and hypotonia; dystonic posturing of the arms) becoming more and more apparent. The characteristic odor of the urine, described as smelling like maple syrup, burnt sugar, or curry, is then noted. Finally, seizures and coma, leading to death (in untreated cases), occurs.[109] Laboratory findings include increased concentrations of BCAAs, ketosis, acidosis, and occasionally hypoglycemia.[114] Patients with intermittent MSUD (enzyme activity 5%–20%) exhibit normal growth and intelligence. These children do not go into metabolic crisis unless the body is in a stressful situation, such as an infection (ie, otitis media) or after surgery.[115] Although patients with intermittent MSUD generally present between 5 months and 2 years of age secondary to a minor infection, some individuals have not shown symptoms until the fifth decade. Concentrations of BCAAs are normal between episodes.

In contrast, patients with intermediate MSUD (enzyme activity 3%–30%) do not present with catastrophic illness during the neonatal period but have gradual neurologic problems, eventually resulting in mental retardation. In one study, most were diagnosed between 5 months and 7 years of age while undergoing evaluation for developmental delay or seizures.[116,117] Several patients have had episodes of ketoacidosis, but acute encephalopathy is rare.[118] Increased concentrations of BCAAs and BCKAs in serum and urine are present. Patients with thiamine-responsive MSUD (enzyme activity 2%–40%) have a clinical course similar to those with intermediate MSUD. These patients have decreased concentrations of BCKAs and/or BCAAs with thiamine therapy in varying dosages ranging from 10 to 1000 mg/day.[119,120] In some instances, the patient does not show the full response to thiamine until therapy has commenced for 3 weeks.[121] In all documented cases, patients required dietary intervention in conjunction with thiamine to achieve metabolic control.[109]

E3-deficient MSUD (E3 deficiency) is rare, with fewer than 20 patients having been described.[109,122,123] Clinically, newborn infants with E3 deficiency are similar to patients with intermediate MSUD, but severe lactic acidosis is also present. The infants develop a persistent lactic acidosis between 8 weeks and 6 months of age followed by progressive neurologic deterioration with hypotonia, developmental delay, and movement disorder. Laboratory findings include mild to moderately increased concentrations of BCAAs and increased lactate, pyruvate, α-ketoglutarate, α-hydroxyisovalerate, and α-hydroxyglutarate concentrations. The patients have a combined deficiency of BCKD, pyruvate, and α-ketoglutarate dehydrogenase complexes, leading to the more complex phenotype. Various combinations of dietary therapy, vitamin therapy (thiamine and biotin), and lipoic acid have been tried without success.[122]

Pathophysiology

The BCKD complex is a macromolecule composed of 3 catalytic components: a thiamine pyrophosphate–dependent decarboxylase (E1) with α and β subunits, a transacylase (E2), and a dehydrogenase (E3). In addition, the BCKD complex contains 2 regulatory enzymes, a kinase and a phosphatase, that control activity of the complex.[109] The genes encoding E1α, E1β, E2, E3, and the specific kinase are cloned. Mutations with genotype/phenotype correlations have been described (see "Inheritance" below).

Inheritance

MSUD is an autosomal recessively inherited condition.[109] Mutations in the E1α subunit result in the molecular phenotype referred to as MSUD type IA (OMIM database No. 248600). The type IA mutations almost always result in the severe classic form of MSUD. The most prevalent mutation is Y393N, the mutation in the Mennonite community in Pennsylvania. DNA testing has been developed for the Y393N mutation because of its prevalence.[124] Only a few mutations have been described in the E1β subunit (type IB mutations; OMIM database No. 248611), all resulting in the classic neonatal MSUD phenotype. Mutations affecting the E2 core of the BCKD complex (type II MSUD mutations; OMIM database No. 248610) characteristically lead to a milder phenotype than types IA or IB. Most patients have the intermediate or intermittent phenotype, and several have been reported to respond to thiamine therapy. All type III mutations (defects in the E3 subunit; OMIM database No. 238331) lead to a distinct severe combined phenotype (MSUD plus primary lactic acidosis).

Benefits of Newborn Screening

Prognosis is poor for the patient with classic MSUD that goes undiagnosed and untreated, with death versus survival with severe neurologic damage as potential outcomes. Patients with classic MSUD who are not treated by 14 days of age generally have a less desirable outcome. In one study, the outcome with treatment was reported in more than 150 patients with classic MSUD and more than 25 patients with the variant forms.[109,125] Most of these cases were detected by newborn screening or because of clinical presentation. In the patients with classic MSUD, one third had IQ scores higher than 90, and one third had scores between 70 and 90. Rapid recognition and treatment (as with newborn screening) is important. When both performance and verbal scores are available, verbal scores are consistently higher than performance scores.[126] The discrepancy between the 2 scores is not surprising, because cerebellar dysfunction is often an early sign of acute metabolic decompensation. Even with newborn screening leading to timely treatment, outcome is not perfect. Short attention span and minor learning disabilities were observed even in patients with normal intellect who were treated soon after birth.[126]

Screening

State-of-the-art screening for MSUD is by MS/MS. The sum of the 3 isomers (leucine, isoleucine, and alloisoleucine) leads to a distinct diagnostic peak.[109] Classic MSUD, the intermediate form, and E3 deficiency can usually be detected by screening in the newborn period. Intermittent MSUD would not be detected, because the patients' concentrations are normal when they are not in crisis. Thiamine-responsive MSUD has been missed by newborn screening.[110]

Follow-up and Diagnostic Testing

A blood leucine concentration greater than 4 mg/dL, or a concentration of 3 to 4 mg/dL (305 mmol) in the first 24 hours of life, requires immediate medical follow-up.[109] Plasma amino acid analysis reveals findings diagnostic for MSUD: increased concentrations of BCAAs, low alanine concentrations, and the presence of alloisoleucine.

Brief Overview of Disease Management

Treatment consists of a carefully regulated diet that provides sufficient BCAAs for normal growth and development without exceeding the patient's degradative enzyme capacity.[109] Because natural protein must be limited, a medical food product (BCAA-free) supplement is necessary. A metabolic team, including not only a physician metabolic specialist but also a metabolic nutritionist, is crucial. A trial of thiamine supplementation (50–300 mg/day for at least 3 weeks) is recommended, because it is therapeutic for some patients and has no adverse effects. There are 2 aspects of treatment: long-term management and treatment during acute metabolic crisis. The goal of long-term dietary management is normalization of blood BCAA concentrations while providing nutrition adequate to sustain growth and development in children. Dietary therapy should be continued for life.[127] Patients with intermediate MSUD may only require protein restriction without supplementation of synthetic formula. Individuals with intermittent MSUD do not require a special diet except during episodes that may lead to metabolic crisis. Treatment during acute illnesses should be aggressive, because the metabolic decompensation can be life-threatening.[109] Toxic metabolites must be removed at the same time that catabolism is minimized and anabolism is promoted. Dialysis (first peritoneal and, more recently, continuous venovenous hemofiltration) has proven useful in BCAA/BCKA clearance.[128] Dietary treatment to break the cycle of catabolism and promote anabolism sometimes requires parenteral nutrition[129] or insulin combined with a large glucose infusion.[130]

Current Controversies

MSUD has been treated since the early 1960s,[131] and consequently, some neurologically intact MSUD-affected women have reached childbearing age and reproduced. As has been reported for other enzyme deficiencies, postpartum metabolic decompensation can be a problem.[132]

MEDIUM-CHAIN ACYL-CoA DEHYDROGENASE

Medium-chain acyl-CoA dehydrogenase (MCAD; OMIM database No. 201450)[133] deficiency is a disorder of fatty acid oxidation (FAO) first described in 1982–1983.[134] All together, 10 disorders affecting mitochondrial FAO and ketogenesis have been identified. Among these, MCAD deficiency seems to be the most important because it is the most common and it has been implicated in some cases of sudden infant death syndrome (SIDS) and Reye syndrome.[135]

Incidence

MCAD deficiency has been diagnosed almost exclusively among individuals of northwestern European origin, with frequencies ranging from 1 in 46 000 to 1 in 6400.[136,137] The heterozygote frequency is 1% to 2%. A few cases have been identified in other populations, including one Pakistani patient, one black patient, and isolated cases in individuals of Southern European and Northern African origin.[138,139] Newborn screening in Japan did not identify any carriers.[138]

Clinical Manifestations

The classic presentation is an episode of vomiting and lethargy after a period of fasting in a child between 3 and 15 months of age. The child may have had a previous viral infection (gastrointestinal or upper respiratory) resulting in decreased oral intake that would have little consequence in an unaffected child.[139] The episode may

result in coma, and the child may remain obtunded even after hours of treatment with intravenous glucose. Undiagnosed disease has a mortality rate of 20% to 25%, many times with death occurring during the initial episode.[140] In a clinical review of 94 families with MCAD deficiency, 19 families (20%) had one or more unexplained child deaths. The diagnosis of MCAD deficiency was made postmortem in all cases.[141]

There are few reports of first symptoms after 4 years of age and fewer recurrent episodes after 4 years of age. Symptoms that require hospitalization during the second decade are unusual. The earliest onset of symptoms and sudden death is in the neonatal period, although this is rare, and the latest documented onset of the first episode was at 14 years of age. Most deaths would be preventable if dietary therapy and measures to prevent fasting were begun before the onset of symptoms. Cases in which children have died have, in some instances, resembled cases of SIDS or Reye syndrome. There is marked clinical variability even within the same family. There are families reported with several affected children with one child in the family dying on the first episode before 2 years of age and other children as old as 10 years never having had an episode.[139]

Although death is certainly the most important potential outcome of not screening for MCAD deficiency, there are findings in survivors that are very concerning regarding morbidity. A follow-up survey of 78 MCAD-deficiency survivors (all older than 2 years) revealed a number of unexpected problems, including developmental disabilities, speech and language delay, behavioral problems, attention-deficit/hyperactivity disorder (ADHD), proximal muscle weakness, chronic seizure disorder, cerebral palsy, and failure to thrive. The finding of ADHD was seen in 9 patients (12%), 8 of whom were female, in contrast to the usual male preponderance of ADHD in the general population. The development of muscle weakness was strongly correlated with length of time between symptomatic presentation and the institution of appropriate measures to prevent additional episodes of illness.[141,142]

Pathophysiology

MCAD deficiency is one defect in the pathway of mitochondrial β-oxidation. It is primarily a disease of hepatic FAO, with the most frequent presentation being episodic hypoketotic hypoglycemia provoked by fasting. FAO disorders do not present under nonfasting conditions and, therefore, have escaped attention for many years. The plasma and urinary metabolites of MCAD deficiency are of 2 types: general indicators of impaired function of the β-oxidation pathway (eg, dicarboxylic acids) and specific metabolites (eg, octanoylcarnitine). The inability to break down fats to ketone bodies for an energy source while fasting eventually leads to hypoglycemia. In addition, medium-chain (C8–C12) acyl-CoA intermediates accumulate in mitochondria, with the end result being inhibition of mitochondrial β-oxidation. Fatty acid is incorporated into triglycerides, resulting in accumulation of fat in the liver during acute episodes. The clinical presentation and many of the routine laboratory observations in MCAD deficiency are indistinguishable from those in Reye syndrome.[143] Encephalopathy and cerebral edema are secondary to accumulation of fatty acids within the central nervous system. Coma results from a combination of hypoglycemia and toxic effects of fatty acids or their metabolites.[134]

Inheritance

MCAD deficiency is inherited as an autosomal recessive trait. The causative gene is known, and multiple mutations have been identified. In studies of clinically affected patients with MCAD deficiency, 90% of mutant alleles identified have a single missense mutation (A985G); other mutations identified seem to individually account for less than 1% of the mutant alleles.[144] Virtually all of the A985G alleles arose on a background with the same haplotype, which suggests a founder effect, with the mutation beginning in northwestern Europe and then spreading throughout the rest of the world.[145] Recent molecular studies performed as follow-up to newborn screening by MS/MS technology have found a lower percentage of individuals with the common A985G mutation.[136,146] A second common mutation (T199C) has been observed in US populations identified initially by MS/MS screening. The T199C mutation is a mild mutation that produces a biochemical phenotype but has never been observed in clinically affected patients.[146]

Benefits of Newborn Screening

The benefits of and rationale for using newborn screening for diagnosis of MCAD deficiency are obvious. As noted above, many individuals affected with MCAD deficiency will die during the presenting episode, sometimes having been misdiagnosed with SIDS or Reye syndrome. Not only is this a tragic outcome for the loss of the child, but the family also has a 25% recurrence risk for the condition or may already have affected children who have not yet had clinical symptoms. The condition is relatively common, with a frequency of 1 in 15 001 in prospective newborn screening of 930 078 blood spots from different areas of the United States.[146]

Screening

The most efficient and sensitive method of screening for MCAD deficiency is MS/MS, measuring octanoylcarnitine (a compound normally not present) on the filter-paper blood spot. The optimal time for testing is the newborn period, because levels of octanoylcarnitine are significantly higher in the first 3 days of life than later (8 days to 7 years).[147] Individuals who are homozygous for

the common mutation (A985G) who are most likely to present clinically will have octanoylcarnitine concentrations higher than 2.3 μmol/L, and individuals with one copy of 985 and one copy of a milder mutation (eg, T199C) will have octanoylcarnitine present but most likely at a lower concentration (≥1.0 μmol/L). The latter group is more challenging to determine the best course of follow-up.

Follow-up and Diagnostic Testing

Any child with an octanoylcarnitine concentration of 1.0 μmol/L or greater will require definitive diagnostic testing. Follow-up testing will consist of plasma acylcarnitine analysis, urinary organic acid analysis, and molecular testing. The plasma acylcarnitine analysis and urinary organic acid analysis will confirm the diagnosis. The molecular analysis should provide guidance regarding prognosis.

Brief Overview of Disease Management

Treatment for MCAD deficiency consists of avoidance of fasting and mildly decreased intake of dietary fat coupled with L-carnitine supplementation. MCAD deficiency results in a secondary deficiency of carnitine, because carnitine couples with toxic intermediates, resulting in their excretion while depleting carnitine stores. Although it remains questionable how helpful supplemental carnitine is during periods when the patient with MCAD deficiency is healthy, there is no doubt that exogenous carnitine is recommended during times of illness.[139] Another important point is that patients should be treated aggressively even during minor illnesses (eg, otitis media) to avoid a severe episode. There should be no hesitation to institute therapy with intravenous glucose and carnitine.

Current Controversies

Genotype/phenotype correlation is not straightforward, and the treatment of individuals with milder mutations remains controversial.[148,149] There are questions yet to be answered, such as whether some (or all) individuals with the less deleterious mutations (either in combination with the common 985 mutation or in combinations with one another) who have a biochemical phenotype would ever have medical problems. In addition, would some such individuals have serious episodes and others would not because of unknown modifying factors? Until we know the answer to these and other questions, we would be remiss in not treating everyone identified, perhaps overtreating some individuals. Newborn screening for MCAD deficiency will be key in answering some of these questions.

PHENYLKETONURIA

Hyperphenylalaninemia (OMIM database No. 261600),[150] an abnormal increase in the concentration of the amino acid phenylalanine (Phe) in the blood, may be a benign condition with little clinical significance. When the concentration of Phe is very high (>20 mg/dL or 1210 μmol/L) and there is accumulation of phenylketones, the condition is called classic phenylketonuria (PKU).

Incidence

Despite the fact that newborn screening has been underway for more than 40 years in the United States, data only allow estimates of the incidence and prevalence of this disorder. This is partly because of the fact that states vary in their definitions of hyperphenylalaninemia and PKU. For PKU, the reported incidence ranges from 1 in 19 000 to 1 in 13 500 newborn infants. For non-PKU hyperphenylalaninemia, the estimated incidence is 1 in 48 000 newborn infants. There are large variations in the incidence of PKU by ethnic and cultural groups, with individuals of Northern European ancestry and American Indian/Alaska Native individuals having a higher incidence than black, Hispanic, and Asian individuals.[151]

Clinical Manifestations

PKU is rarely diagnosed before 6 months of age without newborn screening, because the most common manifestation without treatment is developmental delay followed by mental retardation. Untreated individuals may also develop microcephaly, delayed or absent speech, seizures, eczema, and behavioral abnormalities.

Pathophysiology

PKU results from a deficiency of activity of a liver enzyme, phenylalanine hydroxylase (PAH), leading to increased concentrations of Phe in the blood and other tissues. Certain mutations of the *PAH* gene usually result in non-PKU hyperphenylalaninemia, and others result in classic PKU. Because siblings with the same mutation at the *PAH* locus may have different clinical findings, it is likely that other genetic and environmental factors influence the severity of the disorder.[152] In fact, a few individuals with PKU have no evidence of mental retardation, even without dietary treatment.[151] However, there is evidence that certain genotypes are associated with higher increases of Phe concentration.[153] It is likely that Phe itself leads to the mental retardation and other findings of PKU. In excess, Phe disturbs transport of other amino acids across the blood-brain barrier and impairs synthesis of neurotransmitters.[151] For the enzyme PAH to be active, the cofactor tetrahydrobiopterin (BH4) is required. Impaired synthesis or recycling of BH4 results in increased concentrations of Phe and certain other amino acids. This condition does not respond to routine dietary management of PKU, and hence, states have instituted additional screening programs to identify infants with these rare disorders so that appropriate treatment can be initiated.

Inheritance

PKU is an autosomal recessive disorder, with the *PAH* locus on chromosome 12q24.1. More than 400 different mutations have been described, including deletions, insertions, missense mutations, splicing defects, and nonsense mutations. Most individuals with PKU are compound heterozygotes, meaning that a single individual will have different mutations of each copy of the *PAH* gene.[151] The numerous possible combinations of gene mutations undoubtedly contributes to the variable clinical findings in PKU.

Benefits of Newborn Screening

Children with PKU who are treated appropriately after positive newborn screening results have average intelligence as measured by IQ tests, although their scores are somewhat lower than expected when compared with parent and sibling IQs. There is an inverse relationship between the age at which treatment is begun and the IQ level, even in PKU that is treated early.[154] Tremor of unknown origin has been reported in 10% to 30% of early-treated individuals with PKU.[155] Adolescents and young adults who are treated early and continuously seem to have no increased incidence of psychiatric, emotional, or functional disorders, and there is no increase in problems of self-concept.[156,157] Although children with PKU are not at increased risk of developing dental caries, children with PKU may exhibit increased signs of tooth wear because of the erosive potential of the amino acid supplements in the diet.[158] Therefore, it is important for children and adolescents with PKU to have regular dental care.

Screening

There are 3 main methods used for screening newborns for PKU in the United States: the Guthrie BIA, fluorometric analysis, and MS/MS. The Guthrie BIA is inexpensive and reliable. Fluorometric analysis and MS/MS are quantitative and can be automated; both of these methods also produce fewer false-positive results than BIA.[151] Preliminary data indicate that MS/MS produces fewer false-positive results than the fluorometric method in samples obtained in the first 24 hours of life.[159] Newborn screening laboratories in the United States use cutoff values from 2 mg/dL (125 μmol/L) to 6 mg/dL (375 μmol/L). A positive screening result should lead to rapid evaluation of the newborn for clinical status, age, and diet at the time of sample collection. Severe

deficiency of PAH will usually result in an increased concentration of blood Phe within the first 24 hours of life; however, infants with a less severe deficiency may take longer to develop an abnormal Phe concentration. It is for this reason that a repeat test for all infants initially screened in the first 24 hours of life has been recommended by some authorities.[160] Few states, however, currently require a second screen.

Follow-up and Diagnostic Testing

Early treatment of PKU is associated with improved intellectual outcome. Therefore, an infant with a positive newborn screening result should receive the benefit of rapid diagnostic testing. Diagnostic testing includes quantitative determination of plasma Phe and tyrosine concentrations. If the Phe concentration is increased, additional studies are indicated to determine if the infant has an abnormality in synthesis or recycling of BH4.

Brief Overview of Disease Management

Once the diagnosis of hyperphenylalaninemia is confirmed, metabolic control should be achieved as rapidly as possible. This is achieved through the use of medical foods, including medical protein sources that are low in Phe; small amounts of Phe must also be provided, which is achieved through the use of small amounts of natural protein. The infant with PKU can be given breast milk along with Phe-free formula under the direction of a metabolic dietitian. The response to dietary treatment is monitored through periodic measurement of blood Phe concentrations, assessment of growth parameters, and review of nutritional intake. There is no consensus concerning the optimal blood Phe concentration or the duration of strict dietary management. The most commonly reported blood Phe concentration recommendations for US centers are 2 to 6 mg/dL for individuals 12 years or younger and 2 to 10 mg/dL for persons older than 12 years.[151] Most US centers recommend lifelong dietary treatment. This is particularly important for women, because fetuses exposed to increased concentrations of Phe are at significant risk of microcephaly, congenital heart disease, and reduced IQ.[151] It is recommended that a woman with PKU achieve Phe concentrations of less than 6 mg/dL at least 3 months before conception and that concentrations be maintained between 2 and 6 mg/dL throughout pregnancy.[151] The importance of management throughout the reproductive years illustrates the critical role of long-term follow-up in this disorder.

Current Controversies

As noted previously, there is no national or international consensus regarding the optimal concentration of Phe across the life span. Similarly, there is no consensus regarding discontinuation of dietary therapy. Although appropriately treated young adults with PKU lead normal and productive lives, there are no meaningful data regarding the incidence of long-term sequelae in individuals who remain on dietary therapy into middle and old age. Recent evidence suggests that some individuals with hyperphenylalaninemia and classic PKU may benefit from BH4 treatment in addition to dietary Phe restriction.[161]

SICKLE CELL DISEASE AND OTHER HEMOGLOBINOPATHIES

The term sickle cell disease (SCD) (OMIM database No. 603903)[162] encompasses a group of genetic disorders characterized by chronic hemolysis and intermittent episodes of vascular occlusion that cause recurrent episodes of severe pain and a wide variety of other disease manifestations. Specialized comprehensive medical care markedly reduces mortality in infancy and early child-

hood by preventing some disease-related complications and limiting the severity and sequelae of others.

Newborn screening for SCD also identifies infants with nonsickle hemoglobinopathies, hemoglobinopathy carriers, and, in some states, infants with α-thalassemia.[163,164] Newborn screening results and clinical manifestations for some of these conditions are outlined in Table 1. Guidance for follow-up and diagnostic evaluation of infants with these screening results has been published[163,164] and is often provided by state newborn screening programs or their designated hemoglobinopathy consultants.

Incidence

Overall, SCD occurs in 1 of 2500 to 1 of 2000 US newborns.[165,166] Its incidence is highest in persons of African, Mediterranean, Middle Eastern, Indian, Caribbean, and Central and South American ancestry. The disease occurs less commonly in other ethnic groups, including individuals of Northern European descent. Accurate incidence data for many groups are unavailable. SCD is estimated to occur in 1 of 346 black infants and in 1 of 1114 Hispanic infants in the eastern United States.[167]

Clinical Manifestations

Most infants with SCD are healthy at birth and become symptomatic later during infancy or childhood. The most common clinical manifestation is musculoskeletal or abdominal pain, which occurs unpredictably and is often excruciating. Acute manifestations that may rapidly become life-threatening include bacterial sepsis or meningitis, splenic sequestration, acute chest syndrome, and stroke. Other acute complications include aplastic crises, priapism, and renal papillary necrosis. Chronic manifestations include anemia, jaundice, splenomegaly, hyposthenuria, hematuria, proteinuria, cholelithiasis, and delayed growth and sexual maturation. Avascular necrosis of the hip and shoulder, restrictive lung disease, and leg ulcers may cause chronic disability. Pulmonary hypertension is a risk factor for early death. It is important to note that the severity of SCD varies widely, even among individuals with the same genotype.

Pathophysiology

Sickle hemoglobin is caused by a point mutation in the β-globin gene, which leads to an amino acid change that causes hemoglobin to polymerize when deoxygenated. Sickle red blood cells are dehydrated and show oxidative damage and increased adhesion to endothelial cells. The cumulative effects of these cellular abnormalities are shortened red cell survival and intermittent episodes of vascular occlusion, which cause tissue ischemia and organ damage.

Inheritance

SCD is an autosomal recessive disorder. Heterozygous individuals have a generally benign, asymptomatic genetic carrier state, sometimes referred to as a sickle cell

TABLE 1 Newborn Screening for Conditions Other Than SCD

Screening Results	Possible Conditions	Clinical Manifestations
Nonsickle hemoglobinopathies		
F only	Preterm infant	Repeat screening necessary
	Homozygous β^0-thalassemia	Severe thalassemia
FE	EE	Microcytosis with mild or no anemia
	E β^0-thalassemia	Mild to severe anemia
FC	CC	Mild microcytic hemolytic anemia
	C β^0-thalassemia	Mild microcytic hemolytic anemia
FCA	C β^+-thalassemia	Mild microcytic hemolytic anemia
α-Thalassemia syndromes		
FA + Bart's[a]	α-Thalassemia silent carrier	Normal complete blood cell count
	α-Thalassemia minor	Microcytosis with mild or no anemia
	HbH disease	Mild to moderately severe microcytic hemolytic anemia
	HbH Constant Spring	Moderately severe hemolytic anemia
FAS + Bart's	α-Thalassemia with structural Hb variant	Clinical manifestations, if any, depend on the structural variant (eg, HbE) and severity of α-thalassemia
FAC + Bart's		
FAE + Bart's		
FE + Bart's		
Hemoglobinopathy carriers		
FAS	Sickle cell trait	Normal complete blood cell count; generally asymptomatic
FAC	HbC carrier	No anemia; asymptomatic
FAE	HbE carrier	Normal or slightly decreased MCV without anemia; asymptomatic
FA Other	Other Hb variant carrier	Depends on variant; most without clinical or hematologic manifestations

[a] Hemoglobin Bart's, a tetramer of γ-globulin, is present in infants with α-thalassemia.

Modified from: National Heart, Lung, and Blood Institute. Neonatal screening. In: *The Management of Sickle Cell Disease*. Washington, DC: National Institutes of Health; 2002:7–14. NIH publication No. 02-2117.

trait. Homozygous and compound heterozygous individuals have symptomatic disease. Four SCD genotypes (sickle cell anemia, sickle-hemoglobin C disease, and 2 types of sickle β-thalassemia [sickle β^+-thalassemia and sickle β^0-thalassemia]) account for most SCD cases in the United States.[163,164,168] Less-common forms of SCD are caused by coinheritance of hemoglobin S with other hemoglobin variants such as hemoglobin D-Punjab and hemoglobin O-Arab.

Benefits of Newborn Screening

The primary rationale for newborn screening and presymptomatic diagnosis is prevention of mortality from pneumococcal sepsis and splenic sequestration during infancy and childhood.[167,169–172] Prophylactic penicillin has been shown to reduce the incidence of pneumococcal sepsis by 84%[170] and is used in conjunction with pneumococcal conjugate and polysaccharide vaccines and urgent evaluation and treatment of febrile illness with parenteral antibiotics. Family education about signs and symptoms of splenic sequestration results in earlier detection and reduced mortality from that complication.[169] Data from a number of statewide newborn screening programs confirm that mortality from SCD during the first 3 to 4 years of life, historically as high as 20%, is virtually eliminated by universal screening and appropriate follow-up and treatment.[173]

Screening

Most newborn screening programs use isoelectric focusing to separate hemoglobins eluted from dried blood spots. A few programs use high-performance liquid chromatography (HPLC) or cellulose acetate electrophoresis as the initial screening method. Most programs retest screening specimens with abnormal results using a second complimentary electrophoretic technique, HPLC, immunologic tests, or DNA-based assays. The sensitivity and specificity of isoelectric focusing and HPLC are excellent,[167] but results and interpretation can be confounded by extreme preterm birth or previous blood transfusion.[163,174]

Hemoglobins identified by these screening methods are reported in order of quantity. Because more fetal hemoglobin (HbF) than normal adult hemoglobin (HbA) is present at birth, most normal infants show FA results. Infants with SCD also show a predominance of F at birth; FS, FSC, or FSA are the most common results in children with SCD.

Follow-up and Diagnostic Testing

Infants with screening results indicative of possible SCD (FS, FSC, FSA) should have confirmatory testing of a second blood sample accomplished before 2 months of age. Confirmatory testing is performed by isoelectric focusing, HPLC, hemoglobin electrophoresis (cellulose acetate and citrate agar), and/or DNA-based methods.[164] Most infants with screening results that show HbFS have sickle cell anemia, but other possibilities include sickle β^0-thalassemia, sickle δβ-thalassemia, and hereditary persistence of fetal hemoglobin, a benign condition. For this reason, testing of parents or DNA analysis may help clarify the diagnosis in selected cases. For infants with probable sickle cell disease, the selection of diagnostic tests and the interpretation of results ideally should be supervised by an expert in the diagnosis of hemoglobin disorders in childhood.

Family testing to identify carriers, for the purpose of defining an infant's diagnosis and/or providing genetic education and counseling, requires a complete blood cell count and hemoglobin separation by electrophoresis, isoelectric focusing, and/or HPLC.[164,168] Individuals with hemoglobin variants such as S, C, and E are identified readily. Most individuals with heterozygous β-thalassemia show a decreased mean corpuscular volume (MCV) and increased levels of hemoglobin A_2 and/or hemoglobin F. Thus, accurate quantitation of hemoglobin F and hemoglobin A_2 is needed if the MCV is decreased or borderline decreased. Solubility testing is inadequate and should never be used for carrier testing, in part because it will not identify individuals with the hemoglobin C trait and β-thalassemia.

Brief Overview of Disease Management

SCD is a complex disorder with multisystem manifestations that require specialized comprehensive care to achieve an optimal outcome.[168] Family and patient education about the genetics, clinical manifestations, and treatment of SCD and its complications are important, particularly because prompt recognition of potentially life-threatening complications reduces morbidity and mortality. Important health maintenance issues include prophylactic medications, particularly prophylactic penicillin (should be started no later than 2 months of age), and timely immunizations, especially with the pneumococcal conjugate and polysaccharide vaccines. Periodic comprehensive medical evaluations facilitate documentation of important baseline physical findings and laboratory values, detection of signs of chronic organ damage, and development of individualized patient care plans. Timely and appropriate treatment of acute illness is critical, because life-threatening complications can develop rapidly. Some patients, including those who have suffered a stroke or who are identified as being at high risk of stroke by transcranial Doppler ultrasonography screening, receive chronic blood transfusions to prevent stroke and other complications. Selected patients with frequent or severe disease manifestations may benefit from hydroxyurea therapy and/or may be considered for stem cell transplantation, particularly if there is an HLA-matched sibling donor. Guidelines for the management of SCD were published recently.[168,175]

Current Controversies

Because SCD is more prevalent in some racial and ethnic groups than others, some programs initially implemented selected or targeted screening rather than testing all newborn infants. However, experience with targeted screening showed a rate of missed cases as high as 30%, in part because of difficulties identifying infants' race or ethnicity. In addition, targeted compared with universal screening incurs additional costs and exposes screening programs, nurseries, and physicians to increased litigation risk for the preventable morbidity and mortality that results from delayed diagnosis. For these and other reasons, universal screening is strongly recommended and has been implemented in all 50 states, the District of Columbia, and the US Virgin Islands.

TYROSINEMIA

There are 2 clinically recognized types of tyrosinemia. Type I (hepatorenal) tyrosinemia (OMIM database No. 276700)[176] is characterized by liver toxicity from increased concentrations of tyrosine and other metabolites with hepatocellular damage. Acutely, this produces jaundice and increased transaminase concentrations. Chronically, there is a high risk of hepatic cancer. Other features include the renal Fanconi syndrome and peripheral neuropathy.[177] Type I tyrosinemia is caused by deficiency of the enzyme fumarylacetoacetate hydrolase (FAH). Type II (oculocutaneous tyrosinemia, also known as Richner-Hanhart syndrome; OMIM database No. 276600) exhibits corneal lesions and hyperkeratosis of the palms and soles. It is caused by deficiency of the enzyme tyrosine aminotransferase (TAT). A third entity, neonatal tyrosinemia, should be mentioned. It is more common in preterm infants and, in fact, is the most common cause of abnormal initial newborn screening results for tyrosinemia and PKU.[178] All show increased concentrations of serum tyrosine that can be detected on newborn screening.

Incidence

Type I tyrosinemia has an incidence of 1 in 12 000 to 1 in 100 000 in those of northern European descent. The incidence of type II and neonatal tyrosinemia has not been established.

Clinical Manifestations

Type I

Type I tyrosinemia in the acute form is characterized by failure to thrive, vomiting, diarrhea, a cabbage-like odor, hepatomegaly, fever, jaundice, edema, melena, and progressive liver disease. If untreated, death from liver failure may occur in the first year of life. The chronic form is similar but with milder features characterized by hypophosphatemic rickets. Other features have included hypertrophic obstructive cardiomyopathy, abdominal crises, polyneuropathy, hypertension, and hepatoma (a late complication in one third of patients). Death occurs during the first decade of life. There are increased concentrations of tyrosine in blood and urine. Urinary tests for succinylacetone and tissue analysis (liver or fibroblasts) for FAH activity establish the diagnosis.

Type II

Type II tyrosinemia is a distinctive oculocutaneous syndrome. Eye findings may be limited to lacrimation, pho-

tophobia, and redness. Signs may include mild corneal herpetiform erosions, dendritic ulcers, and, rarely, corneal and conjunctival plaques. Neovascularization may be prominent. Long-term effects include corneal scarring, nystagmus, and glaucoma. The skin lesions usually begin with or after the eye lesions. Skin findings may begin as painful, nonpruritic blisters or erosions that crust and become hyperkeratotic. They are usually limited to the palms and soles, especially the tips of the digits, and to the thenar and hypothenar eminences. They may be linear or subungual. A skin biopsy is not diagnostic and may show nonspecific hyperkeratosis, acanthosis, and parakeratosis. Skin lesions may be difficult to distinguish from any of the more common forms of keratosis. Mental retardation is an inconstant feature; mild-to-moderate retardation, self-mutilating behavior, disturbances of fine motor coordination, and language deficits have been reported. Tyrosinemia is the diagnostic feature of this disorder. Tyrosine is the only amino acid that is found in increased concentrations in the urine in this disorder.

Neonatal

Clinical findings in neonatal tyrosinemia are nonspecific. Infants with persistent neonatal tyrosinemia may be somewhat lethargic and have difficulty swallowing, impaired motor activity, prolonged jaundice, and increased levels of galactose, phenylalanine, histidine, and cholesterol. Mild acidosis may be present in approximately half of the infants. Mild retardation and decreased psycholinguistic abilities have been noted in some studies.[179]

Pathophysiology

Type I

This disorder, although not a primary disorder of tyrosine metabolism, is accompanied by increased concentrations of tyrosine and its metabolites, which inhibit many transport functions and enzymatic activities. It has been proposed that the degree of residual FAH activity determines whether the disease will be acute or chronic in the affected patient.

Type II

This disorder is associated with a deficiency of hepatic TAT, the rate-limiting enzyme of tyrosine catabolism. Tyrosinemia, tyrosinuria, and increases in urinary phenolic acids, *N*-acetyltyrosine, and tyramine persist for life. The metabolism of other amino acids and renal and hepatic function are otherwise normal.

Neonatal

It is generally assumed that this disorder is caused by a relative deficiency of *p*-hydroxyphenylpyruvate oxidase stressed by high-protein diets, with resulting high tyrosine and phenylalanine concentrations. Others have suggested a mild decrease in TAT activity.

Inheritance

Type I and II tyrosinemias are autosomal recessive, with a 25% risk of recurrence in siblings. The heterozygotes for type I have approximately half-normal levels of FAH activity in fibroblasts and lymphocytes. Prenatal diagnosis is complex, requiring at least 3 different procedures using amniotic fluid and cultured amniocytes or chorionic villus cells. These procedures involve the direct measurement of succinylacetone by combined gas chromatography and mass spectrometry in amniotic fluid, FAH enzymatic activity, and the measurement of the ability of succinylacetone to inhibit aminolevulinic dehydrase activity in cultured amniotic fluid or chorionic villus cells.[180]

The carrier state for type II tyrosinemia has not been detected biochemically, and prenatal diagnosis is not currently available. The inheritance of neonatal tyrosinemia is unclear.

The chromosome map location for type I (FAH) is 15q23-25, the location for type II (TAT) is 16q22.1–22.3, and the location for neonatal (*p*-hydroxyphenylpyruvate) oxidase is 12q24-qter. Type I tyrosinemia is most prevalent in French Canadians, with an overall incidence of as high as 1 in 700 in certain regions of Quebec.[181] Type II tyrosinemia cases have been described in several countries including the United States, Canada, Japan, Europe, and the Middle East. Neonatal tyrosinemia is most prevalent in Canadian Inuits.

Rationale for and Benefits of Newborn Screening

Death from complicating liver failure occurs in untreated patients with type I tyrosinemia during the first year of life in the acute form and during the first decade of life in the chronic form. Hepatocellular carcinoma may also be a cause of death. The introduction of 2-(2-nitro-4-trifluoromethylbenzyl)-1,3-cyclohexanedione (NTBC) has changed the outcome of this disorder dramatically.[182] More than 90% of patients respond clinically to treatment with NTBC. The current indications for liver transplantation in type I tyrosinemia are nonresponsiveness to NTBC, risk of malignancy, and decreased quality of life related to dietary restriction and frequency of blood sampling. Successful liver transplantation can further reduce the mortality rate in nonresponders to 5%.[183] There is a strong decrease in the risk of early development of hepatocellular carcinoma in patients with effective, early therapy.

Screening

The BIA can be used to screen for tyrosinemia using dried blood spots. Abnormal concentrations of tyrosine are reported as more than 6 mg/dL. Newer methods include direct measurement of tyrosine by MS/MS. The

test is performed in the neonatal period, but the optimal time for study is unclear. Presumably, it is best if measurements are obtained 48 to 72 hours after milk feeding. The stability of tyrosine in specimens has not been determined specifically but should be similar to that of phenylalanine. The rate of false-negative results has not been determined. Data from the 1999 National Newborn Screening Report[184] showed an initial positive screening result in 136 of 407 118 newborn infants tested (1 in 3000), with 2 positive confirmed cases. Available data on second screenings performed between 1 and 4 weeks of age showed 2 positive results in 60 474 infants (1 in 30 000); no cases of tyrosinemia were confirmed among this group.

Follow-up and Diagnostic Testing

An increased tyrosine concentration on newborn screening requires confirmation and additional testing, because it may be caused by other metabolic disorders (eg, fructose and galactose enzyme deficiencies), giant cell hepatitis, neonatal hemochromatosis, and neonatal infections. The optimal approach is complex and requires determination of the concentrations of tyrosine and other amino acids and metabolites in the blood and urine. Type I tyrosinemia involves increased concentrations of urine succinylacetone and nonspecific aminoaciduria and requires tissue analysis (fibroblasts, erythrocytes, lymphocytes, or liver) for FAH activity. Type II tyrosinemia involves increased tyrosine concentrations only in blood and urine. Confirmation of neonatal tyrosinemia depends on the presence of increased concentrations of tyrosine and phenylalanine.

Brief Overview of Disease Management

Type 1

Treatment options for tyrosinemia include dietary therapy, liver transplantation, and use of the pharmacologic agent NTBC. Clinical signs and symptoms improve with NBTC therapy and diet.[182] Signs of improvement include a decrease in concentrations of metabolites, correction of the secondary abnormality in porphyrin synthesis, improved liver and renotubular function, and regression of hepatic abnormalities by computed tomography. Correction of porphyrin synthesis reduces the risk of porphyric crises.

Type II

Therapy with a diet low in tyrosine and phenylalanine is curative in type II tyrosinemia. Early diagnosis can help avoid the risk of mental retardation in these patients.

Neonatal

Most cases of neonatal tyrosinemia, especially those seen in small preterm infants, may be transient and controlled by reducing the protein intake to 2 to 3 g/kg per day or by breastfeeding. Some patients respond to ascorbic acid supplementation.

Current Controversies

The incidence and pathogenetic mechanisms of specific disorders associated with increased concentrations of tyrosine require clarification. The consequences of early diagnosis and treatment for type I tyrosinemia (the most formidable disorder in this group) should be beneficial. NBTC therapy seems to be very effective. No marked adverse effects have been noted. Follow-up for long-term outcome is needed.

Special Issues/Concerns

Confirmation of the exact cause of increased concentrations of tyrosine requires referral and evaluation by an expert in the field. Outcome with treatment remains variable.

POLICY STATEMENT

Nondiscrimination in Pediatric Health Care

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Workforce

ABSTRACT

This policy statement is a revision of a 2001 statement and articulates the positions of the American Academy of Pediatrics on nondiscrimination in pediatric health care. It addresses both pediatricians who provide health care and the infants, children, adolescents, and young adults whom they serve.

THE MISSION OF the American Academy of Pediatrics (AAP) is "to attain optimal physical, mental, and social health and well-being for all infants, children, adolescents and young adults."[1] In support of this mission, therefore, the AAP is opposed to discrimination in the care of any patient on the basis of race, ethnicity, ancestry, national origin, religion, gender, marital status, sexual orientation, gender identity or expression, age, veteran status, immigration status, or disability of the patient or patient's parent(s) or guardian(s). In addition, the AAP supports the right of pediatricians, pediatric medical subspecialists, pediatric surgical specialists, and other specialist physicians who care for pediatric patients in both educational and practice settings to participate in the delivery of health care without discrimination on the basis of race, ethnicity, ancestry, national origin, religion, gender, marital status, sexual orientation, gender identity or expression, age, veteran status, immigration status, or disability. Physicians with disabilities who maintain the ability to perform the essential functions of their jobs with or without "reasonable accommodation," as defined by the Americans With Disabilities Act (ADA),[2] should not be hindered from participating in such activities.

Regardless of the size of the practice, all pediatricians, whether employers or employees, are encouraged to have nondiscrimination policies and to review all their personnel policies and procedures to monitor how they are implemented to ensure that they do not have an adverse effect on any individual or group.[3] If one wishes to air a grievance concerning discrimination on the basis of any of the above-listed factors, they must be able to do so in an environment that is free of prejudice and discrimination so that the matter may be addressed and resolved expediently.

The AAP recognizes the value of diversity among patients and pediatricians and the importance of proactively establishing and adhering to nondiscrimination policies for both pediatricians (as employers and employees) and the patients in their care. The AAP recommends that both public and private insurers provide nondiscriminatory and continuous coverage of pediatric services. Finally, the AAP encourages its members to support these nondiscrimination principles consistently in their interactions with colleagues, patients, and the patient's parent(s) or guardian(s).

Abstractð Prevention of congenital cardiovascular defects has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Over the past decade, there have been major breakthroughs in the understanding of inherited causes of congenital heart disease, including the identification of specific genetic abnormalities for some types of malformations. Although relatively less information has been available on noninherited modifiable factors that may have an adverse effect on the fetal heart, there is a growing body of epidemiological literature on this topic. This statement summarizes the currently available literature on potential fetal exposures that might alter risk for cardiovascular defects. Information is summarized for periconceptional multivitamin or folic acid intake, which may reduce the risk of cardiac disease in the fetus, and for additional types of potential exposures that may increase the risk, including maternal illnesses, maternal therapeutic and nontherapeutic drug exposures, environmental exposures, and paternal exposures. Information is highlighted regarding definitive risk factors such as maternal rubella; phenylketonuria; pregestational diabetes; exposure to thalidomide, vitamin A cogeners, or retinoids; and indomethacin tocolysis. Caveats regarding interpretation of possible exposure-outcome relationships from case-control studies are given because this type of study has provided most of the available information. Guidelines for prospective parents that could reduce the likelihood that their child will have a major cardiac malformation are given. Issues related to pregnancy monitoring are discussed. Knowledge gaps and future sources of new information on risk factors are described. **(*Circulation*. 2007;115:2995-3014.)**

Key Words: AHA Scientific Statements ■ heart defects, congenital ■ heart disease ■ risk factors

Congenital cardiovascular defects (CCVDs) represent some of the more prevalent malformations among live births[1] and remain the leading cause of death from congenital malformations.[2] Disease prevention has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Over the past decade, there have been major breakthroughs in the understanding of inherited causes of CCVDs, including the identification of specific genetic abnormalities for some types of malformations.[3] Although relatively less information has been available on noninherited modifiable factors that may have an adverse effect on the fetal heart, there is a growing body of epidemiological literature on this topic. The proportion of cases of CCVDs that are potentially preventable through changes in the fetal environment is currently unknown. One study suggests that the fraction of cases attributable to identifiable and potentially modifiable factors may be as high as 30% for some types of defects.[4] The lack of reliable information on modifiable risk factors has made it difficult to create population-based strategies to reduce the burden of

The American Heart Association makes every effort to avoid any actual or potential conflicts of interest that may arise as a result of an outside relationship or a personal, professional, or business interest of a member of the writing panel. Specifically, all members of the writing group are required to complete and submit a Disclosure Questionnaire showing all such relationships that might be perceived as real or potential conflicts of interest.

illness from CCVDs and for couples to make lifestyle choices to reduce the likelihood of having a child with a major cardiac malformation.

The purpose of this article is to review the current state of knowledge regarding noninherited risk factors for structural cardiac anomalies, to provide guidance to potential parents that could reduce the likelihood that their child will have a major cardiovascular malformation, and to provide guidance for pregnancy monitoring after known exposures. The current state of knowledge of inheritable causes of CCVDs is reviewed separately and is not included.[3] Similarly, because this statement focuses on factors that influence cardiac development during weeks 2 to 7 of gestation,[5] this review is limited to parental exposures during the first trimester of pregnancy and the 3 months before pregnancy (ie, periconceptional period) that could result in structural abnormalities; exposures that may cause other types of cardiac injury (eg, congenital heart block, myocardial damage) are not considered.

Methods

This statement summarizes the currently available literature, as of May 2006, on prenatal parental conditions and exposures and risk for CCVDs in offspring. English-language publications in scientific journals reporting data on risks of CCVDs in offspring after maternal or paternal diseases, conditions, or exposures were identified through Medline searches, bibliographies of individual articles, and reviews of scientific journals. The information about maternal drug exposure also includes information from the Teratogen Information System (http://depts.washington.edu/terisweb/teris/) and the online version of *Shepardôs Catalog of Teratogenic Agents*. Publications were assessed to determine the quality of information available (eg, consistency of findings and study design, including the ability to estimate magnitude of risk and exclude chance and bias as possible explanations) regarding a specific type of parental condition or exposure during pregnancy and the risk of having an infant with a major CCVD. Conditions or exposures for which only limited information was available such as a single published epidemiological study were included but generally considered insufficient for discussion. Exceptions were maternal conditions about which there has been some concern (ie, systemic lupus erythematosus and HIV-1 infection). Case reports and case series were not considered to be sufficiently reliable for discussion, unless confirmed by epidemiological studies. From the review of published epidemiological studies, parental conditions and exposures were classified into one of the following categories: factors possibly associated with a decreased risk of CCVDs, factors associated with an increased risk of CCVDs, factors not associated with risk of CCVDs, and factors that have been studied but for which the information about risk of CCVDs is inconclusive. Although some exposures may be risk factors for specific types of CCVDs and not others, quantified measures of overall relative risk such as relative risk (RR) or odds ratios (ORs) are given, if known, to attempt to quantify the increased risk of having a child with any CCVDs, as well as with a specific CCVD, after a specific exposure. Presentation of results for specific types of malformations is, of course, often limited by the different methods used to identify and group malformations in different reports. Confidence limits for the RR or ORs are given if available; confidence limits that contain the value 1.0 indicate that the RR or OR estimate does not differ statistically from the null value (ie, 1.0).

To date, there are no published reports of large prospective cohort studies examining environmental or other exposures associated with CCVDs. The best available information comes from large population-based case-control studies specifically designed to investigate possible risk factors for CCVDs. Two such studies deserve specific mention. The Baltimore-Washington Infant Study (BWIS) was prospectively conducted in the Baltimore, Washington, and northern Virginia area between 1981 and 1989 with a random sample of infants without CCVDs ascertained from the same birth cohort.[6] The National Public Health Institute in Helsinki retrospectively conducted a study in Finland of cases and controls born during 1982 to 1984.[7] In both of these case-control studies, information on potential exposures early in pregnancy was obtained by interview of the parents after the child was born. There were no available reliability or validation studies of the parental reports.

Results

The findings from this review are summarized in the tables. Table 1 summarizes the literature regarding 1 factor that may be associated with a decreased risk of CCVDs, specifically supplementation with a multivitamin containing folic acid. Table 2 summarizes the literature on factors that may increase the risk of a pregnancy resulting in an infant with any CCVDs and with a specific CCVD. Table 3 shows the same information, organized by CCVD phenotype rather than type of exposure. Table 4 shows factors that have been studied but for which no associations have been found thus far. Table 5 shows factors that have been studied but for which too little information is available to make a determination about risk.

Multivitamins and Folic Acid

One of the most important recent discoveries is the possibility that periconceptional intake of multivitamin supplements containing folic acid may reduce the risk of CCVDs in offspring, similar to the known risk reduction for neural tube defects seen with folic acid. This finding was first identified

TABLE 1. Maternal Multivitamin/Folic Acid Supplements and Decreased Risk of Offspring With Congenital Cardiovascular Defects

after analysis of data from a Hungarian randomized trial on birth defects[8,9] (Table 1). Findings from subsequent case-control studies have been generally supportive but not conclusive.[8,10–12]

Two of the studies examined a broad range of heart defects rather than any specific type.[9,10] Use of multivitamins containing folic acid was associated with an ≈60% overall reduction in risk for congenital heart defects in the Hungarian randomized trial (RR, 0.42; 95% confidence interval [CI], 0.19 to 0.98)[8,9] and an ≈25% reduction in risk in a population-based case-control study done in Atlanta (OR, 0.76; 95% CI, 0.60 to 0.97).[10] These and other studies also examined specific types of CCVDs. Multivitamin use was associated with a reduced risk for conotruncal defects in 2 population-based case-control studies (54% and 30%, respectively).[10,11] The Hungarian trial also provides suggestive data (no case of conotruncal defects in the supplemented group, 2 cases in the nonsupplemented), but the trial was too small to provide definitive results. A third study showed possible risk reduction for 1 but not all types of conotruncal heart defects.[6] A fourth, a hospital-based case-control study,[12] showed no evidence of reduction.

For ventricular septal defects (VSDs), 2 studies, a population-based case-control study and the Hungarian randomized trial, were consistent with a reduction in risk (40% and 85% reduction, respectively).[9,10] The hospital-based case-control study again found no risk reduction.[12]

In addition to these studies directly testing the association between multivitamin use and risk for heart defects, other studies among high-risk groups present ancillary evidence supporting a protective effect of folic acid–containing multivitamin supplements. For example, 2 studies have shown that women who used medications that are folic acid antagonists had an increased risk of having babies with heart defects but that this risk was reduced for women who also took multivitamin supplements containing folic acid.[13,14]

In a third study,[15] an increased risk for heart defects associated with maternal febrile illness (see below) appeared to be reduced among women using multivitamin supplements around the time of conception and during early pregnancy. Similar findings have been reported for other birth defects.[16]

The findings of a possible protective effect for CCVDs from folic acid–containing multivitamin supplements are encouraging but inconclusive given the limited number of studies and mixed results. Additional studies are warranted to determine whether the association of specific phenotypes with multivitamins can be corroborated in large population-based studies in which multivitamin intake can be validated, potential confounders such as maternal age and diabetes can be taken into account, and the components of the multivitamin supplements responsible for the association can be identified.

Maternal Illnesses and Conditions

Phenylketonuria

Untreated maternal phenylketonuria is associated with a >6-fold-increased risk of heart defects.[17–20] The most frequent defects are tetralogy of Fallot, VSDs, patent ductus arteriosus (PDA), and single ventricle. Fortunately, with strict diet control before conception and during pregnancy, this excess risk can be reduced.[18–22]

Maternal Diabetes

CCVDs have been associated with maternal pregestational and, less consistently, with gestational diabetes.[6,23–34] The associations with gestational diabetes are hypothesized to be due to inclusion of a group of women with previously undetected type 2 diabetes among women classified as having gestational diabetes.[27–29] Specific types of cardiovascular malformations associated with maternal pregestational diabetes include laterality and looping defects,[6] transposition of the great vessels,[6,33] nonchromosomal atrioventricular septal defects,[6] VSDs,[6,33,35] hypoplastic left heart syndrome,[6] conotruncal defects,[36] outflow tract defects,[33,35] cardiomyopathy,[6] and PDA.[33] Diabetes appears to induce malformation before the seventh week of gestation.[37]

Studies have shown a clear link between glycemic control during organogenesis and fetal malformations.[38,39] Although strict glycemic control before conception and during pregnancy has been shown to reduce risk levels comparable to those of the general population,[40] achieving and maintaining euglycemia early in pregnancy remains a challenge because many women with diabetes neither plan their pregnancies nor achieve adequate glycemic control before conception.[39,41] Given the increasing prevalence of risk factors for diabetes,[42–44] it is important to gain a better understanding of the current impact of both preexisting and gestational diabetes on CCVDs.

Although congenital anomalies associated with maternal diabetes are presumed to be related to abnormalities in maternal metabolic fuels essential for embryogenesis,[45] precise pathogenic mechanisms remain unclear. One hypothesis is that abnormal glucose levels characteristic of diabetes mellitus disrupt expression of a regulatory gene in the embryo, leading to embryotoxic apoptotic cellular changes.[46] The prevention of diabetic embryopathy by antioxidants in animal studies suggests that oxidative stress resulting from metabolic abnormalities and generation of free radicals is another possible mechanism.[47–52] The increasing prevalence of type 2 diabetes among women of childbearing age in recent decades[42–44,53,54] makes identifying and implementing effective prevention strategies a high priority.

Rubella, Febrile Illnesses, and Influenza

The potential association between maternal infections and birth defects was first suggested by the observation of the relation between maternal rubella infection early in gestation and the congenital rubella syndrome in offspring.[55–57] It is now well known that maternal rubella infection during pregnancy can result in offspring with PDA, pulmonary valve abnormalities, peripheral pulmonary stenosis, and VSDs[58–60] and that the risk of rubella embryopathy can be virtually eliminated by ensuring that women of childbearing age are immunized against rubella.[61] More recent studies suggest that other maternal febrile illnesses during the first trimester of pregnancy also may be associated with an increased risk for certain heart defects.[6,15,62,63] Mothers reporting any febrile illnesses during the first trimester of pregnancy have a 2-fold-higher risk of offspring with any heart defect in these

studies.[6,15] Specific groups of defects that have been shown to be associated with maternal febrile illness include pulmonic stenosis,[6] all right-sided obstructive defects,[15] tricuspid atresia,[6,15] coarctation of the aorta,[15] all left-sided obstructive defects,[15] conotruncal defects, and VSDs.[15] A case-control study in California found an association of maternal fever with conotruncal defects among offspring born to mothers who did not use multivitamins.[64] In some of these studies, the febrile illness often was characterized as flu-associated fever or influenza; thus flu-associated fever also was a risk factor for any cardiac defect and for some specific malformations.[10,63] The mechanism by which maternal febrile illnesses may result in malformations is unclear. One possibility is altered apoptosis. Apoptosis is known to be involved in cardiac morphogenesis, for example, in the development of the cardiac outflow tract,[65] and can be altered by both fever and infection.[66–69] Another possibility is a direct effect of the underlying infection, as with maternal rubella infection. Most studies to date have been unable to distinguish between independent and joint effects associated with maternal fever, maternal infection, and use of certain medications to control the fever or infection.

Obesity

A number of studies have examined the association between maternal prepregnancy obesity and CCVDs, although findings have been inconsistent. A study by Waller et al[70] reported an association between maternal obesity, defined as a body mass index of >26 kg/m^2, and a grouped category of defects of the great vessels. Two additional studies found no statistically significant increased risks for any heart defect[6,71] or conotruncal heart defects in relation to maternal obesity.[72] A recent study reported a 6.5-fold risk elevation for aggregate cardiac defects among obese black women,[73] and Watkins et al[71] reported a 2-fold increase in risk of aggregate cardiac defects in relation to maternal obesity. Obesity is a complex condition that has to be studied carefully to minimize underreporting of body weight, especially in case-control studies, and the possibility of confounding by other factors associated with nutrition, such as the intake of micronutrients or use of multivitamin supplements, or with obesity, such as type 2 diabetes.

HIV Infection

Maternal infection with HIV can transmit the infection vertically to offspring. Children infected with HIV-1 in utero have an increased risk of dilated cardiomyopathy and inappropriate left ventricular hypertrophy.[74–76] Such children also are more likely to have low left ventricular fractional shortening.[76] Maternal HIV has not been associated with an increased risk of structural congenital cardiovascular malformations thus far.

Systemic Lupus Erythematosus

Although a high proportion of infants with congenital complete heart block are born to women with systemic lupus erythematosus,[77–79] no published reports show an association between maternal connective tissue disease and an increased risk of structural congenital cardiovascular malformations.

Epilepsy

Offspring of women with epilepsy are at an increased risk for congenital malformations,[80,81] including congenital heart de-

fects.[82] Because several therapy-related factors could account for this increased risk, including direct teratogenic effects of anticonvulsant drug therapy and an indirect effect of the drugs by interfering with folate metabolism, it has been difficult to determine whether maternal seizures are independently associated with an increased risk of heart defects.

Maternal Therapeutic Drug Exposure

The US Food and Drug Administration (FDA) has classified a number of medications according to risk for birth defects if ingested during pregnancy. Although this classification relates to birth defects in general and not specifically to congenital cardiac defects, when available, the FDA description of risk as defined in Table 6 is included in each of the therapeutic drug discussions that follow.[83]

Thalidomide

Thalidomide is known to be a cardiac teratogen and therefore contraindicated during pregnancy and among women planning a pregnancy. Thalidomide embryopathy includes cardiovascular malformations ranging from ventricular and atrial septal defects (ASDs) to complex conotruncal defects.[84] No safe dose of thalidomide treatment during the critical period of gestation has been established, and cases of thalidomide embryopathy have been described after maternal ingestion of as little as one 50-mg capsule during this time (FDA category X).

Vitamin A Cogeners/Retinoids

Maternal intake of isotretinoin has been shown to cause congenital cardiac defects in addition to other malformations. Characteristic features of isotretinoin embryopathy include central nervous system malformations, micrognathia, cleft palate, thymic and eye anomalies, and cardiac and great vessel defects. The frequency of congenital anomalies does not appear to be increased among children of women who discontinue therapy before conception.[85] These medications are contraindicated during pregnancy and among women planning a pregnancy (FDA category X).

Etretinate persists in the body for an extremely long time after administration, and the length of time that teratogenic effects may occur is currently not known. In case reports, congenital abnormalities possibly related to prior etretinate therapy have been seen as long as 45 months after therapy was stopped.[86] No large studies examining the association of acitretin have been performed. Because acitretin can be

TABLE 4. Reported Exposures With No Evidence of an Association With Risk for CCVDs

converted to etretinate in the body, the length of time that acitretin may cause teratogenic effects may be longer than its half-life (50 to 60 hours).

Topical therapy with tretinoin in usual doses during pregnancy is unlikely to pose a substantial teratogenic risk, but data are insufficient to state that there is no risk.

Antibiotics

Rothman et al[87] observed an association with maternal ampicillin (FDA category B) treatment ñabout the time pregnancy beganò in a case-control study of 390 infants with congenital heart disease, specifically transposition of the great arteries. Their follow-up study of similar design did not confirm these findings.[88] Additionally, a separate case-control study failed to show an association between ampicillin use and congenital heart disease.[89] Finally, in a large population-based (Hungarian) case-control study of maternal ampicillin use in the second or third month of pregnancy, no association was found among 4468 cases with cardiovascular malformations.[90]

Multiple large studies have shown no association between the use of penicillin (FDA category B) and an increased risk of congenital anomalies in general.[91ï94] One Danish population-based record linkage study that examined the frequency of congenital heart defects in mothers given penicillin during the first trimester showed it to be no higher than expected.[95]

The epidemiological data regarding maternal vaginal metronidazole (FDA category B) use early in pregnancy were summarized in 2 meta-analyses.[96,97] In both instances, the risk of congenital anomalies in offspring was not increased. One of the studies included in these analyses specifically examined a large group (984) of infants with cardiovascular defects.[98] In the BWIS, maternal use of metronidazole during pregnancy was found to be associated with an increased risk of outflow tract anomalies with normally related great arteries (OR, 6.0; 95% CI, 1.8 to 20.7) and an increased risk of membranous VSDs (OR, 12.2; 95% CI, 3.0 to 50.2).[6]

An association was found with maternal trimethoprim-sulfonamide (FDA category C) treatment during the second or third month of gestation in a case-control study among 3870 infants with cardiovascular defects (OR, 4.8; 95% CI, 1.5 to 16.1).[13] Similar findings were reported from the Hungarian case-control surveillance of congenital abnormalities (OR, 2.1; 95% CI, 1.4 to 3.3).[14] The risks were reduced if the mother also took folic acid supplementation.

Antiviral/Antiretroviral Agents

An association was observed between major congenital anomalies, including congenital cardiovascular malformations, and a maternal prescription for zidovudine (FDA category C) during pregnancy in a Medicaid record linkage study.[99] When the exposures were broken down by trimester of pregnancy, the significant association was seen among women who received the prescription in the third trimester, not in the first or second, a finding inconsistent with a teratogenic mechanism. The Antiretroviral Pregnancy Registry has been established and to date has not shown an increase in congenital defects in women receiving therapy in the second or third trimester.

Antifungal Therapies

In a UK cohort study and a Danish record linkage study, the frequency of congenital anomalies was not increased in infants of women who received prescriptions for a single oral dose of fluconazole (FDA category C) in the first trimester of pregnancy.[100,101] Similarly, in a prospective study, the frequency of congenital anomalies was not increased in women receiving fluconazole with median doses of 200 mg. It should be noted that 4 children have been described with a similar and unusual pattern of congenital anomalies (including congenital heart disease) in offspring whose mothers were treated during most or all of the first trimester with a high dose (400 to 800 mg/d) of fluconazole for coccidioidomycosis meningitis.[102ï104] These observations suggest the need for further study of fluconazole treatment with consideration of possible threshold effects.

Anticonvulsants

Although many large epidemiological studies of the offspring of epileptic women have been published, currently available data are incapable of resolving the controversy as to whether the malformations are due to the epilepsy or the anticonvulsant therapy. Additionally, the studies examining congenital malformations in infants of women who took anticonvulsant therapies are difficult to interpret because accurate assessment of the effects of the anticonvulsant treatment may be confounded by multiple other factors.[105ï107] Specifically, many women with seizures are treated with multiple therapies either serially or simultaneously, and most women with seizures are treated with an anticonvulsant drug (leaving no control group). There are characteristic anomalies associated with some of the anticonvulsants (eg, fetal hydantoin syndrome), which may involve cardiac abnormalities (phenytoin, FDA category D; valproic acid, FDA category D).

Lithium

An association has been observed between maternal treatment with lithium carbonate during pregnancy and the occurrence of Ebsteinôs anomaly.[108ï113] In a voluntary reporting registry, serious congenital cardiovascular anomalies were observed in 8% of 225 infants born to mothers who had taken lithium during the first trimester of pregnancy.[114] One third of these infants had Ebsteinôs anomaly. Contradicting these

reports, no association was seen in a case-control study of 10 698 children with congenital anomalies, but the number of exposures in the case and control groups was small.[115] More recent retrospective, prospective, and meta-analysis studies suggest that lithium appears not to be a cardiac teratogen (FDA category D).[116,117]

Benzodiazepines/Barbiturates (Sedatives/Hypnotics)/Tranquilizers

An association with the maternal use of diazepam (FDA category D) or related drugs during the first trimester of pregnancy was observed in 2 case-control studies of almost 400 children each.[87,118] Bracken[89] reanalyzed these data and failed to find a significant association, and Zierler and Rothman[88] found no association in a follow up-study. No association with maternal use of diazepam during the first trimester of pregnancy was seen in case-control studies of 150 children with VSDs.[91,119]

The frequencies of congenital anomalies were not significantly increased among infants of women occasionally treated with amobarbital (FDA category D) as a hypnotic. However, the frequency of cardiac malformations was increased (RR, 2.6; 95% CI, 1.0 to 5.2).[91] The risk for chronic or high-dose maternal use is unknown.

Sympathomimetics

A case-control study by Rothman et al[87] observed a slightly higher rate of exposure to phenylephrine (FDA category C) early in pregnancy in mothers of infants with congenital heart disease than in controls. This observation was not confirmed in a later and more rigorous study by the same authors.[88] No association was seen between the first-trimester use of phenylephrine and congenital heart disease in a large cohort study.[91]

Corticosteroids

A possible association between maternal corticosteroid use and congenital cardiac malformations was identified in the BWIS by univariate analysis (OR, 1.71; 95% CI, 1.01 to 2.88). This finding was no longer significant after other variables were taken into account.[120] Using data derived from a population based case-control study that included 207 cases of conotruncal heart defects, Carmichael and Shaw[121] showed no association between maternal corticosteroid use and congenital cardiovascular malformations.

Folate Antagonists

Associations with maternal treatment with sulfasalazine (FDA category B) or another dihydrofolate reductase inhibitor during the second or third month of pregnancy were observed in a case-control study of 3870 infants with cardiovascular defects (OR, 3.4; 95% CI, 1.1 to 6.1). These associations were not seen among the subset of mothers who took supplemental folic acid. As mentioned, maternal use of trimethoprim-sulfonamide also has resulted in congenital heart defects in offspring,[13,14] with risk reduction if mothers also took folic acid supplementation (see the Antibiotics section).

Nonsteroidal Antiinflammatory Drugs

Ericson and Kallen[122] examined use of nonsteroidal antiinflammatory drugs in early pregnancy in a large registry study (n=2557) and found that the adjusted OR for any congenital malformation was 1.04 (95% CI, 0.84 to 1.29), but for cardiac defects, the OR was 1.86 (95% CI, 1.32 to 2.62). There was no drug specificity for cardiac defects.

Associations with maternal use of ibuprofen (FDA category B) during pregnancy have been reported in evaluations of infants with dextro-looped transposition of the great arteries (OR, 2.5; 95% CI, 1.2 to 4.9), membranous VSDs (OR, 1.9; 95% CI, 1.0 to 3.5), atrioventricular septal defects, Down syndrome (OR, 2.4; 95% CI, 1.1 to 4.2), and bicuspid aortic valve (OR, 4.1; 95% CI, 1.8 to 9.3).[4] No association

TABLE 6. FDA Categories of Risk for Birth Defects

Category	Description of Risk
A	No fetal risk shown in controlled human studies.
B	No human data available. Animal studies show no fetal risk or animal studies show a risk but not a fetal risk.
C	No controlled studies on fetal risk available for human beings or animals, or fetal risk shown in controlled animal studies but no human data available (benefit of drug use must clearly justify potential fetal risk in this category).
D	Studies show fetal risk in human beings (use of drug may be acceptable even with risks, such as in life-threatening illnesses or where safer drugs are ineffective).
X	Risk to fetus clearly outweighs any benefit from these drugs.

was seen in infants with atrioventricular septal defect without Down syndrome.

Two studies by Souter et al[123] and Hammerman et al[124] document the association between indomethacin tocolysis and persistent PDA. The magnitude of these effects appears to be greatest when indomethacin is administered within 48 hours of delivery. Additionally, there have been case reports of persistent pulmonary hypertension and premature closure of the ductus arteriosus in infants whose mothers took other forms of nonsteroidal antiinflammatory drugs, including naproxen,[125,126] diclofenac,[127,128] ketoprofen,[129,130] indomethacin,[131ï 134] and sulindac.[133,135,136]

Female Hormones

A potential risk for congenital cardiac defects in offspring from maternal use of oral contraceptives was identified in 2 case-control studies.[137,138] Wiseman and Dodds-Smith[139] evaluated the case histories included in Heinonen et al[138] study and found that only half were exposed during the critical period of cardiogenesis. Oral contraceptive use was no longer significantly associated with congenital heart disease in an analysis restricted to early exposure. Ferencz et al[140] studied mothers of 110 children with heart disease and found no association with maternal hormone therapy. Additionally, a recent meta-analysis failed to document any associations between oral contraceptive use and CCVD[141]; in general, the data are now thought to support their safety.

An association with maternal use of clomiphene was observed in a case-control study of 126 children with coarctation of the aorta (OR, 4.5; 99% CI, 1.0 to 19.9).[6] No association with maternal use of clomiphene was seen in a case-control study involving 83 infants with conotruncal cardiac defects.[36] In the BWIS, maternal use of clomiphene was found to be associated with an increased risk of tetralogy of Fallot (OR, 3.2; 95% CI, 1.6 to 6.3).[6]

Narcotics

Two case-control studies,[87,88] each involving 300 to 400 children with congenital heart disease, reported an association with maternal codeine (FDA category C) use during the first trimester of pregnancy, but methodological limitations raise doubt as to their validity. No association was observed in 2 other studies.[142]

Chemotherapy

There have been no published studies examining the effect of chemotherapy treatment during pregnancy. The literature has been limited to studies of patients who have been treated with chemotherapeutic agents before becoming pregnant. A large case-control study investigating congenital anomalies in children of patients who received chemotherapy for cancer in childhood and adolescence identified structural congenital cardiac defects in 10.0% (2 of 20) of the offspring of women who had been treated in the past with dactinomycin compared with 0.6% (24 of 144) among the children in a multicenter survey of fetal anomalies ($P=0.01$).[143] Of note, studies examining the use of doxorubicin showed no fetal effects in human or animal experiments[143] (antineoplastics, FDA category D).

Angiotensin-Converting Enzyme Inhibitors

A recent cohort of 29 507 infants from a large database of Tennessee Medicaid patients was linked with vital records and hospitalization claims during the first year of life to study the risk of congenital malformations after maternal exposure to angiotensin-converting enzyme used to treat maternal hypertension.[144] This study identified a prevalence of use of angiotensin-converting enzyme inhibitors in the first trimester of 0.7% and a higher risk of major congenital malformations, including malformations of the heart (OR, 3.72; 95% CI, 1.89 to 7.30), in offspring of mothers exposed to angiotensin-converting enzyme inhibitors in the first trimester of pregnancy. The prevalence of major malformations identified in the reference group (2.6%) was lower than expected in the general population (3.0% to 3.5%), raising questions about possible differences in ascertainment and classification of major malformations by exposure group. There is a need for further studies of this issue using standard methods of case ascertainment and classification and accounting for potential risk factors.

Composite Drugs

Bendectin, a combination of doxylamine and pyridoxine, is no longer available in the United States. Extensive studies provide no evidence that maternal use alters the risk of congenital anomalies in offspring. Specifically, case-control studies provide no consistent indication that maternal use of Bendectin during the first trimester of pregnancy increases the risk of congenital heart disease.[36,80,145,146]

Maternal Nontherapeutic Drug Exposure

Caffeine

Caffeine is known to cross the placenta, and concern that caffeine may cause birth defects prompted the FDA to caution pregnant women to limit their caffeine intake. As illustrated below, there is no clear association between caffeine ingestion during human pregnancy and congenital heart disease.

A case-control study of 2030 malformed infants, including 277 with cardiac defects, evaluated risk associated with caffeine ingestion, including consumption of tea, coffee, and cola. No risk was identified for consumption of any of the 3 beverage types. Risk also was assessed in relation to amount of total daily caffeine ingestion in the categories of any ingestion per day, >200 mg/d, and >400 mg/d. Again, no risk was identified in doses equivalent to 4 cups of coffee per day. Too few mothers consumed as much as 1000 mg/d caffeine to assess the risk of very high consumption.[147]

In a population-based cohort study of 850 mothers who drank ≥8 cups of coffee per day, the frequency of all congenital malformations, including heart disease, was not increased from expected.[148] In another well-controlled cohort study, 595 women who drank ≥4 cups of coffee daily also did not produce offspring with congenital anomalies any more frequently than expected.[149] In addition, in a study of 12 696 women who took caffeine-containing medications in the first 4 months of pregnancy, the frequency of congenital anomalies, including heart disease, was no greater than expected.[91] Caffeine also was evaluated as a potential risk

factor in the BWIS.[6] Again, no association was observed between cardiac defects and caffeine consumption or caffeine dose. Other studies also have failed to identify an association.[150]

Alcohol

Ever since the first description of the fetal alcohol syndrome by Jones and Smith in 1973, several studies have documented a wide range of teratogenic effects of alcohol consumption during pregnancy, including cardiac defects.[151] It has been suggested that ethanol may produce fetal tissue edema and affect the turgor of the primitive cardiac loop. Studies of this topic are especially difficult because of the notorious problem of obtaining reliable estimates of alcohol consumption during pregnancy in addition to other forms of recall bias. In a prospective study that collected information on maternal alcohol consumption during the first trimester of pregnancy, investigators noted no increased risk of major malformations among offspring of women who consumed 1 to 2 drinks per day compared with offspring of nondrinkers.[152] In a case-control study of 90 patients with conotruncal abnormalities and 150 with VSDs born in Finland between 1982 and 1983, the effect of maternal alcohol use was compared with 756 controls.[119] Although more mothers of infants with conotruncal malformations consumed any alcohol, consumed alcohol regularly every week, and consumed >1 drink per occasion, these results did not reach statistical significance. Maternal alcohol consumption during the first trimester of pregnancy was more common among the mothers of infants with VSDs (47%) than among those of controls (38%; $P<0.05$).[119] A case-control study of conotruncal defects in Atlanta showed no association with maternal reports of alcohol consumption (OR, 0.72; 95% CI, 0.49 to 1.06) or ñbingeò drinking (OR, 0.44; 95% CI, 0.13 to 1.46).[36] A more recent case-control study that examined the risk of congenital anomalies with different sporadic and daily doses of alcohol consumption in Spain reported an increased risk of congenital heart defects as a group only with the highest level of maternal consumption of alcohol per day (ie, >92 g/d).[153]

In the BWIS, the only association between alcohol and cardiovascular malformations was limited to increased risk for small muscular VSDs with heavy consumption (5 drinks on a single occasion) during the period defined by the last menstrual period ±3 months. There was no evidence of a trend in the risk of any cardiac defect with increased exposure.[6] A similar study from Finland also reported that maternal alcohol consumption during the first trimester appeared to double the risk of ASDs (OR 1.9; 95% CI, 1.0 to 3.4) but that the dose-response trends in risk were inconsistent with causal association.[154]

Cocaine and Marijuana

A case report by Shepard et al[155] suggested that single ventricle may result from maternal cocaine ingestion by inducing coronary occlusion in the developing fetal heart. Martin and Khoury[156] used data from a case-control study, the Atlanta Birth Defects Case-Control Study, to investigate the role of maternal cocaine ingestion in the induction of single ventricles. None of the 27 case infants were reportedly exposed to cocaine during early pregnancy, and only 7 of the control infants (0.43%) were exposed during early pregnancy. These data suggest that in this population the use of cocaine was rare or underreported.

An increased frequency of cardiovascular malformations was observed among 214 infants with neonatal toxicology screens showing the prevalence of cocaine in 1 study, with peripheral pulmonic stenosis as the leading diagnosis and in far greater numbers than in the general population.[157] A meta-analysis of 6 other epidemiological studies revealed no significant association between maternal cocaine use in pregnancy and fetal cardiovascular malformations.[158] Subsequent case-control studies have reported an association of maternal reports of cocaine use with an increased risk of any cardiac defects (adjusted OR, 11.6; 95% CI, 0.89 to 151.5),[159] heterotaxy (OR, 3.7; 95% CI, 1.3 to 10.7),[160] and membranous VSDs (adjusted OR, 2.4; 95% CI, 1.3 to 4.4).[6] The imprecise results in 2 of these studies are due to small numbers of cases with maternal reports and could reflect rare exposures, underreporting, or sampling variability.

In the Atlanta Birth Defects Case-Control Study, a 2-fold increase in risk of isolated simple VSDs was identified for maternal self- and paternal proxy-reported marijuana use. Risk of isolated simple VSDs increased with regular (≥3 d/wk) marijuana use for both maternal self- and paternal proxy report, although the association was significant only for maternal self-report.[161] Maternal use of marijuana was evaluated in the BWIS and was found to be associated with a slight increase in risk for Ebsteinôs anomaly.[6] Adams et al[36] used a case-control design with sufficient power to identify a 2-fold increase in risk for conotruncal defects and did not find an association (FDA category C).

Cigarette Smoking

A number of studies have investigated maternal cigarette smoking and congenital heart disease. A meta-analysis of studies published between 1971 and 1999 (12 analyses of all heart defects combined and 7 analyses of heart defect groups or specific phenotypes separately) found no association for all heart defects combined (OR, 1.07; 95% CI, 0.98 to 1.17) and mixed results for analyses of specific groups or phenotypes.[162] The latter probably reflects differences in methods, including case ascertainment, classification, control of confounding, and case group sample size, between the different studies. Some recent studies have reported associations of maternal smoking with heart defects combined (OR, 2.1; 95% CI, 1.2 to 3.5 in the Torf and Christianson[163] study; OR, 1.56; 95% CI, 1.12 to 1.82 in the Woods and Raju[164] study), but others such as the BWIS[6] and a Swedish study[165] have not. Some studies have reported associations between maternal smoking and heart defect groups, including ASDs (OR, 2.2; 95% CI, 1.1 to 4.3), atrioventricular septal defects (OR, 2.3; 95% CI, 1.2 to 4.5), and tetralogy of Fallot (OR, 4.6; 95% CI, 1.2 to 17.0).[163] However, these associations were not corroborated by larger studies such as the BWIS[6] and a study conducted in Sweden.[162] Recent exploratory analyses of small case groups based on the BWIS data have identified associations of maternal smoking with single ventricle and L-transposition of the great arteries.[160,166] Further research is needed to determine whether there is a relationship between

maternal smoking and risk of heart defects based on large population-based studies using more standardized case ascertainment and classification methods.

Vitamin A

A number of studies have examined the association between high vitamin A in the diet and/or supplements and neural crest cell defects (ie, cardiac and noncardiac defects) or outflow tract defects. Some studies suggest that a high intake of vitamin A is associated with an increased risk of CCVDs,[167–169] whereas others suggest no increased risk.[170–173] One possible reason for the inconsistency of the findings may relate to the differences in methods of assessing high exposure to vitamin A intake. Worth noting are 2 studies reporting an increased risk of CCVDs with an intake of >10 000 IU retinol in the form of supplements[168,169] and animal studies reporting the occurrence of defects of the cardiac outflow tract and other neural crest–derived structures[174] (FDA category X at dosages >18 000 to 25 000 IU/d).

Maternal Environmental Exposures

Organic Solvents

Studies of this topic can be difficult because organic solvents often comprise a mixture of chemicals, because the composition varies between different commercial preparations, and because of limitations in the way that exposure was defined in retrospective case-control studies. A few have reported associations of cardiac defects with reported maternal exposure to solvents and paints. Reports of exposure to degreasing or other solvents have been associated with an increased risk of hypoplastic left heart syndrome, coarctation of the aorta, pulmonic stenosis, transposition of the great arteries with intact ventricular septum, tetralogy of Fallot, total anomalous pulmonary venous return, nonchromosomal atrioventricular septal defects, and Ebsteinôs anomaly.[6] Maternal reports of occupational exposure to organic solvents have been associated with an increased risk of VSDs[119,175]; dyes, lacquers, and paints with conotruncal malformations[150]; and mineral oil products with coarctation of the aorta.[176]

Herbicides, Pesticides, and Rodenticides

A study suggesting an association of maternal employment in the agricultural industry with an increased risk of conotruncal defects[36] suggested a possible association with chemicals used in agriculture. In the BWIS, maternal reports of potential exposure to herbicides and rodenticides were associated with an increased risk of transposition of the great arteries and of potential exposure to pesticides with total anomalous pulmonary venous return and membranous VSDs.[6] A case-control study of various potential sources and numerous measures of maternal exposure to pesticides and congenital anomalies found mixed results for conotruncal defects.[177] A more recent case-control study of various end-product uses reported an increased risk of conotruncal defects with maternal reports of exposure to insecticides.[175]

Air Quality

Two recent studies have examined possible associations of ambient air pollutants with CCVDs. One study conducted in southern California reported possible increased risks of any heart defects and of VSDs with increased ambient levels of carbon monoxide, of aortic artery and valve anomalies with increased levels of ambient air levels of ozone during the second month of pregnancy,[178] and possible decreased risks of these defects with increased air levels of these pollutants during the third month of pregnancy. Another study conducted in 7 Texas counties evaluating potential exposures during weeks 3 to 8 of pregnancy reported possible increased risks of tetralogy of Fallot with carbon monoxide, isolated ASDs with particulate matter $<10\ \mu$m in aerodynamic diameter, and isolated VSDs with similar dioxide, as well as a possible risk of isolated ASD with carbon monoxide and isolated VSD with ozone.[179] These findings underscore the need for further studies using standard heart defect classification systems to elucidate whether the associations are real or are due to chance or bias.

Groundwater Contamination

The risk of congenital cardiac defects was reported to be greater among children of parents who had contact with areas that had groundwater contaminated with trichloroethylene than among children of parents who had no such contact.[180] This study did not evaluate the relation between maternal water consumption and risk of cardiac defects. Another study that did evaluate maternal consumption of home tap water during the first trimester of pregnancy found an increased risk of cardiac anomalies.[181]

Water Chlorination Byproducts

A possible association between maternal exposure to chlorination byproducts that result from the interaction of residual chlorine and organic matter in tap water and cardiac defects in offspring has been the subject of several investigations.[182–186] These studies evaluated information on the type of chlorination treatment at the water plant or on levels of trihalomethanes measured at sampling points in the water distribution but not on actual levels of contaminants in water consumed or used for showering. These studies found no associations with cardiac defects.

Other Environmental Concerns

Evaluations of possible associations of heart defects with maternal exposure to ionizing radiation have been limited. The BWIS examined possible associations of heart defects with maternal reports of exposure to ionizing radiation in occupational settings or as part of medical or dental evaluations and found few reports of such exposures and no evidence of any associations.[6] Concerns have been raised about the risk of birth defects in communities situated near hazardous waste sites or other sources of environmental pollution. Large population-based studies have evaluated this issue with mixed results. One study found an increased risk of all heart defects as a group,[187] but the results were imprecise because of the small number of exposed cases (n=3). Two studies found no associations with cardiac defects.[188,189] Surveillance data from population-based congenital anomaly registers in 16 regions of Europe (mainly Western Europe) were analyzed to evaluate the impact of the Chernobyl accident on the prevalence of selected congenital anomalies.[190] Chernobyl had no detectable impact on the prevalence of congenital anomalies in Western Europe.

Maternal Sociodemographic Characteristics

Age

In the BWIS, maternal age was not associated with nongenetic CCVDs as a group.[6] Analysis by specific defects found that maternal age of ≥30 years was associated with an increased risk of transposition of the great arteries (OR, 1.7; 95% CI, 1.1 to 2.7) and Ebsteinôs anomaly (OR, 2.6; 95% CI, 1.4 to 4.8), that more advanced maternal age (>34 years) was associated with an increased risk of bicuspid aortic valve (OR, 2.5; 95% CI, 1.3 to 4.8) and ASDs (OR, 1.6; 95% CI, 1.0 to 2.5), and that young maternal age (<20 years) was associated with an increased risk of tricuspid atresia (OR, 2.8; 95% CI, 1.3 to 6.4).[6] An analysis of nonchromosomal birth defects of the Metropolitan Atlanta Congenital Defects Program from 1968 to 2000 found associations of advanced maternal age (35 to 40 years) with an increased risk of all heart defects (OR, 1.12; 95% CI, 1.03 to 1.22), tricuspid atresia (OR, 1.24; 95% CI, 1.02 to 1.50), and right ventricular outflow tract defects (OR, 1.28; 95% CI, 1.10 to 1.49).[191]

Race/Ethnicity

Racial/ethnic variations in risk of a specific CCVD have been noted by a number of reports. Compared with black infants, white infants have been found to have an increased prevalence of Ebsteinôs anomaly, aortic stenosis, atrioventricular septal defects, ASDs,[192] coarctation of the aorta,[36,192,193] truncus arteriosus, transposition of the great arteries, tetralogy of Fallot,[36,192] PDA,[192,194] pulmonary stenosis,[192,194] hypoplastic left heart syndrome,[194,195] and a decreased prevalence of pulmonary stenosis.[194] In a population-based study of variations in prevalence of birth defects in offspring of Hispanic and black women in California between 1987 and 1997, no variations in prevalence were noted compared with the prevalence in offspring of non-Hispanic white women.[196]

Reproductive History

A history of reproductive problems has been associated with an increased risk of tetralogy of Fallot (previous miscarriage: OR, 1.5; 95% CI, 1.0 to 2.2), nonchromosomal atrioventricular septal defects (previous stillbirth: OR, 5.61; 95% CI, 1.94 to 16.21), ASDs (previous preterm birth: OR, 2.1; 95% CI, 1.24 to 3.4), and Ebsteinôs anomaly (previous miscarriage: OR, 3.2; 95% CI, 1.7 to 5.9).[6] Whether a history of reproductive problems represents a proxy for teratogenic exposures (eg, diabetes) or for an inherent increased susceptibility for CCVDs is unclear.

Maternal Stress

Maternal stress as measured by maternal reports of job loss, divorce, separation, or death of a close relative or friend was found to be associated with an increased risk of conotruncal heart defects (OR, 2.4; 95% CI, 1.42 to 4.2) in a case-control study in Atlanta.[36] A more recent case-control study in California obtained a similar result (OR, 1.4; 95% CI, 1.0 to 2.1) with a stronger effect among offspring of mothers who had not completed high school (OR, 2.4; 95% CI, 1.3 to 4.8).[197]

Paternal Exposures

There is growing concern that paternal factors may play a role in the origin of congenital defects in general and of CCVDs in particular. New dominant mutations are more common in older fathers,[198] and paternal age has been shown to be associated with birth defects such as achondroplasia and Alpert syndrome[199] and in genetic conditions known to affect the cardiovascular system such as Marfan syndrome[200]; the average age of fathers of children with sporadic or new mutation forms of Marfan syndrome was greater (37 years versus 30) than the general population. Paternal factors also have been shown to be important in diseases thought to have a combined genetic and environmental origin such as diabetes mellitus; children of a type 1 diabetic father have a greater likelihood of developing type 1 diabetes mellitus[201] than children of a mother with diabetes. This section examines the evidence for various paternal factors.

Paternal Age

Several studies have focused on paternal age as a risk factor for congenital cardiac defects in offspring. Olshan et al[202] evaluated the effect of paternal age on the risk of congenital heart defects in 4110 cases of congenital heart defects from the British Columbia Health Surveillance registry; matched controls were obtained from the birth files of British Columbia. The association of paternal age with 8 cardiac defects was examined after controlling for maternal age and other risk factors. A general pattern of increasing risk with increasing paternal age was found for ASDs, VSDs, and PDA. Offspring of men <20 years of age were also at higher risk for VSDs (OR, 2.0; 95% CI, 1.1 to 3.6) and possibly ASDs (OR, 1.9; 95% CI, 0.9 to 4.3). A separate study by Lian et al,[198] using data from the Metropolitan Atlanta Congenital Defects Program, also found an increased risk for ASDs and VSDs with increasing paternal age after adjustment for maternal age and race. In contrast, a Chinese study found no relationship between advancing paternal age and congenital heart defects.[203] In fact, risk was higher for men <25 years of age compared with men ≥25 years of age at the time of the childôs birth (OR, 2.27; 95% CI, 1.85 to 2.79).

Risk for men ≥25 years of age also was increased for VSDs, PDA, and tetralogy of Fallot. Similarly, an analysis of data from the BWIS[204] that focused on isolated membranous VSDs found no association with paternal age.

Other Paternal Exposures

Some studies have been conducted to evaluate the role of paternal exposures in the origin of congenital heart disease, but the number of studies is limited, and the results are inconclusive. The BWIS reported an association of paternal cocaine use with an increased risk of any CCVD in general and with VSDs and tricuspid atresia in particular.[6]

An analysis of data from the BWIS performed by Ewing et al[204] found that reports of paternal marijuana use (OR, 1.36; 95% CI, 1.30 to 11.86) and use of cocaine among older fathers (OR, 3.92; 95% CI, 1.30 to 11.86) were associated with the occurrence of an isolated membranous VSD in offspring. Other authors suggested that 5% of cases of isolated membranous VSDs may be attributed to older fathers who used cocaine.[205] The potential for recall bias associated with illicit drug use makes it difficult to interpret the conclusiveness of these findings.

Savitz et al[206] evaluated the influence of paternal factors on congenital cardiac anomalies using data from 1959 to 1966 Kaiser Health Plan members who participated in the Child Health and Development Study. The authors could not demonstrate any statistically significant relationships, although trends were identified for paternal cigarette smoking, alcohol intake, and older age.

Discussion

This statement provides a summary of well-known prenatal maternal conditions or exposures associated with an increased risk for cardiac defects (ie, definite risk factors) such as maternal rubella infection, phenylketonuria, diabetes, thalidomide, vitamin A congeners/retinoids, and indomethacin tocolysis. In addition, this article summarizes available information on several prenatal maternal and paternal factors that also may alter the risk for cardiac defects in the offspring (ie, possible risk factors). Particularly noteworthy is the suggestion that maternal use of multivitamin supplements containing folic acid during the periconceptional period may be associated with a reduced risk for some cardiac defects. This association and others reported in the literature warrant further evaluation because findings thus far are based on limited studies and/or tend to be mixed. This article also summarizes available information on a wide range of factors for which no associations have been noted or the evidence has been found to be insufficient to assess the risk for CCVDs.

Caveats

In interpreting findings on possible associations between nongenetic factors and CCVDs, we must remember that such associations from observational studies may be due to the exposures or factors of interest, but they may also be a result of chance, bias, or confounding. An observational study can yield an association as a result of sampling variation of the controls or multiple comparisons in an exploratory study. Recall bias is a potential concern because assessment of exposure to many factors (eg, first-trimester fever, medication use, consumption of vitamin supplements, solvents) often is based on parental recall after the birth of the child. Confounding is also of concern in that an apparent association between reported analgesic use and a heart defect might be due to confounding by the condition for which the analgesic was taken (eg, influenza or a febrile illness), and the apparent protective effect of multivitamin supplement use might be due not to the use itself but to the behavior of the user. Because some maternal illnesses can result in treatment with medications, uncertainty remains in some areas regarding independent effects of the disease or its treatment on fetal risk. A lack of an association between exposure and disease risk may be real, but it also may reflect effect dilution resulting from grouping of phenotypes with different inherent susceptibilities or errors in exposure assessment. In this review, most of the findings on risk factors come from case-control studies, and the best available information comes from 2 large population-based case-control studies specifically designed to investigate risk factors for congenital heart disease in an exploratory manner: the BWIS conducted in the Baltimore-Washington area between 1981 and 1989[6] and the study conducted in Finland by the National Public Heath Institute in Helsinki of cases and controls born during 1982 to 1984.[7] Although these larger, population-based studies used standardized methods for ascertaining and classifying cardiac defects, control selection, and methods to minimize potential biases and confounding, the above methodological issues may still be present. Therefore, the consistency of the findings from among multiple well-designed studies is particularly important.

TABLE 7. Recommendations to Prospective Parents Based on Evidence and the Precautionary Principle*

Mothers who wish to become pregnant should:
Take a multivitamin with folic acid daily
Obtain preconception and prenatal care with specific attention to detection and effective management of phenylketonuria and diabetes and vaccination for rubella
Discuss any medicine use with your doctor, even over-the-counter medications
Avoid contact with people with flu or other febrile illnesses
Avoid exposures to organic solvents

*These are recommendations based on evidence available in the medical literature to reduce risk of offspring with a congenital heart defect only. Prospective parents should discuss other important health behaviors with their healthcare provider and/or obstetrician.

Implications for Prevention

With these caveats in mind, the information presented here and the precautionary principle[207i 209] yield some guidelines that could be useful to prospective parents who wish to minimize their chances of having a baby with a CCVD. These guidelines are listed in Table 7. It is important to note that these guidelines are aimed at minimizing potential prenatal exposure to risk factors for congenital heart defects only, not other adverse health outcomes. Prospective parents should discuss important health behaviors that may affect a pregnancy such as nutrition, physical activity, lifestyle, and occupation with their primary care provider or obstetrician. Women of childbearing age should take multivitamins containing folic acid on a daily basis in the periconceptional period and should avoid certain types of behaviors such as exposure to organic solvents. Women of childbearing age also should obtain prenatal care, including testing for diabetes and past rubella exposure; should discuss any medication use with their obstetrician; and should avoid contact with ill people, especially those with rubella or influenzalike illnesses.

Recommendations also are possible for screening for possible cardiac defects using fetal echocardiography during pregnancy when warranted by reports of prenatal maternal illnesses or exposures. The need for screening any individual should be made on an individual basis from the type, likelihood, and level of potential exposure, as well as the time of gestation during which it occurred. This decision typically will be made as a result of the obstetrical history.

Ultimately, the aim of epidemiological studies is to provide information necessary for development of prevention policies and interventions. Because congenital heart defects represent

some of the more prevalent birth defects, result in significant lifelong morbidity, and are an important cause of mortality attributed to birth defects, the development of effective prevention interventions is paramount from a public health perspective. However, the evidence base to support the development and implementation of effective prevention policies and interventions specifically directed at reducing the public health impact of congenital heart defects is somewhat limited.

Nevertheless, some strategies may be considered that may help to ameliorate risk for congenital heart defects on a population basis. In part, these must be based on concern regarding a broader set of risks for pregnancy outcomes other than heart defects alone. Preconception care and appropriate dietary management for women with phenylketonuria should be an important strategy. Detection and appropriate management of diabetes before and during pregnancy should be an important priority, given the increasing prevalence of type 2 diabetes and glucose intolerance in the general population. Guidelines for managing diabetes before and during pregnancy have been published by the American Diabetes Association.[210,211] Ensuring that women of childbearing age are immunized against rubella is also an important and practical strategy. Medications that are suspected of causing congenital defects, including congenital heart disease, should have warnings about that risk to allow mothers and physicians to make informed decisions about the risks and benefits of use of the medication during pregnancy. One strategy that has already been implemented is the recommendation for use of prenatal vitamins. Continuing to emphasize the importance of using prenatal vitamins containing folic acid is practical and important.

Implications for Further Research

Information available regarding several potential noninheritable risk factors for congenital heart defects is limited because of few studies, few exposures of mothers or fathers to yield highly reliable findings, or possible methodological issues. A recent example of this problem of limited available information involves the drug paroxetine. The FDA has recently changed the pregnancy category of this drug from C to D because of concerns related to possible increased risk of congenital cardiac malformations in the fetus raised by preliminary results from epidemiological studies. A warning has been placed in the prescribing information for the drug and on the FDA Web site (http://www.fda.gov/medwatch/safety/2005/safety05.htm#Paxil3). No evidence-based studies have been published in the scientific literature to date. Clearly, further research on many of the potential risk factors discussed in this statement is needed to expand the evidence base needed for the development of prevention strategies. The potential for expansion of the evidence base may be realized within the next few years, with the recent implementation of 2 large population-based studies in which standard methods for classification and grouping will be used. One of these is the National Birth Defect Prevention Study (NBDPS), a multicenter population-based case-control study of birth defects, which has been ascertaining and collecting clinical information on children with birth defects, including congenital heart defects, on an ongoing basis since 1997.[212] This is the largest case-control study of birth defects conducted in the United States and will include one of the largest collections of cases of heart defects from several regions of the country. The NBDPS will facilitate evaluation of a wide array of known and suspected risk factors for subgroups of the population and will enable investigators to evaluate the relation between various types of heart defects and candidate genes, environmental factors, and gene-environment interactions. A number of data analyses have already been initiated, and some results should become available within the next few years. Another potential future source of information is the National Children's Study (NCS).[213] This study will explore a broad range of environmental factors that influence health and well-being of children. Because this study plans to examine ≈100 000 children across the United States and follow them during prenatal development, through birth, in childhood, and into adulthood, it will provide opportunities to evaluate prospectively the impact of prenatal exposures on some of the more common heart defects, as well as the developmental outcomes, other comorbidities, transition to adulthood issues, and the survival experience of children with heart defects.

Conclusions

In conclusion, this statement summarizes the current state of knowledge of noninherited risk factors for both mothers and fathers that may increase or, in some cases, decrease the likelihood that a congenital cardiac defect may occur in offspring. Much of the recent evidence is preliminary and may not ultimately prove to be causal. Nevertheless, some reasonable recommendations are offered to prospective parents and healthcare professionals that may reduce the risk of having a child with a congenital cardiac defect based on the current state of knowledge for the prevention of other birth defects and the precautionary principle. Similarly, pregnancies with some types of maternal exposures may warrant prenatal screening with fetal echocardiography. To date, no public policies or interventions are specifically directed at reducing the public health impact of congenital heart disease. However, new studies such as the NBDPS or the NCS may yield evidence needed to support the development of such policies or interventions in the future.[214–218]

Acknowledgments

We gratefully acknowledge the assistance and research support provided by Dr Janine Polifka and Jenny Nakahara from Teratogen Information System in compiling the sections on maternal therapeutic and nontherapeutic drug exposure. We would also like to thank Dawn England, MPH, Children's Hospital Boston, and Ralphella Washington, Children's Memorial Hospital, for their support during the writing of this statement.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Noninitiation or Withdrawal of Intensive Care for High-Risk Newborns

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Fetus and Newborn

ABSTRACT

Advances in medical technology have led to dilemmas in initiation and withdrawal of intensive care of newborn infants with a very poor prognosis. Physicians and parents together must make difficult decisions guided by their understanding of the child's best interest. The foundation for these decisions consists of several key elements: (1) direct and open communication between the health care team and the parents of the child with regard to the medical status, prognosis, and treatment options; (2) inclusion of the parents as active participants in the decision process; (3) continuation of comfort care even when intensive care is not being provided; and (4) treatment decisions that are guided primarily by the best interest of the child.

INTRODUCTION

As medical technology has advanced, outcomes for high-risk newborn infants have greatly improved. With advanced technology, such as assisted ventilation, it is now possible to keep some terminally or severely ill or extremely preterm infants alive for long periods of time. The result of such treatment is that dying may be prolonged or the infant may survive with profound neurologic or other debilitating problems.[1–3] The treatment of infants should be based on what is perceived to be in their best interest. Parents and health care professionals often confront difficult treatment decisions when faced with the care of a severely ill, extremely preterm, or terminally ill infant, in part because the effects of treatment decisions on the infant's outcome are not always predictable. In these circumstances, there is no ethical distinction between noninitiation and withdrawal of life-sustaining treatment.

THE TREATMENT DILEMMA

If intensive treatment uniformly resulted in survival with an acceptable quality of life for infants at risk, it would be the obvious choice for all severely ill infants. This outcome, of course, does not always occur. If intensive treatment is not provided to very ill infants, most of them will die, but some may survive with significant neurodevelopmental disability, perhaps in part because specific treatments were withheld. The following dilemma, therefore, exists: intensive treatment of all severely ill infants may result in prolongation of dying accompanied by significant discomfort for the infant or in survival with unacceptable quality of life; on the other hand, nonintensive treatment may result in increased mortality and morbidity. Either approach risks undesired and unpredictable results.

STRATEGY FOR CARE

For infants with poor prognosis, decisions about treatment should be made jointly by the health care team and the infant's family on the basis of the infant's physiologic maturity; the infant's medical condition, including any serious birth defects or medical complications; and the probabilities of death and severe disability based on the best available data.[4]

The types of decisions can be divided into 3 categories on the basis of prognosis[5]:

1. When early death is very likely and survival would be accompanied by high risk of unacceptably severe morbidity, intensive care is not indicated.
2. When survival is likely and risk of unacceptably severe morbidity is low, intensive care is indicated.
3. There may be cases that fall within these first 2 categories in which the prognosis is uncertain but likely to be very poor and survival may be associated with a diminished quality of life for the child; in these cases, parental desires should determine the treatment approach.

Whenever possible, discussion between the physician and parents should begin before the birth of a child with anticipated poor prognosis.[6] The obstetric care provider and the health care professional who will care for the infant after birth should collaborate in communicating with the expecting parents before the birth of the child. Such dialogue helps to ensure that appropriate care is provided for the individual infant on the basis of the infant's condition and prognosis at the time of birth. Sometimes, as when the woman is in active labor, it may seem that there is inadequate time for such a discussion. Nevertheless, it is essential that the meeting be conducted promptly and with great empathy. Follow-up meetings can take place if the situation changes over subsequent hours and days. Despite efforts to the contrary, an infant with a poor prognosis is sometimes born quickly, before the physicians can converse with the parents about the plan for treatment of the infant after birth. In such cases, the physician must use his or her judgment on behalf of the infant in deciding whether to initiate resuscitation of the infant until the parents can be involved in the decision. In making these decisions, the physician should err on the side of resuscitating the infant if the appropriate course is uncertain.

Once intensive care is initiated, the infant is continuously reevaluated, and the prognosis is reassessed on the basis of the best available information in conjunction with the physician's best medical judgment. This approach places significant responsibility on the physician and health care team to evaluate the benefits to and burdens on the infant with continuing intensive care. The family of the infant must be kept fully informed of the infant's evolving status and prognosis. The physician and family must be involved together in major decisions that ultimately could alter the infant's outcome.[7] Unless circumstances dictate otherwise, one physician should be designated as the spokesperson for the health care team and should discuss treatment options with the family and communicate decisions to the full health care team. When there is more than one valid approach to treatment, the physician should present these options to the family for their consideration and opinion. When the health care team is unable to agree on a treatment strategy, the physician, serving as the team leader, should attempt to resolve existing differences by using an independent medical consultant or consulting with the hospital bioethics committee.

The physician spokesperson must recognize that the parents' view of their child's status and the treatment choices is influenced by how the information is presented by the physician.[8] This recognition imposes a special obligation on the physician to present prognostic information in a frank and balanced way without coercion. The physician spokesperson must be sensitive to the parents' concerns and desires, which are often based on a complex combination of values and influences derived from their cultural, religious, educational, social, and ethnic backgrounds. The physician's role is to present the treatment options to the parents and provide guidance as needed. The parents' role is to participate actively in the decision-making process. Decisions to continue, limit, or stop intensive care must be based only on the best interest of the infant and not on the financial status of the parents or the financial interests of the physicians, the hospital, or any third-party payer.

The important role of the parents in decision-making must be respected. However, the physician's first responsibility is to the patient. The physician is not obligated to provide inappropriate treatment or to withhold beneficial treatment at the request of the parents. Treatment that is harmful, of no benefit, or futile and merely prolonging dying should be considered inappropriate. The physician must ensure that the chosen treatment, in his or her best medical judgment, is consistent with the best interest of the infant.

When there is conflict or disagreement between the recommendations of the physician and the desires of the infant's parents, continued discussion will often lead to agreement. If the disagreement continues, one option is to consult with the hospital bioethics committee. Another option is for the physician and family to seek another physician who is willing to provide care for the infant in the manner desired by the family. This disagreement between the physician and the family may result in the involvement of the court system. If this occurs, the physician should continue to serve as an advocate for the infant. Involvement of the court system is adversarial by nature and should be considered the last possible choice in resolution, to be used only in the case

of irreconcilable differences of opinion, and it should be avoidable in nearly all cases.

RECOMMENDATIONS

1. Decisions about noninitiation or withdrawal of intensive care should be made by the health care team and the parents of a high-risk infant working together. This approach requires honest and open communication. Ongoing evaluation of the condition and prognosis of the high-risk infant is essential, and the physician, as the spokesperson for the health care team, must convey this information accurately and openly to the parents of the infant.
2. Parents should be active participants in the decision-making process concerning the treatment of severely ill infants.
3. Compassionate basic care to ensure comfort must be provided to all infants, including those for whom intensive care is not being provided.
4. The decision to initiate or continue intensive care should be based only on the judgment that the infant will benefit from the intensive care. It is inappropriate for life-prolonging treatment to be continued when the condition is incompatible with life or when the treatment is judged to be harmful, of no benefit, or futile.

TECHNICAL REPORT

Katherine M. Shea MD, MPH, and the Committee on Environmental Health and Committee on Infectious Diseases

Nontherapeutic Use of Antimicrobial Agents in Animal Agriculture: Implications for Pediatrics

ABSTRACT. Antimicrobial resistance is widespread. Overuse or misuse of antimicrobial agents in veterinary and human medicine is responsible for increasing the crisis of resistance to antimicrobial agents. The American Academy of Pediatrics, in conjunction with the US Public Health Service, has begun to address this problem by disseminating policies on the judicious use of antimicrobial agents in humans. Between 40% and 80% of the antimicrobial agents used in the United States each year are used in food animals; many are identical or very similar to drugs used in humans. Most of this use involves the addition of low doses of antimicrobial agents to the feed of healthy animals over prolonged periods to promote growth and increase feed efficiency or at a range of doses to prevent disease. These nontherapeutic uses contribute to resistance and create health dangers for humans. This report will describe how antimicrobial agents are used in animal agriculture and review the mechanisms by which such uses contribute to resistance in human pathogens. Although therapeutic use of antimicrobial agents in agriculture clearly contributes to the development of resistance, this report will concentrate on nontherapeutic uses in healthy animals. ***Pediatrics*** **2004; 114:862–868;** ***antibiotic, antimicrobial, resistance, child, infant, agriculture, foodborne, epidemiology.***

ANTIMICROBIAL USE IN ANIMAL FEEDS

Rationale for Use

In livestock and poultry production, antimicrobial agents are used therapeutically, prophylactically, and to promote growth and improve feed efficiency.[1] Therapeutic use in clinically ill animals involves using curative doses of antimicrobial agents for a relatively short period of time. However, antimicrobial agents used for acute illness may be delivered not just to sick individuals but to the entire group of animals to which the sick individuals belong. Many therapeutic antimicrobial agents are administered in water to animals raised in large numbers under industrial conditions, which may result in individual animals or birds receiving inadequate doses. The nature of swine and poultry production makes it difficult to treat individual animals; if a few birds show signs of clinical illness, the entire house (10 000–30 000 birds) is treated. Of the wide variety of agents approved for therapeutic use in animals, many are identical or similar to drugs used in human medicine[2] (Table 1). Only some require a veterinarian's prescription. Although the therapeutic uses of antimicrobial agents in agriculture have significant impact on the development of resistant organisms, they are not the focus of this report.

Antimicrobial agents are also used in animal production to promote growth, primarily by enhancing feed efficiency; the mechanism of action is not known. When used for this purpose, low doses of antimicrobial agents are added to the feed of healthy animals for much of their life span. In addition, prophylactic antimicrobial agents are used to control the dissemination of clinically diagnosed infectious diseases identified within a group of animals or to prevent an infectious disease that has not yet been clinically diagnosed.[1] Prophylactic antimicrobial agents may be used at either low doses or therapeutic doses. These uses generate selection pressure on microbial populations that is similar to growth-promotion use and will be discussed under the common term "nontherapeutic use" to denote their use in healthy animals. Prophylactic antimicrobial agents are used to prevent diseases common to animals grown under industrial conditions.[1] Feed efficiency refers to the ability to grow animals faster with less food. This results in shorter time to slaughter at less expense to the producer, improving profits and decreasing consumer costs.[3] Addition of subtherapeutic doses of antimicrobial agents to feed also results in bigger animals, an effect known as growth promotion.

Scope of Use

Manufacturers and users of antimicrobial agents are not required to report data on production or use for human or food-animal applications. Annual production estimates range from 35 million[4] to 50 million[5] pounds per year. The major nonhuman use of antimicrobial agents is in food-animal production. The Institute of Medicine estimates that 40% of an-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

nual antimicrobial use in the United States is veterinary, and approximately three fourths of this use is categorized as nontherapeutic "supplements" in food animals.[5] Other estimates of nontherapeutic use in livestock are as high as 78%[4] of the total annual use of antimicrobial agents in the United States.

EVIDENCE OF SELECTION FOR ANTIMICROBIAL RESISTANCE ATTRIBUTABLE TO AGRICULTURAL USES OF ANTIMICROBIAL AGENTS

One of the most efficient ways to select for resistance genes in bacteria is to expose bacteria chronically to low doses of broad-spectrum antimicrobial agents. Levy et al[6] examined the effect of low-dose tetracycline in feed on the intestinal flora of chickens. Chickens were divided into experimental and control groups; the experimental group received feed containing oxytetracycline at concentrations similar to those used for therapy or prophylaxis; the control group received feed without oxytetracycline. The baseline resistance to tetracycline was generally less than 10%, with many samples exhibiting less than 0.1% resistance. Within 36 hours, resistance began to increase, and after 2 weeks, 90% of the chickens in the experimental group were excreting bacteria that were 100% resistant to tetracycline. Chickens in the control group did not exhibit an increase in resistant organisms during this same time period. Although the chickens were exposed only to tetracycline, multidrug resistance developed (to tetracycline, sulfonamides, streptomycin, ampicillin, and carbenicillin) through plasmid transfer. By 12 weeks, almost two thirds of the chickens in the experimental group excreted organisms resistant to tetracycline and at least 1 additional antimicrobial agent, and more than one quarter were resistant to 4 antimicrobial agents (tetracycline, ampicillin, streptomycin, and carbenicillin). Over time, chickens in the control group, despite isolation in different pens, also developed resistance, although at lower levels. One third of chickens in the control group were excreting more than 50% resistant organisms after 4 months. Transfer of resistance to humans also occurred, although more slowly and at lower levels than in the control-group chickens. Within 6 months, more than 30% of fecal samples from farm dwellers contained more than 80% tetracycline-resistant bacteria versus 6.8% from control neighbors ($P < .001$). A 4-drug resistance pattern was found in farm families corresponding to that of the experimental-group chickens but was not found in neighborhood controls. Six months after the removal of all tetracycline feed from the farm, no tetracycline-resistant organisms were isolated from stool samples in 8 of 10 farm dwellers tested. This experiment demonstrated that resistance can develop quickly in the presence of antimicrobial pressure, that single-drug resistance becomes multidrug resistance, that resistance spreads beyond individuals exposed to the antimicrobial agent to other members of their species within the environment and to humans living and working on the farm, and that stopping feed supplementation with oxytetracycline leads to decreased incidence of resistance.

MECHANISMS OF SPREAD OF RESISTANT BACTERIA TO HUMANS

When animals become colonized with resistant organisms, these organisms can eventually reach humans through the food chain, direct contact, or contamination of water or crops from animal excreta.[7] Increasingly, food animals are raised in large numbers under close confinement, transported in large groups to slaughter, and processed very rapidly.[8] These stressful conditions cause increased bacterial shedding and inevitable contamination of hide, carcass,[9] and meat[10] with fecal bacteria. Dissemination of resistant pathogens via the food chain is facilitated further by centralized food processing and packaging, particularly of ground meat products, and broad distribution through food wholesalers and retail chains.[11] Farmers, farm workers, and farm families[6] as well as casual visitors[12] are at risk of infection with resistant organisms.

Environmental reservoirs may also contribute to the movement of resistance genes. Active antimicrobial agents have been detected in water near animal

waste lagoons,[13] surface waters, and river sediments,[14] giving rise to concerns that environmental contamination with antimicrobial agents from agricultural and human use could present microbial populations with selective pressure, stimulate horizontal gene transfer, and amplify the number and variety of organisms that are resistant to antimicrobial agents. Supporting this concern, investigators recently found resistance genes identical to those found in swine waste lagoons in groundwater and soil microbes hundreds of meters downstream.[15]

Finally, there may also be direct human exposure to antimicrobial agents. Because many antimicrobial agents used in food-animal production can be obtained without a veterinarian's prescription, they are available for direct purchase and are often manually added to feed or water at farm level. This may be another pathway leading to development of resistance in occupationally exposed individuals, their families, and neighbors.[6]

EFFECT ON TREATMENT OF INFECTIONS IN CHILDREN

This section of the report reviews evidence that links agricultural use of antimicrobial agents to disease in infants and children for 2 major foodborne pathogens, *Campylobacter* species and *Salmonella* species, and for the opportunistic pathogen *Enterococcus* species.

Campylobacter Species

Campylobacter organisms cause approximately 2.5 million cases of foodborne illness annually in the United States and are the leading cause of bacterial foodborne illness.[16] The incidence of *Campylobacter* infections in infants younger than 1 year is twice that in the general population (54.1 vs 21.7 per 100 000 population).[17] Almost 20% of all reported cases of *Campylobacte*r infections occur in children younger than 10 years.[18]

Erythromycin or another macrolide is the drug of choice for *Campylobacter* infections in infants and children; fluoroquinolones and tetracyclines are used frequently in adults. Antimicrobial resistance in *Campylobacter* species is an increasing problem.[19] Currently, macrolide resistance in human isolates of *Campylobacter jejuni*, the species causing 90% of human infections, is stable and usually less than 5%.[19] *Campylobacter coli*, which causes approximately 10% of human infections, has a much higher resistance rate, reaching 70%.[20] The major reservoirs are poultry for *C jejuni* and turkeys and swine for *C coli*.[21] Differences in resistance rates may reflect differences in the use of antimicrobial agents.[20] Erythromycin and tetracyclines are approved for use in food-producing animals for therapeutic and growth-promotion purposes.

Fluoroquinolone resistance in *Campylobacter* species demonstrates the links among agricultural use of antimicrobial agents, selection of resistance, and dissemination of resistant infections through the food chain. Fluoroquinolones were approved for use by prescription in diseased poultry flocks in the United States in 1995.[22] In Minnesota between 1996 and 1998, infections in humans caused by fluoroquinolone-resistant organisms increased, parallel with the prevalence of retail domestic chicken products contaminated with fluoroquinolone-resistant organisms. Data from the National Antimicrobial Resistance Monitoring System (NARMS) demonstrate that fluoroquinolone resistance among *Campylobacter* isolates from humans began to increase nationwide in the late 1990s, from 13% in 1997 to 20.5% in 1999.[23] A 1999 survey of grocery store chicken found that 44% of samples were contaminated with *Campylobacter* species; 24% of the isolates were resistant to ciprofloxacin, and 32% were resistant to nalidixic acid.[24] Increasing resistance is even more worrisome, because data suggest that strains of resistant *Campylobacter* species may be more virulent than sensitive strains. In a case-control telephone study, investigators found that untreated patients with fluoroquinolone-resistant *Campylobacter* infection had an average of 12 days of diarrhea versus 6 days in patients with sensitive strains ($P = .02$).[25] For patients who were treated with fluoroquinolones, the duration of diarrhea was significantly longer in those infected with resistant versus sensitive strains (8 vs 6 days [$P = .02$]).

Salmonella Species

Nontyphoidal *Salmonella* organisms cause 1.4 million illnesses annually, 95% of which are thought to be foodborne.[16] It is estimated that 600 deaths occur annually from *Salmonella* infections, primarily among the elderly and very young.[16] More than one third of all cases occur in children younger than 10 years,[18] and the incidence in children younger than 1 year is 10 times higher than in the general population (128.9 vs 12.4 per 100 000).[17] Ten percent of blood and central nervous system infections caused by *Salmonella* species as reported to the Centers for Disease Control and Prevention occur in children younger than 1 year.[26] Children of all ages with chronic conditions such as sickle cell anemia are at high risk of serious complications from infections with *Salmonella* species.[27]

The dissemination of resistant *Salmonella* infections through the food chain is well documented. A 6-state outbreak of plasmid-mediated, multidrug-resistant *Salmonella newport* infection attributed to consumption of contaminated beef was traced back to a feedlot that used nontherapeutic doses of chlortetracycline as a growth promoter in feed.[28] Investigators found the outbreak organism in isolates from both animals and humans on an adjacent dairy farm. An increased risk of illness caused by a resistant strain was observed in patients who were taking antimicrobial agents for other infections (odds ratio, 51.3; $P = .001$), suggesting that asymptomatic carriage was converted to symptomatic infection by the use of antimicrobial agents. Of 3 children younger than 10 years, 2 had received antimicrobial agents before onset of their illness.

Neonatal infections caused by *Salmonella* species also have been attributed to indirect exposure to foodborne sources. Bezanson et al[29] described a plasmid-mediated, 6-drug–resistant strain of *Salmonella*

serotype Typhimurium acquired asymptomatically by a pregnant woman from raw milk and passed to her infant at birth. The infant became ill within 24 hours with septicemia and meningitis. Three to 4 days later, several other infants in the newborn nursery developed diarrhea with the same resistant organism. In another newborn nursery outbreak, *Salmonella heidelberg* resistant to chloramphenicol, sulfamethoxazole, and tetracycline caused bloody diarrhea in 3 infants.[30] The index case was a term infant born by cesarean delivery after 18 hours of ruptured membranes. The mother was a farmer's daughter who, until shortly before delivery, had been working with new calves from a herd containing several sick calves.

The treatment of *Salmonella* infections, especially in young children, has become increasingly difficult because of antimicrobial resistance. In the early 1980s, the prevalence of multidrug-resistant *Salmonella* species began to increase and by 1995 had reached 19% in the United States.[31] Some strains, particularly *Salmonella* serotype Typhimurium DT104, cause invasive disease that frequently requires treatment but may be resistant to 5 or more classes of antimicrobial agents.[32,33] Currently, extended-spectrum cephalosporins have become the preferred drugs for empiric treatment in pediatrics, and fluoroquinolones are preferred in adults. The efficacy of these drugs may now be threatened. In 1999, Molbak et al[34] described an outbreak in Denmark of *Salmonella* serotype Typhimurium DT104 resistant to ampicillin, chloramphenicol, streptomycin, sulfonamides, tetracycline, and quinolones, linked by molecular fingerprinting (the process of identifying unique clones by DNA typing) to 2 swine herds. Two patients died in this outbreak, and therapeutic failure was considered related to antimicrobial resistance. Of 4 children, 1 was an infant who was hospitalized and treated with cefotaxime. Fey et al[35] reported on a child from Nebraska who became infected with *Salmonella* serotype Typhimurium DT104 resistant to ampicillin, chloramphenicol, tetracycline, sulfisoxazole, kanamycin, streptomycin, several classes of cephalosporins, aztreonam, cefoxitin, gentamicin, and tobramycin. An analysis of recent NARMS data revealed that 77% of patients with culture-proven ceftriaxone-resistant *Salmonella* infection between 1997 and 1998 were younger than 18 years and that the prevalence of ceftriaxone-resistant human isolates increased fivefold from 0.1% in 1996 to 0.5% in 1999.[36] Human isolates of *Salmonella* species resistant to 8 or more agents increased almost sevenfold from 0.3% in 1996% to 2% in 1999. Decreased susceptibility to fluoroquinolones may also be emerging. According to NARMS data, the prevalence of resistance to ciprofloxacin among *Salmonella* isolates increased from 0.4% in 1996 to 1% in 1999.

Major reservoirs for *Salmonella* infection are food animals, including poultry, cattle, and swine. Nontherapeutic antimicrobial agents are routinely used, particularly in swine. One survey of 825 retail samples of raw chicken, turkey, pork, and beef revealed an overall rate of 3% contamination with *Salmonella* species.[37] White et al[38] recently reported that 20% of retail ground meat samples were contaminated with *Salmonella* species; 80% of these samples were resistant to at least 1 antimicrobial agent, 53% were resistant to at least 3 antimicrobial agents, and 16% were resistant to ceftriaxone.

Enterococci

Enterococci are normal flora in food animals, domesticated animals, wild animals, and humans. In the 1990s, vancomycin-resistant enterococci (VRE) became common bacterial pathogens responsible for an increasing number of nosocomial infection in the United States, including in children.[39] Hospitalized and seriously ill children are increasingly affected.[40,41] Patterns in the prevalence of VRE infection have developed differently in the United States and Europe, helping to elucidate the links between use of antimicrobial agents in animals and resistance in humans. Whereas the epidemic of VRE infection in the United States seems related to the large increase in vancomycin use in human medicine,[42] the increased incidence of VRE infection in Europe seems to be attributable to the use of antimicrobial agents in animals. Vancomycin has not been used widely in Europe in human medicine, but avoparcin, a related glycopeptide, has been used as a growth promoter for decades.[43] Avoparcin selects for cross resistance to vancomycin when used in farm animals.[44,45] In the United States, VRE is rarely cultured from healthy individuals in the community,[46] but it is often isolated from healthy community members in Europe.[47] In Europe, VRE can also be cultured from healthy poultry, pigs,[48] ponies, and dogs[49]; uncooked chicken meat[50] and minced pork; and raw sewage from urban and rural locations.[51] Molecular fingerprinting of these isolates shows much higher heterogeneity in European isolates compared with US isolates, suggesting that the prevalence of VRE in Europe is a response of multiple enterococcal populations to the presence of avoparcin in a variety of host species and locations.

Recent reports from the United States, however, suggest a strong and emerging link between VRE and agricultural use of antimicrobial agents. In response to the epidemic of VRE infection, quinupristin-dalfopristin (Q-D) was licensed for use in 1999 by the US Food and Drug Administration as treatment for highly resistant strains. Q-D is a streptogramin, a class of antimicrobials not used previously in humans because of unacceptable toxicity.[52] Virginiamycin is a related streptogramin that has been used in the United States as a growth promoter for poultry, swine, and cattle since 1974.[53] In a recent study, 58% of 407 retail chicken samples and 1% of human stool samples were found to harbor Q-D-resistant enterococci 1 year before its release for human use, and humans were also found to carry resistant organisms without previous exposure to Q-D.[54] This suggests that ingestion of resistant enterococci in retail meats resulted in colonization of the human gut by these foodborne pathogens; such colonization of the gut of humans has been documented for up to 14 days after ingestion.[55] It also demonstrates the potential risks of using antimicrobial agents thought not to be impor-

tant to human medicine as growth promoters. As antimicrobial resistance increases, it is likely that more veterinary agents may be modified for human use. If resistance has already developed in animal populations, however, the period of their efficacy in human disease may be quite limited.

EUROPEAN EXPERIENCE

Sweden led Europe in banning antimicrobial growth promoters in 1986.[56] The ban in Sweden has resulted in decreased use of antimicrobial agents in food animals and, accompanied by improved animal husbandry practices, sustained productivity and profitability of the industry.[57] Denmark, which has a more industrialized animal production system similar to that in the United States, instituted a voluntary ban on antimicrobial growth promoters in 1998. Denmark has had a similar decrease in antimicrobial use and decreased prevalence of resistant organisms in food animals without loss of productivity or profitability.[58]

CONCLUSIONS

Resistance to antimicrobial agents is an increasing and serious problem. Judicious use of antimicrobial agents in humans will address only approximately 50% of use and will be insufficient to curb the accelerating upward trend in resistance. The largest nonhuman use of antimicrobial agents is in food-animal production, and most of this is in healthy animals to increase growth or prevent diseases. Evidence now exists that these uses of antimicrobial agents in food-producing animals have a direct negative impact on human health and multiple impacts on the selection and dissemination of resistance genes in animals and the environment. Children are at increased risk of acquiring many of these infections with resistant bacteria and are at great risk of severe complications if they become infected. Improved surveillance and continued documentation will elucidate the magnitude of the impact that these uses have on public health in general and children's health in particular.

CLINICAL REPORT

Office-Based Counseling for Unintentional Injury Prevention

Guidance for the Clinician in Rendering Pediatric Care

H. Garry Gardner, MD, and the Committee on Injury, Violence, and Poison Prevention

ABSTRACT

Unintentional injuries are the leading cause of death for children older than 1 year. Pediatricians should include unintentional injury prevention as a major component of anticipatory guidance for infants, children, and adolescents. The content of injury-prevention counseling varies for infants, preschool-aged children, school-aged children, and adolescents. This report provides guidance on the content of unintentional injury-prevention counseling for each of those age groups.

INTRODUCTION

Unintentional injuries continue to be the leading cause of death in children older than 1 year. In 2003, unintentional injuries caused 34.6% of all deaths in 1- to 4-year-olds, 37.8% of all deaths in 5- to 9-year-olds, 37.5% of all deaths in 10- to 14-year-olds, and 49.7% of all deaths in 15- to 19-year-olds. Among all children from 1 to 19 years of age, 64.7% of unintentional injury deaths involved motor vehicles.[1]

Pediatricians play a key role in educating parents about the risks of unintentional injuries and specific measures to minimize those risks, including environmental modification or the use of safety equipment. Anticipatory guidance is a major component of well-child care and injury visits, and parents value the advice and counseling they receive from their pediatricians. Anticipatory guidance for injury prevention should be an integral part of the medical care provided for all infants, children, and adolescents.

Counseling for the prevention of unintentional injuries needs to be appropriate for the child's age and locale. Initially, it is necessary for the counseling to be provided to the parent or caregiver as both the role model for the child's behavior and the person who is most capable of modifying the child's environment. As children mature, counseling should be directed increasingly toward children or adolescents as they become responsible for their own behavior. Physicians are encouraged to document injury-prevention counseling in the medical chart.

In 1983, the American Academy of Pediatrics introduced The Injury Prevention Program (TIPP). TIPP includes a safety-counseling schedule, age-appropriate safety surveys, and age-appropriate safety sheets for families to take home.[2] Physicians may use different parts of TIPP to supplement their anticipatory guidance.[2] The interventions outlined here and in TIPP have been shown to be effective in improving parental safety practices.[3–9] A review of the literature on childhood injury-prevention counseling in primary care settings demonstrated that 18 of 20 studies have shown positive outcomes in increasing knowledge and behavior and in decreasing injury rates in children.[10] A systematic review of 22 randomized,

doi:10.1542/peds.2006-2899

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

controlled trials of counseling and other interventions in a clinical setting demonstrated improvement in certain safety practices, specifically motor vehicle restraint use, smoke alarm ownership, and maintenance of safe hot-water temperature.[11]

INFANTS

Advise parents about the following issues:

1. Traffic safety: The correct use of currently approved child safety restraints needs to be discussed. The infant car safety seat should be rear-facing in the back seat, never in the front seat if there is a passenger-side air bag. Infants should never be left unattended in an automobile. Parents need to be reminded of the importance of using their own seat belts.[12]
2. Burn prevention: Smoke alarms in the home should be installed and maintained.[13,14] Hot-water temperature should be set at a maximum of 120°F to avoid scald burns. Parents should be advised not to carry their infant and hot liquids or foods at the same time. Milk and formula should not be heated in the microwave because it can heat unevenly, causing pockets of liquid hot enough to scald the infant's mouth. Electrical outlets should be covered with devices that will not pose a choking hazard.
3. Fall prevention: Window and stairway guards/gates are necessary to prevent falls from heights.[15] Infant walkers should not be used.[16] Infants should never be left alone on any furniture such as changing tables, beds, or sofas.
4. Choking prevention: Small parts or objects can pose a choking hazard to young children. Round or cylindrical and compressible objects and foods can pose life-threatening risks of airway obstruction. Balloons pose a similar risk for young children. To avoid risk of strangulation, parents should be advised to avoid clothes and toys with long strings and cords and to cut looped blind and drapery cords. Suffocation may occur from entrapment in unsafe crib environments and access to waterbeds or plastic bags. Parents should be aware of hazards in any home where an infant spends time.
5. Drowning prevention: Because very young infants drown most commonly in bathtubs and buckets while unsupervised, advise parents never to leave infants or young children in the bathtub or around other bodies of water without constant adult supervision, and advise them to empty and properly store buckets immediately after use.[17–19] Parents should be reminded that infant bath seats or supporting rings are not a substitute for adult supervision.
6. Safe sleep environment: Infants should be placed for sleep in a supine position in a crib that conforms to current safety standards. Infants should not be put to sleep on soft surfaces such as waterbeds or sofas. Avoid soft materials in the infant's sleep environment. If bumper pads are used, they should be removed when the infant begins to stand. Never leave the crib sides down when the infant is in the crib.[20]
7. Cardiopulmonary resuscitation: It is important that parents become trained in infant and child cardiopulmonary resuscitation and learn how to access their local emergency medical services (eg, 911).

PRESCHOOL-AGED CHILDREN

Toddlers and young children are more able to explore their environment but do so with little regard to risk or consequences. Parents of preschool-aged children need to be counseled to take a proactive role in protecting their children.

1. Traffic safety: Toddlers may be placed in a forward-facing car safety seat when they reach 1 year and 20 pounds, but it is best for them to remain rear-facing until they reach the highest weight or height allowed in that position by the car safety seat. Preschool-aged children should always ride in the back seat. Parents need to be reminded again of the importance of using their own seat belts.[12] Young children should never be left unsupervised in or around cars. Driveways and streets are particularly dangerous places for children to play. Supervised pedestrian safety begins at this age. Preschool-aged children are not ready to cross the street alone. Children must be watched closely when near driveways and streets.[21] Use of an approved bicycle helmet begins with riding a tricycle or bicycle with training wheels.
2. Burn prevention: Smoke alarm batteries should be checked regularly.[22] Children should be kept away from hot oven doors, irons, wall heaters, and grills. Advise parents to keep hot food and coffee out of the reach of young children.[14] Electrical outlets should be covered.
3. Fall prevention: Toddlers learning to walk and climb need to be protected from stairways, open windows, and heavy furniture that could topple over.[15]
4. Poison prevention: Medicines and household products should be kept out of the sight and reach of children and locked up whenever possible. These items should be purchased and kept in original child-proof containers or blister packs. Ipecac is no longer recommended and, if present in the home, should be discarded. Keep the poison control telephone number (1-800-222-1222) handy.[23]
5. Drowning prevention: Backyard swimming pools or spas need to be completely fenced on 4 sides to separate them from the house and yard; the fence should

have a self-closing, self-latching gate.[24] The gate should open away from the pool and should be checked often to ensure that it is in good working order. Children younger than 5 years should swim only with close adult "touch" supervision.[17–19]

6. Firearm safety: Because of the dangers that in-home firearms, particularly handguns, pose to young children, parents should be advised to keep handguns out of places where children live and play. If parents choose to keep a firearm in the home, the unloaded gun and ammunition must be kept in separate locked cabinets.[25]

SCHOOL-AGED CHILDREN

Advice to parents of elementary school–aged children begins to be more focused on the child's behavior. Children begin to learn home safety rules by 3 to 4 years of age.[26] The child should then be included in this learning process, and the parents should be reminded again of their need to model safe behaviors.

1. Traffic safety: When children reach the top weight or height allowed for their car safety seat, they need to ride in booster seats. A booster seat should be used until the child properly fits in the adult seat belt with the shoulder belt lying across the chest, the lap belt low and snug across the upper thighs, and the legs bent at the knees when sitting against the vehicle seat back (usually around 4 feet 9 inches in height and between 8 and 12 years of age).[12] Remind children and parents that no one should ride in the bed of a pickup truck.[27] All-terrain vehicles (ATVs) should not be used by children younger than 16 years.[28,29] Review safe pedestrian practices.[21] Approved bicycle helmets should be worn on every bike ride.[30,31]
2. Water safety: Children 5 years and older should be taught to swim and should be taught appropriate rules for water play. Children must never be allowed to swim alone. Coast Guard–approved personal flotation devices should be worn by all children engaged in any boating activity.[17]
3. Sports safety: Adults who supervise children participating in organized sports programs and recreational activities need to emphasize the importance of safety equipment for the particular sport as well as appropriate physical conditioning for that sport.[32–35] The use of protective equipment for in-line skating and skateboarding needs emphasis.[36,37]
4. Firearm safety: In addition to removing firearms from the home environment where children explore and play, it is important for parents to ask whether there is a gun in any home that their child visits. If parents choose to keep a firearm in the home, the unloaded gun and ammunition must be kept in separate locked cabinets.[25]

ADOLESCENTS

Injury-prevention advice to adolescents ideally is included in a broader discussion of healthy lifestyle choices, especially the avoidance of alcohol, tobacco, or other drug use. It is important for pediatricians, parents, and schools to remain united in their efforts to promote community choices that, by modifying the adolescent environment, make adolescent risk-taking less likely to occur, thus decreasing the risk of significant injury. Specific areas of injury-prevention guidance include the following:

1. Traffic safety: Encourage seat belt use and discuss the role of alcohol and drugs in teenage motor vehicle crashes. Discuss specific ways to minimize distracted driving, including eating, drinking, and especially using a cellular phone or electronic device while driving. Alert parents and adolescents to the dangers of high-risk situations, including speeding and reckless driving. Encourage compliance with graduated driver-licensing laws. Parents should enact strict rules to limit nighttime driving and the number of passengers in the car.[38] A helmet should be worn whenever riding a bicycle, motorcycle, or ATV.[28,30] ATVs should not be used by children younger than 16 years.[28]
2. Water safety: Discuss the risks of swimming in remote locations and at sites that are not designated as swim areas as well as the dangers of alcohol and other drug consumption during aquatic recreation activities (eg, swimming, diving, boating). The first entry into any body of water should be feet first, and it is important to know the water's depth and the location of any underwater hazards before jumping or diving. Discuss the need to use an approved personal flotation device whenever the child is riding on a boat or other watercraft or fishing.[17]
3. Sports safety: Adolescents participating in organized sports programs and recreational activities need to be reminded of the importance of safety equipment, including protective eyewear, for their particular sport as well as appropriate physical conditioning for that sport.[32–35] The importance of using protective equipment for in-line skating and skateboarding needs emphasis.[36,37]
4. Firearm safety: In-home firearms are particularly dangerous during adolescence because of the potential for impulsive, unplanned use by teens resulting in suicide, homicide, or serious unintentional injuries. Firearms, and especially handguns, should be kept out of the home. If parents choose to keep a firearm in the home, the unloaded gun and ammunition must be kept in separate locked cabinets. Parents should ask whether there is a gun in any home that teenagers visit.[25]

CONCLUSIONS

Injury-prevention counseling should be integrated into every well-child visit. Because of time constraints, specific topics could be addressed at different visits and tailored to be appropriate for the season, the child's activities, and concerns and questions raised by the parent. The topics addressed should be documented in the medical record. TIPP information sheets could be attached to vaccine information sheets on each visit. Telephone numbers (eg, poison control center) and Web sites could be posted in the waiting room along with brochures and posters. Parents and children are often receptive to injury-prevention counseling during a sick visit, especially if it is related to an injury, a recent emergency department visit, or injury to a sibling.[39] Finally, pediatricians can be more effective advocates for injury prevention by working with community resources that have a major influence on children,[11] such as the school system, park district, Head Start, child care centers, organizations such as the YMCA, and local media.

Ophthalmologic Examinations in Children With Juvenile Rheumatoid Arthritis

James Cassidy, MD, Jane Kivlin, MD, Carol Lindsley, MD, James Nocton, MD, the Section on Rheumatology, and the Section on Ophthalmology

ABSTRACT

Unlike the joints, ocular involvement with juvenile rheumatoid arthritis is most often asymptomatic; yet, the inflammation can cause serious morbidity with loss of vision. Scheduled slit-lamp examinations by an ophthalmologist at specific intervals can detect ocular disease early, and prompt treatment can prevent vision loss.

INTRODUCTION

Chronic uveitis is an important and sometimes devastating complication of juvenile rheumatoid arthritis (JRA).[1–3] The intraocular inflammation primarily affects the iris and ciliary body (iridocyclitis), but the choroid may also be involved.[4] Overall, the frequency varies from 2% to 34% in children with JRA.[5–8] Diagnosis of early involvement is not possible by direct ophthalmoscopy, but slit-lamp examination will reveal the presence or absence of inflammatory cells and increased protein within the anterior chamber of the eye.

Morbidity includes cataracts, glaucoma, band keratopathy, phthisis bulbi, and loss of vision.[7,9] Visual outcome has improved in the past 20 years; most children have a relatively good prognosis if the disorder is detected and treated early.[9,10] However, uveitis in children with JRA remains a leading cause of loss of vision and blindness in the United States.

RISK FACTORS FOR CHRONIC UVEITIS

Articular Features

The classification of JRA describes a heterogeneous group of disorders of predominantly peripheral arthritis with onset of disease before 16 years of age. The 3 major onset types defined by clinical manifestations in the first 6 months of the disease are oligoarticular (pauciarticular), polyarticular, and systemic.[11] The onset type is determined by the systemic features of the illness and the number of joints with arthritis at diagnosis. Oligoarticular JRA is defined by involvement of 4 or fewer joints; polyarticular JRA is defined by involvement of >4 joints (usually 10–20); and systemic-onset JRA is defined by quotidian fevers during the first 6 weeks of the illness, almost always associated with a characteristic rash. Less than 1% of children with systemic-onset JRA develop chronic uveitis.[5,7] Most children with uveitis have an oligoarticular onset.[1,2,7]

TABLE 1 **Frequency of Ophthalmologic Examination in Patients With JRA**

Type	ANA	Age at Onset, y	Duration of Disease, y	Risk Category	Eye Examination Frequency, mo
Oligoarthritis or polyarthritis	+	≤6	≤4	High	3
	+	≤6	>4	Moderate	6
	+	≤6	>7	Low	12
	+	>6	≤4	Moderate	6
	+	>6	>4	Low	12
	−	≤6	≤4	Moderate	6
	−	≤6	>4	Low	12
	−	>6	NA	Low	12
Systemic disease (fever, rash)	NA	NA	NA	Low	12

ANA indicates antinuclear antibodies; NA, not applicable.
Recommendations for follow-up continue through childhood and adolescence.

Chronic uveitis may be detected at the time of initial diagnosis of arthritis; however, if not present at onset, it most often presents during the next 4 to 7 years.[7,12] The period of highest risk is within 4 years of onset of arthritis, although the risk is never entirely absent.[7,12] Eye involvement precedes involvement of the joints in approximately 5% of cases.

Children with JRA remain at risk of developing uveitis into adulthood. There are reports of uveitis diagnosed initially more than 20 years after onset of arthritis.[13] The activity of the uveal inflammation does not parallel that of the joint disease.[14,15]

Age

Children at greatest risk of developing uveitis are those with oligoarticular-onset JRA.[1,2,13] The peak age of onset of arthritis in oligoarthritis is 1 to 5 years.[12]

Immunogenetic and Serologic Markers

The serologic marker most strongly associated with chronic uveitis is the presence of antinuclear antibodies.[1,2,16] Antinuclear antibodies are present in 65% to 90% of children with chronic uveitis and are a major risk factor for its development.[7,17] They are usually detected in low to moderate titers on HEp-2 cells and are of unknown antigenic specificity. Rheumatoid factor is not usually present in children with JRA, including those with uveitis. Immunogenetic factors may predispose to the development of chronic uveitis. The associated alleles are located predominantly in the major histocompatibility complex (MHC) region on chromosome 6 and involve specificities in the HLA-DR, DP, and DQ regions.[18]

Clinical Characteristics

The onset of ocular inflammation is insidious and asymptomatic in most young children.[1,2,17] Because of the lack of symptoms or the cognitive recognition by the child, the exact time of onset of ocular involvement is frequently difficult to determine. This observation emphasizes the requirement for slit-lamp examination by an ophthalmologist at diagnosis of JRA and periodically thereafter.

Signs or symptoms in older children, rare as they are, may include a red eye, decreased vision, unequal pupils, ocular pain, and headaches and should prompt an urgent eye examination. Most cases of uveitis are bilateral (70% to 80%); unilateral disease may progress to bilateral involvement.

Data compiled before widespread therapy with methotrexate and tumor necrosis factor blockers indicated that the prognosis was good in 25% of cases, and 25% of children responded poorly to treatment and/or might require surgery for cataracts or glaucoma.[3] Approximately 50% of patients required prolonged treatment for moderate to severe chronic inflammation; the visual prognosis in these patients remained guarded. Early and aggressive treatment of intraocular inflammation has helped to reduce the morbidity of the ocular disease.[19]

FREQUENCY OF OPHTHALMOLOGIC EXAMINATIONS IN CHILDREN WITH JRA

The suggested frequency of ophthalmologic visits for children with JRA without known uveitis at diagnosis and during follow-up is presented in Table 1. Once uveitis is diagnosed, the pediatric ophthalmologist will determine the frequency of examinations on the basis of response to therapy and complications. Because a substantial number of patients may have the eye disease before or shortly after their arthritis is diagnosed, they should have their initial eye examination within 1 month of the diagnosis of arthritis rather than waiting for the first available appointment.

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Nancy Kellogg, MD; and the Committee on Child Abuse and Neglect

Oral and Dental Aspects of Child Abuse and Neglect

ABSTRACT. In all 50 states, physicians and dentists are required to report suspected cases of abuse and neglect to social service or law enforcement agencies. The purpose of this report is to review the oral and dental aspects of physical and sexual abuse and dental neglect and the role of physicians and dentists in evaluating such conditions. This report addresses the evaluation of bite marks as well as perioral and intraoral injuries, infections, and diseases that may cause suspicion for child abuse or neglect. Physicians receive minimal training in oral health and dental injury and disease and, thus, may not detect dental aspects of abuse or neglect as readily as they do child abuse and neglect involving other areas of the body. Therefore, physicians and dentists are encouraged to collaborate to increase the prevention, detection, and treatment of these conditions. ***Pediatrics*** **2005;116: 1565–1568;** ***bite marks, sexual abuse, physical abuse, dental neglect.***

ABBREVIATION. ABFO, American Board of Forensic Odontology.

PHYSICAL ABUSE

Craniofacial, head, face, and neck injuries occur in more than half of the cases of child abuse.[1–10] A careful and thorough intraoral and perioral examination is necessary in all cases of suspected abuse and neglect. In addition, all suspected victims of abuse or neglect, including children in state custody or foster care, should be examined carefully not only for signs of oral trauma but also for caries, gingivitis, and other oral health problems. Some authorities believe that the oral cavity may be a central focus for physical abuse because of its significance in communication and nutrition.[11] Oral injuries may be inflicted with instruments such as eating utensils or a bottle during forced feedings; hands; fingers; or scalding liquids or caustic substances. The abuse may result in contusions, burns, or lacerations of the tongue, lips, buccal mucosa, palate (soft and hard), gingiva alveolar mucosa, or frenum; fractured, displaced, or avulsed teeth; or facial bone and jaw fractures. In 1 study,[12] the lips were the most common site for inflicted oral injuries (54%), followed by the oral mucosa, teeth, gingiva, and tongue. Discolored teeth, indicating pulpal necrosis, may result from previous trauma.[13,14] Gags applied to the mouth may result in bruises, lichenification, or scarring at the corners of the mouth.[15] Some serious injuries of the oral cavity, including posterior pharyngeal injuries and retropharyngeal abscesses, may be inflicted by caregivers with factitious disorder by proxy[16] to simulate hemoptysis or other symptoms requiring medical care; regardless of caregiver motive, all inflicted injuries should be reported for investigation. Unintentional or accidental injuries to the mouth are common and must be distinguished from abuse by judging whether the history, including the timing and mechanism of injury, is consistent with the characteristics of the injury and the child's developmental capabilities. Multiple injuries, injuries in different stages of healing, or a discrepant history should arouse a suspicion of abuse. Consultation with or referral to a knowledgeable dentist may be helpful.

SEXUAL ABUSE

Although the oral cavity is a frequent site of sexual abuse in children,[17] visible oral injuries or infections are rare. When oral-genital contact is suspected, referral to specialized clinical settings equipped to conduct comprehensive examinations is recommended. The American Academy of Pediatrics statement "Guidelines in the Evaluation of Sexual Abuse of Children"[18] provides information regarding these examinations.

Oral and perioral gonorrhea in prepubertal children, diagnosed with appropriate culture techniques and confirmatory testing, is pathognomonic of sexual abuse[19] but rare among prepubertal girls who are evaluated for sexual abuse.[20] Pharyngeal gonorrhea is frequently asymptomatic.[21] When oral-genital contact is confirmed by history or examination findings, universal testing for sexually transmitted diseases within the oral cavity is controversial; the clinician should consider risk factors (eg, chronic abuse, perpetrator with a known sexually transmitted disease) and the child's clinical presentation in deciding whether to conduct such testing. Although human papillomavirus infection may result in oral or perioral warts, the mode of transmission remains uncertain and debatable. Human papillomavirus infections may be transmitted sexually through oral-genital contact, vertically from mother to infant during birth, or horizontally through nonsexual con-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

doi:10.1542/peds.2005-2315

tact from a child or caregiver's hand to the genitals or mouth.[22] Unexplained injury or petechiae of the palate, particularly at the junction of the hard and soft palate, may be evidence of forced oral sex.[23] As with all suspected child abuse or neglect, when sexual abuse is suspected or diagnosed in a child, the case must be reported to child protective services and/or law enforcement agencies for investigation.[24–27] A multidisciplinary child abuse evaluation for the child and family should be initiated.

Children who present acutely with a recent history of sexual abuse may require specialized forensic testing for semen and other foreign materials resulting from assault. If a victim provides a history for oral-penile contact, the buccal mucosa and tongue can be swabbed with a sterile cotton-tipped applicator, then the swab can be air dried and packaged appropriately for laboratory analysis. However, specialized hospitals and clinics equipped with protocols and experienced personnel are best suited for collecting such material and maintaining a chain of evidence necessary for investigations.

BITE MARKS

Acute or healed bite marks may indicate abuse. Dentists trained as forensic odontologists can assist physicians in the detection and evaluation of bite marks related to physical and sexual abuse.[28] Bite marks should be suspected when ecchymoses, abrasions, or lacerations are found in an elliptical or ovoid pattern. Bite marks may have a central area of ecchymoses (contusions) caused by 2 possible phenomena: (1) positive pressure from the closing of the teeth with disruption of small vessels or (2) negative pressure caused by suction and tongue thrusting. Bites produced by dogs and other carnivorous animals tend to tear flesh, whereas human bites compress flesh and can cause abrasions, contusions, and lacerations but rarely avulsions of tissue. An intercanine distance (ie, the linear distance between the central point of the cuspid tips) measuring more than 3.0 cm is suspicious for an adult human bite. [29]

The pattern, size, contour, and color of the bite mark should be evaluated by a forensic odontologist or a forensic pathologist if an odontologist is not available. If neither specialist is available, a physician or dentist experienced in the patterns of child abuse injuries should observe and document the bite-mark characteristics photographically with an identification tag and scale marker (eg, ruler) in the photograph. The photograph should be taken such that the angle of the camera lens is directly over the bite and perpendicular to the plane of the bite to avoid distortion. A special photographic scale was developed by the American Board of Forensic Odontology (ABFO) for this purpose as well as for documenting other patterned injuries and can be obtained from the vendor (ABFO No. 2 reference scale, available from Lightening Powder Co, Inc, 1230 Hoyt St SE, Salem, OR 97302-2121). Names and contact information for ABFO-certified odontologists can be obtained from the ABFO Web site (www.abfo.org). In addition to photographic evidence, every bite mark that shows indentations should have a polyvinyl siloxane impression made immediately after swabbing the bite mark for secretions containing DNA. This impression will help provide a three-dimensional model of the bite mark. Written observations and photographs should be repeated daily for at least 3 days to document the evolution of the bite. Because each person has a characteristic bite pattern, a forensic odontologist may be able to match dental models (casts) of a suspected abuser's teeth with impressions or photographs of the bite.

Blood-group substances can be secreted in saliva. DNA is present in epithelial cells from the mouth and may be deposited in bites. Even if saliva and cells have dried, they should be collected by using the double-swab technique. First, a sterile cotton swab moistened with distilled water is used to wipe the area in question, dried, and placed in a specimen tube. A second sterile, dry cotton swab cleans the same area and then is dried and placed in a specimen tube. A third control sample should be obtained from an uninvolved area of the child's skin. All samples should be sent to a certified forensic laboratory for prompt analysis.[30] The chain of custody must be maintained on all samples submitted for forensic analysis. Questions regarding evidentiary procedure should be directed to a law enforcement agency.

DENTAL NEGLECT

Dental neglect, as defined by the American Academy of Pediatric Dentistry, is the "willful failure of parent or guardian to seek and follow through with treatment necessary to ensure a level of oral health essential for adequate function and freedom from pain and infection."[31] Dental caries, periodontal diseases, and other oral conditions, if left untreated, can lead to pain, infection, and loss of function. These undesirable outcomes can adversely affect learning, communication, nutrition, and other activities necessary for normal growth and development.[32] Some children who first present for dental care have severe early childhood caries (formerly termed "infant bottle" or "nursing" caries); caregivers with adequate knowledge and willful failure to seek care must be differentiated from caregivers without knowledge or awareness of their child's need for dental care in determining the need to report such cases to child protective services.

Failure to seek or obtain proper dental care may result from factors such as family isolation, lack of finances, parental ignorance, or lack of perceived value of oral health.[33] The point at which to consider a parent negligent and to begin intervention occurs after the parent has been properly alerted by a health care professional about the nature and extent of the child's condition, the specific treatment needed, and the mechanism of accessing that treatment.[33] Because many families face challenges in their attempts to access dental care or insurance for their children, the clinician should determine if dental services are readily available and accessible to the child when considering whether negligence has occurred.

The physician or dentist should be certain that the caregivers understand the explanation of the disease and its implications and, when barriers to the needed

care exist, attempt to assist the families in finding financial aid, transportation, or public facilities for needed services. Parents should be reassured that appropriate analgesic and anesthetic procedures will be used to ensure the child's comfort during dental procedures. If, despite these efforts, the parents fail to obtain therapy, the case should be reported to the appropriate child protective services agency.[31,33]

CONCLUSIONS

Pediatricians should be aware that physical or sexual abuse may result in oral or dental injuries or conditions that sometimes can be confirmed by laboratory findings. Furthermore, injuries inflicted by one's mouth or teeth may leave clues regarding the timing and nature of the injury as well as the identity of the perpetrator. Pediatricians are encouraged to be knowledgeable about such findings and their significance and to meticulously observe and document them. When questions arise or when consultation is needed, a pediatric dentist or a dentist with formal training in forensic odontology can ensure appropriate testing, diagnosis, and treatment.

Pediatric dentists and oral and maxillofacial surgeons, whose advanced education programs include a mandated child abuse curriculum, can provide valuable information and assistance to physicians about oral and dental aspects of child abuse and neglect. The Prevent Abuse and Neglect Through Dental Awareness (also known as PANDA; telephone: 501-661-2595; e-mail: lmouden@healthyarkansas.com) coalition, which has trained thousands of physicians, nurses, teachers, child care providers, dentists, and dental auxiliaries, is another resource for physicians seeking information on this issue. Physician members of multidisciplinary child abuse and neglect teams are encouraged to identify such dentists in their communities to serve as consultants for these teams. In addition, physicians with experience or expertise in child abuse and neglect can make themselves available to dentists and dental organizations as consultants and educators. Such efforts will strengthen our ability to prevent and detect child abuse and neglect and enhance our ability to care for and protect children.

Oral Health Risk Assessment Timing and Establishment of the Dental Home

ABSTRACT. Early childhood dental caries has been reported by the Centers for Disease Control and Prevention to be perhaps the most prevalent infectious disease of our nation's children. Early childhood dental caries occurs in all racial and socioeconomic groups; however, it tends to be more prevalent in low-income children, in whom it occurs in epidemic proportions. Dental caries results from an overgrowth of specific organisms that are a part of normally occurring human flora. Human dental flora is site specific, and an infant is not colonized until the eruption of the primary dentition at approximately 6 to 30 months of age. The most likely source of inoculation of an infant's dental flora is the mother or another intimate care provider, through shared utensils, etc. Decreasing the level of cariogenic organisms in the mother's dental flora at the time of colonization can significantly impact the child's predisposition to caries. To prevent caries in children, high-risk individuals must be identified at an early age (preferably high-risk mothers during prenatal care), and aggressive strategies should be adopted, including anticipatory guidance, behavior modifications (oral hygiene and feeding practices), and establishment of a dental home by 1 year of age for children deemed at risk.

INTRODUCTION

The Centers for Disease Control and Prevention reports that dental caries is perhaps the most prevalent of infectious diseases in our nation's children. Dental caries is 5 times more common than asthma and 7 times more common than hay fever in children.[1] More than 40% of children have tooth decay by the time they reach kindergarten.[2] Infants who are of low socioeconomic status, whose mothers have a low education level, and who consume sugary foods are 32 times more likely to have caries at the age of 3 years than children in whom those risk factors are not present.[3] Decay of primary teeth can affect children's growth, lead to malocclusion, and result in significant pain and potentially life-threatening swelling. Because pediatricians and other pediatric health care professionals are far more likely to encounter new mothers and infants than are dentists, it is essential that they be aware of the infectious pathophysiology and associated risk factors of early childhood dental caries to make appropriate decisions regarding timely and effective intervention. Dental decay can be well advanced by 3 years of age.

BACKGROUND

Dental caries results from an overgrowth of specific organisms that are part of normally occurring human dental flora.[4] *Streptococcus mutans* and *Lactobacillus* species are considered to be principal indicator organisms of those of aciduric bacteria responsible for caries. Human dental flora is site specific, and an infant is not colonized with normal dental flora until the eruption of the primary dentition at approximately 6 to 30 months of age.[5,6] The vertical colonization of *S mutans* from mother to infant is well documented.[7,8] In fact, genotypes of *S mutans* in infants appear identical to those present in mothers in approximately 71% of mother-infant pairs.[9] Furthermore, evidence suggests that specific organisms exhibit discrete windows of inoculation; the acquisition of *S mutans* occurs at an average age of approximately 2 years.[10]

The significance of this information becomes focused when considering 3 points. First, high caries rates run in families[11] and are passed from mother to child from generation to generation. The children of mothers with high caries rates are at a higher risk of decay.[12] Second, approximately 70% of all dental caries are found in 20% of our nation's children.[13] Third, the modification of the mother's dental flora at the time of the infant's colonization can significantly impact the child's caries rate.[14–16] Therefore, an oral health risk assessment before 1 year of age affords the opportunity to identify high-risk patients and to provide timely referral and intervention for the child and allows an invaluable opportunity to decrease the level of cariogenic organisms in the mother with a significant caries risk before and during colonization of the infant.

BASIC PREVENTIVE STRATEGIES

Historically, the approach to preventing the development of dental caries has been to establish and maintain good oral hygiene, optimize systemic and topical fluoride exposure, and eliminate prolonged exposure to simple sugars in the diet. The success of this age-old approach is also the foundation for the ideal standard of establishment of the dental home

by 1 year of age, as endorsed by the American Dental Association, the American Academy of Pediatric Dentistry, supporting organizations of Bright Futures, and numerous other children's health organizations.

Dental caries typically results from diet-mediated shifts in dental bacterial populations that favor acidogenic-aciduric (cariogenic) organisms.[17] The judicious optimization of diet, fluoride intake, and hygiene reverses the aciduric shift, resulting in fewer cariogenic flora and decreased rates of caries. Clinical observations suggest that aciduric shifts are often associated with pregnancy, with return to prepregnancy cariogenic-benign flora ratio occurring on the same timeline as the colonization of the infant with dental flora (6 to 30 months of age). The overall strategy is to lower the numbers of cariogenic bacteria in the mother's mouth and delay colonization as long as possible (avoid sharing of spoons, orally cleansing pacifiers, etc).

Tooth decay is a disease that is, by and large, preventable. Because of how it is caused and when it begins, however, steps to prevent it ideally should begin prenatally with pregnant women and continue with the mother and young child, beginning when the infant is approximately 6 months of age. The primary thrust of early risk assessment is to screen for parent-infant groups who are at risk of early childhood dental caries and would benefit from early aggressive intervention. The ultimate goal of early assessment is the timely delivery of educational information to populations at high risk of caries to avoid the need for later surgical intervention.

ORAL HEALTH RISK ASSESSMENT

Every child should begin to receive oral health risk assessments by 6 months of age by a qualified pediatrician or a qualified pediatric health care professional. The Caries Risk Assessment Tool (provided and continually updated by the American Academy of Pediatric Dentistry and available at http://www.aapd.org/members/referencemanual/pdfs/02-03/Caries%20Risk%20Assess.pdf) can be used to determine the relative risk of caries of the patient. In the case of the very young patient, a risk assessment to identify parents (usually mothers) and infants with a high predisposition to caries can easily be performed by taking a simple dental history from a new mother. Questions directed at dietary practices, fluoride exposure, oral hygiene, utilization of dental services, and the number and location of the mother's dental fillings can give a relative indication of the mother's baseline decay potential. Frequent sugar intake, low fluoride exposure, poor oral hygiene practices, infrequent utilization of dental services and/or active decay and/or multiple dental fillings in multiple quadrants of the mouth indicates a high caries risk in the mother. Because the dental history of the mother has a direct correlation to that of her infant, it is justifiable and appropriate for the pediatrician to garner permission to examine the mother's dentition and gingival tissues. Additionally, clinical observations suggest that second and third infants tend to be colonized earlier, when the mother's cariogenic flora is at a higher level. Therefore, the later-order offspring of a mother with mildly to moderately high caries rate may be at higher risk of caries than are offspring born earlier. Unfortunately, the lack of accessible longitudinal dental databases has not yet allowed these observations to be epidemiologically confirmed.

RISK GROUPS FOR DENTAL CARIES

The caries risk potential of an infant can be determined by the use of the Caries Risk Assessment Tool. However, even the most judiciously designed and implemented caries risk assessment tool can fail to identify all infants at risk of early childhood dental caries. If an infant is assessed to be within 1 of the following risk groups, the care requirements would be significant and surgically invasive; therefore, these infants should be referred to a dentist as early as 6 months of age and no later than 6 months after the first tooth erupts or 12 months of age (whichever comes first) for establishment of a dental home:

- Children with special health care needs
- Children of mothers with a high caries rate
- Children with demonstrable caries, plaque, demineralization, and/or staining
- Children who sleep with a bottle or breastfeed throughout the night
- Later-order offspring
- Children in families of low socioeconomic status

Despite all efforts to predict children at high risk of caries, patients can and do fall outside statistical expectations. In these cases, the mother may not be the colonization source of the child's dental flora, the dietary intake of simple carbohydrates may be extremely high, or other uncontrollable factors may combine to place the patient at risk of caries. Therefore, screening for risk of caries in the parent and patient coupled with oral health counseling, although a feasible and equitable approach to early childhood caries control, is not a substitute for early establishment of the dental home. Whenever possible, the ideal approach to early childhood caries prevention and management is the early establishment of a dental home.

ESTABLISHING THE DENTAL HOME

The concept of the "dental home" is derived from the American Academy of Pediatrics concept of the "medical home." The American Academy of Pediatrics states, "the medical care of infants, children, and adolescents ideally should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. It should be delivered or directed by well-trained physicians who provide primary care and help to manage and facilitate essentially all aspects of pediatric care."[18] Pediatric primary dental care needs to be delivered in a similar manner. The dental home is a specialized primary dental care provider within the philosophical complex of the medical home. Referring a child for an oral health examination by a dentist who provides care for infants and young children

6 months after the first tooth erupts or by 12 months of age establishes the child's dental home and provides an opportunity to implement preventive dental health habits that meet each child's unique needs and keep the child free from dental or oral disease. The dental home should be expected to provide:

- An accurate risk assessment for dental diseases and conditions
- An individualized preventive dental health program based on the risk assessment
- Anticipatory guidance about growth and development issues (ie, teething, digit or pacifier habits, and feeding practices)
- A plan for emergency dental trauma
- Information about proper care of the child's teeth and gingival tissues
- Information regarding proper nutrition and dietary practices
- Comprehensive dental care in accordance with accepted guidelines and periodicity schedules for pediatric dental health
- Referrals to other dental specialists, such as endodontists, oral surgeons, orthodontists, and periodontists, when care cannot be provided directly within the dental home

ANTICIPATORY GUIDANCE AND PARENT AND PATIENT EDUCATION

General anticipatory guidance for the mother (or other intimate caregiver) before and during the colonization process should include the following:

- Oral hygiene—the parent should be instructed to brush thoroughly twice daily (morning and evening) and to floss at least once every day.
- Diet—the parent should be instructed to consume fruit juices only at meals and to avoid all carbonated beverages during the first 30 months of the infant's life.
- Fluoride—the parent should be instructed to use a fluoride toothpaste approved by the American Dental Association and rinse every night with an alcohol-free over-the-counter mouth rinse with 0.05% sodium fluoride.
- Caries removal—parents should be referred to a dentist for an examination and restoration of all active decay as soon as feasible.
- Delay of colonization—mothers should be educated to prevent early colonization of dental flora in their infants by avoiding sharing of utensils (ie, shared spoons, cleaning a dropped pacifier with their saliva, etc).
- Xylitol chewing gums—recent evidence suggests that the use of xylitol chewing gum (4 pieces per day by mother) had a significant impact on decreasing the child's caries rates.[16]

General anticipatory guidance for the young patient (0 to 3 years of age) should include the following:

- Oral hygiene—the parent should begin to brush the child's teeth as soon as they erupt (twice daily, morning and evening) and floss between the child's teeth once every day as soon as teeth contact one another.
- Diet—after the eruption of the first teeth, the parent should provide fruit juices (not to exceed 1 cup per day) during meals only. Carbonated beverages should be excluded from the child's diet. Infants should not be placed in bed with a bottle containing anything other than water. Ideally, infants should have their mouths cleansed with a damp cloth after feedings.
- Fluoride—all children should have optimal exposure to topical and systemic fluoride. Caution should be exercised in the administration of all fluoride-containing products. The specific considerations of the judicious administration of fluoride should be reviewed and tailored to the unique needs of each patient. Review articles with applicable fluoride recommendations and supplementation algorithms are available.[19–22]

RECOMMENDATIONS

1. Early childhood caries is an infectious and preventable disease that is vertically transmitted from mothers or other intimate caregivers to infants. All health care professionals who serve mothers and infants should integrate parent and caregiver education into their practices that instruct effective methods of prevention of early childhood caries.
2. The infectious and transmissible nature of bacteria that cause early childhood caries and methods of oral health risk assessment, anticipatory guidance, and early intervention should be included in the curriculum of all pediatric medical residency programs and postgraduate continuing medical education curricula at an appropriate time.
3. Every child should begin to receive oral health risk assessments by 6 months of age from a pediatrician or a qualified pediatric health care professional.
4. Pediatricians, family practitioners, and pediatric nurse practitioners and physician assistants should be trained to perform an oral health risk assessment on all children beginning by 6 months of age to identify known risk factors for early childhood dental caries.
5. Infants identified as having significant risk of caries or assessed to be within 1 of the risk groups listed in this statement should be entered into an aggressive anticipatory guidance and intervention program provided by a dentist between 6 and 12 months of age.
6. Pediatricians should support the concept of the identification of a dental home as an ideal for all children in the early toddler years.

SUMMARY

Early childhood dental caries emerges within all cultural and economic pediatric populations; however, it approaches near epidemic proportions in populations with low socioeconomic status. Dental caries is an infectious disease usually passed from mother to child from generation to generation. Judicious optimization of diet, fluoride intake, and hy-

giene can decrease bacterial levels of specific organisms responsible for dental caries residing within normal dental flora. Decreasing the levels of cariogenic flora in the mother before and during the colonization process coupled with counseling directed toward optimal practices of diet, oral hygiene, and fluoride exposure can significantly and positively impact the child's predisposition to early childhood caries.

Pediatricians and pediatric health care professionals should develop the knowledge base to perform oral health risk assessments on all patients beginning at 6 months of age. Patients who have been determined to be at risk of development of dental caries or who fall into recognized risk groups should be directed to establish a dental home 6 months after the first tooth erupts or by 1 year of age (whichever comes first).

The ideal deterrence to early childhood caries is the establishment of the dental home when indicated by the unique needs of the child. Although not always feasible because of manpower and participation issues, best practice dictates that whenever feasible, all patients should have a comprehensive dental examination by a dentist in the early toddler years.

Organized Sports for Children and Preadolescents

ABSTRACT. Participation in organized sports provides an opportunity for young people to increase their physical activity and develop physical and social skills. However, when the demands and expectations of organized sports exceed the maturation and readiness of the participant, the positive aspects of participation can be negated. The nature of parental or adult involvement can also influence the degree to which participation in organized sports is a positive experience for preadolescents. This updates a previous policy statement on athletics for preadolescents and incorporates guidelines for sports participation for preschool children. Recommendations are offered on how pediatricians can help determine a child's readiness to participate, how risks can be minimized, and how child-oriented goals can be maximized.

INTRODUCTION

Participation in organized sports can have physical and social benefits for children. However, the younger the participant, the greater the concern about safety and benefits. The involvement of preadolescents in organized sports is a relatively recent phenomenon. In the early 20th century, physical activity was a more regular part of life for the average child. Sports and games provided an additional outlet for physical activity and were characterized by play that was generally spontaneous, unstructured, and without adult involvement. Participation in such sports and games allowed for development of motor skills, social interaction, creativity, and enjoyment for participants.

During the latter part of the 20th century, "free play" or unstructured games primarily gave way to organized sports. The starting age for organized sports programs has also evolved to the point that infant and preschool training programs are now available for many sports. Organization of sports has potential benefits of coaching, supervision, safety rules, and proper equipment but can also create demands and expectations that exceed the readiness and capabilities of young participants. Organization can also shift the focus to goals that are not necessarily child oriented. Clearly, the nature of the organization can determine if it has a positive or negative influence.

This statement is an update to a previous policy statement on athletics for preadolescents[1] and incorporates guidelines for sports participation for preschool children.[2] Recommendations are made on how pediatricians can help determine a child's readiness to participate in organized sports, how risks can be minimized, and how child-oriented goals can be maximized.

ORGANIZED SPORTS PROGRAMS: LIMITATIONS AND RISKS

The effects of organized sports participation on growth and maturation have come under question, as have the effects of growth and maturation on the ability to participate in sports. Because children are beginning to train and compete at earlier ages, there is increasing concern about potential negative effects on growth and maturation. Reports of gymnasts and divers with short stature or ballet dancers with lean body types or late menarche have contributed to such concerns. Despite such reports, it is unclear if these characteristics were a result of intensive training or other factors, such as dietary practices, psychological and emotional stress, or selection bias for the sport.[3]

The effects of immaturity on sports participation are more obvious. When the demands of a sport exceed a child's cognitive and physical development, the child may develop feelings of failure and frustration. Even with coaches available to teach rules and skills of a sport, children may not be ready to learn or understand what is being taught. Furthermore, many coaches are not equipped to deal with the needs or abilities of children. Basic motor skills, such as throwing, catching, kicking, and hitting a ball, do not develop sooner simply as a result of introducing them to children at an earlier age.[4] Teaching or expecting these skills to develop before children are developmentally ready is more likely to cause frustration than long-term success in the sport.[5] Because most youth sports coaches are volunteers with little or no formal training in child development, they cannot be expected to correctly match demands of a sport with a child's readiness to participate. Educational programs are available for youth sports coaches, but most coaches do not participate. Nonetheless, coaches may still try to teach what often cannot be learned and blame resulting failures on shortcomings of athletes or themselves.

Parental or adult supervision of children's activity is usually considered to be desirable. However, in organized sports, inappropriate or overzealous parental or adult influences can have negative effects. Adults' involvement in children's sports activities may bring goals or outcome measures that are not oriented toward young participants. Tournaments, all-star teams, most valuable player awards, tro-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

phies, and awards banquets are by-products of adult influences. Despite good intentions, increased involvement of adults does not necessarily enhance the child athlete's enjoyment. The familiar image of a parent imploring their 5-year-old to "catch the ball," "kick the ball," or "run faster" is a reminder of how adult encouragement can have discouraging effects.

ORGANIZED SPORTS PROGRAMS: BENEFITS

In contrast to unstructured or free play, participation in organized sports provides a greater opportunity to develop rules specifically designed for health and safety. Organization can allow for the establishment of developmentally sound criteria for determining readiness to play. Organization can also allow for a fair process in choosing teams,[6] matching competitors,[7] and enforcing rules. Rules specifically targeted at younger athletes can reduce injuries. Recommendations have been made to limit dangerous practices, such as headfirst sliding in baseball[8] and body checking in hockey.[9] Safety accommodations associated with organized youth sports can also include smaller playing fields, shorter contest times, pitch counts for Little League pitchers, softer baseballs, matching opponents by weight in youth football, and adjusting play for extreme climatic conditions.[10] The availability of qualified coaches in organized sports can be a key factor in providing safety and a positive experience.

In this regard, the effects of organization provide positive environments for young participants. Unfortunately, not all youth sports participants have access to all known safety measures. Furthermore, a great deal remains to be learned about safety in youth sports. Additional resources are needed to study injury prevention and ensure that all participants will benefit from existing safety measures. The prospects for additional development and implementation of safety measures are far greater for organized sports than for unstructured free play.

Despite many potential benefits of organization, there is no consensus as to the overall value of organized sports for preadolescents. A return to the days of free play has been suggested as one means to eliminate negative aspects of organized sports. Unfortunately, the days when children had the time, opportunity, or inclination to play in neighborhoods or local parks have passed. Today, there are more demands on a young person's time, more options for free time, diminished requirements for regular physical activity, and fewer opportunities for free play. School-based physical education programs have also been reduced throughout the years and can no longer be relied on to provide adequate levels of healthy activity.[11]

Regular physical activity can help reduce the risk of many adult health problems, including diabetes, obesity, and heart disease.[12] However, with less time dedicated to free play and school physical education programs, the result may be lower activity levels and lower levels of fitness for children. There is a greater need to protect opportunities for structured and unstructured physical activity for children. Organized sports may not provide all physical activity needs but can be a viable means to increase activity levels in children and, hopefully, lead to the adoption of active lifestyles as adults.

Organized Sports Programs: Optimizing the Benefit-to-Risk Ratio

If organized sports are going to be safe, healthy, and beneficial for children and preadolescents, there must be reasonable goals for participation and appropriate strategies to attain these goals. Reasonable goals for children and preadolescents participating in organized sports include acquisition of basic motor skills, increasing physical activity levels, learning social skills necessary to work as a team, learning good sportsmanship, and having fun.[13]

Organized sports sessions should be tailored to match the developmental level of participants. Most preschool children have short attention spans and are easily distracted; therefore, exercise sessions should be short and emphasize playfulness, experimentation, and exploration of a wide variety of movement experiences. A reasonable format would consist of no longer than 15 to 20 minutes of structured activity combined with 30 minutes of free play. Concentration will be maximized if instructional sessions take place in a setting with minimal distraction. Instructing younger children using a show-and-tell format with physical demonstration may be more effective than with verbal instruction.

For children and preadolescents, factors such as fun, success, variety, freedom, family participation, peer support, and enthusiastic leadership encourage and maintain participation, whereas others such as failure, embarrassment, competition, boredom, regimentation, and injuries discourage subsequent participation.[14]

Pediatricians, as experts in child development, can help parents and coaches determine readiness of a child to participate in organized sports. Readiness is often defined relative to the demands of the sport. Because different sports and even the same sport may vary widely with respect to demands and expectations, pediatricians must understand these demands to help determine if they are appropriate for the physical and cognitive maturation of participants. Preparticipation examinations are typically not mandated until junior high and high school. However, annual examinations for younger children afford an opportunity to promote physical activity and address issues of readiness as they apply to organized sports.

Pediatricians can further advocate safe sports participation by promoting better education and training of youth sports coaches. Standards for coaching competency are available, and certification for youth sports coaches should address these competencies.[15] In addition, pediatricians can work with sports administrators and coaches within their community to share relevant information on child development, injury assessment, first aid, and injury prevention. Pediatricians can also take an active role in developing safety programs while ensuring that existing safety measures are observed. A pediatrician may be

one of the few adults who can objectively determine when pressures and expectations of organized sports become excessive for any individual or group. Finally, pediatricians can serve as role models for appropriate sideline behavior and can help parents and other adults remember the reasons children want to participate.

SUMMARY AND RECOMMENDATIONS

Organized sports for children and preadolescents provide an opportunity for increased physical activity and an opportunity to learn sports and team skills in an environment where risks of participation can potentially be controlled. Unfortunately, when demands and expectations of the sport exceed the maturation or readiness of the participant, benefits of participation are offset. The shift from child-oriented goals to adult-oriented goals can further negate positive aspects of organized sports.

To optimize the safety and benefits of organized sports for children and preadolescents and to preserve this valuable opportunity for young people to increase their physical activity levels, the American Academy of Pediatrics recommends the following:

1. Organized sports programs for preadolescents should complement, not replace, the regular physical activity that is a part of free play, child-organized games, recreational sports, and physical education programs in the schools. Regular physical activity should be encouraged for all children whether they participate in organized sports or not.
2. Pediatricians are encouraged to help assess developmental readiness and medical suitability for children and preadolescents to participate in organized sports and assist in matching a child's physical, social, and cognitive maturity with appropriate sports activities.
3. Pediatricians can take an active role in youth sports organizations by educating coaches about developmental and safety issues, monitoring the health and safety of children involved in organized sports, and advising committees on rules and safety.
4. Pediatricians are encouraged to take an active role in identifying and preserving goals of sports that best serve young athletes.
5. Additional research and resources are needed to:
   a. determine the optimal time for children to begin participating in organized sports;
   b. identify safe and effective training strategies for growing and developing athletes;
   c. educate youth sports coaches about unique needs and characteristics of young athletes; and
   d. develop effective injury prevention strategies.

Overcrowding Crisis in Our Nation's Emergency Departments: Is Our Safety Net Unraveling?

ABSTRACT. Emergency departments (EDs) are a vital component in our health care safety net, available 24 hours a day, 7 days a week, for all who require care. There has been a steady increase in the volume and acuity of patient visits to EDs, now with well over 100 million Americans (30 million children) receiving emergency care annually. This rise in ED utilization has effectively saturated the capacity of EDs and emergency medical services in many communities. The resulting phenomenon, commonly referred to as ED overcrowding, now threatens access to emergency services for those who need them the most. As managers of the pediatric medical home and advocates for children and optimal pediatric health care, there is a very important role for pediatricians and the American Academy of Pediatrics in guiding health policy decision-makers toward effective solutions that promote the medical home and timely access to emergency care. ***Pediatrics*** **2004;114:878–888;** ***access to emergency care, ambulance diversion, emergency medical services for children, EMTALA, emergency department overcrowding.***

INTRODUCTION

Much has been written about the use of emergency services. A prophetic 1958 study examining a significant increase in emergency department (ED) utilization suggested that physicians and hospitals should plan for the future by increasing the number of emergency facilities.[1] Since that time, the number of ED visits in the United States has increased more than 600%, with an estimated 108 million ED visits in 2000.[2] Thirty million of those ED visits were for children 0 to 18 years of age.[2]

Over the past 2 decades, there has been increasing concern about this dramatic growth in ED visits. During the mid-1980s and early 1990s, many health care policy analysts viewed these increases as evidence of overutilization of EDs, specifically for nonemergent problems.[3,4] Armed with data suggesting that care provided in the ED was more expensive and perhaps less effective, policy-makers and managed care organizations worked to limit patients' access to emergency care. This perception was perhaps best summarized in 1993 by President Clinton, who in a nationally televised speech to Congress and the nation referred to EDs as "the most expensive place of all" to get care.[5]

In the past decade, physicians and administrators responsible for the management of municipal emergency medical services (EMS) systems and hospital EDs have been voicing their concern regarding the capacity of their services. Their concern has been driven by an increasingly familiar phenomenon, overcrowding of EDs, which has worsened to the point of crisis in certain communities.[6–13] Surprisingly, this saturation of emergency services is not primarily a result of excessive, inappropriate use of the ED by those with nonemergent problems. It is a byproduct of increasing numbers of patients with serious illnesses or injuries requiring hospital and/or intensive care unit admission.[14,15] Evidence of the severity of the problem may be found in numerous articles in the lay press and in publications from the American College of Emergency Physicians (ACEP),[16–19] the Emergency Nurses Association,[20,21] and the American Hospital Association (AHA)[22–24] and in peer-reviewed journals such as *Academic Emergency Medicine*, which recently devoted an entire issue to this crisis and its related problems.[25] The US Senate has commissioned a study of ED overcrowding, as reported by the US General Accounting Office (GAO) in March 2003.[26] This problem has also garnered the attention of the Joint Commission on Accreditation of Healthcare Organizations, which developed a standard regarding overcrowding for publication in the *2004 Hospital Accreditation Manual*.[27]

So, how did this happen, what are the implications, and what can pediatric health care professionals do to help? ED overcrowding has evolved from a complex series of problems. An understanding of the key legislative, social, and health care economic factors that have led us to where we are today is warranted before considering potential solutions.

THE EMERGENCY MEDICAL TREATMENT AND ACTIVE LABOR ACT: THE UNDERFUNDED FEDERAL MANDATE FOR UNIVERSAL HEALTH CARE

The Emergency Medical Treatment and Active Labor Act (EMTALA) was enacted in 1985 as part of the

Consolidated Omnibus Budget Reconciliation Act. Its purpose was to protect the rights of indigent patients seeking emergency care.[28] The law was a response to the practice of patient "dumping," the refusal of a hospital (and/or hospital-based physicians) to provide emergency care for patients who could not pay for their care. This regulation requires all Medicare-participating hospitals to provide a medical screening examination (MSE) for all patients who present for care to the ED regardless of their ability to pay.[29–31]

Subsequent revisions, reinterpretation, and increased enforcement of this law over the past decade have expanded the reach of EMTALA, delineating the responsibility of hospitals, EDs, and their physicians to provide services to all patients who request them in a nondiscriminatory and consistent manner. The law specifies that the scope of the MSE should include all ancillary services routinely available to the ED, such as physician consultation and inpatient care, if required.[32] In the absence of a national universal health benefits program, hospital EDs are essentially the only place in our current health care system at which all patients are guaranteed medical care.[3,4,29,33]

Although clearly intended to promote the public good, EMTALA poses a profound economic challenge for hospitals and emergency care professionals, because this mandate for care does not carry with it a mandate for reimbursement for services rendered. Nationwide, EMTALA requirements are estimated to cost emergency care professionals more than $425 million annually.[17] Mitchell and Remmel[34] projected the financial impact of uncompensated emergency care in the state of Florida to reach an annual cost of $100 000 per emergency physician. This "free care" was estimated to be 5 times the amount provided by primary care physicians in that state. National data from 1998 suggest that the total direct expense for emergency physician services provided to uninsured patients approximated $1 billion.[17,35] Hospital facility costs for this same group of patients exceeded another $2 billion.[29,35] This incredible economic burden is exacerbated by insufficient Medicare reimbursement, which frequently fails to cover the direct costs of either the hospital facility or the emergency physician. In most states, services provided under Medicaid are reimbursed at 30% to 50% less than the same services provided under Medicare, creating an even greater funding gap for those providing care to our nation's 44.3 million Medicaid recipients.[36,37] It is little wonder that these financial stresses have resulted in the closure of nearly 500 hospitals and more than 1000 EDs over the past decade.[38]

More recently, the Centers for Medicare and Medicaid Services published a set of rule changes[39] that seem to be an effort at moving the law back toward its original intent as well as giving the courts clearer guidance for enforcement. The new rules clarify that a hospital must maintain an on-call physician list "that best meets the needs of the hospital's patients."[39] Physicians no longer have to be available all the time, but the hospital must have a written policy on how to deal with times when the on-call specialist is unavailable. Although this seems to be good news for rural and smaller hospitals and their medical staff members who have struggled to provide 24-hour coverage, this relaxation ultimately could contribute to a greater reliance on hospitals that suffer the most from overcrowding: large urban tertiary care centers, trauma centers, and academic medical centers.

Although EMTALA interpretation and enforcement has become increasingly punitive,[40,41] EMTALA is arguably more important today than when it was first enacted. With growing numbers of uninsured Americans, more physicians opting not to provide services to Medicaid and Medicare beneficiaries, and a failing public health and social welfare network, the ED has become one of the few reliable points of health care access in an unraveling safety net.[3,4,25,42–45]

THE EXPANDING ROLE OF THE ED IN A SHRINKING PUBLIC HEALTH SAFETY NET

Hospital EDs hold a very strategic position in the continuum of care in our society. Accessible and always open, the ED remains one of the few institutions available to aid all persons. Services are provided regardless of economic or social status and without an appointment. As previously noted, this societal responsibility has been both affirmed and mandated through federal legislation.

The importance of the ED's role has increased over the past decade as other public health and social care programs have eroded. Many people in need do not qualify for public support or are unable to take advantage of services to which they are entitled, including several million uninsured and underinsured children who could qualify for Medicaid or State Children's Health Insurance Program (SCHIP) benefits.[46,47] Disadvantaged Americans may pass through the entrance of an ED more than any other public institution. Some have suggested that this represents a remarkable opportunity for EDs to serve the needs of the disadvantaged by developing their full potential as social welfare institutions.[48–51]

In 2000, the Institute of Medicine (IOM) published a report titled *America's Health Care Safety Net: Intact but Endangered*.[52] The goal of the IOM was to "examine the impact of Medicaid managed care and other changes in health care coverage on the future viability of safety net providers operating primarily in ambulatory and primary care settings."[52] In its report, the IOM panel expressed grave concern for the current and future state of our nation's unraveling health care safety net and the vulnerable populations it serves. The report described several trends that seem to threaten the viability of safety net providers. These trends included inadequate monitoring of safety net viability and function, poor integration of services, financial instability of core safety net providers, and rapid shifts to Medicaid managed care.[44] Although this report did not specifically focus on the role played by EDs, it is clear that EDs meet the 2 defining characteristics of core safety net providers: 1) maintenance of an open-door policy, offering ser-

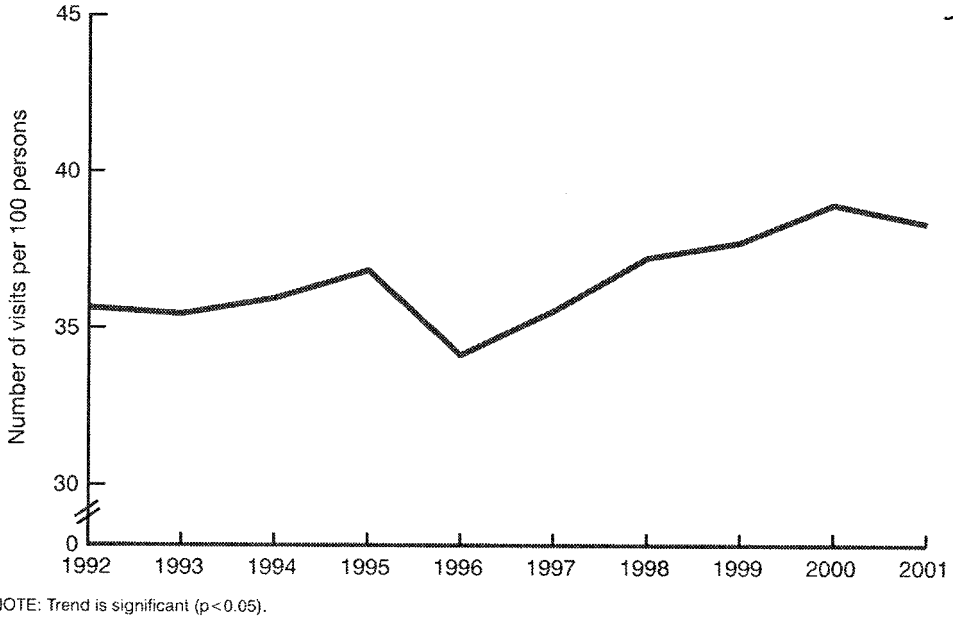

Fig. 1. Trend in ED visit rates: United States, 1992–2001. Source: McCaig LF, Burt CW. *National Hospital Ambulatory Medical Care Survey: 2001 Emergency Department Summary.* Hyattsville, MD: National Center for Health Statistics; 2003.

vices to patients regardless of their ability to pay; and 2) caring for a patient mix with a substantial share of Medicaid, uninsured, and other vulnerable populations.[52]

The number of uninsured Americans has grown steadily every year, even during the economic boom of the 1990s. In our nation of amazing wealth, there is also great poverty. There were approximately 43.6 million uninsured Americans in 2002, including 12.5 million children through 21 years of age. In fact, the proportion of the nonelderly American population (younger than 65 years) with health insurance coverage decreased in 2002 to a post-1987 low of 82.7%.[53] Although difficult to assess, there are between 4 and 13 million homeless persons in America.[54] More than 30% of children younger than 21 years (24.2 million) receive their health care benefits through the Medicaid program.[37] Although there are data showing that the Medicaid program has significantly improved the primary care access of impoverished children,[46,47,55,56] the program has fallen far short of creating equity between Medicaid beneficiaries and children living above the poverty line.[46,47,55–57]

An analysis of data from the 1988 National Health Interview Survey provides additional insight into the problem. Indigent children with Medicaid insurance were more likely to have a regular source of health care than those without Medicaid coverage. However, in comparison with children living above the poverty line, poor children with Medicaid were less likely to receive routine care in a physician's office, were more likely to lack continuity between their usual sources for sick and well care, and were more likely to identify hospital EDs as their preferred source for sick care.[46] In all, the survey determined that 6 million children lacked a usual source for primary care, and 12 million had not made a timely visit for preventive health care.[46] Although studies a decade later indicated significant improvement in access to care for Medicaid beneficiaries, these children are still less likely to have a consistent source of health care and are 3 times more likely to have unmet health needs than are nonpoor children with private insurance.[57,58] Recent studies by the GAO indicate that less than half of Medicaid and SCHIP recipients have received early and periodic screening, diagnosis, and treatment services and that most states are doing little to monitor the use of primary or preventive health care services in this vulnerable population.[59,60]

Complaint urgency aside, inadequate or inaccessible sources of primary care are frequently cited as the most common reason for use of emergency services.[61–66] Studies examining the use of EDs by children for routine sick care have found several key demographic risk factors for "excessive" ED use, including black versus white race, single versus 2-parent family, parent with less than high school education versus education at the high school level or greater, poor versus nonpoor, and urban versus suburban location.[67] Children who receive their usual care in a neighborhood health clinic seem to be twice as likely as private-office practice patients to seek care in the ED. Furthermore, the absence of readily available primary care physicians is significantly associated (twofold increase) with ED use.[67]

What remains unclear is the role that health insurance plays in the use of emergency services. Data for 1998 from the National Center for Health Statistics indicate different utilization rates for commercially insured (19.9 visits per 100 individuals), Medicaid (64.2 visits per 100 individuals), and uninsured (34.2 visits per 100 individuals) patient groups.[29,68] Viewed as a proportion of total ambulatory care utilization, data from the 2001 National Ambulatory Medical Care Survey indicate that ED visits represented 25% of all outpatient use by the uninsured versus 17.5% by Medicaid recipients and nearly 8% by those with private insurance.[69] Although it would

seem that Medicaid and uninsured patients are more likely to use the ED for acute episodic care, when one controls for confounding variables, this does not hold true.[70] Several studies have found that the lack of an established primary care relationship or the lack of accessible primary care services (not the lack of health insurance) are the primary risk factors for nonurgent ED visits.[61,67,71,72] In fact, it was the steady growth in the utilization of emergency services by privately insured patients that represented the largest segment of increased ED visits between 1996 and 2001 (Fig 1).[73]

A primary influence for the great attention and concern regarding ED utilization by these populations is the well-held perception of a relatively high cost for those services. Various studies have suggested cost differentials between ED care and the same care in a doctor's office to be between 50% and 100%.[3] Although charges are a poor reflection of true cost, the relative cost of ED care may be best understood through an analysis of marginal cost, or the cost of seeing 1 additional patient. In a study of 6 EDs in Michigan, Williams[35] found the marginal cost (the direct cost incurred from providing care for 1 additional patient) of an urgent ED visit to be $148, whereas for nonurgent visits, that cost was only $24, an amount likely less than the marginal cost associated with keeping a doctor's office open after regular office hours for nonurgent patient visits. In other words, EDs may be a cost-effective solution for certain components of after-hours ambulatory care.

DEFINING ED OVERCROWDING

Although the subjective assessment that a particular ED (or any public facility) is overcrowded may be inherently obvious to the average observer, objective and generalizable indicators of ED capacity and precise patient volume or acuity thresholds consistent with saturation of ED resources have proven to be difficult to define scientifically.[14] ED overcrowding is defined by the ACEP as a situation in which the identified need for emergency services outstrips available resources in the ED[16] (the Appendix contains a list of terms and metrics typically used in describing ED overcrowding and their definitions). In fact, part of the problem faced by those who manage emergency care systems is that there is not a universally held gold-standard definition for ED overcrowding.[43] Some have described overcrowding on the basis of excessive waiting times to see an ED physician or by treatment time delays in the ED. Others have based the definition on delays in the movement of admitted ED patients to inpatient beds. For some, the definition is based on the number of patients versus the number of available ED treatment stations (beds) or the forced use of nontreatment areas (eg, the ED hallway) to care for or hold ED patients. Others have attempted to define overcrowding on the basis of an assessment of patient acuity in the ED in relation to staffing resources. Finally, some link ED overcrowding to the need to divert incoming ambulance transports.[43]

Surveys of ED medical directors have identified a number of commonly held definitions for overcrowding, including patients placed in hallways, all ED beds occupied for more than 6 hours per day, a full ED waiting room for 6 hours or more per day, physicians feeling rushed for 6 hours or more per day, and acutely ill patients who wait more than 60 minutes to see a physician.[7,74] To better understand increasing demand for emergency services, pursue multicenter or regional research on overcrowding, and plan for future ED resource needs, some have proposed the use of standard formulas to assess ED capacity (Table 1).[75]

STUDIES ON ED UTILIZATION AND OVERCROWDING

ED overcrowding is an obvious, almost predictable symptom of steadily growing demand that has exceeded available resources. ED visits have increased nearly 20% over the past decade. In 1988, 5200 US hospitals had 86 million ED visits. A decade later, emergency care was provided for 103 million encounters, but by this time only 4700 hospital EDs provided emergency care.[17] Many EDs are experiencing significant increases in their patient volumes because of regional population growth, an increasing number of visits from uninsured and underinsured patients, and decreased access to primary care services. In general, the pace and extent of facility and personnel resource expansion in the remaining EDs has not kept up with patient volume and acuity increases.

As the prevalence and severity of the phenomenon has grown, so have the number of descriptive reports and studies attempting to assess overcrowding. A decade ago, only a small percentage (less than 10%) of ED directors, mostly those from urban public hospitals, reported concerns about overcrowding.[19] More recent studies find nearly all ED medical directors reporting at least periodic ED saturation, with a steadily increasing number of directors reporting it as a frequent problem.[7,8,10,12,16,22,26,74,76,77]

Derlet et al[7] conducted a national random survey of 575 ED directors in 1998–1999 regarding the definition and extent of ED overcrowding and factors associated with it. Ninety-one percent of the responding medical directors reported ED overcrowding, with 53% reporting overcrowding occurring several times a week and 39% stating that it was a daily

TABLE 1. Calculations to Assess ED Overcrowding[66]

Bed ratio (BR): the relationship between the number of ED patients and the number of treatment stations (beds) in the ED at any given time.
BR = (number of patients in ED + predicted arrivals − predicted departures)/ED beds
Acuity ratio (AR): a measure of total patient acuity in the ED at a given point in time
AR = sum of patient triage category/number of patients or sum of all triage scores/number of patients
Provider ratio (PR): the relationship between patient arrivals and ED physician staff, specifically the number of patients per hour (PPH) that each provider can manage
PR = arrivals per hour/the sum of PPH for each physician
Demand value (DV): an overall measure of ED demand, including bed capacity, total patient acuity, and provider resources
DV = (BR + PR) × AR

problem. Overcrowding problems were similar (more than 90%) in academic and private hospitals, although hospitals serving populations of greater than 250 000 had higher rates of overcrowding than did hospitals serving smaller populations (96% vs 87%). One third of the directors reported that patients had experienced poor outcomes as a result of overcrowding. Most frequently cited causes for overcrowding were high ED patient acuity, hospital bed shortage, high ED patient volume, ancillary service delays, and insufficient ED space.[7]

The AHA surveyed member hospitals regarding ED capacity and overcrowding in November 2001.[22] A total of 1500 hospitals responded. ED visit volume had grown by 5% over the previous year. Overall, 62% of respondents reported that they were either at or above the operating capacity of their ED, with 80% of teaching hospitals and urban hospitals and 90% of level I trauma centers experiencing this problem. One third of all hospitals experienced "ED diversion," with more than half of the urban hospitals reporting some time on diversion. One third of urban hospitals reported being on ambulance diversion at least 10% of the time, with 1 of 8 reporting time on diversion at 20% or greater. Lack of available, staffed critical care beds was the number one reason cited by hospitals for ED diversion.[22]

Lambe et al[76] conducted an analysis of the changes in California's hospital ED capacity between 1990 and 1999. Over the decade, the number of EDs in California decreased by 12%. The total number of ED treatment stations (ED beds) increased by 16%, but there was a 27% increase in visits per ED, with disproportionately greater volume increases in public versus private hospitals. In regard to patient acuity, critical care visits per ED increased by 59%, and nonurgent visits decreased by 8%.[76] The combination of volume and acuity increases was hypothesized to be the source of ED overcrowding. A 1999 survey of California ED medical directors found that 96% reported overcrowding as a problem, and 28% reported daily overcrowding.[74] The most frequently cited causes for overcrowding were increasing patient acuity and volume, hospital bed shortage, laboratory delays, and nursing shortage.

A 2001 survey of ED medical directors in the state of Washington revealed that 100% of large hospitals and 91% of small hospitals reporting overcrowding problems.[16] Frequent overcrowding (more than 3 times per week) was reported by 59% of large hospitals. On average, hospitals were on ambulance diversion 18 times per month, with an average time on diversion of 7.5 hours. The 3 most common reasons cited for overcrowding were volume overload, full hospital capacity, and nonphysician staff shortages.[16]

ED medical directors in Massachusetts were surveyed in 2000 regarding the causes of ambulance diversion.[77] Diversion was attributed most often to a lack of inpatient bed capacity and increased numbers of high-acuity patients in the ED. Nearly 90% reported facing a nursing shortage, which contributed to the problem. Seventy-two percent of the medical directors believed that patient care was compromised in some manner by overcrowding, and 21% reported adverse patient outcomes directly attributable to overcrowding.[77]

In response to numerous anecdotal reports in the news media, the Committee on Government Reform of the US House of Representatives commissioned a study on ambulance diversion in 2000. In their report, *National Preparedness: Ambulance Diversions Impede Access to Emergency Rooms*,[13] the committee found ambulance diversion impeding timely access to metropolitan emergency services in 22 states, affecting nearly 75 million Americans residing in those areas.[13]

The GAO, commissioned by the US Senate Committee on Finance to study ED overcrowding, conducted a national survey of more than 2000 hospital EDs in 2001.[26] Two of every 3 EDs reported diversion at some point during that year. ED overcrowding and diversion was reported to be more common by hospitals located in areas with larger populations or those with high rates of population growth and by hospitals in areas with higher-than-average proportions of people without health insurance. Overcrowding was also more prevalent at trauma centers and teaching hospitals. Although no single factor stood out as the primary reason for ED overcrowding, the factor most commonly associated with crowding was the inability to transfer existing ED patients to hospital inpatient beds. Ninety percent of the surveyed hospitals reported "boarding" of admitted patients in their ED, with nearly 50% indicating an average boarding time of 2 hours or longer. Inpatient beds in greatest demand were intensive care unit and other monitored beds.[26]

KEY FACTORS CONTRIBUTING TO ED OVERCROWDING

Although increasing demand and fewer EDs are part of the problem, as indicated in the GAO report, many experts feel that the primary source of ED overcrowding is the increasing difficulty that most EDs face in moving acutely ill "admitted" patients from ED beds to inpatient beds. Intense economic pressures over the past 2 decades have forced most hospitals to decrease inpatient care capacity, leaving many with an inadequate number of inpatient beds or insufficient qualified nursing staff to handle fluctuating levels of demand. According to the AHA, there were 1.36 million inpatient beds in 6933 hospitals in 1981, 927 000 staffed beds in 5370 hospitals in 1991, and 829 000 beds in 4956 hospitals in 1999.[78]

With nearly all hospitals running at a higher census, it has become more difficult to admit patients. This seems especially true for patients (including children) who require admission on an unscheduled or emergency basis and compete for a limited number of beds with scheduled inpatient procedures and semielective admissions.[26] Tertiary and critical care beds are particularly in short supply. With no other place to move seriously ill or injured patients in need of admission, EDs must hold these patients for increasingly greater periods of time until an inpatient bed is available. These admitted patients, commonly referred to as "ED boarders," require ongoing care, consuming already taxed ED resources. Boarders es-

sentially shrink the capacity of the ED and compromise its ability to provide timely care for incoming ambulance cases as well as acute patients who are still waiting to be seen. Although not conclusive, risk-management studies suggest that overcrowding and boarded inpatients pose considerable risk for medical errors.[43] ED overcrowding also has a deleterious effect on the teaching missions of academic medical centers, with more than 90% of teaching hospitals reporting overcrowding.[79]

Adding to the mismatch between a steadily growing patient demand and relatively fixed ED capacity is a shortage of qualified ED staff. Real shortages exist in the supply of residency-trained emergency physicians[80] and subspecialty-trained pediatric emergency physicians. The effects of new residency training rules and the reduction of trainee work hours on both hospital and ED capacity at teaching hospitals are yet to be appreciated. Among all the supply shortages in health care professional groups, the greatest deficiency is found within the ranks of registered nurses. Experienced ED nurses are truly the backbone of emergency care. Nationwide, there is a well-recognized deficiency of nurses, with vacancy rates in some states as high as 18%.[81] Annual turnover rates in high-stress practice settings such as EDs can be 30% or higher. Added to the dilemma of a small workforce is the fact that this workforce is aging steadily. The latest studies indicate an average age of 46 years for the nursing workforce, with only 9% of nurses now younger than 30 years of age, a 40% decrease from 1983 to 1998. One study projects a deficit of nearly 300 000 registered nurses by 2020.[82]

Another notable problem that threatens the viability of our emergency care system and the well-being of the patients it serves is a decreasing number of medical and surgical subspecialists who are willing or available to provide consultative backup to the ED.[83,84] A growing number of hospitals no longer have a "full panel" of on-call specialists who, because of the EMTALA mandate, are expected to provide consultative support to the ED. This problem has grown beyond small rural hospitals to affect large urban hospitals, including trauma centers. This problem will likely spread further in the wake of the November 2003 revisions to EMTALA that relax on-call physician requirements.

Global shortages in key medical subspecialties and surgical specialties and variations in geographic availability are both long-standing contributors to ED overcrowding, particularly for rural hospitals. More recently, 2 pressing issues are driving this growing deficiency. The first is a recent and alarming increase in professional liability insurance premiums. A recent American Medical Association study identified 44 of 50 states as having a current or impending liability crisis, with premiums for some subspecialists increasing as much as 25% to 50% annually.[85] Physicians who provide ED or trauma on-call services typically pay higher liability insurance premiums than those who do not. Many subspecialists have concluded that they can no longer afford to provide ED on-call services. The second issue is the increasing percentage of uninsured or underinsured ED patients and managed care barriers, all of which contribute to poor reimbursement for the mandated emergency services provided by these on-call specialists.

Numerous other factors have contributed to the overcrowding crisis (Table 2). Although some problems are internal to the ED, most are not. Insufficient access to primary and subspecialty care services and barriers to follow-up care each contribute significantly to the problem. The ED has been characterized by some as the proverbial "canary in the coal mine," with ED overcrowding representing a warning sign of growing distress within hospital and primary care delivery systems and a fraying health care safety net.

DELETERIOUS EFFECTS OF ED OVERCROWDING

Overcrowding of EDs produces a series of negative effects. First and foremost is that overcrowding places all involved parties, both patients and health care professionals, at risk. Excessive clinical demands on an already saturated ED often lead to medical errors and poor outcomes.[43] Overcrowding has promoted the expansion of ED facility capacity through increased utilization of hallways and other suboptimal, poorly equipped locations as patient treatment areas, challenging patient comfort, care satisfaction, and confidentiality and adding additional risk for error.[26] The only way busy clinicians faced with too many patients can care for all is to spend less time with each patient. The fine line between a highly efficient assessment and an incomplete assessment is easily crossed, generally at the expense of the patient. In teaching-hospital EDs, effective clinical teaching is an early casualty of excessive patient volumes.[79] The high-stress practice environment of a crowded ED is one that also contributes mightily to staff burnout, higher turnover rates, and worsening deficiencies in clinical staffing.

Lengthy waiting times also promote patient dissatisfaction. More importantly, for patients with acute injuries and other painful conditions, it means prolonged pain and needless suffering. For others, inappropriately long waiting times pose an even greater risk if the acuity of their condition was underassessed during triage or if there has been signif-

TABLE 2. Causes of ED Overcrowding

Increased ED patient volumes
Increased ED patient acuity
Increased complexity of diseases and associated evaluations
Lack of inpatient hospital beds and related resources
Nursing shortage
Physician shortage
On-call physician/consultant availability
Insufficient physical plant space for the ED
Ancillary service (eg, lab, radiology) delays
Reduced access to primary care services
Reduced access to subspecialty care services
Difficulty in arranging follow-up care
Language and cultural barriers
Increased medical record documentation requirements
Medical liability issues
Managed care issues
Uninsured and underinsured patients
Inadequate funding for emergency services

icant progression of illness during a lengthy stint in the waiting room.

ED patient safety concerns aside, perhaps the most prominent deleterious effect of overcrowding is ambulance diversion. As suggested by survey data, ambulance diversion has become an increasingly common solution pursued by overcrowded EDs. Diversion had previously been confined to large urban teaching hospitals, timed with peak winter influenza outbreaks. Ambulance diversion now has become a year-long phenomenon, affecting more than two thirds of US hospitals in urban, suburban, and rural settings.[16,26,86] It is now fairly common for numerous hospitals within the same city or state EMS region to be on ambulance diversion at the same time. Many EMS systems have reacted to this by eliminating diversion as an option for overcrowded EDs during periods of peak patient volumes or when more than a certain number of institutions are saturated.[16–18,26]

When most or all major hospitals in an area are "on diversion," an entire municipality's EMS system can be paralyzed. This represents failure of the health care safety net at a rudimentary level, one that affects all economic and social strata. With saturated EDs on bypass, ambulance patients with true emergencies are forced to travel to more distant and perhaps less appropriate facilities. For an adult with a myocardial infarction or a stroke or a child with respiratory failure, the additional time to definitive care necessitated by ambulance diversion is a very meaningful factor. For children with special health care needs, this may limit their access to specialized EDs or tertiary care professionals who are familiar with their condition. Once an acutely ill patient is in the back of an ambulance, neither socioeconomic status nor special health care needs may have any bearing on disposition when diversion is in place.

SOLUTIONS TO ED OVERCROWDING: WHAT CAN PEDIATRICIANS DO TO HELP?

The ED overcrowding crisis did not mysteriously appear and, in reality, has been lurking in the shadows for some time. It is attributable, in part, to the absence of a coherent national health policy to create a comprehensive health care and social services delivery system for all Americans. For many adults and children, the ED has become and still remains the access point to health care by default. Intense economic pressure over the past decade has forced a reduction in the capacity of all aspects (primary care through tertiary care) of the American health care system. The result in certain communities is a dangerously overburdened and underfunded EMS system, with our nation's EDs sustaining the brunt of the problem.

The definitive solutions to ED overcrowding are complex, resource intensive, and expensive. Hospitals must improve their inpatient capacity, particularly the number of staffed critical care beds. Hospitals must also become better prepared to manage seasonal variations in acute illness and coordinate elective and nonelective admissions. Existing inpatient beds must be managed in a manner that promotes efficient utilization. Effective use of observation units may help to maximize availability of limited inpatient beds. If the hospital capacity problem can be remedied, one of the root causes of ED overcrowding will have been addressed.

Hospital EDs must also adapt to meet growing patient demand. In the face of steadily growing utilization, there must be a corresponding expansion in the number of ED treatment stations and in the levels of physician and nurse staffing. Of course, this may be easier said than done considering current workforce shortages. Hospital EDs must also strive to improve the efficiency of the care provided to all patient acuity levels, both emergent/urgent and nonurgent groups. Improving ancillary service support will also help to make the ED more effective.

RECOMMENDATIONS

Pediatricians must serve as powerful advocates for improved health care for all children. The problem of ED overcrowding cannot be solved without solutions in our current health care systems that will provide an accessible and comprehensive medical home.[87] There are some specific actions that both primary care pediatricians and pediatric subspecialists can pursue to address this growing problem.

1. Include the management of acute illness or injury and the utilization of emergency services in anticipatory guidance. The best time to educate families about the appropriate use of an ED, calling 911, or calling the regional poison control center is before the emergency occurs. Although parents will continue to view and respond to acute medical problems as laypersons, they may make better-informed decisions if they are prepared.
2. Work with emergency care professionals to make every ED experience an educational opportunity for the patient and family. Components of this education should include: (*a*) clear instructions for the illness or injury of immediate concern; (*b*) instructions regarding the management or maintenance of chronic conditions and special health care needs; (*c*) preventive health education; and (*d*) guidance about EMS and ED utilization and available sources of primary and specialty care.
3. Connect patients to a fully functional medical home, thereby improving access to office-based acute care and coordinating utilization of after-hours clinical services. Although it would be unreasonable to expect a physician's office to be available 24 hours a day, pediatricians should take a critical look at the accessibility of their practice to patients with acute (nonscheduled) complaints. Hours of operation, same-day appointments, walk-in visits, the function of the practice's answering service, and the application of telephone triage systems should be scrutinized carefully. It might be especially helpful to interview families who have sought emergency care during office hours or those who have visited the ED without first calling the doctor's office to determine if communication or access was an issue in choosing to use the ED. An effective

primary care delivery system may prevent ED visits for low-acuity complaints and may enable timely interventions that prevent low-acuity illnesses from becoming high-acuity illnesses.

4. Coordinate effective follow-up care for ED visits. Even with optimal access to primary care and the medical home, patients will still require access to emergency services. Pediatricians should work closely with local institutions and providers of emergency services to ensure coordination of effective primary and subspecialty follow-up care. This communication and coordination of care is especially important for children with special health care needs.
5. Advocate for improved Medicaid reimbursement. On average, Medicaid reimbursed pediatricians for only 68% of the amount that would be paid under Medicare.[88] Many pediatricians are already doing more than their fair share, devoting a significant amount of their practice to the care of underserved and underfunded populations. In fact, pediatricians' average Medicaid caseload increased from 24.3% in 1983 to 30.0% in 2000, according to American Academy of Pediatrics survey data.[89] Health services research data suggest that we need more pediatricians and other pediatric care professionals to follow suit. We must strongly advocate for fair Medicaid reimbursement rates so that more pediatricians will have the financial incentive to care for these patients. Until then, many Medicaid and uninsured patients will continue to use EDs in the absence of a functional and accessible medical home.
6. Encourage SCHIP enrollment. There is a growing number of children from low-income families who are uninsured or underinsured who would qualify for SCHIP or Medicaid benefits. Because many of these patients have no medical home, pediatricians should partner with their community EDs to identify opportunities to enroll eligible children and families who pass through the ED. Facilitating the enrollment of these children into SCHIP will not be successful in improving their access to a medical home if the SCHIP or Medicaid reimbursement is not sufficient to encourage the participation of pediatric care professionals.
7. Become familiar with local hospital ED and EMS services and their constraints. Pediatricians can play an important role as "consumers" in advocating for expansion of hospital services. Pediatric centers are not immune to overcrowding and now experience many of the same problems as larger adult facilities. This may be an even greater problem for acutely ill or injured children, because many communities are served by a single pediatric tertiary care center. Pediatricians should play a direct role in addressing pediatric inpatient bed (particularly critical care beds) and ED capacity concerns at both their local community hospital and at regional pediatric tertiary care centers.
8. Support advocacy efforts directed toward medical professional liability and tort reform. In states in which tort reform has not occurred, the economic effect is on all health care professionals including pediatricians. Hospital-based specialists and high-risk service providers are affected disproportionately by this burden, which has diminished the availability of key medical subspecialists and surgical specialists for patients when they might need them most. Pediatricians should partner with their state medical society and other professional organizations in this important effort.
9. Conduct and/or advocate for health services research directed toward ED overcrowding. The numerous medical, economic, cultural, and social factors that have led to emergency service saturation are admittedly complex. In sharp contrast to the enormity of this problem is the relative paucity of health services research in this area, particularly regarding pediatric populations. A better understanding of these complex factors might promote a clearer perspective for policy-makers and provide a foundation for effective problem solving. This research agenda also should focus on the unique issues faced by children, including the effect of ED overcrowding and ambulance diversion on the outcome of pediatric emergency care.
10. Advocate for effective reforms in current health care delivery systems. As managers of the pediatric medical home and advocates for children and optimal pediatric health care, there is a very important role for pediatricians in educating citizens, elected officials, and health policy decision-makers about ED overcrowding and effective solutions. This advocacy must be directed toward both optimization of primary care access and improvement of hospital and emergency service capacity. The goal should be for every child to have a fully functional medical home. To maximize the effectiveness of their advocacy, pediatricians should partner with other key stakeholder groups including emergency physicians, emergency nurses, EMS professionals, hospital administrators, legislators, and others in efforts to repair the fraying health care safety net and overburdened emergency services. Organizations such as the ACEP, American Academy of Emergency Medicine, Society for Academic Emergency Medicine, National Association of EMS Physicians, American College of Physicians, Emergency Nurses Association, and others have each engaged in active advocacy programs to address this concern.

APPENDIX: ED Overcrowding Metrics and Definitions (adapted with permission from the American College of Emergency Physicians, Crowding Resources Task Force. *Responding to Emergency Department Crowding: A Guidebook for Chapters*. Dallas, TX: American College of Emergency Physicians; 2002)

ED overcrowding: a situation in which the identified need for emergency services exceeds the available resources in the ED. Evidence of ED overcrowd-

ing is typically found when the number of ED patients receiving care exceeds the number of staffed ED beds, which may lead to the use of hallways and other nontreatment areas to assess or monitor patients and is usually associated with lengthy waiting times for treatment.

ED saturation: a situation in which patient needs, including timely evaluation and treatment, as defined by patient acuity or triage level, cannot be met for existing or new patients because of fully committed ED resources.

ED treatment station (ED bed): a gurney or bed in a space designed to be a treatment area in the ED. Beds in such areas as the hallway, waiting room, conference rooms, etc, are not ED beds.

ED boarder: a patient who remains in the ED beyond the time of disposition after the decision has been made for either inpatient admission or transfer to another facility.

ED boarding time: the time interval between the acceptance of an admission or transfer request for an ED patient and the time the patient actually leaves the ED.

Boarding burden: the proportion of the ED functional treatment spaces or beds occupied by boarding patients.

Hospital ED or ambulance diversion: a situation in which a hospital has determined that it does not or will not have the required capacity or capability to accept additional patients from prehospital or EMS ambulance transports. Diversion can be for a specified category of patients (eg, trauma, critical care) or all prehospital or interhospital ambulance transfers.

Left prior to triage: a patient who has been logged as having arrived in the ED requesting medical care yet leaves prior to the triage assessment.

Left without being seen: a patient who has been triaged but leaves the ED prior to receiving an MSE by the ED physician or other qualified personnel.

Refusal of MSE or treatment: a patient presenting to the ED requesting medical evaluation who subsequently declines additional evaluation or treatment prior to the completion of care (also known as leaving against medical advice).

Waiting room time: the time interval between the completion of the triage assessment and placement of that patient in a waiting area and the time at which the patient is placed in a treatment bed.

CLINICAL REPORT

Overuse Injuries, Overtraining, and Burnout in Child and Adolescent Athletes

Guidance for the Clinician in Rendering Pediatric Care

Joel S. Brenner, MD, MPH, and the Council on Sports Medicine and Fitness

ABSTRACT

Overuse is one of the most common etiologic factors that lead to injuries in the pediatric and adolescent athlete. As more children are becoming involved in organized and recreational athletics, the incidence of overuse injuries is increasing. Many children are participating in sports year-round and sometimes on multiple teams simultaneously. This overtraining can lead to burnout, which may have a detrimental effect on the child participating in sports as a lifelong healthy activity. One contributing factor to overtraining may be parental pressure to compete and succeed. The purpose of this clinical report is to assist pediatricians in identifying and counseling at-risk children and their families. This report supports the American Academy of Pediatrics policy statement on intensive training and sport specialization.

INTRODUCTION

Overuse injuries, overtraining, and burnout among child and adolescent athletes are a growing problem in the United States. Although inactivity and obesity are on the rise, the number of children and adolescents who participate in organized or recreational athletics has grown considerably over the past 2 decades. It is estimated that 30 to 45 million youth 6 to 18 years of age participate in some form of athletics. Sports participation is more accessible to all youth, from recreational play and school activities, to highly organized and competitive traveling teams, to pre-Olympic training opportunities. The variety of available, organized sporting activities has also grown from the typical American favorites, such as football, baseball, and soccer, to include lacrosse, field hockey, rugby, cheerleading, and dance, each with its own list of sports medicine concerns. This report will assist the clinician managing young athletes by first defining the medical, psychological, and developmental concerns of intensive, focused athletic participation. In addition, it will highlight specific overtraining issues such as participation in endurance events, weekend athletic tournaments, year-round training on multiple teams, and the multisport athlete. This clinical report should be used in conjunction with the American Academy of Pediatrics policy statement on intensive training and sports specialization in young athletes.[1] There is currently a very small body of scientific evidence pertaining to these issues. Therefore, some of the recommendations are based on committee opinion and/or expertise.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Overuse Injuries

An overuse injury is microtraumatic damage to a bone, muscle, or tendon that has been subjected to repetitive stress without sufficient time to heal or undergo the natural reparative process. Overuse injuries can be classified into 4 stages: (1) pain in the affected area after physical activity; (2) pain during the activity, without restricting performance; (3) pain during the activity that restricts performance; and (4) chronic, unremitting pain even at rest.[2] The incidence of overuse injuries in the young athlete has paralleled the growth of youth participation in sports. Up to 50% of all injuries seen in pediatric sports medicine are related to overuse.[3]

The risks of overuse are more serious in the pediatric/adolescent athlete for several reasons. The growing bones of the young athlete cannot handle as much stress as the mature bones of adults.[4,5] For example, a young baseball pitcher who has not yet learned proper throwing mechanics (ie, recruiting the entire kinetic chain—from foot to hand—instead of just the arm) is at risk of traction apophysitis of the medial elbow. A young gymnast who performs repetitive hyperextension activities may develop spondylolysis (ie, a stress fracture of the spine), which is an injury particular to the pediatric age group. In addition, young swimmers may not recognize signs of rotator cuff tendonitis, because they may be unable to cognitively connect vague symptoms, such as fatigue or poor performance, as a sign of injury. Identifying youth at risk of overuse injuries is the first step to prevention. Guidelines for parents, coaches, and athletes need to be developed to provide opportunities for education, injury reduction, and early recognition of overuse injuries.

Overtraining

A question often asked of the practitioner who cares for young athletes is, "How much athletic training is too much?" There are no scientifically determined guidelines to help define how much exercise is healthy and beneficial to the young athlete compared with what might be harmful and represent overtraining. However, injuries tend to be more common during peak growth velocity, and some are more likely to occur if underlying biomechanical problems are present.

A sound training regimen is essential, recognizing that although repetition is important, it may induce harm. Sport-specific drills that use a variety of modalities, such as water running for the track athlete on alternate days, may provide similar fitness benefits with less stress to the body. The American Academy of Pediatrics Council on Sports Medicine and Fitness recommends limiting 1 sporting activity to a maximum of 5 days per week with at least 1 day off from any organized physical activity. In addition, athletes should have at least 2 to 3 months off per year from their particular sport during which they can let injuries heal, refresh the mind, and work on strength, conditioning, and proprioception in hopes of reducing injury risk. In addition to overuse injuries, if the body is not given sufficient time to regenerate and refresh, the youth may be at risk of "burnout."

"Burnout" or Overtraining Syndrome

Burnout, or overtraining syndrome, has been well described in the literature for adult athletes, but little is found regarding its applicability in youth. The overtraining syndrome can be defined as a "series of psychological, physiologic, and hormonal changes that result in decreased sports performance."[6] Common manifestations may include chronic muscle or joint pain, personality changes, elevated resting heart rate, and decreased sports performance.[6,7] The pediatric athlete may also have fatigue, lack of enthusiasm about practice or competition, or difficulty with successfully completing usual routines. Burnout should be recognized as a serious sequela of overtraining syndrome. Prevention of burnout should be addressed by encouraging the athlete to become well rounded and well versed in a variety of activities rather than 1 particular sport. The following guidelines are suggested to prevent overtraining/burnout:

1. Keep workouts interesting, with age-appropriate games and training, to keep practice fun.
2. Take time off from organized or structured sports participation 1 to 2 days per week to allow the body to rest or participate in other activities.
3. Permit longer scheduled breaks from training and competition every 2 to 3 months while focusing on other activities and cross-training to prevent loss of skill or level of conditioning.
4. Focus on wellness and teaching athletes to be in tune with their bodies for cues to slow down or alter their training methods.[6]

Endurance Events

Endurance athletic events (triathlons, marathons, and half-marathons) are becoming more popular in the United States, and legitimate concerns have been raised for the safety of youth participating in these events. The American Academy of Pediatrics has stated that triathlons for children and adolescents are reasonably safe as long as the events are modified to be age appropriate.[8] Specifically, such events should be of shorter duration/length, and careful attention should be given to safety and environmental conditions.[8,9] Children and adolescents must be properly trained to avoid hypothermia or hyperthermia, overtraining, overuse injuries, and burnout.

Recent concerns regarding the participation of children in marathon running has led to different opinions being expressed in the literature.[10–12] There is, at present, no scientific evidence that supports or refutes the safety of children who participate in marathons. There are no recorded data on injuries sustained by children who run marathons. Marathon training requires a gradual increase in total weekly mileage, which may be less than or equal to the total weekly distance that is generally logged by high school cross-country teams (35–40 miles). Regardless, a clearly devised weekly plan, ensuring that safe running conditions are in place, and the provision of proper education on endurance activities (including environmental conditions and appropriate hydration) should all be part of the training process. A critical environmental safety concern is the ambient temperature and relative humidity, because a child is less able than an adult to handle heat stress.[13] Weather-related guidelines have been set for all marathons, and these guidelines should be strictly enforced by the medical director for all youth endurance events.[14] Ultimately, there is no reason to disallow participation of a young athlete in a properly run marathon as long as the athlete enjoys the activity and is asymptomatic.[15]

Weekend Athletic Tournaments

Weekend-long sports tournaments for soccer, baseball, or tennis are common across the country. Often, these athletes are actively participating at least 6 hours each day in their sport and are exposed to the associated weather elements for an additional 2 to 3 hours. The risks associated with these events include heat-related illness, nutritional deficiencies, overuse injuries (eg, pitching in multiple games over a 48-hour span), and burnout from having a lack of "free time." Research examining the possibility of fatigue contributing to an increased injury risk in the tournament situation does not exist, but the general overtraining-prevention guidelines outlined earlier should also apply.

Year-Round Training on Multiple Teams

Single-sport, year-round training and competition is becoming more common for children and adolescents. A focus on participating in 1 sport, or single-sport specialization, to improve, advance, and compete at the highest level may drive youth to participate for long hours daily on 1 or more teams at a time. This is common in soccer, baseball, and gymnastics. The motivation behind this overinvolvement may be induced by the child or parent. As more young athletes are becoming professionals at a younger age, there is more pressure to grab a piece of the "professional pie," to obtain a college scholarship, or to make the Olympic team. Most young athletes and their parents fail to realize that, depending on the sport, only 0.2% to 0.5% of high school athletes ever make it to the professional level.[16] Yet, youth continue to specialize in 1 sport while participating on multiple teams and risk overuse and/or burnout if there is no break from athletics during the year. Young athletes who participate in a variety of sports have fewer injuries and play sports longer than those who specialize before puberty.[1]

Multisport Athlete

Well-rounded, multisport athletes have the highest potential to achieve the goal of lifelong fitness and enjoyment of physical activity while avoiding some of the pitfalls of overuse, overtraining, and burnout provided that they participate in moderation and are in tune with their bodies for signs of overuse or fatigue. Many youth will play multiple sports throughout the year either simultaneously or during different seasons. They may do this because they enjoy multiple sports or because their coach or parent pushes them to participate in other sports to condition them for their primary sport or in hopes of being noticed by college or professional scouts. There may be additional pressures from other coaches who wish to better their team by calling on well-rounded athletes from other sports. Multisport athletes are at risk of overuse injuries if they do not get sufficient rest between daily activities or if they do not get a break between seasons. Multisport athletes who participate in 2 or more sports for which the major emphasis is the same body part (eg, swimmers and baseball pitchers) are at higher risk of overuse injuries than are those who participate in sports that have a different emphasis (eg, track and golf).

What Is the Goal of the Athlete?

The ultimate goal of youth participation in sports should be to promote lifelong physical activity, recreation, and skills of healthy competition that can be used in all facets of future endeavors. As providers of care for youth, it is important to obtain a physical activity history (type of activity, frequency, duration) and take the opportunity to promote healthy participation and preventive care measures. Education of parents, athletes, and coaches must be part of the plan to promote fun, skill development, and success for each individual athlete. Skilled young athletes must be mentored carefully to prevent overparticipation, which may affect them physically as well as psychologically. The parent or pediatrician may wonder how hard a child should be pushed to train and compete. Ultimately, it is important for the practitioner to discuss the underlying motivation for sport participation with the athlete, the parent, and, possibly, the coach. Unfortunately, too often the goal is skewed toward adult (parent/coach) goals either implicitly or explicitly. The parent often hopes the child will get a scholarship, become a professional athlete, or fulfill the parents' unfulfilled childhood dreams. It is best to identify and focus on the child's motivation and goals to provide guidance.

GUIDANCE FOR THE CLINICIAN

1. Encourage athletes to strive to have at least 1 to 2 days off per week from competitive athletics, sport-specific training, and competitive practice (scrimmage) to allow them to recover both physically and psychologically.
2. Advise athletes that the weekly training time, number of repetitions, or total distance should not increase by more than 10% each week (eg, increase total running mileage by 2 miles if currently running a total of 20 miles per week).
3. Encourage the athlete to take at least 2 to 3 months away from a specific sport during the year.
4. Emphasize that the focus of sports participation should be on fun, skill acquisition, safety, and sportsmanship.
5. Encourage the athlete to participate on only 1 team during a season. If the athlete is also a member of a traveling or select team, then that participation time should be incorporated into the aforementioned guidelines.
6. If the athlete complains of nonspecific muscle or joint problems, fatigue, or poor academic performance, be alert for possible burnout. Questions pertaining to sport motivation may be appropriate.
7. Advocate for the development of a medical advisory board for weekend athletic tournaments to educate athletes about heat or cold illness, overparticipation, associated overuse injuries, and/or burnout.
8. Encourage the development of educational opportunities for athletes, parents, and coaches to provide information about appropriate nutrition and fluids, sport safety, and the avoidance of overtraining to achieve optimal performance and good health.
9. Convey a special caution to parents with younger athletes who participate in multigame tournaments in short periods of time.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Bioethics and Committee on Hospital Care

Palliative Care for Children

ABSTRACT. This statement presents an integrated model for providing palliative care for children living with a life-threatening or terminal condition. Advice on the development of a palliative care plan and on working with parents and children is also provided. Barriers to the provision of effective pediatric palliative care and potential solutions are identified. The American Academy of Pediatrics recommends the development and broad availability of pediatric palliative care services based on child-specific guidelines and standards. Such services will require widely distributed and effective palliative care education of pediatric health care professionals. The Academy offers guidance on responding to requests for hastening death, but does not support the practice of physician-assisted suicide or euthanasia for children.

ABBREVIATION. AAP, American Academy of Pediatrics.

In modern society, we expect children to outlive their parents. However, 53 000 children in the United States die every year from trauma, lethal congenital conditions, extreme prematurity, heritable disorders, or acquired illness.[1] The causes of death in children are substantially different from the causes of death in adults; thus, palliative care guidelines that are appropriate for adults are often inappropriate for children. For children living with life-threatening or terminal conditions, medical professionals are obligated to ensure that medical technology is used only when the benefits for the child outweigh the burdens. An infant or child will benefit from palliative care when no treatment has been shown to alter substantially the expected progression toward death.

Palliative care seeks to enhance quality of life in the face of an ultimately terminal condition. Palliative treatments focus on the relief of symptoms (eg, pain, dyspnea) and conditions (eg, loneliness) that cause distress and detract from the child's enjoyment of life. It also seeks to ensure that bereaved families are able to remain functional and intact. Hospice care refers to a package of palliative care services (including, for example, durable medical equipment, and both diagnostic and therapeutic interventions), generally provided at a limited per diem rate by a multidisciplinary group of physicians, nurses, and other personnel, such as chaplains, health aides, and bereavement counselors.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

Palliative care includes the control of pain and other symptoms and addresses the psychological, social, or spiritual problems of children (and their families) living with life-threatening or terminal conditions.[2,3] The goal of palliative care is the achievement of the best quality of life for patients and their families, consistent with their values, regardless of the location of the patient.[4] The American Academy of Pediatrics (AAP) has previously addressed the limitation or withdrawal of life-sustaining medical treatment.[5–7] Specific strategies for palliative management of pain, dyspnea, agitation, nausea, vomiting, seizures, depression, anxiety, grief, and other symptoms can be found in other sources.[8–11]

PRINCIPLES FOR PALLIATIVE CARE

The AAP calls for the development of clinical policies and minimum standards that promote the welfare of infants and children living with life-threatening or terminal conditions and their families, with the goal of providing equitable and effective support for curative, life-prolonging, and palliative care.[12] The following principles serve as the foundation for an integrated model of palliative care.

Respect for the Dignity of Patients and Families

The provision of palliative care for children includes sensitivity to and respect for the child's and family's wishes. In consultation with the child's parent or guardian, the plan of care incorporates respect for the terminally ill child's preferences concerning testing, monitoring, and treatment. Consistent with this principle of respect, information about palliative care should be readily available and parents may choose to initiate a referral to a pediatric palliative care program. The needs of families must be attended to both during the illness and after the child's death to improve their ability to survive the ordeal intact.

Access to Competent and Compassionate Palliative Care

In addition to alleviating pain and other physical symptoms, physicians must provide access to therapies that are likely to improve the child's quality of life.[13] Such therapies may include education, grief and family counseling, peer support, music therapy, child life intervention or spiritual support for both the patient and siblings, and appropriate respite care. Respite care, the provision of care to an ill child (in his or her usual state of health) by qualified caregivers other than family members, allows the family

time to rest and renew, whether for hours or days, on a schedule, or intermittently as needed. Families may benefit from the provision of respite care throughout a child's illness, not only near the end. Appropriate pediatric respite care is often lacking, but is considered by many families to be essential for their continued integrity and ability to care for the ill child, siblings, and themselves. Ideally, the patient's pediatrician, family physician, pediatric subspecialist, or surgeon will offer to continue to care for the child, while making a timely referral to palliative and hospice care. Palliative care programs should assist the child's usual medical caregivers in maintaining an ongoing role in the child's care.

Support for the Caregivers

Health care professionals must be supported by the palliative care team, their colleagues, and institutions in dealing with the child's dying process and death. Institutional support may include paid funeral leave, routine counseling with a trained peer or psychologist, and regularly scheduled remembrance ceremonies or other interventions such as inviting bereaved families to return and celebrate with staff the deceased child's life.

Improved Professional and Social Support for Pediatric Palliative Care

Regulatory, financial, and educational barriers often bar families from access to pediatric palliative care services. Professional and public education may foster awareness of the need for, and value of, pediatric palliative care and lead to efforts to remove bureaucratic and economic obstacles to its availability.

Continued Improvement of Pediatric Palliative Care Through Research and Education

Clinical research concerning the effectiveness and benefits of pediatric palliative care interventions and models of service provision should be promoted. In addition, information about pediatric palliative care that is already available must be effectively disseminated and incorporated into education and practice.

AN INTEGRATED MODEL OF PALLIATIVE AND CURATIVE TREATMENT

The AAP supports an integrated model of palliative care "in which the components of palliative care are offered at diagnosis and continued throughout the course of illness, whether the outcome ends in cure or death."[8] It is difficult to determine which children may benefit from palliative care. If palliative care is reserved for children who are dying or have a terminal condition, other patients who may benefit from these services may not receive them. Time of death is often difficult to predict. If the nearness of death is used to determine if children receive palliative care, some children may die without the benefits of individualized family-centered palliative care. With a broader definition that includes children living with a life-threatening condition, all children who need palliative care may benefit. In addition, aspects of an integrated palliative care approach, including symptom management and counseling, may prove beneficial when provided early in the course of a child's illness.[11]

Curative treatments seek to reverse the disease process, whereas palliative treatments focus on relieving symptoms, regardless of their impact on the underlying disease process. Rigid distinctions between curative, life-prolonging, and palliative interventions may hinder the appropriate provision of palliative care to children living with a terminal condition. Physicians and family members may exhaust all curative options before they consider palliative care, which delays the timely introduction of palliative care or referral to palliative care specialists. Finally, it may be difficult to define individual therapies as either curative or palliative. For example, mechanical ventilation often is viewed as a life-prolonging or curative therapy that should be forgone with palliative care. However, such support, especially noninvasive forms of positive pressure ventilation, may provide symptomatic relief from dyspnea and significantly improve a child's quality of life.

Moreover, the assumption that there is no place for palliative care until all curative options have been exhausted may interfere with an early discussion of palliative issues, including limitations of unduly burdensome interventions at the end of life. Parents and children may infer that a discussion of issues such as do not resuscitate orders or comfort care is equivalent to "giving up." Such inferences may inhibit family members from voicing fears and concerns about the burdens of life-prolonging interventions and the dying process. Communication with patients and families about these concerns must be done with respect and empathy. An explanation of the usefulness of specific therapies, such as cardiopulmonary resuscitation, and a discussion of the value of advance directives to ensure that treatments that have become burdensome are not used, can be comforting to families. The ability of health care professionals to communicate difficult messages well can be learned through directed education and practice.

DEVELOPING A PALLIATIVE CARE PLAN

As no one person can provide all the necessary support for the child and family, palliative care is best provided using an integrated interdisciplinary approach. The provision of palliative care for children involves a partnership between the child, family, parents' employer(s), teachers, school staff, and health care professionals, including nurses, chaplains, bereavement counselors, social workers, primary care physicians, subspecialty physicians, and consultants. Physical, emotional, psychosocial, and spiritual/existential domains of distress must be addressed. The child should participate to the fullest extent possible, given his or her illness experience, developmental capacities, and level of consciousness. Regardless of the prognosis, respect for the child requires that he or she be given a developmentally appropriate description of the condition along

with the expected burdens and benefits of available management options, while soliciting and listening to the child's preferences.[14] For example, burdens may include time away from home and friends; benefits may include participation in research studies based on an altruistic motive.[15] The discussion should focus on what interventions, from the child's and family's perspective, will be of the most benefit.

Each available diagnostic or therapeutic intervention needs to be considered within the context of the goals and expectations of the child and family. The decision to forgo certain treatments means that only those selected interventions are withheld or withdrawn. As the goals of therapy change with the progression of the child's condition or disease, the desirability of some interventions may change. Early interdisciplinary discussion and planning facilitates the smooth integration of these changes. The relief of pain and anxiety is an essential aspect of palliative care, and should be addressed throughout the course of illness. In some instances, pain relief may free a child to participate more fully in his or her final days, weeks, or months of life. Openness to the day-to-day experience of the child and flexibility in considering all options that may palliate distressing symptoms and conditions are essential when developing a treatment plan. *The goal is to add life to the child's years, not simply years to the child's life.*

WORKING WITH PARENTS OF DYING CHILDREN

While acknowledging uncertainty, a pediatrician needs to provide a realistic appraisal of prognosis and the range of time in which death is likely to occur. Pediatricians should support parental expression of the disappointment, anger, grief, and suffering associated with the child's illness. Acknowledging grief is often the first step toward facing the reality of the child's illness. Such acceptance may help parents focus on the quality of the child's remaining life.[16] Most importantly, the pediatrician needs to reassure the parents and child of the continued involvement and support of caring, skilled clinicians throughout the child's life, as well as after death. Fear of abandonment and isolation, especially during a child's long illness, is a major concern to chronically ill or dying children and their families.[17]

The place where death occurs, whether in an intensive care unit, another area of the hospital, another institution, or at home, may depend on such factors as the wishes of the child and family, the physical layout and visitation policies of the alternative sites, the desire and ability of staff to remain involved, and the availability of other caregivers such as bereavement counselors and clinicians with palliative care expertise. Whether death is anticipated or unexpected, pediatricians are expected to help support parental grief and guilt as parents struggle to cope with their fundamentally incomprehensible loss. The family must have the opportunity to carry out important family, religious, and/or cultural rituals and to hold the child before and after death.[18] Members of the extended family, friends, primary care physicians, and religious advisors are to be included, if the family chooses. These individuals can support the family and each other during this time of crisis and in bereavement. A handwritten note of sympathy from the pediatrician or attendance at the funeral can be healing for the family and the physician. In addition, an opportunity for either organ and/or tissue donation when feasible, and an explanatory meeting with the pediatrician to share the results of a limited or full autopsy, may provide some comfort for a grieving family.

The death of a child who has been chronically ill presents added challenges. Parents grieve the loss of the expected normal child from the time of diagnosis of a condition likely to result in disability and childhood death. Often, these parents may find it difficult to accept the reality of impending death, perhaps because previous predictions proved inaccurate. For some parents, continued hope for cure, no matter how unlikely, may be an important coping mechanism or may conform with deeply held religious or cultural beliefs.

WORKING WITH CHILDREN

As many children with chronic, life-shortening illnesses are now living into adolescence and young adulthood, the pediatrician needs to acknowledge the child's own recognition of the likelihood of premature death, to help the child communicate his or her wishes, and to plan for the child's death.[19]

The pediatrician should assist parents in understanding and supporting the siblings of the ill child, all of whom are affected by the child's condition and eventual death. Parents are to be supported in attending to the needs of the ill child and siblings while acknowledging the sadness that results from life-threatening illness. The child should be reassured that he or she has done nothing wrong and is not responsible for his or her own illness or that of a sibling. Children should be encouraged to talk about feelings of anger, sadness, fear, isolation, and guilt, or to express themselves through art or music therapy.[13,20,21] Pediatricians should provide families with developmentally appropriate guidance about these difficult communications, encourage parents of older children and adolescents to talk together as a family about their feelings, and encourage the sharing of memories to facilitate bereavement and healing.[22,23] Families may benefit from the pediatrician or another member of the palliative care team participating in such family discussions. In these tragic situations, it is also helpful for the primary care pediatrician to work with the schools and other youth organizations to assist other children affected by the death of the child.

The pediatrician and the child's parents may consider the following factors when discussing death with a child: the disease experience and developmental level of the child; the child's understanding of and prior experience with death; the family's religious and cultural beliefs about death; the child's usual patterns of coping with pain and sadness; and the expected circumstances of death. The appropri-

ate time to start a conversation about a child's impending death is difficult to determine, as cultural beliefs must be respected and denial by family members may provide some relief from the overwhelming sense of loss and pain. However, avoiding this conversation ignores the fact that ill children and their siblings are usually aware of their condition. Children may maintain silence out of a desire to protect their parents, while feeling painfully isolated from those they need most.[20,24] Hints that a child wants to talk about death may be subtle. Open and honest communication is usually most effective in relieving the child's distress, allowing for mutual support and personal growth during the final phases of the child's life.

HASTENING DEATH

The decision to forgo life-sustaining medical treatment does not necessarily imply an intent or choice to hasten the death of a child.[25] Although a child's life may be shortened by forgoing burdensome interventions or providing adequate sedation in the face of otherwise unrelieved symptoms, the goal of palliative care is to optimize the quality of the child's experience rather than hasten death. On occasion, the relief of severe, progressive symptoms such as pain or dyspnea may require a rapid escalation in the doses of administered analgesics and sedatives. If the child becomes obtunded and less responsive, parents and staff may feel that the medication is to blame, rather than the disease process—a misunderstanding that is reinforced by referring to the procedure as "terminal sedation."[26–28] The child's progressive deterioration and death may be attributable to the disease process, and not the medication.[7,29] Rarely, the relief of progressive symptoms may require deep sedation. Dying with dignity and without pain or distress is the primary goal.

If a child or adolescent requests euthanasia, the health care team is to respond compassionately, with a renewed focus on determining and alleviating the sources of distress, including perceptions of abandonment, depression, loneliness, physical symptoms, and communication problems. Patients and families are never to be prevented from forgoing burdensome life-sustaining medical treatment under appropriate circumstances—regardless of worry that others may view such a decision as euthanasia or suicide. With the provision of competent and compassionate palliative care, including the use of adequate analgesia and sedation for the treatment of rapidly progressive symptoms, requests to hasten death are generally abandoned. The informed decision of an adolescent or young adult patient nearing death to refuse further life-sustaining medical treatment ought to be respected; such respect does not imply the right of a patient to obtain assistance to commit suicide.[30]

The AAP is concerned about reports of involuntary euthanasia of infants and young children and of physician-assisted suicide of adolescents.[30–32] The AAP does not support the practice of physician-assisted suicide or euthanasia for children.

BARRIERS TO THE PROVISION OF PEDIATRIC PALLIATIVE CARE

Primary care pediatricians may be unfamiliar or uncomfortable with counseling or managing a child and family in palliative care, given the infrequency of death in most practices.[33] Thus, early consultation with pediatric hospice or palliative care professionals may be useful. Nevertheless, pediatricians who have established relationships with a child and family may assist in evaluating proposed interventions, help monitor the health and well-being of the siblings and family, and attend to the sometimes subtle and prolonged effects of grief on the family after the palliative care or hospice program is no longer involved.

Unfortunately, the majority of children who die have not had the benefit of palliative care services.[34,35] A major factor impeding pediatric palliative care is that the federal Medicare model was used to create most state Medicaid hospice benefits.[36] The Medicare model of hospice care was designed for adult patients with cancer, restricting admission to patients with a life expectancy of 6 months or less. This stipulation restricts the availability of hospice services to children, given the difficulty in predicting length of survival for many of the childhood diseases that result in premature death. Some hospice programs may require that patients and families agree to forgo life-prolonging or curative treatments and perhaps authorize a do not resuscitate order as a requirement for admission. Such requirements ignore the fact that many families accept the concept of hospice care only after a counseling process that is available within a hospice or palliative care program.[34] In addition, children living with a life-threatening or terminal condition may be receiving therapies that improve their quality of life, but are not adequately reimbursed through Medicaid hospice benefits. Treatment that generally is not reimbursed, for example, includes the use of newer, more expensive antibiotics for children with cystic fibrosis, long-term ventilator therapy for children with neuromuscular disorders, or surgical interventions that may palliate the child's symptoms. Reimbursement and regulatory policies may also preclude appropriate hospitalizations for children with life-threatening conditions. Moreover, families qualifying for Medicaid hospice benefits may lose other state-provided benefits, including dietary supplements and, more importantly, skilled home nursing care. Finally, health benefits from private insurance companies often mimic those from Medicare, and most do not have specific provisions in place for children.

Although hospice personnel are better equipped than most health care professionals to address issues surrounding terminal conditions, many hospice programs lack pediatric expertise and thus deprive chil-

dren and their families of the benefits of palliative care. Limited access to pediatric-specific palliative care and hospice services deprives children of knowledgeable health care personnel for home-based pain and symptom management. Many families may have to choose between life-prolonging or palliative care, and between pediatric or nonpediatric health care professionals, rather than have the opportunity to develop an individualized treatment plan that accounts for the specific needs of the child and family. As a result, the child living with a life-threatening or terminal condition may suffer an unnecessarily poor quality of life, leaving surviving family members with an excessively difficult bereavement.

MINIMUM STANDARDS FOR PEDIATRIC PALLIATIVE CARE

Excellence in pediatric palliative care is essential for hospitals and other facilities caring for children. Program development in pediatric palliative care, along with community outreach and public education, must be a priority of tertiary care centers serving children.

Minimum standards of pediatric palliative care must include a mechanism to ensure a seamless transition between settings, including at least 1 consistent caregiver, the availability of expert pediatric palliative care assistance 24 hours a day, 365 days a year, and the availability of an interdisciplinary care team with sufficient expertise to address the physical, psychosocial, emotional, and spiritual needs of the child and family. At the minimum, this team will include a physician, nurse, social worker, spiritual advisor, and child life therapist.

Although palliative care services may not be necessary for all families, the full range of clinical and educational resources must be made available. In addition, comprehensive palliative care cannot be accomplished without a designated care coordinator who can maintain continuity and ensure the care provided is consistent with the child's and family's goals despite the intermittent care and high staff turnover associated with tertiary care centers. The coordinator can ensure that the plan of care is coordinated with community care professionals to ensure a realistically achievable plan. Tertiary centers must provide community caregivers with explicit instruction in the care of the child, and appropriate pediatric palliative care consultation must be available 24 hours a day. Creative ways of coordinating care between the tertiary center and the community may involve individualized video conferencing or other forms of electronic communication. Respite for family caregivers and home nursing care are essential to maintain the integrity of families and the safety and well-being of the ill child. Finally, bereavement support must be available to the family, caregivers, and others affected by the death of a child, for as long as necessary. These essential services must be reimbursed equitably. The early inclusion of insurance case managers on the palliative care team may assist in accomplishing some of these goals.

Nursing, medical, pastoral care, and social work curricula must include the interdisciplinary management of childhood life-threatening conditions. Practical exercises involving interdisciplinary education, including hospice visits, may best achieve this goal. In addition, attending to the needs of children who experience the death of a significant adult must be addressed. The requirement to achieve competency in these areas must be reinforced by adding questions on palliative care to professional certification examinations. The needs of the medical caregivers who provide pediatric palliative care must be recognized and actively addressed to allow them to continue to provide this rewarding but emotionally draining care.

RECOMMENDATIONS

1. Palliative care and respite programs need to be developed and widely available to provide intensive symptom management and promote the welfare of children living with life-threatening or terminal conditions.
2. At diagnosis of a life-threatening or terminal condition, it is important to offer an integrated model of palliative care that continues throughout the course of illness, regardless of the outcome.
3. Changes in the regulation and reimbursement of palliative care and hospice services are necessary to improve access for children and families in need of these services. Modifications in current regulations should include 1) broader eligibility criteria concerning the length of expected survival; 2) the allowance of concurrent life-prolonging and palliative care; and 3) the provision of respite care and other therapies beyond those allowed by a narrow definition of "medically indicated." Adequate reimbursement should accompany these regulatory changes.
4. All general and subspecialty pediatricians, family physicians, pain specialists, and pediatric surgeons need to become familiar and comfortable with the provision of palliative care to children. Residency, fellowship training, and continuing education programs should include topics such as palliative medicine, communication skills, grief and loss, managing prognostic uncertainty, and decisions to forgo life-sustaining medical treatment, spiritual dimensions of life and illness, and alternative medicine.[33,37,38] Pediatric board and subboard certifying examinations should include questions on palliative care.
5. An increase in support for research into effective pediatric palliative care programming, regulation and reimbursement, pain and symptom management, and grief and bereavement counseling is necessary. The pharmaceutical industry must provide labeling information about symptom-relieving medications in the pediatric population and provide suitable formulations for use by children.
6. The practice of physician-assisted suicide or euthanasia for children should not be supported.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

TECHNICAL REPORT

Patient- and Family-Centered Care of Children in the Emergency Department

Patricia J. O'Malley, MD, Kathleen Brown, MD, Steven E. Krug, MD, and the Committee on Pediatric Emergency Medicine

ABSTRACT

Patient- and family-centered care is an innovative approach to the planning, delivery, and evaluation of health care that is grounded in a mutually beneficial partnership among patients, families, and health care professionals. Providing patient- and family-centered care to children in the emergency department setting presents many opportunities and challenges. This technical report draws on previously published policy statements and reports, reviews the current literature, and describes the present state of practice and research regarding patient- and family-centered care for children in the emergency department setting as well as some of the complexities of providing such care. This technical report has been endorsed by the Academic Pediatric Association (formerly the Ambulatory Pediatric Association), the American College of Osteopathic Emergency Physicians, the National Association of Emergency Medical Technicians, the Institute for Family-Centered Care, and the American College of Emergency Physicians. This report is also supported by the Emergency Nurses Association. *Pediatrics* 2008;122:e511–e521

INTRODUCTION

Patient- and family-centered care (PFCC) is an innovative approach to the planning, delivery, and evaluation of health care that is grounded in a mutually beneficial partnership among patients, families, and health care professionals. PFCC applies to patients of all ages, and it may be practiced in any health care setting.[1] Providing PFCC to children in the emergency department (ED) setting presents many opportunities and challenges. This technical report is intended to supplement the joint policy statement of the American Academy of Pediatrics (AAP) and American College of Emergency Physicians published in 2006.[2] It draws on previously published AAP policy statements and reports[3–16] and reviews current literature. The present state of practice and research regarding PFCC for children in the ED setting is described, as are some of the complexities of providing such care. Best practices from a number of acute care and nonemergency settings with implications for the care of children and families in the ED are also described. The 3 appendixes include several resources for PFCC, including potential solutions for common challenges to providing PFCC faced in the ED, a draft protocol for family-member presence during invasive procedures, and resources for promoting institutional change. This technical report has been endorsed by the Academic Pediatric Association (formerly the Ambulatory Pediatric Association), the American College of Osteopathic Emergency Physicians, the National Association of Emergency Medical Technicians, the Institute for Family-Centered Care, and the American College of Emergency Physicians. This report is also supported by the Emergency Nurses Association.

BACKGROUND

PFCC ensures the health and well-being of children and their families through a respectful patient/family-professional partnership. It honors the strengths, cultures, traditions, and expertise that all members of this partnership bring to the relationship.[2] PFCC embraces the following concepts: (1) we are providing care for a person, not a condition; (2) the patient is best understood in the context of his or her family, culture, values, and goals; and (3) honoring that context will result in better health care, safety, and patient satisfaction. ED health care professionals, the family, and the child team up to optimize the child's care.

The development of PFCC is well described elsewhere.[1–3,17] The essence of PFCC is an understanding of the relationship between the patient/family and health care professionals as a partnership. In the past, the fiduciary duties of a physician toward a patient were interpreted to give the physician an implied authority and ability to

determine unilaterally what is in the patient's best interests. In recent years, an understanding of the relationship as one between professional and consumer gave greater authority to the voice of the "client" (ie, patient).[14] PFCC represents further evolution in understanding the physician-patient relationship, one that will undoubtedly continue to evolve. The Institute of Medicine (IOM) has identified PFCC as 1 of the 6 attributes of high-quality health care in its 2001 report *Crossing the Quality Chasm: A New Health System for the 21st Century*.[18] Furthermore, the Joint Commission has incorporated a patient bill of rights and standards for patient comfort in its accreditation evaluation, as well as an acknowledgment that a patient's active involvement in his or her own care is a potent strategy for ensuring patient safety.[19] In its 2006 report *Emergency Care for Children: Growing Pains*,[20] the IOM concluded that failure to incorporate PFCC and culturally effective care into emergency care practice "can result in multiple adverse consequences, including difficulties with informed consent, miscommunication, inadequate understanding of diagnoses and treatment by families, dissatisfaction with care, preventable morbidity and mortality, unnecessary child abuse evaluations, lower quality care, clinician bias, and ethnic disparities in prescriptions, analgesia, test ordering, and diagnostic evaluation."

PFCC relies on a model of partnership with common goals and mutual respect for the contributions of each partner. This alliance is most successful when information is shared in an unbiased and nonjudgmental manner and when the patient and family are supported in their use of that information to make their own health care decisions. The clinician can be viewed as the knowledgeable navigator who is able to describe and recommend the available options with all their benefits and shortcomings; nonetheless, it is the patient and family who must fly the plane. ED health care professionals must understand that patients and families may not always know what questions to ask or may feel an inherent inequality in the partnership because of the vulnerability brought about by their medical circumstances; this may be particularly true of emergency circumstances. In addition, the possibility exists that the patient and family may value potential risks or benefits differently from how the treating physician does. Thus, the physician's ability to share information openly is vital to good patient care. Recognizing the role of the patient and family as team members in shared decision-making and validating their concerns while providing information about potential risks and benefits are critical for the entire team to feel comfortable with the plan and to ensure good patient care.

PFCC FOR THE CHILD IN THE ED

There are significant challenges to providing PFCC for children in the ED. Overcrowding and acuity in the ED may cause delay or disruption of care, which challenges the ability of health care professionals to provide respectful and sensitive care. The lack of a previous relationship between the patient/family and ED health care professionals, as well as the acute nature of many events prompting an ED visit, can limit the ability to create an effective partnership, and the many cultural and societal variations constituting families compound the difficulty in identifying with certainty who, in fact, is a child's legal guardian. Situations particular to the ED (such as arrival of a child by ambulance without family; the unaccompanied minor seeking care without the knowledge of his or her family; visits related to abuse or violence; time-sensitive invasive procedures, including attempted resuscitation; unanticipated critical illness, injury, or death of a child) require our most thoughtful advanced planning. Finally, reluctance on the part of health care professionals to allow family-member presence during invasive procedures or attempted resuscitation has limited family access that may be beneficial to the patient, family, and health care professional alike.

Despite these challenges, achieving excellence in provision of PFCC is possible in the ED (see Appendix 1). Communication between health care professionals in the ED and in the child's medical home[4,5] will enhance support of PFCC in the ED. Because PFCC is, by its nature, interdisciplinary, embracing the philosophy of PFCC across disciplines often available in an ED but possibly less accessible in other practice locations (such as nursing, interpreter services, child life and social services, chaplaincy, or mental health services), it can promote patient safety, comfort, and satisfaction despite the challenges of the environment.

All aspects of emergency care can reflect the practice of PFCC, including clinical operations and patient flow, policies and practice, physical plant, and education, training, and research of staff. Although the following examples may apply in other patient care settings, they are presented here in the context of the ED.

1. Patient Flow

Patient flow that exemplifies PFCC does not limit the child's access to family members or vice versa unless the demands of evolving patient independence, need for private interview or examination, or safety of the patient, family, or staff dictate otherwise. For example, an operational patient flow that requires the parent to leave the child for registration while the child is receiving care can be made more patient and family centered with a bedside registration system. Assistance can also be provided for the single parent who arrives with an ill child in the ED driveway so that he or she can remain with the child.

2. Security and Identification of Family

For security reasons, many EDs have a policy of identifying family members with a "visitor" badge. Changing that label to read "family" is a small step that may help to reinforce the commitment to moving beyond thinking of family as visitors and truly welcoming them as partners in care of the child.

3. Family Presence

A practice that requires parents to leave a child during certain procedures, such as fracture reduction or others, because the ED health care professional judges that it would be too disturbing for parents to watch is another opportunity for change. The ED can be made more pa-

tient and family centered by allowing the patient and family members to choose for themselves whether to be present after receiving complete and unbiased information about what will happen and by supporting their decision about whether to be present. Guidelines for establishing a program of family-member presence in the ED have been published.[21–23] A sample family-member presence policy is presented as Appendix 2.

4. Interpretation Services and Communication

Because communication is a cornerstone of PFCC, timely access to professional interpreter services is essential for providing PFCC when a language or communication barrier exists. A 1996 study suggested that nearly half of patients who need interpreter services do not receive them.[24] Moreover, children of families with language barriers are more likely to be admitted to the hospital, have more tests ordered, and have more severe disease and are less likely to get good follow-up care[25]; thus, evidence shows that language and communication barriers do indeed lead to lower quality of ED care. A commitment to hiring and funding professional interpreter services is a high mark of an institution's dedication to principles of PFCC. The common practice of using family members or accompanying friends as translators, particularly in the setting of unfamiliar medical terms or sensitive information, runs the risk of allowing faulty communication and may compromise patient privacy and safety as well. In addition, this practice disregards the National Standards on Culturally and Linguistically Appropriate Services. These standards elaborate on Title VI of the Civil Rights Act of 1968 (42 USC §2000), which requires that all health organizations receiving federal financial assistance ensure timely and effective interpreter services for patients.[26]

5. Comfort Care

The routine measurement of patient pain, anxiety, and comfort as part of initial and continuing patient assessment is central to PFCC, as is the commitment to respond to identified needs for comfort with interventions such as pharmacologic and nonpharmacologic treatment, child life services,[8] and psychosocial and spiritual support. Moreover, institution-wide commitment to these practices is urged by the IOM report on quality of care[18] and sought by the Joint Commission.

6. Coordination With the Medical Home

In the emergency setting, the patient's usual health care professionals can be considered an extension of that patient's family. Not only will health care professionals from the patient's medical home be able to provide valuable information at the time of the initial evaluation, but their input is necessary to shape an appropriate disposition as well. It is likely also that the patient and family will feel more comfortable with ED care when they know that their medical home health care professionals are involved and that the ED has access to essential parts of the child's medical history. This ED/medical home communication can be supported further through electronic health records and automated health-information exchange.[27]

7. Discharge Planning and Instructions

Standard discharge instructions can be a vehicle for PFCC when they can be customized to reflect solicited family preferences that are incorporated into the family's assumption of care at discharge and include appropriate input from and follow-up with the patient's medical home health care professional.

8. The ED Physical Plant

A physical plant that embodies PFCC will accommodate family members, including well siblings, and provide restrooms, diaper-changing space, safe and dedicated pediatric waiting areas, and simple refreshments. It should also provide children protection from the sights, sounds, and smells of emergency care of other ED patients and ensure adequate privacy on-site for sensitive interviews and for families who are experiencing grief or loss.

9. Patient and Family Input in Policies and Procedures

When new policies, practices, or physical plant changes are considered, they are more likely to reflect a PFCC philosophy if family representatives are included in the planning stages. For example, patients or family representatives have provided their input on drafts of printed materials and participated in the design of new ED facilities. They may be members of a family or teen advisory board or participate as part of an interdisciplinary team to develop and implement a policy to support families and staff when family members choose to be present during resuscitation.[1]

10. Modeling PFCC in the ED

For EDs in an academic center, providing supervision and teaching to trainees at the bedside, with the active participation of the patient and family, is an opportunity to model PFCC. Curricula that include precepts of PFCC[28,29] or use families and patients as teachers[30] reflect another enhancement. EDs that engage in research to examine the relationship of specific PFCC practices and short-term and long-term outcomes for both patients and health care professionals can ensure that progress made toward the goals of PFCC will continue.

CHANGING THE CULTURE OF THE ED

In many institutions, changing long-standing health care professional–centered practice to be congruent with PFCC requires an interdisciplinary paradigm shift. If there is an institutional will to change, there are ample tools available to assist in the process.[31] An Emergency Nurses Association assessment tool[32] provides guidelines for implementing change and focuses on 8 domains: (1) PFCC approach in the stated mission of the department; (2) evidence of family participation in care; (3) resources for family support; (4) practice regarding information sharing and decision-making; (5) coordination of services and continuity of care; (6) personnel practices; (7) evaluation practices; and (8) community partnerships. The assessment tool has been piloted in 9 EDs.[33]

A first step in promoting change is the assessment of current practice by using the self-assessment tool and soliciting information through satisfaction surveys, follow-up telephone calls, focus groups, and/or a family advisory group. Incorporating PFCC principles into the departmental mission statement can encourage influential individuals to strive for consensus and to provide leadership for change. Evaluating existing policies and procedures in light of a PFCC model can provide the impetus to change those policies. Hospital community forums through which staff can voice their concerns and share personal experiences as patients can be effective in recruiting staff commitment to PFCC.

Increasing PFCC awareness and understanding of patient/family perspectives and needs through staff education is important in the transition to PFCC. Engaging family members to assist with this task can be a powerful strategy. Staff involvement in measuring outcomes (such as satisfaction with care) and family-member presence can help overcome reluctance to support those activities. Reinforcement of PFCC values by incorporating them into job descriptions, competency assessments, and performance evaluations can help to achieve a change in culture. Finally, working to provide a physical environment that supports and reflects PFCC provides visible confirmation of PFCC. Some tool kits and additional resources for change are provided in Appendix 3.

BENEFITS TO HEALTH CARE PROFESSIONALS

PFCC has benefited health care professionals through greater job satisfaction and less burnout on the job.[34] Collaboration with the patient and family can lead to a more comprehensive medical record, a better sense of the patient as a person, and a better understanding of how the patient will function at home. When parents are present for the care of their child, they can help the staff provide support to the patient, understand the patient's attempts to communicate, position the patient, reduce a need for sedatives or restraints, and provide essential medical information. This may be especially important for children with special health care needs.[35,36]

Timely and convenient interpreter services will improve both family and ED health care professional satisfaction, improve the quality and efficiency of care, and limit otherwise unnecessary use of testing and resources.[37] In adult patient care settings, implementing a PFCC approach has led to improvements in patient safety, fewer medical errors, and lower cost of care.[38] In pediatric EDs, a PFCC design of in-process rooms with a playroom-like environment can allow for better neurologic and extremity evaluation by promoting a normal repertoire of behaviors in a more normal setting.

FUTURE DIRECTIONS

Well-designed research that establishes the effects of a PFCC approach to care of the child in the ED is limited.[39] The IOM report on emergency care for children[20] highlights the importance of PFCC and recommends that emergency medical services agencies and hospitals integrate principles of PFCC into emergency care practice. The IOM report gathers many voices (including the Institute for Family-Centered Care, the Emergency Nurses Association, and others) calling for increased evaluation and research regarding PFCC in emergency practice. Among the issues to be examined are the following:

- Regarding PFCC:
  - long-term and short-term outcomes associated with implementing PFCC, including patient satisfaction, safety and quality of care, cost of patient care, and staff satisfaction and retention
- Regarding family-member presence:
  - long-term effects of family-member presence on patient outcomes, families, and staff
  - best methods for educating health care professionals regarding family-member presence
  - potential legal ramifications of implementing or not implementing policy on family-member presence
  - relationship of family-member presence to tissue donation or autopsy
  - relationship of family-member presence to pain management (ie, is it improved by family-member presence or, conversely, does improved pain management allow for greater staff willingness to support family-member presence?)

CONCLUSIONS

Commitment to PFCC ensures that patients'/families' experiences and perspectives guide the practice of culturally sensitive care that promotes patient dignity, comfort, and autonomy. In the ED setting, particular issues deserve specific attention. The patient and family are key decision-makers regarding the patient's medical care. The option of family-member presence should be encouraged for all aspects of ED care. Information and support should be provided to the family during interventions regardless of the family's decision to be present or not. Because communication is a cornerstone of PFCC, timely and culturally effective professional interpreter services should be available to the ED. The interdependence of child and parent, patient and family wishes for privacy, and the evolving independence of the pediatric patient should be respected. PFCC encourages collaboration along the continuum of care (prehospital, ED, hospital, and rehabilitation) and commitment to the importance of the patient's medical home. With the collaboration of patients and families, institutional policies can be developed for the provision of PFCC through environmental design, practice, and staffing. Education of ED health care professionals should include the teaching of principles of PFCC to ensure active participation by patients and families in formal medical education and so that the ED setting can provide the venue for continued evaluation and research into the benefits of PFCC.

APPENDIX 1: CHALLENGING SITUATIONS COMMON TO THE CARE OF CHILDREN IN THE ED

1. Identifying "Family"

The Institute for Family-Centered Care defines family as:

> "two or more persons who are related in any way—biologically, legally, or emotionally. Patients and families define their families. In PFCC, the definition of family, as well as the degree of the family's involvement in health care, is determined by the patient, provided that he or she is developmentally mature and competent to do so. In pediatrics, particularly with infants and young children, family members are defined by the patient's parents or guardians."[40]

In the acute care setting of the ED, it is necessary to identify both a legal guardian and the primary family members who can offer support to a child and the child's parent or guardian, recognizing that those entities may not be one and the same, particularly in situations of child protective services custody, parental custody disputes, domestic violence, sexual assault, families with nontraditional composition, or families of different language or culture. However, in the case of emancipated or mature minors or for patients with selected conditions (such as sexually transmitted infections, physical or sexual assault, or potential pregnancy), the "legal guardian" may properly be construed as the patient himself or herself. Honoring the patient's implicit or explicit identification of primary family members who can provide support is essential, even recognizing that they may be different from legal guardians. When compounded by lack of a preexisting relationship, these factors make the ED practice of PFCC complex. To be able to develop policies and implement procedures for identifying family members and legal guardians that reflect a PFCC philosophy, ED health care professionals may need access to resources such as social services, interpreters, chaplaincy, security personnel, and legal counsel. Nevertheless, in providing PFCC, we are still bound by the legal obligation to share decision-making around the care of minors with a parent or legal guardian unless specific exemptions exist, such as those mentioned previously.

2. Arrival of a Child Who Is Unattended by Family

The unaccompanied child may arrive by ambulance or in the company of a teacher, child care provider, home nurse, or bystander. Providing a surrogate such as a volunteer, child advocate, or a child life specialist to the child without family, engaging ED and outside resources to locate family members, and enabling timely reunification of family and child are important for the safety and comfort of the pediatric patient of any age. As was demonstrated during Hurricane Katrina, the issue of timely reunification is an important consideration in disaster planning.

Under the Emergency Medical Treatment and Active Labor Act of 1986 (EMTALA [42 USC §1395dd]), ED providers are required to provide a medical screening examination for any unaccompanied minor who requests examination or treatment. It also requires that the same screening be provided when requested on behalf of the patient in a circumstance under which a "prudent layperson" would perceive a need for care. In fact, if the medical screening examination process identifies an emergency condition, a minor can be examined, treated, stabilized, and even transferred to another hospital without consent ever being obtained from a parent or legal guardian.[41] The implications and application of this regulation have been summarized previously.[10,15,42] A PFCC philosophy does not alter the ED health care professional's obligation to follow guidelines for a medical screening examination required by the EMTALA.

3. Care of the Adolescent Patient

Providing PFCC to the adolescent patient requires a careful balance to respect the patient's privacy and evolving independence and to communicate with the parent or guardian. Adolescents must routinely be given an opportunity to speak privately with the health care professional without other family members or partners being

present.[15] Requesting a private interview with the teenaged patient should be framed as the need to protect the young person's dignity and privacy while ensuring that information that may be critical to his or her health will not be withheld because of concern that it may worry, anger, or alienate the parent. The health care professional should be able to assure the patient that any information so obtained will be confidential to the extent that state law permits,[43,44] unless doing so poses a direct threat to the patient's or others' safety. Clinicians must recognize that the services that are protected and accessible for confidential access vary from state to state.

Many states allow for treatment without parental knowledge if the condition may reasonably involve transmission of sexually transmitted infection, mental illness, substance abuse, or reproductive concerns.[45] Although the EMTALA specifically states that ability to pay for care must not affect care delivered, ED health care professionals should be aware that billing notification of an ED visit may constitute a breach of the adolescent's privacy and, therefore, should make provisions to safeguard patient confidentiality, including identifying with the adolescent patient the financially responsible party to be billed. ED health care professionals should be familiar with the limitations to and obligations of providing care to the unaccompanied older pediatric patient who is seeking care without the knowledge of his or her family[10,11,46] and should make those limits and obligations clear to the patient. It is prudent to identify a means of communicating follow-up information by mail or telephone that will be secure and confidential if that is desired by the patient. One potential means of resolving conflicting obligations to the adolescent patient and guardian is for the health care professional to facilitate communication between the adolescent patient and parent.[47] This role may include exploring with the patient the potential consequences of nondisclosure to the parent, offering to disclose information to the parent without the patient present, or mediating a conversation between the patient and parent.

4. Family-Member Presence

In the procedure-intense acute care setting of the ED, PFCC is often most tested in the area of family-member presence. In the 1980s, studies demonstrated that parents were an asset in the setting of venipuncture and other simple procedures[48–50] if they had been prepared for what would happen and if they were given a role other than passive witness. This finding has been extended successfully to other more-invasive procedures, and parents have been demonstrated to be successful partners in providing sucrose to soothe an infant undergoing lumbar puncture or in calming the child who is receiving procedural sedation for laceration repair or fracture reduction with a familiar voice, story, poem, or song.[50]

Although some parents would not choose to be present during resuscitation, nearly all parents surveyed by Boie et al in 1999 reported that they would want the option to choose to be present or not. Other surveys have shown similar findings.[52,53] However, surveys of pediatricians, ED staff, and trauma care providers have noted a reluctance to allow family members to be present during resuscitation.[54–56] Providers often cite fears that it will be traumatic for the family members, that families will be disruptive, or that it may result in increased litigation. EDs that have reported their experience with family-member presence for resuscitation have noted rare instances of disruption by family members and increased acceptance by staff members once they had experience with family-member presence.[52,57–59] Staff members at these institutions noted that the family members were often helpful to the staff, providing support to the patient, essential medical information, enhanced communication, and assistance with positioning of the patient.[53,57,60,61] They have also reported perceived benefits to the family, including a positive effect on the grieving process when a resuscitation attempt results in death.[62] A recently published study designed to evaluate the outcomes of a structured program of family presence during pediatric trauma team activations demonstrated no instances of family interference with medical care in 197 instances of family-member presence. The time taken for completion of key components of the trauma evaluation was not different for trauma team activations with the family present versus those without family presence. In this study, most health care professionals reported that family presence either had no effect on or improved medical decision-making (97%), institution of patient care (94%), communication among health care professionals (92%), and communication with family members (98%).[63] Although no studies have directly addressed the effect of family-member presence on malpractice litigation, there is reason to believe that family-member presence may actually decrease litigation by improving patient and family satisfaction.[64,65]

Although there have been few rigorous studies to date and patient numbers in those studies have been small, there is more clinical evidence to support the benefits of family-member presence to patient, family, and health care professionals than there is for the competing concerns that family-member presence might be disruptive during procedures, might be traumatic to bereaved family members, or might result in increased litigation.[66] The Emergency Nurses Association, the American Association of Critical-Care Nurses, the National Association of Emergency Medical Technicians, and the AAP have all issued policy statements in support of offering family-member presence in emergency care.[2,67–69] Since 2000, the American Heart Association has recommended offering the option of family-member presence during resuscitation attempts (although the 2005 Pediatric Advanced Life Support teaching materials still use an example of parents who are excluded from the resuscitation room as the model for breaking news of the death of a child).[70] Guidelines for family-member presence have also been integrated into the Advanced Pediatric Life Support, the Pediatric Emergency Medicine Resource, the Emergency Nurses Association's Trauma Nursing Core Course, and the Emergency Nursing Pediatric Course. A national consensus panel that

convened in 2005 conducted an in-depth literature review of studies examining family-member presence and recommended that family-member presence be encouraged for all aspects of ED care.[71] The consensus report described criteria for support staff and for possible exclusion from family-member presence (such as threat of violence to self, staff, or patient). Benefits to patient, family, and health care professionals were detailed and included the potential to optimize medical information gathering, improve the assessment of how the patient might function at home, and enhance the understanding of the patient as a person rather than a condition. This report also noted that although many institutions' practices support family-member presence, fewer than 5% of surveyed institutions reported having a written protocol. Appendix 2 presents a draft protocol for family-member presence.

5. When the Child and Parents Disagree Regarding Treatment

Disagreements between the patient and the family present a difficult challenge to providing PFCC. When the child and parents disagree regarding a proposed treatment, the ED provider must weigh the child's ability to give or withhold assent within the context of that child's ability to understand and make reasonable decisions. A toddler cannot be deemed capable of either consent or assent and will not commonly cooperate with a laceration repair. On the other hand, a 14-year-old brought by a parent with the request for drug screening can withhold assent in such a way that it might constitute assault for the ED provider to attempt to obtain a blood sample. Such a patient may well be capable of understanding the decision to refuse. Similarly, a 10-year-old who has experienced repeated relapses of cancer may be able to understand the consequences of a refusal of further invasive treatments such as a ventriculoperitoneal shunt or central venous catheter placement. That child's withholding of assent merits serious consideration by ED staff and consultation not only with parents and the child's subspecialty care team but also potentially with the primary care physician, palliative care team, chaplaincy, hospital ethics team, or child protective services. The legal aspects of when and under what circumstances minors can refuse and consent to medical treatment remain largely unresolved and complex,[72,73] and ED health care professionals may not be able to resolve them in any particular case without the assistance of resources outside the ED.

6. When the Family Refuses a Proposed Treatment

It is not uncommon in the acute care setting for parent and health care professional to have different opinions about the value of a particular treatment or outcome. When that happens, the child's well-being should remain the primary focus, recognizing that parents and ED health care professionals may not always agree on what constitutes the child's best interest. Remembering the parents' and child's role as team members, ED health care professionals should explore the parents' reasoning and concerns in a manner that is sensitive to that reality, particularly regarding concerns about the risk of a procedure, the pain involved, the cost, the possible infringement of religious rules, or previous negative experiences in similar settings. Because there is rarely a preexisting relationship between the family and the ED health care professional, it can be helpful to enlist the health care professional of the patient's medical home in these discussions if time permits.

Parents are generally considered free to make choices regarding medical care unless those choices place their child at substantial risk of serious complications. For instance, a parent of a febrile neonate may not allow a lumbar puncture or a bladder tap. Alternatives to the standard practice of a full sepsis workup and empiric antibiotics do exist. It is possible to consider a plan to admit and observe the well-appearing febrile infant without empiric treatment or to presumptively treat an infant with risk factors or ill appearance with the hope for an opportunity to perform a diagnostic lumbar puncture later in the course of care if the family reconsiders after consulting with others.

One of the roles of the ED health care professional is to provide parents with the risk and benefit information that will allow the family to make an informed decision, ensuring that the family understands the diagnostic burden of obtaining a sterilized cerebrospinal fluid sample or the potential risks associated with a delay in initiating antibiotics. On both sides of this negotiation, there may be resources that will support a respectful and full discussion. ED health care professionals may want to avail themselves of the resource of the medical home or a subspecialty opinion; they will also want to ensure that the family members have access to the supports on which they rely to assist them with difficult decisions, such as a family elder or faith advisor. The ED health care professional should "listen carefully and respectfully to the parents' concerns, recognizing that some parents may not use the same decision criteria as the physician and may weigh medical evidence very differently."[12] Very few medical interventions are completely without any risk, although the ED health care professional can help the family to weigh any risks in the context of the untreated conditions for which they sought care. Physician liability in these circumstances is best addressed by good documentation of discussions with the family and of the steps taken to negotiate a medically safe course. In a situation in which the ED health care professional feels that a parent's decision places the child in jeopardy, then the appropriate child protective services agency should be engaged.

If a family decides to leave the ED rather than pursue the treatment choices outlined by the ED health care professional, the ED health care professional must consider the potential consequences to the child. Some institutions specifically forbid the option of allowing the family and child to leave, even after signing a form that states that they are aware that they are leaving against medical advice when the patient is a minor. In other institutions, a form and policy on leaving against medical advice exist but are rarely invoked; instead, the practice is to negotiate an alternative that is acceptable to all and to document the attempts and reasoning used to arrive

at that negotiated agreement. If a family leaves before or without such a discussion (a category often labeled "left without being seen" or "left without completing treatment"), further communication with the family should be informed by the potential for adverse outcome to the child and may range from a simple follow-up call to the family and primary health care professional to involvement of police and child protective services (personal communication, Pediatric Emergency Medicine Database discussion list [http://listserv.brown.edu/archives/cgi-bin/wa?A0=PED-EM-L], 2007).

The time frame of an ED visit does not commonly allow for the judicial process to provide a solution, although in less time-sensitive situations, many courts have shown reluctance to require medical treatment over the objection of parents "except where immediate action is necessary or where the potential for harm is rather serious."[74] The urgency of certain interventions, therefore, requires proactive planning for such events and a well-defined process for resolving a refusal of care, including, if needed, emergency custody.

7. Visits Related to Abuse or Violence

In situations in which the patient presentation prompts consideration of possible inflicted injury, ED health care professionals need to keep all involved parties (patient, family members, and staff) safe. Precepts of PFCC in no way reduce the obligation to report suspected abuse or neglect. However, it is important to remember that the intent of such reporting is to protect the child, a goal that most families, even abusive ones, will acknowledge. Understanding that a report of suspected abuse or neglect is filed on behalf of a child rather than against a suspected perpetrator ensures that the process is patient and family centered. ED health care professionals have no obligation and no expertise to be judge or prosecutor in such situations. However, although it is not the physician's place to indict a parent or caregiver, it is clearly the ED health care professional's responsibility to ensure an appropriate safety plan, which may involve hospitalization or otherwise removing the child from parental care until the child's safety can be ensured.

8. Unanticipated Critical Event or Death

Caring for the child with unanticipated critical injury, illness, or death in the ED is one of the most difficult tasks for any ED health care professional, one that requires careful planning, training, and previous identification of resources within and outside the ED. Several important resources exist to guide planning and preparation for such an event.[4,75,76] Having protocols and procedures in place is critical for anticipating the needs of family members, who often arrive separate from their child and in emotional disarray. Under such circumstances, immediate response from designated, trained staff who are not required for the medical management of the child but whose role is to support the family is vital. Protocols should address how the ED team is to relate to media, police, private physicians, the medical examiner, child protective services, and organ- and tissue-procurement teams. Protocols should address a plan for safe and compassionate family-member presence and identify additional resources available to the ED, such as social service, chaplaincy, acute psychiatric services, and child life services. Space should be designated for family privacy, with adequate seating, local and long-distance telephone capability, an accessible restroom, tissues, water, and writing materials.

If family members are not able to be present with the child in the ED, conveying the information of the child's death can be a very difficult task for an ED health care professional. Recommended bereavement guidelines[74] include: informing the family in a private location; using the child's name; informing the family of all medical procedures performed; noting any family efforts to help or comfort the child (such as seeking medical care, giving a good medical history, providing comfort by touching the child); offering information about autopsy and tissue donation; contacting important family supports such as members of the family's faith community; offering private or accompanied time with the child's body; allowing for time to make meaningful mementos consonant with religious or cultural precepts; and providing a follow-up contact. For most parents, the image of their child's body lying unattended in a hospital morgue inflicts additional pain after loss. If a medical examiner's evaluation is not required, many EDs have found a way to keep an attendant with the child's body until a designated funeral home can come, in that way reassuring and comforting surviving family members. The death of a child is the beginning of a lifelong condition of bereavement for parents and siblings, one on which ED health care professionals can have a profound effect.[76]

APPENDIX 2: SAMPLE PROTOCOL FOR FAMILY PRESENCE IN THE ED (ADAPTED FROM MASSACHUSETTS GENERAL HOSPITAL ED POLICY)

Practice Statement

Family-member presence should be considered as an option in all phases of ED care, including invasive procedures and resuscitation efforts, unless the patient's own wishes, demands of evolving patient independence, need for private interview or examination, or safety of the patient, family, or staff dictate otherwise. The health care team will be responsible for assessing patient and family needs and supporting the family and patient during their time in the ED, whether at the bedside or not.

Definitions

Family member: a relative or person (significant other) with an established relationship with the patient.

Invasive procedure: a procedure that involves penetration or manipulation of the body.

Resuscitation: life-sustaining or life-saving measures.

Family support facilitator: a staff member (nurse, clinical nurse specialist, physician, chaplain, paramedic, or other suitable staff member) assigned to support the psychosocial needs of the family; this person should not be needed for the immediate re-

suscitation or direct assistance with the invasive procedure.

Procedure

- Designate family support facilitator
- Assess/screen family members:
  - Determine the preference of the patient, if possible. Assess the family's perception and understanding of the clinical situation and scope of crisis, need to be with the patient, coping abilities, comfort level with medical environment, and ability to ask for help or leave the area. Consider cultural preferences.
  - Exclusion criteria may include combativeness, agitation, extreme emotional instability, altered mental status, and intoxication. Families who do not wish to participate should be supported in that decision and should be supported while they are separated from the patient. If the family is not offered the option of family-member presence, the reason should be documented (eg, risk of combative or threatening behavior, extreme emotional lability, behaviors consistent with intoxication or altered mental status, disagreement among family members).
- Consult with health care team: As early as possible, inform the health care team of the family's presence. Discuss with the team the family's wish to be with the patient. Both the team and the facilitator should be in agreement and determine the appropriate time for the family to be at the patient's bedside. Departmental situations or constraints should be considered.
- Prepare family member(s): The facilitator will present the clinical situation, explaining what the family member may expect to observe during the patient's treatment. The facilitator will explain to the family that patient care is the top priority and alert them to any potential limitations on time or numbers of family members who may be present, where they may sit or stand to optimize patient contact without impeding care, and any situations in which they would be escorted out of the room and will reassure them that they may leave at any time. Family members agree to the structure of their time at the bedside.
- Escort family member(s) to the bedside: The facilitator will remain with the family at all times during the visit and explain procedures and answer questions. The family will be allowed to see, touch, and speak with the patient when possible. If the time at the bedside must be limited, the facilitator will escort family to a private room and provide clinical updates on the patient's condition. A facilitator, primary nurse, or psychiatric clinical nurse specialist will follow-up with the family.

Note that this policy should undergo institutional legal review and, when verified as part of hospital policy, be part of staff education and orientation.

abstract

FREE

Children with disabilities and their families have multifaceted medical, developmental, educational, and habilitative needs that are best addressed through strong partnerships among parents, providers, and communities. However, traditional health care systems are designed to address acute rather than chronic conditions. Children with disabilities require high-quality medical homes that provide care coordination and transitional care, and their families require social and financial supports. Integrated community systems of care that promote participation of all children are needed. The purpose of this clinical report is to explore the challenges of developing effective community-based systems of care and to offer suggestions to pediatricians and policy-makers regarding the development of partnerships among children with disabilities, their families, and health care and other providers to maximize health and well-being of these children and their families. *Pediatrics* 2011;128:795–802

INTRODUCTION

Children with special health care needs are a group of 10 million US children with a wide variety of conditions, medical needs, and caregiving requirements.[1] However, children with disabilities, a subset of children with special health care needs, tend to have more complex conditions and functional impairments, often with technology dependencies and recurrent hospitalizations. In fact, 6.3% of US children between 5 and 15 years of age have 1 or more disabilities, and approximately 1%, or nearly one-half million children, are unable to care for themselves.[2] Over the past 50 years, the number of children living with disabilities has tripled, largely as the result of health care advances that have allowed the survival of children with conditions that were historically incompatible with life.[3] Children and adolescents have had the highest growth rate of disability of any age group during the past decade.[3] Despite these changing demographics, the current system of health care continues to use an outdated system that emphasizes acute illness and well-child care at the expense of long-term management of chronic conditions and disabilities.

Historically, hospital-based or institutional care was the only option for most children with complex medical conditions, technology dependence, and significant behavioral and emotional needs. More recently, social policy has promoted community-based programs that provide care for children with disabilities in their homes and communities.[4] For

example, Healthy People 2010 set a goal of reducing to zero the number of children and youth living in congregate care settings. These well-intentioned efforts to care for all children with disabilities in their homes and communities rather than congregate care centers have benefitted many children and families. However, community-based care has also brought new and unanticipated challenges for some children with disabilities, their families, communities, and health care systems. The purpose of this clinical report is to explore the challenges of developing effective community-based systems of care and to offer suggestions to pediatricians and policymakers regarding the development of partnerships among children with disabilities, their families, and health care and other providers to maximize the health and well-being of these children and their families.

ADDRESSING THE NEEDS OF CHILDREN WITH DISABILITIES

Children With Disabilities Require Medical Homes

It is a national health care objective to ensure that all children with special health care needs have access to comprehensive health care consistent with the standard of a medical home.[5,6] A core component of community-based systems of care, the medical home ideally comprises providers who are knowledgeable in the area of chronic condition management and actively screen all children for developmental disability.[4] Children with disabilities cared for in medical homes that provide care coordination benefit from increased access to subspecialty care, fewer missed days of school, and decreased family financial burden.[7] Moreover, having a medical home is a predictor for less inpatient and emergency department utilization[8] and fewer unmet medical and support-service needs.[9] The longitudinal relationship between medical home providers, children with disabilities, and their families provides a comfortable and trusted framework for shared decision-making and, in some instances, end-of-life discussions. Despite these benefits, only half of all children with special health care needs currently receive care consistent with an ideal medical home, a proportion that is significantly lower than that of their typically developing peers.[7] Living in poverty or certain geographic locations and having a more severe disability or certain conditions, such as autism, further limit a child's access to a medical home.[9–11]

Beyond access, care coordination within the medical home matters. Care coordination facilitates strong partnerships between families and physicians and supports shared medical decision-making. Providers beyond the medical home are frequently involved in the care of children with disabilities in emergency departments, subspecialty clinics, and hospitals. Even if they do not participate directly in care delivery, medical homes can collaborate with providers and families to foster trust, provide information, and assist in treatment planning.[12] Without such collaborations, children with disabilities are at increased risk of experiencing adverse events related to delayed or incomplete information transfer between providers.[13] However, nearly half of all children with special health care needs do not receive adequate care coordination, at least in part because of inadequate payment to providers.[14,15] Eliminating barriers to effective care coordination within the medical home is essential if pediatric systems of care are to effectively address the needs of children with chronic conditions and disabilities.

Pediatricians have a vital role in linking medical homes with other community-based services for children with disabilities and their families. With universal approaches to developmental surveillance and screening, providers can make timely referrals for at-risk children to educational services, such as early intervention and special education programs. Familiarity with the Individuals With Disabilities Education Act and Section 504 of the Rehabilitation Act can help pediatricians effectively advocate for children with disabilities and their families in the development and implementation of individualized educational plans that are family centered and goal directed.[16,17] Likewise, the medical home should be a clearinghouse of information for potential sources of support for families and assist in providing medical information to agencies to facilitate the eligibility process.[18] For example, the Supplemental Security Income (SSI) program can provide financial assistance and establish eligibility for other vital services that may not otherwise be accessed.[19]

Although financing the critical aspects of the medical home has been a barrier for implementation, recent national policy changes have improved the outlook on providing these services for children with disabilities. The Children's Health Insurance Program Reauthorization Act of 2009 contains several provisions that support state initiatives to strengthen medical homes for children with disabilities. For example, Idaho and Utah are using electronic health records and other health information technology and placing medical home coordinators in primary and subspecialty practices to improve care coordination.[20] In addition, section 2702 of the Affordable Care Act (Health Home for Enrollees With Chronic Conditions) provides states the option to receive an enhanced federal match if they amend

state plans to fund medical home services for children with disabilities.[21]

Youth With Disabilities Require Transitional Care

Every year, more than one-half million youth with disabilities transition to adulthood.[22] This process may include participation in postsecondary education, vocational training, employment, independent or supported living arrangements, and adult health care systems. However, for children with complex chronic conditions and lifelong functional limitations, the transition process can be complex and fraught with barriers, particularly for those who are uninsured, poor, or lacking medical homes or who have more severe disabilities.[23] Not all youth with disabilities transition fully into independent or supported living arrangements; for example, more than half of young adults with autism continue to live with their parents.[24] Uninterrupted comprehensive health care; coordinated transfers of medical information; and accessible, affordable, and continuous health insurance coverage are core elements of successful health care transitions.[25] Lack of adult provider expertise and experience in the care of youth with child-onset disabilities creates additional access barriers, even for those young adults with insurance coverage. Changes in insurance rules and training for the medical workforce would improve transition processes.[26] Several pilot programs that provide clinical services during the late adolescent/young adult years or deliberate transition-specific care coordination offer promising approaches to health care transitions for youth with disabilities.[26]

Pediatricians can assist in the transition of youth with disabilities into adult health care systems by preparing families well in advance, assisting in the identification of adult providers, and communicating relevant patient information with adult providers via written medical summaries and current care plans. Provisions in the Individuals With Disabilities Education Act mandate the development of an individualized transition plan (ITP) to prepare youth with disabilities to enter the adult community. Pediatricians can assist youth with disabilities by encouraging pursuit of identified vocational goals and advocating for implementation of an appropriate individualized transition plan.[27]

ADDRESSING THE NEEDS OF FAMILIES OF CHILDREN WITH DISABILITIES

Parents of Children With Disabilities Need Opportunities to Promote Their Own Health and Well-being

Parents of children with disabilities often experience unrecognized and, therefore, unaddressed negative consequences of long-term caregiving. They are in poorer physical and emotional health than are parents of typically developing children.[28,29] When compared with others, parents of children with cerebral palsy report greater chronic distress and higher rates of back problems, migraine headaches, stomach/intestinal ulcers, and chronic pain.[30] Parents of children with technology dependencies report limited time for sleep and for participation in social and community activities.[31] Behavioral problems in children with autism spectrum disorders are strongly associated with parental stress.[32,33]

When parents of children with disabilities experience poor health, they may be less able to care for their children, which sets up a vicious cycle of negative outcomes for all family members.[30,34] In fact, the physical health of parents is directly associated with the physical health of their children with cerebral palsy, and their mental health is significantly associated with the psychosocial function and total quality of life of their children.[35] Strategies that promote the health and well-being of parents might benefit the entire family through these complex, reciprocal interactions. For example, resilient families of children with autism find a positive meaning in the disability, mobilize resources, and gain spiritual strength, which culminates in greater family cohesion and appreciation of life.[36] Linking parents of children with disabilities to appropriate family organizations and peer support has been shown to positively affect both parents and children.[37–40]

Siblings of Children With Disabilities Need Support

Living with a child with a disability changes the childhood experience for siblings. Many siblings report that family routines are focused and planned around the sibling with a disability. Older siblings report that they have provided nursing and respite care, which limits their own time for social activities outside the home. Nearly half of all siblings report that their attendance and performance at school is negatively affected by the home care regimen of a sibling dependent on technology.[31] The caregiving responsibilities and frustration about perceived competition for parental attention render siblings of children with disabilities at heightened risk of negative psychological effects such as anxiety and depression.[40] Despite these challenges, nearly 40% of parents of children with developmental disabilities report positive outcomes for siblings.[41] Family-based interventions that enrich sibling experiences while minimizing negative consequences are needed.

Parents of Children With Disabilities Need Financial Support

Forty percent of families with children with special health care needs experience financial burden related to their child's condition.[42] Although most families of children with special health care needs have medical insurance, underinsurance resulting in financial stress preferentially affects families of children with disabilities.[43] Reports of financial hardship are more frequent in families with children with more severe disabilities, those with lower incomes,[44] and those with certain conditions such as autism spectrum disorders.[45,46] Hopeful investment in unproven interventions can further deplete family finances.

At the same time that families of children with disabilities experience greater financial demands, nearly 30% of them also contend with loss of income secondary to the need to reduce or eliminate employment.[47] Although some innovative employers offer benefits that might support employees of children with disabilities,[48] having a child with a disability is still associated with reduced parental employment. Single parents of children with technology dependencies are 15 times more likely to quit employment secondary to care responsibilities at home than those in 2-parent families.[49] Lower financial stress is associated with receipt of coordinated care in a medical home, having adequate insurance, and access to organized and accessible community-based service systems.[42] Beyond reducing financial stress, employment builds resilience in parents by offering challenges and rewards that are distinct from the complex responsibilities of caregiving.[49]

The recently enacted Affordable Care Act contains several provisions within private insurance reform that benefit families of children with disabilities: (1) elimination of lifetime and annual caps on benefits; (2) guaranteed coverage through elimination of preexisting condition denials; and (3) expansion of dependent coverage up to the age of 26 years. Once exchanges are established by 2014, benefits for health plans must include chronic disease management, behavioral health treatment, habilitation and rehabilitation services and devices, and oral and vision care. The scope of each of these benefits is yet to be defined.[21]

Families of children with disabilities rely on a variety of public and private programs such as private insurance, Title V programs, special education services, Supplemental Security Income (SSI), and Medicaid. SSI can be an important source of financial support for low-income families of children with disabilities.[19] Since 1993, the Family Medical Leave Act (FMLA) has afforded parents of children with disabilities the option of taking up to 12 weeks of excused absence from their work per year to better balance work and family obligations.[50] The mix of support varies depending on geographic location, parental income, and eligibility factors, and pediatricians can guide parents as they navigate these complex systems of funding.[3] Family coordinators in medical homes can identify community resources and offer supports for both families and providers of children with disabilities.[51]

Families Require Options for High-Quality Care Outside the Home

With proper support, most children with disabilities thrive at home.[52] Although home is the ideal place for most children, it may not be the best place for every child. In 1997, approximately 1 per 1000 (nearly 25 000) children and youth were cared for in congregate care settings, including group homes and residential centers.[53] Healthy People 2010 established an objective to reduce this number to zero. Five years later, the percentage of children and youth cared for in congregate care settings was nearly unchanged,[53] which may relate to the unpredictable and often unavoidable circumstances that necessitate that children with disabilities receive intervals of care outside of their homes. The long-term demands of addressing the physical, emotional, and behavioral needs of some children with disabilities may periodically exceed that which their parents and families can manage, particularly when financial and social supports are limited.[28] In such instances, the stress of caregiving can lead to disrupted parenting and poor child outcomes.[54] For example, children with disabilities are 3 to 4 times more likely to be neglected or abused than are typically developing children.[55] Community-based congregate care options can offer safe harbor for children with disabilities when families find themselves in need of respite or when facing crisis situations. By maintaining strong partnerships, pediatricians can recognize families in crisis and assist them with finding appropriate resources.

ADDRESSING NATIONAL GOALS

Communities Must Promote the Participation of All People, Including Children With Disabilities

The World Health Organization's International Classification of Function characterizes people with disabilities according to their ability to participate in meaningful community activities rather than diagnostic groupings. It emphasizes what children do rather than how they do it and note that the presence of a disability does not suggest an absence of health.[56] The participation of each child is influenced by contextual elements such as interactions between the child, family, and community. Although all children, including those with disabilities, can

benefit from participation in sports, recreation, and physical activities, personal and societal barriers need to addressed.[57] In general, children with disabilities are less involved in leisure activities than their peers and engage in activities that are more passive, home based, and less varied.[58] Parents and children with physical disabilities describe architectural barriers, restrictive policies, limited personal assistance, cultural biases, and inadequate social support as major barriers to community participation.[59] Age, gender, activity limitations, family preferences, and coping, motivation, and environmental resources are other determinants of participation.[58]

Coordinated Systems of Care for Children With Disabilities Need Universal Implementation

A well-functioning system of family-centered, coordinated health care for children with disabilities would comprise a full range of health care, education, and social services.[50] The overarching goal would be to address each child's mental, physical, emotional, and social needs to optimize function and participation according to the International Classification of Function model of disability. Regardless of the point of entry, children and their families would be linked to other necessary services, because the system would be accessible, flexible, and responsive. Family partnerships would lie at the hub of this system, consistent with the fact that families know their children best and make decisions on behalf of their children.[50] This community-based system of service would be universally accessible, equitable, and organized to promote the cost-effective provision of evidence-based care.[60]

A comprehensive community-based system has been conceptualized but not implemented. Despite the evidence that a sense of partnership between families and providers is associated with fewer unmet needs and better outcomes overall, of US families of children with special health care needs, 1 million (14%) report a lack of such partnerships.[61] Poverty, minority status, lack of insurance, and greater severity of functional limitations are associated with greater risk of lacking a sense of partnership.[61] The barriers to implementation include lack of integration, coordination, and communication between various service providers and agencies; lack of adequate funding to develop system infrastructure; lack of funding sources to meet children's needs; and balancing privacy concerns with service providers' need for information.[50] Although our society expects that parents will unconditionally and indefinitely care for their children with disabilities, our health care system offers, at best, a fragmented and 1-size-fits-all response to their individualized and often changing needs.[62] The Affordable Care Act addresses several of these shortcomings with provisions that strengthen community-based options for long-term services and supports for children with disabilities: (1) the Community First Choice Option; (2) new options for home- and community-based services in Medicaid; and (3) extension of "money follows the person" demonstration grants.[63]

Analogous to Russian nesting dolls, children with disabilities do not live in isolation but are embraced by their parents, who function within family units, which are, in turn, nested in communities and, ultimately, in local and national health care systems.[64] This social ecological framework of human development illustrates the critical importance of community-based systems response to the multifaceted and dynamic interdependencies among children with disabilities and their parents, families, communities, and health care systems.[65] Because the characteristics of each child and family, their shared history, and the social, economic, and cultural contexts within which they find themselves combine to create an infinite variety of circumstances,[66] care must be individualized and based on the tenets of mutual trust, respect, and family-centered decision-making.

SUGGESTIONS FOR PEDIATRICIANS

1. Provide a medical home for children with disabilities that emphasizes the family as a valued partner in decision-making, coordinates care with subspecialists, and links families with community-based services.
2. Ensure coordinated, deliberate, and community-based transitions for all youth with disabilities by advocating for access to appropriate educational and related community-based transition services and coordinating with adult medical providers.
3. Recognize the unique needs of parents and siblings of children with disabilities, and offer strategies for them to promote their own physical and emotional health and well-being, including links to family support groups and mental health services.
4. Understand and promote access to financial supports for families of children with disabilities, including Medicaid, Supplemental Security Income, and Family Medical Leave Act programs.
5. Recognize caregiver stress and ensure that all parents are aware of self-care strategies and options for high-quality care for their children with disabilities, both inside and outside the home.
6. Encourage participation of children with disabilities and their families in educational, recreational, and social activities by actively linking

them to community-based agencies and organizations.

7. Adopt a family-centered approach to the care of children with disabilities by involving families in all aspects of medical decision-making.

SUGGESTIONS FOR POLICY-MAKERS

1. Ensure enforcement of health insurance reforms that benefit children with disabilities under the Affordable Care Act, including the elimination of lifetime and annual caps on benefits, guaranteed coverage through elimination of preexisting-condition denials, and the expansion of dependent coverage up to the age of 26 years.
2. Adopt models that support essential functions of medical homes for children with disabilities, including care coordination and telephone management.[67]
3. Advocate for the continuous provision of vital public health services that support families of children with disabilities, including state Title V programs and Family-to-Family Health Information Centers.
4. Maintain and extend public coverage options (Medicaid and Children's Health Insurance Program) for children with disabilities through Affordable Care Act initiatives, such as simplifying eligibility requirements and amending state Medicaid plans to fund medical home activities.

Patient- and Family-Centered Care and the Role of the Emergency Physician Providing Care to a Child in the Emergency Department

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

AMERICAN ACADEMY OF PEDIATRICS
Committee on Pediatric Emergency Medicine

AMERICAN COLLEGE OF EMERGENCY PHYSICIANS
Pediatric Emergency Medicine Committee

ABSTRACT

Patient- and family-centered care is an approach to health care that recognizes the role of the family in providing medical care; encourages collaboration between the patient, family, and health care professionals; and honors individual and family strengths, cultures, traditions, and expertise. Although there are many opportunities for providing patient- and family-centered care in the emergency department, there are also challenges to doing so. The American Academy of Pediatrics and the American College of Emergency Physicians support promoting patient dignity, comfort, and autonomy; recognizing the patient and family as key decision-makers in the patient's medical care; recognizing the patient's experience and perspective in a culturally sensitive manner; acknowledging the interdependence of child and parent as well as the pediatric patient's evolving independence; encouraging family-member presence; providing information to the family during interventions; encouraging collaboration with other health care professionals; acknowledging the importance of the patient's medical home; and encouraging institutional policies for patient- and family-centered care.

INTRODUCTION

Patient- and family-centered care (PFCC) is an approach to health care that recognizes the integral role of the family and encourages mutually beneficial collaboration among the patient, family, and health care professionals. PFCC ensures the health and well-being of children and their families through a respectful family-professional partnership. It honors the strengths, cultures, traditions, and expertise that all members of this partnership bring to the relationship. PFCC is the standard of practice that results in high-quality services.[1] PFCC embraces the concepts that (1) we are providing care for a person, not a condition, (2) the patient is best understood in the context of his or her family, culture, values, and goals, and (3) honoring that context will result in better health care, safety, and patient satisfaction.

Although there are many opportunities for providing PFCC in the emergency department (ED), there are significant challenges to doing so.[2] Overcrowding and

acuity in the ED may result in delay or disruption of care, challenging the ability of ED staff to provide respectful and sensitive care. The lack of a previous relationship between patient/family and health care professionals and the acute nature prompting an ED visit can make it difficult to create an effective partnership. The many cultural and societal variations among families can increase the difficulty in identifying who is a child's legal guardian. Situations unique to the ED, such as the arrival of a child by ambulance without family, the unaccompanied minor seeking care without the knowledge of family, visits related to abuse or violence, time-sensitive invasive procedures including resuscitation efforts, and the unanticipated death of a child, require the most thoughtful advanced planning.[3–5]

The option of family-member presence during invasive procedures including resuscitation efforts has been recommended in a statement by the Ambulatory Pediatric Association[2] that was endorsed by the American Academy of Pediatrics (AAP) in November 2004. PFCC includes respect for the privacy of the patient and acknowledgment of the pediatric patient's evolving independence, especially with regard to reproductive issues. Communication between health care professionals in the ED and the child's medical home primary care physician who is accessible and community-based and offers coordinated, comprehensive, continuous, culturally effective care[6] will enhance support of PFCC in the ED.

The AAP and American College of Emergency Physicians have a long tradition of supporting PFCC and have issued independent and joint policy statements in the past.[7,8] This policy statement addresses the particular challenges in, and opportunities for, providing PFCC in the ED setting and is in concert with and as an adjunct to earlier statements.

RECOMMENDATIONS

The AAP and American College of Emergency Physicians support the following:

1. Knowledge of the patient's experience and perspective is essential to practice culturally effective care that promotes patient dignity, comfort, and autonomy.
2. The patient and family are key decision-makers regarding the patient's medical care.
3. The interdependence of child and parent, patient and family wishes for privacy, and the evolving independence of the pediatric patient should be respected.
4. The option of family-member presence should be encouraged for all aspects of ED care.
5. Information should be provided to the family during interventions regardless of the family's decision to be present or not.
6. PFCC encourages collaboration with other health care professionals along the continuum of care and acknowledgment of the importance of the patient's medical home to the patient's continued well-being.
7. Institutional policies should be developed for provision of PFCC through environmental design, practice, and staffing in collaboration with patients and their families.

POLICY STATEMENT

Patient Safety in the Pediatric Emergency Care Setting

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine

ABSTRACT

Patient safety is a priority for all health care professionals, including those who work in emergency care. Unique aspects of pediatric care may increase the risk of medical error and harm to patients, especially in the emergency care setting. Although errors can happen despite the best human efforts, given the right set of circumstances, health care professionals must work proactively to improve safety in the pediatric emergency care system. Specific recommendations to improve pediatric patient safety in the emergency department are provided in this policy statement.

BACKGROUND

Since the release of 2 landmark reports by the Institute of Medicine (IOM) Committee on Quality of Health Care in America in 1999 and 2001,[1,2] patient safety has become a priority issue and area of focus for health care professionals and researchers, hospital administrators, policy makers, accrediting agencies, health care purchasers, and patients and families. The US Department of Health and Human Services, through the Agency for Healthcare Research and Quality, launched a $50 million initiative in 2001 to increase and improve research in patient safety.

Despite an increased focus on patient safety at a national level, leaders in patient safety and quality improvement have reported little progress in reduction of harm since the release of the IOM reports.[3] Professional societies, national health care agencies, individual health care systems, and hospitals have demonstrated some successes such as a reduction in serious infections or fewer patients dying from accidental injections of concentrated potassium chloride. Overall, however, there is still much room for improvement in delivering safe, high-quality health care in America.

Health care can be risky and highly complex. Thousands of patients still die or suffer harm from medical errors while receiving health care services despite the dedication and hard work of well-trained health care professionals who seek to provide good care. Leape, in a seminal article published in 1994,[4] sought to explain the epidemic of medical errors by comparing the American health care system to other highly complex, high-risk industries such as nuclear power and aviation. Researchers in these industries found that mishaps and accidents were often caused by poorly designed systems rather than by mistakes of irresponsible or ill-prepared individuals. Leape further noted that skilled people predictably make some mistakes, especially when distracted or fatigued, so the complex systems in which they function must be designed in a way to defend against human error.

Reason, a noted psychologist and expert in human performance, described numerous human factors that predictably lead to errors when humans work in complex systems.[5] For example, memory, vigilance, and attention to detail often decrease when people are fatigued or stressed. Errors occur more readily when people are required to perform multiple complex cognitive tasks simultaneously, such as calculating a dose of medicine for a child while performing clinical tasks such as airway maneuvers or establishing intravascular access, as might be the case in the out-of-hospital emergency medical services (EMS) or emergency department (ED) setting.

A limited number of studies have been published describing problems related to pediatric patient safety; however, the body of literature is growing.[6–9] Unique aspects of pediatric care that may increase the risk of medical error include lack of standardized dosing because of size variation in the pediatric age range; inability of young children to provide a medical history or clearly communicate complaints; and the unique physical and developmental characteristics of children that may affect treatment strategies and medication regimens. The American Academy of Pediatrics (AAP) has published 2 policy statements on patient safety that describe these risks in more detail and provide useful recommendations for all pediatric health care professionals.[10,11]

Studies have suggested that medication dosing in children is a particularly high-risk activity, because it requires manual dosing.[12] Standardized unit doses are rarely used in children; rather, each dose of medicine is calculated by using a dosing equation based on the child's weight. The act of calculating dosing equations has been identified as a high-error activity, and several factors compound the risk of error when medications are given emergently.[13] For example, the child's weight is often not known and, therefore, must be approximated. There are limited opportunities for prescription monitoring or double checking, and in some cases, the inherent stress of managing a life-or-death situation can lead to errors. Indeed, a study that reviewed medical errors in academic medical centers found the pediatric service to be the most error-prone setting and the ED to be a close second.[14]

Three reports from the IOM Committee on the Future of Emergency Care in the United States Health System in 2006 identified patient safety as a significant concern.[15–17] The report dedicated to pediatric care, *Emergency Care for Children: Growing Pains*, noted that the state of pediatric emergency care in 2006 was best described as "uneven." This assessment of the current performance of our nation's EMS system for ill and injured children offered specific observations and recommendations relating to pediatric patient safety, including that "hospitals and EMS systems should implement evidence-based approaches to reduce errors in emergency and trauma care for children."[15]

STATEMENT OF THE PROBLEM

Caring for children in the emergency setting is especially prone to error because of a number of environmental and human factors. The ED environment is often hectic and chaotic, with frequent workflow interruptions. The out-of-hospital emergency care setting can be similarly chaotic. Wide fluctuations in patient volume, especially including large numbers of children who are not seriously ill or injured, require increased resources and attention from physicians and nurses, who then become distracted from caring for more critically ill or injured children.[18] Shift work, especially overnight shifts—although necessary for fulfilling the 24/7 mission of EDs—can lead to provider fatigue and increased risk for errors.[19]

There are many opportunities for communication errors in the ED because of numerous hand-offs of care, decision-making by multiple health care professionals and consultants, and frequent verbal orders during emergency events, which preclude the opportunity for redundancy and "double checks."[20] In addition, a growing number of children and families who present to an ED do not speak English. Studies have shown that these patients may represent a group that is at high risk for medical errors.[21]

Most children in this country are cared for in EDs that are located in general hospitals rather than in hospitals dedicated to the care of children. Because a minority of patients in general hospitals are in the pediatric age group, many ED staff may lack familiarity with pediatric emergencies and sufficient opportunities to regularly practice the cognitive and technical skills necessary for providing emergent pediatric care.

Finally, there is great opportunity for improvement during the process of ordering and administering medications to children in the emergency setting. Observational studies of simulated pediatric emergency events have identified problems with dosing of medications[22] and conversion of medication doses ordered in units by weight (eg, milligrams) to the appropriate number of units by volume (eg, milliliters), depending on the formulation of the drug.[23] These studies have also described a prolonged period of time required to calculate doses and administer certain critical medications.[22,23]

STRATEGIES FOR IMPROVEMENT

High-Reliability Organizations

A key concept in the development of a safer environment in the ED is that of a high-reliability organization (HRO). HROs are those that operate in a high-risk environment but maintain very low rates of injury or

harm.[24] In these organizations, there is a general acknowledgment among all members that a mishap can happen at any time, given the right set of circumstances, and that only through a constant mindfulness that no person or organization is perfect can the risk of mishap be minimized. It is this desire to achieve perfection, while at the same time recognizing that mishaps can occur, that allows HROs to achieve such impressive safety records.

Systems-Based Approach to Patient Safety

A preoccupation with the potential for harm manifests itself in a systems-based approach to patient safety, an approach that acknowledges that human beings and their limitations must be accounted for in the design of the system.[24] By proactively designing a system that takes into account the strengths and limitations of individual health care professionals, the ED team can improve the safety of patients and minimize the risk of harm.

Examples of the systems-based approach include the standardization of processes or procedures as guided by evidence rather than by individual preference. A specific example provided by Pronovost et al[25] demonstrated how use of a standard approach to the insertion of central venous catheters could reduce the number of associated bloodstream infections.

A number of national organizations are beginning to identify evidence-based safe practices that can lead to improved patient safety. The National Quality Forum recently published its recommendations for 30 safe practices for better health care,[26] and the AAP Safer Health Care for Kids project, funded by a Physician's Foundation for Health Systems Excellence grant, is assembling various safe practices as part of a suite of Web offerings, including Web seminars and an unprecedented pediatric patient safety Web site, to improve the care of children.[27]

Hand-washing is a simple example of a safe practice for all clinicians, including pediatric emergency care professionals. Ample evidence suggests that handwashing is an important component of infection-control practices,[28] and patients and families should be taught that the most important thing they can do to prevent the spread of infectious diseases is to wash their hands at home. Health care professionals have a great opportunity to provide an example and model behavior that will lead to improved patient safety by washing their hands before and after examining each patient in the ED.

Best Practice in Emergency Stabilization and Resuscitation

Emergency care is most complex and risky in the setting of resuscitation, when assessment, information transfer, and treatment must occur simultaneously at the hands of a multidisciplinary team.[15] Many members of the ED team maintain training in resuscitation techniques through life support courses such as Pediatric Advanced Life Support,[29] Advanced Pediatric Life Support,[30] and Advanced Trauma Life Support (ATLS).[31] These courses offer a well-structured "ABC" approach as a standard that should be used to direct patient assessment and potentially life-saving interventions. After addressing concerns related to airway, breathing, and circulation, the team must continue through the resuscitation protocol to identify signs of critical illness or injury that require prompt treatment. However, observational studies have demonstrated that health care professionals do not always adhere to ATLS guidelines.[32] A recent study described marked variation in the clinical performance of ED professionals in a simulated pediatric trauma event.[32] Resuscitation tasks associated with both the primary survey (a quick examination to identify life- or limb-threatening injuries) and the secondary survey (a complete head-to-toe examination to identify all signs of injury) were often skipped or performed incompletely by the ED team.

Evidence-Based Clinical Guidelines and Decision Support

Researchers in many other areas of health care have described clinical practice variability, even in areas for which best practice has been defined on the basis of strong scientific evidence and a high degree of expert consensus.[33] In the past few years, there have been many efforts to increase the use of evidence-based care guidelines and therapies by health care professionals through regulatory mechanisms (such as the pay-for-performance initiative of the Centers for Medicare and Medicaid Services and the use of quality measures by the Joint Commission on Accreditation of Healthcare Organizations), provider organizations (AAP, American College of Emergency Physicians, American College of Surgeons), and individual health care institutions. A number of quality improvement initiatives have been implemented to improve compliance with clinical guidelines and evidence-based therapies. A recent review of 59 published evaluations of clinical guidelines showed that the most effective implementation strategies were those that provided patient-specific advice at the time of decision-making,[34] such as at the time of entering orders.

Information Technology

Computerized physician order entry (CPOE, or clinical provider order entry) systems can provide a useful platform for integrating evidence-based guidelines into clinicians' workflow by providing "just-in-time" treatment advice or decision support tailored to the needs of the individual patient.[35] It is important to note, however, that unanticipated problems may result from implementation of a CPOE system that is not customized for children.[36] Although CPOE is not yet available in many EDs,

ED providers should advocate for pediatric-specific information technology tools and systems such as this, which can help improve the quality and safety of care provided to patients.

Safety WalkRounds

In HROs, the clear goal of every team member is to improve safety. This requires open lines of communication, such that any individual who has a critical piece of information is expected to communicate it to whomever needs to know, regardless of hierarchy, seniority, title, gender, pay grade, or ethnic background. ED leaders can initiate activities that will help create a culture in which every team member is comfortable to speak up about safety concerns. One such activity is Safety WalkRounds,[37] which was developed to help executives and leaders learn from front-line staff how to improve care and reduce the risk of error in clinical care areas. Hospital executives or clinical and operational leaders and managers walk around care units and talk directly with staff to identify "what will hurt the next patient here." This experience helps to close the gap between leadership and front-line staff perspectives on safety. It allows physicians, nurses, and other staff members to express their safety concerns directly to hospital leaders and executives, and it allows executives an opportunity to model safety as a priority and provide appropriate resources to improve care.[38]

Safety Event Reporting Systems

Another opportunity for staff to share concerns is through the use of a voluntary reporting system. Many institutions and states have implemented reporting systems in response to the recommendation of the IOM to expand reporting of serious adverse events and medical errors.

The primary purpose of reporting is to learn from experience, especially when near-misses are included in the reports. Ideally, when an adverse or near-miss event occurs, an analysis is completed and changes are made to prevent a recurrence of the event. When aggregate voluntary reporting-system data are reported to an external body, the lessons learned can be shared more broadly, which then can lead to improved safety throughout the organization through the identification of trends or recurrent hazards and development of best practices to reduce risk.[10]

A number of computerized reporting systems have been developed, but many hospitals and health care agencies still use hand-written reports. Whatever reporting method or system is used, it should be nonpunitive, readily accessible, and easy for staff to use. Feedback to the reporter is important for addressing the concerns raised, offering possible solutions, and encouraging future reporting. As the AAP recommended in "Principles of Patient Safety in Pediatrics,"[10] reporting systems should require that information reported to internal and external review groups should not be discoverable in civil or legal actions.

Teamwork Training

The ED environment is similar in many ways to other high-risk workplaces, such as in aviation settings, where behavioral principles known as crew resource management (CRM) were developed to improve safety.[39] Crew training led to reductions in aviation mishaps, beyond those eliminated by improvements in equipment and technology, by focusing on behaviors of the people (team members) who use the technology. The basic principle of CRM is that team communication and coordination behaviors are identifiable and teachable. Indeed, specific teamwork behaviors have been observed in high-reliability teams performing in very demanding, high-risk, time-stressed environments such as combat aviation.[40]

The IOM recommended in its 1999 report that organizations "establish interdisciplinary team training programs that incorporate proven methods for team management, such as CRM."[1] A number of institutions are now providing teamwork training for physicians and staff members who work in high-acuity areas such as emergency medicine, critical care, perinatology, and surgery.

When the physician, as team leader, sets a tone of mutual respect and "psychological safety" by calling team members by name and inviting their input, staff satisfaction improves, staff turnover decreases, and team members report a safer environment for patients.[41,42] Too often, procedure-related errors occur when a member of the care team is aware of the error but is unable to communicate it to the physician. Staff can be taught communication skills, such as critical language skills, that will help avoid this type of situation. A consistent phrase can be used by all team members to signal an impending adverse event without disrupting the care environment. When such a phrase is used (such as "I need clarity"), the message communicated to the team leader is that he or she must stop and listen to the team member who has a concern about the patient's safety. Additional communication techniques, such as SBAR (situation, background, assessment, recommendation),[42] provide staff with a tool for facilitating the exchange of pertinent and important clinical information by using a standard format. Communication techniques such as this are critically important at times of hand-off in care, such as at change-of-shift when patients are transferred from one care team to another.

Patient- and Family-Centered Care

Patient- and family-centered care is an approach to health care that recognizes the integral role of the family and encourages mutually beneficial collaboration and partnership among the patient, family, and health care professionals.[43] Although there are many opportunities for providing patient- and family-centered care in the ED, there are also significant challenges to doing so. The lack of a previous relationship between patient/family and health care professionals, as well as the acute nature of many events prompting an ED visit, can limit efforts to create such a partnership and, likewise, may limit effective communication with the family. Situations particular to the ED, such as the arrival of a child by ambulance without his or her family, the unaccompanied minor who is seeking care without the knowledge of his or her family, or the day-to-day phenomena of overcrowding and high patient acuity in the ED, also pose significant challenges to patient- and family-centered care.

Family members and the medical home are both vital sources of information regarding the patient. The emergency care team should invite the family to be present during all phases of care, and the resources necessary to promote effective communication should be available. Timely identification of, and appropriate communication with, the child's medical home should also be considered in designing care processes. As mentioned previously, language and cultural barriers can present another challenge to successful communication and may increase the likelihood of medical errors when caring for non–English-speaking children and their families. This risk can be lessened by providing linguistically competent care through professional interpreters.[21]

Shift Work and Fatigue

In HROs, systems are designed to take into account the limitations of human beings, yet limitations related to fatigue are often not acknowledged. Cognitive and psychomotor skills cannot be consistently maintained by individuals who are fatigued, and prolonged wakefulness of 18 hours has been shown to have a negative effect on human performance approximately equivalent to a blood alcohol concentration of 0.1%.[44] Fatigue can negatively affect a variety of abilities that are critical in the emergency setting, including reaction time, hand-eye coordination, clerical accuracy, memory, and reasoning.[45] Sleep-deprived surgeons have been reported to make 20% more errors and take 14% longer to complete a laparoscopic surgical procedure in virtual-reality exercises.[45] Studies linking fatigue with medical errors have been reported for anesthesiologists,[46] residents,[47] and nurses[48]; residents attribute their medical errors to fatigue in 41% of cases.[47]

Joffe[19] and others have described strategies that can be used to reduce fatigue of health care professionals in the ED, and many of these strategies are related to shift work. The length of shifts should be carefully considered by those making the ED schedule. Although many workers prefer 12-hour shifts, a study that compared 8- and 12-hour shifts among nurses demonstrated increased fatigue and some safety concerns associated with the longer shift.[49] Another important consideration is shift sequence and rotation because of circadian rhythms. As human beings, we have an intrinsic biological clock, which cycles with an approximate period of 1 day. This cycle is not the result of cultural conditioning; rather, it is a property of neurons in the suprachiasmatic nucleus.[50] No amount of determination or professional commitment can fully override this fundamental biological function.[19]

Circadian rhythms can be altered over time, but this process transpires slowly. Generally, it takes at least 1 week to accomplish an 8-hour circadian phase change. Thus, ED providers who work a few consecutive overnight shifts usually are not able to accommodate to the schedule, and they are often significantly sleep deprived. If an ED group is large enough, it may be best to schedule single overnight shifts.[50]

Strategic napping is another fatigue countermeasure that might be considered by leaders of emergency medicine programs. After completion of an overnight shift, physicians can be encouraged to consider napping in a call room before driving home.[19] Strategies such as this can help ED providers meet the demands of the profession without compromising performance and without compromising their own health and safety or that of their patients.

Pediatric-Specific Clinical Tools

When performing resuscitation tasks in children, opportunities for error are magnified by several unique aspects of pediatric emergency care. Medication dosing, choice of equipment size, and determination of fluid volume for resuscitation all depend on the size of the child; thus, each must be determined or calculated in a high-risk environment by using high-level cognitive skills. Studies have shown that simple tools, such as a length-based tape that provides precalculated medication doses in color-coded zones,[51] can reduce deviation from the recommended dose range (dosing error) by 25% in simulated resuscitation scenarios, compared with other traditional dosing references.[22] By providing a precalculated dose for a specific length or weight zone, the tool helps to simplify and standardize the complex task of pediatric resuscitation.

Although helpful, the Broselow length-based tape is not ideal. Medication doses are listed on the tape in milligrams, yet nurses must draw up medications by volume. Although this tape provides precalculated medication doses for physicians to order, it does not provide the nurse with a precalculated volume (mil-

liliters) of medication to administer. There is currently no clinical tool universally available to ED nurses that provides them with this critical information, and a recent study of a simulated pediatric emergency event suggests that errors may occur at this point in the process of emergent medication administration.[23]

Many hospitals and health care systems are developing and/or implementing CPOE systems. Currently, few systems are available that provide precalculated doses of medications based on a weight that is entered into the system. Even fewer systems provide a precalculated dose in both milligrams and milliliters; without this capability, nurses and pharmacists will still be left to perform conversion calculations. Pediatric emergency health care professionals should advocate for a computerized dosing system to help reduce one of the greatest risks in pediatric care: that of medication dosing within the ED and hospital and at the time of discharge.

TRANSPARENCY AND DISCLOSURE: WORKING WITH PATIENTS AND FAMILIES

Physicians historically have been trained to be autonomous and ultimately responsible for the care of patients, including any errors that may occur. In the traditional "blame and shame" culture of medicine, errors were attributed to incompetent, lazy, or irresponsible people, so physicians and other health care professionals are often devastated when errors occur. Physicians feel guilty, frustrated, and often fearful of legal consequences. Most want to talk to patients and families about what happened, but few have been trained how to disclose unanticipated outcomes or medical errors appropriately. Worse yet, some health care professionals continue to be trained to avoid talking about adverse events.

Studies have clearly shown that patients and families want to know what happened at the time of an adverse event or unexpected outcome.[52,53] Sorrel King, as the mother of a young child who died after a medical error, has become a spokesperson for disclosure and patient safety and relates very clearly what she believes parents and families want: an honest explanation about what happened, a sincere apology, and to know what will be done to prevent a recurrence of the error in the future so that no one else will be hurt.[53] Consumer- and parent-driven groups have emerged that are aggressively demanding a change in culture on how health care organizations report errors to guarantee patient safety. One such organization worked with the Joint Commission on Accreditation of Healthcare Organizations to include kernicterus as a sentinel event alert for all hospitals, and the Agency for Healthcare Research and Quality has sponsored consumer-led workshops to advance patient safety.

Many institutions have implemented educational programs to teach physicians and other health care professionals how to appropriately disclose information to patients and families at the time of a medical error or unexpected outcome. Risk managers and hospital attorneys are most often supportive of such efforts, and many are willing to participate in educational sessions. In addition, instruction in disclosure and transparency is now being introduced in medical schools and nursing schools, and some institutions have implemented an educational experience on disclosure into the core competencies of residency training.

SUMMARY AND RECOMMENDATIONS

The ED is a stressful, risky, highly complex environment in which dedicated, hard-working professionals strive to provide safe, high-quality care to children and families. Over the past decade, a great deal has been learned about medical errors and patient harm, and there is a much better understanding of the environmental and human factors that can lead to adverse events. Health care professionals need first to acknowledge that mishaps can happen any time, given the right set of circumstances, and then must understand how critically important it is to proactively integrate safety into the pediatric emergency care system. Through collective efforts, a system can be designed that takes into account the strengths and limitations of health care professionals, and a culture can be established in which every team member understands how important it is to speak up and actively participate in initiatives to improve patient safety.

The following are recommendations to improve pediatric patient safety in the ED:

1. Raise awareness of safety as everyone's highest priority.
   a. Provide education on core patient safety concepts and topics at orientation for all ED staff and trainees and provide ongoing, regularly scheduled, multidisciplinary patient safety conferences and grand rounds.
   b. Include a discussion of patient safety issues and concerns as the first agenda item at health care organization governance (board of directors) meetings, medical and nursing department leadership meetings, performance improvement meetings, and operational meetings.
   c. Provide performance metrics and incentives related to patient safety for all clinical and administrative leaders.
2. Participate in, and model, important safety practices, including:
   a. hand-washing;
   b. time-outs before procedures;
   c. structured communication during hand-offs (ie,

times when patient care is transferred from one provider to another);

d. teamwork training; and

e. mock codes or simulated patient scenarios to rehearse the use of clinical guidelines (eg, ATLS, Advanced Pediatric Life Support, Pediatric Advanced Life Support).

3. Implement Safety WalkRounds.
   a. Encourage active and regular participation by hospital and department leaders and managers.
   b. Keep a log of risks and concerns that are identified and addressed, and document feedback to clinicians.
   c. Include front-line staff in the process.
4. Encourage nonpunitive voluntary reporting of medical errors and near-misses, and provide a convenient, user-friendly mechanism for filing the report.
   a. Promote use of a voluntary reporting system.
   b. Advocate that reported information not be discoverable, and design a system that allows individuals to maintain anonymity.
   c. Develop a clearly stated and timely process for addressing reports and tracking trends.
   d. Provide feedback to event reporters regarding resolution of the reported concern.
5. Provide training in teamwork and communication to include information on:
   a. CRM and psychological safety;
   b. the SBAR (situation, background, assessment, recommendation) technique;
   c. critical language; and
   d. briefing and debriefing.
6. Recognize fatigue as an important safety risk, and implement strategies for reducing fatigue in health care professionals.
   a. Consider the impact of length of shift on staff performance.
   b. Recognize effects of shift sequence and rotation on provider fatigue.
   c. Consider strategic napping to decrease fatigue.
7. Develop, implement, evaluate, and update multidisciplinary evidence-based clinical practice guidelines for pediatric emergency care.
8. Encourage the use of clinical tools to aid medication dosing and administration.
   a. Educate ED staff on the correct use of length-based tape.
   b. Promote development of CPOE systems with dosing parameters or other clinical tools.
9. Establish a link between efforts to improve care quality and safety within the ED to those in other units or departments that care for children.
10. Build a partnership between ED- or hospital-based safety improvement and efforts to improve the quality and safety of care provided by prehospital and intrahospital care providers.
    a. Work with EMS professionals to develop evidence-based prehospital care protocols for the treatment, triage, and transport of children.
11. Define pediatric emergency care competencies for all disciplines (physicians, nurses, paramedics, emergency medical technicians), and require health care professionals to receive the appropriate level of initial and continuing education necessary to achieve and maintain those competencies.
    a. Require regular training for key cognitive and technical skills and updates on resuscitation guidelines.
12. Integrate patient- and family-centered care into all aspects of pediatric care and in all settings.
    a. Provide timely access for emergency care providers to qualified language-translation support.
    b. Institute a system for timely identification of, and appropriate communication with, the child's medical home.
13. Advocate for formal training in transparency and disclosure of medical errors.
    a. Engage parents and families in training to convey the patient/family perspective to staff.
    b. Invite risk management and legal staff to participate.
    c. Include medical students, residents, and fellows in training.
    d. Revise morbidity and mortality conferences to include a discussion of system-based problems and error-reduction strategies.
14. Support the IOM recommendation that federal agencies and private industry should fund research on pediatric-specific technologies, equipment, and medications used by emergency care providers to improve patient safety.
    a. Implement CPOE and decision-support systems to aid in pediatric dosing.
    b. Use standard dosing guidelines and formulations for pediatric medications.
    c. Include focus on the prescribing of discharge medications.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Payment for Telephone Care

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Section on Telephone Care and Committee on Child Health Financing

ABSTRACT

Telephone care in pediatrics requires medical judgment, is associated with practice expense and medical liability risk, and can often substitute for more costly face-to-face care. Despite this, physicians are infrequently paid by patients or third-party payors for medical services provided by telephone. As the costs of maintaining a practice continue to increase, pediatricians are increasingly seeking payment for the time and work involved in telephone care. This statement reviews the role of telephone care in pediatric practice, the current state of payment for telephone care, and the practical issues associated with charging for telephone care services, a service traditionally provided gratis to patients and families. Specific recommendations are presented for appropriate documenting, reporting, and billing for telephone care services.

BACKGROUND

Telephone care is an increasing component of pediatric practice. Pediatricians are forced to provide more care to children and their families by telephone because of changing consumer and health plan expectations for enhanced access to care, 2-parent employment, the use of cellular phones by a "connected" society, a new focus on chronic disease management, and continued pressure by employers and health plans to reduce the costs of medical services. To address these concerns, pediatricians are required to develop new practice styles and provide more "non–face-to-face" medical services outside the traditional office or hospital setting.

Expansion of telephone care has great potential to further decrease health care costs, in part by providing a convenient and safe alternative to more costly in-person services. As a cost-containment strategy, telephone triage and advice, combined with indicated prescriptive therapy, often serves as a substitute for a patient visit to the office, urgent care center, or emergency department (ED). Tools to improve triage, provide advice for acute illnesses, and improve clinical and functional outcomes for the chronically ill patient include guidelines, disease and case management, and patient education. Many of these interventions depend heavily on the telephone.

Despite the fact that telephone care involves challenging medical decision-making, medicolegal risk, and practice expense and provides convenience and cost benefits to patients and health plans, physicians are rarely paid for providing telephone care. Arguments against payment have included the difficulty in determining appropriate payment without a more exact assessment of physician work than that contained in the *Current Procedural Terminology* (CPT) telephone codes, the absence of time-based codes as a proxy for work, and the absence of Centers for Medicare and Medicaid Services–published resource-based relative value units (RVUs) for these services. Additional barriers to payment for telephone

care include educational gaps in telephone management, perceived ethical concerns in billing families for services traditionally provided free of charge, and practical concerns for documentation and billing for services.

Recognizing the growing importance of telephone care in today's physician practices and acknowledging the significant barrier posed by the lack of a consistent and rational system for payment of these services, the American Academy of Pediatrics (AAP) has developed this policy statement, which will review the role of telephone care in pediatric practice, summarize the evidence for clinical effectiveness of telephone care, review the current state of telephone care payment, and discuss practical considerations for pediatricians seeking payment for telephone care. Finally, this statement presents recommendations for determining which telephone care services delivered by physicians should be considered separate and distinct from the preservice or postservice work of evaluation and management (E/M) services. For physicians who elect to charge for telephone care, suggestions for practical implementation are provided. These suggestions include office procedures, communication with families, and documentation and reporting of telephone codes.

TELEPHONE CARE IN PEDIATRIC PRACTICE

The first recorded use of the telephone in pediatric practice was reported in *The Lancet* in 1879, describing the evaluation of an infant with croup using the newly developed telephone. By 1968, a practice survey reported that pediatricians spent up to 30% of their work day on the telephone,[1] and in 1981, practice surveys reported that pediatricians spent more time on telephone care than did physicians in other specialties.[2] The increasing burden of telephone care in pediatric practice was reflected in a 1987 survey in which pediatricians reported that telephone care was the least satisfying part of their practice. In 1993, the first pediatric after-hours call center (AHC) opened in Denver.[3] By 1999, more than 35 children's hospitals had opened call centers,[4] and some estimates indicate that 25% of all after-hours calls to pediatric offices are handled by call centers.

Practice surveys have reported that telephone care by physicians and nurses accounts for at least 20% of all clinical care in a general pediatric practice and as much as 80% of after-hours pediatric care.[1,5–7] A study of Colorado- and Utah-based office pediatric practices showed that an average of 2500 calls were managed during office hours and an additional 1000 calls were managed after hours per pediatrician per year.[8,9] Twenty-seven percent of all decisions by pediatricians to have a patient seen by a specialist are made during a telephone encounter rather than a face-to-face encounter.[10] Telephone care, including standardized protocols, has become a key tool in the management of children with special needs and those with chronic diseases such as diabetes.[11,12] Many pediatric medical subspecialists caring for children with chronic and special needs, such as asthma or attention-deficit/hyperactivity disorder, provide significant amounts of telephone-based disease management. It has been suggested that in a busy pediatric neurology practice, more care is provided during telephone encounters than during face-to-face encounters.[13]

Although the practice expenses associated with pediatric telephone care have not been widely studied, a 1999 study showed that the average cost per call at children's hospital–sponsored telephone triage programs was $12.50.[4] One study of Colorado office practices estimated the cost of in-office telephone triage to be $6750 per physician per year.[9]

Telephone care not only is costly but also exposes the physician to increased medical liability risks.[14] This is especially true for after-hours telephone calls, during which the patient's medical history may not be available, a physical examination cannot be performed, nonverbal communication is challenged by the lack of face-to-face contact, and documentation of the telephone calls is often less than optimal. Telephone care is especially risky for pediatricians compared with other specialists. In an analysis of closed malpractice claims from 1985 to 2004, the AAP Committee on Medical Liability found that pediatricians were more likely to have paid claims for telephone care compared with other specialists, and the average payment per claim was also higher for telephone claims than for other claims ($281 300 [pediatric telephone claims] vs $254 100 [all pediatric claims]).[15,16]

CLINICAL EFFECTIVENESS OF TELEPHONE CARE

Telephone care in pediatric practice currently includes triage and advice, disease and case management, medication adjustments, acute illness care, test result interpretation, counseling, and education. Telephone care has been used for follow-up after ED visits[17] and was shown to decrease missed appointments, increase compliance with instruction, and ensure appropriateness of follow-up care.[18,19] In the area of chronic illness, telephone care has been shown to reduce medical costs, hospitalization, and ED visits for children with diabetes.[11,20] In a randomized trial of a self-directed parent training program for those with oppositional preschoolers that included weekly telephone encounters as part of a parenting program, investigators found reduced behavior problems in the children, and parents reported lower levels of anxiety, depression, and stress compared with parents in a control group.[21]

Perhaps the best evidence available describing the outcomes of telephone care is in the area of AHCs using standardized algorithms and nurses to deliver telephone care. Studies of telephone care provided in this setting have shown a high rate of parental satisfaction with AHC care[3,22] and compliance with urgent and home care dis-

position.[23] Disposition decisions made through AHCs using standard telephone triage protocols are also relatively accurate, with reported rates of hospitalization within 24 hours for calls with nonurgent disposition of approximately 1.5 per 1000 calls.[24] Although referral rates for urgent care using telephone triage protocols is approximately 20%,[24,25] this referral rate can be decreased by 50% with the use of second-level physician triage, a process whereby a physician is consulted to review triage dispositions made by call center nurses that include referring a patient for urgent or emergency care.[26]

PAYMENT FOR TELEPHONE CARE

The American Medical Association's CPT manual, the standard reference for coding medical encounters with patients, categorizes telephone calls under case management services.[27] Telephone calls by physicians for case management, including counseling, medical management, and coordination of care, are categorized by complexity of medical decision-making. Case management telephone calls involving simple, intermediate, or complex decision-making are described by CPT codes 99371, 99372, and 99373, respectively. Telephone calls are also included within care plan oversight services codes, which reflect physician work in the complex and often multidisciplinary management of patients being cared for by a home health agency, hospice, or nursing facility. Recent changes in these codes will make them applicable for children managed at home without home health care agencies (ie, by parents or relatives). These services, which can be reported using CPT codes 99374, 99375, and 99377 through 99380, are cumulative over a 30-day period and are reported according to total physician time spent with these activities. Although telephone time is included in these codes, the services provided are much broader. Reporting these charges requires that a physician document the encounter and the complexity (telephone codes) or time (care plan oversight) and submit the charge on a CMS-1500 form. Physicians must be prepared to collect a patient's copay if required by the insurance carrier. Furthermore, if the insurance carrier allows the charge but deems it an uncovered service, the physician must then bill the patient directly for the service.

Physician experience with payment for telephone care is limited, because government payors and most private health plans do not pay physicians for these services even when available CPT codes are used.[28] Certain Medicare plans pay for telephone calls during which care plans are organized or reviewed. Although most Medicaid programs do not reimburse providers for telephone care, some Medicaid managed care plans include telephone triage as one of their covered services under capitation. A study of payment for telephone codes (99371–99373) at a clinic in Texas for care provided by physicians or nurses for children with diabetes showed that Texas Medicaid did not reimburse for telephone management of complex problems, but 14 of 18 insurance companies reimbursed at 26% of charges, and parents paid copays at 54%.[12] In that study, the authors reported that the collection rate for telephone care for patients with diabetes in a largely insured population was 33%.

Practice surveys indicate that payment for telephone care is supported by most pediatricians.[29] Pediatricians convincingly argue that the physician work component of telephone care shares all the characteristics of in-office care except for the hands-on physical examination. They also cite the increased liability risks and practice expenses[30] of telephone care as a justification for payment and note that the increased documentation required for telephone care compensation would actually decrease the liability of telephone calls and increase patient continuity of care. Additional arguments for payment of specific telephone encounters include benefits to patients, physicians, and third-party payors, because telephone care is cost-effective compared with traditional face-to-face encounters in the office or ED.[31]

Among pediatricians, there is evidence of increasing advocacy for payment for telephone care. In its statement titled "Principles of Child Health Financing,"[32] the AAP defined a set of principles of child health care financing and concluded that such financing should encourage the delivery of services in the most timely, medically appropriate, and cost-effective setting, including appropriate payment for medical care provided via telephone. In addition, the AAP statement acknowledged that all chronically ill children have special needs that require appropriate health care financing for E/M, care coordination and case management, team meetings and conferences, and delivery of medical and surgical subspecialty care. The AAP also recently developed a white paper titled "Reimbursing Physicians for Non-Face-to-Face Care," which supported payment for non–face-to-face care in preparation for the development of a new set of CPT codes and corresponding RVUs for telephone care and Internet medical services.[33]

Support for payment for telephone care is not limited to pediatricians. In a recent policy statement, the American College of Physicians[34] also endorsed payment for telephone care, stating that it supports "payment by Medicare and other payors for health-related communications, consultations, and other appropriate services by telephone."

PRACTICAL CONCERNS WITH SEEKING TELEPHONE CARE PAYMENT

Although support for payment for telephone care is widespread, some physicians, reluctant to charge for telephone care, have raised ethical concerns that billing

for telephone care may create a barrier to health care access and deter poor families from calling with serious problems. Of course, this concern was also true with patient copayments, a practice that no longer generates either ethical or access concerns in most offices. The issue of access to telephone care reflects the broader societal nature of the problems of access to care and the inequities that exist within our current health care system.[35] In a market-driven health care system such as that found in the United States, it is difficult to make the case that physicians should provide clinical care without payment, and as such, the AAP believes that there are no ethical conflicts in charging for telephone-care services rendered. The problem of access to care by telephone should not be laid before physicians but put before citizens and policy makers, and the AAP believes it is appropriate for pediatricians to advocate for more comprehensive coverage.

Another concern that has been raised regarding payment for telephone care is that this practice will increase the overall financial burden placed on the nation's health care industry. In response, others argue that an even greater risk is that, without compensation for telephone encounters, medical practices already facing increasing financial and productivity pressures may be unable to provide telephone care and instead may require patients to come in for face-to-face visits to either the office or the ED to address medical concerns that could be managed readily over the telephone. This will result in patient access limitations, unwarranted ED use, decreased chronic care and disease management, increased expenses to patients and third-party payors, and an overall increased burden on the health care industry.

Given that the current payment system encourages the provision of care in an office setting, it is expected that increases in costs for telephone care will be more than offset by the savings incurred when physicians begin to provide more efficient telephone care for certain illnesses and chronic diseases rather than requiring patients to be seen in a more expensive face-to-face encounter. From the perspectives of both the patient facing copayments or an increasing portion of out-of-pocket expenses and the insurance companies paying for costly emergency and office visits, telephone care makes economic sense. As consumer-driven health plans become more commonplace, demand for telephone care will likely grow as consumers seek more cost-effective and convenient care choices.

Other concerns with charging for telephone care include the risk that this practice might create a negative physician image or allow for overuse or fraudulent billing for these services. With trends among consumers of increased expectations for services on demand at the time and place of the customer's choosing, it can be argued that the responsiveness of physicians will increase, rather than decrease, consumer satisfaction and improve physician image. Physicians often fear that the introduction of fees for selected medical services, such as telephone care, or office services, such as form completion, will alienate patients and cause them to leave their practice. Yet, anecdotal reports suggest that many of these fees have become commonplace in offices across the country without patient exodus. Regarding concerns that physicians charging for telephone care may be tempted to overuse and/or abuse charges, no evidence has been uncovered that the ability to charge for telephone care, especially if codes with clear reporting criteria were used, would create any new or unique opportunities for physician fraud or abuse.

RECOMMENDATIONS

1. The AAP supports reimbursement by payors, including state Medicaid agencies, for telephone care services provided by physicians to established patients, including the following categories of medical services:
   - calls for physician management of a new problem, including counseling, medical management, and coordination of care not resulting in an office visit within 24 hours;
   - calls for physician management about an existing problem for which the patient was not seen in a face-to-face encounter in the previous 7 days; and
   - calls related to care plan oversight for patients with special needs in residential settings and/or those with a chronic disease who require physician supervision over a period of time during a calendar month.
2. The AAP believes that pediatricians should make efforts to negotiate fee schedules and/or capitated rates for telephone care payment with all payors including state Medicaid agencies. When necessary and appropriate, physicians are encouraged to track utilization of telephone care codes and to appeal insurance denials.
3. Within the terms of existing payor contracts, the AAP supports pediatricians charging families for telephone care. The AAP also supports the exploration by pediatricians of different charge structures for telephone care, such as "per-call" rates or prepaid monthly telephone "access fees" that may help families anticipate telephone care expenses. Pediatricians choosing to charge patients and families for telephone care should ensure that they do the following:

- Develop office policies and procedures to ensure consistent processes for reporting telephone care charges to third-party payors and collecting payment for uncovered but allowable telephone care services while maintaining compliance with the Health Insurance Portability and Accountability Act (HIPAA) (Pub L No. 104-191 [1996]).
- Develop a clear communication plan for patients before initiating a fee for telephone care. Patients should be informed about the types of calls that will be billed and should be instructed that a copay (or possibly the entire charge) may be their responsibility if their insurance company does not cover telephone care service. Patients should be instructed that if they choose not to use care provided by telephone, standard office-based care will remain available, and they will always have the choice to have a face-to-face encounter if they so choose.

4. The AAP believes that physicians should document telephone care in a consistent manner.
   - Documentation should fulfill the need for continuity of care, demonstrate the complexity of the call, and meet the requirements of the typical E/M visit. Suggested items to document include the date and time of the call, patient's name and date of birth, name of caller, reason for the call, total encounter time, relevant patient history and evaluation, assessment of the issue at hand, plan, and disposition of the call.
   - It is suggested that the physician document the type of telephone encounter (eg, new problem, review of chronic problem with change in management, interpretation of test results, coordination of care, etc) to demonstrate the expertise required and the complexity of the decision-making process. Documentation for all telephone encounters for which a patient is charged should be placed in the medical record.
5. The AAP supports the development of mechanisms for payment for telephone care services provided by pediatric providers, including triage and advice, care coordination, patient education, and chronic disease management, and will provide support, along with other professional societies, for efforts to develop a new set of CPT codes with assigned RVU values for non–face-to-face medical services including telephone care.
6. The AAP believes that additional research should be undertaken to evaluate and report the clinical and economic effects of seeking payment for telephone care on patient access to care, quality of care and outcomes, total health care expenditures, and patient and physician satisfaction.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Policy Statement—Pedestrian Safety

abstract

Each year, approximately 900 pediatric pedestrians younger than 19 years are killed. In addition, 51 000 children are injured as pedestrians, and 5300 of them are hospitalized because of their injuries. Parents should be warned that young children often do not have the cognitive, perceptual, and behavioral abilities to negotiate traffic independently. Parents should also be informed about the danger of vehicle back-over injuries to toddlers playing in driveways. Because posttraumatic stress syndrome commonly follows even minor pedestrian injury, pediatricians should screen and refer for this condition as necessary. The American Academy of Pediatrics supports community- and school-based strategies that minimize a child's exposure to traffic, especially to high-speed, high-volume traffic. Furthermore, the American Academy of Pediatrics supports governmental and industry action that would lead to improvements in vehicle design, driver manuals, driver education, and data collection for the purpose of reducing pediatric pedestrian injury. *Pediatrics* 2009;124:802–812

INTRODUCTION

Morbidity and Mortality Statistics

According to the Web-Based Injury Statistics Query and Reporting System (WISQARS) of the Centers for Disease Control and Prevention,[1] approximately 6000 pedestrian deaths occurred in the United States in 2005. Of this total, 876 (14%) of the victims were 19 years or younger. In 2007, estimates from the National Electronic Injury Surveillance System (NEISS), which uses a sampling of hospital emergency department data, indicate that approximately 51 000 individuals 19 years or younger were injured as pedestrians, and 5300 of them were hospitalized for their injuries.[1] Although pedestrian fatality rates are actually higher in adults, children in the 10- to 15-year-old and 15- to 19-year-old groups have had the highest rates of nonfatal injuries in recent years (see Table 1).

According to the National Highway Traffic Safety Administration (NHTSA), in the 10-year period from 1997 to 2007, the number of pedestrian fatalities decreased by 49% in children 14 years and younger, with the greatest percent drop (57%) in the 4- to 7-year age group.[2] It is most likely that much of this decrease is attributable to less walking and lower exposure to traffic. The contribution from educational programs, increased law enforcement, and/or environmental modifications is not clear.

One of the goals of *Healthy People 2010* is to substantially increase the proportion of trips less than 1 mile being made by walking. In 1969, 42%

TABLE 1 2005 Pedestrian Death and 2007 Injury Rates per 100 000 Population

Age, y	Deaths, *n*	Rate	Injured, *n*	Rate
0–4	284	1.40	5274	25.45
5–9	130	0.66	8595	43.30
10–14	152	0.73	13716	67.52
15–19	310	1.47	23518	109.52
20–55	3307	2.19	91850	61.79
≥56	1884	2.97	28924	40.97

The number of pedestrian fatalities and injuries that are published by the NHTSA are somewhat lower than those found in the WISQARS database. Rather than using emergency room data, NHTSA information comes primarily from police traffic reports and, therefore, may not include driveway and parking lot crashes that frequently injure and kill toddlers. The NHTSA data do, however, contain more information about the cause and nature of the crash event.[67]

Data are from Centers for Disease Control and Prevention WISQARS.

of all schoolchildren and 87% of those living within 1 mile of school walked or bicycled to and from school.[3] More recently, only approximately 16% of children walk or bike to school, and even 37% of those who live within 1 mile are driven to school.[4,5] This situation is especially problematic considering the nation's major health challenge with pediatric obesity and the need for increased physical activity.[6]

Demographics

In addition to age, several factors increase the risk of child pedestrian injury. As with adults, approximately 60% to 70% of children killed and injured as pedestrians are male. Black and American Indian/Alaska Native children have higher rates of pedestrian death and injury,[1] in great part because of the environments in which poor children live.[7] The worst time of day for child (16 years and younger) pedestrian injury is between 3 and 7 PM, during which time 36% of fatalities occur.[8] A disproportionately high number of deaths (40%) occur on the weekend, but this was not found with nonfatal injuries.[9] As would be expected, pedestrian injury is more common when children are outside playing in the spring and summer.[10] The vast majority of pedestrian crashes actually occur under optimal driving conditions in full daylight, when the road is dry, and in the absence of precipitation.[11]

Nature of Injuries Sustained

Although most pediatric pedestrian injuries are minor, approximately 20% of the injuries score in the "serious-severe" category and roughly 10% are rated "critical-unsurvivable" on the Abbreviated Injury Scale or the Injury Severity Score.[12–14] In cases in which the child sustains an injury that is at least "moderate" in severity, the head and face are most frequently involved. Except for the youngest children, when there is at least 1 "serious" injury, the lower extremity is most often hurt.[12,15] A questionnaire study designed to study long-term outcomes of pediatric pedestrian crashes found impairment of cerebral function in 1.8% and disability related to the lower extremity in 2.8% of the children.[16]

In addition to physical injuries, childhood victims of pedestrian-automobile crashes and their parents very often have psychological sequelae. Both acute stress disorder and/or posttraumatic stress disorder are seen commonly (approximately 30%) in pediatric pedestrian injury cases.[17–19] Children may develop reexperiencing, avoidance, hyperarousal, and/or dissociation (emotional numbing).[19] Unfortunately, most parents do not seek professional help for their child's psychological symptoms.[19] At 6-month follow-up, in addition to stress disorders, many children who had serious physical injuries were found to have continuing difficulties with problem solving, memory, and social interaction.[20]

THE CHILD

Development

Young children have the motor skills to access roadways, yet they do not have the cognitive, perceptual, and behavioral abilities to negotiate traffic. Children move quickly and impulsively, which places them at high risk of pedestrian injury.[7,21,22] Furthermore, children have been shown to have difficulty seeing cars in their peripheral vision, localizing sounds, comprehending traffic, and understanding the meaning of road signs.[23] Children have difficulty scanning for traffic, judging vehicle distance and speed, anticipating driver behavior, and determining whether there is adequate time to cross the street safely.[21] Observations of children walking to school showed that they often neglect to look for traffic or stop at the curb before entering the street.[24] Normal developmental characteristics, such as magical thinking, egocentricity, distractibility, and impulsivity, increase pedestrian risk for children.[21,25] A high percentage of pediatric pedestrian crashes result from the child not paying attention to the traffic and road environment.[26]

In a study designed to compare pedestrian skills of children aged 4 to 5, 7 to 8, and 10 to 11 years, there were clear improvements with increasing age.[27] Compared with the 7- to 8-year-olds, the children in the 10- to 11-year-old group were significantly better at (1) identifying safe places to cross the road, (2) detecting traffic and road dangers, and (3) coordinating information from multiple parts of the traffic environment. Development of pedestrian skills was highly variable such that a few of the 5-year-olds did better than some 11-year-olds on the overall pedestrian skills score. Subjects who scored better seemed to use more effective visual search strategies (where, how often, and how fast they checked the road before crossing). Although some of the mature search strategies were occurring by 7 to 8 years of age, "there were continuing levels of sophistication unattained by

many of the oldest children (10–11 years of age) but present among the adult sample." In a study of attentional skills of 4- to 10-year-old children, older age was associated with better ability to appropriately switch focus to important pedestrian tasks.[28] This ability, which correlated with more awareness of traffic and better observed pedestrian behavior, continued to improve through the entire 5- to 9-year age range.

Unfortunately, many parents are not aware of these developmental limitations and overestimate their child's abilities to handle the traffic environment as a pedestrian.[29,30] In 1 study, one third of parents allowed kindergarten-aged children to cross residential streets alone and first-grade children to walk to school unsupervised.[31]

Child and Family Education

No randomized clinical trial has demonstrated that an educational intervention can decrease pediatric pedestrian injury rates. Systematic reviews of traffic skills-training programs have demonstrated improvements in attitudes, knowledge, and observed street-crossing behaviors.[32–34] A variety of educational programs aimed at school-aged children, including classroom sessions and individual instruction, use of audiovisual materials, training and practice in real and model traffic situations, behavior-modification techniques, and virtual reality computer simulations, have been shown to provide modest benefit. In a study in which an educational program was a component of a broad community campaign that included parent education, legislative changes, construction of separate pedestrian pathways, lowering of speed limits, and rigorous police enforcement measures, the rate of child pedestrian injuries dropped significantly.[35] There is evidence that involving parents as trainers or role models may add to the success of an educational program for child pedestrians.[36]

Because educational programs alone rarely result in safe pedestrian behaviors, supervision by parents or other adults is critically important. Unfortunately, in addition to overestimating childhood street-crossing abilities, parents often lack basic knowledge about pedestrian injury and do not adequately teach children about road safety.[37] Although it is reasonable for pediatricians to counsel parents regarding the risk of pedestrian injury in the context of child development and the need for supervision, no published randomized clinical trial has evaluated an office-based educational intervention.[38]

THE VEHICLE

Vehicle Speed

Vehicle speed is a strong risk factor for pedestrian injuries and is associated with greater injury severity.[13] Pedestrians who are hit by a car traveling 40 mph have a 15% chance of survival, but 85% survive when hit by a car moving at 20 mph. Because a faster-moving vehicle has a longer braking distance, impact with a pedestrian is more likely. Although several factors, such as driver reaction time, vehicle weight, brake quality, and road-surface conditions, play a role, the stopping distance for a vehicle traveling at 30 mph is considerably greater than that of a car traveling at 20 mph (197 vs 112 ft, respectively).[39] In residential neighborhoods, an average vehicle speed of 30 mph, compared with 20 mph, was associated with more than a sevenfold greater risk of children being hospitalized for pedestrian injuries.[40]

Vehicle Characteristics

Overall, the risk of pedestrian fatality is 18% to 29% higher with elevated-body vehicles (sport utility vehicles, pickup trucks, vans) than with passenger cars. Sport utility vehicles are especially dangerous for children. When children in the 4- to 7- and 8- to 15-year age groups were struck by an SUV, the relative risk of death was 87% and 46% higher respectively, than if the vehicle had been a passenger car.[41] Sport utility vehicles and pickup trucks are also more likely to cause severe injuries to children than are passenger cars.[42] When hit by an elevated vehicle, children are often thrown forward or knocked to the ground and run over instead of rolling up onto the vehicle's hood as an adult would do. This may explain why, compared with adults, children are at greater risk of death when hit by an elevated vehicle.[41,43]

Vehicle Modifications

The movements of a victim struck by a motor vehicle depend on the pedestrian's size and weight and the shape and structure of the car's front end. When a car hits a 6-year-old child, initial impact is usually with the upper leg, pelvis, and torso, followed by contact of the head with the front portion of the hood.[44] Injury severity generally is more related to these initial impacts than from contacts with the ground.[45] Modifications to automobiles, such as bumpers that are lower and more compliant, hoods that are more energy absorbent, and external windshield airbags can add to pedestrian protection.[45,46] How beneficial automobile structural modifications will be to children (who have different crash biomechanics than adults do) still requires study. Since 2005, new cars with structural modifications sold in Europe are required to pass various pedestrian safety crash tests, but no such testing is currently required in the United States.

Some automobile modifications have been developed to deal specifically with the blind spot behind the car and the problem of nontraffic back-over

pedestrian injuries. One study showed that young children do not respond consistently to back-up warning devices.[47] Back-up sensor alarms to warn drivers of objects behind the car are now available, but their shallow, narrow detection zones make prevention of pedestrian back-overs unlikely, because drivers cannot react fast enough at the speeds involved in such collisions.[48] Similarly, rear-window wide-angle lenses and auxiliary mirrors do not provide adequate visualization of the entire blind spot.[49] The combination of a video camera and a sensor alarm provides the best blind-spot coverage, but the high cost of such a system may be problematic.[49]

THE DRIVER

Driver Characteristics

Driver characteristics also contribute to child pedestrian injuries. Male drivers, drivers younger than 40 years, and those with a record of multiple driving infractions and suspended or revoked licenses are more likely to be involved in a collision with a child pedestrian.[50,51] Two studies performed by the National Safe Kids campaign show that large numbers of drivers speed and fail to stop at stop signs in school zones.[52,53] Information from the Pedestrian and Bicycle Crash Analysis Tool database from North Carolina showed that approximately 2% of the pediatric (15 years and younger) pedestrian crashes that occurred from 2000 to 2004 involved a driver who had been drinking alcohol.[54] One 1970s study of drivers involved in fatal collisions with pedestrians showed that even the experience of hitting and killing a pedestrian did not change the frequency of speeding convictions.[55] Because children are smaller than adults, drivers often falsely perceive that children are further away than they actually are. The result is that drivers misjudge time-to-impact and make inadequate speed adjustments in the presence of children.[56,57]

Driver Education and Enforcement

Although pedestrian advocates recommend driver-education programs to remedy dangerous driving, there is little research regarding interventions aimed at improving driver knowledge, attitudes, or skills to avoid pedestrian crashes. Furthermore, a study that looked at state driver's license manuals showed that most of these publications had no information about common locations for pedestrian-vehicle conflicts, automobile movements that are most hazardous for pedestrians, safest ways to conduct turns, or requirements for yielding to pedestrians at stop signs and intersections.[58] One 4-year program that combined a media campaign with strong police enforcement of crosswalk laws did not result in drivers becoming more willing to stop for pedestrians.[59]

ENVIRONMENT

Neighborhood

Children who come from low-income families tend to live in dense, low-income, urban residential neighborhoods where they are at much higher risk of sustaining a pedestrian injury.[40,60–65] Commonly, there are inadequate play areas in these neighborhoods, with children playing in and around streets in the afternoon and evening hours. The increased traffic, faster average speed, and number of parked cars along the curb add to the risk of pedestrian injury in these neighborhoods.[60,64,66] Parked cars along a residential street obscure visibility for both drivers and pedestrians, especially children.[40,66] In contrast to the crowded inner city, studies of American Indian/Alaska Native populations living in rural areas have identified the lack of traffic-control devices, poor lighting, and alcohol (driver and pedestrian) as important risk factors in pedestrian injury.[67]

Location of Event: Street Traffic

Children are most likely to be struck by a motor vehicle in an urban area on a residential street close to their home.[68] The most common type of pediatric crash is the pedestrian "dart-out" or "dash" in which a child walks or runs into the road, either at midblock or at an intersection, often from a position out of view of the motorist. This type of crash accounts for 43% of crashes that involve 5- to 9-year-olds, 30% of crashes that involve 10- to 15-year-olds, and 26% of crashes that involve children younger than 5 years.[69] In 2005, 82% of the pediatric pedestrian deaths occurred at nonintersection locations.[2] A study of 139 urban children who were struck by automobiles found that 29% were playing in or near the street at the time of the crash, and 71% were walking to a specific destination.[70]

Nontraffic Injuries (Back-Overs)

Although only 2% of all pedestrian fatalities are attributable to impact with the rear of a backing vehicle,[71] 14% of toddler pedestrian deaths in 2002 resulted from such non–traffic-related back-overs.[9] One study found that 57% of pedestrian injuries to children 2 years and younger resulted from a vehicle in reverse.[72] The typical event involves a vehicle backing out of a driveway driven by a family member who is unaware of an unsupervised child playing behind the car. The child's short height makes it difficult for the driver to see him or her, especially from an elevated vehicle (van, sport utility vehicle, or pickup truck). Toddlers do not perceive the hazard, and frequently the car rolls over (rather than strikes) the child, resulting in severe or fatal injury. It is estimated that each year, these back-over events injure approximately 2500 children younger than 14 years and that 48% of these children are 1 to 4 years old.[73] In addition to driveways, many

rear-impact crashes that involve pediatric pedestrians occur in parking lots.[69,72,74]

The Safe Kids Worldwide "Spot the Tot" program[75] advises parents to (1) hold children's hands in driveways, parking lots, and on sidewalks, (2) when driving, look for children at all times, and (3) walk all the way around the parked vehicle to check for kids, toys, and pets before entering the car and starting the motor. As previously mentioned, automobile modifications to prevent back-overs are available, but their efficacy has not yet been tested adequately.

Traffic Calming

Child pedestrian injury has been shown to be much less common in neighborhoods with a large number of streets with low speed limits.[76] In addition to lower speed limits, other speed-reduction street modifications include speed bumps, curved and narrow traffic lanes, traffic circles (instead of intersections), intersection curb extensions, and trees planted along curbs (to increase the driver's sense of speed). Methods designed to separate pedestrians from cars by either time or space include wide sidewalks, fences and barriers to prevent mid-block pedestrian crossing, raised medians/refuge islands (allow 2-step crossing of wide street), overpasses and underpasses, traffic signals exclusively for pedestrians (all traffic stopped simultaneously), and restrictions to keep traffic low in residential areas. These environmental changes that result in slower traffic and lower volumes of traffic (known as "traffic calming") can be effective.[77–82] A meta-analysis of 33 studies showed that injury-causing crashes decreased by approximately 15% (25% on residential streets, 10% on main roads) with the institution of various urban traffic-calming methods.[83]

Playgrounds

Keeping children off streets and away from traffic can be an effective method of reducing pediatric pedestrian injury. This was demonstrated by construction and renovation of playgrounds in Harlem, New York, where the number of pediatric pedestrian injuries decreased by 45% over a 7-year period.[84]

Walkability Checklists

The Partnership for a Walkable America (Centers for Disease Control and Prevention, National Highway Traffic Safety Administration, Federal Highway Administration, Institute of Transportation Engineers, Pedestrian and Bicycle Information Center, and the Robert Wood Johnson Foundation) advises the use of a "walkability checklist," available on the Internet,[85] to score the walkability of a community and identify the safest pedestrian routes for children. For each type of pedestrian problem, the checklist outlines specific strategies to help individuals and community groups who want to create safe walking routes for children. Formal evaluation of the ability of such checklists to decrease pediatric pedestrian injury is lacking.

School Trip Safety

It seems that the number of children struck while walking to or from school may actually be quite small (8%–15% of crashes that involve children).[70,86] Between 1994 and 2004, incidents that involved school buses were responsible for the deaths of approximately 11 school-aged pedestrians annually.[87] Surveys of parents have found that the major barriers that prevent children from walking to school are distance (62%), traffic dangers (30%), weather (19%), and crime (12%).[73]

The use of qualified, well-trained adult crossing guards is an effective method to help children cross streets safely.[88] According to Federal Highway Administration regulations, these individuals should wear high-visibility reflective apparel and should use a standard-sized, octagonal shaped "stop" paddle to control traffic.[89] Flashing speed limit signs, fluorescent school-zone signs, specially marked crosswalks, and strict police enforcement of speed limits and stop signs also are helpful.[90] It is recommended that drop-off and pick-up zones for parents driving their children to school be clearly marked and placed far from child pedestrians and school bus drop-off areas (www.walkinginfo.org).

The "Walking School Bus," a program supported by the Partnership for a Walkable America, fosters groups of children walking to school together with 1 or more adults. The "bus" may have meeting points, a timetable, and a regular rotation of trained volunteers or be as simple as 2 families taking turns walking their children to school.[91]

Many organizations and programs, such as Safe Routes to School, Kids Walk, and Walk to School Day have information available to help parents identify safe walking routes and teach their children pedestrian skills.[92] Significant federal funding has recently been allocated to Safe Routes to School to help states develop programs and infrastructure to encourage children to walk to school in a safe environment. Some concern has been voiced that low-income communities, where pedestrian rates are highest, do not always have the resources to compete for this funding.[93]

Low-Light Conditions

Although crashes that involve adult pedestrians often occur in low-light conditions, darkness is less often a factor for pediatric pedestrians who do not walk alone at night often. Reflective clothing has the ability to make pedestrians visible to drivers at considerably greater

distances; however, there are inadequate data to show that such clothing actually decreases collisions and injuries.[94] Enhanced illumination of crosswalks[90] and extending daylight savings time throughout the year[95,96] may have some significant benefit, but pediatric-specific data are not available.

RECOMMENDATIONS

To create safe pedestrian environments for children to enable greater amounts of walking and physical activity, the American Academy of Pediatrics recommends the following:

1. Through the use of counseling and/or with anticipatory guidance handouts, pediatricians should advise parents and caregivers that:
   - Young children have developmental limitations that prevent them from being safe pedestrians. In deciding when a child can cross streets independently, parents must consider the child's age and maturity, the distance to be traveled, the amount of on-street parking, and the volume and speed of traffic. On the basis of developmental considerations and currently available research data, the American Academy of Pediatrics recommends that children should not be unsupervised pedestrians before 10 years of age, except in limited situations.
   - Parents should be good pedestrian role models, supervise children carefully around traffic, and teach children how to be safe pedestrians.
   - To avoid injuries from vehicle back-overs, driveways, alleyways, and the adjacent unfenced front yard should not be used as a play area. Parents should be reminded of the large blind spot behind the car (especially in larger, elevated vehicles) and the need to walk completely around the car before getting in and starting the engine.
   - Reflective clothing and other visibility aids should be used in low-light conditions.
2. Parents, schools, community agencies, and policy makers should work with chapters of the American Academy of Pediatrics to increase the number of children who can safely walk regularly for the purpose of exercise and weight control. Residential neighborhoods should have sidewalks and be designed to foster low traffic volume and speed.
3. Although some pedestrian education programs for children have been shown to modestly improve road-crossing behaviors, their efficacy in reducing injury rates is not clear. Close adult supervision and environmental modification are more effective strategies for preventing motor vehicle-pedestrian collisions.
4. Community groups, municipal governments, and school systems should collaborate to design safe routes for children to use to walk to school. Methods to meet this goal could include sidewalks, traffic calming, on-street parking limits, hiring adequate numbers of well-trained adult crossing guards, locating schools close to residential areas, and helping parents develop special escort programs for young children. Highly visible, strict police enforcement of traffic regulations in school zones is extremely important.
5. Federal funding of Safe Routes to School and other programs to encourage walking and make it safe to do so should continue to be supported nationally. Priority for funding and grant application technical assistance should be given to low-income communities where the risk of child pedestrian injury is highest.
6. Communities should create play areas to keep children away from traffic as much as possible.
7. State driver's manuals should include a section that informs drivers about avoiding pedestrian collisions. Drivers should be warned not to have unrealistic expectations of a child's pedestrian abilities and reminded about the need to slow down and be alert for dart-outs when children are nearby. This pedestrian section should include information, photographs, and diagrams about pedestrian-vehicle conflicts at intersections, safest ways to conduct turns to avoid pedestrian injury, and requirements for yielding to pedestrians at stop signs and when making right turns after stopping at red lights.
8. Automobile manufacturers should develop design modifications that will decrease injury from automobile-child pedestrian collisions.
9. Pediatricians should be aware of the high incidence of acute and posttraumatic stress disorder after a pedestrian injury. Pedestrian crash victims and their close family members should be carefully screened for these conditions. Patients should be given emotional support, reassured that acute and posttraumatic stress disorders are common problems, and referred for counseling as needed.
10. Governmental agencies should expand pedestrian injury surveillance systems so that detailed information regarding the pedestrian, the vehicle, the specific

location (to allow geographic information systems mapping), the nature of the crash, the speed and volume of traffic, and the features of the road and sidewalks can be collected and analyzed. Furthermore, parameters for describing children's exposure to traffic should be defined and measured. Such information will be needed to determine the effectiveness of interventions designed to decrease pediatric pedestrian injury.

RESOURCES FOR PEDIATRICIANS

National Highway Traffic Safety Administration (www.nhtsa.gov/portal/site/nhtsa/menuitem.dfedd570f698cabbbf30811060008a0c): contains excellent data summaries ("Traffic Safety Facts: Children" and "Traffic Safety Facts: Pedestrians"), tip sheets for parents and teachers, resource guides, major research reports, information regarding pedestrian laws, and links to programs designed to encourage safe walking. The entire NHTSA site can be "searched" for information about child pedestrians. The Fatality Analysis Reporting System (FARS) (www-fars.nhtsa.dot.gov) can be used to obtain detailed information about fatal crashes. In addition to reviewing detailed tables, users can generate custom reports through an interactive query system. NHTSA staff also accept data requests at this site.

Centers for Disease Control and Prevention (www.cdc.gov/nccdphp/dnpa/kidswalk/resources.htm and www.cdc.gov/injury/wisqars/index.html): contains extensive information about the Kids Walk-to-School program, including brochures, slide shows, fact sheets, and a sample press release. The site also has links to various Centers for Disease Control and Prevention reports about pedestrian safety. The Web-Based Injury Statistics Query and Reporting System (WISQARS) can be used to obtain data about fatal and nonfatal pedestrian injuries, categorized according to age (or age group), race, gender, state, and year.

Insurance Institute for Highway Safety (www.iihs.org/research/topics/peds.html): contains detailed statistics ("Fatality Facts: Pedestrians"), a Q&A, status reports, and a selected research bibliography.

Federal Highway Administration (www.tfhrc.gov/safety/pedbike/index.htm and http://safety.fhwa.dot.gov/local_program/pedcampaign): the Turner-Fairbank Highway Research Center site contains pedestrian-related articles, facts, issue briefs, publications, research, resources, and links. The Federal Highway Administration Pedestrian Safety Campaign site has a tool kit with videos, slide shows, brochures, posters, and other materials for individuals, organizations, or communities interested in implementing a pedestrian safety campaign.

Pedestrian and Bicycle Information Center (http://pedbikeinfo.org and www.walkinginfo.org): contains a Walkability checklist, an extensive research review ("Review of Pedestrian Research in US and Abroad"), crash facts and crash type definitions (with diagrams), and the Pedestrian and Bicycle Crash Analysis Tool, which allows access to a database of extensive pedestrian crash information.

Walking School Bus program (www.walkingschoolbus.org): contains a handout describing how a "walking school bus" works as well as guides for people who want to start a program and descriptions and evaluations of existing programs.

National Center for Safe Routes to School (www.saferoutesinfo.org): contains pedestrian safety tip handouts, applications and information about obtaining funding, state contact personnel, and an online library of materials, documents, and reports used by Safe Routes to School program administrators.

Safe Kids USA (www.usa.safekids.org; search "pedestrian"): contains facts and safety tips for parents, a checklist on how to teach children pedestrian safety, research reports, and a report to the nation that describes the pedestrian problem and offers solutions.

Harborview Injury Prevention Center (http://depts.washington.edu/hiprc/practices/topic/pedestrians/index.html): the "best practices" section on "child pedestrians" contains detailed research reviews on skills training, daylight savings time, reflective clothing, road environment changes, community campaigns, and vehicle modifications.

Kids and Cars (http://kidsandcars.org): contains statistics regarding nontraffic injuries and deaths from back-overs, hyperthermia, and power-window strangulation. The site also has fact sheets and public service announcement videos on these topics.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Technical Report—Pediatric and Adolescent Mental Health Emergencies in the Emergency Medical Services System

abstract

FREE

Emergency department (ED) health care professionals often care for patients with previously diagnosed psychiatric illnesses who are ill, injured, or having a behavioral crisis. In addition, ED personnel encounter children with psychiatric illnesses who may not present to the ED with overt mental health symptoms. Staff education and training regarding identification and management of pediatric mental health illness can help EDs overcome the perceived limitations of the setting that influence timely and comprehensive evaluation. In addition, ED physicians can inform and advocate for policy changes at local, state, and national levels that are needed to ensure comprehensive care of children with mental health illnesses. This report addresses the roles that the ED and ED health care professionals play in emergency mental health care of children and adolescents in the United States, which includes the stabilization and management of patients in mental health crisis, the discovery of mental illnesses and suicidal ideation in ED patients, and approaches to advocating for improved recognition and treatment of mental illnesses in children. The report also addresses special issues related to mental illness in the ED, such as minority populations, children with special health care needs, and children's mental health during and after disasters and trauma. *Pediatrics* 2011; 127:e1356–e1366

BACKGROUND

Emergency department (ED) health care professionals often care for patients with previously diagnosed psychiatric illnesses who are ill, injured, or having a behavioral crisis. ED health care professionals also need to identify and manage patients with previously undiagnosed and/or undetected conditions such as suicidal ideation, depression, anxiety, psychosis, substance use and abuse, and posttraumatic stress disorder (PTSD). This report will address the roles that the ED and ED health care professionals play in emergency mental health care of children and adolescents in the United States. This technical report supports the 2006 joint statement from the American Academy of Pediatrics (AAP) and American College of Emergency Physicians (ACEP) titled "Pediatric Mental Health Emergencies in the Emergency Medical Services System."[1,2] Previous policy statements, clinical reports, and technical reports by the AAP that have addressed specific pediatric emergency mental health issues and formulated guidelines for model programs include, but are not limited to, "Adolescent Assault Victim

PSYCHIATRIC ILLNESS AND THE ED

The current and increasing concerns regarding pediatric mental health emergencies occur within the context of the overall crisis in pediatric ED care. First, there has been an increase in the prevalence of ED visits for psychiatric illness.[14–18] This situation is complicated by a shortage of inpatient and outpatient services available for patients who need mental health care and an unfunded mandate to care for these patients in an ED setting. The 1999 Surgeon General's report on mental health[19] indicated that 21% of US children 9 to 17 years of age have a diagnosable mental or addictive disorder. The National Institute of Mental Health has reported that 10% of children in the United States currently suffer from mental illness, and more than 13 million children require mental health or substance abuse services.[20,21] The World Health Organization has estimated that by the year 2020, neuropsychiatric disorders will become 1 of the 5 most common causes of morbidity, mortality, and disability for children.[22] A study at the University of Pittsburgh found that from 1979 to 1996, the rate of psychosocial problems identified in primary care visits of 4- to 15-year-olds increased from 7% to 18%.[23] Suicide in the United States currently ranks as the fourth leading cause of death for 10- to 14-year-olds and the third leading cause of death for 15- to 19-year-olds, accounting for 11.3% of all deaths in the latter age group in 2006. More than half of adolescents 13 to 19 years of age have suicidal thoughts, nearly 250 000 adolescents attempt suicide each year, and up to 10% of children attempt suicide sometime during their lives.[24–26] Of great concern is the fact that, despite its increasing prevalence, the risk of suicidal behavior in many children and adolescents is often undetected. One study found that 83% of adolescent patients who had attempted suicide were not recognized as suicidal by their primary care physicians.[27] Rotheram-Borus et al[28] reported that fewer than 50% of adolescents seen for suicidal behavior in the ED were ever referred for treatment, and, even when they were referred, compliance with treatment was low. Another study revealed that only one-fifth of these children receive necessary treatment.[21]

Patients who need mental health care can be disturbing to the routine and flow of the ED and require more resources than many medical or trauma patients. In a 2006 study, Santiago et al[29] reported that 210 patients with a median age of 14 years and requiring psychiatric evaluation spent a median of 5.7 hours in the ED. Hospital police monitored 51.9% of these patients, and 45 patients exhibited dangerous behaviors. Among children who frequently used mental health services in the ED, approximately 50% of them were seen again within 2 months of their initial visit, which suggests that patterns of recidivism are high for psychiatric patients. Repeat patients are more likely to threaten to harm others; to have a diagnosis of adjustment, conduct, or oppositional disorder; and to be under the care of a child welfare agency. Repeat users were also significantly more likely than one-time patients to be less compliant with outpatient follow-up, be admitted to the hospital, and require more social support. These youth also have increased risk of involvement with juvenile justice; a large proportion of them have related behavioral, emotional, and cognitive disabilities and have greater difficulty remaining in residential treatment. The total proportion of children admitted to general inpatient services from the ED for mental health problems is also increasing. In Washington State, psychiatric disorders were the leading cause of adolescent hospitalization and accounted for one-third of hospital days for 5- to 19-year-olds over a 10-year period from 1994 to 2003.[30]

According to a 2004 AAP policy statement, ED overcrowding threatens access to emergency services for those who need them the most and further complicates the ability of EDs to serve the needs of patients who need mental health care and their families.[31] A 2008 report from the Centers for Disease Control and Prevention noted that ED visits increased 32% from 1996 to 2006, whereas the number of EDs decreased by 5%. Approximately one-third of EDs reported having to divert incoming patients to another ED in the previous year.[32] Boarding of patients with mental illness in the ED has many deleterious effects on the health care of those patients and others.[33] The ED is often a high-stimulation environment that is not conducive to calming agitated patients. In addition, privacy is not as easy to arrange, which leads to distraction and disruption of care for these patients and their families as well as the other ED patients.

The pediatrics section of the 2007 Institute of Medicine report on emergency services described the burgeoning problem of pediatric mental health problems in the saturated emergency medical services (EMS) system.[34] The report cited studies that have demonstrated inadequate or nonexistent screening and evaluation for children with mental health complaints, inadequate training and comfort levels for ED physicians and nurses in caring for pediatric patients with mental health complaints, suboptimal ED environment for mental health patients in crisis, and extended ED wait times for patients who need mental health care and require admission because of lack of psychiatric inpatient resources. According to the Institute of Medicine report, not only is ED use increasing, but younger patients are being seen, and depression, bipolar disorder, and anxiety are now being identified in children of elementary school age. EDs are increasingly used as the safety net for diagnosing and managing psychiatric illness in these children. The pediatric ED at Yale noted an increase of 59% in psychiatric illness-related visits between 1995 and 1999; the most common complaints were behavioral changes, ingestions, suicide attempts, and violence.[35] The Cincinnati Children's Hospital ED reported an annual increase in visits by psychiatric patients from 800 in 1995 to more than 2000 in 2004.[36] In their 1999 study of pediatric EMS usage, Sapien et al[37] found that 15% of pediatric EMS responses were for suicide, assault, or alcohol and drug intoxication, which emphasizes the need for first responders to have an informed approach to these problems. The actual number of psychiatric emergencies may be underestimated, because many children and adolescents who present with trauma may have made a suicide attempt, and vague somatic complaints may actually represent depression, PTSD, suicidal ideation, or abuse.

BARRIERS TO MENTAL HEALTH SERVICES IN THE EMS SYSTEM

Hoyle and White[38] outlined the barriers to adequate pediatric mental health services in the EMS system. These barriers can be categorized as (1) a lack of information relating to pediatric psychiatric illness, (2) limitations of the ED setting that influence timely and comprehensive evaluation, (3) need for education and training of ED staff regarding identification and management of pediatric psychiatric illness, and (4) a lack of access to and effectiveness of inpatient and outpatient mental health services.

Lack of Information Relating to Pediatric Psychiatric Illness

In a 2002 report, Horwitz et al noted, "Federal agencies' planning documents devote considerable attention to the need to understand the identification and treatment of children's behavioral and emotional issues within primary medical settings. Nevertheless, a paucity of evidence exists to demonstrate that such attention has resulted in aggressive programs of research in this area."[39] They found that adults received 15 times more research attention than did children and adolescents. Some epidemiologic data regarding psychiatric problems are available from national database sources including the National Hospital Discharge Survey, the National Hospital Ambulatory Medical Care Survey, and the National Electronic Injury Surveillance System. However, because children's psychiatric issues were largely unrecognized during the development of these databases, information regarding children and adolescents is obtained most often by extrapolation or inference. The National Hospital Discharge Survey and National Hospital Ambulatory Medical Care Survey use broad age groupings (younger than 15 and 15 through 44 years) that obfuscate the data pertinent to children and do not always subcategorize psychiatric illness or ED visits. Olson et al[40] used National Electronic Injury Surveillance System data from 10 hospitals over a 3-month period in 2000 to categorize presentations to the ED and found that psychiatric or violence-related complaints represented a relatively high proportion of pediatric ED visits.

Limitations of the ED Setting That Influence Timely and Comprehensive Evaluation

ED health care professionals recognize the difficulties in providing care to all children with psychiatric emergencies and note a lack of psychiatric specialists and inpatient and outpatient facilities and an increase in referrals from schools, primary care physicians, and mental health therapists who cannot admit patients directly from their offices.[34] These limitations, coupled with a mandate to care for all patients who present to the ED, create a difficult obligation for ED practitioners to fulfill. The Emergency Medical Treatment and Active Labor Act (EMTALA), enacted in 1985 with the purpose of protecting the rights of indigent patients seeking emergency care, requires Medicare-participating hospitals to provide a medical screening examination for all patients who present for care to the ED, regardless of the patient's ability to pay.[41] Subsequent revisions have clarified the responsibility of hospitals, EDs, and their physicians to act on this medical screening examination if the patient is determined to have an acute medical or psychiatric condition, such as suicidal ideation, by providing all ancillary services routinely available to the ED, such as a physician consultation, inpatient care, and mental health services, in a nondiscriminatory and consistent manner. This revi-

sion guarantees that hospital EDs are essentially the only place in our current health care system in which all patients with acute psychiatric illness can be guaranteed thorough evaluation.[42–44] A comprehensive emergency psychiatric examination may take several hours, and often there is no private or quiet area within the ED to facilitate effective consultations. In addition, the ED is not the optimal setting for assessing and managing patient and family anxiety, because they are crowded, noisy, and full of distressing sights and sounds that may even exacerbate some patients' symptoms or behavior. Given the declining numbers of available consultants, the formal psychiatric evaluation often begins hours after initial medical stabilization. Regulatory agencies have recognized the importance of standardized approaches toward high-risk psychiatric patients in the ED. Since January 1, 2007, the Joint Commission has required accredited organizations to conduct suicide risk assessment for any patient with a primary diagnosis or primary complaint of an emotional or behavioral disorder.[42]

Need for Education and Training of ED Staff Regarding Identification and Management of Pediatric Psychiatric Illness

Education about the causes, signs and symptoms, and optimal management of pediatric mental illness is essential for pediatric, family practice, and emergency medicine practitioners, including residents and pediatric emergency medicine fellows as well as those who practice in community hospitals. This education includes the use of appropriate mental health screening tools, appropriate discharge instructions, and mental health follow-up for depressed patients and patients who have considered or attempted suicide. However, residency program education may be insufficient in many of these areas.[45,46]

Lack of Access to Inpatient and Outpatient Mental Health Services

Nationally, the number of adult and pediatric beds in state mental health facilities plummeted 32% between 1992 and 1998 and has since dropped significantly below 60 000, and fewer than half are allocated for acute care.[47] Media reports have highlighted the fact that these inpatient cost reductions have not been offset by outpatient expenditures, and as a consequence, the ED has more frequently become a location for nonurgent mental health complaints.[48–50] They cite the combination of fewer inpatient psychiatric beds and insufficient outpatient services, which leaves EDs to hold pediatric psychiatric patients or admit them to a medical unit with little hope of being reimbursed for that admission. This process can be resource-intensive, because these patients sometimes must be restrained and/or constantly monitored.

POTENTIAL SOLUTIONS TO THE CRISIS IN MENTAL HEALTH CARE

Solutions to the mental health care crisis are not easily found within other, nonmedical systems, which are equally unprepared to handle children with acute psychiatric illness. A nationwide survey of juvenile detention centers, the results of which were presented at a Senate hearing in July 2004, revealed that 15 000 children with psychiatric disorders were improperly incarcerated the previous year because no mental health services were available.[48] Many community health centers that traditionally provide mental health care have lost their state funding and often turn away patients or place them on long waiting lists. Schools, therefore, frequently function as the de facto mental health system for children and adolescents; 70% to 80% of schoolchildren who need mental health services receive that care in the school setting.[51–53] School counselors are primarily funded by state and local funds, but school districts also use funds from federal programs such as the Safe and Drug-Free Schools grants that are authorized by the Elementary and Secondary Education Act, otherwise known as the No Child Left Behind Act (Pub L No. 107-110 [2002]). However, it is important to remember that this program, like other legislative mandates, depends on the vagaries of federal funding and budget cuts. Primary care physician offices are another point of contact for children and youth at which there is high potential for identifying and managing mental illness, but even when children are seen in the general medical setting, identification and management of mental illness are still challenging.[54–57] To address these issues, the AAP Task Force on Mental Health has developed algorithms to help pediatricians identify, manage, and develop safety plans for children and adolescents and offers strategies for diverting patients from the ED and referring more directly to mental health resources when available.[51] However, primary care physicians cannot do this alone. For this approach to be successful there needs to be an increase in the flow of pediatric trainees into child psychiatry training programs and a concomitant increase in payments for child psychiatric services to these program graduates. Telepsychiatry, first piloted in Britain, also offers a potential solution to the lack of mental health care providers in rural and remote areas.[58,59]

Stabilization and Management of Patients in Psychiatric Crisis

Patients who arrive with a psychiatric emergency require a rapid, thoughtful response by the ED team to assess the degree of stress and safety of the patient, provide medical stabilization,

and use specific interventions to alleviate symptoms and increase safety for the patient and ED staff and other patients. During these evaluations, ED health care professionals maintain a delicate balance between maintaining patient confidentiality and engaging the external support systems that already exist for these patients. In many states, adolescents can seek and receive care for mental health issues and drug/alcohol use without parental involvement, and EDs must maintain confidentiality except if the child is at risk of harming himself or herself or others. However, the ED must also recognize the primary support role of the family and caregivers, as well as the child's primary care providers, in all phases of pediatric mental illness. In this light, ED health care professionals must encourage, but not coerce, the adolescent to allow family involvement whenever possible.

Of paramount importance is for EDs to have the capacity to provide such care within an overall system of mental health care. The most important element is establishing an effective relationship with a specialized mental health team. Team composition and availability may vary but should be predefined. When consultations are requested, the degree of urgency and the expected response time should be communicated clearly. Additional dialogue should take place after consultation to ensure that there is agreement with a treatment plan and to facilitate expeditious and appropriate disposition. Acute drug ingestions present a specific challenge in this regard and require ED health care professionals to blend the usual resuscitation protocols with psychosocial management by medical staff, social workers, psychiatrists, and security personnel. Preexisting relationships with psychiatric inpatient facilities promote efficient disposition. It is also helpful to have familiarity with child protection laws and to establish relationships with local law enforcement and child welfare and social service agencies. School nurses, often the liaisons among family, health care professionals, and school personnel, can also be included, with appropriate consent, to help inform as well as facilitate management plans after the ED visit.[60] Adequate and appropriate physical space should be available for children and families in crisis; a private room with monitoring equipment that is out of the patient's reach is considered optimal. Patients should be within the sight of ED staff; screening for suicide risk or potential self-harm should occur, and one-to-one supervision should be provided as needed. If a patient requires medical admission or must wait in the ED for transfer to another facility, guidelines should be available for staff and faculty members in handling inpatient psychiatric patients and their family members.

On occasion, children and adolescents with psychiatric illness will require physical or chemical restraint to protect them or others from harm. The AAP and ACEP offer guidelines or policies related to patient restraint and reaffirm the need for frequent safety checks, vital-sign monitoring, evaluation of limb neurovascular status, and assistance with nutritional and bathroom needs.[61,62] It is more common for EDs to use anxiolysis and mild sedation to avoid the need for physical restraint. The decision to use physical restraints should be made by an attending physician but may be initiated by nursing staff in extenuating circumstances. Even with proper restraint, mental or cardiopulmonary status may deteriorate unexpectedly; therefore, patients in restraints should be monitored continuously with time-limited orders. The Joint Commission carefully monitors the institutional policies around implementation and documentation of patient restraint and emphasizes that it must be used as a last resort and that the treatment is for the patient's benefit.[63,64]

The Role of the ED in Discovering Mental Illness in Children

As mentioned above, in 2007, the Joint Commission recommended a suicide risk assessment for any patient with a primary diagnosis or primary complaint of an emotional or behavioral disorder.[42] Some suicide-assessment instruments, such as the Suicidal Behavior Interview and the Suicide Intent Scale, are not options for EDs, because they are designed to be administered by trained mental health specialists or require complicated computations by clinicians.[65,66] Although there is no standard or optimal instrument that screens for suicidality, high sensitivity and rapid administration are 2 highly valued characteristics. One tool with such characteristics is the Suicidal Ideation Questionnaire (SIQ), a 30-item instrument originally designed for 10th- through 12th-grade students.[67] A 15-item instrument (SIQ-JR) is also available for students in grades 7 through 9 and has been standardized for older students as well.[68] These tools may take longer than desired in an ED setting but have strong psychometric validity and reliability. Shorter tools that are more appropriate for the ED setting have also been developed. Horowitz et al[69] demonstrated good content validity of the Risk of Suicide Questionnaire (RSQ), a brief screening tool for screening for suicidal ideation in the ED that assesses major facets for suicide risk, present and past suicidal ideation, previous self-destructive behavior, and current stressors. Folse et al[70] piloted a 2-question version of this screening tool in the pediatric emergency setting, and almost 30% of the adolescents screened positive for suicidal

ideation within the previous week. The authors recommended that clinicians ask the questions: "Are you here because you tried to hurt yourself," and "In the past week have you thought about killing yourself" as an initial assessment for adolescents coming to the ED for medical care, regardless of the presenting symptoms.

Patients may exhibit "externalizing" symptoms that initially have been identified by a caregiver, teacher, health care professional, or even criminal justice personnel. However, many children with psychiatric illness do not present to the ED with overt psychiatric symptoms. It is also clear that many patients with psychiatric disorders exhibit somatic symptoms, such as headache and abdominal pain; some chronic medical illnesses, such as asthma and diabetes, can be exacerbated by stress and anxiety.[71,72] Scott et al[73] found a 30% rate of moderate or severe depression in 13- to 19-year-olds in the pediatric ED. Similarly, Rutman et al[74] found that 37% of the adolescents in a pediatric ED research study were above the threshold for depression on the Center for Epidemiologic Studies Depression Scale.

The US Preventive Services Task Force recommends screening of adolescents 12 to 18 years of age for major depressive disorder when systems are in place to ensure accurate diagnosis, psychotherapy, and follow-up.[75] Because the ED may be the only point of contact for children with undiagnosed psychiatric illness, it is imperative to have adequate resources in this setting to link patients who "screen positive" with inpatient or outpatient services. In addition, it is necessary to have efficient, culturally sensitive, and developmentally appropriate screening tools that promote the accurate detection of suicidal ideation, depression, and other psychiatric illnesses. Some investigators have adapted full-length, adult scales for use with younger populations, but they require 20 to 40 minutes to administer.[76] Some EDs have developed their own mental health screening tools to help in the evaluation of child and adolescent patients. Adolescents at the Children's Hospital of Philadelphia use computers to complete the self-administered Behavioral Health Screen for Emergency Departments, which provides their physicians and nurses with information about their risk for depression, suicidal ideation, PTSD symptoms, and substance abuse.[77,78]

Similar developments have occurred in the real-time assessment of traumatic stress in pediatric ED patients. Just like adults, children's previous adverse experiences can influence their response to acute illness and their ED visit. When children experience sustained stress attributable to traumatic experiences, neurohormones, such as cortisol, are increased. These elevated neurohormones can lead to permanent changes in their developing brain structures, such as the amygdala and hypothalamus.[79] Unrecognized and untreated, acute stress symptoms can cause lifelong behavioral and mental health problems attributable to changes in neurodevelopment and function.[80–86] Children with a history of a traumatic experience, be it from unintentional injury, violence, or sexual or physical abuse, can be expected to have more acute stress symptoms in the immediate aftermath of a specific event.[87] Shemesh et al[88] identified PTSD in 29% of the patients in a small convenience sample of pediatric patients who presented to a pediatric ED. All patients but 6 identified at least 1 previous salient traumatic event; most of the events were not immediately related to the reason for the ED presentation. Knowledge of trauma symptoms significantly altered the ED clinical management in 16% of the cases.[88] Winston and colleagues[89] have developed brief screening tools for acutely injured children and their families and have achieved some success in providing these families with practical print and Web-based management tools. Although these data suggest that early identification and management of psychological trauma and its consequences are feasible in the pediatric ED, further efforts are required to incorporate these techniques into the routine systems and processes in the ED.[90] Parents and caregivers also need education from appropriate personnel on what to expect, how to parent a traumatized child, how to know when additional help is needed, and where to find it. Information such as this can be found at sites for the National Child Traumatic Stress Network (www.nctsnet.org) and the Center for Pediatric Traumatic Stress at the Children's Hospital of Philadelphia (www.healthcaretoolbox.org).

SPECIAL ISSUES RELATED TO MENTAL ILLNESS IN THE ED

Minority Populations

Children from minority populations have less access to mental health services and are less likely to receive needed care.[91] Likely because of the complexity and cultural interpretation of psychiatric illness, the lack of proper translation when needed, even by trained interpreters, may contribute to difficulty in receiving information and following through with mental health referrals.[92] According to Rand's 2001 *Mental Health Care for Youth*,[93] 31% of white children who needed mental health services received them, compared with 22% of black and 14% of Hispanic children. In addition, the same study found that people from minority populations in treatment often receive a poorer quality of mental health care and are underrepresented

in mental health research. After adjusting for other demographic factors and parent characteristics, Hispanic children with mental health problems had greater odds of having no care or unmet need compared with white children. This finding is particularly concerning given the increased suicidal ideation, depression, anxiety symptoms, and school dropout rates among Hispanic compared with white adolescents. Cultural factors, particularly around the stigma of mental illness, were noted to be important for Hispanic people. Financial factors also play a role in these disparities; although they differ according to state, these differences are more likely the result of varied state policies and health care market characteristics rather than differences in racial or ethnic makeup.[94]

Children With Special Health Care Needs

It is well known that children with special health care needs frequently have coexisting psychiatric morbidity.[95–97] For example, children with asthma and allergies are especially prone to having anxiety disorders.[98] Obesity is also associated with problems such as depression, especially in Hispanic and black children.[99] The Emergency Information Form (EIF), developed jointly by the AAP and ACEP (www.aap.org/advocacy/blankform.pdf), allows providers to include psychiatric and behavioral diagnoses for children with special health care needs and also includes information about their health care professionals, medications, and significant medical history.

Children's Mental Health During and After Disasters and Trauma

The ED is the initial source of physical care for child victims of disasters (natural or man-made) or trauma (unintentional or intentional). Many studies have demonstrated the development of depression and PTSD in child survivors of trauma and disaster.[100–104] Unrecognized and untreated, acute and posttraumatic stress symptoms can cause lifelong behavioral and mental health problems as a result of changes in brain neurodevelopment and function. These alterations in function create a lifetime risk of subsequent poor school performance, depression, suicidal ideation or attempts, aggression, and risk-taking behaviors. Current research is ongoing to identify these at-risk children as early as possible and to develop validated interventions to cope with the stress and avoid later psychiatric morbidity. An AAP-funded Agency for Healthcare Research and Quality resource, "Pediatric Terrorism and Disaster Preparedness: A Resource for Pediatricians," includes information on children's mental health in disasters (www.ahrq.gov/research/pedprep/resource.htm).

RESEARCH AND ADVOCACY AGENDA FOR MENTAL HEALTH EMERGENCIES IN THE ED

The President's New Freedom Commission on Mental Health was convened in 2002 to study the mental health service delivery system and make recommendations to enable adults and children with emotional disturbance "live, work, and learn and participate fully in their communities." The 2003 report of the commission addressed awareness, disparities, early screening, the use of technology, and the need for research in this area. Specifically, research that focuses on the identification and management of pediatric mental health emergencies is critical for establishing best practices for screening of undiagnosed psychiatric illness, formal psychiatric evaluation in the ED setting, and engagement into community care. The development of a mental health interest group in the Pediatric Emergency Care Applied Research Network provides an ideal vehicle through which to conduct much-needed large-scale studies that elucidate and evaluate identification, identification, engagement, and treatment methodologies for the emergency setting.[105] Support of funding for local and regional fatality-review teams can also promote surveillance and understanding of factors related to suicide in children and adolescents.[106] Pediatricians can also petition legislators and policy makers to increase reimbursement for mental health services for children and adolescents at all levels, including funding for Medicaid, school-based and community-center services, inpatient services, and mental health providers who provide Medicaid services. This petitioning includes encouraging private insurers to promote need-based coverage rather than fixed limits for mental health and to increase reimbursements to hospitals and consultants who provide pediatric mental health services. A recent joint statement from the American Academy of Pediatrics and the American Academy of Child and Adolescent Psychiatry outlined recommendations to insurers that could decrease the impediments to providing mental health care in the primary care setting.[107] In October 2008, Congress passed the Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act of 2008 (Pub L No. 110-343).[108] The new law, which went into effect January 1, 2010, requires equity between mental health and substance abuse benefits and medical and surgical benefits in employer-sponsored group health insurance plans for companies with more than 50 employees. The law also requires equity in all financial requirements, including deductibles, copayments, coinsurance, out-of-pocket expenses, and all treatment limitations, including frequency of treatment, number of visits, days of coverage, or other similar limits. The federal legis-

lation will not override state laws that require additional coverage and subjects the definition of mental health conditions to state law.

SUMMARY

Pediatric psychiatric emergencies constitute a large and growing segment of pediatric emergency medical care, and EDs play a critical role in the evaluation and management of these child and adolescent patients. The ED has increasingly become the safety net for a fragmented mental health infrastructure in which the needs of children and adolescents, among the most vulnerable populations, have been insufficiently addressed. Inpatient bed shortages, private and public insurance changes, and shortages of pediatric-trained mental health specialists create particular challenges in this effort. Ideally, these challenges can be addressed through a reinvigorated outpatient infrastructure that supports pediatric mental health care, advance planning for crises on a local level using community resources, and the establishment of a stronger mental health support and education network for primary care physicians. Using a skilled, culturally sensitive, multidisciplinary approach, EDs can safely and effectively manage child and adolescent patients. In addition, EDs can play a significant role in identifying and referring patients with previously undiagnosed and undetected conditions such as suicidal ideation, depression, substance abuse, and PTSD.

The 3-pronged approach of education, research, and advocacy are crucial for improving the accurate and timely ED management of childhood psychiatric illness. Education of medical students, residents, fellows, faculty members, and nurses can focus on not only rapid diagnosis and medical management but also the internal social supports and available external resources for their local service area. Researchers need to develop easy and rapid pediatric screening tools and test strategies that enlist the family and primary care physicians as partners in the effort to provide basic psychiatric care and appropriately access the mental health system. Finally, because this issue permeates almost all aspects of pediatric medicine, it is clear that pediatricians need to advocate for fairness and parity with respect to the provision and reimbursement for mental health care for children.

TECHNICAL REPORT

Pediatric Aspects of Inpatient Health Information Technology Systems

Council on Clinical Information Technology

ABSTRACT

US adoption of health information technology as a path to improved quality of patient care (effectiveness, safety, timeliness, patient-centeredness, efficiency, and equity) has been promoted by the medical community. Children and infants (especially those with special health care needs) are at higher risk than are adults for medical errors and their consequences (particularly in environments in which children are not the primary patient population). However, development and adoption of health information technology tools and practices that promote pediatric quality and patient safety are lagging. Two inpatient clinical processes—medication delivery and patient care transitions—are discussed in terms of health information technology applications that support them and functions that are important to pediatric quality and safety. Pediatricians and their partners (pediatric nurses, pharmacists, etc) must develop awareness of technical and adaptive issues in adopting these tools and collaborate with organizational leaders and developers as advocates for the best interests and safety of pediatric patients. Pediatric health information technology adoption cannot be considered in terms of applications (such as electronic health records or computerized physician order entry) alone but must be considered globally in terms of technical (health information technology applications), organizational (structures and workflows of care), and cultural (stakeholders) aspects of what is best. *Pediatrics* 2008;122:e1287–e1296

health information technology, electronic health record, quality improvement, quality of care, pediatrics

Abbreviations
HIT—health information technology
CPOE—computerized provider order entry
CDS—clinical decision support
EHR—electronic health record
AAP—American Academy of Pediatrics

INTRODUCTION

US adoption of health information technology (HIT) has been advocated by federal agencies, health care industry groups, and patient-advocacy organizations as a major approach to improve patient safety through reduction and prevention of medical errors.[1–5] Adoption of HIT tools such as electronic health records (EHRs), computerized provider order entry (CPOE), and clinical decision support (CDS) is increasing, and although current implementation of all these HIT tools is not yet widespread in US hospitals,[6,7] most hospitals that provide care for children and infants use some form of an electronic information system to manage personal health information and other data that affect children's health.[8]

Children and infants have vulnerabilities and needs that are distinct from adults with regard to the management of their clinical care and its associated information. The extended normal ranges of body weights, sizes, and physiologic responses require modifications of clinical, technical, and information workflows to provide pediatric-specific care that is safe. A systematic evidence base for design and implementation of effective HIT that improves care quality and safety is needed but lacking,[9] and recent observations and experience indicate that changes (such as the adoption of information technology) can introduce new and unanticipated errors.[10–12]

MOTIVATIONS

The primary reason for adopting HIT is to improve the quality and safety of care. Information technology can reduce variations that lead to task failures[13] and uncertainties that increase cognitive burdens that lead to incorrect decisions. An important component in safety is the consideration (and estimation) of risk:

$$\text{risk} = \text{likelihood of error} \times \text{severity of error (harm)}.$$

Children seem to be at higher risk than adults for medical errors, with estimates based on inpatient data suggesting that hospitalized children may be at higher (up to triple) risk of preventable adverse drug events. Contributors to these may include wider ranges of children's and infants' weights (neonates seem to be at the highest risk of adverse drug events), greater complexity of medication dosing (universal weight-based dosing is prone to calculation errors

and must include consideration for adult maximum-dose limits), and higher risk in special domains (continuous intravenous infusions and chemotherapy may have higher immediate and/or cumulative toxicities than other drug types).

Another contributor to children's risk of medical errors is the variety of institutional settings in which they receive medical, surgical, and psychiatric care. Environments range from academic centers that specialize in tertiary pediatric care to general community hospitals that care primarily for adults. Each type of inpatient setting (and each individual setting) has specific attributes that may contribute to error likelihood.

BARRIERS

The major technical barrier to adoption of pediatric HIT tools is a lack of pediatric-specific information technology standards. Among these needs for standards are pediatric data that are machine-readable, terminologies and dictionaries that fully describe pediatric clinical entities (such as pediatric drug-dose data), and electronic standards (Health Level 7 Child Health Functional Profile[14] is currently in development) that adequately describe pediatric clinical events.

To establish these technical standards, there must be recognized leadership and authority as well as legislative and financial support at national, regional, and institutional levels. Standards for HIT products and practices designed for pediatric care must be based on pediatric data, not extrapolated from adult data.[9] Recent efforts by the American Academy of Pediatrics (AAP) Council on Clinical Information Technology have promoted collaboration to define standard pediatric functionalities for EHRs, and the requirements for pediatrics are being addressed by the Certification Commission for Health Information Technology.[15]

STAKEHOLDERS IN PEDIATRIC INPATIENT CARE

The child and family caregivers are central to pediatric care. Health care structures and processes, including errors and their disclosure, must be transparent to patients and families. Inpatient HIT applications must support family-centered, developmentally appropriate care of children[16] and must preserve transparency and patient/family empowerment.

The primary care provider and the medical home are central in the longitudinal care of children, particularly those with special health care needs. Inpatient HIT applications and workflows must support facilitated communication and continuity among patients' primary care providers, families, and inpatient care teams as well as (real-time) interoperability between inpatient and medical home clinical data systems.

Hospitalists and nursing and affiliate staff (such as pharmacists) are central to the inpatient care process. The progressive compartmentalization of health care has separated clinical responsibilities for transitional and inpatient care: emergency physicians for emergent care, hospitalists for general inpatient and observation-unit services, neonatologists and intensivists for critical care services, specialists for specific problems and procedures, and nursing for inpatient unit management and patient care administration. Inpatient HIT tools must support the work of inpatient staff to organize patient care, facilitate communication, and make care transitions (including shift change, admission, transfer, and discharge) safe while reinforcing staff roles in patient care[17–23] (including issues of training and certification requirements[24–26] for pediatric care).

WORKFLOWS IN PEDIATRIC INPATIENT CARE

Medication delivery and patient care transitions are 2 inpatient processes that are vulnerable to errors and are the focus of current research and development of information technologies.

Medication Delivery

Medication delivery is a set of common inpatient processes consisting of a series of role-based functions and handoffs. Certain environments and processes have higher risk because of a higher likelihood and/or impact of errors, but at the core:

1. A prescriber determines a patient's need for a drug regimen; specifies a medication and its dosage, form, route, and frequency; and then generates a formal order for the regimen and transcribes it for transmission to the pharmacist.
2. The pharmacist receives and checks the order; consults patient data and the prescriber (when needed) for errors and clarifications; makes certain independent decisions on form, route, and dose adjustments; and prepares and dispenses drug doses and instructions.
3. Drug doses are delivered to the inpatient unit nurse, who accepts and stores the drug doses; retrieves, administers, and documents drug doses to the patient according to the original order/schedule and pharmacy instructions; and makes certain independent decisions within practice scope (such as with "as-needed" orders or optional administration routes [oral versus rectal]).

Inpatient Patient Transitions

During an inpatient stay, patients undergo numerous care transitions, including admission (from emergency departments, transport services, and physician offices), discharge (to home or other facilities), and/or transfer to different locations within the institution for tests (imaging), procedures (surgery), and special levels of care (postanesthesia recovery care). Patients in transit (away from the "home" inpatient unit) may have needs, including life (ventilator) and environmental (temperature regulation for preterm infants) support, maintenance of scheduled and continuous medical care, physical transport, patient-location tracking, and contingencies that must be anticipated and coordinated before transition. Information (in the form of notes, orders, and other documentation) accompanies personnel until the patient reaches his or her destination, where transition (handover) occurs.

The most common transition is the transfer of care responsibilities (handovers, handoffs, or sign-outs). Physicians, nurses, consultants, and ancillary staff members transfer responsibilities in parallel (physician to physician, nurse to nurse, etc) and, in most cases, asynchronously according to shift and call schedules. Higher rates of handovers of information, authorization, and responsibility are associated with higher risks of incomplete or incorrect information transfer but may be necessary because of residency hour requirements.[27] Currently identified transition problems include needs for medication reconciliation and structured and interactive information transfers during handovers.

GENERAL CONSIDERATIONS FOR INPATIENT HIT APPLICATIONS

The consideration of adopting HIT for clinical use involves assessments of both the clinical and institutional environment and of available products.

Assessment of the Clinical and Institutional Environment

Within any clinical environment or workflow, HIT adoption is high-risk change that must be managed carefully. In assessing HIT-adoption initiatives, stakeholders should consider HIT applications globally, in terms of the anticipated technical and adaptive changes that will be needed for adoption,[28] including the ways that information will be presented, communicated, and used; downtime and recovery procedures; anticipated benefits; and how these changes will be measured. These considerations (plus others, including the political climate for change) and the presence or lack of answers can focus and guide efforts in securing resources and expertise.

Assessment of Information Technology Products

Institutional awareness about specific HIT products gained through interchange with similar institutions can help reduce trial-and-error. Beyond sharing of knowledge about technology (hardware, software, interoperability with other systems, messaging), information assurance (data confidentiality, integrity, and availability), and accessibility/usability requirements (including the ability to override CDS) that a system must meet, institutional leaders involved with HIT decisions should communicate, not only with other institutions but with vendors and workers from all levels involved in using HIT applications. Site visits to external deployments can help decision-makers to gain familiarity with products, to assess a product's applicability to specific work environments, and to learn from the experience of their peers with products, vendors, and the adoption process. A "community-of-practice"[29] approach encourages information sharing and dissemination about HIT adoption among practitioners (as well as others) and provides firsthand experiences of current users that can impart information on challenges and shortcomings that new customers need to make informed decisions. Collective formal and informal knowledge forums[30] will be needed for specific applications if informed HIT adoption is to increase.

SPECIFIC HIT APPLICATIONS: CONTEXTS, PURPOSES, FUNCTIONS, AND PEDIATRIC FEATURES

Medication Delivery

Computerized Provider Order Entry

Context, Purpose, and Functions

CPOE[31] provides support for prescribers at the prescribing/ordering step of the medication-delivery process, with the purpose of standardizing and ensuring completeness in orders for drugs, tests, and procedures. CPOE interfaces promote standardization through default options[32] and guide prescribers in creating and formatting structured orders through an electronic interface. CPOE differs from stand-alone prescription writers by an electronic data connection (excluding fax) to a pharmacy information system. In most cases, inpatient CPOE is linked to CDS, which improves its ability to reduce errors.[33]

Pediatric-Specific Features

CPOE for pediatric inpatients should provide:

- universal weight/body surface area–based dosing (with standard and consistent units of measurement (eg, metric) to prevent conversion and calculation errors);
- drug dictionaries with pediatric-specific dose ranges and alerts that include single-dose, daily-dose, and cumulative-dose decision support, including lifetime cumulative dose for chemotherapies;
- drug-dosing decision support that is contextual for pediatric-specific health issues that can include neonatal, renal, oncology, and other illness or wellness states;
- automated calculations and automatic dose limits/caps for larger patients;
- medication-reconciliation tools;
- pediatric-specific order sets;
- ability to link vaccination ordering to current immunization schedules; and
- linkage to pediatric-appropriate nutrition, laboratory, radiology, and other ancillary service orders (eg, orders linked to pediatric-specific tests [smaller blood volumes]).

Clinical expertise by pediatricians, pediatric nurses, and pediatric pharmacists familiar with both HIT and pediatrics must guide pediatric CPOE implementation. Specific pediatric medication-delivery processes pose specific challenges in error reduction because of the potential for increased errors or increased impact of errors as follows:

- continuous intravenous infusions, because of the immediate and dynamic impact of administered drugs and complex calculations that change in critically ill patients, benefit from in-line calculators that deter-

mine dosing and appropriate standard concentration choices (per Joint Commission regulations[34]) of drugs[35,36];

- pediatric chemotherapy, because of the narrow therapeutic indices and acute and cumulative effects of drugs as well as complex schedules that are prone to interruption as a result of changes in patient condition, is an area of research and development of management and decision-support tools[37,38]; and
- total parenteral nutrition (a special case of continuous intravenous infusion), because of the complexity of rules and calculations and schedule-critical dependence on timed laboratory results and order, may benefit from in-line calculators with automated rules to avert incorrect dosing, interactions, precipitation of solutes, and other costly errors.[39]

CDS: Clinical Calculators

Context, Purpose, and Functions

Automated calculation (of drug doses, dates, etc) eliminates manual computation errors, especially in high-stress situations[40] such as cardiopulmonary resuscitation of a child. For cases in which parameters (such as weight and height) are known, precalculated charts may provide an alternative.[41–43] The primary failure point for calculators is manual numerical entry (decimal, unit errors), which must be considered in the design and evaluation of interfaces and user training.

Pediatric-Specific Features

Because possible pediatric weights may vary over orders of magnitude, the wide range of allowed values may facilitate decimal errors and evade detection. Incorporation of independent and redundant checks (automated and human) into workflow to mitigate this type of error is an important consideration of design.

CDS: Electronic Prescribing Systems

Context, Purpose, and Functions

Electronic prescribing systems are designed help clinicians to generate paper or electronic medication prescriptions. The use of CDS, default options, and improved legibility offer the potential for improved patient safety.[44] In the hospital environment, these applications are usually used in the discharge process.

Pediatric-Specific Features

Features and requirements are similar to the CPOE requirements discussed previously.

CDS: Management Systems

Context, Purpose, and Functions

Management systems can provide high-level decision support by applying clinical and business rules to information processes across different but related systems (such as laboratory, imaging, and hospital admission systems) to improve prevention, therapy, and efficiency. In conjunction with CDS at CPOE interfaces, these tools can provide users with situational awareness of patient and hospital status. Examples of management tools include electronic whiteboards (census displays),[45] antimicrobial restriction programs (decision support to reduce inappropriate antibiotic use),[46] and early notification systems for infection risks for patient cohorting.[47] The specification of rules requires close interaction of clinicians and developers to specify alerts of high impact and to avoid "alert fatigue."[48]

Pediatric-Specific Features

Systems have been devised to provide alerts for respiratory syncytial virus and rotavirus.[49] The extension and linkage of such systems beyond hospitals to public health information systems may have value as resistant organisms previously confined to inpatient settings migrate to the community.[50,51]

CDS: Reference (or Teaching) Materials

Context, Purpose, and Functions

Automatic or on-demand linkages of patient-specific data (from EHRs)[52] and general medical knowledge (from formularies or electronic textbooks and handbooks) can aid decisions and help physicians in training.

Pediatric-Specific Features

Application-specific pediatric reference data should be checked by pediatric domain experts for conflicts with accepted norms from trusted data sources. Institutions should decide on "final authority status" of specific resources to resolve discrepancies. Many standard texts and references are available in multiple electronic formats (online, CD-ROM, handheld devices), and availability of trusted pediatric-specific information resources should be coordinated with a pediatrician and a hospital medical librarian. In institutions where children receive care on a partial basis, a core library (which may be available as an online subscription package, either commercially or through organizations such as the AAP or the Centers for Disease Control and Prevention), should be established and maintained. The AAP publishes authoritative policies on most pediatric issues[53] and on infectious disease diagnosis and management in children (the *Red Book* online).[54] The Centers for Disease Control and Prevention publishes current immunization schedules as well as surveillance data for influenza, respiratory syncytial virus, and rotavirus in the *Morbidity and Mortality Weekly Report*.

Pharmacy Information Systems

Context, Purpose, and Functions

Pharmacy information systems[55] support the dispensing step of the medication-delivery process, with the purpose of providing inventory selection and management and decision support for pharmacists and a redundant check for dosing, drug-allergy, and drug-drug interaction errors and for other pharmacology problems (such as solute precipitation in intravenous solutions). Pharmacology information systems may be linked to or require prompts for data from laboratory information systems (or from previous drug orders) and may be

partially automated (such as in creation of standard-concentration intravenous solutions or parenteral alimentation solutions).[56]

Pediatric-Specific Features

Because most of the details of pharmacy preparation of drug doses are invisible to prescribers and nurses, the most valuable component of a pediatric pharmacy information system is a qualified and experienced pediatric pharmacist and pharmacy staff[57] who actively participate in clinical care of inpatients (such as daily work rounds).[58,59] This expertise provides an additional layer to error catching and safety in medication ordering; however, neither CPOE nor pharmacy information systems may be effective in directly preventing medication-administration errors.[57] Essential expertise also provided by pediatric pharmacists is knowledge that populates (weight/body surface area) drug-dose range tables and alerts for pediatrics.

Administration Tools: Radio Frequency Identification, Bar Coding, Smart Pumps, Patient-Controlled Anesthesia, and Medication-Administration Records

Context, Purpose, and Functions

The administration step is the last step before a prescribed/ordered medication dose is given to the patient. The substeps of administration (usually performed by a nurse within inpatient environments) include receipt of drug doses from the pharmacy, storage of medication doses before final delivery, scheduled dose retrieval and preparation, identification of patient/drug/dose/form/route ("5 rights"), and final dose delivery. Radio frequency identification[60–62] and bar-coding[63,64] systems are used to verify and record identification of patient and drug dose and to track inventory. "Smart" infusion pumps programmed for specific workflows with appropriate drug doses and alerts may be useful in pediatrics[65] but require caution in deployment because of poor compliance with alerts by human operators.[66,67] Electronic medication-administration records link administration tools such as radio frequency identification, bar coding, and smart pumps to documentation and tracking of drugs and are used by multiple members of the medical team,[68] and usability by nursing is an important factor in success.[69]

Pediatric-Specific Aspects

The 2006 Joint Commission mandate for universal use of standardized concentrations in continuous infusion medications[70] created a debate among pediatric intensivists, particularly neonatologists, about fluid overload in extremely low weight infants. Hierarchical task analysis of neonatal infusion ordering/administration concluded that use of standardized admixtures could be associated with a higher risk of errors than ad hoc ("rule of 6") admixtures in patients in critical condition who require frequent adjustments in infusion rates.[71] Because of the feedback from this debate, the Joint Commission extended a transition period (until 2008) for pediatric/neonatal acute care if certain safeguards, including the use of "smart" pumps, were in place.[72,73] A published description of the implementation process of standard concentrations for neonatal care includes allowances for nonstandard concentrations,[74] with key knowledge being the lowest infusion rate allowed by the pump.

Errors in expressed human milk administration (wrong mother, wrong infant, wrong milk, wrong expiration date) in the NICU have been described with suggested methodologies for reducing their incidence.[75,76] In addition to system design to prevent such errors, barcoding systems have been developed, explored, and advocated[77] as a means of tracking and ensuring correct administration of human milk.

Certain "high-alert" medications are associated with an increased risk of causing harm to patients[78] when involved in errors. Approaches to these medications include proactive monitoring and redundant checks to prevent errors[79] in addition to the use of technology. Pediatric patient-controlled analgesia and patient-controlled analgesia by proxy pose challenges to implementation, and inpatient protocols should be developed in consultation with specialists in pediatric pain control.[80]

Patient Care Transitions

Electronic Health Records

Context, Purpose, and Functions

EHRs are a central structure for patient-specific data documentation. Their multiple roles include facilitating communication among providers, standardizing medicolegal documentation of care, historical record archiving and retrieval, and coordination of care. They can facilitate centralized clinical communication and documentation among hospitalists, primary care providers in medical homes, consultants, and emergency care providers. They also will start to hold artifacts of historical significance over time, such as records of patients who will become persons of public importance as well as historical trends in disease and wellness. They form the basis for medication reconciliation and may support personal health records to inform and empower patients and families about their care. Important technical functions of EHRs include interoperability of data elements, connectivity to other electronic records, and information assurance (according to established standards). Essential in their implementation is effective user training to prevent misuse that may lead to errors.

Pediatric-Specific Features

Pediatric functions in an EHR have been articulated in an AAP policy statement[81] and include:

- immunization management (recording data, linking to immunization systems, decision support);
- growth tracking (graphing and percentile calculation);
- medication dosing (dosing by weight, dose-range checking, safe and convenient dose rounding, age-based decision support, dosing for the school day);
- patient identification (prenatal identifiers, newborn identifiers, name changes, ambiguous gender);

- norms for pediatric data (numeric; nonnumeric; complex normative, such as blood pressures; gestational age); and
- privacy (adolescent, foster/custodial care, consent by proxy, adoption, guardianship, emergency treatment).

Technical standards and certification criteria for inpatient systems are still in development.

Ancillary Information Systems: Laboratory and Radiology (Imaging) Information Systems

Context, Purpose, and Functions

Laboratory and radiology information systems may exist independently or may be integrated with other inpatient information systems. They allow the ordering, managing, processing, billing, and result reporting for laboratory or imaging services. Interoperability and connectivity with inpatient systems (CPOE, EHRs, electronic medication-administration records) is usually limited to single hospitals but may be a safety issue in related institutions that share clinical care of a patient[82] during a single inpatient stay.

Pediatric-Specific Features

Pediatric-specific features are similar to those outlined for the EHR. Pediatric/age-specific norms for parameters and result reporting for radiologic and laboratory tests are critical.

Ancillary Information Systems: Admission, Discharge, and Transfer Systems

Context, Purpose, and Functions

Admission, discharge, and transfer systems track and facilitate the patient flow throughout the hospital by providing correct and unique patient identifiers for other clinical information technology systems for clinical care and billing.

Pediatric-Specific Features

Pediatric-specific issues that may contribute to increased errors include identification of individual infants in multiple births, mother-infant link, the ability to register patients before arrival (especially for critical and emergency patients), and reconciliation of alerts across information systems.

Standardized Handoffs, Whiteboards, and Patient-Tracking Tools

Context, Purpose, and Functions

Standardized care transitions have been identified as a national patient safety goal.[83] Within inpatient settings, types of transitions include:

- admissions and discharges;
- transfers to other units within the same institution; and
- handoffs of care (shift change).[84]

Each transition involves an exchange of information, responsibility, and authority from a provider (or team of providers) to another and involves a complex interaction of communication and dialogue between the sender and receiver in the transition process. The level of interactivity depends on a variety of factors including the acuity and intensity of care, the uncertainty of the patient's status, the specialty, the level of care, and the experience of the provider (supervising attending, hospitalist, resident, intern). An important aspect of transition is the provision of an appropriate time and location for transition, protected from the interruptive nature of care environments.[85] Models for handoff transitions and for creating standard checklists and for handoffs have been published.[86–88] HIT applications that support the handovers or transfers include electronic patient records, electronic whiteboards, and personal information tools that allow organization, management, and transfer of patient-specific task information.

Pediatric-Specific Features

Drivers for this area of efficiency and patient safety are medication discrepancies at sign-out[89] and the restriction of resident work hours.[27,90] A general structured template for transitions developed at an academic pediatric program has been proposed and is based on the mnemonic "PEDIATRIC"[88]:

- Problem list
- Expected tasks to be done
- Diagnostic one-liner
- If/then contingency plans
- Administrative data/advance directive
- Therapeutics
- Results and other important facts
- Intravenous access/invasive devices/procedures
- Custody and consent issues

Other approaches may be preferred in specific specialties or units (such as a systems-based approach used in pediatric and neonatal intensive care).

PRAGMATIC ISSUES

Data Conversion, Accumulation, and Noise

A proposed advantage of electronic data in HIT systems is data reuse.[91] Advantages of electronic data in this regard include reduction of costs and effort of storage and retrieval; however, technical limitations to realizing the full advantage include:

- Current technical ability to convert legacy print information into an electronically usable form. Optical character-recognition technology is limited in its capability to convert handwriting into computer-usable text. Legacy paper documents are typically scanned as photographic images for inclusion into electronic records. Limitations of this format include difficulty searching documents by text matching (other than by reading them) unless documents are labeled. The assignment of scanned records to the correct patient is challenging, and bar-code technologies have been

used to aid in the process.[92] EHRs may contain many such scanned documents, which are electronically inaccessible and of little added value other than for (manual) searching.

- Default values on clinical forms (such as review of systems and physical examination) are intended to ensure completeness for quality assurance and billing. However, when the printed or retrieved versions of the contents of such forms are generated, very long notes with many negatives (pertinent and extraneous) result in low information "signal-to-noise" ratios and reduce clinical usefulness of form data. The value of notes generated from structured data has been improved with the addition of narrative text,[93] which may be richer (or different) than structured data entry.[94] In addition, "copy-and-paste" behaviors that allow providers to generate notes from previous entries may result in inflated notes and persistent propagation of errors.[95]

Effective solutions are difficult, and considerations should include which product options (such as optical character-recognition conversion) to use and how data-input forms should be designed.

Assurance and Certification

HIT purchasers and clinicians want assurances that the systems they purchase and use will provide needed technical functions and interoperate with other systems securely. To accomplish these goals, public-private processes are in development to define standards for HIT products and evaluate which systems meet them. Efforts aimed at certifying EHRs and their networks (including CPOE) have been implemented by the Certification Commission for Healthcare Information Technology and the Leapfrog Group.[15,96,97] The current list of certifications for pediatric HIT functions is small (limited to pediatric ambulatory EHRs) but growing.

Liability Risk Modification

The accessibility of data afforded by electronic information systems creates new types of medicolegal liabilities. Increased availability of personal health data from multiple locations creates the potential for information breaches and confidentiality violations. New federal rules extend discovery to electronic information beyond the patient record, including e-mails, electronic business records, archived data, and administrative metadata on the origins and times of records.[98] Electronic clinical records can facilitate discovery of practice deviations and record alterations,[99] and converted legacy records, although they may have limited clinical value, may be admissible, although their paper counterparts may have long been discarded.

Ethnic and Minority Populations and Special Health Information Needs

Language and literacy barriers may add to the complexities of care in non–English-speaking populations and may contribute to poor outcomes. Preformatted patient information sheets may not match the needs of patients,[100,101] which may be missed by providers. The special needs of these patients and families include cultural competence by providers (including knowledge of language and health literacy issues) and information tools (such as personal health records and information sheets) adjusted to patient needs (including forms and scripts that ensure true informed consent).

For children with special health care needs, special communication needs may include extended discussions to ensure access to timely and appropriate care. An indirect effect of inpatient HIT adoption for minority populations may ultimately be related to the financial barriers of access and where families seek care. Low HIT-implementation rates in institutions where these patients receive care may reflect health disparities that are only part of the complex issues of the effects of poverty on children and their care.[102]

CONCLUSIONS

The adoption, incorporation, and use of HIT in inpatient settings to ensure patient safety where children receive care goes beyond consideration of available technical products. Pediatricians and child health advocates interested in adopting HIT for inpatient care must be aware of the technical and adaptive considerations that go into its successful acquisition, implementation, and deployment.

HIT adoption involves a global consideration of local institutional issues including:

- existing safety problems and outcomes that are to be improved with HIT;
- organizational structure and clinical process changes that will be required, including the work of implementation and the costs of adoption, deployment, use, and maintenance; and
- cultural and political factors that facilitate and block the changes.

Pediatric-specific HIT adoption involves familiarity with collective experience and knowledge.

- Similar institutions with the same problems, experiences, and data can be key in providing input and experiences.
- Specific products, their functions, and pediatric-centered features must be evaluated.
- Shared information resources can be consulted to aid evaluation and decision-making.

HIT adoption involves expertise in clinical informatics among the following:

- pediatric clinicians (physicians, nurses, pharmacists) with information technology experience in analysis, implementation, and evaluation of systems;
- organizational change managers versed in information technology transitions in clinical settings; and
- pediatric and institutional leaders who understand the goals and values of health care improvement and clin-

ical information technology adoption with regard to the health needs of children, including those with special health care needs.

Introduction of HIT may significantly improve clinical performance, reduce costs, and reduce workloads; however, every HIT-system implementation will invariably introduce new and sometimes unforeseen errors and challenges.

The Society for Academic Emergency Medicine Position on Pediatric Care in the Emergency Department

Roger J. Lewis, MD, PhD, on behalf of the SAEM Board of Directors

PREAMBLE

The Society for Academic Emergency Medicine (SAEM) Board of Directors recognizes the importance of providing quality emergency care to all pediatric patients in all emergency department settings, as well as our responsibility to teach medical students, residents, and fellows the skills and knowledge necessary to provide such care. Further, the SAEM Board of Directors is aware that the abilities of emergency physicians to provide quality emergency care to children occasionally has been questioned, most commonly in the lay media. While not in response to any particular event, the Board felt it important to assert certain principles regarding the qualifications of emergency physicians to provide emergency care to children. Thus, in collaboration with a variety of emergency medicine and pediatric organizations, the following position statement was developed and approved by the Board. This position statement has been approved by the following pediatric and emergency medicine organizations: The Ambulatory Pediatric Association (APA); the American Academy of Emergency Medicine (AAEM); the American Academy of Pediatrics (AAP); the American College of Emergency Physicians (ACEP); the Association of Academic Chairs in Emergency Medicine (AACEM); and the Council of Residency Directors in Emergency Medicine (CORD).

Received July 2, 2003; accepted July 7, 2003.
Address for correspondence and reprints: Society for Academic Emergency Medicine, 901 N. Washington Ave., Lansing, MI 48906. Fax: 517-485-0801; e-mail: saem@saem.org.
doi:10.1197/S1069-6563(03)00503-7

POSITION STATEMENT

Physicians who are certified in emergency medicine by the American Board of Emergency Medicine (ABEM) or the American Osteopathic Board of Emergency Medicine (AOBEM), or those who are certified in pediatric emergency medicine by ABEM or the American Board of Pediatrics (ABP), possess the knowledge and skills required to provide quality emergency medical care to children. To provide quality care, the emergency physician must have all necessary and age-appropriate medical equipment readily available. The emergency physician must also have access via consultation, admission, or transfer, to appropriate specialty and subspecialty physicians, who will provide any needed patient care after emergency department treatment. Although physically separate care areas for children are ideal, they are not mandatory to provide high-quality care.

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine

Pediatric Care Recommendations for Freestanding Urgent Care Facilities

ABSTRACT. Freestanding urgent care centers are not emergency departments or medical homes, yet they are sometimes used as a source of pediatric care. The purpose of this policy statement is to provide updated and expanded recommendations for ensuring appropriate stabilization in pediatric emergency situations and timely and appropriate transfer to a hospital for definitive care when necessary. ***Pediatrics*** **2005;116:258–260;** ***urgent care, equipment standards, emergency preparedness, pediatric preparedness.***

Freestanding urgent care facilities remain a fixture in the provision of health services for children in some communities. Although the American Academy of Pediatrics does not encourage the routine use of urgent care facilities because it may undermine the provision of coordinated, comprehensive, family-centered care consistent with the medical home concept,[1] the use of these facilities as part of urgent and emergent care systems is not uncommon. The term "urgent care" may imply to the public that a facility is capable of managing critical or life-threatening emergencies. This was the case for the youngest victim of the sniper in the Washington, DC, area on October 7, 2002. After being shot in the abdomen, despite the advice of the 911 operator to stay and wait for help, this 13-year-old child was driven to a local freestanding urgent care center.[2] He survived because this freestanding urgent care center was properly equipped and staffed to handle this child's initial stabilization and transfer to a level I pediatric trauma center.

Freestanding urgent care centers are not emergency departments. However, they must have the capability to identify patients with emergency conditions, stabilize them, and coordinate timely access to definitive care. These facilities must have appropriate pediatric equipment and experienced staff trained to provide critical support for ill and injured children until transferred for definitive care. It is necessary for freestanding urgent care facilities to have prearranged access to comprehensive pediatric emergency services through transfer and transport agreements. Available modes of transport should be identified in advance and be appropriate for the acuity of illness of the child.

If freestanding urgent care facilities are to be used as a resource for pediatric urgent care, they should first solicit help from the pediatric professional community to define expectations and levels of plans for pediatric consultation. Pediatricians who are prepared to assist in the stabilization and management of critically ill and injured children should be accessible. Pediatricians should be certain that freestanding urgent care centers are prepared to stabilize and transfer critically ill and injured children before they are recommended to their patients and families for after-hours use.

doi:10.1542/peds.2005-0958

RECOMMENDATIONS

Freestanding Urgent Care Facility Emergency Preparedness

1. Administrators at freestanding urgent care facilities should ensure that their staff is capable of providing resuscitation, stabilization, timely triage, and appropriate transfer of all pediatric patients.
2. Although the minimum standards for drugs, equipment, and supplies are listed in Tables 1 and 2, freestanding urgent care facilities with emergency medical systems response times of >10 minutes and transport times of >20 minutes to an emergency department need to have all suggested equipment, resuscitation drugs, and supplies as detailed in "Care of Children in the Emergency Department: Guidelines for Preparedness," issued jointly by the American Academy of Pediatrics and American College of Emergency Physicians.[3]
3. Freestanding urgent care facilities that provide care for children must be staffed by physicians, nurses, and ancillary health care professionals with the certification, experience, and skills necessary for pediatric basic and advanced life support during all hours of operation.
4. Triage, transfer, and transport agreements should be prearranged with definitive care facilities that are capable of providing the appropriate level of care based on the acuity of illness or injury of the child.[4]
5. Mechanisms for notifying the primary care physician or another on-call health care professional about the treatment given to ensure appropriate follow-up with the child's medical home should be in place and should be compliant with the regulations of the Health Insurance Portability and Accountability Act (HIPAA) (Pub L No. 101-

TABLE 1. Office Emergency Equipment and Supplies

	Priority*
Airway management	
Oxygen-delivery system	E
Bag-valve-mask (450 and 1000 mL)	E
Clear oxygen masks, breather and nonrebreather, with reservoirs (infant, child, adult)	E
Suction device, tonsil tip, bulb syringe	E
Nebulizer (or metered-dose inhaler with spacer/mask)	E
Oropharyngeal airways (sizes 00–5)	E
Pulse oximeter	E
Nasopharyngeal airways (sizes 12–30F)	S
Magill forceps (pediatric, adult)	S
Suction catheters (sizes 5–16F) and Yankauer suction tip	S
Nasogastric tubes (sizes 6–14F)	S
Laryngoscope handle (pediatric, adult) with extra batteries, bulbs	S
Laryngoscope blades (straight 0–4; curved 2–3)	S
Endotracheal tubes (uncuffed 2.5–5.5; cuffed 6.0–8.0)	S
Stylets (pediatric, adult)	S
Esophageal intubation detector or end-tidal carbon dioxide detector	S
Vascular access and fluid management	
Butterfly needles (19–25 gauge)	S
Catheter-over-needle device (14–24 gauge)	S
Arm boards, tape, tourniquet	S
Intraosseous needles (16, 18 gauge)	S
Intravenous tubing, microdrip	S
Miscellaneous equipment and supplies	
Color-coded tape or preprinted drug doses	E
Cardiac arrest board/backboard	E
Sphygmomanometer (infant, child, adult, thigh cuffs)	E
Splints, sterile dressings	E
Automated external defibrillator with pediatric capabilities	E
Spot glucose test	S
Stiff neck collars (small/large)	S
Heating source (overhead warmer/infrared lamp)	S

* E indicates essential; S, strongly suggested (essential if emergency medical services response time is >10 minutes).

191 [1996]). If a primary care physician is not identified, efforts should be made to refer the patient to a pediatrician able to promote a medical home environment.

6. Administrators at freestanding urgent care facilities must ensure that there is an organized and structured quality-improvement program to monitor and improve care for ill or injured children.
7. Freestanding urgent care facilities should have in place and should monitor compliance with policies, procedures, and protocols for emergency care of children consistent with those listed in "Care of Children in the Emergency Department: Guidelines for Preparedness."[3]
8. Freestanding urgent care facilities should have a policy for disaster preparedness and participate in their community disaster plan.[5]

Pediatrician's Role in Freestanding Urgent Care Facilities

1. Pediatricians should refer patients for after-hours care only to freestanding urgent care facilities that have the capability to identify patients with emergency conditions, stabilize them, and arrange transfer for definitive care.
2. When referring a patient, the pediatrician should provide to the freestanding urgent care facility necessary clinical information and be available to provide consultation.

If freestanding urgent care centers are staffed and equipped properly and have appropriate triage, transfer, and transport guidelines, the safety of children using these services for emergencies can be protected.[6]

NEW BUREAUCRATIC JOBS WOULD PAY FOR 2,000 MORE DOCTORS AND 6,000 NURSES

"The NHS was accused . . . of wasting millions of pounds of taxpayers' cash on 'unnecessary' jobs and hospital bureaucracy. Figures released by the Conservative Party show that in the last nine months a staggering 3,300 non-clinical jobs have been advertised in one health magazine alone. The salaries for these jobs amount to more than £133 million, enough for 6,000 more nurses, 2,000 more doctors or 29,000 hip replacements."

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Pediatric Fellowship Training

In 1996, the Federation of Pediatric Organizations revised its 1990 statement on pediatric fellowship training. The following statement represents the current (2004) position of the federation regarding the purpose and objectives of fellowship training.

The goal of subspecialty fellowship training is to advance the health of children by preparing graduates who are competent in clinical care, education, and research. This goal is best achieved by fellowship training that fosters the development of future academic pediatricians, recognizing the diverse roles they now play. This goal requires that graduates of training programs have a keen curiosity about issues in their subspecialty field, a healthy skepticism of their own experience (and the published experience of others), and a working understanding of the analytic tools relevant to exercising critical judgment. Training is best provided in an environment in which there are faculty role models committed to scholarly activities.

Subspecialists may serve as expert clinicians providing direct and consultative care to patients based on their experience and critical evaluation of scientific evidence and research. They may serve as educators helping to guide and facilitate life-long learning of medical students, residents, fellows, and others who provide care for children. They also may be investigators adding to the body of knowledge in their subspecialty. The eventual careers of subspecialists may involve 1 or more of these roles to varying degrees. Therefore, training programs should provide all trainees with experiences that will allow them to develop competence for each of these roles, and applicants must be selected on the basis of their potential to achieve appropriate skills in each of these domains. The following are guidelines for fellowship programs and trainees.

1. Fellowship training must educate trainees to develop and maintain life-long learning skills for themselves, especially the ability to critically evaluate new knowledge to determine its appropriate use in caring for patients.
2. Fellowship training programs must provide the opportunity for trainees to acquire appropriate clinical skills and must incorporate into their curriculum mastery of each of the 6 general competencies identified by the Accreditation Council of Graduate Medical Education and the American Board of Medical Specialties (medical knowledge, patient care, communication, professionalism, practice-based learning and improvement, and systems-based practice.) Relevant benchmarks and thresholds must be developed to ensure that competency in each area can be verified as achieved by all subspecialty graduates by the conclusion of their training program.
3. To achieve and maintain the goal of subspecialty training, in addition to acquiring appropriate clinical skills and competencies during the period of training, subspecialty trainees must acquire skills that will enable them to provide quality care throughout their professional lifetimes. These skills include the ability to critically analyze and evaluate their own observations and the observations of others; assimilate new knowledge, concepts, and technology; formulate clear and testable questions (hypotheses) from a body of information; and communicate ideas verbally and in writing.

   Programs must provide opportunities for trainees to acquire these skills. These opportunities for scholarship may include a variety of activities, but they must result in the acquisition of the skills referred to in the preceding paragraph, and the trainee's participation must be guided by 1 or more mentors.

   Scholarly activities, including but not limited to basic, clinical, or translational biomedical research, must be undertaken and successfully completed by trainees. These activities must be integrated into the training experience along with the core curriculum for the subspecialty and any formal coursework that is part of the training experience. Obtaining a graduate degree is not a substitute, per se, for such scholarly activities.
4. Fellowship training must be structured to provide a scholarly experience for every trainee, because it is essential to a successful subspecialty career in clinical care, education, research, or a combination of these activities. The subspecialty training program must have an oversight committee (at least 3 individuals, one of whom should be outside the trainee's subspecialty) for each trainee with appropriate expertise in scholarly endeavors. This committee must assess and confirm the presence of an adequate scholarly experience for each fellowship trainee and evaluate the product of the individual's scholarly experience.
5. Fellowship programs must provide training and experience to ensure that graduates will be effec-

tive teachers for all learners in need of understanding and collaboration in the subspecialist's area(s) of expertise. This training must include the ability to participate effectively in all aspects of the educational process including curriculum development, delivery of information, and assessment of educational outcomes. Graduates should be scholarly and effective in teaching both individuals and groups of learners in clinical settings, classrooms, lectures, and seminars and through electronic and print modalities.
